

Although we found that DNA methyltransferase 1 (**Dnmt1**) mediates Sirt1-induced CpG methylation, there is a lack of evidence showing whether **Dnmt1** in podocytes (Pods) reduces albuminuria (Alb).

**Methods:** To elucidate the role of Dnmt1, we used gene delivery of NPHS2-Dnmt1 cDNA vector (**Dnmt1 cDNA**), **Dnmt1 siRNA**, and control (**Cont**) plasmid using the HVJE vector by tail vein injection. Efficiency of transfer was tested by immunostaining and immunoelectron microscopy. Mice were injected with saline (**Sal**) or streptozotocin (**STZ**) to induce diabetic nephropathy (DN).

**Results:** We found that Sirt1 directly activates **Dnmt1** via its deacetylation using cultured and laser micro-dissected Pods.In **Cont+Sal**, endogenous Dnmt1 was mainly detected in Pods. Gold particles labeling Dnmt1 were characteristically located on the bottom and sides of foot processes. In **Dnmt1 cDNA+Sal**, Dnmt1 upregulation was detectable in a Pods-specific way owing to the NPHS2 promoter. The **Dnmt1 siRNA** successfully silenced Dnmt1 in kidneys. In **Cont+STZ**, Dnmt1 activity was decreased resulting in increased claudin-1 expression and Alb, which were prevented in **Dnmt1 cDNA+STZ** and worsened in **Dnmt1 siRNA+STZ**. In **Cont+Sirt1 CKO**, reduced Dnmt1 activity was accompanied by increased claudin-1 levels and Alb, which were blocked in **Dnmt1 cDNA+Sirt1 CKO**. Alb was dramatically enhanced by the **Dnmt1 siRNA** but not by a scrambled siRNA. These changes were blocked in **Dnmt1 siRNA+Sirt1 TG**. These phenomena were also observed in obese-type DN (**db/db**) and **Dnmt1 hetero-KO** (Dnmt1 +/-) mice, but not in 5/6 nephrectomized mice.

**Conclusions: Dnmt1** epigenetically protects against Alb and is beneficial for the maintenance of Pods function in DN.

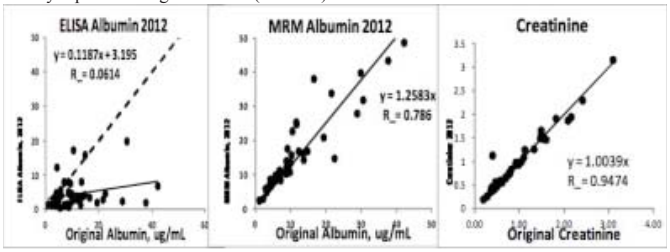
## TH-PO390

**Analysis of Urinary Albumin by Peptide MRM Circumvents Partial Protein Degradation and Loss of Antibody Recognition after Long-Term Storage**
Yun Jiang,[1] Susan E. Kupcho,[1] Blanche M. Chavers,[1] Gregory P. Rynders,[1] John H. Eckfeldt,[1] Michael Mauer,[1] Gary L. Nelsestuen,[1] Theodore E. Mifflin,[2] Dawei Xie,[2] Harold I. Feldman,[2] Vasan S. Ramachandran,[3] Paul L. Kimmel,[4] William Knowler,[4] Robert G. Nelson.[4] *[1]Univ of Minnesota; [2]Univ of Pennsylvania; [3]Boston Univ; [4]NIDDK/NIH.*

**Background:** Many potentially valuable biological samples have been stored for extended time under sub-optimal conditions such as -20° C. Unfortunately, proteins can aggregate or denature at -20° and become refractory to standard methods of protein analysis. Peptide-level analysis may overcome these effects, thereby permitting the use of these samples in clinical research. For the CKD Biomarkers Consortium.

**Methods:** Urine samples were collected in 1982-91 from 49 Pima Indians with type 2 diabetes. Creatinine and albumin were measured (original) and the remaining sample was stored at -20° C. Albumin and creatinine were assayed again in 2012 after storage at -20°C. Albumin was measured by two antibody-based methods and by a newly developed multiple reaction monitoring (MRM) method with peptide-based mass spectrometry. MRM assay of fresh samples compared favorably with 3 established antibody-based assays. Proper sampling for MRM required prior homogenization of particulate material.

**Results:** Antibody-based assays (in 2012) detected lower albumin concentration than the original antibody-based assay. In contrast, analysis of albumin by MRM recapitulated the original measure ($R^2$=0.78). New measurement of creatinine by chemical assay also closely replicated original values ($R^2$=0.95).



**Conclusions:** Long term sample storage under sub-optimal conditions need not impede all uses of valuable sample collections. Analysis of albumin and potentially other proteins by peptide MRM can overcome protein degradation that occurs at -20°. This may prove valuable to many sample collections.

## TH-PO391

**Rapamycin Fails to Ameliorate Established Renal Injury and Augments Mortality in Diabetic Mice**
Kavithalakshmi Sataranatarajan, Alex F. Bokov, Denis Feliers, Hak Joo Lee, Meenalakshmi M. Mariappan, Goutam Ghosh-Choudhury, Jeffrey L. Barnes, Arlan Gilbert Richardson, Balakuntalam S. Kasinath. *Univ of Texas Hlth Sc Ctr, San Antonio, TX.*

**Background:** Rapamycin (Rapa) ameliorates kidney injury in young diabetic mice; its efficacy in aging diabetic mice with established kidney injury is not known.

**Methods:** We performed 2 studies in type 2 diabetic mice. **Reversal Study**: Male and female 7 month-old db/m (non-diabetic) and db/db (diabetic) mice received control diet or rapa (2.5mg/kg/day) diet for 4 mos (n=20, each group) and sacrificed at 11 mos of age. **B. Life span Study**: 4 month-old male and female db/db mice were treated with control diet or rapa diet (n=40, each group) till natural death; necropsy was done.

**Results: A. Reversal Study**: At 11 mos of age, diabetic mice showed increase in glomerular area, mesangial matrix area, albuminuria vs. non-diabetic mice; creatinine clearance was unchanged. Rapa did not change any of these parameters. Glomerular hypertrophy, PAS+ fractional mesangial area, and, increase in renal cortical type IV collagen (male) and fibronectin seen in diabetic mice was not reversed by rapa. Signaling assays did not show evidence of mTORC1, Akt or Erk activation in the kidney of diabetic mice and rapa did not affect these parameters. Whole blood rapa levels by HPLC were 1.25-3ng/ml. **B. Life span Study**: Including 120 days when diet study started, the median life span of male and female diabetic mice on control diet was 349 and 487 days, respectively. After 210 days on diet, rapa fed diabetic mice had greater mortality than control diet mice (p=0.02 female, NS for male) (log rank). Cox proportional hazard analysis showed mortality risk was lower (60%) for female vs. male in control diet fed diabetic mice. Adjusting for gender difference, rapa increased mortality risk by 1.7-fold for both male and female diabetic mice (p=0.05). On necropsy, suppurative inflammation in several organs was the main cause of death; this was augmented by rapa. About 30% of deaths were due to neoplasms, mostly hepatocellular carcinoma; rapa reduced these neoplasms.

**Conclusions:** Rapa not only fails to ameliorate established renal injury but worsens mortality in type 2 diabetic mice.

## TH-PO392

**Protective Effects of Endogenous Vasohibin-1 on Podocytes in Diabetic Nephropathy**
Norikazu Hinamoto,[1] Yohei Maeshima,[1] Hiroyuki Watatani,[1] Haruyo Ujike,[1] Katsuyuki Tanabe,[1] Kana Masuda,[1] Hitoshi Sugiyama,[1] Yasufumi Sato,[2] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [2]Vascular Biology, Development, Aging, and Cancer, Tohoku Univ, Sendai, Miyagi, Japan.*

**Background:** We recently demonstrated the protective role of Vasohibin-1 (VASH1),a negative feedback regulator of angiogenesis, in mouse models of diabetic nephropathy. Regulatory roles of VASH1 on albuminuria, renal inflammatory/fibrotic alterations, angiogenic factors and slit-proteins were observed. In endothelial cells, VASH1 mediates cell survival under oxidative stress via inducing Sirt1 and SOD2 and Ezh2 mediates down-regulation of VASH1. Here, we aimed to elucidate the mechanism involved in the protective role of endogenous VASH1 in diabetic nephropathy.

**Methods:** Type 1 diabetes was induced in male VASH1+/- or wild-type littermates by injections of low-dose streptozotocin. Mice were sacrificed after 16 weeks, kidneys were obtained and subjected to real-time PCR and immunoblot analysis. Conditionally immortalized mouse podocytes were cultured under high glucose condition (HG) with VASH1 siRNA (24 hrs). Then, cells were harvested and subjected to immunoblot or real-time PCR analysis.

**Results:** Renal mRNA levels for Sirt1 were reduced in the diabetic wild-type mice, but was partly recovered in the diabetic VASH1+/- mice.Renal mRNA levels of Ezh2, SOD1, SOD2 were not significantly different between diabetic wild-type and VASH1+/- mice. In cultured podocytes, mRNA levels of nephrin were reduced under HG, and treatment with VASH1 siRNA resulted in further reduction. VASH1 siRNA, augmented the expression of VEGF-A, attenuated the expression of Ang-1 and ZO-1 (immunoblot). Treatment with VASH1 siRNA increased mRNA levels of Ezh2, and tended to suppress mRNA levels of SOD1, but did not alter mRNA levels of SOD2 under HG.

**Conclusions:** These results suggest that endogenous VASH1 may exert the direct protective effects on podocytes through regulating slit-proteins and stress response in association with the amelioration of albuminuria, thus implicating its potential use in treating diabetic nephropathy.

**TH-PO393**

**SGLT2 Inhibition Only Excretes 50-60% of Filtered Glucose in Euglycemic Mice Because of Compensation by SGLT1** Takahiro Masuda,[1] Timo M. Rieg,[1] Maria Gerasimova,[1] Eric Mayoux,[2] Hermann Koepsell,[3] Volker Vallon.[1] *[1]Div of Nephrology, UC San Diego & VA San Diego Healthcare System, San Diego, CA; [2]Boehringer-Ingelheim, Biberach, Germany; [3]Anatomy and Cell Biology, Univ of Wurzburg, Germany.*

**Background:** The sodium-glucose cotransporter SGLT2 reabsorbs most of the filtered glucose in the kidney. Inhibitors of SGLT2 enhance urinary glucose excretion (UGE) and are new antidiabetic drugs but they only excrete 50-60% of the filtered glucose under euglycemia. We aimed to define the role of SGLT1 under these conditions which accounts for ~3% of renal glucose reabsorption in euglycemic mice (Gorboulev 2012).

**Methods:** A. Wild-type (WT) and Sglt1-deficient mice (Sglt1-/-) were treated by oral gavage with vehicle (veh) or SGLT2 inhibitor, empagliflozin (EMPA; 0.1-10mg/kg) followed by quantitative urine collection in metabolic cages for 3 hrs. B. WT and Sglt1-/- were treated with EMPA (300mg/kg of diet) for 3 weeks. Urine was collected weekly followed by renal $^3$H-inulin clearance studies under terminal anesthesia. * P<0.001 vs WT.

**Results:** A. EMPA dose-dependently increased UGE in WT: 0.1±0.1 (veh) to maximum of 30±5nmol/min/g ($ED_{50}$ ~1.3mg/kg); compared with WT, the EMPA-induced UGE was doubled in Sglt1-/-: 1.2±0.2* (veh) to 63±3*nmol/min/g; $ED_{50}$ of ~0.3mg/kg (n=6). B. Within 24h, EMPA (in diet) increased urine glucose/creatinine ratio from 8±1 (basal) to 2283±519µmol/mg in WT and from 95±10* to 3868±450*µmol/mg in Sglt1-/- (n=10-11); doubling of the ratio in Sglt1-/- vs WT was maintained at 1-3 weeks. EMPA-induced reduction in blood glucose (BG) was enhanced in Sglt1-/- vs WT after 24h (-33±5* vs -11±5%); BG and food intake were similar between groups at 1-3 weeks. Subsequent clearance studies in chronic EMPA-treated mice revealed fractional renal glucose excretion (FGE) of 36±2% in WT and 83±2%* in Sglt1-/- (n=9-10). Additional application of EMPA (10mg/kg ip; 1hr prior to study) increased FGE to 56±3% in WT (mimicking values of FGE in Sglt2-/- mice - Vallon 2011) and to 101±3%* in Sglt1-/- (n=4-6).

**Conclusions:** SGLT2 and SGLT1 account for renal glucose reabsorption. SGLT1 reabsorbs 40-50% of filtered glucose during SGLT2 inhibition in euglycemic mice.

**TH-PO394**

**Relevance of Myo-Inositol Oxigenase (MIOX) in Renal Tubular Injury in Obesity/Metabolic Syndrome** Tatsuya Tominaga, Ming Zhan, Yashpal S. Kanwar. *Pathology, Northwestern Univ, Chicago, IL.*

**Background:** MIOX, a renal tubular enzyme, channels myo-inositol into xylulose-pentose pathway. Previous studies indicate that its expression increases in diabetic state and its transcription is modulated by high glucose ambience, osmotic agents and oxidant stress. Overexpression of MIOX also increases the synthesis of ECM fibronectin, analogus to tubulo-interstitial fibrosis seen in diabetic nephropathy. Its modulation in obesity or glycolipid disorder, such as, metabolic syndrome is unknown. We examined its transcription/translational regulation under the influence of high fat diet (HFD) in vivo and free fatty acid (FFA) in vitro.

**Methods:** Mice were fed with HFD for 2 -8 weeks, and their kidneys harvested for various studies. Similarly, HK2 cells were subjected to FFA (palmitic acid) treatment, and processed for MIOX expression, Chromatin Immuno-Precipitation (ChIP) and MIOX promoter analysis following the binding to the consensus sequence of Sterol Regulatory Element-Binding Protein 1 (SREBP1).

**Results:** MIOX expression increased in renal tubules in mice receiving HFD compared with those receiving normal diet. In addition, increased expression of SREBP1 and Bax was detected in the renal cortices. MIOX expression also increased following FFA treatment in a dose-dependent (0.01-0.3 mM) manner in HK2 cells. Simultaneously, FFA treatment increased p53 and Bax expression. MIOX promoter included multiple segments with consensus binding sequence for sterol regulatory element-binding site (-2460 to -1887, -1032 to -458, -523 to -22). ChIP assay confirmed that SREBP1 binds to MIOX promoter. Furthermore, we cloned the MIOX promoter (-1463 to +33) in pGL3 vector. MIOX promoter activity was increased by 100% with FFA treatment in HK2 cells.

**Conclusions:** These preliminary findings indicate that the MIOX transcription, besides being regulated by hyperglycemic, osmotic and oxidant stresses, is also modulated by FFA and HFD, suggesting that this enzyme may be responsive to the adverse effects of obesity and is likely to lead to tubulointerstitial disease, as seen in other metabolic disorders.

**TH-PO395**

**A Novel Dipeptidyl Peptidase IV Inhibitor Ameliorates Diabetic Nephropathy Independent of Metabolic Effects in db/db Mice** Mi Jin Lee,[1] Young Sun Kang,[1] Jin Joo Cha,[1] Young Youl Hyun,[2] Ji Eun Lee,[3] Hyunwook Kim,[3] Mihwa Lee,[1] Jung Eun Kim,[1] Hye Kyoung Song,[1] Jee-Young Han,[4] Dae R. Cha.[1] *[1]Nephrology, Korea Univ Ansan Hospital, Ansan, Kyunggido, Republic of Korea; [2]Nephrology, Sungkyunkwan Univ Kangbuk Samsung Hospital, Seoul, Republic of Korea; [3]Nephrology, Wonkwang Univ Sanbon Hospital, Republic of Korea; [4]Pathology, Inha Univ Hospital, Incheon.*

**Background:** Although DPP IV inhibitor has been widely used for management of hyperglycemia in type 2 diabetic patients, its role on renal function is not clear yet. The aim of present study is to investigate the effects of DA-1229, a newly developed DPP IV inhibitor, on glucose and lipid metabolism and renal injury in db/db mice.

**Methods:** Experimental groups were divided into three groups; non-diabetic db/m mice (n=8), untreated db/db mice (n=8), and db/db mice treated with DA-1229 (300mg/kg/d) for 12 weeks (n=8).

**Results:** DPP-4 activities in heart, liver, and adipose tissue did not significantly different between db/m and db/db mice. However, DPP-4 activity in kidney showed significantly higher in diabetic kidney, and DA-1229 treatment significantly suppressed DPP-4 activity in the kidney. Although DA-1229 treated db/db mice showed an improvement in dyslipidemia, DA-1229 did not induce significant improvement in insulin resistance determined by HOMA-IR and insulin tolerance test, glycemic control and HbA1c levels. Additionally, DA-1229showed a little effect on body weight and systolic blood pressure. However, DA-1229 treatment markedly decreased urinary albumin excretion, kidney/body weight, serum creatinine levels and improved pro-fibrotic molecule synthesis including TGFβ1, PAI-1 and type IV collagen. Furthermore, DA-1229 treatment improved renal lipid metabolism. Interestingly, DA-1229 treatment significantly protected urinary loss of nephrin and restored renal nephrin expression in diabetic glomeruli. In addition, DA-1229 also markedly suppressed renal expression of HMGB-1 protein expression observed in diabetic kidney.

**Conclusions:** These results suggest that a novel DPP IV inhibitor, DA-1229 provide renal protective effects independent of its hypoglycemic metabolic effects.

**Aggravation of Diabetic Nephropathy in Bis-Haploinsufficient Mice along with Impaired Induction of SOD Activity** Keun Suk Yang, Ji Hee Lim, Min Young Kim, Sungjin Chung, Seok Joon Shin, Hyung Wook Kim, Yong-Soo Kim, Cheol Whee Park. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea.*

**Background:** Bcl-2 interacting cell death suppressor (Bis), known as anti-stress and anti-apoptotic protein, has been reported to modulate susceptibility to oxidative stress. In this study, we investigated the potential role of Bis as an antioxidant protein in diabetic nephropathy (DN).

**Methods:** DN was induced in Bis-heterozygote mice (Bis-HT) via streptozotocin injections and the resulting phenotypes were compared to those of wild type (Bis-WT) mice over the course of 20 weeks after diabetes induction.

**Results:** Renal injuries, represented by increased plasma creatinine levels and increased albuminuria, were greater in diabetic Bis-HT (Bis-HT DM) mice than in diabetic Bis-WT (Bis-WT DM) mice, accompanied by a significant increase in oxidative stress markers. Moreover, glomerular matrix expansion, TGF-b1 and HIF-1a expression, tubulointerstitial fibrosis and proportion of apoptotic cells were significantly higher in Bis-HT DM mice than in Bis-WT DM mice with the same degree of hyperglycemia. These severe outcomes of DN were all restored by tempol treatment. The expression of SOD1 and SOD2 increased on the induction of DM in Bis-WT mice, correlating with the total SOD activity, but was not observed in Bis-HT and Bis-HT DM mice. An in vitro study showed that the knockdown of Bis expression also resulted in the impaired induction of SOD activity as well as SOD expression in HK-2 and NMS cells.

**Conclusions:** Our results suggest that decreased antioxidant capacity of Bis may aggravate DN in Bis-HT DM mice, which could possibly result from disruption in the regulation of SOD1 or SOD2 protein quality upon oxidative stress.

**TH-PO397**

**Fenofibrate Ameliorates Diabetic Nephropathy through the Activation of AMPK-PGC-1α-ERR-1α Signaling in *db/db* Mice** Keun Suk Yang, Yul Hee Cho, Min Young Kim, Ji Hee Lim, Hoon Suk Park, Sun Ryoung Choi, Seok Joon Shin, Hyung Wook Kim, Yong-Soo Kim, Cheol Whee Park. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea.*

**Background:** The peroxisome proliferative-activate receptor-α is a lipid-sensing transcriptional factor that has a role in gluco-oxidative stress and lipotoxicity. Here, we evaluated whether fenofibrate has renoprotective effects through the change of AMPK-PGC-1α-ERR-1α and their downstream PI3K-Akt pathway in *db/db* mice.

**Methods:** Male C57 BLKS *db/db* mice and *db/m* controls at 8 weeks of age were divided to receive either a regular diet chow or a diet containing fenofibrate (0.2% wt/wt, n=6, respectively). The treated *db/m* mice and *db/db* mice were administrated fenofibrate for 12 weeks and were evaluated about renal functional and pathologic phenotypes and the AMPK-PGC-1α-ERR-1α pathway.

**Results:** The mesangial area expansion, inflammatory cell infiltration, and the accumulation of intra-renal lipids were observed in *db/db* mice and this was related to a downregulation of PPARα suppressed AMPK-PGC-1α-ERR-1α expressions and increased

PI3K-Akt-phosphorylation of FoxO3a, which led to oxidative stress and decreases fatty acid oxidation. Fenofibrate significantly decreased albuminuria and reversed all of the renal phenotypes by increasing the PPARα expression with concomitant activation of AMPK-PGC-1α-ERR-1α and inactivation of PI3K-Akt pathway, dephosphorylation of FoxO3a signaling in *db/db* mice. Fenofibrate ameliorated high glucose induced oxidative stress and apoptotic cell death in cultured mesangial cells through the same pathways.

**Conclusions:** Our results suggest that PPARα agonists are associated with improvement of lipotoxicity and oxidative stress through the activation of AMPK-PGC-1α-ERR-1α signaling in *db/db* mice, which may be a potentially therapeutic modality to treat diabetic nephropathy.

## TH-PO398

**Inhibition of Factor Xa with Rivaroxaban Ameliorates Proteinuria and Reduces Inflammatory Cytokines with Diminished Loss of Glycocalyx in Animal Models of Diabetic Nephropathy** Jan Menne, Nelli Shushakova, Joon-Keun Park, Torsten Kirsch, Anna Bertram, Putri Andina Agustian, Hermann G. Haller. *Clinic of Hypertension, Hannover Medical School, Hannover, Germany.*

**Background:** Activated factor Xa(FXa) plays an important role in the coagulation cascade. In addition, FXa binds to protease-activated receptors PAR-1 and PAR-2 and may exert cellular function in the endothelium. We have recently shown that the endothelial glycocalyx surface layer (ESL) is important for the initiation of proteinuria and contribute to the early inflammatory changes in diabetic nephropathy. We therefore tested the hypothesis that (1) treatment with a FXa inhibitor prevents proteinuria and inflammatory changes in diabetic and ATII-infused mice and (2) that this effect is mediated via the endothelium.

**Methods:** STZ (*n*=8), db/db mice (*n*=8) and control animals received sham or rivaroxaban RIVA (50 mg/kg/day) before or during hyperglycemia. After 2 and 8 weeks of hyperglycemia, the animals were analyzed. Immunohistochemistry was performed on cryostat/paraffin sections. EM analysis of ESL was carried out after Alcian blue perfusion. Gene and protein expression was analyzed by rt-qPCR and western blot analysis. Signal transduction of FXa was assessed by measuring ERK phosphorylation pERK.

**Results:** Treatment with RIVA reduced the hyperglycemia–induced increase in proteinuria in both STZ and db/db mice significantly. Decrease of heparansulfates and endothelial glycocalyx density was prevented. The increase in inflammatory cytokines and adhesion molecules in diabetic animals was also reduced by RIVA treatment. Macrophage infiltration in the diabetic kidney was reduced by RIVA treatment. The increase in pERK in diabetic glomeruli was diminished by RIVA treatment. All these changes were not observed in AngII-treated animals.

**Conclusions:** Inhibition of factor Xa signalling with rivaroxaban in glomerular endothelial cells reduces proteinuria in diabetic animals. The amelioration of proteinuria is associated with reduced breakdown of endothelial glycocalyx and less inflammation. Rivaroxaban may have beneficial effects on endothelial glycocalyx thereby improving proteinuria and inflammation in diabetic nephropathy.

## TH-PO399

**Increased Tubulointerstitial Damage, Macrophage Infiltration, and Nuclear Factor-κB Activity in the Kidneys of Diabetic STAT5 Knockout Mice** Karen T. Coschigano,[1,2] Erich P. Heine,[3] Ramiro Malgor.[1,2] *[1]Dept of Biomedical Sciences, Ohio Univ College of Osteopathic Medicine, Athens, OH; [2]The Diabetes Institute of Ohio Univ, Athens, OH; [3]Ohio Univ College of Osteopathic Medicine, Athens, OH.*

**Background:** Diabetic nephropathy is currently the most common cause of chronic renal failure in the United States. Mounting evidence indicates that inflammatory mechanisms are involved in the development of diabetic nephropathy. Our prior analysis of nondiabetic and streptozotocin-induced diabetic wildtype and Signal Transducer and Activator of Transcription 5 (STAT5) knockout mice revealed that RNA expression of many inflammation-related genes is dramatically upregulated in kidneys of diabetic STAT5 knockout mice. We hypothesized that Nuclear Factor κB (NF-κB), a major inflammatory transcriptional activator, would have increased activity in diabetic STAT5 knockout mice that would coincide with this increased gene expression, as well as with increased macrophage infiltration and kidney damage.

**Methods:** We used immuno- and histochemical methods to assess lymphocytic infiltration and kidney morphology and a DNA binding assay to measure NF-κB activity of kidneys isolated from nondiabetic and streptozotocin-induced diabetic wildtype and STAT5 knockout mice.

**Results:** We demonstrated that diabetic STAT5 knockout mice had a greater number of macrophages and lymphocytic aggregates, increased fibronectin expression, and tubulointersititial damage when compared to the other nondiabetic and diabetic mice. In addition, we showed that NF-κB DNA binding activity was significantly greater in diabetic STAT5 knockout mice when compared to their counterparts.

**Conclusions:** The data suggest that the STAT5 knockout mice have lost some inherent protection from inflammatory responses that wildtype mouse groups retain, indicating that the STAT5 proteins may serve a protective role in diabetic nephropathy.

## TH-PO400

**CYP2C-Derived EETs Contribute to Insulin Sensitivity in Mice and in Humans** James M. Luther, Mahesha Gangadhariah, Jorge H. Capdevila, Ambra Pozzi. *Medicine, Vanderbilt Univ, Nashville, TN.*

**Background:** The P450 arachidonic acid epoxygenases (CYP2C, CYP2J) modulate blood pressure via renal and vascular effects, and interventions which prevent degradation of their epoxyeicosatrienoic acid products (EETs) via epoxide hydrolase inhibition may favorably alter glucose homeostasis.

**Methods:** We tested the hypothesis that endogenous CYP2C-derived epoxyeicosatrienoic acids alter insulin sensitivity in vivo using *Cyp2c44*-deficient mice during 16 weeks of high fat or regular chow diet. We assessed whole organism insulin sensitivity using hyperinsulinemic clamps and tissue insulin sensitivity using 2-deoxyglucose uptake. To examine this association in humans, we assessed insulin sensitivity and plasma EETs during controlled dietary sodium intake in healthy and metabolic syndrome subjects.

**Results:** Despite similar body weight and adiposity, insulin sensitivity decreased in *Cyp2c44(-/-)* mice compared to wild-type (WT) controls (40.4±2.7 vs 57.8±3.8 mg/kg/min; *P*=0.003). High fat-fed WT and *Cyp2c44(-/-)* mice were both significantly insulin resistant compared to WT mice, but were similar between genotype. Hepatic glucose production during regular chow diet was similar at baseline, but was incompletely suppressed in *Cyp2c44(-/-)* mice during insulin-glucose infusion (-1.2±1.8 vs 6.4±0.6). Muscle and adipose tissue $^{14}$C 2-deoxyglucose uptake in vivo was diminished in *Cyp2c44(-/-)* mice. However, insulin-stimulated 2-deoxyglucose uptake was similar in isolated muscle *ex vivo*, suggesting that tissue perfusion may contribute to the defect. In human subjects with metabolic syndrome, plasma EETs were reduced compared to healthy controls (*P*=0.014) and were positively associated with insulin sensitivity assessed during intravenous glucose tolerance tests ($R^2$=0.62, *P*<0.001).

**Conclusions:** These studies demonstrate that CYP2C-derived EETs contribute to insulin sensitivity in mice and in humans. Interventions which increase circulating EETs in humans could provide a novel approach to improve insulin sensitivity and treat hypertension.

## TH-PO401

**Urinary Podocalyxin Reflects Podocyte Injury in Hypoxia-Exacerbated Diabetic Glomerulosclerosis** Naoki Takahashi,[1] Kenji Kasuno,[1] Kazuko Kamiyama,[1] Tomomi Kurose,[2] Hiroyuki Kurosawa,[3] Yoshiaki Hirayama,[3] Seiji Yokoi,[1] Yoshinari Yokoyama,[1] Daisuke Mikami,[1] Hideki Kimura,[2] Haruyoshi Yoshida,[4] Masanori Hara,[5] Masayuki Iwano.[1] *[1]Nephrology, Fukui Univ; [2]Clinical Laboratories, Fukui Univ Hosp.; [3]Reagent R&D Dept, Denka Seiken Co.; [4]Internal Medicine, Obama Hosp.; [5]Pediatrics, Yoshida Hosp.*

**Background:** We have previously reported that chronic hypoxia exacerbated diabetic glomerulosclerosis (GS) in db/db mice exhibiting microaneurysms with podocyte loss after 16 weeks of hypoxic breeding, and that urinary albumin (U-Alb) levels were increased at 2 weeks in hypoxia. In this study, we examined urinary podocalyxin (U-PCX) in the early stage of the hypoxia-exacerbated GS in db/db mice, because U-PCX has been reported as a useful biomarker for early podocyte injury in diabetic patients (Diabetologia 55: 2913, 2012).

**Methods:** Eight w.o. male db/db mice were bred in a normobaric hypoxic chamber (12% $O_2$) for 4 weeks (n=6) (H-group) and the control mice were bred in room air (n=6) (N-group). U-PCX and U-Alb were weekly measured by ELISA using 24h urine samples. Urine samples were centrifuged at a low speed to detect cellular PCX in sediments or the resulting supernatants were further ultracentrifuged for analyzing cytoplasmic PCX, by immunofluorescence and western blotting. The kidney specimens obtained at 12 w.o. were immunoenzymatically stained for WT-1 positive podocytes.

**Results:** The average podocyte number per glomerulus did not differ between the two groups, however, the number per glomerular area was significantly decreased in H-group associated with glomerular swelling. Both U-PCX and U-Alb levels were significantly increased in H-group as compared with N-group at 1 week in hypoxia and continued to be elevated. U-PCX and U-Alb showed a positive correlation ($p<0.01$). In both group, PCX-positive cells were not found in urinary sediments, however, PCX-positive granular particles were detectable in the bottom fraction after the ultracentrifugation.

**Conclusions:** U-PCX may be a novel biomarker for podocyte injury characterized as cytoplasmic shedding and U-Alb may be attributable to such podocyte injury in the early stage of diabetic GS in this mouse model.

## TH-PO402

**Effect of Febuxostat (FBX) on the Development of Nephropathy in Obese Zucker Rats (ZO) with Type 2 Diabetes (DM2)** Radko Komers,[1] Bei Xu,[1] Terry T. Oyama,[1] Robert Jackson,[2] Robert N. Palmer.[2] *[1]Div of Nephrology and Hypertension, Oregon Health and Science Univ, Portland, OR; [2]Global Medical Affairs, Takeda Pharmaceuticals, Deerfield, IL.*

**Background:** Xanthine oxidase (XO) inhibitors have beneficial effects in the diabetic kidney. However, the long-term protective potential of XO inhibition in advanced diabetic renal lesions remains to be determined.

**Methods:** We tested the effects XO inhibitor FBX on the development of nephropathy in ZO in vivo, and in vitro in renal tubular cells (RTC) stimulated with a RAGE agonist s100B and with TGF beta (TGFb).10-week old ZO were divided in groups treated with FBX (ZO-FBX, 5mg/kg), enalapril (E) (ZO-E, 10mg/kg) and a combination of both agents (ZO-FBX+E) for 18 weeks and compared to vehicle-treated ZO (ZO-V) and lean controls (ZL).

The late intervention with FBX initiated at 20 weeks of age was also studied (ZO-FBXlate).

**Results:** ZO-V developed severe glomerulosclerosis (GS) and tubulointerstitial fibrosis (TIF), albuminuria, and mild elevations of BP as compared to ZL. ZO-FBX and ZO-FBXlate rats demonstrated significant decreases in GS score (27% and 25%, resp., $p<0.05$) and in proportion of obsolete glomeruli, compared with ZO-V. The TIF score was also reduced by FBX (35%, $p<0.05$ vs. ZO-V), albeit not after delayed treatment. Treatment with E, or combination of both agents resulted in resp. 44% and 55%, reduction in GS and resp. 70% and 80% reduction in TIF scores (<0.001 vs. ZO-V, $p<0.05$ vs. ZO-FBX). In ZO-FBX+E, the GS score was no more different from ZL, suggesting additive effect of FBX+E. Significant reductions in BP and albuminuria were observed in ZO-E and ZO-FBX+E. The uric acid (UA) levels, elevated in ZO rats, were only slightly reduced in FBX-treated rats. On the molecular level, FBX reduced expression of collagen 4 (Col4), fibronectin (FN) and CTGF to a similar extent as in ZO-E., and attenuated s100B- or TGFb-induced increases in Col4 and FN production in RTC in vitro.

**Conclusions:** FBX slowed down the development of GS and TIF in experimental DM2, although to a lesser degree than E. These effects were BP-independent and not entirely attributable to UA lowering. Moreover, there were additive effects of FBX+E.

## TH-PO403

**Genome-Wide Profiling of Inflammation Related Genes in High Glucose Stimulated Mesangial Cells and Tubular Epithelial Cells**

Yasunori Iwata,[1] Kengo Furuichi,[1] Haruka Yasuda,[2] Norihiko Sakai,[1] Shinji Kitajima,[1] Tadashi Toyama,[1] Yasuyuki Shinozaki,[1,2] Akihiro Sagara,[1] Takashi Wada.[1,2] *[1]Nephrology, Kanazawa Univ, Kanazawa, Ishikawa, Japan; [2]Laboratory Medicine, Kanazawa Univ, Kanazawa, Ishikawa, Japan; [3]Disease Contorol and Homeostasis, Kanazawa Univ, Kanazawa, Ishikawa, Japan.*

**Background:** Diabetic nephropathy (DN) is a major cause of end stage kidney disease and a strong risk factor for cardiovascular diseases. Growing data show chronic inflammation plays an important role for the progression of DN. As for the immune cells, anti- inflammatory leukocytes as well as inflammatory leukocytes play an important role in DN. In addition to leukocytes, renal resident cells contribute to the inflammatory process of DN. However, precise functions, phenotypes and immune balance of renal resident cells remain to be explored. Therefore, we hypothesized that the aberrant immune balance of renal resident cells contributes to the pathogenesis of DN.

**Methods:** To explore this, we performed genome-wide transcriptome profiling in mesangial cells and tubular epithelial cells (TECs), which were stimulated by high glucose (HG) and detected the expression of inflammation associated genes.

**Results:** High glucose (HG) increased the mRNA expression of oxidative stress, inflammasome and mammalian target of rapamycin (mTOR) related genes in mesangial cells. Pro-inflammatory/Th1 gene expression was upregulated, but Th2 related gene expression was downregulated in mesangial cells. In TECs, HG stimulation increased pro-inflammatory/Th1/Th2 gene expression. Phosphorylation of signaling proteins shifted towards pro-inflammatory phenotype with suppressed phosphorylation of Th2 related signaling in TECs.

**Conclusions:** The data taken together indicate that HG shifts the immune balance toward pro-inflammaotry/Th1 phenotype in mesangial cells and TECs, which might initiate and/or prolong inflammation, thereby possibly resulting in diabetic nephropathy.

## TH-PO404

**Febuxostat Attenuates Diabetic Renal Injury via an Anti-Inflammatory and Anti-Oxidative Mechanism**

Hong Joo Lee,[1] Jungkook Wi,[2] Ju Young Moon,[3] Sang Ho Lee,[3] Chun-Gyoo Ihm,[3] Tae-Won Lee,[3] Kyung Hwan Jeong.[3] *[1]Div of Nephrology, Gachon Univ Dongincheon Gil Hospital; [2]ISU Medical Center; [3]Div of Nephrology, School of Medicine, Kyung Hee Univ.*

**Background:** Oxidative stress and inflammation are known to play a central role in the development of diabetic nephropathy. Febuxostat (Fx) is a novel nonpurine xanthine oxidase (XO)-specific inhibitor for treating hyperuricemia.The reduction in oxidative stress by administering the XO inhibitor has been shown to slow the progression of renal dysfunction. In this study, we investigated whether Fx could attenuate diabetic kidney injury and impart renoprotective effects, including anti-oxidative stress and anti-inflammatory mechanisms.

**Methods:** Male Sprague–Dawley rats were divided into three groups: normal, vehicle-treated diabetes (DM), and febuxostat-treated diabetes (DM+Fx). We administered 5mg/kg of Fx to experimental rats for 7 weeks.

**Results:** Diabetic rats (DM and DM+Fx groups) had higher blood glucose, higher kidney weight relative to body weight, and increased urine output compared to normal rats. Urinary albuminuria was only significantly reduced in Fx-treated diabetic rats. Quantitative analysis showed that hepatic XO and XDH activity was increased in the DM group but reduced after treatment with Fx. Urine 8-OHdG concentrations and renal cortical nitrothyrosine also indicated reduced oxidative stress in the DM+Fx group. We observed no differences in renal histopathology between the three groups. However, we observed a greater number of ED-1 stained cells in the glomerulus and tubule of diabetic renal tissue compared to normal; after administration of Fx, ED-1 stained cell count decreased. Finally, diabetic rats showed increased mRNA expression of inflammatorygenes (E-selectin and VCAM-1), inflammation inducible enzymes (COX-2), and inflammatory mediators (ED-1 and NF-kB): after administration of Fx, these showed decreased significantly.

**Conclusions:** Febuxostat ameliorates the diabetic renal injury such as albuminuria. Renoprotective effects of Fx may attenuate the inflammatory and oxidative stress mechanisms of renal damage in diabetes by inhibiting XO and XDH activity.

## TH-PO405

**Regulation of Fatty Acid Oxidation Affects the Susceptibility of Podocytes to Palmitic Acid: Critical Role of Acetyl-CoA Carboxylase 1 and 2**

Kapil Dev Kampe,[1] Jonas Sieber,[2] Jana Orellana,[1] Peter H. Mundel,[2] Andreas Werner Jehle.[1,3] *[1]Dept of Biomedicine, Molecular Nephrology, Univ Hospital, Basel, Basel Stadt, Switzerland; [2]Div of Nephrology, Massachusetts General Hospital, Boston; [3]Dept of Internal Medicine, Transplantation Immunology & Nephrology, Univ Hospital, Basel, Basel Stadt, Switzerland.*

**Background:** Type 2 diabetes (T2D) is characterized by dyslipidemia with elevated free fatty acids (FFAs). FFAs and renal FFA-oxidation (FAO) potentially play a direct role in the pathogenesis of diabetic nephropathy (DN), and a SNP in acetyl-CoA carboxylase (ACC) 2 is associated with proteinuria in T2D. SNP results in higher expression of ACC2 which likely inhibits FAO by producing higher malonyl-CoA, an inhibitor of carnitine palmitoyltransferase I (CPT1), the rate-limiting enzyme of FAO. Here, we addressed the role of FAO in palmitic acid induced podocyte death, and further explored the role of ACCs in this process.

**Methods:** Conditionally immortalized murine podocytes differentiated for at least 11 days were used. 5-aminoimidazole-4-carboxamide-1β-D-ribofuranoside (Aicar) and etomoxir (CPT1 inhibitor) were employed to alter FAO. $^3$H palmitic acid was used to determine FAO by measuring the release of $^3H_20$. ACC 1 and 2 were silenced using lentiviral system.

**Results:** Aicar decreased palmitic acid induced apoptosis and necrosis by 50.5 ± 1.5% ($p < 0.01$) and 42.5 ± 6.1% ($p < 0.05$). Contrariwise etomoxir exacerbated apoptosis and necrosis by 184.3 ± 6.0% ($p < 0.001$) and 185.1 ± 16.3% ($p < 0.01$) respectively. Aicar phosphorylated AMPK and ACC. Aicar increased oxidation of palmitic acid by 146.6 ± 22.0% ($p < 0.05$) and co-treatment with etomoxir reversed this effect. Only knocking down of both ACC 1 and 2 reduced palmitic acid induced apoptosis 59.6 ± 4.5% ($p < 0.01$) and necrosis 64.4 ± 6.4% ($p < 0.01$). Aicar did not cause added protection in ACC depleted podocytes.

**Conclusions:** Regulation of FAO in podocytes profoundly affects their susceptibility to palmitic acid cytotoxicity. Our data may explain the risk for proteinuria in T2D patients with SNP in ACC2 as reported in previous studies. AMPK-ACC-CPT1 pathway is a potential target to prevent and treat DN.

## TH-PO406

**Role of the TNF Pathway in the Progression of Diabetic Nephropathy**

Tomohito Gohda, Keisuke Omote, Yasuhiko Tomino. *Div of Nephrology, Dept of Internal Medicine, Juntendo Univ Faculty of Medicine, Tokyo, Japan.*

**Background:** Chronic inflammation promotes the progression of diabetic nephropathy (DN). However, the role of TNFα remains unclear. The objectives of the present study are 1) to examine whether TNFα inhibition with a soluble TNF receptor 2 (TNFR2) fusion protein, Etanercept (ETN) improves DN in type 2 diabetic model of KK-$A^y$ mouse, and 2) to also investigate which TNF pathway, TNFR1 or TNFR2, involves predominantly in the progression of DN.

**Methods:** ETN was injected intraperitoneally to the diabetic mice for 8 weeks. Urinary and serum samples were collected at the beginning and end of the experiment. Renal damage was evaluated by immunohistochemistry and/or real time PCR. In vitro, mouse tubular proximal (mProx) cells were stimulated by TNFα and/or high glucose, and treated by ETN. Their supernatants and mRNA were collected.

**Results:** ETN treatments dramatically reduced the levels of not only urinary albumin but also casual blood glucose and HbA1c. However, they did not affect the levels of body weight and blood pressure. Renal mRNA and/or protein expression levels of TNFR2, but TNFα and TNFR1, in the ETN treated diabetic mice (treated mice) were significantly decreased compared with the non-treated diabetic mice (non-treated mice). The mRNA expression levels of ICAM-1, VCAM-1 and MCP-1, and the number of F4/80 positive cells were all dramatically decreased after the treatment. The numbers of cleaved caspase 3 and tunel positive cells in non-treated mice were very few, and did not different from the treated mice. In vitro, TNFα or high glucose markedly increased both TNFRs (TNFR1 and TNFR2) mRNA expression levels unlike in the case of in vivo. While, ETN treatment partly recovered TNFα induced both TNFRs mRNA expressions, but did not affect high glucose induced those expressions.

**Conclusions:** It appears that ETN may improve the progression of DN through predominantly anti-inflammatory action of TNFα-TNFR2 pathway.

## TH-PO407

**Characterization of Angiotensin-Converting Enzyme 2 Shedding from Proximal Tubular Cells**

Fengxia Xiao,[1] Joe A. Zimpelmann,[1] Susan B. Gurley,[2] Lawrence Puente,[1] Kevin D. Burns.[1] *[1]Div of Nephrology, Dept of Medicine, Kidney Research Centre, Ottawa Hospital Research Institute, Univ of Ottawa, Ottawa, Canada; [2]Div of Nephrology, Dept of Medicine, Duke Univ Medical Centre, Durham, NC.*

**Background:** Angiotensin-converting enzyme 2 (ACE2) is expressed in the proximal tubule (PT), where it converts angiotensin (Ang) II to Ang-(1-7). Since urinary ACE2 levels increase in diabetes, the aims of this study were to determine if ACE2 is shed from PT cells, to characterize ACE2 fragments, and to study pathways for shedding.

**Methods:** Studies involved primary cultures of mouse PT cells, and urines from mice with streptozotocin (STZ)-induced diabetes. ACE2 activity was measured with a fluorogenic substrate, and ACE2 fragments were analyzed by immunoblots and mass spectrometry (MS).

**Results:** In media from unstimulated mouse PT cells, a time-dependent increase in ACE2 activity was observed. ACE2 activity also increased in media from cells from ACE2 knockout mice transfected with a human ACE2 vector. In culture media, mouse ACE2 was detected as two bands at ~90 and ~70 kDa on immunoblots. Deglycosylation reduced fragment sizes to ~75 and ~60 kDa. MS of the two fragments identified peptides matching mouse ACE2 at positions 18-706 and 18-577, respectively. The amino acid $Met^{706}$ was identified as a candidate cleavage site for ACE2 shedding. Incubation of PT cells in high D-glucose for 48-72 h significantly increased ACE2 activity in the media ($p<0.001$), an effect blocked by a disintegrin and metalloproteinase (ADAM)-17 antagonist, TAPI-1 ($p<0.001$). High D-glucose significantly increased ADAM-17 activity in cell lysates ($p<0.05$). Wild type STZ-diabetic mice showed a time-dependent increase in urinary ACE2 activity, compared to non-diabetic mice. On immunoblots from diabetic mouse urines, ACE2 appeared as two bands of ~100 and ~75 kDa. MS of these fragments confirmed their origin from ACE2.

**Conclusions:** These data indicate that two glycosylated ACE2 fragments are shed from mouse PT cells. ACE2 shedding is stimulated by high D-glucose via an ADAM-17-mediated pathway. Our results also suggest that diabetes stimulates shedding of ACE2 fragments into the urine.

*Funding:* Government Support - Non-U.S.

## TH-PO408

**Lipoxins Attenuate High-Fat-Diet Induced Chronic Kidney Disease**

Emma Borgeson,[1] Catherine Godson,[2] Kumar Sharma.[1] *[1]Center for Renal Translational Medicine, Div of Nephrology-Hypertension, Dept of Medicine, Institute for Metabolomic Medicine, San Diego, CA; [2]Diabetes Research Centre, Conway Institute, School of Medicine, Dublin, Ireland.*

**Background:** Obesity is an independent risk factor for CKD, even when excluding variables such as diabetes.Visceral obesity is considered a driving force of obesity-related complications and the adiponectin/AMPK pathway has been linked to CKD. Lipid-related metabolites may have disease-promoting and modifying effects, e.g. Lipoxin$A_4$ ($LXA_4$) which displays potent anti-inflammatory and anti-fibrotic actions.

**Methods:** We investigated the therapeutic potential of LXs in a 12wk model of high-fat-diet (HFD) induced CKD in C57BL/6 mice, and the potential underlying role of adiponectin. $LXA_4$ (5ng/g) and benzo$LXA_4$analogue (1.7 ng/g) were given as interventional therapeutics 3 times weekly, between wk 5-12 of standard (10% fat) or HFD (60% fat) regime.

**Results:** HFD increased albuminuria and $H_2O_2$, a marker of ROS and renal injury. LXs significantly attenuated urine $H_2O_2$ (-41% $p<0.05$) and glomerular expansion (-78% $p<0.01$), although albuminuria was not reduced. Interestingly, LXs attenuated adipose inflammation and switched adipose macrophage (MΦs) phenotype from M1 ($CD11c^+$) to M2 ($CD206^+$). LXs did not affect renal MΦ infiltration in this model, suggesting that the LX-mediated reno-protective effect occurred via attenuation of adipose inflammation. We further evaluated the role of the reno-protective adipokine adiponectin, by comparing LX-mediated effects in HFD-WT and HFD-Adiponectin-KO mice. As predicted, KO mice presented with augmented renal injury (increased $H_2O_2$) compared to WT. Surprisingly, LX-induced reduction of renal $H_2O_2$ was augmented in the KO strain (-69 % $p<0.01$). LXs restored insulin-stimulated glucose uptake in the KO strain, although not in the WT animals, suggesting that adiponectin may mask some of the protective LX effect. Importantly, LXs did not alter weight gain, ensuring that the protective phenotype was not due to altered caloric intake.

**Conclusions:** Collectively these data suggests that LXs, through adiponectin-independent reduction of inflammation and MΦ phenotype, may have therapeutic potential in obesity-induced CKD.

## TH-PO409

**Association of Serum Amyloid A with Diabetic Kidney Disease in People and Mice**

Katherine R. Tuttle,[1,2] Sheryl K. Cooney,[1] Robert J. Anderberg,[1] Kelly L. Hudkins,[2] Renee C. Leboeuf,[2] Charles E. Alpers,[2] Rick L. Meek.[1] *[1]Providence Sacred Heart Medical Center, Spokane; [2]Pathology; Metabolism, Endocrinology, Nutrition; Nephrology, Univ of Washington School of Medicine, Seattle, WA.*

**Background:** Serum amyloid A (SAA) is a powerful pro-inflammatory mediator that we detected in the glomeruli and tubulointerstitium of kidneys in mouse models of early/type 1 diabetic kidney disease (DKD) and advanced/type 2 DKD. SAA also directly induced podocyte apoptosis. The study objectives were to assess: 1) SAA in human kidneys; 2) associations of plasma SAA levels with DKD in people and mice; 3) effects of SAA on apoptosis in kidney cells other than podocytes.

**Methods:** SAA immunostaining was performed on kidneys from people with DKD and controls (normal; non-diabetic glomerular disease). Plasma SAA (ELISA) was measured in diabetic people and mice (early/type 1 DKD: streptozotocin C57BL/6; advanced/type 2 DKD: BTBR ob/ob). Mesangial cells and tubular epithelial cells were cultured with SAA to assess early and late-phase apoptosis (caspase 3/7 activity and TUNEL staining).

**Results:** Kidneys from people with DKD (n=3) showed greater amounts of SAA in the glomeruli and tubulointerstitium in a pattern similar to the mouse models. Plasma SAA levels in people with type 2 diabetes and macroalbuminuria were higher than in those with diabetes and normoalbuminuria or non-diabetic controls (0.75+/-0.54, 0.52+/-0.38, 0.28+/-0.17 ug/ml, mean+/-SD, n=10-11 per group, p=0.018). Plasma SAA inversely correlated with estimated glomerular filtration rate (CKD-EPI, r=-0.38, p=0.029). SAA was higher in plasma of diabetic compared to non-diabetic mice: early/type 1 DKD (0.49±0.19 vs 0.10±0.08 ug/ml, n=6-9, p=0.010); advanced/type 2 DKD (0.53±0.38 vs 0.04±0.03 ug/ml, n=5-6, p=0.034). After SAA exposure, mesangial cells and tubular cells exhibited increased caspase 3/7 activity (3-5-fold, n=6-7) and TUNEL staining (2-3-fold, n=8).

**Conclusions:** In people and mice with DKD, SAA localized at sites of glomerular and tubulointerstitial injury and was significantly elevated in plasma. As in podocytes, SAA induced death of mesangial cells and tubular cells, which may contribute to widespread kidney damage in DKD.

*Funding:* NIDDK Support, Pharmaceutical Company Support - Astra Zeneca

## TH-PO410

**Enhanced Store-Operated $Ca^{2+}$ Entry in Glomerular Mesangial Cells in Diabetes Suppresses Extracellular Matrix Protein Expression**

Rong Ma,[1] Sarika Chaudhari,[1] Peiwen Wu,[2] Yanxia Wang.[1] *[1]Integrative Physiology, Univ of North Texas Health Science Center, Fort Worth, TX; [2]Endocrinology, The First Affiliated Hospital of Fujian Medical Univ, Fuzhou, Fujian, China.*

**Background:** The ubiquitous store operated $Ca^{2+}$ entry (SOCE) has a diverse array of function, including promoting cell growth and proliferation. Diabetic nephropathy is characterized with glomerular/mesangial cell (MC) hypertrophy and extracellular matrix expansion. The aim of the present study was to determine if SOCE was involved in the glomerular pathology in diabetes.

**Methods:** Western blot was used to detect the expression levels of STIM1/Orai1 proteins which are molecular components of SOCE, as well as fibronectin and collagen IV proteins, which are the major extracellular matrix proteins in glomerular mesangium. Fura-2 fluorescence ratiometry was utilized to assess SOCE. Whole-cell patch clamp was employed to measure store-operated currents.

**Results:** In cultured human MCs, high glucose (HG) treatment (25 mM for 7 days) significantly increased STIM1/Orai1 protein expressions in a dose dependent manner. The abundance of STIM1/Orai1 proteins was also increased in glomeruli and the renal cortex isolated from diabetic rats induced by streptozotocin and high fat diet, respectively. $Ca^{2+}$ imaging showed that the cyclopiazoic acid (25 μM)-stimulated $Ca^{2+}$ entry was significantly enhanced in human MCs with HG treatment and this enhancement was nearly abolished by GSK-7975A (10 μM), a selective inhibitor of SOCE. Similarly, the whole cell currents induced by the intracellular $Ca^{2+}$ store depletion were significantly augmented in the human MCs with HG treatment. To our surprise, activation of SOCE by thapsigargin (1 μM) dramatically suppressed HG-induced fibronectin and collagen IV protein expressions. In agreement with those findings, inhibition of SOCE by 2-APB (50 μM) or by siRNA against STIM1 increased fibronectin expression.

**Conclusions:** Our results indicate that diabetic hyperglycemia enhances SOCE in MCs by upregulating STIM1/Orai1 proteins, and this enhanced $Ca^{2+}$ signals may protect kidney from diabetic insults by inhibiting synthesis of extracellular matrix proteins.

*Funding:* NIDDK Support

## TH-PO411

**Genetic Deletion of $P2Y_2$ Receptor Confers Significant Resistance to Development of Diet-Induced Obesity and Improves Glucose Tolerance**

Yue Zhang,[1] Carolyn M. Ecelbarger,[2] Bellamkonda K. Kishore.[1] *[1]VA Medical Center & Univ of Utah, Salt Lake City, UT; [2]Georgetown Univ, Washington, DC.*

**Background:** Experimental, clinical and epidemiological data link obesity to the development of diabetes mellitus, metabolic syndrome and chronic kidney disease. Extracellular ATP modulates insulin secretion, and P2 receptors have a role in insulin-stimulated letpin production and lipolysis in white adipocytes. We hypothesized that mice with whole-body knockout (KO) of $P2Y_2$ receptor (R) may have altered response to high-fat diet (HFD)-induced obesity and glucose tolerance.

**Methods:** Groups of age-matched adult wild type (WT) and KO mice were fed regular diet (10% calories as fat; n = 6) or high-fat diet (HFD; 60% calories as fat; n = 14) with free access to food and water for 16 weeks, and euthanized. Feces samples were collected periodically, and glucose tolerance (GT) test was performed during the $14^{th}$ week.

**Results:** Adjusted for body weights (bw), KO mice consumed modestly, but significantly more HFD vs. WT mice, and excreted well-formed feces with no taint of fat or oil. Starting from the $2^{nd}$ week the HFD KO mice displayed significantly lower bw, with terminal mean difference of 20% vs. HFD WT mice. Terminal weights of total white or brown fats were significantly lower in the HFD KO vs. HFD WT mice. Serum insulin, leptin and adiponectin levels were significantly elevated in the HFD WT mice, but not in the HFD KO mice. HFD KO mice had significantly lower levels of blood glucose vs. HFD WT mice at all time points of a GT test, including time 0. Real-time RT-PCR analysis of white fat showed significantly higher expression of PPAR-α, associated with significantly lower expression of angiopoietin-like 4 protein (Angptl4) and IL6 in HFD KO mice vs. HFD WT mice.

**Conclusions:** Since the KO mice consumed modestly higher quantities of the HFD and did not show signs of steatorrhea, these data suggest a higher metabolic rate in the KO mice. Thus, $P2Y_2$-R may have a role in energy metabolism, and can be a potential target for the treatment of diet-induced obesity and/or metabolic syndrome. Future studies should establish the pathways involved in $P2Y_2$-R regulation of energy metabolism.

*Funding:* Veterans Affairs Support, Private Foundation Support

**TH-PO412**

**Renoprotective Effects of Dipeptidyl Peptidase-IV Inhibition in High Fat Diet-Induced Obese Mice** Hyunwook Kim,[1] Ji Eun Lee,[1] Jung Eun Kim,[2] Mihwa Lee,[2] Hye Kyoung Song,[2] Jin Joo Cha,[2] Mi Jin Lee,[2] Sang Youb Han,[3] Young Youl Hyun,[4] Jee-Young Han,[5] Young Sun Kang,[2] Dae R. Cha.[2] *[1]Wonkwang Univ College of Medicine, Korea; [2]Korea Univ College of Medicine Ansan Hospital, Korea; [3]Inje Univ College of Medicine, Korea; [4]Kangbuk Samsung Hospital, Korea; [5]Inha Univ College of Medicine, Incheon, Korea.*

**Background:** Dipeptidyl peptidase-IV (DPP-IV) inhibition is currently being regarded as a promising strategy for diabetes management. However, its direct anti-enzymatic effect on kidney and its consequences are largely unknown.

**Methods:** Normal chow-fed control mice, vehicle-treated high fat diet-induced obese mice, and DPP-IV inhibitor (LC15-0444)-treated high fat diet-induced obese mice were assessed for changes in various metabolic parameters, DPP-IV activity in target organs including kidney, and the parameters for renal damages.

**Results:** After 3 months of treatment, the high fat-induced obese mice administered LC15-0444 at the dose of 3 mg/kg showed no differences in the levels of blood glucose, blood pressure, insulin resistance, and oxidative stress parameters both in kidney and adipose tissue compared with control obese mice. However, treatment with LC15-0444 significantly decreased levels of DPP-IV activity in serum, kidney, fat, and liver of the experimental mice. Furthermore, the mice treated with LC15-0444 showed significantly reduced albuminuria and the tendency to preserve creatinine clearance. In addition, renal histologic examinations showed that the mice treated with LC15-0444 also showed a significantly decrease in glomerulosclerosis and expression of pro-fibrotic markers. In support for these results, a subsequent in vitro study showed that LC15-0444 ameliorated obesity-induced increases in protein expressions of HMGB1, NF-κB, and P-ERK1/2 in renal cortical tissues.

**Conclusions:** In conclusion, Administration of LC15-0444 reduced obesity-induced Increases in enzymatic activity of DPP-IV in the kidney as well as in plasma, and ameliorated renal damages independently of glucose-lowering effect. This renoprotection might be at least partly mediated by anti-inflammatory and anti-proliferative properties.

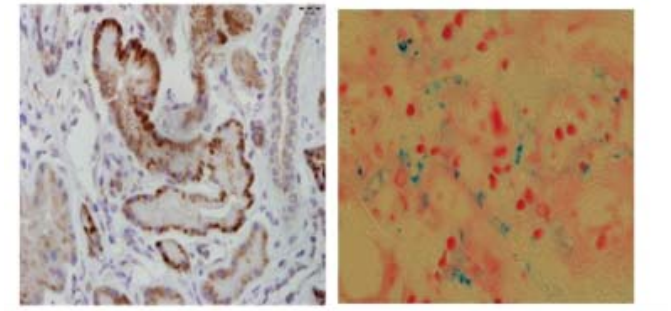
**TH-PO413**

**Increased Expression of Oxidation-Stress and Apoptosis Are Associated with Haptoglobin Genotype in Diabetes Mellitus Patients** Farid M. Nakhoul,[1,2,3] Inbal Mezrahi.[1] *[1]Nephrology Div Baruch Padeh Poriya Medical Center; [2]Diabetic Nephropathy Lab; [3]Faculty of Medicine Bar Ilan Univ, Israel.*

**Background:** We had demonstrated that in diabetic mice with different haptoglobin genotype ( 1-1 , 2-2) there is different susceptibility to diabetic nephropathy (DN). Hp 1-1 DM mice appears to be more protective against diabetic nephropathy than DM mice with Hp 2-2. We found increased iron deposition and oxidative stress in kidney proximal convolute tubules (PCT) of Hp 2-2 vs Hp 1-1, Impaired Hb clearance and increased iron release, induces oxidative stress leading to apoptosis and kidney damage.

**Methods:** 1. We used slides from kidney biopsies of diabetes mellitus patients with different Hp genotype for iron deposition and oxidative stress markers. 2. We will define whether increased renal iron deposits correlates with increased Expression of Oxidation-Specific Epitopes (OSEs) and apoptotic cells in the glomerular and proximal tubules. 3. Quantification of OSEs will perform by immunostaining using an EO6 and IK17 antibodies. The percentage of apoptosis-positive cells will quantify by different apoptotic assays such as Tunel assay, Immunohistochemistry of cleaved caspase 3.

**Results:** 1.Increased iron deposition in PCT of kidney biopsies from patients with Hp 2-2 than in kidney biopsies of patients with Hp 1-1.



Incrased caspase-3 expression H0 2-2 | Increased iron deposition in PCT Hp 2-2

2. Increased expression of Caspase-3 in kidney biopsies of Hp 2-2 patients than in patients with Hp 1-1 genotype.

**Conclusions:** These findings provide insights into genetic predisposition to oxidative stress in Hp 2-2 DM patients. The relationship between increased iron deposition in Renal PCT and macrophage apoptosis that may explain advanced kidney damage and sclerosis in human Hp2-2 kidney biopsies.

**TH-PO414**

**The SGLT2 Inhibitor Empagliflozin Ameliorates Albuminuria in BTBR ob/ob Type 2 Diabetic Mice with and without Hypertension** Florian Gembardt,[1] Natalia Jarzebska,[1] Christoph Bartaun,[1] Eric Mayoux,[2] Vladimir T. Todorov,[1] Bernd Hohenstein,[1] Christian Hugo.[1] *[1]Div Nephrology, Dept Internal Medicine III, Univ Hospital CGC, Dresden, Germany; [2]Div Research, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach/Riss, Germany.*

**Background:** Diabetic nephropathy (DN) is the leading cause of end-stage renal disease in man in the western world. Recent development of sodium-glucose co-transporter (SGLT) inhibitors offers a new anti-diabetic therapy via enhanced glucose excretion. Whether this strategy exerts beneficial effects on developing type 2 DN is unclear. We investigated the effects of the SGLT 2 inhibitor empagliflozin (EMPA; Boehringer Ingelheim) in BTBR ob/ob mice, which spontaneously develop type 2 DN.

**Methods:** First, 25 eight week old female BTBR ob/ob mice either received a 12 week diet containing 300ppm EMPA or equicaloric placebo chow. Second, 16 female BTBR ob/ob mice received osmotic minipumps releasing 1µg/kg BW/d angiotensin (Ang) II and were separated in the same 2 diet groups for 6 weeks. Urine, blood, and tissues were harvested and blood pressure was monitored by tail cuff measurements.

**Results:** In both experiments, EMPA treatment enhanced glucosuria vs vehicle (1191±127 vs 384±118 mg/mg-creatinine, $P<0.001$; Ang II: 1887±96 vs. 1113±250 mg/mg-creatinine, $P<0.05$), thereby lowering blood glucose (204±16 vs 402±27mg/dl $P<0.001$; Ang II: 170±20 vs 368±40mg/dl $P<0.01$). While Ang II infusion induced profound hypertension (146±4 vs 84±1mmHg, $P<0.0001$), EMPA treatment had no influence on blood pressure in normotensive or hypertensive mice (81±1 vs 84±1mmHg; 139±6 vs 146±4mmHg). In both experiments, EMPA reduced albuminuria in diabetic mice (0.5±0.1 vs 1.3±0.4mg/mg-creatinine, $P<0.05$; Ang II: 1.5±0.2 vs 4.8±1.8mg/mg-creatinine $P<0.05$). Immunohistochemical analysis assessed glomerular hypertrophy, matrix expansion, inflammation and proliferation. In contrast to albuminuria findings, histology did not demonstrate any differences.

**Conclusions:** Empagliflozin demonstrated significant anti-hyperglycemic effects ameliorating the development of albuminuria in female BTBR ob/ob mice with and without hypertension while no effects on histology were observed.

**Angiotensin Converting Enzyme-2 (ACE2) Deficiency Accelerates Maternal Diabetes-Induced Perinatal Programming** Shiao-Ying Chang,[1] Min-Chun Liao,[1] Xin-Ping Zhao,[1] Yun-Wen Chen,[2] Yessoufou Aliou,[1] Isabelle Chenier,[1] Julie R. Ingelfinger,[3] Shao-Ling Zhang.[1] *[1]CRCHUM-Hotel Dieu, Univ of Montreal, Montreal, Canada; [2]Pharmacology, National Cheng Kung Univ, Tainan, Taiwan; [3]Pediatr Nephrol Unit, MassGeneral Hosp. for Children, Boston, MA.*

**Background:** Increasing evidence suggests that alterations in the ACE2/ACE ratio within the kidney may participate in perinatal programming of hypertension. We aimed to determine whether ACE2 knock-out ($ACE2^{-/-}$ mice on C57BL/6 background) increases the risk of programmed hypertension and kidney injury in the offspring of dams with gestational diabetes and examined the potential underlying mechanisms *in vivo*.

**Methods:** The 20-week-old offspring of non-diabetic and diabetic dams ($ACE2^{-/-}$, $ACE2^{-/+}$, and $ACE2^{+/+}$) were studied. Systolic blood pressure (SBP), glomerular filtration rate (GFR), renal morphology and reactive oxygen species (ROS) generation, as well as protein expression of Wilms tumor-1 (WT-1), transforming growth factor-beta 1 (TGF-β1) and components of the intrarenal renin-angiotensin system (RAS)--e.g., angiotensinogen (Agt), angiotensin converting enzyme (ACE) and angiotensin II receptor 1 and 2 (AT1R and AT2R), were assessed by immunohistochemistry staining (IHC).

**Results:** As compared with the control littermates, $ACE2^{-/-}$ mice with decreased AT2R in the kidney had a small increase in SBP and age-dependent development of glomerulosclerosis. Offspring of diabetic $ACE2^{+/+}$ dams developed hypertension, renal hyperfiltration, podocyte loss and kidney injury. Renal ROS generation and TGF-β1, Agt, AT1R/AT2R and ACE protein were markedly upregulated in kidneys of hypertensive offspring of diabetic $ACE2^{+/+}$ dams. These changes were more pronounced, but, without affecting AT2R expression in the offspring of diabetic $ACE2^{-/-}$ dams.

**Conclusions:** Our data suggest that ACE2 deficiency is pivotal for the development of the adverse perinatal programming induced by maternal diabetes.

**Urinary miR-29a Content Correlates with Proteinuria and Small Vascular Fibrosis in Type 2 Diabetes Patients** Hui Peng, Meirong Zhong, Wenbo Zhao, Cheng Wang, Jun Zhang, Yuanqing Li, Xun Liu, Tan-Qi Lou. *Div of Nephrology, Dept of Medicine, The Third Affiliated Hospital of Sun Yat-Sen Univ, Guangzhou, Guangdong, China.*

**Background:** Cell-free microRNAs are small non-coding RNAs which stably exist in urine, plasma and other body fluids. Emerging evidence has shown that content of cell-free microRNAs may correlate with particular pathophysiologic conditions and might serve as diagnostic biomarkers. MiR-29 family was reportedly down-regulated in renal fibrosis; therefore, we investigated the possibility of urinary miR-29s as biomarker for diabetic nephropathy in patients with type 2 diabetes (T2DM).

**Methods:** 83 patients with T2DM were divided into 2 groups: with proteinuria (n=42, age 60.62±12.00yrs) and without proteinuria (n=41, age 58.54±14.40yrs). There were no significant differences in age and gender between groups. The content of miR-29a, miR-29b and miR-29c in urine supernatant was determined by TaqMan qRT-PCR, and a synthetic cel-miR-39 was added to the urine as a spike-in control. The clinical laboratory parameters were collected, while retinopathy serves as non-invasive method to assess vascular fibrosis.

**Results:** There was no significant difference in HA1C levels and duration of diabetes between two groups, while the diabetes with proteinuria group had higher comorbidity of diabetes retinopathy and decline in renal function compared with the results of diabetes without proteinuria group. Patients with proteinuria group showed significantly higher level of miR-29a in urine (p=0.035), and urinary albumin excretion rate were significantly correlated with urinary miR-29a level (r = 0.286, p = 0.016). However, there was no significant difference in urinary miR-29b (p=0.148) or miR-29c level (p=0.321) between groups. Similar, no correlation was found between miR29b/c and each of clinical parameters.

**Conclusions:** Urinary miR-29a level rather than miR-29b or miR-29c correlated with proteinuria and vascular fibrosis in patients with T2DM and could serve as alternative biomarker for diabetic nephropathy in T2DM.

## TH-PO417

**Puerarin Attenuated Diabetic Kidney Injury through Down-Regulation of Matrix Metalloproteinase 9 in Streptozotocin-Induced Diabetic Rats**

Yifei Zhong,[1] Yueyi Deng,[2] Yiping Chen.[3] *[1]Nephropathy, Longhua Hospital, Shanghai Univ of Traditional Chinese Medicine, Shanghai, China; [2]Inst#1; [3]Inst#1.*

**Background:** Radix puerariae, a traditional Chinese herbal medication, has been used successfully to treat patients with early stage of diabetic nephropathy (DN). However, the underlined mechanism of its renal protective activity has yet to be investigated. Oxidative stress is one of the key mechanisms in DN. Over-production of ROS induces several changes in the kidneys, which could be detrimental to podocyte during DN.

**Methods:** STZ induced diabetic rat model was successfully generated. Treatment of STZ diabetic rats with puerarin and/or an angiotensin II receptor blocker (ARB) was compared with vehicle control. Kidney morphology and podocyte slit diaphragm were examined by PAS staining and electron microscope respectively. Expression of MMP9, nephrin and podocin were examined by both realtime PCR and immunostaining or western blot. Oxidative stress was determined by measuring 8-hydroxy-2'-deoxy-guanosine (8-OHdG) in the kidney cortex by ELISA.

**Results:** Both puerarin and losartan significantly attenuated proteinuria and podocyte foot process effacement in STZ rats compared with vehicle control.In addition, both puerarin and losartan increased expression of podocyte slit diaphragm proteins such as nephrin and podocin in STZ-induced diabetic rats. However, puerarin appeared to have more potent effect on reduction of oxidative stress and MMP-9 level in diabetic kidneys than ARB.

**Conclusions:** These data suggest that puerarin could prevent podocyte injury in diabetic nephropathy through a mechanism that is different from ARB. Therefore, puerarin could be used with ARB for early stage of diabetic nephropathy.

## TH-PO418

**LP-925219, a Dual SGLT1/SGLT2 Inhibitor, Markedly Increases Urinary Glucose Excretion in Mice Lacking SGLT2**

David R. Powell, Melinda G. Smith, Deon D. Doree, Angela L. Harris, Wendy W. Xiong, Faika Mseeh, Brian Zambrowicz, Zhi-Ming Ding. *Lexicon Pharmaceuticals, Inc, The Woodlands, TX.*

**Background:** Inhibiting sodium glucose cotransporter 2 (S2) to increase urinary glucose excretion (UGE) improves glycemic control in diabetic patients, but clinical trials show that inhibitors highly selective for S2 over SGLT1 (S1) block glucose (G) reabsorption by only 30%. Our past work explained this by using S1 knockout (KO), S2 KO and S1/S2 double KO (DKO) mice to show that S1 reabsorbs 70% of filtered G in the absence of S2. This suggests that dual S1/S2 inhibitors will increase UGE to much more than 30% of maximal values in S2 KO mice and in wild type (WT) mice, a hypothesis tested here.

**Methods:** We developed LP-925219 (LP219) and tested its' ability to inhibit G transport by HEK293 cells expressing mouse S1 or S2. S1 KO, S1 KO/S2 heterozygous (Het), S2 KO, S2 KO/S1 Het, DKO and WT mice were bred, fed G-free diet, and kept in metabolic cages to measure 24-hr UGE after pretreatment with either vehicle or 60 mg/kg LP219 delivered by oral gavage. GFR was measured using FITC-inulin. G was measured by Cobas Integra 400.

**Results:** LP219 IC50=22 nM vs mouse S1, =0.5 nM vs mouse S2; GFR (10-12/group): WT=345±82, S2 KO=426±99, DKO=359±59 uL/min; Blood G (10-12/group): WT=130±15, S2 KO=117±12, DKO=113±10 mg/dL; DKO (10/group): predicted G filtered=586±126 mg/day; measured UGE=648±166 mg/day; UGE data are in Table 1:

Table 1. 24-hr UGE as % of Maximal (DKO) Value

Study 1. Effect of Genotype on 24-hr UGE (n = 12 for each group)

| WT | S1 KO | S1 KO/S2 Het | S2 KO | S2 KO/S1 Het | DKO |
|---|---|---|---|---|---|
| 0 ± 0 | 2 ± 1 | 2 ± 1 | 28 ± 21 | 58 ± 21 | 100 ± 26 |

Study 2. Effect of LP219 on 24-hr UGE (n = 4-5 for each group)

| WT | WT + LP219 | S2 KO | S2 KO + LP219 | DKO |
|---|---|---|---|---|
| 0 ± 0 | 61 ± 11 | 26 ± 18 | 82 ± 22 | 100 ± 38 |

**Conclusions:** 1) UGE differences reflect differences in G reabsorption, not differences in GFR or blood G; 2) in DKO, predicted G filtered over 24-hr is similar to measured UGE, suggesting DKO UGE is maximal; 3) the amount of renal S2 >> S1; 4) dual S1/S2 inhibitor LP219 increases UGE to > 60% of maximal (DKO) in WT and S2 KO mice, suggesting that combined inhibition of renal S1 and S2 can significantly increase UGE over selective inhibition of renal S2 alone.

## TH-PO419

**Profiling of Urinary Proteases in Patients with Diabetic Nephropathy**

Luca Musante,[1] Dongfeng Gu,[1,2] Dorota Ewa Tataruch,[1] Carol Forsblom,[3,4] Per-Henrik Groop,[3,4] Harry B. Holthofer.[1] *[1]Centre for Bioanalytical Sciences, Dublin City Univ, Ireland; [2]The Third Affiliated Hospital of Southern Medical Univ, Guangzhou, China; [3]Folkhälsan Institute of Genetics, Folkhälsan Research Center, Helsinki, Finland; [4]Dept of Medicine, Div of Nephrology, Helsinki Univ Central Hospital, Helsinki, Finland.*

**Background:** Urinary extracellular vesicles originate from all nephron segments and epithelial cell lining the urinary tract. They are released by direct budding of the plasma membrane or through established endosomal secretory pathways. Interestingly they contain a wide spectrum of different molecules including proteins, DNA and various RNA classes. Accordingly, urinary vesicles can be a source of disease biomarkers.

**Methods:** We have deviced a new and simple method to enrich vesicles from urine and employed it successfully in a pilot study of diabetic nephropathy (DN) to detect the variety of proteases associated with the vesicles. Here we wanted to study whether specific proteases similarly characterize DN progression. For this purpose, urinary vesicle from 16 healthy volunteers and a total of 36 patients with type 2 diabetes mellitus (T2DM) were divided into three groups based on the level of albuminuria were concentrated and screened for relative changes of 34 different proteases. Protease profiles were established from the pixel average of fluorescent density changes of spots using an infrared Odyssey scanner and plotted with its image analysis software.

**Results:** The results showed a progressive increase of cathepsins C, D, and X/Z/P in the samples with macroalbuminuria while no changes were observed in the array of kallikreins. The array recapitulates the altered expression of metalloproteases MMP2, -8 and -9. Similarly dysregulation of gelatinase activity were visualized by gel based zymography. Distinct protease activities, including DDP-IV were verified employing specific chromogenic substrates.

**Conclusions:** This study shows for the first time characteristic alterations in protease profiles associated with urinary vesicles in DN and suggests that the underlying mechanisms may reveal important mechanistic, prognostic and diagnostic features in advancing kidney damage.

## TH-PO420

**Akita-DBA2J Mouse: A Model of Diabetic Nephropathy**

Cynthia C. Nast,[1,2] Ying Wang,[2] Janine A. La Page,[2] Sharon G. Adler.[2,3,4] *[1]Cedars-Sinai Medical Center, Los Angeles; [2]LA Biomedical Sciences Inst; [3]Harbor-UCLA Medical Center, Torrance, CA; [4]DaVita Clinical Research.*

**Background:** Better animal models of diabetic nephropathy (DN) are needed. The Akita ($Ins2^{-/-}$) mouse (Ak) develops some DN features. The DBA2J (hematopoietic growth factor-inducible neurokinin-1 (HGFIN) KO) mouse is susceptible to and develops DN features after streptozotocin-induced DM. Ak backcrossed with DBA2J (Ak/DBA2J) mice are reported to have albuminuria, but have not been characterized morphologically.

**Methods:** Ak, DBA2J, and Ak/DBA2J mice had urine ACR, plasma glucose (Glu) and BUN measured. Animals were weighed and kidneys collected at 6 months (mos), stained with PAS and Jones for light microscopy, processed for EM, and examined using semiquantitative scores for features of DN as recommended by the Animal Models of Diabetic Complications Consortium (AMDCC).

**Results:** Glu was normal in DBA2J and increased similarly in Ak and Ak/DBA2J (NS). BUN was numerically, but not statistically, higher in Ak/DBAJ. At 6 mos ACR was increased in non-diabetic DBA2J ($p<.05$ vs 3 mos DBA2J). At 6 mos ACR in Ak/DBA2J (711) trended higher vs DBA2J (290) and was significantly higher vs Ak (180, $p<.02$). Weights were not different. Ak/DBA2J had significantly more diffuse and nodular mesangial matrix expansion (p=0.002 vs DBA2J and vs Ak). Focally, Ak/DBA2J nodules had increased cells, sometimes peripheral. All strains had similar arteriolar hyalinization. Ak/DBA2J (201 nm) and Ak (209 nm) had similarly thickened glomerular basement membranes (GBM) (NS). DBA2J had extensive tubular cell vacuoles, less frequent in Ak/DBA2J and absent in Ak; ultrastructurally these had outer double membranes consistent with autophagic vacuoles.

**Conclusions:** With similar Glu levels, Ak/DBA2J have more albuminuria and matrix expansion with nodules, and similar hyalinization and GBM thickening compared with Ak at 6 mos. Ak/DBA2J and DBA2J have tubular cell vacuolar injury consistent with autophagosomes. The Ak/DBA2J mouse is a potentially useful DN model, meeting several AMDCC criteria. This may be mediated, in part, by arrested autophagosome maturation due to HGFIN reduction from the DBA2J strain, providing a potential therapeutic target in DN.

## TH-PO421

**Evolution of Glomerular Nodular Lesions in Diabetic Pigs Carrying a Dominant-Negative Mutant Hepatocyte Nuclear Factor 1-Alpha** Satoshi Hara,[1] Kazuhiro Umeyama,[2] Takashi Yokoo,[3] Hiroshi Nagashima,[2] Michio Nagata.[1] *[1]Kidney and Vascular Pathology, Univ of Tsukuba, Tsukuba, Ibaraki, Japan; [2]Meiji Univ International Institute for Bio-Resource Research, Kawasaki, Kanagawa, Japan; [3]Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** Glomerular nodular lesion is characteristic pathology in human diabetes, however its morphogenesis is still unknown, partly because of lacking good animal model to have nodular sclerosis. We created diabetic pigs carrying a dominant-negative mutant hepatocyte nuclear factor 1-alpha P291fsinsC and analyzed the process of diabetic nodular formation in these diabetic pigs.

**Methods:** Biochemistry and renal pathology between diabetic pigs and wild-type were analyzed with age of one to nine months. Immunostaining using collagen fibers (type I, III, IV, V, VI), advanced glycation end-products (AGE), and carboxymethyl lysine (CML) was performed to see the content of the lesion. In addition, transmission electron microscopy (TEM) for detecting nodular components and glomerular basement membrane (GBM) thickness were estimated.

**Results:** In diabetic pigs, the blood glucose levels have elevated around 600 mg/dl from 2 weeks old. Proteinuria and renal dysfunction were absent. Glomerular nodular lesions were formed as early as 4 weeks old. The nodules increased and enlarged at 19 weeks old. They distributed deep cortex superior to superficial cortex. Immunohistochemically, the nodules consisted of collagen fibers (type I, III, IV, V, VI). AGE and CML were also deposited in the nodules. TEM showed that the main components of the nodules were interstitial type form of fibril collagens which were located in mesangial area. GBM thickness was not significant between diabetic and wild-type pigs. Moreover, these diabetic pigs did not show any other characteristic features in human diabetic nephropathy.

**Conclusions:** Glomerular nodules in this model of diabetes were characterized by juxta-medullary predominant growth with various types of collagens as well as AGE and CML deposition, without having associated lesion in humans. Thus persistent hyperglycemia and hemodynamic factor can be associated with glomerular nodular formation in diabetic pigs.

## TH-PO422

**Effects of Recombinant Adenoviral Vector-Mediated PC Gene Transfection on Diabetic Nephropathy Atherosclerosis Rats** Li Wang. *Renal Dept, Sichuan Provincial People's Hospital, China.*

**Background:** To observe the expression of plasma APC after recombinant adenovirus gene transfection. And to explore the possible mechanism between atherosclerosis as measured by apoptosis, inflammation, and oxidative stress and APC generation in diabetic nephropathy (DN).

**Methods:** DN with atherosclerosis model rats were randomly divided into three groups: NS group,Ad-GFP group ,Ad-FLT1/PC group. Normal saline, Recombinant adenoviral carrying green fluorescent protein (GFP) gene and recombinant adenoviral carrying GFP gene and FLT-1/PC gene capable of rendering endothelial-specific transgene expression were respectively injected to caudalvein. They were then randomly sacrificed to observe fluorescence distribution in vessel wall. The expression of TNF-a and ICAM-1 and SOD and MDA in the plasma were measured. Cell apoptosis were measured by TUNEL.

**Results:** 3 days after injection of Ad-FLT-1/PC, the green fluorescent was observed in vascular endothelium and PCmRNA was observed. IHC showed the protein C locating in the endothelial cells in Ad-FLT1/PC group was higher.The plasma APC in Ad-FLT1/PC group was significantly higher than GFP or NS group at four time points ($P<0.05$). Detection of TNF-a,ICAM-1 in the vessel wall: Ad-FLT-1/PC transfection significantly decreased the expression of TNF-a, ICAM-1 at 7 days and 14 days ($P<0.05$.GFP group and NS group had no difference at any time ($P>0.05$). Ad-FLT1/PC group, GFP group and NS group rats were showed the phenomenon of cell apoptosis in the vessel wall. The incidence of the cell apoptosis was no statistical difference at each time point ($P > 0.05$).14 days after transfection, Ad-FLT-1/PC group rats had higher concentration of plasma SOD and lower concentration of plasma MDA than Ad-GFP group rats and NS group rats had ($P < 0.05$).

**Conclusions:** The recombinant adenovirus Ad-FLT1/PC can targetly transfect endothelial cell of diabetic nephropathy associated with atherosclerosis rats. The PC can effectively express and be activated into APC in vivo. The APC protects the vessel wall by inhibiting inflammatory cytokines expression and oxidative stress. These dates demonstrate APC may be used as a new therapeutic target to prevent the development of atherosclerosis in diabetic nephropathy.

## TH-PO423

**Augmenting Podocyte Injury Promotes Advanced Diabetic Kidney Disease in Akita Mice** Liming Wang,[1,2] William Eisner,[1,2] Robert F. Spurney.[1,2] *[1]Medicine, Duke Univ Medical Center, Durham, NC; [2]Medicine, Durham VA Medical Center, Durham, NC.*

**Background:** To determine if augmenting podocyte injury promotes the development of advanced diabetic kidney disease, we created mice that expressed the yeast enzyme cytosine deaminase (CD) specifically in podocytes of diabetic Akita mice (Akita-CD mice). In these mice, treatment with the prodrug 5-flucytosine causes podocyte injury as a result of conversion to toxic the metabolite 5-fluorouracil (5-FU) in podocytes.

**Methods:** Akita-CD mice were treated with 5-FC for 5 days at the onset of hyperglycemia in 4-5 week old animals.

**Results:** Treatment with 5-FC significantly enhanced albuminuria at 16 and 20 weeks of age compared to 5-FC treated Akita controls, which do not express the CD transgene (Akita CTL mice). By 20 weeks of age, there was a significant increase in mesangial expansion in Akita-CD mice compared to Akita CTLs, which was associated with interstitial fibrosis in some animals. Podocyte number was reduced in both Akita-CD mice and Akita CTLs at 20 weeks of age and was inversely correlated with the degree of mesangial expansion. Serum creatinine levels were mildly and similarly elevated in Akita-CD and Akita CTLs compared to 5-FC treated wild type controls (CTL mice). Blood glucose levels were similar in both groups of Akita mice.

**Conclusions:** Enhancing podocyte injury at the onset of hyperglycemia promotes the development of advanced features of diabetic kidney disease later in the disease process. Taken together, these data provide additional evidence that glomerular podocytes play a key role in the pathogenesis diabetic nephropathy.

## TH-PO424

**Improved Renal Function after Gastrectomy in Patients without Severe Obesity** Jeong Eun Kim,[1] Gheun-Ho Kim,[1] Chang Hwa Lee.[1] *[1]Internal Medicine, Hanyang Univ College of Medicine, Seoul, Korea; [2]General Surgery, Hanyang Univ College of Medicine, Souul, Korea.*

**Background:** Obesity is a risk factor for developing chronic kidney disease (CKD) that may be improved with bariatric weight reduction. The benefitof renal function after bariatric surgery is generally interpreted as a result of weight loss. The effect of weight loss caused bygastrectomy on glomerular filtration rate (GFR) in patients without severe obesity is unclear. We analyzed the changes in renal function after gastrectomy in patients without severe obesity.

**Methods:** Serum from 99 patients were tested before and 6, 24 months after gastrectomy. The estimation of the glomerular filtration rate (GFR) was addressed by the CKD-EPI creatinine equation.

**Results:** The subjects of this study were 99 patients who did not receive chemotherapy after gastrectomy patients without severe obesity and more than 60 ml/min/1.73 $m^2$ body surface of CKD-EPI eGFR. The patients completed the 6 months follow-up in 99 patients and 2 years follow-up in 55 patients. Of these, ( )% were female. The mean age was 62.5 ± 12.93 years and the mean body mass index was 23.7 ± 3.35 kg/$m^2$, decreasing to 21.3 ± 2.99 kg/$m^2$ at 6 months and 21.4 ± 2.59 kg/$m^2$ at 2 years after gastrectomy. Before surgery, the estimated GFR was 87.2 ± 12.29 mL/min. At the 6 months follow-up, favorable changes in the GFR (90.74 ± 12.13 mL/min, $p<0.001$) not related BMI status were observed and it was continued until 2 years follow up (91.03± 12.94 mL/min, $p<0.01$).

**Conclusions:** A favorable change of gastrectomy in patients without severe obesity was not related BMI change.

## TH-PO425

**Inflammation and Endothelial Function Biomarkers in Adolescents with Obesity and Type 1 Diabetes Mellitus** Salim Aljabari, Sudha P. Chennasamudram, Ruchi Singh, Christopher Sheehan, Grant C. Weinheimer, Tetyana L. Vasylyeva. *Pediatrics, Texas Tech Univ Health Science Center, Amarillo, TX.*

**Background:** Obesity and diabetes have a common pathway in the pathogenesis of atherosclerosis and microvascular damage as both conditions are characterized by chronic low grade inflammatory state which leads to endothelial dysfunction(ED). The aim of the study was to evaluate urinary biomarkers of inflammation and ED in adolescents with obesity(OA) and diabetes(DA). Our ultimate goal is to provide a basis for the development of non-invasive biomarkers that improve diagnostic tests for cardio-vascular health monitoring.

**Methods:** Research subjects were recruited from TTUHSC clinic. An EndoPat 2000 device was used to measure the reactive hyperemia index (RHI). Urine samples were tested for interleukin 6 (IL-6), endothelin 1(ET-1), alpha-1-acid glycoprotein(AGP), and tumor necrosis factor (TNF-α). Statistical significance was assessed using analysis of variance followed by t-tests. Pearson's correlation was calculated between various study parameters. All the markers were normalized with urinary creatinine.

**Results:** 87 adolescents with an average age of 14 years were enrolled. 21 teenagers had diabetes, 30 were obese, 13 were overweight (OW), and 20 had normal weight (NA) (control group). The urinary concentration of TNF-α was significantly higher in the OA (3.01±0.41), OW (2.15±0.35) and DA (2.11±0.22) compared to the NA (1.37±0.08) ($P <0.01$). DA had significantly higher ET-1 (0.68±0.35) vs. NA (0.37±0.20) ($P= 0.03$), and OA and OW showed a higher trend of ET-1 compared to NA (0.63±0.75 $P = 0.13$, and 0.55±0.43; $P=0.11$). There were no significant differences of RHI among different groups.

Levels of IL-6 and AGP were lower in the urine of DA (0.56±0.07 units; P<0.01; 57.3 ±5.8 units; P<0.01) compared to NA (1.28±0.21, 141.7±11.9 Units) and highly correlated (P<0.001) with each other.

**Conclusions:** Urinary levels of TNF-α, IL-6, ET-1, and AGP are significantly different in adolescents with obesity and diabetes compared to their healthy peers. TNF-α seems to be the most sensitive factor. Noninvasive urinary biomarkers are useful in evaluating the degree of inflammation and endothelial function.

## TH-PO426

**Elevations in Fibroblast Growth Factor-23 in Obese, Normotensive Adolescents Are Associated with Adverse Cardiac Structure** Farah N. Ali,[1] Bonita E. Falkner,[2] Heather E. Price,[1] Craig B. Langman.[1] *[1]Pediatrics, Div of Kidney Diseases, Northwestern Univ, Chicago, IL; [2]Div of Nephrology, Thomas Jefferson Univ, Philadelphia, PA.*

**Background:** Fibroblast Growth Factor-23 (FGF23) is a new biomarker for cardiovascular disease in populations with and without chronic kidney disease. Animal models suggest that adipocyte-derived leptin may modulate FGF23 production. Our objectives were: to determine whether obese African American (AA) adolescents without CKD have elevated FGF23 levels compared to non-obese AA adolescents; to determine if FGF23 is related to markers of insulin resistance; to determine if FGF23 is associated with cardiac structure.

**Methods:** Cross-sectional data were obtained from a cohort of 146 normotensive, AAs aged 13-18 yrs with normal kidney function and absent proteinuria; 87 were obese and 59 were non-obese. Plasma C-terminal FGF23, fasting glucose, insulin, adiponectin, and hsCRP were measured; M-mode echocardiography was performed.

**Results:** FGF23 levels were higher in obese versus non-obese subjects (43 vs 22 RU/mL, p<0.001). FGF23 directly correlated with multiple measures of adiposity, including BMI (p<0.001), BMI z-score (p<0.001), and waist circumference (p=0.001). FGF23 directly correlated with fasting insulin (p<0.0005) and HOMA scores (p=0.001). FGF23 directly correlated with hsCRP (p=0.044) and inversely correlated with adiponectin (p=0.040). Median LVM and LVMI increased with increasing quartiles of FGF23, including models adjusted for age, sex, and hsCRP. Left atrial dimension indexed to height increased with increasing FGF23 quartiles. In the obese, FGF23 values above the group median value of 40 RU/mL were associated with larger diastolic time interval ratio. Subjects with eccentric and concentric left ventricular hypertrophy (LVH) had higher FGF23 values than those without LVH (p=0.003).

**Conclusions:** In this homogeneous cohort only differing by BMI, FGF23 was associated with adverse cardiac structure. We postulate that FGF23, a novel CV risk factor in CKD, may be operative in otherwise healthy obese AA adolescents and that the adipocyte may be a critical determinant for the cardiovascular risk in obesity, mediated by FGF23.

## TH-PO427

**A Study of Pattern of Emphysematous and Non Emphysematous Pyelonephritis amongst Hospitalized Type 2 Diabetes Mellitus Patients** Krishan L. Gupta, Raja Ramachandran, Harbir Singh Kohli, Vivekanand Jha, Vinay Sakhuja. *Nephrology, PGIMER, Chandigarh, India.*

**Background:** Diabetes Mellitus is a common cause of pyelonephritis both emphysematous (EPN) and, non-emphysematous pyelonephritis (NEPN) associated with poor outcome. This study aimed at finding the incidence and outcome of these complications in diabetic patients in a tertiary care centre.

**Methods:** A total of 105 diabetic patients with pyelonephritis were admitted from July 2009 to June 201and diagnosis of EPN was based on Huang classification. Patients were treated with appropriate antibiotics and percutaneous drainage (PCD) as and when indicated. Nephrectomy was carried out in patients of EPN who were refractory to conservative measures for 2 weeks. Outcome was termed as poor if there was a need of nephrectomy or the patient died.

**Results:** NEPN and EPN were seen in 79 (75.2) and 26 (24.7) patients respectively. E.coli was the commonest organism. Stone disease (n=13) and poor glycemic control (n=76) were important predisposing factors. Pyelonephritis was associated with renal abscess and papillary necrosis in 13 (12.4) and 4 (3.8) patients. Worsening of renal functions were seen in 92 and 93% of patients with EPN and NEPN respectively. Class 1 EPN was seen in 2(7.7%), class II in 8(30.7%), IIIa in 7(27%), IIIb in 5(19.3) and IV in 4(15.4%) patients. Antibiotics alone were sufficient in 38.5% of EPN vs 62% in NEPN, additional PCD was required in 42.3% in EPN & 21.4% in NEPN. Nephrectomy was required in 5(19.2%) EPN patients with class IIIB or IV. A total of 13 patients (12.4%) expired, 4 (15.4%) in EPN and 9 (11.4%) in NEPN group. Patients with EPN had higher incidence of shock (6 vs. 0; p<0.05) & poorly controlled blood sugar (26 vs. 50; p<0.05). Presence of shock and altered sensorium were associated with poorer outcome in patients with EPN.

**Conclusions:** There is no difference in treatment outcome in both EPN and NEPN group other than a greater need for nephrectomy in EPN patients. Presence of shock and altered sensorium at presentation were poor prognostic factors in EPN.

## TH-PO428

**Urinary Free Light Chain Excretion in Obesity and Diabetes** Tina Kaur Thethi,[1,2] Bonnie Katalenich,[1] Shuqian Liu,[3] Radha Pasala,[1,2] Vivian A. Fonseca,[1,2] Vecihi Batuman.[1,2] *[1]Dept of Medicine, Tulane Univ Health Sciences Center, New Orleans, LA; [2]Dept of Medicine, Southeast Louisiana Veterans Health Care System, New Orleans, LA; [3]Global Health Systems and Development, Tulane School of Public Health and Tropical Medicine, New Orleans, LA.*

**Background:** Obesity is a risk factor for type 2 diabetes (DM). DM is a leading cause of chronic kidney disease (CKD). Urinary free light chains (uFLC) excretion is elevated in early diabetic nephropathy before GFR decline. Purpose was to investigate uFLC, Kappa (k) and Lambda (λ) light chains in obese subjects with and without DM.

**Methods:** Cross sectional, subjects aged 18 to 70 with body mass index(BMI) <27 or >30. uFLC was measured on $SPA_{PLUS}$ analyzer (The Binding Site, Inc., San Diego, CA) using Binding Site Freelite® immunoassays.

**Results:** Table 1 shows comparison between obese subjects with DM and hypertension [HTN](DM+/HTN+) and those without DM and HTN(DM-/HTN-). Comparison between obese(n=442) vs non-obese(n=195) group shows significant differences in urinary(U) k(43.6+81.8,29.4+51.4, $p$<0.01) and Uλ (5.2+17.1,3.0+8.9,$p$=0.04). Multiple regression showed significant positive relationship of urinary microalbumin creatinine[Cr] ratio(UMACR) with λ/UCr($p$<0.001) not Uk/UCr after adjusting for DM, obesity, HTN, gender, age, glucose, BMI, diastolic blood pressure, serum(S)Cr, GFR. UMACR is expected to increase by 178 mg/g for each 1 unit increase in λ /UCr.

**Conclusions:** Excretion of k and λ uFLC is significantly increased in obese subjects with DM and HTN compared to those without DM and HTN. Longitudinal study is needed to assess if uFLC excretion predicts CKD onset earlier than UMACR.

| | Obese DM+/HTN+ | Obese DM-/HTN- | *P* Value |
|---|---|---|---|
| BMI | 37.0 ± 7.1 | 32.3 ± 8.7 | <0.001 |
| S. Cr (mg/dL) | 0.9 ± 0.4 | 1.1 ± 0.6 | <0.001 |
| UMACR (mg/g) | 12.2 ± 42.1 | 2.5 ± 10.9 | <0.05 |
| Urine κ (mg/L) | 61.0 ± 115.0 | 34.4 ± 60.3 | <0.05 |
| Urine κ/Cr (mg/L) | 0.4 ± 0.6 | 0.2 ± 0.3 | <0.05 |
| Urine λ (mg/L) | 8.9 ± 2.0 | 3.5 ± 1.3 | <0.05 |
| Urine κ+λ/Cr (mg/L_ | 0.42 ± 0.7 | 0.2 ± 0.3 | <0.05 |
| Glucose (mg/dL) | 131.0 ± 55.3 | 83.5 ± 21.0 | <0.001 |

## TH-PO429

**Elevated Serum Free Light Chains Predict Poor Cardiovascular Outcomes in Type 2 Diabetes** Srikanth Bellary,[1] Jeffrey Faint,[2] Lakhvir Assi,[2] Stephen Harding,[2] Anthony H. Barnett.[1] *[1]Heart of England NHSFT, Birmingham, United Kingdom; [2]The Binding Site Group Ltd., Birmingham, United Kingdom.*

**Background:** Several risk factors including glycated hemoglobin, proteinuria and hypertension are associated with increased risk of cardiovascular disease (CVD) in diabetes; however, their ability to predict the risk of CVD events is limited. Elevated polyclonal combined serum free light chains (cFLC) are associated with adverse outcomes in chronic kidney disease and other inflammatory conditions, reflecting both the degree of renal impairment and the severity of inflammation. Here we investigate the role of cFLC in predicting CVD related events in chronic diabetes.

**Methods:** Serum cFLC and hsCRP were assessed in 352 South Asian type 2 diabetic patients and compared with other standard clinical measurements, treatment and prior history of CVD. Each variable was assessed for utility in predicting CVD related deaths or events, over 2 years, using logistic regression analysis.

**Results:** 29/352 (8%) patients suffered an adverse CVD outcome and cFLC was significantly elevated in these patients, compared to patients with no events (50.7vs 42.8mg/L p=0.004); hsCRP did not show a significant difference (4.5vs3.6mg/L p=0.389). cFLC>57.2mg/L (odds ratio (OR) 3.3,95%CI 1.3-8.2, p=0.012), triglycerides>6.7mmol/L (OR 18.3, 95%CI 5.1-65.5, p<0.001), and SBP>155mmHg (OR 3.6, 95%CI 1.5-8.7, p=0.004) were independently associated with CVD outcomes and remained significantly associated after adjusting for age, ACR, diabetes duration or treatment. ACR and prior history of CVD were not independently associated with outcome. Individually, elevated cFLC, SBP or triglycerides identified 45%, 41% and 21% of patients with adverse CVD outcomes, respectively. A simple risk stratification model including these 3 markers identified patients with 0, 1 (OR 5.7, 95%CI 2.1-15.0 p=0.001) or 2 (OR 15.4, 95%CI 4.8-49.3 p<0.001) risk factors. 79% of patients who suffered an adverse CVD event were abnormal for ≥1 risk factor.

**Conclusions:** Elevated cFLC concentrations independently predicted CVD outcomes in diabetic patients. Further studies are required to assess the utility of cFLC measurements in this setting.

## TH-PO430

**Renal Amyloidosis in Patients with Type 2 Diabetes Mellitus** Ramón A. Díez,[1] Gerardo Gamba,[3] Virgilia Soto,[1,2] Juan Soriano,[2] Magdalena Madero.[1] *[1]National Heart Institute Mexico; [2]Hospital General de Mexico; [3]INCMNS.*

**Background:** Type 2 Diabetes Mellitus (T2DM) is the leading cause of chronic kidney disease (CKD) and a major cause of cardiovascular disease (CVD) mortality. Inflammation is closely involved in the pathogenesis of T2DM and in the development of

chronic vascular complications. Reactive amyloidosis (AAA) is a condition that occurs in the presence of chronic inflammation. We hypothesized that patients with T2DM may have a higher prevalence of Renal Amyloidosis (RAAA) and that this could contribute to worse kidney and vascular disease.

**Methods:** This was an observational cross-sectional study that included autopsy kidneys from patients with previous diagnosis of T2DM. Vascular tissue damage (chronic ischemic cardiomyopathy, myocardial infarction, aortic, coronary and intrarenal atherosclerosis) and RAAA were the variable outcomes of interest. The kidney tissue was evaluated by two different pathologists in order to determine the presence of diabetic nephropathy, RAAA (defined as the positivity of immunohystochemistry through indirect immunoperoxidase with the primary AA antibody) and the severity of vascular tissue damage.

**Results:** 330 autopsy cases of T2DM were included in the study. The mean age of the population was 61± 13 years and 47% were female. Eighty percent of the population had diabetic nephropathy. RAAA was detected in 9% of our population and was associated with an increased risk [OR (95% CI)], [11 (2.04 to 59.16)] for nodular sclerosis, [4.59 (2.02 to 10.42)] for chronic ischemic cardiomyopathy, [3.41 (1.52 to 7.64)] for myocardial infarction and [4.75 (1.09 to 20.69)], [3.22 (1.47 to 7.04)] and [3.84 (1.46 to 10.09)] for aortic, coronary and intrarenal atherosclerosis, respectively. The presence of RAAA was confirmed by electronic microscopy in some randomly selected cases.

**Conclusions:** RAAA is prevalent amongst T2DM and is associated with worse cardiovascular, aortic and renal disease. RAAA is a marker of severe chronic inflammation and this likely explains our results. Studies replicating our findings in other populations are warranted in order to confirm these associations.

## TH-PO431

**Pulse Pressure Is Not a Predictor of Outcome in Type 2 Diabetes Patients with Chronic Kidney Disease and Anemia–The TREAT TRIAL**

Simone Theilade,[1] Brian Claggett,[2] Jerome A. Rossert,[3] Tine Hansen,[1] Hicham Skali,[2] Eldrin F. Lewis,[2] Scott D. Solomon,[2] Hans-Henrik Parving,[4,5] Marc A. Pfeffer,[2] John J. Mcmurray,[6] Peter Rossing.[1,4] *[1]Steno Diabetes Center, Denmark; [2]Harvard Medical School, Brigham and Women's Hospital; [3]Amgen; [4]Univ of Copenhagen, Denmark; [5]Rigshospitalet, Denmark; [6]Univ of Glasgow, United Kingdom.*

**Background:** After more than 2 decades of research pulse pressure (PP) remains an elusive cardiovascular (CV) risk factor with findings being inconsistent. We clarified the prognostic value in patients with the triad of type 2 diabetes, chronic kidney disease (CKD), and anemia in the Trial to Reduce cardiovascular Events with Aranesp (darbepoetin-alfa) Therapy (TREAT).

**Methods:** In TREAT, 4038 patients were randomized to darbepoetin alfa or placebo. Using Cox proportional hazards models we calculated multivariable-adjusted (including age, gender, kidney function, CV disease, $HbA_{1c}$, hemoglobin and other conventional risk factors) hazard ratios (HRs) to assess risk related to PP at randomization.

**Results:** Median (IQR) age was 68(60-75) years, 57.3 % women, diabetes duration was 15.4(8.3-21.7) years, eGFR was 34(26-43) ml/min/1.73m$^2$. SBP, DBP and PP was 136(122-148), 71(64-80) and 60(50-74) mmHg.

Over 29.1 months (median), the number of patients experiencing the composite of CV death, nonfatal myocardial infarction (MI), stroke, hospitalization for myocardial ischemia, or heart failure, that is, the primary end point excluding non-CV deaths was: 1010, MI:253, stroke 154 or end stage renal disease (ESRD) 668.

Unadjusted analyses showed that higher quartiles of PP was associated with increased event rates per 100 years of follow up ($p\leq0.04$), except for stroke ($p=0.52$). However, adjusted HRs (95% confidence interval) per 10mmHg increase in PP were 1.00(0.96-1.04) for fatal and nonfatal combined CV events, 1.06(0.98-1.14) for MI, 0.96(0.87-1.06) for stroke, and 1.02(0.98-1.07) for ESRD.

**Conclusions:** In patients with type 2 diabetes, CKD, and anemia, PP did not predict CV events or ESRD. This may reflect the relatively narrow range of PP, partly because of extensive antihypertensive treatment in this specific population.

## TH-PO432

**Central Hemodynamics Is Associated with Diabetic Complications in Type 1 Diabetes**

Simone Theilade,[1] Tine Hansen,[1] Peter Rossing.[1,2,3] *[1]Steno Diabetes Center, Denmark; [2]Aarhus Univ, Denmark; [3]Univ of Copenhagen, Denmark.*

**Background:** To investigate the associations between central hemodynamics and diabetic complications in type 1 diabetes.

**Methods:** Cross-sectional study, 676 type 1 diabetes patients, mean±SD age 55±13, 375(56%) male. Arterial stiffness was measured by pulse wave analyses (PWA), as central aortic systolic pressure (CASP), central diastolic pressure (CADP), central pulse pressure (CPP) and subendocardial viability ratio (SEVR) (an index of myocardial oxygen supply and demand). All measurements were obtained with the SphygmoCor device (Atcor Medical, Australia), and standardized values of hemodynamic measures used in adjusted analyses. Complications were presence of albuminuria ( ≥30mg/24-hour), cardiovascular disease (CVD), retinopathy or autonomic dysfunction (heart rate variability <11 beats/minute).

**Results:** PWAs were available in 636 patients. Mean±SD CASP: 118±17 mmHg, CADP: 75±10 mmHg, CPP: 43±14mmHg, and SEVR: 150±32. Albuminuria, CVD, retinopathy and autonomic dysfunction was present in 52, 21, 78 and 59% of patients. CVD and autonomic dysfunction were associated with: CASP (per 1 SD increase): odds ratios (OR)=3.7(2.0-6.6) and 4.7(2.6-8.4); CADP: OR=0.3(0.2-0.6) and 0.3(0.2-0.6); CPP: OR=2.0(1.5-2.8) and 2.2(1.6-3.0); and SEVR: OR=0.6(0.4-0.9) and 0.4(0.3-0.6) (adjusted for gender, diabetes duration, mean arterial pressure, heart rate, height, urinary albumin excretion rate (UAER), eGFR, $HbA_{1c}$, cholesterol, antihypertensive medication and smoking). None of the hemodynamic variables were associated with albuminuria or retinopathy ($p\geq0.14$). However, when UAER was analysed as a continuous variable in adjusted regressions, all hemodynamic variables were significantly assocatiated with the level of UAER ($p\leq0.001$).

**Conclusions:** In patients with type 1 diabetes, measures of central hemodynamics are independently associated with CVD, autonomic dysfunction and level of UAER, but not with albuminuria or retinopathy. Future studies are needed to determine if targeting central hemodynamics improve outcome.

## TH-PO433

**Long-Term Intraindividual Variability in Albumin Excretion Rate with Type II Diabetes**

Amanda Leong,[1] Elif I. Ekinci,[2,4,5] George Jerums,[2] Richard J. MacIsaac.[3] *[1]The Univ of Melbourne, Australia; [2]Dept of Endocrinology, Austin Health, Australia; [3]Dept of Endocrinology & Diabetes, St. Vincent's Health, Australia; [4]Senior Research Officer Menzies School of Health Research; [5]Senior Research Officer The Univ of Melbourne.*

**Background:** There is paucity of data on the long-term variability of Albumin Excretion Rate (AER) in patients with type II diabetes. This study aimed to determine the variability of AER and factors that influence it, in type II diabetic patients.

**Methods:** Consecutive AER measurements from 1999-2012 of 497 type II diabetic patients were recorded in a cohort study. Coefficient of variation (CV) was used as a measure of intraindividual AER variability. First three AER measurements were used to classify individuals into normo-, micro- and macroalbuminuria groups at baseline. Linear regression examined the effects of baseline demographic variables on the AER CV: AER group, HbA1c, age, gender, duration of diabetes, total cholesterol, HDL, systolic BP, BMI, ACEi/ARB use at baseline and smoking. Logarithmic transformation was applied to CV prior to analyses.

**Results:** The intraindividual variability in AER was higher in those treated with ACEi/ARB use in 2000 (n=312) than those untreated (n=185) patients (p=0.003). There was no evidence of a relationship between the AER CV and baseline characteristics. Linear regression of log CV in treated and untreated groups and AER groups was used. After adjustment for AER groups, the difference in mean CV between the treated and untreated groups remained significant (p=0.013). After adjustment for ACEi/ARB use, the mean CV in the microalbuminuria group was 1.27 times that of the normoalbuminuria group, 1.15 times greater in macroalbuminuria compared to the normoalbuminuria, with no difference for micro- versus macroalbuminuria groups. Overall, p<0.001.

**Conclusions:** Patients with type II diabetes and micro- or macroalbuminuria have a greater AER CV than those with normoalbuminuria at baseline. There was a greater intraindividual CV in those treated with ACEi/ARB indicating greater changes in AER over time in these patients. These results emphasize the need for serial AER measurements in assessing AER trajectory.

## TH-PO434

**The Effect of Insulin Sensitivity on the Magnitude of Albuminuria**

Amy K. Mottl, Jasmin Divers, Dana Dabelea, David M. Maahs, Santica M. Marcovina, David J. Pettitt, Lawrence M. Dolan, Michael Mauer, Elizabeth Mayer-Davis. *The SEARCH for Diabetes in Youth Study Group.*

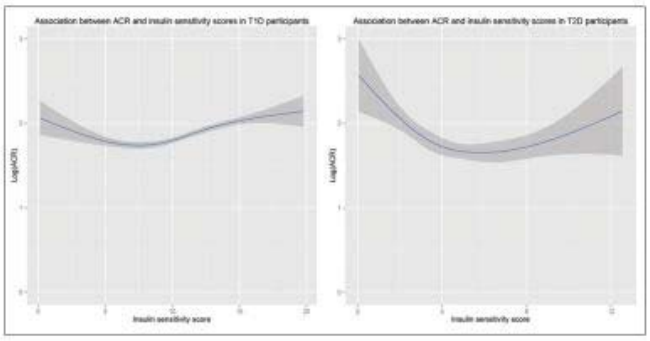
**Background:** We sought to identify a threshold of insulin sensitivity (IS) below which urine albumin excretion increases, and whether this threshold differs according to diabetes type.

**Methods:** SEARCH is an observational study of children with newly diagnosed DM. IS was estimated using a validated equation. Urinary albumin to creatinine ratio (UACR) was calculated from a random urine specimen. Within each diabetes type, segmented regressions were fitted to identify the threshold at which the slope of the function relating insulin sensitivity to UACR changes. After estimating the threshold, multivariate regression analyses were performed using the generalized linear model, stratifying according to the estimated IS threshold.

**Results:** Baseline characteristics stratified by diabetes type are shown below.

| Characteristics | Type 1 n=2551 mean (SD) | Type 2 n=399 mean (SD) |
|---|---|---|
| Age, yrs | 11 (4) | 15 (3) |
| Male, n(%) | 1352 (53) | 160 (40) |
| Non-Hispanic White, n(%) | 76 (4) | 24 (42) |
| IS score | 10.5 (3.3) | 4.4 (2.2) |
| Microalbuminuria, n(%) | 10 (30) | 17 (38) |

The IS threshold below which UACR was statistically associated with IS was 4.7 for type 2 and 6.7 for type 1 diabetic participants (Figure 1). For both DM types, analyses stratified by the IS threshold showed an association with UACR only in the stratum below the threshold. The beta coefficient in the model adjusted for age, gender and race/ethnicity was -0.17 ($p=4.6\times10^{-6}$) in type 1 participants and -0.27 ($p=2.1\times10^{-4}$) for type 2 participants.



**Conclusions:** In youth with diabetes, there is a threshold of IS, below which UACR is negatively associated with IS. In children with type 2 versus type 1 DM, the effect is stronger, but the threshold is lower.

## TH-PO435

**Pathologic Classification of Diabetic Nephropathy in Predicting Renal Death**

Amy K. Mottl, A. Gasim, Fernanda Payan Schober, Yichun Hu, Caroline J. Poulton, Susan L. Hogan, J. Charles Jennette. *Univ of North Carolina Kidney Center.*

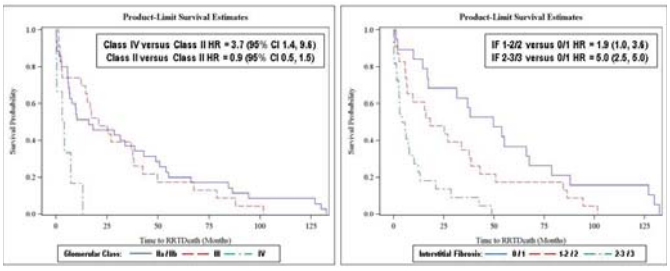
**Background:** A novel nephropathological classification scheme for diabetic nephropathy was devised by the Renal Pathology Society (RPS) in 2010. The utility of this system in predicting subsequent end-stage renal disease (ESRD) has not been determined across populations of broad ethnic background.

**Methods:** Specimen from clinical kidney biopsies performed between 1998-2006 and containing diabetic glomerulosclerosis in the final diagnoses, were reanalyzed according to the RPS classification system for diabetic nephropathy. Tubular atrophy was categorized between 0 and 4. Clinical data was extracted from medical records from the time of biopsy until the onset of renal replacement therapy (RRT). Kaplan–Meier estimates calculated the percentage of participants who required RRT during follow-up, stratified by glomerular class or severity of fibrosis. Univariate and multivariate Cox proportional-hazards regression analyses were run, adjusting for ethnicity, baseline creatinine and urine protein:creatinine ratio.

**Results:** Demographic and clinical data from the date of biopsy are displayed in the following table.

| Characteristics | Mean (95% CI))<br>N=70 |
|---|---|
| Age, years | 51 (47,55) |
| Female gender, % | 35 (50) |
| NonHispanic Black, % | 34 (46) |
| HbA1c, % | 8.2 (7.4,9.1) |
| Diabetes duration, yrs | 13.0 (11.1,14.1) |
| Body mass index | 54 (45,62) |
| Serum creatinine, mg/dl | 3.8 (3.2,4.4) |
| Urine protein:creatinine | 6.5 (4.9,8.0) |
| Glomerular class:<br>IIa/IIb<br>III<br>IV | <br>38 (54%)<br>25 (36%)<br>7 (10%) |
| Interstitial fibrosis:<br>0/1<br>1-2/2<br>2-3/3 | <br>19 (27%)<br>25 (36%)<br>26 (37%) |

Survival analysis according to glomerular class and interstitial fibrosis and unadjusted hazard ratios are displayed in the following figures. Multivariate adjustment did not significantly change the results.



**Conclusions:** The severity of glomerular sclerosis and interstitial fibrosis are highly predictive of impending need for RRT.

## TH-PO436

**A New Cutoff for Abnormal Proteinuria in Diabetes Mellitus Patients: Relationship to Albuminuria**

Arie Erman,[1] Orit Erman,[1] Alina Vodonos,[3] Uzi Gafter,[1,2] David Jonathan Van Dijk.[1,2] *[1]Nephrology and Hypertension, Rabin Medical Center, Petah Tikva, Israel; [2]Sackler School of Medicine, Tel Aviv Univ, Tel Aviv, Israel; [3]Public Health, Faculty of Health Sciences, Ben-Gurion Univ of the Negev, Beer Sheva, Israel.*

**Background:** New and more sensitive methods have been developed to detect low levels of proteinuria, which could not be detected in the past. The main goal of this study was to evaluate the association between proteinuria below 300mg/24 hours and albuminuria, as well as a possible association with renal function in patients with diabetes mellitus (DM).

**Methods:** Medical files of patients with type 1 and type 2 DM who presented with proteinuria below 300 mg/24h at three different visits to the Diabetic Nephropathy Clinic, spaced with a minimal three months interval, were screened. The 245 patient files that were screened, included 723 visits. The data collected included demographics; protein, albumin and creatinine levels in urine collections; blood biochemistry; clinical and treatment data. The data were analyzed using SPSS 18.

**Results:** A moderate association was found between proteinuria in the range below 300mg/24hr and albuminuria. The strongest association was found in type 2 diabetic patients (r=0.624, P<0.001). Proteinuria cutoff, based on albuminuria cutoff of 30mg/24hr, was found to be 160.5mg/24hr. BMI was the sole independent predictor of proteinuria above 160.5mg/24hr. The other variables examined such as creatinine clearance, age, hypertension, duration of diabetes, HbA1c, ACE inhibitors and angiotensin II blockers, were not predictive. Changes in proteinuria, but not albuminuria, were not associated with changes in creatinine clearance.

**Conclusions:** A new cutoff value of 160.5mg/hr was set empirically, for the first time, for abnormal proteinuria in diabetic patients. As there was no association between proteinuria and creatinine clearance, it appears that proteinuria below 300mg/24hours is not sufficient as a sole prognostic factor for kidney injury.

## TH-PO437

**Non-Invasive Assessment of Electrochemical Skin Conductance Associates with Kidney Function in African Americans (AA) with Type 2 Diabetes (T2D)**

Barry I. Freedman, Jasmin Divers, Susan Carrie Smith, Jianzhao Xu, Donald W. Bowden. *Wake Forest Univ Health Sciences.*

**Background:** SUDOSCAN® (Impeto Medical, Paris France) is a patented non-invasive measure of sweat gland dysfunction employing electrochemical skin conductance (reverse iontophoresis and chronoamperometry) and is useful for assessing peripheral small fiber and autonomic nerve function.

**Methods:** We tested whether SUDOSCAN® measures differed between AA and European Americans (EA) and for associations with parameters of diabetic kidney disease (estimated glomerular filtration rate [eGFR] and urine albumin:creatinine ratio [UACR]) within each population. A cross-sectional study of renal parameters and SUDOSCAN® skin conductance was performed in 390 cases with T2D (206 AA; 184 EA) and 168 non-diabetic controls (93 AA; 73 EA). Linear models were fitted stratified by population ancestry and T2D status, adjusted for co-variates.

**Results:** Relative to EA, AA had markedly lower mean (hand + foot) skin conductance (AA T2D vs. EA T2D p<0.0001; AA controls vs. EA controls p<0.0001). As expected, mean (hand + foot) skin conductance was also lower in T2D cases vs. non-diabetic controls within each population ancestry (p<0.0001 for both AA and EA). Adjusting for age, gender, body mass index, and HbA1c, significant positive associations were detected between mean (hand + foot) skin conductance and eGFR in AA cases with T2D (parameter estimate 15.4, standard error 5.7; p=0.0073); but not in EA with T2D (p=0.44). Significant associations between UACR and mean skin conductance were not observed in AA or EA with T2D.

**Conclusions:** Non-invasive measures of skin conductance previously associated with diabetes mellitus and neuropathy, strongly associate with eGFR in AA. This replicates results in a Hong King Chinese population. In contrast, skin conductance was not associated with measures of kidney disease in EAs. SUDOSCAN® may prove useful as a low cost and non-invasive screening tool in African ancestry populations with T2D allowing for the detection of undiagnosed kidney disease. Differences in skin conductance between EA and AA with T2D and non-diabetic controls is an interesting finding that warrants further study.

## TH-PO438

**Vitamin D Levels and Renal Progression in Type 2 Diabetic Patients with Blockade of the Renin Angiotensin System**

Jose Luno,[1] Fernández Gema Maria,[2] Soledad Garcia de Vinuesa,[1] Marian Goicoechea,[1] Jesus Oliva Dominguez,[3] Luisa Casas Losada,[2] Vicente Lahera.[4] *[1]Hospital General Universitario Gregorio Marañon, Madrid, Spain; [2]Hospital Fundación Alcorcon, Madrid, Spain; [3]IS Carlos III, Madrid, Spain; [4]Universidad Complutense, Madrid, Spain; [5]On behalf of the PRONEDI Study Group.*

**Background:** Experimental studies show that vitamin D is a suppressor of renin biosynthesis and that vitamin D deficiency has been associated with the progression of chronic kidney disease (CKD). Patients with type 2 diabetes and CKD have an exceptionally high rate of severe vitamin D deficiency, but it is not known whether this deficiency is a risk factor for progression of diabetic nephropathy (DN).

**Methods:** We measured 25 (OH) vitamin D levels in the patients included in a multicenter randomized controlled trial to compare the efficacy of combining the

angiotensin-converting enzyme inhibitor lisinopril and the angiotensin receptor blocker irbesartan with the efficacy of each drug in monotherapy to slow progression of established type 2 DN. The primary composite outcome was a >50% increase in baseline serum creatinine or end-stage renal disease or death. Samples from 103 patients were obtained to determine levels of 25 (OH) vitamin D at baseline and at 4 and 12 months.

**Results:** Fifty-three (51.5%) patients had 25 (OH) vitamin D deficiency (<15 ng/mL). After a median follow-up of 32 (18-48) months, the endpoint was reached by 23 patients with deficiency (43.4%) and 8 patients without (16%). Cox regression analysis showed that 25 (OH) vitamin D deficiency was associated with primary outcome (HR, 2.88; 95% CI, 1.84 -7.67; p=0.04) and renal outcome (HR, 3.79; 95% CI, 1.20-12.02; p=0.02). The effect of 25 (OH) vitamin D did not change with age, gender, weight, treatment with RAS blockers (monotherapy or combined treatment) or levels of aldosterone, PTH, albumin, and phosphorus.

**Conclusions:** Our results show that 25 (OH) vitamin D deficiency is an independent risk factor for renal progression of type 2 DN.

## TH-PO439

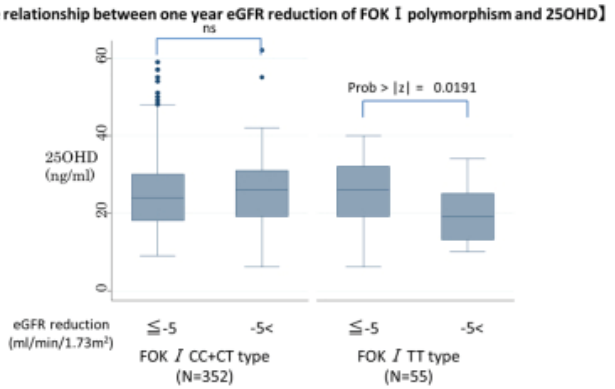
**Interaction between Vitamin D Receptor Polymorphisms and 25OHD Levels on Reduction of eGFR in Type 2 Diabetes Mellitus** Akio Nakashima,[1] Keitaro Yokoyama,[1] Ichiro Ohkido,[1] Mitsuyoshi Urashima,[2] Takashi Yokoo.[1] *[1]Div of Kidney and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan; [2]Div of Molecular Epidemiology, Jikei Univ School of Medicine, Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** FokI polymorphisms of vitamin D receptor (VDR) gene were shown to be different in patients with type 2 diabetes mellitus from controls. Furthermore, deficiency of 25-hydroxyvitaminD (25OHD) was reported to decrease insulin production, increase insulin resistance and diabetic nephropathy. However there are few reports to research interactions between 25OHD and VDR polymorphisms in diabetic patients.Therefore, we aimed to investigate the relationship between one year-reduction of eGFR and serum 25OHD levels stratified by VDR FokI polymorphisms in patients with diabetes.

**Methods:** The prospective cohort study was carried out at Jikei University hospital. A total of 407 type 2 diabetic outpatients agreed to participate in this study. We used polymerase chain reaction and direct sequencing analyze VDR FokI polymorphisms.

**Results:** Median age was 63 years, mean eGFR was 66.3±23.0 ml/min/1.73/m$^2$ and average disease duration of diabetes was 12.4±8.8 years. Genotype frequencies were FokI: CC:180 CT:172 TT:55. Mean reduction of eGFR during one year was -2.2 ml/min/1.73m$^2$. Primary outcome was defined as -5ml/min/1.73m$^2$ reduction in eGFR during one year in this study. Lower 25OHD levels significantly increased the risk of the primary outcome in patients with FokITT polymorphism (P=0.0191), whereas 25OHD levels had no significant associations with the primary outcome in those with either FokICC or CT polymorphisms.

**Conclusions:** These results suggest that eGFR may rapidly decrease in diabetic patients with lower 25OHD levels and FokITT polymorphism.



## TH-PO440

**Effect of Aldosterone Blockade on Galectin 3 in Patients with Diabetic Nephropathy** Morten Lindhardt,[1] Maria Lajer,[1] Hiddo Jan Lambers Heerspink,[2] Peter Rossing,[1,3,4] Rudolf A. de Boer.[2] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Univ Medical Centre, Univ of Groningen, Netherlands; [3]Univ of Aarhus, Denmark; [4]Univ of Copenhagen, Denmark.*

**Background:** Fibrosis and expansion of extra cellular matrix in the kidney is part of the pathogenesis of diabetic nephropathy. Plasma galectin-3 (p-gal3) is linked to fibrogenesis in the heart and kidney, and treatment with spironolactone has beneficial effect in patients with heart failure. We hypothesize, that a potential beneficial effect of spironolactone on fibrosis in diabetic nephropathy is mediated through a reduction in p-gal3.

**Methods:** A post-hoc analysis of three clinical controlled double masked intervention trials all with randomisation to either spironolactone or placebo for 8 weeks in a cross-over design. The first trial consist of 25 patients with 1 DM and macroalbuminuria, the second consist of 23 patients with type 2 DM and macroalbuminuria and the third consist of 21 patients with type 1 DM and microalbminuria. Mean(SD) age of 53 years (10.8) and a mean duration of DM of 28 years (14.6).

**Results:** As previously reported albuminuria was reduced with 30, 33 and 60% in the three trials. P-gal3 was associated with GFR in the placebo period ($R^2$=0.42 p<0.0001). Mean(95% CI) level of plasma p-gal3 after treatment with spironolactone was 16.0(14.7-17.4) and after placebo 15.5(14.3-16.7). In an unadjusted mixed model, the effect of treatment insignificant increased p-gal3 by 1.03 ng/ml (1.02-1.05) (p=0.074). However, when adjusted for after treatment values of mean 24h systolic blood pressure, 24h urine albumin excretion, $^{51}$Cr GFR, $Hba_{1c}$ and cholesterol, the treatment effect on p-gal3 was attenuated (p=0.69). Patients with p-gal3 below the median in the placebo period had a greater reduction in albuminuria 31.3%(25.1-37.6) vs. those above 8.8%(-2.9-20.4), p=0.021.

**Conclusions:** Galectin 3 was associated with GFR. Spironolactone for two months reduced albuminuria but did not change p-gal3 levels. This suggests an initial effect mediated by hemodynamic changes, whereas an effect on fibrosis may require a longer treatment period or p-gal3 is not affected by spironolactone. Low level of p-gal3 was associated with greater reduction in albuminuria.

## TH-PO441

**A Panel of Novel Biomarkers to Predict Renal Function Decline in Type 2 Diabetes** Michelle Pena,[1] Sara S. Roscioni,[1] Stephan J.L. Bakker,[2] Paul Perco,[3] Dick de Zeeuw,[1] Hiddo Jan Lambers Heerspink.[1] *[1]Dept of Clinical Pharmacology, Univ Medical Center Groningen; [2]Div of Nephrology, Univ Medical Center Groningen; [3]Emergentec Biodevelopment GmbH.*

**Background:** We aimed to explore a panel of novel biomarkers representing different disease pathways for their potential association with accelerated renal function decline in type-2 diabetes.

**Methods:** A systematic data integration approach was used to identify promising biomarkers for this study. The following biomarkers were selected and tested in 82 patients with type-2 diabetes recruited from an outpatient diabetes center in The Netherlands: amino-terminal propeptide of CNP (NTproCNP), tumor necrosis factor receptor-2 (TNFR2), sclerostin, fibroblast growth factor-23 (FGF23), endostatin, alpha-2-glycoprotein-1 zinc-binding (AZGP1), nephrin, neuropilin, podocin, and galectin-3. Follow-up for renal function decline was 3.7 ± 1.1 years. Associations between concentrations of individual biomarkers and annual eGFR decline were assessed by univariable regression and multivariable regression adjusted for conventional risk markers age, gender, baseline eGFR, and baseline UACR.

**Results:** The average rate of renal function decline was -2.0 ± 4.4 mL/min/1.73m$^2$/year. Serum NTproCNP and podocin, and serum and urine endostatin and TNFR2 were significantly associated with annual eGFR decline in univariable analysis. Serum TNFR2 and urine endostatin remained significant in multivariable analysis (Table). Finally, serum TNFR2 and urine endostatin were combined as a panel that significantly improved prediction of annual renal function decline on top of conventional risk markers ($R^2$ increase from 0.41 to 0.49; p<0.001).

| Biomarker | | Univariable | | | Multivariable | |
|---|---|---|---|---|---|---|
| | | β | p-value | | β | p-value |
| Serum | Endostatin | -3.2 | 0.02 | | -2.2 | 0.24 |
| | NTproCNP | -2.1 | 0.01 | | -1.6 | 0.07 |
| | Podocin | -2.1 | <0.01 | | -0.9 | 0.24 |
| | TNFR2 | -4.5 | <0.01 | | -4.1 | 0.02 |
| Urine | Endostatin | -1.3 | <0.01 | | -1.0 | 0.05 |
| | TNFR2 | -1.3 | 0.04 | | -0.6 | 0.30 |

**Conclusions:** A panel of novel biomarkers representing different disease pathways can improve prediction of accelerated renal function decline on top of conventional risk markers in type-2 diabetes. These results need to be confirmed in a large prospective cohort.

## TH-PO442

**Novel Urinary Exosome Isolation as a Platform to Study Diabetic Nephropathy (DN)** Daniel Armando Flores,[1,2] Yu Liu,[2] Belinda Bun Jim,[3] Payal B. Mittal,[2] Weijia Zhang,[2] Ruijie Liu,[2] Sandeep K. Mallipattu,[2] John C. He,[1,2] Rajeev Rohatgi.[1,2] *[1]Medicine, James J. Peters VAMC, Bronx, NY; [2]Medicine, Icahn School of Medicine, New York, NY; [3]Medicine, Jacobi Medical Center, Bronx, NY.*

**Background:** DN remains a major cause of end-stage renal disease (ESRD) worldwide. Discovery of early and reliable biomarkers of disease progression promises to help physicians develop personalized care plans for patients based on their risk of ESRD. Exosomes are plasma membrane bound vesicles secreted by all cells which contain protein, mRNA and miRNA, representative of the cells of their origin. The goal of these studies is to test the hypothesis that urinary exosomal miRNAs, which originate from cells lining the genitourinary tract, are an ideal source of biomarkers for DN.

**Methods:** Urinary exosomes were isolated from patients without diabetes (DM; controls), early DN, and moderate DN. RNA was extracted and microRNAs assayed by qRT-PCR array (Exiqon).

**Results:** 742 miRNAs were assayed in 4 control (no DM, normal kidney function, no proteinuria), 3 early DN (normal kidney function, with microalbuminuria), and 4 later stage DN (serum creatinine>1.3) subjects. Because this novel technique is unvalidated, we tested whether the miRNAs known to play a role in research models of DN (miRNA-192, 21, 29a, 216a, 217, 377, 200b, 93, and 29C) were expressed in urinary exosomes of DN

patients. Of these miRNAs, miR-192, 21, 29a, 200b, 93, and 29C were up-regulated in DN patients compared to controls, recapitulating the prior studies. Finally, of the 742 miRNAs evaluated 89 (12%) were dysregulated in exosomes derived from DN patients compared to controls. Of these 89 dysregulated miRs, miR-200b, miR-99b, and Let-7b were upregulated in DN patients and have been implicated in TGF-β-dependent fibrosis, TGF-β-dependent epithelial–mesenchymal transition, and podocyte-specific laminin downregulation, respectively.

**Conclusions:** Six of nine miRNA dysregulated in models of DN were also dysregulated in urinary exosomes of DN patients, suggesting that miRNAs associated with DN are expressed in exosomes. Evidence from our array also suggests potentially novel miRNAs are associated with DN.

## TH-PO443

**Urinary Type IV Collagen: Can It Be Used as an Indicator for the Progression of Diabetic Nephropathy?** Salah S. Naga,[1] Iman Ezzat Elgohary,[2] Doaa I. Hashad,[3] Marwa Abdelahad Elaty.[4] *[1]Internal Medicine, Faculty of Medicine, Alexandria, Egypt; [2]Internal Medicine, Faculty of Medicine, Alexandria, Egypt; [3]Clinical Pathology, Faculty of Medicine, Alexandria, Egypt; [4]Internal Medicine, Faculty of Medicine, Alexandria, Egypt.*

**Background:** Diabetic nephropathy is a complication seen in long standing diabetes mellitus where progressing impairment of kidney function leads to end-stage renal disease. In the advanced diabetic nephropathy, immunoreactive type IV collagen was detected in glomerular basement membrane (GBM), tubular basement membrane and Bowman's capsule much more than that in the normal kidney. However, there is little information on whether the increase in type IV collagen excretion in urine is a predictor of progression of diabetic nephropathy or deterioration of renal function in type 2 diabetic patients. We conducted this work with the aim to determine whether the urinary levels of type IV collagen can predict the progression of diabetic kidney disease in Type 2 DM.

**Methods:** This study included 100 adult patients; who were classified into: 20 diabetic normoalbuminuric patients (group1), 20 diabetic microalbuminuric patients (group2), 20 diabetic macroalbuminuric (group3), 20 diabetic CKD patients with GFR: 60-90ml/min (group4), 20 diabetic CKD patients with GFR: 30-59ml/min (group5), and compared with 20 controls (group 6). All included subjects were subjected to renal function test and estimated creatinine clearance by Modification of Diet in Renal Disease (MDRD) formula. Measurements of urine albumin/creatinine ratio. Fasting blood glucose and hemoglobin $A_{1C}$. The urinary concentrations of type IV collagen were measured using a highly sensitive one-step sandwich enzyme immunoassay kit.

**Results:** Urinary type IV collagen was significantly higher in normoalbuminuric patients than the control group, in microalbuminuric patients than both control and normoalbuminuric, in macroalbuminuric than normo and micro albuminuric and control, in CKD1, CKD2 groups it was significantly higher than all other groups and highest in CKD2.

**Conclusions:** Urinary type IV collagen can be used as an indicator for the progression of kidney disease in diabetic patients.

## TH-PO444

**Global Metabolomic Profile in Type 2 Diabetes and Subsequent Progression to ESRD** Monika A. Niewczas,[1] Tammy L. Sirich,[2] Anna V. Mathew,[3] Jan Skupien,[1] Adam Smiles,[1] Edward D. Karoly,[5] Joseph V. Bonventre,[4] Subramaniam Pennathur,[3] Timothy W. Meyer,[2] James Warram,[1] Andrzej S. Krolewski.[1] *[1]Genetics and Epidemiology, Joslin Diabetes Center, Harvard Medical School; [2]Dept of Medicine, Stanford School of Medicine; [3]Dept of Internal Medicine, Univ of Michigan; [4]Renal Div, Brigham and Women's Hospital, Harvard Medical School; [5]Metabolon Inc.*

**Background:** We studied plasma metabolomic profiles as determinants of progression to ESRD in Type 2 diabetes (T2D).

**Methods:** This case-control study used Joslin Kidney Study participants with T2D with well-preserved renal function at baseline: 40 cases who progressed to ESRD and 40 controls who remained alive without ESRD during a 10 year follow-up. Controls were matched with cases regarding baseline clinical characteristics. Plasma metabolites at baseline were measured by mass spectrometry-based global profiling.

**Results:** Of the named metabolites in the library, 274 were detected in at least two-thirds of the study subjects. Among the 78 uremic solutes recognized by the platform, 12 were elevated in baseline plasma of cases. Other uremic solutes were either not different or not commonly detectable. Essential amino acids and their derivatives were depleted in the cases, whereas related acylcarnitines were increased. All our findings remained highly significant after adjustment for multiple comparisons and controlling for clinical covariates.

| **metabolite** | **univariable** OR (95%CI) | **eGFR adjusted** OR (95%CI) |
|---|---|---|
| p-cresol sulfate | 4.0 (1.7,9.6) | 3.5 (1.4, 8.8) |
| pseudouridine | 21 (6.0, 77) | 44 (9, 219) |
| leucine | 0.3 (0.1, 0.7) | 0.4 (0.2, 0.8) |
| 2-hydroxyisocaproate | 0.2 (0.1, 0.4) | 0.2 (0.1, 0.5) |
| methylglutarylcarnitine | 3.7 (1.6, 8.6) | 3.3 (1.4, 7.8) |

**Conclusions:** Certain metabolomic signatures (increased plasma concentrations of the putative uremic solutes, decreased levels of essential amino acids accompanied by increased levels of acylcarnitines) are associated with subsequent progression to ESRD in T2D and those changes in plasma levels are already present at an early stage of diabetic nephropathy.

## TH-PO445

**Glycemic Control and the Risk of Mortality among Hemodialysis Patients in Japan** Noriko Kaneyama,[1] Hirotaka Komaba,[1] Hajjime Suzuki,[2] Takatoshi Kakuta,[1] Takao Suga,[3] Masafumi Fukagawa.[1] *[1]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan; [2]Div of Nephrology and Diabetes, Tokai Univ Oiso Hospital, Oiso, Japan; [3]Medical Corporation Showakai, Japan.*

**Background:** Diabetes mellitus is the most common cause of end-stage renal disease in Japan. While tight glycemic control decreases the risk of diabetic complications, it remains to be determined whether better glycemic control reduces the risk of death in diabetic patients undergoing dialysis.

**Methods:** We retrospectively collected data on maintenance hemodialysis patients (n = 2,292) beginning in December 2008. The diagnosis of diabetes was made based on the medical records. We analyzed the association between presence or absence of diabetes, glycemic control, and the risk of death over three years, using Cox proportional hazards models. We also performed time-dependent Cox models to account for changes in glycemic control over time. Data were collected at quarterly intervals.

**Results:** A total of 1,038 patients had diabetes. Overall, diabetes is well controlled and the mean HgbA1c values were <7.0% in 86%. HgbA1c values showed a significant correlation with random glucose values (r = 0.58; P <0.001). Patients with diabetes had a significantly increased risk of death compared to those without (HR, 0.62; 95% CI, 0.49 to 0.77). No significant association was observed between HbA1c values and the risk of death. These results were unaltered in time-dependent Cox models.

**Conclusions:** More studies are needed to define the optimal management of diabetes for patient receiving dialysis.

## TH-PO446

**Effect of Dapagliflozin on Blood Pressure and Body Weight in Patients with Type 2 Diabetes and Cardiovascular Disease** Tjerk de Bruin,[1] Shamik Parikh,[1] Jennifer Sugg,[1] Shoba Ravichandran.[2] *[1]AstraZeneca, Wilmington, DE; [2]Bristol-Myers Squibb, Princeton, NJ.*

**Background:** Patients with type 2 diabetes (T2D) often have hypertension (HTN) and cardiovascular disease (CVD). Selective SGLT2 inhibitor dapagliflozin (DAPA) reduces hyperglycemia by promoting renal glucose excretion and is associated with osmotic diuresis and caloric loss that provide additional benefits. Our analysis assessed the effect of DAPA vs placebo (PBO) on blood pressure (BP) and body weight (BW) in patients with T2D and established CVD treated for 52 weeks in 2 clinical trials (Study 18, NCT01031680, N=922; Study 19; NCT01042977, N=965).

**Methods:** Patients with glycated hemoglobin ≥7% and ≤10% were randomized to double-blind PBO or DAPA 10 mg/d, added to pre-existing anti-hyperglycemic (including insulin), antihypertensive (ACEI/ARBs, diuretics), antiplatelet, and lipid-lowering drugs. A medical history of HTN was an inclusion criterion for Study 18 and was present in 93% of Study 19 patients. Adjusted mean changes from baseline to week 52 were analyzed by longitudinal repeated measures.

**Results:** Compared with PBO, DAPA reduced systolic BP and BW **(Table)**. Small decreases in diastolic BP were also observed. Hematocrit increased, and urine albumin/creatinine decreased with DAPA. There were small decreases in eGFR across treatment groups. Frequency of volume-related adverse events was low and inconsistent across studies (Study 18, DAPA 2.8% vs PBO 0.4%; Study 19, DAPA 1.5% vs PBO 2.7%). Urinary tract infections in 1 study (Study 18, 5.9% vs 5.8%; Study 19, 11.0% vs 5.8%) and genital infections in both studies (Study 18, 6.1% vs 0.9%; Study 19, 7.5% vs 0.4%) were more common with DAPA vs PBO.

**Conclusions:** In patients with T2D and CVD, DAPA added to usual care reduced BW. BP was also reduced, potentially through a diuretic-like mechanism, without compromising renal function.

| | Adjusted Mean Change (SE) From Baseline to Week 52 | | | | | |
|---|---|---|---|---|---|---|
| | Study 18 | | | Study 19 | | |
| | PBO | DAPA | Difference (95% CI) | PBO | DAPA | Difference (95% CI) |
| Seated Systolic BP, mm Hg | 0.2 (0.6) | −3.4 (0.6) | −3.6 (−5.4, −1.8) | −0.9 (0.6) | −3.6 (0.6) | −2.7 (−4.3, −1.0) |
| Seated Diastolic BP, mm Hg | −0.2 (0.4) | −1.7 (0.4) | −1.5 (−2.7, −0.4) | −0.6 (0.4) | −2.4 (0.4) | −1.7 (−2.8, −0.7) |
| Body weight, kg | −0.2 (0.2) | −2.7 (0.2) | −2.5 (−3.0, −2.0) | −1.0 (0.2) | −2.9 (0.2) | −1.9 (−2.4, −1.4) |

## TH-PO447

**Effect of Atorvastatin on Renal NO Availability and Tubular Function in Patients with Stage II-III Chronic Kidney Disease and Type 2 Diabetes**

Frank H. Mose,[1,2] Thomas Larsen,[1,2] Janni Majgaard Jensen,[1,2] Jesper N. Bech,[1,2] Erling B. Pedersen.[1,2] *[1]Dept of Medical Research, Holstebro Hsopital, Holstebro, Denmark; [2]Univ of Aarhus, Aarhus, Denmark.*

**Background:** Statins have beneficial effects on cardiovascular morbidity and mortality independently of reduction of plasma cholesterol.

**Methods:** In patient with type 2 diabetes and nephropathy, chronic kidney disease stage II-III, we tested the hypothesis that atorvastatin increased systemic and renal nitric oxide (NO) availability using L-NMMA as an inhibitor of NO production. We performed a randomized, placebo-controlled, crossover study, using atorvastatin/placebo treatment for five days with a standardized diet and fluid intake. We measured brachial BP (bBP), central BP (cBP), GFR, urinary output (OU), free water clearance ($C_{H2O}$), fractional excretion of sodium ($FE_{Na}$), urinary excretion of albumin (UAER and UACR), AQP2 (u-AQP2) and ENaC (u-ENaC$_\gamma$) and plasma concentrations of vasoactive hormones: renin, angiotensin II, aldosterone, arginine vasopressin, endothelin-1 and brain natriuretic peptide.

**Results:** During L-NMMA infusion, atorvastatin and placebo changed the effect variables significantly to the same extent, i. e. an increase in bBP and cBP, and a decrease in GFR, OU, $C_{H2O}$, $FE_{Na}$, u-AQP2 and u-ENaC$_\gamma$. In addition, renin and angiotensin II was reduced, aldosterone increased, and vasopressin, endothelin-1 and brain natriuretic hormone unchanged.

**Conclusions:** During inhibition of nitric oxide synthesis, atorvastatin and placebo induced the same response in brachial and central blood pressure, GFR, renal tubular function and vasoactive hormones. Thus, atorvastatin did not change nitric oxide availability in type 2 diabetic nephropathy.

*Funding:* Private Foundation Support, Government Support - Non-U.S.

## TH-PO448

**Proteinuria Reduction with Probucol and Telmisartan in Patients with Type 2 Diabetic Nephropathy**

Xiang-Mei Chen, Hanyu Zhu, Guangyan Cai, Ying Zheng. *Dept of Nephrology, State Key Laboratory of Kidney Disease, General Hospital of Chinese People's Liberation Army, Beijing, China.*

**Background:** Combination therapy with telmisartan and probucol in the treatment of diabetic nephropathy has not been proved with sufficient clinical evidence. This study examined the clinical efficacy of telmisartan and probucol in proteinuria reduction of type 2 diabetic nephropathy.

**Methods:** A total of 160 type 2 diabetic nephropathy patients with proteinuria (0.5-3.0 g/24h) were enrolled in a randomized, double-blind, placebo-controlled, multicenter study. The patients were randomly divided into two groups. Telmisartan group (n=80) was administered with telmisartan (80 mg/day) and probucol placebo (1000 mg/day for 24 weeks, and then reduced to 500 mg/day for next 24 weeks). Probucol group (n=80) was administered with telmisartan (80mg/day) and probucol (1000 mg/day for 24 weeks, and then reduced to 500 mg/day for next 24 weeks). All patients were followed throughout the 48-week period, and the percentage change of urinary protein from baseline to 48 weeks was assessed.

**Results:** The baseline characteristics of the two groups were similar, as well as the BP and HbA1c profile over the study period. There was a significant reduction (27.02%) in urinary protein level in the probucol group from baseline to 48 weeks. However, urinary protein level was increased in the telmisartan group (1.45%). For patient with lower urinary protein (<1.0g/24h at baseline), the reduction in urinary protein level from baseline is significantly greater in probucol group than in telmisartan group (36.54% vs. 8.55%, P=0.013). For the patient with higher urinary protein ( ≥ 1.0g/24h at baseline), there was a significantly reduction of 15.38% in urinary protein level in probucol group from baseline. However, urinary protein was increased in telmisartan group, with an average increase of 10.96% ( P=0.011 for the comparison with probucol group).

**Conclusions:** The combination therapy of probucol and telmisartan lowers urinary protein more effectively than telmisartan alone.

*Funding:* Government Support - Non-U.S.

## TH-PO449

**In Type 1 Diabetic Patients with Albuminuria Insulin Pump Treatment Is Associated with Reduced Arterial Stiffness**

Signe Rosenlund,[1] Simone Theilade,[1] Tine Hansen,[1] Peter Rossing.[1,2,3] *[1]Steno Diabetes Center, Denmark; [2]Univ of Copenhagen, Denmark; [3]Aarhus Univ.*

**Background:** Insulin pump treatment is often associated with reduced glucose variability and in improvements in glycemic control, which could reduce development of vascular complications. We investigated the relationship between arterial stiffness, evaluated by pulse wave velocity (PWV), and treatment with insulin pump in patients with type 1 diabetes, and examined if this association was dependent of glucose control.

**Methods:** Cross-sectional study, from 2009-2011, including 639 Caucasian patients with type 1 diabetes. PWV measurements (SphygmoCor, AtCorMedical, Australia) were available in 59 patients with insulin pump (35 with albuminuria ≥ 30mg/d) and 580 (296 with albuminuria ≥30mg/d) treated with multiple daily insulin injections ((MDI) ≥2 injections). ANCOVA compared groups and adjusted multiple linear regression analyses investigated the association between insulin pump treatment and arterial stiffness.

**Results:** In the albuminuric group insulin pump *vs.* MDI treated patients were 46% *vs.* 60% men, 50±12 *vs.* 56±11 years of age, 36±10 *vs.* 36±13 years diabetes duration and $HbA_{1c}$ 65±11 *vs.* 67±14mmol/mol ($p$>0.45 for all except age ($p$=0.01)). PWV was lower in patients with insulin pump (9.3±2.5 *vs.* 11.3±3.4m/s; $p$<0.001). This difference remained significant ($p$=0.002) after adjustment for gender, diabetes duration, eGFR, albuminuria, $HbA_{1c}$, total-cholesterol, smoking, office MAP, heart rate and BMI. For all patients, PWV was also lower in the insulin pump group (9.3±2.8 *vs.* 10.4±3.4 m/s, (adj. $p$=0.002)). In multiple regression analysis, pump treatment was significantly associated with lower PWV, while $HbA_{1c}$ was not associated with PWV in neither patients treated with MDI or insulin pump.

**Conclusions:** Insulin pump treatment was independently associated with reduced arterial stiffness, while $HbA_{1c}$ was not. Although glucose variability was not assessed, our results suggest that glucose variability and not $HbA_{1c}$-level may modify arterial stiffness. This needs confirmation in randomised prospective studies.

## TH-PO450

**Risk Stratification with P-NT-proBNP and Coronary Calcium Score Predicts All-Cause Mortality in Microalbuminuric Type 2 Diabetic Patients**

Bernt Johan Illum von Scholten,[1] Henrik Reinhard,[1] Peter Godsk Jørgensen,[2] Simone Theilade,[1] Peter R. Hansen,[2] Niels Wiinberg,[3] Andreas Kjaer,[4] Hans-Henrik Parving,[4] Jan Skov Jensen,[2] Peter Karl Jacobsen,[4] Peter Rossing.[1] *[1]Steno Diabetes Center, Denmark; [2]Gentofte Hospital; [3]Frederiksberg Hospital; [4]Rigshospitalet.*

**Background:** The burden of CAD is significantly increased in type 2 diabetes and associated with mortality. An effective screening tool for subclinical CAD is needed to predict and prevent cardiovascular mortality in these patients.

**Methods:** NT-proBNP, coronary calcium score (CCS) and echocardiography (echo) were performed in 200 asymptomatic type 2 diabetic patients with elevated UAER (>30mg/24h) and without prior history of CAD. NT-proBNP >45.2 ng/L and/or CCS ≥400 stratified patients as high risk for CAD and were further examined for significant CAD by MPI and/or CT-angiography and/or CAG. Following imaging, patients were stratified into low risk (n=67), high risk without CAD (n=63) and high risk with CAD (n=70). After 5.3 years of follow-up, vital status was assessed, and echo re-performed in available patients (n=130).

**Results:** At baseline, patients were 59±9 years, 152(76%) male with eGFR: 96±26 ml/min/1.73m$^2$. Of 130 patients with follow-up echo-data, 117 had normal ( ≥50%) LVEF at baseline. Of these, 2(5%) and 9(12%) patients with low *vs.* high risk had reduced LVEF (<50%) at follow-up ($p$=0.324). During follow-up, 22(11%) patients died, of which 1(1%) low risk, 9(14%) high risk without CAD and 12(17%) high risk with CAD (log rank p=0.012). In Cox regression analysis high risk no CAD patients *vs.* low risk had higher mortality ($p$=0.041), as was the case for high risk CAD patients *vs.* low risk ($p$=0.017). All high risk *vs.* low risk had higher mortality (HR: 8.7, $p$=0.047, adjusted for gender, age, HbA1c, cholesterol, SBP, smoking and creatinine). Mortality was similar in the high risk groups ($p$=0.5).

**Conclusions:** Risk stratification with p-NT-proBNP and CCS predicts all-cause mortality in asymptomatic type 2 diabetes patients with microalbuminuria and normal kidney function. Additional cardiovascular evaluation did not improve risk prediction. Deterioration from normal to impaired LVEF was not different between groups.

## TH-PO451

**Lowering of Albuminuria Reduces Cardio-Renal Events: Insights from ALTITUDE**

Hiddo Jan Lambers Heerspink,[1] Frederik I. Persson,[2] Toshiharu Ninomiya,[1] Barry M. Brenner,[2] Nish Chaturvedi,[2] Scott D. Solomon,[2] Marc A. Pfeffer,[2] Hans-Henrik Parving,[2] Dick de Zeeuw.[1] *[1]Clinical Pharmacology, UMC Groningen, Netherlands; [2]ALTITUDE Steering Committee.*

**Background:** Direct renin inhibition with aliskiren on top of ACEi/ARB therapy decreases albuminuria but did not decrease renal or cardiovascular (CV) events in the ALTITUDE (The Aliskiren Trial in Type 2 Diabetes Using Cardiorenal Endpoints) trial. Could the overall reduction in albuminuria (14%) have been too small to afford protection? We investigated post-hoc whether in ALTITUDE albuminuria predicts renal/CV outcome, and whether the degree of albuminuria reduction is related to renal/CV risk reduction.

**Methods:** In a randomized controlled double blind trial, 8561 subjects with type 2 diabetes and CKD, CV disease, or both were assigned to aliskiren 300 mg daily or placebo on top of ACEi or ARB therapy. Renal and CV events were collected during a median follow-up of 2.8 years.

**Results:** After adjusting for multiple risk markers, patients with high albuminuria ( ≥1000 mg/g creatinine; N=1903) at baseline showed a 9-fold renal (p<0.001) and 2-fold CV (p<0.001) risk increase compared to the low albuminuria group (<100 mg/g; N=2678). The change in albuminuria in the first 6 months of aliskiren therapy varied widely (IQR -49 to +42%). Subjects with larger reductions in albuminuria in the first 6 months (>30%; N=2738) showed a risk reduction of 58% for renal (95% CI: 69 to 45%; p=0.01) and 22% for CV (95% CI: 35 to 5%; p<0.01) events compared to subjects with an albuminuria increase between 0 and 30% (N=1251). Similar results were obtained when the aliskiren or placebo groups were separately analyzed. Residual albuminuria at month 6 showed an almost identical association with renal/CV outcome as baseline albuminuria.

**Conclusions:** Change in albuminuria is associated with a proportional effect on renal and CV outcome: the greater the reduction in albuminuria the greater the risk reduction. Baseline as well as residual albuminuria is directly related to renal and CV risk: the higher the albuminuria the more risk. These data imply that albuminuria should be monitored and targeted to the lowest achievable level in an attempt to reduce renal and CV risk.

## TH-PO452

**No Increase in Bone Fractures with Empagliflozin (EMPA) in a Pooled Analysis of More Than 11,000 Patients with Type 2 Diabetes (T2DM)**

Christoph Wanner,[1] Robert D. Toto,[2] John Gerich,[3] Thomas Hach,[4] Afshin Salsali,[4] Gabriel Kim,[4] Stefan Hantel,[5] Hans-Juergen Woerle,[4] Uli Christian Broedl.[4] *[1]Univ of Würzburg, Germany; [2]Univ of Texas Southwestern Medical Center, Dallas; [3]Univ of Rochester School of Medicine, Rochester, NY; [4]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; [5]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany.*

**Background:** The SGLT2 inhibitor EMPA is in development for the treatment of T2DM. SGLT2 inhibitors may alter the renal reabsorption of calcium and phosphate, and may potentially have effects on bone metabolism.

**Methods:** Using pooled data from Phase I, II and III trials, adverse events (AEs) consistent with bone fracture were evaluated through a search of investigator-reported AEs in patients with T2DM treated with placebo (PBO; n=3522), EMPA 10 mg (n=3630) or EMPA 25 mg (n=4602) in sub-groups of gender, age (<50, ≥50–<65, ≥65–<75, ≥75 yrs), BMI (<25, ≥25–<30, ≥30–<35, ≥35 kg/m²) and eGFR ( ≥90, ≥60–<90, ≥30–<60, <30 mL/min/1.73m²). Mean (SD) baseline age was 59.6 (10.0) yrs, BMI 30.0 (5.5) kg/m², eGFR 80.1 (22.1) mL/min/1.73m² and 63% of patients were male.

**Results:** The percentage of patients with fractures was similar with PBO (55/3522 [1.6%]) and EMPA 10 mg (59/3630 [1.6%]), but slightly lower with EMPA 25 mg (51/4602 [1.1%]). A greater proportion of female than male patients reported fractures in all groups (females: 1.2–2.5%; males: 1.0–1.3%) with comparable rates between PBO and EMPA. The percentage of patients with fractures was generally similar between PBO and EMPA in subgroups defined by age, BMI or eGFR. No changes in serum calcium or phosphate were observed. Small changes from baseline were observed in iPTH (mean [SD] changes -3.0 [15.7], 0.4 [15.0], -2.1 [31.1] ng/L with PBO, EMPA 10 mg, EMPA 25 mg, respectively), 25-OH vitamin D (mean [SD] changes 2.6 [40.0], 3.1 [34.8], 8.4 [36.2] nmol/L, respectively), and N-telopeptide (NTx)/creatinine ratio (mean [SD] changes -2 [17], 3 [19], 6 [23] nM/mM Cre, respectively).

**Conclusions:** In a pooled analysis of data from >11000 patients with T2DM, EMPA was not associated with an increased frequency of bone fractures versus PBO.

*Funding:* Pharmaceutical Company Support - Boehringer Ingelheim

## TH-PO453

**Is Peritoneal Dialysis Associated with New-Onset Diabetes Mellitus?**

Chih-Chiang Chien. *Dept of Nephrology, Chi-Mei Medical Center, Taiwan.*

**Background:** Few published studies have focused on post-dialysis new-onset DM.This study investigates whether there is an association between dialysis modality and new-onset DM.

**Methods:** In the Taiwan National Health Insurance Research Database, we examined records of ESRD patients who initiated dialysis between 1999 and 2005. Patients were followed until death, transplant, dialysis withdrawal, or 31 December 2008. Predictors of new-onset DM were calculated using Cox models.

**Results:** A total 51,487 incident dialysis patients were examined in this study, including 25,321 patients with pre-existing DM, 3,346 with new-onset DM, and 22,820 without DM at any time. Patients' age (mean ± SD) was 61.8 ± 11.5, 61.6 ± 13.7 and 56.5 ± 16.6 years in pre-existing, new-onset DM and without DM groups, respectively. The cumulative incidence rate of new-onset DM was 4% at one year and 21% at nine years. Being female, being older, and having baseline comorbidities were independent risk factors for new-onset DM in dialysis patients. Dialysis modality was not a risk factor for new-onset DM (HD to PD hazard ratio of new onset DM = 0.94 (95% CI: 0.83-1.06). The mean duration between new-onset DM diagnosed and death was 6.10 ± 1.01 years. Pre-existing DM was associated with 80% higher death risk (HR: 1.81, 95% CI: 1.75-1.87), whereas the new-onset DM was associated with 10% increased death risk (HR: 1.10, 95% CI: 1.03-1.17).

**Conclusions:** Whereas dialysis modality does not appear to associate with new-onset DM, both pre-existing and new-onset DM are related to higher long-term mortality in maintenance dialysis patients.

## TH-PO454

**Diabetic Foot Ulcers and Mortality in Chronic Hemodialysis Patients**

Eduardo K. Lacson, Weiling Wang, Shu-Fang Lin, Franklin W. Maddux, Jeffrey L. Hymes. *Fresenius Medical Care, North America, Waltham, MA.*

**Background:** Foot ulcers are associated with poor outcome in diabetic hemodialysis (HD) patients. We evaluated the development of foot ulcers detected by a national monthly foot check program at Fresenius Medical Care, North America facilities.

**Methods:** All adult diabetic HD patients with ≥1 foot check documented electronically during 7/1/09-6/30/12 in 329 facilities with ECube clinical systems were included. Foot ulcer status and deaths were tracked until 12/31/12. Patients developing ulcers on follow-up were "cases", others only "at-risk". As of the 1st foot check date, age, gender, race, & incident patient status (vintage ≤120 days) were recorded. Logistic regression defined odds ratio (OR) for death between cases and patients at-risk.

**Results:** 764 (5.4%) of 14,103 patients had foot ulcers at 1st recorded exam. Among 13,339 ulcer-free patients, 1,769 (13.3%) developed ulcers (cases). The mean age was 63.5±12.6 years, with more males (58.4% vs. 52.8%) and whites (71.0% vs. 63.0%) in cases (all p<0.0001). Cases had longer median follow-up time at 462 vs. 352 days. The nested median time to first ulcer was ~5 months (Table); the nested median time to death from the 1st foot ulcer was ~3.5-4.0 months. Unadjusted OR of death was 1.45 compared to patients at-risk, and remained OR=1.51 after adjusting for case-mix (both p<0.0001). Mortality risk was not significantly different in incident patients.

| (Excludes 5.4% with pre-existing ulcer) | All Cases | Subset: Incident Cases |
|---|---|---|
| N (%) | 1,769 (13.3) | 377 of 1,769 (21.3) |
| Days of follow-up, Mean (SD) | 462 (235) | 421 (219) |
| Median (IQR) | 428 (269, 645) | 388 (253, 577) |
| Days to 1st Ulcer, Mean (SD) | 211 (174) | 183 (151) |
| Median (IQR) | 166 (72, 302) | 151 (58, 267) |
| Days to Death after 1st Ulcer, Mean (SD) | 180 (165) | 160 (147) |
| Median (IQR) | 124 (56, 259) | 109.5 (47, 257) |

**Conclusions:** About 1 in 5 diabetic HD patients had or developed foot ulcer over a median follow-up of ~15 months. De novo ulcers associated with ~50% greater risk of death. Routine foot checks may allow for early diagnosis of foot ulcers, neuropathy and peripheral circulatory compromise. Further clinical trials should be considered to identify these issues so that care strategies can be implemented to optimize long term outcomes in this population.

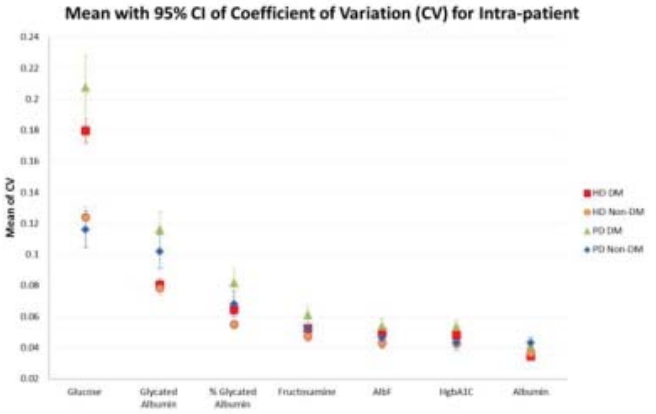
## TH-PO455

**Monthly Variation in Glycemic Indices in Patients Maintained with Dialysis**

Neal Mittman,[1] Lin Ma,[2] Mark E. Williams,[3] Julia I. Brennan,[4] Chinu M. Jani,[4] Curtis D. Johnson,[4] Franklin W. Maddux,[2] Eduardo K. Lacson.[2] *[1]Long Island College Hospital, Brooklyn, NY; [2]Fresenius Medical Care, North America, Waltham, MA; [3]Joslin Diabetes Center, Boston, MA; [4]Spectra Laboratories, Rockleigh, NJ.*

**Background:** Glycemic control is conventionally monitored utilizing quarterly measurement of glycosylated hemoglobin (A1c). Because A1c may not be an ideal marker for dialysis patients, other glycemic indices have been sought. Furthermore, little is known about the comparative variability of these indices which reflect different durations of glycemia.

**Methods:** Simultaneous measurement of pre-dialysis serum fructosamine (SF), glycated albumin (GA), A1c and casual glucose (BG), from residual blood (of routine monthly draws) was obtained from a national sample of 1977 DM and 1454 nondiabetic (NDM) dialysis patients from 26 FMCNA facilities. Mean intra-patient variability was compared by coefficient of variation (CV) for January-March 2013. SF was albumin-corrected (AlbF) and GA was expressed as percent glycated (%GA) as recommended.



**Results:** BG exhibited the highest intra-patient CV in diabetics on PD, followed by DM HD, while NDM HD and PD pts had lesser CV. A1c and AlbF were the most stable for all groups. GA exhibited greater variability than SF or A1c. PD pts (both DM and NDM) had greater CV with GA than HD pts. CV with GA was lower when expressed as %GA, the method recommended by the manufacturer.

**Conclusions:** Monthly intra-patient variability is modest for A1c, SF, AlbF, and %GA, a necessary requirement for a periodic monitoring tool. A1c reflects a longer period of glycemia (2-3 months) and should be the most stable relative to protein-based indices (2-3 weeks of glycemia).These concurrent tests provide baseline information as we prospectively evaluate their utility and association with outcomes.

## TH-PO456

**Correlates of Glycosylated Hemoglobin Level in Diabetic Patients Maintained with Dialysis**

Neal Mittman,[1] Lin Ma,[2] Mark E. Williams,[3] Julia I. Brennan,[4] Chinu M. Jani,[4] Curtis D. Johnson,[4] Franklin W. Maddux,[2] Eduardo K. Lacson.[2] *[1]Long Island College Hospital, Brooklyn, NY; [2]Fresenius Medical Care, North America, Waltham, MA; [3]Joslin Diabetes Center, Boston, MA; [4]Spectra Laboratories, Rockleigh, NJ.*

**Background:** Serial measures of glucose and Hemoglobin A1c is used to monitor glycemic control in diabetic dialysis patients (pts) and in the general population. We explored the distribution of A1c in a national sample of 1979 DM patients from 26 FMCNA facilities across the US.

**Methods:** Residual blood specimens were used to obtain mean monthly chemistries for the period January-March 2013. Pts were stratified by A1c as <=5.6% (n=553), >5.6-7.0% (n=861), and >7.0% (n=565). Demographic and biochemical correlates of glycemia by A1c category were evaluated.

**Results:** As expected, serum glucose increased by A1c group accompanied by a decreasing percentage of pts with casual glucose <120mg%. Higher A1c was associated with younger age, shorter dialysis vintage and peritoneal dialysis modality (all p<0.001). There were no differences by gender, race, ethnicity, HD catheter usage, cardiovascular comorbidities (CVA, CHF, PAD, AMI), mean eKtv and albumin between groups. Interestingly, pts with A1c<5.6%, had lower mean Hgb while receiving higher mean EPO doses to maintain these Hgb levels. WBC count increased in the opposite direction of ESA dose, with no differences in neutrophil to lymphocyte ratios between groups.

| | DM w HgbA1c<=5.6% | DM w HgbA1c:>5.6-7.0% | DM w HgbA1c>7.0% |
|---|---|---|---|
| N | 553 | 861 | 565 |
| *Glucose(Mean±SD) | 119.4±31.6 | 152.3±46.2 | 215.4±78.9 |
| Glucose<120 (%) | 59.0 | 25.0 | 7.2 |
| eKtv (Mean±SD) | 1.5±0.3 | 1.5±0.3 | 1.5±0.4 |
| *Hemoglobin (Mean±SD) | 10.6±1.0 | 10.7±1.0 | 10.9±1.1 |
| Albumin (Mean±SD) | 3.8±0.4 | 3.8±0.4 | 3.8±0.4 |
| Albumin < 3.5 (%) | 19.7 | 19.3 | 21.8 |
| Phosphorus (Mean±SD) | 5.2±1.4 | 5.2±1.3 | 5.3±1.4 |
| Phosphorus <3.5 (%) | 8.5 | 6.8 | 5.8 |
| *WBC (Mean±SD) | 6.5±2.2 | 7.1±2.2 | 7.4±2.4 |
| *Weekly EPO dose (Mean±SD) | 11988.9±14180.6 | 9038.0 ±11805.9 | 8384.6±10568.9 |

**Conclusions:** While A1c tracks with glucose levels, it may be further affected by high ESA dose requirements. Although a high ESA dose may be accompanied by a high red cell turnover that leads to lower A1c, it is also possible that existing factors predisposing to low A1c may likewise induce ESA resistance. Factors unrelated to glycemic control need to be considered in interpreting A1c values in diabetic patients on dialysis.

## TH-PO457

**Glycemic Control Impacts Cardiovascular Outcome in Incident Dialysis Patients with Diabetes** Mi Jung Lee,[1] Shin-Wook Kang,[1,2,3] Chan Ho Kim,[1] Ji Sun Paeng,[2] Hyung Jung Oh,[1] Tae-Hyun Yoo.[1,2] *[1]Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea; [2]Brain Korea 21, Yonsei Univ, Seoul, Korea; [3]On behalf of Clinical Research Center for End-Stage Renal Disease Investigators.*

**Background:** Most current guidelines recommend that target hemoglobin A1C levels (A1C) for patients with diabetes mellitus (DM) should be <7.0% irrespective of the presence of chronic kidney disease. However, there has been much debate whether such recommendation can be generalized to end-stage renal disease (ESRD) population.

**Methods:** A prospective cohort of 907 incident dialysis patients with type 1 or type 2 DM from 36 dialysis centers of the Clinical Research Center for ESRD in Korea was selected for this study. Based on the baseline A1C levels, patients were divided into 5 groups: <6.0%, ≥9.0%, and every 1.0% increment in between. Cox proportional hazard analysis was performed to determine the prognostic value of A1C for primary outcome, a composite of cardiovascular death or non-fatal major cardiovascular events.

**Results:** The mean baseline A1C was 6.6±1.4%. During a mean follow-up duration of 15.0 months, 39 patients died of cardiovascular diseases and 78 non-fatal major cardiovascular events occurred. Compared to patients with A1C of 7.0-7.9%, the adjusted hazard ratios (HRs) of A1C <6.0%, 6.0-6.9%, 8.0-8.9%, and ≥9.0% groups were 1.02 [95% confidence interval (CI), 0.55-1.86; P=0.12], 1.59 (95% CI, 0.89-2.82; P=0.9), 2.04 (95% CI, 0.92-4.52; P=0.08), and 2.17 (95% CI, 1.02-4.62; P=0.04), respectively. Sensitivity analysis revealed that A1C ≥9.0% was significantly associated with an increased risk of reaching the composite outcome in patients with body mass index ≥24 kg/m$^2$ (HR, 2.51; 95% CI, 1.09-5.82; P=0.03) and patients with serum albumin levels ≥3.3 g/dL (HR, 3.93, 95% CI, 1.51-10.25; P=0.01).

**Conclusions:** Poor glycemic control (A1C ≥9.0%) was significantly associated with adverse cardiovascular outcome in incident dialysis patients with DM, especially in patients with a good nutritional status. A further long-term observational study is needed to determine the optimal levels of A1C in these patients.

*Funding:* Government Support - Non-U.S.

## TH-PO458

**Initial Application and Effects of Basic Carbohydrate Counting for Diabetics Undergoing Hemodialysis in Countries in which the Entity of Carbohydrate Counting Has Not Been Introduced** Toru Hyodo,[1,2] Noriko Mikami,[1] Daisuke Ishii,[2] Yasuhisa Kurata,[1] Miho Hida,[1] Kazunari Yoshida,[2] Masatsugu Iwamura,[2] Junko Kawakami.[3] *[1]Dialysis Center, Eijin Clinic and Kurata Hospital, Hiratsuka, Kanagawa, Japan; [2]Dept of Urology, Kitasato Univ, School of Medicine, Sagamihara, Kanagawa, Japan; [3]Dept of Clinical Nutrition, Sagami Women's Univ, Sagamihara, Kanagawa, Japan.*

**Background:** In Japan, carbohydrate counting, which is based on the fact that only carbohydrates change into blood sugar, has not been announced to citizens. In Europe and the United States, this method has been commonly established as diet therapy for diabetics. In this study, we introduced basic carbohydrate counting, which makes the range of blood sugar changes constant by establishing an equivalent intake at every meal based on the carbohydrate contents of foods, in diabetic HD patients, and examined its effects.

**Methods:** The subjects were 19 HD patients. They consisted of 10 males and 9 females, with a mean age of 61.7±10.3 years. The dialysis period was 3.5±4.0 years. Fifteen patients had and 4 had not received insulin. During the observation period, the doses of insulin, oral diabetic and lipids drugs were not changed. Physicians and dietitians explained the dietary method with basic carbhydrate counting. Changes in HbA1c, the dry weight (DW), T-Cho and protein catabolic rate (PCR, = protein intake) were investigated for 6.4± 3.1 months (1 to 9 months).

**Results:** Only the HbA1c value significantly decreased, but DW, T-Cho and PCR did not show significant change.

| Months | 0 | 1 | 3 | 6 | 9 |
|---|---|---|---|---|---|
| Pt. No. | 19 | 19 | 15 | 13 | 10 |
| HbA1c(%) | 7.5±1.23 | 7.16±1.03* | 6.7±0.81* | 6.49±0.54* | 6.64.75 |
| PCR(g/kg/day) | 0.85±0.14 | 0.81±0.12 | 0.81±0.12 | 0.82±0.18 | 0.76±0.15 |
| T-Cho(mg/dL) | 159.7±32.2 | 159.7±34.3 | 160.3±24.7 | 163.4±25.7 | 159.6±35.0 |
| DW(kg) | 61.9±15.9 | 62.0±15.8 | 59.5±14.7 | 54.9±10.7 | 55.0±10.8 |

[ * : $P < 0.05$].

**Conclusions:** Basic carbohydrate counting is simple and beneficial for diabetic HD patients.

## TH-PO459

**Is Albuminuria a Sensitive Biomarker for Early Detection of Kidney Endpoints in Type 2 Diabetes? A Systematic Review** Veeda O. Landeras,[1] Ivy Hsieh,[2] Abdulah Alrifai,[1] Marian Simonson,[3] Donald E. Hricik,[1] Michael S. Simonson.[1] *[1]Dept of Medicine, Div of Nephrology, Univ Hospital Case Medical Center, Cleveland, OH; [2]Physiology & Biophysics, Case Western Reserve Univ, Cleveland, OH; [3]Alumni Library, Cleveland Clinic, Cleveland, OH.*

**Background:** Albuminuria predicts progression to chronic kidney disease and end-stage renal disease in type 2 diabetes. The objective of this systematic review was to synthesize best available evidence regarding performance of albuminuria for early detection of renal endpoints.

**Methods:** We searched PubMed, EMBASE and SCOPUS for longitudinal studies of type 2 diabetes with renal endpoints. Studies were selected if participants had baseline eGFR > 60 ml/min/1.73 m$^2$, measurements of albuminuria at baseline and predefined renal endpoints of chronic kidney disease (eGFR < 60 ml/min/1.73 m$^2$), eGFR decline > 4.0 ml/year or end-stage renal disease (ESRD). Studies with fewer than 500 participants, and therefore few renal events, were excluded. Performance of albuminuria for predicting renal endpoints was assessed as sensitivity and specificity.

**Results:** Eight studies that included 36,947 participants with 2,410 renal endpoints met inclusion criteria. Albuminuria (micro-and macroalbuminuria) was specific for predicting all kidney endpoints: 0.73, or 73% (95% CI, 0.72 – 0.74). However, the sensitivity for predicting different endpoints varied considerably: ESRD, 0.69, (0.63 – 0.75); eGFR < 60 ml/min/1.73m$^2$, 0.44 (0.41-0.46); eGFR decline > 4.0 ml/year 0.24 (0.20-0.28). Summary estimates for sensitivity in a fixed-effects model were not affected by baseline eGFR, patient age, and length of follow-up or method of albumin testing.

**Conclusions:** In patients with type 2 diabetes and eGFR > 60 ml/min/1.73m$^2$, albuminuria is a specific prognostic marker (73%) for kidney endpoints. However, albuminuria may be insensitive for predicting eGFR < 60 ml/min/1.73 m2 and annual eGFR decline > 4.0 ml/year even though it is a reasonably accurate predictor of ESRD.

## TH-PO460

**Onset and Progression of Diabetes in Kidney Transplant Patients Receiving Everolimus or Cyclosporine: Post Hoc Analysis of 2 Open-Label, Multicenter, Randomized Trials** Claudia Sommerer,[1] Klemens Budde,[1] F. Lehner,[1] Wolfgang Arns,[1] Petra Reinke,[1] Ute Eisenberger,[1] Rudolf P. Wuthrich,[1] Martina Porstner,[2] Christoph May,[2] Eva-Maria Paulus,[2] Anja Susanne Muhlfeld,[1] Heiner H. Wolters,[1] Katharina M. Pressmar,[1] Rolf A. Stahl,[1] Oliver Witzke,[1] Hans-Hellmut Neumayer,[1] Markus Guba,[1] Johannes Jacobi,[1] Volker Kliem,[1] Ingeborg A. Hauser,[1] Martin G. Zeier.[1] *[1]ZEUS/HERAKLES Study Group, Germany; [2]Novartis Pharma Nuremberg, Germany.*

**Background:** Analysis of NODAT(new-onset diabetes mellitus(DM) post transplantation(Tx)) or progression of pre-existingDM in *de novo* KTx patients (pts) after conversion to everolimus(EVR)/Enteric-Coated Mycophenolate Sodium(EC-MPS) regimen and withdrawal or reduction of cyclosporine (CsA) combined with EVR.

**Methods:** *Post hoc* analysis from ZEUS &HERAKLES, 12months(Mo),prospective, open-label, multicenter, randomized(RDZ) trials. De novo KTx pts received standard CsA/EC-MPS +steroids after Tx and were RDZ to either continue CsA or convert to EVR at Mo4.5 post Tx(ZEUS) or at Mo3 post Tx(HERAKLES) with 3rd RDZ arm CNI-low. *Post hoc* categorization: according to either NODAT development or progression of DM.

**Results:** ZEUS: 8%(25/300) of pts had DM at Tx. NODAT at Mo12: 8%(22/275) of nonDM pts(Fig1). 7%(20/275) of these already developed at RDZ (13/142 EVR vs 7/133 CsA).NODAT after RDZ was similar(p=0.97). Mean blood glucose change from RDZ to Mo12 was similar in EVR vs CsA within NODAT(p=0.10) and DM(p=0.52) subpop. eGFR was similar at RDZ,significantly higher at Mo12 in EVR vs CsA pts in all subpop(Fig1). HERAKLES: 7%(30/438) of pts developed NODAT to Mo12, but no difference between the 3 regimen(p=0.62)(Fig1).

| Fig.1 | ZEUS | | HERAKLES | | |
|---|---|---|---|---|---|
| | EVR | CsA | EVR (CNI-free) | CsA | CNI-low |
| Incidence of NODAT N(%) from Tx to Mo12 | 14/142 (10%) | 8/133 (6%) | 10/149 (7%) | 11/133 (8%) | 9/143 (6%) |
| eGFR change (SD) from RDZ to Mo12 (Nankivell [mL/min/1.73m2]) | NODAT subgroup: +14.0 (11.4) Pre-exist DM subgroup: +5.5 (5.9) | NODAT subgroup: -9.2 (15.9) Pre-exist DM subgroup: +0.7 (10.0) | NODAT subgroup: +4.9 (16.7) Pre-exist DM subgroup: +5.3 (12.9) | NODAT subgroup: -1.9 (15.8) Pre-exist DM subgroup: +0.1 (11.7) | NODAT subgroup: -2.8 (9.6) Pre-exist DM subgroup: +2.8 (11.8) |
| BPAR in NODAT subgroup N(%) | 2 (14%) | 1 (13%) | 1 (10%) | 2 (18%) | 1 (11.1%) |

**Conclusions:** Within 12Mo post Tx no difference in NODAT or DM progression after CNI withdrawal and EVR conversion were found *post hoc*. However, benefit on renal function from early conversion to EVR translated into NODAT subpop.

## TH-PO461

### Influence of Normal and Bifurcated Cephalic Arch Anatomy and Hemodynamics on Cephalic Arch Stenosis Onset

Mary S. Hammes,[1] Michael Boghosian,[2] Kevin Cassel,[2] Jane E. Hines.[1] *[1]Univ of Chicago; [2]Illinois Institute of Technology.*

**Background:** A primary site of failure for patients with brachiocephalic fistula (BCF) is in the curved cephalic arch (CA). Extreme hemodynamic conditions as a result of fistula creation are responsible for locally low wall shear stresses (WSS), intimal hyperplasia and resultant cephalic arch stenosis (CAS). We compare anatomy, geometry, and hemodynamic parameters (HDP) at 3 and 12 months using computational fluid dynamic modeling (CFD).

**Methods:** Twelve subjects were referred for hemodialysis for permanent vascular access with a decision to place a BCF. A venogram, Doppler, and whole blood viscosity was performed at 3 and 12 months post-fistula. Geometric measurements and HDP were obtained using CFD at these stated time intervals.

**Results:** Of the twelve subjects, six had normal CA anatomy, while six had multiple vessels (bifids) in the CA at baseline. At 12 months, six of the bifids and three of the normal anatomy arches had no CAS. All three patients with CAS evident at 12 months had extensive regions of low WSS at 3 months. Three patients with normal CA anatomy without CAS at 12 months, had smaller average venous diameters (0.44 vs. 0.64 cm) and blood velocities (82.7 vs. 189.2 cm/s) than the three patients that developed CAS.

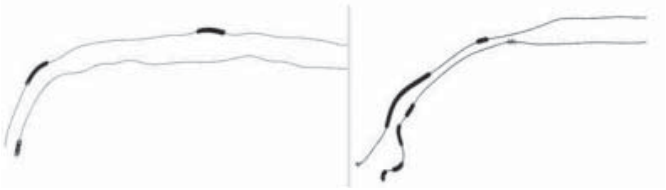

**Figure 1.** An example of a CFD of the CA at 3 months (left) and 12 months (right). Highlighted portions of the boundaries indicate WSS below the threshold for IH (0.076 Pa).

**Conclusions:** The anatomic variant of a bifid CA is common with a lower incidence of CAS at one year. Alternative flow paths in bifid arches mitigate high flow resulting in less extreme hemodynamics. Patients having more extensive regions of low WSS in the CA at 3 months are the most susceptible to CAS at 12 months. These findings support our hypothesis that failure of BCF arises from altered hemodynamics in the CA after fistula creation.

## TH-PO462

### The Negative Hemodynamic Consequence of Acute Angulation by Three Months in Brachiocephalic Fistula Access

Mary S. Hammes,[1] Michael Boghosian,[2] Kevin Cassel,[2] Jane E. Hines.[1] *[1]Univ of Chicago; [2]Illinois Institute of Technology.*

**Background:** Cephalic arch stenosis is a common problem leading to failure in patients with a brachiocephalic fistula (BCF). A contribution to fistula failure is geometrical changes occurring in the cephalic arch resulting from post-fistula creation hemodynamics. From our measurements we find that the cephalic arch angle decreases, becoming more acute, over a 3-month time period beginning at fistula creation. The consequences of this acute angle reduction on subsequent hemodynamic factors are elucidated.

**Methods:** ESRD patients receiving hemodialysis were referred for permanent vascular access with a decision to place an upper arm BCF. Enrollment was by written consent with a venogram, Doppler, and whole blood viscosity performed pre-fistula and at three months. Geometric measurements including arch angle and vein diameter were obtained. Hemodynamic parameters including wall shear stress (WSS) and modeled pressure were calculated using computational fluid dynamic modeling (CFD) at stated time intervals on reconstructions of patient-specific geometries.

**Results:** Eight subjects were included over a three-month time period. The average decrease in arch angles was -16.6±15.5° from the pre-fistula geometry to that at 3 months ($p = 0.02$). The venous pressure and velocity increased by 2.3 ± 3.1 Pa and 41.2 ± 32.1 cm/s, respectively. The minimum WSS decreased by -1.2 ± 2.0 Pa, and the maximum WSS increased by 6.7 ± 10.1 Pa from 0 to 3 months. Thus, the pressure and velocity are found to increase by one order of magnitude, while the range of WSS between its minimum and maximum widens. The arch angle is relatively constant from 3 to 12 months; however, the wall shear stress ranges further diverge.

**Conclusions:** Based on the measured acute arch angle reductions and corresponding CFD simulations, a postulated failure scenario for the BCF is as follows. Increased blood pressure in the vein is responsible for the acute arch angle decrease at 3 months after fistula creation. The resulting geometry changes in the cephalic arch are shown via CFD simulations to contribute to the non-physiological hemodynamics and clinical consequences only 3 months after fistula creation.

### Small Artery Elasticity Index (SAE) Strongly Correlates with Arterial Micro-Calcification and Increased Arterial Media Thickness in Patients Undergoing Arteriovenous Fistula (AVF) Creation

Christopher Heaton,[2] William D. Paulson,[1] Daniel T. Kleven,[2] Mufaddal F. Kheda,[1] James J. Wynn,[3] John Jason White.[1] *[1]Medicine, Georgia Regents Univ, Augusta, GA; [2]Pathology, Georgia Regents Univ, Augusta, GA; [3]Surgery, Georgia Regents Univ, Augusta, GA.*

**Background:** The high maturation failure rate of AVFs is a major unsolved problem, and preoperative methods of accurately predicting failure are urgently needed. We have previously shown that SAE predicts AVF maturation failure, and have hypothesized that this failure is due to impaired dilatation of the inflow artery and outflow vein. In this study, we hypothesized that low SAE correlates with changes in arterial histopathology that indicate calcification and increased arterial media thickness.

**Methods:** Eighteen patients underwent measurement of SAE (ml/mmHg x100) preoperatively on the day of AVF creation. SAE was measured with the HDI/PulseWave CR-2000 System; arterial pulse pressure was measured as an indicator of arterial stiffness. Arterial samples were obtained at the arteriovenous anastomosis during AVF creation. Samples were paraffin embedded and cross-sections were stained with hematoxylin-eosin, trichrome, and von Kossa (for calcium). Arterial intima and media thickness were measured, and calcification was graded on a semi-quantitative scale, by two pathologists who were blinded to all other measurements (0 = none; 1 = mild; 2 = moderate; 3 = severe).

**Results:** Three arteries were excluded from analysis due to processing problems. Multiple regression analysis in the remaining 15 patients indicates that the dependent variable SAE correlated with the independent variables micro-calcification score, arterial media thickness, and pulse pressure (all $P \leq 0.02$). The correlation of SAE with these 3 variables explained two-thirds of patient-to-patient variation in SAE ($R^2 = 0.677$).

**Conclusions:** Pre-operative measurement of SAE appears to be a strong indicator of inflow artery calcification, media thickness, and stiffness in patients undergoing AVF creation. This result suggests that SAE may be a useful tool in planning AVF creation.

## TH-PO464

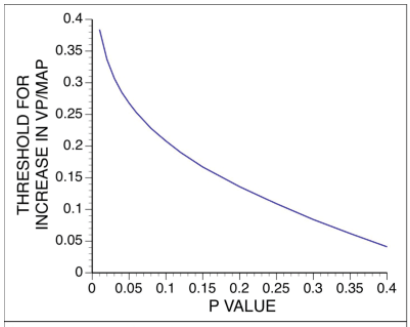
### Thresholds for Significant Increase in Dialysis Venous Pressure (VP): Criteria That Help Decide Whether to Refer for Intervention

Eduard R. Fatakhov,[1] John Jason White,[1] Anatole Besarab,[2] William D. Paulson.[1] *[1]Charlie Norwood VAMC & Georgia Regents Univ, Augusta, GA; [2]Henry Ford Hospital, Detroit, MI.*

**Background:** Vascular access failure is a major cause of morbidity and mortality in hemodialysis. Access failure is usually caused by stenosis, which causes thrombosis and access abandonment. An increase in static VP is an important method of detecting stenosis so that it can be corrected before thrombosis. However, criteria for determining when an increase in VP is statistically significant have not been established.

**Methods:** Fifty-five patients who were dialyzed with synthetic grafts or arteriovenous fistulas had 9 static VP measurements within 2 wks. VP was adjusted for mean arterial pressure (VP/MAP). Thirty-six differences between 2 VP/MAP measurements were computed from each patient's 9 measurements. The standard deviation of all these differences was taken to indicate background variation in VP/MAP that was not influenced by increases in stenosis. After confirming VP's were normally distributed, we used the student t distribution to determine thresholds for a significant increase in VP.

**Results:** The standard deviation for the difference between 2 VP/MAP measurements was 0.160. We computed thresholds for a significant increase in VP/MAP for a range of P values (figure). At $P < 0.05$, the increase must be >0.27 to be significant, whereas at $P < 0.20$, the increase must be >0.14. If avoiding unnecessary procedures is a priority, then a low P value is optimal, whereas if detecting an increase in stenosis is a priority, then a larger P value is optimal.



Thresholds for determining whether increase in static VP/MAP is significant for a range of P values.

**Conclusions:** This study defines thresholds for a significant increase in static VP/MAP that can help determine whether access referral for correction of stenosis is indicated. Selection of a referral threshold should consider the relative importance of avoiding thrombosis vs. avoiding unnecessary invasive procedures.

## TH-PO465

**Analysis of Vascular Access Interventional Therapy: 9-Year Follow Up Survey in 3,000 Cases with Vascular Access Failure** Teruhiko Maeba,[1] Shigeru Owada.[2] *[1]Internal Medicine, Asao Kidney Clinic, Kawsaki, Kanagawa, Japan; [2]Dialysis Center, Asao Clinic, Kawasaki, Kanagawa, Japan.*

**Background:** Keeping a functional vascular access (VA) is one of the most important factors in the maintenance of an HD modality. The application of vascular access interventional therapy (VAIVT) for VA trouble is increasing recently but the effectiveness of VAIVT has not been entirely satisfactory because of the relatively high rate of re-stenosis.

**Methods:** We have experienced 3,000 cases of VA trouble treated with VAIVT over the last 9 years in which primary assisted and secondary assisted rates were analyzed.

**Results:** 1. We have used a noncompliant type of balloon catheter for 97.7% of cases and primary assisted patency rates were 98.9%. 2. Secondary assisted patency rates were 79.6% at two years, 67.5% at 4 years, 59.5% at 6 years and 46.6% at 8years in all patients. 3.In diabetic patients, assisted patency rate was 40.3% at 8 years and it was50.0% in non-diabetic patients (p=0.09, Log rank). There were no significant differences found between the arteriovenous fistulas (AVF) and the arteriovenous grafts (AVG) ; 49.3% and 39.4% at 8 years, respectively. 4. Failure of secondary assisted patency was observed in 271 patients. In these, a new AVF was made on the same side in 39.9% of the patients, a contralateral side AVF was made in 5.5% and an AVG in 45.4%, superficialized reposition of brachial artery in 1.8% and death occurred in 7.4%.

**Conclusions:** 1. It was possible to reduce the economic burden for patients using a noncompliant type of balloon catheter. 2. The results in primary and secondary assisted patency rates were excellent. 3. Long-term maintenance of AVG was possible by the application of VAIVT.

## TH-PO466

**Management of Dysfunctional Vascular Access by Repeated Surgery or Angioplasty. Results on a Series of 264 Procedures at 24 Months** Paola De Rango, Basso Parente, Beatrice Fiorucci, Luca Farchioni, Gianbattista Parlani, Giuseppe Giordano. *Vascular and Endovascular Surgery; Hospital S.M. Misericordia; Univ of Perugia, Perugia, Italy.*

**Background:** Dysfunctional vascular access is a common problem that remains unsolved for patients with end stage renal disease (ESRD) requiring dialysis. Object of this study was to evaluate 24 months outcomes of angioplasty compared to repeated open surgery in patients with dysfunctional vascular access.

**Methods:** Consecutive dysfunctional vascular accesses repaired during 2006-2013 were reviewed. Endovascular repair was performed with angioplasty alone and selective stent. Repeated open surgery was performed with multiple techniques. Patients were followed for 24 months. Primary outcome was functional access patency at 6, 12 and 24 months assessed by Kaplan Meier with log rank test. Secondary outcomes included complications, reinterventions and costs. Costs were derived from procedure hospital fees according to regional codes.

**Results:** A total of 264 dysfunctional vascular accesses (163 males;mean age71.7y) were treated during the study period; 96 underwent angioplasty and 168 open reintervention. Kaplan Meier estimates of primary patency at 6, 12, and 24 months were 75.4%, 68.5% and 46.2% in the angioplasty group and 92.6%, 80.7% and 68.4% in the open group (P<.0001). Access related complications occurred in 5.2% patients in the angioplasty group and 6.8% patients in the open group. A total of 82 reinterventions were required during follow-up ranging from 1 to 5 per patient; rates were 60% in the angioplasty group and 40% in the open group. Patients after angioplasty required a mean 0.6+1.1 and those after open surgery a mean 0.4+0.97 reinterventions after the first procedure. Mean costs per patient (including first procedure and additional reinterventions) ranged from €6900 to €7012,9 in the angioplasty group and from €7114 to €7200 in the open surgical group.

**Conclusions:** Angioplasty can be used as an alternative procedure for the maintenance of vascular access with 46.2% patency rate at 24 months. Costs may be contained when no routine stent is applied.

## TH-PO467

**Fistula Patency Rate after Venous Neointimal Hyperplasia Stripping/ Fistula Reconstruction in Patients with Late Autologous Arteriovenous Fistula Stenosis** Fangping Lu,[1] Xuemei Li.[2] *[1]Nephrology, First Hospital of Tsinghua Univ, Beijing, China; [2]Nephrology, Peking Union Medical College Hospital, Beijing, China.*

**Background:** Although autologous arteriovenous fistula(AVF) is still the best permanent hemodialysis access, but mature AVF can occur venous neointimal hyperplasia ( VNH), which lead to venous stenosis with or without thrombosis, that is the primary cause of vascular access failure. Peri-anastomotic stenosis is the main place. At present treatment of VNH is very limited.We adopt a surgical method( stripping VNH and fistula reconstruction) to repair AVF.Here we report the effect of venous neointimal hyperplasia(VNH) stripping / fistula reconstruction on the patency rate in patients with late autologous arteriovenous fistula(AVF) stenosis.

**Methods:** We retrospectively collected clinical data of the hemodialysis patients receiving AVF operation in our hospital from January 2007 to December 2011. There were a total of 305 patients, including 76 cases of VNH stripping/ fistula reconstruction(see Fig.). We observed the fistula patency rate at 3, 6, 12 months after operation, and compared with 128 non VNH stripping/ fistula reconstruction patients and 101 newly AVF patients during the same period.

**Results:** We found that VNH stripping/ fistula reconstruction had a good fistula patency rate(93.4%, 89.5%, 84.2% at 3,6,12 month respectively).

| | 3 month | 6 month | 12 month |
|---|---|---|---|
| VNH stripping/fistula reconstruction | 71(93.4%) | 68(89.5%) | 64(84.2%) |
| Non-VNH stripping/ fistula reconstruction | 118(92.2%) | 115(89.8%) | 110(85.9%) |
| newly AVF | 93(92.1%) | 89(88.1%) | 82(81.2%) |
| *P* value | 0.935 | 0.913 | 0.622 |
| $x^2$value | 0.135 | 0.183 | 0.95 |

Compared with other two kinds of fistula , there was no significant difference in the patency rate.

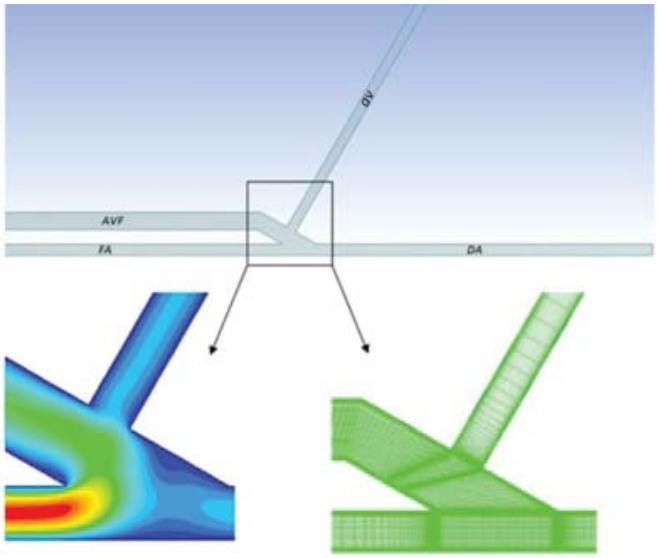
**Conclusions:** VNH stripping / fistula reconstruction operation was an effective method to relieve late stenosis of AVF and improve utilization rate of fistula.

## TH-PO468

**Criteria for Accessory Vein Obliteration. A Scientific Approach towards a Complex Paradigm** Naveed U. Haq, Mamdouh N. Albaqumi. *Nephrology, King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia.*

**Background:** Native arteriovenous fistula (AVF) is the preferred vascular access for hemodialysis. AVF Stenosis and/or accessory vein (*av*) are the most common causes of early fistula failure. While treatment of stenosis is better defined, there are no clear criteria for obliteration of *av*. The purpose of this study was to establish scientific criteria for the management of *av*.

**Methods:** Various Computational Fluid Dynamics (CFD) simulations were performed to analyze blood flow in AVF. The flow was assumed to be incompressible, laminar, Newtonian and transient. 2D model geometries were constructed by ANSYS Design Modeler. The meshing of all AVF models was carried out in ICEM CFD mesh. A finer, high quality mesh was defined at the level of anastamosis, the delicate region (figure). *av* of different diameters, angles, and locations were added in the AVF, and comparison of simulation results was carried out. *av* stealing >20% flow from the AVF was considered significant.



AVF Geometry with pressure, wall shear stress changes and mesh at the anastomosis.
FA: Feeding artery, DA: Distal artery, AVF: Arteriovenous fistula, *av:* Accessory vein

**Results:** *av* diameter was the major determinant of flow while location and angle were insignificant. *av* of at least 60% diameter of the main AVF was significant. If 2 *av*'s were present, effect was additive. *av* presence caused wall shear stress disturbances, while early branching of *av* was also important. This information was combined with known clinical facts to establish the criteria (table 1).

| Table 1: HAQ criteria for *av* obliteration |
|---|
| 1. 60% or greater diameter of the main AVF |
| 2. 50% diameter of AVF with at least one more *av* ≥40% in diameter. |
| 3. 50% in diameter and divides into branches of same size. |
| 4. *av* likely to interfere with cannulation on physical examination. |
| 5. >30% in diameter and associated with stenosis at site of origin. |

**Conclusions:** Our study provides the first standardized and objective criteria for *av* obliteration. This needs to be validated and tested in randomized clinical trials.

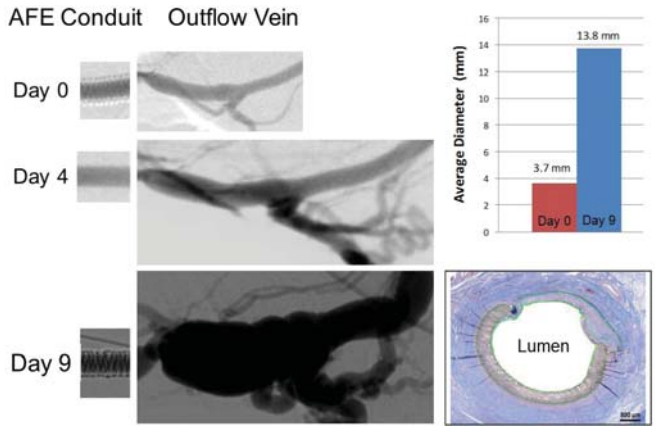
### Rapid Dilation of Porcine Peripheral Vein with Rotary Blood Pump System

Nicholas Franano,[1] Howard M. Loree,[2] Mark R. Cunningham,[3] Dale M. Groth,[3] Lesley A. Szenay,[3] Robert D. Ainsworth,[4] Barrett S. Hutto,[4] James Lee,[4] Steve P. Woodard,[4] Geoff D. Tansley.[5] *[1]Novita Therapeutics LLC, Olathe, KS; [2]Flow Forward Medical LLC, Lowell, MA; [3]Surpass Inc., Osceola, WI; [4]CIRTEC Medical Systems LLC, Los Gatos, CA; [5]School of Engineering, Griffith Univ, Gold Coast, QLD, Australia.*

**Background:** The arteriovenous fistula (AVF) is the preferred form of vascular access for hemodialysis. The Arteriovenous Fistula Eligibility (AFE) System™ is designed to dilate peripheral veins prior to AVF surgery by increasing vein wall shear stress (WSS) and stimulating vascular remodeling, thereby increasing AVF eligibility and improving AVF maturation.

**Methods:** The pre-clinical prototype device comprises a small extracorporeal centrifugal blood pump, cuffed and heparin-coated inflow and outflow conduits, and a benchtop power unit. In a 28 kg anticoagulated pig, the device was implanted in a left external jugular vein to left saphenous vein (SV) configuration and the SV was treated for 9 days with a WSS dose of 4 Pa.

**Results:** Pump flow increased from 270 mL/min on Day 1 to 947 mL/min on Day 9, and the outflow segment of SV dilated from 3.7 mm to 13.8 mm without angiographic evidence of stenosis. Necropsy on Day 9 showed emboli in the lungs and thrombus around the inflow conduit, consistent with known hypercoagulability in the pig model. The dilated SV was easily mobilized. Histology in the treated vein demonstrated remodeling and very minimal intimal hyperplasia, particularly at the graft anastomosis.



**Conclusions:** This pilot study shows the feasibility of the AFE System in a porcine model, demonstrating a 10 mm increase in vein diameter over 9 days of treatment and easily exceeding the 6 mm vein diameter threshold for successful AVF maturation. Ongoing work includes a larger nonclinical study and development of mobile electronics.

## TH-PO470

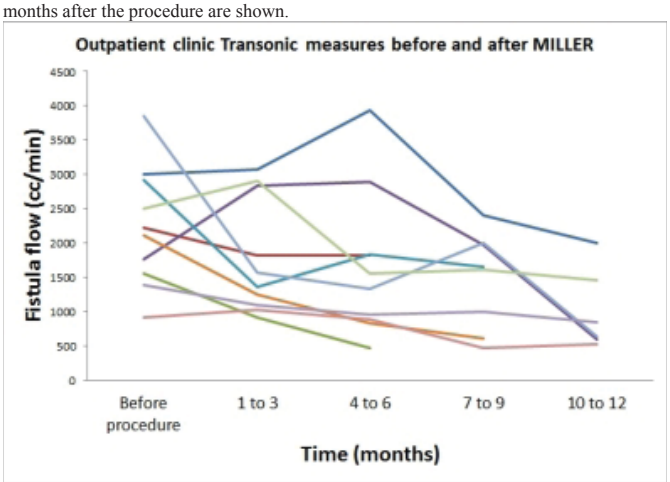
### Hemodialysis Fistula Flow Rates before and after MILLER Procedure: Intra-Operative Flows Are Lower Than Clinic Flows

Jackson Wang,[1] Andrew I. Chin.[1,2] *[1]Div of Nephrology, Univ of California, Davis School of Medicine, Sacramento, CA; [2]Div of Nephrology, VA Health Care, Northern California, Mather, CA.*

**Background:** The **M**inimally **I**nvasive **L**imited **L**igation **E**ndoluminal-assisted **R**evision (MILLER) procedure is a method of decreasing arterio-venous fistula (AVF) diameter to decrease flow rate in hemodialysis (HD) patients who have steal or excessive AVF flow rates. We sought to compare intra-operative AVF flow rates, before and after MILLER, with outpatient clinic measured flow rates.

**Methods:** We included HD patients who had recent MILLER procedures. Intra-operative and outpatient HD clinic flow measures (when available) were analyzed. Paired t-test was used to compare before and after values.

**Results:** 15 patients had MILLER procedures. Baseline factors: mean age 50±11 years; 40% men; 40% diabetic; 14 brachial artery AVFs, 1 femoral AVF. Intra-op AVF flow tests showed significant reduction after the MILLER (1666 ± 953 cc/min vs 849 ± 218 cc/min, p=0.003) with mean flow reduction of 41 ± 17%. All patients had decrease in symptoms. Outpatient clinic measured flow rates (n=10, Figure) before MILLER and for up to 12 months after the procedure are shown.



Outpatient flow rates were: pre-MILLER = 1965 ± 665; 1-3 Mos = 1733 ± 821; 4-6 Mos = 1573 ± 1073; 7-9 Mos = 1148 ± 659; 10-12 Mos = 1086 ± 562. Flow rates were not statistically lower until the 7-9 Mos time period after MILLER. Pre-MILLER outpatient flow rates were higher than intra-operative flow rates (p=0.04).

**Conclusions:** Intra-operative AVF flow rates were significantly lower than outpatient flow rates in patients undergoing MILLER. This may be due to hemodynamic effects of anesthesia, and/or difference in measurement technique. After MILLER, outpatient measured mean flow rates did decrease over time compared with pre-MILLER flow, but did not become statistically lower until 7-9 months later.

*Funding:* Clinical Revenue Support

## TH-PO471

**Arterial Micro-Calcification Is Associated with Coronary Artery Calcium Score in Hemodialysis Patients** Su Jin Choi, Young Soo Kim, Sunae Yoon, Young ok Kim. *Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Uijeongbu-City, Kyunggi-do, Korea.*

**Background:** We have reported that arterial micro-calcification (AMC) of vascular access has a negative impact on access patency and cardiovascular mortality in hemodialysis (HD) patients. Reasons behind increased cardiovascular mortality in AMC are not fully understood, but it is believed that aortic stiffness is a major contributing factor. Whereas, coronary artery calcification (CAC) is quite common in HD patients and it is known as predictor of future cardiovascular events and all cause mortality in HD patients. The aim of this study was to explore the relationship between AMC and CAC in HD patients.

**Methods:** Sixty-four HD patients who received vascular access operation were included in this study. The AMC was diagnosed by pathologic examination of arterial specimen by von Kossa stain, which was acquired during the operation. All patients underwent a multi-detector computed tomography (MDCT) imaging procedure and coronary artery calcium score (CACS) was calculated. Patients were classified into two groups, according to the CACS, as low (<100), in 28 patients, and high ( ≥100), in 36 patients. We compared CACS between the patients with and without AMC.

**Results:** Mean age was 65.8 ± 12.5 years and the male gender was 37 (57.8%). The incidence of AMC was 62.5% (n=40). The mean CACS was 439.3 ± 901.1 (0-5674.1), and the median value was 128.4. Patients with the positive AMC group showed a significantly older age (68.6 ± 10.2 vs 61.2 ± 14.7, p=0.036) and a higher prevalence of diabetes (85.0% vs 45.8%, p=0.001). Positive AMC group showed high incidence of high CACS compared to negative AMC group (77.5% vs 20.8%, p=0.000). By binary logistic regression, high CACS was independently associated with positive AMC (OR 8.894, 95% CI 1.174-46.154, p=0.008).

**Conclusions:** The present study suggests that AMC is closely associated with CACS in HD patients.

## TH-PO472

**Resistance to Erythropoiesis-Stimulating Agents May Be Associated with Arterial Micro-Calcification in Hemodialysis Patients** Su Jin Choi, Hye Sung Won, Young Soo Kim, Sunae Yoon, Young ok Kim. *Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea.*

**Background:** Vascular calcification, which is independent risk factor of cardiovascular mortality, and anemia are very common in hemodialysis (HD) patients. Some uremic milieu such as inflammation, oxidative stress, and mineral bone disturbance may contribute to these conditions. The aim of this study was to evaluate the relationship between arterial micro-calcification (AMC) and erythropoiesis-stimulating agent (ESA) hypo-responsiveness in HD patients.

**Methods:** 84 patients received with ESAs for anemia without iron deficiency were evaluated. We assessed ESA hypo-responsiveness of patients using ESA hypo-responsiveness index (EHRI), defined as the weekly ESA dose per kilogram of body weight divided by the hemoglobin level. The AMC was diagnosed by pathologic examination of arterial specimen by von Kossa stain, which was acquired during the vascular access surgery.

**Results:** AMC was detected in 35 (41.7%) patients. There were no significant differences between patients with and without AMC with respect to clinical characteristics except for age and the presence of diabetes. Among the 35 patients with AMC, 28 (80.0%) patients had diabetes compared with 16 (32.7%) of 49 patients without AMC (p=0.001). The serum levels of albumin and total cholesterol were higher in patients without AMC than in patients with AMC (p=0.048 and 0.014). The serum levels of phosphate, intact parathyroid hormone and calcium-phosphate product were lower in patients with AMC than in patients without AMC (p=0.010, 0.013, and 0.053). The mean EHRI value was higher in patients with AMC than in patients without AMC (p=0.043). The patients were divided into tertiles according to their EHRI values. 6 (21.4%) patients in T1 group, 12 (42.9%) patients in T2 group, and 17 (60.7%) patients in T3 group showed arterial micro-calcification, respectively (p=0.012). In the multivariate logistic regression analysis, diabetes and ESA hypo-responsiveness showed a significant association with arterial micro-calcification.

**Conclusions:** ESA hypo-responsiveness as well as diabetes may be clinically relevant parameters related to AMC in HD patients.

## TH-PO473

**Biocompatibility of Decellularized Bovine Artery and Expanded Polytetrafluorethylene Arteriovenous Grafts in a Sheep Model** Marcos Alexandre Vieira,[1,2] João Gabriel Roderjan,[1] Eduardo Discher Vieira,[1] Francisco D.A. Costa,[1] Miguel C. Riella.[1] *[1]Laboratory of the Center for Cardiovascular Grafts of Tissue Engineering and Cell Culture, Catholic Univ of Parana, Brazil; [2]Nephrology, Pró Rim Foundation, Brazil.*

**Background:** Early dysfunction is a major problem in expanded polytetrafluorethylene arteriovenous(ePTFE) grafts utilized for hemodialysis vascular access. The objective of this study was to evaluate the histological and functional results of decellularized heterografts,and to compare it with that of ePTFE.

**Methods:** ePTFE was implanted in 11 sheep between the carotid artery and the jugular vein and in 10 sheep with a internal thoracic bovine artery(DBA),decellularized following the Brazilian patent PI0800603-2 utilizing sodium dodecyl sulfate.Doppler was conducted prior to graft explantation.Stain:hematoxylin-eosin, alizarin red to assess calcification and Russel Movat's to study the extracellular matrix.Cellular in-growth, re-endothelialization, thrombosis, neovascularization, calcification, neointimal hyperplasia, inflammatory infiltration were studied.Immunohistochemistry:Antibody anti-CD34 [EP373Y](RabMAbs®).

**Results:** Decellularization was confirmed.The DBA extracellular matrix was preserved and repopulated by local tissue.Endothelial cells were expressed by CD34+cells.The DBA was more organized,with intima,media,and adventitia.Both groups exhibited neointimal hyperplasia.Five animals in the ePTFE group had thrombosis versus none in the DBA(p=0,036).A larger internal diameter of the DBA was identified by Doppler(p=0,024).

**Conclusions:** Experimental studies with decellularized grafts described good patency, as well as repopulation of the graft with host cells.The endothelial and hematopoietic progenitor cells was confirmed by staining for CD34, supporting the histologic findings of re-endothelialization, cell growth, migration, and tissue replacement.It is possible that improvement of the blood-graft interface could decrease the rate of thrombosis in the DBA group.The larger internal graft diameter in the DBA group may be related to a mechanism of distensibility similar to what occurs in an arteriovenous fistula.The results suggest a better biological behavior associated with DBA in a sheep model.

## TH-PO474

**In Vivo Tissue Engineered Blood Vessel as Vascular Graft in a Porcine Model** Carolien Rothuizen,[1] Febriyani Damanik,[2] Michel Visser,[4] Tom Lavrijsen,[3] ChunYu Wong,[1] Martijn Cox,[3] Ton J. Rabelink,[1] Lorenzo Moroni,[2] Joris I. Rotmans.[1] *[1]Dept of Nephrology, Leiden Univ Medical Center, Netherlands; [2]Dept of Tissue Regeneration, Univ Twente, Netherlands; [3]Xeltis BV, Netherlands; [4]Dept of Surgery, Leiden Univ Medical Center.*

**Background:** ePTFE grafts are still commonly used as arteriovenous(AV) graft for hemodialysis vascular access, despite their risk of infection and thrombosis. Tailor made tissue engineered blood vessels (TEBVs) that resemble a native vessel may be a suitable alternative. We developed an autologous TEBV generated in the body itself and evaluated its efficacy as vascular graft in a porcine model. Our in vivo tissue engineering method utilizes the foreign body response directed to implanted synthetic material. Implantation of a cylindrical shaped polymer rod evokes an inflammatory response culminating in the encapsulation of the rod by a tube shaped fibrocellular tissue capsule. After extrusion of the rod and grafting the tissue capsule in the vasculature, it can further differentiate into an adequate vascular access conduit.

**Methods:** Per pig, 4 polymer rods were implanted subcutaneously. After 4 weeks, rods with tissue capsules formed around it were harvested and analysed by histology and mechanical tests. Per pig, 1 tissue capsule was implanted as AV-graft in between the carotid artery and jugular vein for 4 weeks and analyzed on wall remodeling.

**Results:** Before grafting, tissue capsules were mainly composed of circumferentially aligned myofibroblasts and few leukocytes. Extracellular matrix consisted mainly of glycosaminoglycans and circular aligned collagen. Tissue capsules exhibited burst pressures of ca. 2000 mmHg and suture strengths of >3N, both exceeding the mechanical properties of native vessels. After 4 weeks of grafting, tissue capsule wall was remodelled, with a 2-fold increase in collagen and 4.3-fold increase in myofibroblast content, while the leukocyte content was reduced to 1%.

**Conclusions:** Using an in vivo tissue engineering approach, a completely biological, autologous TEBV was created with sufficient mechanical strength to enable AV-grafting. Currently we are evaluating patency of these TEBV as vascular graft.

## TH-PO475

**Novel Antithrombotic Fusion Protein to Inhibit Arteriovenous Graft Stenosis** Christi M. Terry,[1] Huan Li,[1] Ilya S. Zhuplatov,[1] Tze-Chein Wun,[2] Alfred K. Cheung.[3,1] *[1]Univ of UT, SLC, UT; [2]EVAS Therapeutics, Ballwin, MO; [3]VASLHCS, SLC, UT.*

**Background:** Coagulation generates activated platelets, thrombin, fibrin and mural thrombi that induce cell proliferation, migration, and matrix deposition that lead to neointimal hyperplasia (NH) and stenosis of arteriovenous grafts (AVG). Yet current antiplatelet and anticoagulant drugs, that yield systemic anti-coagulation, do not substantially prevent AVG stenosis when administered in clinically safe doses. A novel antithrombotic protein has been developed to *locally* inhibit thrombosis: A6L15 consists of an annexin V domain that targets the protein to thrombogenic cell membranes, fused to a Kunitz protease inhibitor domain that inhibits the tissue factor/VIIa complex. A6L15 has potential for safely inhibiting thrombus-induced NH formation and its administration safety was examined in a pig model of AVG stenosis.

**Methods:** Pigs received an i.v. bolus of A6L15 protein (300 μg). A segment of the carotid artery and the ipsilateral jugular vein were isolated by clamping and irrigated with 5, 20 or 100 μg/mL of A6L15 for 5 min. The lumen of a polytetrafluoroethylene graft was filled with A6L15 at the same concentration as the native vessels, then placed between the artery and vein segments. Control pigs had AVG placed but received systemic heparin (n=4) or no anticoagulants (n=1).

**Results:** No bleeding episodes were observed in any animal at any time during the 4-week follow-up. The AVG of the untreated pig clotted at the time of surgery, while the AVG of 1 of 9 pigs treated with high-dose A6L15 clotted at 4 wks. ACT and aPTT at 4 wks were unchanged with either A6L15 or heparin, compared to pre-operative values. In contrast, PT were marginally prolonged after heparin treatment (10.8±0.5 vs. 10.3±0.4 sec; p=0.05 paired t-test; n=4) but not after the highest dose A6L15 treatment (11.0±0.45 vs. 10.8±0.4 sec; p=0.22; n=9). Less fibrosis was noted around the AVG in the 6L15-treated pigs, compared to controls.

**Conclusions:** The A6L15 fusion protein appears safe and well-tolerated. Efficacy studies are ongoing to determine if these fusion proteins inhibit NH associated with AVGs. Preliminary results appear to be promising.

*Funding:* Other NIH Support - NHLBI 2R44HL093848

## TH-PO476

**Differences in Coagulation Protein Concentrations, Platelet Function, and Viscoelasticity among Clot-Forming, and Non-Clot-Forming Hemodialysis Patients with Arteriovenous Grafts**

Chinedu P. Nweke,[1] Daniel E. Carl,[1] Erika Martin,[1] Todd W. Gehr,[1] Donald F. Brophy.[2] *[1]Virginia Commonwealth Univ; [2]Virginia Commonwealth Univ School of Pharmacy.*

**Background:** Arteriovenous Graft thrombosis is a frequent cause of graft failure. We evaluated thrombogenic factors in 20 HD patients with AVGs. The goal was to determine whether significant differences in protein concentrations, platelet function and viscoelasticity factors exist among dialysis patients requiring frequent AVG declot procedures vs those who do not.

**Methods:** 20 HD patients were enrolled: 10 frequent clotters (>3 declots in the previous year) and 10 were non-clotters. Patients on anti-platelets or chronic anticoagulation were excluded. Coagulation protein concentrations including tissue factor (TF), tissue factor pathway inhibitor (TFPI), prothrombin fragment 1+2 (F1+2), von Willebrand's factor (vWf), and fibrinogen were assayed. The time to clot onset was measured by Force Onset Time (FOT) and the Reaction time (R). K represents the time from clot initiation until final clot firmness. Platelet contractile force (PCF) measured the force produced by platelets during clot retraction, while clot rigidity was measured as clot elastic modulus (CEM). FOT, CEM and PCF were measured by Hemodyne; R and K were measured by TEG.

**Results:** There were no significant differences in coagulation protein concentrations and platelet function; however most viscoelasticity factors were statistically significantly different in clotters compared to non-clotters.

| | NORMAL | CLOTTERS | NON-CLOTTERS | P Value |
|---|---|---|---|---|
| PCF | 4.0-9.5 Kdyne | 10.4±4.4 | 6.0±0.7 | 0.003 |
| CEM | 14.0-35.0 kdyn/cm$^2$ | 37.0±14.8 | 21.9±6.4 | 0.008 |
| FOT | 3.0-8.0 min | 6.0±1.9 | 8.1±2.3 | <0.05 |
| R | 3.0-8.0 min | 7.0±1.7 | 8.7±1.7 | 0.04 |
| K | 1.0-3.0 min | 1.4±0.4 | 1.7±0.2 | NS |

**Conclusions:** Our study suggests that HD patients with recurrent AVG thrombotic events form more rapid clots with higher tensile strength compared to HD patients without recurrent graft thrombosis. Identifying effective therapies in modulating these properties that confer higher tensile strength and viscoelasticity as observed among clot-formers may be worth investigating.

## TH-PO477

**Buttonhole versus Rope-Ladder Cannulation for Hemodialysis – A Systemic Review**

Ben C. Wong,[1] Maliha Muneer,[2] Dale Storie,[3] Sabin C. Shurraw,[1] Alexa L. Grudzinski,[4] Gihad E. Nesrallah,[5] Neesh I. Pannu,[1] Robert P. Pauly.[1] *[1]Div of Nephrology and Transplant Immunology, Univ of Alberta, Edmonton, Canada; [2]Alberta Health Services, Edmonton, Canada; [3]Univ of Alberta, Edmonton, Canada; [4]Humber River Regional Hospital; [5]Univ of Western Ontario, London, Canada.*

**Background:** The buttonhole (BH) technique has commonly been a method of arteriovenous fistula (AVF) cannulation in hemodialysis (HD) patients, particularly among patients performing independent home HD. However, an association between BH and a higher incidence of access-related infections has been increasingly noted. We sought to systematically review the documented risks and benefits of BH compared to standard rope-ladder (RL) among HD patients with AVFs.

**Methods:** An extensive search of medical and nursing databases was conducted to identify relevant studies. The results were manually reviewed to identify studies that compare the BH with RL on the following outcomes: cannulation pain, access failure and intervention, infectious outcomes, hemostasis time, and risks of hematoma and aneurysm formation. We excluded the following studies: abstracts, case reports, review articles or editorials without original data, non-English publications, and those that did not include relevant outcomes.

**Results:** Of the 1145 citations, 17 studies were selected for inclusion. Substantial heterogeneity among the studies precluded meta-analysis. BH, as compared to RL, appeared to be associated with an increased risk of local and systemic infections, while conferring a potential benefit in access survival, and reduced risks of hematoma formation and aneurysm formation. There appeared to be equivocal evidence with respect to cannulation pain, the need for access intervention, and hemostasis time.

**Conclusions:** Evidence does not support the preferential use of BH over RL cannulation in either facility-based conventional HD or home intensive HD. This does not preclude BH cannulation as being appropriate for some patients with difficult-to-access AVF.

## TH-PO478

**Utility of Preoperative Vascular Mapping to Select Patients at High Risk for Early Thigh Hemodialysis Graft Failure**

Mark Little,[1] Michael Allon,[2] Michelle McNamara,[1] Song Ching Ong,[2] Mark E. Lockhart,[1] Carlton Young,[3] Michelle L. Robbin.[1] *[1]Dept of Radiology, Univ of Alabama at Birmingham; [2]Dept of Medicine, Univ of Alabama at Birmingham; [3]Dept of Surgery, Univ of Alabama at Birmingham.*

**Background:** To determine whether noninvasive preoperative evaluation of vascular diameters and calcification can identify patients in whom arteriovenous thigh graft survival is likely to be impaired.

**Methods:** IRB approval was obtained and informed consent was waived. Retrospective analysis, including a qualitative assessment of calcification burden, was performed on 143 hemodialysis patients who received ultrasound vascular mapping prior to thigh graft placement. Severity of pelvic arterial calcification was scored in 80 patients who received peri-operative CT, using a semi-quantitative 5-point scale. Patient characteristics and graft outcomes were examined.

**Results:** Preoperative ultrasound screening identified no or mild arterial calcification in 113 of 143 patients (79%) and moderate to severe calcification in 30 of 143 patients (21%). Patients with moderate to severe calcification had significantly increased technical graft failure (hazard ratio=6.59; 95% CI, 2.06-21.05; p=0.002) and decreased cumulative graft survival (hazard ratio=2.32; 95% CI, 1.48-6.69, p= 0.003) compared to patients with no or mild disease. Cumulative graft survival was not associated with venous (HR 1.06; 95% CI, 0.63-1.80, p=0.82) or arterial diameters (HR 1.19; 95% CI, 0.70-2.03, p=0.43). Low CT calcification score was seen in 74 of 80 patients (93%). Primary technical failure occurred in 3 of 6 patients (50%) with high, versus 5 of 74 patients (6.8%) with low calcification score (hazard ratio=7.4; 95% CI, 2.31-23.72, p=0.01). US was more sensitive (64% versus 38%) but less specific (83% versus 96%) than CT in predicting immediate technical graft failure. Positive predictive value of CT and US was 50% and 23%, respectively.

**Conclusions:** Preoperative sonographic assessment of thigh vessel diameter and calcification can select patients who need further CT assessment of pelvic calcifications to identify those at higher risk for primary technical graft failure and decreased cumulative graft survival.

## TH-PO479

**Ultrasonographic Characteristics of Vessels and Survival of AV Fistulas in Octogenarian Population**

Vanja Persic, Rafael Ponikvar, Miha Arnol, Jadranka Buturovic-Ponikvar. *Dept of Nephrology, Univ Medical Center, Ljubljana, Slovenia.*

**Background:** Due to the limited life expectancy, decreased functional status and comorbidities that damage the vessels (e.g. diabetes) native arteriovenous (AVF) placement remains questionable in elderly end-stage renal disease (ESRD) population. We aimed to compare the ultrasonographic (US) characteristics of vessels and the outcome of created AVFs in octogenarians versus younger old patients.

**Methods:** 56 patients aged ≥80 years (G ≥80) and 158 aged between 65 and 80 years (G<80), with the first attempt of AVF placement participated in this retrospective study. Internal diameters (ID) of arteries and veins of both arms and forearms were evaluated by preoperative duplex US examination, and presence of atherosclerotic changes and calcifications was assessed. Position of AVF was recorded after the AVF construction and estimation of patency rates was performed using Kaplan-Meier survival analysis. Cox proportional hazard model was used to determine the effect of age on the primary and secondary AVF patency rate.

**Results:** IDs of cephalic veins and cubital arteries were similar between the two groups, but IDs of radial arteries (RA) were smaller in G ≥80 (right RA 2.1±0,4 vs 2.3±0.5 mm, P=0.04; left RA 2.1±0,5 vs 2.3±0.5 mm, P= 0.06). There was no significant difference in frequency of atherosclerotic changes and calcifications between G ≥80 and G<80 (63% vs 61%, P=0.88 and 54% vs 45%, P=0.27, respectively). AVF was placed in 38 (68%) patients in G ≥80 and in 121 (77%) in G<80 (P=0.2). Patients in G<80 more often received forearm AVF than patients in G ≥80 (82% vs 66%, P=0.04). Primary failure was 17% in both groups. No significant differences between the groups were observed in one-year primary and secondary patency rates (G ≥80: 67% and 77 %; G<80: 68% and 76%; P=0.20 and P=0.22, respectively). Patient age ≥80 years was not an independent predictor of AVF loss (HR 1.47, 95% CI 0.76-2.81; P=0.25).

**Conclusions:** Our results demonstrate that even in patients ≥80 years of age, native AVF can be successfully created with good cumulative patency rate at one year. In our opinion, any patient with ESRD, regardless of age, should be evaluated for AVF placement.

## TH-PO480

**Pre-Operative Fistula Assessment with Ultrasound: Accuracy and Association with Outcome**

Damien Ashby, Jeremy Crane. *Imperial College Kidney and Transplant Centre, Imperial College London, London, United Kingdom.*

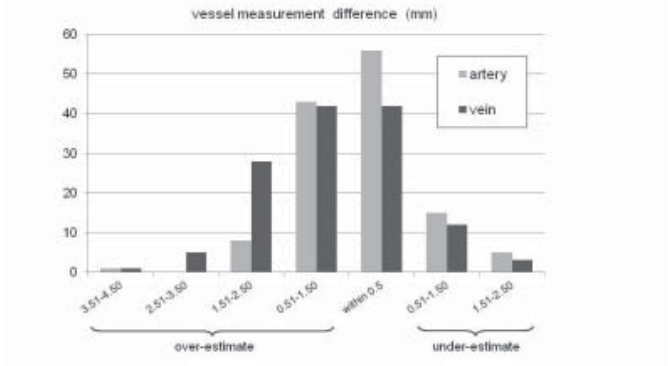
**Background:** The success of arteriovenous fistula formation depends on the quality of artery and vein. The accuracy of pre-operative vessel measurement and relevance to surgical outcome are unclear.

**Methods:** In all patients undergoing elective upper-limb fistula creation during an 18 month period, pre-operative ultrasound vessel measurements were compared with direct intra-operative measurements, and clinical outcomes recorded.

**Results:** In 141 patients (aged 18-85, 71.9% male), 146 fistulae were formed, comprising 18 radiocephalic, 111 brachiocephalic and 17 brachiobasilic.

Pre-operative measurements were closely correlated with intra-operative findings for both arteries (R=0.44, p<0.001) and veins (R=0.35, p<0.001) but biased towards over-estimation for both.

Arterial assessment was reasonably reliable with arteries being within 0.5mm of expected size in 33.6%, and smaller than expected in 40.6%. For vein diameter the pre-operative measurement was less reliable, with veins being within 0.5mm of expected size in 31.6%, and smaller than expected in 57.1%. Gross over-estimation of vein size was common with 25.6% being more than 1.5mm smaller than expected.



The measurements taken intra-operatively appeared to be better predictors of outcome, with primary failure occurring in only 5.7% of cases with optimal vessels at surgery (both artery and vein over 2mm) versus 13.3% of cases where vessels were deemed optimal pre-operatively (p=0.10). If vessel measurements had been more accurately known up to 53% of surgical failures could have been avoided.

**Conclusions:** Pre-operative ultrasound provides reasonable prediction of vessel sizes prior to fistula surgery, but size over-estimation is common, particularly with veins. Measured intra-operatively, both artery and vein size are important predictors of outcome – further refinement of venous assessment could therefore improve access planning.

## TH-PO481

### Haemodialysis Access: Patient Reasoning and Fistula Refusal

Damien Ashby, Lina Johansson, Neill D. Duncan, Jeremy Crane. *Imperial College Kidney and Transplant Centre, Imperial College London, London, United Kingdom.*

**Background:** Compared to other forms of access, arteriovenous fistulae are associated with improved outcomes in haemodialysis patients. Guidelines and incentives have been developed to increase fistula prevalence but some patients are reluctant to undergo fistula formation.

**Methods:** Patient reasoning, knowledge and influences were explored using questionnaires and brief structured interviews, in a group of prevalent haemodialysis patients declining fistula access.

**Results:** Fifty-eight patients (aged 34–87, 58% male) currently dialysing on a tunnelled line were identified. All completed questionnaires and 16 patients went on to give structured interviews.

Most reasons for declining fistula formation were common to a number of patients, including pain during dialysis (cited by 71%), appearance (67%), pain at home (57%), permanence (24%) and fear of bleeding (21%). The risk of surgical failure was often cited (eg. "my veins are really difficult") but other individual-specific reasons were also often given (eg. "I work in a prison"; "I wouldn't be able to use crutches") which were considered by the patient to outweigh other considerations.

All patients understood what a fistula is and were able to describe key features. Most patients reported being told that a fistula is a safer form of access, but in structured interviews, all patients clearly thought that this is not the case.

Other patients were far more influential than professionals in decision making (cited by 87% and 26% respectively, p<0.001). Some patients expressed mistrust of professional advice (eg. "it was told very one-sidedly") often associated with perceived pressure (eg. "they tried to convince me"; "because its more cost-effective"), and all patients felt strongly that access is a personal choice.

**Conclusions:** Patient-specific components to reasoning are not uncommon - many have individual and rational reasons which outweigh generic advice. Decision-making is more influenced by other patients than by professionals, with negative observations leaving a lasting impression. Better understanding of patient reasoning could improve concordance between patient and professional and facilitate informed choice.

## TH-PO482

### Ultrasound-Guided Percutaneous Thrombolysis in Patients with Thrombosed Hemodialysis Grafts

Sara M. Vigano,[1] Giuliana Loizzo,[2] Giuseppe Bacchini,[1] Francesco Locatelli.[1] *[1]Nephrology and Dialysis, A. Manzoni Hospital, Lecco, Italy; [2]Nephrology, Dialysis and Transplantation, Univ of Bari, Bari, Italy.*

**Background:** The purpose of this study is to assess the safety and efficacy of the Arrow-Trerotola percutaneous thrombolysis device (PTD) using ultrasound-guided technique in the treatment of thrombosed vascular access grafts in dialysis patients and to evaluate the immediate and long term outcome in this cohort of patients.

**Methods:** Fifty-nine patients with graft occlusion underwent mechanical thrombolysis with PTD during 107 months. To maintain the patency during the procedure we used saline solution (0.9 %) with 5000 UI of Sodic Heparin. All patients had large clot burden. Technical success, complications, primary and secondary patency rates were noted. Kaplan-Meier analyses were performed.

**Results:** The mean follow-up period was 29.2 months. Whereas patients with a graft vascular access are subjected to a regular Doppler follow-up, the technical success rate was 100%, while the clinical success rate was 91.7%. There were no major complications. Now a day the grafts are still functional in 6 patients. In 47 patients, additional procedures were needed for patency. The 3-month primary and secondary patency rates were 42.2 % and 73.3 % respectively. In fourteen patients the procedure was performed twice, in eight patients three times, in two other patients four and five times respectively.

**Conclusions:** Ultrasound-guided percutaneous mechanical thrombolysis with the Arrow-Trerotola device is a safety and less invasive method for the treatment of thrombosed grafts; it potentially allows to remove clots with minimal risk of wall damage requiring the administration of small amounts of thrombolytics.Moreover it is an out-patients procedure,that not imply patients' hospitalizationand it is performed in a sterile room. Furthermorepatients are not exposed to radiation and to iodinated contrast agents. Thus this procedure could be a valid alternative to the surgical thrombectomy.

## TH-PO483

### Uremia Induces a Proliferative Response through SERCA2a and Related Genes Dysregulation: A Novel Theory for Artero-Venous Fistula Failure

Bertrand N. Mukete,[1,2] Georges Khoueiry,[1] Suchita J. Mehta,[1] Lahouaria Hadri,[2] Jasvinder Singh,[1] Jared M. Radbel,[1] Chadi Saifan,[1] Elie El-Charabaty,[1] Frank M. Rosell,[1] Marianne Smith,[1] Roger Hajjar,[2] Suzanne E. El Sayegh.[1] *[1]Staten Island Univ Hospital, NY; [2]Mount Sinai School of Medicine, NY.*

**Background:** Sacoendoplasmic reticulum calcium ATPase-2a (SERCA2a) has been shown to be reduced in proliferating vascular smooth muscle cells while SERCA2b is upregulated. Arterio-venous fistula (AVF) closure is a major cause of morbidity in patients with end stage renal disease (ESRD). The molecular basis of AVF closure has not been fully elucidated and we hypothesize that the expression of SERCA2a and related genes are affected in subjects with ESRD.

**Methods:** In this case control study, we enrolled 18 patients, nine with ESRD going for AVF insertion and nine with normal renal function (NRF) going for coronary artery bypass surgery. Brachial and saphenous veins from ESRD and NRF patients respectively were isolated. Gene expression for SERCA2a, SERCA2b, phospholamban (PLN), endothelial nitric oxide synthase (eNOS) and CD31 were measured using real time quantitative polymerase chain reaction. Hematoxylin/eosin staining was used to analyze the integrity of the vessels and immunoflouroscense microscopy (IFM) was used to visually quantify genes of interest. Two-tailed t-test was used to calculate the difference between means and 95% confidence interval (CI) between the two groups.

**Results:** The difference in mean and 95% CI for gene expression in NRF versus ESRD was +1.9 (0.74 to 3.1), p < 0.01 for SERCA2a, -1.3 (-2.5 to -0.16), p = 0. 03 for SERCA2b, +1.3 (0.59 to 2.0), p < 0.01 for PLN, -4.4 (-9.6 to 0.83), p = 0.09 for eNOS and -1.1 (-3.8 to 1.5), p = 0.37 for CD31. Protein expression was confirmed using IFM.

**Conclusions:** SERCA2a was significantly decreased while SERCA2b was increased in the brachial vein of ESRD subjects when compared to corresponding genes in the saphenous veins of subjects with NRF. The level of eNOS expression was statistically unchanged in both groups. Our findings suggest a pro-proliferative response of ESRD based on SERCA2 expression, which may exacerbate or accelerate AVF shunt failure in ESRD subjects.

*Funding:* Other U.S. Government Support

## TH-PO484

### Bone Morphogenetic Protein-7 (BMP-7) Inhibits Oxidative Stress-Induced Monocyte Chemoattractant Protein-1 (MCP-1) Expression in Vascular Endothelial Cells

Yong-Soo Kim, Jeong-Sun Han. *Div of Nephrology, The Catholic Univ of Korea College of Medicine, Seoul, Korea.*

**Background:** Oxidative stress and activation of chemokines including MCP-1 are known to be downstream mechanisms responsible for the neointimal hyperplasia after creation of hemodialysis vascular access.

**Methods:** After stimulating the human umbilical vein endothelial cells with $H_2O_2$, cell viability, MCP-1 mRNA expression (by quantitative real-time PCR), MAPK activity and transcription factors activities including NF-kB and AP-1 (by Western blot) were measured. Oxidative stress was analyzed by confocal microscopy using 2',7'-dichlorofluorescin diacetate (DCF-DA) and by measuring 8-isoprostane in cell culture medium.

**Results:** Cell viability was over 90% when the cells were incubated with 0.5 mM of $H_2O_2$ for 4 hr. 0.5 mM $H_2O_2$ stimulated MCP-1 mRNA expression in a dose- and time-

dependent manner with a peak at 4 hr. $H_2O_2$ stimulated phosphorylation of p38 and JNK with a peak at 30 min, respectively. In addition, $H_2O_2$ stimulated phosphorylation of NF-kB subunit, p65, and degradation of cytoplasmic IkBa, and also stimulated phosphorylation of AP-1 subunits, c-Jun and c-Fos. When the cells were pre-incubated with SB203580 (P38 inhibitor), SP600125 (JNK inhibitor), pyrrolidine dithiocarbamate (NFkB inhibitor), or curcumin (AP-1 inhibitor), $H_2O_2$-induced MCP-1 mRNA expression was significantly inhibited. BMP-7 significantly inhibited $H_2O_2$-induced MCP-1 mRNA expression in a dose-dependent manner. BMP-7 significantly inhibited $H_2O_2$-induced intracellular ROS production and 8-isoprostane levels in cell culture medium. BMP-7 significantly inhibited $H_2O_2$-induced phosphorylation of JNK, c-Jun and c-Fos, but did not inhibit $H_2O_2$-induced phosphorylation of p38 and p65.

**Conclusions:** These data suggest that oxidative stress directly stimulates MCP-1 expression in vascular endothelial cells and BMP-7 inhibits it through the anti-oxidant effect and inhibition of JNK-AP-1 pathway. This study provides a new insight into the potential of BMP-7 as an anti-oxidant to prevent neointimal hyperplasia in vascular access.

## TH-PO485

**Association of Intravenous Vitamin D Receptor Activator and Sevelamer with Vascular Access-Related Hospitalization: Japan-DOPPS**
Masatomo Taniguchi,[1] Hirotaka Komaba,[2] Takayuki Hamano,[3] Masafumi Fukagawa.[2] *[1]Depts of Medicine & Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan; [3]Dept of Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Osaka, Japan.*

**Background:** Only a few studies have investigated the association between mineral and bone disorders (MBD) and the risk of hospitalization.

**Methods:** The subjects were 2,215 Japanese hemodialysis patients registered in the Japan-DOPPS Phase III. Main exposure is the medication for MBD, administration of vitamin D receptor activator (VDRA) and phosphate binder (sevelamer, calcium carbonate). Serum phosphorus (P), adjusted calcium (Ca) and parathyroid hormone (PTH) concentrations was entered into the model as covariates. Main outcome was association hospitalization due to cardiovascular disease [CVD], infection and vascular access. Using counts model including the Poisson and negative binomial regression, the association between the drugs and outcome was investigated by the "inverse probability of treatment weighting" method.

**Results:** The total number of hospitalizations was 1,098. Serum P, Ca, and PTH concentrations showed no significant association with each hospitalization. Despite association no statistically significant relationship of VDRA with the hospitalization for CVD or infection, a significant decrease in vascular access-related hospitalization was observed in VDRA users (rate ratio [RR] = 0.67: 95% CI = 0.47-0.95). The risk of vascular access-related hospitalization was also significantly decreased in sevelamer user (RR = 0.71: 95% CI = 0.52-0.98), but not in calcium carbonate user (RR = 0.93: 95% CI = 0.70-1.24). In stratified analyses, both VDRA and sevelamer was associated with markedly decreased risk of vascular access-related hospitalization in male patients.

**Conclusions:** Administration of VDRA or sevelamer was associated with reduced risk of vascular access-related hospitalization, suggesting that practice patterns for MBD are involved in vascular patency.

## TH-PO486

**Clinicopathologic Correlations of Explanted Fistulas and Synthetic Grafts**
Laura Minhui Kim, Pooja Gupta, Rohan John, Jagdish Butany, Charmaine E. Lok. *Toronto General Hospital, Toronto, Canada.*

**Background:** In hemodialysis patients, both fistulas (AVF) and grafts are associated with complications which may require their excision. In contrast, kidney transplanted patients may have arteriovenous accesses that are no longer required and may be excised if they become problematic. We aimed to describe the histopathologic changes associated with excised fistulas and grafts to determine if there is any association with their clinical reason for removal.

**Methods:** All explanted AVF and grafts from 2001-2012 were identified from the Surgical Pathology database of Toronto General Hospital, and detailed histopathologic evaluation performed. Differences in pathologic findings versus access type were compared by Chi-Square (SAS, v9.2).

**Results:** Among 110 explanted specimens, there were 64 AVF and 46 grafts. Patients with AVF were on average 47 years old with 69% males; and those with grafts were 59 years old with 39% males. Patients with grafts were more likely to be hypertensive and have coronary artery disease. Glomerulonephritis was the most common cause of ESRD in both groups. Successful transplant with problematic (e.g. aneurysmal or symptomatic) access was the most common reason for fistula removal whereas aneurysm and infection were the most likely reasons for grafts. There was significantly more adventitial chronic inflammation ($p<0.0001$), medial acute inflammation ($p=0.01$), medial chronic inflammation ($p=0.03$) and intimal acute inflammation ($p=0.004$) in explanted grafts compared to fistulas. The media of synthetic grafts was also more prone to calcification (<0.0001). Neointimal proliferation was commonly seen in both fistulas and synthetic grafts (95% and 93% of specimens in each group).

**Conclusions:** Histopathologically, synthetic grafts were more commonly inflamed, likely corresponding to infection as a more common reason for graft removal compared to AVF. Significant vessel inflammation existed in AVF that would have otherwise been functional if not for transplantation, indicating that inflammation itself cannot be a sole pathologic criteria distinguishing between infection and other causes of inflammation. Gram staining and developing a classification system may be helpful in this regard.

## TH-PO487

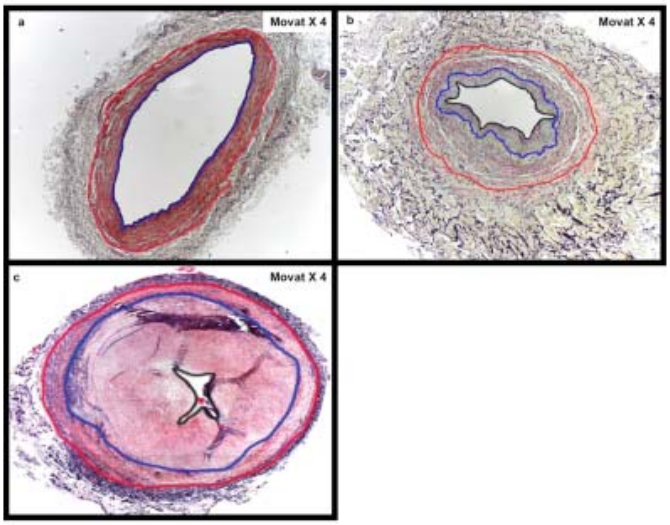
**Natural History of Venous Morphologic Changes in Dialysis Access Stenosis**
Timmy C. Lee,[1,2] Maheshika Srimali Somarathna,[1] Begoña Campos,[1] Lois J. Arend,[3] Prabir Roy-Chaudhury.[1] *[1]Dept of Internal Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Dept of Medicine, Univ of Alabama at Birmingham, Birmingham, AL; [3]Dept of Pathology, Johns Hopkins Univ, Baltimore, MD; [4]Dept of Pathology, Univ of Kentucky, Lexington, KY.*

**Background:** The natural history of arteriovenous fistula (AVF) non-maturation is likely influenced by vascular insults to the vein prior to and after AVF creation and involves different responses to vascular injury from uremia independently, and uremia in combination with hemodynamics. The objective of this study was to perform a morphometric analysis from vein specimens from subjects without chronic kidney disease (CKD), collected at time of new surgery, and from failed stenotic AVFs.

**Methods:** Vein samples from 11 non-kidney disease subjects from deceased donors, 29 CKD subjects at time of new access creation, and 20 subjects with stenotic AVF were collected and morphometric analysis performed.

**Results:** The mean values of average intimal/media thickness and maximal intimal/media thickness±S.E. for veins from subjects with non-CKD, at time of new access creation, and stenotic AVFs were 0.16±0.02 and 0.49±0.10, 0.43±0.07 and 0.86±0.14, and 3.84±0.55 and 7.78±0.88, respectively. Using ANOVA, the mean values were significantly different between the average and maximal intimal/medial thickness analyses, $p<0.0001$. Among non-CKD samples diabetes ($p=0.0007$) was associated with increased average intima/media thickness.

**Conclusions:** Our results show significantly progressive increases in neointimal hyperplasia from non-CKD to stenotic vein samples (see figure). These changes suggest that vascular injuries from uremia and hemodynamics may play a key role in these progressive vascular changes and natural history of vascular access dysfunction.



**Histology of Vein Specimens.** Representative sample from veins collected from (a) non-CKD donor vein sample, (b) vein from advanced CKD subject at time of access surgery, and (c) vein sample from an early AVF failure. Note the progressive increase in amount of neointimal hyperplasia from non-CKD period to early failure.

*Funding:* NIDDK Support

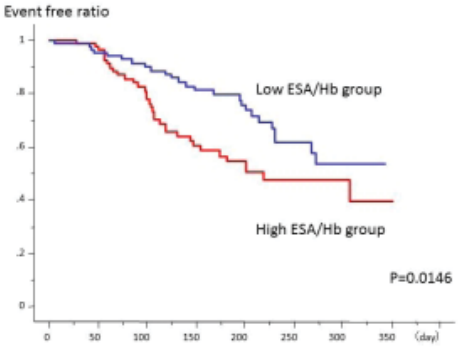
## TH-PO488

**Erythropoiesis Stimulating Agents (ESA)-Hyporesponsiveness Is Associated with Second Patency Rates of Vascular Access in Patients on Maintenance Hemodialysis (MHD)**
Yukiko Hasuike,[1] Naoto Kakita,[2] Motohiro Kamimura,[2] Shoji Kaibe,[1] Soshi Yorifuji,[1] Takeshi Nakanishi.[1] *[1]Dep. Internal Medicine, Div Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; [2]Vascular Access Center, Tanaka-Kitanoda Hospital, Sakai, Osaka, Japan.*

**Background:** Malfunction of the vascular access (VA) is an important cause of poor prognosis in MHD. The purpose of this study was to evaluate the factors affecting VA patency after percutaneous-transluminal angioplasty (PTA).

**Methods:** A total 246 HD patients who were treated with PTA were enrolled. The end points were the re-vascularization of VA during the observational period. ESA/hemoglobin ratio (ESA/Hb) was calculated as an index of ESA-responsiveness. The blood flow volume and resistance index of VA were evaluated by Doppler ultrasonography, and tibial- and ankle-brachial index (ABI) were measured by ABI-form.

**Results:** Dialysis vintage of participants was 69.8±10.4 months, and 134 patients (54.5%) were female, 176 (71.5%) have native arteriovenous fistula, 169 (68.7%) were administered ESA. During follow-up period, re-vascularization was performed in 146 patients (59.3%). Graft use, oral anticoagulant administration, higher ESA/Hb, and lower ABI were associated with patency rates. Based on the median value of ESA/Hb, all the patients were divided into 2 groups: the High and Low ESA/Hb group. The Kaplan-Meier analysis showed High ESA/Hb was significantly associated with VA failure event (p=0.0146).



Cox regression analysis revealed that not only AV graft (hazard ratio 2.267, p=0.0013) but also High ESA/Hb (hazard ratio 1.773, p=0.0303) were related to VA failure event.

**Conclusions:** The present research indicates that ESA-hyporesponsiveness is associated with the risk of VA failure. ESA-hyporesponsiveness could influence on the patency of VA. Further evidence is required to validate the maintenance of long-term patency of VA in MHD.

## TH-PO489

### Effect of Arteriovenous Hemodialysis Shunt Location on Cardiac Events in Patients Having Coronary Artery Bypass Graft Using an Internal Thoracic Artery

Leonid Feldman,[1,2] Shai Efrati,[1,2] Ilia Beberashvili,[1,2] Zhan Averbukh.[1,2]
*[1]Nephrology Dept, Assaf Harofeh Medical Center, Zerifin, Israel; [2]Sackler School of Medicine, Tel Aviv Univ, Tel Aviv, Israel.*

**Background:** The possibility of developing coronary steal in patients having coronary artery bypass graft (CABG) using internal thoracic artery (ITA) and ipsilateral upper extremity arteriovenous (AV) hemodialysis shunt has been reported. The impact of this phenomenon on clinical outcomes is uncertain. The aim of this study was to investigate an association between the AV dialysis shunt location regarding the side of the ITA CABG and clinical outcomes.

**Methods:** This is a retrospective cohort study based on data recorded in the patient files. Inclusion criteria were defined as ages between 18 and 85, availability of clinical data and presence of a patent upper extremity AV shunt (native fistula or synthetic graft) as a vascular access to dialysis. Patients with a catheter or with lower extremity AV shunt as dialysis access and patients having CABG without using an ITAwere excluded from the study. The eligible patients were divided into 2 groups: those with ipsilateral and those with contralateral location of ITA CABG and AV shunt. The outcomes were: death from any cause, cardiac death and a first cardiac event.

**Results:** In a group of 112 chronic hemodialysis patients having CABG, 32 had an ipsilateral and 25 had a contralateral location of ITA CABG and an upper extremity AV shunt. Mean follow up period was 39.0±24.7 months. Significantly more cardiac events occurred in the group with an ipsilateral compared to a contralateral location of coronary ITA CABGs and dialysis AV shunts (hazard ratio, 2.16 [95% CI, 1.11 to 4.19], p=0.023). There was no difference between the groups in the all cause mortality risk (hazard ratio, 1.005 [95% CI, 0.43 to 2.37], p=0.990) and in the risk of cardiac death (hazard ratio, 2.43 [95% CI, 0.64 to 9.17], p=0.191).

**Conclusions:** The ipsilateral location of a CABG with the use of ITA and upper extremity AV dialysis shunt may be associated with increased risk of cardiac events. Placing an upper extremity AV hemodialysis shunt in patient with functioning ITA CABG would be better performed on a contralateral side.

## TH-PO490

### Influence of Dialysis on the Cerebrovascular Supply – Role of Arteriovenous Fistula (Pilot Study)

Ivan Rychlik,[1] Tomas Zahradnicek,[1] Tomas Peisker.[2]
*[1]Dialysis Unit, FMC, Prague 10; [2]Dept. Neurology, 3rd Fac. Med, Prague 10, Czech Republic.*

**Background:** Part of patients(pts) on maintenance hemodialysis(HD) therapy complains of neurological symptoms like vertigo,headache,during HD.No data are available concerning influence of blood flow of the arteriovenous fistula(AVF) on vertebrobasilary(VB) vascular supply.We tested whether AVF flow rate had negative impact on blood supply in VB arteries during HD session.

**Methods:** Pts were defined as stable on HD >1y,with native brachio- or radiocephalic AVF,normotensive,normovolemic according to Fresenius Body Composition Monitor. Using dopplersonography(dUSG),following parameters were measured:i/peak-systolic velocity(PSV),end-diastolic velocity (EDV),calculated mean flow velocity(MFV) before and during HD session in vertebral artery(segm.$VA_2$ and $VA_4$)and basilar artery(BA);ii/ a.brachialis blood flow.Furthermore,AVF-blood flow was measured by Fresenius blood temperature monitor(BTM).We compared the blood flow in VB supply before and during HD session in connection with AVF blood flow.

**Results:** 8 pts(mean age 75y,M/F 5/3, 25% diabetics,50% CHD) were enrolled.During HD session,mean BP=132/72mmHg,mean UF 2530 ml,mean Qb (blood pump) 383 ml/ min.Blood flow data are given in Tab.1:

| No. | dUSG vascular pathology | blood flow AVF (ml/min) | | ipsilateral artery bood flow (cm/s) | | | |
|---|---|---|---|---|---|---|---|
| | | | | BA | | VA4 | |
| | | dUSG-BA | BTM | pre-HD | in-HD | pre-HD | in-HD |
| 1 | + | 850 | 650 | 58 | 31 | 26 | 22 |
| 2 | + | 800 | 620 | 49 | 50 | 30 | 16 |
| 3 | - | 1200 | 1200 | 29 | 24 | 49 | 24 |
| 4 | - | 850 | 643 | 44 | 51 | 46 | 50 |
| 5 | - | 900 | 711 | 27 | 28 | 25 | 22 |
| 6 | - | 800 | 556 | 21 | 16 | 19 | 16 |
| 7 | - | 900 | 643 | 35 | 34 | 29 | 31 |
| 8 | - | 540 | 598 | 57 | 45 | 42 | 37 |

Significant decrease(>25%) of blood flow in distal part of VB arteries($VA_4$ and BA) with VB clinical symptoms was disclosed in 3 pts(37%)and dUSG vascular pathology(>50% stenosis or occlusion)on VB arteries was proven in 2 of them.The influence of inappropriate hydration, intradialysis hypo/hypertension,ion-dysbalances,etc., during dialysis sessions were excluded.

**Conclusions:** According to our results,cerebral hypoperfusion due to the pre-existing vascular pathology on VB arteries seems to be impacted by hemodynamic effect of AVF blood flow. A dUSG-screening of during-dialy sis-symptomatic pts could be useful to prevent cerebral ischemic impairment.

## TH-PO491

### Frequent Pre-Dialysis Nephrology Care and Later Dialysis Initiation Are Associated with Arteriovenous Access Use at Dialysis Start: A DOPPS Study

Brian Bieber,[1] Yun Li,[1,2] Ronald L. Pisoni,[1] Christi Priya Dhayanandhan,[2] Christian Combe,[3] Joan Fort,[4] David C. Mendelssohn,[5] Hideki Kawanishi,[6] Friedrich K. Port,[1,2] Panduranga S. Rao,[2] Bruce M. Robinson.[1,2]
*[1]Arbor Research; [2]U. Michigan; [3]CHU de Bordeaux; [4]Hosp. Vall d'Hebron; [5]Humber River Regional Hosp.; [6]Tsuchiya General Hosp.*

**Background:** Catheter use at dialysis start remains exceptionally high in the US and likely contributes to high early dialysis mortality rates. The average estimated glomerular filtration rate (eGFR) at dialysis start is higher in the US than in Europe and Japan and has risen over the past decade. We hypothesized that arteriovenous fistula or graft (AV access) use at study start would be associated with (a) more frequent pre-nephrology care and (b) later dialysis start.

**Methods:** Data were from phase 4 of the Dialysis Outcomes and Practice Patterns Study (DOPPS, 2009-2011). Among patients on dialysis <120 days at enrollment and with data on eGFR at dialysis start and frequency of pre-dialysis care (n=835), logistic regression was used to estimate odds of an AV access at dialysis start, accounting for facility clustering and listed covariates. AV access at DOPPS enrollment was used when access at dialysis start was missing.

**Results:** 28% of US patients used an AV access at HD start, compared to 51% in Europe and 87% in Japan. In the adjusted model, patients who saw a nephrologist more often in the year before dialysis were more likely to have an AV access(Table). Patients with a lower eGFR at start of dialysis were also more likely to have an AV access.

**Table:** Associations with use of AV access at dialysis start

| Variable | Unadjusted Odds Ratio (95% CI) | Adjusted[a] Odds Ratio (95% CI) |
|---|---|---|
| eGFR at dialysis start (per 2.5 mL/min lower) | 1.15(1.06,1.24)* | 1.13(1.00,1.27)* |
| Frequency of pre-HD care[b] | | |
| 0 visits | 0.68(0.37,1.27) | 0.38(0.16,0.87)* |
| 1 visit | 1.00(ref) | 1.00(ref) |
| 2-4 visits | 2.57(1.52,4.37)* | 2.73(1.40,5.33)* |
| 5+ visits | 4.19(2.35,7.46)* | 4.58(2.26,9.31)* |

a. Adjusted for listed variables plus age, vintage, country and US-black race, 12 summary comorbid conditions, and facility clustering
b. Number of visits in the year before starting dialysis
* p < 0.05

**Conclusions:** AV access use at start of dialysis is much lower in US than Europe or Japan. Emphasis on frequent pre-dialysis nephrology care and avoiding unnecessary early dialysis starts in order to establish an AV access before starting dialysis may improve outcomes during the dialysis transition period.

**TH-PO492**

**Local Anesthesia in Arteriovenous Fistula Placement: Patient Perception of Pain and Early Patency Outcomes** Rick E. Mishler,[1] Amanda M. Valliant,[2] Alexander S. Yevzlin.[2] *[1]Arizona Kidney Disease and Hypertension Centers, Phoenix, AZ; [2]Univ of Wisconsin Hospitals and Clinics, Madison, WI.*

**Background:** US end stage renal disease (ESRD) vascular access outcomes, though improving, continue to lag behind those of Europe. As a result of this persistent trend, US Nephrologists have recently started to create arteriovenous (AV) access. This retrospective study involving 170 patients presenting for AV fistula creation to US Nephrologists explores several aspects of fistula creation using monitored anesthesia care (MAC) rather than brachial plexus nerve blockade, including adequacy of analgesia and early post-operative access patency as well as intraoperative complications.

**Methods:** Patients undergoing AV fistula placement using only MAC from September 2011 to January 2012 were surveyed post-operatively and asked to rate their intraprocedural pain (IPP) using a predefined pain scoring system. In total, 170 patients were included in this retrospective review with 50 patients providing pain score assessments. Additional data was collected at the time of fistula placement and in the subsequent two weeks, including incidence of common medical comorbidities and 2-week post-operative complication rates.

**Results:** Amongst the 170 patients, 60.6% were diabetic, 96.5% were hypertensive,and 37.7% had ESRD (defined as stage 5 CKD) at the time of AV fistula placement. A subset of 50 patients consented to an assessment of pain scores immediately following the fistula placement under local anesthesia; pain scoring system is described elsewhere. Of the 50 patients, 96% reported an(IPP) score of 1, consistent with no pain or minimal pain. Four percent of patients reported an IPP of 2, corresponding to mild to moderate pain. When evaluating the success of fistula placement, 95.88% of the patients underwent a successful procedure with no complications noted and adequately maturing access at 2 weeks.

**Conclusions:** The placement of AV fistulas using MAC can be easily achieved with adequate analgesia. In addition, the success rates of these procedures is high and the rate of early fistula failure in this study significantly lower than the average fistula failure rates demonstrated in the literature.

**TH-PO493**

**Intravenous Ferric Carboxymaltose (Ferinject®) Reduced the Need for the Erythropoietin-Stimulating Agent Aranesp® in Chronic Hemodialysis Patients** Marijke Dekker,[1] Catharina H.M. Kerskes,[2] Constantijn Konings.[1] *[1]Internal Medicine, Catharina Hospital, Eindhoven, Netherlands; [2]Clinical Pharmacology, Catharina Hospital, Eindhoven.*

**Background:** The treatment of iron deficiency and renal anemia in chronic hemodialysis patients is expensive due to frequent iron infusions and, especially, due to prescription of an erythropoietin-stimulating agent (ESA). In our hemodialysis population, we investigated if the frequency and dosage of iron infusions and ESA administration could be reduced, without compromising ferritine and hemoglobin (Hb) levels, by switching from intravenous LMW iron dextran (LMW-ID) (CosmoFer®) to intravenous ferric carboxymaltose (FCM) (Ferinject®).

**Methods:** In this retrospective study, we analyzed chronic hemodialysis patients [HD73; HDF 5], six months before switching from intravenous LMW-ID to intravenous FCM and once a month for six months after the switch. Anemia was treated according to the 2012 KDIGO guidelines; Aranesp® was administered as ESA when Hb levels were below 9g/dl in all patients. We compared: Hb, ferritine, transferrine and CRP values, plus the FCM, LMW-ID and ESA dosages.

**Results:** In total, we analyzed 78 patients, mean age 70±12.9yrs. We found a significant reduction in the weekly ESA dosage from 45.75µg to 39.69µg (p=0.017) between the first and sixth month after introducing FCM. This equals an ESA reduction in 30.8% (N=24) of the patients, and the ESA could even be stopped in 3 patients. Besides, the used FCM dosage could also be significantly reduced in the first 6 months, from 39.64mg to 34.08mg a week (p=0.049), without compromising ferritine levels. Six 6 months after the switch, over 90% of the patients had Hb levels over 9 g/dl as required by the 2012 KDIGO anemia guideline.

**Conclusions:** Using ferric carboxymaltose (Ferinject®) instead of LMW-ID significantly reduced the need for the erythropoietin-stimulating agent (Aranesp®), without compromising Hb levels.

**TH-PO494**

**Soluble Ferric Pyrophosphate (SFP) Administered via Dialysate Reduces ESA and IV Iron Requirements while Maintaining Hemoglobin in CKD-HD Patients** Vivian H. Lin, Ajay Gupta, Tasha M. Farmer, Carrie D. Guss, Raymond D. Pratt. *Rockwell Medical Inc.*

**Background:** The effects of SFP, a soluble form of iron delivered via the dialysate, on ESA, IV iron requirements and hemoglobin, were examined in the PRIME study, a 36 week, double-blind RCT.

**Methods:** Iron-replete CKD-HD patients on stable ESA doses (N=103) were randomized to SFP (2µM or 110µg iron/L) or placebo (standard dialysate without SFP). At baseline, groups did not differ significantly in any study parameter. ESA prescriptions were managed by a centralized anemia management center to facilitate consistent adherence to the protocol-specified hemoglobin target range of 95 to 115 g/L. Per protocol, investigators gave IV iron for ferritin <200 µg/L and/or TSAT <15%.

**Results:** Adverse events did not differ significantly between study groups. From baseline to end of treatment (EoT: last 2 weeks on study), the change in prescribed ESA in the SFP group (388 U/wk) was 35% less (p=0.045) than in the placebo group (3,423 U/wk), the primary endpoint of the trial. At EoT, the SFP group had required 48% less IV iron than the placebo group (24 vs 45 mg/wk; p=0.028). Despite receiving less ESA and IV iron, the hemoglobin in the SFP group was maintained from baseline to EoT (110 to 106 g/L) and did not differ (p=0.833) from that in the placebo group (111 to 104 g/L). In patients who received study drug, no supplemental iron was needed by subgroups of 40 (77%) in the SFP group and of 31 (60%) in the placebo group (p=0.09). At EoT, the prescribed ESA dose was reduced from baseline by 5% in the SFP subgroup and increased by 33% in the placebo subgroup, a difference of 38% (p=0.058). In the SFP subgroup, reticulocyte hemoglobin (CHr) remained stable, but declined in the placebo subgroup by a mean of 1.61 pg (p=0.008) at EoT.

**Conclusions:** SFP, delivered via dialysate, requires 35% less ESA and 48% less IV iron compared to placebo, while maintaining hemoglobin concentrations. SFP reduced ESA requirements by 38% among patients who did not require IV iron, while maintaining iron availability for erythropoiesis, as evaluated by CHr. SFP is a promising means of providing iron to CKD-HD patients.

**TH-PO495**

**Initial Change of Iron Metabolic Flux prior to Differentiation of Erythroid Progenitors after Epoetin Beta Pegol (C.E.R.A.) Treatment** Yusuke Sasaki, Mariko Noguchi-Sasaki, Yukari Matsuo, Junko Fukumura, Fumi Sato-Inomata, Keigo Yorozu, Yasushi Shimonaka. *Chugai Pharmaceutical Co., Ltd., Japan.*

**Background:** Epoetin beta pegol (C.E.R.A.) is a novel long-acting erythropoiesis stimulating agent. C.E.R.A. has been reported to promote mobilization of iron storage through intensive suppression of serum hepcidin levels. The aim of this study is to analyze the mechanism underlying suppression of hepcidin and initial change of iron metabolic flux after C.E.R.A. treatment.

**Methods:** Serum hepcidin and iron levels were analyzed in C57BL/6N (B6) mice intravenously treated with 10 µg/kg of C.E.R.A., carbamylated C.E.R.A. (C-C.E.R.A.) which has erythropoiesis effect silenced by modification of lysines by carbamylation, or vehicle. Initial transitions of hematological and iron parameters, as well as the maturation status of bone marrow erythroblast stained with Ter119 and transferrin receptor (CD71) were analyzed in B6 mice after intravenous treatment with 10 µg/kg of C.E.R.A. or vehicle.

**Results:** C.E.R.A. significantly suppressed serum hepcidin levels at 48 hours after treatment, while C-C.E.R.A. has no effect on them. There were no changes in serum iron levels by C.E.R.A. or C-C.E.R.A. treatment at 48 hours. C.E.R.A. suppressed serum hepcidin levels from 9 to 24 hours after treatment, while serum iron levels were significantly decreased at 9 hours followed by recovery to the control levels at 24 hours. Ter119(+) CD71(high) immature erythroblast was decreased and CD71 expression levels on the same cells were increased at 9 hours after treatment.

**Conclusions:** These results indicate that erythropoietic activity is essential for suppression of hepcidin after C.E.R.A. treatment. Suppression of serum hepcidin levels and transient decrease in serum iron levels in early phase after C.E.R.A. treatment, prior to differentiation of erythroid progenitors suggest that sensing initial change of iron metabolic flux leads to suppression of hepcidin after C.E.R.A. treatment. It is possible that this flux occurs by the accelerated maturation of immature erythroblast which has ability to absorb iron after C.E.R.A. treatment, but further investigation is needed.

**TH-PO496**

**Relative Safety of Peginesatide versus Epoetin Alfa** Eric D. Weinhandl,[1] David T. Gilbertson,[1] Robert N. Foley,[1,2] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Univ of Minnesota, Minneapolis, MN.*

**Background:** Omontys (peginesatide) was recalled in February 2013, after reports of serious hypersensitivity reactions and deaths. We used Medicare Quarterly Standard Analytical Files (QSAFs) to compare adverse event rates in patients who received a first dose of peginesatide (PEG) between July 1 and November 30, 2012, and matched controls who received a dose of epoetin alfa (EPO) during the same era.

**Methods:** PEG and EPO exposure were ascertained from outpatient facility claims. Patients with recent exposure to ferumoxytol or iron dextran or residing in states without PEG use during the study era were excluded. For each PEG user, we identified 2 matched controls with identical dialysis provider affiliation, dialytic modality, and same-day IV iron exposure; and similar propensity score (PS) of PEG initiation. The PS was a function of demographic factors; state of residence; hemoglobin; recent exposure to EPO, darbepoetin alfa, IV iron, and IV antibiotics; and comorbidity. We searched mortality records and institutional claims for the occurrence of 3 outcomes on either the day of or the day after ESA administration: the composite event of death or hospitalization due to cardiovascular disease (CVD), all-cause hospitalization, and emergency department care.

**Results:** We identified 8,693 PEG users (number of composite events, 29) and 17,386 matched controls (21). The hazard ratio (HR) of the composite event for PEG versus EPO was 2.8 (95% confidence interval, 1.6-4.8); among hemodialysis (HD) patients without same-day IV iron exposure, the HR was 3.6 (1.9-6.9). For all-cause hospitalization, the HR was 1.4 (1.1-1.9); among HD patients without same-day IV iron exposure, the HR was 1.5 (1.1-2.1). For emergency department care, the HR was 1.1 (0.9-1.4); among HD patients without same-day IV iron exposure, the HR was 1.3 (1.0-1.7).

**Conclusions:** Relative to treatment with epoetin alfa, initial exposure to peginesatide was associated with increased risk of death or hospitalization due to cardiovascular disease; increased risk persisted in patients without concurrent intravenous iron use. These data illustrate the potential utility of Medicare QSAFs for timely pharmacosurveillance.

*Funding:* NIDDK Support

## TH-PO497

**A Randomized Controlled Trial of Costs Associated with Anemia Therapy in Hemodialysis Patients Treated with Intravenous Darbepoetin alfa versus Intravenous Epoetin alfa** Andrea L. Woodland,[1] Sean W. Murphy,[2] Brendan J. Barrett,[2] Bryan M. Curtis.[2] *[1]Pharmacy Dept, Eastern Health, St.John's, Canada; [2]Dept of Medicine, Memorial Univ, St.John's, Canada.*

**Background:** Anemia of Chronic Kidney Disease is associated with adverse outcomes and a reduced quality of life. Erythropoiesis stimulating agents (ESAs) have improved anemia management and two agents are available in Canada, epoetin alfa(EPO) and darbepoetin alfa(DA). EPO and DA are considered to be equally effective in achieving target hemoglobin in dialysis patients but it is not clear if there is a cost difference. There have been few head-to-head comparisons of the two; most published data is from observational switch studies.

**Methods:** An open label randomized controlled trial of intravenous (IV) DA versus EPO was conducted in 50 hemodialysis patients. A dose stabilization run-in phase was followed by a 12 month active phase. ESAs and iron were dosed using an algorithm to maintain hemoglobin(Hb) within 100-120g/L. The primary outcome was ESA cost (Canadian $) per patient over 12 months. Secondary outcomes included deviation from target ranges in anemia indices, iron dose and cost, time and number of dose changes required for dose stabilization, number of dose changes in the active phase and the dose conversion ratio.

**Results:** The median cost over 12 months was $4179(IQR $2416-5955) for EPO and $2303(IQR $1178-4219) for DA with a difference of $1876 (p=0.017). The median weekly iron dose was 40.4mg for EPO and 41.7mg for DA (p=0.992). There were no significant differences in Hb: 108.0g/L EPO and 109.8g/L DA (p=0.336); serum ferritin: 848µg/L EPO and 726µg/L DA (p=0.202); TSAT: 26.7% EPO and 28.6% DA (p=0.472).The number of dose changes and the time to hemoglobin stability were similar for both groups. The dose conversion ratio was 280:1 (95% CI 197-362:1) at the end of the run-in phase, 360:1 (95% CI 262-457:1) at the 3 month point of the active phase and 382:1 (95% CI 235-529:1) at the 6 month point of the active phase.

**Conclusions:** In this study of hemodialysis patients with comparable anemia management IV darbepoetin cost $1876 less per year per patient than IV epoetin.

## TH-PO498

**Optimal Hemoglobin Target Might Be Different between Elderly Hemodialysis Patients and Non-Elderly Patients** Norio Hanafusa,[1,4] Takanobu Nomura,[2] Takeshi Hasegawa,[3,4] Masaomi Nangaku.[1,4] *[1]Dept of Nephrology and Endocrinology, The Univ of Tokyo Hospital, Bunkyo-ku, Tokyo, Japan; [2]Kyowa Hakko Kirin, Co. Ltd., Chiyoda-ku, Tokyo, Japan; [3]Div of Nephrology, Showa Univ School of Medicine, Yokohama, Kanagawa, Japan; [4]Japanese Dialysis Outcomes and Practice Patterns Study for Anemia Working Group, Tokyo, Japan.*

**Background:** Elderly population is growing in their numbers among hemodialysis population. However, there is no evidence about the relationship between hemoglobin (Hb) level and survival by age. We investigated the effect of age on the relationship between Hb and survival in Japan DOPPS (JDOPPS) cohort.

**Methods:** We included the entire JDOPPS phase 3 and 4 population into the study. The population was divided at the age of 70 years old to make the elderly and the non-elderly population. We used Cox's proportional hazard model to investigate survival with Hb values incorporated as time dependent variable. Interaction between Hb and age was investigated. Inverse propensity treatment weight (IPTW) method was used to adjust propensity for erythropoietin use.

**Results:** The study population included 3,359 patients with 568 deaths during median follow up of 2.66 years. Interaction between age groups and Hb values was significant ($p<0.001$). Non-elderly population experienced poorer survival for Hb <9g/dl compared to elderly population (HR 4.90: 95%CI 3.46 – 6.95 vs HR 1.79: 95% CI 1.30 – 2.48, $p<0.001$ for interaction; with Hb 9 – 10g/dl made as reference group). Hb values between 9 and 10 g/dl among non-elderly population and Hb ≥ 12 g/dl among elderly population were both related to poorer survival after IPTW adjustment (HR 1.37: 95% CI 1.06 – 1.77; HR 1.40: 95%CI 1.04 – 1.88, respectively), although the interaction did not reach its significance ($p=0.089$, 0.364).

**Conclusions:** Older population might be tolerant for lower Hb values, while higher Hb levels might relate to poorer prognosis among the population. Therefore, optimal Hb ranges might be different for the elderly population compared to the non-elderly population. These results render evidences to the detailed consideration about anemia management by patients' characteristics and about its individualization.

## TH-PO499

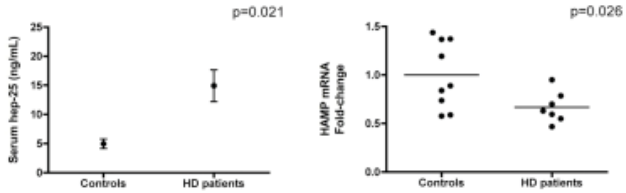
**Is Hepcidin-25 Production Increased in Patients with Chronic Kidney Disease?** Adam Rumjon, Iain C. Macdougall. *Dept of Renal Medicine, King's College Hospital, London, United Kingdom.*

**Background:** Hepcidin-25 (hep-25) plays a critical role in iron metabolism, and the levels of this peptide are greatly increased in end-stage renal disease. It remains unclear whether this is due to reduced clearance, or increased production. The aim of this study was to explore hep-25 production *ex vivo* in haemodialysis patients.

**Methods:** Inclusion criteria for this study were; HD for >3 months, Hb >10 g/dL, CRP <20 mg/L, HD via an AVF/PTFE graft, stable IV iron/EPO dose for >1 month, and no hospitalisations for >1 month. A pre-dialysis blood sample (10ml) was separated by Ficoll Hypaque centrifugation. Serum hep-25 levels were measured using liquid chromatography mass spectrometry. Peripheral blood mononuclear cells (PBMCs) were processed immediately (5-6 x$10^6$ cells/mL); qRT-PCR was performed using the Applied Biosystems 7900HT Fast Real-Time system. Amplification reactions were performed (triplicate) using Taqman HAMP and GAPDH primers.

| Parameter | Mean (SD) |
|---|---|
| Age, years | 55.5 (19.5) |
| Haemoglobin, g/dL | 11.3 (0.8) |
| CRP, mg/L | 10.4 (5.0) |
| Albumin, g/L | 39.7 (1.8) |
| Ferritin, ng/mL | 367 (90) |

**Results:** To date, 7 patients (5 males, 2 females) have been studied. Median IV iron dose was 100mg/week, and median EPO dose was 46.2 [IQR 18.9-114.6] iu/kg/wk. Serum hep-25 levels were significantly elevated in the HD population (14.9±2.7 vs 4.9±0.8, $p=0.021$). Interestingly, HAMP mRNA levels were significantly lower than in healthy controls (mean fold-change 0.667±0.06 in HD compared to controls ($p=0.026$)).



**Conclusions:** Despite higher circulating levels of hep-25, significantly lower transcription of HAMP mRNA was unexpectedly observed in HD patients. This counter-intuitive result, which has not been described previously, requires confirmation in a larger cohort of patients. Elucidation of this effect is also required; it is possible that negative feedback mechanisms may be in operation in HD patients to reduce hep-25 levels.

## TH-PO500

**ESA Hyporesponsiveness Is Associated with Adverse Event in Maintenance Hemodialysis (MHD) Patients, but Not Iron Storage** Takahiro Kuragano, Takeshi Nakanishi. *Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

**Background:** Recently several studies revealed the strong association between hyporesponsiveness to erythropoiesis-stimulating agent (ESA) and adverse events in the MHD patients. An iron deficiency has been cited as the most common cause of hyporesponsiveness in MHD. In this study, we evaluated relationship among iron storage, responsiveness to ESA, and adverse events on the MHD patients.

**Methods:** In 1086 MHD patients, we measured serum ferritin, Hb, and transferrin saturation (TSAT) levels every 3 month during 2 years. The weekly dose of ESA /Hb (ESA/Hb) value was also calculated as an index of ESA responsiveness index. The associations between ESA/Hb and several adverse events were investigated with the cox proportional hazards model for time-dependent variables.

**Results:** At the beginning of this study, patients were stratified into 4 groups according to serum ferritin levels (< 50, 50 ≤ ferritin < 100, 100 ≤ ferritin < 300, ≥ 300 ng/mL). There was no significant difference in ESA/Hb and Hb levels among 4 groups. On the other hand, a significant correlation ($p<0.001$, $R=0.89$) between ferritin and Hb was found only in the patients with ferritin levels under 50 ng/mL. In the multiple regression analysis, female ($p<0.001$, $\beta=0.34$) and prealbumin ($p<0.015$, $\beta=-0.21$) were selected as the significant predictors of ESA/Hb. Compared to the patients with lower ESA/Hb (≤ 280), patients with higher ESA/Hb level (> 280) were associated with the significant higher risk of cerebro-cardio-vascular disease (CCVD) (HR:1.91, $p=0.03$), infection disease (HR:1.22, $p=0.046$), and hospitalization (HR:1.39, $p=0.021$).

**Conclusions:** In patients with ferritin < 50 ng/mL, Hb was dependent on ferritin, but not in those with ferritin ≥ 50 ng/mL. Although the patients with the hypo-responsiveness to ESA had higher risk for CCVD and hospitalization, ESA/Hb were not related to the iron storage. From these results, we concluded that excessive iron storage dose not necessarily lead to the improvement of the responsiveness to ESA in MHD patients.

## TH-PO501

**Continuous Erythropoietin Receptor Activator Improves Chronic Kidney Disease-Associated Anemia via Correction of Iron Availability and Suppression of Plasma Hepcidin-25 Levels in a Rat Model of Chronic Kidney Disease** Michinori Hirata, Yoshihito Tashiro, Kenji Yogo, Koichi Endo. *Chugai Pharmaceutical Co., Ltd.*

**Background:** Resistance to erythropoiesis-stimulating agents (ESAs) is often observed in patients with chronic kidney disease (CKD). A major cause of ESA resistance is the reduction of iron availability due to increased synthesis of hepcidin following stimulation by pro-inflammatory cytokines. Continuous Erythropoiesis Receptor Activator (C.E.R.A.) is widely used to treat anemia in CKD and dialysis patients, but mechanisms of iron metabolism on treatment with C.E.R.A. in CKD-associated anemia have not been fully elucidated. In this study we investigated iron metabolism under conditions of anemia corrected by C.E.R.A. in a rat model of CKD.

**Methods:** C.E.R.A. (0.6 µg/kg, every 2 weeks) was subcutaneously administered from 1 week after 5/6-nephrectomy (Nx). After the start of treatment, we evaluated changes over time in hemoglobin (Hb) level, reticulocyte (Ret) number, plasma iron, and hepcidin-25 (Hep-25) concentration. At Week 9 we measured plasma creatinine, urea nitrogen, ferritin, and interleukin-6 (IL-6).

**Results:** Compared with Hb levels in normal rats, levels in Nx rats gradually and significantly decreased as kidney disease progressed. In contrast, C.E.R.A. significantly inhibited the decreased Hb levels (Hb: Nx, 12.5±0.5 g/dL; C.E.R.A., 14.7±0.6 [p<0.05]; Normal, 15.6±0.3; n=7–9), and increased Ret numbers to around normal range. Whereas iron availability was lowered in Nx rats regarding the significant elevation of plasma Hep-25 and ferritin levels as CKD progressed, C.E.R.A. treatment improved these parameters to within normal range (Hep-25: Nx, 17.1±1.9 ng/mL; C.E.R.A., 9.8±1.6 [p<0.05]; Normal, 9.0±1.5; Ferritin: Nx, 609.8±118.8 ng/mL; C.E.R.A., 322.3±140.1 [p<0.05]; Normal, 298.7±74.3) with improving CKD-associated anemia. There was no significant change in plasma IL-6 levels among these groups.

**Conclusions:** C.E.R.A. protected against gradually decreasing Hb levels in anemia model rats possibly by correcting iron availability in addition to erythropoiesis as reported.

## TH-PO502

**Anemia Management Trends in Hospital-Based Dialysis Centers: 2010-2013** George N. Coritsidis,[1] Anjali Acharya,[1] Chun-Lan Chang,[2] Jerrold W. Hill,[2] Gregory A. Maglinte,[3] Anjali B. Saxena,[4] Mark Stephens,[5] Richard A. Lafayette.[4] *[1]NYC Hospital Corp; [2]IMS Health; [3]Amgen; [4]Stanford; [5]PHA.*

**Background:** In response to changes in the prescribing information of erythropoiesis stimulating agents (ESAs) and dialysis reimbursement, anemia management practices in dialysis have changed in the past three years. Hospital-based dialysis centers (HBDCs) differ from free-standing dialysis centers and may warrant special analysis. This study describes trends and regional variation in anemia management practices in HBDCs from January 2010 to March 2013.

**Methods:** Electronic medical records of 5404 hemodialysis patients in 50 US-based HBDCs were analyzed retrospectively. Patients were at least 18 years old and had at least one hemoglobin (Hb) measurement and one ESA dose between January 2010 and March 2013. Descriptive statistics were collected monthly for Hb and iron biomarkers (serum ferritin and transferrin saturation), and every 4 weeks for darbepoetin alfa, epoetin alfa and IV iron doses.

**Results:** Mean(standard deviation) monthly Hb declined from 11.4(1.2) to 10.7(1.2) g/dL, the percent of patients with mean monthly Hb <10 g/dL rose from 11.3% to 24.4%, and the percent of patients with mean monthly Hb >12 g/dL declined from 30.1% to 11.2%. Most patients received darbepoetin alfa. The darbepoetin alfa median (interquartile range) cumulative 4-week dose declined 41% from 170(100,340) to 100(50,200) mcg, and the median cumulative 4-week IV iron dose increased 50% from 250 to 375 mg. Regional differences were observed in ESA and iron dosing levels, while average Hb differed only slightly by region. Mean darbepoetin alfa doses were 5% lower while IV iron doses were 51% higher in HBDCs in the South and West than in the Northeast/Midwest.

**Conclusions:** Consistent with reported national trends, HBDCs have modified anemia management practices since 2010, with continuing declines in ESA doses, higher doses of IV iron and falling Hb. The relatively small variation in regional ESA utilization, but relatively large variation in IV iron doses, did not have an observable impact on the Hb level achieved, which may be due to demographic differences or other factors not observed in this study.

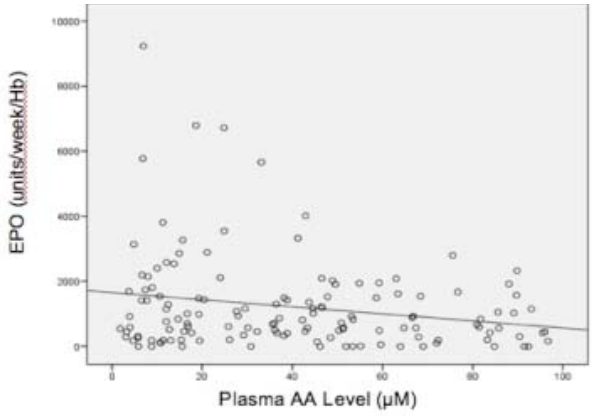
## TH-PO503

**Correlation of Plasma Ascorbic Acid Level with Erythropoietin Resistance** William D. Sirover,[1] Yuguan Liu,[2] Swomya Bal,[1] Krystal Hunter,[1] Amanda Logan,[1] Lawrence S. Weisberg,[1] Garry J. Handelman.[2] *[1]Cooper Medical School of Rowan Univ; [2]Univ of Massachusetts.*

**Background:** In end stage renal disease (ESRD), one cause of erythropoietin (EPO) resistance is functional iron deficiency. Iron stores are normal, but erythropoiesis is less effective due to decreased iron delivery to the bone marrow. Ascorbic acid (AA) may improve iron availability. The relation of plasma AA level with EPO resistance in a contemporary, prevalent hemodialysis (HD) population is not known. We hypothesize that plasma AA level correlates inversely with EPO resistance.

**Methods:** Prevalent HD patients in 2011 were recruited for enrollment. Inclusion criteria were age >18 years and vintage >3 months. Plasma samples collected in the outpatient setting were preserved with metaphosphoric acid and placed on dry ice or stored at -80 $^0$F until assayed for AA by HPLC. Hematologic data on a subset of 179 HD patients with ferritin >100 ng/ml was analyzed. Individual EPO dose was calculated as mean weekly dose over a 3-month period. Pearson correlation was used to assess the relationship between plasma AA level and EPO resistance (units/week/Hb), transferrin saturation (TSAT,%) and ferritin.

**Results:** Over the entire plasma AA range (1.78-409.3 µM), AA did not correlate with EPO resistance. However, in 148 patients with plasma AA levels in the physiologic range (0-100 µM), plasma AA inversely correlated with EPO resistance (r= -0.211,p= 0.01), directly correlated with TSAT (r= 0.162,p= 0.05), and did not correlate with ferritin.



**Conclusions:** AA at physiologic plasma levels is associated with less EPO resistance and increased TSAT. In patients with low plasma AA levels, supplemental AA may treat functional iron deficiency and EPO resistance by increasing iron availability. These results support proceeding with a randomized controlled trial.

## TH-PO504

**Implementation of Anemia Protocol and Changes in Quality of Life for Chronic Hemodialysis Patients** Eduardo K. Lacson, Nien-Chen Li, Cindy Allegretti, Norma J. Ofsthun, Franklin W. Maddux, Jeffrey L. Hymes. *Fresenius Medical Care, North America, Waltham, MA.*

**Background:** A national Medical Advisory Board endorsed anemia management protocol for hemodialysis (HD) patients, consistent with the FDA black box warning on erythropoietin (ESA) use, was incrementally adopted at FMCNA beginning April 2011. We evaluated the impact on Kidney Disease Quality of Life-36 (KDQOL) scores from the first 815 participating facilities.

**Methods:** All 11,307 chronic HD patients with paired KDQOL scores (PCS, MCS, Symptom Problems, Burden, and Effects domains) up to 12 months before and within 3-15 months after protocol implementation were evaluated. The last available hemoglobin (Hgb) and ESA dose/treatment prior to the KDQOL surveys were recorded. Subgroups with large changes in hemoglobin (drop of >1 g/dL) and ESA dose/treatment (drop of >5,000 units) were also evaluated.

**Results:** The cohort: mean age 61.4 ±14.2 years; 54.6% male; 54.4% white (42.2% black); and 53.3% diabetics. The median time from KDQOL to initiating the anemia protocol was 3.3 months (range <1 to 11.9), and from then to the 2nd KDQOL was 9 months (range 3.0 to 14.9, last survey: 4/26/13). Mean scores for PCS (37.7 to 37.6) and Symptoms (79.4 to 79.6) were unchanged while MCS (51.0 to 51.2), Burden (53.1 to 54.6), and Effects (73.9 to 74.9) increased (p<0.05). Mean/median Hgb pre-baseline KDQOL were both 11.5 g/dL and pre-2$^{nd}$ KDQOL was both 11.2 g/dL (p<0.001). Patients with >1 g/dL drop in Hgb (N=2497, 28.8%, ff-up mean Hgb 10.3) had a drop in PCS (-0.7), Symptoms (-0.7), and increase in Burden (+1.3); a >5,000 units decline in ESA dose (N=1934, 22.1%) increased PCS (+0.45), Burden (+1.7), and Effects (+1.9) with all p<0.05. The clinical relevance of these statistically significant score changes is unknown.

**Conclusions:** Implementation of an anemia protocol that was consistent with FDA guidelines significantly decreased our HD patients' mean Hgb and ESA dose over 3-15months. Overall, there was no decline in KDQOL scores in the same patients treated using the protocol over time.

## TH-PO505

**Predicting Hemoglobin Response to Erythropoietin, Effect of Dose and Hemoglobin Concentration** Michael E. Brier, Jenny Feng, Adam E. Gaweda. *Univ of Louisville.*

**Background:** Several factors moderate the response to exogenous erythropoietin (EPO) in hemodialysis dependent end-stage renal failure patients. The determination of starting doses and dosage adjustment schedules were based on data obtained when subjects exhibited a different dose response curve than they do currently. We performed a linear mixed model regression analysis of hemoglobin (Hb) response in individual patients for the years 2004 to 2012 to test the hypothesis that Hb response is a function of the change in 4 months of prior EPO, current Hb, and current EPO dose.

**Methods:** The data consisted of 5580 EPO and Hb combinations from 153 patients. We calculated the mean weekly EPO dose per month, the change in EPO dose from the prior month, change in Hb from the prior month, and the target Hb for the year in which the data were collected. Hb target ranged from about 12.5 in 2004 to 10.5 in 2012 and was estimated as the mean achieved Hb for all Hb measurements for the year. We divided EPO dose in to 5 groups < 3000, 3001-6000, 6001-9000, 9001-15,000, and > 15,000. The independent variable was the change in Hb and we investigated the following factors: Dose, difference in current Hb from target, past 3 months change in Hb, past 4 months change in EPO, and current Hb.

**Results:** The results of the statistical analysis are shown in the following table which represent the change in Hb concentration in response to a increase in dose of 1,000 units.

| | | | | | Dose Group | | |
|---|---|---|---|---|---|---|---|
| | Hb | Dose (1/1000) | 0-3,000 | 3,001 to 6,000 | 6,001 to 9,000 | 9,001 to 15,000 | > 15,000 |
| Parameter Estimate | -0.013 | 0.017 | 0.24 | 0.23 | 0.17 | 0.13 | 0.07 |

The current change in Hb is influenced by up to 4 months of past EPO doses, the prior change in Hb over the last 3 months, current Hb, Dose, and difference between the current Hb and the target Hb.

**Conclusions:** In the range of observed Hb concentrations (10.5 to 12.5 g/dL), the response to a change in EPO dose demonstrates a negative relationship as Hb increases, the response decreases. Also, as dose increases response is decreased by as much 70%. One must take into account up to 4 months prior EPO and Hb in order to predict the response to a EPO dose change.

## TH-PO506

### Therapeutic Effects of Renal Anemia Treated with Two Different Erythropoiesis Stimulating Agents: Darbepoetin Alpha and Continuous Erythropoietin Receptor Activator in Predialysis Patients with Chronic Renal Failure

Takashi Yokoyama. *Nephrology and Dialysis, Sapporo Higashi-Tokushukai Hospital, Sapporo, Hokkaido, Japan.*

**Background:** A study was conducted to clarify the therapeutic effects of Darbepoetin Alpha (DA) and Continuous Erythropoietin Receptor Activator (C.E.R.A.) in predialysis patients with renal anemia.

**Methods:** 36 predialysis patients were observed for six months. They were divided into two groups according to Erythropoiesis Stimulating Agents (ESAs) : Group A (n=19, age=76.47±10.46 years old) was treated with DA and Group B (17, 68.41±12.62) with C.E.R.A. Percutaneous administration of DA (10~180 μg) or C.E.R.A. (75~250 μg) at 21~35 day intervals was performed in order to maintain the target hemoglobin (Hb) level between 10.0 and 13.0 g/dL. The weekly average values of Hb, FRN, high sensitive C-reactive protein (hsCRP), albumin (Alb) and estimated GFR (eGFR) were measured at the same intervals and the serial changes of these clinical markers in both groups were observed.

**Results:** 1) At the baseline, no marked differences were observed between the two groups according to Hb (A : 9.28±1.17 g/dL vs B : 9.37±0.50), eGFR (17.16±7.66 mL/min/1.73$^2$ vs 15.50±10.30), Alb (3.79±0.52 g/dL vs 3.64±0.61) and hs CRP (0.16±0.37 mg/dL vs 0.13±0.17). 2) Hb levels from the second day measured to the sixth day measured in the two groups were as follows : second day (A : 9.97±1.05 g/dL vs B : 9.64±0.53), third (10.36±1.20 vs 10.27±0.86), fourth (10.16±1.36 vs 10.79±1.28), fifth (10.15±1.34 vs 10.44±1.34) and sixth (10.39±1.13 vs 10.13±0.85). No marked differences were found between the two groups during the six months. Administration volumes of ESAs for the two groups were as follows: baseline (A : 68.3±33.3 μg vs B : 141.2±19.6), third month (82.0±50.1 vs 152.9±27.8), six month (104.0±35.8 vs 171.4±56.7). The average rate between DA and C.E.R.A. over the six months was 1:1.74. 3) No marked differences were detected in FRN, hsCRP, Alb and eGFR during this period.

**Conclusions:** The evidences of smaller amounts of administration volume at 21~35 day intervals and equal therapeutic effects of renal anemia demonstrate DA's superiority to C.E.R.A. in predialysis treatment of anemia.

## TH-PO507

### Hemoglobin Variability of Japanese Hemodialysis Patients with Long Acting Erythropoiesis Stimulating Agent Treatment

Kiyohito Kawashima,[1] Hirotake Kasuga,[1] Chieko Matsubara,[1] Keiko Kimura,[1] Ryo Takahashi,[1] Yasuhiko Ito.[2] *[1]Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; [2]Nephrology, Nagoya Graduated School of Medicine, Nagoya, Japan.*

**Background:** Anemia is one of the most important complications in HD patients. Erythropoiesis stimulating agents (ESA) are standard therapy for renal anemia, and these therapies improved not only Hb levels of HD patients, but also their prognosis. In addition, some investigators presented that Hb variability also affects their prognosis. Recently, long acting ESA, epoetin beta pegol (C.E.R.A.), have been used for renal anemia treatment in Japan. In this study, we investigated the Hb variability and its influence for HD patients' prognosis.

**Methods:** 591 HD patients were enrolled. ESA therapy switched from epoetin beta (EPO) to C.E.R.A., and they were followed up for 6 months. According to Hb levels during this period, patients were classified into 6 category groups reported by Ebben; constant target (T, Hb levels of every month within Hb target, from10g/dL to 12g/dL), constant high (H, Hb levels constantly over target), constant low (L, Hb levels constantly under target), high amplitude (HA, Hb levels over, under and within target), low amplitude high (LAH, Hb levels over and within target), and low amplitude low (LAL, Hb levels under and within target). We checked patients' hospitalizations and deaths for next 6months, and examined the influence of every category for these events. We compared these data with our previous data under EPO treatment.

**Results:** Mean Hb level before usage of C.E.R.A. was 10.9±0.8g/dL. Hb levels of every month showed from 10.6±0.9g/dL to 11.0±0.9g/dL during 6 months. Rates of every Hb category under C.E.R.A treatment were 17% (T), 0% (H), 1% (L), 17% (HA), 20% (LAH) and 45% (LAL), and those under epoetin beta treatment were 14.9% (T), 1.1% (H), 5.6% (L), 16.5% (HA), 14.1%(LAH) and 47.9% (LAL). Hospitalization rate were 4.4% (T), 22.2% (L), 14.9% (HA), 11.4% (LAH) and 9.0% (LAL). Hb variability and its effects for prognosis were similar with C.E.R.A. and EPO.

**Conclusions:** C.E.R.A. was useful for renal anemia treatment of Japanese HD patients. Hb variability of C.E.R.A. and its effect for prognosis was similar with that of EPO.

## TH-PO508

### Soluble Ferric Pyrophosphate (SFP) Administered via Dialysate Shows No Acute Safety Signals

Carrie D. Guss, Tasha M. Farmer, Ajay Gupta, Vivian H. Lin, Raymond D. Pratt. *Rockwell Medical Inc.*

**Background:** SFP is the first parenteral iron product that is non-colloidal and free of carbohydrate or polyethylene glycol shell. Ferric iron compounds have been associated with multiple acute toxicities, including anaphylactoid reactions, hypotension and shock. This study examined the acute safety profile of SFP administered to a large cohort of CKD-HD patients compared to placebo.

**Methods:** This safety study was a randomized, double blind, placebo controlled crossover study in CKD-HD patients. Subjects were iron replete and on stable ESA doses. Subjects received either SFP or placebo for 2 weeks followed by a one week washout then a second 2 week period with the alternate treatment. The final SFP concentration in dialysate was 110 μg/L (2 μM). Premixed liquid bicarbonate concentrates with SFP or placebo maintained the blind. Safety assessments included adverse events, assessments of intra-dialytic hypotension (IDH), cardiac events and acute hypersensitivity-like reactions.

**Results:** 718 patients were randomized. 92.8% of subjects completed the blinded treatment. There was an intradialytic increase in serum iron (186%) with a concomitant decrease in unbound iron binding capacity (57%). The most common reasons for discontinuation were adverse events (7 SFP/6 placebo), and withdrawal of consent (9 SFP/8 placebo). There were 2 deaths during the placebo phase and none during the SFP phase. Procedural hypotension was the most common AE reported in 4.6% SFP and 4.7% placebo. There were no differences between treatment groups in intradialytic hypotension, composite CV events, thromboses or infections. No hypersensitivity events were attributed to SFP. There were no differences in other clinical laboratory parameters including serum phosphate and liver function tests between SFP and placebo.

**Conclusions:** The safety profile of SFP delivered via dialysate during dialysis in this large cohort was similar to placebo. No acute first use events, anaphylactoid reactions or hypotensive episodes were associated with SFP. Acute administration of SFP via the hemodialysate in CKD-HD patients is well tolerated and is expected to replace the iron lost during HD treatments.

## TH-PO509

### High-Density Lipoprotein Cholesterol and Matrix Gla Protein Are Implicated in the Progression of Aortic Calcification through Bone Morphogenetic Protein 4- or Activin-Like Kinase 1-Induced Smad1 Activation in Patients Undergoing Maintenance Hemodialysis

Kazuhiro Yoshikawa,[1] Hideharu Abe,[1] Motokazu Matsuura,[1] Kojiro Nagai,[1] Akira Mima,[1] Eriko Shibata,[1] Jun Minakuchi,[2] Toshio Doi.[1] *[1]The Dept of Nephrology, Institute of Health Biosciences, Univ of Tokushima Graduate School, Tokushima, Japan; [2]The Dept of Kidney Disease, Dialysis and Kidney Transplantation, Kawashima Hospital, Tokushima, Japan.*

**Background:** Aortic calcification (AC) is a common finding in patients undergoing maintenance hemodialysis (MHD). High-density lipoprotein (HDL) cholesterol and matrix Gla protein (MGP) are known as inhibitors of AC. In addition, HDL cholesterol progressively enhances expression of MGP mediated by activin-like kinase (ALK) in vitro. However, the exact mechanisms for accelerated AC in MHD patients have not been fully determined. In this study, we explored the role of MGP and HDL cholesterol for the progression speed of AC in MHD patients and investigated the underlying molecular mechanisms of the function of MGP in the bone morphogenetic protein (BMP) 4- or ALK1-induced Smad1 singnals.

**Methods:** First, a retrospective cohort study of MHD patients whose AC could be followed in multi-detector computed tomography (MDCT) examinations was conducted. Serum HDL cholesterol and MGP levels were measured. The progression speed of AC was examined by plotting the abdominal aortic calcium volume scores. Using cultured perivascular cells, molecular mechanisms were investigated.

**Results:** The HDL cholesterol levels were affected by MGP genotype. The progression speed of AC of patients with the MGP -138CC genotype was significantly slower than that of patients with other genotypes. Multiple regression analysis and cell-based analyses revealed that the HDL cholesterol levels and MGP were associated with progression of AC and that MGP was involved in the intracellular negative regulation of activation of Smad1 by BMP4 or ALK1 signaling pathways.

**Conclusions:** Serum HDL cholesterol levels and MGP genotype may be associated with slower progression of AC in MHD patients. In this setting, HDL cholesterol and MGP might be implicated in the molecular regulation of Smad1 in vascular cells.

## TH-PO510

**Effect of Reduced CoQ10 on Anti-Oxidative Status in Hemodialysis Patients** Shigeru Owada,[1] Teruhiko Maeba,[1] Aki Hirayama,[2] Atsushi Ueda,[3] Sohji Nagase.[4] *[1]Dialysis Center, Asao Clinc, Kawasaki, Kanagawa, Japan; [2]Center for Integrative Medicine, Tsukuba Univ of Technology, Tsukuba, Ibaraki, Japan; [3]Nephrology, Tsukuba Univ Hospital Hitachi Medical Education and Research Center, Hitachi, Ibaraki, Japan; [4]Internal Medicine, Nagase Clinic, Moriya, Ibaraki, Japan.*

**Background:** Reduced CoQ10 (CoQH) has a principal role of mitochondrial function and also has an antioxidative properties. Serum CoQH level is lower in dialysis patients. Then we investigated the effects of CoQH supplementation on antioxidative capacities in hemodialysis patients (HD).

**Methods:** 200mg of CoQH /day was administered by orally to 30 HD patients (67±8 years ) for 3 months after written consent obtained. 1. Serum CoQH concentration, 2. soluble lectin-like oxidized low-density lipoprotein receptor-1 (s-LOX-1) and LOX-1 ligand containing Apo B (LAB) were measured and calculate LOX-index (s-LOX-1 x LAB) as a predictive marker for CVD (Clinical Chemistry, 2010. 56:550). 3. Ratio of triglyceride content and negative charge value of LDL (LDL-CMF), 4. hydroxyl radical scavenging activity (OHSA) were measured.

**Results:** Each parameter of 3 months after taking CoQH were as follows: 1. Total and reduced CoQ10 (μg/ml) levels were significantly increased (CoQ10; 0.61±0.19 → 3.36±1.70, CoQH; 0.57±0.18 → 3.20±1.43). 2. LOX-index was significantly decreased (3225±2010 → 2190±1488). 3. Tg ratio in LDL was not different (0.33±0.07 → 0.31±0.07), but LDL-CMF was significantly decreased (2.8±5.8 →-1.0±4.7). 4. Serum OHSA (mM GSH equivalent ) was significantly increased (7.5±1.5 → 8.4±1.7).

5. There were positive correlations were found between LOX-index and LDL Tg ratio (r=0.585), between LOX-index and LDL-CMF (r=0.371), between LDL-CMF and LDL Tg ratio (r=0.419).

**Conclusions:** We investigated the relationship between LOX-index and lipoprotein profile and effects of CoQH on the anti-oxidative activities in HD patients. Before supplementation of CoQH, serum total CoQ10 and CoQH levels were significantly lower compared to normal subjects and these were increased after supplementation. LOX-index and LDL-CMF were decreased and OHSA was increased. These results suggest that oxidative stress in HD patients was improved by CoQH supplementation.

## TH-PO511

**Low Selenium Levels in Diabetic Hemodialysis Patients Correlate with Increased Marker for Oxidative Stress** Anna J. Bryland,[1,2] Ola Carlsson.[1,2] *[1]Therapeutic Fluid Research, Gambro Lundia AB, Lund, Sweden; [2]Dept of Nephrology, Lund Univ, Lund, Sweden.*

**Background:** Hemodialysis (HD) patients are at elevated risk for oxidative stress and inflammation. For diabetic HD patients the risks are further elevated due to the effects of the disease. Deficiencies of selenium could lead to impaired inflammatory defence and oxidative stress. The objectives of this study were to investigate markers for advanced glycation end-products (AGEs), inflammation and oxidative stress in HD patients with or without diabetes compared to a healthy control group. We also wanted to investigate if the markers could be correlated to selenium concentrations.

**Methods:** Forty-seven HD patients (30 non-diabetic and 17 diabetic) were recruited to the study and plasma samples were taken pre- and post-dialysis of one dialysis treatment. Pentosidine levels were analyzed by HPLC; pentraxin-3 (PTX-3) and 8-hydroxydeoxyguanosine (8-OHdG) levels were analyzed by ELISA. Pre- and post-dialysis plasma samples were analyzed for selenium and compared to plasma samples from 51 healthy control subjects by ICP-MS.

**Results:** All HD patients had increased pre-dialysis plasma levels of pentosidine, PTX-3 and 8-OHdG compared to controls; the levels of pentosidine, PTX-3 and 8-OHdG were 10.2-, 2.6-, and 4.2-fold higher, respectively, in HD patients. The HD patients had 35% and 32% lower concentrations of selenium pre- and post- dialysis compared to controls. Selenium concentrations were lowest in the diabetic HD group. Furthermore, there was a correlation between decreased selenium and increased 8-OHdG in the diabetic HD group, figure 1a-b.

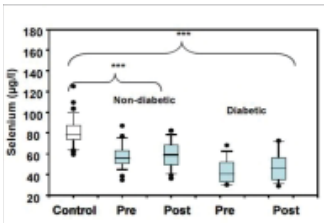

**Figure 1a** Plasma selenium concentrations in healthy controls and pre- and post-dialysis plasma samples from non-diabetic and diabetic HD-patients

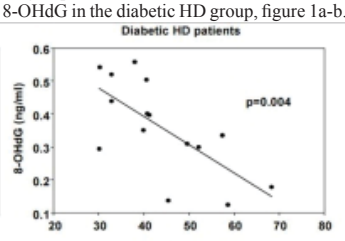

**Figure 1b** Significant correlation between decreased selenium concentrations and increased marker for oxidative stress in diabetic HD patients

**Conclusions:** The correlation between selenium deficiency and oxidative stress in diabetic HD patients supports further investigations on selenium and its effect on the inflammatory and oxidative stress status in HD patients.

## TH-PO512

**Mechanisms Linking Atherosclerosis and End-Stage Renal Disease: Alterations in Lymphocyte Activation Molecules in Dialysis Patients with Atherosclerosis** Miguel Hueso,[1] Mariona Mestre,[2] Estanis Navarro,[3] Juan Torras,[1] Inés Rama,[1] Alberto M. Martinez-Castelao,[1] Jose M. Grino.[1] *[1]Nephrology, Hospital Bellvitge, L'Hospitalet, Barcelona, Spain; [2]Immunology, Hospital Bellvitge, L'Hospitalet, Barcelona, Spain; [3]Laboratori d'Oncologia Molecular, IDIBELL, L'Hospitalet, Barcelona, Spain.*

**Background:** The mechanisms linking Chronic Kidney Disease (CKD) and atherosclerosis (ATS) are not well known. T lymphocytes display a key role in ATS and L-selectin is important in lymphocyte-endothelial cell interaction. Thus, the aim of this study is to investigate if patients on dialysis with atherosclerosis displayed alterations in the expression of L-selectin or of other lymphocyte activation molecules.

**Methods:** Study of cases (dialysis patient with ATS) and controls (dialysis patient without ATS) based in dialysis patients waiting for their first kidney transplantation. Atherosclerosis was diagnosed by angioTAC or arteriography. Whole blood samples were obtained before dialysis and were co-stained with the following mAbs: anti-CD62L$^{PE}$ (L-selectin), anti-CD44$^{PE}$, anti-CD25$^{PE}$, anti-HLA-DR$^{FITC}$ and anti-CD134$^{PE}$ (OX40) with lymphocytes markers CD3$^{FITC/PerCP}$, CD4$^{FITC}$ or CD8$^{PE/PerCP}$ prior to be studied by citometry.

**Results:** 64 dialysis patients (26 with ATS and 38 without ATS) were studied. Patients with ATS displayed a higher proportion of CD4$^+$ lymphocytes (801±360 cells/mm$^3$ in patients without ATS vs 1073±548 cells/mm$^3$ in ATS; p=0.032), CD8hi$^+$ (323±172 cells/mm$^3$ in patients without ATS vs 455±254 cells/mm$^3$ in ATS; p=0.026), CD3$^+$CD25$^+$ (393±196 cells/mm$^3$ in patients without ATS vs 603±336 cells/mm$^3$ in ATS; p=0.008), CD3$^+$CD25$^+$HLADR$^+$ (33±18 cell/mm$^3$ in patients without ATS vs 48±33 cell/mm$^3$ in ATS; p=0.035), CD3$^+$CD25$^{hi+}$(16±10 cel/mm$^3$ in patients without ATS vs 24±16 cel/mm$^3$ in ATS; p=0.030) and less Mean Fluorescence Intensity (MFI) of L-selectin expressed by lymphocytes T (118±73 in patients without ATS vs 84±39 in ATS; p=0.027).

**Conclusions:** Dialysis patients with ATS displayed a down-regulation of L-selectin and the enhanced expression of lymphocyte T activation markers (CD25$^+$ and HLADR$^+$), suggesting the presence of a chronic inflammatory background that is lacking in dialysis patients not suffering ATS.

## TH-PO513

**Malnutrition Inflammation and Survival in End Stage Renal Disease: Association with Variants of Appetite (Ghrelin, Leptin) and Energy Regulation (UCP2) Genes** Raj K. Sharma, Richa Sharma, Anita Saxena, Suraksha Agarwal. *Nephrology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, UP, India.*

**Background:** Malnutrition inflammation syndrome (MIS) is common among ESRD patients. In the present study we have evaluated role of genetic markers associated with appetite and energy regulation with Malnutrition inflammation syndrome in end stage renal disease (ESRD) patients.

**Methods:** 257 patients on maintenance hemodialysis (MHD) and 200 normal healthy controls were included in the study. Nutritional assessment was done by Subjective Global Assessment Scores (SGA). Genotyping of leptin-2548 G/A (rs7799039), ghrelin Leu72Met (rs696217-408 C/A), Arg51Gln (rs34911341-346 G/A), Uncoupling protein 2 (UCP2) 45 bp Insertion deletion (ID) was done using PCR-RFLP. Levels of leptin and acyl ghrelin were assessed using ELISA.

**Results:** Leptin-2548 AA genotype was associated with 2 fold higher risk of disease susceptibility while UCP2 insertion deletion heterozygote's showed protective effect. Ghrelin Gln51gln and met72met genotype were associated with 3.4 and 2.5 fold higher disease susceptibility. The met72 and gln51 allele showed 3.3 and 2.1 fold higher susceptibility to malnutrition in severe SGA group. Further the levels of acyl ghrelin were significantly less in severe category of malnutrition and in poor appetite group. On combined analysis the group-2 (presence of 3-4 risk alleles) showed 1.5 and 2 fold higher susceptibility to disease and malnutrition respectively. On docking analysis it was observed that higher receptor binding energy was associated with the mutant form of ghrelin (gln51). Moderate and severe SGA were associated with 2.2 and 4.1 fold higher death hazard.

**Conclusions:** Our study suggests that ghrelin may be major marker contributing to susceptibility to MIS among ESRD patients.

## TH-PO514

**Monocyte and Plasma Expression of TAM Ligand and Receptor in Renal Failure: Links to Unregulated Immunity and Chronic Inflammation?** Iris J. Lee, Brendan A. Hilliard, Jean Lee, Crystal A. Gadegbeku, Philip L. Cohen. *Dept of Nephrology and Rheumatology, Temple Univ School of Medicine, Philadelphia, PA.*

**Background:** The TAM ligand, Growth Arrest Specific Gene 6 Protein (Gas6) and tyrosine kinase family TAM receptors Axl and Mer are important regulators of proinflammatory monocyte cytokine production. Mer expression in particular is increased upon macrophage differentiation into immunoregulatory M2c macrophages. Upon monocyte activation, TAM receptors are cleaved from the cell surface. We examined plasma and monocyte expression of gas6, Axl and Mer in hemodialysis (HD) and chronic kidney disease (CKD) patients.

**Methods:** Blood samples were from controls, HD and CKD. Plasma and monocytes were studied ex vivo or after culture with normal and uremic serum in the presence of M-CSF and dexamethasone. Gas6, Axl and Mer were evaluated by real time PCR, ELISA and FACS.

**Results:** Monocytes from HD had decreased gene expression of Mer and Axl and increased expression of TNF-α and IL-1b. Mer expression was significantly decreased in circulating CD14++CD16+ monocytes from HD, a specific subset linked to adverse vascular events. Significantly increased levels of soluble receptor sAxl and sMer were found in CKD and HD plasma, consistent with ongoing monocyte/macrophage activation. Furthermore, Gas6 levels, known to be increased in systemic inflammation, were significantly elevated in CKD and HD and associated with increased sMer and sAxl levels. Addition of uremic sera to monocytes cultured with M-CSF and dexamethesone, suppressed the expression of Mer, CD163 and CD206, receptors associated with M2c polarization.

**Conclusions:** TAM receptors have known immunoregulatory function and decrease proinflammatory cytokine secretion. We show increased TAM ligand and circulating soluble TAM receptor in the plasma and decreased TAM receptor expression on monocytes from HD and CKD patients. These data support the hypothesis that there is a deficiency of TAM receptor mediated regulation of inflammation in patients with chronic renal failure.

## TH-PO515

**Modifications of Levels of 1, 25 $(OH)_2$ D Vitamin due to Administration of a Single, Large Oral Dose of 25-Hydroxycholecalciferol in Hemodialysis Patients**

Jose Luis Merino,[1] Jose Luis Teruel,[2] Milagros Fernandez-Lucas,[2] Blanca Bueno,[1] Juan Jose Villafruela,[2] Antonio Gomis,[2] Vicente Paraiso,[1] Carlos Quereda.[2] *[1]Nephrology, Hospital U del Henares, Coslada, Madrid, Spain; [2]Nephrology, Hospital U Ramon y Cajal, Madrid, Spain.*

**Background:** Low levels of Vitamin D have been associated with increased cardiovascular risk, and mortality. The deficiency is common in patients with chronic kidney disease and dialysis. We have evaluated the modifications of serum levels of D vitamin and mineral metabolism markers after the administration of a high and single, oral dose of 25-OHcholecalciferol (3 mg, Hidroferol®, 180,000 UI).

**Methods:** Chronic hemodialysis patients with 25(OH)VitD < 30ng/ml were included. Serum calcium> 10 mg/dl or PTH > 800 pg/ml were excluded. The patients were randomized in treated and controlled group. Time follow-up: 16 weeks. The usual treatment for controlling Ca/P levels neither the dialysis bath (calcium: 2.5 mEq/L) were modified. 86 patients ended the study, 42 patients in treated group.

**Results:** A higher levels of 1,25 and 25(OH)VitD were observed in the treated group and was maintained for 16 weeks. The levels of 1,25 and 25(OH)VitD were even bigger in the treated group than in the controlled one. This fact was associated with a significant decrease of PTH levels in the 8 post-treatment weeks. There were no difference due to technique (HDF-OL group, $1,25(OH)_2D$ level: 29,1+/-22 vs HD group, $1,25(OH)_2D$ level: 27,1 +/- 20) neither due to residual renal function (2 HD/week group: 30,3+/-25 vs 3 HD/ week group: 27,2+/-18). Serum calcium was >10 mg/dl in 16 of 252 (6%) performed samples in the treated group. Only two cases showed serum calcium > 10.5 mg/dl. There were no differences between both groups neither in phosphorous level nor in number of samples with serum phosphorous > 5.5 mg/dl.

**Conclusions:** A higher level of $1,25(OH)_2D$ has been observed due to an isolated dose of 3 mg of 25-OHcholecalciferol, this dose keeps enough levels of 25(OH)Vit D with a decreased level of PTH for three months. This data supports an extrarenal conversion of 25(OH)VitD. The correction of 1,25 and 25(OH)VitD levels and their potentially beneficial effects require long-term follow-up studies.

## TH-PO516

**The Impact of Transferrin Saturation on the Clinical Outcome in Incident Dialysis Patients**

Hyang Mo Koo,[1] Fa Mee Doh,[1] Hye-Young Kang,[2] Hyung Jung Oh,[1] Shin-Wook Kang.[1,2] *[1]Dept of Internal Medicine, Yonsei Univ College of Medicine; [2]Severance Biomedical Science Institute, Brain Korea 21, Yonsei Univ, Seoul, Korea.*

**Background:** Transferrin saturation (TSAT) is a marker reflecting the availability of iron for erythropoiesis and is closely associated with hemoglobin (Hb) levels. Although anemia is an independent risk factor for cardiovascular (CV) events and mortality in patients with end-stage renal disease (ESRD), the impact of TSAT on the clinical outcome has never been explored in dialysis patients.

**Methods:** A total of 879 anemic incident dialysis patients were recruited from 36 dialysis centers of the Clinical Research Center for ESRD in Korea and were divided into 3 groups according to baseline TSAT of ≤ 20%, 20-40%, and > 40%. Cox regression analysis was performed to determine the independent prognostic values of TSAT for a composite of CV mortality or hospitalization and all-cause mortality. The relationships between TSAT and echocardiographic findings and inflammatory/cardiac biomarkers were also evaluated using logistic regression analysis.

**Results:** There were no differences in Hb levels and the proportion of patients on erythropoiesis-stimulating agents or iron supplements between the 3 groups. During a mean follow-up duration of 19.3 mo, 51 (5.8%) patients died. CV composite (11.71 vs. 5.55 events/100 patient-years, P < 0.001) and all-cause mortality rates (5.38 vs. 2.31 events/100 patient-years, P = 0.004) were significantly higher in patients with TSAT ≤ 20% compared to those with TSTA 20-40% (reference group). Cox regression analysis revealed that patients with TSAT ≤ 20% had 1.62- and 2.19-fold higher risks for CV composite outcome (P = 0.046) and all-cause mortality (P = 0.030). Moreover, TSAT ≤ 20% was an independent predictor of left ventricular hypertrophy [odds ratio (OR), 1.46], high-sensitivity C-reactive protein ≥ 3 mg/dL (OR, 2.09), N-terminal pro B-type natriuretic peptide ≥ 10000 pg/mL (OR, 2.04), and troponin-T ≥ 0.1 ng/mL (OR, 2.02).

**Conclusions:** Low TSAT was a significant independent risk factor for adverse clinical outcomes in incident dialysis patients with anemia, which may be partly attributed to cardiac dysfunction and inflammation.

## TH-PO517

**Evil Communications between Scavenger Receptor Expression and Highly Elevated Macrophage Stimulating Factor in Hemodialysis Patients**

Miki Nishida,[1] Minoru Ando,[2] Yusuke Iwamoto,[3] Ken Tsuchiya,[1] Kosaku Nitta.[1] *[1]Dept Medicine, Kidney Center, Tokyo Women's Medical Univ; [2]Tokyo Metropolitan Komagome Hospital; [3]Saitou Memorial Hospital.*

**Background:** Macrophage-colony stimulating factor (M-CSF) may develop atherosclerosis by increasing macrophage viability/differentiation and the expression of the class A macrophage scavenger receptor (SR-A). SR-A plays a pivotal role promoting foam cell formation by binding and internalizing oxidized low-density lipoprotein (LDL).

**Methods:** Transcriptional levels of SR-A, M-CSF, and c-fms (M-CSF receptor) were simultaneously measured in peripheral monocytes by quantitative real-time RT-PCR, using the comparative threshold (Ct) method. Relative quantity of the gene was calculated as $2^{-\Delta\Delta Ct}$. Peripheral monocytes were isolated using magnetically-labeled Whole Blood $CD14^+$ MicroBeads (Miltenyi Biotec). Plasma level of M-CSF was measured with a M-CSF ELISA kit. Subjects included 39 chronic HD patients and 14 healthy controls.

**Results:** The SR-A gene expression was significantly higher in monocytes from the HD patients than in that from the controls (mean [95% CI of the mean]; 3.14 [2.58-3.69] versus 1.09 [0.80-1.39], P <.0001). Moreover, the gene expression was significantly higher in HD patients who had cardiovascular disease (CVD) than in those who did not (3.56 [2.89-4.22] versus 2.19 [1.29-3.10], P=0.0137). Plasma concentration of M-CSF was 6-fold higher in HD patients than in controls (995 ± 252 versus 157 ± 44.2 pg/ml, P <.0001). It was significantly correlated with the gene expression of SR-A ($r^2 = 0.244$, P = 0.0002), and inversely with that of c-fms ($r^2 = 0.134$, P = 0.0071); however, not with that of M-CSF.

**Conclusions:** Plasma M-CSF concentration is extremely increased in HD patients, which is not due to up-regulation of M-CSF gene, but likely due to excessive suppression of c-fms gene. SR-A expression is constitutively enhanced in the HD patients, and increased with increasing plasma M-CSF concentrations. This vicious collaboration could be one of the hidden mechanisms for atherosclerosis in HD patients.

## TH-PO518

**Relationship between Immune System and Morbidity and Mortality in Hemodialysis Patients**

Maria Molina, Enrique Morales, Luis Allende, Manuel Praga. *Nephrology, Hospital 12 de Octubre, Madrid, Spain.*

**Background:** Last stages of chronic kidney disease are associated with increased of morbidity and mortality, mainly for cardiovascular disease (CVD) and infections. Uremia is linked with a dysfunction of immune system and it could be associated with the most important causes of morbidity and mortality in hemodialysis (HD). The aim of this study was to analyse the relationship between morbidity and mortality with cuantitative changes of immunological system in HD patients.

**Methods:** We began a single centre prospective cohort study from April 2011 to April 2013 in HD patients. We analysed complement (C3 and C4), immunoglobulins (IgA, IgG, IgM) and lymphocytes (CD4 helper T lymphocyte and CD8 citolytic T lymphocyte; B lymphocytes; and natural killer (NK)) levels. We considered low range as lower than usually normal range used in our laboratory department. We followed patients just they died, received a kidney transplant or they were admitted to a hospital for CVD or infection disease.

**Results:** We included 103 patients (52% males) with mean age 64,4±15,1 years. Charlson comorbidity index medium (interquartile range: IQR) was 3 (1-4), 33% of patients had a previous kidney transplantation, 29% were diabetic and 22% had a positive hepatitis C virus antibodies. Meidum time with renal replacement therapy was 36 (9-84) months and 43% received online haediafiltration therapy. The rate of death was 23% with a medium follow of 8 (5-14) months. Low range of NK lymphocytes (OR:3,5; 1,1-10,8, p=0,02) and higher CRP (OR: 2,5; 1,1-6,2, p = 0,03) were associated with higher risk of death. The incidence of infection and CVD hospitalization were 24% and 14%, respectively. Both cases, B lymphopenia was linked with higher risk of develop a event, (OR: 3,8; 1,3-11,1; p=0,01) and (OR: 9,6; 1,2-73,5; p=0,02), respectively. Higher CRP was associated with more risk of infection hospitalization (OR:2,5; 1,1-5,8 p=0,03).

**Conclusions:** NK lymphopenia and higher CRP is associated with higher risk of death and B lymphopenia is linked with higher incidence of hospitalization (CVD and infection causes). These findings suggest quantitative immunological change could be new markers of morbidity and mortality in HD patients.

## TH-PO519

**The Impact of Inflammatory/Anti-Inflammatory Macrophages/Monocytes for the Immune Response to Influenza Vaccination in Hemodialysis Patients**

Haruka Yasuda, Yasunori Iwata, Kengo Furuichi, Takashi Wada. *Nephrology, Kanazawa Univ.*

**Background:** The infection of influenza is a high risk for the progression to pneumonia and can be a life-threatening in the hemodialysis patients. However, the effectiveness and mechanisms of the immune response to influenza vaccine are not clear in the hemodialysis patients. Moreover, resent data show that the balance of inflammatory/anti-inflammatory cells play an important role for the immune status in inflammatory diseases. Therefore, we hypothesize that the balance of inflammatory/anti-inflammatory cells are involved in the immune response to influenza vaccine in the hemodialysis patients.

**Methods:** Thirty five hemodialysis patients and 20 healthy controls were vaccinated. Influenza hemagglutination inhibition (HI) assay was performed before and 1 month after the influenza vaccination. At the same time, flow cytometory analysis of peripheral blood leukocyte was conducted to detect inflammatory (M1) macrophage/monocyte (Mf) ($CD14^+$ $CD16^+$), anti-inflammatory (M2) Mf ($CD14^+$ $CD206^+$), myeloid derived suppressor cell (MDSC) ($CD14^+$ $HLA\text{-}DR^-$) and regulatory T cell ($CD4^+$ $CD25^+$ $Foxp3^+$). Responder wad defined as ≥4 fold increase in HI titer.

**Results:** There was no difference in the number of responder after vaccination between the hemodialysis patients and healthy controls. The number of responder was lower in the hemodialysis patients with diabetes as compared to those without diabetes. Responder showed the decreased frequency of M1 Mf before vaccination. The frequency of MDSC was also decreased but not significant. The balance of inflammatory/anti-inflammatory cells was not different between responder and non-responder in the hemodialysis patients.

**Conclusions:** The frequency of M1 Mf might have the impact for the immune response of influenza vaccination in the hemodialysis patients, even though the balance of inflammatory/anti-inflammatory cells did not differ.

## TH-PO520

**Cinacalcet Treatment Decreases Serum Free Testosterone Concentration in Male Hemodialysed Patients with Chronic Kidney Disease and Secondary Hyperparathyroidism** Andrzej Wiecek, Piotr Kuczera, Marcin Adamczak. *Dept of Nephrology, Endocrinology and Metabolic Diseases, Medical Univ of Silesia, Katowice, Poland.*

**Background:** Calcium Receptor is expressed, among others in testis. Cinacalcet is used in the treatment of secondary hyperparathyroidism (sHPT) in hemodialysed patients with chronic kidney disease (HDP). In most of male HDP, serum free testosterone concentrations are low. The aim of this study was to assess the influence of six-month treatment with cinacalcet on the serum free testosterone concentration.

**Methods:** In 40 male HDPwith sHPT (PTH>300pg/ml), enrolled in this prospective, open-label, single arm study, plasma PTH and serum free testosterone concentrations were assessed before the first dose of cinacalcet and then after 3 and 6 months of treatment. Wilcoxon matched pairs test and Spearman test were performed. Results are shown as means with 95% confidence index.

**Results:** In the 35 patients who completed the study cinacalcet treatment caused significant decrease of serum PTH from 1106pg/ml (805-1407pg/ml) at the baseline, to 781pg/ml (475-1086pg/ml) after 3 month of treatment (p=0.002), and to 605pg/ml (298-912pg/ml; p<0.0001) after 6 months of treatment and also led to decrease of serum free testosterone concentration from 6.96pg/ml (5.61-8.30)pg/ml to 5.87pg/ml (4.99-6.95)pg/ml; p<0.05 and to 5.94pg/ml (4.93-6.95)pg/ml; p=0.03, respectively. There were no significant correlation between changes of serum free testosterone concentration and changes of plasma PTH concentration and cinacalcet dose, respectively.

**Conclusions:** 1. Treatment with cinacalcet decreases serum free testosterone concentration in male HDP with sHPT. 2. Such a decrease is not related to the changes of plasma PTH concentration.

## TH-PO521

**Ferric Citrate as a Phosphate Binder Reduces IV Iron and Erythropoietin Stimulating Agent (ESA) Use** Kausik Umanath,[1] Samuel S. Blumenthal,[3] Mohammed Sika,[2] Barbara A. Greco,[5] Diana I. Jalal,[4] Efrain Reisin,[6] John Manley,[7] Steven Zeig,[8] Dana G. Negoi,[9] Anand N. Hiremath,[10] Jamie P. Dwyer,[2] The Collaborative Study Group.[11] *[1]Henry Ford Hosp; [2]Vanderbilt Univ; [3]Med Coll Wis/VA; [4]Univ of Colorado; [5]W New Engl Renal & Tplt Assoc. & Baystate Med Ctr; [6]Louisiana State Univ; [7]Mt Kidney & HTN Assoc.; [8]Pines Clin Res; [9]Fletcher Allen Health Care; [10]Neph HTN Clin; [11]CMM.*

**Background:** Ferric Citrate (FC), a novel phosphate binder, has potential for iron absoprtion.

**Methods:** We report the IV iron and ESA use in a multi-center, randomized trial in 441 dialysis subjects treated with FC or active control (AC), sevelamer carbonate and/or calcium acetate. After a 2 week washout period, subjects were randomized 2:1 to FC or AC, and followed during a 52-week safety assessment period (SAP). IV iron use was at the discretion of the site as long as the serum ferritin was ≤ 1000ng/mL and the transferrin saturation (TSAT) was ≤ 30%. Oral iron and vitamin C were prohibited. Hemoglobin (Hgb) levels, IV iron and ESA use were collected and analyzed.

**Results:** 292 subjects were on FC and 149 subjects were on AC. FC subjects received less IV elemental iron (1.88 mg/day) than AC (3.84 mg/day; p<0.001) in the SAP. More subjects on FC did not require IV iron compared to AC, Table 1. At week 52 Hgb was 11.4 g/dL in FC and 11.1g/dL in AC (treatment difference, p=0.01). FC subjects received less erythropoietin units (U) per day (756 U/day) than AC subjects (993 U/day, p<0.05).

| Time in SAP (Weeks) | % FC Subjects Not Receiving IV Iron | % AC Subjects Not Receiving IV Iron | P Value |
|---|---|---|---|
| 0 - 12 | 31 | 19 | 0.014 |
| 12 – 24 | 53 | 26 | <0.0001 |
| 24 - 36 | 67 | 39 | <0.0001 |
| 36 - 52 | 67 | 37 | <0.0001 |

**Conclusions:** Use of FC as a phosphate binder both reduced the total amount of IV iron and ESA subjects received on dialysis as well as the frequency with which they received IV iron. These results suggest some ferric iron absorption in this patient population. Thus, FC, an efficacious phosphate binder, also reduced the need for IV iron and ESA in dialysis patients.

*Funding:* Pharmaceutical Company Support - Keryx Biopharmaceuticals

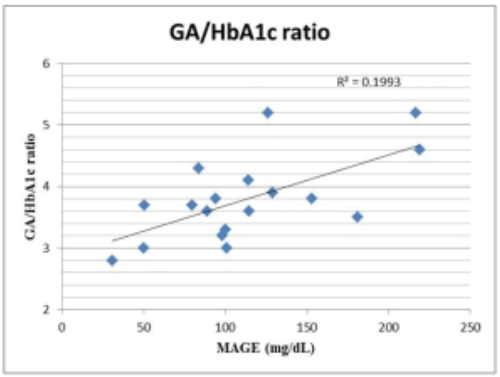
## TH-PO522

**Underestimation of Glycated Hemoglobin (HbA1c) Relative to Glycated Albumin (GA) Caused by Glycemic Variability in Diabetic Hemodialysis (HD) Patients: Assessment Using Continuous Glucose Monitoring (CGM)** Yoshiaki Lee,[1] Satoshi Funakoshi,[1] Kenichi Miyazaki,[1] Jyunichiro Hashiguchi,[1] Kenji Sawase,[1] Takashi Harada,[1] Tomoya Nishino,[2] Yoko Obata,[2] Shigeru Kohno,[2] Kazunori Utsunomiya.[3] *[1]Div of Blood Purification, Nagasaki Renal Center, Nagasaki, Japan; [2]Dept of Internal Medicine, Nagasaki Univ Graduate School of Medicine, Nagasaki, Japan; [3]Dept of Diabetology, Jikei Univ, Tokyo, Japan.*

**Background:** Several reports indicate that GA is a better glycemic indicator than HbA1c in HD patients with diabetes due to altered erythrocyte survival and erythropoiesis-stimulating agents (ESA) therapy, and HbA1c significantly underestimates glycemic control relative to GA. We herein investigated the significance of glucose variability in GA and HbA1c in diabetic HD patients using a CGM system.

**Methods:** We recruited 17 relatively well-controlled patients with type 2 diabetes under maintenance HD with monthly GA HbA1c values recorded for 3 months, and GA / HbA1c ratio in each patient was calculated over the period. Administrated dose of ESA stayed the same. To measure glycemic variability, we calculated mean amplitude of glucose excursion (MAGE) as described in detail elsewhere.

**Results:** Mean ± SD diabetes duration was 14.4 ± 7.8 years and dialysis vintage 2.7 ± 2.1 years, and mean HbA1c 6.4 ± 2.5, GA 24.5 ± 7.7, respectively. As shown in Figure 1], significant positive correlations were found for GA / HbA1c ratio and MAGE ($R^2 = 0.1993$), indicating HbA1c is underestimated relative to GA as daily glycemic variability increase.



**Conclusions:** Glycemic control measured by HbA1c was dissociated from GA in diabetic HD patients, with the degree of underestimation getting worse as glycemic variation increases.

*Funding:* Private Foundation Support

## TH-PO523

**Gastrointestinal Microbiota and Inflammation in Dialysis Patients** Teena Cherian, Madhumathi Rao. *Medicine/Nephrology, Tufts Medical Center, Boston, MA.*

**Background:** Alterations in gastrointestinal (GI) microflora could potentially mediate inflammation in dialysis patients. We examined the relationship between GI microbiota, markers of bacterial translocation and immune activation among hemodialysis (HD), and peritoneal dialysis (PD) patients and healthy controls (HC).

**Methods:** Blood and stool samples were collected from 22 HD and 13 PD patients and 9 age-matched HC. Recent antibiotic use, dialysis catheter, GI pathology or surgery were excluded. Stool microbiota was studied by pyrosequencing the 16S rRNA genes. Serum concentrations of Interleukin-6 (IL-6), C-reactive protein (CRP), soluble CD14 and LPS binding protein were measured; bacterial translocation from the GI tract was measured using quantitative PCR of the 16S rDNA genes in spent dialysate and plasma.

**Results:** Table 1 compares clinical and laboratory parameters among HD, PD and HC; CRP, IL-6, sCD14 and LPS binding protein concentrations were significantly higher among dialysis patients. Profiles of GI microbiota showed differences in diversity and equitability indices and the numbers of operational taxonomic units in dialysis patients and in the Firmicutes and Bacteroidetes phyla compared to healthy controls. Finally spent dialysate tested positive for LPS in 6 of 22 HD patients suggesting bacterial translocation during dialysis.

**Conclusions:** Dialysis patients show measurable alterations in GI microbiota in the setting of elevated immune activation markers. This could predispose to colonization by pathogens, impair barrier function and immune response in GI epithelium.

| Clinical Characteristics | HD (N=22) | PD (N=13) | HC (N=9) |
|---|---|---|---|
| Age (yrs) | 59±12 | 59±15 | 55±8 |
| Male (%) | 73% | 69% | 44% |
| Caucasian | 23% | 54% | 78% |
| Median duration on dialysis (months) | 56 | 23 | - |
| GI symptoms (bloating, bowel disturbance, anorexia) | 18%-68% | 23%-62% | - |
| **Immune marker assays** | | | |
| hsCRP (mcg/mL) | 7.9±12.0 | 3.6±2.5 | 1.5±1.2 |

## TH-PO524

### The Relation between Serum Hepcidin-25 (HPC) Level and Other Iron Metabolism Markers during Intravenous Iron Administration in Hemodialysis (HD) Patients

Noriko Saito,[1] Shigeru Miyazaki,[1] Kazuhide Saito,[2] Hiroki Takimoto,[1] Masaaki Shimotori,[1] Yutaka Tsubata,[1] Kozo Ikarashi,[1] Tetsuo Morioka,[1] Hisaki Shimada.[1] *[1]Shinraku-en Hospital; [2]Niigata Univ.*

**Background:** HPC is a crucial player of iron metabolism. Iron-overload and inflammation stimulate HPC production, whereas anemia, iron depletion inhibit HPC production. It is not elucidated that the sequential changes of the relation between HPC level and other iron parameters during intravenous iron administration in HD patients.

**Methods:** 21 anemic HD patients with low serum ferritin level ( 23±16 ng/ml ) were administered saccharated ferric oxide (Fe 40mg) intravenously for 11 consecutive HD sessions. We evaluated the following markers at 0 to 16 weeks after starting the therapy: HPC, GDF15, soluble transfferin receptor(sTfR) andstandard hematological parameters including high sensitive CRP (hs-CRP). Serum HPC level was determined by LS-MS/MS. GDF 15 and sTfR levels were measured by ELISA. Serum samples of 20 normal volunteers (N) were served as controls.

**Results:** HD patients with low serum ferritin level showed lower Fe(μg/ml) and HPC(ng/ml), higher GDF15(ng/ml), sTfR(nmol/ml) and hs-CRP(ng/ml) than N at 0W ( 43±31 vs 110±52**, 5.8±9.4 vs 11.1±11.9*, 7.4±2.4 vs 0.6±0.2**, 30.8±11.7 vs 16.3±6.5** and 1454 ± 2100 vs 237±290**, respectively). HPC level was increased at 4W(30.0± 33.1) and then decreased to 0W level at 10W(5.6±9.3). Hb (g/dl) was increased from 8.8±1.1 at 0W to 10.9±1.0 ** at 10W. In stepwise multiple regression analyses, UIBC and Fe were independently associated with HPC before the therapy, and at 4W, ferritin, GDF15 and hs-CRP were significant variables influencing HPC level which were the same as seen in N. At 6W and thereafter, ferritn was the only significant predictor of HPC. *:p<0.05, **:p<0.01.

**Conclusions:** Predictors of HPC level were quite different before and after intravenous iron administration. HPC level were significantly influenced by ferritin concentration after iron administration therapy in HD patients.

## TH-PO525

### Plasma Pentraxin-3 Levels Are Associated with Risk of Nutritional Status in Hemodialysis Patients

Tetsu Miyamoto,[1] Mika Matsumoto,[2] Hiroshi Tanaka,[3] Emi Hasegawa,[1] Akihiro Kuma,[1] Yoko Fujimoto,[1] Kenichiro Bando,[1] Ryota Serino,[1] Narutoshi Kabashima,[1] Yutaka Otsuji,[1] Masahito Tamura.[1] *[1]Second Dept of Internal Medicine, Univ of Occupational and Environmental Health School of Medicine, Kitakyushu, Japan; [2]Yukuhashi Clinic; [3]Iseigaoka Clinic.*

**Background:** Persistent inflammation is a major driving force of the uremic phenotype including protein energy wasting (PEW). Regular monitoring of inflammatory biomarkers in dialysis patients may help clinicians to estimate patient nutritional risk. Development of new inflammatory markers which are closely and specifically linked to nutritional status is thus needed in the dialysis population. Pentraxin 3 (PTX3) is a multifunctional soluble pattern recognition receptor which modulates immunoinflammatory response.

**Methods:** Plasma PTX3 levels (n=382) and one-year changes in PTX3 levels (ΔPTX3, n=160) were analyzed in relation to nutritional risk assessed by geriatric nutritional risk index (GNRI) in maintenance HD-patients.

**Results:** PTX3 [5.2 (2.6–10.5) ng/mL] were positively correlated with duration of dialysis (P<0.001) and HDL-cholesterol (P<0.001), and negatively with GNRI (P<0.001), BMI (P<0.001), and triglyceride (P<0.001). In a multivariate logistic regression model, both PTX3 (OR 1.12, 95%CI 1.05-1.29, p<0.01) and CRP (OR 1.22, 1.02-1.50, p<0.05) were independently associated with nutritional risk defined by GNRI < 91.2. While CRP levels were positively associated with Body weight/Ideal body weight (BW/IBW, P<0.001) but negatively with albumin (P<0.001), PTX3 had a negative association with BW/IBW (P<0.001), but not with albumin. ΔPTX3 levels were inversely correlated with ΔGNRI (p=0.02) in patients with lower PTX3 levels.

**Conclusions:** Both PTX3 and CRP predict nutritional risk in HD-patients. The association between CRP and nutritional risk calculated on the basis of GNRI depends on albumin levels, yet PTX3 had a strong association with anthropometric parameters. An increase of PTX3 levels has an association with nutritional risk marker. PTX3 may be a candidate for emerging inflammatory markers for the assessment of PEW because of the unique correlation with nutritional status in the dialysis population.

## TH-PO526

### Mild Nutritional Impairment Is Associated with Autonomic Dysfunction and Decreased Survival in Hemodialysis Patients

Dan Sapoznikov, Rebecca Backenroth, Yosef S. Haviv, Dvora Rubinger. *Nephrology and Hypertension Services, Hadassah Univ Medical Center, Jerusalem, Israel.*

**Background:** Severe malnutrition is associated with poor prognosis in end stage renal disease. The predictive value of mild nutritional impairment in chronic hemodialysis (HD) patients is not well established.

**Methods:** Multivariate analysis was performed to assess the role of nutritional risk (NR) as predictor of mortality and cardiovascular morbidity in HD. NR was evaluated using the NRS2002 screening method (*Clin Nutr 2003, 22:321-336*).The study population (n=112) was divided according to NR score into 4 categories: 0 (normal nutritional status), 1 (mild), 2 (moderate) and 3 (severe) impairment. Clinical and biochemical markers, CRP and the variability in the low frequency range of systolic blood pressure (LF SBP) and of interbeat intervals (LF IBI) rate, representative of autonomic function, were also analyzed in all patients. Primary (death) and secondary (fatal and non-fatal cardiovascular events) outcomes were recorded during a follow-up period of 60 months (range 1-60).

**Results:** Plasma albumin, LF SBP and LF IBI progressively decreased from NR1 to NR3, while CRP increased in NR2 and NR3. Kaplan-Meier analysis of primary outcome (5 y mortality) showed gradually decreasing survival rates for patients with increasing NR score from NR1 to NR3 (p 0.004, 0.001 and 0.001). Cox regression analysis with age, clinical and biochemical data, CRP and autonomic markers in the model identified NR score and age as powerful predictors of all cause mortality.The probability of the secondary outcome was markedly increased in NR2 and NR3 as compared to NR0 and NR1.Ischemic heart disease and intradialytic hemodynamic instability were significant predictors of cardiovascular events (p 0.015 and 0.001).

**Conclusions:** In HD, even mild nutritional impairment is associated with autonomic dysfunction and increased mortality. Moderate and severe nutritional impairment are associated with both increased mortality and cardiovascular morbidity, especially in patients with cardiac disease. Malnutrition in concert with autonomic dysfunction and inflammation are associated with increased mortality and morbidity in elderly HD patients.

## TH-PO527

### The Longitudinal Change of Corrected Mid-Arm Muscle Area Predicts Mortality in Hemodialysis Patients

Sumi Hidaka, Kunihiro Ishioka, Hidekazu Moriya, Takayasu Ohtake, Shuzo Kobayashi. *Dept of Nephrology, Immunology and Vascular Medicine, Shonan Kamakura General Hospital, Kamakura, Japan.*

**Background:** Protein-energy wasting is associated with increased morbidity and mortality in maintenance hemodialysis (HD) patients. Therefore, nutritional status needs to be regularly assessed and to detect malnutrition earlier. The aim of this study was to investigate the predictive value of anthropometric parameters on mortality.

**Methods:** This study included a cohort of 52 maintenance HD patients (36 men, mean age 63.3 ± 4.2 years). Anthropometric measurements were made in 2001, 2003, and 2005 and patients were followed up until 2012. Anthropometric measurements included body mass index (BMI), mid-arm circumference (MAC), triceps skinfold (TSF), mid-arm muscle circumference (MAMC) and corrected mid-arm muscle area (cMAMA). We investigated the predictors for all-cause death using Kaplan-Meier analysis and Cox proportional hazards analyses.

**Results:** During the mean follow-up of 117.8 months, 27 patients died. The deceased group had a significantly higher age at the enrolment in the study (p=0.001), but there was no significant difference in HD duration between the surviving and the deceased groups. Basal serum albumin level in deceased group was lower and serum β2-microglobulin level was higher than those in the surviving group (p=0.012 and p=0.042, respectively). Basal BMI, AC, and cMAMA did not differ significantly between the two groups, but the 4-year changes (Δ) of each value were significantly increased in the surviving group. Kaplan-Meier analysis revealed that the patients with decreased Δ cMAMA (N=15) had a significantly lower survival rate compared with those with increased Δ cMAMA (N=37, p=0.003). Multivariate Cox proportional hazards analyses demonstrated that the Δ cMAMA was a significant predictor of all-cause mortality after adjustments for confounding factors, such as age, serum albumin, serum β2-microglobulin, and Δ BMI. An increase in Δ cMAMA of 1 $cm^2$ reduced mortality by 6.0%.

**Conclusions:** These results demonstrate that the decrease in cMAMA is a significant predictor for mortality in HD patients. The interventions to increase Δ cMAMA are well worth trials.

## TH-PO528

### Relationship of Nutritional Intake and Body Composition for Undergoing Stable Hemodialysis

Yukie Kitajima,[1] Taeko Takahashi,[2] Yuzuru Sato.[2] *[1]Tokyo Healthcare Univ, Tokyo, Japan; [2]Sato Junkanki Hospital, Matsuyama, Japan.*

**Background:** It is important to maintain activities of daily living (ADL) in elderly dialysis patients. Further, cardiovascular disease (CVD) is a major cause of morbidity and mortality. Assessment of body composition is necessary for evaluating the nutritional status of patients with hemodialysis patients. We investigated the factors of for undergoing stable hemodialysis by examining the relationship of nutritional intake and changes of body composition, especially grip strength for six years in hemodialysis patients.

**Methods:** The studied subjects were 40 stable outpatients who were undergoing hemodialysis between 2007 and 2013. Grip strength measurement was measured before dialysis. Body composition was measured after completion of dialysis on the last day of the week. Patients were divided into two groups according to rate of grip strength; those

with rate of change (decrease) of grip strength ≥ - 15% (Group A) and with < - 15% (Group B). The method of evaluating for nutritional intakeused the meal recording method.

**Results:** Average of grip strength of hemodialysis patients was lower than average value of a healthy person (60.5%), their grip strength was significantly reduced for six years (-17.0%). Grip strength correlated with lean body mass (r=0.552, p<0.002). In nutritional intake, their energy intake (p<0.05) were significantly higher, protein catabolic rate (PCR) did not show significantly change. N-3 fatty acid intake (p<0.001) were significantly higher. % grip strength (46.8%, p<0.001) and Alb (3.5mg/dL, p<0.0002) of Group A were significantly lower than % grip strength (73.2%) and Alb (3.9mg/dL) of Group B. Group A was hospitalized with CVD and fracture (p<0.01) than Group B.

**Conclusions:** For six years, the more rate of decrease of grip strength is large, the more patient's malnutrition and amount of muscles decreases, hospitalization including CVD and fracture increase. However, it is necessary for hemodialysis patients to maintain energy intake and activity for stable survival and ADL. Therefore, to prevent thedecrease inmuscle mass, to intake enough energy is important factor for undergoing stable hemodialysis.

## TH-PO529

**The Effects of Parenteral Amino Acid Therapy on Protein Carbamylation in End Stage Kidney Disease** Sahir Kalim,[1] Anders H. Berg,[2] Caitlin A. Trottier,[1] Hector Tamez,[1] Julia Beth Wenger,[1] Joseph James Deferio,[1] S. Ananth Karumanchi,[3] Ravi I. Thadhani.[1] *[1]Nephrology Div, Massachusetts General Hospital, Boston, MA; [2]Div of Clinical Chemistry, Beth Israel Deaconess Medical Center, Boston, MA; [3]Nephrology Div and Center for Vascular Biology Research, Beth Israel Deaconess Medical Center, Boston, MA.*

**Background:** Carbamylation is a spontaneous chemical modification of proteins and amino acids by reactive cyanate, a byproduct of urea. Protein carbamylation is associated with adverse outcomes in ESRD. Proteins and free amino acids can compete with each other for binding reactive cyanate and our recent work in *Science Translational Medicine* demonstrates that increasing amino acid concentrations in vitro and in animals can attenuate the carbamylation reaction. Thus, amino acid therapy in humans may reduce uremic complications if targeted to reducing protein carbamylation.

**Methods:** 5 long-term hemodialysis subjects have undergone 6 weeks of post dialysis infusions of the amino acid supplement NephrAmine 5.4% (2 subjects receiving 125cc infusions and 3 subjects receiving 250cc infusions; 18 infusions total per subject). Carbamylated albumin levels (a surrogate for overall carbamylation burden) measured at baseline and 6 weeks were compared.

**Results:** No metabolic, hemodynamic, or other adverse events were observed. Baseline carbamylated albumin levels (C-Alb, mmol C-Alb/mol albumin) for the 5 subjects were 9.0, 7.8, 5.1, 6.2, and 8.0. Respective percent changes in C-Alb at the end of the 6 week study period were: -23.6%, -17.0% +12.9%, -4.8%, and -4.6%. Notably, the only subject experiencing an increase in C-Alb level had the lowest baseline level.

**Conclusions:** Amino acid therapy is safe and may be effective in reducing C-Alb levels in ESRD patients, especially those with high baseline carbamylation levels. Results from several additional subjects enrolled in this ongoing pilot study will be available at Kidney Week 2013 and will be useful in better characterizing the effects of amino acid therapy on protein carbamylation in ESRD.

## TH-PO530

**Effects of Branched-Chain Amino Acid on Elderly Dialysis Patients Suffering from Malnutrition** Taeko Takahashi,[1] Yuzuru Sato,[1] Yukie Kitajima,[2] Ayako Naka,[1] Yoshiko Miyazaki.[1] *[1]Sato Junkanki Hospital, Matuyama, Ehime, Japan; [2]Tokyo Healthcare Univ, Tokyo, Japan.*

**Background:** The present study investigated whether elderly dialysis patients suffering from malnutrition accompanied by decrease in both body protein and skeletal muscle experienced improvement in nutrition as a result of ingesting branched-chain amino acid (BCAA).

**Methods:** 29 hemodialysis patients (13 males, 16 females, average age 78.5 ± 7.0 years, average dialysis duration 6.7 ± 4.8 years, diabetes mellitus 48.3%) were chosen from a total of 61 people subjected to dietary management in our hospital and nursing home. Patients receiving tube feeding or with ALB of ≥3.5 g/dl were excluded. The patients consumed galette-like food (4,000 mg containing BCAA ). Results of amino acid well as ALB, CRP, BUN analyses and appetite survey conducted for 3 months before and after BCAA ingestion were compared.

**Results:** The average daily amount of food containing BCAA was 3,318.8 mg. BUN significantly increased from 63.6 ± 12.8 mg/dl to 70.7 ± 16.8 mg/dl. A comparison of median values for essential amino acids showed that the following 6 of 9 items increased significantly: valin from 186.3 ± 47.6 to 246.7 ± 76.3 nmoL/mL, methionine from 23.0 ± 4.7 to 25.9 ± 7.7 nmoL/mL, isoleucine from 63.5 ± 21.4 to 86.2 ± 43.5 nmoL/mL, leucine from 97.1 ± 28.8 to 153.7 ± 78.4 nmoL/mL, phenylanine from 65.0 ± 14.6 to 71.5 ± 14.5 nmoL/mL, and histidine from 83.2 ± 14.2 to 89.1 ± 15.4 nmoL/mL. In addition, BCAA levels increased significantly from 346.8 ± 93.4 to 499.8 ± 188.0 nmoL/mL and the Fisher ratio increased significantly from 3.96 ± 4.7 to 4.04 ± 1.6 nmoL/mL. No significant changes were observed for TP, Alb, CRP levels or the appetite surveys.

**Conclusions:** It is difficult for hemodialysis patients suffering from malnutrition to supplement the BCAA intake with diet alone. Therefore, the consumption of food containing BCAA by dialysis patients who are able to take food orally has the potential to improve their nutritional status. Continuous ingestion results in increase in both BCAA levels and the Fisher ratio; thus, it is also effective in the regulation of the balance of the amino acids necessary for protein synthesis within the body.

## TH-PO531

**Salt and Sodium: HD Patients Do Not Know the Difference** Camila Machado de Barros,[1] Carolina Quintella,[1] Thalita Lima Melho,[2] Camila Morales,[2] Felipe Linhares Arruda,[2] Letícia Alberto,[2] Edeli Simioni Abreu,[2] Rosana Farah,[2] Cláudia Gimenes,[1] Bárbara Margareth Menardi Biavo,[1] Jacqueline Santos,[1] Carmen B. Tzanno-Martins.[1] *[1]Grupo CHR; [2]Universidade Presbiteriana Mackenzie.*

**Background:** The control of dietary sodium is a challenge in the treatment of patients with chronic kidney disease (CKD) on hemodialysis. However, the use of educational strategies may contribute to a better adherence to the treatment of these patients. **Objective**: To evaluate the knowledge of salt and sodium in patients with CKD and effectiveness of nutritional approach for content assimilation.

**Methods:** The study was described as pre and post-test, where one group was its own control. 448 patients undergoing hemodialysis therapy (57% males, 57.5 ± 14.5 years) participated in the intervention for a period of 3 weeks. The educational material used included a questionnaire assessing knowledge, a lecture of 50 minutes and the presentation of food labels. In the pre-test was assessed knowledge about the topic and the post-test was evaluated assimilation of the content.

**Results:** In the pre and post-test: 66.8% knew and 85.5% assimilated what was salt, 38% knew and 65.8% assimilated what was sodium, 14% knew and 58% assimilated the difference between salt and sodium, 30% knew and 61.5% assimilate which the recommendation salt grams/day (p <0.05), 8.8% knew and 25% assimilate which equivalence in mg of sodium (p <0.05 ), 63.2% knew and 72% assimilated in household measures as they could consume salt/meal (p <0.05) and 44.4% knew and 66% assimilated to identify sodium on food labels (p <0.05), respectively.

**Conclusions:** The increase in knowledge after the lectures presented reinforces the need for intervention programs in sectors of hemodialysis as a prevention of clinical complications and consequent improvement in quality of life.

*Funding:* Private Foundation Support

## TH-PO532

**Nutrition Education: New Tool for Guidance of Hemodialysis Patients with Focus on Humidity, Phosphorus and Potassium** Camila Machado de Barros,[1] Bruna Benedetti,[2] Juliana Salgado Azeg,[2] Maria Flávia Sgavioli,[2] Edeli Simioni Abreu,[2] Rosana Farah,[2] Bárbara Margareth Menardi Biavo,[1] Jacqueline Santos,[1] Elzo Ribeiro Júnior,[1] Carmen B. Tzanno-Martins.[1] *[1]Nutrition, Grupo CHR, São Paulo, Brazil; [2]Nutrition, Universidade Presbiteriana Mackenzie, São Paulo, Brazil.*

**Background:** The objective of this study was to determine humidity, potassium and phosphorus of foods (fruits, leaf vegetables and non-leaf vegetables) in order to evaluate the best foods to be consumed by CKD patients and develop an educational material for them.

**Methods:** We prepared an educational material to be presented to patients. Three comparative tables were created, one for each of three food groups: fruits, leaf vegetables and non-leaf vegetables.The food selection was made according to the nutritional guidelines for patients with CKD. The survey data for the elaboration of the project was carried out by three different sources: TACO - Brazilian Table of Food Composition (UNICAMP, 2000); UNIFESP Nutritional Table; and Food Composition Table of the United States Department of Agriculture (USDA, 2007).

**Results:** We've confirmed that fruits considered 'dry' obviously contain less water in its composition (69% moisture). However, phosphorus (30 mg / 100 g) and potassium (321 mg / 100g) levels are concentrated. So they have great increase of its percentage. The three fruits with higher humidity content were pyriform orange (*Citrus aurantium pyriforme*) (89.6%), Key lime (*Citrus aurantifolia*) (87.4%) and strawberry (91.5%). And the ones with the lowest rates, excluding 'dry' fruits, were avocado (83.8%), tangerine (83.7%) and guava (80.8%). It was found that all plant foods should be cooked, because they have large amount of potassium. Although we have examined the phosphorus content in these foods, it is known that these are not the usual sources for this mineral, but they can influence phosphorus' increase in the patient's body when consumed in large quantities.

**Conclusions:** It was evident the lack of literature related to the amount of water contained in food. Therefore, it is necessary to develop more studies in order to analyze the influence of foods in daily intake of liquid by CKD patient.

*Funding:* Private Foundation Support

## TH-PO533

**Effects of Carnitine on Oxidative Stress and Inflammatory Responses to Intravenous Iron Administration to Patients with CKD** Zaher Armaly,[1] Amir Abd Elkadir,[1] Adel Rafik Jabbour,[1] Bishara Shafik Bisharat,[1] Abdalla Bowirrat,[1] Hashem J. Bishara,[1] Zaid Abassi.[2] *[1]Nazareth Hospital-EMMS, Galilee Faculty of Medicine - Bar Ilan Univ, Zafed, Israel; [2]Physiology, Faculty of Medicine, Technion, Israel.*

**Background:** Anemia is a common problem in CKD patients. It is attributed to decreased erythropoietin (EPO) and iron stores. Therefore, therapy includes EPO and iron replenishment. However, the latter induces oxidative stress. Randomized studies suggested that L-carnitine supplementation might have positive effects on the response to EPO in long term HD patients. Unfortunately, there is no evidence whether this approach is also beneficial in earlier-stage of CKD .

**Methods:** This study included 26 anemic CKD patients (stages 2-4) that were given a weekly IVIR (Sodium ferric gluconate, 125 mg/100 ml) for 8 weeks, and during weeks 5-8

also received carnitine (20mg/kg, IV) prior to IVIR administration. Weekly blood samples were drawn before and after each IVIR for advanced oxidative protein products (AOPP), neutrophil gelatinase-associated lipocalin (NGAL), in addition to routine complete blood count and biochemical analyses.

**Results:** IVIR for 4 weeks did not increase hemoglobin levels, yet worsened the oxidative burden as was evident by elevated plasma AOPP from 229.1±27.3 to 318.1±39.3 and 367.8±41.8μM ($p<0.05$) after 1 and 4 weeks, respectively. Plasma NGAL levels were not significantly affected by IVIR (265.4±48.6 vs. 265.1±44.7 and 205.7±39.4 ng/ml, after 1 and 4 weeks, respectively). Simultaneous administration of carnitine with IVIR resulted in a mild hemoglobin increase. Interestingly, carnitine therapy abolished the IVIR-induced oxidative stress, where AOPP levels were 237.4±31.85 and 271.8±23.8 μM after 1 and 4 weeks, respectively,P=NS). Furthermore, carnitine therapy decreased NGAL levels to 201.3±36.63 ($p=0.02$), and 239±48.55 ng/ml ($p=0.05$). No changes in CRP, SCr, BUN, albumin or WBC were observed following IVIR alone or combined with carnitine.

**Conclusions:** This study demonstrates that IVIR in CKD patients provokes oxidative stress, as evident by elevation of AOPP. The antioxidative effects of carnitine, suggests a role for carnitine therapy also in earlier-stage CKD patients.

*Funding:* Government Support - Non-U.S.

## TH-PO534

### The Plasma Concentration of Free Carnitine Should Be Increased above Normal in Order to Reduce the Darbepoetin Alfa Dose in HD Patients Administered Levocarnitine

Masaki Aono, Yuzuru Sato. *Sato Junkankikanaika, Matuyama, Ehime, Japan.*

**Background:** Plasma concentration of free carinitine decreases significantly in hemodialysis patients, and the free carnitine depletion impairs the response to Darbepoetin Alfa (DA) in renal anemia patients on HD. Levocarnitine can be administered to improve DA-resistance anemia, but the adequate dose for improvement has not yet been determined.

**Methods:** Over a three-month period, a daily dose of levocarnitine chloride (1800mg/day) was administered orally to 134 patients on HD who were diagnosed with carnitine deficiency (plasma concentration of free carnitine < 30μmol/L). At the end of the three months, the patients were divided into 3 groups according to the concentration of plasma free carnitinne (FC) as follows: group1: FC<30umol/L, N=22, group2: 30<FC<72, N=13, group3: FC>72, N=99. DA dosage and the erythropoietin resistance index (ERI: DA dose (μg/week)/Hb (g/dL)/body weight (Kg) x 100) were compared among the patients in the three groups before and after the treatment.

**Results:** In group 2, the plasma concentration of free carnitine increased from a mean ± SD of 22.5±4.7μmol/L to 45.8±11.3μmol/L after administration of levovcarnitine (paired t-test $P<0.01$);in group 3, it increased from 20.4±4.6μmol/L to 275.5±136.6μmol/L (paired t-test $P<0.01$). But in the group 1, it did not increase significantly (from 23.4±3.1 to 25.0 ± 4.6 mol / L, n.s). The dosage of DA and ERI decreased significantly only in group 3 (DA: from 23.8±19.4 to 18.4±15.6μg/week,$p<0.01$,ERI:4.7±4.2 to 3.5±3.1,$P<0.01$)), but remained unchanged in the other two groups (in group 1, DA : from 23.3±18.2 to 20.3±15.4, $P=0.43$.ERI:from 4.4±3.9 to 3.9±2.8, $P=0.46$);in group 2, DA: from 11.4±11.4 to 10.2±13.7, $P=0.87$. ERI: from 3.4±4.7 to 2.0±2.9, $P=0.36$).

**Conclusions:** This study suggested that levocartine can reduce the dose of DA and improve the resistance to DA in renal anemia patients on HD. But it appears to be necessary to increase the level of plasma carnitine above normal to obtain a sufficient effect of carnitine in HD patients. The monitoring of plasma concentration of free carnitine is important to assess the effect of levocarnitine to improve erythropoietin resistance.

## TH-PO535

### Predictors of Habitual Physical Activity in Hemodialysis Patients

Sivakumar Sridharan,[1] Jocelyn Berdeprado,[1] Kirsten L. Rennie,[2] Neil Ashman,[3] Andrew Davenport,[4] Michael K. Almond,[5] Anindya Banerjee,[6] Enric Vilar,[1,2] Justin Roberts,[2] Ken Farrington.[1,2] *[1]Lister Hospital; [2]Univ of Hertfordshire; [3]Royal London Hospital; [4]Royal Free Hospital; [5]Southend Hospital; [6]Arrowe Park Hospital.*

**Background:** Hemodialysis (HD) patients have reduced levels of physical activity (PA). It is vital to understand factors influencing PA to develop interventions to encourage PA in this patient population.

**Methods:** Each study subject was administered the validated Recent Physical Activity Questionnaire (RPAQ). RPAQ enquires about time spent on activities at home, at work and during various recreational activities in the preceding 4 weeks. We assigned MET (metabolic equivalent of task) values for each activity. Resting energy expenditure (REE) was estimated using a novel predictive equation validated in renal failure. Total energy expenditure (TEE) was estimated from MET and REE. TEE estimation assumed 6-8 hours sleep and that the remaining unreported hours from RPAQ were spent in light activity. Energy Expenditure from physical activity (PAEE) was calculated as TEE – REE.

**Results:** 1500 HD patients (910 males) completed the RPAQ. Mean age was 62.9(±15.5) years. There were 682 Whites, 418 Asians and 400 Blacks. 790 patients were on Hemodiafiltration(HDF). Mean REE was 1545 kcal/day, mean TEE 1840 kcal/day and mean PAEE 295 kcal/day. Male patients, those aged < 65 and those who were employed, had significantly higher REE, PAEE and TEE ($p<0.001$). No significant difference was noted in PAEE among various ethnic patients. PAEE was significantly less in those with heart disease, diabetes and arthritis and higher in those receiving HDF. In multivariate regression analysis, the independent predictors of PAEE were age, sex, employment status ($p<0.001$ for all), HDF therapy ($p=0.01$) and dialysis vintage ($p=0.02$) with these factors accounting for 50% of the variance in PAEE.

**Conclusions:** Mean daily MET values of the study subjects indicate a sedentary lifestyle for most HD patients. Age, sex, employment status, HDF therapy and dialysis vintage are the principal determinants of energy expenditure from physical activity in HD patients.

## TH-PO536

### Effects of Kibow Probiotic Supplementation Renadyl™ on Uremic Toxins in Hemodialysis Patients

Subodh J. Saggi,[1] Mary C. Mallappallil,[1] Usha N. Vyas,[2] Griet Lrl Glorieux,[3] Peter Liang,[1] Pari Ranganathan,[2] Bohdan Pechenyak,[2] Gary R. Briefel,[1] Lorraine L.A. Thomas,[1] Raymond C. Vanholder,[3] Natarajan Ranganathan,[2] Eli A. Friedman.[1] *[1]SUNY Downstate Medical Center, Brooklyn, NY; [2]Kibow Biotech, Inc, Newton Square, PA; [3]Ghent Univ Hospital, Ghent, Belgium.*

**Background:** Our prior studies in patients with CKD 3-4 (n=31) given Renadyl™, a safe proprietary probiotic dietary supplement that metabolizes nitrogenous wastes in the bowel, at a dose of 90-270 B CFU per day, over a 4 month period showed that BUN, creatinine and $K^+$ levels declined.

**Methods:** We now conducted a prospective double blind cross over trial with placebo and Renadyl™ in 26 stable CKD patients on hemodialysis. Dosage administered was 180 B CFU per day, given in 3 divided doses. Our primary aim was a 20% reduction in BUN levels over an 8 week period. Patients' dialysis prescriptions were unchanged. Our secondary aim was to see if there would be changes in WBC count, C-reactive protein (CRP), total and/or free serum concentrations of indoxyl sulfate, indole acetic acid, p-cresyl sulfate, hippuric acid, serum pentosidine, 3-carboxyl-4-methyl-5-propyl-2-furan-propanoic acid (CMPF), uric acid and beta-2 microglobulin. Solutes were measured by HPLC and ELISA. QoL changes were assessed by a modified SF-36 questionnaire. Patient adherence was assessed by pill count and stool culture to verify probiotic growth during study and absence during placebo period. Data were analyzed using ANOVA for a crossover study with a mixed model methodology in SAS to account for treatment, period and sequence effects.

**Results:** Administration of probiotics was safe and showed a decline in WBC counts ($6.02x10^3$/uL to $5.51x10^3$/uL, $p=0.05$) and total indoxyl glucuronide (0.76mg/dL to 0.65mg/dL, $p= 0.05$) and a trend towards reduction in CRP (13.72mg/dL to 5.11mg/dL, $p= 0.07$). Other chemicals and QoL were unchanged.

**Conclusions:** Administration of Kibow Probiotic Renadyl™ in ESRD patients is safe and showed a protective effect by the trend to reduce markers of inflammation. Further investigation in a larger population or at a higher dose might yield mechanistic insights into the probiotic effects on the inflammatory cascade of uremia.

## TH-PO537

### Effect of Convection Therapy on Advance Glycation End Products

Arkom Nongnuch,[1,2] Andrew Davenport.[2] *[1]Renal Unit, Dept of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand; [2]Centre for Nephrology, Royal Free Hospital, Univ College London, London, United Kingdom.*

**Background:** Cardiovascular disease (CVD) is a major cause of death in the dialysis population. Advance Glycation End Products (AGEs) have been strongly association with CVD. AGEs are formed by the Maillard reaction and are predominantly renally excreted. Thus both serum AGEs and AGEs deposited in tissues are increased in dialysis patients. Previous studies have shown that tissue AGEs had greater association with CVD than serum AGEs, and tissue AGE deposition can be measured by skin autofluorescence (sAF). As AGEs are middle molecules we determined whether patients treated by HDF with increased convective clearance had lower tissue AGEs compared to those treated by standard highflux HD.

**Methods:** We measured tissue AGEs using skin autofluorescence (sAF) (DiagnOptics, Groningen, Netherland) on the non-fistula arm of 332 chronic hemodialysis patients, 169 on HD and 163 on HDF.

**Results:** The results are shown in the table (figure).

| Parameters | Hemodialysis | Hemodiafiltration | P value |
|---|---|---|---|
| Skin autofluorescence AU (mean ± SD) | 3.18 ± 0.83 | 3.35 ± 1.06 | NS |
| Age years | 64.1 ±14.7 | 66.4 ± 15.4 | NS |
| Diabetes (%) | 72 (42.6) | 67 (41.1) | NS |
| Hypertension (%) | 105 (62.1) | 100 (61.3) | NS |
| Smoking (%) | 69 (40.8) | 54 (33.1) | NS |
| B2 Microglobulin (median, IQR) mg/dL | 28.5 (12-57) | 26 (7-164) | NS |
| History of CVD | 43 (25.4) | 64 (39.2) | 0.001 |
| History of PVD | 24 (14.2) | 29 (17.1) | 0.01 |
| Dialysis vintage (median, IQR) months | 24 (1-350) | 55 (2-413) | 0.01 |

Previous studies have reported that sAF increases with renal failure, age, diabetes and history of CVD. Our groups were comparable for age, diabetes and hypertension. Despite substantially longer dialysis vintage, and greater history of cardiovascular and peripheral vascular disease the sAF measurements were not higher in the HDF cohort. B2 microglobulin levels, a marker of middle molecule clearance and residual renal function were also similar between the groups despite the differences in dialysis vintage.

**Conclusions:** The addition of convective clearance with HDF appears to reduce the accumulation of tissue AGEs, by improving middle molecule clearances. Prospective studies are required to determine whether HDF reduces the risk of cardiovascular death in long term hemodialysis patient.

## TH-PO538

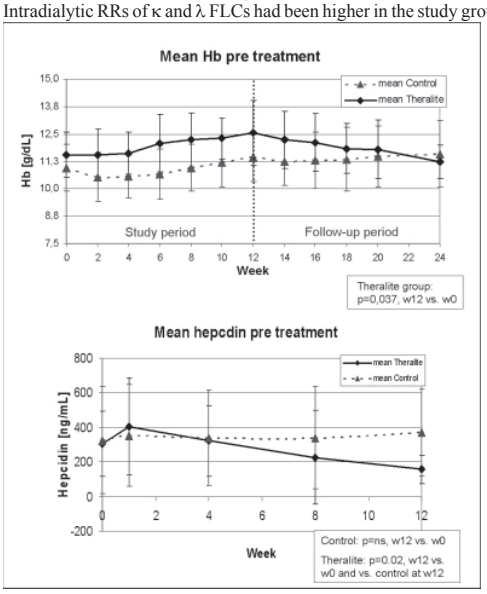
**Treatment by High Cut-Off Hemodialysis Leads to Higher Hemoglobin and Decreased Hepcidin in HD Patients** Ugo Teatini,[1] Werner Beck,[2] Ariane Liebchen,[2] Giorgio Romei Longhena.[1] *[1]Bollate Hospital; AO Garbagnate M.se, Milan, Italy; [2]Gambro Dialysatoren GmbH, Hechingen, Germany.*

**Background:** Multiple inflammatory stimuli are linked to clinical signs and symptoms and CV mortality in HD patients. Inflamed HD patients also show impaired responses to erythropoiesis-stimulating agents (ESAs).

Aim of this pilot study was to investigate if HD treatment with a membrane having a high molecular permeability in a broad MW range improves ESA responsiveness (ESA resistance index, ERI) and decreases inflammatory markers.

**Methods:** 24 ESRD patients (6 w, 65±16 years, 70±11 kg) on 3x/week high-flux HD/HDF ( ≥3 months) with adequate iron status (TSAT >20%, ferritin >100 ng/mL) were randomized into a study group (Theralite high cut-off membrane (Gambro) alternating with routine high-flux HD/HDF) or control group (routine HD/HDF) and treated for 12 weeks. ESA dose was adapted acc. to guidelines to maintain Hb levels in between 10-12 g/dL. Hepcidin, κ- and λ-FLCs, ESA dose, Hb and albumin were analyzed. (NCT01526798)

**Results:** 5 patients dropped out during the study period. One patient was excluded due to unusual high ferritin. In both groups a reduction of ERI has been observed. Only in the study group a significant increase in Hb levels and a decrease of hepcidin values to a significant lower level was detectable during the study period (fig. 1). An albumin drop was detectable in the study group and values stabilized after ~2 weeks at the lower level. Intradialytic RRs of κ and λ FLCs had been higher in the study group compared to controls.



**Conclusions:** High cut-off dialysis allows a significant better removal of large uremic toxins (λ FLCs) and improves ESA responsiveness (indicated by rise in Hb and fall in hepcidin). Larger studies are needed to confirm if regular treatment with high permeability membranes leads to an improvement in anemia of chronic inflammation in HD patients.

## TH-PO539

**Depressive Affect in Incident Hemodialysis Patients: Prevalence and Risk Factors** John W. Larkin, Kathryn A. McDougall, Len A. Usvyat, Rebecca L. Wingard, Eduardo K. Lacson, Franklin W. Maddux. *Fresenius Medical Care North America (FMCNA), Waltham, MA.*

**Background:** Depression is common among patients with end-stage renal disease, yet is not well studied in incident hemodialysis (iHD) patients in their first month of chronic outpatient dialysis. This study investigated the prevalence of and risk factors for depressive affect (DA) in the FMCNA RightStart Program.

**Methods:** From a random sample of 108 dialysis centers, 429 iHD patients in their first month of dialysis at FMCNA during Jan-Mar 2013 were contacted by telephone for up to three tries for depression screening utilizing the Patient Health Questionnaire 2 (PHQ2). The PHQ2 consists of two questions that determine presence of depressed mood and anhedonia during the previous two weeks. Scores range from 0-6; a positive DA score was defined as ≥3. Clinical and lab parameters were collected up to the first 120 days of dialysis and associations between DA were assessed using multivariate logistic regression.

**Results:** Of 429 patients, 172 (40.1%) were successfully screened with the PHQ2, 192 (44.8%) could not be reached, 6 (1.4%) refused and 59 (13.8%) did not have a valid telephone number. Responders were: 41.3% females; mean age of 65.0±14.6 years; 64.5% had diabetes; and 67.4% utilized dialysis catheters. The PHQ2 was positive in 23.3% of patients. Logistic regression identified male iHD patients had significantly lower risk of DA (OR=0.32, p=0.02), while higher log of creatinine (Cr) trended towards greater risk for DA (OR=3.48, p=0.08). There were no associations between DA and age, diabetes, access type, ethnicity, race, body mass index, residual renal function, number of comorbidities, albumin, interdialytic weight gain, or urea reduction ratio.

**Conclusions:** The prevalence of DA by PHQ2 was 23.3% in this iHD patient cohort, consistent with prior reports in the literature. A decreased risk for DA was observed in males. Creatinine levels may play a role as a determinant of DA, but further studies are required to better understand these associations.

## TH-PO540

**Reduced Renal Fibrosis after Unilateral Ureteral Obstruction in Mice Lacking $\alpha_{1B}$ Subunit of N-Type Calcium Channels** Akito Maeshima, Keiichiro Mishima, Masao Nakasatomi, Noriyuki Sakurai, Hidekazu Ikeuchi, Toru Sakairi, Keiju Hiromura, Yoshihisa Nojima. *Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Japan.*

**Background:** Renal tubules are innervated by sympathetic nerves in which N-type $Ca^{2+}$ channels are densely distributed. It has been reported that sympathetic nerve activity was increased in patients with chronic renal diseases. We recently reported the increased expression of N-type $Ca^{2+}$ channel in the kidneys after unilateral ureteral obstruction (UUO) and the reduction of renal fibrosis by L/N-type $Ca^{2+}$ channel blocker in rats (AJP Renal Physiol 304: F665-73, 2013). However,the role of N-type $Ca^{2+}$ channel in renal fibrosis is not totally understood.

**Methods:** To address this issue, we induced UUO in male mice lacking the $\alpha_{1B}$ subunit of N-type $Ca^{2+}$ channel (Cav2.2) and wild type (WT) littermates and analyzed several renal fibrotic parameters in this study.

**Results:** In C57BL/6N mice, the expression of Cav2.2 was absent in normal, contralateral, and sham-operated kidney, while Cav2.2 became detectable in the interstitium of the kidney after UUO. In UUO kidneys, Cav2.2 was expressed in the interstitial cells positive for a-SMA, a marker for myofibroblasts, but not in T-lymphocytes, Macrophages, and endothelial cells. At baseline as well as after UUO, there was no significant difference in mean blood pressure, heart rate, and renal function (serum creatinine and blood urea nitrogen levels) between WT mice and Cav2.2 mutant mice. The expression level of a-SMA in the UUO kidneys of Cav2.2 mutant mice was significantly decreased compared to that in WT mice. Cav2.2 deficiency reduced the production of fibronectin, but not type I or type III collagen in the kidney after UUO. Sirius red-positive area was significantly reduced in Cav2.2 mutant kidney compared to that in WT kidney after UUO (1.97% vs. 3.57%, P<0.001).

**Conclusions:** Our data suggest that Cav2.2 is implicated in myofibroblast activation and the production of extracellular matrix during renal fibrosis. Cav2.2 might be a novel therapeutic target for the treatment of fibrotic kidney disease.

## TH-PO541

**Effects of Tissue-Specific, Targeted Expression of Baculovirus p35 Pan-Caspase Inhibitor on Renal Fibrogenesis following Ureter Obstruction** Tsutomu Inoue, Hiromichi Suzuki, Hirokazu Okada. *Nephrology, Saitama Medical Univ, Irumagun, Saitama, Japan.*

**Background:** The caspase family of enzymes participates in cell apoptotic and proinflammatory reactions. Although caspase activation was known to be involved in renal fibrogenesis following unilateral ureter obstruction (UUO), in such an obstructive kidney where and how caspase activation plays a role remain to be determined.

**Methods:** Three lines of transgenic (tg) mice were used. p35 tg mice that bear the pan-caspase inhibitor protein p35 gene separated from a universal CAG promoter by a floxed STOP sequence were crossed with γGT.Cre and FSP.Cre tg mice that express Cre recombinase in tubular epithelial cells and fibroblasts, respectively. Two double-tg mice (γGT.Cre;p35 and FSP.Cre;p35) and wild-type mice were then challenged with UUO. Cell apoptosis was defined by in situ end labeling and the point-counting method. Fibrosis-related parameters in the kidneys were determined by histopathology and qPCR.

**Results:** Matrix deposition by Masson's trichrome staining in the peritubular interstitium and mRNA levels of fibronectin(FN)-EIIIA were significantly increased in the UUO kidneys of the wild-type and FSP.Cre;p35 tg mice, but not in those of the γGT.Cre;p35 mice, possibly due to tubular epithelium-specific induction of p35 gene product, compared to the native kidneys (8.1+1.9, 7.9+3.2, 3.8+1.2, vs. 0.9+0.1 [% blue area]; 9.4+3.1, 10.3+3.6, 5.7+1.5, vs. 1.0+0.5 [FN-EIIIA mRNA/GAPDH mRNA]). Additionally, compared to the wild-type mice, the number of apoptotic cells and mRNA levels of NLRP3, a caspase-1-dependent, central component of inflammasome, in the UUO kidneys were significantly lower in the γGT.Cre;p35 mice while those were not significantly altered in the FSP.Cre;p35 tg mice.

**Conclusions:** Tissue-specific, targeted expression of p35 pan-caspase inhibitor provides evidence of the critical role of caspase activation, i.e., induction of apoptosis and inflammasome, in tubular epithelium, but not in fibroblasts, in renal fibrogenesis following ureter obstruction.

## TH-PO542

**Induction of Renal Fibrosis by a Cell Cycle Regulator** Judit Megyesi,[1,2] Adel Tarcsafalvi,[1] Nang San Hti Lar Seng,[1] Shenyang Li,[1,2] Didier Portilla,[1,2] Peter M. Price.[1,2] *[1]Univ AR Med Sci; [2]VA Med Ctr.*

**Background:** Expression of a cell cycle regulatory protein, $p21^{WAF1/Cip1}$, in cells after partial nephrectomy is associated with fibrotic changes and progression. The p21 protein is an inhibitor of cyclin-dependent kinases-1 and -2 (Cdk1, Cdk2), but the mechanism of how its expression contributes to fibrosis is unclear.

**Methods:** Cultured mouse proximal tubule cells were transduced by adenoviruses including those expressing full-length p21, N- and C-terminal p21, and DN-Cdk2. The Cdk-inhibitory drug purvalanol was used at 9 μM. Also, several mouse models of renal fibrosis were used, either unilateral ischemia/reperfusion, ureteral obstruction, or partial nephrectomy.

**Results:** We reported previously that p21 KO mice were protected from renal fibrosis using 5/6 nephrectomy, UUO/release, or unilateral ischemia/reperfusion and that after AKI, proximal tubules were the major sites of p21 mRNA induction. We now show that in a p21 KO background, induction of transgenic p21 specifically in proximal tubules resulted in expression of fibrotic markers after unilateral ischemia or 14 days following UUO that was released after 3 days, showing that proximal tubular cells are a significant source of the signal for induction of fibrosis. We also show that p21 over-expression in cultured kidney cells increased TGFβ mRNA 5.5 to 8.2 times control levels. This increase was not by transcriptional activation, but rather by stabilization of the mRNA.

The TGFβ protein was detected in wild-type mouse kidney after UUO in thick ascending limbs and in the S1 and S2 segments of convoluted proximal tubules. TGFβ is reported to play a major role in stimulating extracellular matrix production after UUO and release of active TGFβ by injured epithelial cells is implicated in the pathogenesis of epithelial cell injury and interstitial fibrosis in the kidney.

**Conclusions:** Based on these findings, we propose that induction of p21 following kidney injury, subsequent stabilization and accumulation of TGFβ mRNA and release of TGFβ protein by proximal tubule cells is a major causative mechanism for development of kidney fibrosis *in vivo*.

## TH-PO543

**Sonic Hedgehog Is an Inducible, Tubule-Derived Growth Factor for Interstitial Fibroblasts after Kidney Injury** Dong Zhou,[1] Yingjian Li,[1] Li Li Zhou,[1] Roderick J. Tan,[2] Youhua Liu.[1] *[1]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

**Background:** Tubular epithelium constitutes the major part of renal parenchyma, and is the primary target of various kidney injuries. However, how the injured tubules drive fibroblast proliferation and activation in the interstitium remains elusive. Here we show that sonic Hedgehog (Shh), an evolutionarily conserved, secreted and extracellular signaling protein, is an inducible, tubule-derived growth factor that plays an important role in promoting fibroblast proliferation and expansion.

**Methods:** Various animal models of CKD as well as human kidney biopsies were used. Shh signaling was inhibited by cyclopamine (CPN) in vitro and in vivo.

**Results:** We found that Shh was specifically induced in renal tubular epithelia in various models of CKD induced by adriamycin (ADR), ischemia/reperfusion injury (IRI) and 5/6 nephrectomy, respectively. Shh was also markedly induced in renal tubules of human kidney biopsies from CKD patients with different etiologies. In vitro, recombinant Shh promoted rat kidney fibroblasts (NRK-49F) proliferation, as assessed by cell counting, MTT assay, and BrdU incorporation assay, which was accompanied by induction of numerous proliferation-related genes, including c-fos, c-myc, proliferative cell nuclear antigen, and cyclin D1. However, Shh had no appreciable effect on the proliferation of other major kidney cells, such as podocytes, proximal tubular epithelial cells (HKC-8) and inner medullar collecting ducts cells (mIMCD-3). To investigate the role of Shh in fibroblast proliferation in vivo, we administered CPN, a small molecule Smo inhibitor, at 3 days after IRI. At 10 days after IRI, we found that CPN markedly inhibited fibroblast proliferation, reduced myofibroblast population, and attenuated fibrotic lesions in vivo.

**Conclusions:** Collectively, these studies identify Shh as a potent tubule-derived growth factor that specifically promotes interstitial fibroblast proliferation. Our data also indicate that blockade of Shh signaling is a novel strategy for therapeutic intervention of renal fibrosis.

## TH-PO544

**Matrix Metalloproteinase-7 Is a Biomarker and Pathogenic Mediator of Kidney Fibrosis** Dong Zhou,[1] Li Li Zhou,[1] Roderick J. Tan,[2] Fan Fan Hou,[3] Youhua Liu.[1] *[1]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA; [3]Renal Div, Nanfang Hospital, Southern Medical Univ, Guangzhou, Guangdong, China.*

**Background:** Matrix metalloproteinase-7 (MMP-7), a secreted, zinc and calcium dependent endopeptidase that degrades a broad range of extracellular matrix (ECM) and other substrates, is a transcriptional target of canonical Wnt/β-cateninn signaling. We previously demonstrated that urinary MMP-7 is surrogate biomarker for renal Wnt/β-catenin activity. However, Whether MMP-7 plays a role in renal fibrogenesis is completely unknown.

**Methods:** Urinary MMP-7 from normal subjects and CKD patients was measured by ELISA. MMP-7 knockout and wild-type control mice were subjected to UUO. Cultured human proximal tubular cells were treated with recombinant MMP-7.

**Results:** Urinary MMP-7 level was markedly increased in CKD patients, comparing to normal subjects. Similarly, increased MMP-7 was observed in renal tubules of human kidney biopsies from CKD patients. MMP-7 mRNA and protein expression were also induced in animal models of renal fibrosis such as UUO. To study the role of MMP-7 in renal fibrogenesis, MMP-7-/- mice and their WT controls were subjected to obstructive injury for 7 days. Compared with WT controls, MMP-7-/- kidneys displayed reduced fibrotic lesions, characterized by decreased expression of Snail1, α-smooth muscle actin, vimentin, Fsp1, PAI-1, fibronectin, type I and type III collagen. Ablation of MMP-7 in vivo also preserved E-cadherin primarily by inhibiting its extracellular shedding, with no effect on E-cadherin mRNA abundance. In vitro, MMP-7 incubation reduced E-cadherin staining in plasma membrane of proximal tubular cells (HKC-8), which resulted in increased β-catenin nuclear translocation. Co-immoprecipitation revealed a diminished E-cadherin/β-catenin complex formation, with concomitant increase of b-catenin/LEF1 binding, after MMP-7 treatment in HKC-8 cells.

**Conclusions:** These observations suggest that MMP-7 not only is a biomarker, but also plays a crucial role in mediating tubular injury and interstitial fibrosis by promotes E-cadherin shedding and β-catenin activation.

*Funding:* NIDDK Support, Government Support - Non-U.S.

## TH-PO545

**Slit2 Inhibits Renal Fibrosis after Ischemia Reperfusion Injury** Darren A. Yuen,[1] Yi-Wei Huang,[1] Guang-Ying Liu,[1] Sajedabanu Patel,[1] Rohan John,[2] Lisa Robinson.[1] *[1]Hospital for Sick Children, Canada; [2]Univ Health Network, Canada.*

**Background:** Fibrosis is a critical contributor to CKD progression for which no specific therapies exist. Acting on its cognate Robo receptors, Slit2 is a secreted protein that modulates the actin cytoskeleton of multiple cells. As fibroblast activation is dependent upon cytoskeletal rearrangements, we hypothesized that Slit2 may exhibit anti-fibrotic activity and prevent renal fibrosis after AKI.

**Methods:** Renal fibroblasts were examined for Robo1 expression using qRT-PCR, immunoblotting, and immunostaining. The effects of Slit2 alone or in combination with its decoy receptor RoboN on TGF-β-induced fibroblast collagen production were tested using a [$^3$H]-proline incorporation assay. To assess the effects of Slit2 *in vivo*, mice undergoing left renal ischemia-reperfusion injury (IRI) received 3X weekly i.p. injections of N-Slit2 (a bioactive Slit2 fragment), C-Slit2 (an inactive Slit2 fragment) or vehicle. Thirteen days post-IRI, mice underwent right nephrectomy and 24 h later, renal function and structure were analyzed.

**Results:** Renal fibroblasts expressed Robo1 mRNA and protein. Slit2 dose-dependently reduced TGF-β-induced [$^3$H]-proline incorporation, whereas Slit2 incubation with its decoy receptor blocked its anti-fibrotic activity. In the mouse model of renal IRI, administration of inactive C-Slit2 had no effect, but bioactive N-Slit2 improved serum creatinine and urea. N-Slit2 also reduced α-SMA$^+$ activated fibroblast number and collagen deposition in the injured kidney.

**Conclusions:** These data demonstrate that Slit2 exerts previously undescribed anti-fibrotic effects by inhibiting TGF-β-induced fibroblast activation. Slit2 may represent a novel therapy targeting renal fibrosis.

## TH-PO546

**Reduced Renal DDAH1 Activity Protects against Progressive Kidney Damage** James Alexander Tomlinson,[1] Ben Caplin,[2] Dirk Dormann,[1] Peter Allen Faull,[1] Sanjay Khadayate,[1] Jill T. Norman,[2] David C. Wheeler,[2] James M. Leiper.[1] *[1]Medical Research Council Clinical Sciences Centre, Imperial College, London, United Kingdom; [2]Centre for Nephrology, UCL Medical School Royal Free, London, United Kingdom.*

**Background:** Asymmetric dimethylarginine (ADMA) competitively inhibits nitric oxide (NO) synthesis whilst dimethylarginine dimethylaminohydrolase 1 (DDAH1) metabolises ADMA; representing an alternative pathway for NO regulation. Although an association between elevated circulating ADMA and poor cardiovascular and renal outcomes has been widely reported, a causal link is unresolved. We recently published evidence of a DDAH1 gene variant that leads to lower plasma ADMA but counter-intuitively, associates with a *steeper* rate of eGFR decline.

**Methods:** The principal site of renal DDAH1 expression is within the renal proximal tubule (PT). We tested the hypothesis that reduced kidney DDAH1 activity slows the progression of kidney function decline by; (**A**) generating a novel PT-specific DDAH1 gene knock-out (PTD1KO) mouse; (**B**) subjecting it to a folate model of CKD and (**C**) confirmed gene expression associations observed in the KO mouse within human renal allografts.

**Results:** (**A**) KO mice had elevated PT cell ADMA (60%, $p<0.05$), with a reduction in NO synthesis (60%, $p<0.05$) and no effect observed in other organs, urine, plasma or systemic BP. Urinary proteomic analysis revealed an 8-fold reduction in uromodulin (UMOD; $p<0.001$) with PTD1 deletion. (**B**) At 12 weeks post folate injury, WT mice had a >2-fold rise in fibrotic gene expression (Col12α and TGFβ; $p<0.05$), whereas KO mice

were protected. Renal collagen deposition was reduced in KO mice (WT vs KO; 7.2 vs 4.5%, $p<0.01$). (**C**) A significant correlation between UMOD and DDAH1 gene expression was confirmed in human renal allograft protocol biopsies ($p<0.05$).

**Conclusions:** Renal DDAH1 activity contributes to the progression of kidney function decline following injury. Our work highlights the importance of NO-ADMA imbalance at a tissue level and suggests that circulating ADMA may be misrepresentative of organ-specific disease. Our animal and human data demonstrate an association between UMOD and DDAH1 gene expression and suggest a plausible mechanistic role of uromodulin in kidney injury.

### TH-PO547

**A Simple Method for Detection of Epithelial-Mesenchymal Transition during Renal Fibrosis In Vivo** Masao Nakasatomi, Akito Maeshima, Noriyuki Sakurai, Hidekazu Ikeuchi, Toru Sakairi, Keiju Hiromura, Yoshihisa Nojima. *Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.*

**Background:** Epithelial-mesenchymal transition (EMT) in renal fibrosis is generally defined by the loss of epithelial markers and the acquisition of mesenchymal phenotypes by damaged tubules. However, structural details of this process have not been clarified. Using bromodeoxyuridine (BrdU) labeling method, we previously reported that renal progenitor-like tubular cells, also called as label-retaining cells, migrated into the interstitium after unilateral ureteral obstruction (UUO) (JASN 16: 2044-51, 2005). By modifying this method, we examined in this study whether EMT process could be detected and quantified in vivo.

**Methods:** Using osmotic pump, BrdU (20mg/kg/day) was continuously given into 7-week-old Wistar rats for 1, 2, 3 and 4 weeks. UUO was induced in these rats and the kidneys were removed at 4, 6, 8, 10 days after UUO. Localization, phenotype, and number of BrdU+ cells were examined by immunostaining. The number of BrdU+ bone marrow cells was also measured.

**Results:** The number of BrdU+ cells was positively associated with labeling period. BrdU+ cells were detectable in AQP1-positive proximal tubules, but not in the interstitium of normal rat kidneys. Most proximal tubular cells became BrdU+ after 4-week labeling. After UUO, some of BrdU+ tubular cells were protruded from the basement membrane and were migrated into the interstitium. Interstitial BrdU+ cells were co-localized with alpha-SMA, fibroblast-specific protein 1, and type I collagen. The number of interstitial BrdU+ cells significantly increased and reached the maximum at 8 days after UUO. Few BrdU+ cells were observed in the interstitium of normal and sham-operated kidneys. UUO treatment did not significantly change the number of bone marrow BrdU+ cells.

**Conclusions:** Long-term BrdU treatment labels most proximal tubular cells with BrdU and enabled us to detect and quantify EMT in vivo. This technique will be useful for the search of novel EMT inhibitor(s) for the treatment of renal fibrosis.

### TH-PO548

**Sphingosine Kinase 2 Deficiency Attenuates Kidney Fibrosis in Mice** Amandeep Bajwa, Piotr Chroscicki, Liping Huang, Hong Ye, Mark D. Okusa. *Dept of Med./CIIR, Univ of Virginia.*

**Background:** S1P and the sphingosine kinases(SphK1/SphK2) responsible for its formation are important in acute and CKD. In the current study we examined the role of SphK2 in kidney fibrosis.

**Methods:** Fibrosis was induced in WT, SphK1$^{-/-}$ and SphK2$^{-/-}$ mice by folic acid (FA; 250mg/kg) or unilateral ischemia-reperfusion(IRI) and mice were followed for 14d and RT-PCR and IHC were performed.

**Results:** SphK2$^{-/-}$ mice had less fibrosis (trichrome staining) compared to WT or SphK1$^{-/-}$ mice 14d after FA or unilateral IRI. Compared to kidneys of FA-treated SphK1$^{-/-}$ mice, SphK2$^{-/-}$ mice expressed lower mRNA encoding TGF-β (15.79%, $p<0.001$), α-SMA (30.8%, $p<0.01$) and fibronectin (36.9%, $p<0.01$) and had lower expression of collagen and fibronectin immunoreactivity in kidney. Kidneys of FA-treated SphK2$^{-/-}$ mice had reduced infiltration of macs (45.1%, $p<0.05$)) neuts (27.9%, $p<0.01$) and T cells (55.8%, $p<0.05$) compared to SphK1$^{-/-}$ mice. SphK2$^{-/-}$ CD4$^{+}$ T cells are hyperproliferative and produce significantly higher amounts of IFN-γ compared to WT or SphK1$^{-/-}$ T cells. In chronic studies IFN-γ is anti-fibrotic; therefore, we examined the role of SphK2$^{-/-}$ CD4$^{+}$ T cells in fibrosis. Transfer of CD4$^{+}$ T cells from SphK2$^{-/-}$ to WT or SphK1$^{-/-}$ mice attenuated the progression of fibrosis (less trichrome staining 14d after FA) in the recipients. Treatment of SphK2$^{-/-}$ mice with blocking IFN-γ Ab resulted in more FA-induced fibrosis compared to control IgG-treated mice. Additionally, IFN-γ$^{-/-}$ or SphK2$^{-/-}$/IFN-γ$^{-/-}$ double KO mice had more fibrosis compared to WT and SphK1$^{-/-}$ mice after FA and/or unilateral IRI. Treatment of WT mice with a SphK2 inhibitor (SKX002411, 3mg/kg; SphynKx Therapeutics) 2d after FA lowered fibrosis compared to vehicle- treated mice.

**Conclusions:** In summary 1) susceptibility to fibrosis is similar in WT and SphK1$^{-/-}$ mice but SphK2 deficiency or SK2 inhibitor attenuates fibrosis, and 2) the protective phenotype in SphK2$^{-/-}$ mice is dependent on IFN-γ. Understanding the function of SphK2 may contribute further to our understanding of the pathogenesis of fibrosis. Development of selective SphK2 inhibitors may lead to a new therapeutic strategy to impede or reverse the progression of kidney injury to ESRD.

### TH-PO549

**Different Roles for the Three AKT Isoforms in TGF-β Induced Fibrogenesis** Benaya Rozen-zvi, H. William Schnaper, Tomoko Hayashida. *Pediatrics, Northwestern Univ Feinberg School of Medicine, Chicago, IL.*

**Background:** The transforming growth factor (TGF)-β pathway is known to activate phosphoinositide 3-kinase (PI3K) and its main target, AKT. We have reported that this activity has complex regulatory effects on TGF-β-induced fibrogenesis. Since the three isoforms of AKT may have different and sometimes conflicting biological actions, here we evaluated the role of specific isoforms in TGF-β-induced collagen expression.

**Methods:** Collagen expression was evaluated in TGF-β-treated human mesangial cells (HMC) in which the three isoforms were silenced transiently or stably by shRNA. We also treated HMC with a pan-AKT inhibitor (AKT inhibitor X) and a more selective inhibitor that acts only on AKT1 and AKT2 (AKT inhibitor VIII). In addition, we evaluated mouse embryonic fibroblast (MEF) from mice null for AKT1 or for both AKT1 and AKT2. Collagen expression was evaluated by reporter assay and western blot. Smad3 and GSK3-β phosphorylation were evaluated by western blot.

**Results:** TGF-β-induced collagen expression was increased by stably or transiently silencing AKT2. In contrast, silencing AKT3 and, to a lesser degree, AKT1, inhibited collagen expression. Treatment with the pan-AKT inhibitor prevented TGF-β-induced collagen expression, whereas treatment with the AKT1/2-specific inhibitor was stimulatory. In similar fashion, collagen expression was increased in AKT1/2-null MEF but was reduced in AKT1 null MEF. As Smad3 phosphorylation and nuclear translocation were not changed in any of the conditions tested, the effect of the different AKT isoforms on TGF-β-induced collagen induction appears to be Smad3 independent. Inactivating phosphorylation of glycogen synthase kinase 3 (GSK3)-β was reduced by silencing AKT3 but not by silencing AKT1 or AKT2.

**Conclusions:** AKT3 activity is essential for TGF-β-induced collagen expression while AKT2 has an inhibitory effect. AKT1 inhibition reduces collagen expression, possibly by increasing AKT2 activity. Since GSK3-β activity is known to be antifibrotic, the antifibrotic effect of AKT3 inhibition may occur through enhanced GSK3-β activity. Selective inhibition of AKT3 is a potential target for anti-fibrotic therapy.

**A Splice Site Mutation in Mouse *Col4a4*: Detection of Abnormal Collagen IV Protomers, and Effects of Genetic Background on the Alport Syndrome Phenotype** Jeffrey H. Miner,[1] Christina R. Caputo,[2] Susan A. Cook,[2] Roderick T. Bronson,[2] Muriel T. Davisson,[2] Ron Korstanje.[2] *[1]Renal Div, Washington Univ, St. Louis, MO; [2]The Jackson Laboratory, Bar Harbor, ME.*

**Background:** A spontaneous autosomal recessive mutation termed bilateral wasting kidneys (*bwk*) was identified in a colony of NONcNZO recombinant inbred mice. Mutants exhibit a rapid increase of urinary albumin at an early age associated with glomerulosclerosis, interstitial nephritis, and tubular atrophy. The mutation was hypothesized to affect a gene important for kidney function, so we set out to map and identify the mutation.

**Methods:** Mapping of the mutation in an intercross with CAST/EiJ mice identified a location on Chromosome 1 containing the *Col4a3* and *Col4a4* genes, for which mutations in the human orthologs cause the hereditary glomerulonephritis Alport syndrome. *Col4a3* was ruled out as the affected gene because animals carrying both *bwk* and *Col4a3* null mutations were normal. The *Col4a4* gene was therefore sequenced.

**Results:** We identified a G to A mutation in the conserved GT splice donor of *Col4a4* intron 30, resulting in skipping of exon 30 but maintenance of the reading frame. Protein and histological analyses showed that mutant collagen α3α4α5(IV) protomers were secreted and formed NC1 hexamers in the GBM, but levels were low, and Alport GBM lesions were still observed. Moving the mutation into the more renal damage-prone DBA/2J and 129S1/SvImJ genetic backgrounds showed differences in albuminuria and its rate of increase, suggesting an interaction between the *Col4a4* mutation and modifier genes.

**Conclusions:** This novel mouse model of Alport syndrome is the only one shown to accumulate abnormal collagen α3α4α5(IV) in the GBM, a phenomenon observed in a subset of Alport patients. These mice will serve as a valuable new tool for testing potential therapies, for understanding abnormal collagen IV structure and assembly, as well as for gaining better insights into the mechanisms leading to Alport syndrome and to the great variability in the age of onset and associated phenotypes.

### TH-PO551

**Selective Delivery of Interferon Gamma to Renal Interstitial Myofibroblasts Reduces Renal Fibrosis** Fariba Poosti,[1] Ruchi Bansal,[3] Jai Prakash,[3] Eduard Post,[2] Catharina Reker-Smit,[2] Pieter A. Klok,[1] Geert Harms,[1] Marian L.C. Bulthuis–van der Horst,[1] Klaas Poelstra,[2] Jan-Luuk Hillebrands.[1] *[1]Pathology, Univ Medical Center Groningen, Groningen, Netherlands; [2]Pharmacokinetics, Toxicology and Targeting, Univ of Groningen; [3]MIRA Institute, Univ of Twente, Enschede, Netherlands.*

**Background:** Although mechanisms underlying the pathogenesis of renal fibrosis have been uncovered, yet no therapies are available that specifically target fibrosis. IFNγ is a potent antifibrotic cytokine to halt & inhibit fibrosis. However, administration of IFNγ may cause systemic side effects. Interstitial myofibroblasts are key effector cells in renal

fibrogenesis. We here tested the hypothesis that cell-specific delivery of IFNγ to platelet-derived growth factor receptor beta (PDGFRβ)-expressing myofibroblasts attenuates renal fibrosis & reduces systemic side effects.

**Methods:** PDGFRβ expression was determined in fibrotic mouse and human kidney by specific staining. IFNγ conjugate (IFNγ-PEG-PPB) was synthesized by coupling of PDGFRβ-specific peptide (PPB) to IFNγ via a PEG linker. The biological activity & anti-fibrotic effects were analyzed *in vitro*. Anti-fibrotic effects of targeted (IFNγ-PEG-PPB) and free IFNγ were investigated in the unilateral ureteral obstruction (UUO) model in C57BL/6 mice at 3 & 7 days.

**Results:** PDGFRβ expression was highly upregulated in mouse & human fibrotic kidneys. PDGFRβ expression co-localized with αSMA-positive myofibroblasts. In vitro, IFNγ-PEG-PPB induced NO release in RAW cells (indicative of biological activity) & inhibited expression of col1a1, col1a2 and αSMA in fibrotic NIH 3T3 fibroblasts. In vivo, IFNγ-PEG-PPB specifically accumulated in the PDGFRβ-positive myofibroblasts. IFNγ-PEG-PPB treatment induced a significant reduction of renal collagen I, fibronectin and αSMA expression (both at mRNA & protein level), and was more effective than non-targeted IFNγ. In contrast to non-targeted IFNγ, IFNγ-PEG-PPB did not induce IFNγ–related side effects.

**Conclusions:** Specific targeting of IFNγ to PDGFRβ-expressing myofibroblasts attenuates renal fibrosis without causing adverse effects in an experimental for renal fibrosis in mice.

## TH-PO552

**Contribution of Hydrogen Peroxide-Inducible Clone-5 to the Regulation of Mesangial Cell Proliferation in Mesangioproliferative Glomerulonephritis** Ariunbold Jamba,[1] Shuji Kondo,[1] Maki Urushihara,[1] Takashi Nagai,[1] Toshiaki Tamaki,[2] Shoji Kagami.[1] *[1]Dept of Pediatrics, Institute of Health Bioscience, Univ of Tokushima, Tokushima, Japan; [2]Dept of Pharmacology, Univ of Tokushima, Tokushima, Japan.*

**Background:** Hydrogen peroxide-inducible clone-5 (Hic-5) is a transforming growth factor (TGF)-β1-inducible focal adhesion protein homologous to paxillin. We have previously demonstrated that Hic-5 was localized in mesangial cells (MC) and its expression has been associated with glomerular cell proliferation and matrix expansion in rat and human glomerulonephritis (GN) (Nephron Exp Nephrol 120: e59-68, 2012).

**Methods:** The potential role of Hic-5 was investigated in cell proliferation and extracellular matrix (ECM) expression in mesangioproliferative GN produced by injection of Habu venom (4 mg/kg) into heminephrectomized wild type (Hic-5+/+) and Hic-5 deficient (Hic-5-/-) mice. In addition, we examined how Hic-5 is involved in MC proliferation using isolated cultured MC from Hic-5+/+ and Hic-5-/- mice.

**Results:** Habu venom-induced GN in Hic-5+/+ mice demonstrated glomerular cell proliferation at day 7. Surprisingly, glomerular cell number was significantly increased in Hic-5-/- GN mice compared to Hic-5+/+ GN mice ($P<0.01$). Ki-67 positive cells as well as expressions of fibronectin and alpha-smooth muscle actin were also increased in Hic-5-/- GN mice compared to Hic-5+/+ GN mice ($P<0.01$). In vitro experiments about MC proliferation by cell counting and WST-8 assay showed that Hic-5-/- MC significantly proliferated compared to Hic-5+/+ MC. Interestingly, TGF-β1 induced proliferation in Hic-5-/- MC but did not in Hic-5+/+ MC. In contrast, PDGF-BB, another growth factor, increased both Hic-5+/+ and Hic-5-/- MC in the same degree. These data suggest that Hic-5 might be a specific downstream molecule of TGF-β1 to control MC proliferation in glomerular injury. Finally, Hic-5-/- MC showed increased level of phospho-paxillin$^{118}$, which has mitogenic potential, suggesting competitive role of Hic-5 against paxillin signaling for MC growth.

**Conclusions:** In conclusion, Hic-5 might regulate MC proliferation under TGF-β1 stimulation in the development of mesangioproliferative GN.

## TH-PO553

**AMP-Kinase Activation by AICAR Inhibits Renal Fibrosis and Inhibits Transforming Growth Factor-β1 Induced Activation of Kidney Myofibroblasts** Kuan-hsing Chen, Hsiang-Hao Hsu, Ming-Yang Chang, Cheng-chieh Hung. *Nephrology, Chang Gung Memorial Hospital, Taoyuan, Taiwan.*

**Background:** Activation of interstitial myofibroblasts and excessive production of extracellular matrix proteins are final common pathways contributing to chronic kidney disease. In a number of tissues, AMPK (AMP-kinase) activation has been shown to inhibit fibrosis *in vitro*. Here, we examined the effect of an AMPK activator, AICAR, on inhibiting the progression of renal fibrosis *in vivo* and TGF-β1 activation of renal interstitial fibroblasts *in vitro.*

**Methods:** Urinary unilateral obstruction (UUO) model was induced in adult male BALB/c mice. Mice with UUO were given with intra-peritoneal AICAR (500 mg/Kg body weight/day) or saline daily, one day prior the UUO surgery. Both obstructed and contralateral kidneys were harvested 7 days after surgery. Kidney tissues were prepared for further pathological and molecular biological analysis. Cultured rat renal interstitial fibroblasts (NRK-49F) were stimulated with recombinant human TGF-β1 1ng/ml. Alternatively, NRK-49F cells were pre-incubated with AICAR or specific inhibitors for 30 mins before TGF-β1 treatment. Total RNA was extracted for RT-PCR or real-time PCR and total cell lysates were extracted for Western Blot analysis.

**Results:** In a mouse model of renal interstitial fibrosis induced by unilateral ureteral obstruction (UUO), administration of AICAR attenuated the extracellular matrix protein deposition following injury. AICAR suppressed the expression α-smooth muscle actin (α-SMA), type I collagen and fibronectin in UUO kidney. Treatment of cultured rat renal interstitial fibroblasts with AICAR inhibited their activation by TGF-β1, as evidenced by dose-dependent blockade of α-SMA and collagen I expression. Moreover, the effects of AICAR in inhibition of kidney myofibroblast activation by TGF-β1 were associated with down-regulation of ERK 1/2 MAPK pathways.

**Conclusions:** Thus, our results suggest that AICAR reduces the tubulointerstitial fibrosis in UUO mice and inhibits TGF-β1 induced kidney myofibroblast activation. The AMPK activation by AICAR may hold therapeutic potential in the treatment of renal tubulointerstitial fibrosis.

*Funding:* Government Support - Non-U.S.

## TH-PO554

**The Cannabinoid Receptor 1 Is Involved in Renal Fibrosis** L. Lecru,[1] J. Giron-Michel,[1] C. Desterke,[4] S. Ferlicot,[1] C. Ledent,[3] S. Vandermeersch,[2] B. Charpentier,[1] C. Chatziantoniou,[2] A. Durrbach,[1] H. Francois.[1] *[1]INSERM U1014, Villejuif; [2]INSERM U702, Paris; [3]Univ Libre de Bruxelles, Brussels; [4]INSERM U972, Villejuif.*

**Methods:** To explore new pathways involved in renal fibrogenesis, we performed a microarray analysis during the Unilateral Ureteral Obstruction (UUO) experimental model of renal fibrosis. Unexpectedly, the Cnr1 gene expression, coding for the cannabinoid 1 receptor (CB1R), was found higher during UUO ($p<0.01$, n=6). We decided to determine the role of CB1 during renal fibrogenesis in both mice and humans.

**Results:** The CB1R expression is increased during various nephropathies in human kidney biopsies (Acute Interstitial Nephritis, IgA and diabetic nephropathies) (n=6 compared to normal kidneys, $p<0.05$). Similarly, in the UUO model in mice, using both genetic disruption of Cnr1 (KO mice) and a specific CB1R pharmacological blockade (rimonabant-treated mice, R), we found a 33 to 65% reduction in the collagen accumulation (12.90±0.94% versus 8.50±0.81% in WT versus KO, $p<0.01$, n=6-11; 9.62±1.82% in vehicle mice compared with 4.25±0.61% in R, $p<0.01$, n=7), with no modulation of TGFb1 expression. Mesenchymal markers such as vimentin were reduced in both KO (n=6-11, $p<0.05$) and R mice (n=7, $p<0.05$). Interestingly, obstructed kidneys of R but not KO presented a reduction of F4/80$^+$ cells infiltrating the kidney cortex with a significantly reduced expression of M1 markers compared to controls (n=7, $p<0.05$ and n=7, $p<0.05$). Conversely, KO mice presented an increase of M2 markers in kidneys (n=6-11, $p<0.05$) suggesting that CB1 genetic invalidation promoted a macrophage type M2 polarization. Also, as CB1 and CB2 may exert opposite effects, we investigated the role of CB2 during UUO as its expression is also increased ($p<0.01$, n=11). However, both CB2 agonist and antagonist treatment did not modify fibrogenesis during UUO when associated with CB1 pharmacological blockade ($p<0.05$, n=7) suggesting that the anti-fibrotic effect of CB1 blockade is independent of the CB2 pathway.

**Conclusions:** Overall, CB1 blockade represents a new anti-fibrotic strategy during renal disease and may act in part through resident macrophages signaling.

## TH-PO555

**Ets-1 Targeted by MicroRNA-221 Regulates Angiotensin II-Induced Renal Fibroblast Activation** Jia Di, Chunsun Dai, Junwei Yang. *2nd Affiliated Hospital, Nanjing Medical Univ, Nanjing, China.*

**Background:** Fibroblast activation is one of the most important non-hemodynamic effects of Angiotensin II (Ang II) on the progression of renal fibrosis. Transcription factor Ets-1 is a transcription factor up-regulated in fibrosis. However, the mechanisms of Ets-1 activation in fibrotic kidney are not fully understood.

**Methods:** Mice were subcutaneously administered with Ang II at a dose of 1.4mg/kg body weight daily via osmotic mini-pumps. At day 28, mice were killed with their kidney harvested. Cultured normal rat kidney interstitial fibroblast (NRK-49F) was incubated with Ang II at different doses for various time periods.

**Results:** Ang II administration resulted in renal interstitial fibrosis at day 28. Ets-1 protein expression was up-regulated in fibrotic kidney, which is located mainly in interstitial spaces. Similarly, Ang II activated cultured NRK-49F as demonstrated by up-regulated α-SMA and fibronectin expression and increased cell migration. Ang II induced Ets-1 expression in cultured NRK-49F in a dose and time dependent manner. Knock-down of Ets-1 by RNA interference attenuated Ang II-induced activation of NRK-49F. Ets-1 was previously reported as a target of microRNA-221 (miR-221). In Ang II-induced fibrotic kidney, miR-221 was markedly down-regulated. Similar results were observed in Ang II treated NRK-49F. Ectopic expression of miR-221 attenuated the up-regulation of Ets-1 by Ang II in cultured NRK-49F, which further prevented the activation of NRK-49F. However, Knock-down of miR-221 aggravated Ang II induced Ets-1 expression and NRK-49F activation.

**Conclusions:** Ets-1 mediates Ang II-induced renal fibroblast activation, whose up-regulation is probably resulted from the derepression after the down-regulation of miR-221 in activated fibroblast.

## TH-PO556

**Loss of Endothelial Nitric Oxide Augments Renal Fibrosis via Promoting Local Fibroblast Proliferation** Jinhua Li,[1] Yu Bo Yang Sun,[1] Xinli Qu,[1] David J. Nikolic-Paterson.[2] *[1]Dept of Anatomy and Developmental Biology, Monash Univ, Australia; [2]Dept of Medicine, Monash Univ, Australia.*

**Background:** Deficiency in nitric oxide synthase 3 (NOS3/eNOS) exacerbates renal injury in the remnant kidney and diabetic nephropathy. Nitric oxide (NO) is a potent vasodilator released by the endothelium which suppresses vascular smooth muscle cell growth and inhibits platelet aggregation. This study investigated whether the loss of endothelial-derived NO contributes to renal interstitial fibrosis through promoting local fibroblast proliferation.

**Methods:** Unilateral ureteral obstruction (UUO) and STZ-induced diabetic nephropathy were performed in wild type (WT) and NOS3-/- C57BL/6J mice.

**Results:** Within 6hr of UUO surgery in WT mice, Western blotting showed a marked reduction in total NOS3 levels. Interstitial fibroblast proliferation was first seen at 48hr in WT UUO, indicating that endothelial injury proceeds interstitial fibroblast proliferation. Compared to WT mice, UUO in NOS3-/- mice had significantly increased accumulation of α-smooth muscle actin (α-SMA)+ myofibroblasts and a higher level of myofibroblast proliferation (Ki67+α-SMA+ cells), which was associated with increased deposition of collagen I and fibronectin. Similarly, STZ-induced diabetes resulted in greater accumulation of α-SMA+ myofibroblasts and higher levels of myofibroblast proliferation compared to WT mice. In vitro, the supernatant from mouse microvascular endothelial cells (MMECs) in which NO production was blocked by L-NAME, significantly increased the proliferation of renal fibroblasts (NRK49F) compared to normal media. Also, fibroblasts stimulated by hypoxia (5% oxygen) or PDGF-BB showed greater proliferation in the presence of L-NAME-treated supernatant. Finally, the supernatant from MMECs overexpressing NOS3 significantly inhibited PDGF-BB-induced proliferation of NRK49F cells. Since the half-life of NO is less than 5 seconds, this effect is likely through an indirect pathway.

**Conclusions:** In summary, our studies show that endothelial NO production is a powerful regulator of fibroblast proliferation and renal fibrosis.

*Funding:* Government Support - Non-U.S.

## TH-PO557

**Role of Interactions between the Slit Diaphragm and Glomerular Basement Membrane in Alport Syndrome** Diana Rubel, Jenny Kruegel, Rainer Girgert, Gerhard A. Mueller, Oliver Gross. *Nephrology & Rheumatology, Univ Medicine Goettingen, Goettingen, Germany.*

**Background:** Heterozygous Podocin-mutations and -polymorphisms can aggravate the phenotype of heterozygous carriers of type IV collagen mutations (COL4A3/4/5) with an unusual early onset of renal failure. This points toward an interaction between the slit diaphragm and glomerular basement membrane (GBM), which appears essential for podocytes´ structure and function. In the present study, we report about COL4A3-, integrin α2β1 (ITGA2)- and DDR1- single (sKO), double (dKO) and triple knockout (tKO) mice, respectively, and its effect on slit diaphragm proteins.

**Methods:** COL4A3$^{-/-}$, ITGA2$^{-/-}$, DDR1$^{-/-}$ and their respective dKO, as well as tKO and wildtype (WT) mice were investigated at different ages using real-time PCR, light and electron microscopy and immunogoldhistochemistry.

**Results:** In sKO mice, the relative expression of nephrin and podocin was strongly reduced compared to WT. Their expression in COL4A3/ITGA2 or COL4A3/DDR1 dKO and tKO, was comparable to WT till 4.5 weeks of age and decreased by 7.5 weeks. These results were consistent with a longer survival, later progress of kidney fibrosis and maintenance of podocyte footprocesses. In immunogoldhistochemistry, quantity of nephrin and podocin in 4.5 week COL4A3$^{-/-}$ was comparable to WT, but podocin accumulated in the areas of podocyte effacement in an age-dependent manner.The same accumulation was found in tKO at a later stage of disease. Nephrin increased in tKO in areas of still preserved footprocesses.

**Conclusions:** In conclusion, the impaired GBM in Alport-mice has an impact on podocyte function and development of fibrosis. Nephrin and podocin expression is strongly regulated by impaired GBM composition as well as altered signaling to the collagen IV receptors integrin α2β1 and DDR1. The knockout of these collagen receptors in Alport-mice results in preserved expression of nephrin and podocin proteins. Knowledge about the regulatory mechanisms of these interactions could lead to a better understanding of the podocyte behavior in pathological processes, the impact of GBM maturation on podocytes and direct to new therapeutic targets for glomerular diseases.

## TH-PO558

**MMP-9-Dependent Notch Signalling Contributes to Endothelial-Mesenchymal Transition in Kidney Endothelial Cells** Ye Zhao,[1] Yun Zhang,[3] Jianlin Zhang,[2] Guoping Zheng,[1] David C. Harris.[1] *[1]The Univ of Sydney; [2]Shanxi Medical Univ; [3]First Teaching Hospital of Shanxi Medical Univ; [4]Children's Hospital at Westmead, Sydney.*

**Background:** Endothelial-mesenchymal transition (EndoMT) has been shown to be a major source of myofibroblast formation in kidney fibrosis. Previously we showed that MMP-9 induced EndoMTin glomerular endothelial cells. This study investigated whether Notch signaling plays a role MMP-9-induced EndoMT.

**Methods:** Mouse renal peritubular endothelial cells (MRPEC) were isolated by magnetic microbead separation using anti-CD146 Ab. MRPECs were co-cultured with tubular epithelial cells over a polyester insert to maintain their phenotype. Human renal glomerular endothelial cells (HRGEC) and MRPECs were treated with TGF-β1 to induce EndoMT. EndoMT was assessed by morphological changes, immunofluorescence staining and Western blot (WB) of endothelial (CD31 and VE-cadherin) and mesenchymal markers (α-SMA and vimentin). Snail expression and Notch signaling were examined by RT-PCR and WB. MMP-9 expression was examined by zymography.

**Results:** TGF-β1 (10 ng/ml) and recombinant MMP-9 (2 μg/ml) induced EndoMT in HRGEC and MRPEC as evidenced by significant downregulation of VE-cadherin & CD31 and upregulation of α-SMA & vimentin. Recombinant MMP-9 also induced EndoMT in both HRGECs and MRPECs with upregulation of Notch signaling evidenced by an increase of Notch intracellular domain (NICD) accompanied by a decrease of Notch 1. Inhibition of MMP-9 or Notch signaling demonstrated a dose-dependent response in preventing TGF-β1-induced α-SMA and NICD in HRGECs. MMP-9 deficiency also led to a significant reduction in TGF-β1-induced NICD and α-SMA proteins in MRPECs of MMP-9 KO mice.

**Conclusions:** MMP-9-dependent Notch signaling plays an important role in TGF-β1-induced EndoMT in mouse renal endothelial cells.

*Funding:* Government Support - Non-U.S.

## TH-PO559

**ASK1-p38/JNK Signalling Promotes Renal Fibrosis and Apoptosis in the Obstructed Mouse Kidney** David J. Nikolic-Paterson,[1,2] Frank Yuanfang Ma.[1,2] *[1]Dept of Nephrology, Monash Medical Centre, Clayton, Victoria, Australia; [2]Dept of Medicine, Monash Univ, Clayton, Victoria, Australia.*

**Background:** Apoptosis signal-regulating kinase 1 (ASK1) is a member of the large mitogen-activated protein kinase kinase kinase (MAP3K) family. ASK1 is activated in response to oxidative stress and then can activate the downstream stress-activated protein kinases, p38 and JNK, which have been implicated in promoting renal fibrosis. The aim of this study was to determine whether ASK1 plays a role in p38/JNK signalling and interstitial fibrosis in experimental kidney disease.

**Methods:** Unilateral ureteric obstruction (UUO) was induced in groups of 6 wild type (WT) and ASK1 gene deficient (Ask1-/-) and mice. Mice were killed on day 7 after UUO.

**Results:** Western blotting of WT UUO kidney identified a 3-5 fold increase in the levels of phosphorylation of ASK1, p38, and JNK compared to the non-obstructed kidney. The WT UUO kidney exhibited marked accumulation of α-SMA+ myofibroblasts and macrophages together with increased deposition of collagen IV, up-regulation of mRNA levels for pro-fibrotic (Col I, Col IV, α-SMA, PAI-1, TGF-β1) and pro-inflammatory molecules (CCL2), and increased tubular and interstitial cell apoptosis. In contrast, increased activation of p38 and JNK signalling was prevented in Ask1-/- UUO mice (P<0.001 vs WT UUO). Ask1-/- UUO mice were protected from renal fibrosis on the basis of: □29% in α-SMA+ myofibroblasts (P<0.001 vs WT UUO); □53% in macrophage accumulation (P<0.001); □43% in collagen IV deposition (P<0.001), and; □40-51% mRNA levels of pro-fibrotic and pro-inflammatory molecules (all P<0.05). In addition, apoptosis of tubular epithelial cells and interstitial cells was significantly reduced in Ask1-/- UUO (□37% and □41%, respectively; both P<0.05). However, Ask1-/- UUO kidney showed no protection from tubular injury based on KIM-1 mRNA levels.

**Conclusions:** This study defines ASK1 as an important upstream activator of p38 and JNK signalling in the obstructed kidney, and identifies ASK1 as a potential therapeutic target in renal fibrosis.

*Funding:* Government Support - Non-U.S.

## TH-PO560

**Kruppel-Like Factor 15 Modulates Renal Interstitial Fibrosis by ERK/MAPK and JNK/MAPK Pathways Regulation** Xiang Gao, Changlin Mei, Guiqun Wu. *Kidney Institute of PLA, Changzheng Hospital, Second Military Medical Univ, Shanghai, China.*

**Background:** Renal interstitial fibrosis is a hallmark of progressive chronic kidney disease (CKD). Previous studies reported that kruppel-like factor 15 (KLF15) is an important regulator of cardiac fibrosis and could reduce the expression of extracellular matrix in mesangial cells. However, the role of this transcription factor in renal interstitial fibrosis has not been reported.

**Methods:** In this study, we examined KLF15 expression in the remnant kidney of 5/6 nephrectomized rats 12 or 24 weeks after operation. In vitro we examined the effect of altered KLF15 expression on the production of extracellular matrix and the pro-fibrotic factor CTGF in rat renal fibroblasts (NRK-49F), and further explored the related mechanisms.

**Results:** The level of KLF15 was drastically decreased in the renal interstitium of 5/6 nephrectomized rats with progressive interstitial fibrosis, especially at 24 weeks. Our in vitro evidence showed that overexpression of KLF15 repressed basal and TGF-β1-induced extracellular matrix and CTGF in NRK-49F cells. In addition, transforming growth factor-β1 (TGF-β1)-mediated activation of extracellular-regulated kinase (ERK) / mitogen-activated protein kinase (MAPK) and Jun N-terminal kinase (JNK) /MAPK downregulated KLF15 expression and increased the level of extracellular matrix and CTGF, and all these effects were completely abolished by ERK1/2 inhibitor and JNK inhibitor in NRK-49F cells.

**Conclusions:** Our findings implicate that KLF15 plays an important role and may prove to be an antifibrotic factor in renal interstitial fibrosis through regulation of ERK/MAPK and JNK/MAPK signaling pathways.

*Funding:* Government Support - Non-U.S.

## TH-PO561

**The Interstitial Compartment in Kidney Disease: Toxin and Fluid-Rich, with Biological Significance?** Leonard Ebah, Shiv Bhutani, Paul E. Brenchley, Sandip Mitra. *Renal Medicine and Renal Research, Manchester Royal Infirmary, Manchester, United Kingdom.*

**Background:** Fluid and (uremic) toxins are retained in chronic kidney disease (CKD), with their accumulation in plasma (P) and its impact extensively studied. Little attention has been paid to interstitial fluid (IF) and toxin accumulation and their potential physiological impact. We studied IF biochemical composition and mechanical properties in CKD patients.

**Methods:** Microdialysis (MD), reverse iontophoresis (RI), subcutaneous cannulae and microneedles were used to sample IF in CKD patients.IF pressure was measured by the wick-in-needle technique and volume by bioimpedance. Comparisons were made with plasma and with healthy controls.

**Results:** IF volume was significantly expanded in CKD patients with edema (mean difference with controls 9L; p=0.0009), with plasma and intracellular volumes being similar. IF in CKD patients was a high pressure compartment; mean 4.6±1mmHg (-0.9mmHg in controls; p=0.0005). A novel parameter, the edema refill time (ERT) correlated strongly with IF pressure and volume . Small uremic toxins seemed to circulate relatively freely between IF and plasma, with high IF:P correlations for urea, creatinine, urate and phosphate in "steady states" (r=0.74-0.98). Hemodialysis (HD) induced a difference in the IF and plasma decay curves, especially for phosphate where IF decay seemed to lag behind that of plasma (p=0.04). Paired metabolomic (LCMS/MS) analysis identified at least 36 "small" uremic toxins up to 444Da with similar IF:P ratios. Proteomics revealed a clearly different large molecule expression between P and IF, with IF accumulation of several molecules including known large uremic toxins such as beta-2 microglobulin, complement factor D, IgG kappa light chain, cystatin C and retinol binding protein (IF: P normalized relative abundance 1.5 -10.2).

**Conclusions:** Volume accumulation in CKD is mainly in IF, a high pressure compartment with mechanical properties potentially defined by the ERT. IF is toxin-rich, with small toxins circulating freely between plasma and IF although IF toxin decay on HD may lag behind, with potential implications for dialytic efficacy. Large uremic toxins may be "sequestered" in IF in spite of deceptively "normal" plasma levels.

## TH-PO562

**Oral Treatment with PBI-4050 Reduces Kidney Fibrosis** Lyne Gagnon, Brigitte Grouix, Kathy Hince, Lilianne Geerts, Liette Gervais, Mikaël Tremblay, François Sarra-Bournet, Alexandra Felton, Shaun Abbott, Jean-Simon Duceppe, Martin Leduc, Boulos Zacharie, Christopher Penney, Pierre Laurin. *ProMetic BioSciences Inc., Laval, Canada.*

**Background:** PBI-4050 is a first-in-class novel orally active compound which displays anti-inflammatory/antifibrotic activities via a novel mechanism of action. PBI-4050 has demonstrated strong anti-fibrotic activities in different kidney fibrosis animal models. PBI-4050 plays a key role in inflammation/fibrosis regulation by reducing pro-fibrotic cytokines, fibrocyte differentiation, myofibroblast activation and epithelial–mesenchymal transition (EMT) resulting in improvement of organ function.

**Methods:** PBI-4050 was tested in the following animal models: 5/6-nephrectomized rats (end-stage renal failure), doxorubicin-induced nephrotoxicity and renal ischemia (acute kidney injury), and db/db mice (diabetic kidney disease).

**Results:** PBI-4050 reduces fibrosis via the regulation of macrophages, T cells, fibrocytes/fibroblasts/myofibroblasts and epithelial cells. In a pro-fibrotic phase, PBI-4050 plays a regulation role by promoting a Type 1, anti-fibrotic cytokine production phenotype in macrophages and T cells, resulting in a reduction of the over-expression or over-production of TGF-β, MCP-1, CTGF, IL-4, IL-13 and IL-23. Interestingly, MCP-1 is also an important inducer of fibrocyte precursor migration in tissue. Fibrocyte differentiation, resident fibroblast activation and EMT are the key sources of activated myofibroblasts and successive accumulation of extracellular matrix protein deposition and fibrosis. PBI-4050 inhibits fibrocyte differentiation, fibroblast activation and EMT as demonstrated by a reduction in alpha smooth muscle actin (α-SMA), collagen I and fibronectin mRNA expression. PBI-4050 also plays a role in tissue remodeling by regulating MMP and TIMP expression.

**Conclusions:** Taken together, these preclinical results suggest that PBI-4050 offers the potential as a novel therapy for the treatment of kidney fibrosis.

## TH-PO563

**The RNA-Binding Protein QUAKING Is a Potent Modulator of the Fibrogenic Response to Kidney Injury** Ruben de Bruin,[1] Eric P. Van der Veer,[1] Hetty C. de Boer,[1] Janine van Gils,[1] Roel Bijkerk,[1] Jacques Duijs,[1] Erik Biessen,[2] Ton J. Rabelink,[1] Anton Jan Van Zonneveld.[1] *[1]Nephrology, LUMC; [2]Pathology, MUMC.*

**Background:** Chronic progressive kidney diseases are characterized by tubule-interstitial deposition of extracellular matrix, tubular atrophy and dilation. Recruitment of circulating monocytes to sites of tissue injury leads to the local generation of cytokines and growth factors that promote fibroblast activation, proliferation and production of extracellular matrix. We have identified Quaking (QKI) as a novel post-transcriptional regulator of both monocyte and fibroblast activation and differentiation, implicating a central position in the pathogenesis of renal fibrosis.

**Results:** Following FACS sorting of human $CD14^{++}CD16^{-}$, $CD14^{++}CD16^{+}$ and $CD14^{+}CD16^{+}$ monocyte subpopulations, we identified that QKI mRNA is moderately expressed in $CD14^{++}CD16^{-}$ monocytes, while QKI is potently induced in the activated $CD16^{+}$ monocytes (n=3, p<0.05). Importantly, the differentiation of monocytes to macrophages by GM-CSF was coupled with a further increase in QKI expression (n=6, p<0.05). Abrogation of QKI in THP-1 and U937 monocytes using lentiviral shRNA reduced cellular adhesion in a cell perfusion assay that simulates endothelial denudation (p<0.05,n=6). In parallel, we investigated the consequences of reduced QKI protein levels in human renal fibroblasts (TK173), which yielded marked attenuation of cellular proliferation, and a perturbed capacity to acquire the myofibroblast phenotype in response to TGF-β1, as evidenced by decreased SM-α-actin expression as compared to control cells (n=3, p<0.05). Finally, we performed unilateral urethral obstruction on mice hypomorphic for QKI (quaking viable). These studies revealed a two-fold reduction in macrophage (F4/80 and CD115) and fibroblast (collagen, FSP-1 and SM-α-actin) marker expression as compared to wild-type mice (n=6, p<0.05).

**Conclusions:** Collectively, we identified that QKI serves as a double-edged sword in renal interstitial fibrosis, as it possesses the capacity to drive critical events in both myeloid and mesenchymal cells.

## TH-PO564

**Glomerular Fibrosis Revisited: Podocyte Injury Shuts Down *Col1a2* mRNA, Leading to Abnormal Collagen Accumulation** Masahiro Koizumi, Masafumi Fukagawa, Taiji Matsusaka. *Tokai Univ School of Medicine, Japan.*

**Background:** Type I collagen (ColI) accumulates in sclerotic glomeruli, which is often ascribed to transcriptional upregulation of the *Col1* genes. On the other hand, our microarray analysis indicated that normal mouse glomeruli abundantly express *Col1a2* mRNA, which is markedly decreased after podocyte injury. Normal ColI is composed of two a1(I)and one a2(I) chains. It has been shown that *Col1a2* mutant mice abnormally accumulate $a1(I)_3$ homotrimer, forming glomerulosclerosis. We, therefore, hypothesized that podocyte injury downregulates *Col1a2* mRNA, which leads to accumulation of ColI.

**Methods:** Glomerular *Col1a2* mRNA was quantified by RT-PCR in immunotoxin-inducible podocyte injury mice (NEP25, n=9). *Col1a2* transcriptional activity was also monitored, utilizing *Col1a2-EGFP* mice (n=12).

**Results:** Glomerular *Col1a2* mRNA was decreased to 24% 7 days after induction of podocyte injury, while *Col1a1* mRNA did not change. In non-injured *Col1a2-EGFP* mice, EGFP was intensely expressed in podocytes and mesangial cells. Unlike previous reports, immunostaining detected intense ColI in normal glomeruli. We next induced various degrees of podocyte injury in *NEP25/Col1a2-EGFP*. Two weeks after high dose toxin, most glomeruli were severely injured with podocyte loss, mesangial expansion and mesangiolysis. EGFP almost disappeared in them. ColI staining also declined in the lesion of mesangiolysis. Two weeks after moderate dose toxin, EGFP declined in both podocytes and mesangial cells in glomeruli containing injured podocytes, with EGFP area being 15.9±7.7%, but not in normal glomeruli (30.5±9.8%, p<0.05). Eight weeks after mild podocyte injury, FSGS was established, where EGFP disappeared in sclerotic glomeruli, in which ColI was intensely stained.

**Conclusions:** Collectively, podocyte injury suppresses *Col1a2* mRNA in both podocytes and mesangial cells. The latter, in severe case, causes mesangiolysis. Our study also suggests that prolonged suppression of *Col1a2* may induce accumulation of MMP-resistant $a1(I)_3$ homotrimer, thereby leading to the characteristic phenotype of glomerulosclerosis.

## TH-PO565

**A Selective JAK3 Inhibitor, CP690,550, Suppresses Bone Marrow-Derived Fibroblast Activation and Renal Fibrosis** Jingyin Yan, William E. Mitch, Yanlin Wang. *Dept of Medicine, Div of Nephrology, Baylor College of Medicine, Houston, TX.*

**Background:** Renal fibrosis is the final common manifestation of chronic kidney disease resulting in progressive loss of kidney parenchyma and renal function. We have recently demonstrated that bone marrow-derived fibroblast precursors contribute significantly to the pathogenesis of renal fibrosis. However, the signaling mechanisms underlying the activation of bone marrow-derived fibroblast precursors in the kidney are not fully understood. In this study, we investigated the role of JAK3/STAT6 signaling pathway in the activation of bone marrow-derived fibroblasts using a selective JAK3 inhibitor, CP690,550.

**Methods:** We examined the role of JAK3/STAT6 signaling in monocyte-to-fibroblast transition in vitro and myeloid fibroblast activation and renal fibrosis induced by unilateral ureteral obstruction.

**Results:** In cultured mouse monocytes, profibrotic cytokines IL-4 and IL-13 activated STAT6 and induced expression of α-smooth muscle actin and extracellular matrix proteins (fibronectin and type I collagen), which was blocked by CP690,550. Obstructive injury led to activation of STAT6 in the interstitial cells of the kidney, which was abolished by treatment with CP690,550. Furthermore, mice treated with CP690,550 accumulated fewer bone marrow-derived fibroblasts in the kidneys after the obstructive injury compared with vehicle-treated mice. Finally, treatment with CP690,550 significantly reduced myofibroblast activation and suppressed expression of fibronectin and type I collagen in response to the obstructive injury.

**Conclusions:** Our results demonstrate that JAK3/STAT6 signaling plays an important role in the activation of bone marrow-derived fibroblasts during the development of renal fibrosis. CP690,550 may serve as a novel therapeutic agent for the treatment of chronic kidney disease.

## TH-PO566

**Matrix Metalloproteinase 12 Directly Act on the Proliferation and Extracellular Matrix Production of Renal Fibroblasts** Beáta Szebeni,[1,2] Leonora Himer,[1,2] Erna Szikszs,[1,2] Domonkos Pap,[2] Anna Ónody,[2] Andrea Fekete,[3] Yoichiro Iwakura,[4] Gyorgy S. Reusz,[2] Tivadar Tulassay,[1,2] Adam Vannay.[1,2] *[1]Research Laboratory for Paediatrics and Nephrology, SE-HAS, Budapest, Hungary; [2]First Dept of Paediatrics, SE, Budapest, Hungary; [3]SE-HAS, Budapest, Hungary; [4]Center for Experimental Medicine, Institute of Medical Science, Univ of Tokyo, Tokyo, Japan.*

**Background:** Chronic kidney diseases (CKDs) affect millions and are leading cause of morbidity and mortality in the western word. Renal fibrosis is an uncontrolled wound-healing process defined by excessive deposition of the extracellular matrix (ECM). Recently the determinative role of interleukin (IL)-17 has been suggested in matrix metalloproteinases (MMP) dependent ECM remodeling. However, the role of MMP12 in progressive kidney diseases is still unknown.

**Methods:** Unilateral ureteral obstruction induced (UUO) mice model of renal fibrosis on C57Bl/6J (WT) and IL17 KO mice and HK2 proximal tubular epithelial (PTEC) and NRK49F renal fibroblasts were used in our experiments.

**Results:** 5 days after the onset of UUO the number of IL17+ T cells was elevated in the kidney. Simultaneously the number of MMP12 positive PTECs increased in WT but not in IL17 KO mice. IL17 treatment of the HK2 cells resulted in a JNK dependent increase in the number of MMP12+ cells. rMMP12 treatment of NRK49F cells increased the proliferation and collagen production of the fibroblasts. Specific MMP12 inhibitor treatment of WT animals decreased the level of renal αSMA and collagen1.

**Conclusions:** Our data suggest that PTECs are responsible for the production of MMP12 in the fibrotic kidney. According to our observations MMP12 may be a link between inflammation and the severity of renal fibrosis. Moreover, beside the previoulsy hypothetised role of MMP12 on ECM degradation we suggest that MMP12 may directly act on renal fibrosis by inducing proliferation and ECM production of renal fibroblasts.

## TH-PO567

**Proximal Tubule PPARalpha Attenuates Renal Fibrosis and Inflammation Caused by Unilateral Ureteral Obstruction (UUO)** Shenyang Li,[1,2] Nithya Mariappan,[1,2] Judit Megyesi,[1,2] Brian B. Shank,[1,2] Sue Theus,[2] Peter M. Price,[1,2] Jeremy Stuart Duffield,[3] Didier Portilla.[1,2] *[1]Medicine/ Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR; [2]Medicine, Central Arkansas Veterans Healthcare Systems, Little Rock, AR; [3]Medicine, Univ of Washington, Seattle, WA.*

**Background:** Previous studies suggest that activation of proximal tubule PPARα reduces inflammation and ameliorates tissue fibrosis but the mechanisms involved are not clear.

**Methods:** We compared the effects of UUO on wild type and proximal tubule PPARα Tg mice and also examined the effects of increased PPARα expression using adenovirus transduction in cultured mouse proximal tubules exposed to aristolochic acid.

**Results:** After 5 days of UUO PPARα expression was significantly reduced in kidney tissue of wild type mice but this downregulation was attenuated in PPARα Tg mice. When compared with wild type mice subjected to UUO, PPARα Tg mice had reduced mRNA and protein expression of proximal tubule TGFβ1, with reduced production of extracellular matrix proteins including collagen 1, fibronectin, α-SMA, and reduced tubulo-interstitial fibrosis. UUO-mediated increased expression of microRNA 21 in kidney tissue was also reduced in PPARα Tg mice. Over-expression of PPARα in cultured proximal tubular cells by adenoviral transduction reduced aristolochic acid(AA)-mediated increased production of TGFβ, collagen4, and laminin B demonstrating PPARα prevented AA-induced TBM degradation. Flow cytometry studies of dissociated whole kidneys demonstrated reduced macrophage infiltration to kidney tissue in PPARα Tg mice after UUO. Increased expression of pro-inflammatory cytokines including IL1-β, IL-6, and TNF-α in wild type mice was also significantly reduced in kidney tissue of PPARα Tg mice. In contrast, the expression of anti-inflammatory cytokines IL-10 and Arginase-1 was significantly increased in kidney tissue of PPARα Tg mice when compared with wild type mice subjected to UUO.

**Conclusions:** Our studies demonstrate several mechanisms by which preserved expression of proximal tubule PPARα reduces tubulo-interstitial fibrosis and inflammation associated with obstructive uropathy.

## TH-PO568

**Myeloid Cells-Derived Tissue-Type Plasminogen Activator Promotes Renal Fibrosis and Inflammation** Ling Lin, Kebin Hu. *Dept of Medicine, Penn State Univ College of Medicine, Hershey, PA.*

**Background:** Tissue-type plasminogen activator (tPA), a serine protease up-regulated during chronic kidney disease, has been shown to promote renal fibrosis and inflammation by activating various signaling cascades. However, the origin and the responsible cells of the activated tPA signaling remain unknown.

**Methods:** We created chimeric mice that lack tPA in either their myeloid cells or renal parenchyma by bone marrow transplantation between tPA wild-type (WT) and knockout (KO) mice using the following donor/recipient combinations: WT/WT, WT/KO, KO/WT, and KO/KO, and subjected these mice to unilateral ureteral obstruction for 7 days, followed by evaluation of renal damages, fibrosis, and inflammation.

**Results:** It was found that WT/WT and WT/KO mice displayed similar level of tubulointerstitial injuries, fibrosis, and inflammation as demonstrated by HE staining, Western blot or immune fluorescence staining for α-SMA and collagen1, as well as quantitative PCR for chemokines. However, KO/WT and KO/KO mice showed lower level of damages and decreased fibrosis and inflammation than that from WT/WT and WT/Ko mice, suggesting that mice that lack of tPA in the myeloid cells were protected from fibrotic and inflammatory injuries.

**Conclusions:** Thus, it is persumable that myeloid cells contribute to tPA signaling in response to chronic kidney injury.

## TH-PO569

**Fibrogenic Pathways Are Activated by the Macrophage Phagocytic Receptor CD36 with Apoptotic Cell Clearance** Daryl M. Okamura,[1] Lixia Zeng,[2] Ikuyo Yamaguchi,[1] Subramaniam Pennathur.[2] *[1]Dept of Pediatrics, Div of Nephrology, Seattle Childrens Research Institute, Seattle, WA; [2]Dept of Internal Medicine, Div of Nephrology, Univ of Michigan, Ann Arbor, MI.*

**Background:** The progression of chronic kidney disease is due to a maladaptive wound healing response where tubular apoptosis and macrophage activation are two important processes. The removal of apoptotic cells is an innate function of tissue macrophages (mphi), however, its role in disease progression is unclear.

**Methods:** The present study was designed to investigate the role of mphi CD36, a recognized receptor of apoptotic cells, by unilateral ureteral obstruction (UUO). In order to differentiate the mphi CD36-specific effects in vivo, we generated CD36 chimeric mice by bone marrow transplantation and performed UUO surgery: CD36 ko/wt (donor/recipient) with chimeric controls.

**Results:** CD36 expression is up-regulated with M2 activation. After UUO, CD36 mphi comprise 30-50% of the phagocytic subpopulation. Following phagocytosis of apoptotic cells, there was 65-75% reduction in TNF-a and TGF-b mRNA levels in CD36-/- compared to CD36+/+ mphi. Fibrosis severity was decreased by 41% and fibronectin and procollagen mRNA levels were decreased by 40-50% in CD36 ko/wt mice at day 14. There was a 30% decrease in NF-kB activation in CD36 ko/wt mice at day 14 after UUO compared to CD36 wt/wt mice. There was a 60-70% reduction in kidney TGF-b and TNF-a mRNA levels in CD36 ko/wt mice after UUO. Since oxidized phospholipids/lipids are the major ligands for CD36, we measured the level of apoptotic cells by TUNEL staining. We found that there was a 56% increase in TUNEL+ cells in CD36 ko/wt at day 14 despite a reduction in fibrosis severity. Furthermore, mphi isolated from UUO kidneys demonstrated that there was 40-50% reduction in lipid hydroperoxides and a 60-70% reduction in F2 isoprostane levels in CD36-/- mice compared to CD36+/+ mice at day 14.

**Conclusions:** These data suggest that mphi CD36 is a critical regulator of fibrogenic signaling and extracellular matrix expansion during chronic kidney injury and suggests that oxidative mechanisms may play a key role in mediating these pathways.

## TH-PO570

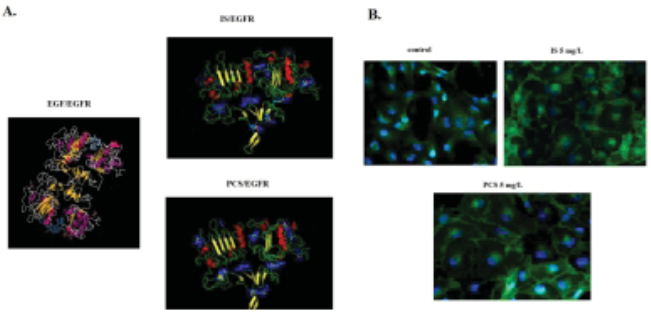
**Tissue Remodeling Induced by Indoxyl Sulfate and *p*-Cresol Sulfate: Roles of Epidermal Growth Factor Receptor Activation** Chiao-Yin Sun. *Nephrology, Chang Gung Memorial Hospital, Keelung, Taiwan.*

**Background:** Uremic toxins have determinant roles in the progression of chronic kidney disease clinically. Indoxyl sulfate (IS) and p-cresol sulfate (PCS) could cause renal fibrosis by activating RAAS. Epidermal Growth Factor (EGF) is known for its role in promoting cell cause proliferation and matrix deposition. It is hypothesized that EGFR activated by IS and PCS might cause renal tissue remodeling and fibrosis.

**Methods:** Cultured renal tubular cells (HK2) and B-6 mice with ½-nephrectomy were used for this study. EGFR activation was analyzed by dimerlization and phosphorylation of EGFR. The downstream signal proteins of EGF pathway and the expression of MMP2 and MMP9 were quantified *in vitro* and *in vivo*.

**Results:** Docking models for the putative interaction between IS/PCS and EGFR were made based on the x-ray structure of extra-cellular domains of EGFR. The results showed that IS/PCS interacted with extracellular domains of EGFR near the EGF binding site by the hydrophobic force. EGFR diamerlization and phosphrylation increased by IS and PCS *in vitro*. IS and PCS activated EGFR downstream signaling proteins (Jak1, and Stat1/3) *in vitro.* Increased cell membrane localization of EGFR was noted *in vitro*.

**Figure 1.**



IS and PCS increased MMP2 and MMP9 expression *in vitro,* which was antagonized by N-acetylcystein and EFGR inhibitor. *In vivo* study with 1/2 nephrectomy mice showed that IS and PCS significantly increased the serum EGF concentration and renal EGFR phosphorylation. IS and PCS also increased renal MMP2 and MMP9 expression significantly *in vivo*.

**Conclusions:** It was suggested that IS and PCS could activate EGFR via a ligand independent and dependant pathway by direct EGFR biding and increasing EGF level. The EGFR activation might induce renal tissue remodeling by increasing the expression of MMPs.

## TH-PO571

**Participation of WNT Protein in Acute Kidney Injury** Akihiro Kuma, Tetsu Miyamoto, Ryota Serino, Narutoshi Kabashima, Masahito Tamura, Yutaka Otsuji. *The Second Dept of Internal Medicine, School of Medicine, Univ of Occupational and Environmental Health, Kitakyushu, Fukuoka, Japan.*

**Background:** Acute kidney injury (AKI) can recover or progress to chronic kidney disease (CKD) or end-stage renal disease. Furthermore, kidney fibrosis which is not effectively treated can lead to renal failure. WNT family proteins have been implicated in organ fibrosis. Although previous studies revealed the expression of WNT10A in fibroblasts, the mechanisms of such expression have been elusive. We focused on kidney fibrosis following interstitial fibrosis in AKI and investigated the function of WNT10A protein in kidney fibroblasts.

**Methods:** Expressions of WNT10A were confirmed by immunohistochemical staining in kidney biopsy tissue from 25 male AKI patients (age, ≥60 years) who were received biopsy to diagnose cause of AKI in the past 6 years. *In vitro,* we used COS1(kidney fibroblasts of African green monkey) transfection of WNT10A plasmid (COS1-W10). The COS1-W10 was investigated cell survival ability and proliferation against oxidative stress and high glucose stress.

**Results:** 10 Patients with WNT10A expression had a significantly lower estimated glomerular filtration rate than 15 WNT10A-negative patients (15.2 ± 8.5 vs 46.5 ± 36.9 mL/min per 1.73m$^2$, p = 0.015). COS1-W10 exhibited cell survival ability against oxidative stress induced hydrogen oxide ($p < 0.05$), and the COS1-vector reduced the proliferation rate in high-glucose medium (11mM and 22mM) compared with low-glucose medium (5.5mM). However, COS1-W10 maintained proliferation ability in high-glucose medium ($p < 0.05$).

**Conclusions:** WNT10A protein protects fibroblasts from oxidative stress and high glucose stress. Taken together, expression of WNT10A protein in kidney fibroblasts in AKI might lead to CKD. Therefore, inhibition of WNT10A protein can improve kidney function in AKI patients and prevent progression to kidney dysfunction.

## TH-PO572

**Hyaluronan Exacerbates Renal Fibrosis in NZB/W Mice through Increased Monocyte Chemoattractant Protein-1 and Transforming Growth Factor-β1 Secretion by Mesangial Cells** Susan Yung, Wan Wai Tse, Mel Chau, Daniel Tak Mao Chan. *Dept of Medicine, The Univ of Hong Kong, Hong Kong.*

**Background:** Lupus nephritis is characterized by the production of anti-dsDNA antibodies and immune-mediated renal injury leading to glomerular and tubulointerstitial fibrosis. We have previously demonstrated that circulating hyaluronan (HA) level and glomerular HA expression are increased in patients and lupus-prone mice with active lupus nephritis, and are associated with increased glomerular matrix protein accumulation. This study investigates the role of HA on disease manifestations and renal fibrogenesis in a murine model of lupus nephritis.

**Methods:** Pre-disease female NZB/W mice were randomized to receive sterile PBS or high molecular weight HA by tail-vein injection (1mg/ml, 200µl) once weekly for periods up to 24 weeks, after which the mice were sacrificed, blood and urine collected, and kidneys harvested to assess renal histology and expression of fibrosis mediators. Mesangial cells were isolated from the renal cortex of NZB/W mice to investigate the mechanisms that mediate increased HA synthesis.

**Results:** Treatment of mice with HA had no effect on survival, proteinuria or anti-dsDNA antibody level compared to control mice, but was associated with increased glomerular IgG and C3 deposition, significantly increased glomerular and tubulointerstitial expression of HA receptor CD44, MCP-1, TGF-β1, fibronectin and collagen type I from 18 to 24 weeks. Exogenous HA for 24h had no effect on mesangial cell proliferation, but significantly increased CD44, HA synthase III, fibronectin, laminin and collagen synthesis, in part through the induction of MCP-1 and TGF-β1 secretion ($P<0.01$ for both). Stimulation of mesangial cells with exogenous MCP-1 and TGF-β1 significantly increased cell associated and secreted HA levels respectively ($P<0.05$ for both).

**Conclusions:** These results suggest that HA plays a significant role in renal fibrosis of lupus nephritis by inducing MCP-1 and TGF-β1 secretion, which in turn increase HA synthesis resulting in a positive feedback loop that amplifies the fibrotic process.

*Funding:* Government Support - Non-U.S.

## TH-PO573

**Periostin Staining as Novel Biomarker in Progressive Glomerular Injury** Bancha Satirapoj,[1] Wiwat Charungkiattikul,[1] Peepattra Wantanasiri,[2] Prajej Ruangkanchanasetr,[1] Naowanit Nata,[1] Ouppatham Supasyndh,[1] Panbubpa Choovichian.[1] *[1]Div of Nephrology, Dept of Medicine, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand; [2]Dept of Pharmacy Practice, Faculty of Pharmaceutical Sciences, Bangkok, Thailand.*

**Background:** Glomerulonephritis (GN) is a progressive kidney injury and is a common form of kidney disease. Periostin, a recently characterized matricellular protein participating in the tissue remodeling, is markedly induced in renal injury. There is limited information about periostin expression in GN.

**Methods:** In this study involving 49 patients with IgA nephropathy (IgAN) (n=12), lupus nephritis (LN) (n=33) and minimal change disease (MCD) (n=4), periostin was stained by immunohistology in renal biopsies. Perisotin expression and intensity was studied with other kidney injury markers. Progression kidney injury, assessed as declining of glomerular filtration rate (GFR), was evaluated during follow-up.

**Results:** Periostin expression was predominantly located in the injured regions and the sites of fibrosis including periglomerular and tubulointerstitial areas. Periostin staining had significantly increased patients with LN (14.97±8.41, p=0.02) and IgAN (18.50±9.69, p=0.01) when compared to MCD patients (5.80±4.76). Periositn staining correlated positively with renal activity index in GN patients. It also correlated positively with renal chronicity index in GN and LN patients. By multivariate analysis, renal periostin were inversely related to GFR. After a median follow-up of 34 weeks, a trend for higher declining of GFR was found in patients with higher periostin scores (-0.19 (IQR -1.21 to 0.46) vs -0.05 (IQR -0.54 to 4.36) mL/min/1.73 m$^2$/month, p=0.239), and higher periostin scores were not predictor of end stage renal disease.

**Conclusions:** Periostin is markedly induced in glomerular disease and the levels correlated positively with the severity of renal lesions. Periostin staining may serve as a marker of progressive glomerular injury.

## TH-PO574

**Antisense Oligonucleotides Targeting Kirsten Ras Reduce Interstitial Fibrosis and Protect Kidney Function in the Chronic Folic Acid Nephropathy Model** Lucy Jade Newbury,[1] Gene Hung,[2] Bruce M. Hendry,[1] Claire C. Sharpe.[1] *[1]Dept of Renal Sciences, Kings College London, London, United Kingdom; [2]Isis Pharmaceuticals, Carlsbad, CA.*

**Background:** Previously we have demonstrated the importance of Kirsten Ras (Kras) in the pathogenesis of renal fibrosis secondary to ureteric obstruction. In this study we have characterised a novel mouse model of chronic folic acid nephropathy (CFAN) and have used antisense oligonucleotides (ASO) to silence Kras expression within this model. Here we report the effects of these ASOs on interstitial fibrosis and renal function.

**Methods:** CFAN model: Male CD1 mice were given Folic acid (FA) 125mg/kg IV in $NaHCO_3$ on day 0 (d0) and d21. Shams received $NaHC0_3$. CFAN and Shams were sacrificed at d35, d56 and d85 for model characterisation. Therapeutic study: CFAN groups received saline (vehicle) or ASO (20mg/kg) SC 3X per week from d35 reducing to 2X per week from d49 and were sacrificed at d85.

**Results:** CFAN model: Induction of fibrosis was seen at d56 and d85 with a 3.4 fold mean increase in collagen staining and a 2 fold increase in collagen mRNA by D85 associated with a doubling of Kras mRNA (p= 0.0016, n=11). An induction of α-SMA expression was seen at d56 and d85 of 2.2 and 1.6 fold respectively (n=3); IHC showed diffuse α-SMA expression in fibrotic areas, co-localising with collagen deposition. Therapeutic study: ASO resulted in a knockdown of Kras of 43% compared to saline treated (p= 0.0185, n=7). IHC for ASO showed marked accumulation of the ASO in the proximal tubules and interstitium. Total area of fibrosis, as measured by collagen deposition, was reduced by 37% on PMT staining and 27% on PSR staining in ASO-treated groups compared with saline mice (n=7). ASO-treatment was associated with a 70% reduction in serum creatinine and 40% reduction in Blood Urea Nitrogen at d85 compared with saline. (p=0.053/p=0.0693, n=7).

**Conclusions:** In this study we have demonstrated that Kras inhibition inhibits renal fibrosis in a new model of CFAN. We have also shown that this is associated with an improvement in renal function. We conclude that targeting Kras may prove to be a useful therapeutic tool for treating human chronic kidney disease.

## TH-PO575

**Modulating Alternative Splicing of Fibronectin with Antisense Oligonucleotides** Felicia Heidebrecht,[1] Vaishnavi Gnanananthan,[1] Benjaman To,[1] Frank Rigo,[2] Susan M. Freier,[2] Mark Edward Dockrell.[1] *[1]SWT Institute for Renal Research, London, United Kingdom; [2]Isis Pharmaceuticals, Carlsbad, CA.*

**Background:** The EDA+ splice variant of fibronectin(Fn) is an important component of fibrotic extracellular matrix facilitating fibroblast activation and collagen deposition. Directing the alternative splicing away from EDA inclusion could provide a therapy to limit fibrosis. The aim of this study was to test the possibility of modulating the TGFβ-induced Fn splicing using RNase-H independent antisense oligonucleotides(ASO).

**Methods:** In a pilot study 20 ASOs targeting overlapping sequences within both exon-intron junctions were assessed for their ability to inhibit EDA+ protein and mRNA in primary tubule epithelial cells. Selected ASOs were administered pre and post TGFβ1

challenge as a model of therapeutic intervention. Expanding the study we analysed further 42 ASOs covering the whole exon, including splicing enhancer and silencer sites, and assessed their effects on EDA+ and EDA- splice variants.

**Results:** From the pilot study an ASO designated ASO5 reproducibly inhibited EDA+ mRNA and protein expression. Furthermore, treatment with ASO5 post TGFβ1 inhibited a number of TGFβ-induced fibrotic markers including αSMA & MMP9. Many ASOs that showed a switch in the splicing (reducing EDA+ > 3 fold and inducing EDA- 2 to 3.5 fold) did so in the presence of TGFβ stimulation or the effect in shifting the balance away from EDA+ was stronger with TGFβ. Thus, this is an attractive therapeutic approach as it alters the ratio EDA+/EDA- when TGFβ is present. The best sites for ASO-mediated splicing modulation were not predicted a priori. This might reflect the role of the 3-D structure of the mRNA on the accessibility of a target sequence and efficacy in splicing inhibition.

**Conclusions:** These observations together with striking differences between various ASOs including ASOs with a high degree of overlap demonstrate the importance of complete screening for finding the most effective sequence. Detailed analysis of this screening could highlight unknown regulatory sequences. Altering Fn splicing using ASO may provide an effective therapy by inhibiting EDA+ production and limiting subsequent fibrogenesis.

## TH-PO576

**Gremlin1 Displays Differential Affinities for Bone Morphogenetic Proteins – Implications for Diabetic Nephropathy** Derek P. Brazil,[1] Rachel Church,[1] Arjun Krishnakumar,[1] Stefan Geschwinder,[2] Barbro Basta,[2] Maria Stromstedt,[2] Finian Martin.[3] *[1]Centre for Vision and Vascular Science, Queen's Univ, Belfast, United Kingdom; [2]UCD Conway Institute, Univ College, Dublin, Ireland; [3]AstraZeneca, Gothenburg, Sweden.*

**Background:** Gremlin1 is a secreted glycoprotein that limits the action of bone morphogenetic proteins (BMP) in multiple cell types in the body. Grem1 dimers bind directly to BMP dimers preventing binding to their membrane receptors. Our group has shown that levels of Grem1 increase in the kidneys of patients with DN, and correlate well with decreased renal function. We also demonstrated that mice lacking one copy of the *grem1* gene are partially protected from early DN-like changes.

**Methods:** Therefore, the aim of this project was to determine the relative affinities of Grem1 for various pro- and anti-fibrotic BMPs in vitro and in vivo.

**Results:** Surface plasmon resonance (Biacore) kinetic and affinity analysis allowed a rank order of affinity for Grem1 to be determined with BMP-2>2/7>4 >4/7 >6>7. In HK-2 cells, the addition of 25ng/ml rhGrem1 caused complete inhibition of pSmad1/5/8 phosphorylation, whereas cells treated with rhBMP-4 required 200ng/ml rhGrem1 for maximal inhibition. Consistently, higher concentrations of Grem1 were required to inhibit BMP4-mediated Id1 and Smad6 gene expression in HK2 cells compared to BMP2, with little or no inhibition of BMP7 responses seen. Overexpression of Grem1 inhibited BMP2 and 4, but not BMP7-mediated Smad1/5/8 phosphorylation. Analysis of *grem1*-/- mice on a mixed genetic background showed that these mice survive post-natally, are smaller, and develop only one kidney that is larger than wild-type controls and display tubular damage.

**Conclusions:** Our data suggest that in the extracellular milieu of the diabetic kidney, secreted Grem1 is more likely to bind BMP2 than BMP4. In addition, *grem1*-/- mice are viable and will be further analysed to determine which BMPs are involved during the critical stages of BMP-driven kidney development. These mice will also be useful tools to determine if the absence of Grem1 in the kidney can protect against DN, further validating current efforts to target Grem1 protein in human kidney disease.

## TH-PO577

**Automated Quantitation of Interstitial Fibrosis by Sirius Red Staining/ Polarization Microscopy Is More Objective Than Masson Trichrome** Jonathan Street, Alejandro Alvarez-Prats, Taro Horino, Xuzhen Hu, Robert A. Star, Peter S.T. Yuen. *NIDDK, NIH, Bethesda, MD.*

**Background:** Histological measurement of interstitial fibrosis by Masson Trichrome staining is only *semi*-quantitative because of subjective scoring by an ordinal scale, which limits statistical power. Sirius Red staining enhances the birefringence of type I and III collagen fibrils which appear bright against a dark background with polarization contrast microscopy. This striking contrast is more amenable to automated analysis than the subtle color differences of Masson Trichrome. An automated technique to measure the fibrotic area might also reduce operator-dependent error and reduce variability.

**Methods:** Paraffin-embedded kidney sections from a folic acid injury model (21 mice) were stained with Masson Trichrome and scored by two independent observers. Adjacent sections were stained with Sirius Red and then imaged at 100x magnification using polarization contrast microscopy. Images were collated by Leica software, and a Fiji/ ImageJ script was developed to set thresholds, based on a histogram-shape based analysis, and quantitate fibrosis within the region of interest.

**Results:** The intra-observer correlation for Sirius Red was r = 0.919 (n = 16) compared to r = 0.607 (n = 42) for Masson Trichrome. The correlation for Sirius Red scores between the left and right kidney for a) 20 high power fields or b) the whole kidney sections were r = 0.960 and r = 0.971 (n = 7), respectively. For Masson Trichrome the correlation between left and right kidneys for 20 high power fields was r = 0.866 (n = 7). The correlation for Masson Trichrome measured on 20 high power fields and Sirius Red measured on 20 high power fields or whole kidney sections were r = 0.789 and 0.478 (n = 7) respectively.

**Conclusions:** Sirius Red staining is an objective and quantitative technique with superior reproducibility compared to Masson Trichrome. Sirius Red staining is reproducible on both entire kidney sections as well as 20 high power fields. Analysis of entire kidney sections is more easily automated and would support high-throughput preclinical screening of anti-fibrotic therapeutics and validation of non-invasive biomarkers for interstitial fibrosis.

## TH-PO578

**Comprehensive Analysis of Hypoxia-Regulated Gene Transcripts in Chronic Kidney Disease and Renal Cells** Natallia Shved,[1] Maja Lindenmeyer,[1] Simone Brandt,[2] Matthias Kretzler,[3] Peter Wild,[2] Clemens D. Cohen.[1] *[1]Univ of Zurich, Zurich, Switzerland; [2]Univ Hospital Zurich, Zurich, Switzerland; [3]Univ of Michigan, Ann Arbor.*

**Background:** Most chronic kidney diseases (CKD) are initiated as glomerular damage with loss of glomerular capillaries. The best morphologic indicator of disease progression and development of end-stage renal disease, however, is interstitial fibrosis accompanied by capillary rarefaction. As hypoxia has been associated with fibrosis the question arises whether renal cells indeed face hypoxia in CKD and respond with a transcriptional program which could lead to progression of renal disease.

**Methods:** Proximal tubular cells (HK-2 cells) and podocytes with stable hypoxia-induced transcription factors (HIF1a and/or HIF2a) suppression were generated. Gene expression profiles from cell lines and more than 160 renal biopsies from patients with different CKD stages were obtained using Affymetrix arrays.

**Results:** Expression of hypoxia-associated genes in genome-wide expression profiles revealed correlation of HIF-target genes with eGFR in the cortical tubulointerstitium and glomerular samples. These correlations were both positive and negative and in part compartment-specific. To study the celltype-specific response to hypoxia and the relevance of given HIFs we investigated gene expression profile of HK-2 cells and podocytes with stable HIF1α and/or HIF2α suppression under hypoxic conditions. In HK-2 cells microarray analysis revealed 163 (86% HIF1α and/or HIF2α dependent) significantly upregulated and 31 (81%) downregulated hypoxia target genes. In podocytes, 416 (47% HIF1α and/or HIF2α dependent) genes were significantly up- and 318 (95%) significantly downregulated. To validate the results on protein level immunohistochemistry of HIF-target genes in human biopsies with different eGFRs was established and showed a similar pattern to correlation analysis.

**Conclusions:** Our gene expression studies do not indicate an over-all hypoxic milieu in acquired kidney diseases. However, the data clearly point to compartment- and celltype-specific dysregulation of hypoxia-associated gene transcripts.

## TH-PO579

**Transcriptome Analysis of Human Hypertensive Chronic Kidney Disease Highlights the Role of Peroxisome Proliferator-Activated Receptor (PPAR) Pathway in Tubulointerstitial Fibrosis** Hyun Mi Kang,[1] Peter Choi,[1] Jianling Tao,[1] Sang Youb Han,[2] Ae Seo Deok Park,[1] Yi-An Ko,[1] Katalin Susztak.[1] *[1]Renal Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia; [2]Dept of Medicine, Ilsan Paik Hospital, Korea.*

**Background:** Hypertensive chronic kidney disease (H-CKD) is the second most common cause of end stage renal disease in the United States. Very little is known about the pathomechanism of H-CKD. Here we perform gene expression analysis on tubule samples obtained from control, hypertensince and H-CKD patients to catalogue differentially expressed genes and pathways. The results were compared mouse models of kidney fibrosis.

**Methods:** Human kidney tissues (n=92) were obtained from elective nephrectomies and they were grouped based on the clinical and histological parameters. Tubular epithelial cells were isolated by manual microdissection. Affymetrix GeneChip expression arrays (U133A 2.0) were used to analyze transcript levels. We also cultured renal epithelial primary cells from control and H-CKD samples. The results were compared mouse models of non-diabetic kidney fibrosis induced by Notch overexpression or folic acid administration.

**Results:** We identified 1,792 differentially expressed probesets in CKD tubules, with 1372 unique gene transcripts. Among them, the probesets with the highest fold change were albumin, EGF, and uromodulin known to play a role in CKD. Pathway analysis highlighted differences in PPAR alpha and gamma signaling. Lipid oxidation, mitochondrial biogenesis and lipid synthesis pathways were also differentially expressed. We also found that these pathways are also regulated in mouse models of fibrosis induced by folic acid administration or Notch1 overexpression. PPARa seems to have a direct role in fibrosis development as cells treated with PPARa agonist showed significantly reduced the expression of fibronectin, collagen1, SMAD7 and aSMA following TGFb1 treatment.

**Conclusions:** This is the first genome wide transcriptome analysis of tubular epithelial cells in human hypertensive nephropathy. These results demonstrate that PPAR pathways are regulated in the H-CKD and PPAR agonists could present a novel treatment approach in H-CKD patients.

## TH-PO580

**Thrombin Activated Fibrinolysis Inhibitor (TAFI) Inhibition Increases Survival and Halts the Progression of Renal Fibrosis in the Rat 5/6th Subtotal Nephrectomy Model** John M. Atkinson,[1] Nick Pullen,[2] Timothy Scott Johnson.[1] *[1]Sheffield Kidney Institute, United Kingdom; [2]Pfizer PGRD.*

**Background:** Previously we reported that application of the TAFI inhibitor UK-396082 increased plasmin activity & reduced ECM levels Induced by high glucose treatment of NRK52E cells.

**Methods:** To test whether TAFI inhibition could inhibit renal fibrosis and improve renal function, we tested UK-396082 in the 5/6th sub-total nephrectomy (SNx) rat in preventative & remission treatment arms. Rats were fed normal rat chow or chow containing UK-396082 (60mg/kg/d) from day (d)14 post SNx (prevention, p) or 35 (remission, r).

**Results:** Serum TAFI activity increased & plasmin activity decreased in untreated SNx animals. UK-396082 reduced TAFI activity (-45%/-30%, p/r) & increased plasmin activity (+52%/+52%). 16% of untreated SNx rats survived to d60 c.f. 80% treated from d14. 75% of SNx rats receiving UK-396082 from d35 survived to d60 c.f 27% left untreated. Creatinine clearance increased (+35%, p), while serum creatinine (-35%/-29% p/r)), proteinuria (-45%/-26%) & urea fell (-65% /-32%). Tubular damage biomarkers NGAL (-31%/-24%, p/r) & KIM-1 (-68.3%/-31.3%) were lower in urine. Scarring was ameliorated as measured by Masson's Trichrome staining (-77%/-45%, tubules/glomeruli) due to decreases in collagens I (-60%/-52%), IV (-57%/-52%) and III (-55%). Collagen reduction was confirmed by total kidney hydroxyproline (-65%). ECM proteins fibronectin (-72%/-46%) and laminin (-11%/-33%) were also lower. UK-396082 had no effect on blood pressure. Supporting the importance of this axis in patients with CKD, TAFI serum activity was also measured. In a mixed cohort of CKD patients, serum TAFI activity was 1.5x elevated c.f normal individuals serum and TAFI activity showed a strong correlation with the extent of renal function impairment.

**Conclusions:** In conclusion, we demonstrate here that TAFI inhibition with UK-396082 is highly effective in the rat SNx model. Collagen reduction suggests some benefit is by protecting plasmin activation of matrix metalloproteinases as collagens are poor plasmin substrates. These data support the hypothesis that TAFI is a potential therapeutic target for CKD.

## TH-PO581

**Biglycan Fragmentation Is Associated to Survival in Patients Undergoing Hemodialysis** Federica Genovese,[1] Diana Julie Leeming,[1] Morten Asser Karsdal,[1] Alexandra Scholze,[3] Martin Tepel.[3] *[1]Biomarkers and Research, Nordic Bioscience, Herlev, Denmark; [2]Nephrology, Institute for Molecular Medicine, Cardiovascular and Renal Research, Odense, Denmark.*

**Background:** Biglycan is a small leucine-rich proteoglycan which is found in the extracellular matrix (ECM) of many organs, including kidneys. It is a key regulator of lateral assembly of collagen fibers and by binding to TGF-β1, biglycan is able to inhibit its activity. MMP mediated tissue turnover has clearly been described to be associated with many connective tissue diseases. BGM is a neo-epitope of biglycan generated by matrix metalloproteinase-9 (MMP-9) degradation and has previously been associated with ECM remodeling in fibrosis.The objective of the study was to investigate the association of plasma BGM levels with survival among hemodialysis patients.

**Methods:** BGM was measured by means of a specific enzyme-linked immunosorbent assay (ELISA) in an observational cohort study of 371 hemodialysis patients followed-up for 5 years. Survival was analyzed in an adjusted Cox model.

**Results:** Hemodialysis patients with a plasma BGM concentration higher than the median of 7.87 ng/mL had increased risk of death (hazard ratio, 1.35; 95% confidence interval, 1.01 to 1.81), with a survival of 388 days compared to 744 days. Multivariable-adjusted Cox regression showed increased odds for death with higher age and higher BGM concentrations.

**Conclusions:** Biglycan fragmentation can lead to TGF- β1 release and activation, with a consequent worsening of the fibrotic process and it is highly deposited in sites affected by fibrosis. This is the first time an association among levels of circulating biglycan fragments and mortality in kidney failure has been observed.

## TH-PO582

**Tamoxifen Ameliorates UUO-Induced Tubulointerstitial Fibrosis by Modulation of Renal TGF-β1/Smad Pathway in Mice** Kyung Pyo Kang, Dal Kim, Aesin Lee, Yujin Jung, Sik Lee, Won Kim. *Internal Medicine, Chonbuk National Univ Medical School, Jeonju, Korea.*

**Background:** After insult to the kidney, renal fibrotic process is initiated with sustained inflammation, activation of matrix-producing fibroblast and accumulation of extracellular matrix, which is part of repair process. Tamoxifen, known as selective estrogen receptor modulator, has been used anti–estrogen for the prevention and treatment of the breast cancer and also has antifibrotic properties. Therefore, we investigated the effect of tamoxifen on unilateral ureteral obstruction (UUO)-induced renal tubulointerstitial fibrosis and their mechanism.

**Methods:** Renal fibrosis was induced by UUO in the six-week-old C57BL/6 mice for 14 days. Tamoxifen (50 mg/kg) was treated by oral for 5 days before induction of renal fibrosis. Histologic examination and Western blot analysis for α-SMA, vimentin, fibronectin and ICAM-1 were performed. We also evaluated TGF-β1/Smad signaling pathway after ureteral obstruction.

**Results:** Renal tubular injury and fibrosis was increased after ureteral obstruction. The number of FSP-1 (+) fibroblast and expression of α-SMA (+) myofibroblast were increased in UUO kidney. Tamoxifen treatment significantly decreased UUO-induced renal tubular injury and fibrosis and also decreased UUO-induced increase of FSP1 (+) fibroblast and α-SMA (+) myofibroblast infiltration. The deposition of extracellular matrix such as type I collagen and fibronectin was increased after ureteral obstruction. Tamoxifen ameliorated UUO-induced increase of extracellular matrix deposition. For evaluation of renal inflammation, ER-HR3 (+) macrophage infiltration and ICAM-1 expression were determined after ureteral obstruction. Tamoxifen treatment significantly decreased UUO-induced increase of ER-HR3 (+) macrophage infiltration and ICAM-1 expression. Finally, tamoxifen was effectively suppressed UUO-induced activation of TGF-β1/Smad signaling pathway.

**Conclusions:** These results suggest that tamoxifen has a beneficial effect on UUO-induced tubulointerstitial fibrosis and inflammation by modulation of renal TGF-β1/Smad pathway.

## TH-PO583

**Silencing of Pericyte MicroRNA-132 Reduces Renal Fibrosis and Myofibroblast Proliferation and Is Associated with Altered Sirt1 and Cox2 Expression** Roel Bijkerk,[1,2] Jacques Duijs,[1] Ton J. Rabelink,[1] Benjamin D. Humphreys,[2] Anton Jan Van Zonneveld.[1] *[1]Nephrology and Einthoven Laboratory for Experimental Vascular Medicine, LUMC, Netherlands; [2]Renal Div, Dept of Medicine, Brigham and Women's Hospital and Harvard Medical School.*

**Background:** Lineage analysis has shown that during nephrogenesis, FoxD1-positive mesenchymal cells give rise to adult interstitial pericytes. These FoxD1-derivative interstitial (FDI) cells expand and differentiate into smooth muscle actin (α-SMA) positive myofibroblasts during renal fibrosis, accounting for a large majority of myofibroblasts. MicroRNAs (miRNAs) involved in this differentiation could serve as a target to decrease myofibroblast formation in fibrotic kidney disease.

**Methods:** Fibrosis was induced in FoxD1-GC;Z/Red mice by unilateral ureteric obstruction (UUO) and FDI cells (dsRed positive) were isolated using FACS sorting. To identify differentially expressed miRNAs we profiled these cells in UUO and healthy controls. To investigate the role of miRNA-132 in vivo in renal fibrosis we injected antagomirs i.v. to silence its function. Mice were sacrificed both 5 and 10 days after surgery.

**Results:** miR-132 was amongst the most highly upregulated miRNAs in the FDI cells in the fibrotic kidney. In vitro we demonstrated that silencing miR-132 results in reduction of myofibroblast marker α-SMA, reduced proliferation and increased levels of its established target Sirt1. In vivo silencing of miR-132 in the UUO model resulted in a 35% decrease in collagen deposition and decreased tubular apoptosis after 10 days as compared to scramblemir controls, while no difference was observed yet after 5 days. IHC analysis demonstrates that the number of interstitial α-SMA positive cells is similarly decreased, which is confirmed by both western blot and qRT-PCR analyses. No difference is observed in capillary density. Surprisingly, silencing miR-132 is associated with reduced levels of Sirt1. Furthermore, we demonstrated that miR-132 silencing decreases the number of proliferating interstitial cells.

**Conclusions:** miR-132 is a new microRNA that regulates pericyte and fibroblast activation during renal fibrosis.

## TH-PO584

**Human Anti-dsDNA Antibodies Induce Amplification Loop of Transforming Growth Factor-β1, Fibronectin and Collagen Type I in Proximal Renal Tubular Epithelial Cells** Daniel Tak Mao Chan, Shirli S.K. Ho, Claudia Ng, Kwok Fan Cheung, Susan Yung. *Dept of Medicine, The Univ of Hong Kong, Hong Kong.*

**Background:** Nephritis affects up to 60% of patients with systemic lupus erythematosus and is characterized by the production of anti-dsDNA antibodies and immune-mediated renal injury. Severity of tubulointerstitial fibrosis is a strong predictor of reduced renal survival. Fibronectin (FN) is amongst the matrix components showing early deposition during the process of tubulointerstitial fibrosis. This study investigates the mechanisms through which FN is induced in renal proximal tubular epithelial cells (PTEC) following stimulation with human anti-dsDNA antibodies, and its role in tubulointerstitial fibrosis of lupus nephritis.

**Methods:** Confluent growth-arrested PTEC were incubated with serum free medium (SFM), control IgG or human polyclonal anti-dsDNA antibodies (10μg/ml) for 24h in the presence or absence of Gö6976 or TGF-neutralizing antibody, and the synthesis of FN assessed. In separate studies, PTEC were stimulated with soluble FN to determine its effect on fibrotic processes.

**Results:** Control IgG had no effect on FN synthesis compared to SFM. Anti-dsDNA antibodies significantly increased cell-associated and soluble FN compared to SFM and control IgG (6.4- and 5.2-fold respectively for cell-associated FN; 1.85- and 1.62-fold respectively for soluble FN, $P<0.01$ for all). This was accompanied by significantly increased TGF-β1 secretion ($P<0.05$), and increased PKC-α ($P<0.05$) and PKC-βII ($P<0.01$) but not PKC-βI phosphorylation. Pre-treatment of PTEC with Gö6976 (20μM) and TGF-neutralizing antibody (100μg/ml) significantly suppressed anti-dsDNA antibody-induced FN ($P<0.01$ for both cell-associated and soluble FN). Incubation of PTEC with soluble FN significantly increased TGF-β1 secretion and collagen type I synthesis in a dose-dependent manner ($P<0.05$ and $P<0.01$ respectively for 10μg/ml soluble FN).

**Conclusions:** These results suggest that anti-dsDNA antibodies induce an amplification loop comprising TGF-β1, FN and collagen type I in PTEC through PKC activation.

*Funding:* Government Support - Non-U.S.

## TH-PO585

**Fibroblast-Specific PAI-1 Depletion Ameliorates Renal Interstitial Fibrosis in Mice after Unilateral Ureteral Obstruction (UUO)** Lan Yao, Laura S. Peterson, Amir Khan, Haichun Yang, Agnes B. Fogo. *Pathology, Microbiology, and Immunology, Vanderbilt Univ Medical Center, Nashville, TN.*

**Background:** Plasminogen activator inhibitor-1 (PAI-1), a member of the serine proteinase inhibitor family,inhibits matrix breakdown and regulates cell migration and proliferation. Systemic PAI-1 knockout mice have decreased interstitial fibrosis after UUO, but worse injury in a crescentic anti-GBM model. Multiplerenal cells express PAI-1 after injury. We explored impact of fibroblast-specific PAI-1 depletion on interstitial fibrosis in the UUO model.

**Methods:** We bred floxed PAI-1 mice with tenascin C Cre mice,in which PAI-1 in fibroblasts can be knocked down after tamoxifenadministration. UUO was performed in *PAI-1$^{loxP/loxP}$*/Cre after tamoxifen treatment (Cre/lox, n=11) and control *PAI-1$^{loxP/loxP}$* mice (Cont*, n=8)*, and kidneys were harvested and injury assessed after 10 days.

**Results:** *PAI-1$^{loxP/loxP}$*/Cre mice showed no PAI-1 immunostaining in fibroblasts and cortex PAI-1 mRNA was decreased 41% in Cre/lox *vs.* control mice. Sirius red staining, a marker of interstitial fibrosis,was decreased in Cre/lox mice (0.88±0.10 *vs.* Cont 1.34 ± 0.16, P<0.05). In parallel, collagen I mRNA was decreased in Cre/lox *vs.* control(0.59± 0.32 *vs.* 1.23± 0.82, P<0.05). The number of fibroblasts in obstructed kidneys, measured by FSP-1 immunostaining, was decreased in Cre/lox mice (21.33 ± 1.7 *vs*. Cont 31.8 ± 1.1/ HPF, P<0.05). Less fibroblast proliferation was found inCre/lox *vs.* control mice, detected by PCNA/α-SMA double staining (Cre/lox 253.4±34.3 *vs.* Cont 405.4 ±53.4/mm2, P<0.05). E-cadherin mRNA level in obstructed kidney cortex, was preserved in Cre/lox mice (Cre/lox 1.55 ± 0.41 *vs*. Cont 1.09 ± 0.5, P<0.05). Surprisingly, F4/80 positive cells were increased in Cre/lox (32.9 ± 1.1 *vs.* Cont 24.1 ± 2.1/HPF, P<0.05).

**Conclusions:** Deletion of PAI-1 in fibroblasts ameliorates interstitial fibrosis, in part by reducing fibroblast proliferation, despite increased macrophage F4/80 infiltration. Whether these cells' phenotype is altered in paracrine fashion by fibroblast PAI-1 knockdown awaits further study.

*Funding:* NIDDK Support

## TH-PO586

**Fibrosis of Kidneys and of Other Solid Organs: Towards a Unifying Classifier across Species** Hans-Peter Marti,[1] James C. Fuscoe,[2] Joshua C. Kwekel,[2] Aikaterini Anagnostopoulou,[3] Andreas Scherer.[4] *[1]Dept of Clinical Medicine, Univ of Bergen, Bergen, Norway; [2]Div of Systems Biology, National Center for Toxicological Research, FDA, Jefferson, AR; [3]Institute of Anatomy, Univ of Bern, Bern, Switzerland; [4]Spheromics, Kontiolahti, Finland.*

**Background:** Fibrosis causes solid organ failure. We described a transcriptomic classifier consisting of metzincins and related genes (MARGS) discriminating renal allograft biopsies with/without fibrosis and extended analyses to non-transplant solid organs (AJT,9:2009; Virchows Arch,458:2011). We have also used our classifier in experimental, lithium-induced nephropathy (Nephrology,17,S2:2012). We now apply our MARGS-based algorithm to a rat model of age-induced interstitial renal fibrosis.

**Methods:** Untreated Fisher 344 rats (n=76) were sacrificed from 2 to 104 weeks of age. For gene expression studies we used single color (Cy3) Agilent Whole Rat Genome 4x44k microarrays; males: n=4 at weeks 2, 5, 6, and 8; n=5 at weeks 15, 21, 78, and 104; females: n =5 at weeks 2, 5, 6, 8, 15, 21, 78 and 104. Intensity data were subjected to variance stabilization including log2 transformation (www.Partek.com). Data were analyzed with ANOVA using gender/age as factors and with Pearson correlation.

**Results:** Fibrosis severity increased with age. Across age groups 60 MARGS were differentially expressed. PCA visualized segregation of age groups by gender from week 6. More MARGS were differentially expressed in older males than in older females. Expression level of MMP-7 correlated best with fibrosis grade. Expression values of 15/19 genes of the original classifier present on the Agilent array, in conjunction with linear discriminant analysis, were sufficient to correctly classify a set of 20 samples - for which gene expression data and fibrosis scores were available - into non-fibrosis (n=4) and fibrosis (n=16). Immunofluorescence confirmed up-regulation of MMP-2, CD44 and osteopontin in fibrosis.

**Conclusions:** Our MARGS classifier represents a cross-organ and cross-species classifier of fibrosis irrespective of etiology. This finding provides evidence for a common pathway leading to fibrosis and helps to design a PCR-based clinical test.

*Funding:* Government Support - Non-U.S.

## TH-PO587

**Apelin Receptor Blockade Exaggerates Unilateral Ureteral Obstruction Induced Tubular Injury in Rats** Gurdal Birdal,[1] Zarife Ozdemir,[2] Naziye Ozkan,[3] Dilek Ozbeyli,[2] Aysin Tulunay,[4] Sule Cetinel,[3] Berrak Yegen,[2] Mehmet Koc.[1] *[1]Div of Nephrology, Marmara Univ; [2]Dept of Physiology, Marmara Univ; [3]Dept of Histology, Marmara Univ; [4]Dept of Immunology, Marmara Univ, Medical Faculty, Turkey.*

**Background:** Unilateral ureteral obstruction (UUO) is a well-characterized fibrosis model exhibiting tubular injury and interstitial inflammation in the obstructed kidney. Apelin (Ap), a peptide identified as the endogenous ligand of the human orphan G-protein-coupled receptor, is reported to have anti-fibrotic and anti-inflammatory actions in the cardiovascular system, while the blockade of Ap receptor was shown to be effective in reducing hepatic fibrosis and angiogenesis. However, the role of Ap in the development of UUO model has not yet been elucidated.

**Methods:** In male Wistar albino rats under ketamine anesthesia (100 mg/kg; intraperitoneally, ip) UUO was performed by ligating left ureters. The rats were injected ip with either saline (n=8) or the Ap-receptor blocker Ala-Ap (75 mg/kg/day, n=8) for 7 days. On the 7th day, obstructed and non-obstructed kidneys were removed for the isolation of leukocytes by flow cytometry and for the assessment of histopathological changes.

**Results:** Tubular injury scores, which were calculated by grading interstitial edema, tubular dilatation, hyalinization and atrophic/necrotic tubular cells, were similar in non-obstructed and saline-treated obstructed kidneys. On the other hand, in the obstructed kidneys with Ala-Ap-treatment, injury score was significantly elevated (p<0.05), but the interstitial fibrosis score determined by Masson-trichrome staining was not increased. The percentages of $CD3^+$ T-lymphocytes and $CD3^+/CD8^+$ T-lymphocytes infiltrating obstructed kidneys were increased in the Ala-Ap-treated non-obstructed and Ala-Ap-treated obstructed-kidneys (p<0.001) as compared to corresponding saline-treated groups.

**Conclusions:** The present data demonstrate that pharmacological blockade of Ap exaggerates UUO-induced tubular injury that appears to involve the infiltration of lymphocytes. These data suggest that Ap may have a regulatory role in protecting against obstruction-induced tubular injury.

## TH-PO588

**Reversal of Epithelial to Mesenchymal Transition following Relief of Unilateral Ureteral Obstruction in the Rat** Nan Shen, Hong Li Lin, Wang Da Peng. *Dept of Nephrology, The 1st Affiliated Hospital of DaLian Medical Univ, Da Lian, Liao Ning Province, China.*

**Background:** Renal fibrosis begins with renal tubular epithelial mesenchymal transition (EMT); the progression thereafter depends upon a number of fibrotic factors. Unilateral ureteral obstruction (UUO) is a well-described model of EMT. We used an improved reversible unilateral ureteral obstruction (RUUO) model to investigate whether a progressive renal injury model of EMT could be reversed into the opposite direction, into mesenchymal-epithelial transition (MET) after relief of UUO in rats.

**Methods:** Rats were subjected to UUO or sham operation and the obstruction was removed five days later (or was left in place). Rats developed EMT after reversal of 2 or 4 weeks of ureteral obstruction as assessed by the expressions of fibrotic factors, EMT and MET markers in this post-obstructive model.

**Results:** We found a significant decrease in the kidney weight and renal cortical thickness in the UUO group compared with the sham groups. This rise in the RUUO group was significantly reduced. The elevated level of TGF-β1, TGF-β receptors and core fucosylationin the UUO group was significantly reduced in the RUUO groups. The EMT markers staining showed results parallel to those of TGF-β1 expression levels. In addition, UUO rats exhibited pronounced inflammatory and intrinsic proliferative cellular responses, and ultimately fibrosis. By comparison, RUUO mice had more controlled and measured extrinsic and intrinsic responses to EMT with a return to MET within several weeks after release of ureteral obstruction.

**Conclusions:** Our findings provide a model that allows investigation of the fibrotic factors during reversal of EMT that contribute to the development of fibrosis. EMT of the progressive renal injury could be actively reversed into MET and renal architecture is better maintained throughout injury and recovery from injury after relief of UUO in rats.

## TH-PO589

**Long-Term Amiloride Therapy Attenuates Lithium-Induced Kidney Interstitial Fibrosis** Priyakshi Kalita,[1] Andrew Bahn,[1] Jennifer J. Bedford,[2] John P. Leader,[2] Robert J. Walker.[2] *[1]Physiology, Univ of Otago, Dunedin, New Zealand; [2]Medicine, Univ of Otago, Dunedin, New Zealand.*

**Background:** Long-term lithium therapy may produce chronic interstitial fibrosis. Short term amiloride attenuates lithium-induced NDI. However, the effect of amiloride on renal interstitial fibrosis induced by long-term lithium treatment, is unknown. This study investigated the effects of long-term amiloride on lithium-induced interstitial kidney fibrosis.

**Methods:** Male Wistar rats were divided into control, lithium alone, and lithium + amiloride groups (N=6 each group). Lithium was provided in rat chow (60 mmol $kg^{-1}$ food) for 6 months. Amiloride was introduced in drinking water (0.2 mmol $l^{-1}$) after 1 month of lithium treatment and continued for 5 months. At 6 months, rats were euthanized and kidneys were processed for histology, immunohistochemistry and Western blotting.

**Results:** In rats given lithium alone, histology revealed extensive dilatations of the cortical collecting ducts and focal areas of cortical fibrosis (0.5±0.04% area) vs controls (0.1± 0.003% .area), p<0.001. Rats given lithium for 1 month, followed by lithium + amiloride for a further 5 months showed significantly less fibrosis (0.1%± 0.01. area), p<0.001. Tubular morpholgy was unchanged

Western blotting (%) demonstrated greater expression of fibrotic markers in the rats treated with lithium alone compared with the rats given lithium + amiloride, and both groups showed greater expression than in the controls.

| *p<0.05, **p<0.01 | Controll | Lithium alone | Lithium and amiloride |
|---|---|---|---|
| alpha SMA | 100 ± 14 | 206 ± 29 | 114 ± 14 * |
| TGFβ | 100 ± 20 | 235 ± 15 | 114 ± 14 * |
| CTGF | 100 ± 13 | 375 ± 50 | 125 ± 25 ** |
| collagen III | 100 ± 35 | 350 ± 40 | 150 ± 40 ** |

**Conclusions:** This study reveals that amiloride appears to limit the fibrosis induced by lithium, although the abnormal morphology remains. Decreasing intracellular lithium concentrations may alter cAMP regulation of key pro-fibrotic pathways. Additional studies are underway to examine these possibilities.

*Funding:* Government Support - Non-U.S.

### TH-PO590

**Therapeutic Efficacy of DNA-Demethylation Therapy Initiated during Progressive Renal Fibrosis** Nathalie Le Clef, Patrick C. D'Haese, Benjamin Arthur Vervaet. *Biomedicine, Univ Antwerp, Belgium.*

**Background:** Acute kidney injury (AKI) can lead to chronic kidney disease (CKD). Research in animal models demonstrated that a DNA-demethylating treatment, when started immediately after induction of AKI, is able to attenuate development of chronic renal fibrosis, the hallmark of CKD. In patients diagnosed with CKD, however, fibrosis often has already developed to a substantial degree. Therefore, the efficacy of such a treatment, when initiated late in the progression of fibrosis, was tested in a mouse model of ischemia/reperfusion (I/R)-induced renal fibrosis.

**Methods:** Male C57BL/6J mice underwent left renal I/R (30 min, 37°C) and were treated with (a pre-optimized dose of) 0.25 mg/kg/day decitabine (AdC) or 0.9% NaCl, injected s.c. for 10 days. Treatment started either at 6 (early chronic phase) or 9 weeks (late chronic phase) after I/R. Sham operated mice were included as controls. Animals were killed either 1.5 week after end of treatment or 12 weeks after I/R. Kidney fibrosis was evaluated through gene expression (qPCR) analysis of TGFβ and collagen I. In addition, gene expression of DNA-methyltransferase (Dnmt) 1, 3a and 3b was examined.

**Results:** In vehicle treated animals, I/R led to a stable 32.1±10.7 (p=0.010) and 6.2±0.9 (p=0.004) fold upregulation of TGFβ and col I (vs. sham) from 6 weeks after I/R on, respectively. AdC treatment, irrespective of start of intervention was able to suppress median TGFβ upregulation by ca. 39%, however this was not significant (p>0.05 vs. vehicle). No effect was noted on col I expression. Likewise, the impact of AdC on gene expression of the various Dnmt's is limited, although all Dnmt's showed a (non-significant; resp. ca. 13% Dnmt 1, 28% Dnmt 3a and 37% Dnmt 3b) decrease when treatment was started at 6 weeks post I/R.

**Conclusions:** In this model of rather severe AKI induced renal fibrosis, a demethylating therapy is not that effective in attenuating progression of fibrosis. Whether AdC treatment as anti-fibrotic therapy might be effective only when administered during AKI or in a milder model of kidney damage remains to be determined.

### TH-PO591

**AqF026 Is a Pharmacologic Agonist of the Water Channel Aquaporin-1** Olivier Devuyst,[1] Johann Morelle,[2] Andrea J. Yool.[3] *[1]UZH, Zurich, Switzerland; [2]UCL, Brussels, Belgium; [3]Univ Adelaide, Adelaide, Australia.*

**Background:** Aquaporin-1 (AQP1) facilitates the osmotic transport of water across the capillary endothelium, among other cell types, and thereby has a substantial role in water removal during peritoneal dialysis. At present, pharmacologic agents that enhance AQP1-mediated water transport, which would be expected to increase the efficiency of peritoneal dialysis, are not available.

**Methods:** In the present study, we tested the capacity of the novel agent AqF026 (Aq: aquaporin ligand; F: furosemide scaffold) to potentiate the water channel activity of AQP1 *in vitro* and *in vivo*.

**Results:** In the *Xenopus laevis* oocyte system, extracellular AqF026 potentiated the channel activity of human AQP1 by >20% but had no effect on channel activity of AQP4. *In silico* modelling suggested the binding of AqF026 to the intracellular loop D domain, a region associated with channel gating. Site-directed mutagenesis of intracellular residues in the human AQP1 loop D domain showed that the agonist effect of AqF026 could be reversed by mutations of Thr157 or Arg159. In a mouse model of peritoneal dialysis, AqF026 enhanced the osmotic transport of water across the peritoneal membrane but did not affect the osmotic gradient, the transport of small solutes, or the localization and expression of AQP1 on the plasma membrane. Furthermore, AqF026 did not potentiate water transport in *Aqp1*-null mice, suggesting that indirect mechanisms involving other channels or transporters were unlikely. Last, in a mouse gastric antrum preparation, AqF026 did not affect the Na-K-Cl cotransporter NKCC1.

**Conclusions:** These results are the first to define a pharmacological ligand that potentiates AQP1 water channel activity, to show that it is effective *in vitro* and *in vivo*, and to identify a candidate molecular site of action. The data are consistent with direct binding of the arylsulfonamide compound AqF026 at a site involving the intracellular regulatory domain loop D in AQP1. AqF026 directly and specifically potentiates AQP1-mediated water transport, suggesting a potential interest for peritoneal dialysis and clinical situations associated with defective water handling.

**Ser-261 Phosphorylation Is an Endocytotic Signal of Aquaporin-2 Water Channel** Naofumi Yui, Shinichi Uchida, Sei Sasaki. *Dept of Nephrology, Graduate School of Medcine, Tokyo Medical and Dental Univ, Tokyo, Japan.*

**Background:** Recently, several new vasopressin (VP)-sensitive phosphorylation sites other than Ser-256 (S256) were identified in the C-terminus of aquaporin-2 (AQP2). S261 is one of these newly identified phosphorylation sites, which is significantly decreased after VP stimulation. The importance of S261 phosphorylation on AQP2 ubiquitination was reported recently, however, its importance on AQP2 intracellular trafficking remains unclear.

**Methods:** In this study, we investigated intracellular trafficking of pS261-AQP2 in rat AQP2-stably expressing MDCK (AQP2-MDCK) cells using specific pS261-AQP2 antibody.

**Results:** Under control condition, AQP2 was mainly located in the perinuclear region (PNR), and the plasma membrane accumulation of AQP2 was clearly increased after FK (20 μM, 10 min) treatment. However, pS261-AQP2 was located in PNR, and was not detected in the plasma membranes with or without FK treatment. These results suggested two possibilities: one is that pS261-AQP2 is not transported and stably located in the intracellular site, and the other is that pS261-AQP2 is continuously targeted to the plasma membranes, however, immediately endocytosed. Therefore, we further investigated plasma membrane targeting of pS261-AQP2 using cold shock (4°C, 15 min). We previously reported that clathrin function is instantly arrested during cold shock. As a result, rapidly occurring plasma membrane targeting and subsequent internalization of proteins, which is usually undetectable under normal condition, can be visualized. Surprisingly, pS261-AQP2 was strongly accumulated in the plasma membrane after cold shock.

**Conclusions:** These observations clearly indicated that pS261-AQP2 is continuously targeted to the plasma membranes, then, instantly retrieved into intracellular vesicles. Thus, the phosphorylation of AQP2 at S261 might be a potent endocytotic signal. Further investigations to identify agents to modify S261 phosphorylation might contribute to the development of novel therapy for water balance disorders.

### TH-PO593

**Intrarenal Mechanisms for Cyclophsophamide-Induced Water Retention in Rat Kidney** Gheun-Ho Kim,[1] Sua Kim,[1] Chor Ho Jo,[1] Joon-Sung Park,[1] Hyo-Jung Choi,[2] Tae-Hwan Kwon.[2] *[1]Dept of Internal Medicine, Hanyang Univ College of Medicine, Seoul, Korea; [2]Dept of Biochemistry and Cell Biology, Kyungpook National Univ School of Medicine, Taegu, Korea.*

**Background:** Cyclophosphamide can produce hyponatremia when hypotonic fluid intake is not limited. Because cyclophosphamide-induced hyponatremia was reported to occur in central diabetes insipidus, we hypothesized that cyclophosphamide or its active metabolite 4-hydroperoxycyclophosphamide (4-HC) may directly dysregulate the expression of water channels or sodium transporters in the kidney.

**Methods:** After a single intraperitoneal cyclophosphamide (25 mg/kg BW) administration to male Sprague-Dawley rats, kidneys were harvested for immunoblotting, immunohistochemistry, and real-time PCR. Primary cultures enriched ininner medullary collecting duct (IMCD) cells prepared from pathogen-free male Sprague-Dawley rats were treated with 10 and 30 μM of 4-HC. Laser scanning confocal miscroscopy was used for AQP2 localization.

**Results:** Cyclophosphamide-treated rat kidneys showed increases in the expression of aquaporin-2 (AQP2) protein (137 ± 10% vs. 100 ± 6%, $P < 0.05$), Na-K-2Cl cotransporter type 2 (NKCC2) protein (205 ± 32% vs. 100 ± 11%, $P < 0.05$) and $V_2R$ (vasopressin receptor type 2) mRNA (169 ± 18% vs. 100 ± 13%, $P < 0.05$) compared with vehicle-treated controls. Immunohistochemistry for AQP2 and NKCC2 revealed compatible results with immunoblot analyses. In primarily cultured IMCD cells, AQP2 protein abundance was increased by 10 μM 4-HC treatment (118 ± 6% vs. 100 ± 6%, $P < 0.05$). The expressions of AQP2 mRNA (185 ± 18% vs. 100 ± 29%, $P < 0.05$) and $V_2R$ mRNA (221 ± 49% vs. 100 ± 5%, $P < 0.05$) were also increased by treatment with 10 μM of 4-HC. Moreover, AQP2 targeting to the apical plasma membrane was remarkably increased when primary cultured IMCD cells were treated with 4-HC in the absence of vasopressin stimulation.

**Conclusions:** In rat kidneys, cyclophosphamide may induce upregulation of AQP2 and NKCC2 via activation of $V_2R$ and increasing AQP2 trafficking in the absence of vasopressin stimulation. These intrarenal mechanisms suggest a possibility of drug-induced nephrogenic syndrome of inappropriate antidiuresis.

*Funding:* Government Support - Non-U.S.

### TH-PO594

**Characterization of the Putative Phosphorylation Sites of Aquaporin-2 C-Terminus and Their Role in Aquaporin-2 Trafficking in LLC-PK1 Cells** Julian R. Arthur,[1,2] Jianmin Huang,[1,2] Dennis Brown,[1,2] Hua Ann Jenny Lu.[1,2] *[1]Center for Systems Biology, Program in Membrane Biology, Div of Nephrology, Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

**Background:** Phosphorylation dependent apical accumulation of water channel Aquaporin-2 (AQP2) mediates water reabsorption in the principal cells of kidney collecting ducts in response to vasopressin (VP), contributing to water homeostasis in mammals. Using an unbiased mutational analysis of all the potential phosphorylation sites in AQP2 C-terminus, we were able to study the role of each potential site in regulated trafficking and constitutive recycling of AQP2.

**Methods:** We generated stable LLC-PK1 cell lines with point mutations of alanine (A) or glycine (G) to replace all seven potential C-terminal phosphorylation sites in AQP2. We then introduced phosphorylation mimics (D, aspartic acid) to each individual site in the S all A/G background. For Western blots, membranes were incubated with Goat anti-AQP2 and Mouse anti-β-actin. For chemical treatments, cells were treated with 10 nM VP, 10 μM Forskolin (FK), or 10 mM methyl-β-cyclodextrin (MβCD) for 30 min. For cold block, cells were pre-treated with cyclohexamide for 60 min, then incubated at 20°C for various timepoints to visualize the formation of AQP2 "perinuclear patches." Fixed cells were visualized using the Nikon 80i.

**Results:** S all A/G AQP2 showed no membrane accumulation in response to VP/FK, but accumulated in response to MβCD, which disrupts endocytosis. S all A/G AQP2 with either S226D, S229D, T244D, S256S, S261D, S264D, or S269D did not exhibit membrane accumulation under basal conditions. These mutant AQP2 accumulated at the plasma membrane after MβCD treatment and in the trans Golgi network after cold block. S all A/G AQP2-S256D showed membrane accumulation in the absence of VP/FK, and was largely resistant to cold block as previously reported. S all A/G AQP2-S256S responded to VP/FK similarly to AQP2-WT.

**Conclusions:** Our data suggest for the first time that constitutive recycling of AQP2 does not require any phosphorylation in its C-terminus. Phosphorylation of S256 alone is sufficient to cause membrane accumulation of AQP2.

## TH-PO595

**Changes in the Excretion of Urinary Exosomal AQP1 and AQP2 in Rats with PAN-Induced Nephrotic Syndrome** Ayaha Kaito, Hiroko Sonoda, Saki Takahashi, Masahiro Ikeda. *Veterinary Pharmacology, Univ of Miyazaki, Miyazaki, Japan.*

**Background:** Nephrotic syndrome exhibits abnormal handling of renal water excretion and this abnormality is thought to be associated with the level of expression of renal aquaporin water channels (AQPs). Urinary exosomes are small vesicles secreted into urine from all renal epithelial cell types and known to contain proteins that are involved in renal secretion and reabsorption. Among these proteins, the level of urinary exosomal AQP1 or AQP2 excretion has been reported to be altered by renal insults such as renal ischemia/reperfusion and cisplatin, accompanied with the changes of their renal expression levels. However, it is unclear whether the urinary exosomal AQP1 and AQP2 excretion are affected by nephrotic syndrome.

**Methods:** In this study, we examined the levels of urinary exosomal AQP1 and AQP2 excretion in a well-characterized animal model viz. puromycin aminonucleoside (PAN) nephrosis. PAN (125 mg/kg) or saline was intravenously injected to rats. Urinary exosomes were isolated from the urine samples by differential ultracentrifugation.

**Results:** Plasma creatinine concentration and urinary protein level were significantly increased 96 h or later after the injection of PAN. Urine osmolarity was higher 96 h and lower 168 h after the injection, in comparison with controls. Urinary exosomal AQP1 was decreased 120 h or later, whereas reduced urinary exosomal AQP2 excretion was detected even 24 h after the injection. We then examined the abundance of AQP1 and AQP2 proteins in the renal cortex and medulla. Both proteins were not changed 48 h, but significantly decreased only in the cortex 120 h after the injection of PAN.

**Conclusions:** Together with these results, only urinary exosomal AQP2 excretion was decreased before proteinuria without being accompanied with renal protein level, whereas both urinary exosomal AQP1 and AQP2 excretion were reduced after proteinuria, associated with renal protein levels. These data suggest that urinary exosomal AQPs may be potential biomarkers for nephrotic syndrome.

## TH-PO596

**Kidney Stone Risk during Microgravity and Long-Term Bed Rest: Role of Hypercalciuria and Aquaporins** Grazia Tamma,[1] Annarita Di Mise,[1] Marianna Ranieri,[1] Maria Svelto,[1] Giancarlo Bilancio,[2] Massimo Cirillo,[2] Natale Gaspare De Santo,[3] Giovanna Valenti.[1] *[1]Dept Biosciences, Biotechnologies and Biopharmaceutics, Univ of Bari, Bari, Italy; [2]Dept of Medicine, Univ of Salerno, Salerno, Italy; [3]Dept of Medicine, Second Univ of Naples, Naples, Italy.*

**Background:** Exposure to microgravity results in alterations of renal function, fluid redistribution and bone loss which contributes to the potential risk of renal stone formation. Hypercalciuria is recognized as a condition predisposing to calcium nephrolitiasis and long-term space flights cause bone loss coupled to a rise of urinary calcium excretion.

**Methods:** AQP2 excretion was measured by ELISA in urines collected from healthy volunteers participating at the studies.

**Results:** We recently demonstrated that high calcium delivery to the collecting duct reduces local Aquaporin 2 (AQP2) mediated water reabsorption under vasopressin action, thus limiting the maximal urinary concentration and reducing calcium saturation. To analyze alteration of renal water handling during microgravity, we evaluated two ground-based analog of spaceflight, thermoneutral water immersion and bed rest. AQP2 excretion and diuresis were measured in two separated studies mimicking acute adaptation (6 hours water immersion) or chronic adaptation (35 days bed rest) to microgravity. Water immersion resulted in a significant increase in urinary output apparently not related to AQP2 alteration and manly due to reduced vasopressin secretion. On the other hand 35 days bed rest resulted in an increase in urinary calcium, which coincided with a significant decrease in AQP2 excretion (645±7.4 fmol/ml to 569±10.3 fmol/ml), which is expected to result in urine dilution reducing the risk of calcium saturation.

**Conclusions:** Our data indicate that calciuria and water balance have to be strictly controlled during microgravity and long-term bed rest as key elements for the risk of kidney stone formation.

## TH-PO597

**Vasopressin Inhibits Apoptosis in Renal Collecting Duct Cells** Jason D. Hoffert, Pablo Sandoval, Lance Miller, Trairak Pisitkun, Mark A. Knepper. *Epithelial Systems Biology Laboratory, NIH, Bethesda, MD.*

**Background:** Arginine vasopressin (AVP) plays a critical role in regulating salt and water transport in the mammalian kidney. In addition to its central role in renal physiology, recent studies have demonstrated that AVP can promote cell survival in glomerular mesangial cells as well as in cultured hippocampal neurons through V1 receptors. The current study addresses whether AVP can inhibit apoptosis in kidney collecting duct cells via V2 receptors and also explores the downstream signaling pathways regulating this phenomenon.

**Methods:** The amount of cellular apoptosis was assessed in a cultured cortical collecting duct cell line (mpkCCD) by measuring the amount of DNA damage (i.e. TUNEL assay) as well as by measuring the relative amounts of cleaved caspase isoforms by immunoblotting.

**Results:** We found that an analog of AVP, 1-desamino-8-d-arginine vasopressin (dDAVP), inhibited staurosporine-induced apoptosis in mpkCCD cells. Incubation with dDAVP also inhibited apoptosis induced by the phosphatidylinositol 3-kinase (PI3K) pathway inhibitor LY294002, suggesting that the anti-apoptotic effects of dDAVP are largely independent of PI3K signaling in collecting duct cells. The V2 receptor antagonist SR121463 completely abolished the anti-apoptotic effects of dDAVP in mpkCCD cells. In addition, incubation of cells with 8-cpt-cAMP, a cell permeable analog of cyclic AMP, reproduced the anti-apoptotic effects of dDAVP. Both dDAVP and 8-cpt-cAMP increased phosphorylation of pro-apoptotic Bcl-2 family member proteins Bad and Bok. Two of these phosphorylation sites in Bad, Ser-112 and Ser-155, are known to inhibit pro-apoptotic activity. Pre-incubation of cells with H89 blocked dDAVP-induced phosphorylation of both Bad and Bok suggesting dependence on protein kinase A (PKA).

**Conclusions:** This study provides evidence that AVP can inhibit apoptosis through the V2 receptor and downstream cAMP-mediated pathways in mammalian kidney, a process that may be relevant in the context of renal proliferative disorders such as autosomal dominant polycystic kidney disease (ADPKD).

## TH-PO598

**Cyclooxygenase-2 Mediates Induction of the Renal Stanniocalcin-1 Gene by Arginine Vasopressin** Graham F. Wagner,[1] Richard L. Hebert.[2] *[1]Physiology & Pharmacology, Western Univ, London, Canada; [2]Dept of Cellular and Molecular Medicine, Univ of Ottawa, Ottawa, Canada.*

**Background:** The hormone, stanniocalcin-1 (STC-1), is expressed in most nephron cells. But the gene is differentially induced in cortical and medullary segments in response to dehydration. The cortical gene is upregulated solely by hypertonicity, whereas that in medulla is induced by hypovolemia. In both cases gene induction is mediated by arginine vasopressin (AVP) acting via V2 receptors (V2R). V2R occupancy activates two pathways in response to dehydration; 1) antidiuresis mediated by direct V2R occupancy and 2) AVP counter-regulation mediated indirectly via COX-2 (cyclooxygenase-2). Because the role of renal STC-1 is still unknown, we sought to establish if V2R mediated gene upregulation occurred directly or indirectly, as a means of narrowing the scope of its possible actions.

**Methods:** Models of COX inhibition and COX gene deletion were employed to address the possible involvement of the COX pathway.

**Results:** Both general and specific inhibitors of COX-2 blocked STC-1 gene induction in response to dehydration. Gene induction in response to dehydration was also abolished in COX-2 null mice (cortex and medulla), but not in COX-1 null mice.

Gene induction in response to V2R occupancy was also abolished in COX-2 nulls (cortex and medulla), but not in COX-1 nulls.

In situ hybridization analysis revealed that gene upregulation took place in most nephron segments except for the thin loops of Henle.

**Conclusions:** The findings clearly showed that all V2R-mediated rises in renal STC-1 gene expression are wholly dependent on functional COX-2 activity. This implies that STC-1 is not part of the antidiuretic pathway and that it likely has actions that include AVP counter-regulation, renal cytoprotection and/or renal osmolyte synthesis.

## TH-PO599

**Transcriptional and Translational Heterogeneity of the SLC2A9 Gene Encoding the GLUT9 Urate Transporter** Asim Mandal,[1] David B. Mount.[1,2] *[1]Renal Div, Brigham and Women's Hospital, Boston, MA; [2]Renal Div, VA Boston Healthcare System, Boston, MA.*

**Background:** There are ~30 genes linked to serum uric acid (SUA) levels and gout, yet variation in the SLC2A9 gene encoding the urate transporter GLUT9 remains the major single genetic determinant; however, the causative variants are unknown. Two distinct N-terminal isoforms, GLUT9a and GLUT9b, are generated by alternative 5' ends and alternative promoters.

**Methods:** Novel exons, alternative splicing, and transcriptional start sites were identified by database mining, 5'-RACE PCR of kidney mRNA, and RT-PCR. GLUT9 expression constructs were generated in for $^{14}$C-urate uptake experiments in *Xenopus oocytes.*

**Results:** Five novel 5' UTR exons were identified, with substantial alternative splicing of these exons in human renal transcripts. RT-PCR did not link exon 1a and 1b, indicating that GLUT9a and GLUT9b are generated by transcriptional initiation at separate promoters. A transcriptional initiation site flanking exon 1a was identified by 5'-RACE; a second site was identified in GLUT9b transcripts, flanking a novel 5' UTR exon that is ~35 kb 5' of

exon 1b. Alternative splicing that deletes coding exons 3 +/- 4 was also identified; exon 3 is a cassette exon encoding most of transmembrane domain 1 (TM1) and part of the first, glycosylated extracellular loop. Surprisingly, GLUT9b constructs with deletion of exon 3 (GLUT9b-delta3) were functional, generating urate uptakes that were 10-fold higher than that of water-injected control Xenopus oocytes - versus 40-fold higher in oocytes injected with full-length GLUT9b cRNA. Western blotting indicated that GLUT9b-delta3 protein is not glycosylated, likely due to altered topology of the first extracellular loop.

**Conclusions:** We have identified substantial 5' heterogeneity of SLC2A9 transcripts, with five novel 5' UTR exons and at least two transcriptional initiation sites. There are thus at least two 5' promoters in SLC2A9, one some 35 kb 5' of exon 1b flanking a novel 5' UTR exon. Alternative splicing that removes exon 3 generates functional GLUT9 urate transporters, despite removal of TM1, absent N-glycosylation, and scrambled topology of the amino terminus of GLUT9 protein.

## TH-PO600

**SGLT2 Inhibitors Act from the Extracellular Surface of the Cell Membrane** Chiara Ghezzi, Edurne Gorraitz, Erika Patino, Bruce A. Hirayama, Donald D.F. Loo, Ernest M. Wright. *Physiology Dept, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

**Background:** SGLT2 inhibitors are a new class of drugs that have been developed to treat diabetes. They lower glucose levels by blocking the renal Na/glucose cotransporter SGLT2, thereby increasing the amount of glucose excreted in the urine.

Questions have arisen about how these inhibitors reach SGLT2 in the brush border membrane of the S1 and S2 segments of the renal proximal tubule: are these drugs filtered by the glomerulus and act from within the tubule, or do they act from the blood?

**Methods:** Human SGLT2 was expressed in HEK293T cells and we determine the relative potency of SGLT2 inhibitors from the extra- and intracellular side of the plasma membrane We used the selective hSGLT2 inhibitor JNJ-30980924, that is similar to canagliflozin, and phlorizin that is a non selective SGLT2 inhibitor. SGLT2 activity ($Na^+$/glucose currents) was measured using the whole cell patch-clamp method that allowed us to control the composition of both the extracellular and intracellular solutions.

**Results:** Our result confirmed that JNJ-30980924 is a SGLT2 specific inhibitor and a potent extracellular inhibitor of the inward SGLT2 transport. We estimated a $IC_{50}$ of 10-40 nM that is 10 times higher than the one estimated for hSGLT1 (300 nM). To test if the inhibitor can act from the intracellular side we add the compound to the patch pipette solution and we measured the effect on the glucose inward current generated by SGLT2. Both phlorizin and JNJ-30980924 were ineffective from the intracellular compartment at both low (5 mM) and high (150 mM) intracellular NaCl concentrations.

**Conclusions:** We conclude that SGLT2 inhibitors only bind to SGLT2 from the extracellular side of the plasma membrane and this suggests that they act from the glomerular filtrate and not from the blood through the tubular epithelium.

## TH-PO601

**14-3-3s Regulate Osmoprotective Gene Expression by Regulating NFAT5 Activity** Yuichiro Izumi, Maurice B. Burg, Joan D. Ferraris. *National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD.*

**Background:** Nuclear Factor of Activated T-Cells 5 (NFAT5) is a transcription factor that induces transcription of osmoprotective genes in response to high NaCl. In the renal medulla NFAT5 protects cells from the effects of NaCl, which normally is present in concentrations high enough to perturb and even kill cells. When cells are exposed to high NaCl, NFAT5 accumulates in the nucleus where it binds to the Osmotic Response Elements (OREs) flanking target genes and increases their transcription. 14-3-3s are regulatory proteins that have numerous roles in protein interaction, phosphorylation, and enzymatic activity. There are multiple 14-3-3 isoforms that form homo- and hetero-dimers and play isoform-specific regulatory roles. We previously identified six isoforms of 14-3-3 in nuclei of HEK293 cells and found that their abundances in the nucleus decrease in response to high NaCl (Physiol. Genomics. 2012). The purpose of the present studies was to test whether 14-3-3s modulate the activity of NFAT5.

**Methods:** The effects of knocking down 14-3-3s on NFAT5 function were examined in HEK293 cells incubated at 300 and 500 mosmol/kg (NaCl added). Using small interfering RNAs, we knocked down 14-3-3 isoform β, ε, γ, η, θ, and ζ either individually or in combination. We used Luciferase reporters to measure NFAT5 transcriptional (ORE-X) and transactivating (TAD) activity. We quantified mRNA abundance of the NFAT5 target genes, aldose reductase (AR) and betaine/GABA transporter (BGT1), and of NFAT5, itself, by real time PCR. We also measured nuclear localization of NFAT5 by quantitative Western analysis of nuclear and cytoplasmic proteins.

**Results:** Knock down of 14-3-3-β or 14-3-3-ε significantly inhibited high NaCl-induced ORE-X and TAD activities, but knockdown of the other isoforms had no significant effect. Knockdown of β or ε also decreased mRNA abundances of AR and BGT1, but not of NFAT5. The effects of knocking down β and ε were not additive. Knock down of β and ε did not affect the nuclear localization of NFAT5.

**Conclusions:** 14-3-3 isoforms β and ε contribute to NFAT5 transcriptional activity by supporting high NaCl-induced increase of NFAT5 transactivating activity.

*Funding:* Other NIH Support - The Intramural Research Program of NHLBI, NIH

## TH-PO602

**Mechanisms of Erythropoietin Production by Aldosterone in the Intercalated Cells** Yuichiro Izumi,[1] Yukiko Yasuoka,[2] Takanori Nagai,[3] Kahori Hori,[3] Yushi Nakayama,[4] Masayoshi Nanami,[3] Takeshi Nakanishi,[3] Akito Tanoue,[5] Kimio Tomita,[4] Katsumasa Kawahara,[2] Hiroshi Nonoguchi.[6] *[1]National Heart, Lung, and Blood Institute, NIH, Bethesda, MD; [2]Physiology, Kitasato Univ, Sagamihara, Saitama, Japan; [3]Kideny and Dialysis, Hyogo Coll. of Med., Nishinomiya, Hyogo, Japan; [4]Nephrology, Kumamoto Univ, Kumamoto, Japan; [5]Pharmacology, National Res. Inst for Child Health and Develop., Setagaya-ku, Tokyo, Japan; [6]Int Med, Kitasato Univ Med. Cent., Kitamoto, Saitama, Japan.*

**Background:** Erythropoietin (Epo) production occurs in the peritubular cells, which experimentally requires severe anemia and hypoxia. Other site maintaining basal Epo production is speculated. We have shown that cultured intercalated cells of the collecting ducts (CD) (IN-IC cells) produce Epo by hypoxia and aldosterone and that vasopressin V1a receptor (V1aR) is required for the effect of aldosterone. In the present study, we investigated the Epo production in basal condition and the mechanisms of aldosterone-induced erythropoiesis in intercalated cells.

**Methods:** Mice in basal condition, blood-draw induced anemia with 4-hr hypoxia and fludrocortisone treatment were used for high sensitive in situ hybridization (ISH) of Epo mRNA and Immunohistochemistry (IHC) of PHD2. Double staining of anti AQP3 and AE1 was performed to distinguish intercalated cells of CD. V1aR-KO and wild type (WT) mice and the IN-IC cells were used for Western blot analysis of HIF1α,2α, and PHD1,2,3.

**Results:** Epo mRNA was detected in type B intercalated cells (IC-B) and slightly in proximal tubule (PT) but not in periubular cells in basal condition. Hypoxia increased Epo mRNA expression in IC-B and remarkably in peritubular cells. PHD2 was not detected on basal condition while it was stained in DCT, CCD and peritubualr cells by anemia and fludrocortisone. Fludrocortisone increased PHD2, HIF1α and 2α expressions in WT mice but not in V1aR-KO mice. Aldosterone increased PHD2, HIF1α and 2α expressions in IN-IC cells.

**Conclusions:** IC-B is the main site of Epo production in basal conditions. Aldosterone stimulates Epo production in IC-B through the activation of HIF1α, 2α and PHD2 pathway. V1aR is required for Epo production by aldosteorne.

*Funding:* Pharmaceutical Company Support - Dainippon Sumitomo Pharma Co., Government Support - Non-U.S.

## TH-PO603

**Urinary Citrate Excretion in NaDC1 Knockout Mice** Kathleen S. Hering-Smith,[1] Federico Teran,[1] L. Lee Hamm.[1,2] *[1]Medicine, Tulane Univ, New Orleans, LA; [2]Research, SLVHCS, New Orleans, LA.*

**Background:** Citrate is an important inhibitor of calcium stone formation. Citrate excretion in the urine has been thought to be predominantly regulated by NaDC1 (Na-dicarboxylate cotransporter 1) in the apical membrane of the proximal tubule. However, since we have recent evidence of another citrate reabsorptive process in the proximal tubule, we reexamined citrate excretion in NaDC1 knock out mice.

**Methods:** Citrate and other Krebs cycle intermediates were measured by LC/MS in plasma and spot urine collections from wild type (WT), KO and heterozygotes (Het) and are expressed in ug/mL.

**Results:** Renal function and urine concentration were not different in the three groups of animals as indicated by plasma and urine creatinines. Excretion of succinate, fumarate, and malate were significantly higher in KO animals compared to Het or WT: succinate 92 ± 29, 37 ± 11, 32 ± 6; fumarate 45 ± 11, 3 ± 0.7, 3.8 ± 0.9; malate 161 ± 47, 24 ± 3, 32 ± 11, respectively in KO, Het, and WT. However, citrate excretion was not higher in KO compared to WT and Het, 89 ± 15, 115 ± 42, 149 ± 24. Interestingly lactate excretion in urine was significantly lower in KO compared to WT or Het. Phosphoenolpyruvate, pyruvate, isocitrate, and alpha-ketoglutarate were not different in the three groups.

**Conclusions:** In sum, NaDC1 KO animals exhibit increased excretion of several Krebs cycle intermediates but not increased urinary citrate. This data is consistent with transporters other than NaDC1 having a potentially important role in regulation of urinary citrate excretion and hence in prevention of calcium stone formation.

## TH-PO604

**Effect of Direct Renin Inhibitor Aliskiren on the Urinary Concentrating Defect in Obstructive Nephropathy** Weidong Wang,[1] Renfei Luo,[1] Yu Lin,[1] Moshe Levi,[2] Tianxin Yang,[1] Chunling Li.[1] *[1]Institute of Hypertension and Kidney Research, Zhongshan School of Medicine, Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Div of Hypertension and Kidney Diseases, Univ of Colorado Denver, Aurora, CO.*

**Background:** Ureteral obstruction is associated with reduced expression of renal aquaporins (AQPs) and urinary concentrating defect, in which renin-angiotensin system (RAS) activation may play an important role. We evaluated whether RAS blockade by injecting renin inhibitor aliskiren in mice would prevent decreased protein expression and intracellular trafficking of AQPs in bilateral ureteral obstruction (BUO) and unilateral ureteral obstruction (UUO).

**Methods:** BUO was performed for 24 hours and UUO was performed for 3 days and 7 days. Protein, mRNA expression and staining of aquaporins were examined by western blots, RT-PCR, and immunohistochemistry.

**Results:** There were no significant changes in serum osmolality, sodium, and potassium concentrations between BUO/UUO mice and aliskiren-treatment groups. During BUO, aliskiren (BUO+Ali) prevented the reduction of AQP2 protein expression (1.06±0.07 in BUO+Ali vs. 0.73±0.05 in BUO, P<0.05), but not AQP1 and AQP3. Aliskiren reversed the weak intracellular and apical staining of AQP2 in the cortical and inner medullary collecting duct (CD) principal cells during 24 hr BUO. In UUO mice, at day 3 (3U) and day 7 (7U), aliskiren prevented downregulation of AQP2 protein (0.85±0.07 in 3U+A vs. 0.51±0.07 in 3U, P<0.05; 1.00±0.02 in 7U+A vs. 0.73±0.04 in 7U, P<0.001) and mRNA levels (1.54±0.32 in 3U+A vs. 0.60±0.11 in 3U, P<0.05; 0.64±0.18 in 7U+A vs. 0.14±0.03 in 7U, P<0.05), but not AQP1 and AQP3 protein expressions in the obstructed kidneys. There were no changes of AQP1, 2 and 3 expression in non-obstructed kidneys with or without aliskiren treatment. The reduced immunostaining of AQP2 in the cortical and medullary CD principal cells of obstructed kidneys at day 7 of UUO was also prevented by aliskiren.

**Conclusions:** RAS blockade with renin inhibitor was associated with increased AQP2 expression in the kidney and activation of renal RAS may play an important role in urinary concentrating defect seen in obstructive nephropathy.

## TH-PO605

**Primary Cilia Modulate the Effects of TRPM3 and TRPV4 on Survival of Renal Epithelial Cells Exposed to Osmotic Stress** Bradley P. Dixon,[1] Brian J. Siroky,[1] Raven Gail Comer,[1] Nancy Kleene,[2] John J. Bissler.[1] *[1]Div of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Dept of Cancer and Cell Biology, Univ of Cincinnati College of Medicine, Cincinnati, OH.*

**Background:** Primary cilia detect osmolality, but the mechanism is unclear. Both TRPV4 and TRPM3 channel activities are inhibited by hyperosmolality. We investigated the role of primary cilia in response to acute hyperosmolal stress, and whether TRPV4 and TRPM3 mediate this response.

**Methods:** TRPV4 and TRPM3 expression in ciliated (176-5) and nonciliated (176-5Δ) renal epithelial cells was determined by qPCR. Cells were challenged with 16-24 hours of osmotic stress at 400, 500, or 600mOsm/kg with NaCl, or maintained under control conditions. This stress was applied either in the presence or absence of a TRPV4 agonist (GSK1016790A), or a TRPM3 agonist (pregnenolone). Cell number was measured by crystal violet DNA binding assay, and viability was determined by calcein uptake. Markers of apoptosis were measured by immunoblotting.

**Results:** Both ciliated and nonciliated renal epithelial cells expressed TRPV4 and TRPM3, and TRPV4 expression was several fold higher in nonciliated cells. Nonciliated cells had reduced cell number and viability at and above 400mOsm/kg in comparison to ciliated cells. Nonciliated cell survival following osmotic stress was reduced further in the presence of a TRPV4 agonist, suggesting that TRPV4 may be critical for osmosensation in the absence of cilia. Cleavage of caspase 3 and PARP was seen in nonciliated cells treated with TRPV4 agonist under hyperosmolal and, to a lesser extent, isoosmolal conditions. Cell viability was reduced in ciliated cells pretreated with TRPM3 agonist at 600mOsm/kg, suggesting the importance of this channel for osmotic response in ciliated cells.

**Conclusions:** These findings support a role for TRPV4 and TRPM3 in osmosensation by renal epithelial cells. In ciliated cells, TRPM3 may be the predominant osmosensor, and increased expression of TRPV4 in nonciliated cells may represent a compensatory adaptation to loss of ciliary osmosensation.

## TH-PO606

**Na-K-ATPase and the Urine Concentrating Mechanism in the Rodent Medulla** Thomas Pannabecker, C. Michele Nawata, Tamara M. Armstrong, Kristen K. Evans, Mohammad Shahidullah. *Physiology, Univ of Arizona, Tucson, AZ.*

**Background:** Na reabsorption by medullary thick ascending limb and collecting duct is driven by basolateral Na-K-ATPase (NKA) with apical transport via NHE3/NKCC2 or ENaC. Reabsorption rates are influenced by regulated apical transport. By comparing NKA activity and expression in water-restricted Sprague-Dawley rats and in the kangaroo rat, a desert rodent that drinks no free water, we are investigating regulatory mechanisms that directly impact the active transport step.

**Methods:** Outer medullary tissue from control rats (*ad libitum* access to water) and water-restricted rats (water reduced to 40% of controls) was homogenized and a crude membrane fraction was prepared by centrifugation at 1100 x *g* (15 min) and at 150,000 x *g* (45 min). The membrane fraction was immunoblotted for NKA α-subunit (NKA-α) and ATP hydrolysis was determined by measuring release of $P_i$. NKA activity is the difference between ATP hydrolysis in the presence and absence of ouabain. Real-time PCR analysis was conducted on 1 μg total RNA from tissue homogenates.

**Results:** Urine osmolality (mOsm/kg $H_2O$) of Sprague-Dawley rats increased from 1185 (controls) to 2121 with 72 hr water restriction. Outer medullary NKA-α gene expression was unchanged with water restriction, whereas AQP2 gene expression increased 2-fold. Inner medullary NKA-α gene expression increased 2-fold. Prior studies have shown outer medullary NKA-α protein expression levels increase with restricted water intake. In the kangaroo rat (urine osmolality = 4159), outer medullary NKA-α protein expression levels are 2 to 3-fold higher than Sprague-Dawley control rats; however, NKA activity is no different.

**Conclusions:** Low correlation between outer medullary NKA-α1 gene expression and total NKA-α1 protein in water-restricted Sprague-Dawley rat suggests multiple regulatory mechanisms, possibly including lower protein degradation rate. Greater expression of outer medullary NKA-α1 protein but with equivalent NKA activity, in a species with sharply higher concentrating capacity could be consistent with greater fractional NKA-α1 expression in the plasma membrane. NIDDK DK083338, NSF IOS095285.

## TH-PO607

**Missing Link between Hyponatremia and Impaired Thyroid Function** Christian Stefan Haas, Matthias J. Berndt, Birgit Harbeck, Ulrich Lindner. *Dept of Medicine I, Univ of Luebeck, Luebeck, Germany.*

**Background:** Hyponatremia (HN) is the most common electrolyte disorder in both out- and in-patients. Hypervolemic states (e.g. heart failure, liver cirrhosis), hypovolemia, and the syndrome of inappropriate ADH secretion account for most of the cases, while endocrine disorders are less frequently responsible. Despite insufficient data on a relationship between thyreotropin (TSH), free thyroxine (fT4) and serum sodium, hypothyroidism is often cited as a possible cause of HN. The study objective was to assess the association between impaired thyroid function and HN.

**Methods:** In a retrospective analysis, patients admitted to the emergency room (ER) or the intensive care unit (ICU) having manifest hypothyroidism (TSH>10 mU/L and fT4<2 ng/L) were identified. Serum sodium levels and distribution were determined, HN prevalence ($Na^+$<135 mmol/L) assessed and the results compared with an ER and ICU population presenting with a normal TSH level (0.1-4 mU/L). The desired statistical power to detect a difference of 1.5 mmol/L between both groups was ≥90%. Pearson correlation was used to determine dependence of TSH and sodium.

**Results:** A total of 132 patients with significant hypothyroidism were identified and compared with 1253 euthyroid individuals. The sodium level (mean±SD) in hypothyroid patients did not differ when compared to controls (137.8±5.1 vs. 137.4±5.3 mmol/L, n.s.). HN prevalence in the control group was 21% (n=259), with 87 patients (7%) having even moderate ($Na^+$<130 mmol/L) or severe HN ($Na^+$<120 mmol/L). In the hypothyroidism group, HN prevalence was comparable; of note, most patients had mild HN, while moderate or severe HN was virtually not present in patients with severe hypothyroidism (TSH>50 mU/L).

**Conclusions:** In summary, we showed that: (1) mean sodium in hypothyroid patients and controls is comparable; (2) HN prevalence in hypothyroidism is not higher than in control patients; and (3) there is no correlation between serum sodium and TSH levels. These data suggest that hypothyroidism is not likely to be a cause for the development of HN and that measurement of TSH may be waived in the differential diagnosis of the electrolyte disorder.

## TH-PO608

**Chronic Hyponatremia: A Novel Risk Factor for Bone Fractures in Chronic Kidney Disease** Sagar U. Nigwekar, Julia Beth Wenger, Ravi I. Thadhani, Ishir Bhan. *Massachusetts General Hospital.*

**Background:** Chronic hyponatremia is associated with reduced bone density and increased fracture risk in the general population. Given the high fracture risk and prevalence of chronic hyponatremia in chronic kidney disease (CKD), we evaluated whether chronic hyponatremia is associated with increased fracture risk in CKD.

**Methods:** Subjects for this matched case-control study were identified from the Partners Healthcare Research Patient Data Registry. CKD was defined as estimated glomerular filtration rate < 60 mL/min. Chronic hyponatremia was defined as serum sodium (sNa) < 135 mEq/L on at least 2 occasions (prior to fracture for cases). Cases comprised ambulatory elderly (> 60 y) CKD patients with femoral and/or vertebral fractures diagnosed between January 2009 and December 2011. Controls were ambulatory elderly CKD patients without femoral or vertebral fractures and were matched to cases by age, gender, and race. Associations between chronic hyponatremia and fractures were evaluated in univariate and multivariable logistic regression analyses.

**Results:** We identified 3,027 eligible subjects (cases=937; controls=2,090). Chronic hyponatremia was more common in cases than controls (13 vs. 9%; p=0.03). Amongst the hyponatremic subjects, sNa was between 130 and 134 mEq/L in 85%. Subjects with chronic hyponatremia had higher prevalence of lung disease (30 vs. 25%, p=0.04), diuretic use (61 vs. 51%, p<0.01), and cirrhosis (4 vs. 2%, p<0.01), but similar rates of congestive heart failure, hypothyroidism, psychiatric disorders, and antidepressants use compared to those without chronic hyponatremia. Chronic hyponatremia was associated with increased odds of fracture in univariate analysis (OR 1.32, 95% CI 1.03- 1.69). Additional significant associations with fracture included female gender, hyperparathyroidism, osteoporosis, lung disease, and absence of obesity. Adjusted for these covariates and demographic factors, chronic hyponatremia remained a significant predictor of fracture (OR 2.20, 95% CI 1.19-4.07).

**Conclusions:** Chronic hyponatremia is associated with increased fracture risk in CKD. Future studies are needed to examine whether correcting chronic hyponatremia can reduce fracture risk.

## TH-PO609

**Collecting Duct Derived-Adenylyl Cyclase 3 Deficiency Does Not Affect Renal Sodium or Water Excretion** Wararat Kittikulsuth,[1] Deborah Stuart,[1] Elena V. Mironova,[2] James D. Stockand,[2] Donald E. Kohan.[1] *[1]Univ of Utah Health Sciences Center, Salt Lake City, UT; [2]Univ of Texas Health Sciences Center, San Antonio, TX.*

**Background:** The collecting duct (CD) is responsible for the final adjustment of renal water and Na excretion. Adenylyl cyclase (AC)-stimulated cAMP is a key mechanism for mediating these effects in the CD. At least two AC isoforms, AC3 and AC6, may be involved in vasopressin (AVP)-stimulated cAMP production in inner medullary CD (IMCD) cells. Recently, we showed that CD-derived AC6 is involved in regulation of CD water and Na transport. However, the role of CD-derived AC3 in regulating water and Na homeostasis is unknown.

**Methods:** We generated CD-specific knockout (KO) of AC3 mice using the Cre/loxP system. AC3 DNA recombination in microdissected nephron segments was determined by PCR and AVP-stimulated cAMP levels were determined in IM. KO mice and controls were placed under normal water intake, moderate and severe water restriction, or chronic water loading. These studies were done with a normal (0.3%Na) salt diet (NS). Mice were also fed a high (3.15%Na) salt diet (HS).

**Results:** IMCD from KO mice underwent 100% *Adcy3* gene recombination, while no DNA recombination occurred in proximal tubules of KO mice. AVP-enhanced cAMP production was reduced by 25% in the IM of KO mice. There were no detectable differences in water intake, food intake, urine volume or urine osmolarity between KO and controls during all water intake conditions. Plasma AVP levels tended to be higher in KO mice, but did not achieve statistical significance. Dietary Na intake and urinary Na excretion was similar between KO and controls on day 2 and day 3 of either an NS or HS diet. Arterial pressure was similar between both genotypes fed either an NS or HS diet. There were no differences in plasma renin concentration or urinary aldosterone excretion between KO and controls fed an NS diet. Finally, baseline or AVP-stimulated ENaC activity revealed no difference between KO and controls.

**Conclusions:** These data suggest that AC3 in the CD regulates AVP-stimulated cAMP accumulation, but this effect is modest and likely elicits changes that fully compensate for its absence.

*Funding:* Veterans Affairs Support

## TH-PO610

**The Rab-GAP Protein TBC1D4 (AS160) Regulates GLUT4 but Not ENaC and AQP2 in Mouse Kidneys** Marianna Di Chiara,[1,2] Dominique Loffing-Cueni,[1,] Bob Glaudemans,[3] Olivier Devuyst,[2,3] Nourdine Faresse,[1] Johannes Loffing.[1,2] *[1]Institute of Anatomy, Univ of Zurich, Zurich, Switzerland; [2]Zurich Center of Integrative Human Physiology (ZIHP), Univ of Zurich, Zurich, Switzerland; [3]Institute of Physiology, Univ of Zurich, Zurich, Switzerland.*

**Background:** The Rab-GTPase-activating protein TBC1D4 is implicated in GLUT4-mediated glucose uptake in adipo- and myocytes. We recently demonstrated that TBC1D4 is also expressed along the renal distal tubule, where it was proposed to control ENaC- and AQP2-mediated $Na^+$ and water reabsorption, respectively.

**Methods:** Here we used TBC1D4-deficient (KO) mice to characterize the role of TBC1D4 in the kidney in vivo. Functional phenotyping included analysis of mice on standard diet, low $Na^+$/high $K^+$ intake, and water restriction.

**Results:** Under these conditions, plasma ion concentrations, aldosterone levels, and urinary ion excretion and concentration ability did not differ between genotypes. Moreover, the abundance and subcellular localization of major renal sodium and water transport proteins (e.g. ENaC, AQP2, NCC, NKCC2) were similar in both genotypes. However, KO mice showed a prominent down-regulation of GLUT4 in the basolateral membrane of renal distal tubules.

**Conclusions:** TBC1D4-deficiency does not appear to perturb renal $Na^+$ and water transport, but TBC1D4 may play a role for GLUT4-mediated basolateral glucose uptake in the distal nephron. The latter may contribute to the known anaerobic glycolytic capacity of distal tubules.

*Funding:* Government Support - Non-U.S.

## TH-PO611

**Chronic Consumption of Fructose Increases Proximal Tubular Transport by Enhancing the Sensitivity to Angiotensin II** Agustin Gonzalez-Vicente, Nancy J. Hong, Pablo D. Cabral, Jeffrey L. Garvin. *Physiology & Biophysics, Case Western Reserve Univ, Cleveland, OH.*

**Background:** Salt-sensitive hypertension is a disease in which blood pressure increases with dietary salt. Consumption of high-fructose corn syrup as a sweetener has been implicated in the epidemic of diabetes, obesity, renal failure and hypertension. While high-fructose diets are able to increase blood pressure independently of salt intake, moderately-enriched fructose diets cause salt-sensitivity. The proximal tubule reabsorbs 60-70% of the filtered fluid, Na and $HCO_3$ via the Na/H exchanger 3 (NHE3). Salt reabsorption by this segment is regulated by angiotensin II (Ang II). We hypothesized that a moderately-enriched fructose diet increases Na reabsorption in proximal tubules by enhancing their sensitivity to Ang II.

**Methods:** To test this, rats were given 20% fructose in drinking water for 9 to 13 days. After treatment, the effects on transport of 1 pM Ang II were evaluated by oxygen consumption ($QO_2$) in proximal tubule suspensions from either fructose-fed rats or controls drinking tap water. NHE3 protein abundance was measured in cortical homogenates from either group. Components of the renin-angiotensin-system, angiotensinogen and AT1 receptor, were measured by mRNA expression.

**Results:** We found that 1 pM Ang II did not stimulate $QO_2$ in proximal tubule suspensions from control rats (-7±4 %; n=5). In contrast, it increased $QO_2$ in proximal tubules from fructose-fed rats by 18±8 % ($p<0.04$). To test whether this was due to increased NHE3, we measured protein abundance in cortical homogenates. We found that dietary fructose also increased NHE3 expression by 18±4 % ($p<0.03$; n=4) compared to the controls drinking tap water. We next tested whether components of the renin-angiotensin-system were elevated. AT1 receptor and angiotensinogen mRNA in cortical homogenates from the fructose-fed rats group were not different from controls.

**Conclusions:** We conclude that moderate fructose intake increases the sensitivity of the proximal tubule to Ang II and that enhanced NHE3 expression may contribute to this. AT1 receptor and angiotensinogen expression are not involved in this mechanism.

## TH-PO612

**Amiloride Inhibits uPA Activity and Plasminogen Activation in Urine from Rats with PAN-Induced Nephrotic Syndrome** Kristian B. Buhl,[1] Per Svenningsen,[1] Rikke M. Zachar,[1] Claus Bistrup,[2] Boye Jensen.[1] *[1]Dept of Cardiovascular and Renal Research, Institute of Molecular Medicine, Univ of Southern Denmark, Denmark; [2]Dept of Nephrology, Univ Hospital of Odense, Denmark.*

**Background:** Sodium retention in nephrotic syndrome (NS) is mediated by ENaC. The gamma subunit of ENaC is proteolytically activated in nephrotic syndrome. Aberrant filtration of serine protease zymogen plasminogen and conversion to active plasmin in the urinary space is a likely mediator. Urokinase-type plasminogen activator (uPA) is thought to mediate the activation in preurine. Amiloride is an inhibitor of uPA *in vitro*. We addressed the hypothesis that nephrotic syndrome results in aberrant glomerular filtration of uPA and urine uPA is inhibited by amiloride which prevents activation of plasminogen and ENaC proteolysis, sodium retention and edema *in vivo*.

**Methods:** Urine and kidney tissue uPA was determined in the PAN treated rat model of acute nephrotic syndrome and amiloride was tested for its ability to inhibit uPA. Rats were kept in metabolic cages and the effect of treatment was compared to vehicle treated nephrotic and healthy control rats.

**Results:** Development of proteinuria in the PAN rat model of nephrosis coincided with increased urinary serine protease activity as judged by gelatine zymography. PAN rats showed significant elevated urinary uPA activity. Immureactive uPA was detectable in urine samples of control and PAN treated rats. Amiloride significantly reduced uPA activity in nephrotic rat urine; it reduced urine gelatinolytic activity and concurrently increased the ratio plasminogen/plasmin and normalized 24 hour sodium excretion.

**Conclusions:** Urokinase–type plasminogen activator (uPA) is a target for amiloride in urine. Amiloride counteracts urinary plasminogen activation in proteinuric disease *in vivo*. ENaC is responsible for excess renal sodium retention in nephrotic syndrome.

*Funding:* Private Foundation Support

## TH-PO613

**Incidence and Factors of Post-Adrenalectomy Hyperkalemia in Patients with Aldosterone Producing Adenoma** Shih-Hua P. Lin, Sung-Sen Yang, Yu-Juei Hsu, Chih-Jen Cheng. *Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

**Background:** In patients with aldosterone-producing adenomas (APA), aldosterone secretion by the lesion severely suppresses the contralateral adrenal gland [8]. After adrenalectomy, patients with APA usually exhibit a state of hypoaldosteronism and are susceptible to developing hyperkalemia, a potentially serious complication. The aim of this study is to analyze the incidence and risk factors for hyperkalemia after adrenalectomy in patients with APA.

**Methods:** We retrospectively analyzed the records of 55 patients who underwent adrenalectomy for APA over the past 9 years. Demographic features, biochemical and hormonal profiles, imaging, and relevant medications were reviewed. Nadir serum $K^+$ was defined as the serum $K^+$ level when APA was first diagnosed. Hyperkalemia was defined as serum $K^+ > 5.0$ mmol/L and the exclusion of pseudohyperkalemia. Hyperkalemia that resolved during the first three months after adrenalectomy was defined as "transient;" those lasting more than three months requiring mineralocorticoid supplementation was defined as "persistent".

**Results:** Sixteen of 55 APA patients (29.1%) developed hyperkalemia (mean serum $K^+$ 5.6 ± 0.3 mmol/L) after adrenalectomy and three had persistent hyperkalemia requiring mineralocorticoid supplementation for more than nine months. Compared with normokalemic patients, hyperkalemic patients were characterized by male predominance, older age, longer duration of hypertension (12.8 ± 9.3 vs. 6.7 ± 5.0 years, $p < 0.05$), lower nadir serum $K^+$ ($p < 0.05$), higher preoperative serum creatinine ($p < 0.01$), and higher likelihood of residual hypertension. Using multivariate regression analysis, longer duration of hypertension and impaired renal function were the most important factors of post-adrenalectomy hyperkalemia.

**Conclusions:** Post-adrenalectomy hyperkalemia in patients with APA is not rare and associated with impaired renal function and longer duration of hypertension. Serum $K^+$ must be cautiously monitored in patients with long-term hypertension and kidney disease.

## TH-PO614

**Etiological and Therapeutic Analysis in Patients with Hypokalemic Paralysis due to Potassium Deficit** Chih-Chien Sung, Chih-Jen Cheng, Sung-Sen Yang, Shih-Hua P. Lin. *Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

**Background:** Non-hypokalemic periodic paralysis (non-HypoPP) represents a group of diverse causes of a large potassium ($K^+$) deficit. To rapidly diagnose its underlying causes with appropriate management is still challenging.

**Methods:** Fifty-eight patients (43 male and 15 female) with non-HypoPP and the exclusion of HypoPP were consecutively enrolled over an eight-year period. Blood and spot urine samples were collected for electrolytes, acid-base and biochemistry measurement on admission and during therapy. Intravenous potassium chloride (KCl) at a rate of 10-20 mmol/hour was administered until muscle strength recovered.

**Results:** The average $K^+$ concentration was 1.8 ± 0.3 mmol/L. Their etiology could be simplified by the urinary $K^+$ excretion rate and blood acid-base status. For a low urinary $K^+$ excretion, chronic alcoholism, anorexia/bulimia nervosa, and remote diuretics use were the most common caues. For a high urinary $K^+$ excretion with metabolic acidosis, renal tubular acidosis and chronic toluene abuse were common causes. Mineralocorticoid excess state with primary aldosteronism, Gitelman's or classic Bartter's syndrome, and diuretics use were common causes for metabolic alkalosis with high and normal blood pressure, respectively. Muscle strength was restored at serum $K^+$ concentration of 2.6 ± 0.2 mmol/L after administering approximately 245 mmol (3.8 ± 0.8 mmol/kg) KCl. Of note, non-HypoPP patients with high urinary $K^+$ excretion needed a higher KCl dose than those with low $K^+$ excretion (4.0 ± 0.8 vs 3.2 ± 0.5 mmol/kg, $p < 0.001$). KCl supplementation was higher in patients who developed a paradoxical fall in serum $K^+$ concentration (1.6 ± 0.2 mmol/L) than those without (4.1 ± 0.7 vs 3.4 ± 0.7 mmol/kg, $p < 0.001$). These patients often had typical volume depletion with higher plasma renin activity.

**Conclusions:** Understanding the common etiology of non-HypoPP may aid in early diagnosis. Non-HypoPP patients associated with renal $K^+$ wasting or hypovolemia that tend to develop paradoxical hypokalemia require a larger dose of KCl to prevent life-threatening complications.

## TH-PO615

**Revisiting the Effectiveness of Sodium Polystyrene Sulfonate in Treating Hyperkalemia** Baidaa Najeeb Mohammed,[1] Farhad Mohammed- Hasan,[1] Richard H. Sterns.[1,2] *[1]Medicine, Rochester General Hospital, Rochester, NY; [2]Medicine (Nephrology), Univ of Rochester School of Medicine and Dentistry, Rochester, NY.*

**Background:** Sodium polystyrene sulfonate (SPS) is a $K^+$ -binding resin commonly used to treat hyperkalemia. No studies in humans or animals show that SPS increases $K^+$ elimination [Sterns RH, J Am Soc Nephrol. 2010;21(5):733-5]. A recent study cited a dose- response relationship as evidence that SPS is effective [Kessler C, J Hosp Med. 2011;6(3):136-40 [4] .

**Methods:** We reviewed all records of inpatients who received SPS for hyperkalemia ( > 5.1 mEq/L) at Rochester General Hospital between November 1, 2011 and December 31, 2012. We excluded cases of SPS Rx with: chronic use; other Rx modalities for hyperkalemia (including dialysis) ; repeated doses < 6 hrs apart ; hemolysis and absence of follow up labs.

**Results:** 116 hyperkalemic subjects (mean pre-Rx serum $K^+$ = 5.64 ± 0.36 mEq/L) receiving oral SPS as sole Rx were studied. Mean serum $K^+$ dropped by 13% after a median of 8 hrs. A higher SPS dose (30 Gm, n = 49) was associated with a greater fall in serum $K^+$ (0.89 ± 0.49 mEq/L) than a lower dose (15 Gm , n = 67) (0.66 ± 0.53 mEq/L); $p = 0.02$ . However, a higher SPS dose was also associated with a higher pre- Rx serum $K^+$ level (5.76 ± 0.39 mEq/L in the 30 Gm subgroup vs. 5.56 ± 0.31 mEq/L in the 15 Gm subgroup; $p = 0.005$) and there was a statistically significant positive correlation between pre-Rx serum $K^+$ and the decrement in serum $K^+$ ($r = 0.51$, $p < 0.001$). Within the 30 Gm subgroup a similar correlation was found between pre-Rx serum K and decrement in $K^+$ ( $r= 0.3$; $p = 0.006$) but not in the 15 Gm subgroup. There was no correlation between the magnitude of the decrement in serum $K^+$ and the time to subsequent testing ($r = 0.01$, $p = 0.13$) , suggesting that serum $K^+$ may not fall progressively with time after SPS as would be expected for an oral drug that works in the distal colon.

**Conclusions:** A dose-response relationship between SPS and correction of hyperkalemia does not prove cause and effect. Placebo controlled trials of SPS are needed.

## TH-PO617

**Relowering Sodium after Overcorrection of Hyponatremia: Save the Brain. Cases Series and Literature Review** Alain Soupart,[1,2] Guy Decaux,[2] Michel Coffernils,[1] Fabrice Gankam,[3] Frédéric Vandergheynst,[2] Bruno Couturier.[2] *[1]Internal Medicine, Jolimont/Tubize Hospital, Tubize, Belgium; [2]Internal Medicine, Erasmus Univ Hospital, Belgium; [3]Nephrology, Erasmus Univ Hospital, Belgium.*

**Background:** Overcorrection of severe chronic hyponatremia (HN) can lead to osmotic demyelination syndrome (ODS) with major brain damage.Too fast correction produces excessive brain dehydration, intracellular hyperionisation and demyelinating lesions. We showed in rats that relowering SNa after overcorrection dramatically reduced ODS and mortality (Kidney Int, 1994, J Neuropathol Exp Neurol 1996) and we report the first case in man (Clin Nephrol, 1999). Clinical experience of this therapy is however limited.

**Methods:** We report a series of 11 patients from our hospital with HN of various origins submitted to inadvertent overcorrection (DSNa > 10 mEq/l/24 h) in whom SNa was relowered using DDAVP and hypotonic fluids. After literature review, 7 cases with same inclusion criteria were found and added in series. Cases were separated whether they are asymptomatic (group I, 5 cases from our center) or present neurologic symptoms (group II, 6 cases from our center) prior relowering.

**Results:**

| Groups | Age | SNa T0 | ΔSNa/24hr | Relowering time from T0 | Final ΔSNa into next 24hr | Clinical Outcome |
|---|---|---|---|---|---|---|
| Group I n = 9 | 62±9 | 110±3 (106-117) | +17±3 (12-22) | Day 1-2 | +10±3 (3-16) | N (9/9) Brain MRI: N |
| Group II n = 9 | 64±11 | 108±6 (97-118) | +17±6 (12-26)* | Day 1-7 | +12±3 (8-19) | N (9/9) Brain MRI: N |

*Data means ± SD; SNa : mEq/l; *one case relowered after correction of 5 mEq/l/day during 3 successive days*

**Conclusions:** This largest reported series shows that SNa relowering in patients after overcorrection is safe and associated with a good clinical outcome and no ODS.

## TH-PO618

**Tritherapy (Saline, Urea, Desmopressin = SUD) as Initial Therapeutic Regimen for Sodium Rate Control in Patients with Non-Oedematous Severe Hyponatremia** Alain Soupart,[1,2] Guy Decaux,[2] Michel Coffernils,[1] Bruno Couturier,[2] Frédéric Vandergheynst.[2] *[1]Internal Medicine, Jolimont/Tubize Hospital, Tubize; [2]Internal Medicine, Erasmus Univ Hospital, Brussels.*

**Background:** There is no consensus about optimal treatment of severe hyponatremia (HN). Significant risks of inadvertent overcorrection and ODS exists with the usual methods of correction (normal or hypertonic saline ± furosemide). We evaluate the effect of a treatment combining normal saline with urea and DDAVP (SUD regimen) during the first 24hr as initial treatment in non-oedematous HN owing to control the rise (ΔSNa < 12 mEq/l/24hr) in SNa (DDAVP) and to protect brain against ODS (urea).

**Methods:** Ten consecutive non-oedematous patients with severe HN were included in the study. Patients with severe symptoms (coma, epilepsia) were excluded. Treatment consists in: [normal saline 1 l + oral urea 30 gr + DDAVP 4 µg s.c] every 12 hours during the first 24hr. Treatment was adapted at 12hr depending on the correction level (if ΔSNa ≥5 mEq/l, no second urea dose; ≤ 2 mEq/l, no second DDAVP dose; > 10 mEq/l at any time, active treatment stopped).

**Results:**

| N = 10 | T0 | T6hr | T12hr | T24hr | T48hr |
|---|---|---|---|---|---|
| SNa (mEq/l) | 113±3 | 117±3 | 118±3 | 121±3 | 126±2 |
| ΔSNa (mEq/l) Range | - - | 3.2±3 (0-12) | 4±3 (0-11) | 7.6±1.9 5-11) | 12.5±5 (3-21) |
| SUrea (mg/dl) | 18±8 | 70±26 | 66±29 | 61±27 | 39±19 |
| UNa (mEq/l) | 21±17 | 34±22 | 26±23 | 32±26 | 58±30 |
| UOsm (mOsm/Kg/$H_20$) | 353±175 | 455±113 | 579±146 | 575±141 | 515±180 |

*Data means ± SD*

The outcome was good in all the patients and brain CT or MRI were normal.

**Conclusions:** SUD regimen is associated with a good sodium rate control and a favourable outcome in patients with non-oedematous HN of various origins.

## TH-PO619

**Hyponatremia Is Associated with Increased Osteoporosis and Bone Fractures in a Large Health System Population** Laura Cowen,[1] Stephen Fernandez,[2] Nawar M. Shara,[1,2] Julianna Barsony,[1] Joseph G. Verbalis.[1] *[1]Endocrinology, Georgetown Univ, Washington, DC; [2]Medstar Health Research Institute, Washington, DC.*

**Background:** Four independent studies have shown increased bone fractures in patients with hyponatremia (HN). Likely major contributors include gait instability and increased falls in HN patients. Recent animal studies have also demonstrated HN-induced bone loss, and analysis of human subjects in NHANES III showed a significantly increased odds ratio for osteoporosis in HN subjects.

**Methods:** To assess the clinical significance of these findings, we analyzed the patient database of the MedStar Health system using the Explorys electronic health record (EHR) tool.

**Results:** A search of >2.8 million unique EHR records showed that 55,510 patients had osteoporosis by ICD-9 coding; of this group, 8,060 had HN by either ICD-9 coding or laboratory measurement (serum [$Na^+$] <135 mmol/L) and 47,450 did not. The prevalence of osteoporosis in the HN patients was 4.6% (8,060/177,100 total HN patients), compared to 1.8% in the non-HN patients (47,450/2,623,200 total non-HN patients). Because not all bone fractures are associated with osteoporosis, we also analyzed the occurrence of fractures in this database. A larger number of patients, 112,840, had bone fractures by ICD-9 coding; of this group, 16,820 had HN and 96,020 did not. The prevalence of fractures in the HN patients was 9.5% (16,820/177,100 total HN patients), compared to 3.7% in the non-HN patients (96,020/2,623,200 total non-HN patients). Demographic analysis of HN and non-HN patients with osteoporosis and fractures indicated a larger percentage of affected men in the HN group (17.5%) versus the non-HN group (14.2%). Age group predominance

was similar in both groups with the majority of affected patients aged 70-89. This analysis indicates that both osteoporosis and bone fractures are increased approximately 2.6-fold in HN compared with non-HN patients.

**Conclusions:** These results support the hypothesis that HN is a risk factor for both osteoporosis and bone fractures in patients; our results also demonstrate the power of focused analysis of the EHR to assess the clinical relevance of findings generated from translational science studies.

### TH-PO620

**Hyponatremia Is a Surrogate Marker of Severity in Uremic Patients with Peritoneal Dialysis-Related Peritonitis** Min-Hua Tseng,[1] Shih-Hua P. Lin,[2] Sung-Sen Yang,[2] Chih-Jen Cheng.[2] *[1]Div of Nephrology, Dept of Pediatrics, Chang Gung Memorial Hospital, Taoyuan, Taiwan; [2]Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, Taipei, Taiwan.*

**Background:** The association of hyponatremia with clinical outcome in dialysis patients is not well studied, especially in peritoneal dialysis-related peritonitis (PDRP). The aim of this study was to evaluate the impact of hyponatremia in patients with PDRP.

**Methods:** We retrospectively reviewed the medical records of the dialysis patients admitted with PDRP over the past eight years. Patients were divided into two groups: one with serum $Na^+$ <130 mEq/L (group I) and the other ≥130 mEq/L (group II). Primary endpoint was mortality during hospitalization. Secondary outcomes included length of hospital stay, removal of peritoneal dialysis (PD) catheter, peritonitis occurrence, and failure of PD.

**Results:** Of 99 patients with PDRP, group I had 27 and group II 72 patients. Gram-negative bacilli and gram-positive cocci accounted for the majority of PDRP in Group I and II, respectively. Despite no significant difference in age, duration of dialysis, PD catheter removal rate and technique failure between 2 groups, group I had a significantly higher serum CRP ($p < 0.001$), lower serum albumin ($p < 0.001$) and phosphate ($p < 0.05$). There was a positive correlation between serum $Na^+$ and albumin concentration ($p<0.001$) as well as serum phosphate level ($p<0.04$). Length of hospital stay ($p< 0.001$) and hospital mortality ($p < 0.001$) were also significantly higher in group I than II. In a multivariable logistic regression, hyponatremia on admission remained an independent predictor of hospital mortality (OR 76.89 95% CI 3.39-1741.67, $p< 0.05$) and independently associated with length of hospital stay (OR 5.37, 95%CI 1.58- 18.19, $p< 0.05$).

**Conclusions:** The degree of hyponatremia in uremic patients with PDRP reflects the severity of peritonitis and is associated with length of hospitalization and mortality.

### TH-PO621

**Prognostic Impact of Hyponatremia Occurring at Various Time Points during Hospitalization on Long-Term Mortality in Patients with Acute Myocardial Infarction** Joon Seok Choi, Ha Yeon Kim, Yong Un Kang, Chang Seong Kim, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Dept of Internal Medicine, Div of Nephrology, Gwngju, Korea.*

**Background:** We investigated the incidence and prognostic impact of hyponatremia occurring at various time points during hospitalization on long-term mortality in patients surviving an episode of acute myocardial infarction (AMI).

**Methods:** We retrospectively studied 1,863 patients diagnosed with AMI. Baseline, nadir, discharge, and average sodium levels during hospitalization were recorded and statistically analyzed. Hyponatremia was defined as a serum sodium level <135 mEq/L.

**Results:** On the basis of baseline, nadir, discharge, and average sodium levels during hospitalization, hyponatremia was diagnosed in 309 (16.6%), 518 (27.8%), 147 (7.9%), and 140 (7.5%) patients, respectively. In a multivariate Cox-proportional regression analysis, discharge sodium level had the strongest significant relationship to long-term mortality (hazard ratio [HR] as continuous variable = 1.07, 95% confidence interval [CI]: 1.01-1.13, P = 0.014; HR as categorical variable = 1.75; 95% CI: 1.09-2.80; P = 0.021), but baseline sodium had no prognostic impact on long-term mortality after adjustment.

**Conclusions:** The serum sodium level and incidence of hyponatremia varied at different time points during hospitalization. In addition, the association between sodium level and long-term mortality differed at these various time points. The discharge sodium level appears to be the best predictor of long-term mortality in patients surviving an acute episode of AMI.

### TH-PO622

**The Physiological Role of Adaptor Protein 1B on the Surface Trafficking of Kidney Anion Exchanger 1** Ensaf Yousef Almomani, Emmanuelle Cordat. *Physiology, Univ of Alberta, Edmonton, Canada.*

**Background:** Distal Renal Tubular Acidosis (dRTA) is a disease characterized by metabolic acidosis, an inability to acidify urine, the development of kidney stones and renal failure if untreated. DRTA patients may carry a mutation on the SLC4A1 gene encoding the kidney anion exchanger 1 (kAE1), a $Cl^-/HCO_3^-$ exchanger basolaterally expressed in acid-secreting kidney intercalated cells. KAE1 binds to the epithelial-specific adaptor protein 1B (AP-1B) complex, which is essential to trafficking and recycling cargo proteins. The apically mistargeted kAE1-R901X that occurs naturally, and the engineered C-terminal Y904A/V907A mutants, both lack the interaction site with the mu subunit of AP-1B. We hypothesized that AP-1B is important for kAE1 stability at the cell surface of kidney epithelial cells and that the missing interaction of the kAE1-R901X mutant with AP-1B causes dRTA.

**Methods:** To study the role of AP-1B, we stably expressed kAE1 wild-type (WT) or mutants in porcine epithelial kidney cells (LLC-PK1) that are naturally devoid of endogenous AP-1B.

**Results:** Cell surface biotinylation and immunoblotting showed that the expression of AP-1B significantly increased the amount of total and cell surface kAE1-WT in LLC-PK1 cells treated with cycloheximide for 8 hours, but not that of kAE1-R901X or Y904A/V907A mutants. The AP-1B independent $Na^+/K^+$-ATPase did not show a significant difference of surface expression upon AP-1B expression, suggesting that the effect of AP-1B is specific to kAE1. We further examined the effect of AP-1B on kAE1 endocytosis and recycling to the cell surface.

**Conclusions:** This study highlights the importance of AP-1B for kAE1 stabiltity at the cell surface. Loss of mutated kAE1 / AP-1B interaction may explain the pathogenicity of dRTA.

### TH-PO623

**Comparison of Arterial Blood Gas versus Laboratory Electrolyte Measurements in Critically Ill Patients at Cleveland Clinic Florida** Julianne M. Parente, Rute C. Paixao, Mauro Braun, Dianne T. Sandy. *Nephrology, Cleveland Clinic Florida, Weston, FL.*

**Background:** Electrolyte measurements are performed by Arterial Blood Gas (ABG) analyzers and laboratory analyzers. However, a significant time gap exists between availability of these results, with ABG giving faster results. The aim of the present study was to investigate weather ABG analyzers can provide an accurate measurement of electrolytes as compared to laboratory based analysis. ABG results may enable the critical care team to make faster clinical decisions, improve quality of care and decrease mortality rates. Data on sodium, potassium and chloride were examined.

**Methods:** We retrospectively studied 111 patients admitted to the Cleveland Clinic Florida (CCF) Intensive Care Unit (ICU) between February and June 2013. ABG electrolyte results were compared with results from that day's laboratory results when the samples were obtained within one hour of each other. All patients with any acute or chronic condition were considered possible subjects for the study. The research protocol was approved by the Institutional Review Board.

**Results:** A total of 111 blood samples were analyzed. The mean patient age was 66.7 years. 64.8% of the subjects were males. 57% of the patients were admitted to the Surgical ICU and the remainder to the Medical ICU. 66.6% of the patients had an arterial line in place at the time of the sample collection. The mean sodium concentration was 140.6 mmol/L (SD 5.74) using the serum and 137.7 mmol/L (SD 5.66) ($p=0.293$) using the ABG analyzer. Mean potassium level was 4.1 mmol/L (SD 0.63) using the serum and 3.96 mmol/L (SD 0.63) ($p=0.006$) using the ABG analyzer. Mean chloride values were 102.4 mmol/L (SD 7.58) and 104.8 mmol/L (SD 7.37) ($p=0.016$) using the laboratory and ABG analyzers, respectively.

**Conclusions:** Based on the above analysis, we found no significant difference between the sodium values measured by the blood gas machine and the laboratory analyzer. However, the differences between the measured potassium and chloride were found to be significant. We therefore conclude that critical decisions can be made by trusting only the sodium levels obtained from the blood gas analysis.

### TH-PO624

**Analysis of Chondroitin Sulfate Proteoglycans and Reactive Astrogliosis in a Rat Model of Osmotic Demyelination Syndrome** Bruno Couturier,[1] Fabrice Gankam,[2] Alain Soupart,[3] Guy Decaux.[1] *[1]Internal Medicine, Erasme Hospital Free Univ of Brussels, Brussels, Belgium; [2]Nephrology, Erasme Hospital Free Univ of Brussels, Brussels, Belgium; [3]Internal Medicine, Jolimont Hospital Free Univ of Brussels, Brussels, Belgium.*

**Background:** Osmotic demyelination syndrome (ODS) results from overly rapid correction of chronic hyponatremia (HypoNa) and its pathophysiology is not yet fully understood. Specifically it is not clear which factors might promote or impede remyelination and clinical recovery. Using a rat model, we studied several molecules known as markers of glial activation (nestin and vimentin) and inhibitors of axonal growth including chondroitin sulphate proteoglycans (CSPG's) in order to determine their role in CNS regeneration after osmotic insult.

**Methods:** Chronic hyponatremia was induced in rats by continuous infusion of ADH and corrected with hypertonic saline. At various times after the correction we used immunohistochemistry to assess expression of vimentin, nestin and several CSPG's. Immunofluorescence was used to identify which cells expressed these molecules.

**Results:** We confirmed the increase in glial fibrillary acidic protein at the borders of the ODS lesions after rapid correction of chronic hypoNa. Moreover, we showed an upregulation of Nestin and vimentin in astrocytes of corrected animals from day-to-day after the correction. We also confirm the expression of three CSPG's, CD44, neurocan and phosphacan KS in the direct vicinity of osmotic lesions following a peculiar pattern. CD44 and neurocan were distributed in the lesions penumbra whereas phosphacan KS was mainly found in the lesion core. CSPG's deposition only appeared 72h after correction and was more prominent 6 days after correction.

**Conclusions:** These results suggest a specific pattern of CSPG's and nestin/vimentin expression in brain after osmotic insult. Their role in myelin regeneration after osmotic insult remains to be determined.

## TH-PO625

**Role of Tubular Luminal H(+)/Organic Cation Antiporter, MATE, in Natriuresis as a Dopamine Transporter** Moto Kajiwara, Tsuyoshi Ban, Kazuo Matsubara, Satohiro Masuda. *Clinical Pharmacology and Therapeutics, Kyoto Univ Hospital, Kyoto, Japan.*

**Background:** The intrarenal dopaminergic system is likely responsible for regulating over 50% of net renal salt and water excretion when salt intake increases. Although dopamine synthesis is localized at proximal tubular cells, the molecular mechanism underlying dopamine secretion into urine remains unknown. Multidrug and toxin extrusion (MATE, SLC47A) was identified in 2005; it is expressed in high levels in the brush border membrane of proximal tubular cells mediating the efflux of organic cations, such as metformin and cisplatin, from epithelial cells into urine. Therefore, we hypothesized that MATE mediates secretion of dopamine, a cationic catecholamine, into tubule lumen and consequently regulates natriuresis.

**Methods:** Sodium levels in the urine and whole blood of mice were respectively measured using an ion-selective electrode (cobas6000, Roche) and an iSTAT analyzer (Abott). Urinary dopamine concentration was measured with a liquid chromatography-tandem mass spectrometry.

**Results:** To determine whether dopamine is a substrate of MATE, we examined [$^3$H] dopamine uptake in HEK293 cells transiently expressing human (h) MATE1, hMATE2-K, and mouse (m) MATE1. Uptake of [$^3$H]dopamine by cells expressing hMATE1, hMATE2-K, and mMATE1 was higher than that of vector-expressing cells. *In vivo* acute saline-loading experiments using infusion pump were performed to examine MATE contribution on urinary dopamine transport in mice. Urinary dopamine was detected in wild-type mice (WT), but was hardly present in MATE1-knockout mice (KO). Another experiment showed that the amount of urinary sodium excretion in WT increased to 12.3-fold than that of the control group, although the amount in MATE1-KO increased to only 1.5-fold than that of the control group. In intact mice, average whole blood sodium levels were significantly higher ($n = 3$, mean ± SD, $P < 0.003$) in MATE1-KO (146.7 ± 0.58 mmol/L) than those in WT (143.7 ± 0.58 mmol/L).

**Conclusions:** In conclusion, our results indicated a critical role of MATE in dopamine secretion into tubular lumen, along with MATE's regulation of sodium excretion into urine.

*Funding:* Government Support - Non-U.S.

## TH-PO626

**Mapping of pH Sensor, GPR4, to Peritubular Capillaries** Doris P. Molina,[1] Xuming Sun,[1] Glen S. Marrs,[3] Thomas D. DuBose,[1,2] Snezana Petrovic.[1,2] *[1]Physiology and Pharmacology, Wake Forest Univ, Winston Salem, NC; [2]Internal Medicine Section of Nephrology, Wake Forest Univ, Winston Salem, NC; [3]Biology, Wake Forest Univ, Winston Salem, NC.*

**Background:** GPR4 is a proton receptor, a member of a unique family of G protein-coupled receptors that are activated by an acid pH within the physiological pH range. This family of receptors function as pH sensors in blood vessels, bone, kidney, airway smooth muscle, lung cancer, and possibly brain. GPR4 is the most abundant proton receptor in the kidney. We previously demonstrated that GPR4 mRNA is expressed in all three kidney zones and in kidney epithelial cells. Lack of specific GPR4 antibodies precluded more detailed studies of GPR4 distribution in the kidney.

**Methods:** Here, we employed an alternative strategy, mapping transgenic GFP expression driven by the GPR4 promoter. Namely, GPR4-/- mice (Mol Cell Biol 27: 1334-1347, 2007) were generated with a construct with a GFP insert, which was tagged with anti-GFP rabbit polyclonal antibody. As GFP expression is driven by the GPR4 promoter, GFP labeling was present selectively in GPR4-/- mice in cells which natively express GPR4, with GPR4+/+ mice serving as control.

**Results:** We found abundant expression of GPR4 in endothelial cells of the peritubular capillaries, consistent with reports of GPR4 expression in endothelial cell cultures. Double-labeling with isolectin IB4 confirmed the presence of GPR4 within endothelial cells and peritubular capillaries. GPR4 was expressed at lower levels in the glomerulus, localizing to mesangial cells (5' nucleotidase co-localization) as well as glomerular endothelial cells (IB4-co-localization). GPR4 did not co-localize with Wilms tumor antigen, indicating that GPR4 is absent from podocytes.

**Conclusions:** The expression of a pH sensor in the peritubular capillaries is an intriguing finding given the typically low pH of the kidney interstitium and its anticipated fluctuations with dietary acid loads. It is plausible that the response of GPR4 to a decline in interstitial pH may initiate a response by the peritubular capillaries, with potential implications for redox status, release of endothelin, activation of RAS, and renal perfusion.

## TH-PO627

**Dietary Protein Restriction Induces an Integrated Response Involving Multiple Aspects of Renal Ammonia Metabolism** Hyun-Wook Lee,[1] Jesse M. Bishop,[1] Mary E. Handlogten,[1] Jill W. Verlander,[1] I. David Weiner.[1,2] *[1]Renal Div, Univ of Florida, Gainesville, FL; [2]Nephrology and Hypertension Section, GVAMC, Gainesville, FL.*

**Background:** Both low protein diets and systemic acid-base status have important effects on the progression of chronic kidney disease. Because ammonia metabolism is a major determinant of renal acid-base homeostasis, we examined the effect of dietary protein restriction on renal ammonia metabolism. Because we identified novel effects of protein restriction on expression of the ammonia transporter family member, Rhbg, we also determined the effect of collecting duct-specific Rhbg deletion (CD-Rhbg-KO) on the response to protein restriction.

**Methods:** C57Bl/6 mice were acclimated in metabolic cages and then randomly assigned to either low (6%) or control (20%) protein diets for two weeks. Daily 24 hr urine was collected. At the end of the study, tissue was obtained for immunoblot analysis and immunohistochemistry. CD-Rhbg-KO mice were generated using Cre-loxP techniques and were studied using an identical protocol.

**Results:** Low protein diet decreased urinary ammonia excretion by 85-90%. It also decreased by 40% renal cortical PEPCK, did not alter either renal cortical or outer medullary PDG expression, and increased renal cortical glutamine synthetase expression. Rhbg expression increased in the outer medulla, and immunohistochemistry demonstrated changes in expression were limited to intercalated cells in the outer medullary collecting duct (OMCD). However, CD-Rhbg-KO did not alter changes in urinary ammonia excretion in response to low protein diet, nor did it alter urine pH or low-protein induced changes in PEPCK, PDG or GS in renal homogenates.

**Conclusions:** We conclude: (1) Low protein diet decreases renal ammonia excretion through mechanisms involving both decreased ammoniagenesis involving PEPCK and increased ammonia assimilation involving glutamine synthetase; (2) low protein diet results in increased OMCD intercalated cell Rhbg expression which is not necessary for the reduced urinary ammonia excretion; and, (3) Rhbg may have previously unidentified roles in the renal response to low protein diet which are unrelated to ammonia excretion.

*Funding:* NIDDK Support, Other U.S. Government Support, Veterans Affairs Support

## TH-PO628

**Acid-Stimulated Pyk2 Regulates $H^+$,$K^+$-ATPase Activity via a p38 MAPK Signaling Pathway in Outer Medullary Collecting Duct Cells** Kimberly Fisher,[1,2] Thomas D. DuBose.[2] *[1]Medicine, Vanderbilt Univ, Nashville, TN; [2]Medicine, Wake Forest School of Medicine, Winston Salem, NC.*

**Background:** Proton secretion increases in the OMCD in response to an acid load that occurs as a product of the metabolism of protein derived from a typical Western diet to defend against metabolic acidosis. We have shown that proline-rich tyrosine kinase-2 (Pyk2), a putative a pH sensor, participates in the regulation of apical ATPase-mediated proton transport in the OMCD.

**Methods:** In the current study we used the $NH_4Cl$ pre-pulse technique to generate an acid intracellular pH ($pH_i \sim 6.7$) in mouse-derived inner medullary (mOMCD1) cells *in vitro* (control $pH_i = 7.4$). We then analyzed rates of $pH_i$ recovery after an $NH_4Cl$ pre-pulse using spectrofluorometry of BCECF-AM-loaded cells. Pyk2 inhibition was accomplished by two approaches: using an adenovirus expressing a truncated Pyk2 construct (AdCRNK), and inhibition of p38, using the inhibitor SB203580.

**Results:** Analysis of protein phosphorylation using immunoblot shows that Pyk2 and MAPK p38 are rapidly phosphorylated at acid $pH_i$ (3.4 and 3.8 fold increase, respectively, after 1 minute). $H^+$,$K^+$-ATPase-mediated $pH_i$ recovery was significantly inhibited after an $NH_4Cl$ pre-pulse (68% by the adenovirus construct and 69% by SB203580). We assume that the unaffected $pH_i$ recovery may be attributed to unaffected $H^+$-ATPase-mediated $pH_i$ recovery.

**Conclusions:** In summary, we show that Pyk2 is required for p38 phosphorylation and subsequent $H^+$,$K^+$-ATPase activation in response to acid pH in the outer medullary collecting duct. Taken together with our previous study (*Am J Physiol Renal Physiol* 303: F1353–F1362, 2012), these new findings indicate that in response to an acute decrease in $pH_i$, two distinct MAPK pathways (p38 and ERK1/2) regulate $H^+$-ATPase and $H^+$,$K^+$-ATPase activity, respectively, via the pH sensor, Pyk2.

## TH-PO629

**Chronic Metabolic Acidosis Enhances SPAK-Dependent Phosphorylation of Thiazide-Sensitive Sodium Chloride Cotransporter** Yu-Wei Fang,[1,2] Sung-Sen Yang,[2,3] Chih-Jen Cheng,[3,] Shih-Hua P. Lin.[2,3] *[1]Div of Nephrology, Dept of Medicine, Shin Kong Wu Ho-Se Memorial Hospital; [2]Graduate Institute of Medical Sciences, National Defense Medical Center; [3]Div of Nephrology, Dept of Medicine, Tri-Service General Hospital.*

**Background:** Although chronic metabolic acidosis (MA) has been shown to increase the activity and abundance of renal Na-Cl cotransporters (NCC) in the distal convoluted tubule (DCT), its molecular mechanism remains unexplored. We evaluated whether SPAK–NCC signaling pathway is involved in chronic MA *in vivo or not.*

**Methods:** $Na^+/HCO3^-$ cotransporter 1 (NBC1) W516X/+ mice were used as spontaneous renal tubule MA model. Wild-type (WT) and SPAK null mice received water with $NH_4Cl$ (280mM) ad libitum for 5 days for inducing MA. Blood biochemistries were measured before and after $NH_4Cl$ treatment. The abundance of total and phosphorylated (p-) NCC and SPAK in kidney tissues was evaluated by immunobloting and immunoflurescence. NCC function was assessed by hydrochlorothiazide (HCTZ, 25mg/kg) inhibition test.

**Results:** Like the $NBC1^{W516X/+}$ mice (pH: 7.15 ±0.14 vs 7.42 ±0.18 in WT mice; $HCO^{3-}$: 21.5 ±0.3 vs 24.2 ±0.2 in WT, n=8, $p<0.01$), MA was induced in WT mice (pH: 7.29±0.03; $HCO^{3-}$: 22.8 ±0.5, n=6, $p<0.05$) and SPAK null (pH: 7.31±0.02; $HCO^{3-}$: 23.4 ±0.6, n=7, $p<0.05$) mice by oral $NH_4Cl$ intake. $NBC1^{W516X/+}$ mice and WT mice with $NH_4Cl$ both have significantly increased p-NCC (143.3 ±11% in $NBC1^{W516X/+}$ and 135 ±8% in WT with $NH_4Cl$) accompanied by the increased p-SPAK (137 ±12% in $NBC1^{W516X/+}$ mice and 122 ±6% in WT mice with $NH_4Cl$). These results were further confirmed by the immunoflurescence stain of the DCT. In addition, exaggerated response to HCTZ was observed in both $NBC1^{W516X/+}$ mice

(6.7±0.4% v.s 2.5±0.6% in WT, n=7, P<0.05) and WT mice with $NH_4Cl$ (FeNa 7.8±1.5% v.s 2.7±0.4% in WT without $NH_4Cl$, n=5, P<0.05). However, the NCC expression and activity was not increased in SPAK- null mice with $NH_4Cl$.

**Conclusions:** Chronic metabolic acidosis might alter NCC phosphorylation and function at least in part through SPAK-dependent signal cascade. Whether WNK1/4 kinase, the upstream stimulators of SPAK, is involved needs to be further investigation.

## TH-PO630

**A Mouse Model of Kidney Stone Caused by Double Deletion of Pendrin and the Na-Cl Cotransporter (NCC)** Sharon L. Barone,[1,2] Jie Xu,[1,2] Hassane Amlal,[1] Kamyar A. Zahedi,[1,2] Manoocher Soleimani.[1,2] [1]*Internal Medicine, Univ of Cincinnati, Cincinnati, OH;* [2]*Research Services, VA Administration, Cincinnati, OH.*

**Background:** Kidney stones are a *major cause of morbidity* due to associated infection and kidney failure. The $Cl^-/HCO_3^-$ exchanger pendrin and NCC are expressed on the apical membranes of distal nephrons and mediate salt absorption. In mice, solitary KO of NCC causes hypocalciuria whereas KO of pendrin in isolation causes mild hypercalciuria. Neither NCC- nor pendrin-KO mice have salt wasting under baseline conditions. Mice with simultaneous knockout of pendrin and NCC (dKO), on the other hand, show severe salt wasting and volume depletion.

We hypothesize that NCC deletion offsets the hypercalciuric effect of pendrin deletion in dKO mice.

**Results:** 24 hr urine analysis showed a 3-fold increase in calcium excretion in dKO mice. The histological analysis of kidneys demonstrated multiple calcium stones in the medullary collecting ducts in dKO mice but not in pendrin or NCC single KO mice. The stones did not polarize under microscope but stained with Von Kossa stain, consistent with calcium phosphate stones. Phosphate excretion increased by 2-fold and correlated with significant reduction in NaPi2a expression in proximal tubule in dKO mice. Serum calcium was mildly reduced in dKO mice but remained normal in single KO or WT mice. Blood levels for PTH, 1,25 Vitamin D and FGF23 in dKO mice were comparable to WT or single KO mice. Urine pH in dKO mice was comparable to WT animals (~6.2) even though it was reduced in pendrin KO mice (<5.0). Salt loading for 7 days in dKO mice rectified the volume depletion, increased the urine output and dissolved the kidney stones, but did not affect the hypercalciuria or hyperphosphaturia.

**Conclusions:** We were wrong about our prediction of calcium excretion in dKO mice. We conclude that the combined deletions of NCC and pendrin cause profound hypercalciuria and hyperphosphaturia and result in calcium phosphate kidney stones, which were resolved by salt repletion. Whether the combination of pendrin deletion, which down regulates TRPV5, and volume depletion predispose dKO mice to kidney stones remains to be determined.

**Key Insights into the Regulation of Pendrin and AE1 Transporter Expression in Cortical Collecting Ducts by 3D Morphometric Analysis** Jeffrey M. Purkerson, George J. Schwartz. *Pediatrics, Univ of Rochester School of Medicine, Rochester, NY.*

**Background:** Previous studies utilizing kidney sections suggested altered distribution or trafficking of pendrin and AE1 as possible mechanisms for adaptation of the cortical collecting duct (CCD) to acid/base disturbances.

**Methods:** To better understand regulation of anion exchanger function in intercalated cells (ICs), we examined pendrin and AE1 morphology via 3D cell reconstruction of confocal images of microdissected CCDs. The α-IC cell shape was measured by calculating the width:depth (W:D) ratio of AE1 staining.

**Results:** The pendrin cap in normal rabbits (urine pH: 8.28±0.25, $HCO_3^-$:27.2± 4.1 mM) extended beyond the apical boundary defined by ZO-1 and overlapped with nuclear staining (DAPI). A subset of pendrin was contained within $EEA1^+$ endosomes. Acidosis (urine pH: 4.78±0.51, $HCO_3^-$ :17.6±4.3 mM) decreased the pendrin cap volume without shifting distribution. AE1 distribution in α-ICs during acidosis was more rectangular due to increased width and decreased depth (Normal W:D=1.3±0.05; Acidosis =2.4±0.2; p<0.001). Recovery from acidosis (rabbits administered $NH_4Cl$ for 3 days then abruptly transitioned to $NaHCO_3$ for 12-18 h; urine pH: 8.16±0.32, $HCO_3^-$ :29.4±5.6 mM) restored the W:D ratio to the normal range (W:D=1.4±0.05; Recovery: p<0.003). Acidosis also induced a radial redistribution of AE1 in α-ICs: AE1 staining intensity along the outer edge (O) versus staining overlapping the nuclear boundary (I) was measured. During acidosis, AE1 staining intensity increased the O:I ratio, reflecting an increase in AE1 expression on the outer edge (Normal= 1.1±0.03, Acidosis =1.6±0.09; p<0.0004). Upon recovery from acidosis, the ratio returned to near normal (1.2±0.04; vs. NL, p >0.5).

**Conclusions:** Pendrin trafficks through early endosomes, and adaptation to acidosis occurs at least in part via reduction in recycling pendrin. The observed changes in α-cell shape and AE1 distribution likely function to increase basolateral surface area and the supply of AE1 available for anion exchange.

## TH-PO632

**The Thick Ascending Limb Is an Important Site of Furosemide-Induced Urinary Acidification** Pauline I.A. de Bruijn,[1] Nina Himmerkus,[2] Markus Bleich,[2] Helle A. Praetorius,[1] Jens G. Leipziger.[1] [1]*Dept of Biomedicine-Physiology, Aarhus Univ, Aarhus, Denmark;* [2]*Institute of Physiology, Christian Albrechts Univ, Kiel, Germany.*

**Background:** Furosemide is a loop diuretic that inhibits NaCl reabsorption in the thick ascending limb (TAL). In addition, furosemide causes urinary acidification and eventually metabolic alkalosis. It is traditionally explained by an increased $Na^+$ load to the distal tubule, which is suggested to facilitate $H^+$ secretion via the apical $H^+$-ATPase in α-intercalated cells. The direct role of TAL on the urinary acidification, however, has never been investigated.

**Methods:** We measured $pH_i$ and $pH_{lumen}$ in single perfused mouse mTALs with BCECF-AM and BCECF acid, respectively.

**Results:** Interestingly, luminal furosemide (100 μM) caused a major, stable and reversible intracellular alkalinization both in HEPES (0.33 ± 0.04, n=7) and $CO_2/HCO_3^-$-buffered conditions (0.14 ± 0.03, n=5). This alkalinization likely indicates increased $H^+$ excretion from the mTAL cytosol. Intriguingly, the furosemide-induced alkalinization was completely blocked by 1 mM luminal amiloride that fully inhibits the apical NHE3 antiporter. This was confirmed with the NHE3 specific blocker #4167, which also was capable of fully inhibiting the alkalinization by furosemide. Blocking of the basolateral NHEs did not have any effect on the furosemide-induced alkalinization. Thus, furosemide likely causes a NHE3-dependent secretion of $H^+$ to the lumen. To investigate this, we measured the $pH_o$ of the tubular lumen with BCECF acid. Furosemide indeed caused a reversible luminal acidification from pH 6.92 ± 0.04 to 6.46 ± 0.03 (n=5) providing direct evidence for this suggested mechanism. In contrast, luminal amiloride alkalinized the lumen providing again direct evidence for an NHE-dependent mechanism of urinary acidification.

**Conclusions:** We show that furosemide causes an intracellular alkalinization in the mTAL that is mediated through activation of apical NHE3. This alkalinization is mirrored by an acidification of the tubular fluid, suggesting that furosemide-induced urinary acidification already takes place in the TAL. These results revise the mechanistic understanding of furosemide-induced urinary acidification.

## TH-PO633

**Acid-Induced Off-Response of PKD2L1 Channel in Xenopus Oocytes and Roles of Ca** Shaimaa Hussein, Chris Dyte, Wang Zheng, Jungwoo Yang, Xing-Zhen Chen. *Membrane Protein Disease Research Group, Dept of Physiology, Univ of Alberta, Edmonton, Canada.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is due to mutations in PKD1 or PKD2. PKD2L1 is a homologue of PKD2 but does not seem to be implicated in ADPKD. PKD2L1 is a non-selective cation channel that was reported to be implicated in sensing extracellular pH in the tongue as well as in the nervous system. PKD2L1 is activated by Ca and acid. Ca-induced activation was demonstrated when PKD2L1 alone was expressed in *Xenopus* oocytes while acid-induced activation was shown when PKD1L3, a homologue of PKD1, was co-expressed. Acid induces an off-response, ie; channel is not activated until the extracellular acid is removed. The mechanisms of, and relationship between, Ca- and acid-induced activations remain unclear.

**Methods:** Here, we showed by the two-microelectrode voltage clamp technique that PKD2L1 over-expressed alone in *Xenopus* oocytes exhibits acid-induced off-response current that was augmented with decreasing the extracellular pH than pH 4.5, in a dose-dependent manner.

**Results:** Neither acid application time nor extracellular trace amounts of Ca is essential for the off-response. Interestingly, addition of Ca to extracellular solution at pH 7.5 blocked the off-response current, with a Ki value ~150 μM, a phenomenon that we called 'Ca reset'. In addition, pre-injection of Ca chelator, EGTA, to PKD2L1-expressing oocytes abolished Ca-induced activation as reported but did not block the off-response. Further, EGTA pre-injection abolished the 'Ca reset', ie; extracellular Ca no longer blocked the off-response current, suggesting that the off-response is inhibited by intracellular Ca. Finally, we showed that PKD2L1 mutation D523N abolished Ca-induced activation and substantially reduced the off-response.

**Conclusions:** Taken together, our study showed that Ca- and acid-induced activations have distinct mechanisms and that Ca plays an important role in the off-response. PKD2L1 expressed alone in oocytes exhibits acid-induced off-response current that have similar characteristics as those previously reported for the PKD2L1/PKD1L3 channel complex. Supported by CIHR, AIHS (to XZC) and AITF (to SH).

## TH-PO634

**The Role of Sevelamer Carbonate in Increasing Serum Bicarbonate in Hyperphosphatemic CKD Patients with Metabolic Acidosis** Sarah Bezzaoucha,[1] Vincent Pichette,[1] Jean-Philippe Lafrance,[1] Robert Zoël Bell,[1] Louis-Philippe Laurin,[2] Michel Vallee.[1] [1]*Nephrology, Hopital Maisonneuve-Rosemont, Montreal, Canada;* [2]*UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC.*

**Background:** Chronic metabolic acidosis and hyperphosphatemia are prevalent complications in patients with advanced chronic kidney disease. Sevelamer-HCL, a phosphate binder for which the hydrochloride acid is loaded in exchange for phosphate in the intestinal tract, has been previously shown to worsen metabolic acidosis in CKD-patients. However, the use of carbonate sevelamer, a buffered form of sevelamer-HCL in

which chloride is replaced by carbonate, is expected to increase serum bicarbonate and has been proposed as an alternative strategy for the treatment of CKD patients.

**Methods:** To further ascertain the role of sevelamer carbonate in increasing serum bicarbonate, we retrospectively studied the effects of sevelamer carbonate on serum bicarbonate level in 56 acidotic CKD patients not yet receiving maintenance dialysis and for whom sevelamer carbonate was started in order to control their hyperphosphatemia. Serum phosphorus and serum bicarbonate concentrations were assessed before and at monthly intervals (up to 4 months) after using sevelamer carbonate.

**Results:** Bicarbonate mean levels were compared using paired Student's t-tests and mixed-effects linear regression models. The mean bicarbonate level increased from 19.1 ± 2.5 mmol/L before sevelamer carbonate to 21.9 ± 2.9 (p=0.008), 22.2 ± 2.2 (p<0.001) and 22.9 ± 2.5 mmol/L (p<0.001) after the 2nd, 3rd and 4th months of sevelamer carbonate treatment, respectively. In addition, the use of sevelamer carbonate was associated with a statistically significant decrease in the mean serum phosphorus levels: from 1.62 ± 0.22 mmol/L to 1.38 ± 0.26 (p=0.006) and 1.42 ± 0.23 mmol/L (p=0.005) at the 3rd and 4th months, respectively.

**Conclusions:** Our study clearly shows that sevelamer carbonate is actually not only effective as a phosphate binder but also at increasing serum bicarbonate levels to normal values. This could be advantageous for patients who do not receive alkali benefits from dialysis and for whom sodium bicarbonate supplementation is problematic.

### Regulation of the Vacuolar $H^+$-ATPase by 14-3-3 Proteins

Mohammad M. Al-Bataineh,[1] Fan Gong,[1] Hui Li,[1] Vivek Bhalla,[2] Kenneth R. Hallows,[1] Nuria M. Pastor-Soler.[1] *[1]Medicine, U. of Pittsburgh, Pittsburgh, PA; [2]Medicine, Stanford U., Stanford, CA.*

**Background:** The vacuolar $H^+$-ATPase (V-ATPase) mediates ATP-driven transport of $H^+$ across membranes against a gradient. The V-ATPase is expressed at the apical membrane of kidney collecting duct intercalated cells (ICs). Defects in the V-ATPase may cause renal tubular acidosis with kidney and systemic complications. We studied the regulation of V-ATPase in a cell line of IC origin, Clone C cells, and determined that the A subunit is phosphorylated directly by AMPK. In addition AMPK activators induced an acute cytoplasmic redistribution from the apical membrane in ICs. We have identified an AMPK phosphorylation site in the V-ATPase A subunit. We hypothesized that phosphorylation at this site modulates A subunit binding to 14-3-3 proteins, as it conforms to a 'mode 1' 14-3-3 binding sequence. Dimeric 14-3-3 proteins bind to phosphorylated sites on target proteins and thereby modulate their conformation, interactions with other proteins and trafficking.

**Methods:** We used Clone C cells of intercalated cell origin with either wild-type or mutant V-ATPase A subunit at the AMPK phosphorylation site and performed co-immunoprecipitation and immunoblot studies. Extracellular pH measurements, immunoflorescence labeling and confocal microscopy were also performed on polarized Clone C cells to examine V-ATPase activity and subcellular localization.

**Results:** We detected increased co-immunoprecipitation of 14-3-3 proteins to wild-type A subunit in Clone C cells treated with the AMPK activator AICAR as compared with untreated cells. Moreover, additional preliminary results show that the phosphorylation-deficient Ser-to-Ala A-subunit mutant has decreased binding to 14-3-3 proteins. Moreover, AMPK activation inhibits V-ATPase activity and expression at the apical membrane of ICs, an effect that was prevented with expression of this Ser-to-Ala mutant.

**Conclusions:** 14-3-3 proteins may directly bind the V-ATPase A subunit in an AMPK phosphorylation-dependent manner. We propose that this binding participates in the regulation of V-ATPase apical membrane expression and activity by AMPK during metabolic depletion in ICs.

### Changes in Intercalated Cell Subtypes in Response to Chronic Furosemide Administration

Su-Youn Lee,[1] Ji-Eun Kim,[1] Sae Jin Lee,[1] I. David Weiner,[2,3] Ki-Hwan Han.[1] *[1]Dept of Anatomy, Ewha Womans Univ, Seoul, Korea; [2]Div of Nephrology, Hypertension, and Transplantation, Univ of Florida, Gainesville, FL; [3]Nephrology and Hypertension Section, North Florida/South Georgia Veterans Health System, Gainesville, FL.*

**Background:** Renal intercalated cells play a critical role in acid-base homeostasis and also contribute to the regulation of intravascular volume via $Cl^-$ transport. The diuretic furosemide causes intravascular volume depletion and stimulates proton secretion. The purpose of this study was to examine the effect of chronic furosemide administration on intercalated cell subtypes in the rat kidney.

**Methods:** Male Sprague-Dawley rats received furosemide (12 mg/kg/day) via an osmotic minipump for 7 days; control rats received vehicle.

**Results:** Furosemide administration increased urine volume and decreased urine pH significantly and simultaneously induced mild metabolic alkalosis. We determined furosemide's effect on different intercalated cell subtypes, using antibodies to AE1, pendrin, $H^+$-ATPase, Rhbg and AQP2, combined with quantitative morphometric analysis. In the CNT, furosemide increased the height and mean cellular pendrin and $H^+$-ATPase expression of pendrin-positive cells; the relative number of type B and non A-non B intercalated cells did not change. In the CCD, furosemide increased the number of non-A non B cells significantly, and increased the height and cellular $H^+$-ATPase expression of pendrin-positive cells. The number of principal cells decreased significantly. In the OMCD, furosemide increased the number of type B intercalated cells significantly. Furosemide did not alter significantly the number, height or cellular $H^+$-ATPase expression of AE1-positive cells in the CNT, CCD or OMCD.

**Conclusions:** We conclude that adaptive, multimodality changes in non-type A intercalated cells, including integrated changes in relative numbers, cell height and cellular pendrin and $H^+$-ATPase expression, occur in response to chronic furosemide administration.

## TH-PO637

### Exogenous Acid Loads Increase ROS Production by the Kidney

Xuming Sun,[1] Julie Reisz,[3] Doris P. Molina,[1] Nebil Nuradin,[4] Rachel R. Tay,[5] Cristina M. Furdui,[3] Thomas D. DuBose,[1,2] Snezana Petrovic.[1,2] *[1]Physiology & Pharmacology; [2]Internal Medicine, Section on Nephrology; [3]Section on Molecular Medicine; [4]Hypertension & Vascular Research Center, Wake Forest School of Medicine; [5]Biology, Wake Forest Univ, NC.*

**Background:** Evidence from clinical trials indicate that high net endogenous acid production (NEAP) with or without frank metabolic acidosis is associated with enhanced progression of CKD. Activation of complement due to ammonium accumulation, ET-1, aldosterone, and AngII have been implicated in the pathogenesis of the adverse effect of acidosis on the kidney. Here, we hypothesized that the accumulation of ROS is associated with the adaptive response of the kidney to high exogenous acid loads. We based this hypothesis on our previous proteomics studies in mIMCD3 cells exposed to low pH, which revealed that changes in the redox state were associated with cellular response to low pH.

**Methods:** To test the hypothesis *in vivo*, we acid-loaded 6 mice with $NH_4Cl$ and determined 8-isoprostane in the urine as an index of kidney ROS levels. To detect oxidized proteins in tissue, we used two novel redox chemical probes, BP-1 and Alk-KE-585.

**Results:** Acid loading doubled urinary 8-isoprostane from 5156±1192 to 11157±2899 pg/mg creatinine after 7 d; p<0.05. 8-isoprostane remained slightly higher than baseline at 30 d (5881±1370 pg/mg creatinine, p=0.5 vs. baseline). We confirmed this with biotin-conjugated BP1 redox probe, visualized on kidney sections with DAB staining. At baseline, the staining was of moderate intensity, present predominantly in tubular epithelial cells in the outer medulla. Acid loading increased the intensity of the staining in both cortex and medulla, reflecting an increase in protein oxidation. The staining was very prominent in medullary rays, most intense in the collecting ducts, and moderate in the proximal tubules. The results were further validated in isolated tubules with fluorescent redox probe Alk-KE-585.

**Conclusions:** Our data suggest that high acid load increases ROS production by the kidney. We propose that the kidney response to high NEAP alters the redox state of kidney tissue, which, if maintained, may represent a mechanism by which high NEAP facilitates progression of CKD.

## TH-PO638

### Loss of 2Cl/H Exchange Function of CLC-5 Causes Dent's Disease

Nobuhiko Sato,[1] Hideomi Yamada,[1] Osamu Yamazaki,[1] Shoko Horita,[1] Masashi Suzuki,[1] Motonobu Nakamura,[1] Yoshitsugu Kaku,[2] Daisuke Yamamoto,[3] Akira Ashida,[3] Takashi Sekine,[4] George Seki.[1] *[1]Internal Medicine, Tokyo Univ, Japan; [2]Fukuoka Chidren's Hospital, Japan; [3]Osaka Medical College, Japan; [4]Toho Univ, Japan.*

**Background:** The molecular mechanism by which loss of CLC-5 functions induces defective endocytosis in renal proximal tubules remains speculative. In a typical Dent's disease patient we have identified a novel CLC-5 mutation E211Q, which may alter the properties of gatekeeping glutamate.

**Methods:** In Xenopus oocytes, the CLC-5 currents and changes in surface pH were measured by two-electrodes voltage-clamp method and pH-sensitive microelectrodes, respectively. In HEK293 cells, the ratiometric pH sensitive GFP mutant pHluorin fused to VAMP2 was used to measure endosome pH.

**Results:** In Xenopus oocytes, the wild-type (WT) CLC-5 showed strongly outward-rectifying currents at the positive voltages. However, E211Q, like an artificial mutant E211A, showed linear currents at the entire voltages. In oocytes injected with WT, the reduction in extracellular pH from 7.4 to 5.4 suppressed the currents by approximately 30%. Moreover, application of positive voltage pulse trains induced robust reduction in surface pH from 7.4 to less than 7.0, consistent with the operation of 2Cl/H exchange. In oocytes injected with E211Q or E211A, by contrast, the reduction in extracellular pH did not suppress the currents. Furthermore, positive voltage pulse trains did not induce any changes in surface pH, indicating that E211Q, like E211A, functions as a pure Cl channel. The conductance sequence (Cl > I) was unchanged in these mutants. The structural analysis based on the CLCe1 crystal structures also suggests that the E211Q mutation mimics the protonation of E211 side chain, thereby facilitating the Cl transport through the opened gate. In HEK293 cell, E211Q was properly directed to endosome but did not decrease endosome pH.

**Conclusions:** These data showed that, for the first time to our knowledge, the loss of 2Cl/H exchange function of CLC-5 causes Dent's disease. They further suggest that the 2Cl/H exchange function of CLC-5 may be required for the proper endosome acidification.

*Funding:* Government Support - Non-U.S.

## TH-PO639

**Association of Serum Bicarbonate with Incident Chronic Kidney Disease in Community Living Elders: The Health ABC Study** Leonard A. Goldenstein, Linda F. Fried, Todd Hayashida Driver, Dena E. Rifkin, Kushang V. Patel, Anne B. Newman, Mark J. Sarnak, Michael Shlipak, Joachim H. Ix. *Nephrology, UCSD, San Diego, CA.*

**Background:** In populations with prevalent chronic kidney disease (CKD), lower serum bicarbonate (HCO3) is associated with more rapid CKD progression, independent of baseline eGFR. Metabolic acidosis may also be a risk factor for development of CKD but that has not been studied. In addition, high bicarbonate may mark lung disease and smoking and may be associated with CKD.

**Methods:** We evaluated 1,076 well-functioning community-living elders who had HCO3 measured at baseline, creatinine and cystatin C at baseline and 7 years later, and did not have CKD (eGFR $\geq$ 60 ml/min/1.73m$^2$) at baseline. eGFR was measured using the combined cystatin C and creatinine equation. We evaluated the adjusted association of baseline HCO3 with incident CKD 7 years later, defined by an eGFR <60 at follow-up with >5 ml/min/1.73m$^2$ loss from baseline.

**Results:** At baseline, the mean age was 75±3 years, eGFR was 86±13 mL/min/1.73m$^2$, and HCO3 was 25.2±1.9 mmol/L. Factors associated with lower HCO3 included male gender, white race, and ace/arb use. Obstructive lung disease, smoking, and diuretic use were associated with higher HCO3. At follow-up, 270 (25%) had developed incident CKD. In models adjusted for baseline eGFR, demographics, and CKD risk factors, individuals with HCO3 <23mmol/L had a nearly 2-fold odds of incident CKD (Table). Higher levels were not associated with incident CKD.

**Conclusions:** Metabolic acidosis is a novel risk factor for development of incident CKD in community-living elders. If confirmed, HCO3 may give insights into kidney tubule health even among persons without CKD by standard clinical definitions.

Table. Association of HCO3 with Incident CKD in Community-Living Elders

| | HCO3 (mmol/L) | | |
|---|---|---|---|
| | <23.0 | 23.0-27.9 | ≥28.0 |
| | N=77 (7%) | N=896 (83%) | N=103 (10%) |
| Model 1*, OR (95% CI) | 1.88 (1.10-3.23) | 1.00 (ref) | 1.26 (0.75-2.13) |
| Model 2**, OR (95% CI) | 1.93 (1.11-3.35) | 1.00 (ref) | 1.03 (0.59-1.80) |

## TH-PO640

**Lack of Interaction between *APOL1* Variants and Hypertension Treatment: The African American Study of Hypertension and Kidney Disease (AASK)** Wen Hong Linda Kao,[1] Brad C. Astor,[2] Man Li,[1] Rulan S. Parekh,[3] Tom Greene,[4] Jackson T. Wright,[5] Lawrence J. Appel,[1] Jeffrey B. Kopp,[7] Michael S. Lipkowitz.[6] *[1]Epidemiology and Medicine, Johns Hopkins Univ, Baltimore, MD; [2]Medicine and Population Health, Univ of Wisconsin, Madison, WI; [3]Nephrology, Hospital for Sick Children, Toronto, Canada; [4]Biostatistics, Univ of Utah, Salt Lake City, UT; [5]Medicine, Case Western Reserve Univ, Cleveland, OH; [6]Nephrology, Georgetown Univ, Washington, DC; [7]Kidney Disease Section, NIDDK, Bethesda, MD.*

**Background:** The apolipoprotein L1 (*APOL1*) G1 and G2 alleles are strongly associated with ESRD susceptibility in African Americans, but no study has examined the impact of these variants on the effect of hypertension treatments in a clinical trial setting.

**Methods:** We conducted a gene-by-treatment analysis in 693 participants of The AASK trial. Outcome was ESRD or doubling of serum creatinine. Cox regression was used to adjust for age, sex, ancestry, and baseline GFR.

**Results:** Overall, 288 (41.6%) reached the composite outcome. Of the 160 individuals with 2 copies of the *APOL1* high-risk haplotype, 58% progressed (adjusted relative hazard [$RH_{adj}$] of 2.03 compared to all others;p<0.001). There was no evidence for interaction between *APOL1* and baseline proteinuria or intervention assignment. The $RH_{adj}$ comparing the non-ACE inhibitor to ACE inhibitor was 1.36 (95% CI[0.91, 2.04]) for the low-risk *APOL1* group and 1.51 (95% CI[0.83, 2.73]) for the high-risk *APOL1* group ($p_{interaction}$=0.85). There was no effect of assignment to intensive vs. non-intensive blood pressure control in either the low-risk *APOL1* group ($RH_{adj=}$1.11, 95%CI[0.73, 1.65]) or the high-risk *APOL1* group ($RH_{adj=}$1.33, 95%CI[0.73, 2.40]) ($p_{interaction}$=0.85).

**Conclusions:** Almost 60% of these participants with hypertensive nephropathy and 2 copies of the *APOL1* high-risk haplotype progressed, a risk that was two-fold higher than their low-risk counterparts. Blood pressure targets or medications did not modify this association. Thus, it is important to identify other modifiable risk factors or treatment approaches that differentiate the progressors from non-progressors within the high-risk *APOL1* group.

*Funding:* NIDDK Support

## TH-PO642

**Association of the High Risk *APOL1* Genotype with Longitudinal GFR Is Modified by HIV** Michelle M. Estrella,[1] Man Li,[1] Rulan S. Parekh,[1] Alison G. Abraham,[1] Shehnaz K. Hussain,[2] Wen Hong Linda Kao.[1] *[1]Johns Hopkins Univ; [2]UCLA.*

**Background:** *APOL1* risk alleles are associated with kidney disease among African Americans. Whether HIV modifies this association is unknown.

**Methods:** We studied African American men infected with or at risk for HIV in the Multicenter AIDS Cohort Study from 2003 to 2012 (median follow-up 6.9y). Subjects were genotyped for the *APOL1* G1 and G2 risk alleles. We used mixed effects models to estimate the annual rate of eGFR (ml/min/1.73m$^2$) decline, comparing men with 2 vs. 0/1 allele and adjusting for traditional kidney disease and HIV risk factors.

**Results:** Of 272 HIV- and 343 HIV+ men, 37 and 53 had 2 risk alleles, respectively. Compared with men carrying 0/1 allele, those with 2 had a lower mean baseline eGFR (98.8 vs. 90.2, p<0.001) but were similar in age, diabetes and hypertension history, injection drug use as well as hepatitis C and HIV infection. Among HIV+ men, the mean CD4 count and proportion with undetectable HIV RNA were similar in those with 2 vs. 1/0 risk allele. The annual rate of eGFR decline among HIV- men was similar by *APOL1* genotype.

| Annual Change in eGFR (95% CI) Associated with the High Risk *APOL1* Genotype by HIV Status* | | |
|---|---|---|
| 2 vs. 0/1 *APOL1* allele | HIV- | HIV+ |
| Unadjusted | -0.44 (-4.28, 2.99) | -13.07 (-16.00, -9.27) |
| Adjusted for age, baseline diabetes and hypertension | -0.47 (-4.04, 2.77) | -12.88 (-15.72, -9.39) |
| Additionally adjusted for baseline hepatitis C infection and injection drug use | -0.49 (-3.92, 2.89) | -13.68 (-16.77, -10.32) |
| Additionally adjusted for baseline eGFR | 0.30 (-2.28, 3.23) | -4.64 (-7.07, -2.02) |
| Additionally adjusted for baseline HIV factors† | - | -5.03 (-7.34, -2.12) |

*P-int<0.001
†CD4 count, HIV RNA<50 copies/mL, AIDS and antiretroviral therapy

Conversely, HIV+ men with 2 risk alleles had a faster annual rate of eGFR decline compared to those with 0/1 allele (p-int<0.001). This remained significant after adjustment for HIV factors. Adjustment for ancestry (n=575) and exclusion of men with baseline eGFR<60 (n=26) yielded similar estimates.

**Conclusions:** Kidney function decline is augmented by HIV infection among carriers of the *APOL1* high risk alleles.

## TH-PO643

**MYH9 Association with Glomerular Disease Independent of APOL1 Risk Factors** George W. Nelson,[1] Randall C. Johnson,[1] Sophie Limou,[2] Jeffrey B. Kopp,[3] Cheryl Ann Winkler.[2] *[1]BSP-CCR Genetics Core, SAIC-Frederick/FNLCR, Frederick, MD; [2]Basic Research Laboratory, SAIC-Frederick/FNLCR, Frederick, MD; [3]NIDDK-NIH, Bethesda, MD.*

**Background:** The increased risk of FSGS and HIV-associated glomerular disease (HIVAN) in African Americans (AA) prompted the use of admixture mapping which identified the profound association of Chr22 with these diseases. The initial association was centered on *MYH9*, previously associated with glomerular disease. Further screening identified more strongly associated factors, G1 and G2, in the adjacent gene *APOL1*. The associations with *MYH9* SNPs were then seen as resulting from linkage disequilibrium (LD) around G1 and G2, caused by selection for resistance against trypanosome infection. Several studies have reported *MYH9* genetic effects independent of *APOL1* variants. We looked for independent *MYH9* effects in our AA cohorts of FSGS and HIVAN cases and controls, which have shown some of the strongest reported Chr22 effects.

**Methods:** *APOL1* and *MYH9* variants were typed for FSGS on 218 FSGS cases and 386 controls, and 56 HIVAN cases and 243 HIV-positive controls. Due to complete negative LD, only 6 G1/G2 genotypes occur. We analyzed the association of the most strongly associated *MYH9* factor, rs2413396, in subsets of the subjects carrying each of these genotypes, and performed an analysis stratified for the 6 G1/G2 genotypes (CMH test).

**Results:** The stratified analysis shows an independent association for rs2413396 for combined HIVAN/FSGS: OR = 2.0, p = 0.0001. Five of the six subsets defined by G1/G2 genotype showed the same direction of association for rs2413396, which was significant in two subgroups: subjects carrying one copy of G1 and no G2: OR = 5.6, p = 0.006, and subjects carrying one copy each of G1 and G2: OR = 2.8, p = 0.04 (FET).

**Conclusions:** There is residual glomerular disease association of *MYH9* variants not attributable to *APOL1* G1/G2. The source of this association is unknown; rs2413396 is one of several *MYH9* SNPs with similar associations, none of which appear to be functional. It is possible that these SNPs are tracking an unknown factor, either one with a small effect, or a factor with a larger effect, tracked by both G1/G2 and the *MYH9* SNPs.

## TH-PO644

**Factors Related to CKD Progression among African Americans with and without Apolipoprotein L1 (APOL1) Gene Variants** Teresa K. Chen,[1] Wen Hong Linda Kao,[1] Michael J. Choi,[1] Brad C. Astor,[1,2] Julia J. Scialla,[3] Lawrence J. Appel,[1] Deidra C. Crews.[1] *[1]Johns Hopkins U., Baltimore, MD; [2]U. of Wisconsin-Madison, Madison, WI; [3]U. of Miami, Miami, FL.*

**Background:** Common coding variants in *APOL1* are associated with increased risk of progressive CKD, however, not all with this high-risk genetic background experience progressive disease. We examined potentially modifiable factors associated with CKD

progression among African Americans with hypertension-attributed nephropathy by *APOL1* risk allele status.

**Methods:** We performed a retrospective cohort study including 693 African American Study of Kidney Disease and Hypertension (AASK) participants. Using multivariable Cox models, we determined the hazard ratio for CKD progression (defined as development of ESRD or doubling of serum creatinine during follow up) associated with each putative risk factor stratified by *APOL1* status (those with 2 copies of the high-risk variant vs. all others).

**Results:** Participant mean age was 54 years and 160 (23%) had *APOL1* high-risk allele status. A total of 288 (41.6%) participants experienced CKD progression during a mean follow up of 7.8 years. Our base model adjusted for age, gender, % European ancestry, baseline eGFR and randomized blood pressure and drug groups. We confirmed that the hazard ratio (HR) comparing high vs. low risk allele status was 1.87 (95% CI 1.45-2.41). When additional variables were added to the base model, none appeared to modify the association between *APOL1* high-risk allele status and CKD progression.

Table. Factors Associated with CKD Progression among AASK Participants, by *APOL1* Risk Allele Status

| Factors | APOL1 Low-Risk Status HR (95% CI) for CKD Progression | APOL1 High-Risk Status HR (95% CI) for CKD Progression | P interaction (from full Cox model) |
|---|---|---|---|
| **Base Model** | | | |
| Age, per 10 years older | 0.98 (0.97, 0.99) | 0.97 (0.95, 0.98) | 0.17 |
| Female vs. male | 0.98 (0.73, 1.31) | 0.86 (0.55, 1.33) | 0.57 |
| % European ancestry per natural log ↑ | 1.10 (0.93, 1.31) | 1.08 (0.82, 1.41) | 0.96 |
| Baseline eGFR, per 10 ml/min/1.73 m² ↓ | 1.63 (1.46, 1.82) | 1.87 (1.54, 2.27) | 0.21 |
| BP group, standard vs. low | 0.93 (0.69, 1.24) | 0.90 (0.59, 1.38) | 0.78 |
| Drug group | | | 0.68 |
| Ramipril | reference | reference | |
| Metoprolol | 1.13 (0.83, 1.56) | 1.12 (0.70, 1.79) | |
| Amlodipine | 1.19 (0.80, 1.76) | 1.68 (0.92, 3.07) | |
| **Additional Variables Added to Base Model** | | | |
| Current vs. never smoker | 1.15 (0.82, 1.62) | 1.07 (0.64, 1.79) | 0.50 |
| Family history of ESRD, yes vs. no | 0.90 (0.58, 1.40) | 0.80 (0.43, 1.48) | 0.83 |
| Annual income, mid-high vs. $0-14,999 | 0.95 (0.68, 1.33) | 0.84 (0.51,1.37) | 0.69 |
| No H.S. vs. at least H.S. education | 0.97 (0.70, 1.34) | 1.05 (0.63, 1.74) | 0.98 |
| Systolic BP, per 10 mmHg ↑ | 1.03 (0.98, 1.09) | 1.08 (0.99, 1.19) | 0.23 |
| BMI, per 1 kg/m² ↑ | 1.03 (1.01, 1.05) | 1.03 (0.99, 1.06) | 0.78 |
| Total cholesterol, per 10 mg/dL ↑ | 1.04 (1.01, 1.08) | 1.04 (0.99, 1.09) | 0.59 |
| HDL, per 10 mg/dL ↑ | 1.05 (0.95, 1.15) | 1.05 (0.90, 1.22) | 0.52 |
| Hematocrit, per 1% ↑ | 1.00 (0.96, 1.03) | 0.99 (0.95, 1.03) | 0.93 |
| Serum phosphorus, per 1 mg/dL ↑ | 1.18 (0.87, 1.59) | 1.10 (0.71, 1.71) | 0.88 |
| Serum calcium phosphorus product, per 1 unit ↑ | 1.01 (0.98, 1.04) | 1.00 (0.95, 1.05) | 0.87 |
| Serum uric acid, per 1 mg/dL ↑ | 1.03 (0.95, 1.12) | 0.92 (0.81, 1.05) | 0.36 |
| 24 hr urine protein, per 1 unit natural log ↑ | 1.88 (1.68, 2.11) | 1.59 (1.34, 1.88) | 0.37 |
| 24 hr urine sodium, per 1 gram ↑ | 1.05 (0.98, 1.13) | 1.08 (0.98, 1.19) | 0.74 |
| 24 hr urine potassium, per 1 gram ↑ | 1.15 (0.98, 1.35) | 0.96 (0.73, 1.27) | 0.36 |
| 24 hr urine urea nitrogen, per 1 gram ↑ | 1.07 (1.03, 1.12) | 1.01 (0.95, 1.09) | 0.20 |
| Net endogenous acid production, per 10 unit ↑ | 1.06 (1.01, 1.11) | 1.04 (0.98, 1.10) | 0.43 |

**Conclusions:** Among a cohort of African Americans with hypertension-attributed nephropathy, we found no factors modifying the risk of CKD progression associated with *APOL1* high-risk allele status. Further investigation in larger studies is warranted to determine whether other environmental risk factors for progressive kidney disease exist among individuals with high-risk *APOL1* alleles.

## TH-PO645

**APOL1 Genotype and Racial Disparity in Chronic Kidney Disease (CKD) Progression: The CRIC Study** Afshin Parsa,[1] Dawei Xie,[2] Chi-Yuan Hsu,[4] Harold I. Feldman,[3,2] John W. Kusek,[5] Lawrence J. Appel.[6,7] *[1]Dept of Medicine, Univ of Maryland; [2]Dept of Biostatistics and Epidemiology, Univ of Pennsylvania; [3]Dept of Medicine, Univ of Pennsylvania; [4]Dept of Medicine, UCSF; [5]NIDDK, NIH; [6]Welch Center for Prevention, Epidemiology and Clinical Research, Johns Hopkins Univ; [7]CRIC Study Group.*

**Background:** African Americans (AAs) are at increased risk for end-stage renal disease (ESRD) compared to European Americans (EAs). *APOL1* risk variants, present in AAs but nearly absent in EAs, may partially account for this disparity. We evaluated *APOL1* genotype as a mediator of differences in CKD progression between AAs and EAs.

**Methods:** We studied 2955 participants of the Chronic Renal Insufficiency Cohort (CRIC) Study with CKD (48% AA, 46% with diabetes). We performed hierarchical multivariate analyses of CKD progression, stratified by diabetes and *APOL1* genotype. Primary outcomes were slope in estimated glomerular filtration rate (eGFR) and the composite renal event of ESRD or halving of eGFR.

**Results:** Among participants with and without diabetes, AAs without the *APOL1* risk genotype had a persistent, but attenuated elevation in the rate of renal events compared to EAs. Parallel comparisons of eGFR decline showed complete attenuation of AA-EA differences in the absence of *APOL1* risk genotype (Table). Table. Adjusted Differences in eGFR Slope and Rate of Renal Events.

| Comparison groups | | eGFR Slope difference (ml/min/1.73m²/yr) | | Hazard Ratio (HR) of Renal Events | |
|---|---|---|---|---|---|
| | | Estimate | P value | HR | P value |
| With Diabetes | AA with APOL1 Risk vs all EA | **-1.3** | <0.001 | **2.0** | <0.001 |
| | AA without APOL1 Risk vs all EA | **-0.4** | 0.093 | **1.4** | 0.006 |
| | | | | | |
| Without Diabetes | AA with APOL1 Risk vs all EA | **-1.1** | <0.0001 | **2.7** | <0.0001 |
| | AA without APOL1 Risk vs all EA | **0.1** | 0.648 | **1.6** | 0.010 |

**Conclusions:** *APOL1* genotype is significantly associated with CKD progression in Aas compared to Eas, regardless of diabetes status. Our results, in the context of prior studies, suggest that *APOL1* risk alleles increase CKD progression, irrespective of the etiology of CKD.

## TH-PO646

**p.E66Q Variant of α-Galactosidase A Does Not Affect the Progression of Chronic Kidney Disease** Hirofumi Watanabe,[1] Shin Goto,[1] Hiroki Maruyama,[2] Ichiei Narita.[1] *[1]Div of Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Dept of Clinical Nephroscience, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

**Background:** The p.E66Q variant in the *α-galactosidase A (GLA)* is frequently found in the screening of Fabry disease in chronic dialysis patients in Japan. However, recent reports suggested that pathologically and biochemically, p.E66Q of *GLA* is not a disease-causing mutation but a functional polymorphism. To evaluate the role of p.E66Q in progression of renal diseases, we performed a genetic association study in patients with chronic kidney disease.

**Methods:** We extracted genomic DNA from the blood of 2691 patients who attended medical institutions in Niigata Prefecture, Japan and agreed to genome analysis. These patients included 1705 chronic hemodialysis patients and 986 non-dialysis patients. The p.E66Q was detected using TaqMan SNP genotyping assay. We compared the allele frequency of p.E66Q in chronic hemodialysis patients with that of non-dialysis patients and Japanese general population (Eur J Neurol 2013). Furthermore, in non-dialysis patients, we compared eGFR in the presence or absence of p.E66Q variant.

**Results:** Among 2401 alleles in the chronic hemodialysis patients, 21 alleles were found to harbor p.E66Q variant. Five alleles were hemizygotes from 1009 males, 14 were heterozygotes from 696 females, and one was homozygote from one female. The allele frequency in the chronic hemodialysis patients was 0.87%. Among 1505 alleles in non-dialysis patients, 8 were found to harbor p.E66Q variant, and allele frequency was 0.53%. There was no significant difference in the p.E66Q frequency of chronic hemodialysis patients compared with non-dialysis patients ($P$ = 0.22) and with Japanese general population (0.64%, $P$ =0.25). The eGFR of non-dialysis patients harboring p.E66Q was not significantly different compared with that of patients with wild-type allele (66.3 ± 11.4 vs. 62.9 ± 16.8 ml/min/1.73m², $P$ = 0.70).

**Conclusions:** The present genetic association study indicated that the p.E66Q variant of *GLA* does not affect the progression to end stage renal disease.

## TH-PO647

**Discovery of Novel Candidate Genetic Markers Associated with Pediatric CKD Progression in the PediGFR Study** Jayanta Gupta,[1] Peter A. Kanetsky,[1] Nandita Mitra,[1] Elke Wuehl,[2] Anna Kottgen,[3] Matthias Wuttke,[3] Susan L. Furth,[4] Bradley A. Warady,[5] Franz S. Schaefer,[2] Craig S. Wong.[6] *[1]Dept Biost/Epi, U Penn, Philadelphia, PA; [2]Ped Neph Div, U Heidelberg, Heidelberg, Germany; [3]Renal Div, U Frieburg, Frieburg, Germany; [4]Div Neph., Children's Hosp. of Philadelphia, Philadelphia, PA; [5]Sect Neph., Children's Mercy Hosp., Kansas City, MO; [6]Div Nephr, U New Mexico Children's Hosp., Albuquerque, NM.*

**Background:** Traditional risk factors for chronic kidney disease (CKD) only partially explain the varying rate of GFR decline in children with CKD. The PediGFR study is determining the genetic contribution linked to CKD progression via meta-analysis of the most promising SNP markers observed in the genome-wide scans from the pediatric CKD cohort studies:CKiD, ESCAPE, and 4C.

**Methods:** Each prospective study collected genetic samples and longitudinal data on GFR (measured or estimated). We genotyped DNA using the Illumina® Omni 2.5 BeadChip. For each study, we used linear regression models to determine associations between SNP markers and GFR slope adjusting for age, sex and population stratification. The 100 most significant markers from each of five subgroup populations [(CEU ancestry in CKiD (267), 4C (599) and ESCAPE (286); and Turkish ancestry in 4C (331) and ESCAPE (66)] were selected for meta-analysis. Using METAL, subgroup-specific effect estimates were combined by the inverse variance method.

**Results:** Analyses are currently ongoing. To date, 11 markers surpassed a threshold of $P < 1\times10^{-5}$ in combined results from at least 3 subgroup populations, although we noted heterogeneity of effect ($P < 0.05$ for Cochran's Q; $I^2 > 50\%$) at two of these markers. Of the remaining 9 markers, 8 localized to the same genomic region at 2q22.3, and one to 15q21.1.

**Conclusions:** The PediGFR will continue analyses to include association testing of SNP markers with ESRD outcomes and within subgroups defined by glomerular and non-glomerular disease. We will assess the putative biological importance of these markers using publicly available databases such as ENCODE. We will replicate these identified SNP markers in the adult Chronic Renal Insufficiency Cohort study.

*Funding:* NIDDK Support

## TH-PO648

**Genetic Markers Associated with Erythrocyte Traits in the Chronic Renal Insufficiency Cohort (CRIC) Study** Jayanta Gupta,[1] Meredith A. Atkinson,[2] Craig S. Wong,[3] Peter A. Kanetsky,[1] Susan L. Furth.[1] *[1]Univ of Pennsylvania; [2]Johns Hopkins Univ; [3]Univ of New Mexico.*

**Background:** Anemia is a prevalent comorbidity in CKD. However, across patients with CKD there is variability in the severity of anemia, likely due in part to genetic determinants of erythrocyte traits. Previous genome-wide association studies (GWAS) in healthy subjects have identified genetic variants associated with a variety of erythrocyte traits, but the associations in CKD patients has not been well studied.

**Methods:** In 1,450 African American (AA) and 1,560 European American (EA) subjects with CKD in the Chronic Renal Insufficiency Cohort Study (CRIC), we assessed

the association of baseline measures of 6 erythrocyte traits (Hgb, Hct, MCV, MCHC, MCH, and RBC) with previously identified single-nucleotide polymorphisms (SNPs). Linear regression models were adjusted for age, sex, baseline eGFR use of angiotensin converting enzyme inhibitors, erythropoietin stimulating agents, and population stratification (by principal components). We used Bonferroni correction to account for multiple comparisons.

**Results:** Among AA subjects a significant association between multiple SNPs on the 16p13.3 gene and MCH, MCHC, and MCV was found, consistent with previous analyses. A SNP within *MPP1* was associated with higher MCH ($p<0.0001$), higher MCV ($p<0.0001$), and higher RBC ($p=0.003$). None of the markers examined were associated with Hgb or Hct in this group. In EA subjects, a SNP within *SLC17A3* was associated with higher MCH ($p=1.6x10^{-5}$), higher MCHC ($p=0.003$), and higher MCV ($p=0.004$). A SNP within the *HBSIL/MYB* was associated with lower Hct ($p=0.001$). SNPs at *SLC17A3*, *HBSIL/MYB*, and *GCDH* were positively associated with MCH, and a SNP at the *TMPRSS6* locus was negatively associated with MCH. Further adjustment for use of iron supplementation did not alter interpretation of these findings.

**Conclusions:** We have confirmed the association of selected genetic variants with erythrocyte traits in a CKD cohort, including racial differences in specific loci. Further study will allow us to determine if specific SNPs are longitudinally associated with incident anemia.

*Funding:* NIDDK Support

## TH-PO649

**Association of IL6 -174G>C Polymorphism with Type 1 Diabetes and Diabetic Nephropathy** Marcela Ururahy,[1] Karla Souza,[1] Yonara Monique Oliveira,[1] Melina Bezerra Loureiro,[1] Heglayne P. Silva,[1] Thamara R. de Melo,[1] André D. Luchessi,[1] Rosario D.C. Hirata,[2] Maria Das Graças Almeida,[1] Ricardo Fernando Arrais,[3] Sonia Q. Doi,[4] Mario Hiroyuki Hirata,[2] Adriana Augusto de Rezende.[1] *[1]Clinical and Toxicological Analysis, UFRN, Natal, RN, Brazil; [2]Clinical and Toxicological Analysis, USP, São Paulo, SP, Brazil; [3]Pediatrics, UFRN, Natal, RN, Brazil; [4]Medicine, Uniformed Services Univ, Bethesda, MD.*

**Background:** Diabetic nephropathy (DN) is a major complication of type 1 diabetes (T1D). Studies have shown inflammation, and, mainly, pro-inflammatory cytokines, as key pathophysiological factors in T1D and DN development and progression. We aimed to investigate the association of *IL6* gene polymorphisms with T1D and markers of renal function.

**Methods:** *IL6* (-634C>G and -174G>C) polymorphisms were analyzed in 173 children and adolescents with T1D and 144 normoglycemic (NG) subjects. Glycemic control (glycated hemoglobin and fasting serum glucose), lipid metabolism (serum lipids), and kidney function markers (serum urea and creatinine, and urinary albumin-to-creatinine ratio – ACR) were evaluated.

**Results:** *IL6* -174G>C polymorphism was associated with susceptibility to T1D in a Log-additive model (OR=1.53, CI=1.01-2.31, $p<0.05$). Studying only T1D patients (Table 1), CC carriers for *IL6* -174G>C polymorphism showed higher concentrations of ACR, total cholesterol, and LDL-cholesterol ($p<0.05$). No association was found for *IL6* -634C>G polymorphism.

Table 1 - Relationship between *IL6* -174G>C genotypes and biochemical parameters of T1D patients

| Genotype | ACR mg/g of creatinine | Total cholesterol mg/dL | LDL-cholesterol mg/dL |
|---|---|---|---|
| GG+GC | 16.7±2.7 | 171.7±5.1 | 109.0±4.6 |
| CC | 65.6±41.4 | 243.2±43.6 | 172.2±42.9 |
| p-value | 0.001 | 0.002 | 0.002 |

Results are mean±SEM. Only the relationships with significant p-values are represented.

**Conclusions:** These results suggest that *IL6* -174G>C polymorphism is associated with T1D susceptibility, and, moreover, that T1D patients carrying CC genotype could be more susceptive to develop renal injury.

*Funding:* Government Support - Non-U.S.

## TH-PO650

**RREB1, a Modulator of the Renin-Angiotensin System (RAS), Is a Novel Nephropathy Gene in African Americans** Jason A. Bonomo,[1] Maggie Ng,[1] Barry I. Freedman,[2] Donald W. Bowden.[1] *[1]Ctr for Genomics & Personalized Med Res, Wake Forest School of Medicine, Winston Salem, NC; [2]Int. Med/Nephrology, WFSOM.*

**Background:** Genetic efforts to relate the renin-angiotensin (*RAS*) pathway to nephropathy have had mixed results. *RREB1* (ras-responsive element binding protein 1) is little-studied zinc-finger binding protein which represses the angiotensinogen gene (*AGT*).

**Methods:** Exome sequencing data from 500 African American (AA) cases with T2D-ESKD and 500 AA population-based controls from the T2D-GENES study was analyzed for association with T2D-ESKD. Variants from this discovery phase were genotyped in an independent cohort of 1,250 AA T2D-ESKD cases, 1,450 non-T2D ESKD cases, and 850 controls, analyzed, and adjusted for age, gender, admixture, and *APOL1* G1/G2. A locus-wide analysis was performed, compiling putatively functional low-frequency *RREB1* variants from 1000 Genomes, Exome Variant Server, and RegulomeDB, and were genotyped in the above cases and controls. Sequence kernal association testing (SKAT) was performed in non-T2D ESKD cases and controls.

**Results:** Exome-wide analysis identified two *RREB1* variants associated with T2D-ESKD (rs9379084 [N1171D] p=3.6E-4, OR=0.30 and rs41302867 [intron] p=7.5E-4, OR=0.23). Replication confirmed association (p=0.019-0.029; OR=0.54-0.56) with age, gender, admixture, and APOL1 G1/G2 adjustment. 22 *RREB1* variants were genotyped in the locus-wide analysis. A strong preference of *RREB1* association was noted in non-T2D ESKD cases; 6 variants were associated with non-T2D ESKD in single-SNP association testing (p=0.048-0.0075) with covariate adjustment. The most strongly associated variant was rs35147576 (M610I, OR=0.55). In unadjusted and adjusted SKAT model weighted for rare variants, association p-values of 5.6E-6 and 0.0041, resp., were computed.

**Conclusions:** *RREB1* offers a strong, plausible biological association to account for nephropathy risk through interactions with *AGT*. Variants studied were putatively functional, either resulting in missense mutations or functional intronic variants based on RegulomeDB score. These data suggest a novel role for *RREB1* in nephropathy and may provide a missing link between the RAS and nephropathy.

## TH-PO651

**Next Generation Sequencing Identifies Novel Genomic Variants as Candidates for African-American Familial FSGS** Siddharth A. Shah,[1] James Lyons-Weiler,[2] Abhay N. Vats.[1] *[1]Nephrology, Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]Genomics and Proteomics Core Laboratories, Univ of Pittsburgh, Pittsburgh, PA.*

**Background:** In the past decade, various genes have been identified for FSGS. Previously, we described a four generation African American family with phenotype of hypertension and FSGS with a new linkage to 9q31-32 region. We performed whole exome sequencing (WES) to identify the candidate gene.

**Methods:** We identified new affected and non affected members of this family and the collected DNA was used for WES. Individual and pooled samples were used for this approach. Barcodes and final sequencing adapters were applied to each sample prior to pooling for emulsion PCR and sequencing. WES was performed using SOLiD platform with 50X coverage. The quality control, ambiguity analysis, and mapping was performed using various algorithms, databases and software tools including Lifescope V 2.5, Bamstats, Fast QC, Baconator, C-scoring and DbSNP.

**Results:** There were 101 members in the family with 37 affecteds. Unpooled analyses utilized DNA from 2 affected individuals while pooled samples utilized 13 affecteds in pool 1 and 10 non-affecteds in pool 2. DNA capture targeted human exons plus UTR totaling 71 Mb. Bamstats and Fast QC analysis revealed good quality data. The analyses of target 9q31-32 region (between bases 9108672867-114233187) identified 7648 variants in unpooled samples of which 632 were heterozygous (W-score:1.9-2). Further comparison analyses narrowed the focus to several interesting variants including rs114861534, rs 115259973 and rs138519256 in AKAP2, PTPN3 and LTB4DH genes respectively.

**Conclusions:** We were able to generate high quality data from exome sequencing performed on archived, individual as well as pooled samples. Several novel variants were identified as candidates for autosomal dominant FSGS in a large family belonging to the high risk African- American ethicity. 2 of the variants (rs114861534 and rs 115259973) are particularly interesting as they are highly expressed in kidneys and have very low allele frequency in target population. Further functional and population genetic studies will identify the role of identified variants in FSGS pathogenesis.

## TH-PO652

**Anillin-Mediated Dysregulation of CD2AP/Nephrin/AKT Signaling May Underlie Podocyte Dysfunction in Autosomal Dominant Focal Segmental Glomerulosclerosis** Gentzon Hall,[1,3] Alison Homstad,[3] Andrew F. Malone,[1,3] Guanghong Wu,[3] Thomas Lindsey,[3] Robert F. Spurney,[1] Nils Hanke,[4] Mario Schiffer,[4] Michelle P. Winn,[1,3] Rasheed A. Gbadegesin.[2,3] *[1]Internal Medicine, Duke Univ Medical Center, Durham, NC; [2]Pediatrics, Duke Univ Medical Center, Durham, NC; [3]Center for Human Genetics, Duke Univ Medical Center, Durham, NC; [4]Div of Nephrology, Hannover Medical School, Hannover, Germany.*

**Background:** A heterozygous missense mutation (Arg431Cys; R431C) within the F-actin binding domain of the cell cycle regulator anillin (ANLN) has been recently identified as a cause of autosomal dominant FSGS. In addition to its known roles in cytokinesis and the regulation of cytoskeletal dynamics, ANLN is recognized as a regulator of PI-3K signaling through interactions with the PI-3K regulatory subunit, p85, and the slit diaphragm proteins CD2AP and nephrin. Given these essential functions, we sought to characterize the role of ANLN in the modulation of PI-3K signaling and cell motility in podocytes.

**Methods:** Immunoprecipitation studies, immunoblot analyses, targeted gene knockdown (KD) studies and scratch wound healing assays were performed by standard methods in conditionally immortalized human podocytes (CIHPs). Immunoprecipitation studies were conducted in HEK 293 cells. Cell lines stably expressing tGFP-$ANLN_{WT}$ and tGFP-$ANLN_{R431C}$ were created via transduction of CIHPs with lentiviral vectors expressing *tGFP-$ANLN_{WT}$* and *tGFP-$ANLN_{R431C}$* driven by the CMV promoter.

**Results:** *ANLN* (KD) reduced CD2AP expression in CIHPs. $ANLN_{R431C}$ impaired CD2AP binding in HEK 293 cells relative to $ANLN_{WT}$-expressing cells. *ANLN* (KD) impaired basal motility and attenuated AKT phosphorylation at serine 473 (Ser473) in podocytes. Finally, overexpression of $ANLN_{R431C}$ enhanced basal podocyte motility.

**Conclusions:** ANLN appears to be a critical modulator of PI-3K signaling and podocyte motility possibly via a mechanism involving CD2AP/Nephrin/AKT-dependent signaling. Further study of the role of ANLN in the modulation of PI-3K-dependent podocyte motility signaling may uncover novel therapeutic targets for the treatment of FSGS.

*Funding:* NIDDK Support

## TH-PO653

**Discovery, Fine Mapping and Replication of Differential Methylation Associated with MicroRNAs and Chronic Kidney Disease** Laura Jane Smyth, Alexander P. Maxwell, A.J. McKnight. *Nephrology Research, Centre for Public Health, Queen's Univ of Belfast, Belfast, Co. Antrim, United Kingdom.*

**Background:** DNA methylation and miRNAs are associated with complex disease and are altered in uremic patients. This study investigated association between DNA methylation and chronic kidney disease (CKD) using a relatively large-scale, case-control approach.

**Methods:** The Infinium® HumanMethylation 450K BeadChip array (Illumina, Inc, USA) was used to analyse DNA methylation across the methylome in 255 CKD cases and 152 unaffected controls (MDRD eGFR>60 mL/min/1.73m$^2$). Following stringent quality control, methylation levels were analysed and results adjusted for multiple testing using the *BenjaminiHochberg* approach. Quantitative methylation values were obtained at single-CpG level for 2,249 sites associated with miRNA genes across the genome.

**Results:** Six miRNA genes on autosomes were selected for fine mapping and replication based on P<10^-5 in the discovery collection; *MIR550-2*, *MIR940*, *MIR34A*, *MIR429*, *MIR141*, and *MIR329-2*. Bidirectional Sanger sequencing of the genetic region immediately flanking CpG sites of interest in 23 cases and 23 controls for five of these miRNA genes revealed 37 methylated CpG sites; *MIR550-2* did not generate robust sequencing results. Sequencing of untreated genomic DNA revealed 13 known and two novel SNPs flanking the CpG site of interest. Replication using an independent cohort of cases with CKD compared to a general control population (n=400) on the sample 450K platform revealed additional support for methylation at these miRNA loci influencing CKD.

**Conclusions:** Epigenetic features such as DNA methylation and miRNAs may cause or accelerate renal injury. This pilot study has identified several miRNA genes with differential methylation profiles that are associated with CKD. Comparison to RNA-seq data in a subset of these individuals will help elicit the functional effect of the novel findings reported in this abstract on the pathogenesis or progression of CKD.

## TH-PO654

**Nonfunction of the ECT2 Gene May Cause Renal Tubulointerstitial Injury Leading to Focal Segmental Glomerulosclerosis** Akane Izu, Keisuke Sugimoto, Tomoki Miyazawa, Hitomi Nishi, Mitsuru Okada, Tsukasa Takemura. *Pediatrics, Kinki Univ School of Medicine, Osakasayama, Osaka, Japan.*

**Background:** Secondary focal segmental glomerulosclerosis (FSGS) follows congenital or acquired tubulointerstitial alterations such as in Dent's disease, Lowe syndrome, and reflux nephropathy. Failure of adequate regeneration after tubulointerstitial injury, or abnormal tubulogenesis, can disturb intrarenal blood circulation, causing excessive glomerular filtration. The epithelial cell-transforming sequence 2 gene (*ECT2*) contributes to tight junction function in epithelial cells.

**Methods:** Gene expression was screened by the comparative genomic hybridization (CGH) in 15 FSGS patients under treatment at our department. In one patient, a-actinin 4, located on chromosome 19q.13, was deleted. In another, a 6p deletion-associated E2F3 gene aberration was found. Downregulation of *ECT2*, located at 3q26.1 to q26.2, was observed in both patients. To confirm *ECT2* deletions, PCR for *ECT2* and immunohistochemical staining for ECT2 protein in renal tissues was carried out.

**Results:** We encountered two patients with a nonfunctioning ECT2 genotype who later developed FSGS. Renal biopsy specimens showed marked tubulointerstitial nephritis at the onset of proteinuria, later progressing to FSGS consequent to tubulointerstitial injury. Both patients did not respond to corticosteroids and attained only incomplete remission upon cyclosporine A administration. One patient received a maternal renal transplant with good function and no rejection. Some clustered genes localized in chromosome 3q.26.1–3q.26.2 showed downregulation. Signal indicating the loss of copy number was recognized in the log4 zone, suggesting homozygous deletion of *ECT2* in both patients. In both patients, no amplification band was detected, confirming the CGH results. Immunohistological evaluation for ECT2 protein in these two patients revealed no expression of this molecule in renal tubular epithelium.

**Conclusions:** *ECT2* is important for tight junction function and maintenance of cell polarity. Nonfunction of this gene may cause renal tubulointerstitial injury, progressing to glomerular sclerosis.

## TH-PO655

**Whole Genome Sequencing Catalogue of Genetic Variants from 256 Nephrotic Syndrome Cases** Matthew G. Sampson,[1,3,4] Adrian Tan,[1] Crystal A. Gadegbeku,[2,3,4] John R. Sedor,[3,5] Matthias Kretzler,[1,3,4] Hyun Min Kang.[1] *[1]Univ of Michigan; [2]Temple Univ; [3]Nephrotic Syndrome Study Network (NEPTUNE); [4]Michigan O'Brien Renal Center; [5]Case Western Univ.*

**Background:** To identify known and novel genetic variants associated with intermediate and clinical phenotypes of primary nephrotic syndrome (NS), we are performing low-pass whole genome sequencing (WGS) and exome chip genotyping of 550 subjects with NS recruited into one of two prospective, observational cohorts. Here we present data on the first 256 patients.

**Methods:** Subjects were recruited at time of initial biopsy for suspected primary NS or had existing diagnoses of focal segmental glomerulosclerosis (FSGS) or membranous nephropathy (MN). All had Illumina Exome Chip genotyping and Illumina HiSeq WGS. WGS data was analyzed with GotCloud pipeline with linkage disequilbrium refinement and compared to Exome Chip genotypes. Variant frequencies were compared to the latest release of 1000 Genomes and Exome Sequencing Projects, stratified by ancestry.

**Results:** Diagnoses were 52% minimal change/FSGS, 25% MN, and 24% "other glomerulopathy". Ancestry was 49% European (EUR), 29% African (AFR), 15% Admixed American (AMR), and 7% Asian (ASN). Mean read depth was 4.2x. 20.9M SNPs were identified with transition/transversion ratio of 2.16. 330K (16%) SNPs were novel to dbSNP Build 135. Comparing to exome chip data, low-pass WGS had estimated 89% power to detect shared variants in cases and 30% power to detect singleton variants. We identified novel loss-of-function and essential splice-site variants shared in our cases in 55 and 64 genes, respectively. In AFR FSGS cases, the minor allele frequency (MAF) of the FSGS risk haplotype, G1, in *APOL1* was 31% (OR=1.6). In EUR MN cases, the allele frequencies of the known MN risk SNPs, rs2187668 and rs4664308, were 33% (OR=4.4) and 83% (OR=3.5), respectively.

**Conclusions:** With 47% of our cohort analyzed thus far, low-pass WGS has power to assess disease associations of coding and non-coding variants with a MAF >1%. We will integrate this data with molecular, histologic, and clinical data from the same subjects. This could clarify existing, and define new, associations between genetic variants and both endophenotypes and clinical outcomes.

## TH-PO656

**Adjustment for Genetic Determinants of Urinary KIM1 Does Not Alter the Relationship with All-Cause Mortality** Gearoid M. McMahon,[1] Shih-Jen Hwang,[1] Qiong Yang,[2] Caroline S. Fox.[1] *[1]NHLBI's Framingham Heart Study, Framingham, MA; [2]Biostatistics, Boston Univ, Boston, MA.*

**Background:** Kidney Injury Molecule-1 (KIM1) is a novel biomarker of kidney disease. We investigated if there were genetic determinants of KIM1 levels and if the addition of these variants improved the ability of KIM1 to predict clinical outcomes.

**Methods:** We did a genome-wide association (GWAS) of urinary KIM1/cr in 2640 participants from the Framingham Heart Study Offspring cohort (53% female, mean age 58 yrs). We constructed a logistic regression model to evaluate the association between urinary KIM1 and incident chronic kidney disease (CKD), albuminuria, cardiovascular disease (CVD) and all-cause mortality in up to 10yrs of follow-up. Finally, we constructed a model including variants identified in the GWAS to determine whether the addition of these variants altered the relationship between KIM1 and these outcomes.

**Results:** rs6555820, an intronic C□A substitution in the *HAVCR1* gene (MAF 0.43) explained 9% of the variance in KIM1. *HAVCR1* encodes the hepatitis A virus cellular receptor, also known as KIM1, which plays a key role in regulating immune cell activity. Per copy of the minor A allele, KIM1 levels were 0.4 pg/ml lower. In the multivariable-adjusted model, KIM1 was associated with all-cause mortality. There was no association of KIM1 with incident CVD, CKD or albuminuria. The presence of the minor allele was not associated with any outcome. The addition of the variant to the model did not change the relationship between urinary KIM1 and any primary outcome.

| | CKD | Albuminuria | CVD | Mortality |
|---|---|---|---|---|
| **Cases/total** | 178/1971 | 158/1668 | 195/2508 | 324/2635 |
| | **OR (95%CI)** | **OR (95%CI)** | **HR (95%CI)** | **HR (95%CI)** |
| **KIM1** | 1.15 (0.96-1.38) | 1.18 (0.99-1.42) | 1.08 (0.92-1.26) | 1.13 (1.00-1.28) |
| **rs6555820** | 0.92 (0.73-1.16) | 0.86 (0.68-1.10) | 0.98 (0.81-1.20) | 0.95 (0.81-1.11] |
| **Adjusted KIM1** | 1.14 (0.95-1.38) | 1.16 (0.96-1.41) | 1.08 (0.92-1.27) | 1.13 (1.00-1.29) |

**Conclusions:** A variant in the *HAVCR1* gene is associated with KIM1 levels. However, statistical adjustment for the presence of this variant did not alter the relationship between KIM1 and all-cause mortality.

## TH-PO657

**Genome-Wide Scan of Copy Number Variations (CNVs) Identifies a Variable Region at 3p21.1 Regulating the *TLR9* Expression in Familial IgA Nephropathy Patients** Fabio Sallustio,[1,2,3] Sharon N. Cox,[1] Grazia Serino,[1] Francesco Pesce,[4] Giuseppe De Palma,[2] Mario Falchi,[4] Francesco Paolo Schena.[1,2,5] *[1]Dept of Emergency and Organ Transplantation, Univ of Bari, Bari, Italy; [2]C.A.R.S.O. Consortium, Valenzano, Bari, Italy; [3]Dipartimento di Scienze e Tecnologie Biologie ed Ambientali (DiSTeBA, Università del Salento, Lecce, Italy; [4]Dept of Genomics of Common Disease, School of Public Health, Imperial College, London, United Kingdom; [5]Schena Foundation, Research Center of Kidney Diseases, Valenzano, Bari, Italy.*

**Background:** Immunoglobulin A Nephropathy (IgAN) is a multifactorial complex disease whose genetic bases remain unknown. In this context, an intriguing role could be ascribed to copy number variants (CNVs) that have been recognized as an important source of genetic variations in humans.

**Methods:** We performed a whole-genome screening of CNVs in familial IgAN patients, their healthy relatives and healthy subjects (HS). A total of 217 individuals consisting of 51 familial IgAN patients and 166 healthy relatives were included in the study. We used a statistical approach (MSA) that allowed us to identify aberrations that were concordant across multiple samples and that allowed to use a relatively little sample-size, simultaneously increasing the power of the analysis and the resolution.

**Results:** 178 IgAN-specific aberrations were identified, specifically 114 loss and 64 gain. Several CNVs overlapped with regions evidenced by our previous genome-wide genetic studies (AJHG, 2006). Moreover, we found that IgAN patients characterized by deteriorated renal function carried low copy numbers of a CNV in chromosome 3p21.1. This CNV contained the *TLR9* gene whose expression significantly correlated with the

loss aberration in patients with progressive renal damage. Data were validated by RT-PCR. Conversely, IgAN patients with normal renal function did not have this aberration and the *TLR9* mRNA was expressed at the same level as in HS.

**Conclusions:** We performed the first genome-wide CNV study in familial IgAN. We identified some structural variants specific to IgAN patients and provided a collection of new candidate genes and loci that could help to dissect the complex genomic pattern of the disease.

## TH-PO658

**Elevated Klotho Promoter Methylation Is Associated with Deterioration of Renal Function in IgA Nephropathy Patients** Xiaoyan Zhang, Jing Chen, Han Zhang, Yi Fang, Xiaoqiang Ding. *Nephrology, Zhongshan Hospital, Fudan Univ, Shanghai, China.*

**Background:** Recent studies prove Klotho (Kl) functions as a renoprotective factor and inhibition of Kl expression correlates with gene hypermethylation, which suggests epigenetic modification of Kl genes may be an important pathological mechanism of renal fibrosis. Our previous study demonstrates peripheral blood mononuclear cells (PBMC) level of Kl promoter methylation is positively correlated with intra-renal level of Kl promoter methylation and has high sensitivity and specificity at predicting intra-renal Kl promoter hypermethylation in chronic kidney disease patients. The aim of this study is to analyze the relationship of PBMC Kl promoter methylation level with eGFR in IgA nephropathy.

**Methods:** 70 Patients admitted to Shanghai Zhongshan hospital between 2012 April and 2013 April for renal biopsy and diagnosed as primary IgA nephropathy were included in the study. All patients provided informed consent. PBMC Kl methylation level was examined by pyrosequencing.

**Table 1 Primers and sequence for analysis**

| Primers | Sequence(5'→3') | Base pair |
|---|---|---|
| Primer forward | GTGGGAGAAAAGTGAGAGTAG | 21 |
| Primer reverse | AAACCCTCAAATTCATTCTCTTTACCTACC | 30 |
| Primer sequencing | AAGTGAGAGTAGGTG | 15 |
| Sequence for analysis | TTTTTTTAGYGGYGYGTTTYGTTAGGGTTYGGTAG | 51 |
| | GATTTYGTTTTTAAGT | |
| | (*After Bisulfite treatment*) | |

**Results:** The patients included 39 men and 31 women with a mean age of 37.89±11.81yr (range 16 to 66 yr). The eGFR ranged from 4.09~86.73 ml/min/1.73m2 (median 49.24 ml/min/1.73m2). The median of PBMC Kl promoter methylation in 70 IgAN patients was 4.08% (1.50~11.76%). eGFR inversely correlated with age ($\rho$=-0.307, P<0.01), hypertension($\rho$=-0.529, P<0.01), uric acid ($\rho$=-0.423, P<0.01), intact parathyroid hormone (iPTH) ($\rho$=-0.328, P<0.01), proteinuria ($\rho$=-0.427, P<0.01) and PBMC Kl promoter methylation level ($\rho$=-0.809, P<0.01). eGFR positively correlated with hemoglobin ($\rho$=0.246, P<0.05), serum calcium ($\rho$=0.293, P<0.05) and urinary calcium($\rho$=0.419, P<0.01) (table 2) (figure 2). Multiple regression analysis indicated older age (P<0.01), high iPTH (P<0.01), high proteinuria (P<0.05) and high PBMC Klotho promoter methylation level (P<0.01) correlated significantly with lower eGFR (table 3).

**Conclusions:** PBMC Klotho promoter methylation is an independent risk factor of deterioration of renal function in IgAN patients.

## TH-PO659

**Systems Biology of Experimental Alport Syndrome: Computational Identification of Gene Expression Pathways** Xuewen Song,[1] Fei Fang,[1] Rohan John,[1] Ana Konvalinka,[1] Christoph Licht,[2] Paul S. Thorner,[3] James W. Scholey,[1] York P. Pei.[1] *[1]Div of Nephrology, Univ Health Network, Toronto, Canada; [2]Div of Nephrology, Hospital for Sick Children, Toronto, Canada; [3]Dept of Pathology, Hospital for Sick Children, Toronto, Canada.*

**Background:** Mutations of *COL4A-3*, -4 or -5 result in defective glomerular basement membrane assembly in Alport Syndrome (AS) but the downstream molecular events associated with renal disease progression are not well understood.

**Methods:** We sought to define the gene pathways associated with disease progression in Col4a3 $^{-/-}$ knock-out (KO) mice. Using Affymetrix Mouse Gene 2.0 ST arrays, we performed global gene profiling of renal cortical samples from male 129/Svj congenic KO and wild type (WT) mice at 4 and 7 weeks of age (n=8 each) in a 2x2 factorial design. We used Gene Set Enrichment Analysis (GSEA) and Significance Analysis of Microarrays (SAM) to identify overrepresented signaling pathways, biological processes, and genes associated with disease initiation and progression**.**

**Results:** Our data validated some of the known pathological features of AS, including down-regulation of Col4a3-5 and up-regulation of Col4a1-2; and up-regulation of laminins and matrix metalloproteases. At 4 weeks in the KO mice, we only found several genes (i.e. Rasl11A, Ctsl, Fstl, Cald1, Plod2, and R3hdml) that were differentially expressed and increased in expression during disease progression. Comparisons of KO mice between weeks 4 and 7 (minus any overlapping changes in WT at the same time points) identified multiple gene sets associated with tissue injuries and remodelling including collagen metabolism, immune/inflammatory responses (e.g. cytokine/ interleukin/chemokine, JAK-STAT, NF-kB, and complement signaling), TGF-β, ECM, and integrin signaling. By contrast, most down-regulated gene sets represent metabolic pathways.

**Conclusions:** Our study confirmed an arrest of the normal developmental switch from fetal α1-α1-α2 (IV) to mature α3-α4-α5 (IV) collagen network in AS and identified major molecular pathways which may mediate renal injuries and remodelling. Targeting key nodes of convergence of pathways of renal injuries may provide molecular targets for novel therapeutics.

## TH-PO660

**Is There an Epigenetic Predisposition to New Onset Diabetes after Transplantation?** Jennifer A. McCaughan,[1,2] A.J. McKnight,[1] Alexander P. Maxwell.[1,2] *[1]Nephrology Research Group, Queen's Univ, Belfast, United Kingdom; [2]Regional Nephrology Unit, Belfast City Hospital, Belfast, United Kingdom.*

**Background:** New onset diabetes after transplantation (NODAT) is an increasingly common complication of renal transplantation. Recent evidence suggests that pancreatic beta cell toxicity, as a result of hyperglycemia in the peri-transplant period, may play a key role in NODAT pathogenesis. We recently demonstrated that single nucleotide polymorphisms in genes crucial to beta cell function predispose to NODAT in a White population. This study investigates the association between DNA methylation profiles prior to transplantation and the development of NODAT.

**Methods:** NODAT was defined as diabetes developing after transplantation and requiring pharmacotherapy. Epigenome wide methylation analysis was performed at 485,577 CpG sites using the Infinium HumanMethylation 450 BeadChip (Illumina) on blood-derived DNA from 348 renal transplant recipients from Northern Ireland. Quality control measures, including correction for dye bias, sample normalisation and evaluation of probe performance, were undertaken. Beta values were calculated and compared between NODAT cases and controls using ANOVA. Adjustment for multiple testing was performed.

**Results:** There were 46 (13%) cases of NODAT in the study cohort. All individuals were White. Following quality control analysis, methylation at 14 CpG sites was associated with NODAT with a p value < $10^{-5}$. After adjustment for multiple testing, these associations did not persist.

**Conclusions:** There is clinical evidence that a hyperglycemic insult within the peri-transplant period may contribute to the development of NODAT. Variation in genes influencing pancreatic beta cell function may also predispose renal transplant recipients to NODAT. This study did not provide evidence that DNA methylation profiles prior to transplantation are associated with NODAT. However, it is plausible that hyperglycemia alters DNA methylation in key genes following transplantation and may contribute to NODAT pathogenesis in this manner.

## TH-PO661

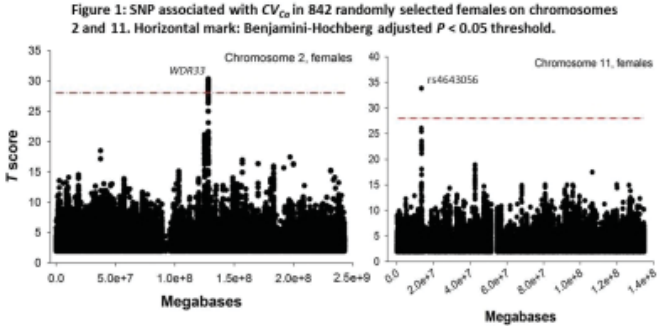
**SNP Associated with the Coefficient of Variation in 24-h Urinary Calcium Excretion Linked to Parathyroid Hormone and WD Repeat Domain 33** Guy M.L. Perry,[1] Martin R. Pollak,[2] Hakan R. Toka,[2] David B. Mount,[2] Gary C. Curhan,[3] Steven J. Scheinman.[4] *[1]SUNY Upstate Medical Univ, Syracuse, NY; [2]Harvard Medical School, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]The Commonwealth College, Scranton, PA.*

**Background:** Residual variance (RV) is heritable in some systems. Our epidemiological and model work on this phenomenon suggests that residual variance in urinary calcium excretion is heritable in humans, and might have effects on conventional genetic analysis.

**Methods:** We performed a genome-wide association study on the coefficient of variation for paired measurements of 24-h urinary calcium ($CV_{Ca}$) in 1210 individuals with a history of confirmed stone disease and randomly-sampled unaffecteds (368 males, 842 females total).

**Results:** No single nucleotide polymorphism (SNP) was associated with $CV_{Ca}$ in the complete sample, or in males. A T/C polymorphism at rs4643056 (Chr 11, 13.5 MB) was significantly associated with $CV_{Ca}$ in females ($P$=6×10$^{-9}$). This region is syntenic with a chromosomal region (Chr 1, 170-227 MB) in rats carrying a quantitative trait locus for $CV_{Ca}$. Fourteen SNP in *WD repeat domain 33* (*WDR33*; Chr 2, 128.2-128.3 MB) were also associated with $CV_{Ca}$ in females ($P$=4×10$^{-8}$).

**Figure 1: SNP associated with $CV_{Ca}$ in 842 randomly selected females on chromosomes 2 and 11. Horizontal mark: Benjamini-Hochberg adjusted $P$ < 0.05 threshold.**



**Conclusions:** These results and our previous work indicate sex-limited genes affecting residual variance in urinary calcium. The nearest gene to rs4643056 is parathyroid hormone (*PTH*, 34 kB downstream); notably, a syntenic genomic region carrying *PTH* is also associated with $CV_{Ca}$ in rats. *PTH* has functions in acetylation, serum calcium regulation and bone mineralization, and WD repeat proteins with signal transduction, mRNA processing and methylation, which suggests mixed generalist/specialist genetic control

of this phenomenon. These SNP were not associated with mean urinary calcium; residual variance genes might dynamically control urinary solute excretion without detectable classical genetic effects.

*Funding:* NIDDK Support

## TH-PO662

**Exon-Skipping in Gitelman's Syndrome Families** Yoichi Takeuchi,[1] Hisato Shima,[1] Eikan Mishima,[1] Yasutoshi Akiyama,[1] Chitose Suzuki,[1] Takehiro Suzuki,[1] Tomohiro Nakayama,[2] Sadayoshi Ito,[1] Takaaki Abe.[1] *[1]Div of Nephrology, Endocrinology and Vascular Medicine, Tohoku Univ Graduate School of Medicine; [2]Nihon Univ School of Medicine.*

**Background:** More than 160 point mutations in SLC12A3 gene causing Gitelman's syndrome have been reported and missense mutations have been examined generally by single amino acid substitution.

However, there is sometimes no functional difference in expression experiment by the mutant sequence.

It is revealed a single mutation on exonic splicing enhancers (ESEs) weaken the exon recognition by spliceosome, which cause exon-skipping. The aim here is to find a single exonic mutation disrupting SLC12A3 exon sequence.

**Methods:** All 80 missense mutations in SLC12A3 were analyzed by ESEfinder to extract putative exonic mutations which generate exon-skipping. The exon sequence with flanking introns were PCR-amplified and subcloned into an exon-skipping detection vector. Resultant plasmids were transfected into HEK293 and evaluated whether the exon was skipped or not by RT-PCR. Total RNA from three Gitelman's syndrome patients (T180K/A588V, L858H/R861H and M672I/c.1926delC) was isolated from the blood and we examined the possibility of abnormal splicing.

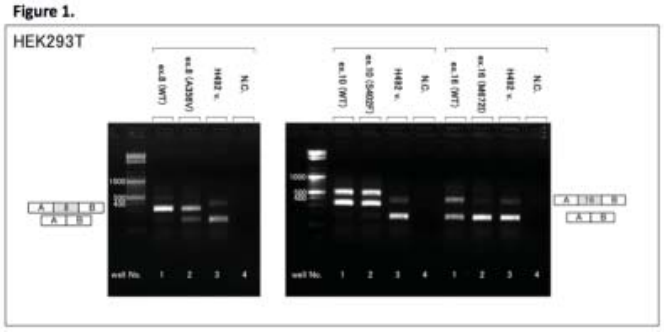
**Results:** ESEfinder detected three exonic mutations (A356V, S402F and M672I) as the best candidates of exon-skipping.

Whereas S402F mutation showed normal splicing by in-vitro assay, A356V and M672I created the skipped transcripts to produce newly aberrant proteins. All the bands were confirmed by sequencing.

Another missense mutation as R861C (frequent in European) showed normal splicing band by in-vitro assay.

All of the mutations of three patients remained normal transcripts.

**Figure 1.**



**Conclusions:** We found exonic mutations caused exon-skipping in SLC12A3. We need to examine not only single amino acids substitution by genomic mutations but also RNA transcripts and resultant loss-of-function.

## TH-PO663

**Do Single Nucleotide Polymorphisms Contribute to Urine pH Variation? A Genetic Association Study** Benjamin Canales,[1] Jennifer Smith,[2] Wei Zhao,[2] Gary C. Curhan,[3] I. David Weiner,[4] John C. Lieske.[5] *[1]Urology, Univ of Florida, Gainesville, FL; [2]Epidemiology, Univ of Michigan, Ann Arbor, MI; [3]Medicine, Renal Div, Brigham and Women's Hospital, Boston, MA; [4]Medicine, Renal Div, Univ of Florida, Malcom Randall VAMC, Gainesville, FL; [5]Medicine, Renal Div, Mayo Clinic, Rochester, MN.*

**Background:** Although a number of gene mutations have been implicated in rare urinary acid-base disorders, little is known regarding genetic control of urine pH in the general population.

**Methods:** 15 genes involved in renal acid-base homeostasis were identified. A genetic association study was performed in 2493 individuals of European descent across 4 cohorts (n=811, Minnesota cohort of the Genetic Epidemiology Network of Arteriopathy (GENOA); n=553, Health Professionals Follow-Up Study (HPS); n=494, Nurses' Health Study (NHS) I; n=635, NHS II). Single nucleotide polymorphism (SNP) dosages from 1000 Genomes imputed data were modeled for association with 24 hr urine pH using linear regression after adjustment for age, sex and body mass index. SNPs with minor allele frequency >0.01 were studied between 5 kb from a targeted gene start or endpoint. A fixed-effects meta-analysis was used with inverse variance weighting by standard error of the beta coefficient.

**Results:** 2906 SNPs met inclusion criteria. 17 SNPs across 5 genes (*ATP6V0A4*, *SLC9A3*, *RHCG*, *GLUD1*, and *OGDH*) had a meta-analysis p-value <0.01 in the joint analysis, plus a consistent direction of effect and at least marginal significance (p<0.1) in both GENOA and the combined sample of HPFS/NHS I/NHS II. The lowest meta-analysis p-value was observed for rs6955765 in the *ATP6V0A4* gene (p=0.0009). Maximal beta-coefficients for identified SNPs were 0.20 for *GLUD1*, 0.06 for *RHCG*, 0.06 for *SLC9A3*, 0.08 for *ATP6V0A4* and 0.20 for *OGDH*. Two blocks of SNPs on genes *ATP6V0A4* (n=9) and *SLC9A3* (n=4) were in strong linkage disequilibrium ($r^2$>0.8).

**Conclusions:** Common genetic variants of several genes involved in renal acid-base homeostasis correlate with basal urine pH. This study suggests that genetic variation in these genes could influence urine pH in the general population.

*Funding:* NIDDK Support, Private Foundation Support

## TH-PO664

**Whether Digenic Inheritance of NPHS1 "And" TRPC6 Polymorphisms Predisposes to Progression of Steroid-Resistant Nephrotic Syndrome in Children?** Larisa Prikhodina. *Pediatric Nephrology, Reasearch Institute of Pediatrics & Children' Surgery, Moscow, Russian Federation.*

**Background:** Mutations in NPHS1 and TRPC6 genes cause steroid-resistant nephritic syndrome (SRNS) in children and adults. The role of digenic inheritance of TRPC6 and NPHS1 single nucleotide polymorphisms (SNPs) in progression of SRNS in children is unknown.

**Methods:** We aim to investigate whether digenic inheritance of NPHS1/TRPC6 SNPs predispose to progression of idiopathic pediatric SRNS to chronic renal failure (CRF). 28 children (20F/8M) with primary non-familial SRNS, originating from Russia, were enrolled. Histological findings were FSGS in 60.7%, MPGN in 17.9%, mesangial proliferative GN in 10.7%, MN in 7.1%, MCD in 3.6% patients. The median age at onset of SRNS was 9.0 (IQR: 4.3; 10.9) years. The disease duration was 63.0 (38.4; 88.50) months. CRF defined as declining of eGFR <60 mL/min/1.73m$^2$. NPHS1 and TRPC6 mutation analysis was performed by Sanger sequencing of all 29 and 13 exons, respectively. Patients with congenital, infantile and secondary SRNS and with identified mutations in *NPHS1* or TRPC6 genes were excluded from the study.

**Results:** Digenic inheritance of NPHS1/ TRPC6 SNPs was identified in 8/28 (28.6%) children with SRNS, including two homo-/heterozygous NPHS1 SNPs: ?.349G>A (rs3814995), c.1223G>A (rs33950747) and three heterozygous TRPC6 SNPs: c.43C>T (rs3802829), c.1211C>T (rs36111323), c.1683T>C (rs12366144). Children with digenic inheritance of NPHS1/TRPC6 SNPs in comparison without the SNPs had no significant differences in frequency of FSGS: 87.5% vs. 100% (p=1.0), medium eGFR at the last follow up: 77.4 (52.0; 143.0)vs. 80.5 (37.1; 120.3) mL/min/1.73m$^2$ (p=0.39), frequency of CRF: 50% vs. 33.3% (p=0.72), annual slope of eGFR decline: 6.4 (-1.3; 20.7) vs. 0.1 (-2.8; 37.6) mL/min/1.73m$^2$ (p=0.46). The 5-year renal survival in patients with digenic inheritance of NPHS1/TRPC6 SNPs in comparison without SNPs had no significant differences: 72.9% vs. 66.7%; 10-year renal survival - 43.8% vs. 66.7%, respectively (p=0.88).

**Conclusions:** Our data indicate that digenic inheritance of TRPC6 and NPHS1 SNPs does not predispose to progression of idiopathic SRNS to CRF in children.

## TH-PO665

**Molecular Effects of Three Mutations Identified in Complement Component C3 in Japanese Patients with Atypical Hemolytic Uremic Syndrome** Akira Ashida,[1] Daisuke Yamamoto,[2] Yoko Yoshida,[3] Fan Xinping,[4] Masanori Matsumoto,[3] Toshiyuki Miyata,[4] Motoshi Hattori,[5] Yoshihiro Fujimura,[3] Hiroshi Tamai.[1] *[1]Pediatrics, Osaka Medical College, Takatsuki, Osaka, Japan; [2]Biomedical Computation Center, Osaka Medical College, Takatsuki, Osaka, Japan; [3]Blood Transfusion Medicine, Nara Medical Univ, Kashihara, Nara, Japan; [4]Molecular Pathogenesis, Research Institute National Cerebral and Cardiovascular Center, Suita, Osaka, Japan; [5]Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

**Background:** Atypical hemolytic uremic syndrome (aHUS) has been associated with dysregulation of the alternative complement pathway. Mutations in complement factor H (CFH), factor I, factor B (CFB), thrombomodulin, C3, and MCP predispose development of aHUS. We identified 7 causative or potentially causative mutations of 6 candidate genes, including the C3 gene, in 8 out of 10 Japanese patients with aHUS. We analyzed the molecular effects of these C3 gene mutations on the alternative pathway of complement activation.

**Methods:** We examined three missense mutations in the C3 gene identified in 10 Japanese patients with aHUS. Each three-dimensional coordinate set was listed in the RCSB Protein Data Bank as 2I07 (C3b), 2WII (C3b-CFH), 2XWB (C3b-CFB/D), 2ICF (C3b-CR1G) and 3L5N (C3b-SCIn).

**Results:** We carried out the structural analysis of the R425, S562 and I1157 residues on the molecular surface, using the X-ray structures of C3b and each of its complexes with CFH, CFB, CR1g and SCIn (staphylococcal complement inhibitor). At the three mutation points, I1157 in the thioester-containing domain (TED) of C3b was located at the interface with CFH. The CR1g interface with C3b lay between R425 and S562, and mutations of these residues were considered to possibly reduce the interaction between C3b and CR1g. All of these mutation points were located at positions where they would have no direct effect on the interface of CFB and SCIn with C3b. From these findings, we postulate that the novel mutations R425 and S562 might cancel the inhibitory trigger of the C3b system by disturbing the interaction with CR1g.

**Conclusions:** We conclude that these mutations of C3 gene including mutations R425 and S562 are causative.

## TH-PO666

**Total Kidney Volume in Healthy Aging Adults** Carlos Kornhauser. *Medical Sciences, Guanajuato Univ, León, Guanajuato, Mexico.*

**Background:** Total kidney volume (TKV) and its relationship with pro-inflammatory factors such as TGF-β, VEGF and aldosterone has been poorly studied in aging. We evaluated the TKV by ultrasonography, and its relationship with eGFR, microalbuminuria, TGF-β, VEGF and aldosterone in healthy aging adults.

**Methods:** Renal ultrasonography was performed in 30 women <75, and 30 ≥75 years, 20 men <75 and 20 ≥75 years. eGFR was estimated according to the MDRD formula. Microalbuminuria, serum TGF-β, VEGF, and aldosterone levels were assessed in all subjects.

**Results:** TKV was significantly higher (p<0.0000) in the two groups of men, as compared to the two groups of women. TKV was significantly higher (p<0.0001) in women <75 y as compared to women >75 y. No difference was found in the TKV between men <75 y as compared to men >75 y. A negative correlation between TKV and age in men (r=.49, p=0.00004), and in women (r=38, p=0.001) was found. TKV and TGF-β (r=.47, p= 0.0001) showed a negative correlation only in men. The TKV and microalbuminuria showed a positive correlation only in men (r=.28, p=0.02). The eGFR did not show correlations with any of the variables. VEGF and aldosterone did not correlate with TKV.

| | Group 1 | Group 2 | Group 3 | Group 4 | p |
|---|---|---|---|---|---|
| | Women <75y | men <75 y | women >75y | men >75y | |
| | (n=30) | (n=20) | women >75y | (n=20) | |
| Total Kidney Volume ($cm^3$) | 102.9 ± 16.9 | 131.1 ± 32.9 | 87.2 ± 8.2 | 119.4 ± 6.6 | 0.000000 |

**Conclusions:** Men have bigger total kidney volumes than women at any age. The TKV in men does not significantly change with age. In women TKV gets significantly smaller with age. Microalbuminuria correlates positively with TKV in men, but not eGFR. TGF-β shows a negative correlation with TKV. In men, the smaller the TKV,the higher the TGF-β levels.

## TH-PO667

**Renal Function in Healthy Aging Adults. Age and Gender Differences** Carlos Kornhauser. *Medical Sciences, Guanajuato Univ, León, Guanajuato, Mexico.*

**Background:** Renal function is poorly studied in healthy aging adults. Role of TGF-β, VEGF and aldosterone in the aging process and its relationship with eGFR, and microalbumiuria needs to be more clearly established.

**Methods:** Two hundred normotensive subjects (100 women and 100 men) were included. Fifty women and fifty men <75 years, and 50 women and fifty men ≥75 years old. Serum glucose, uric acid, lipid profile, eGFR (MDRD), TGF-β, VEGF and aldosterone, and microalbuminuria were assessed.

**Results:** eGFR was significantly higher in men (85.3 ml/min/1.73$m^2$) as compared to women (66.5 ml/min/1.73$m^2$) at any age (p <0.00001). eGFR values were similar in both age groups of women, as well as in both age groups of men. Aldosterone was significantly higher in men <75 y as compared to women <75 y (p<0.0000), but higher in women >75 y as compared to men >75 y (p<0.0000). VEGF was higher in women >75 y as compared to men >75 y. Uric acid (p<0.01) and TGF-β (p<0.0000) were significantly different between each group of age. eGFR and microalbuminuria had a negative association (R= -.41 p=0.03) in men <75 y. Aldosterone did not show associations.

| | Group 1 | Group 2 | Group 3 | Group 4 | p |
|---|---|---|---|---|---|
| | Women <75y | Men <75y | Women >75y | Men >75y | |
| | (n=50) | (n=50) | (n=50) | (n=50) | |
| Uric Acid (mg/dl) | 3.5 ± .7 | 3.6 ± .7 | 3.2 ± .5 | 3.3 ± .6 | <0.01 |
| Cholesterol (mg/dl) | 170 ± 33 | 167 ± 22 | 170 ± 34 | 150 ± 34 | <0.003 |
| Cholesterol LDL (mg/dl) | 96 ± 30 | 88 ± 21 | 107 ± 33 | 77 ± 33 | <0.00001 |
| TGF-β1(pg/ml) | 6707±1729 | 7766 ±3849 | 12345±3317 | 13115±3732 | <0.0000 |
| Aldosterone (pg/ml) | 112 ± 61 | 195 ± 72 | 159 ±73 | 97 ±73 | <0.00000 |
| Microalbuminuria (mg/L) | 7.4 ± 4 | 10.4 ± 6 | 7.4 ± 4 | 9.6 ± 4 | <0.002 |
| eGFR (ml/min/1.73$m^2$) | 69 ± 12 | 88 ± 25 | 64 ±15 | 83 ± 20 | <0.00001 |

**Conclusions:** eGFR decreases in men and women with aging, but values were never under 60 ml/min/1.73$m^2$. Microalbuminuria absence define subjects as healthy. Uric acid, aldosterone, VEGF and TGF-β levels need to be clarified in these subjects without kidney disease.

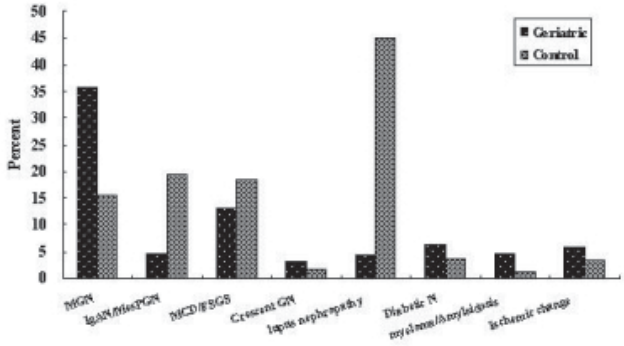
## TH-PO668

**Pattern of Biopsy-Proven Renal Diseases in Geriatric Patients from a Single Center in Taiwan** Cheng-Hsu Chen,[1,2,3,4] Ya-Wen Chuang.[1] *[1]Section of Nephrology, Dept of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan; [2]School of Medicine, China Medical Univ, Taichung, Taiwan; [3]School of Medicine, Chung Shan Medical Univ, Taichung, Taiwan; [4]Dept of Life Science, Tunghai Univ, Taichung, Taiwan.*

**Background:** The elder population is growing fast as a major cause of chronic kidney disease (CKD) burden in Taiwan, however, the distribution of kidney diseases in elderly patients are not well known. The aim of this study was to compare the pattern of renal disease in elderly and control patients who underwent native renal biopsy.

**Methods:** Among 3622 renal biopsies, excluded 588 graft biopsies and 322 inadequate criteria biopsies, we did a single-center, retrospective study (1992-2008) of the biopsy-proven renal diseases between geriatric patients (age ≥65y/o; n=327) and control (18≤ age< 65; n=2385).

**Results:** The geriatric group with mean age was 71.8±4.5 (65.1-87.3 yrs), male gender (74%), age>70yr (n=200, 61%), the control group was 39.7±17.6(18-64.9yrs), male gender (41%). Membranous nephropathy (MN) was the most frequent diagnosis (35.8%), followed by minimal change disease/focal segmental glomerulosclerosis (MCD/FSGS) (13.1%), diabetic nephropathy (6.4%), hypertensive nephrosclerosis (5.8%), and IgA nephropathy (4.6%).



Comparison with the control group showed MN to be more frequent (P < 0.01), and lupus nephritis (P<0.001) and IgAN (P<0.001) less frequent in the elderly. However, ANCA-positive nephritis, and myeloma nephropathy and amyloid nephropathy were also more common in the elderly.

**Conclusions:** Renal biopsy in elderly patients is a valuable diagnostic tool that should be offered the potential to modify treatment with maximal potential benefit. Age should not be considered as a contraindication to renal biopsy.

## TH-PO669

**Renal Biopsy in Elderly Italian: A Single-Center Experience over 12 Years** Fausta Catapano, Lucia B. De Sanctis, Antonio Santoro. *Nephrology, Dialysis and Hypertension Unit, Policlinico S.Orsola Malpighi, Bologna, Italy.*

**Background:** The global increase in life expectancy has translated to more elderly patients affected from renal diseases. The role of renal biopsy (RB) in this subset of patients has never been explored; moreover the histological patterns of renal disease in elderly have rarely been described.

**Methods:** This is a retrospective study of all consecutive elderly patients (age ≥ 70 years) biopsied at S.Orsola-Malpighi Hospital of Bologna between 1st January 2000 and 31 December 2012. Data are extracted from renal biopsies database.

**Results:** No RB has been performed until 2005. 106 (M59, F47) elderly patients have been biopsied in the remnant study period (figure 1). The mean age was 76±4years without difference between sexes. In 8/108 (7.4%) RB was not adequate. Primary glomerulonephritis were seen in 39/100 patients and secondary glomerulonephritis in 25/100. Membranous glomerulonephritis (MGN) was the most common (21/100) and was significantly more frequent in males (M17: F4, p<0.05). Other common diagnoses included cast nephropathy (11/100) and amyloidosis (11/100). Nephrotic syndrome was the most common clinical presentation (43%) followed by acute renal failure (30%). After biopsy, 48% received immunosuppressive therapy.

**Figure 1. Histological diagnosis**

| Diagnosis | N. Patients |
|---|---|
| ***Primary glomerulonephritis*** | 39 |
| Membranous GN | 21 |
| Minimal change disease | 7 |
| Membranoproliferative GN | 8 |
| Mesangio-proliferative GN | 1 |
| Crescentic GN | 1 |
| Focal segmental glomerulosclerosis | 1 |
| ***Secondary glomerulonephritis*** | 25 |
| Amyloidosis | 11 |
| Vasculitis | 6 |
| Crioglobulinaemia | 5 |
| LCDD | 2 |
| Lupus nephritis | 1 |
| ***Non-inflammatory renal disease*** | 20 |
| Cast nephropathy | 11 |
| Diabetic glomerulopathy | 3 |
| Acute tubular necrosis | 6 |
| ***Vascular nephropathy*** | 5 |
| Nephrosclerosis | 4 |
| Atero-aembolic disease | 1 |
| ***Interstitial nephritis*** | 4 |
| ***Others*** | 5 |
| ESRD | 2 |
| CIN-nephrotoxicity | 2 |
| Lymphoproliferative tumor | 1 |

**Conclusions:** Renal biopsy, even in elderly patients, provides us with useful information for an accurate histological diagnosis and, interestingly, ESRD is not very common. In our study, GNM is the most common diagnosis followed by mieloma-related kidney diseases.

## TH-PO670

**Cognitive Impairment in Advanced Chronic Kidney Disease** Simon Richard Walker, Ranveer Singh Brar, Brett M. Hiebert, Frederick Eng, Paul Komenda, Claudio Rigatto, Manish M. Sood, Clara Bohm, Leroy J. Storsley, Rakesh C. Arora, Navdeep Tangri. *Medicine, Seven Oaks General Hospital, Univ of Manitoba, Winnipeg, Canada.*

**Background:** Chronic Kidney Disease (CKD) disproportionately affects the elderly and is associated with frailty and impaired quality of life. Patients with CKD suffer from multiple comorbid conditions putting them at risk of developing cognitive impairment. The purpose of this study was to describe the prevalence of cognitive impairment in patients with advanced CKD (eGFR < 30ml/min).

**Methods:** We approached all patients with advanced CKD who attended an interprofessional non-dialysis CKD clinic at a tertiary care center for enrollment in our study. We excluded patients who did not speak English or were unable to provide informed consent. We collected demographic variables, physical examination measurements, laboratory values, and performed an assessment of cognitive function using the Montreal Cognitive Assessment (MoCA).

**Results:** We studied 86 patients. Their mean age was 67.2 years (Standard Deviation [SD]+/- 12.8), and 34 patients were female (39.5%). The mean eGFR was 20.5 mL/min/1.73m$^2$ (SD +/- 8.1). Sixty seven patients (77.0%) scored < 26 on the MoCA and were thus defined as cognitively impaired. In particular, the recall, visual/executive and language domains were impaired in > 60 % of the participants. In contrast, naming and orientation were relatively well preserved (> 70 % achieving perfect score).

**Conclusions:** Patients with advanced CKD have a high burden of cognitive impairment. Further studies on the pathophysiology of cognitive decline and its impact on patient decision making and outcomes are needed.

## TH-PO671

**Marked Increased Risk of Prediabetes in Elderly ESRD Patients** Mark E. Williams,[1] Neal Mittman,[2] Lin Ma,[3] Julia I. Brennan,[4] Curtis D. Johnson,[4] Chinu M. Jani,[4] Franklin W. Maddux,[3] Eduardo K. Lacson.[3] *[1]Joslin Diabetes Center, Boston, MA; [2]Long Island College Hospital, Brooklyn, NY; [3]Fresenius Medical Care, North America, Waltham, MA; [4]Spectra Laboratories, Rockleigh, NJ.*

**Background:** Prediabetes has become a major public health problem. Diagnosing prediabetes identifies individuals at high risk for diabetes and its complications. Increased age is known to be a significant risk factor for prediabetes in the general population. Because ESRD is also associated with impairments in glucose regulation, we sought to determine the association of aging with prediabetes in a cohort of nondiabetic dialysis patients, using ADA cutoffs of hemoglobin A1c at 5.7-6.4%.

**Methods:** Of 3,447 dialysis patients from 26 facilities with laboratory values obtained the first quarter of 2013, 1454 (with mean age 56.6 years; 78% on hemodialysis) were without known diabetes and had HgbA1c values. Age was categorized into decades (from <45 years to >=75 years) and the HgbA1c distribution was determined for each.

**Results:** 2% for those over age 65 years were found to be in the diabetic range (HgbA1c of >=6.5%). The per cent of patients with prediabetes by age category, using the lowest category as reference and analyzed by chi square, is shown:

| | Age (years) | | | | | |
|---|---|---|---|---|---|---|
| N/Col Pct | <45 | 45-55 | 55-65 | 65-75 | >=75 | Total |
| HgbA1c<=5.6 | 320 | 250 | 280 | 178 | 171 | 1199 |
| % | 87.67 | 81.97 | 82.6 | 77.39 | 79.53 | |
| HgbA1c: >5.6 - <6.5 | 44 | 45 | 51 | 48 | 42 | 230 |
| % | 12.05 | 14.75 | 15.04 | 20.87 | 19.53 | |
| HgbA1c>=6.5 | 1 | 10 | 8 | 4 | 2 | 25 |
| % | 0.27 | 3.28 | 2.36 | 1.74 | 0.93 | |
| Total | 365 | 305 | 339 | 230 | 215 | 1454 |

The prevalence of prediabetes increased dramatically over age 65 years in the nondiabetic ESRD population (both p<0.05).

**Conclusions:** Studies defining the natural history of prediabetes and the benefit of screening the ESRD elderly for preventive intervention are needed. Furthermore, as the population ages, the need for more studies focusing on patients with geriatric chronic kidney disease becomes increasingly apparent.

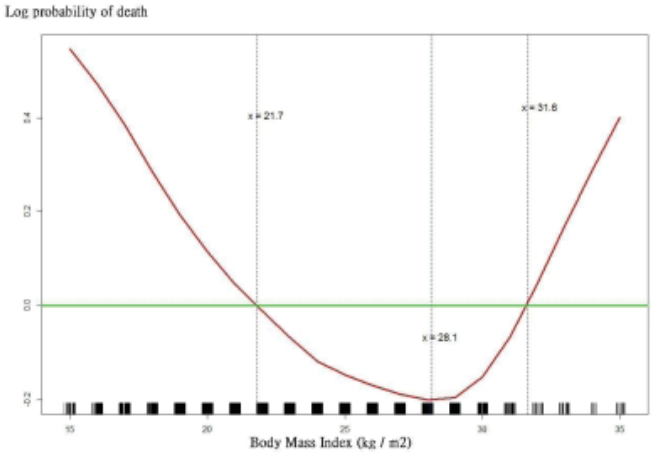
## TH-PO672

**Impact of Body Mass Index on Outcomes after Acute Kidney Injury in Geriatric Patients** Chia-Ter Chao, Hung-Bin Tsai. *Dept of Traumatology, National Taiwan Univ Hospital, Taipei, Taiwan.*

**Background:** Acute kidney injury (AKI) frequently occurs in critically ill patients and impairs both short-term and long-term outcomes. However, studies on outcome-modifying factors in geriatric patients with AKI are few, and the influence of body mass has not been determined previously.

**Methods:** We performed a multicenter prospective observational study and enrolled elderly patients ( ≥65 years) that developed AKI after major surgery in the intensive care units. We analyzed in-hospital mortality within each body mass index (BMI) category utilizing Cox proportional hazard regression analysis and generalized additive modeling (GAM).

**Results:** A total of 2015 postoperative elderly patients (age 75.2±6.4, men 57.8%) were studied. The survivors were significantly younger than the nonsurvivors (p=0.001) and had higher BMIs (23.2±3.9 kg/m$^2$ vs. 22.4±4.2 kg/m$^2$; p<0.001). GAM modeling showed that elderly AKI patients with a BMI between 21 and 31 (normal weight) had a lower mortality risk than those with a BMI < 21 (underweight) or ≥ 31 (obese). Both underweight and overweight individuals had a greater risk of hospital mortality compared with patients with normal BMI (underweight vs. normal, hazard ratio [HR] 1.60, 95% confidence interval [CI] 1.05-2.61; p=0.038; obese vs. normal, HR 1.22, 95%CI 1.01-1.49; p=0.042).



**Conclusions:** Our study is the first to demonstrate the effects of BMI on in-hospital mortality in geriatric patients sustaining AKI. The U-shaped association of BMI with hospital mortality in geriatrics is different from the association in other populations and therefore should alert physicians of factors potentially affecting the outcomes of this patient population.

## TH-PO673

**Association between Body Composition and Frailty among Prevalent Hemodialysis Patients: A USRDS Special Study** Kirsten L. Johansen,[1] Lorien S. Dalrymple,[2] Cynthia Delgado,[1] George A. Kaysen,[2] John Kornak,[1] Barbara A. Grimes,[1] Glenn M. Chertow.[3] *[1]Univ of California San Francisco; [2]UC Davis; [3]Stanford Univ School of Medicine.*

**Background:** Most studies of frailty among patients on hemodialysis have relied on definitions that substitute self-reported functioning for measures of physical performance and omit weight loss or substitute alternate criteria. Associations between body composition and frailty have not been carefully examined.

**Methods:** We examined the association between body composition and a definition of frailty that includes physical performance and weight loss in ACTIVE/ADIPOSE a cohort study of the USRDS Special Studies Centers. We included 638 patients receiving hemodialysis in a cross-sectional analysis. Frailty was defined as three of: weight loss, weakness, exhaustion, low physical activity, and slow gait speed. We performed logistic regression with body mass index (BMI) and estimates of intracellular water (ICW), fat mass, and extracellular water (ECW) by bioelectrical impedance spectroscopy (BIS) as the main predictors and age, sex, race, and comorbidity included as covariates. BMI and BIS data were then added to these covariates in separate models, and the areas under the ROC curves or (c-statistics) of the two resulting models were compared.

**Results:** Thirty percent of participants were frail. Older age (1.31 per 10 years, 95% CI 1.14-1.50) and diabetes (OR 1.65, 95% CI 1.13-2.40) were associated with higher odds of frailty. BMI was not associated with frailty (OR 1.02, 95% CI 0.99-1.05). Higher ICW was associated with lower odds of frailty (OR 0.80 per kg, 95% CI 0.73-0.87), and higher fat mass (OR 1.18, 95% CI 1.02-1.37) and ECW (OR 1.33, 95% CI 1.20-1.47) were associated with higher odds of frailty. Addition of BMI did not change the c-statistic (0.66 without BMI vs. 0.66 with BMI, p=0.71), but addition of BIS data did (0.72, p=0.0004).

**Conclusions:** Our data demonstrate the high prevalence of frailty in the hemodialysis population, and in particular, the poor performance of BMI as an indicator of frailty among patients on hemodialysis. We highlight the associations among variations in body composition and the odds of frailty.

**TH-PO674**

**Evaluation of Nutrition in Elderly Patients with Renal Failure** Rumeyza Kazancioglu,[1] Banu Buyukaydin,[1] Ahmet Turan Isik.[2] *[1]Nephrology, Bezmialem Vakif Univ, Turkey; [2]Geriatrics, Dokuz Eylul Univ.*

**Background:** Both malnutrition and chronic kidney diseases are clinical pathologies that increase morbidity and mortality incidence in elderly. We evaluated nutritional state and comorbidities in this group of patients.

**Methods:** 65 years and over 54 hospitalized patients were included in the study. The glomerular filtration rate (GFR) was calculated by using Modification of Diet in Renal Disease (MDRD) and Chronic Kidney Disease Epidemiology Collaboration (CKD-Epi) formulas. All of the patients' calculated GFR was below 60 ml/min/1.73m$^2$. Nutritional status was evaluated with Mini Nutritional Assessment Short-Form (MNA-SF) and Geriatric Nutritional Risk Index (GNRI). Patients' waist circumference, hip circumference, waist-hip ratio and body mass indices (BMI) were measured and biochemical analysis was performed.

**Results:** Means of patients GNRI score was 97.9±13 (R = 66-128), and MNA-SF score was 7.9±2.9 (R= 1-14). In older patients mean MNA-SF was lower (R = 0.269, p=0.049). Between lower GNRI and higher creatinine level, there was detected significantcorrelation (R= 0.340, p= 0.012). In long-term hospitalized patients, GNRI and MNA-SF scores were lower (R = 0.455, p=0.001), (R = 0.356, p=0.008). Low GNRI correlated with low waist circumference, low hip circumference and low BMI, respectively (R = 0.436, p=0.001), (R = 0.554, p= 0.000), (R = 0.744, p= 0.000). And low MNA-SF correlated with low levels of same parameters also (R=0.377, p=0.005), (R=0.327, p=0.017), (R=0.440, p=0.001).

**Conclusions:** In elderly patients with chronic kidney disease, GNRI is a reliable nutritional test. Also waist circumference, hip circumference and BMI are usable measurements for nutritional evaluation in this group of patients.

**TH-PO675**

**Elderly Renal Replacement Therapy (RRT) Population an Emerging Problem: One Center Analysis** Ilaria Tantillo, Alessandra Brendolan, Monica Zanella, Federico Nalesso, Claudio Ronco. *Nephrology and IRRIV, San Bortolo Hospital, Italy.*

**Background:** The proportion of elderly people is rising throughout the world. Very elderly chronic kidney disease (CKD) patients (pts) are a growing group dialyzed and their morbility and outocomes have important implications for future Health policies. The aim of this study was to analyze the outcomes of incident RRT pts aged 75 years (yrs) or more between January 2008 and March 2013.

**Methods:** We analyzed retrospectively 97 pts (68% M), mean age (80.78±3.7 yrs), 57 hemodialysis (HD) and 40 peritoneal dialysis(PD), at least 2 months (mths) of RRT. The causes of CKD were hypertension (48.5%), glomerulopathy (13.4%), diabetes (DM) (10.3%), unknown (13.4%). In 20.6% of cases, the pts were late referral. Mean time of RRT was 17.04±12.04 mths. We defined 3 classes of age: 1) 51 pts (75-79 yrs); 2) 33 (80-84 yrs); 3) 13 ( ≥80 yrs). The parameters tested were survival between groups (tested by log-rank test and modeled in a multivariate fashion with Cox proportional hazards regression) and hospital admission rate (negative binomial regression, adjusted for exposure). Statistical analysis was performed using Stata 12.

**Results:** In a univariate perspective, a significant difference in survival was observed comparing pts above or below 80 yrs, with or without DM, and with ejection fraction above or below 50%. In a multivariate Cox regression (3 classes of age, DM, malignancy and major cardiovascular events at the beginning of RRT) the only significant 2 predictors of mortality were age class [HR (class 2 vs class 1): 2.80, p<0.01; HR(class 3 vs class 1): 3.25, p=0.048] and DM [HR: 2.48, p<0.01]. In the negative binomial regression of hospitalizations on RRT modality and age at beginning of RRT, we find that – adjusting for age and duration on the treatment – PD pts are hospitalized less frequently than HD pts [p<0.01].

**Conclusions:** This finding suggests that are no medical concernes to avoid RRT therapy in eldery CKD pts but life expectancy of pts who began RRT above 80 yrs is significantly shorter than class 1. DM is the only significative risk factor of poor outcome. The survival of HD than PD pts is the same, but the PD are hospitalized less frequently than HD.

**TH-PO676**

**Hemodialysis Remains a Feasible Option for Renal Replacement Therapy in Elderly Who Are over Eighty-Five Years** Pratima Ghimire, Eli A. Friedman, Moro O. Salifu, Mary C. Mallappallil. *Dept of Nephrology, SUNY Downstate Medical Center, Brooklyn, NY.*

**Background:** There are limited studies on effectiveness of initiating hemodialysis (HD) on elderly patients above 85 years. We studied the quality of life and outcome of hemodialysis among patients who are 85 years and above.

**Methods:** Among 290 adult prevalent hemodialysis patients, we conducted cross-sectional study on 11 patients who had age 85 years and above. Five of eleven were over the age of 90 years. We looked at factors that contributed to the longevity despite needing hemodialysis.

**Results:** The mean age of the group was 88.9 ± 3.5 years. Four of them were men and seven were women. Only two patients were from nursing homes, the rest were from home. Out of eleven patients, seven had arteriovenous fistula, two had arteriovenous grafts and two had permanent cuffed catheters. One of the patients who had a catheter had failed multiple other accesses including a lower extremity arteriovenous graft. Two patients had low ejection fraction, both of whom currently had cuffed dialysis catheters. The mean hemoglobin and serum albumin were 10.6 ± 1.0 gm/dL and 3.5 ± 0.4 gm/dL respectively. Seven were diabetic and only one had peripheral vascular disease. The vintage on dialysis ranged from less than one year to twenty five years, most of them have been on dialysis for more than 3 years and most had initiated dialysis after the age of 85.

**Conclusions:** Most of our patients, who are 85 years and above, come from home, are diabetic, have working accesses, have normal cardiac function and have laboratory parameters that indicate stable dialysis. Age alone should not prevent initiation of hemodialysis in the very elderly even over the age of eighty five.

**TH-PO677**

**Dialysis in Elderly Patients in a Multi-Ethnic Population: A Single Centre Unit's Experience** Alvin Kok Heong Ng. *Renal Medicine, Changi General Hospital, Singapore.*

**Background:** The incidence of elderly dialysis patients is rising worldwide as life expectancy improves with more advanced and better access to healthcare. We analyzed our multi-ethnic population of elderly dialysis patients, and describe their demographics, dialysis treatment and access at initiation, and mortality data.

**Methods:** This is a retrospective longitudinal analysis of incident dialysis patients from 1 January 2010 to 30 April 2013, aged 70 and above. Cases were identified from our unit's database. Outcomes were identified from electronic case notes and follow-up is from date of initiation of dialysis to death or 30 April 2013. The data was then analyzed via SPSS programme.

**Results:** 43 patients aged 70 years and above were started on long-term dialysis. There were 62.8% females and 37.2% males. Ethnicity was divided to Chinese, Malay, Indian and Others with a distribution of 79.4%, 14%, 2.3% and 4.7% respectively. Patients aged 70-74.99 years and 75-79.99 years contributed to 34.9% each, 18.6% were aged 80-84.99 years and finally 11.63% at 85 years and above.

The predominant cause of end stage kidney disease (ESKD) was diabetic nephropathy (62.8%). Initiation of dialysis in the elderly involved temporary vascular catheter in 41.9% and 30.2% of patients required continuous renal replacement therapy (CRRT). None of our patients had a functioning dialysis access during their initiation of dialysis. 20.9% of the patients were established on peritoneal dialysis and 79.1% hemodialysis. Median time to arteriovenous fistula or graft (AVF/AVG) creation was 81 days and to Tenckhoff insertion was 23 days.

There were only 3 deaths at 90 days (11%) from a total of 27 patients who had follow-ups of at least one year. Death rates were not calculated as the small number of patients may skew the results.

**Conclusions:** Diabetes remains a predominant aetiology of ESKD in elderly population with a large proportion requiring temporary vascular access and CRRT. Time to dialysis access creation was shorter with Tenckhoff catheter than AVF/AVG creation. Number of deaths appeared to be low but may not be accurate. We hope to improve the access to dialysis treatment, timely intiation, and care in our elderly population with the above findings.

**TH-PO678**

**Unplanned Dialysis Start Despite a Follow-Up by a Nephrologist in Elderly Patients Reaching End Stage Renal Disease. The PSPA Cohort Study** Olivier Moranne,[1,3] Cecile M. Vigneau,[2,3] Cécile Couchoud.[3,4] *[1]Nephrology, CHU Nice, France; [2]Nephrology, CHU Rennes, France; [3]For PSPA Investigators, France; [4]French Registry REIN, La Plaine St Denis, France.*

**Background:** Elderly (i.e > 75 yrs) represent about 40% of incident dialysis patients in the French REIN Registry. These patients have an higher risk of unplanned starting dialysis (30%) which is documented as a strong prognosis factor [REIN 2011]. Unplanned starting dialysis in elderly patients despite a follow-up by a nephrologist needs to be better understood. The objective of this study is to identify predialysis patient characteristics and therapeutic project associated with unplanned vs planned dialysis start from the French prospective multicenter cohort PSPA study [Moranne et al, J Gerontol A Biol Sci Med 2012].

**Methods:** From the 581 elderly patients followed by nephrologist included in the PSPA study (mean MDRD at initiation 14±4ml/min/1.73m²), 253 (43%) started dialysis during 3 years-follow-up. Patient's clinical characteristics, way of life, share therapeutic project about the option for dialysis at inclusion in the cohort and medical reasons to start dialysis between groups starting unplanned vs planned dialysis were analysed.

**Results:** Median age was 82 [79-85] yrs with 64% men and 57(23%) started dialysis in an unplanned manner (for life-threatening risk). Those patients were significantly older, had more often active cancer, lower functional mobility, lived more often in institution. They had more often a "non dialysis option" as therapeutic project, because of patient's request or stable GFR consideration according to nephrologist. Nondialysis option at nephrologist's request was not associated with unplanned dialysis. The starting dialysis reason for those patients were significantly more often anemia and hyperkalemia.

**Conclusions:** These results show that elderly reaching ESRF followed by nephrologists start unplanned dialysis in 23% of cases. Unplanned dialysis start was associated with frailty and institutionalized patients and if therapeutic project about the option for dialysis was postponed by patient or according to stable GFR by nephrologist. The results should alert nephrologist about the necessity of share therapeutic project and better enhanced the organization of initiation of dialysis.

**Efficacy of Intradialytic Rehabilitation in Renal Anemia among Elderly Patients** Yoshimi Ueda,[1,2] Junitiro Kato,[1,2] Keitaro Yokoyama,[2] Takashi Yokoo.[2] *[1]Tokyu Hospital, Tokyo, Japan; [2]The Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** Increasing numbers of elderly patients (Pts) with end-stage renal disease are starting dialysis. Previous reports have shown that the initiation of dialysis is associated with a substantial and sustained decline in functional status among them. The impact of a lower functional status may be reduced by offering rehabilitation to dialysis Pts. Correction of anemia and physical activity are effective for at least moderate improvements in physical function although these studies have been conducted primarily in younger Pts. The effect of exercise on renal anemia in elderly Pts is unclear. Therefore, we examined the efficacy of intradialytic rehabilitation (IDR) to prevent functional decline and renal anemia in elderly Pts.

**Methods:** We evaluated 16 hemodialysis outpatients over 65 yr of age who participated in our IDR program since September 1, 2009 to Feburary 28, 2013. All Pts underwent our program during each dialysis session for at least 12 weeks. Pts who were initiated hemodialysis within 3 months were excluded. We prescribed the stretch of the lower limbs and progressive resistance exercise using an elastic band and the gizzard. We assessed following parameters at the start and following 3 months of our program: physical tests (e.g. muscular strength, 10-meter walking test), anthropometrics, nutritional status, erythropoiesis stimulating agents (ESA) dose and hemoglobin (Hb), and data known as risk factors for ESA hyporesponsiveness.

**Results:** Pts were mean age 74.7 ± 6.0 years, 78.5% male, 18% diabetic; dialysis vintage was 125.4 ± 120.3 months. 3 Pts withdrew because of offering decline from the program, and of admission due to fall and severe hypotension. In more than half of Pts, physical strength was maintained after our program. Weekly ESA dose significantly declined from 6923IU to 5423IU ($p = 0.021$), while mean Hb concentrations increased from 10.8g/dl to 11.4g/dl at the start and 3 months, respectively.

**Conclusions:** IDR for elderly Pts has a potential not only to prevent their functional decline, but also to improve renal anemia.

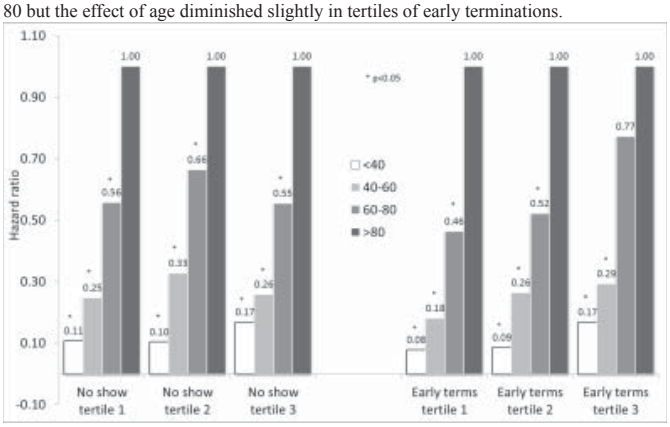
**TH-PO680**

**Relationship of Non-Compliance and Outcomes Stratified by Age Groups in Dialysis Population** Suzette Thompson,[1] Penny Faith Sheppard,[1] Len A. Usvyat,[2] Mary T. Sullivan,[1] Peter Kotanko,[1] Paul M. Zabetakis,[1] Nathan W. Levin.[1] *[1]RRI, NY, NY; [2]FMCNA, Waltham, MA.*

**Background:** Non-compliance is a significant issue in US hemodialysis (HD) patient population. We aim to understand whether non-compliance rates are different in different age groups as well as whether age affects relative risk of death in different groups of non-compliance.

**Methods:** All RRI in-center HD patients with >100 treatments and treated for >365 days between Jan 1, 2010 and Feb 28, 2013 were selected. Patients were stratified based on age (<40, 40-60, 60-80, >80) at start of the study period. For each patient, we computed % of treatments with unexcused no shows as well as % of treatments with early terminations (defined as terminated >15 minutes prior to their prescribed treatment time) during entire study period. Patients were divided into tertiles of no show and early termination rates. To determine if hazard risks of death are different at different levels of non-compliance, we constructed Cox proportional hazards models in each tertile of no shows and early terminations separately.

**Results:** We studied 7029 patients. Non-compliance was inversely related to age (not shown) as previously shown (Vega, EDTA 2011). In each tertile of no shows and early terminations, older patients had poor survival. Compared to patients >80 years, patients <40 years had similar although increasing hazard ratios in no show tertiles 1, 2, and 3 (0.11, 0.10, 0.17) for no shows respectively and for early termination tertiles 1, 2, and 3 (0.08, 0.09, 0.17). As expected, hazard risks of death were higher in age group 40 to 60 and 60 to 80 but the effect of age diminished slightly in tertiles of early terminations.



**Conclusions:** Older patients appear to have better treatment compliance than younger patients. Relative impact of age on survival appears similar across tertiles of no shows but diminishes in tertiles of early terminations.

**TH-PO681**

**Safety and Feasbility of Structured Exercise Training in Older Deconditioned Adults with CKD** Stephen L. Seliger,[1,2] Jamie Giffuni,[2] Leslie I. Katzel,[1,2] Andrew M. Well,[3] Christopher W. Washington,[2] Kieran Reid,[4] Daniel E. Weiner.[3] *[1]Medicine, U Maryland, Baltimore, MD; [2]Medicine, Baltimore VAMC, Baltimore, MD; [3]Medicine, Tufts NEMC, Boston, MA; [4]Human Nutrition Rsch Cntr Aging, Tufts Univ, Boston, MA.*

**Background:** CKD is associated with lower physical performance, especially in older adults. The feasibility and safety of structured aerobic and resistance exercise training in these patients is unclear.

**Methods:** The AWARD study is an ongoing randomized trial among community-dwelling sedentary adults aged 60+ years with stage 3b-4 CKD, comparing the effects of 12 months exercise training vs. health education (control). Thrice weekly in-center treadmill-based exercise sessions are prescribed, with intensity and duration titrated over the first 8 weeks to goal of 40 minutes/session at 70-80% of the heart rate reserve. Additional resistance training is performed twice weekly. Aerobic capacity ($VO_2$peak) is measured with graded treadmill testing, and submaximal gait with the 6-minute walk test.

**Results:** 28 patients have been enrolled to date. Mean age and BMI were 68.8 years and 30.3 kg/m$^2$, mean eGFR 37 cc/min/1.73m$^2$, and 64% had diabetes. $VO_2$peak was 18.8±5.7 mL/kg/min (32% lower than predicted for healthy older adults), and distance walked in 6 minutes was 1330±334 feet (24% lower than predicted). 15 participants were randomized to exercise, with 803 individual exercise sessions prescribed to date. Of these, 76% were attended, with median individual adherence 87%. Target heart rate was achieved or surpassed in 55% of individual sessions. A total of 5 non-serious adverse events (AE) occurred that were potentially related to exercise (minor muscle injuries and post-exercise hypoglycemia). No serious AE's related to exercise occurred.

**Conclusions:** Thrice weekly training with aerobic and resistance training is feasible and safe for sedentary older adults with non-dialysis CKD. Adherence rates are excellent/high when compared with previous long-term exercise trials in frail older adults. Final results of this trial will determine whether such training is effective at improving cardiorespiratory fitness and/or lower extremity function, parameters which are markedly impaired in these patients.

**TH-PO682**

**Association of Chronic Kidney Disease with Falls in Nursing Home Residents** Rasheeda K. Hall,[1,2] Ann M. O'Hare,[3,4] Ruth A. Anderson,[1] Cathleen Colon-Emeric.[1,2] *[1]Duke Univ; [2]Durham VA; [3]VA Puget Sound; [4]Univ of Washington.*

**Background:** Chronic kidney disease (CKD) has been independently associated with falls in community dwelling older adults, but it is not known if this is also the case for nursing home (NH) residents. CKD may be associated with falls in NH residents because it comes with known fall risk factors (i.e., anemia, Vitamin D deficiency). To better understand falls risk in the growing population of NH residents with CKD, this study examines the association of estimated glomerular filtration rate (eGFR) with fall rate.

**Methods:** Secondary analyses of NH resident data obtained in a multicenter randomized controlled trial of NH staff-based fall prevention strategies (2009-2012). In each participating NH, residents with at least 1 fall during either of 2 6-month periods underwent chart abstraction for fall risk factors, serum creatinine, and subsequent fall events. We calculated eGFR using the Modification of Diet in Renal Disease equation, and CKD was defined by an eGFR less than 60ml/min/1.73m$^2$. To test for independent association of eGFR with falls, our multivariable regression covariates included demographics, fall risk factors, resident's time at risk, and location.

**Results:** A total of 510 residents with falls were identified from 9 unique NHs. The mean (± SD) resident age was 77.2±11.5, 27% were female, and 63% resided in Veterans Affairs NHs. Overall median eGFR was 72 ml/min (IQR=50-95) while 35% of residents had CKD. Residents with CKD were older (79.3±11 vs. 76.1±11.6) and more likely to be female (34 vs. 23%). Mean fall rate was 5.6 falls per 100 patient days and did not differ by CKD status (p =0.40). In unadjusted analyses, lower eGFR was not associated with an increase in falls (p=0.58). In adjusted analyses, this relationship was unchanged.

**Conclusions:** In this study of NH residents who fall, one-third had low eGFR, but eGFR was not associated with the risk of recurrent falls. The absence of association suggests that CKD does not further increase falls risk in this high risk population. Given the increasing prevalence of CKD in NHs, this evidence suggests that current NH fall prevention strategies do not need to be altered for those with CKD.

**TH-PO683**

**Patients' and Caregivers' Perspectives on Palliative Care in Chronic Kidney Disease: Systematic Review and Thematic Synthesis of Qualitative Studies** Allison Tong,[1,2] Katharine Cheung,[3] Sumi Sukumaran Nair,[3] Manjula Kurella Tamura,[3] Jonathan C. Craig,[1,2] Wolfgang C. Winkelmayer.[3] *[1]Sydney School of Public Health, The Univ of Sydney, Australia; [2]Centre for Kidney Research, The Children's Hospital at Westmead, Australia; [3]Div of Nephrology, Stanford Univ.*

**Background:** While dialysis offers life-prolonging treatment for end-stage kidney disease, up to 25% of deaths are attributed to dialysis withdrawal. Difficult decisions to withhold or discontinue dialysis may be necessary when the treatment burden outweighs

the benefits. This study aims to describe patients' and caregivers' perspectives on palliative care in chronic kidney disease (CKD).

**Methods:** We conducted a comprehensive literature search in Medline, Embase, PsycINFO, CINAHL and reference lists to May 2013. Thematic synthesis was used to analyze the findings.

**Results:** Twenty-four studies involving over 440 patients and 161 caregivers were included. We identified five themes: relief from suffering (bodily deterioration, loss of freedom and independence, pervasive fatigue and pain, resignation, treatment burden and harm); personal vulnerability (imminence of death, fear of misunderstanding and judgement, maintaining autonomy and dignity, medical abandonment, valuing safety and trust); relational responsibility (being a burden, demonstrating loyalty, protecting others from grief); negotiating existential tensions (accepting natural course of life, disrupted aging, worthlessness, living on borrowed time, respecting sanctity of life, life satisfaction, preserving self-identity); and preparedness (decisional clarity, information support, spirituality and hope).

**Conclusions:** Patients with CKD can experience physical and psychosocial frailty, and feel ambivalent about prolonging life. Caregivers believe in providing relief from suffering but are uncertain about making decisions regarding palliative care. CKD management should encompass palliative care strategies that promote emotional resilience, sense of well-being and self-value. Also, respectful and attentive communication is needed so patients are empowered to convey their values and preferences in treatment decision making.

## TH-PO684

**Understanding Patterns of Place of Death in Patients with CKD 4-5** Fliss E. Murtagh,[1] Natasha B. Lovell,[1] Chris Jones,[2] Baynes Ingrid Dawn,[2] Sarah J. Dinning,[2] Catherine Susanna Vinen.[2] *[1]Dept of Palliative Care, Policy and Rehabilitation, Kings College London, London, United Kingdom; [2]Kings Renal Unit, Kings College Hospital, London, United Kingdom.*

**Background:** Meeting preference regarding place of death is an important marker of quality of care; systematic review shows 42% end stage kidney disease patients prefer home death. These patients have high mortality, yet little research has been done to study place of death. The aim of this study was to understand patterns of place of death in patients with Chronic Kidney Disease (CKD) 4-5 known to a UK renal team.

**Methods:** A retrospective cohort study of CKD patients stage 4-5 known to a UK renal team, who died over 4 years (2009-2012). Demographic and clinical variables were collected, including management pathway and living circumstances. Multi-variable regression analysis was undertaken to determine relationship with place of death.

**Results:** 721 patients were included (mean age 73.9, SD 13.65). 59.6% male. 70.2% died in hospital (95% CI 66.8%-73.4%), 21.9% died in their usual residence (95% CI 19.0%-25.0%), and 7.9% died in an inpatient palliative care unit (95% CI 6.1%-10.1%). 1) Management pathway and 2) Residential setting were most strongly associated with place of death. 1) Patients on the conservative (non-dialytic) pathway had 4.6 times the odds of dying out of hospital (OR 4.6, 95% CI 2.8-7.3, P<0.01). 2) Patients living alone were less likely to die out of hospital (OR 0.6, 95% CI 0.4-1.0, P<0.05). Those where living status was not documented were less likely to die out of hospital (OR 0.5, 95% CI 0.3-0.8, P<0.01). Patients living in a care home had 9 times the odds of dying out of hospital (OR 9.3, 95% CI 3.4-25.7, P<0.01).

**Conclusions:** Hospital death predominated all groups, but place of death varied by management pathway, consistent with national data. Out-of-hospital deaths were higher in the conservative group. This may represent impact of palliative care service development for conservatively managed patients in this unit. This work highlights importance of considering management pathway and living circumstances, so we meet preference for place of death in other management pathway groups, including patients on haemodialysis.

## TH-PO685

**Symptom Scores in End-Stage Kidney Disease: Can They Help U.S. with Timing of Anticipatory Care Planning?** Fliss E. Murtagh,[1] Natasha B. Lovell,[1] Katherine Bristowe,[1] Kate A. Shepherd,[2] Heather Jane Brown,[1] Beverley Matthews,[1] Donal O'Donoghue,[1] Catherine Susanna Vinen.[2] *[1]Kings College London, Cicely Saunders Institute, London, United Kingdom; [2]Kings College Hospital, London, United Kingdom.*

**Background:** Patients with end stage kidney disease report high fatigue (weighted mean prevalence 71%) and up to 58% experience depression (Murtagh AJKD 2007). Good symptom management and being prepared are patient priorities but professionals find timing of discussions challenging. We aimed to identify if routine symptom assessment had potential to inform timing.

**Methods:** Mixed-methods study, including experience survey, and symptom assessment (validated renal Palliative care Outcome Scale). 3 questions concerned anticipatory care planning (ACP): Q1)Have you thought about where you would like to be cared for if you were not able to get better? Q2)Have you thought about who you would like to be involved in decisions about your medical care? Q3)When you raise these concerns do you feel they are taken seriously?

**Results:** 91 dialysis patients, 64.4% male, 30% aged 75 and above. 49.5% white. Fatigue and depression showed significant differences in question response: Q1 responses: 19.1%(95% CI 11.5-28.8) 'yes', 15.7%(95% CI 8.9-25.0) 'to some extent', 58.4%(95% CI 47.5-68.8) 'no', and 6.7%(95% CI 2.5-14.1) 'don't know'. Patients with high depression scores more often considered future care options ($\chi 2$=8.569;p=0.036;n=87). Q2 responses: 55.6%(95% CI 44.7-66.0) 'yes', 21.1%(95% CI 13.2-31.0) 'to some extent', 20.0%(95% CI 12.3-30.0) 'no', and 3.3%(95% CI 0.7-9.4) 'don't know'. Patients with high fatigue more often considered who they wanted involved in decisions ($\chi 2$=9.798;p=0.02;n=85). Q3 responses: 53.5%(95% CI 42.4-64.3) 'yes', 32.6%(95% CI 22.8-43.5) 'to some extent', 8.1%(95% CI 3.3-16.1) 'no', and 5.8%(95% CI 1.9-13.0) 'not applicable'. Patients with high fatigue felt less sure concerns were taken seriously ($\chi 2$=8.799;p=0.032;n=81).

**Conclusions:** These results highlight need to consider symptoms when timing ACP discussion. Routine regular symptom assessment may help inform readiness of patients, particularly if reporting fatigue/ depression. This work is a key component in a project led by NHS Kidney Care.

*Funding:* Government Support - Non-U.S.

## TH-PO686

**Depression, Social Support, Self-Efficacy, and Fluid Adherence in Older Adults on Hemodialysis** Tiffany R. Washington. *Social Work, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.*

**Background:** Controlled fluid intake is an important aspect of kidney disease self-management, yet depression, the most common psychiatric issue affecting older end-stage renal disease (ESRD) patients, negatively impacts fluid adherence. Factors that mitigate depression's deleterious effects are underidentified, and if identified, can aid in the design and development of psychosocial interventions to reduce its negative impact and improve fluid adherence. This paper examines four logistic regression models to determine mediating factors between depression and fluid adherence.

**Methods:** A total of 107 ESRD patients from four hemodialysis facilities in the southeast aged 50 and older were interviewed about their kidney disease self-management behaviors. Four logistic regression models were analyzed: 1) the primary independent variable (depression); 2) the primary independent variable (depression) with a secondary independent variable (social support); 3) the primary independent variable (depression) with a secondary independent variable (self-efficacy); and 4) the primary independent variable (depression) with both secondary independent variables (self-efficacy and social support).

**Results:** Age was associated with an increase in fluid adherence (adjusted odds ratio [AOR] = 1.08, 95% confidence interval [CI] = 1.02-1.14), and depression was associated with a decrease in fluid adherence (AOR = 0.82, 95% CI = 0.67-0.99). When self-efficacy was entered into the model, the association between depression and fluid adherence disappeared. Race comparisons showed that depression was negatively associated with fluid adherence ($r = -0.26$, $p < .05$), and self-efficacy and age were positively associated with fluid adherence among black participants ($r = 0.24$, $p < 0.05$ and $r = 0.32$, $p < 0.01$, respectively).

**Conclusions:** The findings from this study suggest that self-efficacy and age are important factors in fluid adherence, and self-efficacy can potentially mediate the negative effects of depression in older ESRD patients. Advanced statistical methods and longitudinal studies are required to determine the indirect effect of depression to fluid adherence mediated by self-efficacy.

*Funding:* Private Foundation Support

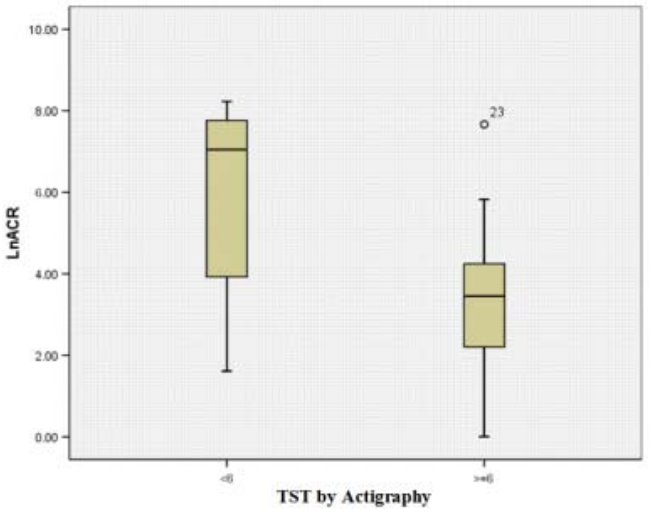
## TH-PO687

**Short Sleep Duration and Albuminuria in Advanced Chronic Kidney Disease** Andrew M. Well,[1] Jamie Giffuni,[2] Stephen L. Seliger,[2] Roger A. Fielding,[1] Leslie I. Katzel,[2] Daniel E. Weiner.[1] *[1]Tufts Univ, Boston, MA; [2]Univ of Maryland, Baltimore, MD.*

**Background:** Short sleep duration (SSD) is a predictor of cardiovascular disease and mortality, and, in one study of younger individuals with normal eGFR, self-reported SSD was associated with dipstick proteinuria. The association between sleep duration and albuminuria has not been evaluated in older individuals with advanced CKD.

**Methods:** AWARD is a randomized controlled trial evaluating the effects of exercise vs. health education in individuals 60 years and older with an eGFR of 15 to 45 ml/min/1.73m$^2$. Participants' total sleep time (TST) at baseline was quantified by actigraphy worn for 5 consecutive nights and by self report using the Pittsburgh Sleep Quality Index. Urine albumin creatinine ratio (ACR) was assessed at baseline.

**Results:** Of 28 participants who have completed baseline testing by May 15, 2013, 27 have complete sleep data and were included. Mean age is 69 ± 7 years, 15% are women, 67% diabetic and 56% on ACEi or ARB therapy; mean eGFR is 37 ± 11 ml/min/1.73m$^2$ and median [interquartile range] ACR is 49 [17 – 878] mg/g. Mean actigraphy TST was 6.6 ± 1.6 hours with 41% sleeping <6 hours. Participants with TST <6 hours on actigraphy had a median ACR of 1152 [66–2580] mg/g while those with a TST ≥6 hours had a median ACR of 31 [9–63] mg/g (p=0.02).



Greater TST on actigraphy was correlated with lower Ln-transformed ACR in univariate (β = -0.443, p=0.02) and multivariable analyses controlling for age, BMI, eGFR, diabetes and ACE/ARB use (β= -0.463, p=0.007). Self reported TST was not associated with ACR (β= -0.08, p=0.70).

**Conclusions:** Among older adults with CKD Stage 3b-4, objectively measured sleep duration is associated with higher ACR. The elevated ACR in SSD may suggest increased inflammation or vascular risk factor burden due to SSD.

*Funding:* NIDDK Support, Veterans Affairs Support

## TH-PO688

**Chronic Pain in Hemodialysis Patients** Sharmeela Saha, Robert E. Olivo, Robin L. Hensley, Julia Lewis. *Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.*

**Background:** We conducted a retrospective analysis of narcotic prescription practices in our outpatient hemodialysis (HD) units. The purpose was to examine management of chronic pain and to develop strategies to improve patient safety.

**Methods:** We studied HD outpatients in 2 units from January 1, 2012 until January 1, 2013. We collected information regarding patient demographics, narcotic prescriptions and prescribers, and documentation of analgesic indication by examining the Tennessee Monitoring Database and Vanderbilt medical records.

**Results:** 52 of 191 (27%) HD patients were supplied with narcotics for at least a continuous 90 day period. Almost 40% of patients in the 40-49 and 50-59 age groups were treated for chronic pain. There was no predominance by gender but 32% of African Americans and 19% of Caucasians received chronic narcotics. Pain medications were most common among patients on HD for over 5 years. Arthritis and diabetic neuropathy were the most prevalent comorbidities. Hydrocodone with acetaminophen was the most commonly prescribed medication. The most frequently recorded indication was peripheral polyneuropathy; however, 52% (27/52) of patients had no documented indication. 90% of patients on chronic pain meds did not have a narcotics contract. 21% of patients had their narcotics solely prescribed by their nephrologist.

**Conclusions:** There is suboptimal documentation of the indication for pain meds for our patients on chronic narcotics; specifically, for over 50% of identified patients we were unable to find a recorded reason for therapy. We propose that the narcotics prescriber indicate semiannually an assessment of the pain and maintain a narcotics contract with the patient. Moreover, the Tennessee Monitoring Database allows providers to determine what other narcotic prescriptions the patient holds and reviewing the database monthly may help control for polypharmacy as well as prevent patients from obtaining narcotics from multiple providers. We hope to improve patient safety by addressing pain management infrastructure including maintaining annual narcotic contracts, regular documentation of indication for prescription and selection of a primary provider who manages pain control.

## TH-PO689

**Renal Function Decline in Community-Dwelling Older Adults** Jennifer Yi-Chun Lai,[1] Mindy Katz,[3] Peter X.K. Song,[2] Richard B. Lipton,[3] Markus Bitzer.[1] *[1]Medicine, Univ of Michigan, Ann Arbor, MI; [2]Biostatistics, Univ of Michigan, Ann Arbor, MI; [3]Neurology, Albert Einstein College of Medicine, Bronx, NY.*

**Background:** Decreased kidney function is associated with increased morbidity and mortality in older adults. The rate of renal function decline varies, but risk factors for accelrated decline are not well-defined in older adults. Therefore, we examined rate of renal function decline and associated clinical factors in community dwelling older adults enrolled in Einstein Aging Study (EAS), a community-based longitudinal study of aging.

**Methods:** We identified 250 subjects (>68 years of age), who were followed up to 7 years since 2005 and had at least three serum creatinine measurements separated by at least 11 months. We calculated creatinine-based eGFR by different formulas (CG, MDRD, CKD-EPI, and Berlin initiative study1 (BIS1)). Rates of eGFR decline were determined by mixed effect modeling. Multivariate linear or logistic regression was used to identify factors associated with mixed effect eGFR decline rate.

**Results:** The mean age of the study subjects was 79 years (60% are female). Mean baseline eGFR was 55 to 74 min/ml/1.73m$^2$ based on different formulas. The mean mixed effect eGFR annual percentage change was between -3.0% to -1.3%. Cross-sectional analysis revealed that higher homocysteine were significantly associated with lower baseline eGFR (P<0.0001). Longitudinal analysis showed that in linear regression, baseline eGFR was the only factor associated with eGFR annual percentage change (β= 0.01-0.04, P<0.0001). In logistic regression, subjects with lower baseline eGFR were more likely to have progressive eGFR decline (OR~16-40, P ≤ 0.001 for CG, MDRD and BIS1; no significance was detected using CKD-EPI formula).

**Conclusions:** The average annual renal function decline in this older adult cohort is 1 to 3 % per year. Baseline eGFR is an independent risk factor for faster eGFR decline. Homocysteine levels are associated with cross-sectional eGFR, but not with eGFR decline. Neverthelss, additional markers are needed to identify subjects with similar eGFR at risk for future loss of renal function, in particular with CKD stage III.

*Funding:* NIDDK Support

## TH-PO690

**Assessment of Renal Function in Elderly with Chronic Kidney Disease Using CKD-EPI and MDRD Equations** Eleni Chelioti,[1] Dimitrios Athanasopoulos,[2] Evangelia Gkalitsiou,[1] Evdokia Efthimiou,[1] Maria Sotiraki,[1] Alexia Papalexandrou,[1] Maria Tsilivigou,[1] Gabriel Papadakis.[1] *[1]Dept of Nephrologr, General Hospital of Piraeus, Athens, Greece; [2]Health Centre of Dimitsana, General Hospital of Tripoli, Tripoli, Greece.*

**Background:** Kidney function loss in the elderly results from physiologic aging of the kidney and lifelong pathologic insults. To estimate glomerular filtration rate (eGFR), MDRD and CKD-EPI formulae are the most frequently use.

**Aim** of the study was to assess the renal function in elderly with chronic kidney disease using the MDRD and CKD-EPI equations.

**Methods:** A cross sectional study was carried out. The study included elderly patients that attended the outpatient nephrology clinic within one year. The patients divided in 2 groups: eGFR>60 and eGFR<60ml/min/1.73m$^2$. Estimated GFR was calculated using MDRD and CKD-EPI formulae on time 0 and 12months.

**Results:** 224 patients were studied (52%men, 42% diabetics, 83% hypertensive, mean age70±13years-old, mean SAP 133,6±15mmHg, mean DAP 73,4±12mmHg, mean serum creatinine 1,8±0,1mg/dl). There are not statistically differences between mean CKD-EPI and MDRD GFR on time 0(43±20 and 42±22 respectively) and 12 months (43±20 and 43±19 respectively) in patients with eGFR>60ml/min/1.73m2. Not statistically differences found between mean CKD-EPI and MDRD on time 0 (30±18 and 31±17 respectively) and 12 months (32±18 and 32±18 respectively)in patients with eGFR<60ml.min/1.73m2.

However, we found that there is a statistically significant correlation between eGFR >60 or eGFR<60 and sex (p=0,001) in both time 0 and 12. Also, the correlation between reduced eGFR and hypertension was statistically significant (p=0,01)in both groups and independent by the using of MDRD or CKD-EPI equations.

**Conclusions:** Our results suggest that at ages>70 years there is not difference between the equations for the assessment of renal function.

## TH-PO691

**Prevalence of Stage 3-5 Chronic Kidney Disease and Anaemia in Elderly and Very Elderly** Eleni Chelioti,[1] Dimitrios Athanasopoulos,[2] Evdokia Efthimiou,[1] Maria Sotiraki,[1] Alexia Papalexandrou,[1] Evangelia Gkalitsiou,[1] Maria Tsilivigou.[1] *[1]Dept of Nephrologr, General Hospital of Piraeus, Athens, Greece; [2]Health Centre of Dimitsana, General Hospital of Tripoli, Tripoli, Greece.*

**Background:** Chronic kidney disease (CKD) is a growing problem due to our aging population, many of who have increased comorbidities.Cross-sectional studies in the general population demonstrate that CKD is seen in up to 15,3% including 39% of those over the age of 65 years.

**Aim** of the study was to examine the prevalence of stage 3-5 CKD in elderly and very elderly at an outpatient nephrology clinic and its association with anemia.

**Methods:** The cohort was defined as all patients that attended the outpatient nephrology clinic within the 2012.The patients divided in 3 age groups (AG):65-75AG1,75-80AG2 and AG3>80 years old.Estimated glomerular filtration rate (eGFR) was calculated using MDRD and CKD-EPI formulae.

**Results:** A total of 231 patients were studied (52%men,mean age76±6years,mean eGFR 31±18ml/min/1.73m$^2$,meanHb 11,98±1,7g/dl).According to the 3 age groups the percentage of patients was:50%AG1,27%AG2 and 23%AG3.There are not statistically difference between mean CKD-EPI and MDRD GFR.The percentage of stage 3,4 and 5 CDK was higher at AG1,AG3 and AG1 respectively.

| Age groups (y) | CKD-EPI GFR ml/min/1.73m2 mean (SD) | MDRD GFR ml/min/1.73m2 mean (SD) | p | Hb(g/dl) mean (SD) | Stage 3 % | Stage 4 % | Stage 5 % |
|---|---|---|---|---|---|---|---|
| 65-75 | 33,5(20) | 33,7(20) | NS | 12,1(1,9) | 43,8 | 23,2 | 23,2 |
| 75-80 | 30,5(17,6) | 30,3(17,5) | NS | 11,9(1,8) | 33,9 | 39 | 18,6 |
| ≥80 | 28,3(12,3) | 30(12,3) | NS | 11,8(1,4) | 29,4 | 52,9 | 15,7 |

The percentage of all patients who had Hb<11,5g/dl or<10g/dl was 41,5% and 10,3% respectively.Correlation between decline of eGFR and Hb was statistically significant (p<0,0001) in all age groups and not statistically significant with the age(p=0,7).

**Conclusions:** Our results suggest that the prevalence of stage 3 CKD is higher in the elderly but the prevalence of CKD stage 4 is highest in very elderly and lower in stage 5.Also the anemia in the elderly and very elderly seems to be in association with the decline of GFR and not with the aging.

## TH-PO692

**Hospitalized Elderly with Acute Kidney Injury Are at Greater Risk of Death and Progressive Chronic Kidney Disease** Jia Liang Kwek, Hui Zhuan Tan, Cynthia Ciwei Lim, Manish Kaushik. *Dept of Renal Medicine, Singapore General Hospital, Singapore, Singapore.*

**Background:** To determine the patient and renal outcomes in elderly patients with AKI as defined by Acute Kidney Injury Network (AKIN) criteria.

**Methods:** A single-center retrospective cohort study on elderly ≥ 65 years old admitted during first week of January 2011. Demographic data, co-morbidities and laboratory findings were retrieved from the electronic medical records. Patients with <2 serum creatinine values were excluded. AKI was present if serum creatinine increased ≥ 26.4 µmol/L within a 48h during hospitalization. The primary outcome was kidney function measured by MDRD estimated glomerular filtration rate (eGFR) at latest visit. The secondary outcomes were in-hospital mortality and incident end-stage renal disease (ESRD) requiring dialysis. Patients were followed up until 31st December 2012.

**Results:** Of 709 elderly admitted, 324 (median age 77, male 48.6%, diabetes mellitus 46%, hypertension 78.7%, ischemic heart disease 38.3%) were studied. Baseline serum creatinine was available in 264 patients (81.5%). Median baseline eGFR was 71.3 ml/min/1.73m$^2$ (range 2.7-228.7) and median eGFR on admission was 58.6 ml/min/1.73m$^2$ (range 1.5-292.6). 46 patients (14.6%) had AKI at median 2 days (range 1-33) during hospitalization. 3 patients (0.9%) required dialysis. Comparing AKI group (n=46) with non-AKI group (n=278), the only significant risk factor for AKI found in this study was hypotension (34.8% vs 13.7%, p=0.001). Median follow-up period was 14.5 months (range 0-24). 52.2% of AKI group had eGFR < 30 ml/min/1.73m$^2$, compared to 20.5% of non-AKI group (p <0.001). Significantly, 34.8% of AKI group had decreased eGFR from baseline by ≥ 50%, as compared to 11.9% of non-AKI group (p<0.001). In-hospital mortality was increased for AKI group (21.7% vs 3.6%, p < 0.001). However, there was no difference in incident ESRD requiring dialysis (4.3% vs 1.1%, p=0.149).

**Conclusions:** This study confirmed that even mild AKI is associated with significant risk of deterioration in renal function and death. Future interventional study can target preventive measures and timely treatment of hospitalization AKI to lower the risk of adverse outcomes.

## TH-PO693

**Triamterene-Hydrochlorothiazide Is Associated with Chronic Kidney Disease in Hypertensive Elderly Patients** Manish K. Saha, Ann L. Rinehart. *Nephrology, HealthPartners, St. Paul, MN.*

**Background:** Triamterene-HCTZ (TR-HCTZ) is a commonly prescribed antihypertensive medication combination. TR can cause abnormal urinary sediment, nephrolithiasis, and acute renal failure but has not been implicated in causing chronic kidney disease (CKD).

**Methods:** A case series of 95 patients referred for CKD to a single nephrologist at a tertiary center in St. Paul, MN from Jan 1995 to June 2010. All received TR-HCTZ for hypertension (HTN). Data was collected for: serum creatinine (CR) prior to TR-HCTZ exposure, at drug cessation, and at 1-3 and 6-12 month follow up; age, BMI, gender, and race; TR-HCTZ dosage and duration; patient reported NSAID use; UA and urinary microalbumin; ace inhibitor (ACE) or angiotensin receptor blockade (ARB) use; HgbA1c; mean outpatient blood pressure (BP) readings in prior year; BP uncontrolled if mean > 140/90; history and physical exam; IV contrast or other nephrotoxin exposures; and renal ultrasound.

**Results:** 42 patients had no alternative CKD diagnoses identified except for TR-HCTZ exposure (24% TR-HCTZ 37.5/25 mg vs 76% 75 mg/50 mg) with or without NSAID use. Mean age was 71.8 yrs (range 51-92) with 81% female, 17% diabetic without microalbuminuria, and 31% taking ACE/ARB, which was discontinued with TR-HCTZ and resumed after 6 months in all patients. Median TR-HCTZ exposure was approximately 10 years (range 2.3-20). 19 used NSAIDs > 2 times weekly; 1 patient with unavailable data. Mean (SD) eGFR (ml/min/1.73m$^2$)

| | n=17 | n=25 | NSAIDs: none or < 1x/wk (n=22) | NSAID > 2x/wk (n=19) |
|---|---|---|---|---|
| eGFR pre TR-HCTZ | 65.9 (19.7) | NA | NA | NA |
| eGFR at TR-HCTZ discontinuation | 33.5 (10.2) | 32.3 (9.8) | 32.7 (10.1) | 33.2 (9.9) |
| eGFR at 1-3 months post TR-HCTZ | 43.2 (12.3) | 40.8 (12.6) | 43.4 (13.5) | 40.5 (11.4) |
| eGFR at 6-12 months post TR-HCTZ | 46.1 (10.6) | 43.6 (15.0) | 46.6 (15.5) | 42.6 (10.1) |

**Conclusions:** Excluding other causes of CKD, TR-HCTZ is associated with CKD in primarily female elderly hypertensive patients with or without NSAID use. Its cessation resulted in partial improvement in renal function, even when ACE/ARB and HCTZ were resumed. TR should be avoided in elderly patients to reduce the risk of chronic kidney disease. Its role in hypertension management should be further studied and reassessed.

## TH-PO694

**Use of Beers Criteria Medications and Opioids among Very Elderly Hemodialysis Patients** Eric D. Weinhandl,[1] Wendy L. St. Peter,[1,2] Anne M. Murray.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Univ of Minnesota, Minneapolis, MN.*

**Background:** The very elderly constitute the most rapidly growing segment of dialysis patients in the United States and cognitive impairment (CI) is highly prevalent among them. Beers Criteria (BC) include several medication classes that are recommended to be avoided in older adults with CI. Opioids are commonly prescribed to dialysis patients and may further worsen cognitive function. We used Medicare Part D data to assess use of both potentially inappropriate medications in CI and opioids in very elderly hemodialysis patients in 2011.

**Methods:** Included patients carried Medicare coverage during all of 2010; initiated dialysis no later than September 30, 2010; received hemodialysis from October 1 to December 31, 2010; were age ≥80 years on January 1, 2011; and carried Part D coverage from January 1, 2011, to the earliest of death or December 31, 2011. We categorized patients as unsubsidized (UN); subsidized and not institutionalized (SUB); or subsidized and institutionalized (SUB+IN).

**Results:** We identified 8,459 UN; 7,196 SUB; and 3,052 SUB+IN patients. Regarding BC, 44.7% of patients used ≥1 medication that is recommended to be avoided in older adults with CI, including agents with anticholinergic effects (27.8%), H-2 receptor antagonists (12.1%), zolpidem (11.1%), and antipsychotics (7.0%). Factors associated with use of ≥1 BC medication were age ≥90 vs. 80-84 years (adjusted odds ratio, 0.75), white vs. black race (1.33), female vs. male sex (1.33), diagnosed dementia (1.28), SUB vs. UN status (1.54), and SUB+IN vs. SUB status (1.48). Regarding opioids, 51.0% of all patients used ≥1 medication; estimates of opioid use in patients with and without diagnosed dementia were 50.9% and 51.1%, respectively. Opioid use was associated with diagnosed dementia (0.88), SUB vs. UN status (1.27), and SUB+IN vs. SUB status (1.30).

**Conclusions:** Use of potentially inappropriate medications in cognitive impairment was common among very elderly hemodialysis patients and almost 30% more likely among patients with diagnosed dementia. Use of opioids was also common. Studies are needed to determine whether these medications are prescribed appropriately.

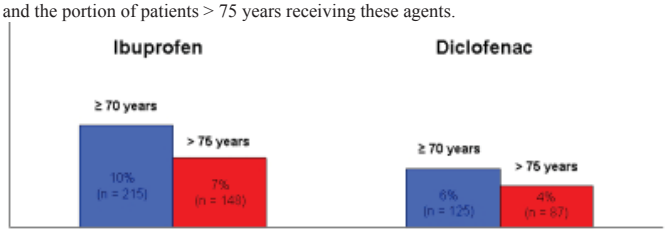
## TH-PO695

**Non Steroidal Anti-Inflammatory Drugs and Kidney Function in the Elderly** Antonios Douros,[1] Natalie Ebert,[2] Olga Jakob,[3] Reinhold Kreutz,[1] Elke Schaeffner.[2] *[1]Clinical Pharmacology, Charite, Berlin, Germany; [2]Nephrology, Charite, Berlin, Germany; [3]Clinical Epidemiology, Charite, Berlin, Germany.*

**Background:** There are several limitations regarding the use of non steroidal anti-inflammatory drugs (NSAIDs) in the elderly among which impaired kidney function (KF) represents an important clinical problem. The present study investigates the relationship between intake of NSAIDs and KF in people ≥ 70 years.

**Methods:** Individuals included in this analysis were participants of the Berlin Initiative Study (BIS). BIS is a population-based cohort study initiated in 2009 in Berlin, Germany, in order to evaluate KF in individuals ≥ 70 years. Medication was assessed through personal interviews and coded using the Anatomical Therapeutic Chemical Classification System. For estimation of glomerular filtration rate (eGFR) we used the CKD-EPI equation.

**Results:** From overall 2070 individuals 440 subjects (21%) received NSAIDs, either regularly or on demand. Mean age of the NSAIDs population was 79.8±6.4 years (females 62%). Figure 1 illustrates the frequency of use for the two most commonly taken NSAIDs, and the portion of patients > 75 years receiving these agents.



In comparison to the overall cohort analysis of the subpopulation with eGFR < 30 ml/min/1.73m$^2$ revealed no considerable difference concerning NSAIDs use, i.e. 20% of subjects.

**Conclusions:** As acute or chronic pain conditions are frequent in advanced age, use of NSAIDs in the elderly is a common topic of debate. Our data show that about 20% of this population take NSAIDs. Most of these patients were > 75 years, despite the recent classification of nearly all NSAIDs as potentially inappropriate medication for this age group by the American Geriatric Society. Presence of severe renal impairment did not seem to affect the prescription behavior of physicians regarding NSAIDs, although this represents a formal contraindication.

**TH-PO696**

**Antiviral Dose and Hospitalization with Urgent Computed Tomography Scan and Mortality in Older Patients with and without Chronic Kidney Disease – A Population-Based Study** Ngan Lam,[1,2] Jamie L. Fleet,[1] Eric McArthur,[2,3] Stephanie Dixon,[2,3] Amit X. Garg.[1-3] *[1]Nephrology, Western Univ, London, Canada; [2]Epidemiology and Biostatistics, Western Univ, London, Canada; [3]Institute for Clinical Evaluative Sciences, Toronto, Canada.*

**Background:** Higher versus lower doses of antiviral drugs used to treat herpes zoster infection may lead to more adverse events in older adults, particularly those with chronic kidney disease (CKD) where drug elimination is reduced.

**Methods:** We conducted a matched retrospective population-based cohort study of older adults (mean 77 years) in Ontario, Canada who were initiated on a higher (n = 23,256) versus lower (n = 3876) dose of one of three study oral antivirals (acyclovir, valacyclovir, or famciclovir) for the treatment of herpes zoster infection. Patients were enrolled between 2002 and 2011. The primary outcome was 30-day hospitalization with evidence of an urgent head computed tomography (CT) scan (a proposed proxy for acute delirium). The secondary outcome was 30-day all-cause mortality. We stratified our results based on the presence or absence of CKD.

**Results:** A higher dose of antiviral drug was not associated with a higher risk of hospitalization with CT head scan (247 [1.06%] events with higher dose versus 43 [1.11%] events with lower dose, relative risk 0.96, 95% confidence interval 0.69 to 1.33, p-value 0.79). There was also no significant difference in mortality between the two dose groups. Results were consistent in all subgroups, including those with and without CKD (p-value for interaction 0.25).

**Conclusions:** In this study, a higher vs. lower dose of antiviral drug for the treatment of herpes zoster was not associated with a higher risk of hospitalization with CT head or mortality in older patients with and without CKD.

**TH-PO697**

**Serum Anion Gap Is Predictive of Mortality in an Elderly Population** Shin-Young Ahn, Seon Ha Baek, Jiwon Ryu, Ho Jun Chin, Ki Young Na, Dong Wan Chae, Sejoong Kim. *Internal Medicine, Seoul National Univ Bundang Hospital, Seongnam-si, Gyeonggi-do, Republic of Korea.*

**Background:** An elevated serum anion gap is known to be associated with hypertension, low cardiorespiratory fitness, and decreased renal function. We evaluated whether serum AG might be predictive of elderly mortality in a community-based cohort in Korea.

**Methods:** We analyzed the available data from 862 elderly people in the Korean Longitudinal Study on Health and Aging. In the baseline study of the KLoSHA, the participants were required to visit Seoul National University Bundang Hospital on two occasions for comprehensive interviews and laboratory tests.

**Results:** Over a 5-year observational period, 151/862 (17.5%) participants died, and a high albumin-adjusted anion gap (SAAG) was associated with an increased risk of all-cause mortality in unadjusted analyses (hazard ratio [HR], 1.96; 95% confidence interval [CI], 1.41 - 2.71) and fully adjusted analyses (HR, 1.77; 95% CI, 1.24 - 2.52), compared with a low SAAG group. In particular, the participants with high SAAG had higher cardiovascular and infection-related mortality rates than those with low SAAG (HR, 2.11; 95% CI, 1.06 - 4.19, and HR, 9.69; 95% CI, 1.12 – 83.4, respectively).

**Conclusions:** High SAAG may be an independent predictor of mortality and can affect cardiovascular- and infection-related mortality in the elderly Korean population.

*Funding:* Government Support - Non-U.S.

**TH-PO698**

**Polypharmacy Is a Risk Factor for Acute Renal Failure in the Elderly Population** Osman Z. Sahin,[1] Fatih Sumer,[2] Teslime Ayaz,[2] Kadir Ilkk?l?c.[2] *[1]Nephrology, Recep Tayyip Erdogan Univ Faculty of Medicine, Turkey; [2]Internal Medicine, Recep Tayyip Erdogan Univ Faculty of Medicine, Turkey.*

**Background:** Because of the rapid growth in elderly population, polypharmacy has become a serious public health issue worldwide. Particularly, angiotensin coverting enzyme (ACE) inhibitors and angiotensin receptor blockers (ARB) are increasingly used in the elderly for heart failure and hypertension. Acute renal failure (ARF) is one negative consequence of polypharmacy. We therefore aimed to assess the impact of polypharmacy, especially usage of ACE inhibitors and/or ARBs on the development of ARF in elderly poupulation.

**Methods:** 42 consecutive patients who were older than 65 years and admitted to our emergency unit or Nephrology outpatient clinic between January 2010 and June 2012 for ARF included in this study. Polypharmacy was defined as more than 5 prescriptions per day. All the patients were using an ACE inhibitor or ARB for at least 3 months. We recorded all the other medications especially diuretics and nonsteroidal anti-inflammatories (NSAIDs). We especially noted the change in medication for 10 days prior to admission. ARF was defined as a sudden increase in serum creatinine from normal to more to 2 mg/dl or an increase 50% above the baseline within 3 months.

**Results:** The study population consisted of 44 patients, aged 65-86 years (mean: 74.27 ± 6.6) and 54.5% of them were male. 61.4% of them had hypertension, 22.7% had diabetes, 11.4% had congestive heart failure and 22.7% had chronic renal failure. 83.3% of the patients were receiving ACE-I or ARB and 52.4% of them were usingNSAIDs. Mean number of prescriptions per day was 6.1. Basal urea and creatinine levels of the patients were 4.71±2.67 mg/dl and 49.2±57.76 mg/dl respectively. Potassium levels were ≥6 mEq/lt in 22.5% of the patients. ACE-I or ARB and NSAIDs were stopped. 15.9 % the patients were undergone on hemodialysis. % 40.9 patients had recovered and serum creatinine level came back to normal.

**Conclusions:** We observed an association between the polypharmacy, usage of ACEI or ARBs and the occurrence of ARF in elderly population.

**TH-PO699**

**Initiatives by the Geriatric Nephrology Advisory Group (GNAG) of the American Society of Nephrology (ASN)** Markus Bitzer,[1] Mark E. Williams.[2] *[1]Internal Medicine, Univ of Michigan, Ann Arbor, MI; [2]Joslin Diabetes Center, Harvard Medical School, Boston, MA.*

**Background:** There is growing interest in the care of older adults with kidney disease among Nephrologists and the increasing use of dialysis and kidney transplantation in older adults has attracted the attention of geriatrics and palliative care.

**Methods:** We describe resources and initiatives of the ASN's Geriatric Nephrology Advisory Group (GNAG) to improve care for older adults with CKD.

**Results:** To improve the quality of dialysis rounds of geriatric patients GNAG, in partnership with the Association of Specialty Professors (ASP) and under the direction of Mark Williams, created a video series that discusses critical aspects of care for elderly patients, including patient assessment, dialysis care, recognition of physical and mental decline, quality of life issues, and sharing decision-making information, which is freely available at www.asnrounds.org and has already over 5,000 views. To enhance education of Nephrology fellows in Geriatric Nephrology, GNAG developed and updates an on-line Geriatric Nephrology curriculum with teaching tools in the diagnosis and management of various geriatric entities (with ASP support). For an in-depth discussion of specific aspects of Geriatric Nephrology, the GNAG with support of the ASN Post-Graduate Education Committee has organized the Dimitrios G. Oreopoulos Memorial Program in Geriatric Nephrology, a two-day course on Geriatric Nephrology included in the annual meeting of the ASN since 2008. The 2013 course is entitled "Patient-Centered Care for Older Adults with Kidney Disease". To provide guidance in the care of older adults with kidney disease and to promote scientific collaborations to advance research in Geriatric Nephrology GNAG established the Dimitrios G. Oreopoulos Visiting Professor Program, which supports visits from experts in Geriatric Nephrology to Nephrology fellowship training programs, with ASP support. A Career Development Grant in Geriatric Nephrology is supported by the ASN Foundation for Kidney Research.

**Conclusions:** The GNAG has implemented a variety of initiatives by which health care providers can improve care of older adults with kidney disease.

**TH-PO700**

**Elevated Prorenin Induces Dose-Dependent Podocyte Injury in cyp1a1-Prorenin Transgenic Rats** Chunyan Gu, Alfred K. Cheung, Yufeng Huang. *Div of Nephrology & Hypertension, Dept of Internal Medicine, Univ of Utah School of Medicine, Salt Lake City, UT.*

**Background:** Plasma prorenin levels are commonly elevated in diabetic patients and appear to predict the development of albuminuria and progression of DN. Albuminuria is often the result of podocyte injury. However, the potential pathogenic role of prorenin in podocyte injury is unclear. In this study, we examined the associations of plasma prorenin levels in transgenic animals in which prorenin is produced in the liver with damages to podocytes.

**Methods:** Cyp1a1 prorenin transgenic rats at 12 wks of age were fed with normal diet containing incremental amounts of indole-3-carbinol (I3C) at 0.05% (n=6), 0.15% (n=6) or 0.3% (n=4) respectively. Wild-type rats with normal diet (n=6) served as healthy controls.

**Results:** Transgene induction by I3C for 4 wks increased plasma prorenin levels in the transgenic rats by 7-, 18-, and 24-fold respectively. However, plasma renin levels are not increased. The induction of prorenin expression by I3C resulted in a dose-dependent decrease in expression of nephrin and podocin, and WT-1-positive podocytes in the kidney as determined by immunofluorescent staining, associated with segmental podocyte foot process effacement and podocyte body hypertrophy assessed by transmission electron microscope. These data strongly suggest that prorenin induces podocyte injury. There were also significant increases in the mean arterial pressure and urine albumin/creatinine ratio in the prorenin transgenic rats treated with I3C, although the dose-dependency of these phenomena was less apparent.

**Conclusions:** These findings suggest a novel link between elevated plasma prorenin levels and structural changes in diabetic kidney. Of note, treatment of transgenic rats with either amlodipine (10mg/kg/d by gavage)or enalapril (200mg/L in drinking water) for 6wks prevented the development of hypertension and ameliorated, but did not prevent, the development of podocyte injury and albuminuria. Our findings further indicate that hypertension in this model is Ang II-dependent. However, the prorenin-induced podocyte injury is only partially dependent on hypertension and Ang II, suggesting additional Ang II-independent effects.

### Critical Role of Proximal Promoter Elements and Their Interacting Factors in the Transcription of Angiotensin II Binding and Inhibitory Protein in Renal Tubule Cells

Kouichi Tamura. *Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Japan.*

**Background:** The Angiotensin II (Ang II) type 1 receptor (AT1R)-associated protein (ATRAP/Agtrap) promotes constitutive internalization of the AT1R so as to specifically inhibit the pathological activation of its downstream signaling but yet preserve the baseline physiological signaling activity of the AT1R. Thus, tissue-specific regulation of *Agtrap* gene expression is relevant to the pathophysiology of cardiovascular and renal disease. However, the regulatory mechanism of *Agtrap* gene expression has not been fully elucidated yet.

**Methods:** In the present study, we examined whether the proximal promoter of the mouse *Agtrap* gene, which contains the X-box, E-box and GC-box consensus motifs, is able to elicit substantial transcription of the *Agtrap* gene. We focused our analysis on a functional role of the E-box and characterization of its putative binding transcription factors *in vitro* and *in vivo*. We also examined a possible role of the E-box of the human *AGTRAP* proximal promoter in the transcriptional regulation.

**Results:** We showed that the E-box-Usf1/Usf2 binding regulates *Agtrap* gene expression, because: (1) mutation of the E-box so as to prevent Usf1/Usf2 binding reduces *Agtrap* promoter activity; (2) knockdown of Usf1 or Usf2 affects both endogenous Agtrap mRNA and Agtrap protein expression and (3) the decrease in Agtrap mRNA expression in the afflicted kidney by unilateral ureteral obstruction (UUO) is accompanied by changes in Usf1 and Usf2 mRNA. Furthermore, the results of siRNA transfection in mouse distal convoluted tubule cells and those of UUO in the afflicted mouse kidney suggest that Usf1 decreases but Usf2 increases the *Agtrap* gene expression by binding to the E-box. The results also showed a functional E-box-USF1/USF2 interaction in the human *AGTRAP* promoter.

**Conclusions:** Collectively, these results demonstrated that an interplay between E-box and Usf1/Usf2 is important for *Agtrap* gene regulation. A strategy of modulating the E-box-Usf1/Usf2 interaction may have novel therapeutic potential.

*Funding:* Government Support - Non-U.S.

## TH-PO702

### T Type Ca-Channel Blocker Exerts Anti-Albuminuic Effect through Amelioration of eNOS Uncoupling in Hypertensive Kidney Disease Model

Seiji Itano, Kengo Kidokoro, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

**Background:** Tetrahydorbiopterin (BH4), an essential cofactor for endothelial Nitric oxide (NO) synthase (eNOS), is easily oxidized by oxidative stress. In such condition, eNOS generates superoxide rather than NO (eNOS-uncoupling), thus further aggravates oxidative stress. Certain class of calcium channel blocker (CCB) has shown to improve endothelial dysfunction by 'recoupling' eNOS. We investigated the molecular mechanisms underlying recoupling of eNOS and reno-protective effects by two different classes of CCBs, Benidipine(T/L type) and Amlodipine(L type).

**Methods:** We used 6 week-old male Dahl salt sensitive (Dahl) rats and treated them with either Benidipine (BN:3mg/kg/day) or Amlodipine (AM:3mg/mg/day) for 4 weeks. Urinary albumin excretion, glomerular BH4 level, expression of GTP cyclohydrolase 1 (GTPCH I), a rate-limiting enzyme of BH4 synthesis, were evaluated in the kidney tissues. Production of NO and reactive oxygen species (ROS) in the kidney tissues were imaged by confocal laser microscopy after renal perfusion with two types of fluorescent dyes, DCFH-DA and DAR-4M AM, ROS and NO indicators respectively.

**Results:** With elevation of blood pressure, increased UAE were observed in Dahl group. Furthermore, glomerular BH4 level and GTPCH I expression were decreased in the kidney tissues of Dahl group. Exacerbated ROS production and diminished bioavailable NO were noted in the glomeruli of Dahl group. Western analysis revealed eNOS uncoupling in Dahl kidney. No significant difference in blood pressure was observed between BN group and AM group. However, all the above mentioned changes were ameliorated to a greater degree in BN group. The expression of ICAM-1, VCAM-1 mRNA and the number of infiltrated ED-1 positive cells in glomerulus were also significantly suppressed in BN group. AMP-activated protein kinase activity which attenuates GTPCH I degradation was significantly higher in BN group compared with AM group.

**Conclusions:** T/L type CCB, Benidipine attenuates hypertensive kidney injuries via improvement of eNOS uncoupling by maintenance of BH4 and GTPCH I level.

## TH-PO703

### Valsartan Improves Myocardial Cellular Viability in Renovascular Hypertension

Xin Zhang,[1] Zi-Lun Li,[1] John A. Crane,[1] Stephen C. Textor,[1] Amir Lerman,[2] Lilach O. Lerman.[1,2] *[1]Nephrology and Hypertension, Mayo Clinic; [2]Cardiovascular Diseases, Mayo Clinic.*

**Background:** Renal artery stenosis (RAS) leads to renovascular hypertension and alterations in cardiac structure and function. The Angiotensin II receptor blocker Valsartan (VAL) lowers blood pressure and is cardioprotective, although the exact mechanisms remain unclear. We hypothesized that processes of cellular self-digestion (autophagy) and mitochondrial digestion (mitophagy) develop in the myocardium in response to renovascular hypertensive stress. We tested the hypothesis that Val would alleviate autophagy and improve left ventricular (LV) myocardial cellular viability in swine RAS.

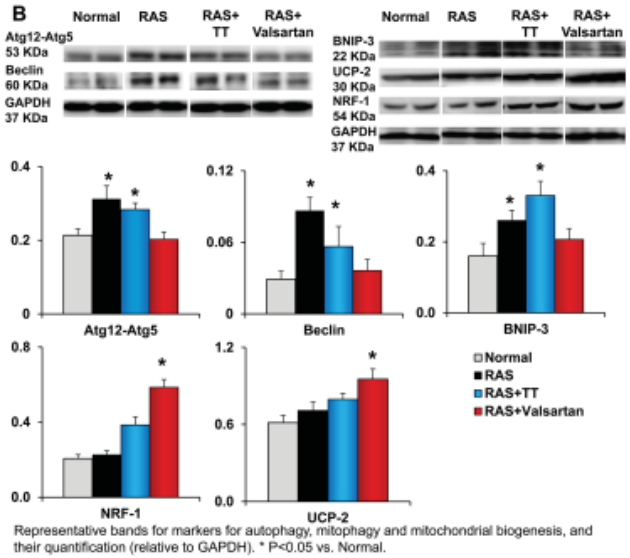
**Methods:** Domestic pigs were randomized to control, unilateral RAS, and RAS treated with Val (320 mg/day; RAS+Valsartan) or conventional triple therapy (Reserpine+hydralazine+hydrochlorothiazide, RAS+TT) for 4 wks post 6-wks of RAS (n=7 each). Kidney and LV function were assessed by CT, myocardial cellular autophagy by expression of Atg12-Atg5 and Beclin-1, signaling for mitophagy by BNIP-3, and mitochondrial biogenesis by NRF-1 and UCP-2.

**Results:** Valsartan and TT similarly decreased blood pressure, but did not alter renal function. RAS induced LV hypertrophy (LVH), accompanied by increased markers of myocardial autophagy and mitophagy. Val alleviated LVH, lowered myocardial autophagy, normalized mitophagy, and increased mitochondrial biogenesis. In contrast, TT did not improve LVH, or affected the cellular and mitochondrial viabilities.

A

| | Normal | RAS | RAS+TT | RAS+Valsartan |
|---|---|---|---|---|
| Mean arterial pressure (mmHg) | 107±5 | 163±12* | 127±9.0*$ | 130±5*$ |
| Stenotic kidney GFR (ml/min) | 82±7 | 66±9* | 57±6* | 62±5* |
| LV muscle mass (g/kg ) | 80±6 | 115±13* | 102±38* | 91±16*$ |
| LV-EDV ($mm^3$) | 70±5 | 62±7 | 74±3 | 73±7 |
| Ejection fraction (%) | 62±5 | 67±9 | 63±4 | 59±5 |

GFR: glomerular filtration rate. LV: left ventricle. EDV: end diastolic volume.
*P<0.05 vs. Normal; $: p<0.05 vs. RAS.



Representative bands for markers for autophagy, mitophagy and mitochondrial biogenesis, and their quantification (relative to GAPDH). * P<0.05 vs. Normal.

**Conclusions:** Val-induced improvement in cardiac structure in renovascular hypertension was associated with improvement in myocardial cellular viability. Valsartan may promote cardiac repair in RAS by directly improving cell survival by mechanisms independent of blood pressure control.

## TH-PO704

### Renal Dopamine-Induced Diuresis and Natriuresis Is Mediated by CYP Epoxygenase 2c44

Ming-Zhi Zhang, Bing Yao, Yinqiu Wang, Kimberly Fisher, Jorge H. Capdevila, Raymond C. Harris. *Medicine, Vanderbilt Univ School of Medicine, Nashville, TN.*

**Background:** We have recently demonstrated that intrarenal dopamine plays an important role in preventing the development of systemic hypertension. Similarly, renal cytochrome P450 (CYP)-epoxygenase-derived arachidonic acid metabolites, epoxyeicosatrienoic acids (EETs) are also anti-hypertensive. The current studies investigated potential interactions between renal dopamine and epoxygenase systems.

**Methods:** COMT-/- mice with increased intrarenal dopamine levels and ptAADC-/- with renal dopamine deficiency were treated with low-salt diet or high-salt diet for 2 weeks. Wild type or Cyp2c44-/- mice were treated with gludopa, which selectively increased renal dopamine levels.

**Results:** In low-salt treated mice, renal EET levels correlated with renal dopamine levels, being highest in COMT-/- mice and lowest in ptAADC-/- mice. In high-salt treated mice, total EET and individual EET levels in both kidney and urine were also highest in COMT-/- mice and lowest in ptAADC-/- mice. Selective increases in renal dopamine in response to gludopa administration led to marked increases in both total and all individual EET levels in the kidney without any changes in blood levels. qPCR and Western analysis indicated that gludopa increased renal Cyp2c44 mRNA and protein levels. Dopamine also increased Cyp2c44 mRNA levels dramatically in cultured mouse proximal epithelial cells. Gludopa induced marked increases in urine volume (ml/16-h: control: 0.95 ± 0.11; gludopa: 3.77 ± 0.23, $P < 0.001$, $n = 4$) and urinary sodium excretion (μM/16-h: control: 99.65 ± 9.93; gludopa: 302.08 ± 23.43, $P < 0.001$, $n = 4$) in wild type mice. In contrast, gludopa did not induce significant increases in urine volume (ml/16-h: control: 0.67 ± 0.11; gludopa: 0.90 ± 0.30, $P > 0.05$, $n = 4$) or urinary sodium excretion (μM/16-h: control: 116.04 ± 7.83; gludopa: 157.71 ± 21.72, $P > 0.05$, $n = 4$) in Cyp2c44-/- mice.

**Conclusions:** These studies demonstrate that renal EET levels are maintained by intrarenal dopamine, and Cyp2c44-derived EETs play an important role in intrarenal dopamine-induced natriuresis and diuresis.

**Sorting Nexin 1 Knockout Mice Manifest with Hypertension and Impaired Natriuretic Response** Van Anthony M. Villar, Laureano D. Asico, Jun B. Feranil, Ines Armando, John Edward Jones, Pedro A. Jose. *Univ of Maryland, School of Medicine, Baltimore, MD.*

**Background:** Dopamine is important for the regulation of blood pressure (BP), sodium balance, and renal function by engendering natriuresis via the inhibition of tubule NaCl reabsorption. The dopamine $D_5$ receptor ($D_5R$) interacts with sorting nexin 1 (SNX1), a protein involved in agonist-activated receptor trafficking.

**Methods:** We evaluated the effect of a congenital absence of Snx1 on the regulation of BP and sodium excretion in mice through an array of *in vitro* (confocal microscopy, RNAi, biochemical assays) and *in vivo* approaches.

**Results:** SNX1 depletion in human renal proximal tubule cells impaired receptor trafficking and $D_5R$-mediated Ga activation, cAMP response, and sodium transport, indicating that SNX1 loss results in impaired $D_5R$ function. To evaluate the *in vivo* correlates of these *in vitro* observations, we used an innovative approach to acutely silence the renal Snx1 via subcapsular infusion of Snx1-specific siRNA in mice, which resulted in 50% knockdown of expression. Renal depletion of Snx1 in salt-sensitive C57BL/6J and salt-resistant BALB/cJ mice resulted in high BP (ΔSBP of 13 and 25 mm Hg, and ΔDBP of 15 and 23 mm Hg from baseline, respectively; P<0.05, n=3-4/group), conceivably due to perturbed $D_5R$ function; $Drd5^{-/-}$ mice also develop hypertension. Moreover, salt-loaded Snx1-depleted BALB/cJ mice failed to excrete sodium (ΔUNaV of -13.8±13.4% and +40.5±24.1% from baseline in Snx1-depleted vs. control BALB/cJ mice, respectively; P<0.05, n=3-4/group) in response to $D_1R$ and $D_5R$ agonist treatment. We next extended our studies to $Snx1^{-/-}$ mice, which have a congenital absence of Snx1. We found that adult male $Snx1^{-/-}$ mice, compared to wild-type littermates, are hypertensive (131.3±6.3/107.3±5.4 mm Hg vs. 105.5±6.4/84.2±8.9 mm Hg, P<0.05, n=3/group) and have impaired natriuretic response (ΔUNaV of -17.011.5 ±13.4% and +201.5±40.1% from baseline, respectively; P<0.05, n=3/group), similar to the phenotypes observed in acutely (Snx1)-depleted mice.

**Conclusions:** These data demonstrate a novel and crucial role for SNX1 in direct $D_5R$ and indirect $D_1R$ regulation in the pathogenesis of essential hypertension.

## TH-PO706

**PACAP and Stress-Mediated Regulation of Renal Plasminogen Activator Inhibitor-1 Gene Expression *In Vivo*** Neill A. Gingles,[1,2] Marc A. Olivier,[1,2] Lindsey A. Miles,[3] Robert J. Parmer.[1,2] *[1]Univ of California; [2]VA San Diego Healthcare System; [3]The Scripps Research Institute, La Jolla, CA.*

**Background:** Sympathetic nervous system (SNS) hyperactivity contributes to renal disease progression; however, the specific factors mediating SNS-related renal injury have not been fully elucidated. Pituitary adenylate cyclase-activating polypeptide (PACAP), a member of the VIP/secretin/glucagon family, is a major effector of sympathoadrenal physiologic responses and is a potent transcriptional activator. Also, plasminogen activator inhibitor 1 (PAI-1), the major inhibitor of fibrinolysis, has been shown to be a key mediator of renal fibrosis in a variety of disorders, including hypertensive nephrosclerosis, diabetic nephropathy, experimental glomerulonephritis, and transplant rejection.

**Methods:** To explore potential links among SNS stress responses, the PACAP peptidergic system, and renal PAI-1 biosynthesis, we investigated PAI-1 expression in response to stress and to PACAP *in vivo*. PAI-1 expression was monitored by quantitative RT-PCR in kidneys from C57BL/6 mice that were either unstressed or subjected to sympathoadrenal activation by restraint stress for 2 hours.

**Results:** Renal PAI-1 mRNA expression was markedly increased in stressed mice (3.2±0.3 fold, n=5, compared to controls, P<0.001). PACAP1-38 agonist (0.006 to 0.6 mg/kg IP) resulted in a dose-dependent increase in renal PAI-1 mRNA (up to 6.5±0.8 fold induction versus 1.0±0.3, n=5, for vehicle treated mice, P<0.001). Renal PAI-1 protein expression also increased significantly (by 3.1±0.2 fold, P<0.001). Neither restraint stress nor PACAP1-38 affected renal expression of plasminogen activators, suggesting that local tPA/PAI-1 or uPA/PAI-1 biosynthetic balance is markedly altered by stress. The observed increases in PAI-1 mRNA during stress were substantially blunted (by 62±11%, P<0.05) by pretreatment with the specific PACAP receptor antagonist, PACAP6-38, compared to pretreatment with vehicle.

**Conclusions:** Renal PAI-1 expression is substantially increased by stress and by PACAP, suggesting key links among the SNS, the PACAP peptidergic signaling pathway, and renal PAI-1 biosynthesis, which may contribute to SNS-mediated renal injury.

## TH-PO707

**Compensatory Activation of the Sympathetic Nervous System after Deletion of Angiotensin Type 1 Receptors from Vascular Smooth Muscle Cells** Matthew A. Sparks, Johannes Stegbauer, Susan B. Gurley, Thomas M. Coffman. *Div of Nephrology, Duke Univ Medical Center, Durham, NC.*

**Background:** Vasoconstriction is a key physiological action of angiotensin II (Ang II). Precisely how $AT_1$ receptors ($AT_1R$) on VSMCs contribute to vasoconstriction *in vivo* has not been completely defined.

**Methods:** In order to define the role of direct actions of $AT_1R$ in VSMCs, we generated mice with deletion of $AT_{1A}R$ from VSMCs using a floxed *Agtr1a* allele and a mouse expressing *Cre* only in VSMCs.

**Results:** We compared vascular responses to acute infusions of Ang II in mice lacking $AT_{1A}R$ in VSMCs (SMKOs) and controls. Surprisingly, brisk vasoconstrictor responses to 1μg/kg Ang II were preserved in SMKOs with peak increases in MAP only modestly reduced to ~75% of control levels (15±2 vs. 23±1 mmHg P<0.05). Robust systemic vasoconstriction to Ang II was observed whether elimination of $AT_{1A}Rs$ was carried out *in utero* with a constitutively expressed SM-Cre or in adult mice with a tamoxifen-inducible SM-Cre. By contrast, Ang II-dependent vasoconstriction in the renal circulation was largely abrogated in SMKOs. Moreover, despite preserved systemic vascular responses to acute Ang II in SMKOs, baseline BPs was reduced and susceptibility to Ang II-dependent hypertension was significantly attenuated. To determine if the minor $AT_{1B}R$ isoform might be responsible for their residual vascular responses, we generated SMKOs on an $AT_{1B}$-null background (SMKO $1B^{-/-}$); the absence of $AT_{1B}Rs$ did not affect this response (SMKO $1B^{-/-}$ 16±2 vs. SMKO-$1B^{+/+}$ 15±2 mmHg; ns). As an alternative explanation, we tested for an involvement of the sympathetic nervous system (SNS) by infusing 400μg/kg of the α-blocker phentolamine (PT) 5 min before Ang II. While PT had no effect on Ang II-dependent vasoconstriction in controls (pre-PT: 23±1 vs. post-PT: 23±3 mm Hg), it almost completely abrogated vasoconstriction in SMKOs (pre-PT: 15±2 vs. post-PT: 3±1 mm Hg; P<0.005).

**Conclusions:** Thus, we find a significant capacity for the activation of the SNS to maintain acute Ang II-dependent vasoconstriction when $AT_1R$ signaling in VSMCs is absent. This pathway induces brisk vasoconstriction in the systemic but not the renal circulation.

**Renal Denervation Deriving Cardiorenal Protection beyond Blood Pressure Control via Sympathetic Regulation of Local Renin-Angiotensin System** Masahiro Eriguchi,[1] Kumiko Torisu,[1] Toshiaki Nakano,[1] Kosuke Masutani,[1] Kazuhiko Tsuruya,[2] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

**Background:** Recently catheter-based renal sympathetic denervation (DNx) is beginning to be applied for clinical aim. The sympathetic nerve system (SNS) and renin-angiotensin system (RAS) would be suggested as possible cardio-renal mediators. The mechanisms behind the beneficial effects of DNx for cardio-renal vicious cycle are not fully elucidated but may include disruption of local RAS in addition to the vicious cycle of SNS-RAS.

**Methods:** We tested the effects of renal denervation on cardiorenal injury induced by chronic administration of L-NAME (nitric oxide synthase inhibitor) in Wistar rats. The rats were divided into four groups (control, L-NAME, L-NAME with bilateral DNx and L-NAME with hydralazine group). Cardiorenal injury, SNS, circulating RAS and local RAS (heart and kidney angiotensin II (AII) and urinary angiotensinogen (AGT)) were evaluated. We also observed rats treated with L-NAME + unilateral DNx to confirm the sympathetic direct regulation of intrarenal RAS. Serial measurements of kidney AII and urinary AGT of both kidneys were performed to examine the laterality of local RAS in the body of the same individuals.

**Results:** Bilateral DNx ameliorated over-activity of SNS and circulating RAS accompanied with downregulation of heart and kidney local RAS, and prevented cardiorenal injury. Cardiorenal protective effects of bilateral DNx were greater than the hydralazine treatment that blood pressure (BP) was kept to the same level. In unilateral DNx model, kidney AII and urinary AGT from the denervated kidneys were smaller than the innervated kidneys under the same circulating conditions and renal injury of the denervated kidneys were alleviated compared to the innevated kidneys.

**Conclusions:** DNx derives the beneficial BP-independent effects associated with local RAS amelioration in cardiorenal syndrome.

## TH-PO709

**Fructose Stimulates Sodium/Hydrogen Exchanger 3 Activity via Protein Kinase C Activation in the Proximal Tubule** Pablo D. Cabral, Jeffrey L. Garvin. *Physiology and Biophysics, Case Western Reserve Univ, Cleveland, OH.*

**Background:** Consumption of high-fructose corn syrup as a sweetener has increased dramatically. Fructose has been implicated in the epidemic of diabetes, obesity and salt-sensitive hypertension. However, the mechanisms are poorly understood. The proximal nephron reabsorbs 60-70% of the fluid and Na, and most of the filtered bicarbonate via Na/H exchanger 3 (NHE3). It has been shown that protein kinase C (PKC) stimulates fluid and bicarbonate absorption in this segment. Enhanced proximal nephron transport has been implicated in several forms of hypertension. We hypothesized that fructose stimulates NHE3 activity in the proximal tubule via a PKC-dependent mechanism.

**Methods:** To test our hypothesis we isolated and perfused proximal tubules from Sprague Dawley rats. NHE3 activity was measured as the recovery of intracellular pH after an NH4Cl acid pulse using the pH sensitive dye BCECF. The rate of pH recovery was measured in Fluorescent Units per second (FU/sec).

**Results:** In the presence of a 5.5 mM glucose-containing physiological saline the basal rate of pH recovery was 3.1 ± 0.8 FU/sec. When the luminal solution was exchanged to a 0.6 mM glucose + 5 mM fructose-containing physiological saline in a second period, the rate of pH recovery increased to 5 ± 1 FU/sec ($p$<0.03, $n$=8).To study whether this effect was due to the addition of fructose or the subtraction of glucose to the lumen, we performed a separate set of experiments where 5 mM glucose was substituted for 5 mM fructose. In the presence of 0.6 mM glucose the basal rate of pH recovery was 3.6 ± 1.5 FU/sec. When 5 mM fructose was added the rate of pH recovery increased to 5.9 ± 2 FU/sec ($p$<0.02, $n$=5). Control experiments showed no differences between periods when 5 mm glucose was added back to the luminal perfusate. Finally, we tested the effect of the general PKC inhibitor staurosporine on the effect of fructose. In the presence of the general PKC inhibitor staurosporine $10^{-10}$ M Fructose did not stimulate NHE3 activity (from 6.0 ± 1.2 to 6.5 ± 1.7; $n$=6).

**Conclusions:** We conclude that acute treatment with fructose stimulates NHE3 activity in the proximal tubule via a PKC-dependent mechanism.

**CXCR6 Plays a Critical Role in Angiotensin II-Induced Renal Injury and Fibrosis** Yunfeng Xia, Yanlin Wang. *Dept of Medicine, Div of Nephrology, Baylor College of Medicine, Houston, TX.*

**Background:** Recent studies have shown that inflammation plays a critical role in the pathogenesis and progression of hypertensive kidney disease. However, the signaling mechanisms underlying the induction of inflammation are poorly understood. In this study, we examined the role of CXCR6 in Ang II-induced renal injury and fibrosis.

**Methods:** Wild-type (WT) and CXCR6-KO mice were treated with Ang II via subcutaneous osmotic minipumps at 1500 ng/kg/min for up to 4 weeks. To accelerate renal injury, all mice were subjected to unilateral nephrectomy and received 1% NaCl in drinking water.

**Results:** WT and CXCR6-KO mice had virtually identical blood pressure at baseline. Ang II treatment led to an increase in blood pressure that was similar between WT and CXCR6 knockout mice. CXCR6 knockout mice were protected from Ang II-induced renal dysfunction, proteinuria, and fibrosis. Deletion of CXCR6 suppressed bone marrow-derived fibroblast accumulation and myofibroblast formation in the kidneys of Ang II treated mice, which was associated with a reduction in extracellular matrix protein expression. Furthermore, deletion of CXCR6 inhibited infiltration of $F4/80^+$ macrophages and $CD3^+$ T cells in the kidney of Ang II treated mice compared with WT mice. Finally, deletion of CXCR6 reduced gene expression of proinflammatory cytokines in the kidney of Ang II treated mice.

**Conclusions:** Our results demonstrate that CXCR6 plays a pivotal role in the development of Ang II induced renal injury and fibrosis through regulation of macrophage and T cell infiltration and bone marrow-derived fibroblast accumulation. These findings suggest that inhibition of CXCR6 signaling could constitute a novel therapeutic target for hypertensive kidney disease.

## TH-PO711

**Suppression of Insulin Resistance by Renal Sympathetic Denervation in Obese Rats** Akira Nishiyama, Daisuke Nakano. *Dept of Pharmacology, Kagawa Univ Medical School, Kagawa, Japan.*

**Background:** Recent studies have shown that renal sympathetic denervation improves glucose metabolism and insulin sensitivity in patients with resistant hypertension. To elucidate its precise mechanism, studies were performed to examine the effect of renal sympathetic denervation on glucose metabolism and blood pressure in obese rats.

**Methods:** Uninephrectomized obese Otsuka Long Evans Tokushima Fatty (OLETF) underwent renal denervation (RDX) at 6 weeks of age (prediabetic stage).

**Results:** At 22 weeks of age, RDX resulted in undetectable kidney tissue norepinephrine (NE) levels and decreased plasma NE levels, but did not significantly change blood pressure (measure by telemetry system) in type 2 diabetic OLEFT rats. As compared to sham-operated OLETF rats, RDX OLETF rats showed lowered blood glucose and plasma insulin levels as well as decreased areas under the glucose response curvesafter oral glucose loading during the oral glucose tolerance test. Whole body insulin sensitivity was also assessed by the hyperinsulinemic-euglycemic clamp study at 20 week of age, and RDX OLETF rats showed an improved glucose infusion rate. Furthermore, RDX improved in vivo glucose uptake by adipose tissues, soleus muscle and liver. Interestingly, RDX also decreased proximal tubular SGLT2 expression and increased urinary glucose excretion rate in OLETF rats.

**Conclusions:** Renal sympathetic denervation at a prediabetic stage improves glucose metabolism and insulin sensitivity through suppression of glucose uptake and enhancement of urinary glucose excretion.

## TH-PO712

**The Transcription Factor ETS-1 Mediates Renal Injury in Salt Sensitive Hypertension** Wenguang Feng,[1] Phillip H. Chumley,[1] Huma Fatima,[2] Gabriel Rezonzew,[1] Ping Hua,[1] Edgar A. Jaimes.[1,3] *[1]Medicine/Nephrology; [2]Pathology, Univ of Alabama at Birmingham; [3]VA Medical Center.*

**Background:** ETS-1 regulates the expression of several growth factors and cytokines and mediates pro-fibrotic effects of Angiotensin II. Herein, we tested the hypothesis that increased expression of ETS-1 in Dahl salt-sensitive (DS) rats mediates renal injury in this model of hypertension.

**Methods:** DS rats (n=6 per group) were fed normal salt diet (0.5%, NS) or a high salt diet (4%, HS) for 4 weeks. Four additional groups of HS rats received: ETS-1 dominant negative peptide (HS/DN, 10mg/kg/day), a control ETS-1 mutant peptide (HS/MU, 10mg /kg/day), the AT1 receptor blocker Candesartan (HS/ARB 10 mg/kg/day) or a combination of DN and ARB (HS/DN/ARB).

**Results:** HS rats had a 3 fold increase in the cortical expression of ETS-1. Treatment with DN, MU, ARB or DN/ARB resulted in non-significant reductions in BP. HS increased proteinuria, glomerular injury score (GIS), fibronectin expression (western blot), urinary TGF-β (ELISA) and macrophage (ED1) infiltration, that were improved by DN (table). ARB partially reduced proteinuria, GIS and macrophage infiltration. Treatment with DN/ARB resulted in further improvements as compared to DN or ARB.

**Conclusions:** Increased expression of ETS-1 mediates renal injury in salt sensitive hypertension.

**Differential Regulation of Epithelial Sodium Channel (ENaC) and Sodium-Chloride Cotransporter (NCC) by Gilz** Priyanka Rashmi, Michael Ng, David Pearce. *Div of Nephrology, Dept of Medicine, Univ of California, San Francisco, CA.*

The renin-angiotensin-aldosterone (RAAS) system is the central regulator of $Na^+$ reabsorption and $K^+$ secretion primarily through the tubular effects of aldosterone. Among the multiple transporters implicated in electrolyte homeostasis and regulated by the RAAS are the $Na^+Cl^-$ cotransporter (NCC) and epithelial sodium channel (ENaC).Electrogenic $Na^+$ reabsorption via ENaC stimulates $K^+$ excretion, while electroneutral reabsorption of $Na^+$via NCC inhibits $K^+$secretion by competing with ENaC for $Na^+$ reabsorption. Serum- and glucocorticoid- induced kinase 1 (Sgk1) is an aldosterone regulated serine-threonine kinase that phosphorylates the ubiquitin ligase Nedd4-2, and Raf-1 kinase to stimulate ENaC. *In vitro* evidence from our laboratory shows that another aldosterone regulated protein; glucocorticoid-induced leucine zipper protein 1 (Gilz1) acts in concert with Sgk1 to stimulate ENaC cell surface expression. We now show that in contrast to its effect on ENaC, Gilz blocks Sgk1-mediated stimulation of NCC, with important consequences for $Na^+$ and $K^+$ handling *in vivo*. When placed on a low salt diet, Gilz knock out mice are able to come to sodium balance more rapidly than the wild type animals suggesting an upregulation of another sodium transporter. Surface expression of NCC and NKCC2 (as well as phosphorylated NKCC2) is increased in plasma membrane fractions of kidneys from Gilz knock out animals while the expression of ENaC is decreased. In cultured HEK293 cells, Sgk1 stimulates the surface expression of NCC while simultaneous co-expression of Gilz abrogates the effect of Sgk1 in a dose dependent manner. Overexpression of Gilz in mpkDCT tubular epithelial cells results in downregulation of NCC while simulataneously inducing ENaC surface expression. Furthermore, Gilz1 overexpression inhibits the interaction between WNK4 and Sgk1 allowing WNK4 mediated inhibition of NCC. Taken together, these results suggest that: Gilz1 is part of a "shift" mechanism, which allows the differential regulation of ENaC and NCC in order to balance $Na^+$ reabsorption and $K^+$ secretion.

## TH-PO714

**Early Hypertensive Renal Injury Is Associated with Capillary Hypertrophy, Preceding Pathological Angiogenesis and Capillary Loss** Timo Rademakers,[1] Floortje Steegh,[1] Petra Hautvast,[1] Marcella M. Baldewijns,[1] Sylvia Heeneman,[1] Victor L. Thijssen,[3] Mat Daemen,[4] Ben Janssen,[2] Carine Peutz-Kootstra.[1] *[1]Pathology, Maastricht Univ Medical Center, Maastricht, Netherlands; [2]Pharmacology, Maastricht Univ, Maastricht, Netherlands; [3]Medical Oncology, VU Medical Center, Amsterdam, Netherlands; [4]Pathology, Academic Medical Center, Amsterdam, Netherlands.*

**Background:** Chronic hypertension predisposes for end-organ damage in e.g. the kidney. Both patients and animal models have shown peritubular capillary (PTC) loss in chronic hypertensive renal disease, yet PTC rarefaction in early disease is poorly understood. We hypothesized that in early hypertensive renal disease PTC hypertrophy precedes PTC loss, in association with a distinct angiogenic profile.

**Methods:** Patient study: Healthy renal tissue from patients undergoing nephrectomy (n=50; 31 hypertensive, 19 non-hypertensive) was included. Tissue was scored histologically and PTC per tubule (PTC/tub) was assessed by CD31/CD34-staining. Animal study:

C57Bl/6 mice underwent one-sided nephrectomy, after which mice (n=6/group) were left untreated (control), treated with DOCA and/or angiotensin-II (ATII). Renal tissue was scored histologically. RNA for angiogenic profiling via qPCR was isolated from the cortex.

**Results:** Patients with early hypertension showed increased PTC/tub (1.08±0.18 vs. 0.97±0.15; p=0.04) compared to controls. DOCA-treated mice resembled these patients, showing 1.3-fold increased PTC/tub (p=0.05) and 2.2-fold increased VEGFR-2 expression (p=0.04) by angiogenic profiling. DOCA+ATII-treatment, resembling chronic damage, reduced PTC/tub 1.3-fold compared to DOCA-treatment (p=0.04), reduced angiopoietin (ang)-1/ang-2 ratio 5.5-fold (p=0.01), and 2-fold increased PDGFR-β/ang-1 ratio (p=0.02), indicative of pathological angiogenesis and capillary loss.

**Conclusions:** We showed that capillary hypertrophy occurred in human hypertensive renal disease, preceding capillary loss. Murine hypertensive renal disease revealed specific angiogenic profiles associated with capillary phenotype, pending validation in the human cohort. Further study will allow more insights into disease processes and potential targets for therapy.

## TH-PO715

**The Role of Nitric Oxide in Blood Pressure Regulation by $D_3$ Dopamine Receptor** Zhenyu Diao, Laureano D. Asico, John Edward Jones, Jun B. Feranil, Ines Armando, Pedro A. Jose, Xiaoyan Wang. *Univ of Maryland, Baltimore.*

**Background:** $D_3$ dopamine receptor ($D_3R$)-deficient ($Drd3^{-/-}$) mice have increased blood pressure (BP); the increase BP in $Drd3^{-/-}$ mice is associated with activation of the renin-angiotensin system. However, the renal production of reactive oxygen species (ROS) is normal.

**Methods:** We measured BP, renal protein expression of nitric oxide synthases (NOS) and nitrotyrosine, and nitrite/nitrate (NOX) excretion in $Drd3^{-/-}$and wild-type ($Drd3^{+/+}$) mice on normal (0.8%) and high (1.6 or 4%) NaCl diets (1week).

**Results:** The systolic BPs were higher in $Drd3^{-/-}$(114±1 mm Hg, n=4, under anesthesia) than $Drd3^{+/+}$(92±2 mm Hg, n=6) on normal salt intake. The renal expression of inducible NOS (iNOS, 127±14 vs. 100±14, % of $Drd3^{+/+}$mice) tended to increase in $Drd3^{-/-}$compared to $Drd3^{+/+}$ (n=5/group). Extracellular NOS (eNOS, 158±12 vs. 100±17) was increased in $Drd3^{-/-}$ relative to $Drd3^{+/+}$(t-test, P<0.05). The renal expression of nitrotyrosine, a product of ROS and NO interaction, was not altered in $Drd3^{-/-}$ compared to $Drd3^{+/+}$(107±30 vs 100±10). But L-NAME (0.5 mg/kg, i.v. x 1) markedly increased systolic BP in $Drd3^{-/-}$ and slightly in $Drd3^{+/+}$(145±5 vs. 113±6 at 10 min; 151±1 vs. 107±10 at 30 min, n=3-4/group, P<0.05, ANOVA, Holm-Sidak test) under normal salt intake, suggesting an increase in eNOS activity. Increasing the salt diet to 4% NaCl increased systolic BP (>10% over 0.8% NaCl diet, via telemetry) in $Drd3^{-/-}$, but not in $Drd3^{+/+}$. 1.6% NaCl diet normalized renal expression of iNOS (96±6 vs. 100±4, n=4/group) and eNOS (91±12 vs. 100±4) and did not affect BP in either strain. However, nitrotyrosine was decreased in $Drd3^{-/-}$(49±8) relative to $Drd3^{+/+}$(100±14, t-test, P<0.05); NOX excretion was similar between the 2 mouse strains (2.5±1.88 vs. 3.9±1.9, mM/mg Cr) at baseline but it was increased in $Drd3^{+/+}$ (13.6±4.6, P<0.05), not in $D_3$-/- (8.2±1.8) (ANOVA, Holm-Sidak test, n=4-5/group).

**Conclusions:** Our studies suggest that the increased renal expression of eNOS in $Drd3^{-/-}$ mice may be a compensatory mechanism for the increased BP seen with germline deletion of the Drd3 gene and the normalization of eNOS with high salt diet may contribute to the salt sensitivity in $Drd3^{-/-}$ mice.

## TH-PO716

**Salt Sensitivity of Blood Pressure in Nephrotic Syndrome Rats** Yan Qin, Lijun Mou, Xuemei Li, Xuewang Li. *Nephrology Dept, Peking Union Medical College Hospital, Beijing, China.*

**Background:** The prevalence of salt sensitivity of blood pressure is striking in CKD patients. The kidney is the key peripheral organ involved with salt sensitity. In this present study we found the Adriamycin Nephropathy Rats (ADRs) represent as an useful mouse model to study sodium sensitivity of BP in CKD.

**Methods:** In this study the circadian characteristics of MAP, SBP, DBP, HR, pulse pressure (PP) and locomotor activity were measured in conscious and unrestrained 12-week old ADRs and age-matched SD control rats by the radiotelemetry system. After baseline studies were obtained, the rats were were provided a high salt diet (8.0%) for a 1-wk period prior to the 7 day telemetry study.

**Results:** 1. The ADRs presented with the reversed circadian rhythms of MAP, SBP, DBP, and PP compared with SD control rats. 2.In the ADRs, the circadian rhythm of the urine sodium excretion was disturbed, the RUNa in Dark period was significantly lower than that in the Light period of the same group[(14.69 ±3.65) v.s (27.66± 5.84) μmol/h, *P*=0.001] and also significantly lower than that in the Dark period of the control group[(14.69 ±3.65)v.s (39.49±22.44) μmol/h,*P*=0.023].3.In the ADRs, the FENa in Dark period was significantly lower than that in the Light period of the same group(0.15±0.06 v.s 0.29±0.06,*P*=0.008) and also significantly lower than that in Dark period of the control group(0.15±0.06 v.s 0.31±0.19,*P*=0.050).4.Under high salt diet, SBP and MAP in Dark period increased significantly by 19.8mmHg and 18.5mmHg respectivelyin ADRs (*P*<0.001); In the control group, the SBP and MAP in Dark period increased significantly by 8.4mmHg and 6.2mmHg respectively. In the ADRs, the SBP and MAP in Light period increased significantly by 20.1mmHg and 17.7mmHg respectively(*P*<0.001); In the control group, the SBP and MAP in Light period increased by 7.2mmHg and 3.0mmHg respectively, but both differences were not significant.

**Conclusions:** We concluded that the ADR nephropathy rats showed a striking salt sensitive of blood pressure. The ADR rat was a suitable CKD animal model with disturbed circadian BP rhythm and sodium sensitivity.

## TH-PO717

**Simvastatin Induces a Central Hypotension Effect via Ras-Mediated Signaling to Integrate Endothelial Nitric Oxide Synthase Upregulation** Wen-Yu Ho,[1] Wen-Han Cheng,[2] Ching-Jiunn Tseng.[2] *[1]Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung Medical Univ, Kaohsiung City, Taiwan; [2]Dept of Medical Education and Research, Kaohsiung Veterans General Hospital, Kaohsiung City, Taiwan.*

**Background:** Clinical studies indicate that statins have a blood pressure (BP)-lowering effect for hypertensive hypercholesterolemic patients. Statins would modulate BP through the upregulation of endothelial nitric oxide synthase (eNOS) activation in the brain. However, the signaling mechanisms through which statins enhance eNOS activation remain unclear. Therefore, we examined the possible signaling pathways involved in statin-mediated BP regulation in a BP-control center of brain stem, nucleus tractus solitarii (NTS).

**Methods:** BP responses of simvastatin administered intracerebroventricularly in spontaneously hypertensive rats (SHRs) were measured in the presence or absence of various inhibitors, inculinding farnesylthiosalicylic acid (FTS), geranylgeranyltransferase inhibitor (GGTI-2133), LY294002 or PD98059. Western blotting was used to confirm the activation of various signaling molecules in the NTS.

**Results:** Pretreatment with a Ras-specific inhibitor, FTS, significantly attenuated the depressor effect and nitric oxide (NO) production evoked by simvastatin. Additionally, immunoblotting and pharmacological studies further showed that inhibition of Ras activity by FTS significantly abolished simvastatin-induced extracellular signal-regulated kinases 1/2 (ERK1/2), ribosomal protein S6 kinase (RSK), Akt phosphorylation and decreased eNOS phosphorylation. Likewise, administration of Akt and ERK1/2 signaling inhibitors into the NTS attenuated the depressor effects evoked by simvastatin. Furthermore, the addition of simvastatin also decreased Rac1 activation and the number of ROS-positive cells in the NTS.

**Conclusions:** These results suggest that distinct Ras and Rac1 signaling-mediated simvastatin control of central BP regulation in SHRs. Both Akt and ERK1/2-RSK signaling at least partly contribute to the eNOS activation of simvastatin.

## TH-PO718

**Fidelity of Podocyte Number in Preeclampsia due to Podocyte Regeneration** Maria Elisabeth Penning,[1] Kitty Bloemenkamp,[2] Tom T. Van der Zon,[1] Joke M. Schutte,[3] Jan A. Bruijn,[1] Ingeborg M. Bajema,[1] Hans J. Baelde.[1] *[1]Pathology, Leiden Univ Medical Center, Leiden, Netherlands; [2]Obstetrics, Leiden Univ Medical Center, Leiden, Netherlands; [3]Obstetrics, Isala Clinics, Zwolle, Netherlands.*

**Background:** Preeclampsia (PE) is characterized by increased numbers of podocytes in the urine. This observation led to our hypothesis that there may be a decreased number of podocytes in the glomerulus in PE. Furthermore, we evaluated possible parietal epithelial cell activation as this could play a role in the replacement of injured and lost podocytes.

**Methods:** We performed a search for renal autopsy-tissues using a nationwide computerized database (PALGA) to collect a unique large cohort ofwomen who died during pregnancy or postpartum due to PE (n=11). Three control groups were included consisting of young women who died during pregnancy without hypertension (n=25) and non-pregnant controls with (n=14) and without (n=13) chronic hypertension. WT-1 staining was used to quantify the numbers of podocytes. To evaluate cellular proliferation Ki-67 staining was performed. To investigate parietal epithelial cell migration, but to exclude CD44-positive leukocytes, a double staining with CD44 and CD45 was performed.

**Results:** No significant difference was found between the numbers of podocytes in the preeclamptic group and the controls. However, preeclampsia was significantly (p<0.05) more often associated with intraglomerular Ki-67 positivity. Furthermore, the numbers of Ki-67 positive parietal cells were significantly (p<0.05) higher in the women with PE than in the pregnant- and hypertensive controls. CD44 positive (and CD45 negative) cells were observed within the glomerular tuft.

**Conclusions:** This study shows for the first time that, although PE is characterized by significantly increased numbers of podocytes in urine, glomerular podocyte numbers remain stable. Significantly increased intraglomerular Ki-67 positivity and CD44 positive parietal cells suggest that regeneration of podocytes may play an important role in the maintenance of the glomerular filtration barrier during PE.

## TH-PO719

**Enhanced Phosphorylation of NKCC2 by SPAK/OSR1 in a Murine Model of Diet Induced Obesity** Matthew R. P. Davies,[1,2,3] Marina Katerelos,[1] Kurt Gleich,[1] Scott Andrew Fraser,[1] Peter F. Mount,[1] David A. Power.[1,2,3] *[1]Nephrology, Austin Health, Heidelberg, Victoria, Australia; [2]Institute of Breathing and Sleep, Victoria, Australia; [3]Medicine, Univ of Melbourne, Victoria, Australia.*

**Background:** Obesity promotes salt-sensitive hypertension. Tubular mechanisms of enhanced sodium retention in obesity are not well defined.

**Methods:** C57Bl/6 mice were fed 40% (high fat, HFD) or 12% (control, CD) fat diets for 14 weeks. Abundance and phosphorylation of proteins were determined by western blotting. Surface expression was analysed with immunofluorescence and confocal microscopy. *In vitro* studies used stimulation of AMPK with 100uM A769662, and stimulation of WNK/SPAK/OSR1 with 26mM $Cl^-$ solution, in murine embryonic fibroblasts (MEF's) from β1-AMPK-/- and β1-AMPK+/+ mice.

**Results:** HFD mice gained weight and developed hyperinsulinaemia & hyperleptinaemia. Cortical expression of NKCC2 was reduced but activating phosphorylation (T96/T101) was increased. No change in expression or phosphorylation of NCC, or expression of α- or γ-ENaC was found. Surface localisation of transporters was unchanged. SPAK/OSR1 is known to phosphorylate NKCC2 on T96/101. Phosphorylation of SPAK/OSR1 on S373/325 was increased, consistent with increased activity of the WNK/SPAK/OSR1 pathway. AMPK inhibition is involved in mediating obesity-related renal injury. Active AMPK (phosT172) was reduced in HFD mouse cortex. SPAK/OSR1 and AMPK were found to co-immunoprecipitate with NKCC2, indicating a possible kinase-kinase interaction. *In vitro*, activation of AMPK led to a reduction in S373/325-phos SPAK/OSR1 in β1-AMPK+/+ MEF's. No effect was seen in β1-AMPK-/- MEF's, indicating a specific AMPK-mediated effect. Low $Cl^-$ solution invoked a significantly greater increase in S373/325-phos SPAK/OSR-1 in β1-/- than in β1+/+ MEF's, supporting an inhibitory role of AMPK in modulating the WNK/SPAK/OSR1 pathway.

**Conclusions:** NKCC2 is the most important sodium co-transporter in this model of obesity-related hypertension. Enhanced phosphorylation of NKCC2 occurs due to activation of SPAK/OSR1, which itself may be secondary to AMPK inhibition . These data identify NKCC2, SPAK/OSR1 and AMPK as therapeutic targets in obesity-related hypertension.

## TH-PO720

**Effects of L/N-Type $Ca^{2+}$ Channel Blocker Cilnidipine on the Cardiac Histological Remodeling and Inducibility of Atrial Fibrillation in the High-Salt-Fed Rats**

Eri Harada,[1,2] Kazumi Sugino,[1,2] Akira Takahara,[2] Makoto Shiozaki.[1] *[1]Ajinomoto Pharmaceuticals Co., Ltd., Japan; [2]Dept of Pharmacology and Therapeutics, Faculty of Pharmaceutical Sciences, Toho Univ, Japan.*

**Background:** High-salt intake has been shown to induce hypertrophy and fibrosis in the atria and ventricles, which would cause the development of atrial fibrillation (AF). Whereas development of AF is suggested to be prevented by RAS inhibitors, recent findings have indicated that the preservation is closely associated with their antihypertensive effects. In this study, we investigated whether the L/N-type $Ca^{2+}$ channel blocker cilnidipine counteracts salt-induced atrial and ventricular remodelings and inducibility of AF.

**Methods:** Seven-week-old Dahl salt-sensitive rats were fed an 8% NaCl diet. Seven weeks later, cilnidipine of 5 or 10 mg/kg (Cil-L or Cil-H group) was administered orally for 5 weeks, and then echocardiography, electrophysiological evaluation and histological analyses were performed. The effects were compared with those of the L-type $Ca^{2+}$ channel blocker amlodipine (1.5 or 3 mg/kg; Aml-L or Aml-H group).

**Results:** Following the 8% NaCl diet intake, the BP and urinary protein levels increased, and fibrosis was induced in the atria and ventricles. Cilnidipine decreased the BP in a dose-dependent manner, and the extents in the Cil-L and Cil-H groups were similar to those in the Aml-L and Aml-H groups, respectively. Cilnidipine and amlodipine significantly ameliorated increases in urinary protein excretion. Cilnidipine produced a greater decrease of the fibrosis-area than amlodipine in the atria and ventricles. The fractional shortening and ejection fraction were greater in the Cil-H group than those in the Aml-H group. The 8% NaCl diet intake tended to induce shorteratrial effective refractory period and longer AF cycle length. The Cil-H group had tendency to suppress AF duration increased by NaCl intake. Plasma noradrenaline levels in the Cil-H group were lower than Aml-H group.

**Conclusions:** Cilnidipine effectively suppressed salt-induced atrial and ventricular remodelings and dysfunction at the dose causing antihypertension and renoprotection, probably through its N-type $Ca^{2+}$ channel-blocking actions.

## TH-PO721

**Indoxyl Sulfate Stimulates Cardiac Fibrosis with Enhanced Oxidative Stress and Reduced Anti-Oxidative Defense in Hypertensive Rats**

Toshimitsu Niwa,[1] Maimaiti Yisireyili,[1] Hidehisa Shimizu,[1] Shinichi Saito,[1] Fuyuhiko Nishijima.[2] *[1]Nagoya Univ Graduate School of Medicine; [2]Biomedical Research Laboratories, Kureha Co.*

**Background:** Cardiovascular disease (CVD) is common in chronic kidney disease (CKD) patients. Indoxyl sulfate (IS) is a nephrovascular uremic toxin that induces oxidative stress in kidney and vascular system. The present study aimed to examine the effect of IS on fibrosis and oxidative stress in rat heart.

**Methods:** The effects of IS on heart were examined by Masson's trichrome (MT) staining and immunohistochemistry using; (1) Dahl salt-resistant normotensive rats (DN), (2) Dahl salt-resistant normotensive IS-administered rats (DN+IS), (3) Dahl salt-sensitive hypertensive rats (DH), and (4) Dahl salt-sensitive hypertensive IS-administered rats (DH+IS).

**Results:** DH+IS rats showed significantly increased heart weight and left ventricle weight compared with DN. DH and DH+IS rats showed significantly increased diameter of cardiomyocytes, increased MT-positive fibrotic area, increased staining for transforming growth factor (TGF)-β1, α-smooth muscle actin (SMA), type 1 collagen, NADPH oxidase Nox 4, malondialdehyde (MDA), and 8-hydroxydeoxyguanosine (8-OHdG) and decreased staining for nuclear factor (erythroid-derived 2)-like 2 (Nrf2) and heme oxygenase-1 (HO-1) in the heart compared with DN. More notably, DH+IS rats showed significantly increased diameter of cardiomyocytes, increased fibrotic area, increased staining for TGF-β1, SMA, type 1 collagen, Nox4, 8-OHdG and MDA, and decreased staining for Nrf2 and HO-1 in the heart compared with DH.

**Conclusions:** IS aggravates cardiac fibrosis and cardiomyocyte hypertrophy with enhanced oxidative stress and reduced anti-oxidative defense in hypertensive rats.

## TH-PO722

**Reduced Firing Activity of Afferent Renal Innervation in the 2Kidney/1Clip Model of Hypertension**

Wolfgang Freisinger,[1] Annalena Karl,[2] Tilmann Ditting,[2] Sonja Heinlein,[2] Roland E. Schmieder,[2] Karl F. Hilgers,[2] Johannes Schatz,[2] Jens Lutz,[1] Roland Veelken.[2] *[1]Nephrology, Med. Clinic, Universitätsmedizin Mainz, Mainz, Germany; [2]Nephrology and Hypertension, Med. Clinic 4, Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany.*

**Background:** Renal denervation has been shown to be effective in hypertension. Recently, we found that afferent renal neurons show a distinctive feature, exhibiting predominantly a sustained firing upon current injection due to a specific expression of TTX resistant Na-channels. So far, the firing pattern of these specific sensory neurons in hypertension is unclear. Hence we wanted to test the hypothesis that the firing pattern of renal afferent neurons is altered in the 2K/1C model of hypertension.

**Methods:** Hypertension was induced by unilateral clipping of the renal artery in male Sprague Dawley rats 3 weeks prior to experiments. Labelling (DiI) allowed the identification of renal afferent Dorsal root ganglion (DRG) neurons. Current clamp was used to characterize neurons as "tonic", i.e. sustained action potential (AP) firing or "phasic", i.e. <5 APs. Electrophysiological parameters and AP properties were determined in neurons of hypertensive animals and compared to controls.

**Results:** Renal DRG neurons of hypertensive animals (n=88) showed a significant decrease in tonic firing compared to controls (44.3% [39/88] vs. 59.5% [50/84], $p< 0.05$). Current Clamp analysis revealed no significant change in action potential shape e.g. overshoot, firing threshold in hypertensive animals. Tonic cells had a higher capacity in hypertensive neurons (124pF vs 87.8pF, $p<0.01$), other cell parameters were equal. Renal morphology in hypertensive animals was equal in the clipped vs. non-clipped kidney.

**Conclusions:** For the first time we could show that excitability of afferent renal neurons in the 2Kidney/1Clip model of hypertension is significantly altered, as renal afferent DRG neurons exhibit less sustained firing upon stimulation. Sustained high blood pressure is possibly characterized by a generally decreased afferent renal activity with impaired sympathoinhibition. The underlying mechanisms causing a "switch" from tonic to phasic need further elucidation.

## TH-PO723

**Increased Neurokinin Release from Afferent Renal Nerves Is Accompagnied by Decreased Afferent Electric Activity**

Tilmann Ditting,[1] Kristina Rodionova,[1] Christian Ott,[1] Johannes Schatz,[1] Sonja Heinlein,[1] Roland E. Schmieder,[1] Wolfgang Freisinger,[2] Karl F. Hilgers,[1] Roland Veelken.[1] *[1]Med Clinic 4, Nephrology & Hypertension, Friedrich-Alexander Univ Erlangen, Erlangen, Germany; [2]Med Clinic 1, Dept of Nephrology, Johannes Gutenberg Univ Mainz, Mainz, Germany.*

**Background:** Afferent renal nerves exhibit a dual function. They influence intrarenal immunological processes by release of neurokinins like CGRP and control central sympathetic outflow via afferent electrical activity. The former seems to be important in renal inflammation whereas the sympathetic modulation by afferent electrical activity is not fully understood. Hence, we hypothesized that augmented effects of CGRP in renal inflammation occur with increased afferent renal nerve activity.

**Methods:** As inflammatory model, normotensive renal inflammation (RI) was induced by i.v. injection of 1.75 mg/kg BW OX-7 antibody to rats. These were investigated neurophysiologically and pathomorphologically using standard techniques 6 days after RI induction.

**Results:** Blood pressure (BP) was normal, hence confounding BP effects were unlikely. RI rats exhibited albuminuria (61±6 µg/24h), infiltration of macrophages in the interstitium (26 ± 4 cells/hp field) and glomeruli (3.7±0.6 cells/glomerular X-section). Pretreatment with the CGRP antagonist rCGRP 8-37 (15nmol/kg) significantly reduced proteinuria and macrophage infiltration suggesting increased activity of CGRP. In an *in-vitro* assay, renal RI tissue exhibited increased CGRP release (14 ± 3 pg/ml vs. controls 6.8 ± 2.8 pg/ml; $p<0.05$, n=8). RI tissue from renally denervated rats showed no CGRP. Afferent renal nerve activity (ARNA; spikes/sec) was unexpectedly lower in RI compared to controls (8.0 ± 1.8 vs. 27.4 ± 4.1 Hz*,n=6, $p<0.05$). On the other hand, the burst-frequency renal sympathetic nerve activity (RSNA) in RI was significantly higher than in controls (14.7 ± 0.9 vs. 11.5 ± 0.9 bursts/sec*; n=6, *$p<0.05$).

**Conclusions:** In contrast to our hypothesis increased release of neurogenic CGRP aggravating RI occurred with decreased ARNA. Increased RSNA pointed to a reduced tonic inhibition by ARNA. The latter mechanism might worsen sympathetic dysregulation and renal damage.

## TH-PO724

**The Prorenin Receptor (PRR) Mediates Compensatory Responses to Buffer the Actions of the Renin-Angiotensin System (RAS) in the Collecting Duct through Cyclooxygenase-2 Upregulation in the Renal Medulla**

Alexis A. Gonzalez,[1] Minolfa C. Prieto.[2] *[1]Instituto de Química, Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile; [2]Physiology, Tulane Univ, New Orleans, LA.*

**Background:** Angiotensin (Ang) II-induced hypertensive rats exhibit augmented secretion of prorenin and prorenin receptor (PRR) mRNA, which contrast with the reduced levels of full-length PRR in the renal medulla. The urine of these rats contains high levels of the soluble form of PRR (sPRR). PRR stimulates cyclooxygenase-2 (COX-2) in the

intercalated cells (IC) via ERK1/2. However, whether the PRR-mediated stimulation of COX-2 in the renal medulla varies during the course of AngII-induced hypertension remains unknown.

**Methods:** We examined the temporal changes of renin, full-length PRR, sPRR, ERK1/2 and COX-2 during chronic AngII infusion for 3, 7, and 14 days in the rat renal medulla and in cultured inner medullary collecting duct (IMCD) cells.

**Results:** AngII infusion (80 ng/min) increased full-length PRR and COX-2 protein levels, phospho-ERK1/2 and $PGE_2$ during the early normotensive phase of the AngII infusion (day 3). In contrast, during the established hypertensive phase (day 14), no changes were observed. At day 14, the urines of AngII-infused rats showed increased renin, sPRR and AngII. In cultured IMCD cells, AngII treatment (100 nM, 6 hrs) increased prorenin, full-length PRR, phospho-ERK1/2 and COX-2. AT1R blockade abolished these effects. Interestingly, after 16 hours of AngII incubation, the sPRR became detectable in cell culture media.

**Conclusions:** These results suggests that during early phase of AngII-induced hypertension, the collecting duct harbors compensatory mechanisms directed to buffer the actions of the RAS, in which the secretion of prorenin by the principal cells exerts a paracrine activation of PRR-membrane bound in IC, stimulating COX-2 and PGE2. By contrast, during the late phase, sPRR secretion into the collecting duct exerts hypertensinogenic effects by binding local prorenin, increasing intratubular AngII.

## TH-PO725

**SIRT1 Activation Protects the Endothelial Dysfunction by Inhibiting PDGF and TGF-β Generation** Hideyuki Negoro. *Medicine, Harvard Medical School, The Graduate School of Project Design, Boston.*

**Background:** SIRT1 is a conserved NAD(+)-dependent deacetylase and possesses beneficial effects against aging-related diseases, but little information is available on a putative role of SIRT1 in endothelial and vascular homeostasis. Endothelial senescence causes endothelial dysfunction to promote atherosclerotic change and contribute to age-related vascular diseases. Growth factors, such as platelet-derived growth factor (PDGF) and transforming growth factor (TGF)-β can be produced by additional cells involved in the pathogenesis of arteriosclerosis and play an important part in the progression of age-related vascular diseases.

**Methods:** We established an in vitro senescence model by prolonged culture of primary endothelial cells isolated from bovine aorta. The freshly isolated young endothelial cells gradually underwent senescence during 1 month of repetitive passages. We knocked down SIRT1 to evaluate the protein levels of LKB1, phosphorylated AMPK, PDGF and TGF-β in the knocked down cells.

**Results:** It was observed that protein expressions of SIRT1 were decreased time dependently in the senescent endothelial cells. In contrast, the protein levels of LKB1, a serine/threonine kinase, the phosphorylation of its downstream target AMP-activated protein kinase (AMPK), PDGF and TGF-β generation were dramatically increased in the senescent cells. On the other hand, resveratrol activated SIRT1 in the endothelial cells. SIRT1 activation with resveratrol inhibited the increase of LKB1, AMPK. At the same time, SIRT1 activation with resveratrol reduced PDGF and TGF-β generation in the endothelial cells significantly. We knocked down SIRT1 and the protein levels of LKB1, phosphorylated AMPK, PDGF and TGF-β elevated in the knocked down cells. The protein levels of LKB1, phosphorylated AMPK, PDGF and TGF-β generation did not changed in the SIRT1 knocked down cells even if they were stimulated with resveratrol.

**Conclusions:** These findings indicate that activation of SIRT1 provides beneficial effects against the endothelial dysfunction to promote atherogenesis by inhibiting PDGF and TGF-β generation.

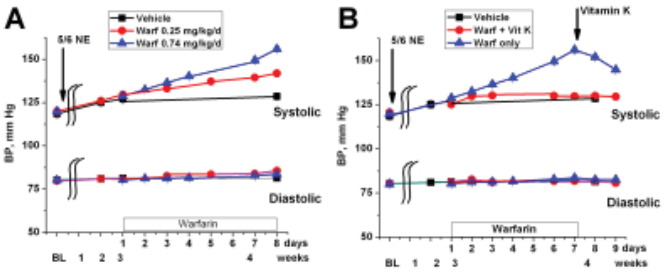
## TH-PO726

**Oral Warfarin Increases Blood Pressure in Control and 5/6 Nephrectomy Rats** Jay C. Vance, Kyle M. Ware, Zahida Qamri, Lee A. Hebert, Anjali A. Satoskar, Gyongyi Nadasdy, Iouri Ivanov, Tibor Nadasdy, Brad H. Rovin, Sergey V. Brodsky. *Depts of Pathology and Medicine, The Ohio State Univ, Columbus, OH.*

**Background:** Hypertension is a common comorbidity in patients with chronic kidney diseases (CKD). In our animal model of warfarin-associated nephropathy we found that the blood pressure (BP) of rats with CKD increased with warfarin treatment. Because an effect of warfarin on BP has not been previously reported, the aim of this study was to examine the relationship of warfarin therapy to hypertension.

**Methods:** Sham-operated (control) and 5/6 nephrectomy rats (5/6NE) were treated with different doses of warfarin. Blood pressure (BP) was measured by a tail cuff.

**Results:** Warfarin increased BP in control and 5/6 NE rats in a dose-depended manner. Warfarin affected predominantly systolic BP with little or no change in diastolic BP (Figure 1, A, effects in 5/6 nephrectomy rats, 3 weeks after the ablative surgery are shown). The hypertensive effects of warfarin were more prominent in animals with progressing CKD. Treatment with vitamin K attenuated the effects of warfarin on BP (Figure 1, B, 0.74 mg/kg/day of warfarin was used. Vitamin K 40 mg/kg was injected i.p. daily in the co-treatment with warfarin (red) or once after 1 weeks of 0.74 mg/kg/day warfarin (blue)).



**Conclusions:** Warfarin increases systolic, but not diastolic, BP in both control and CKD rats. Warfarin effects are Vitamin K dependent. The pathogenesis of this effect is not yet clear. Warfarin is the most commonly prescribed anticoagulant and is used extensively in patients with CKD.Our data indicate that BP should be carefully monitored in patients on warfarin therapy, especially those with CKD.

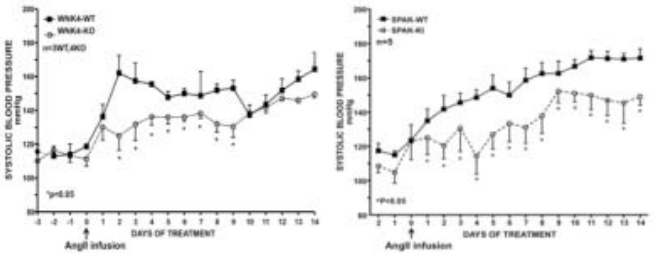
## TH-PO727

**Disruption of the WNK4/SPAK Pathway Reduces the Hypertension Induced by Angiotensin II** Luz Graciela Cervantes-Perez,[1] Maria Castañeda-Bueno,[1] Norma Hilda Vázquez,[1] Dario Alessi,[2] Norma Bobadilla,[1] Gerardo Gamba.[1] *[1]Molecular Physiology Unit, INNSZ-IIB, UNAM, Mexico City, Mexico; [2]MRC Phosphorylation and Ubiquytilation Unit, Dundee Univ, Dundee, United Kingdom.*

**Background:** Angiotensin II (AngII) induces systemic hypertension by its renal effects in reducing salt excretion. The effect of AngII is associated with increased phosphorylation of the renal NaCl cotransporter, NCC. The AngII activation of NCC requires the presence of an intact WNK4-SPAK pathway. We thus analyzed the effect of AngII infusion on blood pressure in genetically altered mice either lacking WNK4 ($WNK4^{-/-}$ mice) or expressing a version of the SPAK kinase that cannot be activated by WNKs ($SPAK^{T245A/T245A}$ knockin mice).

**Methods:** $WNK4^{-/-}$ and SPAK knockin mice and their respective controls were infused with AngII at 1440/μg/kg/day by osmotic minipumps during 14 days. $WNK4^{-/-}$ mice and their respective wild type controls were resistant to the AngII-inducing high blood pressure at the infused dose. To over come this, unilateral nephrectomy was performed in this colony. Blood pressure was assessed by radiotelemetry from three days before the beginning of AngII infusion and during the next 14 days after infusion. At the end of the infusion period mice were sacrificed and renal tissue was used for protein extraction to assess total NCC and phosphoT58-NCC with specific antibodies.

**Results:** Figure 1 shows the effect of AngII infusion in $WNK4^{-/-}$ and SPAK-KI and their controls. The response to AngII in $WNK4^{-/-}$ was reduced during the first week, but eventually was similar, owing in part to a reduction of AngII effect in wild type mice. In contrast, the response to AngII was clearly reduced in SPAK-knockin animals. AngII induced NCC phosphorylation in wild type mice but not in $WNK4^{-/-}$ or SPAK-KI mice.



**Conclusions:** Hypertension induced by AngII infusion is due in part to NCC activation through WNK4-SPAK pathway.

**TH-PO728**

**Treatment with Azilsartan and Chlorthalidone Lowers Blood Pressure and Reduces Renal Inflammation in a Rodent Model of the Metabolic Syndrome**
Chunhua Jin, David M. Pollock, John Jason White. *Medicine, Georgia Regents Univ, Augusta, GA.*

**Background:** The metabolic syndrome (metS) and chronic kidney disease are global health issues. The metS induces hypertension (HTN) and commonly results in renal damage. The optimal therapy for HTN in the metS is unknown. JNC7 recommends thiazide diuretic as first line therapy for all patients with HTN. However, these drugs may have untoward metabolic effects. This study was conducted to investigate the effects of azilsartan (AZL), chlorthalidone (CLTD), and the combination (AZL + CLTD) on blood pressure and renal injury in a rodent model of metabolic syndrome.

**Methods:** In order to mimic the metS in a hypertensive model, male Dahl salt sensitive rats were fed a high fat (36% fat) high salt (4% NaCl) diet. Groups of rats were then treated with vehicle, AZL (3 mg/kg/day), CLTD(5 mg/kg/day) or AZL+CLTD. Mean arterial pressure (MAP) was recorded continuously by telemetry. After 4 weeks, rats were sacrificed and kidneys were harvested for histology.

**Results:** After 4 weeks, both AZL and CLTD attenuated the rise in blood pressure compared to vehicle, and the combination further reduced blood pressure compared to CLTD alone. All treatments reduced proteinuria and albuminuria. However, only groups treated with AZL prevented nephrinuria (a podocyte injury marker). The nephrinuria was 57% lower, and proteinuria was 47% lower with combination therapy compared to AZL alone. All treatments reduced the number of ED1+ (monoclonal antibody) cells in the kidney. Plasma monocyte chemoattractant protein-1(MCP-1) was significantly lower only in the AZL group.

**Conclusions:** In our rodent model of the metS, AZL and CLTD lower blood pressure and exhibit renal protective effects. Treatment with either reduces albuminuria and renal cortical inflammatory cell infiltration. AZL treatment offers additional protection as evidenced by lower nephrinuria and plasma MCP-1. These findings indicate that combination therapy afforded the greatest protective effects and thus may be the best choice for hypertensive therapy in the metS.

**Systemic PPARγ Deletion in Mice Leads to Sympathoactivation**
Tianxin Yang,[1] Mi Liu,[2] Zhanjun Jia.[1] *[1]Internal Medicine, Univ of Utah and Veterans Affairs Medical Center, Salt Lake City, UT; [2]Institute of Hypertension, Sun Yat-sen Univ School of Medicine, Guangzhou, Guangdong, China.*

**Background:** PPARg and sympathetic nerve activity (SNA) antagonistically regulate energy metabolism and cardiovascular function but their precise relationship is not known.

**Methods:** Systemic inactivation of PPARg was generated constitutively by using Mox2-Cre mice or inducibly by using the tamoxifen system (TM KO). Sympathetic activity was evaluated.

**Results:** Radiotelemetrydemonstrated consistent increases in resting heart rate (HR) in both strains of null mice; this was associated a more than 10-fold increase in urinary epinephrine and norepinephrine. Subsequently, more detailed analysis of SNA was performed in TM KO mice. In response to a bolus ip injection of the gangalion blocker pentolinium at 7.5 mg/kg, the decreases in HR and MAP were greater inthe null mice than in the flox controls (delta HR:-254.2 vs. 92.3 beat/min; delta MAP: -67.8 vs. 33.4 mmHg).The HR decrease in response to the beta-blocker metaprolol was greater in the null mice than in the flox controls so was the MAP decease in response to the alpha1-blocker prazosin. Baroreflex sensitivity (BRS) assessed by the HR responses to bolus injections of sodium nitroprusside (NP-BRS) or phenylephrine (PE-BRS) showed normal PE-BRS but blunted NP-BRS. Echocardiographydemonstrated that the ejection fraction (EF) was 11% lower after administration of metaprolol contrastingto a drop of only 1.5% for the flox controls, in parallel with a greater reduction of HR in the KO mice. In contrast, the increase in HR following administration of the beta1 agonist dobutamine was less in the KO mice than in the flox controls.

**Conclusions:** Together, PPARg deletion causes the SNA activation, accompanied with suppressed beta1 receptor activity.

**Imatinib Mesylate Has a Protective Effect on Angiotensin II-Induced Podocyte Injury**
Qian Yang, Zhilong Ren, Xinghua Chen, Wei Liang, Guohua Ding. *Div of Nephrology, Renmin Hospital of Wuhan Univ, Wuhan, Hubei, China.*

**Background:** c-Abl is a non-receptor tyrosine kinase involved in cytoskeleton formation, cell proliferation and apoptosis. Ang II stimulates c-Abl expression in kidneys and podocytes, suggesting that c-Abl participates in Ang II-induced damage. Imatinib mesylate is a 2-phenylaminopyrimidine-based inhibitor of the Abl tyrosine kinase family. In this study, we evaluated the effect of imatinib mesylate on Ang II-induced podocyte injury.

**Methods:** 36 male Wistar rats were randomly assigned to receive Ang II (400 kg/kg/min), Ang II + imatinib mesylate (50 mg/kg/day) or saline by osmotic mini-pumps. SBP and 24 hr Uprot were measured weekly. Kidneys were collected at 14 and 28 d. Glomerular expression of c-Abl was evaluated by immunotechniques and Western blotting. immortalized mouse podocytes were treated with Ang II (10-8M) in the presence or absence of the imatinib mesylate (0.5-20ug/ml). Cytoskeleton formation was evaluated by FITC-phalloidin staining and apoptosis by flow cytometry and Hochest-33258 staining. Western blotting and immunofluorescence assays were used for the expression of c-Abl and p-c-Abl (phosphorylation at Y245 and Y412).

**Results:** Ang II-infused rats had hypertension and proteinuria, and podocyte damage, which was alleviated by imatinib mesylate. C-Abl was localized along capillary loops. Imatinib mesylate attenuated the expression of c-Abl in Ang II rats .($P<0.05$). A significantly positive correlation was found between the c-Abl expression and the amount of Uprot ($r=0.665$, $P<0.05$). Ang II significantly stimulated c-Abl expression in cultured podocytes, and increased its phosphorylation at Y245 and Y412. In controls, c-Abl staining in the nucleus was increased by Ang II, with no changes in cytoplasmic levels. Cytoskeleton reorganization and apoptosis were observed in Ang II-stimulated podocytes. Pretreatment with Imatinib mesylate prevented these effects.

**Conclusions:** c-Abl specific inhibitor Imatinib mesylate has a protective effect on Ang II-Induced podocyte injury, which conforms that c-Abl plays an important role in Ang II-induced podocyte injury.

**Immunoreactive (Pro)renin Receptor in the Human Plasma**
Kazuhito Totsune,[1] Takuo Hirose,[1] Shiro Oguma,[2] Itiro Ando,[1] Hiroshi Sekino,[3] Hiroshi Sato,[4] Kazuhiro Takahashi,[5] Yutaka Imai.[1] *[1]Planning for Drug Development and Clinical Evaluation, Tohoku Univ Grad Sch of Pharm Sci and Med; [2]Koujinkai Nagamachi Clinic; [3]Koujinkai Central Clinic; [4]Labotratory of Clinical Pharmacology and Therapeutics, Tohoku Univ Grad Sch of Pharm Sci and Med; [5]Endocrinology and Applied Med Sci, Tohoku Univ Grad Sch of Med, Sendai, Japan.*

**Background:** (Pro)renin receptor ((P)RR) is a new member of renin-angiotensin system. It is reported that soluble type of (P)RR (s(P)RR) with 28 kDa is present in human blood. However, the characteristics of immunoreactive (P)RR (IR-(P)RR) in plasma have not been clarified yet.

**Methods:** We therefore examined a profile of IR-(P)RR in human plasma by a gel chromatography and two types of assay systems: a competitive enzyme immunoassay (CEI-assay) which we reported previously (Kidney Week 2011) and a commercially available s(P)RR sandwich ELISA kit (s(P)RR-assay) (IBL Co., Ltd.). Plasma IR-(P)RR levels also were measured in 10 non-dialyzed subjects and 16 hemodialysis patients.

**Results:** Gel chromatography of human plasma showed a major peak of IR-(P)RR at the elution position of human γ-globulin (158 kDa) by CEI-assay, and in contrast a small peak at 158 kDa accompanied with a major peak at 29 kDa by s(P)RR-assay. These data indicate that IR-(P)RR in human plasma is composed of two components, one with a large molecular size and s(P)RR. By s(P)RR-assay, which turned out to be sensitive to s(P)RR, plasma IR-(P)RR levels in HD patients were 2.0-fold higher than non-HD subjects ($P<0.01$), and the levels significantly increased during HD sessions in diabetic HD patients from 1.04±0.04 to 1.14±0.07 pmol/ml (mean±SE, n=8, $P<0.05$), whereas, the levels decreased in non-diabetic HD patients from 1.19±0.06 to 1.04±0.05 pmol/ml (n=8, $P<0.05$). There was no significant correlation between plasma IR-(P)RR levels measured by CEI-assay and those by s(P)RR-assay.

**Conclusions:** These results suggest that measurement of IR-(P)RR in plasma, s(P)RR in particular, is important to clarify the role of (P)RR in the cardiovascular regulation.

**Co-Assembly of GABA(A) Receptor π, α1 and β3 Subunits and Its Expression in Rat and Human Kidney**
Kozue Takano,[1] Junichi Yatabe,[2] Midori Sasaki Yatabe,[1] Hironobu Sanada,[3] Pedro A. Jose,[4] Tsuyoshi Watanabe,[3] Junko Kimura.[2] *[1]Dept of Pharmacol, Fukushima Med Univ Sch Med, Japan; [2]Dept of CKD Initiatives, Fukushima Med Univ Sch Med; [3]Dept of Nephrol, Hypertens, Diabetol, Endocrinol and Metabol, Fukushima Med Univ Sch Med, Japan; [4]Univ of Maryland.*

**Background:** Gamma aminobutyric acid (GABA) lowers blood pressure and induces diuresis/natriuresis. We have reported characteristic expressions of GABA-related molecules in rat kidney. In contrast to brain, GABA(A) receptor π subunit may be dominant in the kidney, constituting $\alpha1/\alpha1/\beta3/\beta3/\pi$ pentamers. In this study, coexpressions, intra-renal localizations and relative expressions of the subunits in addition to GABA-related molecule expressions in human kidney were examined.

**Methods:** Renal cortices of Wistar-Kyoto rats (WKY) were used for immunohistology and immunoprecipitation. Renal cortical messenger RNA expressions of WKY on normal diet and on high-salt diet (8%, 7 days) were compared by quantitative RT-PCR. Quantitative RNA assays using human brain and kidney RNA were also performed for those GABA-related molecules found in rat kidney.

**Results:** GABA(A) π subunit mRNA in WKY kidney was more than 100 times that in the brain. Costaining of α1, β3 and π subunits was observed mainly on the apical side of cortical tubules. There was significant π subunit signal in collecting duct, suggesting coexpression with GABA(B) receptor. Kidney protein immunoprecipitated with π subunit antibody revealed α1 and β3 subunits, with molecular weights suggesting dimerization. Salt loading reduced π subunit mRNA in WKY kidney. In human kidney, mRNA of GABA(A) α1, β3 & π subunits, GABA(B) R1 & R2 subtypes, and GABA(C) ρ1 & ρ2 subunits in addition to GABA transporter, GAT2, GABA producing enzymes, GAD65 & GAD67, and GABA degrading enzyme, ABAT, were found similar to WKY kidney.

**Conclusions:** Characteristically high expression of GABA(A) π subunit in the kidney suggests its role in mediating kidney-specific actions of GABA. Components for GABA

synthesis, action, and dedgradation exist also in human kidney. Further analyses of GABA receptor composition, distribution, and function may elucidate novel blood pressure regulatory mechanism in the kidney.

## TH-PO733

**Effect of Gender and Diabetes in Circulating ACE2 and ACE Activity in Streptozotocin-Induced Mice** Sergi Clotet-Freixas, Maria Jose Soler, Julio Pascual, Marta Riera. *Hospital del Mar - IMIM, Barcelona, Spain.*

**Background:** Male gender predisposes to chronic kidney disease. We showed before increased circulating ACE2 and ACE in diabetic male mice. We study gender differences and effect of diabetes and gonadectomy(GDX) in circulating ACE2 and ACE in STZ-induced mice.

**Methods:** Study groups:Control and diabetic females(fCONT,fDB),males(mCONT,mDB) and GDX males(mCONT-GDX,mDB-GDX).GDX was performed 12 days after STZ injection.At the end of the study(19wks postSTZ) blood glucose(BG),body weight,kidney/body weight,blood pressure and urinary albumin excretion(UAE) were measured.Serum ACE2 and ACE activity were determined by fluorometric assays.

**Results:** Hyperglycemia was observed in STZ groups.BG was significantly higher in males as compared to females.GDX significantly decreased BG in mDB(298.3±17.0 vs 431.5±21.8mg/dL; p<0.05).ACE2 and ACE in fDB and mDB were increased as compared to controls.Male control mice showed significantly higher ACE2 and ACE than females. GDX resulted in significant reduction of ACE2(in both mCONT and mDB) and ACE(only in mDB).We found direct correlation between BG and ACE2 and ACE(r=0.6/r=0.5,p <0.01).

| | fCONT (n=11) | mCONT (n=18) | mCONT-GDX(n=7) | fDB(n=10) | mDB(n=9) | mDB-GDX (n=9) |
|---|---|---|---|---|---|---|
| ACE2(RFU/µl/h) | 60.0±4.8 | 75.4±4.4* | 50.9±1.6$ | 132.6±32.6& | 130.6±15.8& | 63.7±1.7$& |
| ACE(RFU/µl/min) | 1546.5±111.5 | 2143.9±133.4* | 1856.6±172.0 | 2279.7±181.9& | 2984.1±198.1*& | 2123.3±107.5$ |
| KW/BW(%) | 0.91±0.02 | 0.97±0.03* | 0.79±0.03$ | 1.44±0.08& | 1.32±0.06& | 0.89±0.02$& |
| SBP(mmHg) | 98.2±2.1 | 96.4±1.6 | 101.0±1.4$ | 106.0±3.8 | 97.6±1.9* | 97.8±1.7 |
| UAE(µgAlb/mgCrea) | 14.8±3.2 | 18.5±2.5 | 19.6±7.9 | 86.4±26.2& | 308.0±133.9*& | 22.2±5.6$ |
| p | *p<0.05vs.female;$p<0.05vs.male;&p<0.05vs.CONT | | | | | |

**Conclusions:** STZ injection increased BG and ACE2 and ACE activity in all experimental groups.GDX diminished BG and circulating ACE2 and ACE.Thus,increased levels of circulating ACE2 and ACE in diabetic male mice may be ascribed to a modulation of male sex hormones.

## TH-PO734

**Physiological and Pharmacological Concentrations of Angiotensin II Yield Distinct Differences in AT1 Receptor Signaling** Lena Scott,[1] Kristoffer Bernhem,[2] Hjalmar Brismar,[2] Anita Aperia.[1] *[1]Karolinska Institutet; [2]Royal Institute of Technology.*

**Background:** Studies on the desensitization of AT1R and the interaction between AT1R and calcium channels are generally done using pharmacological concentrations of angiotensin II (AngII).

**Results:** Here we show that repeated physiological AngII doses will, in contrast to the desensitizing effect of pharmacological AngII concentrations, result in an enhanced calcium response and a redistribution of AT1R receptors. We have recorded the $Ca^{2+}$ response to repeated doses of physiological (1 nM) and pharmacological (100 nM) Ang II in $AT_1R$ expressing HEK293a cells at (three time points) 0 min, following a 5 min and following an additional 30 min recovery. At 100 nM Ang II a significant desensitization was seen in response to the 2nd dose with partial recovery observed at the 3rd dose. At 1 nM Ang II no desensitization was observed to the 2nd dose, and the response to the 3rd dose was 2-fold enhanced. This enhanced response could be explained by increased recruitment of AT1R to the plasma membrane. To study redistribution of AT1R we used HEK293a cells expressing AT1R with an extracellular hemagglutinin tag and a C-terminus Venus tag. The ratio between the intensities from these two tags was 2.5-fold higher at the time of the 3rd dose of 1 nM Ang II as compared to base line expression. Voltage Gated Calcium Channels (VGCC) are therapeutical targets in hypertension and are partially controlled by angiotensin. We have investigated the effect of inhibiting VGCC with Nifedipine on AT1R calcium signaling. Nifedipine did not change the basal level of $[Ca^{2+}]$, but had a strong boosting effect on the $Ca^{2+}$ response to the first 1 nM Ang II dose. This was followed by a gradual desensitization to the 2nd and 3rd pulse.

**Conclusions:** In summary this study shows new aspects of the $AT_1R$ response to physiological angiotensin concentrations and will have several important clinical implications.

## TH-PO735

**The Imaging of Leakage of Red Blood Cells from Submucosal Capillary of the Bladder in Bladder Overdistension** Hideki Mizuno,[1,2] Tokunori Yamamoto,[2] Momokazu Gotoh.[2] *[1]Urology, National Hospital Organization Nagoya Medical Center, Nagoya, Japan; [2]Urology, Nagoya Univ Graduate School of Medicine, Japan.*

**Background:** We previously reported that the effect of tamsulosin on bladder microcirculation in a rat ischemia-reperfusion model, evaluated by pencil lens charge-coupled device microscopy system(Mizuno H et al Urology 2010). In the present study, to elucidate the causes of macrohematuria after bladder ischemia-reperfusion injury.

**Methods:** Changes in blood flow through a submucosal capillary of the rat bladder were measured during bladder filling using the PLCMS. One week after starting infusion of either physiological saline or tamsulosin, blood flow in the bladder was halted by bladder overdistension via an infusion of physiological saline. The bladder was then emptied to be reperfused with blood. Changes in blood flow through a submucosal capillary of the bladder during ischemia and reperfusion were measured using a PLCMS, and the data obtained for the control group and tamsulosin group were compared. Moreover, we investigated 56 cases who had a medical examination in our hospital because of acute urinary retention from September 2009 to August 2012.

**Results:** The leakage of red blood cells from capillary vessels in model rat of bladder ischemia-reperfusion injury could be clearly visualized using the PLCMS. The percentage of the leakage in the tamsulosin group decreased compared to the control group.

In acute urinary retention patients, average residual urinary volume were significantly increased in microhematuria(+) compared to microhematuria(-). The percentage of $\alpha_1$-Adrenoceptor antagonists treated patients was 13.3% in macrohematuria(+) and 42.9% in macrohematuria(-).

**Conclusions:** The PLCMS image showed that leakage of red blood cells from submucosal capillary of the bladder in bladder overdistension. The results of the present study suggest that tamsulosin hydrochloride protects the submucosal capillaries of the bladder from ischemic injury.

## TH-PO736

**Effect of Exercise Training on Angiotensin II, Sodium Excretion, and the Abundance of Sodium Transporters and Channels in Two-Kidney One-Clip Hypertensive Rats** Noreen F. Rossi, Bruce E. Linebaugh, Haiping Chen, Kevin B. Ginsburg, Robert A. Augustyniak. *Internal Medicine and Physiology, Wayne State Univ School of Medicine, Detroit, MI.*

**Background:** Two-kidney one-clip (2K1C) hypertension is characterized by elevated sympathetic tone. Efferent renal sympathetic nerves regulate renin-angiotensin (Ang) and Na reabsorption via norepinephrine actions at the macula densa and renal tubules. One mechanism whereby exercise training decreases mean arterial pressure (MAP) is by decreasing sympathetic output. We hypothesize that Na transporter/channel abundance will be increased in 2K1C rats and that exercise training will decrease mean arterial pressure (MAP), plasma Ang II, Na excretion and increase transporter abundance.

**Methods:** Six-week old sham-clipped (SC) and 2K1C rats were assigned to sedentary housing (standard cages. SED) or exercise training (cages with running wheels, EXT) and pair fed for 12 weeks. MAP was monitored by telemetry. GFR, UNaV and FENa were assessed by standard methods. Renal cortex was harvested, homogenized and Na transporters/channels analyzed by western blot.

**Results:** MAP was 133±3 mmHg in SC SED rats and did not change with EXT. In 2K1C rats, MAP was lower in 2K1C EXT 170±6 mmHg vs 2K-1C SED 191±10 mmHg, $p < 0.05$. Plasma Ang II in 2K1C EXT was 48.9 ± 7.5 fmol/ml which was similar to that in SC rats and lower than 2K1C SED 187.4 ± 43.6 fmol/ml, $p < 0.05$. UNaV and FENa were higher in the non-clipped kidney of 2K1C SED vs either SC SED or EXT groups. UNaV and FENa from the clipped kidney of 2K1C SED rats were similar to those of SC rats. Both clipped and non-clipped kidneys of 2K1C EXT rats had UNaV and FENa similar to SC SED and EXT rats, and were lower than 2K1C SED rats ($p < 0.05$). The abundance of cortical NaK-ATPase and NCC was higher in clipped vs non-sclipped kidneys. NaK-ATPase, 72 kD subunits of αENaC and γENaC and the 95 kD γENaC were increased in 2K1C EXT rats vs 2K1C SED.

**Conclusions:** Exercise training decreases arterial pressure and Ang II in 2K1C rats. 2K1C SED rats display pressure natriuresis. The expression of tubular Na transporters and channels is consistent with the urinary Na excretion pattern observed in sedentary and exercise trained 2K1C rats.

## TH-PO737

**Additive Renoprotective Effect of Renal Liver Type Fatty Acid Binding Protein on Angiotensin II Type 1a Receptor Loss in Renal Injury due to RAS Activation** Daisuke Ichikawa,[1] Atsuko Ikemori,[2] Yugo Shibagaki,[1] Takashi Yasuda,[1] Kenjiro Kimura.[1] *[1]Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Japan; [2]Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Japan.*

**Background:** The aim of this study was to assess the additive renoprotective function of renal human L-FABP (hL-FABP) on angiotensin II (Ang II) type 1a receptor (AT1a) loss in renal injury due to renin-angiotensin system (RAS) activation.

**Methods:** We established hL-FABP chromosomal transgenic mice ($Tg\text{-}AT1a^{+/+}$), crossed the $Tg\text{-}AT1a^{+/+}$ with AT1a knock down homo mice ($AT1a^{-/-}$), generated Tg-AT1a hetero mice ($Tg\text{-}AT1a^{+/-}$). After the back-cross of these cubs, $Tg\text{-}AT1a^{-/-}$ were obtained. In order to activate the renal RAS, wild type mice ($non\text{-}Tg\text{-}AT1a^{+/+}$), $Tg\text{-}AT1a^{+/+}$, $non\text{-}Tg\text{-}AT1a^{+/-}$, $Tg\text{-}AT1a^{+/-}$, $non\text{-}Tg\text{-}AT1a^{-/-}$ and $Tg\text{-}AT1a^{-/-}$ were administered high dose systemic Ang II infusion and were given a high salt diet for 28 days.

**Results:** In the $non\text{-}Tg\text{-}AT1a^{+/+}$, Ras activation ($non\text{-}Tg\text{-}AT1a^{+/+}$-Ras) caused hypertension and tubulointerstitial damage. In the $Tg\text{-}AT1a^{+/+}$-Ras, tubulointerstitial damage was significantly attenuated compared with non $Tg\text{-}AT1a^{+/+}$-Ras. In the AT1a partial ($AT1a^{+/-}$) or completed ($AT1a^{-/-}$) knock out mice, Ras activation led to a significantly lower degree of renal injury compared with $non\text{-}Tg\text{-}AT1a^{+/+}$-Ras or $Tg\text{-}AT1a^{+/+}$-Ras mice. Renal injury in $Tg\text{-}AT1a^{+/-}$-Ras mice was significantly attenuated compared with $non\text{-}Tg\text{-}AT1a^{+/-}$-Ras mice. In both $non\text{-}Tg\text{-}AT1a^{-/-}$-Ras and $Tg\text{-}AT1a^{-/-}$-Ras mice, renal damage was rarely found. The degrees of renal hL-FABP expression and urinary hL-FABP levels increased by Ras activation and gradually decreased along with reduction of AT1a expression levels.

**Conclusions:** Renal hL-FABP expression attenuated tubulointerstitial damage in addition to the renoprotective action depending on the decreasing in AT1a expression in the renal injury due to Ras activation.

### TH-PO738

**The Effect of Nifedipine and Captopril on the Production of Pro-Inflammatory Cytokines by Peripheral Blood Mononuclear Cells**
Gyu Tae Shin, Ka Young Jung, Eunjung Kang, Inwhee Park, Heungsoo Kim. *Dept of Nephrology, Ajou Univ School of Medicine, Suwon, Kyunggi, Republic of Korea.*

**Background:** In the present study, we investigated the effect of nifedipine and captopril on the production of tumor necrosis factor-alpha (TNF-alpha) and interleukin-6 (IL-6) by lymphocytes, monocytes and dendritic cells (MoDCs) derived from peripheral blood mononuclear cells (PBMCs).

**Methods:** PBMCs obtained from healthy volunteers (n = 20) were separated into lymphocytes and monocytes. Monocytes were cultured with GM-CSF and IL-4 to generate MoDCs. Lymphocytes were stimulated with ionomycin and phorbol myristic acetate and monocytes and MoDCs were stimulated with lipopolysaccharide to measure cytokines by ELISA and flow cytometry. The activation of mitogen activated protein kinases (p38, JNK, ERK) was measured by western blot. Throughout the experiment, 100 uM of nifedipine and 10 mM of captopril were used.

**Results:** In lymphocytes, TNF-alpha and IL-6 concentrations were significantly suppressed by nifedipine and captopril and notably the combined treatment of nifedipine plus captopril suppressed TNF-alpha significantly more than the monotherapy of each drug. In monocytes, similar results as seen in lymphocytes were observed for TNF-alpha, whereas only the combination treatment was effective in suppressing IL-6 production. In MoDCs, both TNF-alpha and IL-6 levels were significantly suppressed by captopril but not by nifedipine. Flow cytometry analysis showed that TNF-alpha expression in CD4 cells was significantly suppressed by nifedipine but not by captopril. In CD8 cells, TNF-alpha expression was significantly suppressed only by the combination treatment of both drugs but not by monotherapy of each drug. Western blot showed that p38 activity was significantly decreased by nifedipine but not by captorpil.

**Conclusions:** We first demonstrated that nifedipine and captopril exert differential effects in the suppression of TNF-alpha and IL-6 depending on the cell types of PBMCs and the combination treatment of both drugs has additive effects on the suppression of these cytokines. We also showed that the effect of nifedipine on these cytokines may be partly mediated by p38 MAPK pathways.

### TH-PO739

**Loss of *Gstm1* Alters Blood Pressure Homeostasis and Augments Angiotensin II-Induced Hypertension**
Thu H. Le, Rosa Chan, Sylvia Cechova. *Univ of Virginia.*

**Background:** *GSTM1* gene encodes an enzyme that belongs to a superfamily of glutathione-S-transferases that metabolize xenobiotic and a broad range of reactive oxygen species and electrophilic compounds formed as secondary metabolites during lipid peroxidation. *Gstm1* has been reported to be a positional and functional candidate gene for hypertension in spontaneously hypertensive stroke-prone (SHRSP) rats. We hypothesized that *Gstm1* may influence blood pressure (BP) regulation through its central role in modulating redox homeostasis. The objective of this study was to determine the response of *Gstm1* knockout (KO) mice to 2 models of hypertension that are mediated in part by oxidative stress: 1) high salt (HS) model, and 2) angiotensin II (Ang II) model.

**Methods:** *Gstm1-/-* (KO) mice were generated on the 129S6 background through conventional gene targeting strategy. Hypertension was induced using HS diet (6% NaCl) for 2 weeks or by infusion of Ang II via osmotic pump at dose 1000 ng/kg/min for 3 weeks. Systolic BP (SBP) at baseline and under HS condition was measured using radio-telemetry. Tail-cuff manometry was used to measure SBP in Ang II induced hypertension. Urinary isoprostane (index of oxidative stress) was measured using ELISA assay. For all studies, $n \geq 4$ per group.

**Results:** By radiotelemetry, *Gstm1* KO mice display a modest but significantly higher baseline SBP compared to their wild type (WT) littermates: KO: 138.8 ± 1.3; WT: 132.1 ± 1.1, $p < 0.01$. On HS diet, both WT and KO mice displayed salt sensitivity, and the difference in SBP was maintained between the two genotypes (KO: 148.7 ± 1.6; WT: 143.8 ± 1.3, $p < 0.05$). Urinary isoprostane (ng/100 mg of body weight) is significantly higher in KO mice than WT mice at baseline as well as during HSD (baseline: KO 15.1 ± 2.9; WT: 8.0 ± 0.8, $p < 0.04$; HSD: KO 27.2 ± 2.0; WT: 21.0 ± 1.3, $p = 0.04$). Ang II infusion augments the difference in SBP between WT and KO mice (185.0 ± 3.1; WT mice 175.4 ± 1.4, $p < 0.05$).

**Conclusions:** In an experimental setting, loss of GSTM1 enzymatic activity results in elevated baseline BP and augmented Ang II induced hypertension. The altered BP homeostasis from deficiency in GSTM1 may be mediated by a decreased capacity to handle oxidative stress.

*Funding:* NIDDK Support

### TH-PO740

**Kallikrein Kinin System and Blood Pressure Modulation by Aldosterone**
Pablo J. Azurmendi, Natalia Corbera, Ayelen R. Toro, Fernando Raul Ibarra, Rodolfo S. Martin, Elisabet Monica Oddo, Elvira Arrizurieta. *Lab. Riñón Experimental, IIM Alfredo Lanari, UBA-CONICET, Buenos Aires, Argentina.*

**Background:** Previous results have shown that after gonadectomy (Gx) kallikrein kinin system activity and mineralocorticoid levels increase in both, male and female SHR. A gender difference in urinary kallikrein activity (UKa) was also observed, being UKa higher in female rats.

**Methods:** To further explore the interaction between KKS activity and mineralocorticoid levels, the effect of an inhibitor of Aldosterone receptor (Spironolactone, S) upon kallikrein synthesis (KLK), renal content (RC) and UKa was studied in 12 weeks old SHR, that were Gx at weaning. UKa and RC were measured using a chromogenic tripeptide substrate and KLK expresión by semiquantitative reverse transcription polymerase chain reaction (RT-PCR).

**Results:** UKa (nkat/d/gK) diminished in Gx rats after S treatment from 36.29±2.4 and 41.3±6.5 to 23.4±3.9 and 22.8±2.4 in male and female rats ($p<0.001$), respectively. RC (nkat/gK) instead, did not change in male and female Gx animals by the treatment (18.3±0.56 and 17.1±3.27 to 18.9±1.24 and 17.6±2.02, respectively). S treatment increased RC by 50% in Gx and intact male and female as well while UKa diminished. KLK diminished after S treatment in Gx male and female rats from 0.70±0.02 and 0.73±0.01 to 0.54±0.02 ($p<0.001$) and 0.68±0.03 (NS), respectively.

**Conclusions:** Present results suggests that Aldosterone allows the release of renal tissue kallikrein into urine, since, S treatment increases RK while diminishes UKa. This finding is less evident in Gx animals, as it is, KLK synthesis. This may indicate that sexual hormones could also contribute to KKS modulation.

**The Role of A1AR in Hypertension Induced by Hyperuricemia**
Lin Liu,[1] Jinling Hao,[1] Lanping Jiang,[1] Junping Fan,[2] Xuejun Zeng,[2] Xuewang Lee,[1] Limeng Chen.[1] *[1]Nephrology, Chinese Academy of Medical Science & Peking Union Medical College Hospital, Beijing, China; [2]Internal Medicine, Chinese Academy of Medical Science & Peking Union Medical College Hospital, Beijing, China.*

**Background:** Hyperuricemia is known as an independent risk factor of hypertension with renin activation. Adenosine and A1 adenosine receptor (A1AR) play an important role in tubuloglomerular feedback (TGF) and regulation of renin secretion. We aimed to investigate the possible role of A1AR in the hypertension induced by hyperuricemia.

**Methods:** Hyperuricemia in wild type (WT) and A1AR$^{-/-}$ mice was induced by gavage of 250 mg/kg/d oxonic acid. Arterial blood pressure and urine electrolyte excretion was determined.The expression of renin, α-SMA, COX2, and nNOS in the juxtaglomerular apparatus (JGA) was assessed by immunohistochemistry and confocal laser microscopy.

**Results:** Hyperuricemia was successfully induced in WT and A1AR$^{-/-}$ mice. SBP was increased in hyperuricemic WT mice (106.6 ± 7.4 vs. 114 ± 11 mmHg, $P$=0.017), accompanied by lower expression of nNOS in macula densa cells and higher expression of α-SMA in afferent arterioles. The percentage of renin-positive JGA was increased in hyperuricemic WT mice compared to control and allopurinol treated mice (31.0±6.3% vs. 16.8±6.3% and 19.1±4.7%, $P$=0.008 and 0.013, respectively). Urinary excretion of potassium and chloride was augmented in hyperuricemic mice. In contrast, A1AR$^{-/-}$ mice with similar elevation of serum uric acid did not show hypertension ($P$<0.05), thickening of afferent arteriole smooth muscle, or enhanced excretion of urine electrolytes.

**Conclusions:** A1AR may be involved in the hypertension induced by hyperuricemia. The mechanisms underlying this effect need to be studied further.

**Exenatide and Human Glucagon-Like Peptide-1 (7-36 Amide) Are Diuretic, Natriuretic, and Positive Inotropes**
Melanie K. Shadoan,[1] Donald L. Anderson,[1] Mary J. Numerick,[2] Neetu Rajpal,[1] Jane G. Binz,[1] Sharon Y. Weng,[1] Shane G. Roller,[1] Mandy L. Bergquist,[3] Andrew A. Young.[1] *[1]Metabolic and Cardiovascular Therapeutic Area, GlaxoSmithKline, Research Triangle Park, NC; [2]Laboratory Animal Science, GlaxoSmithKline; [3]Quantitative Sciences, GlaxoSmithKline.*

**Background:** We have developed a comprehensive *in vivo* screen in the anesthetized rat to simultaneously measure multiple renal, cardiovascular and pharmacokinetic properties of test agents.

**Methods:** Inulin (for glomerular filtration rate; GFR), para-amino hippurate (for renal plasma flow; RPF), and test article were continuously infused intravenously (jugular) via 4-way adapter at 3.5 mL/hr. Arterial blood samples and pressure (MAP and total peripheral resistance; TPR, derived from τ) were obtained via Ohmeda pressure transducer. The left ureter was cannulated for timed urine collections, and snares are placed around renal vessels for each kidney for ligation (acute nephrectomy) at desired timepoint.

**Results:** Administration of exenatide (5 nmol/hr) or human glucagon-like peptide-1 (7-36) amide (GLP-1, 50 nmol/hr) increased excretion of $Na^+$ and clearance of free water. Hemodynamic changes included reduced peripheral resistance, increased inotropy, increased

mean arterial pressure (MAP) and increased heart rate (HR). Pharmacokinetic analysis showed that exenatide concentrations in plasma substantially increased following renal ligation, affirming predominantly renal clearance of this peptide.

| | Urine Flow | $Na^+$ Excretion | Free Water Clearance | GFR | RBF | Peripheral Resistance | Inotropy | MAP | HR |
|---|---|---|---|---|---|---|---|---|---|
| Exenatide | ↑23 X | ↑70 X | ↑82 X | ↑30% | ↑3 X | ↓24% | ↑67% | ↑28% | ↑32% |
| GLP-1 | ↑24 X | ↑144 X | ↑54% | ↔ | ↔ | ↓37% | ↑48% | ↑49% | ↑37% |

**Conclusions:** This protocol allows collection of over 120 physiological cardiorenal and pharmacokinetic parameters in association with intravenous administration of test agents.

### Impact of Proton-Pump Inhibitors and Diuretics on the Risk of Hypomagnesemia in Patients Admitted to the Emergency Department

Spyridon Arampatzis,[1,2] Markus Mohaupt,[1] Alexander Benedikt Leichtle,[3] Andreas Pasch,[1] Aristomenis K. Exadaktylos,[2] Gregor Lindner.[2] *[1]Dept of Nephrology, Hypertension and Clinical Pharmacology, Inselspital, Univ of Bern, Bern, Switzerland; [2]Dept of Emergency Medicine, Inselspital, Univ of Bern, Bern, Switzerland; [3]Center of Laboratory Medicine, Univ of Bern, Bern.*

**Background:** The aim of this study was to evaluate the risk of hypomagnesemia under concomitant use of proton pump inhibitors (PPIs) and diuretics and explore the role of hypomagnesemia as a risk factor for adverse outcome in a cohort of emergency department (ED) patients.

**Methods:** Cross-sectional study in 4,919 patients who presented to a large tertiary care ED between 01 January 2009 and 31 December 2010 with measurements of serum magnesium on admission. Hypomagnesemia was defined as serum magnesium concentration of <0.75 mmol/L. Demographic data, electrolyte disorders, data on medication, morbidities and outcome in terms of length of hospital stay and mortality were documented.

**Results:** The mean serum magnesium concentration was 0.81 mmol/L (SD 0.1); 1,195 patients (24%) showed hypomagnesemia on admission. Magnesium levels tended to be lower in patients under diuretic and PPI medication and were significantly lower in subjects taking both drugs ($p<0.001$). Use of loop diuretics ($p=0.002$) and thiazide diuretics ($p=0.02$) was a predictor for hypomagnesemia. In multivariable regression analyses, PPIs (OR 1.7, $p<0.0001$), diuretics (OR 1.3, $p<0.011$) and the presence of diabetes mellitus (OR 2.6, $p<0.0001$) were independently associated with hypomagnesemia. While mortality was not increased in patients with hypomagnesemia alone ($p=0.83$), patients with concomitant hypokalemia had a significantly higher mortality rate ($p=0.03$).

**Conclusions:** Hypomagnesemia is common in patients presenting to the ED and is associated with use of PPIs, diuretics, and the presence of diabetes. Hypomagnesemia with concomitant hypokalemia was an independent predictor of in-hospital mortality.

## TH-PO744

### Mutations in *PCBD1* Are Associated with Hypomagnesemia, Renal Magnesium Wasting and MODY

Jeroen H.F. De Baaij, Silvia Ferrè, Joost Hoenderop, René J. Bindels. *Dept of Physiology, Radboud Univ Nijmegen Medical Centre, Nijmegen, Netherlands.*

**Background:** Mutations in *PCBD1* are causative for transient neonatal hyperphenylalaninemia and primapterinuria (HPABH4D). Until now HPABH4D has been regarded as a transient and benign neonatal syndrome without complications in adulthood.

**Methods:** We assessed 3 patients with PCBD1 for blood magnesium levels and diabetes. Expression levels and localization of PCBD1 in mouse kidney and pancreas was evaluated. Moreover, the ability of PCBD1 wild type and PCBD1 mutants to co-activate the FXYD2 promoter was investigated by luciferase-reporter assays. Additionally, we examined the subcellular localization of PCBD1 wild type and mutants in HEK293 cells.

**Results:** In our study, two adult patients with homozygous mutations in the *PCBD1* gene were diagnosed with hypomagnesemia and renal $Mg^{2+}$ loss. One patient also developed diabetes with characteristics of maturity onset diabetes of the young (MODY). Our results suggest that these clinical findings are related to the function of PCBD1 as dimerization cofactor for the transcription factor HNF1B. Mutations in the *HNF1B* gene have previously been shown to cause renal malformations, hypomagnesemia and MODY. Gene expression analysis in the kidney showed that Pcbd1 is co-expressed with Hnf1b in the distal convoluted tubule (DCT) where *Pcbd1* transcript levels are upregulated by a low $Mg^{2+}$-containing diet. Overexpression in a human kidney cell line demonstrated that wild-type PCBD1 binds HNF1B to co-stimulate the *FXYD2*-promoter, whose activity is instrumental in $Mg^{2+}$reabsorption in DCT. Five out of seven *PCBD1* mutations previously reported in HPABH4D patients caused proteolytic instability leading to a reduced *FXYD2*-promoter activity. Furthermore, HNF1B mutations may disturb PCBD1 localization in the nucleus, since PCBD1 showed an increased cytosolic localization when co-expressed with HNF1B mutants.

**Conclusions:** Overall, our findings establish PCBD1 as an important co-activator of the HNF1B-mediated transcription necessary for fine-tuning of *FXYD2* transcription in DCT. Thus, patients with HPABH4D should be monitored for previously unrecognised late complications, such as hypomagnesemia and MODY diabetes.

## TH-PO745

### Characterization of Osteoclast-Specific NCX1 Knock-Out Mice

Daniel G. Fuster,[1] Olivier Bonny.[2] *[1]Div of Nephrology, Hypertension and Clinical Pharmacology, Univ of Bern, Bern, Switzerland; [2]Institute of Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland.*

**Background:** Bone is dissolved by a polarized cell, the osteoclast. Previous studies indicated that sodium/calcium exchanger (NCX) inhibitors decrease bone resorption in a dose dependent manner in vitro. In addition, siRNA-mediated knock-down of NCX1 significantly suppressed osteoclastic bone resorption in vitro, indicating a critical role of NCX1 in osteoclast-mediated bone resorption. To test the role of NCX1 in osteoclasts in vivo, we generated mice with osteoclast-specific deletion of NCX1.

**Methods:** Mice with a floxed exon 11 of NCX1 were crossed with mice expressing Cre-recombinase under the influence of the cathepsin K promoter to generate osteoclast-specific NCX1 knock-out mice (herein named NCX1 $^{\Delta OC/\Delta OC}$ mice).

**Results:** Osteoclasts differentiated from NCX1 $^{\Delta OC/\Delta OC}$ mice displayed a 80 % reduction of NCX1 mRNA and protein compared to wild-type mice. NCX2 was not expressed in osteoclasts. NCX3 was expressed a low levels in osteoclasts but was not upregulated in NCX1 $^{\Delta OC/\Delta OC}$ osteoclasts. NCX1 expression was unaltered in extraosseus tissues in NCX1 $^{\Delta OC/\Delta OC}$ mice. Structural bone parameters, analyzed by high-resolution microcomputed tomography (μCT) were not different in 12 week old male and female wild-type and NCX1 $^{\Delta OC/\Delta OC}$ mice. Similarly, no differences were observed when we assessed osteoclast differentiation or bone resorption in vitro of cells isolated from wild-type and NCX1 $^{\Delta OC/\Delta OC}$ mice, respectively. Finally, to stimulate osteoclast-mediated bone resorption, we performed surgical ovarectomy in 12 week old female mice. Ovarectomy-induced bone loss, however, was identical in wild-type and NCX1 $^{\Delta OC/\Delta OC}$ mice at 3,6, 9 and 12 weeks after the operation.

**Conclusions:** Thus, our data indicate that genetically induced deficiency of NCX1 in osteoclast-precursors and mature osteoclasts does not affect osteoclast differentiation and bone resorption in vitro. Furthermore, osteoclast-specific deletion of NCX1 seems not seem to affect bone volume in 12 week old mice or ovarectomy-induced bone loss in female mice until 12 weeks after the operation.

## TH-PO746

### Angiotensin II and PDGF Decrease the Phosphorus-Induced Calcification in Vascular Smooth Muscle Cells *In Vitro*

Carmen Herencia,[1] Maria Encarnacion Rodriguez ortiz,[1] Juan R. Muñoz-Castañeda,[1] Julio Manuel Martínez Moreno,[1] Rocio Canalejo,[2] Addy Rosa Montes de Oca Gonzalez,[1] Carmen Marin,[1] Antonio Canalejo,[2] Mariano Rodriguez,[3] Yolanda Almaden Peña.[1] *[1]IMIBIC, Spain; [2]Univ of Huelva, Spain; [3]Reina Sofia Univ Hospital.*

**Background:** High Phosphorus(HP) plays a key role in the pathogenesis of vascular calcification(VC), which occurs through a Wnt/β-catenin(BCTN) induced osteoblastic differentiation of vascular smooth muscle cells(VSMCs). The involvement of AngiotensinII(AII) and platelet derived growth factor(PDGF) in the development of VC is controversial.We evaluated the effect of AII and PDGF on VC in human VSMCs in vitro.

**Methods:** VSMCs were cultured with HP alone or supplemented with $10^{-5}$M AII or 20ng/ml PDGF for 9 days. Calcium deposition (spectrofotometry),osteogenic genes expression(RT-PCR) and BCTN nuclear translocation(confocal microscopy) were measured.

**Results:** High P induced calcification was associated with BCTN nuclear translocation. An increase in mRNA levels of BMP2,Runx2,Osterix and ALP was produced. AII and PDGF supplementation reduced calcification levels,osteoblastic genes expression and BCTN translocation. *p<0.05 vs control.#p<0.05 vs HP.

| | Calcif (μgrCa /mgrProt) | Nuclearβ catenin (D coef. Mander vs Control) | BMP2 (U.Ratio vs Control) | Runx2(U.Ratio vs Control) | OTX (U.Ratio vs Control) | ALP(U.Ratio vs Control) |
|---|---|---|---|---|---|---|
| **Control** | 0.55±0.05 | 1.0±0.03 | 1.0±0.08 | 1.0±0.06 | 1.0±0.04 | 1.0±0.08 |
| **HP** | 3.20±0.38* | 3.50±0.32* | 2.14±0.07* | 1.35±0.05* | 1.74±0.17* | 1.38±0.07* |
| **HP+AII** | 1.86±0.38# | 2.22±0.49# | 1.40±0.07# | 0.90±0.10# | 0.93±0.10# | 0.62±0.16# |
| **HP+PDGF** | 1.08±0.21# | 2.31±0.20# | 1.17±0.11# | 0.33±0.05# | 0.29±0.06# | 0.26±0.06# |

**Conclusions:** AII and PDGF decrease the Phosphorus-induced calcification in human VSMCs in vitro. This appears to be mediated by a reduction in osteogenic genes expression and an inhibition in Wnt/BCTN pathway.

## TH-PO747

### Calcium Salts Affect Acid-Base Balance by Stimulating Differently Type A and B Intercalated Cells in Mouse Kidney Collecting Ducts

Yukiko Yasuoka,[1] Yuichi Sato,[2] Hiroshi Nonoguchi,[3] Katsumasa Kawahara.[1] *[1]Physiol., Kitasato U. Sch. of Med, Sagamihara, Japan; [2]Mol. Diag., Kitasato U. Grad. Sch. of Med. Sci., Sagamihara, Japan; [3]Internal Med., Kitasato U. Medical Center, Kitamoto, Japan.*

**Background:** Calcium salts (calcium carbonate (CaC) and calcium phosphate (CaP)) are widely used for patients with chronic kidney disease (CKD) and osteoporosis. These salts have the potential to affect acid-base balance via the Ca-sensing receptor (CaSR) expressed in type B intercalated cell (IC-B) of the collecting ducts (Yasuoka Y, ASN meeting, 2011).

**Methods:** C57Bl/6J mice (10 weeks, male) fed with different Ca supplements and acid-base conditions (+2.5% $NH_4Cl$ diet and +0.28 M $NaHCO_3$ drinking) for 6-7 days. By using a quantitative in situ hybridization technique, we evaluated the levels of expression

of anion exchanger type 1 (AE1), Pendrin (an apical $HCO_3^-/Cl^-$ exchanger), and CaSR along the collecting duct. Blood and urine samples were also analyzed.

**Results:** Plasma Ca concentration and urinary Ca excretion increased slightly, but not significantly in mice with 2.5% CaC (n=7) and 2.5% CaP diets (n=8). In contrast, these measurements significantly increased from 7.7 to 9.9 (mg/dl) and from 0.12 to 3.21 (mg/d) in mice with 2% $CaCl_2$ diet (n=12). In addition, urine pH significantly decreased from 6.73 to 5.78 ($CaCl_2$), increased from 6.58 to 7.72 (CaC), and was unchanged (CaP). In IC-A, as expected, the level of the AE1 mRNA expression (an index of acid excretion) increased, decreased, and remained unchanged, respectively, in mice with $CaCl_2$, CaC, and CaP supplements. On the other hand, in IC-B, the levels of the pendrin (an index of alkali excretion) and CaSR mRNAs expression decreased due to acidosis caused by the $CaCl_2$ containing diet, whereas they increased in mice showing normal plasma pH consuming CaC and CaP diets.

**Conclusions:** These data strongly suggest that CaC may work as an alkali as well as a Ca supplement, and may increase urinary alkali excretion by stimulation of pendrin mediated by basolateral CaSR in IC-B. Therefore CaC may be the best Ca supplement for patients with CKD and osteoporosis with regards to Ca metabolism and acid-base balance.

## TH-PO748

**β1-Adrenergic Receptor Signaling Activates the Epithelial Calcium Channel, TRPV5, via the Protein Kinase A Pathway** Kukiat Tudpor, Eline A.E. Van der Hagen, Sjoerd Verkaart, René J. Bindels, Joost Hoenderop. *Physiology, Radboud Univ Nijmegen Medical Centre, Nijmegen, Netherlands.*

**Background:** Epinephrine (Epi) and norepinephrine (NE) are present in the pro-urine. β-adrenergic receptor (β-AR) blockers administered to counteract sympathetic overstimulation in patients with congestive heart failure (CHF). Even though Epi and NE are secreted in the pro-urine no effects of these hormones through signaling via β-ARs on renal active $Ca^{2+}$ transport have been reported. Active $Ca^{2+}$ reabsorption in the late distal convoluted and connecting tubules (DCT2/CNT) is initiated by $Ca^{2+}$ influx through the transient receptor potential vanilloid type 5 (TRPV5) $Ca^{2+}$ channel.

**Methods:** Expression levels and localization of β-adrenergic receptors was investigated in mouse kidney by immunohistochemistry and DCT2/CNT were isolated using the COPAS technology. TRPV5 was expressed in HEK293 cells and the intracellular $Ca^{2+}$ concentration was monitored by spectrofluorometry using Fura-2AM. Cell surface expression of TRPV5 was addressed using biotinylation assays.

**Results:** Although it was reported that β-ARs are present in the DCT2/CNT region, their role in active $Ca^{2+}$ reabsorption remains elusive. Here we revealed that β1-AR, but not β2-AR is colocalized with TRPV5 in DCT2/CNT. Treatment of TRPV5-expressing mouse DCT2/CNT primary cell cultures with the β1-AR agonist dobutamine showed enhanced apical-to-basolateral transepithelial $Ca^{2+}$ transport. In human embryonic kidney (HEK293) cells, dobutamine was shown to stimulate cAMP production, signifying functional β1-AR-expression. Fura-2 experiments demonstrated increased activity of TRPV5 in response to dobutamine, which could be prevented by the PKA inhibitor H89. Moreover, non-phosphorylable T709A-TRPV5 and phosphorylation-mimicking T709D-TRPV5 mutants were unresponsive to dobutamine. Surface biotinylation showed that dobutamine did not affect plasma membrane abundance of TRPV5.

**Conclusions:** In conclusion, activation of β1-AR stimulates active $Ca^{2+}$ reabsorption in DCT2/CNT by increased TRPV5 activity via PKA phosphorylation of residue T709 possibly. These data may suggest a calciotropic role in addition to the inotropic property of the β1-AR.

*Funding:* Government Support - Non-U.S.

## TH-PO749

**The Pathophysiology of Aortic Calcification in an In Vitro Model: The Role of Mineral Imbalance** Navid Shobeiri,[1] Julie Cruanes,[1] Rachel M. Holden,[2] Michael A. Adams.[1] *[1]Dept of Biomedical and Molecular Sciences, Queen's Univ, Canada; [2]Medicine, Queen's Univ, Canada.*

**Background:** Vascular calcification (VC) is accelerated in patients with chronic kidney disease (CKD), resulting in increased risk of cardiovascular disease and mortality. Mineral imbalance in CKD contributes to this process, and elevated phosphate is a major risk factor.

**Methods:** An in vitro model of VC was developed to determine the impact of bone minerals (phosphate, magnesium, calcium). Aortas were incubated in pro-calcification DMEM media with or without elevated magnesium. Calcification was assessed by tissue calcium (Ca) levels and visualized with von Kossa staining.

**Results:** The degree of calcification was dependent on time-course and phosphate concentration. Aortic rings calcified in media phosphate concentrations above 3.0mM (>25fold increase in Ca), however elevated calcium media did not cause calcification. Aortas in 3.8mM phosphate media demonstrated accumulation of calcium at day 2 (78.2±17.2nmol/mg), but an accelerated accumulation by day 4 (528.9±62.4nmol/mg). This calcification was associated with the tunica media (histology). Increasing the media magnesium levels (0.8mM to 2.5mM) blunted tissue calcification significantly (□93±4%, p<0.05). Delaying 2.5mM magnesium treatment continued to be effective if the increase occurred prior to day 4 of a 6 day incubation period (addition of magnesium at day 2 □66±14% and day 3 □35±49%tissue Ca). Two day pretreatment with 2.5mM magnesium also prevented calcification. That is, incubation of these vessels for only 2 days in high magnesium prevented *de novo* calcification when transferred to pro-calcification media without high magnesium (+4 days) (10.5±1.3nmol/mg vs 175.5±28.9nmol/mg tissue Ca, p<0.5). Consequently, tissue magnesium remained elevated at day 6 (12.6±1.2nmol/mg vs 2.4±.8nmol/mg, p<0.05).

**Conclusions:** Elevated phosphate appears to be a key signal in the development of pathological calcification. This process is blocked by magnesium, but only if calcification has not already begun.

## TH-PO750

**Estrogen Directly Downregulates NaPi-IIa through the Activation of Both Estrogen Receptor Isoforms (ERα and ERβ) in Rat Kidney Proximal Tubule** Hassane Amlal,[1] Rose P. Webster,[1] Rashma Faroqui,[1] Moshe Levi,[2] Sulaiman Sheriff.[3] *[1]Internal Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Internal Medicine, Univ of Colorado, Denver, CO; [3]Dept of Surgery, Univ of Cincinnati, Cincinnati, OH.*

**Background:** Estrogen depletion in postmenopausal women is associated with hyperphosphatemia. We have demonstrated that 17β-estradiol (EST) downregulates NaPi-IIa and causes phosphaturia and hypophosphatemia in ovariectomized (OVX) rats. However, the signaling mechanism(s) mediating this effect remain unknown.

**Methods:** The expression of ERα and ERβ in the proximal tubule (PT) was examined using RT-PCR. The respective roles of these receptors in EST-induced downregulation of NaPi-IIa were studied using OVX rats placed in metabolic cages and treated with specific agonists of either ERα (PPT) or ERβ (DPN). A cell line (U20S) stably expressing ERα or ERβ or both under doxycycline control and transiently transfected with rat NaPi-IIa was also used. In these cells, ERα and ERβ are expressed in a functional ERα/β heterodimers.

**Results:** RT-PCR data indicate that both ERα and ERβ are expressed in the cortex and PT cells. PT suspensions harvested from OVX rats and incubated on a shaker in a cell culture incubator for 24hrs exhibited a significant downregulation of NaPi-IIa expression (RNA + protein) in the presence of EST vs. vehicle. Treatment of OVX rats with either PPT or DPN alone did not affect NaPi-IIa expression and did not cause phosphaturia. However, combined treatment with PPT+DPN mimicked the effect of estrogen and caused a sharp downregulation of NaPi-IIa along with significant phosphaturia. U20S cells expressing both ERα and ERβ showed a significant downregulation of NaPi-IIa protein in response to EST vs. vehicle only when pre-treated with doxycycline. Interestingly, NaPi-IIa protein abundance was not altered by EST in U20S cells bearing either ERαor ERβ alone.

**Conclusions:** These studies demonstrate that rat PT cells express both ERα and ERβ and that EST downregulates NaPi-IIa by directly acting on PT cells. This effect is mediated via a complex mechanism involving the activation, and likely heterodimerization of ERα and ERβ.

*Funding:* NIDDK Support

## TH-PO751

**Estrogen Downregulates NaPi-IIa in Mice Kidney through a Mechanism Involving the Activation of Estrogen Receptor Isoform α (ERα) and 3'UTR Region of NaPi-IIa mRNA Transcript** Hassane Amlal,[1] Sulaiman Sheriff,[2] Rashma Faroqui,[1] Rose P. Webster.[1] *[1]Internal Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Internal Surgery, Univ of Cincinnati, Cincinnati, OH.*

**Background:** 17b-estradiol (EST) downregulates NaPi-IIa mRNA and protein and causes phosphaturia in rats likely by activating both EST receptor isoforms ERα and ERβ (published report and accompanying abstract). To confirm these findings, we sought to study the effect of EST on NaPi-IIa using mice with genetic deletions of ERα or ERβ.

**Methods:** Females ERα knockout (KO), ERβ KO and their wild-type (WT) mice were placed in metabolic cages with free access to food and water and treated with EST or its vehicle for 3 days. Food and water intake, urine volume and urinary Pi excretion were measured daily. A cell line (U20S) stably co-expressing both ERα and ERβ under doxycycline control and transiently transfected with different mouse NaPi-IIa constructs (mNaPi-IIa) was also used. Molecular studies examined the expression of NaPi-IIa in the kidney or U20S cells.

**Results:** Like rats, EST-treated WT mice exhibited a significant reduction in food intake along with increased renal phosphate wasting. However, unlike rats, the phosphaturic effect of EST resulted from a sharp downregulation of NaPi-IIa protein without affecting its mRNA expression levels. Interestingly, EST-induced phosphaturia and downregulation of NaPi-IIa protein were also observed in ERβ KO but not in ERα KO mice. U20S cells expressing ERα and ERβ treated with EST for 24hrs showed a significant downregulation of NaPi-IIa protein abundance when transfected with a plasmid containing ORF-3'UTR but not 5'UTR-ORF of mNaPi-IIa transcripts. This effect is observed only when cells were pre-treated with doxycycline.

**Conclusions:** EST causes phosphaturia in mice despite a reduction in food intake. This effect results from the downregulation of NaPi-IIa protein abundance with no change in its mRNA expression levels, and is mediated through the exclusive activation of ERα. A cis-acting element in the 3'UTR region of mNaPi-IIa mRNA likely plays an important role in the inhibition of its translation by EST.

*Funding:* NIDDK Support

## TH-PO752

**Conditionally Immortalized Human Proximal-Tubular Epithelial Cells Isolated from the Urine of a Healthy Subject Express Functional Calcium-Sensing Receptor (CaSR)** Annarita Di Mise,[1] Grazia Tamma,[1] Marianna Ranieri,[1] Maria Svelto,[1] Elena N. Levtchenko,[2] Giovanna Valenti.[1] *[1]Dept Biosciences, Biotechnologies and Biopharmaceutics, Univ of Bari, Bari, Italy; [2]Dept of Pediatric Nephrology, Univ Hospital Gasthuisberg, Leuven, Belgium.*

**Background:** The calcium-sensing receptor (CaSR) is a G protein coupled receptor, which plays an essential role in regulating $Ca^{2+}$ homeostasis.

Here we show that conditionally immortalized proximal tubular epithelial cell line (ciPTEC) obtained by immortalizing and subcloning cells exfoliated in the urine of a healthy subject expresses functional endogenous CaSR.

**Methods:** Primary cells isolated from human urine sediment were infected with SV40T and hTERT vectors. Subconfluent cell layers were transferred to 33°C and selected by antibiotics for 15 days. Cells were subcloned and expanded to 70% confluence at 33°C. After maturation at 37°C for 10 days, the cloned cells were used.

**Results:** The obtained ciPTEC cells expressed ZO-1 protein and aquaporin 1 thus confirming their epithelial and PT origin respectively. The expression of the endogenous CaSR in ciPTEC was confirmed by Western blotting revealing the immunodetection of both forms at 130 and ~200 kDa, corresponding to the monomeric and mature receptor. Of note, functional studies with Fura2-AM indicated that the physiological agonist, calcium ($Ca^{2+}$), and the calcimimetic NPS-R568, induced a significant increase in cytosolic calcium, proving a high sensitivity of the endogenous receptor to low concentrations of its agonists. Cytosolic calcium levels were 46.2±2.22% (vs ATP 100%) after stimulation with 2.5µM $Ca^{2+}$ and to the 37±1.76% (vs ATP 100%) after stimulation with 2.5µM NPS-R568. Calcium depletion from the ER using CPA (cyclopiazonic acid) abolished the increase in cytosolic calcium elicited by NPS-R568 confirming the origin of calcium exit from intracellular stores.

**Conclusions:** We conclude that human proximal tubular ciPTEC cells express functional CaSR and respond to its activation with a release of calcium from the ER. These cell lines represent a valuable tool for research into the disorder associated with gain or loss of function of the CaSR by producing cell lines from patients.

### TH-PO753

**Deranged Phosphate Metabolism, Intestinal $Na^+$ Loss, and Volume Depletion in Janus Kinase 3-Deficient Mice** Michael Föller, Anja Umbach, Dong Luo, Bingbing Zhang, Hajar Fahkri, Zohreh Hosseinzadeh, Shefalee Bhavsar, Bernd Pichler, Florian C. Lang. *Univ of Tübingen.*

**Background:** Janus kinase JAK3 participates in the triggering of dendritic cell apoptosis. Lack of JAK3 increases the abundance of dendritic cells and triggers inflammatory bowel disease. Dendritic cells and macrophages express 1 hydroxylase and may thus generate $1,25(OH)_2D_3$, a major regulator of phosphate metabolism. Inflammatory bowel disease is in addition known to affect colonic ENaC activity leading to salt loss. The present study thus analyzed the impact of JAK3 deficiency on $1,25(OH)_2D_3$ formation, phosphate metabolism, extracellular volume and blood pressure.

**Methods:** Gene-targeted mice lacking functional JAK3 ($jak3^{-/-}$) were compared to wild type mice ($jak3^{+/+}$). Serum $1,25(OH)_2D_3$, PTH, FGF23 and aldosterone concentrations were determined by immunoassays, serum, fecal and urinary phosphate and $Na^+$ utilizing photometry, colonic ENaC activity by Ussing chamber experiments and blood pressure by the tail cuff method.

**Results:** $1,25(OH)_2 D_3$ and FGF23 plasma levels were significantly higher in $jak3^{-/-}$ mice than in $jak3^{+/+}$ mice. Intestinal phosphate absorption as well as absolute and fractional renal phosphate excretion were higher in $jak3^{-/-}$ mice than in $jak3^{+/+}$ mice. Bone density was not different between the genotypes. Colonic ENaC activity was reduced in $jak3^{-/-}$ mice resulting in fecal $Na^+$ loss and reduced blood pressure despite compensatory aldosterone release and renal $Na^+$ retention.

**Conclusions:** JAK3 deficiency causes profound derangement of phosphate metabolism and decreased colonic ENaC activity which results in compromised extracellular volume maintenance and in arterial hypotension.

### TH-PO754

**VS-501, a Novel Phosphate Binder, Is Highly Efficacious in 5/6 Nephrectomized Hyperphosphatemic Rats** J. Ruth Wu-Wong, Yung-Wu Chen, Jerry Wessale. *Vidasym.*

**Background:** Inadequate control of serum phosphate in chronic kidney disease (CKD) can lead to pathologies of clinical importance including cardiovascular complications, renal osteodystrophy, and increased mortality. On-market phosphate binders are mainly used in dialysis patients, but their effectiveness is limited by safety concerns and low compliance due to high pill burden and gastrointestinal (GI) discomfort. VS-501 is a proprietary, non-absorbed, calcium- and aluminum-free, chemically-modified, plant-derived compound that effectively adsorbs phosphate in the GI tract.

**Methods:** The 5/6 nephrectomized (NX) male Sprague Dawley rats with established uremia (as indicated by elevated serum creatinine and BUN) were fed a high-phosphate diet (normal diet plus $KH_2PO_4$ at 0.67% and $K_2HPO_4$ at 0.33% by dry weight) with or without VS-501 or sevelamer carbonate added to food for 4 weeks.

**Results:** Increasing dietary phosphate led to an increase in serum phosphate (3.26 ± 0.10 to 3.63 ± 0.13 mmol/L, $p<0.05$) in the group treated with vehicle (unmodified polymer), but no significant changes in serum phosphate were observed in rats treated with VS-501 or sevelamer carbonate at 0.2 – 2%. Hypophosphatemia was observed in rats treated with 5% VS-501 or sevelamer. Urinary phosphate increased from 73 ± 20 to 687 ± 45 µmol/24 hr ($p<0.001$) in the vehicle-treated group; VS-501 or sevelamer (0.02 - 5% in food) reduced urinary phosphate in a dose-dependent manner. VS-501's density is about two-fold higher than that of sevelamer, suggesting a significantly reduced pill size. VS-501 exhibits a low swelling volume when exposed to simulated gastric fluid, a feature likely to mitigate GI discomfort. For example, on adding 5 ml of simulated gastric fluid to 0.1 g (dry powder) of VS-501 or sevelamer, the volume of sevelamer increased to ~4 $cm^3$ (~21-fold) within 20 min at 37°C, but the volume of VS-501 increased to only ~0.2 $cm^3$ (~2-fold).

**Conclusions:** These results strongly support the conclusion that VS-501 effectively controls serum phosphate levels by adsorbing phosphate in the GI tract with minimal swelling volume. VS-501 exhibits a compelling product profile suitable for clinical development as a medical food or prescription drug.

### TH-PO755

**Lanthanum Carbonate: Safety Data after 9 Years** Marc E. De Broe,[1] Rosamund J. Wilson,[2] J. Brian Copley.[3] *[1]Dept of Nephrology, Antwerp Univ, Antwerp, Belgium; [2]Spica Consultants, Marlborough, United Kingdom; [3]Shire Pharmaceuticals, Wayne, PA.*

**Background:** Concerns over the safety of lanthanum carbonate (LaC) are based on fears that long-term La intake may result in accumulation and toxicity in the GI tract, bone, liver, and CNS. The aim of this abstract is to summarize key data from the ongoing clinical development program pertaining to the long-term safety profile of LaC.

**Methods:** Shire PV and Risk Management performs continuous signal detection and monitoring of safety data from worldwide sources for all Shire products, including LaC. SPD405-402 (NCT00557323) is a 5-year observational study with the purpose of collecting safety data on subjects with up to 6 years of treatment with LaC.

**Results:** As of January 2013, estimated worldwide patient exposure to LaC amounts to 497,762 person-years and over 6000 patients in phase 2–4 clinical studies. Pre-clinical and clinical studies of LaC have demonstrated strong evidence of efficacy and safety, confirmed by 9 years of post-marketing monitoring. **GI tract.** The majority of LaC ADRs are related to the GI tract, but are primarily mild/moderate in severity. SPD405-402 does not suggest any change in the GI safety profile of LaC. **Bone.** Bone biopsy studies out to 5 years showed no evidence of aluminium-like accumulation or toxicity, and improved bone formation rates and histology. SPD405-402 showed that long-term LaC use is not associated with bone fracture. **Liver.** Patients treated with LaC for up to 6 years showed no clinically relevant changes in liver enzymes or bilirubin levels; and no increase in the incidence of liver-associated AEs. SPD405-402 does not suggest a change in the hepatic safety profile of LaC. **CNS.** Animal toxicology studies demonstrated that La does not cross the intact blood-brain barrier. Clinical data show no evidence of an effect of LaC on cognitive function.

**Conclusions:** After ~500,000 person-years of exposure, there is no evidence at this time that LaC is associated with adverse safety concerns in the GI tract, bone, or liver; or that La crosses the intact blood-brain barrier. GI tract ADRs seen with LaC are mild/moderate and consistent with those observed with other phosphate binders.

### TH-PO756

**Double-Blind, Dose-Ranging, Study of Lanthanum Dioxycarbonate (SPI-014, RenaZorb) in Healthy Volunteers Shows High Phosphorus Binding Capacity** William F. Finn,[1] Cynthia J. Denu-Ciocca,[2] Melanie S. Joy,[3] Guru Reddy,[4] Shanta Chawla,[4] Armando Garsd,[4] Ronald Goldwater.[5] *[1]Consultant, Chapel Hill, NC; [2]Univ of North Carolina, Chapel Hill, NC; [3]Univ of Colorado, Denver, CO; [4]Spectrum Pharmaceuticals, Irvine, CA; [5]Parexel International, Baltimore, MD.*

**Background:** Hyperphosphatemia continues to be a significant issue among dialysis patients - partly related to the limited phosphorus binding capacity of available agents. Lanthanum dioxycarbonate (SPI-014, RenaZorb), a second generation lanthanum-based phosphate binder, is in development for the treatment of hyperphosphatemia in these patients. Preliminary studies have shown an excellent phosphorus binding profile.

**Methods:** To determine the pharmacodynamic (PD) and pharmacokinetic (PK) parameters of SPI-014, healthy subjects were placed on a phosphorus controlled diet and randomized 3:1 to receive SPI-014 or placebo in 4 sequential cohorts of 8 subjects each. SPI-014 doses were: 1500, 3000, 4500, and 6000 mg/day (p.o. in 3 divided doses within 15 minutes pc). 24-hour urine and feces samples were collected at baseline and on-treatment to determine phosphorus content. PD of SPI-014 was evaluated by comparing changes from baseline in urine and fecal phosphorous excretion. PK samples were collected at pre-specified time points.

**Results:** Enrolled subjects (N=32) were healthy, predominately African American (n=21) and male (n=26) with median age of 40 years (range 22-61). Compared to placebo, all 4 doses of SPI-014 significantly reduced daily urinary phosphorous excretion. The reductions in urine phosphorus (mean; 95% CI) were 202 (24, 380), 350 (172, 528), 420 (242, 598), 441 (263, 619) mg/24 hours for SPI-014 doses of 1500, 3000, 4500 and 6000 mg/day, respectively. Increased fecal phosphorous excretion compared to baseline was observed at each dose. Systemic absorption of lanthanum was negligible.

**Conclusions:** SPI-014 resulted in a statistically significant reduction in daily urinary phosphorous in a dose-related fashion concomitant with increased fecal phosphorus excretion. The pharmacodynamics profile suggests that the binding capacity of SPI-014 exceeds that of currently available agents.

### TH-PO757

**Barriers and Facilitators to Dialysis Patient Self-Management of Phosphate Binders** Teri Browne,[1] Joseph R. Merighi,[2] Tamara Savage,[1] Diana Clynes,[3] Kerri L. Cavanaugh.[4] *[1]College of Social Work, Univ of South Carolina, Columbia, SC; [2]School of Social Work, Univ of Minnesota, Minneapolis, MN; [3]American Association of Kidney Patients, Tampa, FL; [4]Div of Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.*

**Background:** Dialysis patients encounter difficulties self-managing their medication regimes, in particular phosphate binders that make up the majority of patient pill burden. It is critically important to identify ways that dialysis professionals can help patients self-

manage their phosphate binder medications to improve patient outcomes. To achieve this goal, a qualitative study was conducted to pinpoint dialysis patient-centered facilitators and barriers to phosphate binder self-management.

**Methods:** Primary data were gathered from five, 90-minute, small-group interviews with hemodialysis patients (N = 17) in Atlanta, GA. The majority of patients were female (70%), African American (76%), had a dialysis vintage = 87 months (SD=59), and a daily pill burden of 16 pills (SD=13). A constant comparative method was used to identify themes that emerged from a line-by-line review of the interview transcripts.

**Results:** Participants identified three facilitators to self-managing their phosphate binders: social support; placing binders in multiple locations; and seeing images that depict health consequences associated with high serum phosphorus. Patients also identified three main barriers to self-management of phosphate binders: financial burden of medications, privacy concerns about taking medications in a public setting, and medication regimen complexity.

**Conclusions:** The study findings provide the basis for the development of future research and targeted interventions that can improve patient self-management of phosphate binders and improve dialysis patient health outcomes.

## TH-PO758

### At What Stage of CKD Phosphate Binder Treatment Should Be Started?

Juergen Bommer,[1] Martina Fliser,[2] Heinz Juergen Roth,[2] Daniel Saure.[3] *[1]Medical Univ Hospital Heidelberg, Dialysis Center Heidelberg, Heidelberg, Germany; [2]Limbach Laboratory, Heidelberg, Germany; [3]Institute of Medical Biometry and Informatics Univ Heidelberg, Heidelberg, Germany.*

**Background:** Disturbed mineral metabolism plays a major role in vascular calcification followed by an increased mortality. The constant serum P concentration until eGFR decreases to about 30 ml/dl was explained by increasing phosphaturic effect of increasing PTH and FGF 23 in patients with progressing renal failure. Recently an increased vascular calcification {CAC} score was reported in early CKD (eGFR 90-60ml/min) compared with the group with normal renal function This raisesthe issue at which point in the evolution of CKD interventions in mineral metabolism should be started.

To adress this issue we studied in a large cohort of unselected subjects of the outpatient units the association between eGFR/creatinine clearance and serum concentration as well as 24 hr urinary excretion of Ca and P.

**Methods:** Serum concentrations of Ca, P and Crea were measured photometricaly in 26 097 unselected individuals, 60.4% males, a mean age of 68.8± 13.7 years (range 19-99 years). In addition 24 hr urine of 2758 subjects, 59.3% males, mean age of 56.1±14.2 years (range 15-96 years) was collected to quantify excretion of Ca, P and creatinine photometricaly. eGFR was estimated by the MDRD formula.

**Results:** Mean and median of serum Ca and P concentration remained constant at eGFR > 30 ml/min. When eGFR decreased to <30 ml/min serum phosphorous increased ($p < 0.0001$) and serum Ca decreased ($p<0.0001$). In parallel with the decrease of eGFR from 120 down to <20 ml/min a continuous decrease was found for Ca excretion {from 5.3±3.03 to 1.16±0.98 mmol /24 hr ($p<0.0001$)} as well as P excretion {from 27.2±9.5 to 15.4±6.8 mmol/day ($p<0.0001$)}.

**Conclusions:** Serum Ca and P remain constant until eGFR is decreased to levels below 30 ml /min. However, 24 hr. urinary excretion of Ca and P start to decrease at much earlier stages of CKD . These findings may be related to the early onset of soft tissue calcification in CKD patients. In view of these findings the optimal start of P-binder treatment requires further investigation.

## TH-PO759

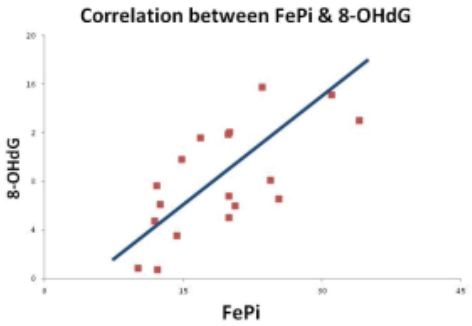
### Effect of High and Low Phosphate Intake on Oxidative Stress Levels

Essam F. Elsayed, Maram Museitif, Makoto Kuroo. *UT Southwestern.*

**Background:** High phosphate (Pi) intake has been shown to be associated with premature aging and increase in oxidative stress in animals and many of these abnormalities are rescued by a low phosphate diet. In humans, serum phosphorus levels positively correlate with mortality but the mechanism by which Pi can be toxic is not clear.

**Methods:** The participants were randomly assigned to a low Pi or a high Pi phase then after a washout period; they were crossed over to the other arm. We used a Pi supplement during the high Pi phase and a Pi binder during the low Pi phase. Pi intake, as measured by fraction excretion of Pi (FePi), was used as the independent predictor and the outcome was the level of 8-hydroxydeoxyguanosine (8-OHdG) as a marker of DNA oxidative stress.

**Results:** The mean age of the 19 participants was 53 years, 100% were men and 60% were African American. The participants had a mean serum phosphorus of 3.7mg/dL, mean FePi of 19.1% and mean eGFR of 73 mL/min.1.73m$^2$. Almost half (47%) of the participant (n=9) were stage 3 CKD with mean e-GFR of 49 mL/min.1.73m$^2$ At baseline, urinary Pi was significantly correlated with 8-OHdG levels (Pearson correlation coefficient of 0.59, P= 0.02).



]In the proportional hazard model, a 1% increase in FePi was associated with a 0.7 ng/mL increase in 8-OHdG (P= 0.008). Repeated observations model, models using 24 hours urinary Pi and models adjusting 8-OHdG to creatinine excretion had similar results. There was no significant effect for randomization group and there was a trend for the interaction between Pi intake and CKD (P-value = 0.07).

**Conclusions:** The novel concept of "phosphotoxicity" is supported by studies in animal models. Induction of high levels of oxidative stress and oxidative DNA damage are potential mechanisms by which Pi might affect cellular aging. This pilot study brings similar finding to the human level as it shows significant association between Pi intake and oxidative stress levels.

## TH-PO760

### Effects of Dietary Phosphorus Load on the Postprandial Blood Glucose and Glucose-Regulating Hormone Levels

Michiyo Yamasaki, Misaki Katsumoto, Yutaka Taketani, Hisami Okumura, Eiji Takeda. *Dept of Clinical Nutrition, Univ of Tokushima, Japan.*

**Background:** Dietary phosphorus (P) loading implicates bone and mineral disturbance in CKD patients. However, disturbance of P metabolism also affects other nutrient metabolism including glucose and lipid metabolisms. In this study, we examined the effects of dietary P loading on the postprandial blood glucose and glucose-regulating hormone levels.

**Methods:** 24 healthy young men (21 to 27 years old) were alternately served with high glycemic index (GI) high P meal (HGHP; white rice, P 1200mg), high GI low P meal (HGLP; white rice, P400mg), low GI high P meal (LGHP; barley, P 1200mg) or low GI low P meal (LGLP; barley, P 400mg). Blood and urine samples were collected before and at 0, 15, 30, 60 and 120min after the meal ingestion and measured serum levels of P, intact-parathyroid hormone (iPTH), glucose, insulin, glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP), and fractional urinary P excretion.

**Results:** In the low GI group (LGHP and LGLP), dietary high P loading significantly increased the postprandial blood glucose levels at 15-30min compared to low P loading ($P<0.05$). Serum insulin and GLP-1 levels tended to increase after high P loading. On the other hand, there was no significant change in serum GIP levels in response to P loading. The area under the curve (AUC) at 0-120min of serum P was positively associated with the change of serum GLP-1 concentration at 0-30min in low GI group ($P<0.05$). However, these associations were not clearly observed in high GI group (HGHP vs HGLP, P=0.90).

**Conclusions:** Our study demonstrates that dietary high P loading can affect the blood glucose concentration and the glucose-regulating hormone such as GLP-1 when glucose loading is not so much.

## TH-PO761

### Minute-to-Minute Regulation of Plasma Calcium and Plasma Phosphate after Experimental Induction of Hypercalcemia and Hyperphosphatemia

Ewa Lewin,[1] Eva Gravesen,[2] Jacob Hofman-Bang,[2] Klaus Olgaard.[2] *[1]Nephrological Dept B, Herlev Hospital, Univ of Copenhagen, Copenhagen, Denmark; [2]Nephrological Dept P, Rigshospitalet, Univ of Copenhagen, Copenhagen, Denmark.*

**Background:** Bone is the main storage of calcium (Ca) and phosphate (P). A 'labile' Ca storage pool, which is in equilibrium with blood Ca, exists on the bone surface, which is supposed to serve as a 'buffer', temporarily storing excess calcium, hereby keeping plasma ionized Ca ($Ca^{2+}$) very stable on a minute-to-minute basis. Whether a similar rapid regulation of plasma P exists is not known. Our purpose was to evaluate the rapid minute-to-minute regulation of plasma $Ca^{2+}$ and P after induction of acute hypercalcemia and hyperphosphatemia.

**Methods:** Acute hypercalcemia or hyperphosphatemia was induced by intravenous (i.v.) injections, and then the rapid recovery of p-$Ca^{2+}$ and P were followed for 80 min. in normal rats and acute nephrectomized (NX) rats.The control group had NaCl.

**Results:** The i.v. bolus of Ca increased p-$Ca^{2+}$ significantly from 1.29±0.03 to 1.64±0.03 mM/L ($P < 0.01$). Within 40 min p-$Ca^{2+}$ was normalized. Another group of rats had a very large Ca bolus, increasing p-$Ca^{2+}$ to 2.35±0.08 and p-$Ca^{2+}$ became normalized within 80 min. Acute hyperphosphatemia was induced by an i.v. bolus of P, which increased p-P significantly from 2.42±0.19 to 5.54±0.17 mM/L ($P < 0.01$). Within the 60 min p-P

decreased to a level of 3.66±0.10 and the remained stable at this level, significantly higher that basal P level (P<0.01). In NX rats the p-P declined to 3.68±0.18 and then increased again significantly to 4.23±0.37 mM/L ($P < 0.05$).

**Conclusions:** The results of the present investigation clearly show that plasma $Ca^{2+}$ levels on a minute-to-minute basis are very tightly regulated. Even extremely severe acute hypercalcemia recovered to normal levels within 80 minutes. Phosphate levels, however, remained significantly elevated after induction of acute hyperphosphatemia in both normal and nephrectomized rats, indicating that the possible exchangeable pool for phosphate is differently regulated from that of calcium.

## TH-PO762

**Denosumab for Hypercalcemia of Malignancy in Renally Impaired Patients** Ilya Glezerman,[1] Karl Insogna,[2] Mimi Hu,[3] Cecile N. Chougnet,[4] Rasim Gucalp,[5] Waldemar Misiorowski,[6] Bennett W. Yu,[7] Paul Zorsky,[7] Diego Tosi,[8] Alberto Bessudo,[9] Arnaud Jaccard,[10] Giuseppe Tonini,[11] Wendy Ying,[12] Ada Braun,[12] Rajul K. Jain.[12] *[1]Memorial Sloan-Kettering Cancer Ctr, Weill Cornell Medical College, New York, NY; [2]Yale School of Medicine, New Haven, CT; [3]MD Anderson Cancer Ctr, Houston, TX; [4]Institut Gustave Roussy, Villejuif, France; [5]Montefiore Medical Ctr-Bronx, New York, NY; [6]Medical Ctr for Postgraduate Education, Warsaw, Poland; [7]Peninsula Regional Medical Ctr, Salisbury, MD; [8]Centre Val d'Aurelle Paul Lamarque, Montpellier, France; [9]California Cancer Associates for Research & Excellence, Encinitas, CA; [10]Centre Hospitalier Universitaire de Limoges-Hôpital Dupuytren, Limoges, France; [11]Policlinico Universitario Campus Biomedico, Rome, Italy; [12]Amgen Inc., Thousand Oaks, CA.*

**Background:** Hypercalcemia of malignancy (HCM), caused primarily by tumor-induced bone resorption, is often treated with IV bisphosphonates (BPs); BPs may not be appropriate for patients (pts) with renal impairment. Denosumab binds to RANKL to inhibit osteoclast-mediated bone resorption.

**Methods:** In this single-arm open-label study, pts with HCM (albumin-corrected serum calcium [CSC] >12.5 mg/dL) despite IV BP treatment ≥7 and ≤30 days (d) before screening received SC denosumab 120 mg on d 1, 8, 15, and 29, then every 4 weeks. The primary endpoint was rate of response (defined as CSC ≤11.5 mg/dL) within 10 d of denosumab initiation.

**Results:** The study enrolled 33 pts (64% men, mean age 60 [SD 15] years). At baseline, estimated creatinine clearance (CrCl; Cockcroft-Gault formula) was <60 mL/min for 11 pts (33%), ≥60 mL/min for 17 pts (52%), and missing for 5 pts (15%). By d 10, 10/17 pts (59%) with baseline CrCl ≥60mL/min and 6/11 pts (55%) with baseline CrCl <60 mL/min had a response. By d 10, 7/17 pts (41%) with baseline CrCl ≥60 mL/min and 3/11 pts (27%) with CrCl <60 mL/min had a complete response (defined as CSC≤10.8 mg/dL). Over the course of the study, 10/17 pts (59%) with baseline CrCl ≥60mL/min and 8/11 pts (73%) with baseline CrCl <60 mL/min had a complete response.

**Conclusions:** In this study of pts with persistent or relapsed HCM despite recent IV BP treatment, similar proportions of pts responded to denosumab treatment regardless of renal function.

*Funding:* Pharmaceutical Company Support - Amgen Inc.

## TH-PO763

**Relationship between Urinary Phosphate with Cardiovascular Disease and Mortality in the AUSDIAB Cohort** Nigel David Toussaint,[1] Eugenia Pedagogos,[1] Stephen G. Holt,[1] Steven J. Chadban,[2] Kevan Polkinghorne.[3] *[1]Nephrology, The Royal Melbourne Hospital, Parkville, Victoria, Australia; [2]Nephrology, Royal Prince Alfred Hospital, Sydney, Victoria, Australia; [3]Nephrology, Monash Medical Centre, Clayton, Victoria, Australia.*

**Background:** Serum phosphate is associated with cardiovascular disease (CVD) and mortality in the general population. Greater dietary phosphorus intake may lead to higher serum phosphate and adverse outcomes. Urinary phosphate excretion is a marker of intestinal phosphorus absorption and may be a more reliable marker of phosphate homeostasis. Studies report good correlation between urine phosphate-creatinine ratio (uPiCr) and 24-hour urinary phosphate excretion, but whether uPiCr is associated with risk of CVD or mortality is uncertain. We aimed to assess the association between urinary phosphate excretion measured by uPiCr and outcomes in a large population-based cohort.

**Methods:** Using the nationally representative AusDiab cohort, uPiCr was determined from available urine samples (n=11,116). Participant baseline characteristics were compared across quartiles of uPiCr and regression analysis was used to determine associations. Relationships between uPiCr and all-cause mortality were determined using Cox proportion hazards regression with uPiCr modelled using fractional polynomials.

**Results:** Mean age 51+/-14y, 45% males and 9.6% had chronic kidney disease (CKD-Epi equation). During a median follow-up 12.1 years there were 1265 deaths. Mean uPiCr was 1.45+/-0.7mmol/mmol. Participants with higher uPiCr were older, more likely female, had higher albuminuria, lower GFR, greater prevalence of CVD and hypertension (all p<0.001) and higher BMI (p=0.002). With increasing quartiles of uPiCr the hazard ratios (HR) for all-cause mortality were 1.27 [95%CI 1.07,1.52], 1.54 [1.30,1.83], and 2.07 [1.76,2.44] (compared to the lowest quartile). When modelled using fractional polynomials, both low and high urinary phosphate were independently associated with increased risk.

**Conclusions:** Low and high uPiCr are associated with increased all-cause mortality in a general population cohort and uPiCr may serve as a useful marker for interventions aimed at improving phosphate balance.

## TH-PO764

**Effects of Gastric Bypass on Mineral Homeostasis and Skeletal Measures in Obese Rats** Benjamin Canales,[1] Anne Schafer,[2] Dolores Shoback,[2] Thomas Carpenter.[3] *[1]Urology, Univ of Florida, Gainesville, FL; [2]Medicine, Div of Endocrinology, San Francisco Veterans Affairs Medical Center, San Francisco, CA; [3]Medicine, Div of Endocrinology, Yale Univ, New Haven, CT.*

**Background:** Due to the invasiveness of bone biopsy and questionable reliability of dual-energy X-ray absorptiometry during surgical weight loss, the skeletal impact of Roux-en-Y gastric bypass (RYGB) surgery is unclear. To better understand bone loss mechanisms, we evaluated mineral homeostasis and skeletal phenotype in diet-induced obese (DIO) rats subjected to RYGB or sham surgery.

**Methods:** DIO male Sprague Dawley rats underwent sham (n=4) or RYGB (n=8) surgery. Animals were then placed on high-fat, normal calcium diets and euthanized after 20 weeks. Calciotropic hormones and bone turnover markers (BTM) were measured pre- and post-surgery. Femurs were analyzed using micro-computed tomography (uCT) and light microscopy (LM).

**Results:** Compared to post-operative controls, RYGB animals had significantly lower body weight, serum calcium, and 25-hydroxyvitamin D with increased parathyroid hormone levels, reflecting vitamin D deficiency and secondary hyperparathyroidism (SHPT). In controls, aging led to coupled decreases in BTM of formation [P1NP] and resorption [CTx]. In contrast, RYGB animals had evidence of relatively high CTx but lower P1NP levels. uCT confirmed reduced trabecular bone volume, number, and thickness as well as reduced cortical volume, thickness, and moment of inertia in RYGB rats relative to controls. Histomorphometric evidence by LM of increased RYGB bone resorption included increased osteoclasts and lower bone volume. RYGB rats also had increased osteoid volume with increased osteoblasts and osteoblastic surface yet serum formative markers were markedly lower than controls.

**Conclusions:** In our DIO model, RYGB-associated bone resorption appears to be driven by vitamin D malabsorption and SHPT. However, bone uncoupling with decreased osteoblastic activity suggests other mechanisms, such as gut hormone signaling, may play a role in bone mass differences. Further mechanistic research to explore these differences may identify targets for RYGB bone loss prevention.

## TH-PO765

**Clinical and Biological Data of Homozygous and Heterozygous Patients with CYP24A1 Mutations** Marie-Lucile Figuères,[1] Maryvonne Hourmant,[1] Gwenaelle Roussey,[2] Bertrand Knebelmann,[3] Amélie Ryckewaert,[4] Marie-Laure Kottler,[5] Sandra Mercier,[6] Emma Allain-Launay.[2] *[1]Nephrology, Nantes Univ Hospital, Nantes, France; [2]Pediatric Nephrology, Nantes Univ Hospital, Nantes, France; [3]Nephrology, Necker Univ Hospital, Paris, France; [4]Pediatric Nephrology, Rennes Univ Hospital, Rennes, France; [5]Medical Genetic, Caen Univ Hospital, Caen, France; [6]Medical Genetic, Nantes Univ Hospital, Nantes, France.*

**Background:** Loss-of-function mutations of CYP24A1, a vitamin D metabolizing enzyme, have recently been involved in infantile hypercalcemia. We report here clinical, biological and genetic data of a french cohort of 17 patients with CYP24A1 homozygous or heterozygous mutations.

**Methods:** 6 homozygous patients (2 adults, 4 children), their 10 heterozygous relatives and one heterozygous patient discovered on clinical manifestations are included in the study.

**Results:** Inaugural manifestations, that began in the first year of life in 5/6 homozygous patients, were symptomatic hypercalcemia (3.99±1.00mM) and medullary nephrocalcinosis. One patient only had nephrolithiasis. Hypercalcemia was associated with hypercalciuria, indetectable PTH, normal 25OH vitamin D, normal or elevated $1,25OH_2$vitamin D. Hypercalcemia occurred with usual doses of oral vitamin D and normal calcium load. Outside these episodes, calcemia usually remained at the upper limit of the normal range with normal or low PTH level, especially in summer, but persistent hypercalciuria. The 2 adults presented extrarenal manifestations (calcic corneal deposits, osteoporosis) and had chronic kidney insufficiency. In the heterozygous patients with the exception of one who had similar abnormalities than the homozygous cases, the phospho-calcic product was normal in 8, one had hypercalciuria and one a slightly increased 1,25OH vitamin D.

**Conclusions:** Hypercalcemia, together with nephrocalcinosis, low PTH, and high $1,25OH_2$vitamin D were the main parameters leading to the suspicion of CYP24A1 mutation. Renal prognosis was associated with nephrocalcinosis. Response to vitamin D load in heterozygous patients still have to be determined.

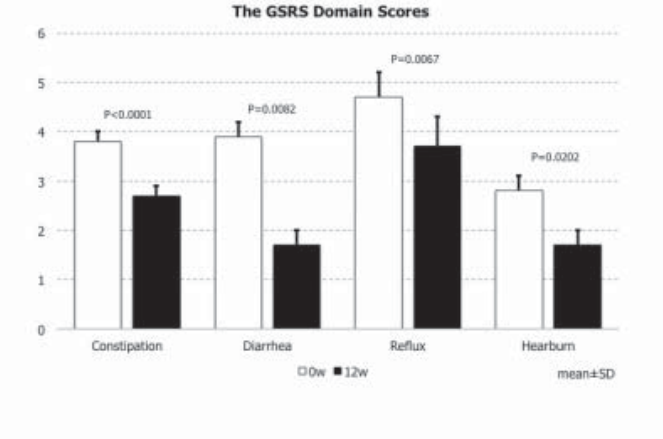
## TH-PO766

**Treatment of Hyperphosphatemia with Bixalomer in Hemodialysis Patients with Sevelamer-Associated Gastrointestinal Symptoms** Hiroaki Ogata,[2] Chiaki Kumata,[1] Kae Ito,[1] Kanji Shishido,[1] Akiko Takeshima,[2] Masahide Mizobuchi,[3] Eriko Kinugasa,[2] Tadao Akizawa.[3] *[1]Internal Medicine, Kawasaki Clinic, Kawasaki, Japan; [2]Dept of Internal Medicine, Showa Univ Northern Yokohama Hospital, Yokohama, Japan; [3]Div of Nephrology, Dept of Medicine, Showa Univ School of Medicine, Tokyo, Japan.*

**Background:** Bixalomer (Bix) is an amine-functional polymer, non-calcium (Ca) containing phosphate (P) binder and has been clinically available in Japan recently. Bix is expected to cause fewer gastrointestinal (GI) side effects as compared with sevelamer hydrochloride (SH), because of less expansion of Bix in the GI tract.

**Methods:** In this retrospective study, we evaluated changes in GI symptoms by the Gastrointestinal Symptom Rating Scale (GSRS) score in long-term hemodialysis outpatients with SH-associated GI symptoms, who switched to Bix from SH. Total 114 patients (age 63.7±10.8 year (mean±SD), female 65.5%, vintage 11.2±8.6 years, diabetes mellitus 27.4%) were enrolled. The GSRS score was checked at 0 and 12 weeks after the start of Bix. Bix was started at the initial dose of 750mg/day, and then was titrated.

**Results:** Serum albumin, P, Ca, and iPTH levels did not significantly change during Bix treatment period. However, serum LDL-cholesterol and bicarbonate levels significantly increased at 12 w as compared with those at 0w (73.1±20.0 vs 92.4mg/dL±23.9, P<0.0001 in LDL-c; 18.7±2.0 vs 19.5±2.3mEq/L, P<0.0001 in $HCO_3$). In GSRS score, total and each domain scores including constipation, diarrhea, and reflux, heartburn, significantly reduced in 12w after Bix treatment as compared with 0w.



**Conclusions:** Bix is an effective P binder in long-term hemodialysis patients. In addition, Bix may be less often associated with gastrointestinal symptoms as compared with SH.

## TH-PO767

**Are Allograft Microcalcifications a Marker of Mineral Bone Disease?** Sarah Margaret Moran,[1] Kate O'Connor,[2] Marek J. Mazur.[1] *[1]Nephrology, Cork Univ Hospital, Ireland; [2]Histopathology, Cork Univ Hospital, Ireland.*

**Background:** Renal allograft calcification has been previously described, however its significance remains unclear. We aim to assess whether renal transplant allograft calcification is associated with mineral bone disease.

**Methods:** A computerized search of histopathological records was conducted. Data on primary renal diagnosis, allograft biopsy diagnosis, transplant & patient outcome and comorbidities were obtained. Serum calcium, phosphate, bicarbonate and parathyroid hormone (PTH) within 3 months of biopsy and serial creatinine measurements were obtained. Pathological slides were assessed by a Consultant Nephropathologist for calcification using a validated scoring system.

**Results:** We identified a total of 32 allograft biopsies in 25 patients. Time to biopsy ranged from 1 to 180 months. Calcification was present in 46.9% (15/32). The number of foci ranged from 1 to 42, mean 7.5. Calcifications were located in tubules in 93.3% (14/15), with 0 to 42 foci, mean 6.3 foci. Interstitial calcification was present in 20% (3/15), 0 to 15 foci, mean 1.1 foci. There was a trend towards an association between calcification and PTH levels which did not reach statistical significance (p=0.3). Mean PTH in those with calcification was 261.71pg/ml (SD 309.5), mean PTH in those without calcification was 185.65pg/ml (SD 173.89). PTH levels in those with calcification were subanalysed into allograft outcome which revealed a trend towards elevated PTH levels but did not reach statistical significance. Mean PTH level in allograft recovery was 197 pg/ml (SD 266.9) and 378.2pg/ml (SD 277.5) in allograft failure (p=0.31). Serum phosphate levels three months prior to biopsy ranged from 0.66 to 1.94 mmol/L (mean 1.12 mmol/L). Serum corrected calcium levels three months prior to biopsy ranged from 2.13 to 3.3 mmol/L (mean 2.52 mmol/L). There was no association between calcium (p=0.8) or phosphate (p=0.72) levels and allograft calcification.

**Conclusions:** This is the first study to examine the significance of microcalcifications in non-protocol allograft biopsies up to 180 months. Non-significant trends were observed towards associations with allograft outcome and elevated PTH levels.

## TH-PO768

**PTH Inhibits Type IIa Sodium Phosphate Cotransporter mRNA Expression through Both Protein Kinase A and Protein Kinase C-Dependent Mechanisms** Rebecca Murray,[1] Nina W. Lesousky,[2] Syed J. Khundmiri,[1,2] Barbara Clark,[3] Eleanor D. Lederer.[1,2,4] *[1]Physiology & Biophysics, Univ of Louisville, Louisville, KY; [2]Medicine, Univ of Louisville, Louisville, KY; [3]Biochemistry & Molecular Biology, Univ of Louisville, Louisville, KY; [4]Robley Rex VAMC, Louisville, KY.*

**Background:** We have previously shown that PTH decreases NpT2a mRNA stability through an effect dependent on both transcription and translation. However, little is known about the signaling pathways responsible for destabilization of NpT2a mRNA by PTH. The PTH receptor activates both cAMP/PKA and PLC/PKC pathways, and both pathways have been shown to decrease proximal tubule phosphate reabsorption. A genome-wide analysis by Zhang et al (PNAS, 2005) identified a half-CRE within the promoter region of the NpT2a gene.

**Methods:** We hypothesize that PTH produces chronic down-regulation of NpT2a mRNA through activation of the PKA pathway. To address this hypothesis, we treated opossum kidney cells, a proximal tubule cell line featuring PTH-sensitive sodium-phosphate cotransport, with 8-bromo-cAMP (8-br) or phorbol myristate acetate (PMA) to activate the PKA and PKC pathways, respectively, and measured Npt2a mRNA expression by qRT-PCR.

**Results:** 2h treatment of OK cells with 10 μM 8-br decreased NpT2a mRNA by 45.46 (±4.12)%, and 8h treatment decreased NpT2a mRNA expression by 55.25 (±4.64)%. Treatment over a period of 8h with 100 nM PMA resulted in no significant decrease versus control. Pretreatment with the PKA inhibitory peptide (PKAi) 2μM to block the activation of PKA followed by PTH 100 nM produced a 65% reduction in NpT2a mRNA expression relative to control. 1 μM PTH(3-34), an analogue that selectively activates the PKC pathway, significantly decreased NpT2a mRNA expression at 6h and 8h by 52.59 (±11.76)% and 49.66 (±9.33)%, respectively, but not at shorter treatment times.

**Conclusions:** We conclude that both PKA and PKC pathways may contribute to regulation of NpT2a mRNA by PTH. Funding provided by VA to EDL.

## TH-PO769

**Urinary Phosphate and Serum FGF-23 Predict Endothelial Function: A Single Blind Cross-Over Trial** Kathryn K. Stevens, Rajan K. Patel, Patrick B. Mark, Christian Delles, Alan G. Jardine. *Insitute of Cardiovascular and Medical Sciences, Univ of Glasgow, United Kingdom.*

**Background:** Acute phosphate loading with a single meal impairs endothelial function but the effect of sustained phosphate loading has not been studied. We studied the effect of sustained phosphate loading and phosphate binding medication on endothelial function in healthy volunteers.

**Methods:** Healthy volunteers attended for 3 visits. Prior to each visit a 24 hour urine collection was performed for urinary electrolytes and cGMP. Bloods were drawn for routine biochemistry and FGF-23. Flow mediated dilatation (FMD) was recorded at each visit. Volunteers were randomised at visit 1 to receive phosphate sandoz (PS) or lanthanum carbonate (LC) for two weeks prior to visit 2. After a wash out period, volunteers took the other drug before attending for a final visit.

**Results:** There were 19 participants. At baseline, mean age was 42±14 years, serum phosphate 1.05±0.18mmol/L and fractional excretion of urinary phosphate (FeP) 14.3±3.4%. Median FMD was 8.4% (IQR 6.2-11.6%). After PS, there was a non-significant trend towards a higher serum phosphate within the normal range, FGF-23 and FeP rose significantly compared to baseline (p=0.013, p<0.001) and FMD reduced significantly (3.38% (IQR 2.57-5.26%), p<0.001). With LC, FMD also reduced significantly (p=0.033). Randomization order had no effect. Urinary cGMP correlated negatively with serum phosphate (p=0.003). In a regression model, higher FGF23 and FeP independently predicted reduced FMD.

**Conclusions:** This is the first study to show that sustained phosphate loading impairs endothelial function. Serum phosphate was unchanged but the deleterious effect seen with PS may be explained by elevated total body phosphate. Elevated FeP and FGF-23 are likely surrogate markers of higher total body phosphate. Urinary cGMP, as a marker of endothelial dysfunction negatively correlates with serum phosphate. This supports the hypothesis that phosphate increases cardiovascular risk by impairing endothelial function, possibly via the nitric oxide pathway and shows that sustained phosphate loading is directly detrimental to the vasculature even when serum phosphate remains within the normal range.

*Funding:* Other NIH Support - British Heart Foundation

## TH-PO770

**Spurious Hyperphosphatemia due to High Bilirubin Levels** Talal A. Khan, Azka Arif, Muhammad R. Syed, Ayesha Waqar, Karthik M. Ranganna, Gregory Malat, PharmD, Bette Seamonds, Parmish Lalit Kohli, Stephen Guy, Alden Michael Doyle. *Drexel Univ College of Medicine, Philadelphia, PA.*

**Background:** We report a case series of spurious hyperphosphatemia in patients with end-stage liver disease (ESLD) that was associated with highly elevated serum bilirubin levels. Hyperphosphatemia was noted with one type of laboratory analyzer, but the results could not be duplicated utilizing a different analyzer that is based on a different calibration method . As treatment of spurious hyperphosphatemia may lead to complications, awareness of this issue may have important ramifications for the care of ESLD patients.

**Methods:** Four patients with ESLD who were listed for liver transplantation presented with severe hyperbilirubinemia. In each patient, unexpectedly high Phosphorus ($PO_4$) levels triggered the use of PO4 binders. Suspicion for an incorrect diagnosis arose because the degree of hyperphosphatemia did not correlate with either the degree of kidney dysfunction or oral intake of $PO_4$. Intact PTH levels were unremarkable & hemolysis was ruled out. Samples were re-analyzed using our Beckman LX20 & DxC analyzers. They were sent out and analyzed on a Roche Integra analyzer as well. We found that the original measurements of PO4 were falsely elevated.

**Results:** The initial mean serum PO4 level was 7.9mg/dl (SD=±2.31) when assayed using the Beckman analyzers. Results on the Roche Integra analyzer revealed a mean PO4 level of 3.9 mg/dl (SD=± 0.43). Mean PTH and Calcium levels were 50pg/ml and 9mg/dl respectively. Mean Total Bilirubin level was 23.7mg/dl(SD=±3.19.

| Patient | Serum PO4 (Beckman) mg/dl | Serum PO4(Roche) mg/dl | Serum Calcium mg/dl | Total Bilirubin mg/dl | Serum PTH pg/dl | Serum Creatinine mg/dl |
|---|---|---|---|---|---|---|
| 1 | 5.9 | 4.1 | 9.2 | 26.4 | 69 | 1.1 |
| 2 | 6.8 | 3.9 | 9.0 | 19.4 | 65 | 4.1 |
| 3 | 7.8 | 3.3 | 8.4 | 23.1 | 23 | 0.66 |
| 4 | 11.2 | 4.3 | 9.9 | 25.9 | 44 | 0.76 |

**Conclusions:** Hyperphosphatemia should be carefully evaluated in ESLD patients with severe hyperbilirubinemia. Analyzers that use time-dependent photometric methods to measure serum PO4 can be affected by high bilirubin levels. In contrast, analyzers that use end-point photometric method remain accurate even in the face of high bilirubin because the blank sample allows for interference correction.

## TH-PO771

**The Etiology of Low Bone Mineral Density in Hypercalciuric Children** Maria Goretti M. G. Penido,[1] Marcelo S. Tavares,[1] Uri S. Alon.[2] *[1]Pediatric Nephrology Unit, Dept of Pediatrics, Federal Univ of Minas Gerais, Belo Horizonte, MG, Brazil; [2]Bone and Mineral Disorders Clinic, Pediatric Nephrology, The Children's Mercy Hospital, Kansas City, MO.*

**Background:** Some children with idiopathic hypercalciuria (IH) develop bone mass reduction but the reason for the decreased bone mineral density (BMD) remains undefined. The aim of this study was to look for the etiology of bone mass reduction in children with IH comparing them to a control group of normal children (C).

**Methods:** We evaluated the data of 88 children (50 males) with IH aged 2.2–17.8 years (median 9.4); and 29 controls (13 males) aged 4.0–16.3 years (median 9.8). 24h urine collections were analyzed for volume, creatinine, calcium, citrate, phosphate, oxalate, magnesium, hydroxyproline. Urine N-telopeptides (NTX) and pH were analyzed on a fasting random sample. Simultaneous blood samples were tested for creatinine, electrolytes, calcium, phosphorus, alkaline phosphatase, magnesium, PTH, osteocalcin, blood gases. Bone densitometry was performed by DXA using a Lunar DPX-IQ 2516 device. Clinical, laboratory, and bone densitometry data were expressed as median, minimum and maximum values. We use the Kruskal-Wallis test to compare the groups.

**Results:** There were no differences in age, BMI Z-scores and gender between the 2 groups. Lumbar spine (L1-L4) BMC, BMC corrected for height and for width of the vertebra, areal BMD, volumetric BMD and Z-score BMD were significantly lower in IH. Serum phosphorus and alkaline phosphatase, and urinary calcium and NTX were significantly higher in the IH group, whereas their serum PTH, urinary volume and citrate were significantly lower compared with C.

**Conclusions:** The calciuria associated with decreased BMD in IH children seems to be due to increased bone resorption, independent of PTH. Further studies should investigate the possible association of increased bone resorption with citraturia and other factors like $1,25(OH)_2$vitamin D and nutrition.

## TH-PO772

**Decreased Bone Mineral Density in Hypercalciuric Children Is Not Related to the Presence of Urolithiasis** Maria Goretti M.G. Penido,[1] Marcelo S. Tavares,[1] Uri S. Alon.[2] *[1]Pediatric Nephrology Unit, Dept of Pediatrics, Federal Univ of Minas Gerais, Belo Horizonte, MG, Brazil; [2]Bone and Mineral Disorders Clinic, Pediatric Nephrology, The Children's Mercy Hospital, Kansas City, MO.*

**Background:** The association between idiopathic hypercalciuria (IH) and decreased bone mineral density (BMD) has been described in adults and children. The risk for low bone density in hypercalciuric children with urolithiasis has not yet been well defined. The aim of this study was to explore if hypercalciuric children with urolithiasis are at higher risk for low BMD compared to those without stones.

**Methods:** We evaluated the data of 88 children with IH. They were divided to group 1 (G1) consisted of 49 children with urolithiasis (29M) aged 9.6±3.6 years, and group 2 (G2) consisted of 39 without urolithiasis (21M) aged 7.5±2.4 years. Group 3 (G3) was a control group composed of 29 children (13M) aged 10.3±3.8 years. 24h urine collections were analyzed for volume, creatinine, calcium, uric acid, citrate, phosphate, oxalate, magnesium, cystine, hydroxyproline. Ntelopeptide and pH were analyzed in a fasting urine sample. Venous blood samples were analyzed for creatinine, electrolytes, calcium, phosphorus, alkaline phosphatase, uric acid, magnesium, PTH, osteocalcin, blood gases and bicarbonate. Bone densitometry was performed by DXA using a Lunar DPX-IQ 2516 device. We use the Kruskal-Wallis and Dunn's multiple comparison tests to compare the groups.

**Results:** There were no differences in age, gender, BMI Z-scores, biochemical and mineral parameters between G1, G2 and G3. The 24h urine volume was higher in G2 when compared to G1 ($p<0.01$) while urine oxalate was lower ($p<0.01$). There were no differences in areal BMD and BMD Z-score of the lumbar spine (L1–L4) between G1 and G2, but values in G3 were higher then in both G1 ($p<0.01$) and G2 ($p<0.001$).

**Conclusions:** The analysis of hypercalciuric children with and without urolithiasis did not show any difference regarding their lower BMD Z-score of the lumbar spine. The only observed difference between patients' subgroups was a higher urinary level of oxalate and lower urine volume, both contributing to stone formation without an effect on bone metabolism.

## TH-PO773

**Increased Arterial Stiffness and Osteopenia in Calcium Nephrolithiasis: A Dangerous Cardiovascular Risk Liaison** Antonia Fabris,[1] Antonio Lupo,[1] Chiara Caletti,[1] Pietro Manuel Ferraro,[2] Gabriele Comellato,[3] Giovanni Gambaro.[2] *[1]Nephrology, Univ of Verona, Verona, Italy; [2]Nephrology, Catholic Univ, Rome, Italy; [3]Geriatrics, Univ of Verona, Verona, Italy.*

**Background:** Recent studies have described high incidence of cardiovascular (CV) disease in calcium nephrolithiasis (CNL). The mechanisms of such an association are not known since a role of obesity, hypertension, diabetes, gout has been ruled out. An inverse relationship between bone density and arterial stiffness (AS) has been reported in osteoporosis and CKD. CNL is often associated with metabolic bone disease (BMD). AS is a predictor of CV mortality. We hypothesized that CNL because of the coexistent BMD have abnormal AS and hence increased CV risk. We analyzed AS and BMD in CNL pts and in healthy controls.

**Methods:** 128 recurrent CNL pts and 39 controls. Exclusion criteria were: hypertension, chronic inflammatory diseases, intestinal and metabolic diseases, diabetes, primary hyperparathyroidism, smoking or menopause since >18 months. Biochemical tests, total body bone densitometry and pulse waive velocity (PWV) (Complior and Augmentation Index) were evaluated. Statistical analysis: Wilcoxon rank sum test.

**Results:** Both carotid-radial and carotid-femoral PWVs are higher in CNL than in controls. In multivariate analysis BMD is an independent predictor of both PWVs being responsible for 70% of the variability.

| | Stone formers (128) | Controls (39) | p |
|---|---|---|---|
| Age (yr) (SD) | 47 (14) | 39 (12) | |
| Gender M (n,%) | 61 (48) | 13 (33) | |
| BMI (Kg/m2)* (SD) | 25 (4) | 23 (3) | |
| Log-PWV carotid-radial (CI 95%) | 8.6 (8.3-8.8) | 7.8 (7.5-8.2) | 0.004 |
| Log-PWV carotid-femoral (CI 95%) | 7.5 (7.2-7.8) | 6.5 (6.1-7.0) | < 0.001 |
| Log-Peripheral Pulse Pressure (CI 95%) | 45 (42-48) | 42 (38-46) | 0.22 |
| Log-Augmentation index (CI 95%) | 9.4 (8.0-10.9) | 9.4 (6.9-12.8) | 0.96 |
| Prevalence osteopenia/osteoporosis | 70% | 23% | |

**Conclusions:** These results show the existence of an association between BMD and functional modification of the elastic arteries in CNL independent of the common CV risk factors. This observation may explain the increased CV risk observed in stone formers.

## TH-PO774

**Nephrolithiasis and Risk of Incident Bone Fracture** Eric N. Taylor,[1,2] Gary C. Curhan.[2,3] *[1]Div of Nephrology and Transplantation, Maine Medical Center, Portland, ME; [2]Channing Div of Network Medicine, Brigham and Women's Hospital, Boston, MA; [3]Renal Div, Brigham and Women's Hospital, Boston, MA.*

**Background:** Higher urine calcium is a central feature of calcium nephrolithiasis and is associated with lower bone mineral density in individuals with kidney stones (KS). Previous reports, albeit small and unadjusted for dietary intakes, suggest that individuals with KS may have higher risk of bone fracture.

**Methods:** We prospectively examined independent associations between a history of KS and incident fracture in the Nurses' Health Study I (N= 77,055 women; 30 years of follow-up) and the Health Professionals Follow-up Study (N=50,982 men; 24 years of follow-up). We excluded pre-menopausal women, men < 45 years old, and individuals who reported osteoporosis at baseline. Medical record review confirmed > 95% of self-reported KS in each cohort, and the majority of stones (> 77%) were predominantly calcium oxalate. We included only cases of incident wrist (distal radius) or incident hip (proximal femur) fractures due to low or moderate trauma. Validated food frequency questionnaires were used to assess dietary intake every four years. Cox proportional hazards regression was used to adjust for age, BMI, thiazide use, supplemental calcium, dietary intake, and other factors.

**Results:** At baseline, participants with KS had higher BMI and were more likely to use a thiazide diuretic than participants without KS. During follow-up there were 3741 wrist and 1160 hip fractures in women and 859 wrist and 634 hip fractures in men. The multivariable relative risk of incident wrist fracture in participants with a history of KS compared to participants without was 1.36 (95 % CI 1.17 to 1.57) in women and 1.22 (95% CI 1.00 to 1.48) in men. The multivariable relative risk of incident hip fracture in participants with KS was 0.99 (95 % CI 0.75 to 1.29) in women and 0.98 (95% CI 0.77 to 1.24) in men.

**Conclusions:** Nephrolithiasis is associated with a significantly higher risk of incident wrist but not hip fracture. Our study is limited by a relatively low number of hip fractures in participants with KS.

## TH-PO775

### Decreased Renal Clearance of Uric Acid Is Present in First Time Female Kidney Stone Formers

Hemamalini Ketha, John C. Lieske, Eric J. Bergstralh, Xujian Li, Rajiv Kumar, Andrew D. Rule. *Dept of Medicine, Mayo Clinic, Rochester, MN.*

**Background:** Elevated serum uric acid (UA) occurs in Ca stone formers (SF), but the mechanism has not been elucidated. We investigated whether serum UA levels in SF differ by gender and are impacted by UA clearance.

**Methods:** Serum UA and urinary pH, UA, sulfate, and the fractional excretion of UA were measured in a sample of first time SF (females (F) = 142, males (M) = 121) and in age-matched controls (C) (F = 151, M = 166) from the general population.

**Results:** In F (mean age 43.5 years), serum UA and FEUA were higher and urinary pH was lower in SF compared to C (Table 1). Despite the lower urine pH, F SF had lower urinary sulfate compared to controls (13.2 vs 18.7 mmol/24 h, p=0.004) suggesting lower protein intake. Urine volume and sodium were similar in F SF vs C. In M (mean age 48.2 years), serum uric acid, %FEUA, pH, and urinary sulfate did not differ between SF and C.

**Conclusions:** Higher serum UA levels among first time SF were only evident in F. Unlike controls, F SF have altered UA metabolism compared to M SF. The higher serum UA in female SF cannot be attributed to increased protein intake as urinary sulfate excretion is lower in SF vs C. Instead, an increase in the reabsorption of UA from tubular fluid, or failure in the excretion of UA into tubular fluid, accounts for the increase in serum UA.

**Table 1**. Serum and urinary parameters in F and M, SF and C

| | Controls (317, F=151, M=166) | Stone Formers (263, F=142, M=121) | P Value |
|---|---|---|---|
| *Serum uric acid, mg/dl* | | | |
| F | 4.2 ± 1.2 | 5.6 ± 1.2 | <0.0001 |
| M | 5.9 ± 1.3 | 5.6 ± 1.3 | 0.14 |
| *FEUA (%)* | | | |
| F | 8.2 ± 3.7 | 6.3 ± 3.4 | <0.0001 |
| M | 6.4 ± 2.9 | 6.2 ± 3.1 | 0.14 |
| *pH* | | | |
| F | 6.3 ± 0.6 | 6.1 ± 0.6 | 0.004 |
| M | 6.2 ± 0.6 | 6.1 ± 0.5 | 0.21 |
| *Urine Volume, mL/24/h* | | | |
| F | 1710 ± 807 | 1560 ± 875 | 0.15 |

## TH-PO776

### The Anti-Phosphaturic Effect of 1,25(OH)2D Is Impaired in Nephrolithiasis

Hemamalini Ketha, Ravinder Singh, Stefan Grebe, Eric J. Bergstralh, Xujian Li, Andrew D. Rule, John C. Lieske, Rajiv Kumar. *Mayo Clinic, Rochester, MN.*

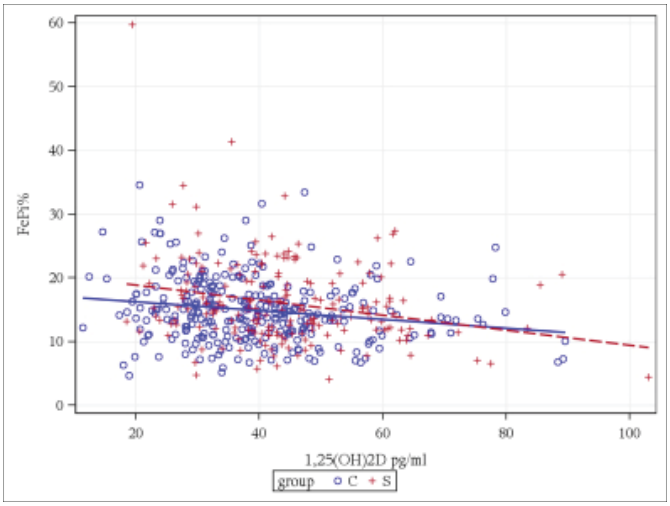
**Background:** Phosphate homeostasis is regulated by parathyroid hormone (PTH) and $1,25(OH)_2D$. Previous studies have shown an increased renal clearance of phosphate in kidney stone formers (SF) with normal serum PTH levels.

**Objectives:** 1. To investigate whether renal phosphate (Pi) clearance is increased in first time kidney SF. 2. To determine the relationship between the renal fractional excretion of Pi (FEPi), serum $1,25(OH)_2D$ and PTH.

**Methods:** Serum $1,25(OH)_2D$ (measured by mass spectrometry), intact PTH, Pi and urinary chemistries were measured in 263 first time SF and 317 controls (C) sampled from the general population. FEPi, $1,25(OH)_2D$, PTH and urine analytes were compared between SF and C groups.

**Results:** SF compared to C showed significantly higher FEPi (mean 16.0% vs 14.9% P = 0.04), higher $1,25(OH)_2D$ (43 vs 39 pg/ml, P = 0.003) and similar PTH (42.2 vs 39.5 pg/mL, P = 0.13). The higher FEPi in SF remained significant after adjusting for age, gender and $1,25(OH)_2D$ (P = 0.0176) (Fig. 1). The FEPi declined by 0.64% when $1,25(OH)_2D$ increased by 10 pg/ml (P = 0.0004) in both SF and C, with no evidence of an interaction (P = 0.21). No association between FEPi% and PTH was observed in SF or C.

**Conclusions:** The anti-phosphaturic response of the kidney to circulating concentrations of $1,25(OH)_2D$ is impaired in SF compared to C. The results suggest a systemic alteration in vitamin D and Pi metabolism common to many first time SF in the community.



*Funding:* NIDDK Support, Other NIH Support - Arthritis and Musculoskeletal, Private Foundation Support

## TH-PO777

### Evidence for Altered Responsiveness of the Vitamin D Endocrine System to Endogenous Circulating Parathyroid Hormone in Kidney Stone Formers

Hemamalini Ketha, Ravinder Singh, Stefan Grebe, Eric J. Bergstralh, Xujian Li, Andrew D. Rule, John C. Lieske, Rajiv Kumar. *Mayo Clinic, Rochester, MN.*

**Background:** Elevated $1,25(OH)_2D$ concentrations have been reported in some kidney stone formers (SF). Additionally, reduced $24,25(OH)_2D$ concentrations have been associated with elevated $1,25(OH)_2D$ and hypercalciuria in some patients with nephrolithiasis.

**Objective:** To investigate the associations between serum $1,25(OH)_2D$, $24,25(OH)_2D$ and PTH concentrations in a cohort of first time adult SF compared to controls (C).

**Methods:** Serum $1,25(OH)_2D$ and $24,25(OH)_2D$ were measured by mass spectrometry in SF (N = 263) and C (N = 317). Serum full-length parathyroid hormone (PTH), calcium (Ca) and inorganic phosphorus (P), and urinary chemistries and supersaturations were measured in the same subjects. Logistic regression was performed to determine if serum vitamin D metabolite, PTH, Ca and P, and urine analytes and supersaturations (SS) differed in SF versus C.

**Results:** In multivariate analysis adjusting for age and gender, mean serum $1,25(OH)_2D$ concentrations were significantly higher in the SF versus C (43.40 vs 39.22pg/mL, P<0.0001). Mean serum $24,25(OH)_2D$ was similar between the two groups (2.92 vs. 3.16 ng/ml, P = 0.175). Serum PTH concentrations were also similar in the two groups (42.16 vs. 39.63 pg/ml, P = 0.053). A higher concentration of $1,25(OH)_2D$ (P = 0.009), and a lower concentration of $24,25(OH)_2D$ (P = 0.055), was observed at any concentration of PTH in SF versus C. Changes in vitamin D metabolites and PTH did not correlate with serum or urinary minerals or SS.

**Conclusions:** Elevated $1,25(OH)_2D$ concentrations were present in a large group of first time SF. Serum $24,25(OH)_2D$ concentrations were similar in the two groups. A higher concentration of $1,25(OH)_2D$ and a lower concentration of $24,25(OH)_2D$ was noted for any level of PTH in SF versus C, suggesting altered responsiveness of the vitamin D endocrine system to circulating PTH.

### Sclerostin Is Associated with Age, Weight, BMI and Ionized Calcium Levels in Recurrent Kidney Stone Formers

Nilufar Mohebbi,[1] Daniel Rodríguez Gutiérrez,[1] Rudolf P. Wuthrich,[1] Carsten A. Wagner.[2] *[1]Div of Nephrology, Univ Hospital of Zurich, Zurich, Switzerland; [2]Institute of Physiology, Univ of Zurich, Zurich, Switzerland.*

**Background:** Kidney stones are common in industrialized countries. Calcium containing stones are the most frequent stone type. Many factors predispose or contribute to the development of kidney stones, including genetic background, diet, and metabolic factors. Sclerostin is secreted by osteocytes and inhibits bone formation at the level of osteoblasts. In humans, Sclerostin mRNA is expressed in several tissues, with high levels in the kidney whereas Sclerostin protein is restricted to osteocytes. The effect of sclerostin on bone formation may not be unique. A potential role in other diseases where bone homeostasis may be disarranged such as nephrolithiasis may be very likely.

**Methods:** We performed a cross-sectional observational study in 96 male and female recurrent kidney stone formers (rKSF) to analyze the potential role of sclerostin.

**Results:** 66 of the patients were male and mean age of all patients averaged to 45±13 years. Mean serum creatinine, phosphate, total calcium levels and venous bicarbonate were 78±1.6 umol/l, 0.95±0.01 mmol/l, 2.41±0.01, and 27±0.2 mmol/l, respectively. Mean 25-OH-Vitamin D levels were 57.1±2.2 ng/ml and PTH levels averaged to 48±2 pg/ml. Consistent with data in healthy adults, sclerostin levels were significantly higher in male than in female rKSF (82.2 ±14.7 vs. 67.3±12.3 pmol/l, p<0.0001). Similar to healthy adults,

we also found a positive correlation between sclerostin and age, weight and BMI ($p<0.05$). Additionally, sclerostin was negatively correlated with ionized calcium. Hypercalciuria (>6.2 mmol/24h) or hyperphosphaturia (>22.6 mmol/24h) were not correlated with sclerostin levels in rKSF. Surprisingly, patients with uric acid stones presented with highest sclerostin levels (50.8±14.2 pmol/l, p=0.0072) when compared to patients with calcium oxalate stones.

**Conclusions:** In recurrent kidney stone formers, sclerostin serum levels are positively correlated with age, weight, BMI, and negatively correlated with ionized calcium. Future studies are required to clarify the role of sclerostin in this population.

## TH-PO779

**Greater Loss of Bone Mineral Density with Exogenous $1,25(OH)_2D_3$ in Genetic Hypercalciuric Stone-Forming Rats** Kevin K. Frick,[1] Adeline Ng,[2] Madison Cohen- McFarlane,[2] John R. Asplin,[3] Christopher D. Culbertson,[1] Kelly Kyker-Snowman,[1] Nancy S. Krieger,[1] Marc Grynpas,[2] David A. Bushinsky.[1] *[1]Medicine, Univ of Rochester, Rochester, NY; [2]Samuel Lunenfeld Research Institute, Toronto, Canada; [3]Litholink Corporation, Chicago, IL.*

**Background:** Genetic hypercalciuric stone-forming (GHS) rats, bred to maximize urine (U) calcium (Ca), have, like humans with idiopathic hypercalciuria, increased intestinal Ca absorption and bone Ca resorption and reduced renal Ca reabsorption, leading to hypercalciuria compared to parental SD rats. GHS rats have increased vitamin D receptors (VDR) at these sites, with normal levels of $1,25(OH)_2D_3$ (1,25D), indicating their VDR is undersaturated with 1,25D. Exogenous 1,25D induces a greater increase in UCa in GHS than SD.

**Methods:** To determine the effect of the increased VDR on the bone response to 1,25D, we fed GHS and SD rats ample Ca and injected them with 1,25D (12.5 or 25ng/100 g body wt/d) or vehicle (veh) daily for 16d. Femurs and vertebrae were examined by DEXA, μCT and histomorphometry.

**Results:** Vertebral areal bone mineral density (aBMD, by DEXA) was decreased from 0.092±0.006 g/cm$^2$ in SD to 0.082±0.005 g/cm$^2$ in GHS+veh ($p<0.05$) and further decreased to 0.075±0.004 in GHS+25ng 1,25D ($p<0.05$). Femoral aBMD was decreased from 0.133±0.003 g/cm$^2$ in GHS+veh to 0.123±0.003 in GHS+12.5ng 1,25D ($p<0.05$) and to 0.123±0.004 in GHS+25ng 1,25D ($p<0.05$) while there was no effect of 1,25D on SD. Both vertebral and femoral volumetric BMD (by μCT) were lower in GHS vs SD and further reduced by 25ng 1,25D. Osteoclast number was decreased from 4.7±0.9/mm bone surface in GHS+veh to 2.0±1.5 in GHS+25ng 1,25D ($p<0.05$). In GHS tibiae, 25ng 1,25D increased trabecular thickness and number; osteoid volume increased 12-fold while bone volume increased only 3-fold. Bone formation rate was decreased from 21.8±1.1mm$^2$/mm$^2$/yr in GHS+veh to 9.8±0.7 in GHS+25ng 1,25D ($p<0.02$).

**Conclusions:** In GHS rats, exogenous 1,25D leads to loss of BMD due to a mineralization defect, which contributes to increased hypercalciuria and should decrease bone strength. The enhanced effect of 1,25D in GHS indicates that the increased number of VDR is biologically active.

**Calcium Oxalate Crystals Induced Changes in Secretion of Proteins from Basolateral Compartment of Renal Tubular Cells That, in Turn, Enhanced Crystal Invasion** Visith Thongboonkerd, Wararat Chiangjong. *Siriraj Hospital, Mahidol Univ, Bangkok, Thailand.*

**Background:** Calcium oxalate monohydrate (COM) crystals cause kidney stone disease by unclear mechanisms. One of hypotheses was that COM crystals induce changes in various cellular mechanisms, leading to enhancement of crystal invasion into renal interstitium. The present study thus aimed to characterize changes in secretion of proteins from basolateral compartment of renal tubular epithelial cells after exposure to COM crystals and then examined functional significance of these changes in association with the stone pathogenesis.

**Methods:** Polarized MDCK cells were cultivated in Transwell containing serum-free medium with or without 100 μg/ml COM crystals for 20 h. Secreted proteins in culture medium from the lower chamber (basolateral compartment) were then collected, desalted by dialysis against deionized water, and finally concentrated by lyophilization. The recovered proteins from five individual cultures in each group with equal amount were resolved in individual 2-D gels and visualized by Deep Purple stain. Proteins with significantly differential levels were then identified by tandem mass spectrometry. The proteomic data were confirmed by Western blot analysis. Finally, functional analysis was performed to validate the significant role of the identified altered proteins in crystal invasion using a recently established crystal invasion assay.

**Results:** Trypan blue exclusion assay revealed comparable cell viability between the two groups of cells. Spot matching and intensity analysis revealed six protein spots with significantly altered levels in the basolateral compartment of COM-treated cells. The altered secreted proteins were then successfully identified by LC-Q-TOF-MS/MS, including enolase-1, phosphoglycerate mutase-1, actinin, 14-3-3 protein epsilon, alpha-tubulin 2 and ubiquitin-activating enzyme E1. The proteomic data were successfully confirmed by Western blot analysis. Finally, functional analysis revealed that some of the identified secreted proteins played an important role in crystal invasion.

**Conclusions:** These data provide an important basis for further elucidation of sophisticated mechanisms of kidney stone disease.

**Adenosine Signaling Inhibits Oxalate Transport by Human Intestinal Caco2-BBE Cells** Hatim A. Hassan, Yong-Chul Jung, Ruhul Amin, Sireesha Ratakonda, Sohee Jeon, Sapna Sharma. *Univ of Chcago.*

**Background:** 80% of kidney stones are composed of calcium oxalate, and minor changes in urine oxalate affect the stone risk. Intestinal oxalate secretion mediated by anion exchanger SLC26A6 (A6) plays a crucial role in limiting net absorption of ingested oxalate; thereby preventing hyperoxaluria and calcium oxalate kidney stones. We recently reported (AJP-Cell Physiol, 2013) that the extracellular nucleotides ATP and UTP inhibit oxalate transport by human intestinal Caco2-BBE cells (C2) through signaling pathways that likely include the $P2Y_2$ purinergic receptor, PLC, and PKC-δ. Since extracellular nucleotides are rapidly degraded (ATP□ ADP□ AMP □ adenosine) by ectonucleotidases, we therefore examined whether intestinal oxalate transport is subject to regulation by one or more of these degradation products.

**Results:** To this end, we measured $^{14}$C-oxalate uptake in the presence of an outward Cl gradient as an assay of Cl-oxalate exchange activity, ≥ 50% of which is mediated by A6 in C2 cells. We found that ADP, AMP, and adenosine significantly inhibited oxalate transport by C2 cells, by > 26%, 27%, and 31%, respectively. The inhibitory effects of adenosine were partially and significantly blocked by pretreatment with the PKC inhibitor Gö6983 (by > 50%) and the PLC inhibitor U73122 (by >80%). The nonselective (8-p-sulfophenyltheophylline: 8-SPT) adenosine receptor antagonist partially and significantly blocked (by > 40%) adenosine-induced inhibition of oxalate transport by C2 cells. Using selective pharmacological inhibitors, we found that ERK1/2, PKA, and Src kinases are not involved in the observed adenosine-mediated suppression of oxalate transport by C2 cells. These findings are of potential importance because intestinal cells are known to be exposed to adenosine, ADP, and AMP under physiological, as well as pathological (e.g. IBD and therefore might have potential relevance to the IBD-associated hyperoxaluria) conditions.

**Conclusions:** We conclude that adenosine signaling inhibits oxalate transport by C2 cells through signaling pathways that likely include PKC, PLC, and one or more of the known adenosine receptors. ADP and AMP also significantly inhibit oxalate transport by C2 cells.

## TH-PO782

**Proinflammatory Cytokines Regulate Oxalate Transport by Intestinal Epithelial Cells** Hatim A. Hassan, Ruhul Amin, Yong-Chul Jung, Sireesha Ratakonda, Sapna Sharma, Sohee Jeon, Peili Chen, F. Gary Toback. *Univ of Chicago.*

**Background:** 80% of kidney stones are composed of calcium oxalate, and minor changes in urine oxalate affect the stone risk. The mammalian intestine plays a crucial role in oxalate homeostasis. Intestinal oxalate absorption is largely passive and paracellular, while anion exchanger SLC26A6 (A6) plays a critical role in active intestinal oxalate secretion. Proinflammatory cytokines (PCs) disrupt intestinal barrier function and increase paracellular flux, as well as inhibit several intestinal transporters. We therefore initiated studies to test the hypothesis that PCs could enhance intestinal oxalate absorption and/or reduce intestinal oxalate secretion.

**Results:** The PCs IFN-γ [IFN] and TNF-α [TNF] caused > 3-fold increase in mucosal to serosal $^{14}$C-oxalate & $^{3}$H-mannitol (a paracellullar marker) absorptive fluxes in human intestinal Caco2-BBE (C2) cells grown on snapwell inserts and mounted in Ussing chambers (UCs). The PC-induced increased absorptive fluxes were completely blocked by pretreatment with AMP-18 and GLP-2, peptides known to improve intestinal barrier function. Importantly, pretreatment of BALB/c mice with TNF before isolating and mounting jejunal segments in UCs led to > 1.9-fold increase in $^{14}$C -oxalate & $^{3}$H-mannitol absorptive fluxes, effects completely blocked by pretreatment with AMP-18 and GLP-2. IFN and TNF also significantly inhibited (by 30-40%) apical $^{14}$C-oxalate uptake, measured as Cl-oxalate exchange, by C2 cells through mechanisms involving reduced A6 mRNA/total protein expression. Another PC, IL-6, also significantly inhibited apical oxalate uptake by C2 cells, while IL-1β, 2, & 8 had no effect. These findings are of potential relevance to pathophysiology of IBD- and obesity-associated hyperoxaluria, in which higher local and systemic PCs levels, respectively, are seen.

**Conclusions:** PCs significantly enhance intestinal oxalate absorption, and that AMP-18 and GLP-2 have therapeutic potential in this process. PCs also significantly reduce oxalate uptake by C2 cells by lowering A6 mRNA/protein expression. Since C2 cells closely resemble the native epithelium, such regulation would likely lead to reduced intestinal oxalate secretion in vivo.

## TH-PO783

**Lithogenic Factors and Inflammatory Bowel Disease: Importance of Disease Severity** Cristina Beato Henriques Outerelo,[1] Fernando Teixeira e Costa,[1] Pedro Figueiredo,[2] Joao Freitas,[2] Aura Ramos.[1] *[1]Nephrology, Hospital Garcia Orta, Almada; [2]Gastrenterology, Hospital Garcia Orta, Almada.*

**Background:** Lithogenic factors are prevalent in patients with inflammatory bowel disease (IBD). Their correlation with the severity of the underlying bowel disease is not yet established. The aim of this study was to evaluate weather the prevalence of known lithogenic factors is related to IBD severity.

**Methods:** Single centre prospective study of eighty-seven consecutive outpatients with IBD. Clinical data was obtained through questionnaire and file consultation; nephrolithiasis

was defined as history of symptomatic renal colic. Routine indices of kidney function were assessed as well as serum concentrations of calcium, phosphorus, magnesium, uric acid and potassium. The 24h urine excretion of these electrolytes was measured, plus oxalate and citrate. Disease severity was defined as 1) need for hospitalization, 2) bowel surgery or 3) imunossuppression (azatioprine, infliximab or adalimumab).

**Results:** Mean age 46±17 years, 43.5% male, 59.8% with Crohn´s disease, median time of disease of 11 years (IQR 5-15). Symptomatic nephrolithiasis had occurred in the past in 19.5%. Patients with at least one severity criteria (62.1%) showed a significantly lower magnesium excretion (64.74±35.02 vs 81.80±40.47, p=0.041), lower calcium excretion (median 2.77 IQR 1.80-4.35 vs 4.25 IQR 2.65-6.32, p=0.015), a trend to higher oxaluria (0.37±0.16 vs 0.31±0.11, p=0.073) but no differences in history of renal colic episodes (16.7% vs 24.2%, p=0.387). Considering the calcium excretion among the different severity variables, only the use of adalimumab was significantly associated with low calciuria (median 2.05 IQR 0.94-2.87 vs 3.34 IQR 2.10-5.40, p=0.008).

**Conclusions:** In spite of no differences found in the prevalence of symptomatic nephrolithiasis, lower urinary magnesium excretion was significantly related with more severe IBD; there was also a trend to higher urinary oxalate excretion. Interestingly, lower urinary calcium excretion was observed, which seemed to be associated with adalimumab use. The impact of these factors on stone formation, renal colic episodes and chronic interstitial nephritis remains to be established.

### Total Stone Volume on Renal CT Predicts Future Symptomatic Stone Events

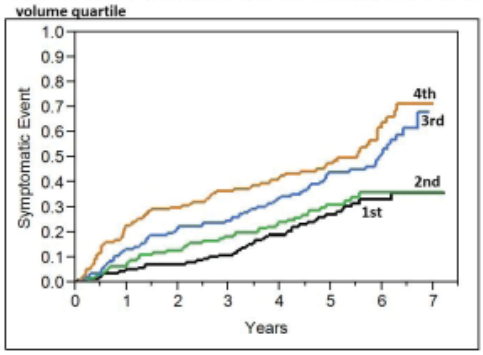
Michael G. Selby,[1] Terri J. Vrtiska,[2] John C. Lieske,[1] Amy E. Krambeck,[3] Eric J. Bergstralh,[4] Andrew D. Rule.[1] *[1]Nephrology, Mayo Clinic, Rochester, MN; [2]Radiology, Mayo Clinic, Rochester, MN; [3]Urology, Mayo Clinic, Rochester, MN; [4]Statistics, Mayo Clinic, Rochester, MN.*

**Background:** The optimal method to quantify radiographic stone burden by renal computed tomographic (CT) scans in order to predict future symptomatic stone events is unknown.

**Methods:** A mailed survey was sent in 2012 to stone formers who had undergone evaluation at the Mayo Clinic between 2005-2009 that included a renal CT scan to evaluate their stone disease while aysmptomatic. The renal CT scan was reviewed to determine the number of kidney stones, largest stone diameter, total stone volume (by automated algorithm), and presence of bilateral stones. Using the survey and electronic medical record, the first symptomatic kidney stone event after the CT scan was identified.

**Results:** The survey was completed by 550 stone formers (55% male, mean age 55 y) of which 43% had a subsequent symptomatic stone event a mean 2.9 years after their CT scan. Stone burden by quartiles was 0-1, 2-3, 4-6, ≥7 for number of stones, 0-2, 3-4, 5-7, ≥8 mm for largest stone diameter, 0-8, 9-70, 71-280, and ≥ 281 $mm^3$ for total stone volume. Forty-eight percent had bilateral stones. The hazard ratio (HR) for a symptomatic stone event by stone burden per quartile level was 1.30 (p<0.001) for the number of stones, 1.26 (p<0.001) for largest stone diameter, and 1.38 (p<0.001) for total stone volume. The HR for an event was 1.80 (p<0.001) for the presence of bilateral stones. On multivariable analysis with all 4 CT characteristics, only total stone volume was an independent predictor of symptomatic events (HR=1.31, p=0.03).

**Figure 1: Risk for future symptomatic stone event by total CT stone volume quartile**



Findings remained similar and statistically significant with exclusion of rare stone types (cystine).

**Conclusions:** An automated total stone volume on renal CT scan optimally predicts future symptomatic stone events.

*Funding:* NIDDK Support

## TH-PO785

### Consecutive CT Scan Monitoring of Total Stone Volume Is More Useful in Patients Who Are Having Interim Symptomatic Stone Events

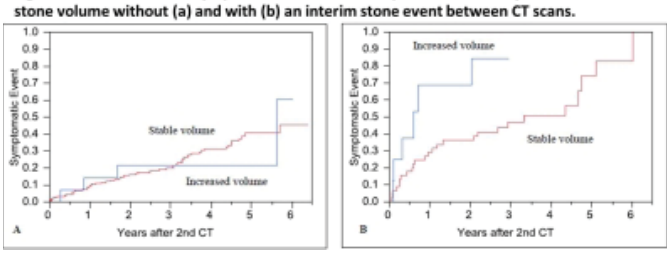
Michael G. Selby,[1] Terri J. Vrtiska,[2] John C. Lieske,[1] Amy E. Krambeck,[3] Eric J. Bergstralh,[4] Andrew D. Rule.[1] *[1]Nephrology, Mayo Clinic, Rochester, MN; [2]Radiology, Mayo Clinic, Rochester, MN; [3]Urology, Mayo Clinic, Rochester, MN; [4]Statistics, Mayo Clinic, Rochester, MN.*

**Background:** The goal of this study was to determine whether the change in kidney total stone volume between two renal computed tomographic (CT) scans was predictive of future symptomatic stone events.

**Methods:** A mailed survey was completed in 2012 by stone formers who had undergone evaluation at the Mayo Clinic that included two renal CT scans between 2005 and 2012 to evaluate their stone disease while asymptomatic. Rare stone types (cystine) were excluded. Both CT scans were reviewed to determine total stone volume using an automated algorithm. The survey and electronic medical record identified any symptomatic stone events between or after the two CT scan dates.

**Results:** The survey was completed by 239 stone formers (62% male, mean age 57 y) with two renal CT scans a median 1.1 years apart. An interim event occurred in 21% and 36% had a symptomatic stone event a mean 3.2 years after their second CT scan. Total stone volume increased a median 17 $mm^3$/year with 10% having a rapid increase in stone volume (>560 $mm^3$/year). The risk of symptomatic stone recurrence was increased in patients with a rapid increase in stone volume who also had an interim stone event (n=50, HR=3.1, p=0.03) but not in those without an interim stone event (n=189, HR=0.49, p=0.26).

**Figure 1: Risk for a future symptomatic stone event in patients with a rapid increase in total stone volume without (a) and with (b) an interim stone event between CT scans.**



Test for interaction was significant (p=0.01).

**Conclusions:** There appears to be a higher risk of symptomatic events in stone formers who have a rapid increase in total stone volume between annual renal CT scans despite passing stones between scans. Annual renal CT scans may not be as helpful in stone formers who are not passing stones.

*Funding:* NIDDK Support

## TH-PO786

### Dietary Acid Load and Risk of Incident Kidney Stones

Ernest I. Mandel,[1,2] Eric N. Taylor,[2,3] Gary C. Curhan.[1,2] *[1]Renal Div, Dept of Medicine, Brigham and Women's Hospital, Boston, MA; [2]Channing Div of Network Medicine, Dept of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [3]Div of Nephrology and Transplantation, Maine Medical Center, Portland, ME.*

**Background:** Higher dietary acid load may reduce urinary citrate excretion, which is associated with an increased risk of kidney stone formation. However, the association between dietary acid load and risk of incident kidney stones has not been explored in population-based studies of individuals.

**Methods:** We prospectively examined the association between dietary acid load, using the diet-estimated net endogenous acid production (NEAP) and potential renal acid load (PRAL), and the risk of incident kidney stones in the Health Professionals Follow-up Study (n=44,581 men; 24 years of follow-up), Nurses' Health Study (n=73,154 older women; 26 years of follow-up), and Nurses' Health Study II (n=91,509 younger women; 16 years of follow-up). We used Cox proportional hazards regression to generate hazard ratios (HRs) adjusted for age, race, BMI, dietary, lifestyle, and medical factors.

**Results:** We identified a combined total of 6361 incident cases of kidney stones during 4,411,939 person-years of follow-up. After adjusting for potential confounders, the multivariable HRs (95% confidence interval (CI)) for kidney stone formation for individuals in the highest quintile of diet-estimated NEAP compared to those in the lowest quintile were 1.59 (1.20 to 2.10; p for trend=0.002) for men, 1.48 (1.11 to 1.99; p for trend =0.05) for older women, and 1.53 (1.18 to 1.98; p for trend=0.007) for younger women. After adjusting for potential confounders, the multivariable HRs (95% CI) for kidney stone formation for individuals in the highest quintile of diet-estimated PRAL compared to those in the lowest quintile were 1.54 (1.19 to 1.98; p for trend=0.003) for men, 1.08 (0.84 to 1.40; p for trend=0.49) for older women, and 1.30 (1.04 to 1.62; p for trend=0.04) for younger women.

**Conclusions:** Higher dietary acid load, especially as measured by diet-estimated NEAP, is independently associated with a higher risk of kidney stone formation.

**TH-PO787**

**Lime Powder Regimen Is a Novel Alternative for Medical Treatment of Nephrolithiasis** Piyaratana Tosukhowong,[1] Chanchai Boonla,[1] Thasinas Dissayabutra,[1] Kriang Tungsanga.[2] *[1]Biochemistry, Chulalongkorn Univ, Pathumwan, Bangkok, Thailand; [2]Medicine, Chulalongkorn Univ, Pathumwan, Bangkok, Thailand.*

**Background:** Lime powder regimen (LPR) is a limeade-based regimen containing active pharmaceutical components of 21 mEq potassium and 63 mEq citrate. Our preclinical and phase 1 studies showed LPR was a safe regimen for daily consumption and delivered the citraturic, urine alkalinizing and antioxidative effects.

**Methods:** 84 nephrolithiasis patients were recruited post-operative stone-free condition, and were randomly allocated into two treatment arms. Eight patients (10%) were dropout, then 33 were allocated into LPR and 32 in placebo group. Urinary citrate, oxalate and uric acid were measured by enzymatic method, total antioxidant status (TAS) by ABTS, Sodium, potassium, magnesium and calcium by ICP-OES.

**Results:** Age and gender distribution between LPR and placebo groups were not significantly different. In LPR group, urinary citrate and pH were significantly increased, while urinary calcium, oxalate and uric acid were reduced, after 6-month treatment compared to the pre-treatment baseline. In placebo group, urinary calcium, uric acid and volume were significantly reduced while urinary citrate trend to reduce after the 6-month treatment. Urinary total antioxidant status was significantly increased for both LPR and placebo treatments. Plasma protein carbonyl content was significantly reduced only in the LPR group. No adverse effect was found in both groups.

**Conclusions:** LPR was warranted to be a safe regimen in the nephrolithiasis patients. The current data indicated that 6-month LPR treatment delivered citraturic, urine alkalinizing and antioxidative effects in nephrolithiasis patients. These medicinal effects potentially reduce the propensity of kidney stone recurrence. Therefore, the phase 3 clinical trial needs to be further conducted to actually evaluate the efficacy of LPR treatment for reducing the recurrence rate.

**TH-PO788**

**Trend of Incident and Prevalent Kidney Stone Disease in a Large Health Care Organization 1997-2007** Jie Tang,[1,3] Angela Keniston,[1] John R. Holmen,[2] Michel Chonchol.[3] *[1]Medicine, Denver Health Medical Center, Denver, CO; [2]Intermountain Health Care, Murray, UT; [3]Medicine, Univ of Colorado, Denver, CO.*

**Background:** Recent epidemiological trend of kidney stone (KS) disease is unclear. We aim to determine the KS incidence and prevalence trends through time in an integrated healthcare system serving a defined geographical region.

**Methods:** Incident and prevalent kidney stone (IKS & PKS) rates were obtained using Intermountain Healthcare (IHC) Data Warehouse. IHC is a healthcare organization serving 2.4 million Utah and Idaho residents. IKS formers were defined as patients having first ever diagnosis of KS disease and were identified by ICD9 codes 592 & 594.0 assigned from 1997 to 2007. PKS formers were defined as patients having prior ICD9 codes 592, 594.0 or V13.01. Negative binomial regression analyses were used to examine the incidence and prevalence trends.

**Results:** 53,045 IKS formers and 342,150 PKS formers were identified. Adjusted for age, gender, race and imaging use, there were no significant changes in KS incidence rates from 1997 (0.49%) to 2007 (0.52%), p=0.2. However, the adjusted KS prevalence rates increased significantly from 1997 (1.45%) to 2007 (4.9%), p<0.0001. For men, age, race and imaging use adjusted incidence rates did not change significantly from 1997 (0.67%) to 2007 (0.63%), p=0.9, but the adjusted prevalence rates increased significantly from 1997 (1.98%) to 2007 (6.15%), p<0.0001. For women, the adjusted incidence rates did not change significantly from 1997 (0.35%) to 2007 (0.44%), p=0.3, but the adjusted prevalence rates increased significantly from 1997 (1.04%) to 2007 (3.93%), p<0.0001. Age, gender and imaging use adjusted incident rates did not change significantly in any of the race categories from 1997 to 2007. However, the adjusted prevalence rates increased significantly in all race categories (p<0.0001) except in African Americans (p=0.06) from the same time period.

**Conclusions:** Even though IKS rates did not change from 1997 to 2007, the PKS rates increased significantly. The causes of these findings remain to be determined.

**TH-PO789**

**Adenine Phosphoribosyltransferase Deficiency: Two Novel Genetic Mutations and United Kingdom Experience** Gowrie Balasubramaniam,[1] Monica Arenas Hernandez,[2] Lynette D. Fairbanks,[2] Anthony Marinaki,[2] Emilia Escuredo Polo,[2] Sarah Mapplebeck,[1] Michael K. Almond.[1] *[1]Southend Univ Hospital, Southend, Essex, United Kingdom; [2]Purine Research Laboratory, Guy's and St. Thomas' NHS Trust, London, United Kingdom.*

**Background:** Adenine phosphoribosyltransferase (APRT) deficiency causes 2,8-dihydroxyadenine (2,8-DHA) crystals and renal failure. We present three cases with two novel mutations from a single centre. UK data of APRT is limited; we undertook a cross-sectional survey of patients identified at the Purine Research Laboratory.

**Methods:** An 18-year old man of presented with a history of recurrent nephrolithiasis. 2,8-DHA stones were identified by UV spectrophotometry. 11 years after his initial symptoms, he re-presented with chronic kidney disease stage (CKD) 4. His younger brother presented with loin pain and acute kidney injury. Renal biopsy showed an acute tubulointerstitial nephritis with crystalline deposits. A 48-year man with a history diabetes and hypertension presented with an acute on chronic kidney injury. Renal biopsy showed minimal diabetic features but chronic tubulointerstitial nephritis with crystalline deposits. We sent questionnaires to obtain clinical information of the identified cases between 1979-2013.

**Results:** All three cases had 2,8-dihydroxadenine in urine and complete APRT deficiency. Genetic studies identified a homozygous novel mutation in the APRT gene from Case 1 and 2; APRTc.543 A>T, p.181X>C, and case 3 APRTc.380a>G, p.127D>G. We identified only 17 patients (12 M) from 14 families. Mean age at diagnosis was 26 (range 2-70). The commonest reason for testing was nephrolithiasis (11/17). Outcome information was not available in 2 patients (1 had ESRD). Of the remaining 15 patients; 3 patients were deceased (1 had ESRD); 8/12 had normal renal function and 4/12 had CKD.

**Conclusions:** APRT deficiency is a rare disease with varied presentation that is currently under-diagnosed in the UK. Stone analysis and family screening are important ways to identify cases. Diagnosis should be sought if unexplained crystalline deposits are found on renal biopsy. It is easily treatable and a more concerted approach should be undertaken to diagnose patients in the UK.

**TH-PO790**

**Profound Life Threatening Hypokalemia as a Manifestation of Topiramate Induced Renal Tubular Acidosis** Osama W. Amro, Narittaya Varothai, Anita Abhyankar. *Nephrology, Tufts Medical Center, Boston.*

**Background:** Topiramate is used for migraine prophylaxis and seizure disorders. One potential side effect is the development of renal tubular acidosis (RTA). We are reporting a case of Topiramate induced RTA that presented with profound hypokalemia.

**Methods:** A 29 year old lady with history of Migraine presented with muscle aches and generalized weakness, patient had no fever, diarrhea, nausea, or vomiting. Physical examination revealed an obese lady in a euvolemic state with no focal neurological signs. Initial studies showed serum K of 1.7, PO4 2.2, HCO3 16, Cl 107, Na 137, CK 5000. ABG showed PH of 7.37, PCO2 28, PO2 105 and HCO3 19. Urinalysis showed a PH of 6.5 and was otherwise unremarkable. Urine anion gap was negative and the TTKG was 8. Renal ultrasound showed 8 mm calculus in the right renal pelvis. The patient received a total of 600 mEq KCL and serum K normalized. The patient's historical blood tests revealed chronic hypobicarbonatemia and hypokalemia for the last 2 years with levels between 17 to 21 and 2.7 to 3.3 respectively. The 2 year period correlates with the time in which Topiramate was initiated (100 mg twice daily for migraine prophylaxis). The patient was taken off Topiramate and a repeat blood level done in 48 hours showed normalization of serum bicarbonate and K levels. Repeat urinalysis showed a urine PH of 5.5. Muscle weakness and rhabdomyolysis resolved.

**Conclusions:** Topiramate can induce mixed RTA picture with features of RTA 1 and 2. This can be explained by the ability of Topiramate to inhibit Carbonic Anhydrase (CA) II. CA II plays an essential role in the reabsorption of HCO3 by the proximal tubule and the urinary acidification by the distal tubule. In our patient Proximal RTA is suggested by non-anion gap metabolic acidosis with negative urine anion gap. The presence of high urine PH in the steady state along with nephrolithiasis are features of distal RTA. The development of metabolic acidosis at the time Topiramate initiation and its resolution following discontinuation of the treatment confirms the diagnosis of Toperimate induced RTA. The case emphasizes the importance of electrolytes monitoring following initiation of Topiramate.

**TH-PO791**

**Extreme Fluctuation of Serum Potassium Level during Hypothermia Induction** Osama W. Amro, Geetha Narayan. *Nephrology, Tufts Medical Center, Boston, MA.*

**Background:** Induction of hypothermia following cardiac arrest is being used to decrease the risk of permanent neurological damage. This method is usually safe but it carries few potential complications including hypokalemia. Hypokalemia is related to intracellular potassium shift. We are reporting a case of extreme fluctuation of serum K level before and after induction of hypothermia.

**Methods:** A 27 year old previously healthy male presented with general weakness to the ER and had witnessed cardiac arrest. Fortunately he was revived with prompt CPR. Initial blood work showed K of 6.4, Cr 2.2, CK of 4000. Repeat electrolytes confirmed serum K level. Following the cardiac arrest patient became anuric mostly secondary shock. Hypothermia was induced and upon reaching target temperature of 32 degree repeat electrolytes showed k level of 2.3. Patient started to develop multiple premature ventricular beats and was given 40 meq KCL IV. Cautions repletion of K was chosen to avoid rebound hyperkalemia following rewarming. No further K supplements were given and repeat K level during rewarming phase showed k levels between 4-5.5. Next day patient urine output and kidney function improved and serum K level remained normal.

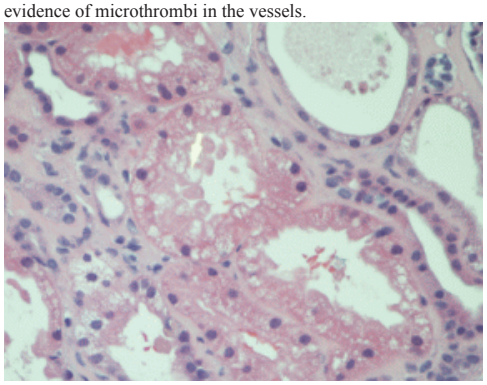
**Conclusions:** Severe hypokalemia may be seen in hypothermic patients, which represents intracellular potassium shift rather than a true depletion. Cautious repletion of hypokalemia is necessary to avoid fatal arrhythmia from extreme hypokalemia or hyperkalemia. Hyperkalemia can occur during rewarming phase. The case we are reporting illustrates the importance of carful electrolytes monitoring during and after induction of hypothermia. In our patient we encountered extreme fluctuation of serum potassium level during hypothermia induction. Potassium shift is the only mechanism explaining fluctuation of serum k level in the case we are reporting as the patient was anuric and had no diarrhea.

## TH-PO792

**Hypokalemic Nephropathy: Rare but Reversible** Rohini Prashar, Sandeep Vetteth, Deepak K. Malhotra, Imran Shafique. *Univ of Toledo Medical Center, Toledo, OH.*

**Background:** Chronic hypokalemia is well known to be associated with renal insufficiency and tubulointerstitial disease. We describe a case of progressive renal failure in a patient with thrombotic thrombocytopenic purpura which was initially thought to be thrombotic microangiopathy but eventually proven to be hypokalemic nephropathy from prolonged hypokalemia, successfully treated by correcting serum potassium.

**Methods:** A 50-year-old female was referred to us for evaluation of progressive increase in serum creatinine from 0.8 mg/dL to 3.7 mg/dL over the last two years. She had a history of thrombotic thrombocytopenic purpura diagnosed 14 years ago, which had been in remission for 4 years, and hypertension, well controlled with hydrochlorothiazide for 5 years. Her blood pressure was 105/65 mm Hg and physical examination was unremarkable. Review of old records revealed that she had been persistently hypokalemic (2.4 meq/l) and hypomagnesemic (1 meq/l) for the last 4 years. Other workup for chronic kidney disease was negative. She had high urinary potassium loss, which persisted even after hydrochlorothiazide was held. Kidney biopsy showed tubular vacuolation and chronic interstitial nephritis consistent with hypokalemic nephropathy. Interestingly, there was no evidence of microthrombi in the vessels.



Her renal function markedly improved with correction of potassium (3.8 meq/l), and creatinine was 2.1 mg/dl within 2 months of follow up.

**Conclusions:** We hypothesize that our patient had nephropathy from severe hypokalemia from the use of thiazides. Late-onset Gitelman's syndrome is also a strong possibility, which might have clinically manifested following the use of hydrochlorothiazide. Our case not only highlights the importance of obtaining renal biopsy in patients with unexplained renal failure, but also emphazises the need for monitoring electrolytes in patients on chronic diuretic therapy.

## TH-PO793

**Refractory Hypokalemia with Sustained Ventricular Tachycardia as the Presenting Sign of Metastatic Cancer** Sajan K. Eapen, Ruchir D. Trivedi. *Nephrology, Univ of Connecticut Health Center, Farmington, CT.*

**Background:** Hypokalemia usually has a readily apparent etiology. However, it can be the first sign of a complex process. We present a patient with refractory hypokalemia in the setting of metastatic disease.

**Methods:** An 84 year old female was repeatedly defibrillated by her AICD. Serum potassium (K+) level was 1.9meq/L and bicarbonate ($HCO3^-$)level 41 meq/L. Physical examination revealed blood pressure of 170/76 mmHg, obesity, and bilateral pitting edema. Urine specific gravity was 1.020, pH 7, otherwise negative for protein or active sediment. Relevant medication use included daily loop diuretics as well as laxatives and calcium citrate. Despite cessation of these medications, her metabolic alkalosis and hypokalemia persisted. 24 hour urine had shown K+ loss of 216meq/day. Mineralocorticoid excess was considered and workup was undertaken. Serum cortisol was 127 µg/dl (3-25). Serum aldosterone ranged from 7.9 - 11.6ng/dl (0 - 44 ng/dl). High-dose dexamethasone suppression test revealed cortisol levels of 138, 126, 119 µg/dl at 0, 30, 60 minutes, respectively. Urinary cortisol measured 15158 µg/d (n- <45µg/day). Serum adrenocorticotropic hormone (ACTH) level was measured at 192 pg/ml (6 -58pg/ml) suggestive of an ACTH mediated process. Imaging studies revealed the presence of multiple lung nodules consistent with metastatic disease as well as a pancreatic mass. Ectopic ACTH syndrome (EAS) was determined to be the underlying disease process.

**Conclusions:** Ectopic ACTH syndrome led to severe hypercortisolism. The mineralocorticoid-like activity of cortisol led to profound hypokalemia as well as metabolic alkalosis and volume overload, mediated both by distal hydrogen secretion as well as sodium reabsorption. EAS is one possible diagnosis of hypokalemia and metabolic alkalosis since similar inherited and acquired pathologies exist. A structured approach is necessary to reveal the underlying diagnosis.

## TH-PO794

**Metformin-Associated Lactic Acidosis in an Alcoholic with Fluorescent Urine** Ian Matthew Rivera, Jorge I. Martinez Osorio, Christina M. Yuan, Dustin J. Little. *Dept of Medicine, Nephrology Section, Walter Reed National Military Medical Center, Bethesda, MD.*

**Background:** Lactic acidosis is a rare but serious complication of metformin use. Patients with comorbidities such as renal insufficiency or liver disease may be at increased risk.

**Methods:** A 63 y.o. diabetic male with a history of alcoholism presented to the ED with abdominal pain. He was hypothermic (31°C) and lethargic but alert with otherwise stable vitals. Initial labs showed serum creatinine 2.64 (baseline 1.0mg/dL), glucose 29mg/dL, arterial pH 6.71, serum bicarbonate 2meq/L, PaCO2 16.5mmHg, lactate 28.5mmol/L, anion gap 45mmol/L, osmolar gap 20, AST/ALT/AlkPhos 396/140/133 U/L, PT 17.1 (11.6-14.2), Tbili 0.4mg/dL, and MCV 109fL. The patient's urine fluoresced brightly under ultraviolet light. Hemodialysis was initiated (only 1 treatment required, 6 hrs duration), and one dose of 4-methylpyrazole was administered. Serum levels of ethanol, toxic alcohols, salicylates, and acetaminophen were normal/negative. Carnitine deficient transferase and urine ethanol metabolites suggested recent heavy ethanol consumption. Serum metformin was 4.7 (therapeutic 1-2µg/mL). The patient's labs normalized and he required no further hemodialysis. He was discharged on hospital day 6. Urine fluoresced for the remainder of his hospital stay, but not on follow-up.

**Conclusions:** This patient survived following prompt initiation of supportive care and hemodialysis. His alcoholism may have predisposed him to metformin-associated lactic acidosis through associated B vitamin deficiencies and liver dysfunction and increased NADH generation by alcohol dehydrogenase. His osmolar gap was likely secondary to AKI and lactic acidosis, and the etiology of his urine fluorescence is unknown. This case suggests that providers should consider alternatives to metformin in patients at risk for alcohol abuse, and highlights the nonspecific nature of urine fluorescence.

## TH-PO795

**Pseudoacidosis after Cardiac Catheterization** Annamalai Arunachalam, Shreya Patel, Sreedhar A. Mandayam. *Nephrology, Baylor College of Medicine, Houston, TX.*

**Background:** Metabolic acidosis is a common problem in hospitalized patients. It is usually detected by a lowering of serum bicarbonate level or an accompanied increase in anion gap. The ADVIA chemistry CO2 concentrated Reagan method used to measure serum CO2 levels in venous blood is affected by hyperlipidemia. To minimize this interference, labs use "Lipoclear Centrifuge Method".

It is unclear other substances also interfere with this method. We report a case of spuriously low CO2 levels in a patient after exposure to contrast agent.

**Methods:** 50 year old gentleman with a history of hypertension, diabetes mellitus, hyperlipidemia was admitted with chest pain. BMP on admission was normal, triglyceride levels 507 mg/dL. Cardiac catheterization was performed. Next day bicarbonate level were less than 10. Arterial blood gas showed ph of 7.41, pC02 41 and Hco3 of 26. The BMP and the ABG were repeated twice with similar results. Nephrology & Clinical Chemistry were consulted. Next day BMP showed normal bicarbonate levels and patient was discharged.

| | admission | precath | d1 post cath | repeat | day 2 |
|---|---|---|---|---|---|
| Creatinine | 1.07 | 0.8 | 0.93 | 0.78 | 0.99 |
| HCO3 | 22 | 25 | <10 | <10 | 27 |
| pH | | | 7.41 | 7.43 | |
| pCO2 | | | 40 | 39 | |
| HCO3 (ABG) | | | 25 | 25 | |

**Conclusions:** ADVIA chemistry CO2 concentrated Reagan method is based on phosphoenolpyruvate carboxylase catalyzed reaction followed by indicator reaction which uses malate dehydrogenase as a catalyst for the oxidization of the reduced NADH analog. Lipemic samples alter bicarbonate levels. Thus the Lipoclear centrifuge method is used. In our patient, bicarbonate levels were normal on admission but turned falsely low for 24 hours despite using the lipoclear centrifuge method prior to running the sample via the routine chemistry analysis. This was repeated twice under supervision. Within 24 hrs, the BMP normalised. As his ABG did not show any evidence of acidosis during his entire stay & his CO2 returned to normal in 24 hrs, we hypothesize that Radiocontrast agent used for heart cath (Omnipaque 350: 90% cleared 24 hrs) interfered with the ability of Lipoclear to clear the serum & lead to an abnormally low CO2 level. Spuriously low venous CO2 levels can be seen in patients with hyperlipidemia after contrast study for 24 hours.

## TH-PO796

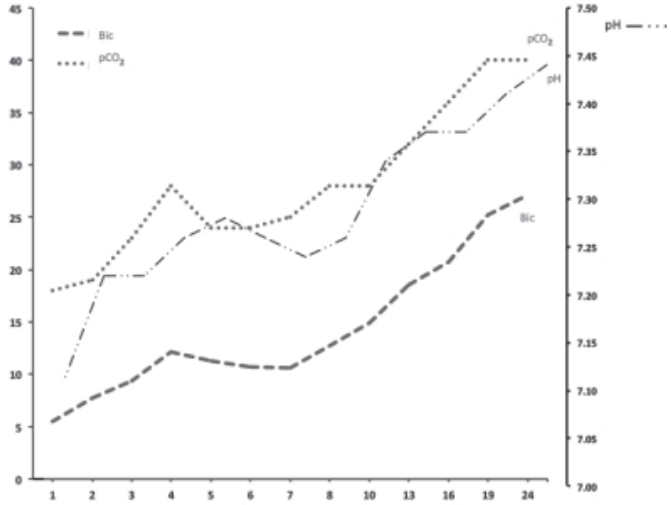
**Severe Ketoacidosis in a Patient with Spinal Muscular Atrophy Type II** Peter Bertke, Spyridon Arampatzis. *Dept of Nephrology, Hypertension and Clinical Pharmacology, Inselspital, Uni. of Bern, Bern, Switzerland.*

**Background:** We describe a patient with spinal muscular atrophy type II resulting in severe ketoacidosis due to starvation.

**Methods:** A 23-y/o Caucasian male with muscular atrophy type II underwent an arm-amputation due to rhabdomyosarkoma. Subsequently, a worsening, severe metabolic acidosis was noted. Laboratory findings included:blood-pH 7.15, Bic:4.6mEq/l, $pCO_2$:14mmHg, Anion-Gap:15mmol/l, creatinine:0.07mg/dl, urea:8.4mg/dl, ketonuria>15mmol/l. The

patient, was fasting overnight due to secondary surgery planned the following day. Other causes being excluded, a diagnosis of starvation-ketoacidosis (SK) was made. Correction by Na+[/sup]-bicarbonate and glucose infusions normalized the severe metabolic disorder within 24h. After starting enteral feeding and despite i.v. substitution of K+[/sup] and phosphate, a transient refeeding-syndrome dyselectrolytemia was corrected. Ketonuria instantly disappeared.

| | Initial | 12h | 15h | 18h | 21h | 24h | Units |
|---|---|---|---|---|---|---|---|
| Phosphate | 0.73 | 0.30 | 0.32 | 0.79 | 1.23 | 1.83 | mmol/l |
| Calcium | 0.81 | | 1.9 | 1.88 | 1.84 | 1.75 | mmol/l |
| Potassium | 3.3 | 3.4 | 3.2 | 3 | 3.5 | 4.9 | mmol/l |



**Results:** The diagnosis of SK was on the rapid therapeutic response without further preexisting conditions.The remarkable low serum creatinine was due to spinal muscular atrophy which could also have aided to the reduced capability of providing energy supplies other than by lipolysis further worsened by the release of excess stress hormones given the surgical intervention.

**Conclusions:** SK should be considered in the differential diagnosis of severe metabolic acidosis. Correction of SK exacerbated by stress need careful monitoring due to the potential development of refeeding-related disturbances.

## TH-PO797

**Acute Severe Lactic Acidosis Associated with Venlafaxine** Chaitanya Iragavarapu, Tanush Gupta, Treta Purohit, Savneek S. Chugh. *Internal Medicine, New York Medical College.*

**Background:** Lactic Acidosis that is not secondary to tissue hypoperfusion or hypoxemia (Type B lactic acidosis) is a rare but potentially fatal condition that has been associated with drugs like Metformin, Linezolid and Nucleoside Reverse Transcriptase Inhibitors (NRTIs). Here, we report a case of severe type B lactic acidosis caused by overdose of a Serotonin-Norepinephrine Reuptake Inhibitor (SNRI), Venlafaxine, which to our knowledge has not been published in current literature.

**Methods:** A 55 year old man with no significant past medical history was brought to our emergency room by the police after intentional ingestion of around eighty capsules of Venlafaxine (a total dose of over 6000 mg) in an attempt to commit suicide. He was awake and alert; his only complaint being mild nausea. On admission, he had a blood pressure of 168/101, pulse rate 115, respiratory rate 16/min and saturating 97% on room air. Physical examination was otherwise unremarkable. Pertinent laboratory findings at admission included bicarbonate of 13 mEq/L with an anion Gap of 22. Other results including complete blood count with differential, blood urea nitrogen, creatinine, creatine kinase and hepatic function panel were normal. Arterial blood gas revealed a pH of 7.39, a $pCO_2$ 19 mm Hg, p02 119 mmHg, calculated bicarbonate 11.5 mEq/L and lactate level of 8.6 mmol/L. He received aggressive intravenous hydration with normal saline along with oral Charcoal and Sorbitol. Repeat blood work after four hours showed an improvement in anion gap (15) and serum lactate (5.6 mmol/L). Patient remained asymptomatic and hemodynamically stable throughout his hospital stay and his lactic acidosis resolved in 24 hours.

**Conclusions:** Type B Lactic acidosis is due to impairment in lactic acid generation and/or utilization at the cellular level. In our case, venlafaxine was the most likely cause of lactic acidosis given the absence of hypotension, hypoxemia, kidney or liver dysfunction, myopathy, malignancy or other medication use. Rapid improvement of acidosis was probably related to clearance of the drug. Venlafaxine is a commonly prescribed medication and physicians should be aware of this potentially lethal consequence from overdose.

## TH-PO798

**Mind the Gap: A Subtle Clue as a Diagnostic Aid** Prashant Kolar. *Nephrology, Univ of Missouri, Columbia, MO.*

**Background:** We present a case of unknown alcohol intoxication with elevated anion and osmolal gap. Patient had a blood lactate level that was significantly higher on arterial blood gas (ABG) compared to serum, suggesting an apparent lactate gap (LG). This finding is an indirect marker of ethylene glycol poisoning which can be a helpful clue, especially in patient with mixed alcohol intoxications. Knowledge of artifactual elevation of lactate is helpful in avoiding unnecessary expensive work up for lactic acidosis including a potential laparotomy for possible bowel ischemia.

**Methods:** A 65 y/o male on gastroenterostomy tube feeding for previous complicated cholecystectomy, was brought to hospital with unsteady gait & shortness of breath. He had respiratory distress without hypoxemia, requiring mechanical ventilation. Lab data showed serum lactate level of 6.6 mmol/L, but the lactate on ABG using auto analyzer showed value of 12.8 mmol/L. This suggest apparent lactate gap, seen in ethylene glycol overdose. The measured ethylene glycol level was 44mg/dl.

**Conclusions:** The metabolites of ethylene glycol, glycolic acid and glyoxylic acid can cross react with the analytical reagent L-lactate oxidase, used in many blood gas analyzers(1). Other methods using lactate dehydrogenase may not be affected by these metabolites(2). Thus finding a "lactate gap" using 2 different methods can help to differentiate ethylene poisoning from true lactic acidosis. Interestingly in the setting of potential ethylene glycol poisoning, the use of the lactate oxidase may be a simple method to "monitor" level of metabolites(3). Treatment with dialysis can be stopped, once the gap disappears. Knowledge of potent artifactual lactate results was the clue to the diagnosis of ethylene glycol poisoning in our case but the mode and motive of intoxication remained an enigma.

Interference by glycolic acid in the Beckman synchron method for lactate: a useful clue for unsuspected ethylene glycol intoxication. Clin Chem 2000;46:874-5.

## TH-PO799

**Two Cases of Acute Renal Injury and Fatal Lactic Acidosis due to Germanium Ingestion as a Supplement** Ikuyo Narita, Michiko Shimada, Takeshi Fujita, Yuko Shimaya, Reiichi Murakami, Norio Nakamura, Hideaki Yamabe, Ken Okumura. *Nephrology, Hirosaki Univ, Hirosaki, Japan.*

**Background:** Germanium supplements have been used as elixir. However, serious adverse effects have been rarely reported. Here, we describe 2 cases of fatal lactic acidosis occurred in a married couple.

**Methods:** Case 1: A 59-year-old female who had been suffering with erythematous rashes for 1 month and gastrointestinal symptoms for 2 weeks visited a clinic and laboratory studies revealed renal dysfunction. She was consulted to nephrology and admitted to our hospital. Her blood pressure was 78/50 mmHg, heart rate was 110/min and her conscious was clear on admission. Laboratory data were as follows:WBC 5640/μl, Hb 14.9g/dl, Plt $6.0x10^4$/μl, BUN 27 mg/dl, serum creatinine 2.5 mg/dl, AST 100 IU/l, ALT 102 IU/l, CPK 6464 IU/l, CRP 16.2 mg/dl. Blood gas analysis: pH7.41, $pO_2$ 95 mmHg, $pCO_2$ 18 mmHg, $HCO_3$ 11.3 mmol/l, lactic acid 10.7 mmol/l. On the 2nd hospital day, she was admitted to the intensive care unit and continuous hemodiafiltration was iniciated. Her general conditions were exacerbated due to low blood pressure, liver damage, renal failure, respiratory distress and disseminated intravascular coagulation. Lactic acidosis was progressively exacerbated and the data finally became pH 6.8 and lactic acid 22 mmol/l. She died on the 6th hospital day. Case2: A 65-year-old male who is the husband of case 1 was hospitalized 2 days after the admission of his wife due to the similar symptoms. His general conditions and lactic acidosis were similarly exacerbated and he died on the 8th hospital day. In both cases, intensive search for infection revealed no positive results. There was no evidence of illicit drug use. However, they had been taking supplements containing germanium for 10 years. Analysis of the hair and nail in both cases revealed very high germanium concentrations. The autopsy of case 1 revealed severe fatty degeneration of the liver and renal tubular epithelial cells. Pellagrous changes were seen in the brain.

**Conclusions:** The symptoms in these cases were compatible with the previous reports of germanium intoxication. These symptoms suggested profound mitochondrial dysfunction.

*Funding:* NIDDK Support

## TH-PO800

**High Anion Gap Metabolic Acidosis and Chronic Acetaminophen Use: An Under Recognized Association** Olutayo T. Olabige, Mamoon Rasheed, Ewalola A. Ijaduola, Sudhanshu Jain, Leroy Herbert, Herman L. Anderson, Jeffrey D. Wallach. *Harlem Hospital Center, New York, NY.*

**Background:** High anion gap metabolic acidosis (HAGMA) is a severe metabolic disorder with diverse causes including lactic acidosis, ketoacidosis, metabolites from various toxic substances (methanol, glycols or paraldehyde) and renal failure. Accumulation of 5-oxoproline (pyroglutamic acid) is another rare and underdiagnosed cause of HAGMA. Chronic acetaminophen ingestion causes depletion of glutathione in malnourished patients (via glycine deficiency) leading to disruption of the gamma-glutamyl cycle with accumulation of 5-oxoproline.

**Methods:** A 55-year old African American male with history of metastatic lung cancer, hypertension, diabetes mellitus, congestive heart failure, atrial fibrillation,and chronic pain presented with worsening dyspnea. Home medications included acetaminophen/codeine and aspirin. Initial ABG showed a pH 7.32, pO2 78mmHg, pCO2 18mmHg HCO3 9mmol/L. He was intubated and placed on mechanical ventilation. Electrolytes showed Na 143 K 4.2 Cl 108 HCO3 11 anion gap(AG) 24. BUN 12mg/dL, creatinine 0.8mg/dL, glucose 108mg/dl, serum osmolar gap 2, AST/ALT normal, and albumin 2.2g/dL. Salicylate 18mg/dL, lactate 2.0mmol/L. Serum acetone was positive initially and rapidly cleared with no improvement in HAGMA. Urine AG +92. Patient developed septic shock and oliguric acute kidney injury

(AKI) requiring continuous renal replacement therapy. Acetaminophen was discontinued, N-acetylcysteine empirically started to replete glutathione stores and his HAGMA and AKI resolved within 72 hours.

**Results:** Urine organic acid assay was positive for 5-oxoproline at concentration of 256 mmol/mol creatinine (NL 15-59), homovanillic acid 275 mmol/mol creatinine (NL 1-5). Glycolic acid and other organic acids were normal.

**Conclusions:** 5-oxoproline accumulation is an increasingly recognized cause of HAGMA. It should be considered in patients with chronic acetaminophen use, especially in the context of malnutrition and multiple comorbidities. A high index of suspicion is necessary to make an accurate diagnosis and institute appropriate supportive therapy. A urinary organic acid screen can confirm the diagnosis rapidly.

## TH-PO801

**Renal Fanconi's Syndrome and Hypophosphatemic Osteomalacia Induced by Low-Dose Adefivir Dipivoxil Therapy for Hepatitis B** Rikako Hiramatsu, Yoshifumi Ubara, Keiichi Sumida, Junichi Hoshino, Tatsuya Suwabe. *Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

**Background:** Adefovir dipivoxil (ADV) at a daily dose of 10 mg is commonly used as an antiviral agent to treat chronic hepatitis B. The safety of a daily dose of 10 mg ADV is advocated by the registration trial. We present here two cases of renal Fanconi's syndrome together with hypophosphatemic osteomalacia induced by low-dose ADV in chronic hepatitis B (CHB) patients.

**Methods:** The first patient was a 67-year-old woman who complained of severe bone pain involving her knees and ankles. She had a history of CHB, and had been treated with ADV for the past 53 months. Laboratory tests showed severe hyphophosphatemia (serum P; 0.8 mg/dL) with urinary phosphate wasting, glucosuria, aminoaciduria, metabolic acidosis, and serum alkaline phosphatase (ALP) elevated to 819 IU/L. Serum creatinine and 1,25-hydroxyvitamn D3 level were normal. A whole bone scan showed intense uptake in both knees, ankles and bilateral ribs.

Fig. 1

The second patient was a 65-year-old woman with CHB who complained of pain in several bilateral ribs and ankles. She had been treated with ADV for 56 months before occurrence of bone pain. She was also found to have hyphophosphatemia (serum P; 1.2 mg/dL) with proximal renal tubule dysfunction and elevation of serum ALP. In both cases, bone biopsy revealed osteomalacia. After discontinuation of ADV and phosphate supplementation, their symptoms resolved, laboratory abnormalities normalized and imaging studies showed improvement in both patients.

**Conclusions:** Despite large clinical trials advocating the safety of ADV at 10 mg daily, long-term use of this agent can be nephrotoxic and in rare cases, can cause renal Fanconi's syndrome and severe hypophosphatemic osteomalacia. Clinicians should be aware of this infrequent but severe complication of low-dose ADV in CHB treatment.

## TH-PO802

**Hydrochloric Acid to Treat Extreme Metabolic Alkalosis** Jose Jesus Perez, Rajeev Raghavan. *Nephrology, Baylor College of Medicine, Houston, TX.*

**Background:** Anorexia-bulimia nervosa are eating disorders that are associated with electrolyte and acid-base disturbances. Extreme alkalosis with a pH greater than 7.65 has a high risk of mortality. We present a bulimic patient with such alkalemia and our subsequent medical management.

**Methods:** A 27-year old female presented to the ER with complaints of nausea, vomiting, weakness, palpitations, and abdominal pain. She denied having an eating disorder, and did not take medications. Within an hour of presentation, she developed ventricular tachycardia requiring cardioversion. Initial resuscitation included 2 liters of normal saline, 2 grams magnesium sulfate, 4 grams calcium gluconate and 20 meq of KCl. She continued to have ventricular arrhythmias including Torsades de Pointes. On exam, blood pressure 96/50 mm Hg, pulse rate 84 beats/min, respiratory rate 20 breaths/min, temperature 98.1°F, weight 90 lbs. The patient was thin, had poor skin turgor, dry mucous membranes, with enamel erosions.

| | Time 0 | 2 hours | 4 hours | 10 hours |
|---|---|---|---|---|
| Sodium (mmol/L | 109 | 110 | 118 | 120 |
| Potassium (mmol/L) | 2.1 | 1.8 | 2.3 | 3.5 |
| Chloride (mmol/L) | <50 | <50 | 65 | 78 |
| CO2 (mmol/L) | >45 | 43 | 35 | 27 |
| BUN (mg/dL) | 12 | 11 | 10 | 10 |
| Creatinine (mg/dL) | 0.6 | 0.6 | 0.5 | 0.6 |
| Calcium (mg/dL) | 9.1 | 8.5 | 16 | 12.8 |
| Phosphorous (mg/dL) | 1.8 | 1.4 | 1.9 | 6 |
| Magnesium (mg/dL) | 2.4 | 1.9 | 8.5 | 3.6 |
| pH | - | 7.89 | 7.71 | 7.60 |
| pCO2 (mmHg) | - | 32 | 25.5 | 40.4 |
| pO2 (mmHg) | - | 399 | 217 | 222 |

The patient had persistent metabolic alkalosis with cardiac instability. Since her serum sodium had corrected by 9 mmol within 4 hours and she had been adequately volume resuscitated, we were hesitant to give normal saline and proceeded to treat with intravenous hydrochloric acid. Preparation of infusion was made with 7.5ml of 10% HCl in D5W infused at 50cc/hr, providing a total of ~21mEq of HCl. Electrolytes were aggressively repleted. Sedation was increased to achieve a target pCO2 of 40. The patient's family later reported a long history of anorexia-bulemia.

**Conclusions:** Patients with eating disorders may develop severe metabolic derangements that could potentially be life threatening. This vignette represents a case of extreme metabolic alkalosis in which the patient was successfully treated with hydrochloric acid and able to survive and recover.

## TH-PO803

**Vancomycin-Induced Nephrotoxicity: A Pitfall of Overestimating GFR for Drug Dosing by Using Serum Creatinine** Ekamol Tantisattamo, Jason Cobb, Tahsin Masud. *Renal Div, Emory Univ School of Medicine, Atlanta, GA.*

**Background:** Widely used as a surrogate of overall renal function, serum creatinine (SCr) is one of the most practical markers of eGFR. We report a case of an amyotrophic lateral sclerosis (ALS) man with very low SCr presenting with vancomycin toxicity from an overestimation of eGFR.

**Methods: Case Description:** A 39 year-old Caucasian man with a history of ALS complicated with chronic respiratory failure and ventilator-dependence, was diagnosed with staphylococcal bacteremia and treated with vancomycin 1,500 mg every 12 hours. His baseline BUN and SCr was 3 mg/dL and <0.3 mg/dL, respectively. Serum albumin was 2.4 g/dL. His weight was 81 kg and BMI was 24.95 kg/m$^2$. Three days prior to admission, he had decreased urine output and lethargy. SCr was elevated to 2.98 mg/dL. Vancomycin level was supratherapeutic (>120 ng/ml 10 days after vancomycin was started). SCr continued to rise up to 3.43 mg/dL and vancomycin level was persistently high. Four days later, he was oliguric and was started on hemodialysis for 3 days. Vancomycin level decreased to therapeutic level 6 days after initiation of hemodialysis and SCr returned to baseline.

**Conclusions:** eGFR is relatively accurate for most patients; however, it cannot be applied to our patient with muscular atrophy from underlying ALS. His lean body mass (LBM) decreases while total body fat increases, leading to artificially decreased SCr. As volume of distribution of relatively hydrophilic drugs such vancomycin correlates very well with LBM, estimated LBM in the patients losing muscle mass should be taken into account when initiating vancomycin. LBM which determines SCr level needs to be considered in estimating GFR when dosing medications. Creatinine clearance from 24-hour urine collection may be warranted. Close monitoring of renal function and vancomycin level is crucial for early detection of vancomycin toxicity. Moreover, as high level of remaining vancomycin in the setting of acute kidney injury can perpetuate the toxicity, low threshold of initiating hemodialysis should be considered to mitigate the toxicity.

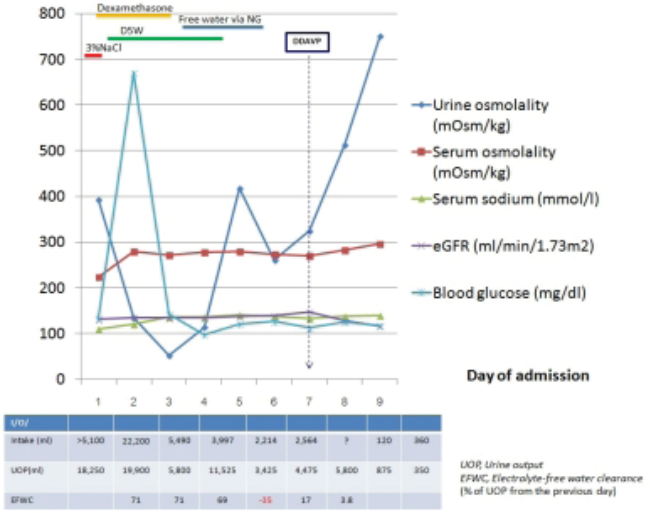
## TH-PO804

**Concomitant Polyuria and Hyponatremia in a Glucocorticoid Deficiency Patient with Transient Nephrogenic Diabetes Insipidus** Ekamol Tantisattamo, Frederic F. Rahbari-Oskoui, John Doran. *Renal Div, Grady Memorial Hospital, Emory Univ, Atlanta.*

**Background:** Hypernatremia and polyuria are classic manifestations of diabetes insipidus (DI). However, glucocorticoid can affect urinary dilution leading to hyponatremia. We report a man with corticosteroid deficiency presenting with symptomatic severe hyponatremia and transient partial nephrogenic DI.

**Methods: Case description:** A 27-year-old man with polysubstance addiction presented with seizures and was intubated. He took no medications. Serum sodium (SNa) was 109 mmol/l and serum osmolality (SO) was 224 mOsm/kg. Blood glucose (BG) was 133 mg/dl. Urine osmolality (UO) were 339 mOsm/kg and urine Na (UNa) was 76 mEq/L. 3% NaCl 30 ml/h was started. Ten hours later, SNa rose to 128 mmol/l and urine output (UOP) was 760 ml/hour. 3%NaCl was switched to D5W and the rate matched with UOP. SNa ranged 130-135 mmol/l and UOP was 18 L over 24 hours. Labs on the following days were shown in the figure. On day 5, D5W was discontinued and UOP decreased to 3 L/day. UO were 418 and SO was 279 mOsm/kg. He was intubated so primary polydipsia was excluded. Water deprivation test was not performed. Desmopressin was given. UO slightly rose to 472 and 481 mOsm/kg 1 and 2 hours after desmopressin administration, respectively. All pituitary hormones were normal except low cortisol of 2 mcg/dl. Dexamethasone was started. He was discharged on day 10 with normal SNa and no polyuria or neurological deficit.

**Conclusions:** Concomitant DI and hyponatremia can occur in glucocorticoid deficiency impairing urinary dilution via an ADH-independent mechanism. Apart from DI, replacement the UOP with D5W led to osmotic diuresis and subsequently persistent polyuria. Glucocorticoid deficiency should be considered as one of the causes of hyponatremia in DI. IV fluid need to be cautiously replaced to avoid prolonged polyuria from iatrogenic hyperglycemia.



## TH-PO805

**Anabolic Steroid-Induced Liver Injury and Cholemic Nephropathy**
Greg T. Means, Leybelis Padilla, Fernanda Payan Schober, Rachel Cianciolo, Marc Richards, Patrick H. Nachman. *Nephrology, Univ of North Carolina, Chapel Hill.*

**Background:** The use of anabolic steroids has increased in both athletes and non-athletes. Acute Liver injury is a well-recognized consequence of androgenic steroid use. Severe hyperbilirubinemia has been hypothesized to cause acute kidney injury through bilirubin tubular cast formation, a phenomenon referred to as cholemic nephropathy. We report a unique case of anabolic-steroid induced cholemic nephropathy.

**Methods:** A 35 year old male with remote history of alcohol abuse presented with a 2 month history of jaundice, fatigue, vomiting, unintentional 7 kg weight loss, and a serum creatinine of 4 mg/dL. There was no history of hypotension (BP 123/59), exposure to IV contrast or NSAIDs. He reported taking 'Epistane', a readily available pro-anabolic steroid 'food supplement', and N-actetyl cysteine for 4 weeks prior to presentation. His total bilirubin was 40 mg/dL with near normal transaminases and intact synthetic liver function (albumin 4.5 g/dL, INR 1.0). Hepatitis serologies, HIV screen, and urine toxicology tests were negative. Abdomen/pelvis CT scan and renal ultrasound were unremarkable. Urine sediment showed darkly pigmented, bile stained granular casts. A renal biopsy revealed diffuse moderate to severe tubular injury in association with bile casts consistent with a bile cast nephropathy. Despite cessation of Epistane, the hyperbilirubinemia persisted. His renal function deteriorated and hemodialysis was started 3 weeks later. Two weeks later, his bilirubin decreased to 15 mg/dL and GFR recovered to 39 ml/min/1.73m2. One month later, bilirubin was 2.2 mg/dL and GFR >60 ml/min/1.73m2.

**Conclusions:** Supplements containing anabolic steroids can be hepatotoxic leading to isolated hyperbilirubinemia, which is implicated in acute tubular injury and cast nephropathy, especially when bilirubin levels are >20 mg/dL [1,2]. Cholemic nephropathy should be considered in the absence of other causes of renal damage. This case suggests the possible benefit of decreasing serum bilirubin concentrations with dialysis to preserve and recover renal function.

## TH-PO806

**A Rare Complication of BCG Therapy**
Kristin M. Corapi,[1] Imran Sajjad,[1] David B. Mount,[2] Robert J. Hamburger.[2] *[1]Renal, MGH/BWH, Boston, MA; [2]Renal, VA Boston, West Roxbury, MA.*

**Background:** We present a rare case of hypercalcemia and acute kidney injury (AKI) following intra-vesical Bacillus Calmette-Guerin (BCG) therapy.

**Methods:** A 64-year-old man with history of bladder cancer was admitted with lethargy, nausea, and vomiting. His lab work revealed AKI and hypercalcemia. His cancer was treated with TURBT and intra-vesical chemotherapy; he remained on maintenance BCG treatments. His most recent dose was complicated by fevers, dysuria, and hematuria. He received Ciprofloxacin for a presumed UTI. On admission his physical exam was unremarkable. His lab results are below.

| Test | Result | Normal Range |
|---|---|---|
| BUN; mg/dL | 52 | 7-25 |
| Creatinne; mg/dL | 3.8 | 0.5-1.5 |
| Ionized Calcium; mg/dL | 6.6 | 4.5 - 5.3 |
| PTH; pg/mL | 12.8 | 10-65 |
| PTHrp; pg/mL | 33 | 14-27 |
| 25 OH Vitamin D; pg/mL | 39 | 10-65 |
| 1,25 OH Vitamin D; pg/mL | 100 | 18-72 |
| ACE; U/L | 163 | 3-67 |
| Alkaline Phosphatase; U/L | 433 | 40-150 |
| Gamma GTP; U/L | 721 | 10-65 |

His course was complicated by pulmonary edema, pancytopenia, and elevated alkaline phosphatase. Renal ultrasound showed no hydronephrosis. A chest CT revealed bilateral reticulo-nodular opacities. Both a bronchoscopy and bone marrow aspirate were normal with negative AFB cultures. Renal biopsy was notable for active interstitial nephritis and chronic vascular changes. Lastly, a liver biopsy was diagnostic of granulomatous hepatitis from disseminated BCG. He was started on prednisone, INH, Rifampin, and pyridoxine with improvement in his labs abnormalities. BCG exerts anti-tumor effects by creating local inflammation; granulomas may form as a hyersensitivity reaction. Hypercalcemia results from extra-renal calcitriol production in the granuloma macrophages.

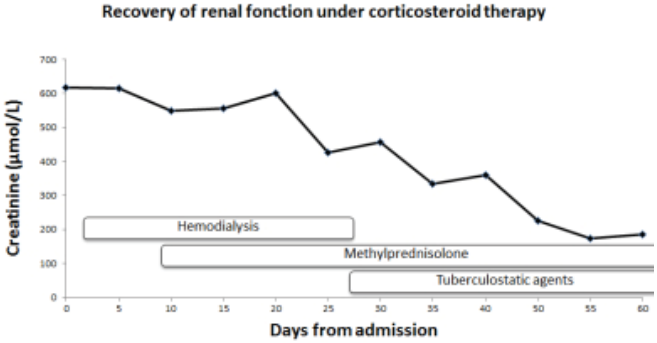
**Conclusions:** BCG is used to treat bladder cancer and is generally well tolerated. The most common side effects are urinary complaints or flu like symptoms. It is important to consider systemic granulomatosis if such a patient develops hypercalcemia, look for granuloma's, and treat with anti-Tb therapy.

## TH-PO807

**Prevention of Kidney-Lung Failure due to Intra-Bladder BCG Therapy**
Quentin Mat, Steffy Larroze, Rim Kada, Olivier Lmc MAT. *Nephrology - Dialysis, EpiCURA, Ath, Belgium.*

**Background:** We observed ARF 9 months after intravesical BCG adjuvant treatment for T1 bladder Transitional Cell Carcinoma (TCC). *Mycobacterium bovis* was identified by PCR on lung biopsy and tubulo-interstitial nephritis (TIN) was proved. He responded well to steroids and tuberculostatic tri-therapy. Prevention requires the eviction of risk factors and regular control of renal function (RF) during therapy.

**Methods:** A 76-year-old man presented ARF. TCC was treated by 10 adjuvant BCG intravesical instillations during one year. Laboratory revealed serum creatinine 699 µmol/L, ACE 140 IU/L. Hemodialysis was started. Chest CT confirmed a "ground glass" interstitial syndrome. A 10 IU PPD skin test was negative. Kidney biopsy showed TIN with eosinophilic infiltrate without granuloma. Lung biopsy demonstrated moderate lympho-neutophilic infiltration, few aspecific granulomatous lesions. Sarcoïdosis was suspected and oral methylprednisolone was started. Serum creatinine decreased to 220 µmol/L; hemodialysis was discontinued. On day 27, Mycobacterium bovis was identified on lung samples by PCR; tuberculostatic agents were initiated. Corticosteroids was gradually stopped.



**Conclusions:** Intravesical BCG is safely used as adjuvant treatment for bladder TCC despite flu-like syndrome in 20%. Dissemination occurs after traumatic bladder instillation and cumulative doses. Prophylactic Isoniazid doesn't prevent BCG complications. Contraindications include recent bladder surgery or radiotherapy, polypectomy, active cystitis, tuberculosis, immunosuppressive treatment. Medline system reported 12 associated ARF : 9/12 TIN, 5/12 granuloma; glomerulonephritis are exceptional. Our case combines the presence of causal Mycobacterium on lung samples. Prevention requires avoiding the risk factors and regular control of RF during prolonged therapy. Corticosteroids and tuberculostatic therapy should always be considered.

## TH-PO808

**Acute Kidney Injury (AKI) due to Multiple Myeloma (MM) Successfully Reversed by Bortezomib: A Medical Emergency Requiring a High Index of Suspicion and Prompt Diagnosis by Plasma Free Light Chains (PFLC)**
Usman Z. Bhutta,[1] Saurabh Dasgupta,[2] Kai Lau.[1] *[1]Nephrology Section, OUHSC, Oklahoma City, OK; [2]Medicine/Pediatrics, OUHSC, Oklahoma City, OK.*

**Background:** MM is caused by plasma cell dyscrasia & excess M protein. It can cause renal failure by cast nephropathy or light chain (LC) deposition. We report a case with AKI where MM was promptly diagnosed & renal failure rapidly reversed by bortezomib, a proteasome inhibitor selective against plasma cells.

**Methods:** We cared for a 56-year-old man with AKI noted in evaluating his back pain. Serum creatinine (Cr) rose from 0.8 to 4.6 mg/dL in 2 months. Serum protein electrophoresis (SPEP) had a small M spike. Urine PEP showed 2 large M spikes (3.1 & 78.9% of 5.1 g protein/d), but dipstick only 1+ positive. PFLC κ was up 2 fold (from renal failure), but λ pathologically up 70fold to 1890 mg/L (vs. 26 in normal),yielding a low κ: λ ratio of 0.02, diagnostic for MM. Other causes for AKI were excluded. 50% λ-restricted plasma cells in the marrow confirmed MM. He got plasma exchange, steroids & 4 doses of bortezomib in 2 weeks. Cr peaked at 9.9 but needed no dialysis. Bortezomib dropped his PFLC λ to 15 mg/L in 10 days & controlled it over next 4 months. Cr also fell in 10 days & hit 2.4, 1.5 , & 1.2-1.4 mg/dL after 0.5, 2, & 3.5-5 months respectively of the 1st dose.

**Conclusions:** 1. Our case illustrates the need for a high index of suspicion for MM in adult AKI.

2. PFLCs are sensitive & specific, useful in monitoring therapy & progression. Myeloma proteins are missed by urine dipstick but detected & quantifiable by UPEP.

3. Contrary to other causes of AKI where therapy is largely supportive, preventing complications & averting nephrotoxins, bortezomib is effective in halting synthesis of LC, the specific culprit, thus reversing AKI in MM. His gratifying response confirms & extends the published short list of similar patients diagnosed & effectively treated by bortezomib without dialysis.

4. Recent experience suggests a much improved outcome in MM despite severe renal failure vs. the era before bortezomib. Myeloma kidneys should be managed as a treatable medical emergency.

## TH-PO809

### Encephalopathy and Profound Hyponatremia due to SIADH Induced by Bortezomib (Velcade)

Usman Z. Bhutta,[1] Kent David Stuber,[2] Kai Lau.[1] *[1]Nephrology Section, OUHSC, Oklahoma City, OK; [2]Medicine/Pediatrics, OUHSC, Oklahoma City, OK.*

**Background:** Velcade-induced hyponatremia is not rare, at times symptomatic though under-recognized & underdiagnosed. We report a case to illustrate its insidious onset & slow spontaneous recovery needing brief tolvaptan therapy.

**Methods:** We consulted on hyponatremia in a 72-year-old woman getting outpatient velcade for symptomatic multiple myeloma. She was admitted for confusion, ataxia and a fall. A month ago, the 1st of 7 doses of velcade was given. Serum (S) Na (in mM) was 140 after the 4th but fell to 125 after the 6th & to 121 after the 7th dose. Though vital signs, volume status & neurologic exam were normal, urine (U) Na (<10) & BNP (13 pg/ml) were low, prompting normal saline for presumed salt depletion. Despite gaining 5.5 L of fluid & accruing edema, SNa peaked only at 127 & then quickly fell to 122. On day 3, U osmolality (osm) (in mOsm/kg) remained high at 567 vs. S osm of 258, despite high UNa of 102. On day 4, when S osm was low at 251-254, plasma ADH was inappropriately normal at 1.1 pg/ml. SIADH was diagnosed. Other known etiologies of SIADH were systematically excluded. To prevent worsening hyponatremia, she got 15 mg oral tolvaptan, which promptly dropped U osm to 50, led to 3 L diuresis in 48 h, & briefly raised SNa to 132-139. By restricting fluids to <1.2 L/day, SNa hovered ~ 130 from days 7-12, at which point, U osm spontaneously fell to 228 & 119. 12 days after the 7th & last dose of velcade, SNa was 130, slowly climbed to 135 & remained normal for the next month on ad lib fluids.

**Conclusions:** 1. Our case illustrates the potential of symptomatic severe hyponatremia due to velcade-induced SIADH.

2. Frequent & continued monitoring of SNa is key as hyponatremia may emerge insidiously, late after multiple doses, & even in outpatients.

3. Ample hydration during velcade may be unwise.

4. She took > 2 weeks after onset to recover spontaneously, suggesting a brief course of tolvaptan is needed if hyponatremia is severe or fluid restriction ineffective.

5. We need more studies to define the mechanism & address the feasibility of resumption after recovery, with or without concurrent tolvaptan prophylaxis.

## TH-PO810

### A Case of Acute Kidney Injury and Calcium Oxalate Deposition Associated with Synthetic Cannabinoids

Mahmoud Kamel, Bijin Thajudeen. *Nephrology, Univ of Arizona, Tucson, AZ.*

**Background:** We report a case of acute kidney injury(AKI) and renal calcium oxalate deposition after synthetic cannabinoids ingestion.

The use of these synthetic cannabinoid preparations has increased significantly in the United States over the past few years, and the incidence of acute kidney injury is underestimated. Also we are pointing to cannabinoids as a cause of hyperoxaluria based on results of renal biopsy and after we excluded all other causes of oxalosis.

**Methods:** 65 yr old male patient, paraplegic with neurogenic bladder, who was brought by EMS for altered mental status for which he was intubated in emergency department for airway protection. Upon presentatin, he was found to have AKI ( Cr 6.3 ) and hyponatremia 113.He was treated with Vanomycin/Zosyn for possible pneumonia.His PMH only includes neurogenic bladder. No previous abdominal surgeries. His home medications include methadone, oxycodone, nortriptyline and pregabalin. He reported recent Cannabis intake. His physical exam is significant for diminished breath sounds at both bases. Normal heart sounds, soft and lax abdomen with no palpable masses. His labs are significant for Na:113, K:5,CL:84,CO2: 14, BUN:88, Cr: 6.3, WBC 8.4 (normal differential), HB: 12.9 and platelet 178. urine sediment was bland. Renal us showed normal sized kidney and no hydronephrosis His pneumonia got better after receiving IV antibiotics and he was extubated but his cr continues to worsen and it peaked to 11.2, and at that time renal biopsy was performed which showed an evidence of active tubulointerstitial nephritis with marked tubular injury and calcium oxalate crystals present within tubular lumen.

**Conclusions:** Review of literature showed two reports demonstrated 14 and 30 patients respectively diagnosed with Acute kidney injury associated with SPICE use. A new article in Alabama showed also 4 cases of AKI assocaited with synthetic Cannabinoids. Here, we present a case of AKI and calcium oxalate deposition in a patient with synthetic cannabinoids use, pointing to cannabis as a cause of secondary oxalosis. Synthetic cannabinoids use is a potential cause for acute kidney njury/acute insterstitial nephritis and can lead to hyperoxaluria.

## TH-PO811

### Acute Kidney Injury Associated with Synthetic Cannabinoids Use

Ali Khalil, Jonathan W. Bazeley, Brian S. Decker. *Indiana Univ.*

**Background:** Synthetic cannabinoids (SC) include a variety of compounds publicized as harmless legal substitutes for Marijuana. SC are increasingly used and have serious toxicities including acute kidney injury (AKI) and myocardial infarction (MI). In this case we describe a patient with AKI and MI associated with use of SC.

**Methods:** A 20-year old previously healthy man, known to be a heavy SC user, had a witnessed seizure minutes after inhaling SC. On hospital presentation he was combative, suffered repeated seizures and was intubated. His blood pressure was 95/56 mmHg and pulse was136 beats/min. Physical exam was otherwise normal. Labs included serum creatinine (SCr) of 1.4 mg/dL, bicarbonate of 18mEq/L, creatine kinase of 149 ng/mL. Urinalysis showed specific gravity of 1.009, protein 100 mg/dL, glucose 30 mg/dL. Due to hypotension and oliguria, he was given normal saline intravenously. His SCr a day later was 5.32 mg/dL and renal replacement therapy was begun. Ultrasound showed normal kidney size and echotexture. Echocardiography revealed an ejection fraction (EF) of 20% with diffuse hypokinesis. Twelve days after initiation, dialysis was stopped. A coronary angiogram was normal with EF of 55%. SCr 4 weeks after presentation was 0.7 mg/dL.

**Conclusions:** The first SC were created by John Hoffman at Clemson. They are similar in structure to tetrahydrocannabinol but are up to 800 times more potent. Commercial names include K2, Spice, Legal Funk, and Gold. Formulations have included dried leaves or powder, typically a mixture of SC and herbal additives. The mechanism of kidney injury is unclear. Renal biopsy was not performed in our case but in a case series of four SC-exposed patients with AKI (Bhanushali et al., CJASN, 2013), three biopsies showed ATN, possibly due to a direct nephrotoxic effect of SC. Poor cardiac output may contribute to AKI in some cases, including ours. Cannabinoid receptor activation may lead to norepinephrine release and parasympathetic blockade, which could cause the cardiomyopathy. SC are also associated with coronary artery syndromes, severe hypotension, seizures and psychosis. Our goal with this report is to promote awareness among clinicians of the increasing use and toxicities of SC, including AKI.

## TH-PO812

### Acute Kidney Injury as a Result of Drug Elution from Antibiotic Impregnated Spacer Device in a Patient with Chronic Kidney Disease

Feroz Abubacker,[1] Prerna Ganjoo,[2] Pooja Singh.[2] *[1]Nephrology, Thomas Jefferson Univ Hospital, Philadelphia, PA; [2]Nephrology, Thomas Jefferson Univ Hospital, Philadelphia, PA; [3]Nephrology, Thomas Jefferson Univ Hospital, Philadelphia, PA.*

**Background:** Antibiotic impregnated cement spacers have been used commonly for the treatment of infected prosthetic hip and knee joints. Vancomycin and aminoglycosides are the most commonly used antibiotics in spacer devices. This modality of treatment provides high concentration of the antibiotic at the infected joint, while minimizing the systemic adverse effects. We present a case of acute kidney injury progressing to end stage renal disease from combined vancomycin and tobramycin toxicity in this setting.

**Methods:** A 78 year old woman, with history of left hip replacement (10 years ago), complicated by chronic periprosthetic infection, hypertension, chronic kidney disease (CKD) stage III , baseline serum creatinine 1.2mg/dl presented with 3 days of nausea and vomiting. Patient had undergone resection arthroplasty, with insertion of antibiotic spacer (3.6gm tobramycin + 3gm vancomycin per pack) to the left hip 3 weeks prior to admission. On examination, she was afebrile, hemodynamically stable, with negative orthostasis. Initial labs revealed elevated serum creatinine of 3.1 mg/dl, magnesium 1.1 meq/l, urinalysis with 1.7gm proteinuria with no active sediment, and normal renal imaging .Serum Tobramycin and Vancomycin levels were elevated at 8 mg/l, and 25 mg/l respectively. Patient developed oliguria and worsening renal function, and had to be commenced on hemodialysis(HD). 12 hour post HD Tobramycin and Vancomycin levels remained elevated, demonstrating continued drug elution. Serum antibiotic levels diminished only after the spacer was removed. The patient, however had progressed to end stage renal disease by this time.

**Conclusions:** Antibiotic spacer devices are currently classified as medical devices, and undergo a less stringent approval process by the FDA. Physicians should be cognizant of nephrotoxicity from drug elution in patients undergoing antibiotic impregnated prosthetic devices and monitoring protocols should be implemented to assess for renal function and drug elution.

**TH-PO813**

**A Case of Acute Tubular Necrosis in the Setting of IgG Kappa Multiple Myeloma: A "Sticky Situation" Solved with Plasmapheresis**
Emmett D. Ratigan, Nancy Miller, Reza Elahimehr, Dena E. Rifkin. *Nephrology, Univ of California San Diego, San Diego, CA.*

**Background:** Renal failure is a frequent complication amongst patients with multiple myeloma and is a well-known predictor of morbidity and mortality. Here we report a case of a patient with IgG kappa multiple myeloma (MM) and chemotherapy-induced acute kidney injury in whom high-flux hemodialysis proved impossible due to intractable clogging of hemodialysis membranes. Hemodialysis was only successful after plasmapheresis pretreatment.

**Methods:** A 72 year-old man with refractory IgG kappa MM was admitted with oliguric renal failure, due to acute tubular necrosis, two days after initiating a salvage regimen of CC (carfilzomib-cyclophosphamide-dexamethasone). He became progressively hyperkalemic and oliguric, prompting hemodialysis catheter placement and initiation of intermittent dialysis using a F160NR high-flux filter. Within minutes of treatment initiation his dialyzer clogged, which recurred on subsequent attempts despite heparin and TPA anticoagulation. A trial of continuous venovenous hemodiafiltration (CVVHD) using regional citrate anticoagulation also failed, as filters clogged within 120 minutes. Heparin-induced platelet antibodies and a hypercoagulability screen were negative. As serum light chain levels were elevated (163 mg/dl) we speculated they were aggregating and sludging through the filter. To acutely reduce their level, we then performed plasmapheresis (100% plasma volume replacement), after which he was able to complete a full hemodialysis treatment without use of anticoagulation. Following three days of paired treatments, he recovered renal function and became dialysis-independent. Following additional treatment with CCd, he redeveloped acute kidney injury necessitating hemodialysis, which we again primed with plasmaphersis. Four months later, he has no evidence of myeloma-related kidney disease, despite persistently elevated serum light chains.

**Conclusions:** Studies have demonstrated that light chains can aggregate and deposit in hemodialysis filters. In cases complicated by frequent filter clogging, plasmapheresis may be a useful tool to facilitate short-term hemodialysis.

**TH-PO814**

**Chronic Urine Leak Causing Acute Kidney Injury due to Abdominal Compartment Syndrome: An Unusual Case Masquerading as Hepatorenal Syndrome I**
Elhami N. Hannan,[1] Jeanie Park.[2] [1]*Nephrology, Emory Univ, Atlanta, GA;* [2]*Nephrology, Emory Univ, Atlanta, GA.*

**Background:** We present a case of a patient with acute onset Ascites, Spontaneous Bacterial Peritonitis ( SBP ), heavy alcohol intake and acute kidney injury ( AKI ), was initially presumed to be due to Type I Hepatorenal Syndrome ( HRS I).

**Methods: Case Description**A 76 year male presented to hospital with abdominal pain, increased abdominal girth and decreased urine output ( UOP ) for 2 weeks. His past medical history was significant for chronic kidney disease stage III, of unknown etiology. He also, has a history of Bladder cancer, was surgically removed, and a construction of neo bladder two decades ago. On exam, he was noted to have a tense ascites. Labwork revealed AKI with serum Creatinine 8.2 mg/dl. Paracentesis done with peritoneal fuid analysis consistent with SBP. Abdominal ultrasound revealed normal appearing kidneys, large ascites and atrophic liver. The patient started on treatment for presumed HRS I, was given Albumin, Octereotide and Midodrine. He did get hemodialysis as he became uremic. The patient remained oliguric and noted to have rapid reaccumulation of ascites, even after large volume paracentesis. Subsequently, MRI of abdomen and pelvis revealed a defect in the posterior wall of the neobladder. Ascitic fluid was then sent for Creatinine level , confirming that the ascitic fluid was urine. A foley catheter was inserted. The patient had significantly increased UOP, resolution of ascites, and a rapid drop in his serum Creatinine to normal. He was discharged home with urological follow up.

**Conclusions:** The patient presented with typical case of HRS I, in an alcoholic patient and ascites with SBP. However, his diagnosis was a much rarer case of AKI due to abdominal compartment syndrome from urine leak, that resolved with Foley insertion.

**TH-PO815**

**Permanent Renal Damage after Implantation of Tobramycin Beads during Orthopedic Surgery**
Cristy Gianna Martinez, Juan C. Lemos, Eddie M. Rodriguez, Carlos Antonio Cortes Sanchez, Carlos S. Rosado-Rodriguez, Hector R. Cordova. *Medical Service, VA Caribbean Healthcare System, San Juan, PR.*

**Background:** Antibiotic-impregnated cement or beads are used in surgeries of infected hip and knee arthroplasties. The incidence of systemic side effects of antibiotics is low because the antibiotic is delivered locally.

**Methods:** A 79 y/o man with history of total left knee arthroplasty in 2008 was admitted to Orthopedic service due to sudden pain and swelling of the knee. His baseline serum creatinine level was 1 mg/dl. Septic arthritis was documented with arthrocentesis. Antibiotic therapy consisted of vancomycin followed by tygecycline. The infected prosthesis was surgically removed. The wound was irrigated and spacer created with tobramycin–impregnated cement. Two strings of 16 tobramycin-eluting beads were also inserted in the metaphyseal cavities of the femur and tibia as shown in this film:

Only the joint fluid was positive for methicillin-sensitive Staph aureus. Thirteen days after surgery, the serum creatinine level increased to 4.7 mg/dl. Renal sonogram was negative. U/A showed 1+ protein, hyaline and granular casts, WBC's, RBC's and bacteria. Gallium scan showed intense tracer concentration involving the tibial and femoral components of the left knee without significant tracer concentration in the kidneys. Hemodialysis was initiated. Serum tobramycin levels were 1.1 and 0.7 mg/l, 17 and 28 days after surgery, respectively. The patient continues on chronic hemodialysis six months after arthroplasty.

**Conclusions:** Serum tobramycin levels above 0.1 mg/L and a dose of tobramycin >2 gm per 40gm of cement have been associated with AKI. Both of these factors were present in our case. Physicians should be cognizant of the potentially severe nephrotoxic effect of the use of aminoglycoside-eluting cement and beads in patients undergoing restorative orthopedic surgery.

*Funding:* Veterans Affairs Support

**TH-PO816**

**Warfarin Associated Nephropathy**
Amita Vasudeva, Muhammad R. Mustafa, Sana R. Akbar. *Nephrology, West Virginia Univ, Morgantown, WV.*

**Background:** Warfarin induced nephropathy is a relatively newly diagnosed disease entity. We hereby present a case of warfarin induced nephropathy.

**Methods:** 79 year old white male with history of Hypertension, atrial fibrillation, mechanical aortic valve replacement on coumadin for 14 years underwent cardiac catheterization due to anginal symptoms, it showed minimal CAD. Home medications were Losartan, Lasix, Bactrim for cystitis, Imdur, Hydralazine, lopressor. Baseline labs were BUN 28, Cr was 1.1. Ten days after cardiac catheterization, he developed gross hematuria. BUN and Cr increased to 39 and 2.4 mg/dl respectively, with INR of 6. Exam was normal without edema. Losartan and Lasix were stopped with no change in kidney function. Ultrasound was normal. Cr worsened to 6.13 mg/dl with BUN 90. Urine sediment showed many normal RBCs. Urine protein to Cr ratio was 2.5mg/ mg. ANCA, Anti GBM antibodies and ANA were negative. Serum C3, C4 were normal. He had to be started on hemodialysis due to uremia. Kidney biopsy showed red blood cells in Bowman's space (one glomerulus), red blood cells in tubular lumina withmild interstitial fibrosis. Immunofluorescence was negative and there were no electron dense deposits. Findings were consistent with the diagnosis of warfarin-related nephropathy. Pt remains dialysis dependent months later.

**Conclusions:** Brodsky et al. reviewed renal biopsies from 9 patients with elevated serum creatinine level (mean, 4.3±0.8 mg/dL) and abnormal INR (mean, 4.4±0.7 IU) after excluding acute/active glomerulonephritis. The biopsy specimens revealed RBCs in both Bowman spaces and tubules. All of these patients had previous underlying kidney disease. Recovery was incomplete in six of nine patients. It appears that in patients with pre-exiting CKD, warfarin may precipitate AKI via either glomerular hemorrhage and intra-tubular obstruction in addition to other processes.

**TH-PO817**

**A Case of Acute Kidney Injury in a Young Male with Recurrence of Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS) Syndrome during Steroid Taper**
Nima Naimi. *Dept of Nephrology, Washington Univ, St. Louis, MO.*

**Background:** Drug reaction with eosinophilia and systemic symptoms (DRESS) syndrome is a rare disease occurring 2 to 9 weeks after exposure to drugs such as antiepileptics, antibiotics, and allopurinol. The most common organs affected include the liver, kidney, and lungs, although any organ may be involved. Ten to 30 percent of patients with DRESS syndrome present with kidney involvement, with age and underlying kidney disease being risk factors.

**Methods:** A 19 year old male with a history of acne was admitted with a fever, pruritic rash, and diffuse lymphadenopathy 3 weeks after starting minocycline for his acne. He was found to have a white blood cell count of 29.7 with 40% eosinophils, alanine aminotransferase of 103, and a creatinine of 1.1. Infectious and rheumatologic work up was negative. He was seen by dermatology who diagnosed him with DRESS syndrome and recommended discontinuation of the minocycline along with prednisone 80mg daily with a taper over 6 weeks. He was discharged home after 2 days once his fevers resolved and his rash improved. Two weeks later, he was readmitted after a routine follow up lab demonstrated a creatinine of 3.28. The patient also noticed a recurrence of his rash when his prednisone was tapered from 80 to 60mg daily. He was initially started on methylprednisolone and then switched to 80 mg of prednisone with a 10 mg per week

taper for a total of 8 weeks. His rash improved, and his creatinine decreased to 2.06 upon discharge. He was seen in the renal clinic a month later with complete resolution of his rash and normalization of his creatinine.

**Conclusions:** Acute kidney injury (AKI) usually occurs in the initial phase of DRESS syndrome. However, AKI can occur during recurrence of DRESS syndrome while patients are tapering their steroids, thus highlighting the importance of a slow taper. The current recommendation is to wean steroids over 8 to 12 weeks once clinical improvement and normalization of laboratory values have been achieved. Serial liver and kidney function monitoring is imperative during this time.

## TH-PO818

**Renal Failure Caused by Drug Reaction with Eosinophilia and Systemic Symptoms Syndrome (DRESS)** Jie Cui, David J. R. Steele. *Nephrology Dept, Massachusetts General Hospital, Boston, MA.*

**Background:** Drug reaction with eosinophilia and systemic symptoms syndrome (DRESS) is a severe adverse drug reaction with rash, fever and multi-organ damage. Kidney involvement of DRESS is usually mild with moderate elevated creatinine. However, severe renal damage required renal replacement therapy can also occur in severe cases.

**Methods:** A 42 year-old healthy male presented with daily fever, diffuse myalgia, sore throat and erythematous, pruritic rash. His lab was unremarkable on initial presentation. He was diagnosed with scarlet fever and his symptoms went away after 5-day course of penicillin VK. However, 7 days after he stopped penicillin, his rash, fever and myalgia returned. Physical exam was remarkable for T 102F, inguinal adenopathy and pinpoint erythematous papules all over the body. Labs are shown in table1.

| | initial presentation | on admission | 6 months after presentation |
|---|---|---|---|
| WBC (per mm$^3$) | 9600 | 8700 | 7600 |
| Eosinophila% | 4 | 5 | 2 |
| Hg (g/dl) | 14.7 | 10.7 | 14.2 |
| Platelet (per mm$^3$) | 199,000 | 144,000 | 211,000 |
| AST(U/liter) | 23 | 37 | 14 |
| ALT(U/liter) | 45 | 168 | 33 |
| Creatinine (mg/dl) | 1.0 | 7.6 | 1.0 |

He was started on ceftriaxone owing to suspicion of infection. However, all infectious work up were negative including throat culture, HIV, parvovirus, coxsackie, HSV, EBV, hepatitis A, B, C, Ehrlichia, lyme, blood culture and urine culture. ANA, RF, schistocytes and renal ultrasound were negative. Patient's renal function rapidly declined, and hemodialysis was initiated. Renal biopsy was performed, which showed severe active interstitial nephritis. Skin biopsy showed interface and spongiotic dermatitis, which was consistent with DRESS syndrome. All antibiotics were discontinued and patient was started on prednisone. His renal function slowly recovered and hemodialysis was discontinued 7 days later. Patient's renal function returned to his baseline 6 months after presentation.

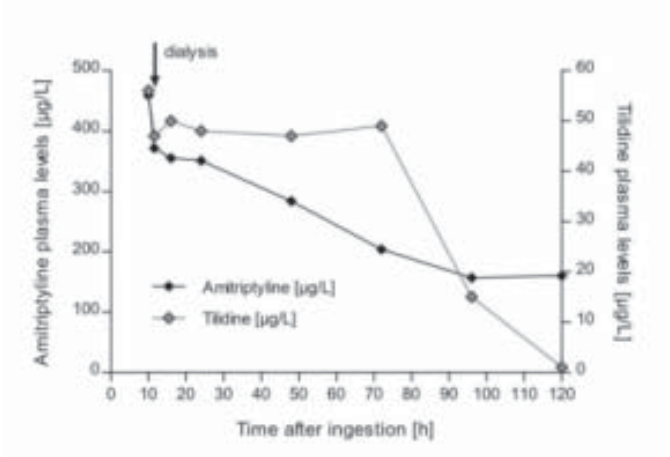
**Conclusions:** DRESS is a potential life threatening hypersensitive reaction that can cause multi-organ involvement. Severe renal failure required renal replacement therapy is a rare complication. Prompt recognition and removal of the offending medication is crucial to limit further end organ damage.

## TH-PO819

**Successful Treatment of Life-Threatening Intoxication with Amitriptyline and Tilidine Using High Cut-Off Dialysis** Anna Bertram,[1] W. Nikolaus Kühn-Velten,[2] Hendrik Suhling,[3] Jan T. Kielstein.[1] *[1]Nephrology, Hannover Medical School, Hannover, Germany; [2]Medical Laboratory of Bremen, Bremen, Germany; [3]Pneumology, Hannover Medical School, Hannover, Germany; [4]Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany.*

**Background:** The antidepressant amitriptyline (MW 313D; protein binding 96%) and the opioid tilidine (MW 273D; PB 10%) are both considered non-dialyzable. New high cut-off dialyzers have not been used for their removal so far. We report a case of mixed intoxication, in which we eliminated amitriptyline and tilidine using a high cut-off dialyzer.

**Methods:** A 54 y old woman was admitted to our hospital 6h after ingesting an unknown amount of amitriptyline and tilidine in suicidal attempt. The patient was deeply unconscious with a GCS of 5, blood pressure was 140/80mmHg and heart rate 94/min. ECG showed a broad QRS complex (134ms) and prolonged QTc (517ms), representing increased risk for ventricular arrhythmias. Based on the clinical condition we started a 5h dialysis using a high cut-off Ultraflux® EMiC2-dialyzer (polysulfone; 1.8m$^2$; dialysate and blood flow 300ml/min). Immediately afterwards slow extended dialysis was started. Plasma levels and samples pre and post dialyzer were drawn at different time points.



Three lines of evidence show that amitriptyline and tilidine are removed by high cut-off dialysis: Dialyzer clearances for amitriptyline and tilidine were 58ml/min and 67ml/min. Reduction rate of amitriptyline and tilidine by 1$^{st}$ dialysis were 27% and 41%. Into the 6$^{th}$ hour of treatment the patient regained consciousness and was transferred to psychiatric care on the 3$^{rd}$ day.

**Conclusions:** We conclude that use of a high cut-off membrane is a feasible method to accelerate elimination in cases of life-threatening poisonings with amitriptyline and tilidine, for which conventional hemodialysis is considered ineffective.

## TH-PO820

**Hyporeninemic Hypoaldosteronism and Renal Insufficiency after Unilateral Adrenalectomy for Primary Hyperaldosteronism** Shing Li, John A. Walker. *Medicine/Nephrology, UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ.*

**Background:** Treatment for primary hyperaldosteronism may be complicated by persistent hyporeninemic hypoaldosteronism and apparent acute kidney injury.

**Methods:** A 49 year old man with a history of longstanding hypertension and hypokalemia (2.7 mEq/L) was diagnosed with primary hyperaldosteronism secondary to an aldosterone producing adenoma (APA) on the bases of undetectable plasma renin activity (PRA), elevated plasma aldosterone concentration (PAC), and abdominal CT showing a 2.5cm right adrenal mass. Baseline renal function was normal (serum creatinine 0.9mg/dL; eGFR 122mL/min). A laparascopic right adrenalectomy was performed and hypertension improved thereafter off medications. However, serum creatinine doubled (creatinine clearance 76.5mL/min) and acidosis and hyperkalemia were noted (6.3 mEq/L); PRA and PAC were undetectable. This pattern persisted for several months. Treatment with fludrocortisone 0.05mg/day resolved the hyperkalemia and acidosis, but only partially attenuated the azotemia.

**Conclusions:** The incidence of persistent hypoaldosteronism with hyperkalemia after adrenalectomy for APA has been reported as 5.5%; concomitant hyporeninemia was even less frequent at 1.8%. Prolonged mineralocorticoid replacement therapy is often necessary. In one study, patients with APA treated with either adrenalectomy or spironolactone had short-term decreases in GFR of 13.6mL/min. Our patient's hyporeninemic hypoaldosteronism in combination with the magnitude of his GFR reduction make this case unique. Though the hyperkalemia is explained by the hypoaldosteronism, the reduction in renal function is more puzzling and has negative prognostic implications. We surmise our patient's postoperative decline in GFR may reflect a combination of 1)diminished renal blood flow due to an abrupt reduction in serum aldosterone, and 2)CKD due to underlying hypertensive nephrosclerosis, previously masked by hyperaldosterone-driven hyperfiltration. Clinicians should be alert to this potential outcome in patients undergoing adrenalectomy for APA, and monitor postoperative laboratory parameters accordingly.

## TH-PO821

**Liddle's Syndrome Caused by a Novel Mutation in the β-Subunit of the Epithelial Sodium Channel Gene SCNN1B** Satomi Nakashima, Keitaro Yokoyama, Masatsugu Nakao, Izumi Yamamoto, Yudo Tanno, Ichiro Ohkido, Takashi Yokoo. *Div of Kidney and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** Liddle's syndrome has been known as a disorder associated with abnormal sodium reabsorption in the distal tubule, and is transmitted as a rare autosomal dominant trait. The epithelial sodium channel (ENaC) was established as a cause of this syndrome by hyper-sensitizing the channel. The ENaC is caused by mutations in the SCNN1B or SCNN1G gene, which truncates the cytoplasmic carboxyl terminus of the β and γ subunit of the ENaC.

**Methods:** The case, a 24-year-old woman, was diagnosed with hypertension, and was started on an antihypertensive agent 8 years ago. But, her blood pressure was not controlled, therefore she was referred to our hospital for further treatment . She showed hypertension , hypokalemia, metabolic alkalosis, low renin and aldosterone levels, hence pseudo-aldosteronism was suspected. Spironolactone was not effective, but triamterene was effective in controlling her blood pressure with an improvement in her serum potassium concentration.

There was no history of familial Liddle's syndrome, therefore sporadic Liddle's syndrome was suspected. Therefore a genetic test was performed . However the previously reported gene muation for Liddle's syndrome was not detected. Further DNA analyses showed the point mutation(Cytosine□Guanine) in the PY (Proline-Proline-x-Tyrosine) motif of the β subunit in the ENaC. Screening for specific mutations of the SCNN1B gene in relatives of patients with Liddle's syndrome can be used to identify previously unrecognized cases within the family. A new nonsense mutation(Y604X) of the SCNN1B gene is the likely cause of Liddle's syndrome in this case.

**Conclusions:** Based on direct DNA sequencing, a novel heterozygous nonsense mutation at codon 604 of the SCNN1B gene from TAC (Tyrosine) to stop codon (TAG) was detected as a cause of Liddle's syndrome in this case.

## TH-PO822

**Reverse of Congestive Heart Failure in Patient with Primary Aldosteronism** Narittaya Varothai, Erdal Sarac. *Internal Medicine, St. Elizabeth Health Center, Youngstown, OH.*

**Background:** Primary Aldosteronism (PA) is a disorder causing hypokalemia, sodium retention, hypertension and cardiovascular damage which can culminate into congestive heart failure. Early adrenectomy reccomended to improve cardiac function. We are reporting a PA case who has progressive CHF with underlying ischemic heart disease which cardiac function improve after delayed adrenectomy for 10 years.

**Methods:** A 70 year old Caucasian male with history of HTN, CAD s/p CABG, chronic Atrial Fibrillation s/p ablation and cardioversion, hypothyroidism. During hospitalization in 2000 for atrial fibrillation, patient had HTN and persistent hypokalemia. Laboratory studies showed PAC 37.1 ng/dL, PRA 0.51 ng/ml/hr with PAC/PRA ratio of 72.74(more than 20). CT abdomen showed hyperplasia of left adrenal gland. Initial treatment included potassium supplement and spironolactone. Patient's clinical status got worse in 2009 when progressive swelling and hypokalemia occurred. A repeat CT scan showed new presence of 2 cm adrenal gland tumor. No Surgery was done uncontrolled atrial fibrillation and marked decline in left ventricular ejection from 43 % in 2003 to 25 % with global hypokinesis in 2011. Subsequently, patient had recurrent admissions with decompensated CHF during 2011-2012 despite optimized medical treatment of CHF. Finally, patient underwent laparoscopic adrenelectomy on 2012 after which there was significant clinical improvement of CHF with NY functional status improving from IV to II. Within 2 months, his blood pressure control improved with number of antihypertensive agents decreasing from five to two. and diuretic dependence resolving. Repeat 2D echo after 1 year showed EF of 55%.

**Conclusions:** PA can cause cardiovascular damage from uncontrolled BP and also induce cardiac hypertrophy and fibrosis. Recommended treatment in PA with possible unilateral disease is unilateral laparoscopic adrenectomy. Although medical therapy could be option for patient who is not surgical candidate (unwilling or poor clinical condition), delayed surgery still help to improve clinical outcome and reverse cardiac function even in ischemic heart patient. So we should consider early adrenelectomy to prevent all the consequences.

## TH-PO823

**Chronic Hyponatremia Associated with Levamisole Adulterated Cocaine (LAC) Use** Anju A. Oommen,[1,2] Harold A. Franch.[1,2] *[1]Nephrology, Atlanta VAMC; [2]Emory Univ, Atlanta, GA.*

**Background:** There are no reports of hyponatremia associated with cocaine use in adults before 2011. In 2002, anti-helminthic Levamisole was identified in cocaine. With the increasing use of Levamisole as an adulterant, a number of complications including acute hyponatremia have been reported among cocaine users. In 2008, Levamisole was found in 69% of cocaine seized and studies report 78% of the cocaine positive urine in hospitalized patients had Levamisole.

**Methods:** A 65 y/o male with hypertension and polysubstance abuse (cocaine, alcohol and tobacco) referred to renal clinic for chronic asymptomatic hyponatremia. Since his presentation in 2005 to our health care system, his serum sodium (Na+) has ranged from 136mmol/L to 124mmol/L. Urine drug screens done along the same time frame always tested positive for cocaine. Review of systems was negative for any causes of hyponatremia. His physical examination was unremarkable. Labs were pertinent for serum Na+ of 130mmol/L, serum osmolality 280 and inappropriately high urine osmolality at 430 mosm/kg. Urine Na+ was 52mmol/L and serum uric acid level was low at 3.1mg/dl. His renal function, TSH, cortisol were normal. Chest X-ray was unremarkable. He was not on schizoaffective medications. A diagnosis of SIADH was made. Despite fluid restriction and addition of salt tablets, serum Na+ continued to remain below 134mmol/L. Urine tested positive for Levamisole through analysis by high performance liquid chromatography/tandem mass spectrometry. Hyponatremia was attributed to LAC.

**Conclusions:** Levamisole was withdrawn from the US market in 2000 because of adverse effects, notably severe agranulocytosis. Levamisole is linked to hyponatremia in cancer patients. But there are no case reports of LAC causing chronic hyponatremia. Although the exact mechanism of hyponatremia is unknown, it has been postulated to cause SIADH. This case is limited by continued cocaine use in our patient and hence the inability to check for resolution of hyponatremia. As LAC becomes more prevalent, it is possible that we will see more cases of unexplained hyponatremia. This case of chronic hyponatremia from LAC suggests a potential complication and testing for Levamisole is indicated early.

## TH-PO824

**Obstructive Jaundice Associated Hyponatremia** Supriya Ravella, Gertrude S. Lefavour, Amay Parikh, Mary O. Carayannopoulos. *Nephrology, UMDNJ-RWJMS, New Brunswick, NJ.*

**Background:** Pseudohyponatremia is associated with a normal serum osmolality. Elevated lipid levels are a known cause of pseudohyponatremia. While the plasma water is approximately 93% of the plasma volume normally, in patients with hyperlipidemia or hyperproteinemia, the plasma water can decrease to 80% or lower leading to a reduced measured sodium concentration.

**Methods:** A 40-year-old man with a past medical history of autoimmune pancreatitis/ lymphoplamacytic sclerosing cholangitis, biliary stricture with stent placement, hyperlipidemia and diabetes mellitus presented with fever for two days. On exam, he was jaundiced and euvolemic. His serum sodium was 119 mEq/L, potassium was 3.3 mEq/L and chloride was 87 mEq/L. Total cholesterol was 2109 mg/dL. His lipid panel however demonstrated a LDL of 68 mg/dL, HDL of 36 mg/dL and triglycerides of 299 mg/dL. The large difference between the total cholesterol and its components prompted a lipoprotein electrophoresis, which detected lipoprotein X.

**Conclusions:** Lipoprotein X (Lp-x) is associated with the low density lipoprotein fraction. It is an abnormal lipoprotein which appears in the sera of patients with obstructive jaundice. Abnormally high levels of Lp-x can cause pseudohyponatremia. Serum sodium is commonly measured with analyzers that use indirect potentiometry with ion-selective electrodes. This utilizes a dilution of the sample. Increased lipid or protein concentrations alters the total water concentration. Then the dilution step and the subsequent calculation of concentration by the analyzer results in a falsely low sodium value. When factitious results are suspected, serum sodium should be measured by direct potentiometry ion-selective electrodes. When serum sodium levels are low in patients with cholestatic jaundice either due to autoimmune pancreatitis or graft versus host disease after stem cell or bone marrow transplantation, the suspicion for pseudohyponatremia should be high.

## TH-PO825

**Hyponatremia Case due to Cerebral Salt Wasting and Underlying Syndrome of Inappropriate Antidiuretic Hormone Secretion: Diagnostic and Therapeutic Challenges** Oana C. Badescu, Khurram Saleem, Farhang Ebrahimi. *Richmond Univ Medical Center, Staten Island, NY.*

**Background:** The existence of cerebral salt wasting (CSW) is controversial, but hyponatremia in patients with central nervous system (CNS) injury, particularly subarachnoid hemorrhage, has been recognized in literature. We present a case of hyponatremia due to CSW complicated with underlying syndrome of inappropriate antidiuretic hormone secretion (SIADH). The coexistence of these conditions has been rarely reported.

**Methods:** We present a 45 year old male with chronic ventriculo-peritoneal shunt admitted for cervical spine injury secondary to seizure induced fall. Patient was found to have hyponatremia. Urine osmolality (UOsm) and urine sodium (UNa) were elevated, and there was hypouricemia. Diagnosis of SIADH was considered. Fluid restriction, Demeclocycline, and combination of normal saline (NS) and diuretics were associated with worsening of hyponatremia. We noticed large volume diuresis in the presence of hemodynamic instability and signs of hypovolemia. Possibility of CSW was considered. Serum sodium was 116 mEq/L, UOsm 833 mOsm/Kg, and UNa 200 mEq/L. Hyponatremia responded to 3% hypertonic saline (HS) and volume expansion with normal saline, with partial correction of serum sodium. Each time we held HS, while on NS alone, hyponatremia worsened, and UOsm would not decrease below 300 mOsm/Kg. This was consistent with underlying SIADH. Patient remained quadriplegic and required long term maintenance HS and NS and eventually serum Na stabilized after addition of large doses of mineralocorticoid therapy. Other unique manifestations of CSW are the absence of hypokalemia despite natriuresis and significant hypouricemia, which both were present in our patient.

**Conclusions:** Our case illustrates the coexistence of CSW and SIADH, which poses challenges to the physician. If the mainstay of therapy in CSW is replacement of sodium and water, in SIADH it is water restriction. Early recognition of the main pathology could reduce complications of inappropriate therapy. Also the unique positive response to mineralocorticoids could help physicians not familiar with this therapy in patients with this rare combination of disorders.

## TH-PO826

**Lamivudine Induced Nephrogenic DI** Mohamad Mudar Morad, Michelle W. Krause, Dumitru Rotaru, Gracen Elizabeth Hauk. *Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

**Background:** Acquired NDI in adults is most commonly caused by lithium, hypercalcemia or hypokalemia. Less frequent causes are medications like: cidofovir, foscarnet, vasopressin V2 receptor antagonists, amphotericin B, demeclocycline, ifosfamide. We are reporting a case of acute NDI induced by lamivudine.

**Methods:** A patient with AML admitted for autologous stem cell transplant (ASCT). His medications included prophylactic antibiotics, antifungals, Acyclovir and Lamivudine. The hospital course was complicated by acute polyuria with 12 L of UOP/day followed by pre-renal AKI with creatinine increasing from 0.9 to 2.2. Urine analysis was normal except low specific gravity of 1.001 and urine sediment was bland. During this time, the patient also had low urine osmolality and high serum osmolality. Patient received repeated doses of DDAVP with no significant change in urine osmolality or urine volume. A diagnosis of acute

nephrogenic diabetes insipidus (NDI) was made. In our patient we stopped Lamivudine and started Maxzide. Over the next 48hrs patient UOP decreased gradually to 2 l/day, his urine osmolarity increased gradually to 400 at 72 hrs and his renal function improved to normal.

**Conclusions:** In the absence of common etiologies we explored the possibility of antivirals causing acute NDI in our patient. We performed a literature research for NDI associated with Acyclovir and/or Lamivudine. We found previous reports of Didanosine causing NDI. Based on similarities between Lamivudine and Didanosine which are both nucleoside analogue drugs with comparable mitochondrial toxicity profile we presumed that Lamivudine was the likely cause of NDI in our patient. Tenofivir use was also reported to increase the concentration and toxicity of Didanosine through competition for OAT1 binding for urinary excretion. The same OAT1 is involved in both Acyclovir and Lamivudine excretion and we propose that Acyclovir use in our patient may have also contributed to increased Lamivudine levels. Further studies may be needed to assess the incidence of acute NDI with Lamivudine.

## TH-PO827

**Supra-Therapeutic Doses of 1-Deamino-8-D-Arginine Vasopressin to Treat a Severe Case of Lithium Induced Nephrogenic Diabetes Insipidus: Back to the Basics** Shaifali Sandal, Catherine A. Moore, Matthew D. Gross. *Nephrology, Univ of Rochester, Rochester, NY.*

**Background:** Nephrogenic diabetes inspidus (NDI) is an inadequate response of the kidneys to the antidiuretic hormone, resulting in polyuria, and water and electrolyte imbalances. We report the successful use of high doses of 1-deamino-8-D-arginine vasopressin (dDAVP) as a successful treatment strategy.

**Methods:** A 51-year-old male with history of schizoaffective disorder on long-term lithium therapy causing NDI (with baseline normal sodium levels) was hospitalized with a 3 day history of confusion and gait instability. Workup revealed serum sodium of 165mmol/L, lithium level of 1.3 mmol/L, acute kidney injury, and a new diagnosis of thrombotic thrombocytopenic purpura (TTP). Lithium was discontinued and patient required aggressive fluid administration due to continued polyuria at 9 to 10 L/day with urine osmolality of 60-80 mosmol/Kg H20. dDAVP at "physiologic dose" of 2mcg was given intravenously with no significant improvement. Plasma exchange was initiated with clinical improvement in TTP, however polyuria persisted at a range of 10-16 L/day despite initiation of a thiazide diuretic. High dose dDAVP was then administered at 4 mcg subcutaneously twice a day, with resultant increase in urine osmolality to 275 mosm/Kg and decrease in urine output to 3-5 L/day.

**Conclusions:** Up to 40% of individuals treated with lithium develop NDI as a side effect via an unknown molecular mechanism. Traditionally, treatment of NDI has involved the use of thiazide diuretics and stopping lithium. In the 90's several different studies were published demonstrating the successful use of indomethacin with or without desmopressin for treatment. However, this fell out of favor potentially due to the impaired renal function caused by indomethacin. Several new therapies are being proposed to treat NDI such as vaptans, statins and heat shock protein 90. We have demonstrated higher doses of dDAVP as a successful treatment modality in a case of severe NDI. Our patient likely had a partial form of NDI, hence the response to higher doses of dDAVP. Through this case we encourage physicians to go back to the basics when treating NDI.

## TH-PO828

**Kidney Transplant Exposing Central Diabetes Insipidus** Todd W. Robinson, Anthony J. Bleyer. *Wake Forest School of Medicine, Winston-Salem, NC.*

**Background:** Central diabetes insipidus (DI) leads to an inability to maximally concentrate the urine. Patients with DI and CKD have less water delivery to the collecting duct (CD), causing less urine output. We describe a patient with central DI whose low GFR was fixed with living related kidney transplantation, resulting in abrupt onset of polyuria.

**Methods:** A 45 year old peritoneal dialysis patient with ESRD due to Wegener's Granulomatosis presented for kidney transplantation. On post-operative day 2 the patient developed urine output between 15 and 16 liters daily without diuretics. The patient did not complain of polydipsia. The serum sodium was 149 mEq/l., bicarbonate 21 mEq/l, chloride 116 mEq/l, BUN 16 mg/dl, and creatinine 1.6 mg/dl. Urine osmolality was measured and noted to be very low at 79 mOs/kg with a serum osmolality of 297 mOs/kg. Immediately, the urine output of the donor was assessed and found to be < 3 liters/day. In the recipient, a water deprivation test was initiated and there was minimal elevation of the urine osmolality with respect to baseline values. With exogenous ADH administration, the patient's urine osmolality markedly increased with a significant decrease in urine volume. MRI of the brain revealed no evidence of neoplasm, mass lesion, or white matter disease. At discharge, he was continued on desmopressin nasal spray with good results.

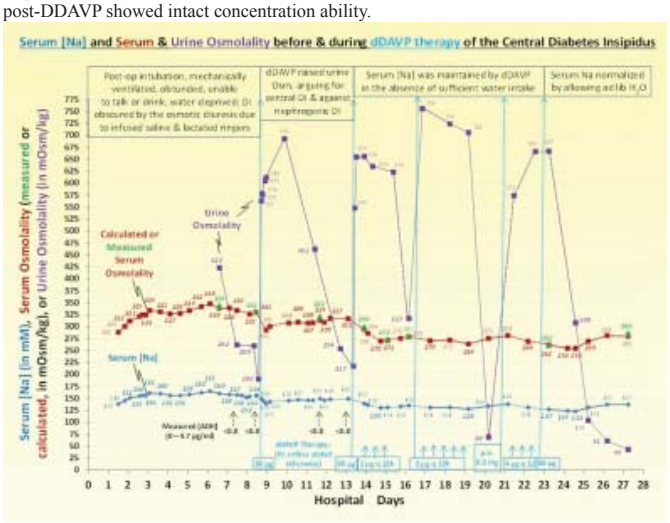
**Conclusions:** This case illustrates the important interaction between GFR and polyuria in DI. Prior to transplant, the GFR was low, with diminished water delivery to the CD and only moderate urine output. Post-transplantation, the increased GFR resulted in increase water delivery to the CD with resulting polyuria. Interestingly, the diagnosis of central DI was made quite rapidly, because determination of the urine output of the donor ruled out nephrogenic DI. The poor perception of thirst may have been due to the free availability of water at the bedside in the hospital. With the urinary catheter, the patient did not realize the extent of urine output. The etiology of central DI in this case was likely granulomatous involvement of the posterior pituitary, which has been described in a small number of Wegener's cases.

## TH-PO829

**Central Diabetes Insipidus (CDI): Undiagnosed for 3 Decades Till Unmasked by Dehydration due to Endotracheal Intubation and Stupor** S .Damera, Laxmi Gadde, Kai Lau. *Nephrology, OU Health Sciences Center, OK.*

**Background:** DI is marked by excessive dilute urine,usually controlled by polydipsia. We here report a man with chronic CDI undiagnosed till revealed by severe hypernatremia from inadvertent water deprivation due to prolonged intubation & stupor.

**Methods:** A 54yo man with strangulated inguinal hernia had emergent bowel resection. He stayed intubated for more surgery on day(d)2 & 3,all under sevoflurane.On d1, urine SG was 1.005.He had since been polyuric to 4-9 L/d.Serum (S)Na,139 mM 2y ago & 135 on d1, rose to 165 by d6.By deleting IV Na & giving more $H_2O$, SNa fell to 154 by d7.Polyuria (10-11 L/d) remained & Uosm fell from 423 Osm/kg on d6 to 190 by d8.Despite Sosm of 331,ADH was repeatedly <0.8 pg/ml,confirming DI.Sevoflurane via F can cause NDI. To differentiate CDI from NDI,he got 80µg IV DDAVP & raised Uosm to 563, 578, 691 respectively by 3rd5th& 31sth.But Uosm fell to 462 by d 3 & 217 by d5.Peak Uosm of 756 post-DDAVP showed intact concentration ability.



On MRI, posterior pituitary had no T1 hyperintensity (i.e. no ADH) confirming CDI. With delirium from SNa & dysphasia from intubation,he could not drink to prevent dehydration.Thus he got 11d of DDAVP to keep SNa 139-149 & allow extubation.When conscious & talking,he denied history of DI but admitted to 12L of $H_2O$/d for 30 years. For 7d before discharge, SNa was normal by ad lib fluids.

**Conclusions:** This man shows classical elusive nature of DI due to usually effective polydipsia.He became dehydrated when prolonged intubation precluded drinking and perpetuated his inability to voice & quench thirst & aggravated SNa,which in turn caused more encephalopathy.Once lucid, drinking kept SNa normal better than DDAVP.CDI was diagnosed by >500 mOsm/kg rise in Uosm with DDAVP, but peak Uosm of only 756 belied a partial NDI.Loss of MRI T1 hyperintensity in posterior pituitary confirms its utility to diagnose CDI.

## TH-PO830

**A Rare Cause of Diabetes Insipidus** Sujata Kale, Neera K. Dahl. *Section of Nephrology, Yale School of Medicine, New Haven, CT.*

**Background:** Central Diabetes Insipidus (CDI) is a disorder characterized by reduced or absent Anti Diuretic Hormone (ADH) presenting with polyuria/polydipsia. Idiopathic DI is the most common cause of CDI. It can also occur secondary to neurosurgery or trauma or from infiltrative diseases such as Langerhans cell histiocytosis (LCH). Patients with LCH with hypothalamic-pituitary disease may develop CDI.

**Methods:** A 35-year-old woman was originally diagnosed with idiopathic CDI in Puerto Rico in February 2010. She was successfully treated with DDAVP. In addition, she had a history of a spontaneous pneumothorax in 2003 requiring chest tube placement, as well as a history of amenorrhea. She had no history of headaches, visual problems or hypothyroidism. On her initial evaluation in Puerto Rico she presented with the following: normal TSH, elevated LH (20.9), borderline high prolactin (23.3), with an undetectable ADH and normal serum osmolality (282). An MRI scan revealed a small pituitary gland. In 2012, she presented for further evaluation and management of CDI. She was doing well on DDAVP. Her vital signs were within normal limits. Her visual fields were full to confrontation, with a normal lung and heart exam. Her repeat LH and FSH were in the low normal range (5-6), cortisol was normal at 11.6, prolactin was now normal at 8, and the TSH normal at 0.98, serum sodium was 141, and a urine specific gravity was 1.015, while on DDAVP. Given her history of amenorrhea and central DI a repeat MRI of the brain was obtained which showed a thickened pituitary stalk. The combination of pituitary stalk lesion with a history of spontaneous pneumothorax raised the possibility of Langerhans cell histiocytosis, which was further substantiated with a high resolution chest CT showing cystic changes. Taken together, these findings established a unifying diagnosis of Langerhans cell histiocytosis. This is a rare autoimmune disorder and a definitive diagnosis is made with tissue biopsy and histology. Her lung function was found to be normal and bone scans were negative for fractures/lytic lesions. The patient has remained stable on DDAVP.

## TH-PO831

**Oxcarbazepine Therapy for Central Diabetes Insipidus** Basmah A. Abdalla,[1] Tara C. Lagu,[1] Daniel L. Landry,[2] Gregory Lee Braden.[2] *[1]Dept of Medicine, Baystate Medical Center/Tufts Univ School of Medicine, Springfield, MA; [2]Dept of Medicine, Div of Nephrology, Baystate Medical Center/Tufts Univ School of Medicine, Springfield, MA.*

**Background:** Oxcarbazepine causes hyponatremia in up to 51% of patients. Mechanisms for this effect have not been completely elucidated.

**Methods:** A 39 year-old female suffered a severe traumatic brain injury in a motor vehicle accident which left her with seizures and complete central diabetes insipidus (CDI). At the time, her serum sodium (SNa) was 158 mEq/L & a urinary osmolality was 137 mOsm/kg. ADH levels by RIA were undetectable. Serum ACTH & cortisol levels were normal. She received intranasal DDAVP 10mcg twice daily & oxcarbazepine 600mg twice daily. 2 years later she developed refractory seizures. Sna was 133mEq/L and oxcarbazepine level was 21 ug/mL (therapeutic). The oxcarbazepine dose was up-titrated to 900 mg twice daily. Concomitantly, Sna gradually fell to 131 mEq/L. DDAVP was discontinued, yet the Sna level declined to 121 mEq/L on day 9. After treatment with 3% saline and fluid restriction, Sna rebounded to 138 mEq/L in 2 days. Serum cortisol and free T4 levels were normal. The patient was discharged on oxcarbazepine 900 mg twice daily, without DDAVP. ADH was undetectable. 9 months later, the patient remained off DDAVP with a normal Sna. Monotherapy with oxcarbazepine effectively controlled her epilepsy and CDI.

**Conclusions:** Proposed mechanisms of oxcarbazepine induced hyponatremia include: SIADH, prolonged ADH half-life, enhanced sensitivity of the renal tubules to ADH, & resetting the osmotic threshold for ADH release in the hypothalamus. Mechanisms of hyponatremia from oxcarbazepine appear to be either direct stimulation of the V2 receptor in renal collecting tubules in absence of ADH or co-stimulation of the V2 receptor in the presence of micromolar ADH concentrations undetectable by current assays. We conclude oxcarbazepine effectively managed both the seizure disorder & complete CDI in our patient and may be a useful alternative to DDAVP in patients with complete CDI.

## TH-PO832

**Use of Continuous Renal Replacement Therapy for Dabigatran Toxicity – Does It Work?** Asif A.K. Ansari, Diana L. Deitzer. *Cleveland Clinic Foundation.*

**Background:** Dabigatran is an oral direct thrombin inhibitor is approved for anticoagulation of non-valvular atrial fibrillation (AF). Drug toxicity in combination with lack of a reversal agent in cases of bleeding has been a major concern, especially in patients with impaired renal function. Extra corporeal therapy (ECT) is considered an effective modality for drug clearance in cases of toxicity, though data supporting its use is sparse. We report a case of critically ill patient with bleeding complications due to toxic levels of Dabigatran that was successfully treated with IHD sessions after inadequate clearance with several days of CRRT.

**Methods:** 70 year old man with AF on Dabigatran 150 mg twice daily that was appropriately dosed for chronic kidney disease stage 3 presented with intra cardiac defibrillator lead infection with enterococcus fecalis leading to septic shock and multi organ failure. He was aggressively treated with mechanical ventilation, pressor support and intravenous antibiotics. His illness was complicated gastro-intestinal bleeding with elevated Dabigatran level of 573 ng/dl and elevated thrombin time >120 seconds requiring multiple blood products. Intriguingly, Dabigatran was discontinued 21 days previously and the patient was receiving continuous renal replacement therapy (CRRT) for the past 15 days for worsening renal failure with fragile hemodynamics. He was then successfully treated with 3 sessions of intermittent hemodialysis (IHD) with resumption of CRRT afterwards that resulted in adequate clearance of the drug. Although bleeding and the indices improved, patient succumbed eventually to multi organ failure.

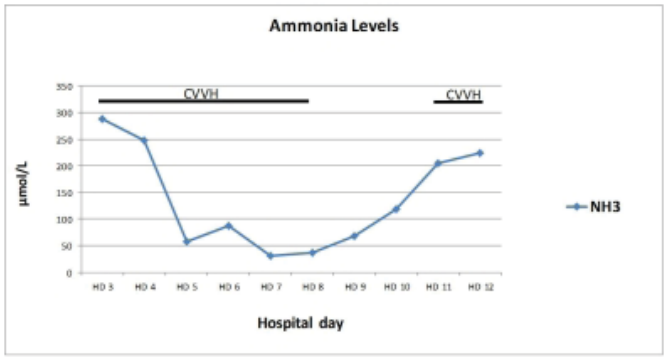
**Conclusions:** Dabigatran eliminates the need for therapeutic drug level monitoring but must be dosed according to the renal reserve to avoid toxicity. Limited data available supports the use of multiple sessions of IHD for drug removal in cases of toxicity; whereas success with CRRT has been variable. In our patient Dabigatran levels remained elevated despite several days of CRRT, suggesting that CRRT is not a reliable modality for drug removal and must not be used in such cases.

## TH-PO833

**Fatal Valproic Acid-Induced Hyperammonemia Despite Continuous Renal Replacement Therapy** Nwamaka Denise Eneanya, Sushrut S. Waikar. *Renal Medicine, Brigham and Women's Hospital, Boston, MA.*

**Background:** Valproic acid can be associated with severe hyperammonemia leading to neuronal injury and cerebral swelling. We report a case of fatal hyperammonemia in a young woman taking Valproic acid despite early initiation of continuous renal replacement therapy.

**Methods:** A 38 y/o female with history notable only for schizoaffective disorder presented with headache and confusion. She was taking Valproic acid with a recent dose increase due to behavioral outbursts. Upon presentation, the patient had frothing of the mouth, large pupils and lower extremity rigidity. Labs revealed normal toxicology screen, renal and liver function. Head CT showed gray-white matter loss and swelling of cerebral hemispheres. Ammonia level, checked on hospital day 3, was 288 µmol/L. Urgent continuous veno-venous hemofiltration (CVVH) was initiated. Additional therapy included scavenging agents (sodium phenylacetate/sodium benzoate), hypertonic saline, and a standard cooling protocol. On hospital day 8, ammonia levels decreased to 34 and CVVH was discontinued.



These levels, however, eventually increased to 205 and CVVH was re-initiated on hospital day 11. Repeat head CT scan on hospital day 12 showed increased intracranial pressure and uncal herniation. Comfort measures only were established for the patient. Although serum orotic acid was elevated to 2.5 mmol/mol-Cr, subsequent genetic testing showed no known ornithine transcarbamylase deficiency.

**Conclusions:** There are currently no published guidelines as to timing of initiation or length of renal replacement therapy in the setting of severe hyperammonemia. Despite reduction of ammonia levels to normal, there was no evidence of neurologic improvement in this patient. Early detection of ammonia levels in encephalopathic patients on Valproic acid should be coupled with urgent renal replacement therapy and frequent monitoring of neurological status.

## TH-PO834

**Dapsone Induced Methemoglobinemia Related Kidney Injury in a Kidney Transplant Recipient** Aditya Kadiyala,[1] James M. Pullman,[2] Madhu C. Bhaskaran,[1] Kellie R. Calderon.[1] *[1]Nephrology, Hofstra North Shore LIJ School of Medicine, Great Neck, NY; [2]Pathology, Montefiore Medical Center/Albert Einstein School of Medicine, Bronx, NY.*

**Background:** Methemoglobin is an oxidative product of hemoglobin which is actively reduced by enzymatic processes in normal state of health. Dapsone, due to its oxidative properties, has been shown to cause methemoglobinemia, a rare cause of kidney injury. It has been shown only in rats to be associated with pigment-induced tubular injury. Here we report a case of dapsone-induced methemoglobinemia causing kidney injury in a kidney transplant recipient. Renal biopsy findings show the similarity of this injury to that in the rat model.

**Methods:** A 65 year old female underwent deceased donor kidney transplantation. Maintenance immunosuppression was achieved with standard triple therapy of tacrolimus, mycophenolic acid and prednisone. A history of sulfa drug allergy precluded the use of trimethoprim/sulfamethoxazole; hence dapsone was used for Pneumocystis Jiroveci prophylaxis. Eleven months post transplant the patient discontinued prednisone against medical advice. Creatinine levels subsequently rose from 0.8mg/dL to 1.7mg/dL and a kidney biopsy was performed. The biopsy revealed acute tubular injury with depositions of brown pigment primarily in the medullary thick ascending limb. Renal parenchyma was otherwise intact with no evidence of rejection or other changes. Laboratory data revealed elevated lactate dehydrogenase, undetectable haptoglobin, macrocytic anemia and signs of hemolysis (appropriately elevated reticulocyte count and erythropoietin levels). Methemoglobin level was elevated at 3.5% (reference range 0-1.5%) and dapsone was immediately discontinued. Serum creatinine declined over the next 10 days to 1.2mg/dL.

**Conclusions:** Acute kidney injury due to methemoglobinemia is documented as a complication of therapy with dapsone. Chronic, low grade hemolysis from methemoglobinemia may lead to tubular toxicity in solid organ transplant recipients receiving dapsone.

## TH-PO835

**Ceftaroline-Induced Allergic Interstitial Nephritis: An Atypical Presentation** Bhupinder Sangha, Judy L. Locati, Ishwinder Sidhu, Karina Sulaiman. *Medicine, LSUHSC-Shreveport, Shreveport, LA.*

**Background:** Allergic interstitial nephritis has commonly been reported with cephalosporins. Ceftaroline is a fifth generation Cephalosporin approved by the FDA for use in community acquired pneumonia and acute bacterial skin structure and skin infections. It has activity against MRSA and has demonstrated non-inferiority to Vancomycin and therefore has been used in off label use for bacteremia. There are no reported cases of AIN with ceftaroline thus far. We describe a case of a patient with atypical presentation of AIN due to suspected use of ceftaroline.

**Methods:** A 52 year old white male with PMH of DM and HTN who presented to the hospital with fever, chills and fatigue was found to have MRSA bacteremia without an identifiable source. He was started on Vancomycin and blood cultures remained positive showing resistance to Vancomycin. Patient was then started on IV Ceftaroline. The serum creatinine was subsequently noted to be elevated from baseline. Urine Wright stain was positive for eosinophils. He was discharged on a six week regimen of IV Ceftaroline. Two weeks following discharge sputum cultures were positive for Mycobacterium kansasii and he was started on four drug regimen. He presented again to the hospital twenty days after completion of Ceftaroline therapy with anasarca and his renal function had improved but had not returned to his baseline. The repeat Wright stain continued to show eosinophils and patient was noted to be in persistent AKI. Renal biopsy showed acute tubular interstitial

nephritis with eosinophils consistent with hypersensitivity reaction. We attributed the nephritis to Ceftaroline and continued the therapy for mycobacterium kansasii. His renal function improved after discontinuation of Ceftaroline.

**Conclusions:** Cephalosporins have long been known to be associated with AIN. Experience with Ceftaroline is limited in clinical practice. We present a case of AIN associated with Ceftaroline use. In this case the offending agent was continued for a prolonged period causing interstitial fibrosis along with tubular damage that subsequently lead to ineffective natriuresis. This may explain his anasarca.

## TH-PO836

**Transient Pigment Induced Nephropathy following Percutaneous Rheolytic Thrombectomy** Rapeepat Lekkham, Eric J. Bloom. *Medicine, Einstein Medical Center, Philadelphia, PA.*

**Background:** The AngioJet® rheolytic thrombectomy system is a catheter-based system for the removal of intravascular thrombi. Hemolysis and hemoglobinuria following the use of AngioJet® has been reported. We present the rare case of severe acute kidney injury following the use of this device that was successfully treated conservatively.

**Methods:** A 49-year-old female with HTN presented with the sudden onset of a severe headache secondary to subarachnoid hemorrhage. Cerebral angiography revealed a ruptured anterior communicating artery aneurysm. She underwent emergency craniotomy with clipping of the aneurysm. Prior to a repeat cerebral angiogram, the AngioJet® device was used to remove a thrombus in the right external iliac artery adjacent to the common femoral sheath. She received IV hydration prior to and during the contrast procedure. The patient was given a total of 85 ml of Iohexol. Immediately following the thrombectomy, her urine became red and progressively decreased in volume from 80-200 cc/hr to anuria within 6 hours. Her serum Cr increased from 0.6 mg/dL to 1.5 mg/dL. A repeat Hb dropped from 11.7 g/dL to 6.9 g/dL. The patient's serum LDH level was elevated and the serum haptoglobin level was low consistent with acute intravascular hemolysis. The urinalysis was strongly positive for blood with only 9 RBC/HPF on microscopy. Centrifugation of a urine sample produced a red supernatant which was positive for heme. Her urine myoglobin was negative. Centrifugation of a blood sample yielded red plasma consistent with a diagnosis of hemoglobinemia. Aggressive hydration with isotonic saline solution was continued without alkalinization or diuretic. The patient did not require renal replacement therapy as her urine output improved significantly over the next 24 hours after thrombectomy. The serum Cr level returned to normal 10 days after thrombectomy.

**Conclusions:** Acute kidney injury caused by intravascular hemolysis and hemoglobinuria can occur following the use of the AngioJet® system. Aggressive hydration may be the best strategy to prevent and minimize the risk of this complication. The risk of AKI should be explained to patients before undergoing thrombectomy by use of AngioJet®.

## TH-PO837

**Propofol Induced Rhabdomyolysis** Pavan K. Annamaraju, James I. McMillan. *Nephrology, VA Loma Linda Healthcare System, Loma Linda, CA.*

**Background:** Propofol induced rhabdomyolysis (RM) is a rare cause of acute kidney injury (AKI), especially in adults. A case of AKI from propofol induced RM is reported.

**Methods:** A 63 year old man was admitted to the hospital for atypical chest pain and dyspnea. Past history included diabetes, hypertension and obesity. Myocardial infarction was ruled out, but he continued to have worsening dyspnea. He developed fever, leukocytosis and pulmonary infiltrates. On hospital day 6, he was transferred to the intensive care unit for respiratory failure and sepsis, likely from pneumonia. He was intubated, placed on mechanical ventilation and given empiric IV antibiotics and vasopressors. Because of agitation, propofol 2.4 mg/kg/hr was added to midazolam and fentanyl on day 14, and subsequent doses of 1.5-1.8 mg/kg/hr were used. From day 19, patient was noted to have progressive transaminitis and worsening renal function with electrolyte disturbances and developed anuria by day 24. RM was confirmed by rise in Creatine kinase (CK) levels and urine blood positivity without urine red blood cells. Emergent hemodialysis was begun on day 24. Propofol induced RM was suspected and drug discontinued. CK level trended down within 72 hrs after stopping propofol, returning to normal in five days. Anterior thigh muscle biopsy showed a monophasic insult pattern of injury excluding chronic inflammatory injury. Dialysis was discontinued on hospital day 40 with subsequent full renal recovery.

| Hospital Day | Serum Creatinine (0.64-1.27 mg/dL) | Serum K (3.6-5.1 mg/dL) | Serum Phosphorus (2.4-4.7 mg/dL) | AST (15-41 IU/L) | Urine RBC (0-2/HPF) | Urine Blood (Neg) | Creatinine Kinase (49-397 IU/L) |
|---|---|---|---|---|---|---|---|
| 1-2 | 1 | 4 | 5.5 | 29 | 1 | Neg | 222 |
| 19 | 2 | 6 | 7.5 | 44 | 1 | Large | |
| 24 | 4.2 | 7.6 | 16.4 | 841 | Anuric | Anuric | >13,200 |

**Conclusions:** Propofol induced RM is rare, and is usually seen at doses > 4 mg/kg/hr over a prolonged time. Our patient developed RM and AKI with doses of only 2.4 mg/kg/hr or less. Differential diagnosis included statins, neuroleptics, paralytics, critical illness myopathy, and pressure-induced ischemia and these were excluded. Discontinuation of propofol led to prompt recovery.

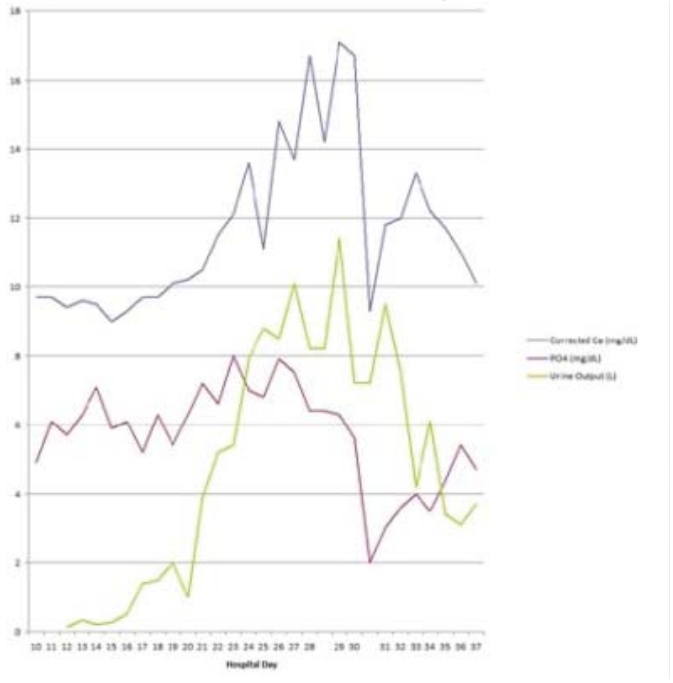
*Funding:* Veterans Affairs Support

## TH-PO838

**Profound Hypercalcemia in Rhabdomyolysis Associated Acute Kidney Injury** Lisa Aimee Hechanova, Seyed-Ali Sadjadi. *Jerry L. Pettis VA Medical Center, Loma Linda, CA.*

**Background:** Rhabdomyolysis is a common phenomenon which results from muscle breakdown due to trauma, extreme exertion, or myotoxins, and results in acute kidney injury (AKI) in 13-50% of cases. Early hypocalcemia is often seen due to precipitation of calcium with phosphate released from lysed muscle cells, and occasionally hypercalcemia can be seen during the recovery phase due to mobilization of calcium phosphate deposits. Herein we present a case of rhabdomyolysis complicated by AKI and profound hypercalcemia.

**Methods:** A 23-year-old male developed AKI after an episode of severe rhabdomyolysis from a car accident which caused extensive crush injuries to his legs, leading to bilateral lower extremity compartment syndrome, requiring several fasciotomies and eventual left above the knee amputation. The rhabdomyolysis was associated with severe hyperkalemia causing multiple episodes of ventricular tachycardia requiring cardioversion, acute respiratory failure requiring mechanical ventilation, and anuric AKI requiring hemodialysis. Renal function recovered 3 weeks after his initial injury, and he entered into the polyuric phase of AKI. During this phase, his serum calcium started rising, reaching a peak of 17.1mg/dL, causing nausea, weakness, drowsiness and polyuria with urine output up to 11L per day. He was treated with IV fluids, calcitonin, pamidronate, and dialysis with a calcium free dialysate. A technetium pyrophosphate scan showed extensive calcium deposition in his left thigh muscles, where he had severe compartment syndrome. His hypercalcemia lasted 16 days, after which his serum calcium level and urine output normalized.



**Conclusions:** It is important to remember that patients with rhabdomyolysis are not out of danger when serum creatinine and urine output start to improve; one must also watch for severe hypercalcemia that is rare but may occur during the diuretic phase of rhabdomyolysis induced AKI.

## TH-PO839

**Biopsy-Induced Tumor Lysis Syndrome** Sharad Virmani, Timothy Muchayi, David Roth. *Nephrology and Hypertension, Univ of Miami Miller School of Medicine, Miami, FL.*

**Background:** Tumor lysis Syndrome (TLS) results from rapid and massive lysis of malignant cells leading to life threatening electrolyte abnormalities. Our case involves the onset of TLS 12 hours following the biopsy of a suspicious tumor.

**Methods:** A 74 y/o Hispanic man with an orthotopic heart transplant in 2009 was admitted with abdominal distention and diarrhea for one month. The patient was hemodynamically stable with baseline creatinine 1.3mg/dl. On day two a computed tomography (CT) scan with contrast revealed a 10.6 x 11.0 x 10.3 cm heterogenous mass in the right lower quadrant causing a small bowel obstruction. Serum labs indicated little concern on day five.

| Day | Potassium | Uric Acid | Calcium | Phosphorous | Creatinine | BUN | LDH |
|---|---|---|---|---|---|---|---|
| Five | 4.4 | N/A | 8.4 | 3.3 | 1.27 | 10 | N/A |
| Six | 9.4 | 40.1 | 5.9 | 17 | 1.94 | 45 | 2,584 |

On day six, A CT guided needle biopsy of the mass yielded seven core samples. Twelve hours post procedure the patient experienced hypotension and tachycardia with peaked T waves. Serum labs showed a potassium of 9.4 mmol/L, bicarbonate of 17 mmol/L, phosphorous of 16.1 mg/dl, and uric acid of 40.9 mg/dl. Hemodialysis was initiated immediately to treat the hyperkalemia, and intravenous fluid resuscitation with one dose of

Rasburicase was given. On day seven CVVHD was started to correct the phosphorous and uric acid. Pathology of the mass showed Burkitt Lymphoma on day 7. Cyclophosphamide and vincristine was initiated to treat the lymphoma.

**Conclusions:** Eectrolyte abnormalities of TLS include hyperuricemia, hyerkalemia, hyperphosphatemia, and hypocalcemia. Clinical consequences include arrhythmias, acute kidney injury, seizures and death. Triggers of TLS can be cytotoxic and biological agents or ischemia. Spontaneous TLS has been documented in Burkitt's lymphoma however little evidence exists demonstrating TLS from biopsies of lymphoma masses. We propose CT-guided biopsies of our patient's abdominal mass caused an acute TLS requiring renal replacement therapy. TLS and AKI should be considered a risk factor when undergoing biopsy of bulky tumors. Patients should be prophylactically treated with allopurinol and hydration.

## TH-PO840

**Prophylaxis of Tumour Lysis Syndrome in Patients Receiving Bendamustine Chemotherapy: A Cautionary Tale** William Petchey,[1] Kristian M. Bowles,[2] Gillian E. Turner,[2] Mahzuz Karim.[1] *[1]Renal Dept, Norfolk & Norwich Univ Hospital, United Kingdom; [2]Haematology Dept, Norfolk & Norwich Univ Hospital, United Kingdom.*

**Background:** Bendamustine is an alkylating agent used to treat Chronic Lymphocytic Leukaemia (CLL). Food and Drug Administration (FDA) approval was granted in 2008, but the product literature was updated in 2009 following post-marketing reports of serious skin complications (Toxic Epidermal Necrolysis [TEN] and Stevens-Johnson Syndrome [SJS]) associated with co-administration with allopurinol. The amended literature no longer recommended prophylactic allopurinol (previously advocated to prevent tumour lysis syndrome [TLS]) and stated that TLS could be mitigated by adequate hydration and careful biochemical monitoring. In a phase III trial of bendamustine, hyperuricaemic prophylaxis was given to all 162 patients in the bendamustine arm. 9/162 (0.06%) developed adverse skin reactions; however only 3 were grade 3 hypersensitivity reactions, and notably no grade 4 reactions, TEN or SJS were reported. The post-marketing incidence of TEN/SJS has not been quantified by the FDA, but is likely extremely low, and the relationship with allopurinol remains only associative.

**Methods:** In view of the concerns regarding skin toxicity we ceased treating our bendamustine patients with allopurinol. However, within 2 months we admitted 3 patients with significant TLS and acute kidney injury: 2 had life-threatening hyperkalaemia, one requiring urgent haemodialysis. All 3 were treated with rasburicase (recombinant urate oxidase) and intravenous hydration. Although renal function improved in all patients, one was left with residual renal impairment. We have since routinely used low dose rasburicase (0.2mg/Kg) in all patients commenced on bendamustine and have observed no further cases of TLS.

**Conclusions:** Bendamustine is an effective treatment for patients with CLL, but we propose conservative measures to prevent TLS are insufficient. Allopurinol is associated with a small but significant risk of life-threatening skin complications; however a single dose of rasburicase pre-cycle 1 of chemotherapy appears an effective alternative in preventing TLS but may not be associated with skin toxicity.

## TH-PO841

**Case Series of Rituximab-Induced Tumor Lysis Syndrome** Venu Velagapudi, Mazen O. Al-Qadi. *Critical Care, Mayo Clinic, Rochester, MN.*

**Background:** Tumor lysis syndrome (TLS) is characterized by hyperuricemia, hyperkalemia, hyperphosphatemia, hypocalcemia, acute kidney injury and metabolic acidosis. Rituximab-induced TLS is extremely rare with only 7 cases reported in the literature. We report a case series of 2 cases of TLS following Rituximab therapy in lymphoproliferative diseases.

**Methods: CASE-1** An 84-year-old female with CLL presented for chemo-therapy with rituximab. After rituximab, she had severe rigors, tachycardia and tachypnea. TLS was diagnosed on the basis of fulfilling Cairo-Bishop laboratory criteria for potassium, phosphorus, uric acid and calcium. She also had pancytopenia, lactic acidosis and acute kidney injury. Clinical grade 2 Cairo-Bishop criteria were fulfilled for renal impairment and arrhythmia. Despite IV fluids, rasburicase, and antibiotics, she developed respiratory failure, *Klebsiella pneumoniae septicemia* and died after withdrawal of care. **CASE-2** An 82-year-old man with angioedema, Gamma heavy chain disease from lymphoplasmacytic lymphoma developed TLS 24 hours after Rituximab. The diagnosis was made by fulfilling 3 laboratory Cairo Bishop Criteria for Phosphorous of 7.2 mg/dl from 5.1 mg/dl, Uric acid 9.6 mg/dl from 5 mg/dl, calcium 6.4 mg/dl from 8.2 mg/dl despite allopurinol and IV fluids. He also fulfilled clinical criteria for grade 2 TLS with serum creatinine of 1.9 mg/dl (>2.3 X Upper limit) and atrial fibrillation requiring treatment. He also had lactic acidosis and respiratory failure. He recovered from TLS, but opted for hospice care later.

**Conclusions:** Rituximab is an anti-CD20 monoclonal antibody that mediates destruction of CD20+ B-lymphocytes. Serious reactions including TLS are seen in 2% with lymphoproliferative disorders (typically high grade lymphomas). Rituximab-induced TLS in patients with low-grade lymphoproliferative diseases is exceedingly rare. We report 2 rare cases of rituximab-induced TLS in low grade lymphoproliferative diseases. TLS may mask sepsis and associated with high mortality in older patients. We suggest diligent monitoring, suspicion and need for prophylaxis when using rituximab in these disorders.

## TH-PO842

**Immobilization-Induced Hyperphosphatemia and Functional Hypoparathyroidism Successfully Treated with Oral Bisphosphonates** Disha D. Trivedi,[1] Elvira Gosmanova,[1] Barry M. Wall.[1,2] *[1]UTHSC, Memphis, TN; [2]VAMC, Memphis, TN.*

**Background:** Immobilization can induce hypercalcemia with suppression of PTH. Functional hypoparathyroidism is an infrequent cause of hyperphosphatemia.

**Methods:** A-46 year-old previously healthy male with 5-month history of paraplegia after motor vehicle accident developed persistent hyperphosphatemia with serum phosphorus levels (Pi) of 6.5-6.7 mg/dL after the injury. Physical examination was remarkable for T5 –T6 level paraplegia and left elbow calcification. Oral intake consisted of tube feeding with 1 Liter per day of "Peptamen" containing 667mg of Pi per L. Laboratory values showed total serum calcium (Ca) of 10.6mg/dL, ionized Ca of 1.32mmol/L (normal range 1-1.35mmol/L), serum bicarbonate 33 mEq/dL, PTH level of 10.5pg/mL (normal range 16.5-70 pg/ml), 25-hydroxy vitamin D level of 16.7ng/ml. Serum albumin, magnesium, cortisol, and TSH levels were normal. Urine Ca to creatinine ratio was 0.149, fractional excretion of Pi (FEPi) 5.2%, and TmP/GFR 7.64md/dL. Serum and urine immunofixation electrophoresis were negative for monoclonal protein. FGF 23 level was 263Ru/mL (normal range 44–215Ru/mL), PTHrP was undetectable. The patient was started on sevelamer 2.4 g with meals; with no improvement in Pi levels. The diagnosis of persistent hyperphosphatemia due to functional hypoparathyroidism from immobilization-induced hypercalcemia was made. Administration of teriparatide 60mcg lead to appropriately increased FEPi, from 14% to 28%. Bone specific markers supported increased bone resorption (N-telopeptide to creatinine ratio of 248, normal range 3-51), and bone turnover (bone-specific alkaline phosphatase 24.7 mcg/L, normal 0 – 20.1 mcg/L), findings characteristic for immobilization. After 3 wk of oral alendronate (70mg weekly), PTH, Pi and Ca levels normalized to 77 pg/ml, 3.2 mg/dL and 8.4 mg/dL, respectively. This was accompanied by decrease in N-telopeptide to creatinine ratio to 112 and bone-specific alkaline phosphatase to 20 mcg/L.

**Conclusions:** Immobilization-induced hyperphosphatemia from increased bone resorption and functional hypoparathyroidism was successfully treated with oral bisphosphonate.

## TH-PO843

**Horsetail Tea Ingestion and End-Stage Renal Disease: An Unrecognized Form of Silica Associated Nephropathy?** Adam Safdi, Shubhada N. Ahya, Yashpal S. Kanwar, Sheldon C. Chen. *Northwestern Univ.*

**Background:** To date, horsetail tea has not been associated with renal disease. Silica is a main component of the plant horsetail, genus Equisetum. Silica is thought to have direct nephrotoxic and inflammatory effects in the kidney. This is a case of a 64 year old woman who presented with accelerated end stage renal disease in the setting of diabetic nephropathy, but renal progression might have been hastened by silica in horsetail tea.

**Methods:** Our 64 year old woman was recently diagnosed with type 2 diabetes and started on insulin therapy 1 month prior to presentation. At the time, her serum creatinine was 1.2 mg/dl, and she was told she had a 'kidney problem.' While vacationing in Mexico, her family encouraged her to drink horsetail tea to 'build up her kidneys.' The tea is made by boiling crushed horsetail which contains copious amounts of silica. For 3 weeks, she drank horsetail tea daily, until she became increasingly ill with tinnitus and head fullness. She was hospitalized and found to have bilateral hemorrhagic strokes and severe kidney failure for which hemodialysis was initiated. Renal biopsy demonstrated findings consistent with diabetic nephropathy, but atypical findings included ATN that was characterized by cytoplasmic vacuolar degeneration. Histologic findings of silica in kidney disease include glomerulonephritis with immune deposits, proximal tubular sloughing, cytoplasmic vacuolization, which might contain aggregates of dense osmiophilic particles. Increased silica in kidney tissue has also been reported. Thus, we suspect that silica contributed to her acute-on-chronic renal failure.

**Conclusions:** Silica can incite or hasten renal injury, acting as a direct nephrotoxin or an inflammatory adjuvant. Though silica nephropathy is usually thought of as an occupational hazard from inhalation (e.g., sandblasting), this is the first report of the disease associated with environmental exposure from purposeful ingestion. We are pursuing various methods to detect increased silica in this patient's kidney tissue. Diagnosing silica-induced renal disease requires a high index of clinical suspicion, because history is paramount and could be the only clue to a potential role of horsetail.

## TH-PO844

**A Fulminant Case of Hypermagnesemia** Mary Muoneke, Ginius Pradhan, Kankam Charity, Deetu Simh. *Internal Medicine, St. Vincent Charity /Case Western Reserve Univ, Cleveland, OH.*

**Background:** The efficiency of renal response to Magnesuim load is such that hypermagnesemia is primarily seen in impaired renal function & iatrogenic (when a large Mg load is taken IV,orally,enema). The symptoms are well known but under-recognized. We report a case of hypermagnesemia presenting with fall& paralytic ileus complicated by cardiopulmonary arrest.

**Methods:** 82 yr old lady presented with fall,nausea&constipation. PMH:HTN,schizoaffective disorder. Meds:cogentin,benazepril,seroquel,haldol. She had stable vital signs,distended abdomen,hypoactive bowel sounds,hard stools in the rectum & diminished reflexes in all extremities. Labs Na.135, K.4.4, Cl.97.Hco3 21, BUN.31 Cr.1.0 KUB:distended bowel suggestive of paralytic ileus. She got enema & surgical consult. Further history revealed intake of large doses of magnesium citrate to relieve constipation. Magnesium level was 15.3mg/dl. She got IV fliuds,lasix,was more lethargic,hypotensive

&bradycardic followed by a cardiac arrest. She was resuscitated successfully as per ACLS protocol. She got IV calcuim gluconate & urgent hemodialysis.Despite these interventions,she coded again& 2nd resuscitation attempt was futile.

**Conclusions:** Magnesuim is a cofactor in more than 300 enzymatic reactions. Homeostasis is maintained by intestines& kidneys. Massive oral ingestion may cause hyperMg if the absorbed Mg exceeds renal capacity. The index patient took large doses of magnesium to relieve constipation. It resulted in a vicious cycle of hypermagnesemia causing paralytic ileus which further enhanced Mg absorption. Hypermagnesemia manifested as fall due to muscle weakness,bradycardia ,hypotension &cardiopulmonary arrest. Deterioration of her renal function is explained by hypermagnesemia-induced hypotension &reduced cardiac output leading to reduced GFR &worsening Mg clearance. Treatment:Removal of exogenous Mg, IV fluids, IV Calcuim carbonate & if therapy fails,hemodialysis against a low Mg bath. She presented with non specific symptoms which retrospectively points to high Mg as the culprit. This case illustrates that hypermagnesemia can occur in patients with normal renal function especially in elderly patients who present with paralytic ileus & generalized weakness.

## TH-PO845

**FGF-23 Mediated Phosphaturia – A Rare Paraneoplastic Disease in Carcinoma** Rupal Mehta, Eudora Eng. *Nephrology, Northwestern Univ, Feinberg School of Medicine, Chicago, IL.*

**Background:** Fibroblast growth factor (FGF) 23, a crucial regulator of serum phosphate and 1,25(OH) vitamin D, is secreted by osteocytes and osteoblasts and is regulated by oral phosphate load and vitamin D levels.

In oncogenic osteomalacia, abnormal secretion of FGF-23 represents a paraneoplastic syndrome of abnormal phosphate and vitamin D metabolism. It is typically described in tumors of mesenchymal origin and presents as hypophosphatemia secondary to renal phosphate wasting.

**Methods:** A 51 year old Chinese male with metastatic nasopharyngeal carcinoma to the bone presented for additional therapy of a pericardial effusion. He was noted to have a phosphorus level of 1.1 mg/dl. Investigation of his hypophosphatemia revealed normal renal function, vitamin D level, parathyroid hormone, and calcium. A fractional excretion of phosphorus was 22.7% (reference < 5% in hypophosphatemia) and phosphorus excretion on 24 hour urine collection was 681.4 mg. A FGF-23 level of 540 RU/ml (reference <181 RU/ml) confirmed the suspected diagnosis of osteogenic osteomalacia. Aggressive oral and IV phosphorus supplementation was started for persistent symptomatic hypophosphatemia.

| Hospital Day | Phosphorus | Phosphorus Repletion in mmol |
|---|---|---|
| 1 | 1.1 | 16 |
| 2 | 1.7 | 21 |
| 5 | 1.9 | 126 |
| 8 | 1.8 | 8 |
| 11 | 1.8 | 60 |
| 13 | 2.7 | 48 |
| 20 - Discharge Day | 1.6 | |

**Conclusions:** Oncogenic osteomalacia is an entity seen mostly in malignancies of bone and soft tissue with definitive treatment being resection. The half life of FGF-23 is approximately 58 minutes, thus, phosphate levels can quickly normalize postoperatively. We present the first reported case of osteogenic osteomalacia in a patient with nasopharyngeal carcinoma. He had exhausted all surgical, chemotherapeutic and radiation options for treatment of his malignancy and no proven nonsurgical therapies exist for treatment of osteogenic osteomalacia. Cinacalcet, an agonist of the calcium sensing receptor, has been used as a potential treatment given that FGF-23 may be PTH dependent however, our patient had normal PTH levels. With limited therapeutic options, this disease entity was extremely difficult and cumbersome to manage.

## TH-PO846

**A Case of Severe Hypocalcemia Induced by Sprue-Like Enteropathy Associated with Olmesartan** Keita Hirano, Kumiko Shimasaki, Masahiko Nagahama, Yasuhiro Komatsu. *Div of Nephrology, Dept of Internal Medicine, St. Luke's International Hospital, Japan.*

**Background:** In this report, we describe a rare case of hypocalcemia with tetanic symptoms. The cause of hypocalcemia in hospitalized patients is most often caused by disorders of parathyroid hormone (PTH) or vitamin D. symptomatic hypocalcemia is as a first sign of celiac sprue.Celiac sprue is an autoimmune disorder of the small intestine. Chronic diarrhea and calcium and vitamin D malabsorption are characteristics of celiac sprue. They cause hypocalcemia.

**Methods:** A previously healthy 64-year-old woman was referred to our hospital because of severe diarrhea and tetanic symptoms. She had diabetes and hypertension treated with olmesartan. Her serum ionized calcium ($Ca^{2+}$) level was 1.63 mmol/L and she presented with high intact-PTH and very low 25-hydroxy-vitamin D levels. Physical examination indicated no abnormalities. Fecal calcium excretion indicated malabsorption of vitamin D, and biopsy of the small intestine demonstrated pathologic changes characteristic of celiac sprue. However, the initiation of a gluten-free diet did not result in correction of all biochemical abnormalities. The results of anti-transglutaminase antibody and anti-endomysium antibody were negative which revealed that the case was not celiac sprue. In August 2012, Rubio-Tapia A et al reported that severe sprue-like enteropathy may be associated with olmesartan (Rubio-Tapia A., Mayo Clin Proc. 2012 Aug;87(8):732-8.). After discontinuing her olmesartan use, her diarrhea improved and calcium level normalized. The final diagnosis was severe hypocalcemia induced by sprue-like enteropathy associated with olmesartan.

**Conclusions:** This patient presented with severe hypocalcemia and diarrhea and showed clinical response and histologic improvement after suspension of olmesartan which was suspected to be causing the sprue-like enteropathy.

## TH-PO847

**Tetany, an Unusual Cause!** Reem Daloul, Abhishek Swami. *William Beaumont Hospital, Royal Oak, MI.*

**Background:** Tetany is a sustained involuntary muscle contraction that often occurs as a result of hypocalcemia or severe alkalosis. Here we report a case of severe acute tetany with a very unusual etiology.

**Methods:** A 34 year old female nurse with history of anxiety disorder and depression presented to the hospital for diffuse tetany. Symptoms started suddenly while driving with numbness and tingling of extremities followed by diffuse spasm and contraction of arms, legs, jaw and chest. Her home medications included seroquel and sertraline. On presentation, the patient was normotensive. She had wide opened eyes, locked jaw, flexed wrists and digits, and flexed posture. Laboratory work revealed severe hypokalemia with potassium of 1.9 mmol/L, and metabolic alkalosis with a bicarbonate level of 37 mmol/L. Ionized and total calcium as well as magnesium levels were normal. Administration of intravenous potassium chloride resulted in prompt muscle relaxation. Further investigations revealed a high urinary potassium indicating renal potassium loss. Urine for diuretic screen was negative. The patient was discharged in stable condition on oral potassium supplement with plan for further evaluation to establish the etiology of hypokalemia as out patient.

**Conclusions:** Neuromuscular effects of hypokalemia typically include generalized weakness, fatigue and muscle paralysis. Tetany, which represents muscle irritability appears to be a paradoxical effect. It has been described in standard text books and there are rare reports in the literature. In our patient, the prompt muscle relaxation following potassium supplements administration indicates that hypokalemia was the principle causative factor. Hypokalemia needs to be considered in the differential diagnosis of acute tetany as early recognition and treatment is needed for this potentially fatal condition.

## TH-PO848

**Acute Development of Resistant Hypertension following Octreotide Therapy for Carcinoid Syndrome** Douglas W. Schwartz,[1] Barry M. Wall.[1,2] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Veterans Affairs Medical Center, Memphis, TN.*

**Background:** Octreotide has been effective in managing symptoms of carcinoid syndrome. Both hypotension and acute hypertensive crises associated with carcinoid syndrome have responded to octreotide therapy. Although carcinoid tumors can produce a number of vasodilatory products, the development of refractory hypertension during octreotide therapy for carcinoid syndrome has not been reported.

**Methods:** 61 yr old male with well controlled hypertension (Lisinopril/HCTZ) was confirmed to have carcinoid syndrome during evaluation for chronic diarrhea and facial flushing. Biopsy of liver lesions showed a carcinoid neuroendocrine tumor. 5-HIAA level was markedly elevated at 26 mg/day. Within 3 days of initiating long acting ocreotide (20mg IM) blood pressure became acutely elevated, 224/101mmHg with no change in heart rate. Despite progressive addition of metoprolol, hydralazine, and amlodipine, systolic BP remained > 150mmHg. Workup for secondary causes of hypertension included: normal hemoglobin, normal serum potassium, creatinine (1.3 mg/dl), urinalysis, and urinary metanephrine excretion. Imaging studies revealed normal adrenal glands and kidneys. Plasma renin activity was not elevated. Volume status was unchanged. During long term monthly octreotide therapy, diarrhea and flushing rapidly resolved and have not recurred. BP control improved (140/80 mmHg), but continues to require multi- drug therapy.

**Conclusions:** Octreotide has not been reported to have direct vasoconstrictor effects. Acute hypertensive crisis has been reported to occur following octreotide therapy in 2 prior patients (pheochromocytoma and diabetic associated diarrhea) that resolved following discontinuation of the drug. The development of refractory hypertension during octreotide therapy for carcinoid syndrome has not been reported. The most likely etiology for the accelerated hypertension in our patient is increased systemic vascular resistance, resulting from decreased production of vasodilatory substances from the carcinoid tumor.

## TH-PO849

**Midaortic Syndrome: An Unusual Cause of Resistant Hypertension in Adults** Prerna Ganjoo, Maria P. Martinez Cantarin. *Medicine-Nephrology, Thomas Jefferson Univ Hospital, Philadelphia.*

**Background:** Resistant hypertension(RH) is defined as BP>140/90 (general population),and >130/80 (chronic kidney disease) despite concurrent use of 3 antihypertensives. The prevalence of RH may be as high as 20% in the hypertensive population.

**Methods:** A 52year old Hispanic male with history of resistant hypertension (diagnosed at age 8), hemorrhagic stroke and chronic kidney disease (CKD) stage III with baseline creatinine 1.7 mg/dL, was admitted with chest pain and severe hypertension. Examination revealed blood pressure in left arm 208/89 mmHg, and right arm 225/118 mmHg, cardiac holosystolic murmur and an abdominal bruit. A work up to rule out aortic dissection was initiated. CTA thorax showed elongated funnel-shaped stenosis with severe luminal narrowing involving the distal descending thoracic aorta. Cardiac workup was negative for ischemia. Further testing showed negative renal artery stenosis, normal bilateral renal size and echotexture, negative ANA, RPR, and urine toxicology screen. Carotid artery ultrasound showed less than 50% diameter reduction. A diagnosis of supraceliac midaortic syndrome was made. Patient underwent Aorto-aorto (descending thoracic aorta to infrarenal

aorta) bypass. At discharge, patient's creatinine was 1 mg/dL, and he required only 2 antihypertensive medications. Nine months after surgery, creatinine and anti-hypertensive regimen remains unchanged from time of discharge.

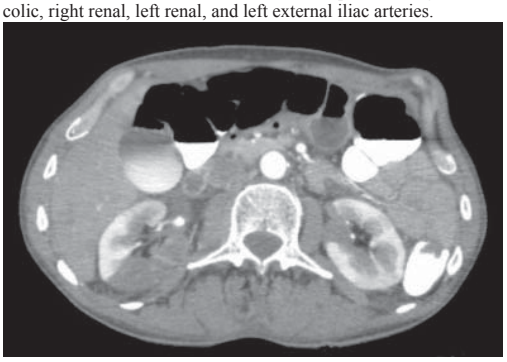
**Conclusions:** Midaortic syndrome (MAS) is a rare anomaly accounting for 0.5% to 2.0% of all aortic coarctations. It is most common in pediatric population, and young adults. MAS is usually congenital, but can also be associated with Takayasu's or temporal arteritis, neurofibromatosis and Williams syndrome. Serious complications of renovascular hypertension, including CKD, heart failure or ischemia, intracranial hemorrhage and aortic rupture may ensue.Treatment is predominantly surgical. We report an unusual case of idiopathic MAS in an adult patient with history of CKD, intracranial hemorrhage and resistant hypertension, with normalization of renal function, and improvement in blood pressure control post surgical repair.

## TH-PO850

**Bilateral Renal Infarction due to Fibromuscular Dysplasia** Taha Ayach, Amir Kazory. *Nephrology, Hypertension and Renal Transplantation, Univ of Florida, Gainesville, FL.*

**Background:** While Fibromuscular dysplasia (FMD) is an established cause of secondary hypertension, its association with renal infarction, which often has a subtle presentation, is less well recognized. Here, we report a case of FMD presenting with acute abdomen, bilateral renal infarcts, and severe hypertension.

**Methods:** A 53-year-old man presented with hematuria and acute severe abdominal and back pain radiating to the scrotum. Physical examination was unremarkable except for a blood pressure of 194/129 mmHg and right lower quadrant abdominal tenderness. Heart rate was regular and there were no skin lesions. Laboratory studies showed a serum creatinine level of 1.3 mg/dL, leukocyturia, and hematuria. Contrast-enhanced abdominal CT showed bilateral renal infarcts and multiple short segment dissections of the middle colic, right renal, left renal, and left external iliac arteries.



A comprehensive immunologic workup as well as hypercoagulability tests were all negative. Echocardiogram did not show any vegetation or thrombus. Conservative management was associated with improvement in symptoms and control of blood pressure.

**Conclusions:** The clinical presentation of FMD depends on the anatomic distribution as well as the extent of vascular involvement and is often asymptomatic or subtle. Although renal arteries are the most commonly involved vascular bed, renal infarction is seen in only 0.9% of the patients. Bilateral renal infarction is extremely rare and has so far been reported in a handful of cases. Revascularization is reserved for patients with resistant hypertension or progressive deterioration in renal function. This case, coupled with previous reports, illustrates the high variability in the presentation of FMD and this diagnosis should be considered in patients presenting with otherwise unexplained renal ischemia/infarction and involvement of multiple arteries.

## TH-PO851

**Weeping Kidney Syndrome** Ankit Rawal, Stuart M. Sprague. *Nephrology, Univ of Chicago - NorthShore, Evanston, IL.*

**Background:** Weeping kidney syndrome has a very low incidence rate with few reported cases and there is confusion in the definition. This report presents one rare case and discusses features of this disease.

**Methods:** A 41 year old african american female with past medical history of type I diabetes mellitus nine years post kidney and pancreatic transplant presents with recurrent abdominal pain, vomiting, and inability to tolerate oral intake. On initial examination, heart and lungs were normal. On abdominal examination, there was distention and soft ballotable swelling of the right lower quadrant. Routine blood examination was normal with the exception of an acutely elevated serum creatinine of 2.0 mg/dL. Radiological evaluation revealed new onset ascites with a cystic lesion in the transplanted kidney causing ureteral obstruction. A therapeutic paracentesis was perfomed which gave the patient symptomatic relief and revealed a high serum-ascites albumin gradient. The patient subsequently presented 3 days later with similar complaints. Imaging studies demonstrated a complex fluid collection throughout the pelvis with a loculated collection around the transplanted kidney. Serological evaluation of liver function and possible causes of hepatic dysfunction all returned negative. An abdominal drain was then placed which drained approximately 1.5 liters of yellow serous fluid per day. This provided the patient minimal relief. A liver biopsy was performed and returned negative. Further ascitic fluid analysis revealed a peritoneal fluid creatinine of 6.7 mg/dL and with a corresponding serum creatinine of 3.1 mg/dL. At this time it was thought the ascites may be nephrogenic in nature or due to urinary leak. She underwent a diagnostic laparoscopy which showed a slow, continuous leak of lymphatic fluid from the transplanted kidney, diagnostic for renal lymphangiectasia. The patient then underwent marsupilization and wrapping of the weeping kidney in omentum. This procedure proved to be successful and resolved her presenting complaints from six months prior.

**Conclusions:** Renal lymphangiectasia is a rare disease of the renal lymphatics with approximately 40 cases being described since 1890. This case depicts a rarely reported complication of renal transplantation.

## TH-PO852

**Chronic Kidney Disease from Functional Urinary Tract Obstruction** Anshul Kumar, Vibha Agrawal, Pradeep Dhakarwal, Joseph C. Guzzo, Henry L. Schairer. *Nephrology, LVHN, Allentown, PA.*

**Background:** Functional obstructive uropathy should be considered in patients with CKD and polyuria/polydipsia, especially who have evidence of central or nephrogenic DI, psychogenic polydipsia or use of anti-cholinergic medications.

**Methods:** 74 year old female was seen for worsening creatinine which rose from 1.7mg/dl in 2007 to 2.4mg/dl in 2011. Her main complaint was polyuria and polydipsia. In early childhood she was diagnosed with Hand Schuller Christian disease. On evaluation she had stable vitals, bilateral nerve deafness and a palpable urinary bladder. Her serum Cr was 2.5mg/dl, serum Na 145meq/l and UA showed a specific gravity of 1.005. Renal USG showed bilateral collecting system dilatation and post void residual of 578ml. Urine osmolality rose from 146mosm/kg to 365mosm/kg 2 hours following a 2mcg i.v. DDAVP. She was taught self catheterization and started on 0.5mg of DDAVP orally daily. Follow up labs showed Na between 133-140meq/l and Cr around 1.9mg/dl. Repeat USG showed mild bilateral collecting system fullness. Her urine output and fluid intake had markedly decreased improving her quality of life.

**Conclusions:** Large urine volumes lead to bladder distension and hypertrophy with subsequent intramural obstruction of the distal ureters. Bladder contractility is compromised, ureteric peristalsis diminishes and large residual volumes worsen this functional obstructive uropathy. Social embarrassment leading to voluntarily urine retention exacerbates it. Corrective therapy, even after prolonged period can lead to improvement in urinary tract dilatation. CKD can occur but ESRD is unknown. Our patient though had central DI did not reach the maximum concentrating ability following DDAVP test. A part maybe due to age related decrease in concentrating ability. Also long standing obstructive uropathy can result in acquired nephrogenic DI. The exact patho-physiology is not known but severe hyposthenuria indicates an intact diluting capability and locates the defect distal to the loop of Henle. Increased collecting duct pressure causes damage to the tubular epithelium resulting in insensitivity or partial sensitivity to the action of AVP.

## TH-PO853

**Perceptions of Nephrology among Internal Medicine Residents** Ivan E. Porter,[1] Hope Kincaid,[2] Stuart J. Hartman,[2] Nabeel Aslam,[1] Sharon E. Maynard.[2] *[1]Nephrology & Hypertension, Mayo Clinic, Jacksonville, FL; [2]Lehigh Valley Health Network, Emmaus, PA.*

**Background:** As interest in nephrology declines, we sought to identify factors influencing nephrology career interest among internal medicine (IM) residents.

**Methods:** This is a cross-sectional survey of IM residents to assess perceptions of nephrology and the impact of these perceptions on career decisions. All categorical IM residents at two institutions (Lehigh Valley Health Network and Mayo Clinic Florida) were invited to participate, prior to the initiation of a nephrology fellowship program. The survey was adapted from a tool previously validated in Australian medical trainees.

**Results:** 58 of 78 residents completed the survey (74% response rate). 53% of the residents were male and 84 % were US graduates. 14% of residents indicated an interest in a nephrology career. Cardiology (32%) and Hospitalist (41%) were the most sought after careers. While 43% of residents stated that their choice of residency was affected by the presence of a fellowship program at their institution, 41% first became interested in their specialty of choice during residency and 55% became certain of their specialty of choice during residency. Figure 1 shows whether subjects agreed or disagreed with several negative statements about Nephrology, and the impact of each statement on the residents' career decision. Factors with the most impact on career choice were that nephrologists have long work hours (42%) and frequent/difficult call (57.9%).

| | % Perceptions | | | % Impact | | |
|---|---|---|---|---|---|---|
| **Statements about Nephrology** | Disagree | Neutral | Agree | Little | Moderate | High |
| Not Interesting | 87 | 7 | 5 | 71 | 26 | 3 |
| Unappealing due to chronic nature of disease | 63 | 14 | 23 | 62 | 35 | 3 |
| Pathophys too complex | 48 | 32 | 20 | 63 | 37 | 0 |
| Poorly prepared in medical school | 52 | 24 | 24 | 86 | 14 | 0 |
| No positive role models | 87 | 7 | 6 | 77 | 14 | 9 |
| No previous Nephrology experience | 71 | 11 | 18 | 79 | 21 | 0 |
| Poorly Paid | 27 | 64 | 9 | 71 | 26 | 3 |
| Few opportunities for procedures | 32 | 34 | 34 | 79 | 13 | 8 |
| Long work hours | 23 | 45 | 32 | 58 | 26 | 16 |
| Not conducive to part time work | 29 | 59 | 12 | 79 | 16 | 5 |
| Frequent/Difficult Call | 24 | 36 | 40 | 42 | 42 | 16 |
| Fellowship long hours/difficult call | 18 | 48 | 34 | 53 | 37 | 10 |

**Conclusions:** Most residents become certain of their specialty choice during residency. We found several negative perceptions of Nephrology among IM residents, which may impact career decisions. Efforts to increase interest in Nephrology careers should focus on improving these negative experiences and perceptions among residents.

**TH-PO854**

**More Women Choose Nephrology, but Publications by Female Senior Authors Have Not Increased** Suzanne M. Norby, LaTonya J. Hickson, Amy W. Williams. *Nephrology & Hypertension, Mayo Clinic, Rochester, MN.*

**Background:** Over the past decades, the number of female physicians has increased, yet women are promoted to associate professor and professor levels at lower rates than for men. Differences in number of peer-reviwed publications by female and male authors likely contribute to the discrepancy. To explore this further in nephrology, this study compared the number of female nephrology fellows in 1994 and 2011 as well as the number and relative percentage of publications by female authors in two nephrology journals.

**Methods:** The number of female nephrology fellows in the U.S. was obtained from published data in the the Journal of the American Medical Association. The tables of contents of regular issues of the Journal of the American Society of Nephrology and the American Journal of Kidney Diseases from 1994 and 2012 were reviewed. The study was limited to articles with first or last authors listing a U.S. institutional affiliation. The gender of first and last authors for original articles was determined, using internet search strategies when gender was not obvious by first name.

**Results:** In 1994, 121/637 (19%) of nephrology fellows were women compared with 336/918(40%) in 2011 (p=<0.0001). 520 original article entries were reviewed. 316 were from U.S. institutions: 168/244(69%) in 1994 and 148/276(54%) in 2012. In 1994, 34(20%) of articles had a female first author compared with 60 articles(40%) in 2012 (p=0.005). Proportion of articles with a female last author was not significantly different; 23(14%) in 1994 compared with 24(16%) in 2012. Female first authors did not increase significantly in JASN [21/91 (23%) to 30/79(38%) ] but did in AJKD [13/77(17%) to 30/69 43%), p=0.014]. Female last authors did not increase significantly for JASN (12% vs 19%) and decreased for AJKD (16% vs 13%).

**Conclusions:** Although the proportion of female nephrology fellows doubled between 1994 and 2011, the number of publications by women in two high-impact nephrology journals does not demonstrate a parallel increase. Since there is a lag between completion of training and achieving academic productivity, the increase in number of female first authors is encouraging. Further analysis is needed to examine trends.

**TH-PO855**

**Documentation of Counseling Performed at Clinic Visits, a CMS EHR Incentive Program Requirement** Anna Burgner, Julia Lewis. *Div of Nephrology, Vanderbilt Univ School of Medicine, Nashville, TN.*

**Background:** One of the requirements of Stage 2 for the CMS Medicare and Medicaid Electronic Health Records (EHR) Incentive Programs is to provide clinical summaries to the patient for each office visit within one business day (meaningful use core measure #8). Part of these clinical summaries includes written documentation of counseling/instructions given to the patients during the visit. Frequently the same counseling can be appropriate for multiple patients during a clinic session.

**Methods:** Using our electronic medical record system, we have created a set of templates in those areas that we frequently counsel our patients, and these can be easily auto-imported into the clinical summary. They include topics such as ACE-I and ARB use and teratogenicity, starting immunosuppression, sodium and fluid restricted diet, low potassium diet, and low phosphorus diet. Each template can be modified with patient specific information, such as the name of their ACE-I or the degree of fluid restriction, allowing for flexibility in the templates and more patient centered care.

**Results:** We find that utilizing preformed templates leads to a more efficient completion of the clinical summary. It saves documentation time. It also allows for the patient to get a consistent, well written, and educational set of counseling at each visit.

**Conclusions:** The use of modifiable templates to document counseling and instructions given during the clinical visit in the clinical summary allows for improved efficiency in clinic, while delivering a consistent, educational directive to the patient.

**TH-PO856**

**A Pilot Renal-Palliative Care Curriculum: Improving Knowledge and Skills among Nephrology Fellows** Katharine Cheung,[1] Sumi Sukumaran Nair,[1] Emilee R. Wilhelm-Leen,[1] Manjula Kurella Tamura.[2] *[1]Stanford Univ School of Medicine; [2]Palo Alto VA Health Care System.*

**Background:** Nephrologists frequently care for frail, older patients with high annual mortality. But the majority of trainees feel unprepared to have end-of-life discussions. This quality improvement project aims to describe the knowledge, attitudes and skills of nephrology fellows at a single center and track their progress through an innovative, renal-palliative care curriculum.

**Methods:** We conducted a focus group of nephrology fellows to assess their knowledge gaps in palliative care. Using that baseline, we collaborated with experts in Palliative Care and Geriatric Nephrology to devise a pilot curriculum. We assessed knowledge, attitudes and skills with surveys before and after the pilot and each learning module. Survey data was collected using Qualtrics survey tool.

**Results:** The curriculum consisted of four lectures (hospice, dialysis withdrawal, cross-cultural care, non-pain symptom management), two workshops (pain management and communication skills) and one journal club (prognostication in kidney disease) over six months. In the pre-test, four of nine trainees reported having no prior training in communication skills, end-of-life or palliative care for renal patients but 90% of trainees reported a sense of responsibility to be trained in these areas. When asked to rate knowledge and/or skills on 21 specific areas (e.g., knowledge of hospice services available to dialysis patients), the mean score ranged from 2.1-3.5 on a five-point scale, with 5 being the best score. Trainees reported particular need for teaching in planning for withholding dialysis. In general, trainees' scores on content-based pre-tests were low (mean correct across three tests 34%) and there was improvement in post-tests (mean correct across three tests 75%). Trainees reported a high score for usefulness of the content as well as their likelihood of recommending the sessions to others (means 4.7 and 4.8 respectively on a five-point scale).

**Conclusions:** Renal fellows have limited training in palliative care, but desire this training. A curriculum covering key topics in palliative care increases content knowledge and is rated by trainees as highly useful.

**TH-PO857**

**Nephrology Elective Experience during Medical Residency: A U.S. Nephrology Fellowship Training Program Directors' Survey** Hitesh H. Shah,[1] Nancy Day Adams,[2] Aditya Kadiyala,[1] Kenar D. Jhaveri.[1] *[1]Nephrology, Hofstra North Shore–LIJ School of Medicine, Great Neck, NY; [2]Univ of Connecticut Health Center, Farmington, CT.*

**Background:** Interest in nephrology careers is declining in the United States (US). The type of nephrology elective that internal medicine (IM) residents experience may play an important role in enhancing interest in nephrology careers. We do not know what types of nephrology electives are offered in IM programs or whether nephrology electives are representative of what practicing nephrologists do.

**Methods:** An anonymous online survey was created & subsequently distributed to all US nephrology fellowship training program directors (N-TPDs) in May 2013.

**Results:** So far, 50 US N-TPDs have responded to our survey (34% response rate). 86% of the programs offered a 4-week nephrology elective at their institution. 48% of the programs did not offer any outpatient (OP) nephrology experiences to their IM residents during a typical 4-week elective. Nearly 90% of the programs did not rotate their residents in either their outpatient HD unit or PD clinic. Only 30% rotated their residents in their OP kidney transplant program. When asked what was most effective in fostering interest in nephrology careers, N-TPDs identified nephrology elective experience (78%) & nephrology faculty mentoring (78%). 72% felt that a 4-week elective would provide adequate exposure to nephrology during residency. 92% of the N-TPDs thought that an "ideal" nephrology elective experience should include both inpatient (IP) & OP experiences. "Inpatient service needs" (48%) and "too much work to coordinate various OP experiences" (26%) were some of the reasons identified by N-TPDs for none or limited OP nephrology experiences for IM residents. Over half of the N-TPDs responded that their elective structure was not representative of what nephrologists do in practice.

**Conclusions:** Nearly half of the responding programs did not offer any OP nephrology experiences to IM residents. To enhance knowledge and interest in nephrology careers during IM residency, a combined exposure to both IP & OP nephrology (including outpatient dialysis and transplantation) should be strongly considered by the training community.

**TH-PO858**

**Creating Interest in Nephrology Careers: A Novel Nephrology Elective Experience for Medical Students** Hitesh H. Shah, Kenar D. Jhaveri. *Nephrology, Hofstra North Shore–LIJ School of Medicine, Great Neck, NY.*

**Background:** Interest in nephrology careers is declining in the United States (US). The type of nephrology elective that US medical students experience may play an important role in creating interest in nephrology careers.

**Methods:** We created a novel 4-week nephrology elective experience for visiting medical students at our institution. Our redesigned elective included both 2-week inpatient (IP) & 2-week outpatient (OP) nephrology experiences. The OP rotation included 10 half-days of various nephrology clinic experiences, 2 half-days of immediate post-transplant clinic, 1 half-day of kidney donor evaluation clinic, 2 half-days of PD clinic and 3 half-days of outpatient HD unit rounding. Our redesigned elective also included educational conferences. From 6/2012 to 12/2012, five 4th year medical students (all from different US medical schools) completed our redesigned nephrology elective. An anonymous online survey was created to evaluate the novel elective experience and was subsequently distributed to all students in June 2013.

**Results:** All students responded to our survey. All reported adequate OP nephrology exposure. 80% of the students had worked with one or two faculty members during the IP setting. In comparison, 80% were exposed to at least four different faculty members during the OP experiences. All students had interacted with at least 3 fellows. All reported that the elective experience enhanced their exposure and knowledge in nephrology and that they would recommend this elective to other medical students. They also thought that this elective provided them with a better insight into what nephrologists do in practice. 80% of the students reported that this elective experience created an interest in nephrology career. Majority (60%) of the students responded that they would consider nephrology as one of their 3 top career choices as a result of this elective experience.

**Conclusions:** We believe that the restructured nephrology elective will provide the medical student with a much needed and realistic exposure to nephrology. Based on our experience, we recommend all nephrology training programs to consider this elective structure for medical students.

**TH-PO859**

**Characteristics of U.S. Adult Nephrology Fellowship Training Program Directors** Hitesh H. Shah, Divya Monga, Aditya Kadiyala, Anna Mathew. *Nephrology, Hofstra North Shore–LIJ School of Medicine, Great Neck, NY.*

**Background:** Characteristics of US adult nephrology fellowship training program directors (N-TPDs) are not known. We do not know how long N-TPDs have served in their role as TPDs and if they had undergone fellowship training in the same program where they were serving as TPD.

**Methods:** Data were abstracted in June 2013 from public websites of Accreditation Council for Graduate Medical Education-Accreditation Data System, Electronic Residency Application Service, Healthgrades.com and webpages of individual nephrology fellowship programs. Data was analyzed for 146 N-TPDs**.**

**Results:** As of June 2013, analysis of this data showed that the average age of N-TPDs was 52.5 years with majority (76%) of them being males. Age stratified data available for 138 N-TPDs showed that only 5.1% were in the younger age group of 30-40 years of age with 19.6% being more than 60 years old. 43.5% were between 41-50 years of age while 31.8% were between 51 to 60 years old. Out of the 146 N-TPDs, 71.2% were United States (US) medical graduates with the remaining 28.8% being international medical graduates (IMG). Interestingly, 42.9% of this IMG group underwent medical school training in India. Half (50.7%) were found to be serving in the role of N-TPD for at least 5 years with 26% having served more than 10 years. 24.5% have served as N-TPD for less than 2 years at the time of this analysis. Out of the data available for 134 N-TPDs, 39.6% held the academic rank of professor of medicine, with 40.3% being associate professors and 20.1% being assistant professors. Also, 33.6% were found to have completed their fellowship training in the same program that they were serving as N-TPD.

**Conclusions:** Majority of the N-TPDs were males and had undergone medical school training in the US. A significant percentage of N-TPDs who were trained in international medical schools were from India. Majority of this group has served as TPD for over 5 years and nearly one fourth have served for more than 10 years. Interestingly, one-third of the N-TPDs had undergone fellowship training in the same program where they were serving as TPD.

**TH-PO860**

**ASN Dimitrios G. Oreopoulos Visiting Professor Program in End-of-Life Care: Results of an Educational Intervention** Jamie Alton Green,[1] Alvin H. Moss,[2] Michael F. Schultz,[1] James E. Hartle,[1] Ion D. Bucaloiu.[1] *[1]Dept of Nephrology, Geisinger Medical Center, Danville, PA; [2]Center for Health Ethics and Law, West Virginia Univ, Morgantown, WV.*

**Background:** Prior studies show that nephrology fellows receive inadequate training in end-of-life care.

**Methods:** We performed a half-day workshop led by a nationally recognized expert in end-of-life care to improve fellow preparedness in this area. The workshop included formal didactic lectures and case-based discussions pertaining to renal palliative medicine. Participants were 1st and 2nd year nephrology fellows at Geisinger Medical Center in Danville, Pennsylvania (n=5). Self-reported preparedness was measured pre- and post-workshop using a 5-point Likert scale (0=not at all prepared to 4=very prepared). Paired t-tests were used to assess changes in fellow preparedness based on the workshop.

**Results:** 60% of the fellows were male and 40% had received formal training in palliative care at baseline. Mean level of preparedness increased significantly for all skills (Table). 100% of fellows "strongly agreed" that the program significantly increased their knowledge and comfort regarding end-of-life care in nephrology. 100% of fellows also "strongly agreed" that based on the program they would be more likely to estimate and discuss prognosis with their kidney patients. Table. Changes in Fellow Preparedness.

| Skill | Pre | Post | p-value |
|---|---|---|---|
| Care for dying patients | 3.2 | 4.0 | 0.02 |
| When to refer to hospice | 2.8 | 4.0 | 0.004 |
| Tell a patient he/she is dying | 3.0 | 4.0 | 0.03 |
| Assess prognosis | 2.8 | 4.0 | 0.004 |
| When to refer to palliative care | 2.6 | 3.8 | 0.03 |
| Respond to requests to stop dialysis | 3.0 | 4.0 | 0.03 |
| Discuss dialysis options including no dialysis | 2.8 | 4.0 | 0.03 |
| When to use the "surprise" question | 2.8 | 4.0 | 0.03 |
| Role of shared decision-making | 2.6 | 4.0 | 0.005 |
| Assess and manage pain | 2.4 | 4.0 | 0.003 |
| Assess and manage depression | 2.0 | 3.8 | 0.001 |
| Assess and manage nausea | 2.6 | 3.8 | 0.03 |
| Assess and manage pruritus | 2.4 | 4.0 | 0.003 |
| **All skills combined** | **2.7** | **4.0** | **<0.001** |

**Conclusions:** A brief educational intervention performed by a nationally recognized expert improved fellow preparedness in end-of-life care in nephrology. These results will be used to implement a more formal renal palliative care training program.

**TH-PO861**

**Formal Clinical Research Training during Fellowship Is Valuable in Initiating a Career in Academic Nephrology** Shilpa Sharma, J. Kevin Tucker. *Brigham & Women's Hospital.*

**Background:** In a survey of ASN members which included an equal representation of academic/private practice nephrologists, most respondents indicated they had "little or no training" in clinical research (Berns et al. cJASN 2010). 11.1% to 35.2% of respondents reported feeling well trained and competent in funding through federal, industry, or foundation/society sources. Traditionally, nephrology fellowship has been 2 yrs in duration, the minimum training period required by ACGME. An increasing number of fellowship programs are requiring fellows to pursue three/four yrs of training with an emphasis on research. One factor that may hinder future funding is lack of formal research training in epidemiology, biostatistics, and related fields. We sought to study the impact of formal clinical research training during fellowship in forming successful academic nephrology careers, within a single large fellowship program based at two tertiary medical centers in Boston.

**Methods:** We conducted a retrospective cohort study including all clinical research fellows over a 10 yr period utilizing a database maintained by the program director. The fellows have an option of pursuing formal research training at the Harvard School of Public Health and affiliates after their first year.

**Results:** 41 clinical research fellows trained from 1998 to 2008, of which 51.2% underwent additional research training, obtaining degrees during fellowship. During fellowship, 57.1% of fellows with additional training were funded compared to 10% of fellows without additional training (p-value <0.05). Within 5 yrs of fellowship completion, 57.1% of the additionally trained fellows obtained independent investigator funding compared to 5% of the fellows without additional training (p-value <0.001, OR 25.3). 95.2% of the additional training group fellows joined academic institutions after completing fellowship compared to 45% of fellows without additional training (p-value<0.001,OR 24.4).

**Conclusions:** This study highlights the value of formal clinical research training during fellowship. For future clinical investigators, formal clinical research training may be a critical factor in improving the chances of acquiring funding and promoting careers in academia.

**TH-PO862**

**Prevalence and Demographic Associations of Health Literacy in Pre-Dialysis Chronic Kidney Disease** Julie A. Wright Nunes,[1] T. Alp Ikizler,[2] Kerri L. Cavanaugh.[2] *[1]Nephrology, Univ of Michigan, Ann Arbor, MI; [2]Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.*

**Background:** Limited health literacy is associated with poor clinical outcomes. Data is limited describing prevalence and demographic associations of health literacy in patients with non-dialysis dependent chronic kidney disease (CKD).

**Methods:** Adult patients with CKD Stages 1-5 not on maintenance dialysis were enrolled in a cross-sectional study from April 2009 to October 2010. The Rapid Estimate of Adult Literacy in Medicine (REALM) was used and an assessment of ≥9th grade reading level was considered adequate health literacy.

**Results:** 556 patients were enrolled. The mean (SD) age was 57 (16) years. 53% were male, 81% were Caucasian, and 78% had CKD Stage 3-5. Nineteen percent of patients had < 9th grade health literacy. Univariate analysis revealed men were less likely than women (OR 0.50[CI 0.32,0.79];p<0.01) to have adequate literacy, as were patients of non-white race compared to white (0.34[0.21,0.54];p<0.01). Patients of higher income had higher odds (1.76[1.33,2.34];p<0.01) of adequate health literacy, as did patients with eGFR ≥60 (2.87[1.48,5.54];p<0.01), and those with higher formal educational attainment (6.53[3.25,13.14];p<0.01). In analysis adjusted for age, sex, race, income, education, and kidney function, these relationships remained significant. In particular, men (0.45[0.27,0.75];p<0.01 vs. women) and patients of non-white race (0.33[0.19,0.57];p<0.01 vs. white) continued to have a lower odds of having adequate health literacy, despite adjustment for income, kidney function and formal education.

**Conclusions:** Low health literacy is associated with less desirable clinical outcomes. More research is needed to determine factors responsible for gender and racial differences in health literacy, and to develop literacy-sensitive interventions for populations at risk.

*Funding:* NIDDK Support, Other NIH Support - T32, Private Foundation Support

**TH-PO863**

**Nephrology Exposure during Medical Residency: A U.S. Internal Medicine Program Directors' Survey** Karen M. Warburton,[1] Kenar D. Jhaveri,[2] Ankit B. Patel,[3] Stephanie A. Call,[4] Vineet Arora,[5] Hitesh H. Shah.[2] *[1]Nephrology, Univ of Pennsylvania; [2]Nephrology, Hofstra NSLIJ School of Medicine; [3]Medicine, Weill Cornell Medical College; [4]Medicine, Virginia Commonwealth Univ; [5]Medicine, Univ of Chicago.*

**Background:** Amid concerns of a workforce shortage in the field of nephrology, little is known about the types of nephrology exposure offered during internal medicine (IM) residency in the US. The relationship of this exposure to success in recruiting future nephrologists from residency programs is also unknown. It is unclear if US IM program directors (IM-PDs) are aware of the annual ASN Kidney Week Training Program (KWTP) for residents.

**Methods:** An online survey was created and distributed to US IM-PDs as part of the 2012 APDIM spring survey.

**Results:** 214 US IM-PDs responded to our survey (54% response rate). 55% of programs had a nephrology fellowship program, and 48% had a nephrology transplant program at their institution. Inpatient nephrology consult service was a required rotation for 41% of programs. 46% of programs did not have a dedicated ambulatory nephrology rotation. Nearly two-thirds of the programs did not have a kidney transplant or outpatient hemodialysis unit experience for IM residents. When asked what was most valuable in fostering nephrology interest among IM housestaff, IM-PDs identified nephrology attending role modeling (69%), nephrology consult experience (67%) and nephrology faculty mentoring (59%). Only 61% of IM-PDs reported familiarity with the ASN KWTP.

**Conclusions:** While nearly two thirds of IM-PDs thought that nephrology consultative experience was important to foster interest in nephrology careers, this experience was not

required by the majority of programs. The majority of programs did not offer a kidney transplant or outpatient dialysis rotation for IM residents. To enhance exposure to and interest in nephrology careers among IM residents, a combined exposure to inpatient and outpatient nephrology, increased offerings in transplant or outpatient dialysis experiences, and increased awareness of opportunities such as the ASN KWTP for residents should be strongly considered by the training community.

## TH-PO864

**Development and Implementation of Nephrology Fellow OSCEs for End-Stage Renal Disease Counseling** Mark G. Parker, Christine Mallar, Jennifer Gammon, Patricia L. Cantlin. *Maine Medical Center, Portland, ME.*

**Background:** Observed Structured Clinical Encounters (OSCEs) are established assessment tools in medical education, but there is little published experience on their use in nephrology fellowships. Surveys of nephrology fellowship graduates indicate that many feel inadequately prepared to counsel patients about dialysis options and palliative care. We have developed two OSCEs to assess these skills.

**Methods:** Two scenarios with trained standardized patients (SP) were administered to fellows in months 7 and 19 of training. The first is a mid-age woman with advanced chronic kidney disease (CKD) and no immediate transplantation prospects. The second is an elderly man with advanced CKD, considerable co-morbidity, and limited life expectancy. Two trained faculty members observed the encounters. Fellows received feedback from SP and faculty, and completed a 7-question learner feedback survey using a 5-point Likert scale for responses (1=strongly disagree, 5= strongly agree) and a narrative self-reflection.

**Results:** 6 unique fellows were assessed over a two-year period. Mean learner feedback survey scores ranged from 4.17-5.0 for questions about the quality of the OSCE administration and 4.33-4.67 for questions about utility of the OSCE for analyzing skills and behaviors. Thematic analysis of narrative self-reflections suggests that fellows identified strengths in their communication skills and core knowledge of dialysis options. However, they identified challenges in their knowledge of nuances of dialysis care, such as financing and home therapy details, as well as description of resources for palliative care. Challenges were greatest for month 7 fellows.

**Conclusions:** We have demonstrated feasibility and potential utility of OSCEs for assessment of dialysis and palliative care counseling skills of nephrology fellows. Our fellows find the experience to replicate true clinical experiences satisfactorily and to provide useful information about their strengths and challenges for improvement. Limitations include the single center nature of this experience and small number of observations. We are initiating a multi-center prospective study to address these limitations.

## TH-PO865

**Testing Strategies to Education Primary Care Physicians on Chronic Kidney Disease** Laura J. Maursetter. *Div of Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI.*

**Background:** It has been shown that there is a knowledge gap in identification and management of chronic kidney disease (CKD) by primary care providers. In an effort to improve this practice the Wisconsin Research and Education Network (WREN) developed a research project aimed to test ways that can help primary care practitioners improve identification of patients with CKD and implement guidelines for CKD management through a local learning collaborative.

**Methods:** All WREN sites were invited to the learning collaborative. A survey was distributed that asked the primary providers if a group would be useful and to identify topics that would be of interest to the group. Teleconferencing and blackboard collaboration were used as methods of communication. A group facilitator, a nephrologist and a lead family medicine physician were part of each meeting. After 3 months of meetings, a participation survey was distributed to determine the utility of the group.

**Results:** 29% of the 84 sites that had been a part of the CKD project responded to the invitation to be a part of the learning collaborative with 46% of the responders indicating that they would be interested in participating in a monthly virtual statewide learning collaborative. After 3 meetings with 1-4 sites participating during each meeting, a follow up survey was done. The results of the follow up survey showed that there was little interest in continuing these meetings with the most stated reason being scheduling conflicts.

**Conclusions:** Despite a group of primary care providers that was primed to be interested in the topic of CKD, there was a very low rate of participation in the learning collaborative. The overwhelming reason for low participation stated it was due to a rigorous schedule. Teleconferencing and blackboard collaborative were used as strategies to bring together those in various geographic areas across the state of Wisconsin but this did not seem to improve participation. It is likely that an asynchronous method of learning may increase participation and ultimately improve recognition and management of CKD.

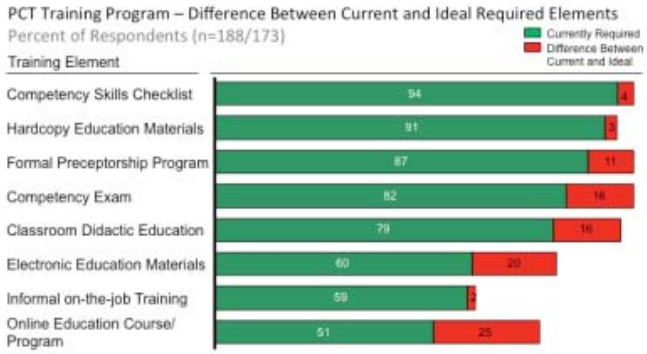
## TH-PO866

**Most U.S. Patient Care Technician Training Programs Leverage Several Required Elements but Fall Short of Ideal and Are Not Sourced from Independent Third Parties** Alex Yang, Jennifer Vavrinchik. *NCS Research.*

**Background:** CMS instituted certification requirements for patient care technicians (PCTs). In this study, we evaluate PCT training programs.

**Methods:** >2000 nephrology professionals were screened against inclusion criteria: US nephrology professional, dialysis practice setting, >1 yr of nephrology experience, and consent. 428 eligible study candidates were invited with eventual 188 study participants (48%). Elements of PCT training programs were evaluated. Analyses were conducted across all study participants with no excluded data for any reason.

**Results:** Percentages of current elements in PCT training programs and difference from ideal are shown (Figure).



>80% of study participants believe patient care would improve if their PCT training program included the ideal elements. Current and ideal percentages of independent 3rd-party sourced elements for PCT training programs are shown (Table 1).

**Table 1: Independent 3rd Party Source for PCT Training Elements**

| Elements of PCT Training Program | Current Actual (Percent) | Ideal (Percent) | Difference (Percent) |
|---|---|---|---|
| Competency Exam | 6 | 62 | 56 |
| Online Education Course/Program | 6 | 62 | 56 |
| Electronic Education Materials | 6 | 62 | 56 |
| Hardcopy Education Materials | 4 | 55 | 51 |
| Competency Skills Checklist | 1 | 48 | 47 |
| Classroom Didactic Education | 2 | 44 | 42 |
| Formal Preceptorship Program | 1 | 44 | 43 |
| Informal on-the-job Training | 0 | 35 | 35 |

**Conclusions:** Although most PCT training programs utilize several elements, study participants believe more PCT training elements would be ideal and would improve patient care. Furthermore, 3rd party independent sources of PCT training/education are currently rarely used but roughly 1/3 to 2/3 of study participants believe it is important for PCT training and education elements to be independent. Efforts to standardize PCT certification should be coupled with efforts to standardize the elements, the content, and the independence of PCT training/education.

## TH-PO867

**Medical Student Test Performance during a Second-Year Kidney Pathophysiology Course Improves with Participation in Small Group Active Learning** Elizabeth J. Brant, Elizabeth W. Dehmer, Gerald A. Hladik. *UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC.*

**Background:** We assessed the impact of participation in active learning on test scores during a second-year medical student kidney pathophysiology course. We hypothesized that participation in active learning would have a favorable impact on test scores.

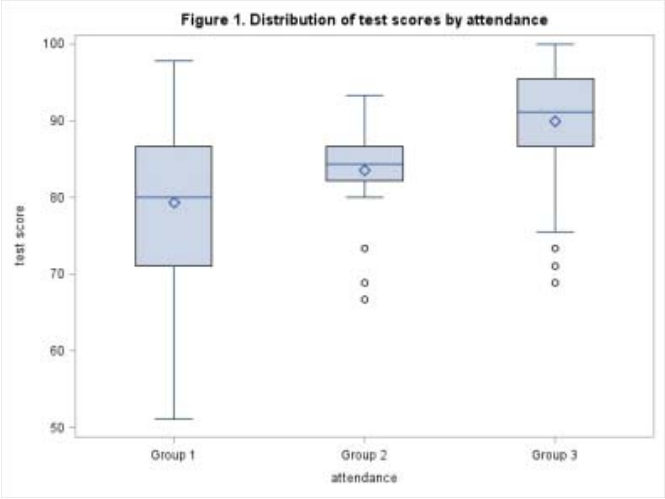
**Methods:** The second-year kidney pathophysiology course consisted of 20 hours of traditional lecture and 20 hours of optional active learning sessions. During active learning, students worked through clinical cases under the supervision of nephrology faculty, with a faculty:student ratio of 1:15. Of the 133 students enrolled in the course, 74 (56%) participated in active learning. Participation in small groups was classified as follows: Group 1: Participation in <30% of sessions; Group 2: Participation in 30-60% of sessions; Group 3: Participation in >60% of sessions. One-way analysis of variance was used to compare participation and mean test scores.

**Results:** The distribution of students according to level of participation in active learning sessions and corresponding test scores is shown in Table 1.

Table 1
Mean test scores according to level of participation in active learning sessions

| Group | Number of students N(%) | Mean test score (standard deviation) |
|---|---|---|
| 1 | 59 (44) | 79.3 (10.4) |
| 2 | 21 (16) | 83.6 (7) |
| 3 | 53 (40) | 89.9 (7.7) |

Participation at the small group active learning sessions was associated with higher mean test scores ($p<0.001$). Tukey's test showed significant differences in scores between Group 3 and each of the other groups (Fig. 1).



**Conclusions:** Student participation in active learning small groups during a second-year kidney pathophysiology course was associated with superior test performance. Limitations of the study include that this was a retrospective analysis at a single center.

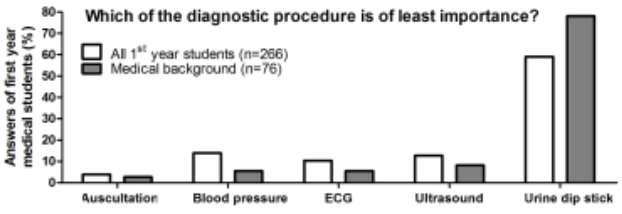
## TH-PO868

**Mind the Dip Ranking of Diagnostic Procedures – An Online Survey among 266 First Year Medical Students at Two German Universities**
Philip Bintaro,[1] Heike Kielstein,[2] Volkhard Fischer,[1] Jan T. Kielstein.[1] *[1]Hannover Medical School, Hannover, Germany; [2]Martin Luther Univ Halle-Wittenberg, Halle, Germany.*

**Background:** Urine dipstick analyses pH, specific gravity, proteinuria, bilirubinuria, glucosuria, ketonuria and nitrite. It is one of the most frequently used diagnostic tests and a screening tool for many diseases as well as part of a guideline based work up ranging from urinary tract infection to assessment of cardiovascular risk and CKD. The aim of our study was to investigate the attitude of first year medical students (in a 6 year curriculum) towards urine analysis and ranking it among other frequently used diagnostic tests and procedures.

**Methods:** 549 first year medical students were invited to fill out an online questionnaire consisting of several questions concerning medical diagnostic tests. The return rate was 47.4 %. Of the 266 participants 64.9 % were female. One question was "Which of the following diagnostic procedures is of least importance?" allowing to select ONE of the following: 1) Auscultation 2) Blood pressure 3) Electrocardiogram 4) Ultrasound 5) Urine dip stick.

**Results:** Urine dip stick and blood pressure were viewed as the least important tests.



Auscultation was selected as the most important test. Concordingly 98.1 % of the medical students selected the stethoscope as the most important medical equipment conveying the image of a doctor, followed by doctors coat (95.5 %) and syringe (25.5 %). Among the 76 students with prior medical training (nurse, paramedic) blood pressure measurement was considered to be more important than in the whole cohort, however, 78.1 % thought that urine dipstick is the least important diagnostic test.

**Conclusions:** Weighing the importance of diagnostic procedures should be an integral part of medical education, keeping in mind that auscultation is closely related to the self (and perceived) image of physicians.

*Funding:* Clinical Revenue Support

## TH-PO869

**Developing a New Pediatric CKD Educational Material: The Increasing Kidney Disease Network (IKAN) Transplant Project**
Bessie A. Young,[2] Bonnie K. Harp,[2] Janice Sabin.[1] *[1]Biomedical Informatics and Medical Education, Univ of Washington, Seattle, WA; [2]Nephrology/Dept Medicine, VA Puget Sound, Univ of Washington, Seattle, WA.*

**Background:** Much research has been done to evaluate disparities in transplantation rates for racial/ethnic populations; however, much less research has focused on determining the best methods by which to overcome educational barriers and increase transplantation awareness among pediatric patients and their families within these groups.

**Methods:** We convened a focus group to assess content and design of a new kidney disease education modality in comic book format. Focus group participants (N=6) included researchers, community members (one kidney transplant recipient), and a nephrologist. Participants were African American (50%) and white (50%). Participants' reviewed the culturally tailored comic book for the African American patient population, aimed primarily at adolescents and young adults with CKD and their families, the final version of which will be evaluated in a pilot study using focus groups at Seattle Children's Hospital.

**Results:** The comic book was reviewed for content, reading level, language, whether it is culturally appropriate, age appropriate, for quality of visual presentation, and organization of the information. The focus group concluded that fact checking of dialog in the book for authenticity with a group of African American adolescents is important, medical terms should include a phonetic pronunciation, the comic book should have a glossary, and the book should be divided into chapters. Comments from the group include; "comic book [will be used] as reference material"; "it hit on all four cylinders"; "as a kidney transplant patient…it is good to have it all in one place"; "the underlying message is that transplant is the best option."

**Conclusions:** Culturally tailored and health literacy-appropriate education materials that use innovative delivery of information are an important tool for both adults and pediatric patient populations. These innovative and unique materials will be field tested and finalized for use in future research among pediatric patients and their families with CKD and ESRD.

*Funding:* NIDDK Support, Veterans Affairs Support

## TH-PO870

**A Novel Journal Club Experience during Nephrology Fellowship Training**
Kenar D. Jhaveri, Shailaja Chidella, Hitesh H. Shah. *Nephrology, Hofstra North Shore–LIJ School of Medicine, Great Neck, NY.*

**Background:** Journal Club (JC) is a forum for fellows to present topics of current interest including clinical and cutting edge research. Despite critical review of the published article during JC, questions may remain unanswered. The lead author's perspective during JC might help better understand the article being reviewed. At our institution, we embarked on an innovative journal club format that included a discussion with the author of the JC article.

**Methods:** At our institution, nephrology JC is a biweekly conference prepared by fellows covering research papers in nephrology. Following the JC article presentation(introduction and presentation for 45 min), the last 15 minutes are traditionally devoted to critically discuss the manuscript. During the 2012-2013 academic year, we introduced a novel JC experience for our group. Many leading or corresponding authors of JC papers discussed were invited few weeks prior to the JC session by our fellows to participate in a 15 minutes teleconference with all fellows and faculty members. An anonymous online survey was created to evaluate this novel JC format. The survey was subsequently distributed to all fellows and participating faculty members in May 2013.

**Results:** So far, 7 out of 8 fellows and 5 faculty members responded to our survey. On a 5-point scale (where 1 being least and 5 being most), respondents rated this experience innovative (4.58), thought provoking (4.17) and relevant (4.0). 75% felt that this format enhanced their understanding and knowledge of the article being reviewed at JC. Two-thirds (66.7%) felt that the direct discussion with the author enhanced their critical thinking skills. All enjoyed participating in this novel JC format and nearly two-thirds responded that this format would increase their JC participation. When asked to rate this format as compared to the traditional JC, the average rating was 4.3 on a 5-point scale (1 being least valuable, 5 being most). All respondents wanted to see such "author participated" JC sessions in the future.

**Conclusions:** This novel "author participated" JC sessions enhanced our JC experience. Based on our experience, we encourage all medical educators to consider this format of JC.

## TH-PO871

**Do Medical Trainees Receive Adequate Training in Understanding, Managing and Treating Chronic Kidney Disease and Its Complications**
Mansoor N. Ali. *Renal Medicine, York Teaching Hospitals Foundation NHS Trust, York, Yorkshire, United Kingdom.*

**Background:** The objective of this survey was to gauge the understanding and the level of competence amongst junior trainees; in treating and managing Chronic Kidney disease (CKD) and its complications. This survey was generated as a result of our previous work in understanding the training needs amongst trainees in understanding Acute Kidney Injury (AKI).

**Methods:** This survey was conducted between December 2012 to March 2013 at York Teaching Hospitals. It was conducted as part of the teaching session on CKD for the trainees with the target group being the Core medical trainees on a medical rotation. The questionnaires were handed out before the lecture and the audience were asked to fill it in during or after the session. Total responses were based on the total number of attendances and were thirty eight in total. The Questionnaire revealed grade and place of work whether acute or rehab setting including subspecialties such as Renal/Gastro/Haematology.

**Results:** The first question asked about the definition of CKD and none were able to answer correctly (CKD classification was accepted). Only 20 had come up with their own definitions of CKD and others left it blank. 34 trainees responded by saying that they have managed more than 16 patients with CKD whereas 4 responses were for < 8-16. On a scale between 1 and 5 where 1 being not confident and 5 being confident/competent no one replied that they were competent (5) to manage CKD; 8 people replied saying they felt confident at (4) as they had managed to do renal rotations where as 30 people thought that they are confident to manage at level (3).

**Conclusions:** The survey highlighted the fact that most trainees felt that teaching on CKD were inadequate at both undergraduate and postgraduate levels. There was evidence of the lack of understanding of the complications of CKD and its management. There also seemed to be a consensus that most junior trainees would like to know how to treat and manage CKD rather than leaving it to the nephrologists. Many have responded by agreeing to do a renal placement and some who have already done one found it very useful.

## TH-PO872

**Development and Validation of a Shared Decision Making Tool for Mortality on Dialysis Compared to Kidney Transplantation: iChoose Kidney**
Rachel E. Patzer,[1] Mohua Basu,[1] William M. McClellan,[2] David H. Howard,[3] Yijian Huang,[3] Kimberly Arriola.[3] *[1]Emory Transplant Center, Atlanta, GA; [2]Dept of Medicine, Emory Univ, Atlanta, GA; [3]Rollins School of Public Health, Atlanta, GA.*

**Background:** End Stage Renal Disease (ESRD) patients have two primary treatment choices: dialysis or kidney transplant (KTx). Predictive models to compare individualized risks of mortality of dialysis or KTx have not yet been developed to help patients and providers make informed decisions about treatment choices.

**Methods:** We examined mortality among a cohort of 721,571 ESRD patients 2005-2001 in the United States Renal Data System (USRDS) surveillance registry who received 1) dialysis vs. 2) KTx. Multivariable logistic regression was used to derive separate risk models for patients on dialysis and for patients who received a living or deceased donor transplant. Data were divided into 50% derivation and 50% validation datasets. Models were evaluated using concordance statistics (c-statistics) and measures for model discrimination and calibration for three-year outcomes.

**Results:** Among dialysis patients (n=663,900), 47.4% of patients died vs. 5.9% of transplant recipients (n=57,671) over the 7-year study period (p<0.0001). Factors significantly associated with a higher odds of death for dialysis and KTx patients included older age; minority race/ethnicity; longer dialysis vintage; non-private insurance; delayed access to pre-ESRD nephrology care; no erythropoietin use prior to dialysis; smoking and drug use; and comorbidities, including cardiovascular disease and congestive heart failure. The discriminatory ability of the models for 1-year and 3-year mortality was moderately high (c-statistics ranging from 0.69-0.72). We used these validated, risk prediction models to develop an electronic, user-friendly, mobile application (iPad) tool called iChoose Kidney.

**Conclusions:** Risk prediction estimates for mortality on dialysis compared to KTx may help assist in identifying patients at high risk for poor outcomes, communicating knowledge about risks of mortality to patients and providers, and encouraging lifestyle or behavioral changes to promote health.

*Funding:* Other NIH Support - National Center for Advancing Translational Sciences (NCATS)

## TH-PO873

**Towards Harmonizing Renal Guidelines: An International Survey of Major Guideline Bodies**
Maria C. Haller,[1] Sabine N. Van der Veer,[1] Evi V. Nagler,[1] Raymond C. Vanholder,[1] Jonathan C. Craig,[2] Wim Van Biesen.[1] *[1]European Renal Best Practice, Ghent Univ Hospital, Ghent, Belgium; [2]KHA-CARI, School of Public Health, Univ of Sydney, Australia.*

**Background:** Several organizations produce renal guidelines, resulting in duplication of effort while many topics remain uncovered. A collaborative work plan based on common, Institute of Medicine-endorsed methods would improve efficiency and impact, and reduce inconsistency. ERBP and KHA-CARI aimed to identify organizational and methodological differences between major renal guideline bodies that might hamper their collaboration.

**Methods:** We invited the chairs of KHA-CARI, CSN, ERBP, KDIGO, KDOQI, SLANH and UK-RA to complete an electronic 62-item survey, based on Institute of Medicine standards.

**Results:** All 7 groups completed the survey. Funding arises from their governing bodies (N=5) or directly from industry (N=2). In no case do funders have any influence on topic selection or guideline content. The available budget to develop one guideline varies from $2,000 to $ 500,000. 3 groups seek patient perspectives and 4 consider health economics. All groups provide training for guideline development groups, 6 communicate their methods to the public. All groups try to avoid overlap by considering guidelines already planned or published by others. 5 conduct systematic searches for evidence, 2 include detailed critical appraisal and all use the GRADE framework. 5 groups organize public review of the guideline draft. All update their guidelines in case of new evidence, and when a pre-set time frame has passed (N=3). Commentaries or position statements on guidelines published by others are produced by 5, with the ADAPTE framework (N=1) and the AGREE II (N=2) used by some.

**Conclusions:** Overall there was considerable commonality in methods and approaches but important differences remain. Increased collaboration will require substantial consensus building activities. The financial and in-kind human resource costs of guideline production are high, and to maximize impact and develop a sustainable work plan, a collaborative approach is now required. This study is a promising first step towards harmonization of guideline development in renal medicine.

## TH-PO874

**Patient and Staff Perspectives of Intradialytic Cycling**
Amy L. Clarke,[1] Hannah M.l. Young,[1] Maurice Dungey,[1] Nicky Hudson,[2] James O. Burton,[1] Alice C. Smith.[1] *[1]Leicester Kidney Exercise Team, Univ Hospitals of Leicester, United Kingdom; [2]School of Applied Social Sciences, De Montfort Univ, Leicester, United Kingdom.*

**Background:** Evidence increasingly shows that exercise benefits haemodialysis (HD) patients, but lifestyle restrictions limit participation. Intradialytic cycling (IDC) is an attractive option but setting up and sustaining a programme can be challenging, partly due to patient and staff resistance. Addressing the user's point of view is key to successful implementation of new initiatives. This study explored patient and staff perspectives prior to the introduction of a new IDC programme, and again when the programme was established.

**Methods:** Ahead of IDC initiation, focus groups were conducted with a purposive sample of 24 HD patients and 9 staff. 6 months after IDC introduction, semi-structured interviews were held with 11 patients and 8 staff. Audiofiles were transcribed verbatim, translated where necessary, and subjected to qualitative framework analysis.

**Results:** Prior to IDC, patients anticipated that the positive experiences of peers would encourage them to participate, whilst post-IDC they were motivated by their own perceived improvements. Staff initially felt making IDC part of the existing routine of the unit would facilitate implementation and later commented that a collaborative approach helped to sustain the programme. Both staff and patients wanted education on the benefits and principles of exercise. Anticipated patient barriers were initially concerns regarding safety and the negative effects of fatigue and depression. None of these concerns proved influential for patients after implementation. Both patients and staff were concerned about IDC adding to the staff workload. This continued to be an issue for both groups post implementation and proved to be the most influential barrier.

**Conclusions:** This study provides a unique perspective into HD patient and staff views on initiating and sustaining an IDC programme. Education is the key element for initial patient and staff engagement and for patients this education is best facilitated through peer interaction. Long term sustainability requires IDC to become a routine part of the work plan of HD unit staff.

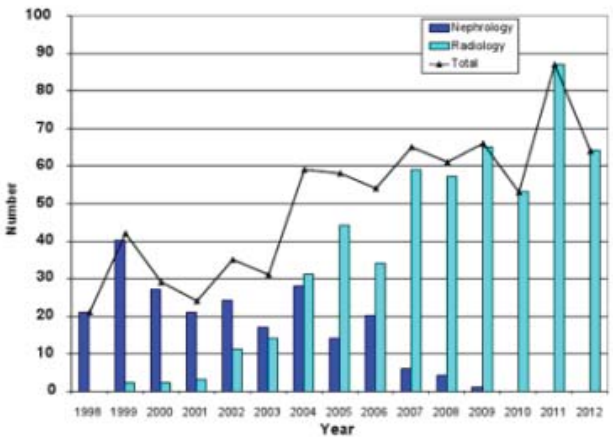
## TH-PO875

**Comparison of Glomerular Yield and Complication Rates between Nephrology Performed and Radiology Performed Percutaneous Renal Biopsy**
Paul D. Sanders,[1] Klaudia Barbara Jumaa,[3] David C. Holland,[2] Ben Mussari.[1] *[1]Dept of Radiology, Queens Univ, Kingston, Canada; [2]Dept of Nephrology, Queens Univ, Kingston, Canada; [3]Dept of Medicine, Queens Univ, Kingston, Canada.*

**Background:** Percutaneous renal biopsy (PRB) is being more commonly performed by Interventional Radiology (IVR) causing concern over lost skills for Nephrology Fellows, safety and post-procedural care. Our study compares glomerular yield and complication rates between IVR and Nephrology following PRB.

**Methods:** A retrospective chart review was performed. Patient charts were analyzed for total glomerular yield, number of passes taken per biopsy and post-biopsy complications that required blood transfusion, endovascular or surgical intervention.

**Results:**



18% of biopsies performed by Nephrology yielded less than 10 total glomeruli vs 9% for IVR (p < 0.001). Complications requiring blood transfusion occurred in 3.1% of Nephrology biopsies vs 1.9% for IVR (p=0.298). Endovascular intervention was required in 1.3% of the Nephrology group vs 0.8% for IVR (p=0.431). No patient required surgical intervention.

| | Total | Nephrology | Radiology | |
|---|---|---|---|---|
| | 749 | n = 223 | n = 526 | p |
| Total Yield (mean # of glomeruli ± SD) | 23.9 ± 13.3 | 20.1 ± 11.9 | 25.6 ± 13.5 | <0.001 |
| Yield per Pass ± SD | 8.6 ± 5.2 | 9.7 ± 6.8 | 8.2 ± 4.3 | <0.001 |
| # with total yield <10 glomeruli (%) | 84 (11.2%) | 40 (17.9%) | 44 (8.6%) | <0.001 |
| Blood Transfusion (%) | 17 (2.3%) | 7 (3.1%) | 10 (1.9%) | 0.298 |
| Endovascular Intervention (%) | 7 (0.9%) | 3 (1.3%) | 4 (0.8%) | 0.431 |

**Conclusions:** Our results show that there is no significant difference in severe complication rates between IVR vs Nephrology performed PRB; however, there were fewer biopsies containing less than 10 total glomeruli in the IVR group.

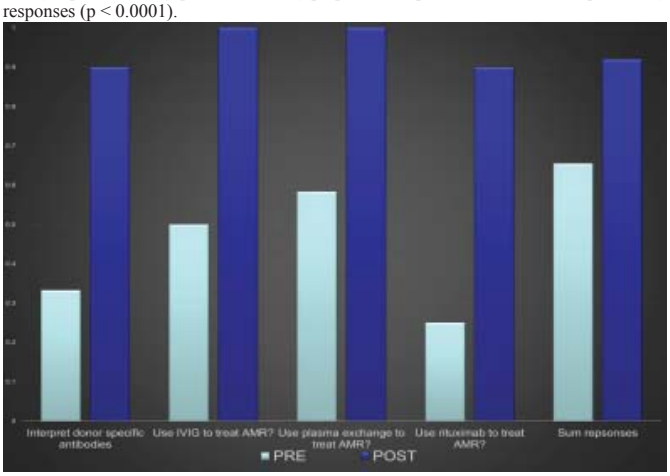
**TH-PO876**

**Improving Self-Reported Provider Preparation to Evaluate and Treat Antibody-Mediated Renal Transplant Rejection** Dustin J. Little,[1] Austin Parker,[3] Mark D. Poirier,[2] Amy J. Zwettler,[1] David J. Yoo,[1] Bruce Reinmuth,[1] Kevin C. Abbott,[1] Christina M. Yuan,[1] Lisa K. Prince.[1] *[1]Walter Reed National Military Medical Center; [2]San Antonio Military Medical Center; [3]Naval Medical Center Portsmouth.*

**Background:** Antibody-mediated kidney transplant rejection (AMR) is a major cause of allograft loss. We designed and implemented a performance improvement project aimed at optimizing the evaluation and treatment of AMR at our institution.

**Methods:** Medical literature on AMR was reviewed, as were AMR cases treated at our institution from 2006-2011. An electronic survey was administered to the nephrology staff and fellows, which included ten questions assessing provider preparation to evaluate and treat AMR. Lectures were given on the evaluation and treatment of AMR and findings of review of institutional AMR cases. An educational electronic "AMR Toolkit" was created, and an identical post-survey was administered 4 months following the pre-survey. Fisher exact test was used to compare pre and post-survey responses, with a p value of 0.05 used to determine significance.

**Results:** Twenty-one cases of AMR were identified in 16 patients. No patients died and two experienced graft loss. Pre and post-survey response rates were 12/13 and 10/12, respectively. Significantly more respondents reported feeling quite or extremely prepared on the post-survey for 5 of the 10 items. Ninety-one of 99 total responses on the post-survey reported feeling quite or extremely prepared, compared to 78/119 of total pre-survey responses ($p < 0.0001$).



**Conclusions:** AMR presents a dilemma, in part because of limited data regarding treatment options. We implemented a comprehensive education strategy, following which providers reported feeling better prepared to evaluate and treat AMR. Our results suggest that this model should be considered for other challenging clinical problems.

**TH-PO877**

**A Pilot Trial of a Computerized Renal Template Note to Improve Resident Knowledge and Documentation of Kidney Disease** Shayan Shirazian, Ray Wang, Dennis Moledina, Vladimir Liberman, Joseph H. Zeidan, Joseph Mattana. *Medicine, Winthrop Univ Hospital, Mineola, NY.*

**Background:** Kidney disease is under-documented in physician notes suggesting under-recognition, especially at earlier stages of chronic kidney disease (CKD). The objective of this study was to determine whether a computerized renal template note (RTN) with clinical documentation support (CDS) improves resident knowledge and documentation of kidney disease.

**Methods:** In this prospective IRB-approved study, first year residents (PGY1s) were encouraged to use the RTN with CDS for documentation over a 1 month period. The RTN included an option for classification of patients into CKD and acute kidney injury (AKI) categories. The CDS consisted of a link to standard classifications of CKD and AKI. Knowledge of CKD and AKI was tested with a quiz given before and after implementation of the RTN. Study investigators determined whether CKD or AKI was appropriately documented in 100 RTNs and 100 historical internal medicine progress notes of patients with known AKI or CKD from the same time period in the previous year. RTN and historical notes were compared using Fischer's exact test. Quiz scores before and after RTN utilization were compared using paired t-testing.

**Results:** 18 PGY1s completed all study procedures. Their average age was 28, 12 were male, and 7 had taken a prior nephrology elective. At the end of the study, approximately 2,436 inpatient encounters were documented using the RTN. Accurate staging of CKD-3 was significantly improved following implementation of the RTN when compared to historical notes (9/46 vs. 0/29, p=0.01), whereas accurate staging did not improve for CKD-4, CKD-5 or AKI. End of study quiz scores were higher than pre-study scores, however this difference did not reach statistical significance (29.6% vs. 20.6%, p=0.13).

**Conclusions:** A computerized RTN with CDS significantly improved documentation of stage 3 CKD though without correspondingly increased knowledge. Given these findings and the opportunities provided by increasing electronic health record use, further studies of the use of computerized RTN with CDS to improve CKD recognition and staging may be warranted.

**TH-PO878**

**Stress and Burnout among Hemodialysis Nurses: A Single Center Survey Study** Ayman Karkar, Betty Mandin, Mohammed Abdelrahman. *Kanoo Kidney Center, Dammam Medical Complex, Dammam, Saudi Arabia.*

**Background:** Hemodialysis (HD) nurses are prone to specific types of stress and burnout, which are capable of having a detrimental impact on organizational productivity, and pose a serious health and safety hazards on the job. We aimed in this study to determine the type and level of stress and the amount of burnout among our HD nurses, evaluate the coping skills, and the impact of stress on their work performance.

**Methods:** The study was conducted using modified stress and burnout questionnaires. The questionnaires consisted of stress and burnout scale, outcomes in workplace, and coping skills. A descriptive correlational design was used to determine if there was a relationship between stress and burnout. There were 93 female dialysis nurses (19 national and 74 expatriate) who participated in this prospective study. Their years of employment and practice varied between 1 to 26 years in the same HD unit. Pearson's product-moment correlation was applied to test the correlation between stress and burnout.

**Results:** Our results show that most nurses (79% national and 68% expatriate) experienced a mild level of stress (42%) and moderate level of burnout (38%), respectively. The most common stressor among national nurses was technological breakdowns of machines (15.9%) and job insecurity (16.9%) among expatriates. The majority of national nurses (21%) coped with by increased sick leaves, whereas majority (25%) of expatriates responded by becoming easily frustrated. The most utilized coping skill among both groups was the relaxation methods (20.8% versus 24.9%) and the least utilized was denial (3.9% versus 0.5%), respectively. There was no correlation between stress/burnout and duration of employment.

**Conclusions:** A dialysis nurse who delivers HD treatment to end-stage renal failure patients with complex social, emotional, psychological and physical needs must have a positive emotional well-being in order to be positively reflected on the quality of care delivered. The support of hospital and nurse managers can provide a healthy atmosphere with an almost stress free environment that would be positively reflected on clinical performance, quality care, productivity and patient and staff safety.

**TH-PO879**

**Raising Public Awareness of Chronic Kidney Disease through the Kidney Disease Screening and Awareness Program (KDSAP)** Laura C. Polding,[1] Andrew J. Pan,[1] Ryan Lindeborg,[1] Jake Cohen,[2] Paul Kim,[2] Michael Ho-Young Ahn,[1] Manjinder Singh Kandola,[1] Tzongshi Lu,[3] Kenneth Lim,[3] Jennie Kuo,[3] Li-Li Hsiao.[3] *[1]Harvard College; [2]Brookline High School; [3]Renal Div, Brigham and Women's Hospital, Boston, MA.*

**Background:** KDSAP has two main objectives: 1) increasing public awareness and early detection of chronic kidney disease (CKD) in the community and 2) student career development. Here, we describe an initiative called the Boston Kidney Health Series (BKHS) as part of KDSAP's community outreach efforts. BKHS is an entirely student-run, day-long program that aims to provide free public education on a range of topics surrounding CKD.

**Methods:** KDSAP students developed a program that contained CKD-related topics with speakers from multidisciplinary health care professions involved in the care of kidney patients, including nephrologists, a renal dietician, a social worker, and a patient. Students designed flyers, compiled a phone directory listing local community organizations, and solicited their support to promote this free event. A survey was then conducted to evaluate the program.

**Results:** BKHS's established directory contains over 100 greater Boston community centers and organizations, including libraries, churches, YMCA, health organizations, and social media. Attendees included CKD patients, kidney transplant recipients and donors, caretakers, family members, and friends from diverse communities around Boston. Survey feedback was highly positive, with 73% and 60% of surveyed participants rating the event usefulness and likelihood of future attendance, respectively, a 5 on a 5-point Likert scale. Furthermore, student volunteers reported that BKHS increased their exposure to and interest in nephrology.

**Conclusions:** KDSAP's BKHS is an effective model to raise CKD awareness. It is unique in including topics and speakers from multidisciplinary health care professions and being entirely student-run. Organizing BKHS provides KDSAP members valuable opportunities for career development, leadership and mentorship. Under the supervision of nephrologists, BKHS can serve as a model to both raise public awareness of CKD and cultivate interest in nephrology among undergraduate students.

## TH-PO880

**Nephrology Blogosphere: An Analysis of Productivity, Longevity, and Consistency** Joel Topf. *Medicine, St. John Hospital and Medical Center, Detroit, MI.*

**Background:** Blogs are web sites with multiple discrete chronologic entries (typically displayed with the most recent at the top and older entries displayed below). There are numerous inexpensive and easy to use tools that allow blogs to be published with little technical friction. There are dozens of blogs that focus on nephrology and nephrology education; while most are still producing content some have ceased publishing. Little is known about the size, productivity, and lifespan of nephrology focused blogs.

**Methods:** Every nephrology blog written in English was assessed for productivity, longevity and inconsistency. Productivity was measured by the number of posts per month. Longevity was measured by duration of publication from first post to either the final post or through May 2013 for active blogs. Inconsistency was defined as the number of months without any posts.

**Results:** From March 2005 through May 2013 we found 30 nephrology blogs that published 10,198 posts. Twenty blogs were still publishing as of May 2013. Mean productivity was 339.9 (95% CI 175.2-504.7) posts per blog or 9.0 posts per month (95% CI 5.7-12.4). Longevity ranged from 1 to 73 months with a mean duration of 31.2 months (95% CI 24.1-38.3). Inconsistency was not common, with a mean of 4.6 months without posts per blog (95% CI 1.8-7.5). 11 blogs never missed a month, and 4 only missed 1 month.

Regression versus time show that most blogs lose productivity over time. Of the 25 blogs with at least 6 months of publication, 15 (60%) had a decreasing productivity over time ($p<0.05$) versus only 1 (4%) with a increasing productivity, 9 (36%) showed no association between time and productivity ($p>0.05$). Despite decreasing productivity in most individual blogs, the entire nephrology blogosphere showed a significant increase in the number of posts per month, R^2 0.38 $p<0.001$, slope 1.17.

There was no association between inconsistency and termination of the blog (R=0.18, p-0.35).

**Conclusions:** Blogging is a new means for distributing nephrology education. The number of blogs is increasing. Most blogs have decreased productivity over time however the nephrology blogosphere in total is growing both in number of voices and monthly posts.

## TH-PO881

**Conditional Inactivation of Exocyst Sec10 in Mouse Kidney Epithelium Causes Primary Cilia Defects and Kidney Cysts** Noemi Polgar,[1] Amanda J. Lee,[1] Vanessa H. Lui,[1] Xiaofeng Zuo,[2] Joshua H. Lipschutz,[2] Ben Fogelgren.[1] *[1]Anatomy, Biochemistry, and Physiology, Univ of Hawaii; [2]Medicine, Univ of Pennsylvania.*

**Background:** The pathogenesis of polycystic kidney disease (PKD) is dependent on disruptions in primary cilia function in renal epithelial cells. Despite intense study, it remains poorly understood how proteins are targeted and delivered to cilia.

**Methods:** In cultured renal epithelial cells, we have previously shown that the eight-protein exocyst complex regulates the length and signaling of the primary cilia. Using the Cre-Lox system, we have generated a novel transgenic mouse allowing tissue-specific deletion of the Sec10 gene, a central component of the exocyst complex.

**Results:** To investigate the role of Sec10 and the exocyst in renal development and primary cilia signaling, we crossed this floxed-Sec10 strain with the KspCadherin-Cre mouse strain to inactivate Sec10 in ureteric bud derived epithelium. Most mice died hours after birth due to upper urinary tract obstructions. However, mice that escaped urinary obstruction and hydronephrosis displayed numerous renal cysts with defects in primary cilia number and length in Cre-expressing tubules.

**Conclusions:** This is the first *in vivo* evidence of the exocyst regulating cilia assembly and trafficking in mammalian development, and the first conditional allele for any exocyst component. Given the known biochemical and genetic interactions between the exocyst and other ciliary proteins, it is likely that the exocyst is an important mechanism by which cells regulate ciliary trafficking.

## TH-PO882

**Nuclear Distribution C Homolog Regulates Mitotic Spindle Orientation and Tubulogenesis** Maoqing Wu,[1] JingJing Zhang,[1] Wassim El-Jouni,[1] Rebecca Powell,[2] Tomoko Obara,[2] Faran E. Ghumman,[1] Maria Rasmussen,[1] Xuefeng Su,[1] Shixuan Wang,[1] Jagesh V. Shah,[1,4] Li-Yuan Yu-Lee,[3] Jing Zhou.[1] *[1]Harvard Center for Polycystic Kidney Disease Research and Renal Div, Dept of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Dept of Cell Biology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK; [3]Dept of Medicine, Baylor College of Medicine, Houston, TX; [4]Dept of Systems Biology, Harvard Medical School, Boston, MA.*

**Background:** Polycystic kidney disease (PKD) is a common cause of renal failure. Misoriented cell division and dysregulated ciliogenesis have been observed in both autosomal dominant and recessive forms of PKD. To understand the cystogenic pathways, we searched for binding partners of PKD proteins.

**Methods:** Mass spectrometry analysis was used to identify proteins co-immunoprecipitated with a PKD protein in kidney tubular epithelial cells. Small hairpin-mediated mRNA depletion, three-dimensional tubulogenesis assay in inner medullary collecting duct (IMCD) cells, and anti-sense morpholino (MO) gene knockdown in zebrafish were used as functional assays.

**Results:** Mass spectrometry analyses identified nuclear distribution C homolog (NudC), a microtubule-associated protein necessary for dynein-mediated nuclear migration in Aspergillus nudulans. NudC is expressed in various phases of mitotic kidney epithelial cells. NudC depletion leads to multiple mitotic defects and misoriented mitotic spindle in kidney cells. In non-mitotic cultured kidney tubular cells and in postnatal kidneys, NudC is localized to the primary cilium. NudC depletion leads to elongated cilia after 48hr serum withdrawal in interphase cells, and exclusive cyst formation in a three-dimensional culture system. Knockdown of nudc in zebrafish resulted pronephric cyst, body curvature, hydrocephalus and pericardial edema, which are typically seen in other cilia mutants.

**Conclusions:** Our work identifies NudC as a novel regulator of mitotic spindle orientation, ciliogenesis, and tubulogenesis. We propose that NudC is a novel candidate for ciliopathy.

*Funding:* NIDDK Support, Private Foundation Support

## TH-PO883

**Nephronophthisis Centrosomal Protein *CEP164* Regulates Cell Cycle Progression, Apoptosis, and Epithelial-to-Mesenchymal Transition** Gisela G. Slaats,[1] Amiya K. Ghosh,[4] Lucas Falke,[2] Stephanie Le Corre,[5] Indra Shaltiel,[3] Marianne C. Verhaar,[1] Roel Goldschmeding,[2] Tri Q. Nguyen,[2] Iain A. Drummond,[5] Friedhelm Hildebrandt,[4] Rachel H. Giles.[1] *[1]Nephrology and Hypertension, Univ Medical Center, Utrecht, Netherlands; [2]Pathology, Univ Medical Center, Utrecht, Netherlands; [3]Medical Oncology, Univ Medical Center, Utrecht, Netherlands; [4]Internal Medicine, Univ of Michigan, Ann Arbor, MI; [5]Genetics, Harvard Medical School, Charlestown, MA.*

**Background:** We recently reported that mutations in centrosomal protein 164 (*CEP164)* in nephronophthisis (NPHP) patients affect cilia and the DNA damage response. Here, we address the role of *CEP164* in NPHP and concomitant fibrosis.

**Results:** Live cell imaging of RPE FUCCI (fluorescent, ubiquitination-based cell cycle indicator) cells after siRNA knockdown of *CEP164* reveals a quicker cell cycle than control cells despite a longer S phase. FACS experiments with renal IMCD3 cells confirm that *Cep164* siRNA knockdown cells accumulate in S-phase, but we demonstrate that this can be rescued by human WT *CEP164* but not disease-associated mutants. siRNA of *CEP164* causes a proliferation defect over time, as measured by xCELLigence, CyQuant as well as PrestoBlue cell assays. We hypothesized that the discrepancy between accelerated cell cycle and inhibited overall proliferation could be explained by induction of apoptosis or epithelial-to-mesenchymal transition (EMT). Indeed, reduction of *CEP164* levels induces apoptosis in immunofluorescence, RT-QPCR and FACS experiments, and this phenomenon can be partially rescued by WT *CEP164*. Zebrafish injected with *cep164* morpholinos show developmental abnormalities and p53-independent apoptosis *in vivo*. Furthermore, knockdown of *Cep164* or overexpression of dominant negative mutant allele *CEP164 Q525X* induced EMT as we demonstrated by RT-QPCR, migration assay and western blot. Accordingly fibrosis mRNA markers are upregulated after *Cep164* knockdown.

**Conclusions:** We reveal a novel role for *CEP164* in NPHP pathogenesis, in which mutations causing ciliary defects are coupled with apoptosis and EMT.

*Funding:* Government Support - Non-U.S.

## TH-PO884

**RUVBL1 Is Part of Disease-Associated Protein Complexes at the Ciliary Base and Essential for Tubular Architecture *In Vivo*** Max C. Liebau,[1,2] Claudia Dafinger,[1] Ingolf Schmedding,[1] Benjamin Schairer,[1] Sandra Habbig,[1,2] Thomas Wunderlich,[3] Oliver Rinner,[4] Thomas Benzing,[1] Bernhard Schermer.[1] *[1]Dept of Internal Medicine 2, Univ Hospital of Cologne, Cologne, Germany; [2]Dept of Pediatrics, Univ Hospital of Cologne, Cologne, Germany; [3]Institue for Genetics, Univ of Cologne, Cologne, Germany; [4]Biognosys AG, Schlieren, Switzerland.*

**Background:** Cystic kidney diseases including Nephronophthisis (NPH) and ARPKD are common genetic causes of end stage renal failure during childhood and adolescence. However, the cellular protein functions of the affected gene products remain poorly understood. Recent work has linked ciliopathies to DNA damage response signaling.

**Methods:** Using immunoprecipitation-based mass spectrometry approaches we recently identified candidates for components of the Nephrocystin-1 and the Fibrocystin protein complex. Various candidates were followed up by independent methods in vitro and *in vivo.*

**Results:** Our candidates include an AAA ATPase with known roles in the regulation of cilia-associated signalling pathways and DNA damage response signalling, called RUVBL1. The interaction of RUVBL1 with various ciliary disease-associated proteins was confirmed by independent measures. In addition to other subcellular compartments, RUVBL1 localizes to the ciliary base during interphase. A newly generated tubule-specific Ruvbl1-knockout mouse shows high neonatal mortality and cystic kidney disease. Work on the cellular mechanisms resulting in this phenotype is ongoing.

**Conclusions:** We identified a member of the Tip60 DNA damage signalling complex as a cysto-protein at the ciliary base and as a component of disease-associated protein complexes. The link between ciliary signaling and DNA damage response signalling requires further investigation.

*Funding:* Government Support - Non-U.S.

## TH-PO885

**Modified Molecular Inversion Probe Analysis in Patients with Nephronophthisis-Related Ciliopathies** Markus Schueler,[1] Jan Halbritter,[1] Dan Doherty,[2] Ian Phelps,[2] Daniela A. Braun,[1] Jonathan Porath,[1] Heon Yung Gee,[1] Neveen Soliman,[3] Marwa Mohamed Nabhan,[3] Jay Shendure,[4] Brian J. O'Roak,[4] Edgar Otto,[5] Friedhelm Hildebrandt.[1,6] *[1]Dept of Medicine, Boston Children's Hospital, Boston, MA; [2]Dept of Pediatrics, Univ of Washington, Seattle, WA; [3]Egyptian Group for Orphan Renal Diseases, EGORD, Cairo, Egypt; [4]Dept of Genome Sciences, Univ of Washington, Seattle, WA; [5]Dept of Pediatrics, Univ of Michigan, Ann Arbor, MI; [6]Howard Hughes Medical Institute, Chevy Chase, MD.*

**Background:** Nephronophthisis is a recessive cystic kidney disease that progresses to terminal renal failure during the first three decades of life. In a cohort of 384 children diagnosed with a nephronophthisis-related ciliopathy two different high-throughput mutation analysis methods were used to identify disease-causing mutations within coding regions of 12 established NPHP genes and compared to each other.

**Methods:** Exon targeted mutation analysis was carried out using a modified molecular inversion probe (MIPs) technique. Previously we had performed mutation analysis in the same cohort using PCR-based Access Array microfluidic technology (AAMT) from Fluidigm™ with consecutive next-generation sequencing (NGS). Significant mutations were confirmed by Sanger sequencing and shown to segregate with the affected status.

**Results:** When using the MIP technology 100 pathogenic mutations were found, revealing the molecular cause in 64 out of 384 families (16%) and discovering 20 novel mutations in the genes NPHP1 (3), INVS (2) >NPHP3 (3), IQCB1 (1), CEP290 (3), RPGRIP1L (3), TMEM67 (1) and TTC21B (4). Whereas, when using the Fluidigm™/NGS approach, bioinformatics analysis of the identical cohort yielded only 84 pathogenic mutations in 52 out of 384 families (13.5%) including 21 novel mutations. Interestingly, only in 37 families the disease causing mutations were detected with both methods.

**Conclusions:** We conclude that the combination of two different high-throughput methods (AAMT and MIP) increases the mutation detection sensitivity in cohorts with broadly heterogeneous Mendelian disorders.

## TH-PO886

**Renal Oxylipin Alterations in the pcy Mouse Model of Nephronophthisis and Modulation by Therapeutic Intervention with Dietary Flaxseed Oil Rich in α-Linolenic Acid** Shizuko Nagao,[1] Clara R. Lysecki,[2] Ashleigh Reid,[2] Tamio Yamaguchi,[2] Jessay Gopuran Devassy,[2] Melissa Gabbs,[2] Mai Sasaki,[1] Amir Ravandi,[2] Harold M. Aukema.[2] *[1]Education and Research Center of Animal Models for Human Diseases, Fujita Health Univ, Toyoake, Aichi, Japan; [2]Dept of Human Nutritional Sciences, Univ of Manitoba, Winnipeg, Canada.*

**Background:** Nephronophthisis (NPHP) is a juvenile form of renal cyst disease characterized by cyst enlargement and interstitial fibrosis. It is the most common cause of end stage renal disease in children. Renal cytosolic phospholipase $A_2$ and cyclooxygenase (COX) 1 are elevated in pcy mice, an orthologous model of NPHP, suggesting that oxylipin formation may be altered. COX is elevated in another PKD model, the Han:SPRD-Cy rat, and COX inhibition reduces COX-derived oxylipins and ameliorates disease progression. If oxylipins are similarly altered in pcy mice, there may be potential for treatment. Flax oil contains the n-3 fatty acid α-linolenic acid and thus may alter oxylipin formation. Therefore, in the current study renal oxylipins were determined early in the disease process, and the effect of dietary flax oil on disease progression and oxylipin alterations were examined.

**Methods:** Kidney homogenates from normal and pcy mice at 15, 30, 60 days were used for initial oxylipin analyses by HPLC-tandem mass spectrometry. In a second study, pcy mice were given dietary soy (control) or flax oil for 16 wk from weaning. Kidney sections were stained with Masson's trichrome for fibrosis analysis and kidneys were analyzed for oxylipins.

**Results:** The earliest significant oxylipin differences between normal and diseased kidneys were observed at 30 days, when several COX derived oxylipins were higher. Lipoxygenase oxylipins were not different until 60 days of age, when several were lower in diseased kidneys. Dietary flax oil treatment significantly reduced kidney weight and interstitial fibrosis and ameliorated many of the renal oxylipin alterations.

**Conclusions:** Renal oxylipins are altered in NPHP and dietary flax oil rich in ALA reduced the progression of renal interstitial fibrosis, possibly via amelioration of oxylipin abnormalities.

*Funding:* Government Support - Non-U.S.

## TH-PO887

**Sheep as a Large Animal Model of a Recessive Ciliopathy** Cherie Stayner,[1] May Pilanthananond,[1] Julia A. Horsfield,[1] David M. Markie,[1] John C. McEwan,[3] C. Anthony Poole,[2] Robert J. Walker,[2] Michael R. Eccles.[1] *[1]Pathology, Univ of Otago, Dunedin, New Zealand; [2]Medicine, Univ of Otago, Dunedin, New Zealand; [3]Invermay Research Centre, AgResearch, Mosgiel, New Zealand.*

**Background:** Autosomal recessive polycystic kidney disease (ARPKD) predominately affects infants and young children. Mutations can arise in genes that cause a number of different recessive syndromes, Meckel-Gruber Syndrome (MKS) showing the earliest lethality. We have identified a sheep model of ARPKD with features that resemble MKS. Affected lambs die *in utero*, or in the early neo-natal period, and show extensive cyst formation and fibrosis in the kidney.

**Methods:** Homozygosity mapping was chosen to map candidate disease loci. DNA from affected lambs was analyzed using a single nucleotide polymorphism (SNP) Beadchip. A knockdown model in zebrafish was employed to investigate the pathogenicity of the missense changes identified in the ovine *Mks3* gene. Zebrafish *mks3* was knocked down by morpholino injection of embryos and rescue experiments were performed by co-injection with mRNA for either the wildtype, or mutant, sheep *Mks3*.

**Results:** A candidate region identified on chromosome 9 contained the *Tmem67*/*Mks3* gene, and sequencing revealed two novel single nucleotide sequence variants in exon 20 of *Mks3* in affected sheep. These lead to missense amino acid substitutions (I680N and I686S) in the cilia-located transmembrane receptor protein, meckelin. Modelling of these sequence variants predict that either variant would have a deleterious effect on protein function. Wildtype sheep *Mks3* was able to rescue the embryonic defects caused by knockdown of zebrafish *mks3* expression. Co-injection of an *Mks3* mRNA that contained the two missense changes found in our affected sheep, was not able to rescue these defects.

**Conclusions:** Two amino acid changes in exon 20 of the *Mks3* gene, discovered in sheep with recessive polycystic kidney disease, have been demonstrated as being potentially pathogenic, and are likely to be the cause of the kidney phenotype in these sheep. A large animal model of renal cystic disease can offer important advantages for screening of novel therapeutics for polycystic kidney disease.

*Funding:* Government Support - Non-U.S.

## TH-PO888

**Loss of Function Mutation of FAT1 May Represent a Novel Disease Causing Gene in Nephronophthisis with Nephrotic Syndrome Overlap** Jonathan Porath,[1] Carolin E. Sadowski,[1] Jan Halbritter,[1] Rannar Airik,[1] Daniela A. Braun,[1] Markus Schueler,[1] Heon Yung Gee,[1] Edgar Otto,[2] Friedhelm Hildebrandt.[1,3] *[1]Medicine, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Pediatrics, Univ of Michigan, Ann Arbor, MI; [3]Howard Hughes Medical Institute, Chevy Chase, MD.*

**Background:** Nephronophthisis-related ciliopathies (NPHP-RC) comprise a group of autosomal recessive cystic kidney diseases. As the disease-causing gene has only been identified in 40-60% of individuals with NPHP-RC, we performed whole exome resequencing (WER) to identify novel disease causing genes.

**Methods:** We performed homozygosity mapping as well as WER (NimbleGen SeqCap EZ™ Exome ver2) followed by next generation resequencing (Illumina HiSeq 2000) in a cohort of 84 families with NPHP-RC. We then screened an additional 720 individuals with nephrotic syndrome using array based multiplex PCR (Fluidigm Access Array™) and next generation resequencing (Illumina MiSeq).

**Results:** A homozygous truncation (p.P1032Cfs*11) was identified in the gene FAT1 (FAT atypical cadherin 1) in a consanguineous Turkish family with one affected child. This individual has a complex phenotype including nephrotic range proteinuria, glomerular sclerosis, and histologic features of nephronophthisis leading to end-stage renal disease at the age of 15 years old. There were also extrarenal manifestations of bilateral ptosis, pulmonary artery stenosis, intellectual disability, pachygyria, and dilated Virchow-Robin spaces. We additionally identified a homozygous truncation of unknown significance in the gene PIDD in this individual. In addition, we identified two compound heterozygous FAT1 mutations (p.N2951S and p.E4374K) in a child with congenital nephrotic syndrome and renal histology of diffuse mesangial sclerosis. FAT1 has been shown to play a role in WNT signaling in which defects have previously been shown to be a mechanism for renal disease. The Fat1$^{-/-}$ mouse displays abnormal podocyte foot processes, brain developmental defects, and eye abnormalities.

**Conclusions:** We identified mutations in FAT1 in individuals with an overlapping phenotype of NPHP-RC and nephrotic syndrome.

## TH-PO889

***CCDC41* Is Mutated in Nephronophthisis-Related Ciliopathy** Heon Yung Gee,[1] Jan Halbritter,[1] Jonathan Porath,[1] Daniela A. Braun,[1] Markus Schueler,[1] Edgar Otto,[2] Friedhelm Hildebrandt.[1,3] *[1]Div of Nephology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Dept of Pediatrics, Univ of Michigan, Ann Anbor, MI; [3]Howard Hughes Medical Institute.*

**Background:** Nephronophthisis-related ciliopathies (NPHP-RC) are degenerative recessive diseases that affect, retina, or brain (1). More than 15 genes are associated with NHPH-RC, accounting for about 40% of all cases (1). About 60% of cases are molecularly unsolved.

**Methods:** To find additional single-gene cause of NPHP-RC, we screened a worldwide cohort of over 700 individuals by multiplex PCR followed by barcoding and next-generation resequencing (1).

**Results:** We identified a homozygous frameshift mutation (p.E669Dfs*14) in CCDC41 (coiled-coil domain containing 41) in an affected individual with NPHP, macrocephaly and heart anomalies. CCDC41 is a component of the distal appendages of centrioles and was shown to be required for ciliary vesicle docking to the mother centriole (2). Loss of CCDC41 blocks centriole-to-membrane docking and inhibits ciliogenesis (3).

**Conclusions:** We identified a mutation in CCDC41 as causing NPHP-RC, adding another component of the distal appendages of centrioles as defective in cystic kidney diseases.

**References** 1. Halbritter et. Al., Hum Genet, in press; 2. Tanos et. Al., Genes Dev, 27:163, 2013; 3. Joo et. Al., Proc Natl Acad Sci U S A, 110:5987, 2013.

## TH-PO890

**A Novel *Cep290* Collecting Duct Tubule Cell Line of the Ciliopathy Joubert Syndrome** Ann Marie Hynes,[1] Rachel H. Giles,[2] Lorraine Eley,[1] Colin Miles,[1] John Andrew Sayer.[1] *[1]Institute of Genetic Medicine, Newcastle Univ, Newcastle upon Tyne, United Kingdom; [2]Univ Medical Center Utrecht, Univ Medical Center Utrecht, Utrecht, Netherlands.*

**Background:** Joubert Syndrome related disorders (JSRD)are autosomal recessive ciliopathies characterised by retinal degeneration, cystic kidney disease and cerebellar vermis aplasia. Mutations in CEP290 are the most common cause of JSRD. Here we described the isolation and characterisation of collecting duct cell lines, isolated from kidneys of $Cep290^{LacZ/LacZ}$ mice backcrossed with H-2Kb-tsA58$^{+/-}$ "immorto" mice. These cell lines have been used to investigate ciliary signallin and disease pathogenesis.

**Methods:** *$Cep290^{LacZ/LacZ}$::H-2Kb-tsA58$^{+/-}$* (mutant) and *$Cep290^{+/+}$::H-2Kb-tsA58$^{+/-}$* (wild-type) collecting duct cells were isolated from kidneys of one month old transgenic mice. Kidney samples were digested in 0.1% collagenase type II andenriched on 6 well plates coated with 10 mg/ml Dolichos Biflorus Agglutinin at 33°C. PCR for collecting duct cell markers, western blotting and staining for cilia were used to characterise these cells under a range of conditions.

**Results:** Mutant and wild type collecting duct cells displayed collecting duct morphology and expressed both the mineralocorticoid receptor and the epithelial sodium channel alpha subunit. There was a loss of primary cilia in Cep290 mutant cells compared to wild type cells (5% vs. 55%, $p < 0.0001$). The cilia that were evident in Cep290 mutant cells were also shortened when compared with the wild type cells (mean length 2.4μm vs. 3.5um). Western blotting showed disrupted signalling in mutant cells. 3D culturing of Cep290mutant cells confirmed a loss of primary cilia and disrupted epithelial polarity.

**Conclusions:** The conditionally immortalised wild type and Cep290 mutant collecting duct cells formed epithelial cell layers and expressed collecting duct cell markers. Cep290 mutation leads to either a loss of cilia or shortened cilia compared to wild type controls. Disrupted signalling in Cep290 mutant cells suggests that these cell lines provide a valuable tool for understanding cystic kidney disease and for drug testing.

## TH-PO891

**Tolvaptan Reduces the Mortality and Ameliorates the Progression of PKD in DBA/2:FG-*pcy* Mice** Miki Aihara, Katsuji Hattori, Koji Ohmoto, Hiroshi Mizuguchi, Hiroyuki Fujiki, Makoto Ishikawa, Keisuke Nagano, Yoshitaka Yamamura. *First Institute of New Drug Discovery, Otsuka Pharmaceutical Co.,Ltd., Tokushima, Japan.*

**Background:** Tolvaptan slowed the increase in total kidney volume and the decline in renal function in patients with ADPKD in the TEMPO 3:4 clinical trial. There still remain the questions of whether tolvaptan has a dose-related effect and whether long-term treatment with tolvaptan is effective in delaying the end stage of the disease.

**Methods:** We examined the dose-related effect of tolvaptan by short-term treatment (0.01% to 0.3% via diet; 5 to 15 weeks of age) and the long-term effect of tolvaptan by whole-life treatment at the optimal dose (0.1% via diet; 5 to 29 weeks of age) in DBA/2:FG-*pcy* mice, an animal model of nephronophthisis.

**Results:** By short-term treatment, at 15 weeks of age tolvaptan dose-dependently prevented increases in kidney weight, kidney cyst volume, kidney fibrosis volume, and mitotic index, and also significantly reduced renal cyclic AMP level and ERK activity, suggesting that the mechanism for these effects was antagonism of vasopressin signals. Urinary NGAL level was also suppressed dose-dependently. Based on the overall efficacy profile, the optimal dose was considered to be 0.1% via diet. In the long-treatment study, left kidney volume was monitored by MRI over time, and tolvaptan significantly inhibited the enlargement of left kidney volume by as much as 50% of the control ($p < 0.01$, repeated measures ANOVA) and also significantly inhibited urinary albumin excretion during the experimental period. Additionally, tolvaptan significantly reduced mortality rate to 20% ($p = 0.0418$, log-rank test) versus 60% in control DBA/2:FG-*pcy* mice.

**Conclusions:** These studies showed for the first time that long-term treatment with tolvaptan at the optimal dose was highly effective in inhibiting cystogenesis, preventing deterioration of renal function, and improving mortality in DBA/2:FG-*pcy* mice. Furthermore, these data strongly indicate that vasopressin-mediated cAMP elevation plays a key role in the pathogenesis of PKD and that tolvaptan ameliorates the progression of PKD by V2 receptor antagonism, providing a promising treatment for PKD.

## TH-PO892

**Loss-of-Function Mutations in *SLCO4C1* as a Cause of Hypertension in Chronic Kidney Disease** Daniela A. Braun,[1] Heon Yung Gee,[1] Eikan Mishima,[2] Jan Halbritter,[1] Jonathan Porath,[1] Markus Schueler,[1] Edgar Otto,[3] Takaaki Abe,[2,4] Friedhelm Hildebrandt.[1,5] *[1]Div of Nephrology, Boston Children's Hospital, Boston, MA; [2]Dept of Clinical Biology, Tohoku Univ Graduate School of Medicine, Miyagi, Japan; [3]Dept of Pediatrics, Univ of Michigan, Ann Arbor, MI; [4]Div of Medical Science, Tohoku Univ Graduate School of Biomedical Engineering, Miyagi, Japan; [5]Howard Hughes Medical Institute, Chevy Chase, MD.*

**Background:** Nephronophthisis (NPHP) a recessive cystic kidney disease represents the most frequent genetic cause of kidney failure in the first decades of life. Although in more than 10% of the cases NPHP is associated with extra-renal involvement, hypertension is characteristically absent from individuals with NPHP.

**Methods:** We performed homozygosity mapping and whole exome resequencing (WER) in a consangineous family with two affected children with NPHP and hypertension.

**Results:** By homozygosity mapping and WER we identified a homozygous missense mutation in the gene SLCO4C1 (p.M1-start loss). SLCO4C1 (solute carrier organic anion transporter family member 4C1) is a kidney-specific organic anion transporter that plays a major role in the excretion of uremic toxins and has been implemented in the pathogenesis of hypertension[1]. By IHC we confirm localization of SLCO41 to the basolateral membrane of proximal tubular epithelium. We show in vitro that the observed mutation represents a functional null allele by ablating the translation initiation codon and causes loss of function.

**Conclusions:** In a consangineous family with two affected siblings we identified a homozygous missense mutation in SLCO4C1 as causing hypertension in children with NPHP.[1] Toyohara et al, JASN 20: 2546, 2009.

## TH-PO893

**Dynamics of E-Cadherin Localization and β-Catenin Activation following Unilateral Ureteral Obstruction in Wild Type and Pkhd1$^{del4/del4}$ Kidneys** Rachel Gallagher,[1] Seung H. Lee,[1] Stefan Somlo.[1,2] *[1]Internal Medicine, Yale School of Medicine, New Haven, CT; [2]Genetics, Yale School of Medicine, New Haven, CT.*

**Background:** Studies on *Pkhd1* have primarily focused on its role in autosomal recessive polycystic kidney disease (ARPKD), however its role in renal homeostasis has yet to be addressed. We have previously described that *Pkhd1$^{del4/del4}$* mice had impaired recovery with sustained tubule dilation when subjected to unilateral ureteral obstruction (UUO) (ASN2010, F-PO1765). In this study, we sought to investigate the molecular basis for the poor recovery in *Pkhd1$^{del4/del4}$*kidneys.

**Methods:** *Pkhd1$^{del4/del4}$* mice and littermate controls were subjected to 3 days of UUO followed by recovery at 14 days post injury. Kidneys were analyzed by immunohistochemistry, BATgal reporter activity, and quantitative PCR (qPCR).

**Results:** Immunohistochemical analysis showed that E-cadherin expression was reduced at the lateral membrane and was re-localized to the cilia following 3 days of UUO in both wild type and *Pkhd1$^{del4/del4}$*mice. β-catenin expression was detected in both the cytoplasm and at the lateral membrane after injury and there was no difference between wild type and *Pkhd1$^{del4/del4}$*injured kidneys. The lateral membrane was repopulated with E-cadherin after 14 days repair in the wild type kidneys but not in *Pkhd1$^{del4/del4}$*kidneys in which very little was detected at the lateral membrane. Since loss of E-cadherin has been shown to release β-catenin from the membrane where it can translocate to the nucleus and activate TCF/lef transcription, we examined whether there was β-catenin-dependent transcriptional activation using qPCR and the BATgal reporter mouse. qPCR analysis showed elevated levels of β-catenin transcriptional targets in the *Pkhd1$^{del4/del4}$*injured kidneys, however the reporter studies showed that the transcriptionally active cells were primarily in the fibroblasts and not in the collecting duct cells.

**Conclusions:** The data show abnormal localization of E-cadherin in cilia during UUO injury and the occurrence of sustained β-catenin activity in fibroblasts in *Pkhd1$^{del4/del4}$* kidneys after 14 days of recovery from UUO. Response to injury may be a feature of *Pkhd1* activity in adult kidney homeostasis.

## TH-PO894

**Ectopic Expression of the Human *PKHD1* Gene Product Can Rescue the Cystic Phenotype of *Pkhd1* Knockout Mice** Ao Li,[1,2] Yuan Li,[1,2] Haichao Liu,[1,2] Wei Li,[1,2] Dan Liang,[2] Guanqing Wu.[2] *[1]State Key Laboratory of Molecular Oncology, Cancer Hospital and Institute, Chinese Academy of Medical Sciences, Beijing, China; [2]Depts of Medicine, Vanderbilt Univ, Nashville, TN.*

**Background:** We have recently produced a transgenic mouse in which a human *PKHD1*-full-length ORF cDNA is controlled by a pCAGGS expression vector.

**Methods:** The pCAGGS expression vector has been reported to express the reporter gene at an early stage of embryonic development and possesses ubiquitous expression in all tissues and organs of the mice. Sixty-six offspring from foster mothers were screened by PCR, and transgene founders were detected in five of them. Four founders (tg5, 20, 46 and 63) can go through germline transmission to produce offspring with the transgene. By qPCR testing, tg5 and 20 do not show human *PKHD1* mRNA overexpression in the disease-affected tissues and organs. Southern analyses indicate that there are approximately three copies of the transgene in tg63 (*PKHD1$^{tg63}$*) and two copies in tg46 (*PKHD1$^{tg46}$*) mice. We used *PKHD1$^{tg63}$* mice for our further studies.

**Results:** *PKHD1$^{tg63}$* mice do not show any abnormal phenotypes during mouse development. Using a mating strategy, *PKHD1$^{tg63}$* mice were crossmated with *Pkhd1$^{-/-}$* mice (Kim et al, *JASN* 2008:19;455) to produce *Pkhd1$^{-/-}$:PKHD1$^{tg63}$* mice. Kaplan-Meier analysis illustrated that approximately 25% of *Pkhd1$^{-/-}$:PKHD1$^{tg63}$* mice survive until 6 months, compared with only 18% of *Pkhd1$^{-/-}$* mice, suggesting that human *PKHD1* transgene can rescue partially lethal phenotype in *Pkhd1$^{-/-}$* mice. By pathological analysis, we also found that the *Pkhd1$^{-/-}$:PKHD1$^{tg63}$* mice (n=5) exhibited significantly decreased cystic number and volume in the pancreas, liver and kidneys, compared to *Pkhd1$^{-/-}$* littermates, suggesting that an increased expression level of human *PKHD1* gene product can significantly rescue cystic phenotypes in the mice model of ARPKD. *Pkhd1$^{-/-}$* mice with *PKHD1$^{tg63}$* also exhibitmuch better improved hepatorenal functions than *Pkhd1$^{-/-}$* mice alone.

**Conclusions:** Our results indicate that ectopic expression of the human *PKHD1* gene product can rescue the cystic phenotypes of *Pkhd1* knockout mice, and underlies a therapeutic potential for gene therapy of ARPKD.

*Funding:* NIDDK Support

**TH-PO895**

**Smad3 Phosphorylated at Both Linker and COOH-Terminal Regions in Cyst-Lining Epithelia in cpk Mouse, a Model of ARPKD**
Taketsugu Hama,[1] Koichi Nakanishi,[1] Hironobu Mukaiyama,[1] Hiroko Togawa,[1] Masashi Sato,[1] Yuko Shima,[1] Masayasu Miyajima,[2] Kandai Nozu,[3] Shizuko Nagao,[4] Hisahide Takahashi,[4] Kazumoto Iijima,[3] Norishige Yoshikawa.[1] *[1]Pediatrics, Wakayama Medical Univ, Wakayama, Japan; [2]Laboratory Animal Center, Wakayama Medical Univ, Wakayama, Japan; [3]Pediatrics, Kobe Univ, Kobe, Japan; [4]Education and Research Center of Animal Model for Human Disease, Fujita Health Univ, Aichi, Japan.*

**Background:** Cystic epithelia acquire mesenchymal features in PKD. In the context of this alteration, however, TGF-β/Smad3 pathway remains not to be fully investigated. TGF-β signaling involves Smad3 phosphorylated at linker regions (pSmad3L), COOH terminal regions (pSmad3C) and both (pSmad3L/C). pSmad3L/C has an important role in colorectal cancer. Mesenchymal-phenotype-specific cell response in TGF-β/Smad3 pathway may be involved also in PKD.

**Methods:** We confirmed mesenchymal features and examined Smad3 phosphorylation profile in *cpk*. Kidneys from 5 *cpk* and control mice (each on days 14 and 21) were harvested. Kidney sections were stained with antibodies to mesenchymal markers and domain-specific phospho-Smad3. TGF-β, pSmad3L, pSmad3C, JNK, CDK4 and c-Myc were evaluated by western blotting (WB). Cophosphorylation of pSmad3L/C was assessed by immunoprecipitation (IP) with WB.

**Results:** Vimentin and α-SMA were *de novo* expressed in *cpk*, showing mesenchymal features, while not expressed in controls. pSmad3L was increased in*cpk*, while no significant staining in controls. pSmad3L was predominantly expressed in nuclei of tubular epithelial cells in cysts. On the other hand, pSmad3C was similarly expressed in both *cpk* and controls. There was no difference in TGF-β level. WB showed that pSmad3L, JNK, CDK4 and c-Myc levels in cell nuclei were significantly higher in *cpk*. IP with WB showed that most Smad3 was cophosphorylated (pSmad3L/C) in *cpk*.

**Conclusions:** These findings suggest that upregulating c-Myc through JNK/CDK4-dependent pSmad3L/C pathway in cell nuclei may be a key pathophysiology in *cpk*. In conclusions, qualitative rather than quantitative abnormality of TGF-β/Smad3 pathway seems to involve PKD, and may be a target for a disease-specific intervention.

**TH-PO896**

**Glycogen Synthase Kinase-3 Inactivation Ameliorates Polycystic Kidney Disease in Cys1$^{cpk}$ Mice**
Reena Rao,[1] Erin Suderman,[1] Shixin Tao.[1] *[1]Kidney Institute, Univ of Kansas Medical Center, Kansas City, KS; [2]Kidney Institute, Univ of Kansas Medical Center, Kansas City, KS; [3]Kidney Institute, Univ of Kansas Medical Center, Kansas City, KS.*

**Background:** Polycystic kidney diseases (PKD) are a family of inherited disorders characterized by the formation of multiple fluid filled cysts primarily arising from the vasopressin responsive renal collecting ducts. Vasopressin mediated increase in cAMP is mitogenic in cystic epithelium. The glycogen synthase kinase-3 (GSK3) family of protein kinases, consisting of GSK3α and GSK3β plays a crucial role in multiple cellular signaling pathways. In previous studies we found that GSK3β inactivation reduces vasopressin-mediated renal cAMP generation. Hence, we evaluated the therapeutic potential for GSK3β inactivation as a novel approach to treat PKD.

**Methods:** Renal GSK3β expression and activity were increased in the Cys1$^{cpk}$ murine model of autosomal recessive PKD. To examine the effect of GSK3 inactivation on cyst development and progression, Cys1$^{cpk}$ mice were administered a GSK3 inhibitor, TDZD-8 from postnatal days 3 to 14, or GSK3β was knocked out in renal collecting ducts of Cys1$^{cpk}$ mice.

**Results:** Pharmacological inhibition of GSK3 or gene knockout of GSK3β in renal collecting ducts of Cys1$^{cpk}$ mice significantly diminished development and progression of PKD, indicated by decreased kidney size, cyst area and fibrosis, and improved renal function. GSK3 inactivation also reduced renal cAMP concentrations, proliferation of cyst-lining epithelial cells and proliferation factors, c-myc and cyclin-D1, independent of canonical WNT signaling.

**Conclusions:** We conclude that GSK3β has a significant role in promoting renal cyst growth in response to cAMP and suggest that GSK3 inhibitors may be therapeutically useful to reduce cyst expansion and preserve renal function in PKD.

**TH-PO897**

**Role of the Epithelial $Na^+$ Channels in Development of Autosomal Recessive Polycystic Kidney Disease**
Alexander Staruschenko, Vladislav Levchenko, Daria Ilatovskaya, Oleg Palygin, Tengis S. Pavlov. *Physiology, Medical College of Wisconsin, Milwaukee, WI.*

**Background:** Autosomal recessive polycystic kidney disease (ARPKD) is characterized by the development of renal cysts of tubular epithelial cell origin. Dysfunction and aberrant regulation of the epithelial $Na^+$ channel (ENaC) leads to a spectrum of diseases ranging from hyper- and hypotension associated with improper renal $Na^+$ conservation and wasting, respectively, to cystic fibrosis. Members of the epidermal growth factor (EGF) family have direct actions on $Na^+$ reabsorption in the distal nephron causing long-term reduction of ENaC activity. It has also been reported high EGF concentration in cystic fluid and that EGF receptor (EGFR) is overexpressed and mislocalized to the apical membranes in the cystic epithelia.

**Methods:** Here we tested whether ENaC plays a role in cyst development in PCK rats, an animal model of ARPKD. 4 weeks old PCK rats were treated with selective ENaC inhibitor benzamil (or vehicle) in drinking water *ad libitum* (15 mg/L) for additional 4 or 12 weeks. In the end of experiments, the kidneys were collected to assess cystic area percentage and kidney to total body weight ratio. PCK and Sprague Dawley rats were also used for patch clamp analysis of ENaC activity in isolated cysts and tubules and immunohistochemical assay.

**Results:** 4 and 12 weeks treatment with benzamil given in drinking water exacerbates cyst development compared to vehicle-treated PCK rats. Patch clamp studies of the freshly isolated tissues revealed that ENaC activity in the cystic epithelia was significantly lower than in the non-cystic cortical collecting ducts of the PCK or Sprague-Dawley rats. Immunohistochemical analysis confirms that β-ENaC expression is decreased compared to the non-cystic cortical collecting ducts within PCK rat kidneys.

**Conclusions:** We conclude that abnormal EGF signaling leads to inappropriately low ENaC activity which contributes to cyst formation in PCK rats. Thus, the disruption of the EGF-EGFR axis reported in ARPKD is linked to suppression of normal $Na^+$ reabsorption, fluid accumulation in cysts and further progress of this kidney disease.

**TH-PO898**

**ADAM17 Regulates Mitochondrial Bioenergetics in Polycystic Kidney Disease (PKD)**
Monika Gooz,[1] Eduardo Maldonado,[1] Yujing Dang,[1] May Y. Amria,[1] Hanna E. Abboud,[2] John Lemasters,[1] P. Darwin Bell.[1] *[1]Medical Univ of South Carolina, Charleston, SC; [2]Univ of Texas Health Science Center, San Antonio, TX.*

**Background:** Previously, we identified ADAM17 as the main sheddase of growth factors in activating the epidermal growth factor receptor and switching on the proliferative extracellular signal-regulated kinase (ERK) signaling pathway in cilia(-) collecting duct cells originating from the Ift88 hypomorph mouse. In this study we investigated the contribution of increased ADAM17 activation to mitochondrial bioenergetics in PKD because recent data showed altered mitochondrial metabolism in several proliferative diseases including cancer.

**Methods:** We assessed ERK activation by Western blotting and ADAM17 activity by a fluorogenic substrate. We determined mitochondrial respiration by a Seahorse XF Analyzer, and measured nicotinamide adenine dinucleotide (NADH) autofluorescence by confocal multiphoton microscopy. Mitochondrial membrane potential ($\Delta\Psi$) was measured by tetramethyl rhodamine methyl ester fluorescence.

**Results:** Expression and enzyme activity of ADAM17, and level of phosphorylated ERK were higher in the highly proliferative cilia(-) cells compared to the less proliferative cilia(+) cells. Cilia(-) cells had also higher basal respiration than cilia(+) cells: 440±31 versus 278±39 pmol $O_2$/min/10,000 cells. Addition of the uncoupler CCCP (5 μM), induced higher maximal respiration in cilia(-) cells compared to cilia(+) cells. NADH level was 36±15% higher in cilia(-) cells compared to cilia(+) cells. Interestingly, $\Delta\Psi$ was 50% lower in cilia(-) cells compared to cilia(+) cells. After chemical inhibition of ADAM17 (10 μM TMI-005, Pfizer) basal respiration (365±9 pmoles/min) and NADH production in cilia(-) cells decreased to the level of cilia(+) cells. Additionally, the ERK inhibitor thiazolidinedione (50 μM) decreased basal mitochondrial respiration to 383±10 pmoles/min in cilia (-) cells.

**Conclusions:** Our data suggest that ADAM17 and ERK activation enhances mitochondrial metabolism in cilia (-) cells compared to cilia (+) cells. Thus, ADAM17-dependent cellular bioenergetics can be an important contributor to the pathobiology of PKD.

**Chronic and Excessive Netrin-1 Expression in Renal Tubular Epithelium Induces Polycystic Kidney Disease in Mice**
Riyaz Mohamed,[1] Calpurnia Jayakumar,[1] Andreas D. Kistler,[2] Ganesan Ramesh.[1] *[1]Vascular Biology Center, Georgia Regents Univ, Augusta, GA; [2]Div of Nephrology, Univ Hospital Zurich, Zurich, Switzerland.*

**Background:** The mechanism of cyst development and pathogenesis leading to end-stage renal disease is not entirely understood due to lack of animal models that closely mimic human disease. This study was done to characterize the new animal model for PKD and determine the role of netrin-1 in PKD.

**Methods:** Two transgenic mice lines (Tg3 and Tg6) that overexpresses netrin-1 in the kidney proximal tubules using L-fatty acid binding protein promoter and their wild-type littermate were used in this study. Netrin-1 overexpression, signaling pathways that are activated in the kidney and role of netrin-1 in PKD was determined by Western blot, RT-PCR, ELISA and siRNA infusion.

**Results:** The transgene chicken netrin-1 excretion in urine is 100 fold more in Tg6 as compared to Tg3 mice and over 1000 fold as compared to WT mice. Tg6 but not in Tg3 transgenic mouse developed multiple cysts at the age of 4 weeks and cyst growth accelerated rapidly reaching a kidney weight of 15-17gram by 32 weeks of age that was accompanied by kidney dysfunction (BUN: 35±5 mg/dl, $p<0.001$ vs. WT), polyuria, albuminuria, increased epithelial cell proliferation and increased excretion of cAMP. Surprisingly, cyst formation in the kidney was restricted to male animals with a penetrance of 85%. Transcription factors (Atf3, NFAT, Cebpb and Fos) and signaling pathways (ERK, focal adhesion kinase) that are associated with cAMP and polycyst formation in human were upregulated in Tg6 mice kidney. Interestingly, p53 expression was increased but present in an inactive unphosphorylated form. To determine whether the observed effects were due to netrin-1 overexpression, netrin-1 expression was suppressed with siRNA infusion. siRNA

mediated suppression of netrin-1 expression completely suppressed polycyst formation in Tg6 animals. Consistent with animal studies, human ADPKD patients excrete significantly more netrin-1 than healthy patients.

**Conclusions:** Our result suggests chronic and excessive overexpression of netrin-1 induce polycyst formation through dedifferentiation and suppression of p53 activation.

*Funding:* NIDDK Support

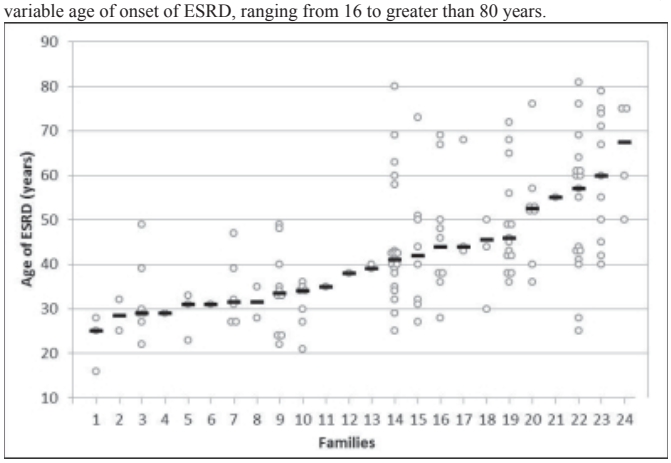
## TH-PO900

**Variable Clinical Presentation in Individuals with a MUC1 Mutation Causing Medullary Cystic Kidney Disease Type 1** Anthony J. Bleyer,[1] Stanislav Kmoch,[2] Kendrah O. Kidd,[1] Victoria C. Robins,[1] Katerina Hodanova.[2] *[1]Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; [2]Institute of Inherited Metabolic Disorders, Charles Univ in Prague, Prague, Czech Republic.*

**Background:** A cytosine insertion in the *MUC1* gene was recently identified as the most common cause of medullary cystic kidney disease type 1 (MCKD1). The clinical expression of this mutation has not been well characterized.

**Methods:** Genotyping and evaluation of clinical characteristics were performed on families with a history of *UMOD*- and *REN*-negative autosomal dominant interstitial kidney disease.

**Results:** 25 of 36 families tested were identified with a *MUC1* mutation (m*MUC1*) . Of 179 members of m*MUC1* families, m*MUC1* was identified in 95 individuals, and 84 individuals did not have a mutation. There were 110 individuals identified as historically affected. Individuals with m*MUC1* suffered from chronic kidney failure with a widely variable age of onset of ESRD, ranging from 16 to greater than 80 years.



There appeared to be 2 types of families. In 13 families, the age of start of dialysis was <50 in almost all individuals, with many young individuals with ESRD. In the other 12 families, there was much more variability in the age of ESRD, with some patients not reaching dialysis until after 70. 38/38 renal ultrasounds of m*MUC1* individuals showed no medullary cysts. While *MUC1* is expressed in many tissues, there were no clinical manifestations of the *mMUC1* in the breasts, skin, respiratory or gastrointestinal tract.

**Conclusions:** *MUC1* mutations are the predominant cause of *UMOD* negative autosomal dominant interstitial kidney disease. Individuals with m*MUC1* have highly variable expression, with some proceeding to dialysis as teens, while others remain dialysis-free into their 80's. While *MUC1* is expressed in many tissues, it only results in clinical abnormalities in the kidney.

## TH-PO901

**Autosomal Dominant Polycystic Kidney Disease (ADPKD) and Medullary Cystic Kidney Disease (MCKD) in an Australian Chronic Kidney Disease (CKD) Cohort** Andrew John Mallett,[1,2,3] Anne Salisbury,[1,2,3] Zaimin Wang,[1,2] Helen G. Healy,[1,2,3] George T. John,[1,3] Wendy E. Hoy.[1,2] *[1]CKD.QLD; [2]Centre for Chronic Disease, School of Medicine, Univ of Queensland, Brisbane, Queensland, Australia; [3]Dept of Renal Medicine, Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia.*

**Background:** 5.7% and 0.3% of Australian and New Zealand patients commencing renal replacement therapy (RRT) in 2011 had ADPDK or MCKD respectively as a Primary Renal Diagnosis. Those with CKD are not well described within Australasia.

**Methods:** To define the frequency and characteristics of CKD patients with APKCK and MCKD. CKD.QLD is a registry and research platform involving all consenting patients in public renal practices in Queensland (~10,800). Primary Renal Disease coding on the first 2359 patients at 5 hospital sites were searched for ADPKD and MCKD. These patients were compared to all patients in the CKD.QLD registry for age, gender and CKD stage.

**Results:** 93 ADPKD and 9 MCKD patients were identified representing 3.9% and 0.4% of the total. Distribution was similar between all 5 CKD.QLD sites. 48% of ADPKD patients and 6/9 MCKD patients were female.

The most common CKD Stages in ADPKD patients, MCKD patients and the broader CKD.QLD registry were 3b (23.7%, 44%, 28%) and 4 (21.5%, 44%, 22%). Men with ADPKD were most commonly CKD Stage 3b (29%). Women with ADPKD were most commonly CKD Stage 4 (28.8%) with suggestion of bidmodal age distribution.

The mean age of ADPKD and MCKD patients were 54.6 and 52.8 years respectively. The most common ADPKD age group was 45-54 years (23.6%) with that for MCKD being 65-74 years (44%). For the full CKD.QLD population mean age was 65.5 years with most common age group 65-74 years (29%).

**Conclusions:** The proportions of patients with CKD due to ADPKD and MCKD are similar to those suggested by RRT data. These patients are younger than the general CKD population. Further patient accrual and analysis is required to corroborate these findings. Future molecular genetic investigation may identify distinct ADPKD and MCKD subgroups for further analysis.

*Funding:* Government Support - Non-U.S.

## TH-PO902

**Identification of Novel Tubulogenesis Genes by Microarray Analysis in 3D-Cultured MDCK Cells** Maria F. Chacon-Heszele,[1] Xiaofeng Zuo,[1] Sarah McKenna,[1] Liwei Huang,[1] Soo Young Choi,[1] Joshua H. Lipschutz.[1,2] *[1]Depts of Medicine, Univ of Pennsylvania; [2]Philadelphia VAMC, Philadelphia, PA.*

**Background:** The kidney originates from two types of "building blocks", cysts and tubules. Cysts (e.g. the renal vesicle during development) are spherical monolayers of epithelial cells surrounding a lumen. Tubules, also lumen-containing monolayers, are cylindrical. Although differently shaped, cysts and tubules are topologically equivalent, as both have an apical surface facing the lumen, a lateral surface with cell-cell contacts, and a basal surface interacting with the basement membrane. Tubules, therefore, in many ways, are morphogen-induced cysts.

Determining the signaling pathways controlling cystogenesis and tubulogenesis is critical for understanding kidney formation and repair. Due to the transitory nature of these processes, it is difficult to study them in vivo.

Although widely used, we hypothesize that traditional two-dimensional (2D) in vitro cell culture models (e.g. cell monolayers on plastic) do not adequately replicate the process of tubulogenesis in vivo. Therefore, we used a 3D cell culture system, where cells are grown to the cyst stage in collagen, and are then induced with HGF to undergo tubulogenesis.

**Methods:** Here, we sought to identify differentially regulated genes involved in early tubulogenesis, which might be missed with 2D studies, and to determine which of these genes are dependent on MAPK signaling. We used microarray analysis of 2D and 3D grown Madin-Darby canine kidney (MDCK) cells treated with HGF and MAPK inhibitors to analyze changes in gene expression during tubulogenesis, and confirmed these results with RT-PCR.

**Results:** We identified 1,857 "tubulogenes". Of these, 840 genes were identified as being MAPK-dependent.

**Conclusions:** Our results show that expression of putative tubulogenes, identified in previous 2D studies, do not always change during tubulogenesis in 3D culture. In contrast, some of the genes we identified as tubulogenes in this study, such as MMP1, were not identified in 2D studies. Supporting our findings we determined that shRNAmediated knockdown of MMP1 inhibited cyst and tubule formation in MDCK cells cultured in a 3D matrix.

## TH-PO903

**Tuberous Sclerosis in Children: Its Variable Renal Presentation and Oucome** Isabel Roberti, Shefali Vyas. *Children's Kidney Center, Saint Barnabas Medical Center, Livingston, NJ.*

**Background:** Tuberous sclerosis (TS) is a multisystem disorder encompassing a wide spectrum of renal lesions. Renal involvement is often asymptomatic but renal failure can affect 1% of adults with TS. A variable number of renal cysts and/or angiomyolipomas have been reported in children with TS but renal failure and renal CA are not expected.

**Methods:** This is a retrospective analysis of children with TS referred to our Pediatric Nephrology Center in the past 15 years. Demographic info, clinical data, therapy and outcome were reviewed.

**Results:** We identified **22 children**, aged 1 day to 14 yrs (median= 5 yrs), half were males, 13 C, 5 AA, 5H. **Reason for referral**: abnormal renal sonogram or MRI= 21 (3 pre-natal, 2 with enlarged abdomen with palpable kidneys, 16 routine), CKD = 1. **FH** + in 9 (41%). **PMH** + for cardiac rabdomyomas. **GFR @ presentation**: ESRD=1, Stage 2 CKD =1, Stage 3 CKD =2; **HTN** =4 (18%); **Proteinuria** =1, **MA** =1. All had **CNS involvement** by brain MRI; 17 (77%) had seizures and developmental delay (varied from mild to autism). **Skin lesions** were seen in 15 (68%). **Renal sonogram @ presentation**: few cysts=4, bilateral cysts (some complex)= 7, angiomyolipomas= 11, hamartomas =2, increased echogenicity= 3, enlarged kidneys (>15 cm)= 2. **Follow-up time** (N=18): 5 ms to 10yrs (median=3 yrs). **Renal outcome**: **3 ESRD** (**1 on PD since birth** died at 9 mos with aortic aneurysm unable to have a txp, **2 txp**: 1 s/p renal CA and nephrectomies died due to seizures and 1 with C1QN with no renal TS), **1 stage 3 CKD** and **14 (77%) stage 1 CKD. Renal sono f/u (16):** 5 stable sonogram; 10 with worse #/size lesions, 1 with less lesions on everolimus. **Meds**: 14 on anti-seizure, 3 on everolimus (2 due to CNS astrocytomas, 1 due to complex renal masses + CKD), 5 on enalapril. Five had partial brain lobectomies.

**Conclusions:** We report 22 children with TS with various degrees of renal and CNS involvement, including an infant with ESRD. Our incidence of CKD/ESRD was higher than expected at 18%. Renal lesions typically progressed with time. Everolimus significantly ameliorated the renal dysfunction in 1 child. Further studies detailing the long-term f/u of such children and the possible benefit of everolimus for ameliorating renal disease are needed.

**TH-PO904**

**Aberrant Glycosylation and Localization of Polycystin-1 Cause Polycystic Kidney in AQP11-Knockout Mice** Yuichi Inoue,[1] Eisei Sohara,[1] Katsuki Kobayashi,[2] Tatemitsu Rai,[1] Kenichi Ishibashi,[3] Shigeo Horie,[4] Xuefeng Su,[5] Jing Zhou,[5] Sei Sasaki,[1] Shinichi Uchida.[1] *[1]Tokyo Medical and Dental Univ; [2]Chiba East National Hospital; [3]Meiji Pharmaceutical Univ; [4]Juntendo Univ; [5]Brigham and Women's Hospital.*

**Background:** We previously reported that the disruption of aquaporin-11 (AQP11) gene in mice resulted in cyst formation in the kidney. However, the mechanism of cyst formation in the AQP11(-/-) mouse is still unknown.

**Methods:** To investigate the mechanism, we analyzed the AQP11(-/-) mouse and AQP11 BAC transgenic ($Tg^{AQP11}$) mouse that expresses 3xHA–tagged AQP11, by focusing on the polycystic kidney disease-related gene products.

**Results:** Immunofluorescence of the kidney from $Tg^{AQP11}$ mice revealed that 3xHA-AQP11 was localized in the cytoplasm of proximal tubule cells. Double immunofluorescence with organelle markers and immunoblots of isolated ER fraction of the kidney of $Tg^{AQP11}$ mice revealed that 3xHA-AQP11 localizes to ER in vivo. Since ER is essential for quality control and trafficking of newly synthesized proteins, we hypothesized that the absence of AQP11 in ER could result in impaired quality control and aberrant trafficking of polycystins, responsible proteins for autosomal dominant polycystic kidney disease. We found an increase in protein expression level of PC-1 and a decrease in protein expression level of PC-2 in AQP11(-/-) mice kidney, compared with wild-type mice. We confirmed higher molecular weight of PC-1 in AQP11(-/-) mice kidney, caused by impaired N-glycosylation processing of PC-1. In addition, density gradient centrifugation of kidney homogenate revealed impaired membrane trafficking of PC-1 in AQP11(-/-) mouse. Finally, we demonstrated that the $Pkd1^{+/-}$ background results in increased severity of polycystic kidney disease in AQP11(-/-) mice kidneys.

**Conclusions:** Our data demonstrated that impaired glycosylation processing and aberrant membrane trafficking of PC-1 in AQP11(-/-) mouse could be a key mechanism of cyst formation in AQP11(-/-) mice.

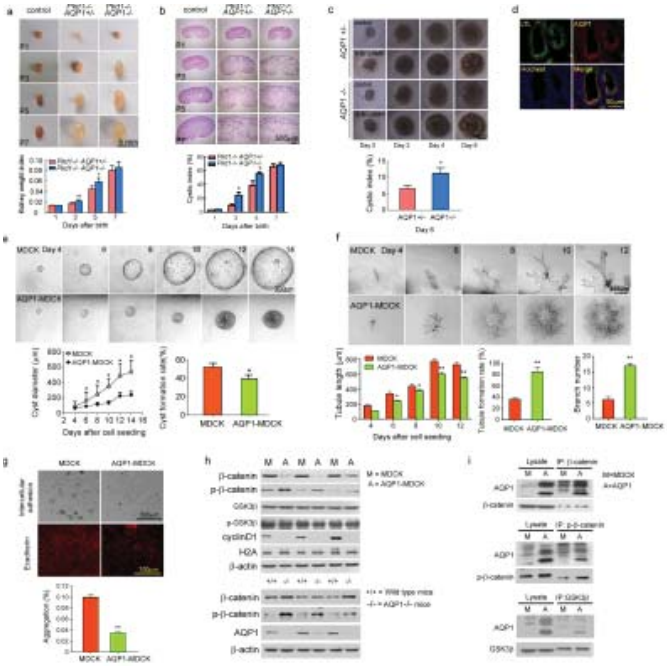
**Aquaporin1 Inhibits Renal Cyst Formation and Enlargement by Down-Regulating Wnt Signaling** Weiling Wang, Baoxue Yang. *State Key Laboratory of Natural and Biomimetic Drugs, Dept of Pharmacology, Peking Univ, Beijing, China.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is characterized by the progressive enlargement of cysts caused by mutations in *Pkd1* or *Pkd2*. Polycystin-1 encoded by *Pkd1* undergoes multiple cleavages that intervene in several signaling pathways involved in cellular proliferation and differentiation mechanisms.Aquaporin1 (AQP1) is a water channel protein, widely expressed in epithelial and endothelial cells. Recent research revealed AQP1 interacted with Lin7 to regulate cytoskeleton remodeling in melanoma cell. Our aim was to study the role of AQP1 in ADPKD development.

**Methods:** We analyzed kidney index and cyst index in both AQP1 null PKD mice and embryonic kidney cyst model.We evaluated β-catenin, p-β-catenin, CyclinD1, GSK3β and p-GSK3β expression by Western blot and immunofluorescence in AQP1 over-expression MDCK cell and MDCK cell as well as AQP1 null mice.

**Results:** With AQP1 null PKD mice, We found AQP1 deficiency significantly promoted renal cyst development. Similarly, 8-Br-cAMP induced cyst enlargement was promoted in AQP1 null embryonic kidney model.Over-expression of AQP1 inhibited cyst development and promoted tubulogenesis in MDCK tubule model. It was found that AQP1 impaired the extracellular adhesion and decreased E-cadherin. AQP1 down-regulated β-catenin expression and up-regulated β-catenin phosphorylation in AQP1-MDCK cells. Furthermore, CyclinD1 was hardly detected in AQP1-MDCK cells. The kidneys from AQP1 knockout mice showed high level of β-catenin.The level of p-GSK3β was lower in AQP1-MDCK cells. It was also found that AQP1 co-immunoprecipitated with β-catenin, p-β-catenin as well as GSK3β.



**Conclusions:** AQP1 may involve in maintaining the stability of the "degraded complex" to promote β-catenin phosphorylation and suppress the Wnt signaling pathway. We speculate that AQP1 might be a new target for ADPKD therapy.

**TH-PO906**

**Implication of Inflammasome Activation via Mitochondrial Reactive Oxygen Species in the Development of Renal Interstitial Fibrosis Induced by Aldosterone** Hiroyuki Kadoya, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

**Background:** The inflammasome plays an important role in a variety of diseases, including atherosclerosis and chronic kidney disease (CKD). The inflammasome is a cytoplasmic multiprotein complex that activates caspase-1, through interaction with ASC (Apoptosis-associated Speck-like Protein Containing a Caspase Recruitment Domain), and finally leads to the processing and secretion of the pro-inflammatory cytokines, such as IL-1β and IL-18. Aldosterone (Aldo) has been indicated to induce kidney damages through activation of pro-inflammatory signaling pathway. We hypothesized that Aldo induces renal damages via activation of inflammasome.

**Methods:** ASC-deficient mice (ASCKO) and control C57Bl/6 mice (WT) were used. All animals were received left uninephrectomy and given drinking water with 1% NaCl. The mice were divided into the following groups: WT-vehicle, WT-Aldo (Aldo, 0.25 mg/kg/day, osmotic pump), WT-Aldo treated with eplerenone (WT-Aldo+Eple; Eple, 100 mg/kg/day, gavage), and ASCKO-Aldo. Three weeks after drug administration, mice were sacrificed. We also examined the mitochondrial superoxide production by Aldo and its possible involvement in inflammasome activation in cultured mouse peritoneal macrophages.

**Results:** Tubulointerstitial damage and increased expressions of inflammasome components, NLRP-3 and ASC, were demonstrated in WT-Aldo. Increased Caspase-1 activity and concomitant overproduction of IL-1β and IL-18 were also demonstrated in the WT-Aldo. Eple treatment suppressed these changes. Tubulointerstitial injuries were significantly attenuated in the ASCKO-Aldo. Increased Caspase-1 activity and expressions of IL-1β and IL-18 were also attenuated in ASCKO-Aldo. Aldo induced mitochondrial superoxide production and resulted in inflammasome activation in cultured macrophages obtained from peritoneal cavity. This was completely blocked by eplerenone.

**Conclusions:** Our results indicate that Aldo induced interstitial fibrosis via activation of inflammasomes in infiltrated macrophages. Thus, inflammasome activation in macrophages could be a new therapeutic target for CKD.

**TH-PO907**

**Altered Excitability of Afferent Renal Innervation in an In-Vivo Model of Renal Inflammation** Wolfgang Freisinger,[1] Annalena Karl,[2] Nadja Tzinis,[2] Tilmann Ditting,[2] Sonja Heinlein,[2] Roland E. Schmieder,[2] Jens Lutz,[1] Roland Veelken.[2] *[1]Nephrology, Med. Clinic, Universitätsmedizin Mainz, Mainz, Germany; [2]Nephrology and Hypertension, Med. Clinic 4, Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany.*

**Background:** Renal innervation is most likely important in renal inflammatory disease. Recently, we found that afferent renal neurons show a distinctive excitability, exhibiting predominantly a sustained firing upon current injection that depends on specific sodium

channel expression. So far, excitability of these neurons under inflammatory conditions in vivo is unclear. Hence we wanted to test the hypothesis that in a model of renal inflammation, Thy1.1 nephritis, the specific firing pattern of renal afferent neurons is altered.

**Methods:** Thy1.1 nephritis was induced (OX7, 1.2mg/kg) in Sprague Dawley rats 7 days before harvesting neurons, controls received vehicle. Nephritis was confirmed by proteinuria and histologically.Labelling (DiI) identified renal afferent neurons situated in dorsal root ganglia (DRG). Current clamp was used to characterize neurons as "tonic", i.e. sustained action potential (AP) firing or "phasic", i.e. <5 APs. AP properties were determined in renal and non-renal neurons of nephritic rats and controls.

**Results:** Nephritic rats had all proteinuria and displayed histologically inflammation. Untreated renal afferent DRG neurons (n=58) exhibited in 64% a tonic firing pattern. In Thy1.1 nephritic rats, renal DRG neurons (n=112) exhibited significantly less a tonic firing pattern (43% vs. 64%, *$p<0.05$). Whereas the characteristic "tonic" vs. "phasic" changed, neither electrophysiological parameters (resistance, cell capacity, membrane potential) nor action potential morphology was altered.

**Conclusions:** We could show that in an in vivo model of renal inflammation, renal afferent neurons exhibited a significantly decreased excitability upon electric stimulation. An altered expression of sodium channel subtypes might lead to a faster inactivation of these channels and decreased firing activity. In consequence, altered afferent renal activity in vivo could lead to sympathetic dysregulation aggravating renal inflammation.

**Nlrp3 Inflammasome Activation Promotes Renal Tubulointerstitial Inflammation in Albumin-Overload Nephropathy** Dan Liu,[1] Bi-Cheng Liu.[1] *[1]Institute of Nephrology, Southeast Univ, Nanjing, China; [2]Institute of Nephrology, Southeast Univ; [3]Institute of Nephrology, Southeast Univ.*

**Background:** Nlrp3 inflammasome are implicated in recognizing certain non-microbial origin 'danger-signals'. This study aimed to investigate whether overload albumin induce Nlrp3 inflammasome activation and contribute to tubular cell stress and tubulointerstitial inflammation.

**Methods:** Albumin-overload nephropathy was induced in adult male Wistar rats that were uninephrectomized or sham operated 5 days before starting bovine serum albumin injection. Rats were given daily intraperitoneal injections of 5g/kg/d BSA (n=10) or sham sterile normal saline (UXN: n=6, Sham: n=6) injections for 9 weeks. Blood samples were taken on weeks 0, 2, 5, 7, 9 after collection of a 24-h urine. At the end of the study, rats were anesthetized and tissue were kept for subsequent analysis. Nlrp3 inflammasome and inflammatory cytokines were examined by real time RT-PCR and Western blotting.

**Results:** Urinary protein excretion assay shows that proteinuria were increased in albumin-overload rats compared to saline-injected controls ($p<0.05$). Tubular injury was confirmed by ELISA examination of NGAL, which increased in albumin-overload rats than controls ($p<0.05$). Immunofluorescence showed Nlrp3 activation in proximal tubular cells. Albumin triggered the upregulation of Nlrp3 inflammasome, which subsequently lead to IL-1β and IL-18 secretion (Nlrp3: $p<0.05$, IL-1β: $p<0.05$, IL-18: $p<0.01$). Real time RT-PCR indicated Nlrp3 mRNA expression increased of renal cortex. Meanwhile, proximal tubular epithelial cells show cell atrophy observed by PAS staining and mitochondrial dysfuntion measured by mitochondrial membrane potential reduction by JC-1 dye after albumin overload ($p<0.01$). Immunohistochemical staining shows that inflammatory cell infiltration in tubulointerstitium was significantly greater in BSA injection group than saline group.

**Conclusions:** Our study demonstrated that albumin caused the tubular injury and tubulointerstitial inflammation through the mitochondrial dysfunction that activate Nlrp3 inflammasome with subsequent secretion of inflammatory cytokines in albumin-overload nephropathy.

## TH-PO909

**Human Leukocyte Antigen-G Attenuates Renal Inflammation in a Mouse Model of Lupus Nephritis** Onkar Kulkarni, Shrikant R. Mulay, Murthy Narayana Darisipudi, Santhosh Kumar VR, Hans J. Anders. *Medizinische Klinik und Poliklinik IV, Univ of Munich, Munich, Bavaria, Germany.*

**Background:** Human leukocyte antigen (HLA-G) interacts with PIR-B expressed on mouse leukocytes. Administration of microbeads coated with HLA-G5-B2m has been shown to induce tolerance of DCs and inhibit DC maturation in transplantation mouse models. PIR-B is the negative regulator of TLR-9 in B1 cells which are primarily responsible for rheumatoid-factor (RF) release. B1 cells depletion attenuate the progression of lupus nephritis in MRL-lpr mice. PIR-B knockout mice have exaggerated release of RF, anti-DNA antibodies and reduced survival. We hypothesized that administration of HLA-G5-B2M absorbed on microbeads will improve renal inflammation by inhibiting DCs maturation and B1 cells activation in MRL-lpr mice.

**Methods:** We injected microbeads coated with HLA-G-B2m (2microgram/week/mouse) for 10 wks starting from week 12 of age. Plasma, urine, tissue samples were collected at the end of the treatment period. Kidney tissues were processed for histological analysis. Various lymphocyte subsets were analyzed by FACS from spleen and kidney. Part of isolated tissue was analyzed for expression analysis by RT-PCR.

**Results:** HLA-G treatment attenuated lupus nephritis, determined by the activity and chronicity index of histomorphological damage. HLA-G treatment improved renal function as observed by reduced BUN levels in the plasma. HLA-G treatment reduced the intra-renal accumulation of CXCR3 positive T cells. IL17- and IFN-gamma-producing T cells were also reduced in the kidney significantly in the HLA-G treated group. Infiltration and activation of dendritic cells and macrophages as well as expression of pro-inflammatory mediators in the kidney was significantly reduced by HLA-G treatment. Plasma levels of RF, IL12p40, TNF-alpha and IL17 were significantly reduced by the treatment. HLA-G treatment did not have any significant effect on the leukocytes subsets in the spleen and autoantibody production.

**Conclusions:** HLA-G5 treatment significantly suppresses lupus nephritis of MRL-lpr mice, mainly by reducing systemic and intra-renal inflammation.

## TH-PO910

**Renal Cytokine Expression during Sepsis Is Repressed in Conditional NFAT5-Knockout Mice** Christoph Kueper,[1] Wolfgang Neuhofer.[1,2] *[1]Dept of Cellular Physiology, Univ of Munich; [2]Dept of Nephrology, Univ of Munich.*

**Background:** The osmosensitive transcription factor NFAT5 (also known as TonEBP) regulates the expression of osmoprotective genes (AR, HSP70) and urinary concentrating genes (AQP-2, UT-A, ClC-K1) in the kidney. Besides, NFAT5 is also involved in the expression of cytokines in immune cells during LPS stimulation. The aim of the present study was to evaluate, if NFAT5 activation is also involved in cytokine expression in renal cells in response to LPS. For this purpose, we generated conditional NFAT5 knockout mice, in which NFAT5 can be deleted in mature animals.

**Methods:** In the genome of the conditional knockout mice, exon 4 of the NFAT5 gene is flanked by two loxP sites; additionally, the animals express the Cre recombinase under control of a tamoxifen-inducible promoter. At the age of 6 weeks, male conditional knockout mice were treated with tamoxifen to induce Cre-mediated NFAT5 knockdown. Knockdown efficiency and expression of defined renal NFAT5 target genes (AR, AQP-2, UT-A, ClC-K1) was measured by qRT-PCR and immunoblotting. In additional experiments the NFAT5-knockout mice or wildtype-mice were treated with LPS (5 mg/kg bw) for 24 h. Expression of various cytokines (CCL-2, CCL-5, TNF-a, IL-6) was measured by qRT-PCR or ELISA.

**Results:** Expression of renal NFAT5 in tamoxifen-treated animals was diminished to approximately 10% compared to control animals. In accordance, expression of NFAT5 target genes AR, AQP-2 and ClC-K1 was also significantly decreased. In a LPS/sepsis model, expression of cytokines CCL-2, CCL-5, TNF-a and IL-6, both in the kidney and in the spleen of NFAT5 knockout animals was significantly reduced compared to control animals.

**Conclusions:** We have developed a mouse model, in which the expression of NFAT5 can be efficiently repressed in mature animals. This mouse model may turn out to be very helpful for future studies investigating NFAT5 function in vivo. First results with this model demonstrate that several cytokines are downregulated in the kidney of NFAT5-knockout animals during LPS treatment, indicating that NFAT5 is an important factor of the inflammatory process in the kidney.

## TH-PO911

**Characterization of Reparative Macrophages in the Kidney Using a Novel IL10 Reporter Mouse: F4/80$^{hi}$ CD11b$^{+}$ Macrophages as a Major Source of IL10 in the Repair Phase of Kidney Inflammation** Julia Lichtnekert, Takahisa Kawakami, Bryce Gordon Johnson, Jeremy Stuart Duffield. *Div of Nephrology, Univ of Washington, Seattle, WA.*

**Background:** IL-10 is a potent anti-inflammatory cytokine that plays an important role in the regulation of immune responses, thereby preventing damage to the host. In various acute and chronic models of kidney diseases, IL-10 administration protected against renal injury. To study the source and characteristics of IL10-producing cells in the kidney in steady state and injury/repair, we analyzed IL-10 production *in vivo* using a novel IL-10-beta lactamase reporter mouse (ITIB).

**Methods:** Single cells from ITIB mouse kidney after systemic LPS administration, bilateral renal ischemia-reperfusion (IRI) and unilateral ureteral obstruction (UUO) were analyzed by flow cytometry analysis.

**Results:** IIL-10 is expressed by 3 distinct mononuclear phagocyte (MPC) populations: CD11b$^{hi}$CD11b$^{low}$, CD11b$^{hi}$CD11c$^{lo}$ and CD11b$^{int}$CD11c$^{int}$. Analyzing IL-10 producing cells using ITIB mice, most MPCs do not synthesize IL-10 in steady state, but a proportion of resident CD11b$^{int}$CD11c$^{int}$F4/80$^{hi}$ MPCs generate IL-10 in healthy kidneys, suggesting they may have a unique role in preventing inflammatory responses. Next, we investigated IL-10 up-regulation in the kidney after systemic LPS administration. After 48h, CD11b$^{+}$Ly6G$^{+}$ neutrophils and 40% of MPCs showed IL-10 production. Analysis of subpopulations indicated that CD11b$^{int}$CD1c$^{int}$F4/80$^{hi}$ and CD11b$^{hi}$CD11c$^{low}$ MPCs are major sources of IL-10. Furthermore, we investigated IL-10 expression after UUO and bilateral IRI. At day 4 after UUO, significantly increased levels of IL-10 producing cells could be detected, which were CD11b$^{int}$CD11c$^{int}$ and CD11b$^{hi}$CD11c$^{hi}$ MPCs, whereas at day 7 CD11b$^{hi}$CD11c$^{low}$ and CD11b$^{hi}$CD11c$^{hi}$ expressed IL-10. Interestingly, these latter subpopulations were positive for F4/80. After bilateral IRI, the major sources of IL-10 were CD11b$^{hi}$CD11c$^{low}$ and CD11b$^{hi}$CD11c$^{hi}$ MCP subpopulations at day 4 and 7 of which the majority was F4/80 positive.

**Conclusions:** These studies demonstrate for the first time that IL-10 is produced *in vivo* in renal reparative macrophages in kidney inflammation and injury.

*Funding:* Government Support - Non-U.S.

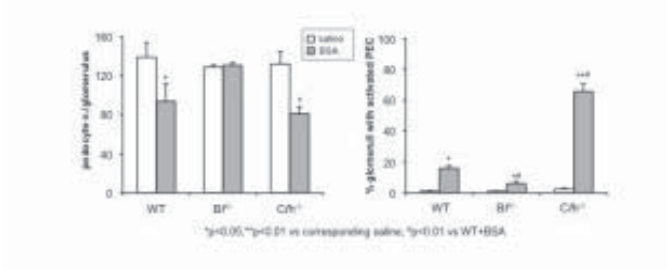
**TH-PO912**

**Alternative Pathway (AP) of Complement (C) Activation Triggers Glomerular Podocyte and Parietal Epithelial Cell (PEC) Dysregulation in Proteinuric Nephropathy** Marina Morigi,[1] Monica Locatelli,[1] Daniela Corna,[1] Simona Buelli,[1] Mauro Abbate,[1] Marina Noris,[1] Ariela Benigni,[1] Giuseppe Remuzzi,[1,2] Carlamaria Zoja.[1] *[1]IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Bergamo, Italy; [2]Unit of Nephrology and Dialysis, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy.*

**Background:** We previously showed that protein overload led to glomerular injury, accumulation of C3 in podocytes and podocyte damage promoting C-dependent dysfunction of glomerular filtration barrier, which accelerated progressive renal injury. Here we sought to evaluate: 1) which of the C pathways were involved in glomerular C3 deposition and podocyte loss; 2) whether C-dependent glomerular injury was related to signs of PEC activation. To this aim,protein overload-proteinuria was studied in mice deficient for the cofactor of the AP-C3 convertase factor B or for the AP inhibitor factor H.

**Methods:** Wild type (WT), *Bf*$^{-/-}$ and *Cfh*$^{-/-}$ mice underwent uninephrectomy and 5d later received daily i.p. injections of saline or BSA up to 28d. Podocyte number was assessed as WT1+cells. Activated PEC were defined as NCAM+/claudin+ cells forming adhesion between capsule and tuft, and glomerulosclerosis (GS).

**Results:**



WT-BSA mice showed glomerular C3 deposits associated with podocyte loss (32%) and PEC activation (16% glomeruli), which were prevented by factor B deficiency (Fig.), indirectly showing that AP of C was involved in both phenomena. Additional evidence of AP involvement was provided by *Cfh*$^{-/-}$-BSA mice that instead had more proteinuria, greater C3 deposits (score, 4±0 vs 2±0.1, p<0.01), more podocyte loss (39%), more severe PEC alterations (66% glomeruli) and higher % of glomeruli with GS (20±3% vs 9±3%, p<0.05) than WT-BSA mice.

**Conclusions:** Inhibiting AP of C attenuates glomerular injury in proteinuric mice, while its uncontrolled activation leads to more PEC-related glomerular sclerotic lesions.

**TH-PO913**

**Interleukin 17-Receptor A on Leukocytes and Tissue Cells Mediates Inflammation in a Murine Model of Crescentic Glomerulonephritis** Joanna R. Ghali,[1,2] Stephen R. Holdsworth,[1,2] A. Richard Kitching.[1,2] *[1]Centre for Inflammatory Diseases and Dept of Medicine, Monash Univ, Clayton, Victoria, Australia; [2]Dept of Nephrology, Monash Health, Clayton, Victoria, Australia.*

**Background:** Interleukin (IL)-17A and IL-17F are inflammatory cytokines which signal through IL-17 Receptor A (IL-17RA), expressed on many cell types, including renal tissue cells (TC). We aimed to explore the role of IL-17RA in experimental glomerulonephritis (GN).

**Methods:** Necrotising, crescentic GN was induced by intravenous administration of sheep anti-mouse glomerular basement membrane globulin, thereby planting sheep globulin (SG) in glomeruli. Mice were culled at day 21. Wild type C57BL/6 (WT), IL-17RA-/- and bone marrow (BM) chimeric mice were used.

**Results:** IL-17RA-/- mice had reduced crescent formation (WT 17±3 vs IL-17RA-/- 9±3%; P<0.05), fewer glomerular neutrophils (1.2±0.1 vs 0.76±0.0 cells/glomerular cross section [c/gcs]; P<0.05), and macrophages (2.0±0.2 vs 1.1±0.2c/gcs; P<0.05). IL-17RA-/- mice had lower circulating anti-SG antibodies than WT mice (IgG $OD_{450}$ 1:100; 0.34±0.06 vs 0.17±0.02; P<0.05). BM chimeric mice (chimerism 96%) were generated, permitting assessment of selective IL-17RA deficiency in BM or TC. Compared to BM+TC+ mice, BM-TC+ mice had reduced glomerular segmental necrosis (BM+TC+ 49±5 vs BM-TC+ 27±5%; P<0.05) and urinary protein:creatinine ratios (BM+TC+ 2.0±0.3 vs BM-TC+ 1.1±0.3mg/mmol; P<0.05), but BM+TC- mice did not. Mice with BM or TC IL-17RA deficiency had impaired cellular immunity (ELISPOT: BM+TC+ 91±19 vs BM-TC+ 41±6 IFNγ+ spots/2x10$^6$ SG-stimulated splenocytes; BM+TC+ 91±19 vs BM+TC- 43±8; both P<0.05). Glomerular neutrophil recruitment did not differ between BM+TC+ and BM-TC+ or BM+TC- mice, but differed between chimeric groups (BM-TC+ 0.6±0.1 vs BM+TC- 1.1±0.1c/gcs; P<0.05). No difference in glomerular macrophage or T cell recruitment was found. Compared to BM+TC+ mice, BM+TC- mice had impaired humoral immunity (IgG $OD_{450}$ 1:100: BM+TC+ 0.58±0.10 vs BM+TC- 0.18±0.03; P<0.05).

**Conclusions:** IL-17A/F signalling promotes glomerular injury. Leukocyte-derived IL-17RA promotes cellular immunity and injury, while IL-17RA on radio-resistant cells enhances antigen-specific cellular and humoral immunity.

*Funding:* Government Support - Non-U.S.

**TH-PO914**

**FMS-Like Tyrosine Kinase 3 Ligand Does Not Protect Mice from Experimental Glomerulonephritis, Despite Inducing Regulatory T Cells** Joanna R. Ghali,[1,2] Stephen R. Holdsworth,[1,2] A. Richard Kitching.[1,2] *[1]Centre for Inflammatory Diseases and Dept of Medicine, Monash Univ, Clayton, Victoria, Australia; [2]Dept of Nephrology, Monash Health, Clayton, Victoria, Australia.*

**Background:** FMS-like tyrosine kinase 3 ligand (FLT3-L) is a growth factor that can expand regulatory T cells (Tregs) and plasmacytoid dendritic cells (pDC). We hypothesised that FLT3-L-induced Tregs would protect mice from experimental glomerulonephritis (GN).

**Methods:** Naive C57BL/6 mice were injected with FLT3-L 10mg or PBS intraperitoneally daily for 10 days. To determine whether FLT3-L altered immune responses to foreign antigen, FLT3-L/PBS was injected for 10 days then mice were primed with sheep globulin (SG) and culled 4 days later. To induce GN, mice were primed with SG, given intravenous sheep anti-mouse glomerular basement membrane (GBM) globulin at day 4 (planting SG in glomeruli), and culled at day 14.

**Results:** Compared to PBS, FLT3-L-treated mice had increased splenic Treg proportions (CD4+Foxp3+/CD4+: FLT3-L 21.4±1.9 vs PBS 11.1±0.8%; P<0.05). Four days after SG priming, FLT3-L-treated mice had higher proportions of lymph node pDC (PDCA-1+/CD11c+: 10.0±1.6 vs 5.0±0.9%; P<0.05) and enhanced SG-specific dermal delayed type hypersensitivity (0.31±0.08 vs 0.09±0.02mm; P<0.05), without an increase in Tregs, suggesting that ceasing FLT3-L therapy enhanced cellular immunity. Mice were given FLT3-L/PBS for 10 days prior to inducing GN. FLT3-L-treated mice were not protected from renal injury (segmental necrosis: 48.3±15.3 vs 46.0±13.2%; P=0.91, crescents: 7.0±3.4 vs 4.0±2.0%; P=0.48). When FLT3-L/PBS was administered daily throughout the GN model, FLT3-L-treated mice developed substantial mortality compared to controls (87.5% vs 12.5%; P<0.05) at day 13. Five days after anti-GBM globulin, FLT3-L-treated mice had enhanced cellular immunity (IL-17A ELISPOT: 12.8±1.8 vs 6.4±0.8 spots/1x10$^6$ SG-stimulated splenocytes; P<0.05), more activated T cells (CD4+CD25+/CD4+: 15.4±0.8 vs 12.9±0.5%; P<0.05) and conventional DC in the spleen (PDCA-1-/CD11c+: 93.4±0.5 vs 83.5±2.3%; P<0.05).

**Conclusions:** FLT3-L therapy enhanced systemic T cells responses, demonstrating that attempts to enhance protective immunity in GN via DC manipulation may be harmful.

**PKC-Theta Modulates Activation of Murine Primary Macrophages via Regulation of Proinflammatory Cytokine Expression** Anna Bertram, Torsten Kirsch, Hermann G. Haller, Nelli Shushakova. *Dept of Nephrology, Hannover Medical School, Hannover, Germany.*

**Background:** Systemic inflammation is a hallmark of sepsis, which is afflicted with a high mortality. A better understanding of underlying mechanisms might lead to new therapeutic targets in inflammatory diseases. Macrophage activation and subsequent release of proinflammatory mediators are critical steps in inflammation. We investigated the role of PKC-theta in the activation of murine primary macrophages.

**Methods:** Peritoneal macrophages were obtained by peritoneal lavage of SV129 wild type and PKC-theta gene-deficient mice and stimulated with LPS. Expression of PKC-theta and cytokines was quantified using RT-PCR, and release of cytokines was measured with ELISA. Confocal microscopy was used to visualize nuclear translocation of NFkB. Peritonitis was induced by intraperitoneal injection of 3% thioglycollate in wild type and PKC-theta gene-deficient mice.

**Results:** PKC-theta is expressed in peritoneal macrophages of SV129 wild type mice. Stimulation of isolated PKC-theta gene-deficient peritoneal macrophages with 100 ng/ml LPS resulted in a significantly impaired secretion of TNF-alpha and MIP-2 after 2, 3 or 4 h in comparison to wild type peritoneal macrophages (44% for TNF-alpha, 34.2% for MIP-2 after 4 h). Consistently, mRNA levels of TNF-alpha and MIP-2, which show a peak 1 h after LPS stimulation, were markedly decreased in PKC-theta gene-deficient macrophages (55.2% for TNF-alpha, 49.8% for MIP-2). However, nuclear translocation of NFkB was not defective, but rather accelerated in PKC-theta gene-deficient macrophages, suggesting a downstream target of PKC-theta. These *in vitro* findings correlated with decreased neutrophil accumulation in a model of experimental peritonitis in PKC-theta gene-deficient vs. wild type mice (41.4%).

**Conclusions:** We conclude that PKC-theta modulates the activation of murine primary macrophages by regulating the expression of proinflammatory cytokines. Further experiments are required to pinpoint the molecular site of action of PKC-theta. Inhibition of PKC-theta may be a novel therapeutic target to modulate the inflammatory response in sepsis and other inflammatory disorders.

**TH-PO916**

**Effection of CagA Protein on the Production and Underglycosylation of IgA1 in DAKIKI Cells** Junming Fan,[1,2] Fugang Li,[2] Li Liu,[2] Man Yang,[2] Zi Li,[1] Wei Qin.[1] *[1]Dept of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China; [2]Div of Nephrology, Dept of Internal Chinese Medicine, Luzhou Medical College, Luzhou, Sichuan, China.*

**Background:** IgA nephropathy (IgAN) is the most common form of glomerulonephrits in the world. The infection rate of Helicobacter pylori (Hp) is very high in China and the Asia Pacific region.Hp infection is associated with IgAN, but the underlying molecular mechanism remains unclear. This study was to investigate the effects of cytotoxin associated gene A protein (CagA), a major virulence factor of Hp, on the production and underglycosylation of IgA1 in DAKIKI, a B cell line.

**Methods:** DAKIKI, was cultured and incubated by recombinant CagA protein. The cells were cultured for 48h with different CagA dose (0.4 ug/ml, 0.8 ug/ml, 1.6 ug/ml, 3.2 ug/ml) in dose-dependent test, and for 24, 48 and 72hs in time-dependent test. The cell proliferation was examined by CCK-8 assay and cell counting. The production and glycosylation of IgA1 in supernatants were determined by ELISA and helix aspersa (HAA) lectin binding assay. For the mechanism of O-glycosylation , cells were incubated with 1.6 ug/ml CagA, lipopolysaccharide (LPS) or Bovine serum albumin(BSA) for 48h, and the protein expression of C1GALT1 and Cosmc were measured by Western blot.

**Results:** For dose-dependent test, while the dose within the range of 0.8~1.6 ug/ml, CagA stimulated cell proliferation. However, 3.2 ug/ml of CagA inhibited cell proliferation. Moreover,CagA promoted the production and underglycosylation of IgA1 in a dose-dependent manner. For time-dependent test, 1.6 ug/ml of CagA stimulated the production and underglycosylation of IgA1 in a time-dependent manner. The protein expression of C1GALT1 and Cosmc is significantly lower in cells stilimulated by CagA and LPS than control or BSA.

**Conclusions:** CagA promoted the B cell proliferation and IgA1 secretion in vitro. CagA protein also induced underglycosylation of IgA1,and which might be resulted from a downregulation of C1GALT1 and Cosmc expression.These results suggested that CagA might play an important role in the pathogenesis of IgAN, and that anti-Hp treatment may be a new target for prevention of IgAN in clinic.

## TH-PO917

**Transfer and Substrate Specificity of Neutrophil Serine Proteases towards Endothelial Cells** Uwe Jerke,[1] Daniel Perez Hernandez,[2] Brice Korkmaz,[3] Gunnar Dittmar,[2] Ralph Kettritz.[1,4] *[1]Experimental and Clinical Research Center, a Joint Cooperation between the Charité and the Max-Delbrück Center for Molecular Medicine (MDC); [2]MDC; [3]3INSERM U-1100/EA-6305 Univ Francois Rabelais; [4]Nephrology and Intensive Care Medicine, Campus Virchow.*

**Background:** Active neutrophil serine proteases (NSPs) are released from neutrophils during inflammation and participate in vascular diseases, including ANCA vasculitis. NSPs consist of proteinase 3 (PR3), human neutrophil elastase (HNE) and cathepsin G (CG). We hypothesized that enzymatically active NSPs are acquired by endothelial cells (EC) and exert common, but also distinct cleavage patterns towards EC substrates.

**Methods:** We used western blotting, flow cytometry, confocal microscopy and Boc-Ala-Pro-Val substrate assay to monitor NSP transfer from neutrophils to EC and terminal-amine isotopic labeling of substrates (TAILS) for substrate characterization.

**Results:** Activated neutrophils released enzymatically active NSPs into the supernatant and this activity was transferred to EC. EC acquired Alexa488-labeled purified NSPs in a time- and concentration-dependent mannor by flow cytometry and confocal microscopy. Importantly, PR3 showed diffuse cytoplasmic staining whereas HNE and CG localized to granular compartments. Approximately 3,000 potential substrates for NSPs were suggested using peptide model libraries. Employing TAILS, active NSPs, and endothelial cell lines we identified native substrates: 93 for PR3, 48 for HNE and 65 for CG. Clustering the substrate sequences showed characteristic extended recognition patterns. PR3 cleaved after valine and isoleucine with an unpolar amino acid (aa) cluster upstream and an acidic cluster downstream of the cleavage site. HNE cleaved after isoleucine or valine with acidic aa upstream and hydrophobic aa downstream, and CG showed a leucine or phenylalanine residue at the cleavage site with downstream aliphatic amino acids.

**Conclusions:** Thus, our data indicate distinct specificities and cellular localization of the three NSPs suggesting distinct biological effects towards EC. The findings could be of therapeutic relevance in inflammatory vascular diseases.

## TH-PO918

**Different Functions of Soluble and Membrane-Bound TNF in Nephrotoxic Serum Nephritis** Martin B. Müller, John M. Hoppe, Andrei Bideak, Nuru Eltrich, Volker Vielhauer. *Nephrologisches Zentrum, Medizinische Klinik und Poliklinik IV, Ludwig-Maximilians-Univ, Munich, Germany.*

**Background:** TNF is a proinflammatory cytokine mediating inflammatory renal diseases such as immune complex glomerulonephritis. The two receptors TNFR1 and TNFR2 play distinct roles in this process, with TNFR2 strongly required for induction of disease. TNFR2 is predominantly activated by membrane-bound TNF (memTNF), but not soluble TNF (solTNF). Thus, we examined the functional role specifically of memTNF in heterologous nephrotoxic serum nephritis (NTN).

**Methods:** NTN was induced by i.v. injection of anti-GBM sheep serum into C57BL/6 wild-type and memTNF knock-in mice with two uncleavable Δ1-9, K11E TNF alleles, which express memTNF, but no solTNF (memTNF mice). At day 5 functional renal parameters, renal histology, leukocyte infiltrates and cytokine production were analysed in the two groups. In addition, we performed stimulation experiments in vitro with glomeruli isolated from wild-type and memTNF mice.

**Results:** NTN induced in memTNF mice was exacerbated compared to wild-type, indicated by increased albuminuria, higher serum levels of urea and more severe glomerulosclerosis and tubular cell injury. Surprisingly, this was accompanied by significantly lower renal leukocyte infiltrates in memTNF mice and correlated with reduced renal mRNA expression of inflammatory chemokines and cytokines. Decreased cytokine production was also present in isolated mTNF glomeruli stimulated with LPS or IL-1β, demonstrating that absent solTNF in the presence of intact mTNF decreases production of proinflammatory mediators in intrinsic glomerular cells.

Furthermore, wild-type mice treated with the TNF antagonist etanercept during NTN exhibited decreased renal leukocyte infiltrates comparable to untreated and treated memTNF mice. This identifies solTNF as a major mediator of renal leukocyte recruitment.

**Conclusions:** In summary, we demonstrate that soluble TNF predominantly mediates renal leukocyte recruitment, whereas uncleaved memTNF is an important inflammatory mediator of renal tissue damage in murine glomerulonephritis. These findings underline the importance of memTNF in inflammatory kidney disease as a possible therapeutic target.

## TH-PO919

**Kinin B1 Receptor Deficiency Abrogates Induction of Anti-Myeloperoxidase Induced Crescentic Glomerulonephritis in Mice** Peiqi Hu, Hong Xiao, Masao Kakoki, Ronald J. Falk, J. Charles Jennette. *Pathology and Laboratory Medicine, Univ of North Carolina, Chapel Hill, NC.*

**Background:** Anti-myeloperoxidase (anti-MPO) IgG causes crescentic glomerulonephritis (CGN) in mice that is a model for human CGN caused by ANCA (anti-neutrophil cytoplasmic autoantibodies). Neutrophils play a critical role in CGN induction in this model. The B1 and B2 receptors, two G-protein-coupled kinin receptors, are expressed on neutrophils and involved in modulation of neutrophil functions including neutrophil migration, activation and apoptosis. In this study, we investigated the role of these kinin receptors in anti-MPO induced CGN.

**Methods:** Anti-MPO IgG was purified from the sera of MPO-/- mice that had been immunized with murine MPO. Mice with knock out B1 receptor (B1 KO) and knock out of both B1 and B2 receptors (B1/B2 KO), and normal wild-type C57BL/6j mice (WT B6) were injected i.v. with 50ug/g body weight anti-MPO IgG. Circulating anti-MPO IgG was monitored by ELISA. Proteinuria, hematuria and leukocyturia were monitored, and mice were sacrificed at day 6 and kidney tissue obtained for pathologic examination.

**Results:** At day 6, all 3 groups of mice that received anti-MPO IgG showed similar levels of circulating anti-MPO. All WT B6 mice developed hematuria and CGN (mean 12% glomeruli with crescents). In contrast, B1 KO mice and B1/B2 KO mice had normal urine and less CGN with mean 1% crescents in B1 KO mice (p=0.01 compared to WT) and 2% crescents in B1/B2 KO mice (p=0.01 compared to WT).

**Conclusions:** Absence of the B1 receptor ameliorates anti-MPO induced CGN. Slightly more severe CGN induction in B1/B2 KO mice than B1 KO mice suggests that B2 receptor may modulate the B1 effect, but additional studies are needed to clarify this. Kinin B1 receptors play an important role in the pathogenesis of CGN induced by anti-MPO antibodies, probably by recruitment and activation of neutrophils. Antagonists of kinin B1 receptors may have a therapeutic role in ANCA disease.

## TH-PO920

**19F-MRI for Noninvasive Visualization of Renal Inflammation in a Murine ANCA-Induced Glomerulonephritis Model** Adrian Schreiber,[1,2] Ralph Kettritz,[1,2] Min-Chi Ku,[3] Helmar Waiczies,[3] Sonia Waiczies,[3] Thoralf Niendorf,[3] Andreas Pohlmann.[3] *[1]Experimental and Clinical Research Center, Max Delbrück Center for Molecular Medicine, Berlin, Germany; [2]Clinic for Nephrology and ICU, Medical Faculty of the Charité, Berlin, Germany; [3]Berlin Ultrahigh Field Facility (BUFF), Max Delbrück Center for Molecular Medicine, Berlin, Germany.*

**Background:** ANCA-activated neutrophils and monocyte cause necrotizing crescentic glomerulonephritis (NCGN). Renal inflammation is assessed in patients biopsies or in murine kidneys after animals were sacrificed. Non-invasive methods with potential for serial studies are needed. We tested the hypothesis that 19F-MRI visualizes renal inflammation in a murine ANCA-induced NCGN model.

**Methods:** 19F MRI.

**Results:** First we studied 19F labeling and tracking of neutrophils and monocytes in a murine thioglycolate peritonitis model. 19F-nanoparticles (100ul, 50mM, 153nm) were injected i.v., cells harvested from the peritoneal cavity (4h for neutrophils, 48h for monocytes), and the 19F-MR signal was assessed by MR spectroscopy. Monocytes were more efficiently labeled compared to neutrophils (neutrophils 2.7±0,2 AU vs. monocytes 25.8±3.2 AU). Next, a murine bone-marrow (BM) transplantation model of ANCA-induced NCGN was employed. 8 weeks after BMTx mice showed severe NCGN with 17.4±3.5% crescents and 9.9±1.8 necrosis (n=9). Immunohistochemistry demonstrated monocyte (0.35±0.23 cells/glomerulus) and neutrophil infiltration (0.10±0.05 cells/glomerulus). 9.4T MR revealed a renal 19F-signal in all animals of the experimental group, a much weaker signal in the control BMTx group and no signal in unchallenged mice. Ex vivo MR-analysis indicated a strong cortical signal pattern. Clinical application requires efficient 19F-nanoparticle uptake by human myeloid cells. Phagocytosis of 19F-DiL-fluorescence nanoparticle showed stronger ingestion by human monocytes compared to neutrophils (monocytes: 455±119 MFI in whole blood and 290±96 MFI in isolated cells; neutrophils: 331±107 MFI in whole blood and 94±44 MFI in isolated cells).

**Conclusions:** Our data suggest that 19F-MRI provides a non-invasive method to monitor renal inflammation in animal models and in patients with ANCA-induced NCGN.

## TH-PO921

**Tissue-Type Plasminogen Activator Promotes Macrophage Mobility through a Novel Signaling Cascade** Ling Lin, Kebin Hu. *Dept of Medicine, Penn State Univ College of Medicine, Hershey, PA.*

**Background:** Macrophage accumulation in the renal interstitium is one of the hallmarks of progressive kidney disease. Our recent work discovered that tissue-type plasminogen activator (tPA) promotes macrophage infiltration and renal inflammation in a model of chronic kidney injury. However, the underlying mechanism remains largely unknown.

**Methods:** We investigated the role of tPA in macrophage mobility and elucidated the underlying signaling mechanism using both in vitro and in vivo approaches.

**Results:** It was found that tPA promoted macrophage migration through its protease-independent function. tPA activated focal adhesion kinase (FAK) and Rac-1 signaling in macrophages in a temporal order. Both FAK and Rac-1 were indispensable to tPA-induced macrophage migration as either infection of macrophages with FAK dominant-negative inhibitor adenovirus or pretreatment of macrophages with Rac-1-specific inhibitor abolished the effect of tPA. We also investigated the role of tPA in macrophage mobility in vivo. Macrophages derived from bone marrow were labeled by fluorescence and adoptively transferred into tPA knockout and wild-type mice, followed by unilateral ureteral obstruction for 7 days. It was found that the number of infiltrated fluorescence-labeled macrophages in the obstructed kidneys from tPA deficient mice was significantly less than that from the wild-type mice. In addition, tPA knockout mice displayed reduced Rac-1 activity in comparison with their wild-type counterparts.

**Conclusions:** Therefore, it is clear that tPA promotes macrophage migration through a novel signaling cascade involving FAK and Rac-1 pathway.

## TH-PO922

**Uric Acid-Induced NLRP3 Inflammasome Contribute to Diabetic Kidney Injury** Su-Mi Kim, Kyung Hwan Jeong, Sang Ho Lee, Chun-Gyoo Ihm, Ju Young Moon. *Div of Nephrology, Dept of Internal Medicine, Kyung Hee Univ, College of Medicine, Seoul, Korea.*

**Background:** Despite of the fact that hyperuricemia is frequently found in a diabetic nephropathy, the definite cause and effect between hyperuricemia and kidney injury have not well investigated yet. Recently, reports showed IL-1β secreting NLRP3 inflammasome in cytoplasm plays a role as a sensor of the innate immune injury in metabolic disease. Therefore, we investigated the cause and effects of hyperuricemia and kidney injury in diabetic nephropathy to demonstrate the role of NLRP3 inflammasome in uric acid-induced kidney injury in diabetes.

**Methods:** We designed four animal groups as following; 1) LETO (Long Evans Tokushima Otsuka); 2) OLETF (Otsuka Long Evans Tokushima Fatty); 3) OLETF + HFD (high fructose diet) for 16 weeks; 4) OLETF + HFD + allopurinol (10mg/dL in drinking water). HK-2 (Human renal proximal tubule cells) and THP1 (Human acute monocytic leukemiacell line) were cultured and stimulated with uric acid.

**Results:** OLETF + HFD group showed a higher serum uric acid ($1.4 \pm 0.1$ vs $2.2 \pm 0.4$ mg/dL) and urinary albumin creatinine ratio ($350 \pm 72$ vs $594 \pm 102$ μg/mg) than OLETF group. In the OLETF + HFD group, the increase trend of NLRP3 and IL-1β expression in kidney was observed. Immunohistochemical staining of $CD68^+$ cells showed significant increase in HFD group compared to OLETF group. Allopurinol attenuated HFD induced hyperuricemia and NLRP3 activation-related renal inflammation. Uric acid-induced NLRP3 activation and IL-1β secretion in THP1 cells were also observed. During the THP1 and HK-2 co-culture it is confirmed that IL-1β secreted in THP1, plays a pivotal role in activating IL-1βR1, MyD88 and IRAK4 signaling in HK-2 cells. This up-regulated IL-1βR1 signaling was resulted in NF-κB activation in HK-2 cells.

**Conclusions:** According to these results we can conclude that hyperuricemia activates NLRP3 inflammasome of macrophage and contribute in renal injury by secretion of IL-1β.

## TH-PO923

**Phenotype Transition of Endothelial Cells with an Activation of NRLP3 Inflammasome by Globotriaosylceramide (Gb3) in Fabry Mice Kidney** Yea-Jin Choi, Hyun-Soo Shin, Kyu Bok Choi, Duk-Hee Kang. *Div of Nephrology, Ewha Womans Univ School of Medicine, Seoul, Republic of Korea.*

**Background:** The lysosomal storage disorder Fabry disease is characterized by Gb3 accumulation in kidney. Defective lysosomal alpha-galactosidase A is responsible for Gb3 accumulation, and vascular endothelium is one of the sensitive cells to the effects of Gb3 accumulation. Recently, NLRP3 inflammasome activated by cellular signals is known to play a role in endothelial dysfunction and renal fibrosis. We aimed to investigate whether Gb3 induced phenotype transition of endothelial cells and activated NLRP3 inflammasome in endothelial cells and Fabry mouse.

**Methods:** Endo-MT was evaluated by the changes in morphology and a comparison of the expression of the endothelial markers, VE-cadherin or CD31 and the mesenchymal marker, α-SMA by real time PCR, WB and ICC in HUVEC exposed to Gb3. Activation of inflammasome was evaluated by real time PCR of NLRP3 and ASC. Effects of recombinant Gla (rGla), anti-oxidant and NO donor on Gb3-induced Endo-MT were investigated. Endo-MT in the kidney of Fabry mouse was examined by double IHC of CD31 and α-SMA.

**Results:** HUVEC with Gb3 (0-40 μM) down-regulated the expression of CD31 and VE-cadherin with an up-regulation of α-SMA in a dose-dependent manner. Gb3 induced a differential phosphorylation of $^{S1177}$eNOS and $^{T495}$eNOS in HUVEC with a decrease in NO production. Gb3 also activated NLRP3 and ASC expressions. rGla or N-acetyl cysteine ameliorated Gb3-induced endo-MT and NLRP3 inflammasome. Although NO donor inhibited Gb3-induced endo-MT, the expression of NLRP3 and ASC was not altered by NO donor. In Fabry mouse, Gb3 accumulation was observed in glomular podocyte, tubular cell and peri-tubular capillaries (PTC) with vacuolar generation in renal tubules. Immunostaining with CD31 and α-SMA revealed capillary rarefaction both in glomerular and PTC with de-novo expression of α-SMA in PTC, suggesting endo-MT in the kidney of Fabry mouse.

**Conclusions:** These findings suggested that Gb3 induced a phenotypic transition of endothelial cells and the activation of NLRP3 inflammasome, which could be the mechanisms of Gb3-induced endothelial dysfunction and nephropathy in Fabry disease.

## TH-PO924

**Lactoferrin Is a Suppressor of Neutrophil Extracellular Traps in Inflammation** Koshu Okubo,[1] Masaomi Nangaku,[1] Toshiro Fujita,[2] Junichi Hirahashi.[1] *[1]Graduate School of Medicine, The Univ of Tokyo, Bunkyo, Tokyo, Japan; [2]Div of Clinical Epigenetics Research Center for Advanced Science and Technology, The Univ of Tokyo, Meguro, Tokyo, Japan.*

**Background:** Neutrophils are endowed with microbicidal functions including phagocytosis, degranulation and neutrophil extracellular traps (NETs), recently identified web-like structures composed of chromatin fibers and serine proteases that protect against invading pathogens. On the other hand, NETs are associated with the development of autoimmune and/or inflammatory diseases and thrombosis. We found that lactoferrin(Lf), one of the components of NETs, is a suppressor of NET formation.

**Methods:** We isolated neutrophils from healthy donors for assay of NET formation. To silence the expression of Lf, we treated Human Leukemia-60 cells with Lf small interference RNA. We observed NET formation under a confocal microscopy with time lapse analysis. We utilized two fluorescence probes, HPF and HySOx, to hydroxyl radical and hypochlorous acid, respectively, to examine the effects of Lf on reactive oxygen species(ROS) generation during NETosis. Spontaneous model of autoimmune small-vessel vasculitis(SCG/kj), localized Shwartzman reaction(LSR), and the model of immune complex(IC)-induced NET formation in the cremaster muscle were used.

**Results:** Lf translocated from the cytoplasm to the inner plasma membrane of neutrophils and suppressed NET formation without effects on ROS upon stimulation. Furthermore exogenous Lf shrunk the chromatin fibers in the released NETs and bound to NETs through charge-charge interaction. In SCG/kj mice plasma DNA release and ANCA titer were decreased and the survival rate improved in Lf-treated mice. Subcutaneous bleeding in LSR decreased, and thrombus and erythrocytes extravasation were less in Lf-treated mice. Furthermore, Lf suppressed the IC-induced NET formation. These observations suggest that Lf serves as an intrinsic inhibitor of NETs and prevents DNA release into the circulation.

**Conclusions:** We found that Lf suppresses NET formation and DNA release into the circulation in inflammation. Our data indicated that Lf may represent a therapeutic lead for controlling NET release in autoimmune and/or inflammatory diseases.

## TH-PO925

**Potential Immunological Role of Renal Intercalated Cells via the P2Y14 Receptor** Anie Azroyan, Virna F. Cortez-Retamozo, Ye Chun Ruan, Mikael Pittet, Dennis Brown, Sylvie Breton. *Program in Membrane Biology, Center for Systems Biology, Nephrology Div, Massachusetts General Hospital, Harvard Medical School, Boston, MA.*

**Background:** Epithelial cell injury leads to inflammation in the kidney. UDP-glucose is a damage-associated molecular pattern (DAMP) molecule that is released from injured cells and signals through the P2Y14 receptor to initiate the release of pro-inflammatory chemokines (PIC).

**Methods:** Immunofluorescence (IF) labeling was used to examine the expression of P2Y14 in mouse kidney sections. Downstream effectors of P2Y14 were analyzed by RT-qPCR and IF in the MDCK-C11 cell line and in intercalated cells (ICs) isolated by FACS from B1-EGFP mice. Infiltration of immune cells in the kidney was assessed by flow cytometry.

**Results:** We showed high expression of P2Y14 specifically in intercalated cells (ICs), identified by their positive labeling for the V-ATPase B1 subunit. RT-qPCR showed P2Y14 mRNA expression in FACS-isolated EGFP-positive ICs, but not in EGFP-negative cells. In vitro stimulation with UDP-glucose increased ERK-phosphorylation (p-ERK) and up-regulated PIC mRNA transcripts in isolated EGFP-positive ICs (CXCL1, CXCL2, CCL2 and CCL3) and in MDCK-C11 cells (IL8, CCL2). Inhibition of p-ERK with a MEK1 inhibitor prevented the UDP-glucose-dependent PIC mRNA increase in MDCK-C11 cells. Tail vein injection of mice with UDP-glucose increased ERK phosphorylation and PIC mRNAs in ICs isolated by FACS after 4 hours, and induced an increased infiltration of neutrophils into the renal medullary regions surrounding collecting ducts after 48 hours.

**Conclusions:** In summary, our data provide evidence for the participation of ICs as DAMP sensors via P2Y14, and indicate the role of ICs as novel mediators of inflammation in the kidney.

## TH-PO926

**Estradiol Reduces Ischemic Renal Atrophy in the 2K1C Model in Female ApoE KO Mice** Carolyn M. Ecelbarger, Chelsee Holloway, Nikhil Sharma, Hong Ji, Kathryn Sandberg, Lijun Li. *Dept of Medicine, Georgetown Univ, Washington.*

**Background:** The incidence of atherosclerosis increases in post-menopausal women likely as the result of the fall in circulating estradiol ($E_2$) levels, although the mechanisms remain obscure. The two-kidney, one clip model (2K1C) of renal ischemia has been demonstrated to lead to marked systemic inflammation in the Apoliprotein E (ApoE) knockout (KO) mouse, a mouse model of atherosclerosis. We aimed to elucidate the protective effects of $E_2$ on kidneys in the 2K1C Apo E KO mouse.

**Methods:** Left renal artery incomplete ligation (LRAL) was performed on 12-week-old, female ApoE KO mice. In the same surgery, mice were ovariectomized (OVX) and physiologically replaced with 17ß estradiol ($E_2$, 2µg/day, slow-release pellet) or placebo pellet (P, n = 6/group). Urine (24-hour) was collected in mouse metabolic cages. Kidneys, blood, liver, and vasculature were obtained at euthanasia after 60 days. Histology was done on fixed tissue sections and blinded sections scored for analysis.

**Results:** $E_2$ replacement did not lead to differences in final body weight (BW, g): 24.5 ± 0.4 (OVX + P) versus 23.7 ± 0.5 (OVX + $E_2$), p = 0.22. However, left kidney (LK) atrophy was markedly attenuated by $E_2$ (LKW, g): 0.058 ± 0.016 (OVX + P) versus 0.125 ± 0.017 (OVX + $E_2$), p = 0.018. In contrast, the contralateral right kidney was similarly sized in both groups (RKW, g): 0.185 ± 0.008 (OVX + P) versus 0.185 ± 0.018 (OVX + $E_2$), p = 0.97. Urine volume (24-hour) was also significantly higher (~30%) in the $E_2$-treated mice, p = 0.007. Semi-fasting (4-hour fast) glucose levels were: 150 ± 6 and 121 ± 13 in the OVX + P and OVX + $E_2$ respectively, not significantly different, p = 0.07. In addition, $E_2$ reduced qualitative indices of renal damage including glomerular injury, tubular atrophy, interstitial fibrosis and interstitial inflammation, with lymphocyte and macrophage infiltration in the LK, as compared to placebo-treated mice.

**Conclusions:** $E_2$ replacement to OVX female ApoE KO in 2K1C mice significantly attenuated atrophy and renal injury due to ischemia. We suggest these differences might result from alterations in inflammatory cascades and/or differential blood pressure control.

*Funding:* Private Foundation Support

## TH-PO927

**Extracellular Histones Drive the Progression of Inflammation and Crescent Formation in Necrotizing Glomerulonephritis** Santhosh Kumar VR, Onkar Kulkarni, Shrikant R. Mulay, Dana Thomasova, Murthy Narayana Darisipudi, Hans J. Anders. *Klinische Biochemie, Universität München, Munich, Bavaria, Germany.*

**Background:** Crescentic glomerulonephritis is characterized by extensive glomerular necrosis. Dying cells release intracellular proteins that act as DAMPs to activate innate immunity. Earlier we demonstrated that dying tubular cells release histones which drive tubulointerstitial inflammation in septic or post-ischemic AKI by activating TLR2/4. Here we speculated that extracellular histones also elicit similar pathogenic effects in necrotizing glomerulonephritis.

**Methods:** Necrotic glomerulonephritis was induced in mice by single i.v. injection of 100µl of anti-GBM serum. Effect of histone neutralisation was evaluated on day7.

**Results:** Anti-GBM treated mice show increased proteinuria, plasma creatinine and BUN levels. This was associated with reduced number of podocytes, increased crescentic glomeruli and infiltration of neutrophils/macrophages in kidney. Neutralization of extracellular histones significantly reduced proteinuria with significant less damage to podocytes. This was associated with improved renal function defined by lower plasma creatinine and BUN levels. Also improved renal inflammation marked with less infiltration and activated neutrophils/ macrophages in kidney. Histone blockade also significantly reduced renal mRNA expression of TNFα and reduced fibrinogen in glomerular capillaries, which was associated with less glomerulosclerosis, crescents and tubular atrophy. In contrast, the autologous variant of the Anti-GBM model that lack necrotizing glomerular lesions did not benefit from anti-histone antibody treatment. In-vitro studies demonstrated that, stimulation of BMDCs with histones significantly increased the TNFα and IL6 levels. Histones show dose dependent cytotoxic effect on GEnC and increased podocyte detachment. Neutralization of histones reverses these cytotoxic effects.

**Conclusions:** We conclude that the release of histones from dying glomerular cells contribute to renal immunopathology and dysfunction during crescentic glomerulonephritis. This may either relate to their direct toxic effects on endothelial and epithelial cells or potential to activate innate immunity via TLR2/4.

## TH-PO928

**LPS-Induced Delayed Preconditioning Is Mediated by Hsp90 and Involves the Heat Shock Response** Peter Hamar,[1] Mária Godó Godó,[1] Csaba Revesz,[1] Miklos M. Mozes,[1] Tamás Kaucsár,[1] Csaba S?ti.[2] *[1]Institute of Pathophysiology, Semmelweis Univ, Budapest, Hungary; [2]Dept of Medical Chemistry, Semmelweis Univ, Budapest, Hungary.*

**Background:** The kidney is an important shock organ, often beeing responsible for the death of septic patients. We and others demonstrated previously that endotoxin (LPS) pretreatment protected from subsequent lethal LPS or from ischemia-reperfusion injury (IRI) of the kidney. The heat shock response is an ancient and essential cellular defense mechanism, which plays a role in resistance to, and recovery from, diseases. The major heat shock protein Hsp90 is as a constituent of the LPS receptor. Here, by using the specific pharmacological inhibitor novobiocin, we investigated the role of Hsp90 and the heat shock response in this delayed-type cross-tolerance model.

**Methods:** Male C57/Bl6 mice were treated with preconditioning (p: 2 mg/kg) LPS alone (p) or in combination with subsequent lethal (p+L: 10 mg/kg) dose of LPS alone (LPS(L)) or in combination with novobiocin (NB: 100 mg/kg) (LPS(p)+NB, NB+LPS(L), LPS/NB+LPS(L)). Controls received saline (C) or NB withouth LPS (NB). Survival and renal HSP expresion were determined.

**Results:** Preconditioning LPS conferred protection from a subsequent lethal LPS treatment. LPS induced a marked heat shock response as demonstrated by Northern and Western blots of Hsp70 and Hsp90 mRNA and protein levels, respectively. Importantly, the protective effect of LPS-preconditioning was completely abolished by a concomittant NB treatment. NB also stimulated Hsp70 and Hsp90 mRNA expression, however, both Hsp proteins were significantly downregulated in NB-treated mice. Similarly, heat shock protein induction in LPS-treated mice was abolished by a concomittant NB treatment, demonstrating a NB-induced impairment of the heat shock response to LPS preconditioning.

**Conclusions:** LPS-induced heat shock protein induction and endotoxin tolerance to a subsequent lethal LPS treatment was prevented by novobiocin. Our findings demonstrate a critical role of Hsp90 and a potential involvement of the heat shock response in LPS-induced delayed preconditioning. Funding: OTKA, K 81972.

## TH-PO929

**Genetic Susceptibility to Experimental Autoimmune Glomerulonephritis** Stephen Paul McAdoo, Zelpha D'souza, Jacques Behmoaras, Frederick W.K. Tam, H. Terence Cook, Charles D. Pusey. *Imperial College London.*

**Background:** The WKY rat strain is susceptible to experimental glomerulonephritides, including nephrotoxic nephritis (NTN) and experimental autoimmune glomerulonephritis (EAG), whereas the LEW strain is resistant. In previous studies by our group, genome-wide screening identified a QTL on Ch13 (crgn1) linked to disease severity in both models. A QTL on Ch16 (crgn2) was additionally linked to disease severity in NTN. We have previously shown that introgression of LEW.crgn1 onto a WKY background conferred partial protection from disease in EAG. We sought to (1) examine the additional effect of introgressing LEW.crgn2 onto a WKY background in this model, and (2) establish if susceptibility to EAG could be conferred to LEW rats by co-introgression of WKY.crgn1 and WKY.crgn2 to a LEW background.

**Methods:** Reciprocal double-congenic (DC) rats were generated - LEW.DC (LEW.WKYcrgn1,2) and WKY.DC (WKY.LEWcrgn1,2) - and immunized with recombinant rat α3(IV)NC1, and assessed for EAG development.

**Results:** Summarised in the table below, at day 28 after disease induction. Expressed as mean/group. Statistical analysis was by one-way ANOVA with Newman Keuls Comparison test.

| | WKY | WKY.DC | p value (WKY v WKY.DC) | LEW | LEW.DC | p value (LEW v LEW.DC) |
|---|---|---|---|---|---|---|
| Proteinuria (mg/day)* | 90 | 8 | <0.05 | 0 | 0 | ns |
| % Crescents* | 76 | 16 | <0.05 | 0 | 0 | ns |
| Macrophages/glomerulus* | 14 | 4 | <0.05 | 1 | 0 | ns |
| Anti-GBM antibody (au)** | 195 | 312 | ns | 144 | 143 | ns |

ns=not significant

**Conclusions:** Additional introgression of LEW.crgn2 onto a WKY background confers greater protection from EAG than seen with LEW.crgn1 alone (Reynolds *et al*, Am J Pathol 2012). This confirms our previous observations in NTN, and highlights the importance of macrophage activation (regulated by crgn2) in these models, and as a potential therapeutic target. Despite making similar levels of anti-GBM antibodies at WKY rats, LEW.DC did not develop disease, suggesting that additional genetic factors contribute to disease susceptibility in the parental WKY rat in this model.

## TH-PO930

**Potential Role of Lysophosphatidic Acid in HIV-Induced Tubular Cell Microcyst Formation** Kamesh R. Ayasolla, Partab Rai, Tejinder Singh, Ashwani Malhotra, Guohua Ding, Praveen N. Chander, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, New York, NY.*

**Background:** HIV-associated nephropathy is characterized by microcyst formation and collapsing glomerulopathy. Lysophosphatidic acid (LPA) and its receptors (LPA1-4) have been implicated in the tubular cell fibrosis (TIF) and cyst formation in autosomal dominant polycystic kidney disease (ADPKD). We hypothesized that LPA might be contributing to tubulointerstitial lesions in HIV milieu.

**Methods:** Primary human proximal tubular cells (HRPTCs) were transduced with either empty vector or HIV (NL4-3). C/HRPTCs, EV/HRPTCs, and HIV/HRPTCs were incubated in media containing either buffer, Ki 16425 (LPA inhibitor), AACOCF3 (LPA synthesis blocker) or DAG kinase inhibitor for 24 hours (n=3). Subsequently, protein blots were probed for TGF-β, cTGF, α-SMA, fibronectin, collagen Ia, III, and IV. The same blots were reprobed for actin. Since Integrin Linked Kinase (ILK-1), focal adhesion kinase (FAK), and G–protein coupled receptor (GPCR) serve as molecules involved in intermediate signaling leading to upregulation and enhanced binding of NFkB, we evaluated expression of these molecules on tubular cell injury in LPA/HIV milieu.

**Results:** Both LPA and HIV milieus altered tubuar cell expression of cTGF, a-SMA, collagen I, III, IV and fibronectin. HIV/HRPTCs also displayed enhanced expression of p-ILK-1, p-FAK, pPI3K,p-Akt, and pP38 MAPK. Moreover, HIV enhanced increased transcriptional binding activity of NF-kB in HRPTCs; however, LPA inhibitors attenuated these effects of HIV.

**Conclusions:** Lysophosphatidic acid may be contributing to HIV-induced tubular cell injury.

### TH-PO931

**Protective Effect of Valproic Acid on Adriamycin-Induced Nephropathy by Regulation of Histone Acetylation** Qin Dai, Jian Liu, Fang Zhong, Lili Xu, Weiming Wang, Nan Chen. *Dept of Nephrology, Ruijin Hospital, Shanghai Jiao Tong Univ, Shanghai, China.*

**Background:** Inflammation and podocyte injury are involved in glomerulosclerosis. Histone acetylation takes a part in the renal disease. In the study, we explored whether HDAC inhibitor valproic acid (VPA) has a protective role in the adriamycin-induced nephropathy (ADN) and podocyte injury.

**Methods:** VPA were administered for 6 weeks after ADN modelling. Serum creatinine, urine creatinine, urinary protein, the total acetylation level of histone H3,H4 and mRNA of CTGF, PAI-1, COL-I, COL-III in the renal tissue were measured .Histone acetylation levels were detected by ELISA. HDAC2 and EP300 mRNA expression were detected by realtime-PCR methods. Renal immflamtion were assesed by evaluating MCP-1, STAT3, suppressor of cytokine signaling-1 (SOCS-1) and SOCS-3 changes in the renal cortex by realtime-PCR. ChIP - qPCR was used to detect H3 and H4 acetylation levels in the promoter of MCP-1 and STAT3. Mouse podocytes were cultured to investigate the in vitro effect of VPA against ADR-induced injury, which were detected by MTS assay, scratch wound assay and F-actin changes. ChIP-qPCR and realtime-PCR were applied to explore the histone acetylation of the MCP-1 and integrin-linked kinase (ILK) and mRNA expression.

**Results:** Compared with ADR group, urinary albumin/creatinine was decreased significantly in VPA group ($P<0.05$); serum creatinine, urinary albumin/creatinine, the total level of histone H3, H4 acetylation, the expression of mRNA of CTGF, PAI-1, COL-III were decreased significantly ($P<0.05$) in renal tissue in VPA group. VPA intervention could reduce glomerulosclerosis, change histone acetylation levels and the expression of HDAC, HAT and inflammatory cytokines. VPA could change the MCP-1 expression by regulating the SOCS-1 and SOCS-3 expression.VPA intervention can reduce podocyte death induced by ADR, increased podocyte proliferation, reduce podocyte motility and improve the structural changes of podocytes.

**Conclusions:** Histone acetylation modification participates in the process of glomerular sclerosis, and regulation of histone acetylation may be a promising mean of intervention in progression of kidney disease.

### TH-PO932

**Interferon Regulatory Factor-4 (IRF-4) Prevents Chronic Kidney Disease after Acute Kidney Injury by Modulating Innate Immunity** Falk Bernhard Batz, Maciej Lech, Georg Lorenz, Heni Susanti, Nora Stigrot, Hans J. Anders. *Clinical Biochemistry, Medizinische Klinik und Poliklinik IV, LMU, München Univ of Munich, Munich, Bavaria, Germany.*

**Background:** Acute kidney injury (AKI) is defined as a rapid decrease in the glomerular filtration rate with an accumulation of serum urea and creatinine. If patients recover from AKI they are still at a greater risk of developing a chronic kidney disease, probably due to incomplete regeneration and persistent renal inflammation. Cells of the innate immune system such as macrophages and dendritic cells play a crucial role in initiating the inflammatory responses and the healing of the tubular compartment. IRF-4 is an immune cell specific regulatory transcription factor which suppresses the TLR-signaling by competitive blocking of the IRF-5 binding site. We hypothesize that genetic factors such as IRF-4, which regulate the activation state and subtype of renal macrophages, have influence on inflammatory processes and regeneration after AKI.

**Methods:** We induced AKI by transient unilateral renal artery clamping for 45min (ischemia/reperfusion kidney surgery) in wild type (WT) and IRF-4 knockout mice (IRF4 -/-). After 5 weeks of IR injury, we evaluated kidney size, histology, inflammatory markers and fibrosis in a chronic phase.

**Results:** After 5 weeks, the IRF4-/- kidneys shrank to 1/3 of their original size due to a loss of proximal tubules. Atubular glomeruli occurred at high density and there were significantly more F4/80+ macrophages compared to the WT kidneys. In IRF4-/- kidneys the mRNA expression levels of proinflammatory and damage markers, also the number of CD11b+ Ly6Chigh cells, were significantly increased. In contrast, WT kidneys showed complete recovery from AKI, with maintained kidney size and improved histology and functional parameters.

**Conclusions:** We conclude that IRF4 suppresses the persistent activation of renal proinflammatory M1-macrophages upon transient renal ischemia. This inhibits intrarenal overexpression of the proinflammatory and proapoptotic cytokines and promotes the recovery of tubular injury. Thus, IRF4 is an important transcription factor for maintaining homeostasis during AKI.

### TH-PO933

**Role of Homeostatic Chemokine SDF1/CXCL12 in Glomerulosclerosis** Simone Romoli, Onkar Kulkarni, Hans J. Anders. *Nephrology Unit, Univ of Munich, Munich, Germany.*

**Background:** Stromal Derived Factor (SDF1) is a homeostatic chemokine, which promotes the homing of hematopoietic stem cells to the bone marrow and innate immune cells to the sites of tissue injury. Therefore, we investigated the role of SDF1 in acute glomerular disorders such as anti-GBM nephritis.

**Methods:** Anti-GBM nephritis was induced by single intravenous injection of anti-GBM serum in C57BL/6 male mice at 6-7 week of age. Anti-GBM injected mice were sacrificed for evaluation on day 2 (acute phase) and day 28 (late phase). Control mice received inactive inhibitor and treatment mice received anti-SDF1 (NOX-A, 50mg/kg s.c. Noxxon), thrice a week. Murine immortalized renal progenitor cells (mPECs) and human PECs (hPECs) were used for in-vitro cell culture studies. In-vivo activity was evaluated by histology,ELISA,FACS,qRT-PCR.

**Results:** Anti-GBM serum induced proteinuria in a dose dependent manner in C57BL/6 mice. Treatment with NOX-A significantly reduced the proteinuria levels at acute phase compared to inactive inhibitor treated group. SDF1 blockade reduced the homing, migration and number of innate immune cells into the kidney during acute phase. After SDF1 blockade FACS analysis of peripheral blood showed an increased number of neutrophils and monocytes, while significant reduction in number of neutrophils and macrophages were detected in the kidney in the acute phase. Additionally, we observed a significantly less podocyte loss and reduction of glomerular lesions during acute injury in the treatment group. However, the SDF1 blockade did not affect the extent of proteinuria and renal histology at later phase of the disease. In-vitro, recombinant SDF1 markedly decreased the proliferation capability of mPECs as well as hPECs in MTT assay but drives the healing in scratch assay. SDF1 inhibited the differentiation of mPECs and hPECs.

**Conclusions:** Blocking SDF1 reduced the infiltration of neutrophils and macrophages into the kidney and inflammation during the acute phase of glomerular disease. Also we observed amelioration of the number of glomerular lesions and more number of podocytes in treatment group.Thus, SDF1 blockade is beneficial in acute phase of the Anti-GBM nephritis for actual mechanisms further studies are required.

### TH-PO934

**SCAP Is a Dual Regulator for Both Cholesterol Homeostasis and Inflammatory Stress in Macrophages and Renal Proximal Tubule Cells** Lung-Chih Li,[1,2] Xiong Z. Ruan.[1] [1]*Centre for Nephrology, John Moorhead Renal Research Laboratory, Centre for Nephrology, Univ College London (UCL), London, United Kingdom;* [2]*Nephrology Dept, Chang-Gung Memorial Hospital-Kaohsiung Medical Centre, Kaohsiung, Taiwan.*

**Background:** Both macrophages and renal proximal tubular cells play important roles in the progression of chronic kidney disease (CKD). Sterol regulatory element binding protein (SREBP) cleavage-activating protein (SCAP) is a cholesterol sensor that regulates LDL receptor (LDLr) and 3-hydroxy-3-methylglutaryl coenzyme A reductase (HMGCoAR) transcription and maintains the intracellular cholesterol homeostasis. The aim of this study is to investigate if SCAP regulates inflammatory response.

**Methods:** SCAP in PMA-activated THP-1 and HK2 cells was knocked down using siRNA or over-expressed by gene transfection. Intracellular cholesterol content was assessed by Oil Red O (ORO) staining and quantitative assay. The mRNA and protein expression of SCAP, pro-inflammatory cytokines, LDLr and HMGCoAR were examined by real-time quantitative RT-PCR and Western blotting. Nuclear p65, phosphorylated IκB and JNK were investigated.

**Results:** Over-expression of SCAP increased, while knockdown of SCAP decreased LDLr and HMGCoAR expression in both cells. Intracellular cholesterol content was significantly increased after over-expression of SCAP and remarkably reduced after knocking down SCAP. Interestingly, over-expression of SCAP also increased the pro-inflammatory cytokines IL-6 and TNF-α. LPS increased IL-6 and TNF-α expression as expected. However, knocking-down SCAP abolished the up-regulatory effects by LPS on IL-6 and TNF-α, accompanying with reduction of phosphorylation of IκB (rather than JNK phosphorylation) and nuclear p65 levels, indicating that SCAP mediates inflammatory response in THP-1 and HK2 cells via IκB phosphorylation.

**Conclusions:** SCAP is not only a cholesterol sensor but also a key regulator for inflammatory response in THP-1 and HK2 cells. SCAP may serve as a novel target for both lipid-lowering and anti-inflammatory therapies in renal diseases.

### TH-PO935

**Overexpression of Leukocyte Kv1.3-Channels Promotes Renal Fibrosis in Rats with Advanced Chronic Renal Failure** Itsuro Kazama. *Physiology I, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan.*

**Background:** Leukocytes, such as lymphocytes and macrophages, predominantly express delayed rectifier $K^+$-channels (Kv1.3), and the channels play crucial roles in the activation and proliferation of the cells. Since lymphocytes are activated in patients with end-stage renal disease (ESRD), the channels expressed in those cells would contribute to the progression of renal fibrosis in advanced stage chronic renal failure (CRF).

**Methods:** Male Sprague-Dawley rats that underwent 5/6 nephrectomy followed by a 14-week recovery period were used as the model of advanced CRF. Age-matched sham-operated rats were used as controls. Cellular proliferation of leukocytes and the expression

of Kv1.3-channels in the kidneys were examined. Histopathological features of the kidneys and the expression of cell cycle markers were also examined before and after treatment with margatoxin, a selective Kv1.3-channel inhibitor.

**Results:** In the cortical interstitium of advanced CRF rat kidneys, leukocytes proliferated *in situ* and overexpressed Kv1.3-channel protein in their cytoplasm. Treatment with margatoxin significantly suppressed the number of leukocytes and slowed the progression of renal fibrosis with a significant decrease in the cortical cell cycle marker expression.

**Conclusions:** This study demonstrated for the first time that the number of leukocytes was dramatically increased in rat kidneys with advanced CRF. The overexpression of Kv1.3-channels in the leukocytes was thought to contribute to the progression of renal fibrosis by stimulating cell cycling and promoting cellular proliferation.

*Funding:* Government Support - Non-U.S.

## TH-PO936

**Modulation of Endothelial Function Attenuates Kidney Fibrosis by Regulation of Soluble Epoxide Hydrolase** Jae-Yoon Park,[3] Jung Pyo Lee,[1] Seung Hee Yang,[2,3] Chun Soo Lim,[1] Yon Su Kim,[2,3] Yun Kyu Oh.[1] *[1]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea; [2]Seoul National Univ Kidney Research Institute, Seoul, Korea; [3]Dept of Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea.*

**Background:** Soluble epoxide hydrolase (sEH) in endothelial cells catalyses the degradation of epoxyeicosatrienoic acids (EETs), which may act as vasoactive agents to control vascular tone. Kidney fibrosis is the final common pathway for most progressive kidney diseases. Here we show that kidney fibrosis was reduced by regulation of sEH activity.

**Methods:** Unilateral ureteral obstruction (UUO) was used as a model of kidney fibrosis in C57BL/6 mice. sEH activity was controlled by continuous release of the sEH inhibitor 12-(3-adamantan-1-ylureido)-dodecanoic acid (AUDA) (8mg/kg/day) for 1 or 2 wks.

**Results:** AUDA treatment restored significantly improved tubulointerstital fibrosis. Fibroblast marker FSP-1 and TGFβ expressions were significantly decreased. sEH inhibition increased the expression of endothelial markers vWF, VE-cadherin, and CD31. On flow cytometric analysis, UUO increased FSP-1 positive cell population and AUDA treatment reduced CD 31 proportion in FSP-1 postive cell. Similarly, sEH inhibition reduced vWF/FSP-1 double positive cells. In an endothelial-to-mesenchymal transition (EndMT) in-vitro model using HUVECs, AUDA treatment restored the morphologic change and reduced the expression of FSP-1. Interestingly, AUDA-activated HUVEC significantly restored the epithelial-to-mesenchymal transition (EMT) of using tubular epithelial cell (TEC) in co-culture system using the Transwell™ system.

**Conclusions:** The results of this study suggest that direct inhibition of EndMT and indirect inhibition of EMT by treatment with sEH inhibitors may be an effective therapy for delaying the progression of fibrosis associated with CKD.

## TH-PO937

**Low Dose Lipopolysaccharide (LPS) Sensitizes Macrophages (MO) and Aggravates Inflammation: An Effect Blocked by Polymixin (PM) and Curcumin (CU)** Siddhartha S. Ghosh, Sam Righi, Todd W. Gehr. *Nephrology, VCU, Richmond, VA.*

**Background:** LPS has been seen in the circulation following high fat diet (HFD) in men and mice. Our studies have shown increased levels of plasma LPS in uremic mice and high fat diet fed mice. Although, the amount of LPS in circulation following HFD or uremia is too low to cause significant inflammation, studies demonstrate that both HFD and uremia are inflammatory disorders. To understand the mechanism we hypothesized that low levels of LPS sensitizes MO to toxins such as Palmitic acid (PA) from HFD and TNFα (from HFD & uremia) and elicits synergistic activation of NFkB.

**Methods:** MO cell line J774 was transduced with 5 MOI of adenovirus with NFkB promoter and luciferase reporter and adenoviral vector containing beta Gal as control. To see if PA or TNF have synergistic effect on the activation of NFkB by LPS, the cells were treated with 50 pg/ml of LPS (a dose which did not activate NFkB) and after 3 hours treated with 50 ng/ml of TNFα and/or 150 μM PA. In a separate experiment J 774 cells were treated with 50 pg/ml LPS to see if this dose could also increase TNFα in MO. TNFα mRNA was measured in MO by qPCR. PM which binds to LPS and CU (inhibits NFkB and reduces renal failure) were used as antagonists. The antagonists were added 2 hours before the addition of LPS.

**Results:** In the absence of LPS, TNFα and PA activated NFkB by 2 and 3 fold, respectively (P<0.05). However, in the presence of LPS the activation was 5 and 8 fold, respectively suggesting synergistic interaction. CU (10 μM) and PM (50μM) significantly inhibited NFkB activity (p<0.05). To understand the mechanism we incubated cells with low dose LPS and found that there was 4 fold increase (P<0.05) in TNFα mRNA in the MO after 18hrs.

**Conclusions:** Although high dose LPS can render MO resistant to LPS stimulation by downregulating TLR4, our study suggest that low dose LPS can potentiate the inflammatory effect of fatty acids and cytokines likely by sensitizing the MO and/or releasing TNFα. This can significantly potentiate inflammation. CU which also blocks TLR4 counteracts the sensitizing effect. Agents such as PM may be used to sequester and block the effect LPS mediated MO sensitization.

*Funding:* Private Foundation Support, Clinical Revenue Support

## TH-PO938

**Effect of Curcumin (CU) and Polymixin (PM) on Renal Failure and Glucose Intolerance in LDLR$^{-/-}$ ¾ Nephrectomy Mice** Siddhartha S. Ghosh, Shobha Ghosh, Todd W. Gehr. *Nephrology, VCU, Richmond, VA.*

**Background:** Uremia and high fat diet (HFD) alters gut microbiota and intestinal permeability resulting in the absorption of lipopolysaccharide (LPS). LPS aggravates inflammation which worsens renal function and promotes glucose intolerance. Our previous studies have shown CU ameliorates renal failure. Since CU is poorly absorbed we speculated that it can mediate its effect by altering the gut absorption of LPS. To examine this hypothesis we compared CU to a nonabsorbable antibiotic, PM, a known inhibitor of LPS.

**Methods:** LDLR-/- mice fed either normal chow or HFD underwent ¾ nephrectomy (Nx) (control,n=6; Control+Nx,n=6; HDF+Nx,n=6). All groups also received either CU (75 mg/kg,n=5) or PM (15 mg/L in drinking water,n=4).

**Results:** Creatinine (CR), BUN and urinary albumin excretion (ACR) was significantly elevated in Nx and Nx+HFD (p<0.01). The parameters shown in table were measured. CU and PM significantly reduced BUN and ACR in Nx and Nx+HFD (p<0.05). CR in all the groups was significantly reduced by CU (p<0.05) but not by PM. Cu and PM treatment significantly improved GTT, IL6 and TNFα in HFD,Nx and Nx+HFD groups (p<0.05). LPS was reduced by 45% by Cu (p<0.01) and 75% by PM (p<0.001).

| | Control | HFD | Nx | Nx+HFD |
|---|---|---|---|---|
| GTT (mg.min/dl) | 36321±2207 | 52133±1278* | 44453±1801* | 608351±2207*,T,♦ |
| LPS (EU/ml) | 0.44±.04 | 2.3±0.22* | 1.5±0.22*,T | 4.0±0.37*,T,♦ |
| IL6 (% control) | 100±10.4 | 183±12.9* | 322±29*,T | 798±233.4*,T,♦ |
| TNFα(% control) | 100±5.8 | 156±18.1* | 217±17.1*,T | 519±52.4* ,T,♦ |

*P<0.05 from Control; T P<0.05 from HFD; □p<0.05 from Nx.

**Conclusions:** In LDLR-/- mice CU and PM effectively blocked the inflammatory response to HFD and Nx and improved glucose tolerance test as measured by GTT. Renal function was also improved by both CU and PM, albeit CU was better than PM. Since PM is confined to the gut we contend that CU might have significant local effect on the gut and that its anti-inflammatory effect is partly mediated through alteration in gut permeability or inhibition of LPS absorption.

## TH-PO939

**Chronic Interstitial Nephritis after Brief Mild Adenine Excess Despite Scarce Crystal Deposition** Ricardo P. Mazzonetto, Orestes Foresto-Neto, Camilla Fanelli, Simone C.A. Arias, Raquel L. Borges, Viviane D. Faustino, Claudia R. Sena, Vivian L. Viana, Denise M.A.C. Malheiros, Niels O.S. Camara, Roberto Zatz, Clarice K. Fujihara. *Univ of Sao Paulo, Brazil.*

**Background:** We showed recently that, in rats on excess adenine (ADE) for 3 weeks, intratubular crystals (Crys) migrate to the interstitium (INT), causing INT nephritis. Here we studied whether renal damage caused by 1 wk ADE would regress/stabilize upon ADE withdrawal or would instead progress to chronic kidney disease (CKD).

**Methods:** Adult male Munich-Wistar rats (n=42) received no treatment (C), or ADE, 0.5% in chow for 1 week, after which Crys/mm$^2$, serum creatinine ($S_{Cr}$, mg/dL), tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/day), % glomerulosclerosis (%GS), INT macrophages (MΦ, cells/mm$^2$), and % INT collagen-1 (%COLL) were assessed. Measurements were repeated 4 and 24 wks later.

**Results:**

| | Crys | $S_{Cr}$ | TCP | ALB | %GS | MΦ | %COLL |
|---|---|---|---|---|---|---|---|
| 1 week ADE | | | | | | | |
| C | - | 0.6±0.1 | 130±4 | 3±1 | 0±0 | 10±3 | 5±1 |
| ADE | 0.3±0.2 | 1.1±0.1$^a$ | 156±6$^a$ | 2±1 | 0±0 | 115±16$^a$ | 5±1 |
| 4 weeks after ADE withdrawal | | | | | | | |
| C | - | 0.6±0.1 | 134±4 | 2±1 | 0±0 | 8±1 | 4±1 |
| ADE | 0.3±0.1 | 0.6±0.1$^b$ | 133±3$^b$ | 2±1 | 0±0 | 61±11$^{ab}$ | 9±2 |
| 24 weeks after ADE withdrawal | | | | | | | |
| C | - | 0.6±0.1 | 137±3 | 16±4 | 0.4±0.2 | 21±3 | 4±1 |
| ADE | 0.2±0.1 | 0.6±0.1$^b$ | 153±4$^{ac}$ | 51±24$^{abc}$ | 2.1±1.0$^{abc}$ | 63±13$^{ab}$ | 12±2$^{ab}$ |

Mean±SE, $^{a,b,c}$, p<0.05 vs C, 1wk and 4 wk, respectively. At 1 wk, Group ADE exhibited, despite very few Crys, $S_{Cr}$ elevation, hypertension, and INT MΦ infiltration, without excess COLL or GS. Four wk after ADE withdrawal, MΦ regressed, while TCP and $S_{Cr}$ were normalized. However, ALB, TCP, %GS and %COLL had risen 24 wk after ADE withdrawal, while MΦ remained elevated.

**Conclusions:** Despite regression of acute renal inflammation/function loss shortly after ADE was ceased, INT fibrosis and GS occurred in the long run, indicating that even light ADE excess can cause changes that lead to self-perpetuating CKD.

FAPESP/CNPq.

**TH-PO940**

**Galactose-Deficient IgA1 Production Enhanced by Abnormal Cytokine Signaling in IgA1-Secreting Cells of Patients with IgA Nephropathy Can Be Controlled by STAT Inhibitors** Koshi Yamada,[1,2] Zhi Qiang Huang,[1] Milan Raska,[1,3] Joshua Anderson,[1] Hitoshi Suzuki,[2,1] Colin Reily,[1] Hiroyuki Ueda,[1] Zina Moldoveanu,[1] Krzysztof Kiryluk,[5] Yusuke Suzuki,[2] Robert J. Wyatt,[4] Jiri F. Mestecky,[1] Yasuhiko Tomino,[2] Ali G. Gharavi,[5] Bruce A. Julian,[1] Christopher D. Willey,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Juntendo Univ, Tokyo, Japan; [3]Palacky Univ, Olomouc, Czech Republic; [4]Univ of Tennessee, Memphis, TN; [5]Columbia Univ, New York, NY.*

**Background:** IL-6 is a B-cell differentiation factor that regulates multiple functions through JAK/STAT pathway. Here, we assessed the effects of IL-6 on IgA1 glycosylation using IgA1-secreting cells derived from the circulation and tonsils of IgA nephropathy patients (IgAN-C and IgAN-T) and of healthy controls (HC-C and HC-T), and characterized signaling pathways associated with the enhanced production of galactose-deficient IgA1 (Gd-IgA1).

**Methods:** IgA1-secreting cells were stimulated with IL-6. Gd-IgA1 levels were determined by lectin ELISA. The role of STAT3 in enhanced production of Gd-IgA1 was assessed by STAT3 siRNA knock-down. The findings were confirmed by specific inhibitors of JAK/STAT pathway. Signaling was assessed in cell lysates from IgA1-secreting cells after IL-6 stimulation, with or without an inhibitor of STAT3 signaling, by kinome profiling using PamStation® 12 PTK (tyrosine kinome PamChip) and Western blotting.

**Results:** Gd-IgA1 production by IgAN-C stimulated with IL-6 was significantly higher than that by HC-C. IL-6 induced STAT3 phosphorylation at Y705 (P-STAT3), and P-STAT3 was greater in IgAN-C than in HC-C (2-fold; $p<0.019$). Increase in Gd-IgA1 production after IL-6 stimulation of IgAN-C decreased after siRNA STAT3 knock-down ($p<0.05$). A specific inhibitor of STAT3 signaling reduced IL-6-induced production of Gd-IgA1 in both IgAN-C and IgAN-T. This effect was associated with down-regulation of P-STAT3. Kinome profiling confirmed STAT-signaling pathways as the main target of the inhibitor.

**Conclusions:** IL-6 enhanced production of Gd-IgA1 in IgAN-C and IgAN-T. The IL-6-signaling pathway with abnormal activation of P-STAT3 may represent another pathogenetic process in IgAN.

**Elevated Soluble Galectin-3 and Monocyte Galectin-3 Levels in Experimental Uraemia Are Reversed by Anti Advanced Glycaemic End Products (AGE) Therapy** Andrew Duncan Stewart Findlay, Petros Andrikopoulos, Steven Michael Harwood, Julius Edward Kieswich, Magdi Yaqoob. *Translational Medicine, William Harvey Research, London, United Kingdom.*

**Background:** Galectin-3 expressing monocytes and macrophages are implicated in the pathogenesis of chronic inflammatory and fibrotic diseases. Moreover, In human studies elevated soluble plasma Galectin-3 levels are associated with Advanced Glycaemic End product (AGE) and determine poor cardiovascular outcomes.

**Methods:** A murine model of progressive tubulointerstitial nephritis - The Adenine Diet (AD)- was used to define Galectin-3 levels in circulating murine leucocytes and tissue resident macrophages (by FACS analysis and Real Time Quantitative PCR) subject to progressive uraemia. Plasma AGE was quantified by ELISA in AD compared to sham diet (SD) at 0 and 2 weeks. Mice were then given the anti-AGE compound Pyridoxamine in drinking water (400mg/kg) or standard drinking water for 2 weeks of 0.25% Adenine diet and leucocyte Galectin-3 expression was re-evaluated.

**Results:** Plasma Galectin-3 is significantly raised at 7 days to 28 days in AD fed mice(n=33) vs SD (n=30). Circulating monocytes and granulocytes in AD fed mice(n=5) demonstrate significantly higher Galectin-3 Median Fluorescence Intensity(MFI) on FACS analysis at 14-28 days vs SD(n=5) ($p=0.0317$ AD vs SD at 28 days). At 28 days resting peritoneal macrophages and cardiac homogenate failed to show increased expression in Galectin-3 MFI and Galectin-3mRNA levels respectively. Plasma AGE is significantly raised at 2 weeks 0.25% Adenine Diet and significantly reduced by supplementation with 400mg/kg of pyridoxamine in drinking water(n-5) vs standard drinking water(n=5)($p=0.0079$). Pyridoxamine supplementation also significantly reduced adenine diet induced Galectin-3 expression of circulating monocytes at 14 days.

**Conclusions:** In experimental uraemia only circulating Galectin-3 monocyte levels are increased with accumulation of AGE's. Targeting elevated Galectin-3 levels by anti-AGE strategies may be important given Galectin-3's pathogenic role in inflammatory cardiovascular disease.

**TH-PO942**

**Oleanolic Acid Attenuates Renal Interstitial Fibrosis in Unilateral Ureteral Obstructive Nephropathy by Facilitating Nuclear Translocation of Nrf2** Sung Jun Kim, Hye Eun Yoon, Seok Joon Shin, Cheol Whee Park, Sungjin Chung. *Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.*

**Background:** Renal interstitial fibrosis is a common final pathological process in the progression of renal disease. This is primarily due to oxidative stress, which contributes to renal inflammation and fibrosis. Nuclear factor-eythroid-2-related factor 2 (Nrf2) is known to coordinate induction of genes that encode antioxidant enzymes. We investigated the effects of oleanolic acid, a known Nrf2 activator, on oxidative stress-induced renal inflammation and fibrosis.

**Methods:** Oleanolic acid treatment was initiated one week before unilateral ureteral obstruction (UUO) in C57BL6/J mice, and was continued until 3, 7, and 14 days after UUO. Renal inflammation and fibrosis, markers of oxidative stress, and changes in Nrf2 expression were subsequently evaluated.

**Results:** Oleanolic acid significantly decreased tululointerstitial fibrosis score that was increased in the kidneys of UUO mice. Furthermore, oleanolic acid attenuated UUO-induced collagen deposition and macrophage infiltration on day 14. Additionally, significantly less apoptosis, a lower ratio of Bax to Bcl-2 expression, and fewer apoptotic cells on TUNEL staining were observed in the obstructed kidneys of oleanolic acid-treated mice. Oleanolic acid increased nuclear Nrf2 as well as the expression of HO-1, and decreased lipid peroxidation in the obstructed kidneys. By contrast, olenolic acid did not affect the expression of catalase and the level of tissue hydrogen peroxide. There were no changes in the expression of total Nrf2 and Kelch-like ECH-associated protein 1 (Keap1), indicating that oleanolic acid enhanced nuclear translocation of Nrf2.

**Conclusions:** These results suggest that oleanolic acid may exert beneficial effects in renal fibrosis by increasing nuclear translocation of Nrf2 and subsequently reducing renal oxidative stress.

**TH-PO943**

**Proteinase-Activated Receptor-2 Transactivation of EGF- and TGFβ-Receptor Signalling Pathways Contributes to Renal Fibrosis** Hyunjae Chung, Morley Hollenberg, Daniel A. Muruve. *Medicine, Univ of Calgary, Calgary, Canada.*

**Background:** During renal injury, kidney-localized proteinases can signal by cleaving and activating proteinase-activated receptor-2 (PAR2), a G-protein-coupled receptor involved in inflammation and fibrosisthat is abundantly expressed in renal tubular cells. We investigated the role for PAR2 in the pathogenesis of renal fibrosis.

**Methods:** (i) We evaluated tubular injury and progression of fibrosis in a murine unilateral ureteral obstruction (UUO) model using both wildtype and PAR2-null mice. Renal tissues were evaluated histopathologically for morphology (H&E), collagen deposition (Masson's Trichrome, collagen assay) and biochemically (western blot) for α-smooth muscle actin (αSMA). (ii) We examined the mechanism of PAR2 signaling that regulates fibrosis and the production of the profibrotic cytokine, connective tissue growth factor (CTGF) was measured using primary human proximal tubular epithelial cells (HPTC). Cells were activated with PAR2-activating peptides (PAR2-AP) in presence or absence of signaling pathway inhibitors for TGFβRI (SB431542), EGFR (AG1478) and MAPKinase (UO126).

**Results:** Following UUO, PAR2-null mice displayed reduced renal tubular injury, fibrosis, collagen synthesis and aSMA gene expression at 7 days, compared to wildtype controls. In HPTC *in-vitro,* PAR2 stimulation with PAR2-AP alone significantly up-regulated the expression of CTGF and did so synergistically to augment TGF-β-induced CTGF. Consistent with these findings, stimulation of HPTC with PAR2-AP induced Smad2/3 phosphorylation in the canonical TGF-β signaling pathway. The Smad2 phosphorylation and the CTGF induction by PAR2 activation were downregulated by the use of inhibitors for TGFβRI and EGFR suggesting that PAR2 utilizes transactivation mechanisms of both receptors to initiate fibrogenic signaling.

**Conclusions:** Our data demonstrate that (i) PAR2 plays a role in the early stages of renal fibrosis in a murine UUO model and that (ii) PAR2 utilizes transactivation mechanisms of EGFR and TGFβR to enhance Smad2 activation and the production of CTGF. PAR2 appears to be a contributor to renal injury and fibrosis in vivo and represents a potential therapeutic target for patients with CKD.

**Oral Activated Charcoal Adsorbent, AST-120 Improves Intestinal Environment and Microbiota in CKD Rats** Ayumi Yoshifuji, Shu Wakino, Junichiro Irie, Kozi Hosoya, Hitoshi Minakuchi, Kazuhiro Hasegawa, Hirobumi Tokuyama, Koichi Hayashi, Hiroshi Itoh. *School of Medicine, Keio Univ, Tokyo, Japan.*

**Background:** Although gut microbiota and colon barrier function were deteriorated in CKD state, the detailed mechanism or pathological relevance has not been elucidated. Oral activated charcoal adsorbent (AST-120) has been reported to delay the progression of CKD by adsorbing uremic toxin from the intestine. However, the effects of AST on the gut environments in CKD have not been fully elucidated.

**Methods:** Six-week-old spontaneously hypertensive rats (SHR) were rendered CKD by 5/6$^{th}$ nephrectomy. Rats were divided into four groups (n=10 each); sham-operated SHR (SHR); SHR given AST-120 (SHR+AST); 5/6$^{th}$ nephrectomized SHR (Nx); Nx given AST-120 (Nx+AST). AST-120 was orally given for 12 weeks.The distribution of the intestinal flora was examined by T-RFLP and real time PCR.

**Results:** Serum level of indoxylsulfate, serum creatinine levels and urinary protein excretion were increased in Nx. Glomerular sclerosis and tissue fibrosis were increased in Nx. These changes were attenuated in Nx+AST. The histological analysis of the colon tissue revealed that the number of goblet cells and the protein expression of mucin-2 were decreased in Nx. These decreases were restored by AST. The expression levels of tight junction protein ZO-1 and Claudin-1 were also decreased in Nx, which were mitigated in Nx+AST. The analysis of the gut flora showed the decrease in the number of *Lactobacillus* in Nx. This decrease was also reversed in Nx+AST.

**Conclusions:** It has been reported that tight junction proteins were downregulated and intestinal barrier function was impaired in mucin-2 deficient mice. Mucin-2 enhances the growth of *Lactobacillus* by inducing their adhesion to the colon. Our data demonstrated that AST-120 improved the gut environment favorable to *Lactobacillus* which affected the expressions of the tight junction proteins. Recent study demonstrated that probiotics that supplement a part of intestinal flora had favorable effects on renal function. These effects provide a novel mechanism whereby AST120 or probiotic therapy improves renal function through modulating the gut environment.

## TH-PO945

**Genetic and Pharmacological Manipulations of Sphingosine Kinase 2, Diminishes Renal Inflammation/Renal Fibrosis in Response to Unilateral Ureteral Obstruction** Shobha D. Thangada,[1] Mallika Ghosh,[1] Herald Yamase,[3] Cynthia J. D'Alessandri,[2] Ferrer Fernando.[1&2] *[1]Vascular Biology, UCHC, Farmington, CT; [2]Urology, CCMC, Hartford, CT; [3]Pathology, UCHC, Farmington, CT.*

**Background:** Sphingosine Kinase-2 (*Sphk-2*) is a metabolizing enzyme responsible for production of bioactive lipid, Sphingosine-1 Phosphate (S1P), which plays a major role in tissue injury. In the present study we address in vivo significance of *Sphk-2*, in renal inflammation/ fibrosis in response to unilateral ureteral obstruction.

**Methods:** For Genetic model studies, *Sphk-2* $^{-/-}$ mice and for pharmacological model studies (treated with novel SphK2 inhibitor, SKX002411, obtained from SphynKx Therapeutics, VA) , wild type (WT) C57BL/6 mice were subjected to complete UUO. Obstructed and unobstructed kidneys were examined for histological changes and expression of key renal injury markers, such as TGF ß and alpha SMA by immunohistochemistry and western blotting. Immune cell profile by flowcytometry and inflammatory cytokine expression by qRT PCR were assessed.

**Results:** Histological examination reveals that WT mice had extensive renal damage with elevated levels of TGF ß and alpha SMA in interstitial spaces when compared to *Sphk-2* $^{-/-}$ mice. Flowcytometric analysis reveals that *Sphk2* $^{-/-}$ mice demonstrated a reduction in pro-inflammatory macrophages (M1) and a corresponding increase in anti-inflammatory (M2) phenotype. Mice treated with SphK2 inhibitor exhibited diminished renal injury histologically, in addition to decreased levels of TGF ß , alpha SMA and reduced infiltration of inflammatory monocytes and macrophages. This observation was further supported by diminished expression of inflammatory cytokines, such as MCP-1, TNF a, CXCL2, IL b1in the drug treated group.

**Conclusions:** The results demonstrate that, genetic and pharmacological manipulation of Sphingosine kinase-2 significantly decreases inflammatory and fibrotic responses, resulting in diminished renal injury. Suggesting that therapeutic modulation of SphK2 signaling pathway may prove beneficial in renal injury representing a novel class of therapeutics.

## TH-PO946

**Changes in Hemodynamic Forces on Glomerular Endothelial Cells following Partial Nephrectomy** Nicholas J. Ferrell,[1] Ruben M. Sandoval,[2] Bruce A. Molitoris,[2] William Fissell.[1] *[1]Nephrology, Vanderbilt Univ, Nashville, TN; [2]Nephrology, Indiana Univ, Indianapolis, IN.*

**Background:** Renal hyperfiltration following loss of functional nephron mass is thought to drive disease progression. Changes in blood flow dynamics in addition to compensatory structural adaptations in the nephron transiently alter the mechanical forces on cells that line the glomerular capillary wall. Therefore, we have characterized disease related changes in fluid shear stress on the surface of glomerular endothelial cells following significant loss of renal mass using the 5/6 nephrectomy (5/6 Nx) model.

**Methods:** Red blood cell (RBC) velocities in the glomerular capillaries of Simonsen Munich Wistar rats were measured by intravital microscopy under physiologic conditions, immediately after 5/6 Nx, and two weeks after 5/6 Nx. Shear forces on the surface of glomerular endothelial cells were calculated based on the measured RBC velocity by accounting for the change in hematocrit (Fahraeus effect) and effective viscosity of blood (Fahraeus-Lindqvist effect) in small diameter vessels.

**Results:** Under normal physiological conditions, RBC velocity was measured at 0.16±0.08 cm/sec and shear stress at the surface of glomerular endothelial cells was 23.6±11.9 dyn/cm$^2$. Blood flow rapidly increased in remnant nephrons prior to structural remodeling of the glomerulus and proportionally increased RBC velocity to 0.22±0.13 cm/sec and shear stress in the glomerular capillaries to 29.9±15.4 dyn/cm$^2$ ($p<0.05$). Shear stress on glomerular endothelial cells further increased at two weeks to 35.8±16.5 dyn/cm$^2$ ($p<0.05$) but not to the extent that would be predicted in the absence of glomerular structural remodeling.

**Conclusions:** These data indicate that mechanical forces on cells in the glomerular capillary rapidly increased following significant loss of functional renal mass. Structural remodeling of the nephron following injury partially normalized these changes but not to levels that are typical of normal physiological conditions. These mechanical and structural alterations may have an effect on chronic renal disease progression.

## TH-PO947

**Differential Effects of Oncostatin M on Proinflammatory and Profibrotic Gene Expression in Human Proximal Tubular Cells** Markus Pirklbauer, Rita Sarkozi, Gert J. Mayer, Herbert Schramek. *Dept of Internal Medicine IV, Nephrology and Hypertension, Innsbruck Medical Univ, Innsbruck, Austria.*

**Background:** Accumulating evidence indicates that inflammatory mechanisms play a role in initiation and progression of diabetic nephropathy. Recently we reported that oncostatin M (OSM) exerts potent antifibrotic effects in the human proximal tubular cell line HK-2. In this study we investigated OSMs effects on mRNA expression of CCL5/RANTES, thrombospondin-1 (TSP-1) and tenascin C (TNC) induced by TNF-α, IL-1β or TGF-β1.

**Methods:** Human kidney-2 (HK-2) cell culture, real-time PCR.

**Results:** 10 ng/ml of TNF-α or IL-1β led to a time-dependent upregulation of TSP-1 and TNC mRNA expression, which was highest after 48 h and 6 h, respectively. After 24 h of incubation, induction of TSP-1 mRNA was 5.9-fold and 3.2-fold in TNF-α- and IL-1β-treated HK-2 cells but 12.4-fold in TGF-ß1-stimulated ones. At the same time point, TNC mRNA expression was hardly affected by TNF-α or IL-1β, but showed strong induction after administration of TGF-β1. After 24 h of co-incubation, 10 ng/ml OSM inhibited mRNA expression of TSP-1 and TNC induced by either one of the three ligands. In contrast to these two profibrotic genes, induction of proinflammatory CCL5 mRNA expression by TNF-α or IL-1β started as early as 3 h after incubation and was highest after 48 h. TGF-β1 did not significantly affect CCL5 mRNA expression at any of the time points investigated. While CCL5 mRNA expression was unaffected by OSM alone, OSM led to a strong additive stimulatory effect after 6 h and 24 h when administered together with either TNF-α or IL-1β.

**Conclusions:** In human proximal tubular HK-2 cells, OSM exerts a strong additive effect on TNF-α- and IL-1β-stimulated mRNA expression of proinflammatory CCL5. In contrast, OSM inhibits TNF-α-, IL-1β- and TGF-β1-induced mRNA expression of the profibrotic genes TSP-1 and TNC after long-term incubation. Thus, OSM may have the ability to act both as pro-inflammatory ligand and anti-fibrotic mediator.

## TH-PO948

**A Serine Protease Inhibitor, Camostat Mesilate, Attenuates the Progression of CKD through Its Antioxidant Effects** Yoshikazu Miyasato,[1] Miki Ueda,[1] Kohei Uchimura,[1] Yuki Narita,[2] Teruhiko Mizumoto,[1] Tomoaki Onoue,[1] Rika Yamazoe,[1] Jun Morinaga,[1] Manabu Hayata,[1] Yutaka Kakizoe,[1] Sakai Yoshiki,[3] Kenichiro Kitamura.[1] *[1]Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; [2]Center for Clinical Pharmaceutical Sciences, Kumamoto Univ, Kumamoto, Japan; [3]Research Headquarters, Ono Pharmaceutical Co., Ltd., Osaka, Japan.*

**Background:** Previously we demonstrated a renoprotective effect of camostat mesilate (CM) in the remnant kidney model. However, the precise mechanisms by which CM delays the progression of CKD still remain poorly understood. Here, we investigated the effect of CM on the progression of CKD in the adenine-induced CKD model and explored the renoprotective mechanisms of CM.

**Methods:** Thirteen week-old SD rats were divided into four groups: 1) Control group, 2) dietary adenine-induced CKD (CKD) group, 3) CKD+CM (CM) group, and 4) CKD+hydralazine (HYD) group. Blood pressure measurements and 24 hr urine collections were made during the treatment period. Rats were sacrificed following 5 weeks treatment period. We also evaluated the radical scavenging activities of CM and hydralazine in vitro by electron spin resonance (ESR).

**Results:** At the end of the experiment, both proteinuria and serum creatinine levels were substantially increased in CKD group. Although CM group and HYD group showed similar reduction in the blood pressure levels, CM significantly reduced proteinuria and serum creatinine levels compared with HYD. CM remarkably decreased the mRNA levels of NADPH oxidase components and the reactive oxygen species generation in the kidney. Furthermore, the ESR-spin trapping method revealed substantial hydroxyl radical scavenging activity of CM in vitro.

**Conclusions:** We demonstrated that CM significantly ameliorated the progression of CKD through its antioxidant effects independently of blood pressure. Our current results suggest the possibility that CM could be a new therapeutic agent against the progression of CKD.

## TH-PO949

**Nrf2 Agonist Decreases Colonic Inflammation and Tight Junction Depletion in Rats with Chronic Kidney Disease** Wei Ling Lau, Jun Yuan, Shuman Liu, Mahyar Khazaeli, Zhenmin Ni, Nosratola D. Vaziri. *Nephrology, Univ of California, Irvine, Orange, CA.*

**Background:** Gut inflammation is prevalent in chronic kidney disease (CKD) and contributes to systemic inflammation via disruption of the epithelial tight junction barrier with subsequent endotoxin translocation. Nrf2 is a key anti-inflammatory transcription factor that is deficient in CKD. We hypothesize that treatment with a potent Nrf2 activator RTA 408 will decrease colonic inflammation and preserve expression of tight junction proteins.

**Methods:** Sprague-Dawley rats were divided into 3 groups: sham controls (n=5), CKD (n=8), and CKD+Nrf2 treatment group (n=8). CKD was induced via 5/6 nephrectomy. CKD+Nrf2 treatment was RTA 408 (2 mg/kg/day) via oral gavage x10 weeks.

**Results:** CKD was associated with elevated plasma malondialdehyde (MDA, a marker of systemic oxidative stress). CKD rats had histological evidence of colitis and depletion of all 3 tight junction proteins (Figure 1). Treatment with RTA 408 significantly raised

tissue Nrf2 levels, and was associated with decreased nuclear levels of NF-kB. Colon from CKD+Nrf2 treated rats had decreased inflammatory mediators (COX-2, MCP-1) and oxidative stress factors (iNOS, NOX4), and lower plasma MDA levels. Additionally, Nrf2 agonist treatment improved expression of tight junction proteins (Figure 1).

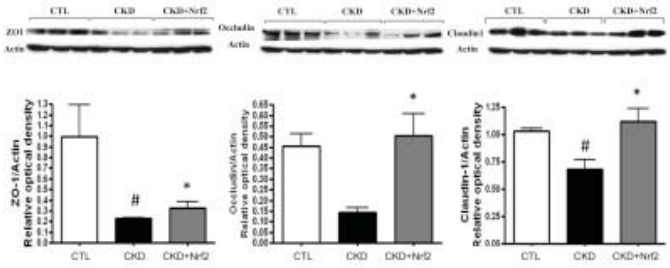

Figure 1. Representative Western blot data showing decreased expression of tight junction proteins (zona occludens-1, occludin and claudin-1) in the colon from CKD rats; this was ameliorated by treatment with a Nrf2 agonist. $P<0.05$ compared to controls (#) or non-treated CKD rats (*).

**Conclusions:** Treatment with a potent Nrf2 agonist decreased colonic inflammation and improved expression of tight junction proteins in CKD rats. There was concurrent decreased systemic oxidative stress. Thus, there are potential benefits of intestinal Nrf2 activation in CKD.

## TH-PO950

**Tissue Kallikrein Mediates Pro-Inflammatory Pathways in Proximal Tubular Epithelial Cells** Wai Han Yiu,[1] Dickson WL Wong,[1] Joseph C. K. Leung,[1] Loretta Y.Y. Chan,[1] Hui Y. Lan,[2] Kar Neng Lai,[1] Sydney C.W. Tang.[1] *[1]Dept of Medicine, The Univ of Hong Kong, Queen Mary Hospital, Hong Kong, China; [2]Dept of Medicine and Therapeutics, Li Ka Shing Institute of Health Sciences, The Chinese Univ of Hong Kong, Hong Kong, China.*

**Background:** Tissue kallikrein (KLK1) expression is up-regulated in human diabetic kidney tissue. Since the kallikrein-kininsystem (KKS) has been linked to cellular inflammatory process in many diseases, we explore the role of KLK1 in tubular pro-inflammatory responses under the diabetic milieu.

**Methods:** Human proximal tubular epithelial cells (PTEC) were incubated with recombinant KLK1 protein to examine the expression of pro-inflammatory cytokines and the activation of signaling pathways. Cells were then transfected with KLK1-specific or control siRNA to investigate the effect of KLK1 on advanced glycation end products (AGE)-induced pro-inflammatory responses.

**Results:** Recombinant KLK1 stimulated the production of inflammatory cytokines including IL-8, ICAM-1 and CCL-2, and activated the phosphorylation of p42/44 and p38 MAPK in PTEC. Increased expression of KLK1 was detected in PTEC stimulated with AGE (0.5 mg/ml), and molecular knockdown of endogenous KLK1 expression attenuated AGE-induced tubular IL-8 and ICAM-1 productions.

**Conclusions:** Our data suggest for the first time that KLK1 mediates pro-inflammatory responses in renal tubule cells under a diabetic milieu, and pave the way for further investigation that targets KLK1 in ameliorating diabetic tubular injury.

Fund support: Research Grant Council of Hong Kong (GRF grant number 7796/11M).

## TH-PO951

**Regulatory T Cells in Nephrocalcinosis and Dystrophic Cardiac Calcinosis in DBA/2 Mice** Alexander H. Kirsch,[1] Alexander R. Rosenkranz,[1] Kathrin Eller,[1] Philipp Eller.[2] *[1]Clincal Div of Nephrology, Medical Univ of Graz, Graz, Austria; [2]Div of Angiology, Medical Univ of Graz, Graz, Austria.*

**Background:** Nephrocalcinosis is characterized by aberrant deposition of calcium in the kidneys and is seen in phosphate nephropathy, primary hyperparathyroidism, and distal renal tubular acidosis.

**Methods:** To further evaluate the specific pathophysiologic role of T cells in ectopic calcification, we used DBA/2 mice that are prone to develop nephrocalcinosis and dystrophic cardiac calcinosis. Female DBA/2 mice were depleted of T cells (n = 10) or regulatory T cells (Tregs) (n = 15) using either an anti-CD3ε or an anti-CD25 monoclonal antibody and compared with isotype-treated controls (n = 9; n = 15), respectively. After this immunomodulation, the DBA/2 mice were given a high-phosphate diet for 9 days and the degree of calcification was assessed by microcomputed tomography. Successful depletion was confirmed by flow cytometry of splenocytes.

**Results:** In DBA/2 mice, the high-phosphate diet induced a phenotype of nephrocalcinosis and dystrophic cardiac calcinosis. T-cell depletion significantly increased renal calcification in microcomputed tomography (P = 0.022). Concordantly, Treg depletion significantly deteriorated acute phosphate nephropathy (P = 0.039) and was associated with a significantly increased mortality rate (P = 0.004). Immunomodulation had no impact on the amount of cardiac calcification. Semiquantitative histopathologic evaluations with Alizarin Red staining independently confirmed the respective radiologic measurements.

**Conclusions:** In summary, our data suggest a pivotal role of T cells, particularly Tregs, in the progression of nephrocalcinosis and emphasize the fact that inflammation deteriorates the outcome in acute phosphate nephropathy.

*Funding:* Government Support - Non-U.S.

## TH-PO952

**Aberrant Activation of Neutrophils Allow ANCA to Aggravate Glomerulonephritis in Experimental Autoimmune Vasculitis** Go Kanzaki, Shinya Nagasaka, Yusuke Kajimoto, Seiichiro Higo, Kayori Tsuruoka, Akira Shimizu. *Dept of Analytic Human Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

**Background:** ANCA-neutrophil and neutrophil-endothelial cell interactions play an important role in the pathogenesis of ANCA-associated vasculitis (AAV). However, it is still unclear whether these interactions aggravate glomerulonephritis (GN) *in vivo*. In the present study, we used an experimental autoimmune vasculitis (EAV) rat model by generation of an immune response to exogenously administered human MPO (hMPO) in adjuvant. We tested this hypothesis in this rat model by using lipopolysaccharide (LPS), phorbol myristate acetate (PMA), or G-CSF as a stimulus for neutrophils. In addition, we analyzed gene expression of cytokines and adhesion molecules in this rat model.

**Methods:** Necrotizing and crescentic GN was induced in WKY rat by immunization with hMPO (1600 μg/kg). Blood and urine samples were obtained at every week. Quantitative RT-PCR was used to determine gene expression of cytokines and adhesion molecules were analysed in isolated glomeruli in 8 weeks after NCGN induction.

**Results:** Hematuria (2-3+) and proteinuria (300-1000 mg/dl) were noted at 4 weeks. hMPO-immunized rats had serum anti-hMPO antibody titers of 1:10000 by ELISA. We demonstrated that the induced anti-MPO antibodies cross-reacted with rat neutrophils inducing IL-1β in vitro. Several cytokines or adhesion molecules, which are mainly involved in neutrophil-endothelial interactions, were induced or up-regulated in glomeruli of hMPO immunized rat. The administration of LPS, PMA, or G-CSF exacerbated disease in EAV rat model, as assessed by both histological and functional parameters.

**Conclusions:** This study suggested that ANCA developed in EAV model rat aberrantly activated neutrophils in vivo. The excess stimuli for neutrophils or endothelial cells would develop glomerulonephritis in AAV.

## TH-PO953

**Innate Immunity Signal, S100 A8/A9, Are Danger Biomarkers of Lupus Nephritis** Yingyos Avihingsanon,[1] Pornpen Tantivitayakul,[2] Thitima Benjachat,[4] Vipawee Kittikovit,[3] Nattiya Hirankarn.[3] *[1]Medicine, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand; [2]Microbiology, Mahidol Univ, Bangkok, Thailand; [3]Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand; [4]Biomedical Science, Interdisciplinary Program, Graduate School, Chulalongkorn Univ, Bangkok, Thailand.*

**Background:** S100A8 and S100A9 are members of S100 family proteins that involved innate immunity. The proteins are co-expressed on macrophages and infiltrating monocytes during an active involvement of skin and kidney in lupus patients. They can activate auto-reactive CD8+T-cell through the TLR4 signaling and can lead to the development of nephritis in lupus mice. In this study, we determined the non-invasive blood monitoring of S100A8/A9 mRNA levels and their usefulness for a prediction of therapeutic response.

**Methods:** We studied S100 messenger RNA levels from blood leucocytes of lupus nephritis patients (n=68) and compared with healthy control (n=15). A 6-month follow-up blood mRNA levels was then measured and correlated with therapeutic response to standard therapy. The 18s mRNA was used as house-keeping gene and the mRNA levels were expressed as log-transformation.

**Results:** All active lupus nephritis (n=38) were biopsy-proven proliferative class III/IV LN. Median (IQR) urine protein and serum albumin were 5.01 (3.03-5.69) g/day and 2.90 (2.30-3.25) g/dL. Serum creatinine was 0.85 (0.72-1.22) mg/dL. S100A8 and A9 mRNA levels from blood leucocytes were tightly correlated with renal disease activity (r = 0.33). Both S100 mRNA levels of active LN were higher than those of inactive LN and healthy control ($p<0.01$). In the study of pre/post treatment of induction therapy, there were 12 responders and 14 non-responders. In the responders, both S100 mRNA levels were significantly reduced after a 6-month course of immunosuppressive treatment.

**Conclusions:** This supports the importance of innate immune response in lupus nephritis. Expression of S100 A8 and A9 of blood leucocytes are potential non-invasive biomarkers of lupus nephritis.

*Funding:* Government Support - Non-U.S.

## TH-PO954

**Diagnostic Value of the Simultaneous Detection of Anti-C1q and Anti-dsDNA Antibodies in the Diagnosis of Active Lupus Nephritis** Katarzyna Smykal-Jankowiak, Zofia I. Niemir, Magdalena Polcyn-Adamczak. *Laboratory of Molecular Nephrology, Univ of Medical Sciences, Poznan, Poland.*

**Background:** Development of lupus nephritis (LN) is one of the most important factors that worsen the prognosis of systemic lupus erythematosus (SLE). Anti-C1q and anti-dsDNA antibodies (Abs) are candidates for non-invasive markers of renal disease, which may by alternative to kidney biopsy in the assessment of LN activity. We examined the prevalence and predictive values of anti-C1q and anti-dsDNA Abs in the judgment about the LN activity.

**Methods:** Sixty-three patients with LN and 86 healthy volunteers (C)were enrolled into the study. LN patients were divided into two sub-groups depending on the activity of SLE, scored according to the systemic lupus disease activity index-2K (SLEDAI-2K). Thirty-eight patients constituted the group with active LN (aLN), whereas the remaining 25 patients were in inactive phase of the disease (inLN). Standardized enzyme-linked immunosorbent assays were used to detect anti-C1q and anti-dsDNA Abs in sera. The C3 and C4 complement components in sera were measured by turbidimetry.

**Results:** Anti-C1q Abs were detected in 81.6% of patients with aLN and 48% of those with inLN ($p<0.01$). Positive anti-dsDNA Abs were found in 89.5% of patients with aLN, compared to 56% of those with inLN group ($p<0.01$). The sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of anti-C1q Abs in the diagnosis of aLN were 81.58%, 52.00%, 72.09% and 65.00%, respectively. For anti-dsDNA Abs, these values were 89.47%, 44.00%, 70.83% and 73.33%. In the whole LN group, both Abs were present in sera of 57.1% patients, compared to 11.1% of those with anti-C1q Abs only, 13.0% with anti-dsDNA only and 12.6% without both Abs ($p<0.001$). Simultaneous detection of both Abs increased the NPP to100%, but not PPV, which reached 75.00%. The addition of decreased levels C3 to the detection of both Abs resulted in 100% of sensitivity, 85% of PPV and 100% of NPV for aLN.

**Conclusions:** Absence of both anti-C1q and anti-dsDNA antibodies in sera of patients with LN seems to exclude the active phase of LN. The addition of C3 to this set of examinations strengthens these results.

*Funding:* Government Support - Non-U.S.

## TH-PO955

**Macrophage Migration Inhibitory Factor (MIF) in Active Lupus Nephritis (LN) – Response to Immunotherapy** Ratana Chawanasuntorapoj, Marie B. Condon, Tom Cairns, Megan Griffith, Frederick W.K. Tam, Liz Lightstone. *Kidney and Transplant Centre, Imperial College.*

**Background:** MIF plays a central role in inflammatory responses and elevated MIF levels have been detected in patients with inflammatory kidney diseases. Kerschbaumer et al ASN 2012 reported MIF in urine correlated with activity of LN, however this was in a relatively small pilot population. In this study, we investigate urinary MIF (uMIF) in a larger cohort looking at response to immunotherapy and it's predictive value at time of biopsy.

**Methods:** uMIF was measured by ELISA on 643 urine samples from 60 patients collected over 54 mths. All patients had biopsy proven ISN/RPS class III/IV/V LN, >75% received Rituximab +/- MMF +/- steroids; the other patients received MMF +/or cyclophosphamide +/- steroids. uMIF levels were normalised for urinary creatinine (creat). uMIF/creat +/- 5 wks of biopsy were compared with uMIF/creat in samples collected at 26-52 wks post biopsy; subdivided into complete remission (CR=uPCR<50mg/mmol+<15% rise in serum creat); partial remission (PR=uPCR 50-300mg/mmol) and non response (NR=uPCR>300mg/mmol).

**Results:** Samples analysed: 75 at biopsy; 82 at 26-52 wks post biopsy (53 CR; 27 PR; 17 NR). uMIF/creat is significantly reduced in all patients at 26-52 wks post biopsy compared with biopsy, however the more significant the clinical response the more significant the reduction (CR = 58% ($p<0.0001$); PR = 44% ($p=0.0002$); NR = 37% ($p=0.0175$)). There is a significant correlation between uMIF/creat and uPCR at time of active biopsy ($p=0.027$, Spearman's correlation R=0.26), but not with serum creat. uMIF/creat at biopsy did not show a significant correlation with time to CR or with class of LN.

**Conclusions:** uMIF is abundant in all patients with active LN on renal biopsy; as the disease goes into remission the levels fall significantly. uMIF is not reported in healthy subjects, any uMIF is pathological, maybe indicative of a "smouldering" disease process. As the treatment protocols at this centre are deemed to be "steroid sparing", the lack of demonstration of a predictive value of uMIF maybe due to this approach being effective at treating the MIF dependent aspect of the disease process as MIF may induce steroid resistance.

## TH-PO956

**Monitoring of Urinary Cytokine Levels as Biomarker for Disease Activity in Thai Lupus Nephritis** Peenida Skulratanasak,[1] Ratana Chawanasuntorapoj,[1] Boonyarit Cheunsuchon,[2] Pisal Parichatikanond,[2] Kriengsak Vareesangthip,[1] Chairat Shayakul.[1] *[1]Medicine, Siriraj Hosp.; [2]Pathology, Siriraj Hosp., Mahidol Univ.*

**Background:** Proliferative lupus nephritis (LN) is one of the most common and severe secondary glomerulonephritis (GN). Early detection and good monitoring are essential to provide optimal care, while delay of the appropiate treatment may worsen the outcome. Regarding the pathogenesis of LN, immune and inflammatory responses play an essential role. Several studies have demonstrated cytokines/chemokines in correlation with LN activities. Using a novel Luminex™ assay to detect such changes has maximized its efficiency and clinical advantages by simultaneous measurement of several cytokines within a short period. This study was to demonstrate the correlation of urinary biomarkers with LN activity and its application.

**Methods:** We measured urinary cytokines; monocyte chemoattractant protein-1(MCP-1), vascular endothelial growth factor(VEGF), interleukin-6 (IL-6), IFN-γ inducible protein 10(IP-10), platelet derived growth factor(PDGF) and interleukin(IL)-1β using Bio-plex assay, and related their levels to the clinical status among active LN and control groups. In active LN, we measured these cytokines along two years during Jan 2011 to Dec 2012.

**Results:** 40 biopsy-proven active proliferative LN were compared with 35 inactive LN, 35 other GN and 35 healthy controls. Urinary MCP-1, VEGF, IL-6, IP-10, PDGF and IL-1β were significantly higher in active LN than healthy and inactive LN. Our cross-sectional part found the sensitivity of MCP-1 to identify the active LN was better than routine serology. In 40 active LN, the clinical response at 6 months therapy were 12 complete, 15 partial, and 9 non-response. Urinary IL-1β, IP-10, PDGF, and VEGF significantly decreased and correlated with the clinical. We described the persistently high level of urinary PDGF at 3rd month could be predicting the non-responder to induction therapy at 6th month. During 2 years, renal flare occurred in 5 cases. Increase of IL-1β might be applied as predictor of renal flare.

**Conclusions:** According to our result, urinary biomarkers could be useful to monitor LN activity and might be minimize kidney re-biopsy in LN patients.

## TH-PO957

**Soluble CR1 – Could It Be a New Marker of Lupus Nephritis Activity?** Aleksandra Rochowiak, Zofia I. Niemir, Magdalena Polcyn-Adamczak. *Laboratory of Molecular Nephrology, Univ of Medical Sciences, Poznan, Poland.*

**Background:** CR1, a membrane receptor for complement components (C3b/C4b), has a soluble form (sCR1) present in the serum and in the urine.The sources of sCR1 are probably erythrocytes and blood leukocytes.CR1 regulates the complement cascade activation and plays an important role in the removal of immune complexes coated with C3b/C4b. Increased serum concentrations of sCR1 were observed in patients with inflammatory diseases and hematologic malignancies. The aim of our study was the analysis of the sCR1 concentration in serum of healthy individuals and patients with primary glomerulonephritides (PGN) and lupus nephritis (LN).

**Methods:** The serum samples were obtained from 147 patients with PGN, 65 with LN and 67 healthy volunteers serving as a control group (C). The activity of the disease was determined by using the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K). Among patients with LN, 32 were in active phase of the disease (aLN) (SLEDAI score ≥10) and remaining 33 in inactive phase of the disease (inLN) (SLEDAI score <10). Serum sCR1 was evaluated by the standardized enzyme-linked immunosorbent assays.

**Results:** The highest level of serum sCR1 was noticed in patients with aLN compared to the results obtained in C ($p<0.01$), PGN ($p<0.01$) and inLN ($p<0.05$). A significant correlation was observed between sCR1 level and SLEDAI-2K score in LN ($r=0.2576$; $p<0.05$), while significant negative correlation appeared between sCR1 level and C3 ($r=-0.269$; $p<0.05$) and C4 concentration ($r=-0.319$; $p<0.001$) in LN.Serum sCR1 did not correlate with C3 and C4 serum level in C and PGN. We also have not found any correlations between sCR1 level and anti-dsDNA concentration in LN, as well as between creatinine serum level and sCR1 in LN and PGN.

**Conclusions:** Increased serum level of sCR1 in aLN and correlations observed between its concentration and C3 and C4, as well as sCR1 and SLEDAI-2K score in LN indicate that serum sCR1 may be a potential marker of lupus nephritis activity.

*Funding:* Government Support - Non-U.S.

## TH-PO958

**Elevated Levels of Lysophospholipid Mediators in Patients with Lupus Nephritis** Junya Yamahana, Kengo Furuichi, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. *Dept of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.*

**Background:** Lysophospholipid mediators are key molecules to regulate cell proliferation, differentiation, and/or apoptosis in the living body. The mediators have also been reported to be involved in fibrosis of the liver, lung, and kidney. In this study, we evaluated the pathogenic involvement of the lysophospholipid mediators in chronic kidney diseases, including lupus nephritis.

**Methods:** Sixty-five cases of biopsy proven kidney diseases were evaluated in this study. Sixty-five cases contained lupus nephritis (LN, 40 cases), membranous nephropathy (MN: 18 cases), minimal change nephrotic syndrome/focal segmental glomerulosclerosis (MCNS/FSGS: 4 cases), and rapidly progressive glomerulonephritis (RPGN: 3 cases). Correlations between clinic-pathological findings, serum levels of autotaxin (ATX) and phosphatidylserine-specific phospholipase A1 (PS-PLA1) were evaluated. Furthermore, response of serum ATX and PS-PLA1 levels to steroid therapy was also analyzed.

**Results:** Serum levels of PS-PLA1 in female patients with LN were higher than those in the patients with MN, or MCNS/FSGS ($90.1 \pm 15.5$, $30.9 \pm 6.0$, $44.5 \pm 28.5$ mg/L, respectively, $p < 0.05$). Serum ATX levels were also higher in female LN patients ($1.06 \pm 0.12$ mg/L) than those in MN ($0.69 \pm 0.09$, $p<0.05$). In regard to the response of steroid therapy in LN, serum levels of ATX and PS-PLA1 were negatively correlated with the doses of oral prednisolone ($p < 0.01$). In cases receiving steroid pulse therapy in LN, serum levels of PS-PLA1 ($97.4 \pm 26.3$ vs. $53.4 \pm 7.4$, $p = 0.17$) and ATX ($1.1 \pm 0.1$ vs. $0.6 \pm 0.1$, $p < 0.01$) were decreased accompanied with prevention of disease activity (SLE Disease Activity Index: decrease from $14.5 \pm 2.2$ to $7.0 \pm 2.1$). Pathologic analysis of untreated LN patient revealed that serum levels of PS-PLA1 were correlated with chronicity index (correlation coefficient 0.629, $p<0.05$). In patients of LN with higher level of serum PS-PLA1, renal function tended to decline rapidly.

**Conclusions:** Serum levels of PS-PLA1 and ATX were elevated in patients with LN, and decreased in accordance with suppression of the disease activity by treatment.

**TH-PO959**

**Urinary Angiogenin – A Novel Biomarker in Lupus Nephritis**
Marie B. Condon, Ratana Chawanasuntorapoj, Megan Griffith, Tom Cairns, Liz Lightstone, Frederick W.K. Tam. *Kidney and Transplant Centre, Imperial College, London.*

**Background:** Angiogenin (Ang), also known as Ribonuclease 5, is a 123 amino acid protein, involved in stimulating RNA transcription after localisation into the nucleus, leading to angiogenesis and growth stimulation. The presence of Ang in glomerular disease is not known. This is the first report in relation to activity of lupus nephritis (LN). Treatment of lupus nephritis with the steroid sparing "Rituxilup" regimen has published outcomes and all patients were treated in a consistent manner.

**Methods:** Ang was measured by ELISA on 342 urine samples from 34 patients collected over a 4 year period. During that time all patients had at least 1 episode of biopsy proven ISN/RPS class III/IV/V LN, for which they received the steroid sparing "Rituxilup" regimen. Median age at time of biopsy 44 yrs (IQR 27 years). Urine Ang (uAng) levels were normalised for urinary creatinine (creat) level. The relationship between uAng/creat ratios and serum creat and urine protein/creat ratio (uPCR) in the samples taken within +/- 5 weeks of biopsy were investigated. Effect of immunotherapy on uANG/creat ratios +/- 5 weeks of achieving partial remission (PR=uPCR <300mg/mmol with a >50% reduction from baseline with <15% rise in serum creat) and complete remission (CR=uPCR<50mg/mmol with <15% rise in serum creat) were evaluated.

**Results:** 33, 28 and 30 samples analysed at biopsy, PR and CR respectively. There is a significant correlation between uAng/creat and serum creat at time of active biopsy (p=0.011, Spearman's correlation R=0.45), but not with uPCR. uAng/creat is significantly reduced in PR and CR by 51% (p<0.05) and 84% (p<0.001) respectively.

**Conclusions:** In a well described cohort, treated in a consistent manner, uAng is associated with the severity of renal impairment at time of biopsy of active lupus nephritis, and showed significant reduction in patients with remission following immunotherapy. The lack of correlation of uAng with uPCR at presentation suggested that uAng is not a simple consequence of proteinuria. The potential role of Ang in the development of LN will need further investigation.

**TH-PO960**

**Interobserver Agreement in Proliferative Lupus Nephritis**
Suzanne Wilhelmus,[1] H. Terence Cook,[2] Laure-Helene Noel,[3] Franco Ferrario,[4] Ron Wolterbeek,[5] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, LUMC, Leiden, Netherlands; [2]Pathology, Imperial College, London, United Kingdom; [3]Pathology, Necker Hospital, Paris, France; [4]Pathology, San Gerardo Hospital, Monza, Italy; [5]Medical Statistics, LUMC, Leiden, Netherlands.*

**Background:** In lupus nephritis the histological class plays a central role in guiding treatment. Although the classification is almost 40 years old and has undergone various revisions (latest ISN/RPS 2003), remarkably few studies have paid attention to the interobserver agreement among pathologists, in particular with respect to the clinically most relevant proliferative lesions. We aimed to determine the interobserver agreement for proliferative lupus nephritis among nephropathologists worldwide.

**Methods:** We distributed a survey with pictures of 30 glomeruli among members of the Renal Pathology Society. We received 34 responses from 12 countries. For each glomerulus it had to be decided if a lesion was present that put the biopsy in class III or IV. If so, additional parameters had to be scored. For each parameter, we calculated the kappa or intraclass correlation (ICC). A value < 0.4 was considered as poor, and between 0.4 – 0.6 as moderate agreement. Pathologists had to indicate their level of experience.

**Results:** The ICC for the presence of a lesion putting the biopsy in class III or IV was 0.39 (poor). The kappa/ICC for the additional parameters were: active, chronic or both 0,36; segmental vs global 0.39; endocapillary proliferation 0.46; inflammatory cell influx 0.32; endothelial cell swelling 0.46; extracapillary proliferation 0.57; crescent type 0.45; wire loops 0.35. Highly experienced pathologists consistently showed less variability for all parameters than those less experienced.

**Conclusions:** Even though the clinical consequences of classifying a biopsy into class III or IV are substantial, the agreement among pathologists as to what constitutes a proliferative lesion is poor. We think improvements can be made by training renal pathologists and by revising the definitions of proliferative lesions provided in the classification system. Our results also underline the importance of central review by at least two experienced pathologists in clinical trials.

**TH-PO961**

**Thrombotic Microangiopathy in IgA Nephropathy Is Strongly Associated with Chronic Lesions**
Jamie S. Chua,[1] Johan W. De Fijter,[2] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden Univ Medical Center, Leiden, Netherlands; [2]Nephrology, Leiden Univ Medical Center, Leiden, Netherlands.*

**Background:** Thrombotic microangiopathy (TMA) is an underappreciated phenomenon in IgA nephropathy (IgAN) (El Karoui, JASN, 2012). We present results of the occurrence of TMA in IgAN from a single center study incorporating 116 cases.

**Methods:** In this single center study, 116 consecutive renal biopsies from the period 2003-2013 were incorporated, of which 98 were previously diagnosed with IgAN and 18 with Henoch-Schonlein nephritis (HSN). Biopsies were re-evaluated according to the Oxford Classification for IgAN. TMA, arterial intimal sclerosis and arteriolar hyalinosis were scored according to the guidelines of El Karoui et al. Patient demographics and clinical data were collected retrospectively from medical records, including blood pressure, history of hypertension and renal function.

**Results:** TMA occurred in 21/116 biopsies (18%), in 19/98 of IgAN patients (19%) and in 2/18 HSN patients (10%). TMA lesions were acute in 10/21 cases (48%) and chronic in 11/21 cases (52%). TMA was primarily located in arterioles (n=16). Endocapillary hypercellularity, IFTA and arterial intimasclerosis were found more frequently in patients with TMA than in those without (X-square test, respective p-values: 0.014, 0.004 and <0.001). Mesangial hypercellularity, hypertension and serum creatinin at time of biopsy were not associated with TMA. All reported associations remained statistically significant when omitting patients with HSN and there were no significant differences between chronic and acute TMA cases.

**Conclusions:** In this single center study, we found fewer TMA lesions in IgAN (18%) than previously reported (53%). It was hypothesized by El Karoui et al. that the high frequency of TMA in IgAN in their study could be explained by the selection of patients from a hypertension-clinic. Our results contradict this hypothesis. In our study, TMA was associated with chronic lesions such as IFTA and arterial intimasclerosis, but not with hypertension.

**TH-PO962**

**Complement Factor C4d Deposition along Glomerular Capillary Walls: C4d beyond Antibody Induced Injury**
Jamie S. Chua,[1,2] A. Gasim,[1] Harsharan Kaur Singh,[1] Volker Nickeleit.[1] *[1]Pathology, Div of Nephropathology, The Univ of North Carolina, Chapel Hill, NC; [2]Pathology, Leiden Univ Medical Center, Leiden, South Holland, Netherlands.*

**Background:** C4d deposits along peritubular capillaries (ptc) mark humoral rejection in ABO compatible renal allografts. However, the diagnostic significance of C4d deposits along glomerular basement membranes (GBM-C4d), which can occur as isolated event in transplant glomerulopathy (TG), is poorly understood.

**Methods:** We analyzed 318 for-cause renal allograft biopsies from 217 patients (excluded: glomerulonephritis and ABO incompatibility). GBM remodeling was analyzed by light (Banff cg-score) and by electron microscopy. C4d staining by immunohistochemistry (IHC) and immunofluorescence (IF) was scored along the GBM and ptcs. Clinical data included donor specific antibody titers post transplantation. Controls: native kidneys with minimal change disease (n=9) and thrombotic microangiopathy (n=16).

**Results:** TG occurred in 52/318 biopsies (16%). By IF, 49/52 (94%) TG cases showed GBM-C4d; 36/52 (69%) had isolated GBM-C4d lacking concurrent ptc C4d deposits. By IHC, performed on 27/52 TG cases, fewer cases showed GBM-C4d (74%, 20/27 cases); 12/27 (44%) cases had isolated GBM-C4d. GBM-C4d staining was associated with GBM remodeling by light and electron microscopy (X-square tests, p <0.001). GBM-C4d staining intensity was associated with Banff cg-score (p=0.023). GBM remodeling by electron microscopy occured in 29 cases with normal GBM by light microscopy; 23/29 (79.3%) had GBM-c4d staining. Associations between GBM-C4d and GBM remodeling remained significant after omitting cases with donor specific antibodies, C4d staining along ptc, or transplant glomerulitis. Controls: Minimal change disease never had GBM-C4d. 13/16 (81%) thrombotic microangiopathy cases had GBM-C4d and GBM remodeling.

**Conclusions:** GBM-C4d staining is associated with GBM remodeling in native and transplant kidneys. It can precede light microscopic GBM changes and occur independent of donor specific antibodies. As complement seems to play a role in TG, blockage of the complement cascade may have future therapeutic implications.

**TH-PO963**

**Predicting Long-Term Outcomes of Henoch-Schönlein Purpura Nephritis in Adults Using the Oxford Classification of IgA Nephropathy**
Chan Ho Kim,[1] Ji Suk Han,[1] Tae ik Chang,[2] Hyung Jung Oh,[1] Seung Hyeok Han,[1] Tae-Hyun Yoo,[1,3] Dae-Suk Han,[1] Shin-Wook Kang.[1,3] *[1]Dept of Internal Medicine, College of Medicine, Yonsei Univ; [2]NHIC Ilsan Hospital, Gyeonggi-do; [3]Brain Korea 21, Yonsei Univ, Seoul, Korea.*

**Background:** Recently, there has been emerging concern that crescents, the main histologic feature of Henoch-Schönlein purpura nephritis (HSPN), merely reflect active inflammation, and may not be a useful predictor of long-term outcomes. We therefore conducted a single-center retrospective study to evaluate whether the new Oxford classification of IgA nephropathy (IgAN) can be used to predict the long-term outcome in adult patients with HSPN.

**Methods:** We included 61 adult biopsy-proven HSPN patients between January 1991 and August 2010. In addition to the International Study of Kidney Disease in Children classification, pathologic findings were also evaluated by the Oxford classification of IgAN. Primary outcome was defined as either the onset of estimated glomerular filtration rate (eGFR) <60 ml/min/1.73m2 with a ≥30% decrease in baseline eGFR or ESRD.

**Results:** During a median follow-up duration of 49.3 months, 13 patients (21.3%) reached the primary endpoint. A Kaplan-Meier plot showed that renal survival rates were significantly higher in patients with <50% crescents compared to those with crescents in ≥50% of glomeruli (P=0.003). Among the Oxford-MEST lesions, patients with endocapillary hypercellularity (E1) (P=0.02) and tubular atrophy/interstitial fibrosis (T1/T2) (P=0.02) had significantly lower renal survival rates than those with E0 and T0. In a multivariate Cox model adjusted for clinical and pathologic factors, E1 (HR, 8.91; 95% CI, 1.47-53.9; P=0.02) and T1/T2 (HR, 8.74; 95% CI, 1.40-54.4; P=0.02) lesions were independently associated with the primary outcome, whereas the extent of crescentic lesions did not (HR, 3.27; 95% CI, 0.76-14.0; P=0.11).

**Conclusions:** The Oxford classification of IgAN can be used to predict the long-term outcomes of HSPN. The significance of crescentic lesions remains to be further explored, as its prognostic value was attenuated in a multivariate analysis.

## TH-PO964

**Clinicopathological Features and Renal Outcomes of IgA Nephropathy in the Elderly** Yusuke Okabayashi, Nobuo Tsuboi, Akira Fukui, Yoichi Miyazaki, Iwao Ohno, Tetsuya Kawamura, Makoto Ogura, Takashi Yokoo. *Div of Nephrology and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** The number of elderly patients with renal diseases is increasing in parallel with an increased longevity in the general population. However, information is limited regarding characteristics of each disease in the elderly. This study therefore investigated clinicopathological features of the elderly patients with IgA nephropathy (IgAN), the most common glomerulonephritis worldwide.

**Methods:** A total of 92 IgAN patients over 60 years old were retrospectively analyzed. Two hundred-fifty IgAN patients of 18 to 59 years of age, from the retrospective cohort of Ministry of Health, Labour and Welfare in Japan, were used as comparison (J Nephrol, 2012). Clinicopathological features at biopsy, therapies during the follow-up, renal outcomes and extra-renal complications were evaluated.

**Results:** The average values at diagnosis were age of 65 years, eGFR of 45 ml/min/1.73m$^2$, and urinary protein excretion (UPE) of 1.8 g/day. These features were more serious than those of the control group. Consistent with these clinical features, chronic pathological findings including glomerulosclerosis or interstitial fibrosis/tubular atrophy were more advanced than the control group, while degrees of acute lesions such as crescent formations were almost the same as the control group. As the result of appropriate treatments such as diet, RAS inhibitors, statins or steroids, more than 50% of the patients showed clinical remission (UPE<0.3g/day) at the last observation (median 4.1 years).On the other hand, 21 patients (23%) showed a 50% decrease in their eGFR or reached ESRD. The eGFR at biopsy and the proteinuria at one year were identified as independent factors that were associated with the slope of renal function.Extra-renal complications observed during the follow-up were hypertension (79%), diabetes (13%), dyslipidemia (35%), hyperuricemia (33%) and cardiovascular diseases (29%).

**Conclusions:** In spite of the advanced clinicopathological features and the presence of various extra-renal complications, therapeutic interventions may lead to better renal outcomes of the elderly patients with IgAN.

## TH-PO965

**Innate and Adaptive Immunity in Patients with IgA Nephropathy Who Underwent Tonsillectomy** Elisa Loiacono, Luca Vergano, Roberta Camilla, Rosanna Coppo, Roberto Albera, Daniel C. Cattran, Shubha Bellur, Ian Roberts, John Feehally, Stephan Troyanov, Licia Peruzzi, Alessandro Amore, Laura Morando, Maria Elena Donadio, Giovanni Cancarini, Roberta Tardanico, Loreto Gesualdo, Cristiana Rollino, Elisabetta Moggia, Gianna Mazzucco, Sara Ravera. *VALIGA Network, Città della Salute e della Scienza di Torino, Turin, Italy.*

**Background:** The benefits of tonsillectomy in IgA nephropathy (IgAN) is still debated. Tonsillectomy might remove pathogen sources and reduce the Mucosal Associated Lymphoid Tissue (MALT), limiting dimeric and undergalactosylated IgA1 production.

**Methods:** In the European network VALIGA 62/1147 IgAN underwent tonsillectomy (TxIgAN); 15 were tested and compared to 45 non-tonsillectomized IgAN (No-Tx) and 30 healthy controls (HC) for: a)degalactosylated IgA1; b)Toll-like receptors (TLRs) 2,3,4,9 mRNAs, c)proteasome (PS) and immunoproteasome (iPS) mRNAs; d) advanced oxidated protein products (AOPP).

**Results:** Levels of degalactosylated IgA1 were lower in Tx IgAN than in No-Tx IgAN (p=0.005), however still higher than in HC (p=0.03). TLR mRNAs were more expressed in Tx IgAN than in HC (TLR2,p=0.018;TLR4,p=0.007;TLR9,p=0.009), higher in Tx IgAN than in No-Tx IgAN (p<0.001 for TLR2,4,9). A switch from PS to iPS was detected in PBMC of Tx IgAN, higher than HC and no-Tx IgAN (LMP2/beta1 p=0.01 and LPM7/beta5 p<0.0001). The levels of AOPP in Tx IgAN were significantly higher in Tx IgAN than HC (P<0.0001)and no-Tx IgAN (p=0.0011).

**Conclusions:** Serum degalactosylated IgA1 were lower in tonsillectomized than non-tonsillectomized IgAN, however significantly higher than controls. Activation of innate immunity via TLRs and ubiquitin-proteasome and pro-oxidative milieu were not affected by tonsillectomy. Tonsillectomized patients had signs of mucosal immunity and oxidative stress higher than non tonsillectomized ones, possibily via extra-tonsillar MALT.

## TH-PO966

**Analysis of the Correlation between the Oxford Classification and Clinical Indicators of IgA Nephropathy** Qiuling Fan. *Dept of Nephrology, The First Affiliated Hospital of China Medical Univ, Shenyang, China.*

**Background:** Analyze the correlation and risk factors between clinical indicators and the four main pathological lesions of the Oxford classification in IgAN.

**Methods:** Clinical and pathological data were collected from 514 patients with biopsy-proven IgA nephropathy who were 18 years or older. Spearman's coefficient of rank correlation was performed to evaluate associations between the Oxford classification of IgAN and various clinical indicators. The independent risk factors affecting the pathological classification were analyzed by multivariate regression.

**Results:** In 514 IgAN patients, the average age was 35.70, and the average disease duration was 18.31±30.42 months. M0E0S0T0 was the major pathologic classification of isolated hematuria. Proteinuria and albuminuria were positively correlated with M lesion, serum albumin, C3 and PLT showed a negative correlation with M lesion. Proteinuria and blood platelet count were the independent risk factors for M lesion. The proportion of M1 in cases with proteinuria ≥3.5 g/d is much higher than that in cases with non-nephrotic range proteinuria. Age, SBP, uRBC, proteinuria, albuminuria were positively correlated with E lesion, Duration, serum albuminshowed a negative correlation with E lesion. Age and duration of nephritis were independent risk factors for E lesion. 73.3% of patients more than 60 years old showed endothelial proliferation. CKD stage, proteinuria were positively correlated with S lesion. Age, CKD stage, SBP, DBP, C4, TC, LDL-C, CRP, Fib, UA, Cys-C and proteinuria were positively associated with T lesion, Hb, serum albumin, IgGshowed a negative correlation with T lesion. High CRP levels, DBP more than 90 mmHg, hypoalbuminemia, high low density lipoproteinemia, and anemia were independent risk factors for T lesion.

**Conclusions:** 1. Proteinuria and blood platelet count were the independent risk factors for M lesion. 2. Age and duration of nephritis were independent risk factors for E lesion. 3. CKD stage, SBP and proteinuria were positively correlated with S lesion. 4. High CRP levels, DBP ≥90 mmHg, hypoalbuminemia, high low density lipoproteinemia, and anemia aggravate T lesion.

## TH-PO967

**Prognostic Significance of C1Q Deposition with Renal Outcomes among Patients with IgA Nephropathy** Abdulkareem Alsuwaida,[1] Sufia Husain,[1] Noura Aloudah,[1] Fayez F. Alhejaili,[2] Khaled Alsaad,[2] Hala M. KFoury,[1] Mohammed A. Al-Ghonaim.[3] *[1]King Saud Univ, Saudi Arabia; [2]King Abdulaziz Medical City, Saudi Arabia; [3]Prince Salman bin Abdulaziz Chair for Kidney Research, Saudi Arabia.*

**Background:** It has been reported in a study that mesangial C1q deposition in the glomerulus is associated with a poor renal outcome and severe pathologic features in patients with IgAN. The objective was to investigate the predictive power of co-deposition C1q in predicting long term outcome in patients with IgAN.

**Methods:** Participants with IgAN were divided into two groups based on the renal tissue C1Q status and their baseline and long-term outcome of worsening renal function (WRF) were compared. The rate of WRF was defined as increase in serum creatinine of ≥25% from baseline.

**Results:** Fifty five patients had IgAN and 54.5% had a positive C1Q. The baseline proteinuria was significantly higher among those with positive C1Q ($P$=0.03) while serum creatinine at baseline was not significantly different ($P$=0.3). The distribution of mesangial hypercellularity (M), segmental sclerosis (S), endocapillary proliferation (E), tubular atrophy and interstitial fibrosis (TF) were equally distributed among those with C1q positive and negative group.

Table 1. Clinical and histological feature.

| | C1Q Positive (n=30) | C1Q Negative (n=25) |
|---|---|---|
| Age (Years) Mean±SD | 31.4 (11.1) | 32.9 (13.0) |
| Clinical Presentation(%) | | |
| Elevated serum creatinine | 23 | 44 |
| Hypertension | 16.7 | 48 |
| Nephritic syndrome | 56.7 | 44 |
| Baseline creatinine μmol/L* | 107 (191±216) | 131 (164±110) |
| Last creatinine μmol/L* | 98 (178±196) | 113 (243±255) |
| Oxford classification(%) | | |
| M1 | 76.6 | 72 |
| E1 | 16.7 | 24 |
| S1 | 76.6 | 52 |
| TF1 | 23.3 | 36 |
| TF2 | 13.3 | 20 |
| *Median (Mean±SD); All $P$ values are not significant. | | |

Among 36 patients whom they were follow up greater than one year and a median of 5 years, the rate of WRF was seen in 29.4% for those with C1Q positive and 31.6% for C1Q negative (p=0.8).

**Conclusions:** The tissue C1Q status among patients with IgAN has no long term prognostic significance.

## TH-PO968

**Renal PLA$_2$R Is a Valuable Biomarker for Idiopathic Membranous Nephropathy** Qionghong Xie, Yan Li, Yueheng Ren, Xiaoye Zhu, Weiyu Zhu, Jianyong Zhong, Jun Xue, Chuan-Ming Hao. *Huashan Hospital, Fudan Univ, Shanghai, China.*

**Background:** The present study characterized PLA$_2$R expression in the kidney and examined its role as a biomarker for idiopathic membranous nephropathy (iMN).

**Methods:** Patients with MN without identifiable secondary causes were included. Anti-PLA$_2$R antibody was detected by indirect immunofluorescence (IF) and renal PLA$_2$R examined using a specific antibody. PLA$_2$R expression has been optimized by testing different antigen retrievals. Microwaving was used in this study unless specified. We compared paraffin-embedded and frozen section of 40 iMNs, 35 were positive and 3 were negative on both sections, 2 were negative on paraffin but positive on frozen section, suggesting frozen sections are more sensitive.

**Results:** In normal kidney, PLA$_2$R was negative by IF or IHC in both paraffin-embedded and frozen section. After antigen retrieval by autoclave, PLA$_2$R was detected in glomeruli along the GBM. However, in renal biopsies with iMN, 47/50 (94%) showed granular staining of PLA$_2$R along the GBM with microwave retrieval. All these 47 tissue samples showed IgG4(+), while the three PLA$_2$R negative samples were IgG4(-) but IgG1(+). In contrast, non-MN primary GN (40) exhibited negative PLA$_2$R staining except one (FSGS) that showed weak PLA$_2$R. In 30 lupus nephritis, 14 exhibited weak PLA$_2$R staining, and in a more scattered pattern.

We then examined the correlation of serum autoantibody and kidney $PLA_2R$ expression. Of 41 MNs with both serum anti-$PLA_2R$ antibody data and renal biopsy $PLA_2R$ (paraffin) available, 24 were anti-$PLA_2R$ antibody positive (59%) and 17 were negative (41%). Among these 17 negative autoantibody cases, 9 exhibited kidney $PLA_2R$(+) staining. Of 24 serum $PLA_2R$ antibody positive cases, only one showed negative for kidney $PLA_2R$.

**Conclusions:** (1) Normally PLA2R is expressed in podocytes, but can only be detected after antigen retrieval (2) In iMN but not non-MN GN, PLA2R immunofluoresecnt becomes positive. (3) Some serum PLA2R autoantibody negative iMN patients show renal tissue PLA2R staining. (4) Kidney PLA2R can also be detected in lupus nephritis. Conclusion: Renal tissue PLA2R can provide additional information for MN diagnosis.

## TH-PO969

**Excellent Long-Term Prognosis and Its Contributing Factors in Korean Idiopathic Membranous Nephropathy Patients** Hyuk Huh, Hajeong Lee, Jung Pyo Lee, Dong Ki Kim, Yun Kyu Oh, Yon Su Kim, Chun Soo Lim. *Internal Medicine, Seoul National Univ Hospital, Seoul, Korea.*

**Background:** Recently, prognosis of idiopathic membranous nephropathy (iMN) has been improved by using antiproteinuric therapies including immunosuppressive agents and renin-angiotensin system (RAS) blockades. In this study, we aimed to explore the long-term prognosis and its contributing factors in Korean iMN patients.

**Methods:** We included consecutive biopsy-proven iMN patients at Seoul National University Hospital. Patients who were younger than 18 years with known secondary causes of MN were excluded. Primary outcome was defined as composite of end-stage renal disease, doubling creatinine. The secondary outcome was complete or partial remission of proteinuria.

**Results:** A total of 302 patients met these criteria between 1979 and 2012. Median length of follow up was 136 months (80 – 249). Mean age was 49 ± 12 years and 183 (60.6%) patients were male. In these patients, 70.9% of patients were treated with immunosuppressant, 74.5% of patients received RAS blockades. Among them, 9.3% of patients reached the primary outcome. Although relapse was observed in 17.3% of patients who was reached remission with primary therapy, patients who reached remission finally was 89.2%. Rate of immunosuppressive agent induced remission was 80.9% and spontaneous remission appeared in 19.1% of patients. RAS blockade significantly improved remission rate even adjusted by age, hypertension, anemia, serum albumin, proteinuria, estimated GFR (eGFR), immunosuppressants (adjusted odd ratio (OR) 4.000, 95% confidence interval (CI) 1.215 – 13.167, P = 0.023). However, increased age and decreased eGFR (eGFR < 60mL/min/1.73m$^2$) (adjusted OR 0.072, 95% CI 0.014 – 0.387, P = 0.002) at the time of biopsy were a significant risk factor for poor response. Also, hypertension (adjusted OR 0.305, 95% CI 0.094 – 0.987, P = 0.048), anemia (adjusted OR 0.200, 95% CI 0.058 – 0.691, P = 0.011) could predict poor response.

**Conclusions:** Patients of Korean iMN had excellent prognosis in comparison with Caucasian. This study suggests RAS blockades ameliorate renal outcome of Korean idiopathic membranous nephropathy.

## TH-PO970

**Subclass Analysis of Glomerular IgG Deposit in Patients with Various Types of Glomerulonephritis** Raima Nakazawa, Noriko Kaneyama, Hisae Tanaka, Qiong Wu, Masayuki Endoh, Masafumi Fukagawa. *Dept of Internal Medicine, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.*

**Background:** IgG subclass restriction is known to be observed in some glomerular IgG deposit. However it is not established as a routine clinical procedure for the diagnosis of glomerular diseases to study IgG subclasses. In order to evaluate usefulness of routine staining of IgG subclasses for renal biopsy specimen, we performed IgG subclass staining for two hundred fifty eight glomerulonephritis (GN) patients who had IgG deposit in their glomeruli shown by ani-whole human IgG antibody.

**Methods:** One hundred thirty nine patients with idiopathic membranous nephropathy (IMN), 67 of lupus nephritis [in which 17 cases are membranous lupus nephritis (MLN)], 20 of IgA nephropathy, 13 of anti-GBM nephritis and 19 of other GN were included in this study. Immunofluorescent microscopy using FITC labeled mouse monoclonal anti-human IgG1, IgG2, IgG3 and IgG4 antibodies (Southern Biotechnology, USA) was used to detect IgG subclasses in the glomeruli of these patients.

**Results:** Fifty two percent of IMN shows IgG1 and IgG4 combination deposit, whereas only 5.9 % of MLN shows IgG1 and IgG4 combination. Specificity of IgG1+IgG4 combination deposit in IMN is 94 %. Patients with LN show various combination of IgG subclasses. Fifty nine percent of LN are shown to have IgG1+IgG2+IgG3 combination. Ninety two percent of anti-GBM nephritis are revealed to be only IgG1 subclass antibody mediated diease. Sixty five percent of IgG deposit in IgA nephritis and Henoch-Shoenlein nephritis was shown to be IgG1 restricted. Three cases of proliferative glomerulonephtitis with monoclonal IgG deposit (PGNMID) were found in this study. All three cases are shown to have IgG3-k deposit.

**Conclusions:** It is concluded that routine IgG subclass staining in renal biopsy is useful tool for definite diagnosis of various types of glomerulonephritis which have glomerular IgG deposit. Further study is mandatory to elucidate the pathogenesis and the mechanism of restricted IgG subclass deposition in each type of glomerulonephritis.

**Dutch Transplantation in Vasculitis (DUTRAVAS)-Study: Outcome of Renal Transplantation in ANCA-Associated Vasculitis** Arda Goceroglu,[1] Chinar Rahmattulla,[1] Annelies Evaline Berden,[1] Marlies Reinders,[1] Marcory van Dijk,[2] Anoek A.E. de Joode,[2] Carine Peutz-Kootstra,[3] Maarten H.L. Christiaans,[3] Iris Noorlander,[4] Roel Goldschmeding,[5] Arjan D. Van Zuilen,[5] Eric Steenbergen,[6] Luuk Hilbrands,[6] Lorraine Harper,[7] Mark Alan Little,[8] Ernst C. Hagen,[9] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Leiden Univ MC; [2]Univ MC Groningen; [3]Maastricht Univ MC; [4]Erasmus MC Rotterdam; [5]Univ MC Utrecht; [6]Radboud Univ MC Nijmegen; [7]Univ of Birmingham; [8]Trinity College Dublin; [9]Meander MC Amersfoort.*

**Background:** We present a multi-center study on the outcome of renal transplantation in ANCA-associated vasculitis (AAV) patients focusing on renal disease recurrence and graft survival within 5 years after transplantation.

**Methods:** In total 113 AAV patients (first renal transplantation) were included from 6 university hospitals. Clinical data and transplant biopsies were collected through PALGA (Dutch national pathology database) and a center-specific search. Three patients had immediate graft loss and were excluded from analysis. Transplant biopsies were scored with Banff '09. Renal disease recurrence was scored with the histopathologic classification of ANCA-associated glomerulonephritis. We focused on the first 5 years after transplantation.

**Results:** Sixteen grafts were lost due to acute rejection (3), renal disease recurrence (4), IFTA (4), sepsis (2), infarction (1), cyclosporine toxicity (1), and post-transplant lymphoproliferative disorder (1). Five year graft survival was 82.8%. Thirteen patients had 16 disease relapses; 14 (11 patients) involved the graft. The risk for a first disease recurrence in the graft was 2.8% per patient year within 5 years follow-up. Ten recurrences were classified as: 5 focal, 1 crescentic and 4 mixed class. Four recurrences were clinically diagnosed (no histological confirmation). Of the 4 recurrences that led to graft loss, 3 could be classified: 1 focal and 2 mixed class.

**Conclusions:** This largest cohort study to date shows that a substantial proportion of patients with renal disease recurrence of AAV lost their graft due to the recurrent disease.

## TH-PO972

**The Histopathologic Classification of ANCA Associated Glomerulonephritis Is Associated with the Occurrence of Renal Relapse** Arda Goceroglu,[1] Marta Fiocco,[1] Annelies Evaline Berden,[1] Jan A. Bruijn,[1] David R.W. Jayne,[2] Ingeborg M. Bajema.[1] *[1]Leiden Univ MC; [2]Addenbrooke's Hospital Cambridge.*

**Background:** Patients with ANCA-associated glomerulonephritis (AAGN) at high risk of relapse should be identified early to improve clinical management. We investigated whether the histopathologic classification of AAGN is associated with the occurrence of renal relapse.

**Methods:** Diagnostic renal biopsies and clinical data of 113 patients with mild-severe AAGN from 2 European randomized clinical trials were included. Renal relapse was defined as new hematuria or proteinuria and/or a >30% rise in serum creatinine attributable to active AAGN. We used 2 competing risks methods (applied when >1 competing endpoints are possible). Competing endpoints were ESRF and death. For an etiological association we used the cause-specific proportional hazards method. For a predictive association we used the Fine & Grey method. We analysed 2 predefined multivariate models. Model 1 included class, age, creatinine and plasmapheresis. Model 2 included class, creatinine, diagnosis and ANCA-type.

**Results:** CAUSE-SPECIFIC PROPORTIONAL HAZARDS METHOD: In both models the histopathologic class was the only independent baseline parameter associated with renal relapse. Focal (model 1: HR=0.10, 95%CI 0.02-0.60, p=0.01; model 2: HR=0.09, 95%CI 0.02-0.55, p=0.01) and crescentic class (model 1: HR=0.21, 95%CI 0.07-0.62, p<0.01; model 2: HR=0.21, 95%CI 0.07-0.64, p=0.01) were associated with less patients experiencing renal relapse compared to sclerotic class. FINE & GREY METHOD: The histopathologic class was not associated with renal relapse in both models. Only higher age (model 1) was associated with lower risk for renal relapse (HR=0.97, 95%CI 0.94-0.99, p=0.02).

**Conclusions:** Results from the analyses indicate that the histopathologic class of AAGN has a role in the etiology of renal relapse, but does not identify patients at high risk for renal relapse. In sclerotic class patients renal relapses may be more readily detected because of the limited compensatory capacity of the kidney. Alternatively, different classes may represent different phenotypes of AAGN in which renal relapses are combined with more chronic lesions.

**TH-PO973**

**ENT Involvement Is Related to Better Renal Function in Patients with ANCA-Associated Vasculitis (AAV)** Chinar Rahmattulla,[1] Robert A. De Lind van wijngaarden,[2] Annelies Evaline Berden,[3] Herbert Hauer,[4] Oliver Flossmann,[5] David R.W. Jayne,[6] Niels Rasmussen,[7] Laure-Helene Noel,[8] Franco Ferrario,[9] Ruediger Waldherr,[10] Charles D. Pusey,[11] Ernst C. Hagen,[12] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Leiden UMC; [2]Erasmus MC Rotterdam; [3]Bronovo Hospital; [4]MC Leeuwarden; [5]Royal Berkshire Hosp.; [6]Addenbrooke's Hosp.; [7]Statens Seruminstitut; [8]Necker Hosp.; [9]San Gerardo Hosp.; [10]Univ of Heidelberg; [11]Imperial College London; [12]Meander MC.*

**Background:** It has been suggested that ear, nose, and throat involvement (ENT+) can prompt early diagnosis of AAV and that ensuing rapid instigation of therapy can prevent renal impairment. Therefore, this study investigates whether ENT+ AAV patients have better renal function and fewer chronic renal histopathologic lesions at time of diagnosis than ENT- patients.

**Methods:** 441 newly diagnosed AAV patients with renal involvement from 4 international, prospective, multicenter trials were included. Age, ENT+, ANCA type, interstitial fibrosis and tubular atrophy (IFTA), tubulitis, interstitial infiltrates and the histopathologic class for ANCA-associated glomerulonephritis (AAGN) (n=151) were correlated with eGFR at diagnosis (eGFR0).

**Results:** Multivariate analysis revealed that ENT+ (n=212) ($r=0.25, p<0.001$), age ($r=-0.34, p<0.001$), IFTA ($r=0.16, p<0.001$), tubulitis ($r=0.16, p=0.001$), interstitial infiltrates ($r=0.20, p<0.001$) and the classification ($r=4.1p<0.001$) were associated with eGFR0. A prespecified sensitivity analysis including only PR3-ANCA-positive patients showed similar results. ENT+ patients had a higher eGFR0 (60 vs. 44 mL/min, $p<0.001$), less IFTA ($p=0.001$) and more often class I/II than class III/IV in their renal biopsies ($p<0.001$). Increasing numbers of BVAS ENT parameters correlated with increasing renal function ($p<0.001$).

**Conclusions:** In AAV, ENT+ is associated with better eGFR0 and characterized by class I/II on renal histopathology, also in the PR3-ANCA subgroup. These findings indicate that ENT+, possibly because symptoms are clinically overt, leads to a prompt diagnosis of AAV. Reduced diagnostic delay means identifying renal impairment at an early stage, which – with prompt start of treatment – has a known favourable effect on renal outcome.

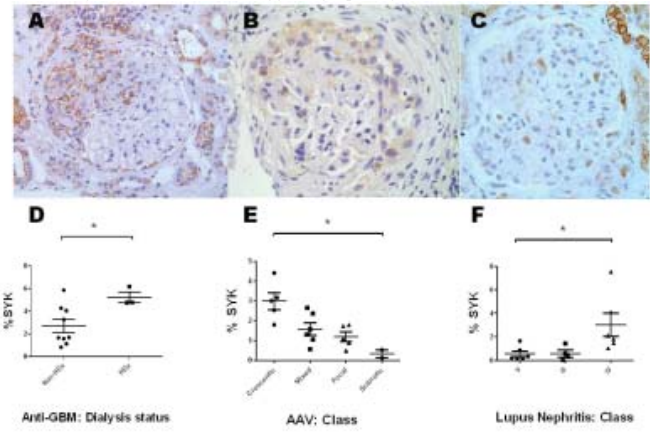
**TH-PO974**

**Spleen Tyrosine Kinase (SYK) Expression Correlates with Disease Activity and Outcome in Glomerulonephritis** Stephen Paul McAdoo, Gurjeet Bhangal, Anisha Tanna, Liz Lightstone, H. Terence Cook, Charles D. Pusey, Frederick W.K. Tam. *Imperial College London.*

**Background:** Spleen tyrosine kinase (SYK) has a critical role in immunoreceptor signaling. SYK inhibition has shown efficacy in animal models of immune-mediated renal injury, including murine lupus and, in work previously reported by our group, autoimmune glomerulonephritis and nephrotoxic nephritis. However, SYK expression in human renal tissue is not well characterised.

**Methods:** We conducted immunohistochemical analysis for total and phosphorylated SYK in clinical biopsy specimens (thin basement membrane, n=4; minimal change, 4; anti-GBM disease, 12; ANCA vasculitis, 18; lupus nephritis, 16). SYK staining was quantified using automated image analysis software and related to histological class and clinical outcome.

**Results:** Glomerular staining for total SYK was positive in anti-GBM disease, AAV and lupus nephritis (Fig A,B,C respectively), but not thin basement membrane disease or minimal change. SYK expression appeared to localise to inflammatory lesions (areas of crescent formation or endocapillary proliferation). SYK expression correlated with disease severity and/or histological class (Fig D,E,F). In anti-GBM and AAV, glomerular staining for phosphorylated SYK was positive and localized to areas of crescent formation, demonstrating SYK activation and suggesting a pathogenic role.



*$p<0.5$.

**Conclusions:** SYK is expressed in a variety of autoimmune renal diseases, and this is the first report that glomerular expression levels appear to correlate with disease activity and outcome. Clinical studies targeting SYK in glomerulonephritis are warranted.

**TH-PO975**

**Immuno-Histological Detection of Parietal Epithelial Cells Distinguishes Early FSGS from Minimal Change Disease** Bart Smeets,[1] Hermann-Josef Groene,[2] Rutger J. Maas,[3] Vivette D. D'Agati,[4] Agnes B. Fogo,[5] Toin Van Kuppevelt,[3] Jürgen Floege,[1] Jack F. Wetzels,[3] Marcus J. Moeller.[1] *[1]Univ Hospital of the RWTH Aachen; [2]German Cancer Research Center (DKFZ); [3]RUNMC, Nijmegen; [4]Columbia Univ; [5]Vanderbilt Univ Medical Center.*

**Background:** Recently, we have shown that parietal epithelial cells (PECs) are crucially involved in the development of FSGS lesions. In the presents study we investigated whether immuno-histological detection of (activated) PECs present on the glomerular tuft can be used to distinguish early FSGS from minimal change disease (MCD).

**Methods:** 95 renal biopsies containing 8 or more glomeruli from 38 adult patients diagnosed with "early" FSGS and 57 patients with newly diagnosed MCD were stained for claudin-1 (PEC marker), CD44 (PEC activation) and LKIV69 (PEC matrix). Unaware of the original diagnosis, the glomeruli were revaluated. Biopsies showing staining of one or more of the PEC markers in a visceral location were assigned as FSGS. Those negative for the PEC markers were assigned as MCD.

**Results:** Revaluation of the biopsies with the PEC markers confirmed the original diagnosis (FSGS or MCD) in 76 biopsies (80% of total) and could confirm in 33 of 38 (87%) biopsies diagnosed with FSGS the presence of glomerulosclerosis. PECs were involved in the development of FSGS lesions from the earliest stages of disease. In the remaining 5 biopsies diagnosed as FSGS, no PEC marker staining was detected – most likely due to the focal nature of the lesions and because only a single slide of each biopsy was evaluated. Interestingly, in 14 of 57 (25%) biopsies originally diagnosed as MCD we detected the presence of FSGS lesions. These lesions were typically small and difficult or non-detectable in PAS stained sections but could be detected by PEC matrix marker LKIV69.

**Conclusions:** Immunohistological detection of PECs on the glomerular tuft very likely improves the sensitivity of the FSGS diagnosis. In particular, the detection of parietal matrix using the LKIV69 antibody may be a more sensitive tool to detect early FSGS lesions, which might otherwise be missed on PAS stained sections.

**TH-PO976**

**Kidney Disease in the Obese: The Full Biopsy Spectrum** Steven Salvatore, Surya V. Seshan. *Pathology, Weill Cornell Medical College, New York, NY.*

**Background:** Obesity related glomerulopathy (ORG) is a well-recognized pathologic process attributed to hyperfiltration podocyte injury in which glomerular hypertrophy, perihilar segmental sclerosis, and partial foot process effacement lead to subnephrotic proteinuria in patients with excess body mass. Renal biopsies are performed in obese patients with clinical renal disease which may be directly related to obesity or secondary to associated or unassociated medical conditions.

**Methods:** Native kidney biopsies from 2000-2012 were retrospectively reviewed from patients with obesity, body mass index >30. Glomerular diameter was measured using a standard micrometer in 1-7 glomeruli cut through the hilum (mean 4). The clinicopathologic characteristics are analyzed.

**Results:** Of 6702 total native kidney biopsies, 287 (4%) were obtained from obese patients (mean: weight 122kg, BMI 40.3kg/m2). Associated factors such as insulin resistance (31%), hypertension (60%), and obstructive sleep apnea (9%) were frequent. Indication for biopsy was proteinuria in 93%, nephrotic (40%) and subnephrotic (53%). 52% also had renal insufficiency, defined as Cr >1.5mg/dL. Typical lesions of ORG were seen in 41% of cases: focal segmental glomerulosclerosis (FSGS) 28% - perihilar variant (9%), and glomerulomegaly alone 13%. Diabetic nephropathy was seen in 22% of all obese patients and 70% of the obese diabetic patients. Immune complex (IC) disease 15%, tubulointerstitial (TI) disease 5%, vascular disease 5%, thin basement membranes 5%, minimal change disease 3%, idiopathic FSGS 2%, and collapsing glomerulopathy 2% were seen. Glomerulomegaly, glomerular diameter greater than 180 μm, was present in 84% of cases (mean 224 μm) vs normal size in 11% (mean 157 μm). Proteinuria was highest in patients with idiopathic FSGS (mean 8g/24hrs) and IC GN (mean 7.4g/24hrs) and was subnephrotic in obesity-related FSGS (61%), glomerulomegaly-alone (82%), and TI diseases (80%). Creatinine levels were highest in TI diseases (mean 8.4mg/dL) and progressive DN (mean 2.5mg/dL).

**Conclusions:** Diverse kidney pathology superimposed on ORG is present in obese patients with clinical renal disease. Kidney biopsy is important for accurate diagnosis, prognosis and treatment.

**TH-PO977**

**Glomerular Lesions in Chronic Smoking and Hypertension Are Not Always Nodular Sclerosis** Steven Salvatore,[1] Megan L. Troxell,[2] Douglas Hecox,[3] Kevin R. Sperling,[4] Surya V. Seshan.[1] *[1]Weill Cornell Medical College, New York, NY; [2]Oregon Health and Science Univ, Portland, OR; [3]Renal Care Consultants, Medford, OR; [4]Crozer-Chester Medical Center, Chester, PA.*

**Background:** Idiopathic nodular glomerulosclerosis (ING) is a well-recognized entity associated with chronic smoking and hypertension leading to glomerular mesangial nodule formation which clinically and pathologically mimics that seen in nodular diabetic nephropathy (DN). However, like DN, diffuse mesangial sclerosing changes may occur in this setting in the absence of nodules.

**Methods:** The clinicopathologic features of 8 non-diabetic patients with long smoking history found in 5139 native kidney biopsies from 2003-2012 showing diffuse mesangial glomerulosclerosis (5) or ING (3) were analyzed.

**Results:** The patients had similar clinical characteristics, 7/8 were men, age 58-84 years with smoking history of 15-72 pack-years. None of the patients manifested obesity or diabetes, but all had hypertension. Other cardiovascular comorbidities were also present including peripheral vascular disease, heart disease and stroke. At the time of biopsy, the mean creatinine was 1.8mg/dL (range 1.4-5.4) and the mean proteinuria was 3.7g/24hrs. The renal pathologic findings were similar in all patients except mesangial nodules in ING. Global glomerulosclerosis was seen in 6-65% of glomeruli (mean 29%), glomerulomegaly in 7/8, and the range of interstitial fibrosis was 10-80% (mean 40%). Moderate (25%) and severe (75%) arteriosclerosis and arteriolar hyalinosis (86%) were also observed. Glomerular hilar neovascularization was prominent. Capillary wall double contours, subendothelial widening, endothelial swelling and new basement membrane formation suggesting chronic healing thrombotic microangiopathy (TMA) was noted in 88%. However, no immune complexes were localized.

**Conclusions:** Kidney biopsies showing either diffuse or nodular mesangial sclerosis from patients with proteinuria and chronic renal insufficiency may be due to prolonged smoking and hypertension. Chronic glomerular endothelial injury may result from smoking and cause a healing TMA appearance in the appropriate setting, even in the absence of mesangial nodule formation.

## TH-PO978

**Endothelial Cell Injury May Involved in Pathogenesis of Secondary Focal Segmental Glomerulosclerosis Associated with Myeloproliferative Disease** Emiko Fujita,[1] Akira Shimizu,[2] Megumi Fukui,[1] Akiko Mii,[1] Shuichi Tsuruoka.[1] *[1]Dept of Nephrology, Nippon Medical School, Bunkyo-ku, Tokyo; [2]Dept of Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

**Background:** Recently, JAK2V617F mutation may cause myeloproliferative disease(MPD) including polycythemia vera (PV), essential thrombocythemia (ET). The frequency of JAK2 mutation may determine which cell lineages increase, possibly leading to the diversity of MPD. Several reports describe MPD cases have some degree of proteinuria due to biopsy proven focal segmental glomerulosclerosis (FSGS). The pathogenesis of FSGS associated with MPD remains unknown. Endothelial cell abnormalities with mutation of JAK2V617F were reported in PV patients. We herein report three cases of FSGS associated with MPD with endothelial cell injury.

**Methods:** We observed three cases with persistent proteinuria, two of them are nephritic range, after a 8 to 10-year history of MPD. The type of MPD was PV in two patients, unclassifiable MPD in one. Renal biopsy was performed and assessed the pathological characteristics of these cases. We examined serum thrombomodulin(TM) and VEGF to assess endothelial cell injury.

**Results:** Renal biopsy revealed some glomeruli have segmental sclerosis with foam cell infiltration and podocyte proliferation, double contours, and mesangial sclerosis and hypercellularity on light microscopy. Arteriosclerosis was seen in all cases and ranged from mild in unclassifiable MPD, to severe in PV case which was looks like onion skin thickening. Electron microscopy showed endothelial cell proliferation, loss of fenestra, and separation of endothelial cells from capillary basement membrane with subendothelial edema. Serum VEGF and TM level was elevated in PV cases accompanied by JAK2V617F mutation, whereas normal in JAK2 mutation –negative unclassifiable MPD. Endothelial cell injuries in glomeruli and small arteries were prominent in the cases with the mutation of JAK2V617F.

**Conclusions:** We described three cases of glomerulopathy with MPD patients revealed FSGS accompanying endothelial cell injuries in glomeruli and small arteries. Endothelial cell abnormalities with mutation of JAK2V617F may have involvement in pathogenesis in FSGS associated with MPD.

## TH-PO979

**Histopathologic Findings Associated with *APOL1* Risk Variants in Chronic Kidney Disease** Christopher Patrick Larsen, Josephine M. Ambruzs, Larry N. Cossey, Nidia Cordeiro Messias, Patrick D. Walker. *Nephropath, Little Rock, AR.*

**Background:** African Americans (AA) have a greatly increased risk of kidney disease which can be explained by the presence of risk alleles in the *APOL1* gene. The *APOL1* disease spectrum includes primary FSGS, non-diabetic ESKD, and collapsing glomerulopathy. We sought to perform an *APOL1* genotype-phenotype correlation in renal biopsies from AA with CKD.

**Methods:** AA patients with an eGFR<60 mL/min/1.73 m$^2$ for 3 months with a diagnosis of arterionephrosclerosis on biopsy were included. *APOL1* risk allele genotyping was performed using TaqMan assays. 114 biopsies were included including 58 biopsies which had 2 risk alleles and 56 biopsies with 0 risk alleles. A blinded morphologic evaluation of each compartment of the kidney was carried out.

**Results:** We found significantly less obsolescent glomerulosclerosis, more thyroidization-type tubular atrophy and more microcystic tubular dilatation in the patients with 2 risk alleles. There was more arteriosclerosis in the 0 risk allele group. The degree of foot process effacement was not significantly different in these two groups.

| Morphology | 0 risk alleles | 2 risk alleles |
|---|---|---|
| Glomeruli, mean (range) | 19.2 (8-48) | 15.8 (8-50) |
| Global sclerosis, mean (%) | 9.4 (49%) | 9.7 (61%) |
| -Obsoclescent, mean (%) | 5.3 (56%) | 3.0 (31%) |
| -Solidified, mean (%) | 2.3 (25%) | 3.4 (35%) |
| -Disappearing, mean (%) | 1.8 (19%) | 3.3 (34%) |
| FSGS, mean (%) | 1.5 (8%) | 1.6 (10%) |
| Degree GBM thickening | 1.1 | 0.9 |
| Degree foot process effacement | 1.3 | 0.9 |
| Degree tubular atrophy | 2.3 | 2.7 |
| -Degree thyroidization-type TA | 0.4 | 0.9 |
| -Degree endocrie-type TA | 0.2 | 0.2 |
| -Degree classic-type TA | 1.7 | 1.6 |
| % cases with microcystic tubular dilitation | 7% | 31% |
| Degree arterial intimal fibrosis | 2.4 | 2.1 |
| Degree arteriolar hyalinosis | 1.5 | 1.0 |

**Conclusions:** We present the first detailed description of the biopsy changes associated with APOL1 risk alleles in the setting of CKD. These findings suggest that APOL1-related CKD is not driven by arteriosclerosis or a primary podocytopathy. Additionally, they allow prediction of the presence of APOL1 risk alleles in this demographic based on renal biopsy findings.

## TH-PO980

**Prediction of Renal Outcome in Patients with Diabetic Nephropathy Using the Pathological Classification** Yu An, Feng Xu, Yongchun Ge, Cai-Hong Zeng, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing Univ School of Medicine.*

**Background:** In 2010, a pathologic classification of diabetic nephropathy (DN) was launched by Tervaert et al. But its value in the prediction of clinical outcome is largely undetermined. Our aim was to evaluate its predictive power in type 2 diabetes mellitus (T2DM).

**Methods:** We enrolled 414 T2DM patients who had biopsy-confirmed DN and were followed for at least a year after biopsy. All cases were categorized according to the pathologic classification of Tervaert et al.Some common pathological changes of DN were also examined. The relevancies between pathological findings and renal outcome were assessed. A renal event was defined as eGFR<15ml/min/1.73m$^2$.

**Results:** Cox regression showed that the glomerular classes, </a>interstitial fibrosis and tubular atrophy (IFTA) and interstitial inflammation can significantly influence renal survival in these patients. Scores of arteriolar hyalinosis and arteriosclerosis were not significant variables. More than one area of arteriolar hyalinosis was commonly found in 95.4% of these patients, indicating that this index may not be suitable for classification. Patients with nodule lesions, glomerular microaneurysms, atubular glomeruli, segmental sclerosis, hyaline caps, fibrinoid exudation, foam cells within loops, glomerular inflammation, crescents, segmental endothelial proliferation and acute tubular injury had a worse renal survival. Multivariate COX analysis showed that the glomerular classes, IFTA and acute tubular injury were independent risk factors for renal prognosis, even when adjusted for proteinuria, blood pressure and eGFR.

**Conclusions:** The glomerular classification and IFTA are significantly associated with renal outcome in patients with T2DM, independently of proteinuria, blood pressure and eGFR. However, the vascular indexes in the classification are incapable to reflect the difference in vascular lesion severity of the patients and can't be used for renal prognosis, suggesting a necessity to redefine them. Finally, acute tubular injury is also an independent risk factor of the progression of DN to ESRD.

## TH-PO981

**Misdiagnosing Renal Amyloidosis as Adult Minimal Change Disease: Is It Time for a Change in Practice?** Rabya H. Sayed,[1,2] Janet A. Gilbertson,[2] Paul Steven Bass,[1] Philip N. Hawkins,[2] Helen J. Lachmann,[2] Julian D. Gillmore.[2] *[1]Centre for Nephrology, UCL. Royal Free Campus, United Kingdom; [2]National Amyloidosis Centre, UCL Div of Medicine, Royal Free Campus, London, United Kingdom.*

**Background:** Minimal change disease (MCD) accounts for 10-15% of all adult nephrotic syndrome (NS) cases and diagnosis relies on normal renal light microscopy with foot process effacement on electron microscopy (EM). Renal amyloid deposits (RAD) are identified by red-green birefringence under cross-polarized light after staining with Congo Red (CR) and fibrils seen on EM support the diagnosis further. Late diagnosis and delayed treatment of renal amyloidosis negatively impacts on renal and overall prognosis.

**Methods:** A retrospective analysis of 2116 patients referred with histologically proven renal amyloidosis to the UK National Amyloidosis Centre (NAC) between 2001 and 2013 was performed. Twenty-nine patients were identified in whom the initial renal histology was reported as MCD before subsequent identification of RAD. All available biopsies from these patients were reviewed by two independent specialists.

**Results:** Mean age at MCD diagnosis was 58.6 years and median time period between the diagnosis of MCD and amyloidosis was 1 year (range 2 weeks to 10 years). MCD was diagnosed in the absence of EM in 13 of 29 cases. EM pictures were subsequently obtained/reviewed in 9 such cases, all of which showed fibrils typical of amyloid. MCD was diagnosed in the absence of CR staining in 17 cases which was diagnostic of amyloid in each of 13 cases that were retrospectively stained. The mean number of renal biopsies taken prior to reaching a diagnosis was 1.6. The overriding reason for reviewing or repeating renal biopsies was steroid-resistance of proteinuria, which averaged 7.8 g/24hr at presentation.

**Conclusions:** This analysis clearly demonstrates the importance of undertaking EM and CR staining in adults with NS and the value of reviewing original biopsies with EM and CR prior to undertaking another renal biopsy. Early diagnosis of amyloid is likely to limit morbidity and mortality associated with a prolonged nephrotic state, progression of untreated amyloidosis and repeated renal biopsies.

## TH-PO982

**Medullary Epithelial Mass Morphometry in Human Renal Biopsies: Progressive Injury and Relationship to Cortical Epithelial Mass**

Alton Brad Farris,[1] Diane H. Lawson,[1] Cynthia Na Cohen,[1] Seymour Rosen.[2]
*[1]Emory Univ; [2]Harvard Univ/Beth Israel Deaconess Medical Center.*

**Background:** The outer medulla has two major zones: outer stripe (OS) and inner stripe (IS). OS cellular mass is primarily formed by proximal tubules and is limited in extent. IS consists of an epithelial cell mass (EPCM) formed mostly by thick ascending limbs and collecting ducts. OS and IS zonal delineation depends on recognizing corticomedullary junction connective tissue/vascular components, adjacent OS, and vasa recta. To characterize injury in these regions, we conducted a morphometric study.

**Methods:** Consecutive native renal biopsies (n=37) were examined; and the sole inclusion criteria was the availability of medulla (primarily outer medulla). Trichrome, PAS, and cytokeratin (CK) immunostained slides were digitally scanned to obtain whole slide images. For the entire cortex and entire medulla, EPCM was quantitated using a positive pixel count algorithm tuned to detect the brown chromogen of the CK stain and the red staining of trichrome. In addition, pathologist visual assessment was recorded for % tubular atrophy (%TA) and % composed of EPCM.

**Results:** The EPCM (mean±standard deviation [SD]) of the cortex and medulla, respectively, were 61±12% and 45±12% on trichrome; 55±11% and 53±11% on CK, and 46±24%; and 24±15% on pathologist assessment. Cortical and medullary EPCM declined together, with linear regression showing direct relationships between cortical and medullary EPCM by trichrome ($r=0.64$ between cortex and medulla, $p<0.0001$) and CK ($r=0.87$, $p<0.0001$). The OS and IS width was 1.7±0.9 and 4.7±2.7 mm (mean±SD), respectively. Notably, IS width inversely correlated with trichrome EPCM ($r=-0.64$, $p<0.0001$ for all tissue and $r=-0.58$, $p=0.002$ for the medulla).

**Conclusions:** Medullary and cortical EPCM are related, diminishing together. Furthermore, IS expansion is associated with reduced EPCM. Thus, as epithelial cell elements are lost, reactive/fibrotic responses cause interstitial expansion and IS zonal widening. Analyzing and quantitating EPCM in medullary injury may provide a unique perspective to examine human chronic kidney disease.

## TH-PO983

**The NEPTUNE Digital Pathology Morphologic Profiling of Nephrotic Syndrome**

L. Barisoni,[1,2] C. Avila-Casado,[2] A. Gasim,[2] J. Troost,[2] S. Bagnasco,[2] J.B. Hodgin,[2] J. Charles Jennette,[2] D.B. Johnstone,[2] Jeffrey B. Kopp,[2] Catherine M. Conway,[2] Stephen M. Hewitt,[2] Cynthia C. Nast.[2] *[1]U Miami; [2]NEPTUNE.*

**Background:** Pathologic classifications of nephrotic syndrome historically have been performed by light microscopy using known diagnostic entities. The Nephrotic Syndrome Study Network (NEPTUNE) has taken a novel approach by a) applying digital pathology review on renal biopsy whole slide imaging (WSI) and immunofluorescence (IF) and electron microscopy (EM) digital images from FSGS, MCD and MN patients; b) morphologically profiling renal biopsies using "descriptors" of injury for all renal compartments.

**Methods:** We defined 49 histologic, 10 IF and 14 EM descriptors. Glomerular histologic descriptors were applied to individually identified, digitally-annotated multilevel-reconstructed glomeruli. As proof of concept and to test descriptor-based profiling reproducibility of WSI and digital EM images, podocyte descriptors (see table) were evaluated in 133 FSGS/MCD biopsies by 3 pathologists: junior, mid-career and senior (P1, P2 & P3). We used Kendall's coefficient of concordance to measure inter-reader reliability on an ordinal scale across all 3 pathologists as well as pairwise comparisons between each pathologist.

**Results:**

| Kendall's coefficient of concordance for each comparison | | | | |
|---|---|---|---|---|
| | Effacement (0-4+) | Cytoskeletal condensation (0-2+) | Microvillous transformation (0-2+) | Loss of primary processes (0-2+) |
| P1, P2, P3 | 0.923 | 0.631 | 0.714 | 0.445 |
| P1 vs P2 | 0.939 | 0.709 | 0.763 | 0.609 |
| P1 vs P3 | 0.925 | 0.741 | 0.788 | 0.514 |
| P2 vs P3 | 0.964 | 0.720 | 0.804 | 0.617 |

**Conclusions:** NEPTUNE descriptor-based morphologic profiling applied to a web-based information system provides comprehensive analysis of renal structures. Preliminary inter-observer reproducibility ranges from excellent (effacement) to good (loss of primary processes), independently from the reader experience. The granularity of morphologic profiling may improve correlation with clinical and molecular signatures, provide more robust information regarding the significance of specific lesions for prognosis and therapeutic response, and set the bases for new classification systems.

**Granulomatous Interstitial Nephritis Secondary to Chronic Lymphocytic Leukemia/Small Lymphocytic Lymphoma**

Samih H. Nasr, Tait Shanafelt, Curtis Hanson, Sanjeev Sethi, Lynn D. Cornell, Mary E. Fidler, Nelson Leung.
*Mayo Clinic.*

**Background:** Granulomatous interstitial nephritis (GIN) is an uncommon lesion with a native kidney biopsy incidence of 6%. Established causes of GIN include drug hypersensitivity, infection (particularly fungi), sarcoidosis, and TINU syndrome. Chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) has not been previously recognized as a potential cause of GIN.

**Methods:** We report the clinicopathologic findings and outcome of 4 CLL/SLL patients who developed GIN.

**Results:** The cohort consisted of 2 males and 2 females, all Caucasians, with a mean age of 72.8 years at renal biopsy. CLL/SLL was diagnosed concurrently with GIN in 1 patient and 2-8 years prior to GIN in the remaining 3. CLL/SLL stage at the time of GIN diagnosis was 0 in two patients, 1 in one, and 3 in one. All patients presented with severe renal impairment with mean serum creatinine at renal biopsy of 4.7 mg/dl. Three patients had leukocyturia and 1 hematuria.

Histologically, all cases showed interstitial inflammation (diffuse in 3 and patchy in 1), lymphocytic tubulitis, non-necrotizing granulomas with multinucleated giant cells, and focal acute tubular injury. Interstitial eosinophils were not prominent in any case. In one case, the granulomatous reaction also involved arteries. Focal interstitial involvement by CLL/SLL was noted in 3 cases. One patient also had granulomatous reaction in skin lesions and lymph nodes.

GIN was treated with steroids alone in 2, steroids and cyclophosphamide in 1, and sequential treatments with steroids, cyclophosphamide, rituximab, vincristine, and alemtuzumab in 1. Duration of follow up ranged from 2 to 66 months. All 4 patients had a partial response to therapy (mean follow up serum creatinine 2.6 mg/dl, mean decrease in serum creatinine 5.1 mg/dl). One patient had multiple relapses of GIN occurring during CLL/SLL flares which responded to lymphoma chemotherapy.

**Conclusions:** We report a novel association between GIN and CLL/SLL. GIN secondary to CLL/SLL may occur with or without interstitial lymphomatous infiltration and extrarenal granulomatous reaction. Steroids (with or without lymphoma directed chemotherapy) leads to partial improvement of kidney function.

## TH-PO985

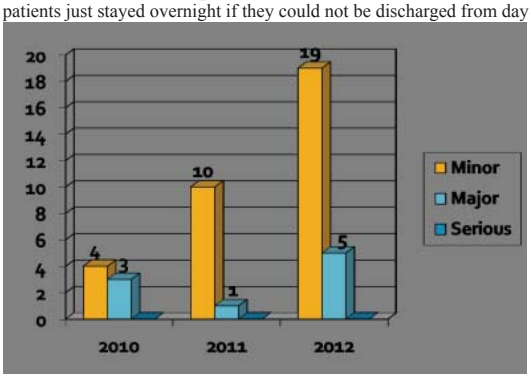
**Day Case Renal Biopsy: Single Centre Experience**

Roshni Rathore.
*Renal Medicine, Royal Preston Hospital, Preston, United Kingdom.*

**Background:** There has been an increase in number of renal biopsies being performed on day case basis in recent years. Day case renal biopsy offers advantage of patients being discharged home same day. We aim to look at our practice in the last 3 years at Royal Preston Hospital, specifically looking at minor and major complications, biopsies with adequate tissue yield, patients discharged home same day and mean length of stay if admission was required.

**Methods:** We retrospectively analysed 312 renal biopsies done between 2010-2012. Data was gathered using Quadramed system and histopathology database. Percutaneous renal biopsies were performed under ultrasound guidance using spring loaded biopsy gun. Minor complications included macroscopic haematuria or perinephric haematoma. Need for transfusion or intervention was regarded as major complication. Serious complications included death, loss of kidney or life-threatening haemorrhage. If complication occurred after discharge, it was regarded as a delayed complication.

**Results:** Number of biopsies has increased with each consecutive year. In more than 93% of biopsies, adequate tissue yield was obtained. While minor complications increased as biopsies increased, major complications remained few. Only 3 patients required intervention in the form of CT angiography in 3 years; only 1 out of these 3 needed embolisation. Most patients just stayed overnight if they could not be discharged from day case unit.



**Conclusions:** If patients suitable for day case renal biopsy are selected using set criteria, they are more likely to be safely discharged from day case unit on the same day. If haematuria warrants inpatient admission, overnight stay is sufficient for most of the patients. With ultrasound guided technique using automated biopsy gun, number of complications is small and the diagnostic yield is reasonably good.Therefore,day case renal biopsy remains a safe procedure in majority of patients.

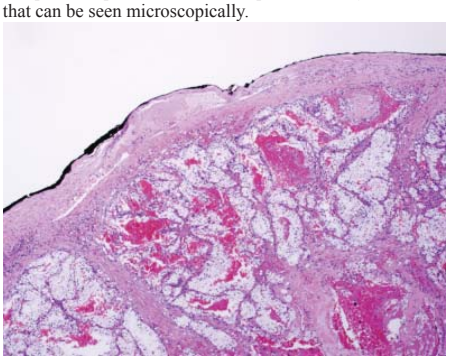
## TH-PO986

**Critical Analysis of the Pseudocapsule after Robotic Assisted Enucleation Partial Nephrectomy** Maria M. Picken,[1] Gopal N. Gupta.[2] *[1]Pathology, Loyola Univ Medical Center, Maywood, IL; [2]Urology, Loyola Univ Medical Center, Maywood, IL.*

**Background:** The optimal surgical margin for small renal masses (SRMs) is contested. Enucleation of SRMs is gaining acceptance as it maximally preserves nephrons and allows for zero warm ischemia time. However, there remains a concern about the oncologic adequacy of enucleation margins. Our objective was to critically examine the pseudocapsule of 7 consecutive SRMs treated with robotic assisted off clamp enucleation.

**Methods:** We retrospectively examined 7 consecutive SRMs that were extirpated utilizing a robotic assisted enucleation partial nephrectomy technique without hilar clamping. The tumor pseudocapsule was used to guide the extirpation. Specimens were reviewed by a genitourinary pathologist with particular attention to pseudocapsule characteristics.

**Results:** Mean pathologic tumor size was 3.1 cm (range 1.2–5.6 cm); clear cell RCC x4, papillary type II RCC x2, renal oncocytoma x1. Surgical margins were negative on all patients. The mean thickness of the pseudocapsule was 0.05 mm (range 0.02-0.15 mm). The pseudocapsule is made of compressed kidney tissue which creates a plane of dissection that can be seen microscopically.



The compressed tissue is mainly composed of sclerosed glomeruli and tubules. In 5 specimens arteries run parallel and in 2 cases perpendicular to the pseudocapsule; perpendicular veins were seen in 3 cases. There was no invasion of tumor into the pseudocapsule itself.

**Conclusions:** The ideal treatment of a SRM would be maximally nephron sparing with no warm ischemia time and be performed with minimally invasive techniques. Robotic assisted enucleation partial nephrectomy accomplishes these goals. It is important for surgeons and pathologists to understand the characteristics of the pseudocapsule which constitutes the oncological margin. Further study is warranted.

## TH-PO987

**Angiotensin II-Regulated Proteins in Human Kidney Cells as Markers of Renal Angiotensin II Activity** Ana Konvalinka,[1] Susan B. Gurley,[3] Thomas M. Coffman,[3] Shao-Ling Zhang,[4] Rohan John,[2] Eleftherios P. Diamandis,[2] James W. Scholey.[1] *[1]Div of Nephrology, Univ of Toronto, Toronto, Canada; [2]Pathology and Laboratory Medicine, Univ of Toronto, Toronto, Canada; [3]Div of Nephrology, Duke Univ Medical Center, Durham; [4]Faculty of Medicine, Univ of Montreal, Montreal, Canada.*

**Background:** Angiotensin II (AngII), the main effector of the renin angiotensin system, mediates kidney disease progression by signalling through AT-1 receptor (AT-1R), but there are no specific measures of renal AngII activity. Accordingly, we sought to define an AngII-regulated proteome in primary human proximal tubular cells (PTEC) in order to identify potential markers of AngII activity in the kidney.

**Methods:** We utilized stable isotope labelling with amino acids (SILAC) in PTECs to compare proteomes of AngII-treated and control cells. Our top hits were verified by Selected Reaction Monitoring (SRM), ELISA and qRT-PCR. We finally used bioinformatics to define key enriched functional protein groups, and validated our findings in AngII-treated mice.

**Results:** Of 4618 quantified proteins, 83 were differentially regulated by AngII. SILAC ratios for 18 candidates were confirmed by SRM. Both SILAC and SRM revealed heme oxygenase-1 (HO-1) as the most significantly upregulated protein in response to AngII stimulation. AngII-dependent regulation of HO-1 gene and protein was further verified in PTECs. In order to extend these in vitro observations, we utilized a bioinformatics approach, which demonstrated that five enriched functional groups containing HO-1 were common to our AngII-regulated proteins and differentially expressed kidney genes from AngII-treated wild type and AT-1R knock-out mice. Furthermore, HO-1 kidney expression and urinary excretion were reduced in AngII-treated mice with PTEC-specific AT-1R deletion compared to AngII-treated wild-type mice, thus confirming AT-1R-mediated regulation of HO-1.

**Conclusions:** Our in vitro approach identified novel markers of AngII activity and the animal studies demonstrated that these markers are relevant in vivo. These interesting proteins hold promise as specific markers of renal AngII activity in patients and in experimental models.

*Funding:* Pharmaceutical Company Support - This work was funded in part by the AMGEN Canada Investigator Sponsored Initiative Research Program.

**Urinary Exosomal Ceruloplasmin Is a Marker of Kidney Disease and a Potential Biomarker of Early Diabetic Nephropathy** Krishnamurthy P. Gudehithlu,[1] Jane Vernik,[1,2] Mark A. Kraus,[1,2] Peter D. Hart,[1,2] Jose A.L. Arruda,[3,4] George Dunea,[1,4] Ashok K. Singh.[1,3,4] *[1]Div of Nephrology, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL; [2]Dept of Internal Medicine, Rush Univ Medical College, Chicago, IL; [3]Section of Nephrology, Univ of Illinois at Chicago, Chicago, IL; [4]The Hektoen Institute of Medicine, Chicago, IL.*

**Background:** Urine exosomal proteins are fingerprints of the metabolic state of the kidney and offer new biomarkers for diagnosing early diabetic nephropathy. Previously we found that urinary exosomal ceruloplasmin, a redox enzyme sensitive to oxidative stress, was up-regulated several fold in nephrotic patients. We also observed that high exosomal cerulopasmin in these patients did not correlate with the ceruloplasmin levels in the urine suggesting that urinary exosomal ceruloplasmin was derived from the kidney and not from filtered ceruloplasmin. In this study we investigated whether urinary exosomal ceruloplasmin could also serve as a biomarker for diagnosing diabetic nephropathy prior to onset of microalbuminuria.

**Methods:** Urine samples from control subjects (n=15) and diabetic patients (n=37) were collected. Exosomal extracts were prepared by ultracentrifugation. Ceruloplasmin levels were measured in the exosomal extracts by ELISA. For analysis of results the diabetic patients were subdivided as: non-albuminuric (<0.03 g albumin/g of creatinine), microalbuminuria (0.03-0.3 g albumin /g of creatinine), subnephrotic (0.31-2.0 g albumin /g of creatinine), and nephrotic (>2.1 g albumin /g of creatinine).

**Results:** Compared to controls (1.3 ± 0.4 (mean ± SEM) ng ceruloplasmin/mg exosomal protein), ceruloplasmin levels increased 5 fold in diabetics with microalbuminuria ($p<0.05$) and remained at that level in subnephrotics and nephrotic groups ($p<0.05$). Importantly, ceruloplasmin levels in the non-albuminuric diabetic patients were 3 fold higher ($p<0.05$) than controls, suggesting that urinary exosomal ceruloplasmin levels increased before the onset of microalbuminuria.

**Conclusions:** We conclude that early increase of urinary exosomal ceruloplasmin levels could be potentially predictive of onset of diabetic nephropathy.

*Funding:* Private Foundation Support

## TH-PO989

**Urine Exosomal Gelatinase – A Potential Biomarker of Early Diabetic Kidney Disease** Krishnamurthy P. Gudehithlu,[1] Carolyn S. Brecklin,[1,3] Jane Vernik,[1,2] Mark A. Kraus,[1,2] Peter D. Hart,[1,2] Jose A.L. Arruda,[3,4] George Dunea,[1,4] Ashok K. Singh.[1,3,4] *[1]Div of Nephrology, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL; [2]Dept of Internal Medicine, Rush Univ Medical College, Chicago, IL; [3]Section of Nephrology, Univ of Illinois at Chicago, Chicago, IL; [4]Hektoen Institute of Medicine, Chicago, IL.*

**Background:** Urinary exosomal proteins are fingerprints of the metabolic condition of kidney and as such offer early biomarkers for onset of diabetic nephropathy. One of the earliest pathological markers of diabetic nephropathy is the accumulation of mesangial matrix in the kidney. Decrease of tissue gelatinase, an enzyme which degrades matrix, is responsible for the matrix accumulation. We investigated whether the previously reported decreased tissue gelatinase would be reflected in decreased gelatinase in the urinary exosomes of diabetic patients.

**Methods:** Urine from diabetic (n=37) and non-diabetic controls (n=19) were collected. For analysis of results the diabetic patients were subdivided according to the level of albuminuria into three groups, microalbuminuria (0.03-0.3 g albumin/g of creatinine), subnephrotic (0.31-2.0 g albumin/g of creatinine), and nephrotic (>2.1 g albumin/g of creatinine). Exosomal extracts were prepared from urine by ultracentrifugation. Gelatinase was quantified by a fluorometeric assay using FITC-gelatin. Few random samples were analyzed by SDS-PAGE-zymography to determine the molecular sizes of the gelatinases in the exosomal extracts. Gelatinase activity was expressed in units/mg exosomal protein (1 unit =1 µg gelatin degraded/hour at 37ºC).

**Results:** Gelatinase activity as compared to controls (311 ± 24 units/mg exosomal protein, n=19) was reduced by 86% in nephrotic patients (; n=6; $P<0.05$), by 32% in subnephrotic patients (n=11; $P<0.05$) and by 20% in microalbuminuric patients (n=22; $P<0.05$). Zymography revealed that the exosomal gelatinase activity was largely confined to the 72 kD and 92 kD proteins in the extracts.

**Conclusions:** We conclude that gelatinase activity in urinary exosomes may serve as a potential biomarker for diagnosing early kidney disease.

**TH-PO990**

**Plasma Pro-Enkephalin Is Associated with Acute Kidney Injury in Critically Ill Patients and Is Not Influenced by Sepsis** Joachim Struck,[1] Rossella Marino,[2] Olle Melander,[3] Andreas Bergmann,[1] Salvatore Di Somma.[2] *[1]Sphingotec GmbH, Hennigsdorf, Germany; [2]Sant'Andrea Hospital, Rome, Italy; [3]Skåne Univ Hospital, Malmö, Sweden.*

**Background:** Novel biomarkers for the detection of Acute Kidney Injury (AKI) in critically ill patients have not been established in clinical routine, as they are not sufficiently accurate, influenced by inflammation and/or detectable only in urine. Opioid receptors are highly expressed in the kidney, but it is not known, whether Enkephalin is associated with kidney function.

**Methods:** 101 consecutive ED patients with the final diagnosis sepsis, severe sepsis or septic shock were enrolled. Plasma samples were obtained on ED admission and on the following day. The 7 day mortality rate was monitored. Patients were categorized for severity of AKI according to the RIFLE criteria. Plasma Pro-Enkephalin (pro-ENK), a stable surrogate marker of the unstable Enkephalin stemming from the same precursor peptide, was measured by a novel immunoassay. For comparison, pro-ENK was measured in a large general population cohort (n=4453).

**Results:** In the general population the mean pro-ENK concentration was 44 pmol/L and the 99$^{th}$ percentile was 80 pmol/L. Pro-ENK was negatively correlated with eGFR (r=-0.33, p<0.0001). Key characteristics of the ED cohort were: median age: 78 y; final diagnosis severe sepsis or septic shock: 29%; 7 day mortality rate: 28%. Pro-ENK was negatively correlated with creatinine clearance (r=-0.74, p<0.0001) and was associated with 7 day mortality rate (survivors: 75 [47-124] pmol/L; non-survivors: 209 [77-499] pmol/L; p<0.001), whereas creatinine clearance was only borderline significant (p=0.071). Multivariate linear regression revealed creatinine clearance to be by far the strongest determinant of pro-ENK (partial $R^2$=0.17). Pro-ENK increased with severity of AKI (RIFLE staging; ANOVA p<0.0001). Importantly, pro-ENK levels in patients without kidney dysfunction or only risk were essentially in the normal range. In contrast, NGAL was markedly elevated over normal already in patients without kidney dysfunction.

**Conclusions:** Pro-ENK is a new plasma biomarker for AKI severity and independent from SIRS and infection.

**TH-PO991**

**The Proteome-Transcriptome-Combined Database of Kidney Distal Tubular Proteins for Novel Urinary Biomarker Discovery** Hidehiko Fujinaka,[1] Tadashi Yamamoto.[2] *[1]Institute for Clinical Research, Niigata National Hospital, Kashiwazaki, Niigata, Japan; [2]Structural Pathology, Institute of Nephrology, Niigata Univ, Niigata, Japan.*

**Background:** Several proteins have been proposed as new urinary biomarkers of kidney injuries, but they do not always identify the injured sites of kidney nephron segments. The aim of the present study is to discover new urinary biomarkers which identify the injured sites as **distal** tubule cells.

**Methods:** The proteome-transcriptome-combined database was completed with 3 databases; the human protein atlas (immunohisotochemistry, http://www.proteinatlas.org/), the microarray database of human kidney (Fujinaka, Nephrology 2010), and the urinary proteome database (http://141.61.102.16/urine/). By the atlas database, kidney proteins of tubule-predominant expression were searched and 468 proteins were selected. Two-hundred sixty eight genes of the 468 genes were verified as kidney tubule-predominant genes by the microarray database. Among them, 64 proteins were confirmed in the urinary proteome database. The localizations of these 64 proteins in kidney tubules were specified visually in the atlas database, and 14 proteins were defined as distal tubule originated urinary proteins. The expressions of these proteins were examined in rat kidney injury models and human kidney disease, by real-time PCR and/or immunohistochemistry of the kidney cortices, and Western Blotting of urine samples.

**Results:** In rat kidney cortices of UUO, mRNA expressions of 8 genes such as CAPG and ANXA3 were increased, while 3 genes such as CALB1 were decreased. Among them, the % change of the CALB1 mRNA was the most prominent. CALB1 protein expression in the kidney distal nephron segment was shown decreased extremely in UUO and gradually in rat anti-GBM GN. The urinary CALB1 protein levels of the anti-GBM GN rats were decreased concomitantly with the reduction in the kidney cortices. The human IgAN patients displayed decreased CALB1 protein expression in their dilated distal tubules, and some patients displayed decreased urinary calbindin 1 levels.

**Conclusions:** Our proteome-transcriptome-combined database may be a good tool to discover new urinary biomarkers which identify distal tubule injuries.

**TH-PO992**

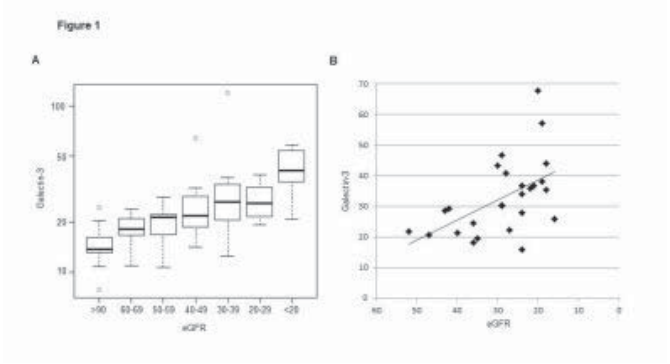
**Galectin-3, a Biomarker of Cardiovascular Risk, Inversely Correlates with eGFR** George Tidmarsh,[1] Pablo E. Pergola,[2] Bhupinder Singh,[3] James Rolke,[1] Stacey Ruiz,[1] Gerard John Smits,[5] Geoffrey A. Block.[6] *[1]La Jolla Pharmaceutical Company, Inc, San Diego, CA; [2]Clinical Advancement Center, San Antonio, TX; [3]Southwest Kidney Institute, Tempe, AZ; [4]Balboa Nephrology Medical Group, La Mesa, CA; [5]CSC, Inc, Santa Barbara, CA; [6]Denver Nephrology, Denver, CO.*

**Background:** Galectin-3,an important fibrosis mediator, is clinically regarded as a marker of CV risk. It has been shown to correlate with kidney function in patients with CV disease, however, alterations in patients without CV disease have not been studied.

**Methods:** We evaluated the relationship between galectin-3 and kidney function in a retrospective study of 99 subjects with an eGFR <20 to >90 mL/min/1.73m$^2$ and in a prospective study of 26 patients with an eGFR of 15 to 50 mL/min/1.73m$^2$. Galectin-3 was measured using an ELISA that exhibits no cross-reactivity with collagens or other galectin family members.

**Results:** In the retrospective study, galectin-3 and eGFR showed a significant inverse correlation (Figure 1A; r=-0.74, p<0.001). In the prospective study, a significant inverse correlation was also observed (Figure 1B; r=-0.56, p=0.003). No statistically significant difference between galectin-3 and eGFR was observed when comparing both retrospective and prospective data. Mean galectin-3 levels in subjects with eGFR >90 were 15±3.8 ng/mL. Using a threshold of 24 ng/mL (2 SD above the mean), 43% of subjects with eGFR 40-49 had elevated galectin-3 while 93% with eGFR <20 had elevated galectin-3. For reference, congestive heart failure patients are considered to be at highest risk when serum levels are >25.9 ng/mL.

**Conclusions:** We find that serum galectin-3 is substantially elevated in the setting of even mildly reduced eGFR. Mean values of galectin-3 were markedly elevated in individuals with eGFR <50. Prognostic utility of measuring galectin-3 remains to be validated in CKD and interventions aimed at reducing galectin-3 are of clinical interest.



*Funding:* Pharmaceutical Company Support - La Jolla Pharmaceutical Company

**TH-PO993**

**Plasma α-Klotho Levels and Its Clinical Implications in Patients with IgA Nephropathy** Hidenori Yamazaki, Fumihiro Tomoda, Kota Kakeshita, Taizo Nakagawa, Tsutomu Koike, Satoshi Kagitani, Hiroshi Inoue. *The Second Dept of Internal Medicine, Univ of Toyama, Toyama, Japan.*

**Background:** α-Klotho has protective actions against renal injury and its renal expression has been demonstrated to decrease in many experimental models of kidney disease. However, circulating α-Klotho levels and its clinical implications remained to be elucidated in human renal disease. In the present study, plasma α-Klotho levels in patients with IgA nephropathy and its relationship to disease severity were evaluated.

**Methods:** Twenty-seven patients with IgA nephropathywere enrolled into the study. Plasma circulating α-Klotho was measured using that commercial assay kit (Immuno-Biological Laboratories Co., Ltd., Gunma, Japan). The disease severity was estimated by effective GFR (eGFR), urinary protein excretion and histological injury score using Oxford classification.

**Results:** Plasma α-Klotho correlated negatively with eGFR (r= 0.438, p=0.022) and positively with urinary protein excretion (r=0.549, p=0.003). Thus, the decrease in plasma α-Klotho was associated with reduced renal function and worsening of proteinuria in IgA nephropathy. Stepwise multiple regression analysis identified plasma α-Klotho as independent determinant factor for urinary protein excretion ($R^2$= 0.706), but not eGFR. Additionally, in histological appearances, the scores for mesangeal hypercellularity and tubular atrophy/interstitial fibrosis were greater in the patients with plasma α-Klotho< 450 pg/mL (i.e., the median α-Klotho value) than in those with plasma α-Klotho> 450 pg/mL.

**Conclusions:** Our cross-sectional study showed that decreased circulating α-Klotho was associated with the progression of IgA nephropathy, suggesting that α-Klotho may be a novel surrogate marker for severity of IgA nephropathy.

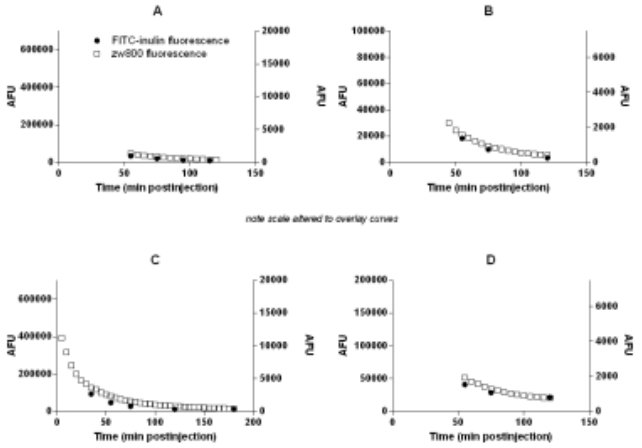
**Near-Infrared Fluorophore ZW800-1: A Potential Marker of Glomerular Filtration Rate (GFR)** Michael Hutchens,[1] Mizuko Ikeda,[1] Hak Soo Choi,[3] Sharon Anderson.[2] *[1]Anesthesiology & Perioperative Medicine, OHSU, Portland, OR; [2]Nephrology & Hypertension, OHSU, Portland, OR; [3]Hematology/Oncology, BIDMC, Boston, MA.*

**Background:** Noninvasive measurements of GFR using clearance of fluorescein-isothiocyanate–inulin (FITCI) and -sinistrin have been reported, but FITC use in injured animals may be limited by temperature- and pH-dependent fluorescence and hemoglobin absorbance.[1] ZW800-1 is a stable, zwitterionic fluorophore, MW 943Da, which is eliminated almost entirely in urine.[2] We hypothesized that elimination of ZW800-1 would be similar to elimination of FITCI.

**Methods:** C57BL/6 mice were used. Group 1: procedurally naïve mice received a jugular catheter under isoflurane anesthesia. On the imaging stage of a whole-animal imager, mice were coinjected with 11.5 μg of ZW800-1 and 10 mg of FITCI diluted in 300 μL of 0.9% saline. Images were acquired via the 800nm filter every 5m for 120m. Blood was collected via tail artery at 55,75,95, and 120m and analyzed for FITC fluorescence

after physiologic buffering. Groups 2&3: the above was performed 24h after cardiac arrest and cardiopulmonary resuscitation (CA/CPR) or in naïve controls. FITCI and ZW800-1 disappearance curves were fit.

**Results:** ZW800-1/FITCI coinjection was well tolerated. FITCI and ZW800-1 disappearance curves were similar.



Clearance halftime ($t_{1/2}$) was 19±2m for FITCI and 22±1m for ZW800-1 (mean±SEM,n=4,p=0.1). CA/CPR delayed ZW800-1 clearance (24±1 vs 17±1 m n=4,3 p=0.01). FITCI and ZW800-1 $t_{1/2}$ correlated in controls and CA/CPR-treated animals ($r^2$ =0.991,n=6 ,p<0.0001).

**Conclusions:** We demonstrate for the first time that near-infrared fluorophore ZW800-1 clearance is correlated with inulin clearance in mice with and without renal injury. ZW800-1 is a candidate marker of GFR. Further study is ongoing.

### Is Coagulation the Missing Pathway of Glomerulonephritis Pathophysiology?

Dimitrios Petras,[1] Glykeria Tsouka,[1] Ploumis Stavros Passadakis.[2] *[1]Nephrology Dept, Hippokration Hospital, Athens, Greece; [2]Dept of Nephrology, Democritus Univ of Thrace, Greece.*

**Background:** In experimental models of GN, plasminogen activator inhibitor-1 (PAI-1) and von Willebrand factor (vWf) are implicated to renal scaring and glomerulosclerosis, but in humans their role and prognostic value have not been elucidated yet. Therefore, we studied the expression of these proteins in human glomerulonephritis.

**Methods:** Renal biopsies, obtained from 87 patients with different types of primary GN and diabetic nephropathy, were scored for severity of glomerulosclerosis and interstitial fibrosis. Serum creatinine level, 24-H urinary protein excretion and other laboratory data were also collected. PAI-1 and vWf intraglomerular deposition was assessed immunohistochemically and expressed semiquantitatively on a 0-3 scale (normal, mild, moderate and severe respectively). 11 normal kidney samples were used as controls.

**Results:** Glomerular PAI-1 and vWf staining scores in glomerulonephritic samples were markedly higher compared to controls. Samples with moderate deposition of PAI-1 had higher levels of glomerulosclerosis (40.1±18.1%), comparing to samples with no (11.8±16.9%) or mild (21.3±14.7%) staining (p<0.001). Moderate/intense level of interstitial fibrosis was found in all specimens with moderate staining for PAI-1, but in only 18.8% of samples with normal staining (p<0.001). Serum creatinine level was significantly higher (3.4±2.1 mg/dl) in patients with moderate deposition of PAI-1, comparing to patients with no (1.4±1.3 mg/dl) or mild (1.5±0.6 mg/dl) deposition (p<0.001).

**Conclusions:** PAI-1 and vWf are deposited intraglomerularly and probably cooperate at human GN. Increased expression of PAI-1 is an ominous finding for renal function, as it is implicated to matrix expansion, fibrosis and glomerulosclerosis.

## TH-PO996

### Urine Screening for Kidney Injury Biomarkers in Children and Adults with Sickle Cell Disease with and without Albuminuria

Ofelia A. Alvarez,[1] Dima Hamideh,[1] Vimal Master Sankar Raj,[1] Thomas Harrington,[2] Monica T. Garcia-Buitrago,[3] Phillip Ruiz,[3] Gaston E. Zilleruelo.[1] *[1]Dept of Pediatrics, Univ of Miami, Miami, FL; [2]Dept of Internal Medicine, Univ of Miami, Miami, FL; [3]Dept of Pathology, Univ of Miami, Miami, FL.*

**Background:** Renal involvement in sickle cell disease (SCD) manifest in several forms. Presence of albuminuria is considered a hallmark of sickle cell nephropathy. The objective of this study was to evaluate kidney injury (KI) biomarkers in urine which could predict onset of sickle cell nephropathy.

**Methods:** We measured KI biomarkers in random urine samples of 38 children and adults with SCD with or without albuminuria in a cross-sectional analysis. Kidney injury molecule 1 (KIM-1), N-acetyl-ß-D-glucosaminidase (NAG), endothelin-1 (ET-1), and transforming growth factor-ß1 (TGF ß1) were measured by colorimetric assays. Prussian blue was used to identify intracellular hemosiderin in urine. Albuminuria was associated to the urine biomarkers by Pearson and Spearman correlation.

**Results:** Participants were classified into two groups based on the presence or absence of albuminuria. Significant differences between two groups by t-test is noted in the table. Patients with albuminuria were more likely positive for urine hemosiderin, and had significantly higher KIM-1 and NAG to urine creatinine ratios.

| Parameter, units | Albuminuria (N=19) Mean±SD | No albuminuria (N=19) Mean±SD | *P* value |
|---|---|---|---|
| KIM-1/urine creat, ng/mg | 0.93±0.73 | 0.35±0.31 | **0.004** |
| NAG/urine creat, unit/g | 10.33±8.25 | 4.26±2.97 | **0.006** |
| ET-1/urine creat, pg/mmol | 3.32±2.96 | 2.76±1.94 | 0.49 |
| Urine hemosiderin | 12/19 | 3/17 | **0.008** |

**Conclusions:** In patients with SCD and normal GFR, kidney injury biomarkers NAG and KIM-1 strongly correlated with albuminuria. Urine hemosiderin, indicating hemolysis, also was associated with albuminuria. Prospective trials will help establish the role of these biomarkers in early detection of renal disease in SCD.

### Glomerular Injury in Patients with Acutely Decompensated Heart Failure and Chronic Kidney Disease

Michael G. Selby, Vesna D. Garovic. *Nephrology, Mayo Clinic, Rochester, MN.*

**Background:** Intrinsic renal alterations that underlie chronic kidney disease (CKD) in patients with chronic heart failure (CHF) have been partially investigated. In these patients, tubular injury noted by specific urinary/serum markers has been studied; however, glomerular injury has not. Urinary podocin is a marker of podocyte loss and injury. Accordingly, urinary podocin was assessed by quantification of a tryptic podocin peptide with high performance liquid chromatography (LC) coupled to tandem mass spectrometry (LC-MS/MS) in patients with CHF and CKD, and in controls.

**Methods:** Twenty-seven patients, who developed CKD while receiving treatment for CHF, were studied during an acute CHF decompensation. Patients were recruited at Tulane University (2010-2011). Urine samples were collected for podocin, creatinine, and protein. Eight healthy subjects served as controls. The LC-MS/MS technology assumes a 1:1 stoichiometric ratio between a tryptic fragment and its related protein. Urinary podocin was expressed in femtomole (fmol) of podocin/mg of creatinine.

**Results:** The mean patient's age was 57 y with 55% male. The majority were New York Heart Association Functional Class 3. Overall, the urinary podocin/creatinine ratio was significantly greater in CHF patients than controls: 0.37 ± 0.77 v. 0.06 ± 0.05 fmol podocin/mg creatinine, p=0.04. 40% of patients had a urinary podocin/creatinine ratio greater than the upper limit of normal (>0.2 fmol podocin/mg creatinine). 55% of patients had protein/creatinine ratio ≥ 0.15 (which correlates to estimated 24-hour proteinuria of > 150 mg). Urinary podocin/creatinine ratio was elevated in 54% of patients with proteinuria, and in 46% of patients without proteinuria.

**Conclusions:** During acute CHF decompensation, 40% of patients with CHF and CKD have evidence of glomerular injury and podocyturia as evidenced by an elevated urinary podocin/creatinine ratio.

Figure 1: LC-MS/MS chromatograms from fixed cells: age and sex matched control (top) and example CHF patient (bottom), with a calculated tryptic peptide concentration of 0.002 versus 1.459 fmol podocin/mg creatinine, respectively.

**TH-PO998**

**Circulating suPAR in Japanese Patients with Glomerular Diseases: A Multicenter Cross-Sectional Study** Takehiko Wada,[1,2] Masaomi Nangaku,[1,2] Shoichi Maruyama,[2] Enyu Imai,[2] Kumi Shoji,[1] Sawako Kato,[2] Tomomi Endo,[2] Eri Muso,[2] Kouju Kamata,[2] Hitoshi Yokoyama,[2] Keiji Fujimoto,[2] Yoko Obata,[2] Tomoya Nishino,[2] Hideki Kato,[2] Shunya Uchida,[2] Yoshie Sasatomi,[2] Takao Saito,[2] Seiichi Matsuo.[2] *[1]Div of Nephrology and Endocrinology, Univ of Tokyo, Tokyo, Japan; [2]Japanese Refractory Nephrotic Syndrome Study Investigators, Japan.*

**Background:** Elevated serum soluble urokinase receptor (suPAR) levels have been described in focal segmental glomerulosclerosis (FSGS) patients in several different cohorts. However, it still remains to be determined if this is the case for Japanese patients and if circulating suPAR can be clinically useful as a diagnostic marker.

**Methods:** We measured serum suPAR levels in 70 Japanese patients with biopsy-proven glomerular diseases from 8 hospitals in a cross-sectional manner, using a commercially-available ELISA kit. We also analyzed the association between the suPAR levels and clinical/histological parameters obtained from medical record.

**Results:** The suPAR levels show a significant positive correlation with age ($R^2$=0.15, p=0.001) and negative correlation with eGFR ($R^2$=0.32, p<0.0001). After excluding patients with low eGFR (< 60 mL/min/1.73m$^2$), the difference in suPAR levels between the diseases was not significant. Analyses based on receiver operating characteristics (ROC) curve revealed that the serum suPAR level was not a potent clinical measure as a diagnostic marker. In a different cohort, patients with ANCA-associated glomerulonephritis had remarkably higher levels of serum suPAR (6791.3 ± 1513 pg/mL) compared with all of the primary glomerular diseases, which may be associated with inflammation and renal impairment.

**Conclusions:** Data in the current study suggest that suPAR may be accumulated in the patients with renal dysfunction. For patients with normal renal function, the difference of suPAR values was not significant among primary glomerular diseases. Assessment of statistical measures based on ROC curve analysis showed that the suPAR level has little value as a diagnostic biomarker.

*Funding:* Government Support - Non-U.S.

**TH-PO999**

**The Role of Inflammatory Marker MRP8/14 in CKD Patients** Tatsuki Matsumoto,[1] Yoshinori Taniguchi,[1] Yoshiko Shimamura,[1] Kosuke Inoue,[1] Taro Horino,[1] Kazu Hamada,[1] Yoshio Terada,[1] Kenji Yuasa,[2] Shinpei Fujimoto,[1] Koji Ogata.[1] *[1]Kochi Univ, Nankoku, Japan; [2]Kochi-Takasu Hospital, Kochi, Japan.*

**Background:** Myeloid-Related Protein 8/14 complex (MRP8/14) is an endogenic ligand of toll-like receptor (TLR)-4, and is considered to be an inflammatory marker. Although it has been reported that MRP8/14 related to arteriosclerosis and coronary lesion in type 2 diabetes, there are no reports about the relationship between MRP8/14 and chronic kidney disease (CKD). We studied the association between MRP8/14 levels and renal function or the other parameter in CKD.

**Methods:** A total of 432 patients (mean age 60±17) with CKD were enrolled. Serum samples were collected, and MRP8/14 levels were measured by using ELISA kit. Serum creatinine (Cr), blood urea nitrogen (BUN), uric acid (UA), urine protein/Cr ratio, and the other parameter of renal function were also measured. This study was approved by Kochi Medical School review board. All patients provided written informed consent.

**Results:** MRP8/14 levels were positively associated with serum Cr (p=0.007, r=0.135), BUN (p<0.001, r=0.175), UA (p=0.011, r=0.127) levels, and urinary protein/Cr ratio (<p<0.001, r=0.212), and Body Mass Index (BMI) (p<0.001, r=0.189). MRP8/14 levels were inversely associated with eGFR (p=0.006, r=-0.137). MRP8/14 levels significantly increased in CKD stage 5 (p<0.05; vs stage1-4). Moreover, MRP8/14 levels in CKD patients with diabetes and hypertension were significantly increased (p<0.05), compared to patients without diabetes and hypertension. Stepwise multiple regression analysis showed that MRP8/14 levels correlated well with BMI, Hb and urinary protein levels.

**Conclusions:** Serum MRP8/14 significantly correlated with renal function and BMI in CKD patients, and might show that MRP8/14 is critical for disease progression and metabolic pathogenesis in CKD.

**TH-PO1000**

**Albumin and Advanced Glycation Endproducts Activated KIM-1 Release by Proximal Tubular Epithelial Cells through Distinct Kinetics and Mechanism** Ai Ing Lim,[1] Loretta Y.Y. Chan,[1] Sydney C.W. Tang,[1] Kar Neng Lai,[2] Joseph C. K. Leung.[1] *[1]Dept of Medicine, The Univ of Hong Kong, Hong Kong; [2]Dept of Health Assessment, Hong Kong Sanatorium and Hospital, Hong Kong.*

**Background:** Tubulointerstitial injury in diabetic nephropathy (DN) is an important factor in disease progression. Kidney injury molecule-1 (KIM-1) is expressed by proximal tubular epithelial cell (PTEC) and released upon kidney injury. In this study, we examine the kinetics and mechanism of KIM-1 release in PTEC under the activation by different mediators of DN, including human serum albumin (HSA), advanced glycation endproducts (AGE) and glucose.

**Methods:** The kinetics of KIM-1 and MMP-3 release by PTEC under the activation with HSA, AGE and glucose; was determined by RT-PCR and ELISA. The activation profiles of major signaling pathways in PTEC cultured with HSA, AGE and glucose, were identified by PCR array. Based on these array data, blockade experiments with various signaling inhibitors were designed to examine their regulatory roles on KIM-1 release.

**Results:** We have shown that HSA induce KIM-1 shedding in PTEC by MMP-3. We further addressed the potency and kinetics of AGE- and glucose-mediated KIM-1 shedding in PTEC as compared to that of HSA. Prompt shedding of KIM-1 was observed in PTEC cultured 4 h with HSA and AGE, but not with glucose. Long term culturing PTEC for 3 days with AGE exhibited sustained release of KIM-1 and this is not observed for HSA. In all experiments, glucose did not induce KIM-1 release by PTEC. HSA and AGE activated the ERK and NF-kB pathways in PTEC. The Jak-Stat pathway was activated by AGE but not by HSA. Incubation of PTEC with diphenylene iodonium, but not pyrrolidine dithiocarbamate, P98059 or fludarabine, blocked the short term release of KIM-1 mediated by HSA or AGE. Interestingly, fludarabine but not diphenylene iodonium, pyrrolidine dithiocarbamate or PD98059, diminished the long term KIM-1 release by PTEC cultured with AGE.

**Conclusions:** Our data suggest that KIM-1 release in PTEC was differentially up-regulated by HSA and AGE. The short term KIM-1 release was mediated by the reactive oxygen species while Jak-Stat pathway controls the long-term KIM-1 release mediated by AGE.

**Urinary Retinol Binding Protein Is a Marker of the Extend of Kidney Fibrosis** Nicolas Pallet,[1,2] Sophie Chauvet,[1] Charlene Levi,[1] Vannary Meas-Yedid,[1] Eric Thervet,[1] Alexandre Karras.[1] *[1]Nephrology, HEGP, Paris, France; [2]Biochemistry, HEGP, Paris, France; [3]Pathology, HEGP, Paris, France; [4]Institut Pasteur.*

**Background:** No specific urinary marker already implemented in routine clinical chemistry has been evaluated as a predictor of the extent of interstitial fibrosis. The aim of our study was to evaluate the diagnostic performance of the measurement of urinary concentration of low and high molecular weight proteins in estimating the extent of interstitial fibrosis.

**Methods:** The urine of 189 consecutive patients who underwent renal biopsy in the Nephrology Department of the Georges Pompidou European Hospital were analyzed. Kidney transplant recipients or patients with acute kidney injury were excluded. The percentage of IF was assessed using a numerical quantification software based on the colorimetric analysis of fibrous areas. Urinary biochemical analyzes were performed to determine total proteinuria, albuminuria, microalbuminuria, as well as urinary levels of retinol binding protein (RBP), alpha1-microglobulin (α1MG), beta 2 microglobulin (β2MG), transferrin, and IgG mmunoglobulins.

**Results:** We found a significant correlation between the degree of IF and RBP/creat ratio ($R^2$: 0.11, p <0.0001). In a lesser extent IF was associated with urinary b2MG and a1MG, but not with total proteinuria or with high molecular weight proteinuria. The correlation of interstitial fibrosis with RBP/creat remained significant after adjustment with estimated glomerular filtration rate, age, body mass index, a1MG and b2MG. The RBP/creat ratio was significantly higher in patients with IF> 30% when compared with patients with FI <30% (16.6 ± 3.6 mg/g vs 4.8 mg/g±1.2, p=0.0007). The specificity of the test for the diagnosis of fibrosis score> 30% of parenchyma was 95% when using a threshold of 30 mg/g creat.

**Conclusions:** We have demonstrated that increased expression of LMW, and especially RBP, is a reliable quantitative and non-invasive marker which may independently predict the extent of kidney IF. The fact that urinary RBP dosage is available in nearly all clinical chemistry departments is appealing for its implementation in the routine care of CKD patients.

**TH-PO1002**

**MicroRNA-27b, an Exosomal Biomarker, Is Required for Angiotensin II-Stimulated TGF-β1 mRNA Expression in NRK-52E Cells** Alejandro Alvarez-Prats, Jonathan Street, Taro Horino, Ana C. Souza, Robert A. Star, Peter S.T. Yuen. *NIDDK, NIH, Bethesda, MD.*

**Background:** Exosomes are secreted by many cell types and contain proteins, miRNAs, and transcription factors that can reflect cell physiology. We previously showed that urinary exosomal miR-27b correlates with renal fibrosis severity in a mouse folic acid model. As AngII can induce fibrosis via TGF-β signaling, we tested whether AngII or TGF-β1 can regulate exosomal miR-27b in vitro.

**Methods:** NRK52E cells were treated with 13ng/ml TGF-β or 100nM AngII. Media was replaced every 12h (exosomal miR-27b time course) until 48h when cells were harvested. Exosomes were isolated from media by 2-step centrifugation (17,000 xg for 15min, and 200,000 xg for 1h). RNeasy-purified miR-27b was measured by RT-qPCR (Taqman) using a pure, synthetic, mature miR-27b standard. TSG101 was quantified by Western blot. In another study cells were treated with vehicle or 5 μg/ml antagomiR-27b for 24h and media was replaced with vehicle or 100nM AngII until cells were harvested at 48h. TGF-β1 expression was measured by Taqman.

**Results:** AngII, but not TGF-β1, increased cellular miR-27b 2-fold. Net media exosomal miR-27b production was constant over time and unchanged by TGF-β1. Ang II increased media exosomal miR-27b, peaking by 12h with sustained elevation until a return to control levels at 48h. To determine if AngII increased the number of exosomes or the concentration of miR-27b per exosome, we measured the pan-exosomal protein TSG101 as a surrogate exosome biomarker. TSG101 levels were constant through 36h for control and both treatments. At 48h control TSG101 was unchanged, but AngII and TGF-β1 increased exosomal TSG101 by 2- and 3-fold, respectively. **If Ang II, but not**

**TGF-β1, stimulated miR-27b, yet both stimulated TSG101, could miR-27b mediate AngII-stimulated TGF-β1 signaling?** Ang II increased TGF-β1 mRNA expression 2-fold, which was completely inhibited by antagomiR-27b.

**Conclusions:** AngII regulates at least two exosomal miR-27b functions: early AngII-specific stimulation of exosomal miR-27b, and a late AngII and TGF-β stimulated exosomal release. miR-27b is essential for AngII-stimulated TGF-β1 mRNA expression.

*Funding:* NIDDK Support

## TH-PO1003

**Combined Cyclosporine and Prednisolone Therapy in Adult Patients with New-Onset Minimal-Change Nephrotic Syndrome** Sayuri Shirai, Daisuke Ichikawa, Kayori Tsuruoka, Naohiko Imai, Yugo Shibagaki, Tsutomu Sakurada, Takashi Yasuda, Kenjiro Kimura. *Nephrology and Hypertension, St. Marianna Univ School of Medecine, Kawasaki, Japan.*

**Background:** Cyclosporine (CyA) is beneficial for the management of steroid-resistant and frequently relapsing nephrotic syndrome. Previously we have reported that absoarption of CyA is improved when given CyA preprandially rather than postprandially and the preprandial administration of CyA would be useful in the managements for the refractory nephrotic syndrome in adults. In this study, we evaluated the therapeutic efficacy of the combined cyclosporine and prednisolone therapy in adult patients with the new-onset minimal-change nephrotic syndrome (MCNS).

**Methods:** Patients with new-onset of MCNS were randomly assigned to two groups, namely, the CyA (about 2mg/kg, C2:600-1200 ng/ml) + PSL (0.8 mg/kg/day) group (n = 10) and the PSL alone (PSL) (0.8 mg/kg/day) group (n = 10), and the clinical characteristics were compared between two groups. All patients used C2 for CyA monitoring.

**Results:** There were no significant difference of relapse rates among both group. The duration of complete remission (CR) preservation in the CyA + PSL group (593 days) was longer than that in the PSL group (565 days). C2 in non-relapsing group (902ng/ml) was higher than that in relapsing group (802ng/ml) in the CyA+PSL group. The total dose of PSL in PSL group was more than that in CyA+PSL group. Incidence rate of side effect in the CyA+PSL group was higher than that in the PSL group.

**Conclusions:** The combined cyclosporine and prednisolone therapy obtained longer CR preservation and reduced the PSL dose and side effects in adult patients with new-onset MCNS.

## TH-PO1004

**Study of Single-Dose Rituximab at an Interval of 6 Months during 24-Month Period on Steroid-Dependent Minimal-Change Nephrotic Syndrome in Adults** Yuko Iwabuchi, Takashi Takei, Takahito Moriyama, Kosaku Nitta. *Medicine, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan.*

**Background:** Steroid dependent minimal-change nephrotic syndrome (MCNS) necessitates administration of prolonged courses of prednisolone, therefore, a paradigm shift from such toxic 'non-specific' therapies to selective immunomodulating regimens is necessary for these cases.

**Methods:** To assess the therapeutic effects of rituximab (an anti-CD20 antibody) in adult patients with steroid-dependent MCNS, we performed a prospective trial of the effects of a single dose of rituximab administered fourth at an interval of 6 months in 27 MCNS patients. We evaluated the biochemical parameters and compared the clinical findings between the 24-month period before and 24-month period after the first rituximab infusion.

**Results:** Significant reduction in the total number of relapses was observed during the 24-month period after the first rituximab infusion as compared with the findings during the 24-month period before the first rituximab infusion (110(100%) vs 8(7%), $p<0.001$). Twenty-one of 25 patients with prednisolone at the first rituximab were able to discontinue prednisolone after 24-month period ($p<0.001$). Complete remission was induced/maintained in all patients under ongoing B-cell depletion.

**Conclusions:** Our results revealed that rituximab therapy was associated with reduction in the number of relapses and in the total dose of prednisolone needed. Therefore, rituximab appears to be a useful therapeutic agent for adult patients with steroid-dependent MCNS. These results suggest that this treatment is rational and should be considered and important patients with steroid-dependent MCNS.

## TH-PO1005

**Nephrotic Syndrome Study Network Baseline Cohort** Debbie S. Gipson, Lawrence B. Holzman, Crystal A. Gadegbeku, John R. Sedor, J. Troost, Peter X.K. Song, Daniel C. Cattran, Fernando C. Fervenza, Patrick H. Nachman, Frederick J. Kaskel, Marva M. Moxey-Mims, Matthias Kretzler. *Nephrotic Syndrome Study Network.*

**Background:** The Nephrotic Syndrome (NS) Study Network (NEPTUNE) is an ongoing longitudinal observational study. Here we introduce the NEPTUNE cohort.

**Methods:** Eligibility: proteinuria >500 mg/d and initial renal biopsy. Comparison of the initial 361 subjects with baseline data and histology are compared between children and adults using two-sample t or chi-square tests. Continuous variables are presented as median (25,75th %tile) and frequencies as n(%). HTN is defined as BP>140/90 for adults and >95th %tile for children. eGFR was calculated using CKD-Epi or CKiD equations.

**Results:**

| None (by m 4) | 14(15) | 93(50) |
| ***p<0.01, **p<0.001, IST=immunosuppression** | | |

**Conclusions:** NEPUTNE exemplifies the potential of enrolling glomerular disease patients into a complex observational protocol with tissue and biospecimen banking. Children and adults were significantly different by race, eGFR, biopsy indication, histology and IST. The low prevalence of MN may in part reflect the proteinuria eligibility criterion as well as a lower frequency of newly diagnosed MN than expected. Baseline data illustrate current practice patterns wherein 71% of children and 23% of adults were treated with IST prior to biopsy.

**Clinicopathological Characteristics of Minimal Change Disease with Glomerular Foam Cell Infiltration** Emiko Fujita,[1] Akira Shimizu,[2] Akiko Mii,[1] Megumi Fukui,[1] Shuichi Tsuruoka.[1] *[1]Dept of Nephrology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan; [2]Dept of Pathology, Nippon Medical School, Bunkyo-ku, Tokyo.*

**Background:** Minimal change disease (MCD) is a major cause of idiopathic nephrotic syndrome. It is defined pathologically as glomerular disease with minimal or no glomerular alterations, no glomerular immune deposits, and extensive effacement of podocyte foot processes . We sometimes experience the cases of MCD with foam cell (FC) infiltration in glomeruli, but can not include the diagnostic criteria for FSGS.

**Methods:** In the present study, we examined renal biopsies of MCD in our department between 1990 and 2013, selected the cases of MCD with or without glomerular FC infiltration, and assessed the clinicopathologic characteristics of these cases.

**Results:** In 312 biopsies with a diagnosis of MCD, glomerular FC infiltration was detected in 10 cases (3.2%) [FC(+) group]. In histopathology, glomerular endothelial cell injuries were present in all FC(+) cases that were characterized by narrowing capillaries, increase number of endothelial cells, swelling of endothelial cells with loss of fenestra, separation of endothelial cells from capillary basement membrane with subendothelial edema, and macrophage infiltration in subendothelial and mesangial areas. In clinical findings, to compared with FC(-) group, FC(+) group showed that age of biopsy was older (46.2±22.0 vs 21.7±17.6, $p<0.01$), the selectivity index of urinary protein was lower (0.15±0.12 vs 0.07±0.10, $p<0.05$), systolic blood pressure was higher (134.4±26.0 vs 118.0±7.2, $p<0.05$), high frequency of complications including diabetes mellitus (2 case), hypertension (40% vs 17%), and limited response to steroid therapy (partial remission in 2 cases), but there was no significance in serum LDL-cholesterol level between two groups.

**Conclusions:** FC infiltration in MCD may be associated with the presence of glomerular endothelial cell injuries and macrophage infiltration into subendothelial and mesangial areas in milieu of nephrotic syndrome. MCD cases with glomrular FC infiltration include the cases of incomplete remission after steroid therapy.

## TH-PO1007

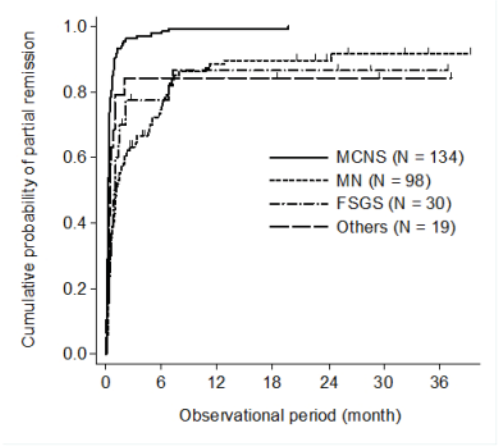
**Resistance to Immunosuppressive Therapy in Patients with Primary Nephrotic Syndrome: Japan Nephrotic Syndrome Cohort Study (JNSCS)** Ryohei Yamamoto,[1] Shoichi Maruyama,[2] Hitoshi Yokoyama,[3] Seiichi Matsuo,[2] Enyu Imai.[2] *[1]Geriatric Medicine and Nephrology, Osaka Univ, Suita, Osaka, Japan; [2]Nephrology, Nagoya Univ, Nagoya, Aichi, Japan; [3]Nephrology, Kanazawa Medical Univ, Uchinada-Cho, Ishikawa, Japan.*

**Background:** In primary nephrotic syndrome (NS), little information is available about the prevalence of resistance to immunosuppressive therapy (IS) and the optimal time to diagnose the resistance to IS.

**Methods:** Study design and setting: A nationwide prospective cohort study including 57 nephrology centers in Japan. Patients: Between 2008 and 2010, 396 primary NS patients were diagnosed by kidney biopsy as primary NS and were registered in JNSCS. The present study included 281 JNSCS participants with ≥3.5 g/day of the baseline urinary protein

(UP) at initiating IS. Outcome: Partial remission (PR) defined as UP <3.5 g/day. Statistics: 90% and 95% distribution of time to PR in minimal change disease (MCD), membranous nephropathy (MN), focal segmental glomerulonephritis (FSGS) and others were assessed.

**Results:** Median baseline ages of MCD (n=134), MN, (n=98), FSGS (n=30) and others (n=16) were 39 (range 12-81), 65 (14-84), 59 (20-83) and 49 (14-83) year, respectively. During median 13 days (range 2-1122) of the observational period, 100%, 88%, 83% and 84% achieved PR, and their cumulative probabilities of the resistance to IS at the final observation were 0.00, 0.08, 0.13 and 0.14.



Among 261 patients with PR, 90% (95%) time to PR were 29 (59), 207 (242), 66 (207) and 30 (60) days. Initial immunosuppressive drugs administered within 1 month were corticosteroid and, in some patients, cyclosporin (11%, 46%, 40% and 32%). Only 5 MN patients received cyclophosphamide.

**Conclusions:** Approximately 10% of primary NS were resistant to IS except MCD. Optimal time to diagnose the resistance may be 1-2, 7-8, 2-7, and 1-2 months in MCD, MN, FSGS and others.

**Oxidative Stress Markers in the Urine from Pediatric Patients with Nephrotic Syndrome** Yaeko Motoyoshi, Tomohiro Udagawa, Eriko Tanaka. *Pediatrics, Tokyo Medical and Dental Univ, Bunkyo-ku, Tokyo, Japan.*

**Background:** Oxidative stress has been shown to be involved in the renal damage especially in diabetes mellitus (DM). Beside DM, we previously found that massive urinary protein is reabsorbed by proximal tubule cells via megalin, and induces Heme oxygenase-1 (HO-1) in a mouse model of nephrotic syndrome (Kidney Int 74: 1262). However, oxidative stress in human patients with nephrotic syndrome has not yet been well studied. The aim of this study is to show that when large amount of protein is filtrated through glomeruli, proximal tubule cells require a great deal of energy to decompose the protein, and oxidative stress is produced according to the dose of urinary protein.

**Methods:** Urine was collected from 9 nephrotic syndrome patients (one to ten years old), every day from development or relapse of the disease until remission. 2 steroid sensitive, 4 steroid dependent, and 3 steroid resistant patients were included to this study. Their peak urinary protein /creatinine ratio (g/g) was 20.0-136.5.

**Results:** We plotted the progress of 3 oxidative stress markers, setting the day when urinary protein/cre ratio was highest as day 0. Urinary L-FABP/Cre ratio reached to peak on day-1 to 2. Urinary 8-OHdG/Cre ratio reached to peak on day 5 to 9. Urinary SOD activity/Cre ratio reached to peak on day -1 to 7. There was no correlation between 3 oxidative stress markers and urinary protein/cre ratio. In contrast, urinary L-FABP/Cre ratio was 1.8-fold higher and urinary SOD activity/Cre ratio was 2.0-fold higher in steroid resistant group compared with steroid dependent group. 3 markers were elevated in nephrotic syndrome patients with massive proteinuria. L-FABP excretion increased, then decreased at almost the same time as total protein change. Value of 8-OHdG and SOD activity ascended after urinary total protein started to decrease in most patients.

**Conclusions:** Although there was no correlation between 3 markers and the dose of urinary protein, we speculate that L-FABP excretion increased, reflecting tubular damage induced by massive urinary protein. SOD activity elevated to neutralize oxidative stress caused by urinary protein, and 8-OHdG excretion increased at last to repair DNA damage.

### TH-PO1009

**Nephrotic Range Proteinuria Has No Significant Effect on Probability of CD19 Depletion following Rituximab Treatment** Emily Glover,[2] Alan D. Salama,[2] Aine Burns.[1] *[1]Centre for Nephrology Royal Free NHS Trust; [2]Univ College London.*

**Background:** Rituximab is used to treat an increasing number of autoimmune conditions. It is an expensive treatment and different units use different frequency and dosing regimens.

In our unit, circulating CD19 counts are routinely checked following first infusion to assess effective depletion (CD19 ≤5 x $10^9$) and to decide if a further dose is indicated. We have previously demonstrated that response to and duration of depletion using this protocol is similar to other published series in vasculitis patients using much higher doses, such as 1g two weeks apart or 375mg/$m^2$ weekly for 4 weeks (Little 2013).

We investigated whether there were any factors that could predict who would deplete following our 1st and 2nd doses of Rituximab treatment (375 mg/$m^2$) and importantly whether nephrotic range proteinuria reduced the chance of depletion.

**Methods:** 101 patients with different diagnoses and ethnicities were treated according to our standard protocol. Age, sex, ethnicity, diagnosis, proteinuria, serum albumin and serum IgG were analysed for predictors of first dose depletion. Of the 79 patients with data on proteinuria, 12 had nephrotic range (mean 5.88 g/L; range 4.21 to 13.38 g/L).

**Results:** Of the 101 patients analysed, 54 depleted (CD19 ≤5 x $10^9$) on the 1st infusion, 14 on the 2nd infusion, 18 did not deplete with either the 1st or 2nd infusion and 15 did not deplete on the 1st infusion and did not receive a 2nd infusion. There were 3 adverse drug reactions of which two involved respiratory distress. There was no statistically significant effect of age, sex, ethnicity or diagnosis on depletion. Critically, nephrotic range proteinuria, albumin and IgG had no predictive value for depletion following rituximab treatment.

**Conclusions:** The finding that nephrotic range proteinuria has no significant effect on probability of CD19 depletion following rituximab treatment is valuable information for reducing the cost of administration as higher doses or longer courses of rituximab would not appear to be indicated in these patients. Little, M et al. 2013. Induction treatment of ANCA associated vasculitis with a single dose of rituximab. *Rheumatology (Submitted)*.

### TH-PO1010

**Tacrolimus Monotherapy after Short Term Steroid Treatment in Treating Adults with Idiopathic Minimal Change Nephropathy: A Pilot Study** Heng Li, Xiayu Li, Jianghua Chen. *Kidney Disease Center, First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

**Background:** Although steroids therapy leading to complete remission in most of patients with minimal change nephropathy (MCN), the wide range side effects of steroids make steroids therapy difficult to be accepted by the patients. This study aimed to observe the efficacy and tolerance of tacrolimus monotherapy after ten days' steroids treatment in patients with MCN caused nephrotic syndrome.

**Methods:** In this observational study, 25 patients with MCN were treated with tacrolimus monothery (Group A, n = 6) from the beginning or after 10 days' steroids therapy (Group B, n =19). Data on serum albumin, proteinuria, serum creatinine, eGFR and other biochemical results were collected during the at least 12 months' follow-up period.

**Results:** Three of six patients in Group A and all 19 patients in Group B achieved complete remission. Acute renal failure was occurred in two patients in Group A and one patient in Group B. One patient in Group A has no response to tacrolimus monotherapy for more than two months and achieved complete remission after treated with steroid. The adverse effects including gastrointestinal symptoms and pulmonary infections were mild and tolerated by the patients. One patient in Group A and 6 patients in Group B underwent 9 relapses during follow-up period.

**Conclusions:** Tacrolimus monotherapy after short-term steroid therapy is effective and safe in treating patients with MCN. It may become a novel method to treat MCN patients.

### TH-PO1011

**Efficacy and Safety of Low-Dose Rituximab on Steroid-Dependent Minimal Change Nephrotic Syndrome in Adults** Susumu Uda,[1] Keiko Kanemoto,[1] Eijin Ashikaga.[2] *[1]Div of Nephrology, Kanto Rosai Hospital, Kawasaki, Kanagawa, Japan; [2]Div of Nephrology, Yokohama Municipal Citizen's Hospital, Yokohama, Kanagawa, Japan.*

**Background:** Recently, B cell depleting therapy by rituximab (RTX) has been used successfully to treat therapy for steroid-dependent minimal change nephrotic syndrome (MCNS) in adults. However, given the cost, unexpected side-effects and the lack of data regarding the optimal dosage of RTX to MCNS patients, it would be useful to limit treatment to these patients. We investigated the effect of low-dose RTX and clinical response in adults with steroid-dependent MCNS.

**Methods:** Data on 7 adults patients receiving single dose of RTX (200mg (range 104-133 mg/$m^2$) IV) for biopsy-proven steroid-dependent MCNS after a steroid-induced complete remission and followed over 6-months is presented. Therapy with prednisone and other immune-suppressive drugs was tapered.

**Results:** To date a total of 8 cases included 1 relapsed patient had been studied (mean age 34±12 years, 6 male and 1 female, mean follow- up time 13±8 months). B cell depletion was found in all cases. At <6 months post-RTX, 7 (88%) cases maintained complete remission, allowing rapid prednisone & immunosuppressive agents taper or discontinuation (100%). Only one B cell depleted case (<5/mL) before RTX infusion relapsed under B cell depletion at 3 week. Two cases (25%) relapsed at 7-12 months after complete recovery of B cell. B cell recovery tendency from depleted state was detectable after 3 to 8 months. Two cases (25%) reached long term remission over 18 months without relapse. An increase of B cells was not always associated with relapse. No serious side effects were noted.

**Conclusions:** A single low-dose RTX was effective and safe for sustained complete remission in adult patients with steroid-dependent MCNS and maintained 6-months remission in about 90% cases.

**TH-PO1012**

**Initial Steroid-Sensitivity Is a Highly Sensitive Predictor for Post-Transplant Recurrence of Steroid-Resistant Nephrotic Syndrome** Wen Y. Ding,[1] Ania Koziell,[2] Agnieszka Bierzynska,[1] Hugh J. McCarthy,[1] Corinne Antignac,[3] Olivia Boyer,[3] Moin Saleem.[1] *[1]Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom; [2]Nephrology, Evelina Children's Hospital, London, United Kingdom; [3]Hôpital Necker - Enfants Malades, INSERM, Paris, France.*

**Background:** The post-transplant recurrence risk of paediatric patients with a primary diagnosis of steroid-resistant nephrotic syndrome (SRNS) is between 30 to 50%. Accumulating evidence indicates that SRNS resulting from single gene mutations has no more than an 8% chance of responding to treatment but a significantly reduced risk of post-transplant recurrence. We therefore hypothesised that SRNS that progresses to end-stage renal failure (ESRF) could be classified into 2 categories: 'likely-genetic' - cases treatment-resistant from the outset and resulting from single gene mutations, and 'likely-circulating factor', - cases presenting at times with initial steroid sensitivity before treatment resistance developed. We posed the question whether these two categories might be linked to a differential risk of post-transplant recurrence.

**Methods:** We studied 153 consecutively transplanted patients with SRNS at 3 large paediatric centres in Europe. We compared a number of phenotypic factors including initial steroid-sensitivity, genetic mutations, extra-renal abnormalities and family history.

**Results:** 55 of 153 children (36%) with SRNS who were transplanted suffered from recurrence. Recurrence occurred in 26/28 (93%) patients who showed initial steroid-sensitivity ($p<0.0001$; OR = 130, 95% CI=6.7 to 2533.3) and 29/125 (23%) patients with primary steroid resistance. No patients with identified genetic mutations, extra-renal abnormalities or a positive family history (n=30) manifested initial steroid sensitivity or recurrence.

**Conclusions:** Our data indicates that initial steroid-sensitivity is the strongest predictor for post-transplant recurrence described to date, whereas SRNS associated with initial steroid resistance and documented or clinical features of a genetic mutation is highly protective. Clear clinical differentiation of these patient groups from the outset would enable accurate patient stratification for immunosuppression and transplantation strategies.

**TH-PO1013**

**The Efficacy of Adrenocorticotropic Hormone in Steroid-Dependent Nephrotic Syndrome: Old and New Therapy** Masao Kikuchi,[1] Yuji Sato,[1] Kazuo Kitamura,[1] Shouichi Fujimoto.[2] *[1]First Dept of Internal Medicine, Univ of Miyazaki, Miyazaki, Japan; [2]Dept of Hemovascular Medicine and Artificial Organs, Univ of Miyazaki, Miyazaki, Japan.*

**Background:** Recently, it has been reported that tacrolimus, mycophenolate mofetil and rituximab are effective therapies for patients with steroid-dependent nephrotic syndrome (SDNS). But, these drugs are off-label use in Japan as well as many countries. Adrenocorticotropic hormone (ACTH), widely used for nephrotic patients in the 1950s, has come under the spotlight for its antiproteinuric, lipid-lowering and renoprotective properties, which are not fully explained by its steroidogenic effects. In addition, ACTH might have the potential to recover adrenocortical suppression with long-term exogenous glucocorticoid therapy. We have reported the efficacy of ACTH in SDNS.

**Methods:** We treated with ACTH (tetracosactide acetate) for three patients who were diagnosed with minor glomerular abnormality on the basis of renal biopsy. Although they were treated with steroid pulse therapy, cyclosporine, cyclophosphamide, mizoribine and LDL-apheresis, they relapse easily after the steroid tapering. 0.5-1 mg ACTH was weekly given for them intramuscularly. We assessed their adrenocortical function before and after ACTH therapy by the rapid ACTH stimulation test.

**Results:** During the follow up (average 10 months), all three cases achieved complete remission after starting ACTH therapy. Their prednisolone dose could taper from 60.7 mg/day (before ACTH therapy) to 14.3 mg/day (after ACTH therapy). Their remission maintenance percentage of follow-up period increased from 12.3% (before ACTH therapy) to 85.3% (after ACTH therapy). There was no obvious adverse effect. Their responses to the rapid ACTH stimulation test after ACTH therapy recovered 2.8 times compared with those before ACTH therapy.

**Conclusions:** For ACTH helps steroid tapering and produces a recovery of adrenocortical function, ACTH is an effective therapy for steroid-dependent nephrotic syndrome.

**TH-PO1014**

**The Efficacies of Cyclosporine Combination Therapy on the First Attack of Minimal-Change Nephrotic Syndrome in Adults** Akira Fujiwara,[1] Nobuhito Hirawa,[2] Mari Katsumata,[2] Sanae Saka,[2] Keisuke Yatsu,[1] Yoshiyuki Toya,[1] Gen Yasuda,[2] Satoshi Umemura.[1] *[1]Medical Science and Cardiorenal Medicine, Yokohama City Univ School of Medicine, Yokohama, Kanagawa Prefecture, Japan; [2]Div of Nephrology and Hypertension, Yokohama City Univ Medical Center, Yokohama, Kanagawa Prefecture, Japan.*

**Background:** A combination of cyclosporine with prednisolone therapy (CPT) has been used as the treatment of frequently relapsing, steroid-dependent, or steroid-resistant minimal-change nephrotic syndrome (MCNS). However, few reports have examined the effects of CPT as first-line treatment of new-onset MCNS. Therefore, we conducted a clinical research to evaluate the efficacies and their safety by using CPT in new-onset MCNS in adults.

**Methods:** Forty-six adult patients with biopsy-proven MCNS, diagnosed for the first time, were analyzed retrospectively. We divided the patients into three groups. In the CPT group (n=17), they were treated with cyclosporine orally (2~3 mg/kg/day) with prednisolone (30 mg/day) after methylprednisolone pulse therapy (0.5 or 1.0 g/day for three days). In the MPP group (n=15), prednisolone (30 mg/day) after intravenous methylprednisolone pulse therapy was employed. The PSL group (n=14) was treated with prednisolone (40~60 mg/day) alone.

**Results:** Complete remission was obtained in all patients except one in the CPT group. Length of hospitalization was shorter in the CPT group ($P<0.05$). The average maintenance dosage of prednisolone at 6 months from the start of therapy was significantly low in the CPT group. During the nine months of following up, the CPT group experienced no relapse, whereas the MPP group and the PSL group experienced some relapses. Moreover, the adverse effects were mild and infrequent in the CPT group.

**Conclusions:** Cyclosporine combination therapy led to shorten the length of hospital stay and reduction of daily prednisolone dosage without severe adverse effects for the first attack adult-onset MCNS patients. Moreover, this combination therapy may be useful in inducing the complete remission in terms of the speed, and in reducing the relapse rates. Cyclosporine combination therapy may be a new treatment option for new-onset MCNS in adults.

**TH-PO1015**

**Clinicopathological Correlates in FSGS: A Single Tertiary Center Study** Maria T. Story,[1] Danniele Gomes Holanda,[2] Fadi Tohme,[1] Ramesh Nair,[2] Manish Suneja.[1] *[1]Internal Medicine, Univ of Iowa Hospital and Clinics, Iowa City, IA; [2]Pathology, Univ of Iowa Hospital and Clinics, Iowa City, IA.*

**Background:** Focal Segmental Glomerulosclerosis (FSGS) is a common pathological finding in kidney biopsies done to evaluate proteinuria. Distinguishing different FSGS pathological variants is helpful in guiding treatments. Guidelines for treating primary and secondary FSGS exist; however, heterogeneity abounds in practice. We investigated the clinical-pathological correlation in adult onset FSGS.

**Methods:** A retrospective analysis of biopsy proven FSGS between 10/2001 and 12/2009 was done. Patients with recurrent FSGS after transplant, age <16, immune complex glomerulonephritis, and on known nephrotoxic medications were excluded. All the remaining biopsies were classified according to the Columbia classification. Patients were than classified as either primary or secondary FSGS based on the presence of nephrotic syndrome (serum albumin<3.5, urine P/C ratio>3.5, edema, and hypercholesterolemia) and the pathology was correlated.

**Results:** 80 patients were initially identified with FSGS based on biopsy reports. After exclusion criteria were applied, we were left with 29 cases. 21 were classified as FSGS NOS, 3 perihilar, 3 collapsing, 1 cellular and 1 tip lesion variant. There were 5 cases of primary FSGS based on presence of nephrotic syndrome (3 collapsing, 1 cellular and 1 tip lesion). All secondary cases were either perihilar (n=3) or FSGS NOS (n=21). Of the cases of secondary FSGS 54% had BMI > 30 and 17% had a single kidney. Serum albumin of < 3.0 was significantly associated with primary FSGS ($p < 0.001$). 4 of the 5 primary cases and 3 of the 24 secondary cases were treated with steroids. One of the primaries and eight of the secondaries progressed to ESRD.

**Conclusions:** At our institution, primary/idiopathic FSGS is far less common than secondary FSGS (17% of FSGS biopsies). FSGS NOS, similar to perihilar lesions, is strongly associated with secondary FSGS. This observation is not reported previously. Low albumin is the strongest predictor of primary FSGS ($p < 0.001$). It is important to distinguish between primary and secondary FSGS to avoid unnecessary treatment with immunosuppressive therapy.

**TH-PO1016**

**Collapsing and Not Otherwise Specified FSGS Have Similar Response to Immunosuppressive Therapy** Louis-Philippe Laurin,[1] A. Gasim,[2] Vimal K. Derebail,[1] JulieAnne G. McGregor,[1] Susan L. Hogan,[1] Caroline J. Poulton,[1] J. Charles Jennette,[2] Ronald J. Falk,[1] Jason M. Kidd,[1] Patrick H. Nachman.[1] *[1]Div of Nephrology and Hypertension, Univ of North Carolina, Chapel Hill, NC; [2]Dept of Pathology and Laboratory Medicine, Univ of North Carolina, Chapel Hill, NC.*

**Background:** Idiopathic collapsing FSGS has been associated with poor renal prognosis. Minimal clinical data exist on the efficacy of immunosuppressive therapy.

**Methods:** Inception cohort study of biopsy-proven collapsing and not otherwise specified (NOS) FSGS patients diagnosed between 1984 and 2012. Statistical analysis performed with Mann-Whitney or Fisher's exact tests. Time to end-stage kidney disease (ESKD) and remission was reported with Cox regression hazard ratio (HR) with 95% confidence interval (CI).

**Results:** 174 patients were studied (Collapsing 46; NOS 128): age 38±20 years; 53% Black; 51% female; and follow-up time 40±39 mo.

| | | Collapsing | NOS | p |
|---|---|---|---|---|
| Onset eGFR (mL/min/1.73m$^2$) | | 51±29 | 66±36 | 0.02 |
| Proteinuria (g/d) | | 11.9±6.7 | 5.8±4.8 | <0.001 |
| Calcineurin inhibitor (CNI) (%) | | 44 | 47 | 0.7 |
| ESKD (%) | | 44 | 26 | 0.04 |
| Response to therapy[1] | | | | |
| | Complete Remission (CR) (%) | 40 | 42 | 1.0 |
| | Partial Remission (PR) (%) | 33 | 22 | 0.3 |
| | ESKD (%) | 31 | 27 | 0.6 |
| **Multivariate determinants of CR or PR[2]** | | HR (95%CI) | | |
| Collapsing variant | | 0.88 (0.38-2.02) | | 0.8 |
| CNI | | 2.31 (0.99-5.41) | | 0.05 |
| **Multivariate determinants of ESKD[3]** | | | | |
| Collapsing variant | | 1.84 (0.68-4.96) | | 0.2 |
| CNI | | 0.43 (0.20-0.95) | | 0.04 |

[1]steroids and/or CNI; [2]correcting for age, sex, race, onset proteinuria, onset albumin, renin-angiotensin inhibition and onset eGFR <30; [3]correcting for sex, race, onset proteinuria and onset eGFR <30.

**Conclusions:** Compared to NOS, collapsing FSGS presents with more severe nephrotic syndrome and lower GFR, but has a similar response to immunosuppression with CNI.

## TH-PO1017

**Clinical Features and Outcomes of Focal Segmental Glomerulosclerosis Pathologic Variants in Korean Adult Patients** Young Eun Kwon,[1] Ji Suk Han,[1] Hyung Jung Oh,[1] Seung Hyeok Han,[1] Shin-Wook Kang,[1,2] Tae-Hyun Yoo.[1,2] *[1]Dept of Internal Medicine, College of Medicine; [2]Brain Korea 21, Yonsei Univ, Seoul, Korea.*

**Background:** Focal segmental glomerulosclerosis (FSGS) is a common cause of nephrotic syndrome (NS) and ESRD, particularly in African-Americans. Many studies have shown that clinical characteristics and outcomes differ depending on pathologic variants of FSGS. However, these are not well defined in Asian populations.

**Methods:** We conducted a retrospective cohort study to evaluate clinical features and outcomes according to pathologic variants of FSGS in 111 adult patients. Primary outcome was the composite of doubling of baseline serum creatinine concentrations (D-SCr) or the onset of ESRD. Secondary outcome included the rates of complete remission (CR) or partial remission (PR).

**Results:** Not-otherwise specified (NOS), tip, perihilar, cellular, and collapsing variants were present in 70 (63.1%), 20 (18.0%), 17 (15.3%), 3 (2.7%), and 1 (0.9%) patients, respectively. Fifty patients (45.0%) presented NS, and among them 47 patients (94.0%) were treated with immunosuppressants. NS were more prevalent in patients with tip lesion than in those with other variants. The overall 5-year and 8-year renal survival rates were 76.8% and 56.3%, respectively. During a median follow-up duration of 34.5 months, only 1 patient (5.0%) with tip lesion reached the composite outcome compared to 2 (11.8%) and 12 patients (17.1%) with perihilar and NOS variants, respectively, but this difference did not reach statistical significance. CR and PR were achieved in 29 (26.1%) and 32 patients (28.8%), respectively. Tip lesion was associated with a significantly increased probability of achieving CR (P=0.044).

**Conclusions:** Similar to other populations, Korean adult patients with FSGS had distinct clinical features with the exception of a rare frequency of cellular and collapsing variants. Although pathologic variants were not associated with the overall outcome, tip variant exhibited favorable outcome in terms of achieving CR. Further studies with a larger sample size are required to delineate the long-term outcome and response to treatment according to the pathologic variants.

## TH-PO1018

**Tacrolimus Therapy in Adults with Steroid Resistant Focal Segmental Glomerulosclerosis** Raja Ramachandran, Harbir Singh Kohli, Manish Rathi, Vivekanand Jha, Krishan L. Gupta, Vinay Sakhuja. *Nephrology, PGIMER, Chandigarh, India.*

**Background:** Management of adults with steroid resistant (SR) focal segmental glomerulosclerosis (FSGS) steroids is a challenging task. Is tacrolimus (Tac) effective in this situation without serious adverse effects? This prospective study was done to answer this question.

**Methods:** This prospective observational study was done from January 2011 to April 2013. Patients with adult onset ( ≥18 yrs) FSGS with SR (prednisolone 1 mg/kg/day for at least 16 weeks) were enrolled. In patients with SR-FSGS, oral Tac was started targeting a trough level of 5-10 ng/ml along with oral prednisolone (0.15mg/kg/day). In patients with complete remission at 24 weeks, Tac dose was reduced to target 3-6ng/ml for next 24 weeks and hiked again if there was a relapse, while in partial responders Tac trough levels were kept at 5-10ng/ml for next 24 weeks. However, in patients with no remission at 24 weeks Tac was discontinued. Outcome viz complete remission (CR) (reduction of proteinuria to <0.3 g/d & sr albumin ≥ 3.5gm/dl), partial remission (PR) (reduction of proteinuria to 0.3–3.5 g/d & sr albumin ≥ 3.5gm/dl) were assessed at the end of 24 and 48 weeks. Relapses defined as increased proteinuria after complete or partial remissions were recorded. Adverse effects viz. nephrotoxicity (>25% rise in creatinine), cosmetic effects, infections and impaired fasting glucose were recorded every month and analysed at the end of 48 weeks.

**Results:** A total of 34 SR-FSGS completed the study. Of 34 patients CR and PR was achieved in 12 (35%) and 05 (15%) patients respectively. Tac resistance was seen in 17 (50%) patients. Time taken to achieve remission was 21.2±12.4 weeks. Two patients had relapse on tapering the dose after 24 weeks. Of 34 patients reversible nephrotoxicity was seen in 6 (17.6%), irreversible nephrotoxicity in 2 (5.8%), Tac related diarrhea in 6 (17.6%), infections in 12 (35.2%), impaired glucose tolerance/ DM in 10 (29.4%), tremors in 4 (11.7%) and gum hypertrophy in 2 (5.8%).

**Conclusions:** Tac is a very effective agent in the management of SR-FSGS. However, strict renal function and blood sugar monitoring is required due to its nephrotoxicity and diabetogenic potential.

## TH-PO1019

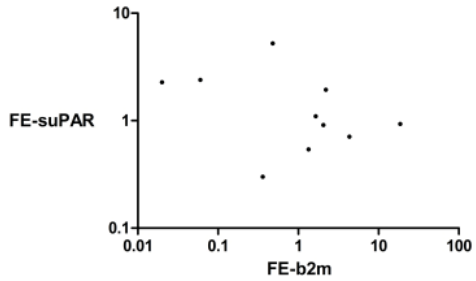
**Kidney Handling of Soluble Urokinase Receptor in Patients with Nephrotic Syndrome** Rutger J. Maas, Jeroen Deegens, Jack F. Wetzels. *Nephrology, Radboud Univ Nijmegen Medical Centre, Nijmegen, Netherlands.*

**Background:** Serum suPAR was recently proposed as a specific biomarker of primary FSGS. However, subsequent studies have shown that eGFR is a major determinant of serum suPAR level in patients with FSGS and non-FSGS CKD. suPAR has a MW of 20-60kDa, which implies free glomerular filtration. Urinary suPAR excretion has been demonstrated. We studied kidney handling of suPAR in patients.

**Methods:** serum and urine samples of patients with FSGS (n=6) and MN (n=4) were obtained using a standardized protocol for measurement of urinary proteins. Urinary beta-2-microglobulin (b2m) was only measured if pH was >6.0. suPAR was measured with the Quantikine Human suPAR Immunoassay (R & D Systems, Minneapolis, MN). We compared fractional excretions (FE) of suPAR with b2m and albumin. eGFR was calculated with the 4 variable MDRD Study Prediction Equation.

**Results:** Median eGFR was 50 (IQR 23-71) ml/min/1.73m$^2$, and median proteinuria was 9.3 (IQR 6.6 -15.8) g /10mmol creatinine. Median serum suPAR was 6185 (IQR 5525-8828) pg/ml, median urinary suPAR was 695 (IQR 357-1355) ng/mmol. FE-suPAR did not correlate with FE-b2m, a marker of tubular reabsorption (figure). There was also no correlation of FE-suPAR with either FE-albumin or FE-IgG.

**Conclusions:** suPAR can be detected in urine. There was no correlation of FE-suPAR with FE-b2m. Thus, we found no evidence for tubular reabsorption of suPAR. FE-suPAR did not correlate with FE-albumin, which suggests that urine suPAR is also not simply a marker of glomerular permeability defect.



## TH-PO1020

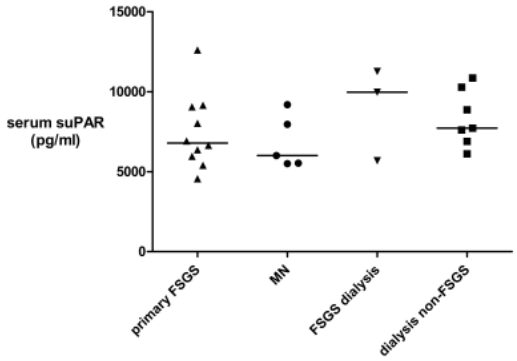
**Soluble Urokinase Receptor Levels in Serum and Urine of Patients with Primary Focal Segmental Glomerulosclerosis and Controls** Rutger J. Maas, Jeroen Deegens, Jack F. Wetzels. *Nephrology, Radboud Univ Nijmegen Medical Centre, Nijmegen, Netherlands.*

**Background:** Serum suPAR was proposed as a diagnostic marker for primary FSGS and post-transplant FSGS recurrence. However, previous studies have shown a correlation between serum suPAR and eGFR, which is a potential source of bias. We investigated if serum or urinary suPAR levels can distinguish between primary FSGS and controls with comparable eGFR.

**Methods:** suPAR was measured with the Quantikine Human suPAR Immunoassay (R&D Systems, Minneapolis, MN) in serum and urine of patients with primary FSGS (n=10) and membranous nephropathy (MN; n=5) with nephrotic syndrome, and in dialysis patients with a history of recurrent (n=3) FSGS, and controls (n=7). eGFR was calculated with the 4 variable MDRD Study Prediction Equation.

**Results:** Median eGFR was 36 (IQR 15-69) ml/min/1.73m$^2$ in patients with primary FSGS and 37 (IQR 22-69) ml/min/1.73m$^2$ in patients with MN. Serum suPAR did not differentiate between patients with primary FSGS and MN (fig. 1). Median urinary suPAR was 822 (IQR 343-2150) ng/mmol creatinine in patients with FSGS and 636 (IQR 423-833) ng/mmol creatinine in patients with MN, a non-significant difference. In patients on dialysis, serum suPAR did not discriminate between patients with previous posttransplant FSGS recurrence and controls (fig. 1).

**Conclusions:** Serum and urinary suPAR levels were similar in patients with primary FSGS compared to eGFR-matched controls.



## TH-PO1021

**Circulating Soluble Urokinase Receptor Levels in Primary Nephrotic Syndrome Predict the Response to Therapy** Keiji Fujimoto, Hiroki Adachi, Hideki Yamaya, Hitoshi Yokoyama. *Nephrology, Kanazawa Medical Univ, Uchinada, Japan.*

**Background:** Circulating soluble urokinase receptor (suPAR) speculated to produce proteinuria and focal segmental glomerulosclerosis (FSGS). However, no studies have investigated the involvement of suPAR in the development of primary nephrotic syndrome (NS) in Japanese.

**Methods:** Circulating suPAR levels were measured by ELISA (R & D system) in 36 primary NS cases including 8 FSGS (4 with tip lesion, 2 with NOS type, and 2 with collapsing type), 14 minimal change nephrotic syndrome (MCNS), 12 membranous nephropathy (MN) and 2 membranoproliferative glomerulonephritis (MPGN), and 15 normal controls. Circulating suPAR levels and clinical parameters during the 6 months after immunosuppressive therapy were analyzed. In this study, refractory NS was defined as daily proteinuria did not decrease to <1 g after 6 months therapy.

**Results:** Circulating suPAR levels before therapy were significantly higher in NS patients than in normal controls (P <0.05), but not significantly different among those with FSGS, MCNS, MN, or MPGN. There was a significant negative correlation between the circulating suPAR levels and eGFR in the total NS, FSGS, and MCNS groups (total, r = -0.54, p <0.001, n=107; FSGS, r = -0.61, p=0.002, n=31; MCNS, r = -0.54, p=0.003, n=41) and a significant positive correlation between the circulating suPAR levels and CRP (r = 0.79, p <0.001, n=24) or age (r = 0.68, p=0.002, n=21) in MN. In addition, circulating suPAR levels decreased significantly in MCNS from 3,288 to 2,723 pg/mL after 2 months therapy (p=0.03), but not in FSGS or MN. Patients with refractory NS showed higher circulating suPAR levels with a tendency to increase during therapy. ROC analysis showed that refractory NS was defined by more than 3,324 pg/mL and the increase of circulating suPAR levels more than 226 pg/mL at 2 months after therapy (AUC 0.89, p=0.012, AUC 0.85, p=0.027, respectively).

**Conclusions:** These results suggested that alteration of circulating suPAR level and the levels at 2 months after the therapy reflected the response to therapy in patients with primary NS, even in MCNS.

## TH-PO1022

**Renal Diagnoses and Outcomes in Women with Disease Identified during Pregnancy Compared with Non-Pregnant Controls – A Multicentre Cohort Study of 1486 Women** Philip Webster,[1] Kate Bramham,[2] Louise Webster,[2] H. Terence Cook,[1] Catherine Horsfield,[3] Isabelle Lydon,[2] Michele Homsy,[2] Raquel Vaz,[1] Clara Santos,[1] Liz Lightstone.[1] *[1]Imperial College Healthcare NHS Trust Renal and Transplant Centre, United Kingdom; [2]King's College London, United Kingdom; [3]Guy's and St. Thomas' NHS Foundation Trust, United Kingdom.*

**Background:** Chronic kidney disease affects approximately 2% of women aged 16-54yrs in England. Pregnancy is frequently the first time women are seen by health services, providing an opportunity to identify disease. Our aims were i) To compare the aetiology of renal disease diagnosed during/after pregnancy with disease identified in non-pregnant women of child-bearing age; ii) To compare long term renal outcomes in these groups. We present the largest and most comprehensive controlled cohort of patients to date.

**Methods:** Native renal biopsies from 2 London centres were studied (1997-2012). Renal disease identified in pregnancy-related (PR) biopsies included antenatal and postpartum biopsies. Controls included biopsies from all women of childbearing age (16 to 49yrs). First biopsies were included. Repeat and inadequate biopsies were excluded.

**Results:** 164 PR biopsies (19 antenatal, 145 postpartum) were identified; mean age at biopsy 32.7yrs. 1322 biopsies in control women; mean age at biopsy 35.3yrs. Focal segmental glomerulosclerosis (FSGS) was most frequently found in PR biopsies, and was more prevalent than in controls (p<0.0001). Lupus nephritis was more common in the control group (p<0.01). There were no significant differences in other diagnoses. Preliminary analysis of renal outcomes from one site (n=864) showed no difference in renal replacement free survival after biopsy in controls and those with disease identified in pregnancy, including those subsets with FSGS.

**Conclusions:** FSGS is the most common diagnosis in PR biopsies, but does not appear to be associated with worse long term renal outcomes compared with controls. It is unclear whether pregnancy reveals or causes FSGS, or whether lesions are primary or secondary. Further work is needed to explore this, and to define risk factors for progression in order to optimise antenatal and postpartum management.

## TH-PO1023

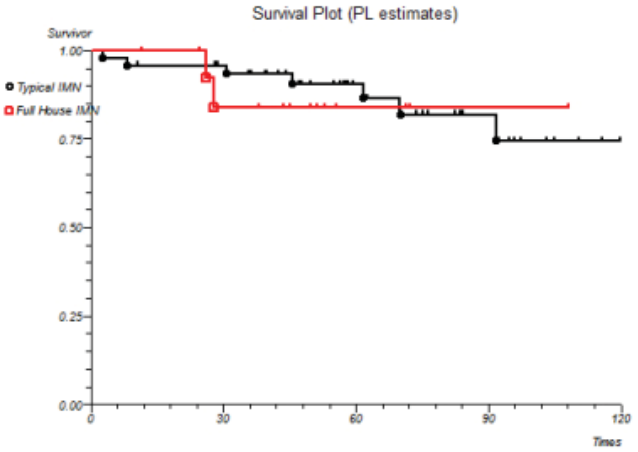
**Clinical Relevance of "Full House Idiopathic Membranous Nephropathy"** Shiv Bhutani, Durga A.K. Kanigicherla, Patrick Hamilton, Roshni Rathore, Mumtaz Patel, Paul E. Brenchley, Michael Venning. *Manchester Institute of Nephrology and Transplantation, Central Manchester Univ Hospitals NHS Foundation Trust, Manchester, United Kingdom.*

**Background:** Idiopathic Membranous Nephropathy is typically characterised by IgG and C3 deposits (Typical IMN, TIMN). Variants that include C1q, IgM, IgA (Full House IMN, FHIMN) without secondary causes at presentation are seen. Outcome in this subset is unclear.

**Methods:** Retrospective analysis of 62 consecutive adult patients with first diagnosis of IMN made by biopsy between 2003 & 2009 at our single center. Remission, CKD-5, and development of systemic diseases was recorded. Where archived serum was available, A-PLA2Rab was tested.

**Results:** 16 patients with FHIMN presented with preserved renal function. Renal survival at median follow up of 50 months was 87%. In comparison to 46 patients with TIMN, there was no significant difference in presentation or renal outcome.

| | Full House IMN | Typical IMN | p |
|---|---|---|---|
| n | 16 | 46 | |
| Initial Proteinuria (Median) | 7.1 | 8.7 | 0.31 |
| Initial eGFR | 82 | 74 | 0.20 |
| Immunosuppression (%) | 56 | 39 | 0.17 |
| Part Rem % | 75 | 83 | 0.32 |
| CKD5 % | 13 | 15 | 0.75 |
| A-PLA2Rab (%) | 50 | 68 | 0.29 |



3 patients with FHIMN (19%) developed secondary causes (SLE in 2 patients within 2 years / disseminated Esophageal malignancy in 1 - within 6 months of presentation). One patient with TIMN (2%), developed Esophageal malignancy, 25 months after presentation, whilst in partial remission (p=0.02). A-PLA2Rab was measured in 41 prevalent patients – positive in 5/10 patients with FHIMN (50%) and 21/31 with TIMN (68%) (p=0.29).

**Conclusions:** Patients with 'Full House IMN' without secondary causes at diagnosis had similar renal outcome as those with 'Typical IMN'. Point prevalence of A-PLA2Rab was similar in both groups. Development of significant co-morbidities suggests that in patients presenting with FHIMN targeted screening for secondary causes would be beneficial.

## TH-PO1024

**Low Serum Albumin and Elevated Serum Creatinine Levels Are Predictors for Thromboembolic Complications in Patients with Membranous Nephropathy** Elion Hoxha, Ina Ellen Thiele, Gunther Zahner, Ulf Panzer, Sigrid Harendza, Rolf A. Stahl. *III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

**Background:** Patients with Membranous Nephropathy (MN) have a high risk to experience thromboembolic complications (TEC). It is currently unclear whether there is a level of albuminuria or serum albumin which predict an increased risk of TEC. Secondly it is also unclear whether there exist differences in the risk for TEC between primary and secondary MN.

**Methods:** We analyzed in a prospective multicenter study 263 adult patients with MN up to 24 months (64.6% primary MN with $PLA_2R$-Ab positivity; 35.4% secondary MN). Patients were seen every three months for analysis of proteinuria, serum albumin and serum creatinine. TEC were assessed at every visit and categorized in emboly of lung arteries, thrombosis of leg veins, central veins, the dialysis fistula or renal venous thrombosis.

**Results:** 29 (11%) out of 263 patients developed a TEC. 17 patients had emboly of the lung arteries. 4 patients had thrombosis of leg veins, 2 thrombosis of central veins, 3 thrombosis of the dialysis fistulae, 3 patients had renal venous thrombosis. 23 patients developed the TEC before or at the time of the diagnosis of MN. There was no relative difference in the TEC between patients with primary or secondary MN (11.2% and 10.8% respectively).There was no statistically significant difference in the $PLA_2R$-Ab levels in patients with primary MN between patients with (221.4±451.0 U/ml) or without a TEC (198.9±341.6 U/ml). In patients with serum albumin <20g/L or proteinuria >8g/24h the incidence of a TEC was higher compared to the remaining patients ($p<0.05$). Surprisingly, patients with serum creatinine >1,2mg/dl also had a significantly higher risk of TEC ($p<0.05$).

**Conclusions:** Serum albumin levels < 20g/L, proteinuria >8g/24h and serum creatinine levels >1.2 mg/L are risk factors for the development of TEC in patients with MN. There was no difference between patients with primary or secondary MN. $PLA_2R$-Ab levels did not influence the incidence of TEC in patients with primary MN.

## TH-PO1025

**Spontaneous Remission of Proteinuria Is a Frequent Event in $PLA_2R$ Antibody Negative Patients with Membranous Nephropathy** Elion Hoxha, Ina Ellen Thiele, Gunther Zahner, Ulf Panzer, Sigrid Harendza, Rolf A. Stahl. *III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

**Background:** Membranous Nephropathy (MN) is the most common cause of nephrotic syndrome in adults. While 70-80% of patients with MN are positive for $PLA_2R$-Ab in the serum, little is known about the pathogenesis of MN in $PLA_2R$-Ab negative patients and whether the clinical course is different from patients with primary MN.

**Methods:** We performed a prospective multicenter study in order to study the clinical outcome in patients with $PLA_2R$-Ab negative MN. 60 adult patients with biopsy-proven MN were studied up to 24 months. Proteinuria, serum albumin, blood pressure and serum creatinine were studied in 3 monthly intervals. Immunosuppressive therapy or supportive medical care was assessed over the time of observation.

**Results:** 18 (30%) patients had non-nephrotic proteinuria (proteinuria <3.5g/24h) at the time of inclusion in the study. These patients had an excellent outcome without immunosuppressive treatment, 5 of them had a secondary cause of disease (3 Lupus Erythemathodes (LE), 1 Sjoergen's syndrome, 1 NSAID-Exposure). Of the 42 patients with proteinuria >3.5g/24h at inclusion in the study, 24 (57%) were treated with immunosuppressive agents (19 calcineurin inhibitors, 9 alkylating agents, 3 rituximab, 2 glucocorticoids). 7 of these patients had a secondary cause of disease (3 LE, 3 Tumor, 1 NSAID-Exposure). 9 patients received 2 or more different immunosuppressants during follow-up. The remaining 18 patients were treated with supportive medication only. 8 of them had a secondary cause of disease (2 LE, 5 Tumor, 1 neurologic chronic inflammatory disease). Patients treated with immunosuppressants had a similar age, gender distribution, proteinuria, serum albumin, and serum creatinine at the start of the study compared with patients on supportive treatment. After 24 months there was no significant difference in the levels of proteinuria and serum creatinine between patients receiving immunosuppressive therapy or supportive treatment only.

**Conclusions:** We conclude that a high number of $PLA_2R$-Ab negative patients with MN have a good prognosis and might not need immunosuppressive therapy.

## TH-PO1026

**Molecular Characteristics of Anti-PLA2R IgG in Japanese Patients with Idiopathic Membranous Nephropathy** Shin'ichi Akiyama,[1] Enyu Imai,[2] Seiichi Matsuo,[1] Shoichi Maruyama.[1] *[1]Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan; [2]Nakayamadera Imai Clinic, Takaraduka, Hyougo, Japan.*

**Background:** We previously reported that a prevalence of auto-IgG against phospholipase A2 receptor (PLA2R) in Japanese patients with idiopathic membranous nephropathy (iMN) is remarkably lower (49%) than cases in Caucasian and Chinese patients (65%~) However, the molecular characteristics of anti-PLA2R IgG in Japanese patient with iMN have not been revealed. In this study, we studied antigenic reactivity and major subclass of anti-PLA2R auto-IgG in Japanese patients with iMN.

**Methods:** We performed Western blotting, under nonreducing or reducing condition, of recombinant PLA2R or the native PLA2R in human glomerular extract (HGE) with anti-PLA2R IgG positive serum specimens from 25 Japanese patients with iMN. To evaluate a influence of *N*-glycosylation of PLA2R to antigenic reactivity against anti-PLA2R auto-IgG, an enzymatic deglycosylated PLA2R was also used in Western blotting as antigen. The major subclasses of anti-PLA2R IgG were determined by ELISA with recombinant PLA2R and subclass specific secondary antibodies.

**Results:** None of the positive serum specimens retained reactivity to PLA2R when the HGE and recombinant PLA2R were electrophoresed under reducing conditions. All serum samples reacted with both native form and deglycosylated form of the PLA2R under nonreducing conditions. These results indicate that *N*-glygosilation of PLA2R is not necessary to bind with anti-PLA2R IgG, a native conformation of PLA2R is essential. The reactive serum samples are highly enriched in IgG4 that react with recombinant PLA2R or the native protein in HGE. Although IgG4 is predominant subclass of anti-PLA2R IgG, other subclasses are also present in smaller amounts.

**Conclusions:** The molecular properties, antigenic reactivity and major subclass, of anti-PLA2R IgG in Japanese patients with iMN are similar to those in Caucasian patients with iMN. The anti-PLA2R IgG in Japanese patients with iMN uniquely recognize a conformation-dependent epitope in PLA2R and their major subclass is IgG4.

## TH-PO1027

**Membranous Nephropathy after Allogeneic Hematopoietic Stem Cell Transplantation** Rikako Hiramatsu, Yoshifumi Ubara, Keiichi Sumida, Tatsuya Suwabe, Junichi Hoshino. *Nephrology Center, Toranomon Hospital, Tokyo, Minato-ku, Japan.*

**Background:** Renal involvement in patients with chronic graft-versus-host disease (cGVHD), presenting as nephritic syndrome, is rare following hematopoietic stem cell transplantation (HSCT). The most frequent form of post-HSCT glomerulonephritis is membranous nephropathy (MN); but data on its clinico-pathological features and long-term outcome are scarce.

**Methods:** From 2000 to 2012, the clinical characteristics, pathological features, and long-term outcome were evaluated in 5 patients with MN after HSCT. Kidney biopsies were analyzed by light microscopy (LM), immunofluorescence (IF), electron microscopy (EM), and IgG subclasses in glomerular deposits were identified.

**Results:** All patients had a history of cGVHD, with active cGVHD prior to MN diagnosis. Mean time between HSCT and diagnosis of MN was 21.8 months (range; 9–33). Serum creatinine was 1.0 mg/dL (0.8 to 1.3). Discontinuation of cGVHD prophylactic immunosuppressants prior to MN onset was a consistent feature, occurring at a median of 12.6 months (range; 2–25) before onset. Significant proteinuria (mean; 8.40 g/day, range; 5.93–13.0) was common. LM did not detect definite spike formation in capillary lumens. EM revealed subepithelial and intramembranous deposits, as well as mesangial deposits with extensive podocyte foot process effacement. Subepithelial deposits were segmental, small and electron-lucent. IF showed that IgG1 and IgG4 were the predominant IgG subclasses in glomerular deposits, which were negative for C3. All MN cases were initially treated with corticosteroids, resulting in complete remission (CR) at a median of 12.2 months (range; 5–24). Long-term follow up at a median of 92.4 months (range; 38–144) showed that relapse of MN paralleling the evolution of cGVHD occurred in 2 patients at 43 and 27 months after initial CR. One patient developed end-stage renal failure requiring hemodialysis.

**Conclusions:** This series of 5 patients with post-HSCT MN is the largest study so far. Initial response to treatment was favorable, but careful observation for MN relapse parallel to cGVHD evolution, and long-term renal monitoring, are necessary.

*Funding:* Government Support - Non-U.S.

## TH-PO1028

**Outcome of Renal Biopsy Proven Membranous Nephropathy Patients – Single Centre Experience** Muhammad A. Imtiaz,[1] Katie Ht Wong,[2] Rosa M. Montero,[1] Mona Wahba.[1] *[1]Dept of Renal Medicine, St .Helier Hospital, Surrey, United Kingdom; [2]Dept of Medicine, St. Peter Hospital, Surrey, United Kingdom.*

**Background:** Membranous Nephropathy(MN) is the commonest cause of nephrotic syndrome in adults. Number of studies that looked at the progression of MN showed variable rate of progression with 8-20% of patients become dialysis dependent.

**Methods:** Patients from 1995-2010 with MN were included.Urinary protein creatinine ratio(UPCR), eGFR, serum Creatinine(Cr), Cholesterol(Ch) and Albumin(Alb) levels were collected at 2, 5 and 10 years. Outcomes were measured as changes in baseline UPCR, baseline Cr, onset of renal replacement therapy(RRT) and patient survival. Significant change in creatinine was defined as 20% increase from baseline. Treatment groups were divided into Non Immunosuppression(Non Immuno) receiving angiotensin converting enzyme inhibitors(ACEi) or Angiotensin 2 receptor blockers(ARB) and a statin or Immunosuppressed(Immuno) group where they received additional immunosuppressive therapy.

**Results:** Non Immuno group included 77/125 patients(61%). 54 male, 23 female; Median age 60.5 years. Immuno group had 48 patients; 26 males. Median age was 59 years. In both groups UPCR reduced significantly by 2 and 5 years from baseline readings(both $p<0.001$). There was a significant increase in Cr at 2 and 5 years in the Non Immuno group from baseline ($p<0.05$, $p<0.01$, respectively) in contrast to the Immuno group where there was no significant change. There were 7 deaths in Non Immuno group compared with Immuno group that had 3 deaths over 10 years. 11 patients in the Non Immuno were on RRT by 10 years compared with 8 patients in the Immuno group that was not significant. There was a significant improvement in Ch and Alb levels from baseline in both groups that was maintained throughout the follow up period($p<0.001$, $p<0.001$, respectively).

**Conclusions:** Irrespective of immuno or non immuno group, patients with MN had similar clinical outcomes with regards to UPCR, Ch and Alb levels over 10 years. There was significant increase in Cr of Non Immuno group at 2 and 5 years. Overall 10/125(8%) died and 19/125(15.2%) became dialysis dependent over 10 years suggesting a survival advantage in the Immuno group.

## TH-PO1029

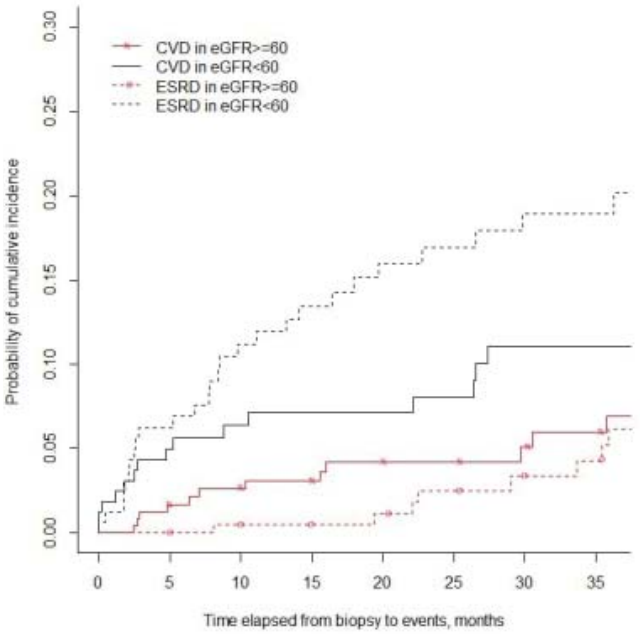
**The Risk of Cardiovascular Events (CVE) Is Similar or Exceeds That of End Stage Kidney Disease (ESKD) in the Early Years of Membranous Nephropathy (MN)** Taewoo Lee, Vimal K. Derebail, Shannon L. Mahoney, Abhijit V. Kshirsagar, Caroline J. Poulton, Susan L. Hogan, Ronald J. Falk, Patrick H. Nachman. *UNC Kidney Center, The Univ of North Carolina at Chapel Hill, Chapel Hill, NC.*

**Background:** We hypothesized that patients with primary MN have an increased risk for CVE. We explored the incidence, risk factors and time to CVE as compared to ESKD.

**Methods:** In an inception cohort of 404 patients with median follow-up of 23 m (IQR 9-50), we investigated the incidence of ESKD, all-cause mortality and CVE defined as acute coronary syndrome, stroke or peripheral artery thrombosis. Cumulative incidence rates of CVE before reaching ESKD were estimated using competing risk analysis. To

determine risk factors, competing risk regression analysis was performed with relevant covariates at baseline. A severity score of nephrotic syndrome (NS) determined by proteinuria ( ≥3.5 g/day) and/or hypoalbuminemia (<2.5 g/dL) at each visit was used as a time-dependent variable.

**Results:** 32 CVE occurred in a median of 8 m (IQR 3-29), 69% within 2 years. Cumulative incidence rates of CVE, ESKD, and death in the entire cohort were 5.7%, 8.9%, and 2.4% at 2 years and 9.1%, 19.4%, and 4% at 5 years, respectively. Among patients with baseline eGFR ≥ 60 ml/min, the risk of CVE [4.2% (95% CI 1.5-6.8)] exceeded that of ESKD [2.5% (0-5)] at 2 years; but not when eGFR <60 ml/min, [8% (3.6-12.4) vs 18.6% (12-25), respectively]. The severity of NS (HR 2.19), previous CVE, diabetes mellitus and age were significant risk factors of CVE after adjusting for smoking and CKD stages.



**Conclusions:** Early after diagnosis, the risk for CVE is similar to that of ESKD, and is greater than ESKD in patients with preserved renal function. CVE are an important complication of MN and may be as relevant an outcome measure as ESKD. CVE are associated with the severity of NS and traditional risk factors.

## TH-PO1030

**Development and Evaluation of a Patient-Reported Outcome (PRO) Measure for Idiopathic Membranous Nephropathy (IMN): The Membranous Nephropathy Quality of Life Tool (MNQoL)** Christine Barrett,[1] Jane E. De Vries,[1] Rachel B. Jones,[2] Lynda C. Doward,[3] Patrick Hamilton,[4] Michael Venning.[4] *[1]GlaxoSmithKline plc; [2]Vasculitis Unit, Addenbrooke's Hospital, Cambridge; [3]RTI-Health Solutions, Manchester; [4]Manchester Institute of Nephrology and Transplantation, Manchester Royal Infirmary, United Kingdom.*

**Background:** Regulators such as the FDA recognise that the patient perspective is important in evaluating new treatments for IMN. No PRO measures currently exist specific for nephrotic states including IMN. Our objective was to develop a new PRO tool, for use in IMN studies as an exploratory endpoint alongside the Kidney Disease Quality of Life 36 item survey (KDQoL-36), and to evaluate content validity of both tools.

**Methods:** Patient interviews (n=4) and a literature review yielded 12 key symptoms of IMN. A 14-item MNQoL was developed with 5 response levels asking the degree of "bother" associated with each symptom, treatment side effects and the quantity of medicines required to treat IMN. Cognitive debriefing was conducted with a new IMN patient sample (n=9) to determine content validity and ease of completion of the MNQoL and KDQoL-36 (study HO-12-955).

**Results:** Patients debriefed were 6M/3F, with median age=51/range 39-68, 4 active disease/5 remitted (partial or complete), mean years since diagnosis=6.3/SD 8.6. Cognitive debriefing demonstrated that the KDQoL-36 and MNQoL, used together, comprehensively represent symptoms and side effects experienced by IMN patients. Patients found the questionnaires relevant and easy to complete. Some minor comprehension issues were identified e.g. how to interpret "bother". Future versions of the MNQoL should also enquire if the patient actually experiences each symptom or side-effect. For the MNQoL to be used alone, additional symptoms would need to be added.

**Conclusions:** This research has shown the MNQoL and KDQoL-36 to be suitable instruments to assess the impact of IMN and its treatment from the patient's perspective. Further validation of the MNQoL is required within IMN clinical trials, as well as in other nephrotic conditions. This research will inform ongoing development of PROs as potential regulatory endpoints in IMN studies.

*Funding:* Pharmaceutical Company Support - GlaxoSmithKline plc

## TH-PO1031

**Serum Anti-Phospholipase A2 Receptor Antibody Testing for Idiopathic Membranous Nephropathy** Vinod Raman, Craig E. Gordon, Laurence H. Beck, Jean M. Francis. *Renal Section, Dept of Medicine, Boston Univ School of Medicine, Boston, MA.*

**Background:** Idiopathic membranous nephropathy (IMN) is diagnosed in 16-33% of kidney biopsies for nephrotic range proteinuria in adults. Anti-phospholipase A2 receptor antibody (anti-PLA2R) has been associated with idiopathic membranous nephropathy. The performance characteristics of the available diagnostic tests for anti-PLA2R have not been well defined. Using systematic review and meta-analysis, we aimed to identify the role of anti-PLA2R testing as a diagnostic tool for IMN in patients with nephrotic range proteinuria.

**Methods:** We performed a systematic review of the literature using Medline (last search: 5/7/2013) to identify studies reporting the use of serum anti-PLA2R as a diagnostic test for IMN in patients with nephrotic range proteinuria and biopsy confirmation of IMN. From reported data, we calculated the sensitivity and specificity for serum anti-PLA2R testing against reference standard of biopsy. IMN incidence data was used to estimate the positive and negative predictive values (PPV, NPV).

**Results:** Of 1125 retrieved studies, 10 studies provided data that allowed the calculation of sensitivity and specificity for serum anti-PLA2R testing. The 10 studies reported on total 620 unique patients with nephrotic range proteinuria. Patients had a mean age of 49.5y, 50% were male, mean proteinuria was 7.9g/g, and mean serum creatinine was 1.07mg/dl. Six studies used western blot and four used immunofluorescence. Sensitivity of anti-PLA2R testing ranged from 66-98% and specificity from 84-100%. Using the median value of IMN incidence in patients with nephrotic range proteinuria obtained from published literature (23%), PPV and NPV ranged from 92%-100% and 78-96%, respectively.

**Conclusions:** Our findings indicate that serum testing for anti-PLA2R is an important diagnostic tool in the evaluation of patients with nephrotic range proteinuria with a high sensitivity, specificity, and at expected incidence levels, a high positive and negative predictive value for IMN.

## TH-PO1032

**Circulating TNF Receptors Is a Significant Prognostic Biomarker for Idiopathic Membranous Nephropathy with Nephrotic Syndrome** Su Mi Lee,[1] Hyun Seop Cho,[2] Yun Jung Oh,[3] Dong Ki Kim,[1] Yun Kyu Oh,[4] Chun Soo Lim,[4] Shin-Wook Kang,[5] Jung Pyo Lee,[4] Yon Su Kim.[1] *[1]Seoul National Univ Hospital; [2]Gyeongsang National Univ Hospital; [3]Cheju Halla General Hospital; [4]Seoul National Univ Boramae Medical Center; [5]College of Medicine, BK21, Yonsei Univ.*

**Background:** Membranous nephropathy (MN) is a common cause of nephrotic syndrome in adults. There is no secure biomarker that can indicate the severity and predict the long-term prognosis of the MN. The aim of this study is to evaluate the clinical significance of TNF receptors (TNFRs) as a prognostic marker.

**Methods:** 94 patients had MN with nephrotic range proteinuria at the time of biopsy were enrolled. Circulating TNFR levels were measured using serum samples stored at the time of biopsy. The primary clinical endpoint was a remission. Secondary outcome was the decline of estimated glomerular filtration rate (eGFR; ≥30% decline compared to baseline).

**Results:** At the time of biopsy, eGFR and proteinuria worsened proportionally as circulating TNFR1 and TNFR2 increased (p<0.001). 73 of 94 patients reached primary outcome. Compared to non-responder group, responder group had significantly lower circulating TNFR 1 (1972.38 ± 1017.67 vs. 3743.32±2125.58, P=0.035). However, there was no significant difference of TNFR2 between responder and non-responder (4785.10±2215.38 vs. 7685.10±4210.6, P=0.074). The risk of reaching the secondary endpoint was significantly higher in the in the highest quartile of TNFR1 or TNFR2 compared with other quartiles by the Kaplan Meier method (P=0.001 and P<0.001, respectively). Highest TNFR1 was a significant risk factor for the secondary endpoint after adjusting for age, sex, amount of proteinuria, eGFR, treatment, and presence of remission (Hazard Ratio [HR] 1.51, 95% confidence interval [C.I] 1.14-2.02, P=0.005). Highest TNFR2 was also statistically significant (HR 1.50, 95% C.I 1.12-2.00, P=0.007).

**Conclusions:** This study showed circulating TNFR 1 could predict remission. In addition, circulating TNFR 1 and TNFR 2 could predict progression of CKD in patients with MN. Further studies would be needed to establish the role of circulating TNFRs to reflect the responsiveness of specific treatment.

## TH-PO1033

**Tacrolimus in Membranous Nephropathy** Paula Jara Caro Espada, Elena Gutierrez-Solis, Jorge Enrique Rojas-Rivera, Manuel Praga. *GLOSEN (Spanish Group for Study of Glomerular Diseases).*

**Background:** Tacrolimus (TAC) monotherapy has shown to be effective in the treatment of idiopathic membranous nephropathy (IMN), but observational studies involving a larger number of patients have not been published.

**Methods:** We performed a retrospective analysis of all IMN patients treated with TAC in 12 Spanish Hospitals. Primary outcomes were complete (CR) or partial (PR) remission. Secondary outcomes were relapses after TAC withdrawal and safety and tolerance to treatment.

**Results:** 122 patients were included. Median interval between renal biopsy and TAC treatment was 9 months (7-30). 43 patients (35%) had received other immunosuppressive treatments. Initial TAC dose was 0.049±0.12 mg/kg/day and only 10 patients were treated simultaneously with corticosteroids (CS). Mean duration of TAC treatment was 17±7 months, including a full-dose TAC period (12±5 months) and a tapering period (5±4). CR

or PR were achieved in 103 patients (84%). Non-responder patients (n=19) showed a non-significant trend for higher proteinuria and worse renal function at the onset of TAC than responders. Among responders, 60 patients (58%) achieved PR and 43 (42%) CR. Patients who achieved CR had a significantly higher percentage of females (44 vs 21%; p<0.015), a shorter time to remission (3 vs 6 months; p<0.018), and a lower proteinuria (6.7±3.2 vs 8.8±3.9 g/day; p=0.005) and serum creatinine (0.9±0.2 vs 1.1±0.3 mg/dL; p<0.0001) at baseline than PR patients. No influence of CS on the rate of remission was observed. TAC was well tolerated. Nephrotoxicity, leading to TAC withdrawal, was observed in 4 cases (3%), and minor/transient side effects in 21 pacientes (17.2%). After 30 (14-66 month) months of follow-up, 44% of patients who had achieved CR/PR, relapsed. Median time to relapse after TAC withdrawal was 9.5 months (3-62). Relapses were significantly more common among patients who had received CS (8% vs 0%). Patients who relapsed showed a higher although non-significant proteinuria (1.96±1.76 vs. 1.19±1.16 g/day; p=0.051) at the onset of TAC tapering.

**Conclusions:** TAC monotherapy induced a high number of remissions in IMN and was well tolerated. New strategies for avoiding frequent relapses after TAC withdrawal should be investigated.

## TH-PO1034

### Tacrolimus in Treating Hepatitis B Virus Associated Membranous Nephropathy with Nephritic Syndrome Who Failed Antiviral Monoyherapy

Jianghua Chen. *The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Kidney Disease Center, Hangzhou, Zhejiang Province, China.*

**Background:** Hepatitis B virus associated membranous nephropathy (HBV-MN) may lead to renal failure in a significant proportion of patients and spontaneous remission is rare. Although antiviral treatment such as lamivudine is considered to improve renal outcome, its potential therapeutic impact on HBV-MN has not been characterized. When a proportion of patient with HBV-MN are resistant to antiviral monotherapy, it is a challenge to find other therapies that are effective.

**Methods:** This prospective observational study enrolled 14 adults with HBV-MN and nephritic syndrome who were no response to therapy with at least 3 months of lamivudine monotherapy. These patients received a regimen of tacrolimus combined with low dose prednisone (0.3 $mg.kg^{-1}.d^{-1}$ of prednisolone). Oral tacrolimus was administered (target trough levels of 5-10 ng/ml) for 24 weeks, and then reduced doses were given (target trough level of 3-6 ng/ml) for another 24 weeks. All patients continuously received lamivudine therapy.

**Results:** Following 24 weeks of therapy, Eight of 14 patients (57.1%) had complete remission (CR) and 4 of 14 patients (28.6%) had complete remission (PR). The mean time to partial remission and complete remission was 6.8 ± 4.7 weeks and 11.5 ± 6.6 weeks, respectively. Two patients developed resistance to TAC therapy due to no response with persistent severeproteinuria after 16 weeks of TAC therapy 3 (25%) of 12 patients who achieved remission experienced relapses during follow-up. Renal function remained stablein all patients with complete remission or partial remission. 1 of 2 non-responder progressed to doubling their baseline Scr. Elevation of AST occurred in 2 (14.3%), and 2 (14.3%) of 14 patients. The marker for HBeAg of all patients did not change during follow-up. HBV replicationwas seen in 1 (7.1%) of 14 patients due to HBV-DNA levelsincreased to $\geq 10^7$copies/mL.

**Conclusions:** The regimen of tacrolimus combined with low dose prednisone seems to beeffective and safety in treating patients with HBV-MN and nephritic syndrome who failed lamivudine monotherapy.

## TH-PO1035

### Efficacy and Safety of Rituximab Plus Cyclosporine in Idiopathic Membranous Nephropathy: Results of an Ongoing Prospective Trial

Meryl A. Waldman, Michelle Braun, Howard A. Austin. *NIDDK/Kidney Disease Section, National Institute of Health, Bethesda, MD.*

**Background:** Cyclosporine (Csa) has efficacy in reducing proteinuria in idiopathic membranous nephropathy (IMN) but partial remissions (PR), rather than complete (CR) are more common and relapse upon drug withdrawal is problematic. Extending treatment may increase remissions and reduce relapses but potential for nephrotoxicity exists. Rituximab (RTX) monotherapy has shown promise in IMN but PRs are more common and effect on proteinuria tends to be delayed. We are conducting a prospective phase 2 trial in 30 pts with IMN to investigate whether "induction" with RTX + Csa for 6 mos followed by "maintenance" RTX may achieve greater reduction in proteinuria than either agent alone, increase number of remissions (especially CR) & reduce relapse rates. Here we report interim data.

**Methods:** Patients with IMN, persistent high grade proteinuria despite conservative rx for min 6 mos & eGFR ≥40 ml/min/1.73 $m^2$ receive RTX (1 gm d 1, 15) + Csa x 6 mos, then tapered. A 2nd course of RTX is given after min of 6 mos & evidence of B cell recovery.

**Results:** To date, 11 pts are enrolled. Mean CrCl 61 ml/min(38 -90); Mean proteinuria 11g/d. Of 8 pts with minimum of 12 mos follow up, all showed response; 4 (50%) PR (defn:protein reduction ≥50% & ≤3.5g/d); 4 (50%) CR (≤0.3 g/d). 1 pt relapsed after achieving PR.

| Pt # | Baseline proteinuria g/24hr | 3 mos | 9 mos | 12 mos | 18-20 mos | 24 mos |
|---|---|---|---|---|---|---|
| 1 | 11.2 | 10.9 | 14 | 5.7 | 1.8 | 0.8 |
| 2 | 10.5 | 0.1 | 0.3 | 0.1 | 0.1 | 0.1 |
| 3 | 14.1 | 11.3 | 2.1 | 1.4 | 0.8 | |
| 4 | 13.9 | 1.1 | 0.3 | 0.2 | 0.2 | |
| 5 | 8 | 1.9 | 0.7 | 0.5 | 0.6 | |
| 6 | 9.8 | 7.2 | 2.1 | 7.4 (relapse) | - | |
| 7 | 9.6 | 1.3 | 0.2 | 0.2 | 0.1 | |
| 8 | 12.6 | 3.5 | 0.3 | 0.2 | | |
| 9 | 15.9 | 2.9 | | | | |
| 10 | 8.3 | | | | | |
| 11 | 5.9 | | | | | |

Regimen was well tolerated.

**Conclusions:** "Induction" with RTX + Csa followed by "maintenance" RTX may be a treatment approach for IMN to achieve a greater number of remissions and may obviate the need for long term immunosuppression. It appears to be well tolerated. Enrollment continues and longer term follow up is needed.

## TH-PO1036

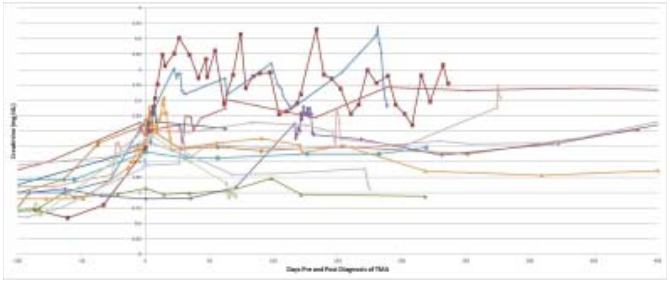
### Thrombotic Microangiopathy in Metastatic Melanoma Patients Treated with Adoptive Cell Therapy and Total Body Irradiation

Meryl A. Waldman,[1] Jennifer Tseng,[2] Michael S. Ring,[1] Howard A. Austin,[1] James Yang,[2] James E. Balow.[1] *[1]NIDDK/Kidney Disease Section, National Institute of Health; [2]NCI, National Institute of Health.*

**Background:** Adoptive cell therapy (ACT)using ex-vivo expanded autologous tumor infiltrating lymphocytes can mediate the regression of bulky metastatic melanoma when administered with high-dose IL-2 following a lymphodepleting preparative regimen of cyclophosphamide & fludarabine. A series of trials showed that addition of total body irradiation (TBI) 12 Gy to regimen led to improved response rates & survival. However,a complication encountered after TBI was thrombotic microangiopathy (TMA). Here we report incidence & course of TMA after TBI.

**Methods:** In the pilot trial, all pts received ACT with TIL + IL2 following non-myeloablative chemo & 12 Gy TBI. The RCT randomizes patients to ACT/ chemo regimen with or without TBI. Dx of TMA made by kidney bx in 3 pts; subsequently dx based on clinical presentation (new onset hemolytic anemia, rise in Scr &LDH, dec plts & haptoglobin).

**Results:** 25 pts enrolled in the pilot trial. To date, 89 pts enrolled in the RCT, 44 in TBI arm. Of 69 pts exposed to TBI in both trials, 16 (23%) were dx'd with TMA. No pts without exposure to TBI dev TMA. Median time to dx was 8 mos after TBI (range 4 -12). All had rise in Scr.



Mean LDH 255 U/L (nl value 113- 226); Proteinuria present in all, most subnephrotic; Urine Protein/cr : range 0.4 -3.6 (mean 1.8). All dev new onset htn or worsening of htn requiring multiple anti-htn agents. Cr values decreased in many over time but did not return to baseline. Low grade proteinuria persisted in almost all at last follow up.

**Conclusions:** Thrombotic microangiopathy is a complication of total body irradiation and occurred in almost 25% of pts exposed to 12 Gy dose. Although hematologic abnormalties are self limiting, most are left with residual renal dysfunction, proteinuria and persistent hypertension.

## TH-PO1037

### Rituximab-Induced Continuous B Cell Depletion for Durable Remission in 28 Consecutive Patients with Idiopathic Membranous Nephropathy

William Franklin Pendergraft,[1-3] Charles T. Owens,[1-3] Andrew P. Murphy,[3] Colin M. Berry,[3] Karen A. Laliberte,[3] John Niles.[2,3] *[1]Joint Nephrology Fellowship Program, Massachusetts General Hospital (MGH) and Brigham and Women's Hospital, Boston, MA; [2]Div of Nephrology, MGH, Boston, MA; [3]Vasculitis and Glomerulonephritis Clinic, MGH, Boston, MA.*

**Background:** Great strides have been made with respect to the pathogenesis of idiopathic membranous nephropathy, and numerous groups are now actively working to develop an optimal strategy for induction and maintenance of remission. Induction therapy

with chlorambucil and corticosteroids appears to be more effective than with calcineurin inhibitors; however, rituximab may be more efficacious. We report here our experience to date with management of the disease.

**Methods:** We performed a retrospective analysis of clinical data from patients with biopsy-proven idiopathic membranous treated by our group with continuous B cell depletion.

**Results:** 28 patients (50% women) received induction of remission therapy for idiopathic membranous nephropathy. All patients received corticosteroids. 15 patients received cyclophosphamide and rituximab. Mean duration of therapy was 172 days (S.D. 139). Mean spot urine protein to urine creatinine ratios went from 9.0 (S.D. 4.8) at the start of therapy to 2.5 (S.D. 2.8). 13 patients received rituximab without concomitant cyclophosphamide. Mean duration of therapy was 301 days (S.D. 117). Mean spot urine protein to urine creatinine ratios went from 5.1 (S.D. 3.3) at the start of therapy to 2.3 (S.D. 3.1). One patient in the rituximab and corticosteroids group died five months into therapy after being institutionalized for advanced Alzheimer's. One patient developed GCSF-responsive neutropenia.

**Conclusions:** Over the past year, our group has seen a dramatic rise in the number of new cases. Induction therapy with cyclophosphamide, corticosteroids and rituximab was more effective than corticosteroids and rituximab alone in reducing proteinuria despite shorter overall duration of continuous B cell depletion. These preliminary results suggest that induction therapy with cyclophosphamide in the setting of B cell depletion may provide more rapid and complete induction of remission.

## TH-PO1038

### Rituximab Therapy in Idiopathic Membranous Nephropathy with Poor Response to Tacrolimus: Long Term Follow Up

Montserrat M. Diaz Encarnacion. *Nephrology, Fundación Puigvert, Barcelona, Spain.*

**Background:** It is still unknown in which patients with idiopathic membranous (MN) Rituximab (RTX) could be a useful therapy.

**Methods:** In this study 17 patients with MN were included and met the following criteria: persistence of nephrotic syndrome (NS) after 6-8 months treatment with angiotensine II blockade and poor response to tacrolimus (Tc) (target level: 5-7ng/ml). RTX is introduced in case of persistence of NS after 4 months period of treatment with Tc (6 patients), partial response (PR) (at 46±26 meses; 9 pacients) and relapse or renal failure during Tc treatment (2 patients). 1 g of RTX was administered on day 1, 15 and every 6 months according to the response. Antibodies anti_PLAR2, B lymphocytes, renal function, proteinuria and serum albumin were evaluated at entry and at months 3,6,12, and 24.

**Results:** aPLAR2 antibodies were present in all patients (Western Blot immunoassay) and in 9 (IFI)

In all patient B cells were depleted (in 11/17 persistently)

Follow up after the first Rx dose was 36,3 months and 16±6 months after the end of treatment.

5/6 patients resistant to Tc achieved P or complete R

5/9 patients with PR achieved CR

Proteinuria decreased in 3 patients with PR

6/7 patients with a GFR<60ml/mn/1,73m2 improved their GFR (16±11ml/mn/ 1,73m2)

The 2 patients who relapsed or with Tc toxicity before RTX were free of relapse during the follow up and with CR.

At the end of follow up 8 patients presented a CR, 8 a PR (proteinuria = 0.7+/-0.4 g/d), 1 a NS.

RTX achieved a P or CR in 90% of patients with poor response to Tc. This response is still persisting after 16 months of follow up.

| | Pre-RTX | Post-RTX | End of followup | p value |
|---|---|---|---|---|
| proteinuria (g/d) mean+/-SD | 4.03+/-3.5 | 0.6+/-0.9* | 1.0+/-1.6 | 0.0009* 0.003 |
| Serum albumin (g/L) mean+/-SD | 33+/-8 | 46+/-5* | 45+/-5 | 0.00001* 0.00004 |
| GFR (CKD-EPI ml/min/1.73 m2) mean+/-SD | 62+/-20 | 72+/-20 | 73+/-20 | NS |

**Conclusions:** RTX could be a useful therapy for patient with poor response or resistant to calcineurin inhibitors therapy.

## TH-PO1039

### Long-Term Treatment of Idiopathic Membranous Nephropathy Based on Cyclosporine and Steroid-Free Regime: A Single Center Experience

Camila Barbosa L. Oliveira, Alline S. A. Oliveira, Carla Queiroz Neves, Clarissa Jacob Barros Carvalho, Luis H.B.C. Sette, Gisele Vajgel Fernandes, Maria Alina G.M. Cavalcante, Lucila Maria Valente. *Nefrologia, Universidade Federal de Pernambuco, Recife, Pernambuco, Brazil.*

**Background:** Cyclosporine A (CyA) is an effective treatment for idiopathic membranous nephropathy (IMN) but the optimal dose and duration remains controversial. We aim to evaluate the effect of CyA as induction and long-term treatment for nephrotic patients with IMN.

**Methods:** Adult patients with IMN and nephrotic syndrome (NS) between 1997 and 2012 were evaluated. CyA was used for patients: NS > 6 months or proteinuria > 8 g/day or deteriorating renal function, at a dose of 3 mg/Kg/day without steroids.

**Results:** Demographic, clinical and prognostic characteristics are shown in Table 1.

| **Baseline characteristics** | **Treated** N = 33 | **Not Treated** N = 12 | **p-value** |
|---|---|---|---|
| Mean age, year | 39.7 ± 17.4 | 48.0 ± 17.4 | 0.168 |
| Male, n (%) | 21 (63.6) | 7 (58.3) | 0.503 |
| SCr, mg/dL | 1.1 (0.5) | 0.9 (0.4) | 0.279 |
| CrCl, ml/min/1.73m$^2$ | 75.5 ± 19.3 | 76.9 ± 18.8 | 0.500 |
| Serum albumine, mg/dL | 1.9 ± 0.7 | 2.0 ± 0.9 | 0.696 |
| Proteinuria, g/day | 8.32 ± 5.3 | 5.8 ± 1.5 | 0.001 |
| Hypertension, n (%) | 23 (69.7) | 7 (58.8) | 0.722 |
| ACEI/ARB, n (%) | 31 (94) | 10 (88.2) | 0.560 |
| **Outcome** | | | |
| Partial remission, n (%) | 16 (48.4) | 4 (33.3) | 0.502 |
| Complete remission, n (%) | 10 (30.3) | 5 (41.6) | 0.722 |
| Relapse, n (%) | 12 (36.3) | 1 (8.3) | 0.133 |
| Doubling Cr, n (%) | 10 (30.3) | 1 (8.3) | 0.239 |
| CrCl < 30, n (%) | 12 (36.3) | 0 | 0.019 |
| RRT, n (%) | 2 (6.1) | 0 | 1.000 |
| Follow-up, months | 60 ± 38.5 | 54.4 ± 53.6 | 0.746 |

Mean duration and dose of CyA was 23.8 months and 2.8 ± 0.67 mg/kg/day, respectively. In CyA group, developing any remission was associated with a reduced risk of doubling creatinine (p=0.016), CrCl < 30 ml/min/1,73m$^2$ (p<0.001) and RRT (p=0.039).

**Conclusions:** Long-term treatment with CyA induced remission in most of the patients. Achieving any remission in CyA group was associated with reduced risk of renal disease progression and RRT.

## TH-PO1040

### A Retrospective Analysis of Patients with Idiopathic Membranous Nephropathy Treated with Steroids and Intravenous Cyclophosphamide

Robin Ramphul, Raja Mohammed Kaja Kamal, David Makanjuola, Rebecca Suckling, Fiona E. Harris, Bhrigu Raj Sood. *Renal Unit, St. Helier Hospital, Carshalton, Surrey, United Kingdom.*

**Background:** The use of steroids and oral Cyclophosphamide in the modified Ponticelli regimen is a recognised treatment for patients with idiopathic membranous nephropathy however the role of intravenous cyclophosphamide for this indication is poorly described. We present our experience of intravenous cyclophosphamide as an alternative to oral cyclophosphamide in 12 patients with idiopathic membranous nephropathy treated between January 2003 and April 2012. The protocol is as follows: **Prednisolone - 40 mg/day for 30 days - months 1, 3 and 5**; **Cyclophosphamide - day 1 - months 2, 4 and 6** (dose as shown in table).

| **Age (years)** | **Creatinine (µmol/L)** | |
|---|---|---|
| | **<300** | **>300** |
| **<60** | 15 mg/kg | 12.5 mg/kg |
| **>60 and <70** | 12.5 mg/kg | 10 mg/kg |
| **>70** | 10 mg/kg | 7.5 mg/kg |

**Methods:** Data on creatinine, albumin and urine protein to creatinine ratio (UPCR) were collected. All patients included were followed-up for at least 6 months. Treatment failure was defined as ESRD, doubling of serum creatinine, switch to, or introduction of alternative immunosuppression. Complete remission (CR) was defined as a reduction in UPCR to < 50mg/mmol. Partial remission (PR) was defined as a reduction in UPCR to < 350mg/mmol and a 50% or greater reduction in UPCR.

**Results:** There were 12 men, age 68yrs (range 37 – 79); 1 died within 12 months. 10 patients had stable renal function, 2 doubled their serum creatinine and progressed to ESRD after 24 months. The mean UPCR reduced over the course of follow-up (mean UPCR at baseline = 1128.2 mg/mmol, 6 months = 849.2, 12 months = 615.3, 24 months = 93.5). 2 patients achieved CR of proteinuria and 3 had PR. 3 patients were switched to calcineurin inhibitor (CNI), 2 after 12 months and 1 after 18 months for worsening of UPCR - all 3 maintained stable renal function.

**Conclusions:** In our cohort of patients, the immunosuppressive regimen reduced the proteinuria and stabilised the decline in renal function. This suggests that pulsed intravenous Cyclophosphamide may be a viable alternative to oral Cyclophosphamide in the treatment of idiopathic membranous nephropathy.

## TH-PO1041

### Safety and Tolerability of Intravenous Cyclophosphamide as an Alternative to Oral Cyclophosphamide in Patients Treated for Idiopathic Membranous Nephropathy – A Single Centre Experience

Robin Ramphul, Raja Mohammed Kaja Kamal, David Makanjuola, Rebecca Suckling, Fiona E. Harris, Bhrigu Raj Sood. *Renal Unit, St. Helier Hospital, Carshalton, Surrey, United Kingdom.*

**Background:** The role of the modified Ponticelli regimen in managing idiopathic membranous nephropathy (IMN) is well recognised. With pulsed intravenous (iv) Cyclophosphamide, the total dose is reduced, but it is not clear whether this is safer, or better tolerated than oral Cyclophosphamide.

**Methods:** We retrospectively analysed the medical records for adverse events in 13 patients treated between January 2003 and April 2012 for IMN with immunosuppressive treatment according to the following treatment protocol: **Prednisolone - 40 mg/day for 30 days - months 1, 3 and 5**; Cyclophosphamide - day 1 - months 2, 4 and 6 (dose shown below).

| Age (years) | Creatinine (µmol/L) | |
|---|---|---|
| | <300 | >300 |
| <60 | 15 mg/kg | 12.5 mg/kg |
| >60 and <70 | 12.5 mg/kg | 10 mg/kg |
| >70 | 10 mg/kg | 7.5 mg/kg |

**Results:** The adverse events are tabulated below. 8/13 patients had no complications. In the 5 remaining patients, the majority of complications were infective. In 1 patient Chronic Lymphocytic Leukaemia (CLL) was diagnosed 5 years after treatment of the IMN. Subsequent treatment of the CLL with Chlorambucil resulted in remission of proteinuria. One patient died of a myocardial infarction.

| | |
|---|---|
| **Sepsis** | **5** |
| LRTI 3 | |
| UTI 0 | |
| GI – D&V 2 | |
| **Bladder toxicity** | **0** |
| **New onset diabetes** | **1** |
| **Malignancy** | **1** |
| Chronic Lymphocytic Leukaemia 1 | |
| **Death** | **1** |
| Myocardial infarction 1 | |
| **Complications necessitating alteration/cessation of treatment** - sepsis | **1** |
| **Hospitalisation** | **5** |
| LRTI 2 | |
| New onset diabetes mellitus 1 | |
| Dehydration caused by D&V 2 | |

**Conclusions:** Our data suggest that in the majority of patients, the use of iv Cyclophosphamide is well tolerated. However, in some patients the iv regimen was associated with significant morbidity. This highlights the importance, even with lower cumulative doses of Cyclophosphamide, of appropriate counselling for potential complications when planning treatment.

## TH-PO1042

### Immunosuppression for Idiopathic Membranous Nephropathy in North East England

Benjamin R. Beattie,[1,2] Shalabh Srivastava,[1,2] Alison Brown.[1,2]
*[1]Dept of Nephrology, Freeman Hospital, Newcastle-Upon-Tyne, United Kingdom; [2]Newcastle Univ, Newcastle-Upon-Tyne, United Kingdom.*

**Background:** Membranous nephropathy is the most common cause of adult-onset nephrotic syndrome in Europe, with an incidence of 5-10 per million population per year. The majority of cases are idiopathic (IMN) and it is now understood that IMN is an autoimmune disease. The current immunosuppressive (IS) protocol used for IMN patients in the North East of England is a variant of that described by Ponticelli using 6 months of steroid and chlorambucil treatment, but the effectiveness and safety of this regimen in populations with a high prevalence of diabetes and obesity, as in this region of the UK, are not well documented.

**Methods:** All patients with biopsy-proven IMN who had started IS before January 2013 were included in this retrospective cohort study. The following disease markers were recorded: serum creatinine and albumin, eGFR and urine protein:creatinine ratio (uPCR). Measurements of these markers were then repeated at completion of IS (or 6 months after commencing if they did not complete) and again at 6 months after completion of IS. Any reasons for non-completion and adverse events were recorded.

**Results:** 25 patients were included in the study. 17 (68%) were male and 8 (32%) were female. The mean age was 65.5 years. Of the 25 patients, 13 (52%) completed IS, 10 (40%) did not complete and 2 (8%) were currently undergoing treatment. Of those that completed, 3 (23%) completed as per protocol and 9 (69%) completed on a reduced dose. Of those that did not complete, 8 (80%) abandoned due to adverse effects and 2 (20%) died whilst on the regime. No patients achieved total remission (uPCR<20mg/mmol). 11 patients achieved partial remission (uPCR<200mg/mmol) by the end of IS and 13 patients were in partial remission 6 months after finishing treatment. There were 4 cases of sepsis and 3 cases of neutropaenia during IS.

**Conclusions:** The rates of remission in this study do not match the success of immunosuppression reported by Ponticelli and the high incidence of adverse events, non-completion and two deaths suggest that the safety of chlorambucil use in this population may warrant more concern than previously expected.

## TH-PO1043

### Maintenance Immunosuppressive Therapy in Membranous Nephropathy

Rosa M. Montero,[1] Katie Ht Wong,[2] Muhammad A. Imtiaz,[1] Mona Wahba.[1]
*[1]Dept of Renal Medicine, St. Helier Hospital, Surrey, United Kingdom; [2]Dept of Medicine, St. Peter Hospital, Surrey, United Kingdom.*

**Background:** Immunosuppressive therapy has been shown to be beneficial in the treatment of Membranous Nephropathy(MN). The benefits of maintenance immunosuppression therapy are unknown.

Aim is to assess outcome and progression of MN with different maintenance immunosuppression regimens.

**Methods:** Patients with biopsy proven MN in single centre from 1995-2010 had demographic data, urine protein creatinine ratio(UPCR in mg/mmol), baseline eGFR at 2, 5 and 10 years, onset of renal replacement therapy(RRT) and patient survival collected. Initial immunosuppressive regimens were; Prednisolone alone(P) and P+Cyclophosphamide(P+CYP). Maintenance therapy was; P+Azathioprine(AZA) or P+Mycophenolate mofetil(MMF).

**Results:** 48/125 were immunosuppressed; 26 male;22 female. 7/48 (14.6%) were on maintenance therapy; 5/7 P+AZA, 2/7 P+MMF. 2 male;5 female with median age 54 years. No significant difference seen in UPCR, Cr, eGFR, Cholesterol or Albumin between the maintenance groups over 10 years. 41/48 were immunosuppressed with no maintenance therapy. Comparing this group with those on maintenance, a significant reduction in UPCR was seen at 5 years compared with baseline($p<0.001$). There was no significant change in Creatinine or eGFR between the groups. Those on maintenance immunosuppression had a significant sustained improvement in albumin at 2, 5 and 10 years compared with baseline($p<0.05$, $p<0.001$, $p<0.01$, respectively). Improvement in albumin was seen at 2 years compared to baseline in those with no maintenance($p<0.01$). Maintenance immunosuppression had 100% survival and remained dialysis independent at 10 years. In contrast 11 of those on immunosuppression with no maintenance became dialysis dependent, 4 died within 2 years.

**Conclusions:** Those on maintenance therapy had 100% survival rates and remained dialysis independent. The cohort size on maintenance therapy is small and larger studies would be required to determine possible benefit of long term maintenance immunosuppression.

## TH-PO1044

### Clinicopathological Features of Membranoproliferative Glomerulonephritis under a New Classification

Preeti R. Nargund,[1] Neeraja Kambham,[2] Kshama Mehta,[1] Richard A. Lafayette.[1] *[1]Div of Nephrology, Stanford Univ School of Medicine, Palo Alto, CA; [2]Div of Pathology, Stanford Univ School of Medicine, Palo Alto, CA.*

**Background:** Membranoproliferative glomerulonephritis (MPGN) is a histologic pattern of glomerular injury, often associated with chronic infection or autoimmune disease. A recent classification relies on the presence of immunoglobulin and complement to help simplify diagnosis and point towards etiologies of the disease. To further substantiate this approach, we reviewed our own experience.

**Methods:** 281 patients diagnosed with MPGN at Stanford from 2000 to 2012 were identified. Patients with known hepatitis, systemic lupus erythematosus, myeloproliferative disorders were excluded. The clinicopathological findings of the remaining 71 patients were further analyzed using Student's t-test and Chi square tests.

**Results:** 51(72%) of the biopsy proven MPGN patients had a C3+/Ig- pattern by IF while 20 (28%) of them had a C3+/Ig+ pattern. Ig negative defined as zero to 1+ staining on IF. Both groups presented with nephrosis, hypertension, hematuria and depressed serum complement levels. There were no significant age or gender differences. While there was a trend for less proteinuria and higher creatinine in the C3+ /Ig- group, this did not reach significance (p=0.10, 0.16 respectively). By light microscopy, the vast majority of patients in both groups had ≤ 50% glomerulosclerosis and ≤50% cortical scarring and predominantly subendothelial deposits, suggesting opportunity for treatment. When the new classification was applied, of the patients in the C3+/Ig- group: 70.5% had C3GN, 11.8% had dense deposit disease, and the remaining had MPGN with exudative features. In the C3+/Ig+ group, 60% of the patients had an MPGN pattern with predominance of C3 on IF while the remaining had MPGN with exudative features (10%) or light chain (Kappa/Lambda) restriction with no known myeloproliferative disorder (30%).

**Conclusions:** The study highlights the clinicopathological features of patients with biopsy proven MPGN with no known historical etiological factors and sheds some light on the incidence of various etiological categories of MPGN, rapidly becoming a descriptive diagnosis.

## TH-PO1045

### Long Term Follow Up According to Reclassification of Membranoproliferative Glomerulonephritis in Multicenter Study

Hyo-Wook Gil,[1] Sungae Woo,[2] Soon Hyo Kwon,[2] Soo Jeong Choi,[3] Dong-Cheol Han.[2] *[1]Dept of Internal Medicine, Soonchunhyang Univ Cheonan Hospital, Cheonan, Chungnam, Korea; [2]Dept of Internal Medicine, Soonchunhyang Univ Seoul Hospital, Seoul, Korea; [3]Dept of Internal Medicine, Soonchunhyang Univ Bucheon Hospital, Bucheon, Gung-gi Do, Korea.*

**Background:** Membranoproliferative glomerulonephritis(MPGN) are progressive diseases and usually display poor prognoses. Recently, new reclassification into immunoglobulin mediated and complement mediated MPGN that respect pathogenesis was proposed. So we investigated clinical course of MPGN according to reclassification.

**Methods:** We conducted a retrospective study of patients diagnosed with MPGN at the three tertiary institution between 2001 and 2010. We investigated the incidence and prognosis of complement mediated MPGN. We analyzed factors contributing to poor renal function. Progressive renal dysfunction was defined as 50% reduction of GFR or need for renal replacement therapy.

**Results:** Among 3294 cases, 77 cases(2.3%) were diagnosed as MPGN. Thirty one cases were excluded because 7 patients were diagnosed as SLE, and the others were not followed until 12 months after diagnosis. Twenty cases(45.6%) had nephrotic range proteinuria. Mean GFR was 61.2±41.9ml/min/1.73m$^2$. Twenty eight cases were classified MPGN type I, eighteen cases were MPGN type III based on electron microscopic findings. Immune mediated MPGN was diagnosed in thirty nine cases and complement mediated GN in two cases(4.3%). Mean follow up duration was 82.8(12-310)months. Seventeen cases(39.6%) ended up with progressive renal dysfunction. All cases of complement mediated GN developed to progressive renal dysfunction. The progressive renal dysfunction was not influenced by Hepatitis B and C. Poor prognosis factors were male, hypertension, decreased GFR and hypoalbuminemia.

**Conclusions:** Complement mediated glomerulonephritis was 4.3% among previously diagnosed as MPGN cases. All cases of complement mediated GN developed to progressive renal dysfunction although the numbers were small. Decreased GFR, hypertension and hypoalbuminemia at the time of diagnosis may be factors predicting progressive renal dysfunction in MPGN patients.

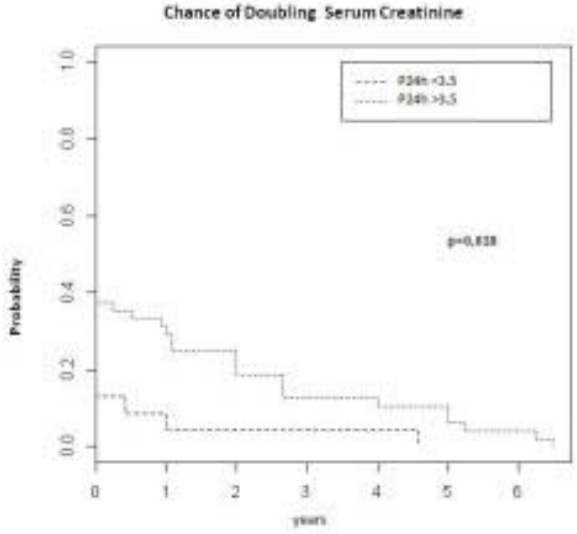
### TH-PO1046

**Factors Involved in the Progression of Membranoproliferative Glomerulonephritis: Retrospective Cohort of 74 Patients** Alline S. A. Oliveira, Camila Barbosa L. Oliveira, Carla Queiroz Neves, Clarissa Jacob Barros Carvalho, Luis H.B.C. Sette, Gisele Vajgel Fernandes, Maria Alina G.M. Cavalcante, Lucila Maria Valente. *Nefrologia, Universidade Federal de Pernambuco, Recife, Pernambuco, Brazil.*

**Background:** Prognosis of membranoproliferative glomerulonephritis (MPGN) is generally considered unfavorable and it is not clear which factors are involved in long-term progression. Reports suggest that the prognosis is worse in cases of nephrotic syndrome compared with non-nephrotic proteinuria but some authors observed that although the trend is less favorable for the patients with nephrotic syndrome in the first years, this difference disappears later during the follow-up.

**Methods:** We evaluated the medical records of patients treated at the ambulatory of Nephrology diagnosed with MPGN between 1995 and 2013. Patients were considered with controlled blood pressure when at least 80% of measurements were below 140 and 90 mmHg.

**Results:** Seventy-four were patients were evaluated, 55% male with a median age of 44 ± 15 and mean follow-up time of 42.5 months. Initial assessment showed hematuria (70%), hypertension (58%) and 24-hour proteinuria (P24h) ≥ 3.5 g/day (61%). Blood pressure control was associated with a lower chance of developing ClCr < 30 (OR 0.34 p-value 0.04) and ESRD (OR 0.18 p-value 0.03). Moreover, for each additional gram on P24h, there was a 20% increase chance of duplicating serum Cr (p-value 0.03). Patients with P24h > 3.5, interstitial fibrosis and tubular atrophy were also correlated to a higher chance of doubling Cr (p-value of 0.018, 0.03 and 0.05, respectively). Male sex was associated with progression to ESRD (OR 8.79, p-value 0.03).



**Conclusions:** Failure to control blood pressure, male sex and high P24H as well as findings of tubular atrophy and interstitial fibrosis were related to poor renal outcomes in patients with MPGN.

### TH-PO1047

**Phenotypic and Genotypic Characteristics of C3 Predominant Glomerulonephritis** Carla M. Nester, Danniele Gomes Holanda, Kristin A. Tiedt, David A. Myers, Jennifer G. Jetton, Patrick D. Brophy, Richard J. Smith. *Univ of Iowa.*

**Background:** *C3 predominant glomerulonephritis* is the pathological designation used to distinguish the C3 Glomerulopathies (C3G) – a group of diseases defined by their immunofluorescent renal biopsy pattern and by an association with dysregulation of the alternative pathway (AP) of complement. The two major subcategories are dense deposit disease (DDD) and C3 glomerulonephritis (C3GN). A portion of postinfectious glomerulonephritis patients will also present with a predominant C3 pattern on IF, however their clinical course will distingquish them from the C3Gs (hypocomplementemia less than 12 weeks and general renal recovery). We present the phenotypic and genotypic characteristics of the C3 dominant glomerulonephritic cases seen in our practice.

**Methods:** We performed a review of all patients seen and biopsied in our practice from 2007-2013 that met the criteria of C3 predominant staining on IF (C3 staining with a magnitude of 2 greater than other stains - except IgM) and at least 6 months of data for review.

**Results:** 26 patients met the criteria for review: 4 DDD, 17 C3GN and 4 PIGN. 100% of DDD pts and approximately 50% of C3GN and PIGN pts had hypertension at biopsy. The level of urine protein was not statistically different at presentation between the groups however was different at followup: DDD>3GN>PIGN. 40% of DDD, 18% of C3GN and 0% of PIGN pts required dialysis during their course with a trend toward worse eGFR for DDD pts at followup. 77% of pts had an abnormal C3 at presentation with 45% at 60 week followup (N = 18). All pts suspected of PIGN resolved their hypocomplementemia by 12 weeks. An AP genetic assessment was available on 15 of the 26 pts and DNA variants were found in 53%. No genetic abnormalities were found in the PIGN pts.

**Conclusions:** C3GN was the most common C3 dominant glomerulonephritis. Four of four PIGN patients who were biopsied for disease severity had a C3 dominant glomerulonephritis on biopsy. C3 dominant glomerular lesions of the non-PIGN type often follow a chronic glomerular disease course with nearly half of patients continuing to have hypocomplementemia. To our knowledge, this is the largest reported American cohort of C3Gs.

### TH-PO1048

**Bortezomib Is Highly Efficient in Monoclonal Immunoglobulin Deposition Disease** Camille Cohen,[1] Jean Paul Fermand,[3] Bertrand Arnulf,[3] Bertrand Knebelmann,[1] Frank Bridoux.[2] *[1]Nephrologie, Hopital Necker, Paris, France; [2]Nephrologie, CHU, Poitiers, France; [3]Immuno-Hematologie, Hopital Saint Louis, Paris, France.*

**Background:** Monoclonal immunoglobulin deposition disease (MIDD) is a rare complication of plasma cell disorders. Recent data from small case series suggest that novel anti-myeloma agents may improve patient and renal survival.

**Methods:** Thirty-patients with LCDD and 3 with HCDD, all treated with bortezomib plus dexamethasone (BD)–based chemotherapy, were retrospectively analyzed. Data were recorded at baseline and after completion of chemotherapy. Hematologic response was defined according to International Myeloma Working Group. Renal response was defined as a ≥50% decrease in 24H proteinuria (at least 0.5 g), in the absence of a reduction in eGFR ≥ 25% or an increase in serum creatinine ≥ 0.5 mg/dL.

**Results:** Median age at diagnosis was 57 years. Serum and/or urine monoclonal gammopathy was found in 32 patients (97%), 26 of whom (67%) had multiple myeloma and 1 had Waldenstrom macroglobulinemia. Serum free light chain (FLC) ratio was abnormal in all 32 patients tested, with raised kappa (28, 84%) or lambda (4, 12%) FLCs. At diagnosis, median serum creatinine was 213 mmol/l, with 24H proteinuria of 1,27g. Seven patients (21%) required hemodialysis at diagnosis. Patients received a median of 4 courses of BD, alone or reinforced with cyclophosphamide (n =11), thalidomide (n=2), or lenalidomide (n=1). In 14 patients (42%), treatment was followed by HDT/SCT. Hematological response (partial response or above) was achieved in 24 patients (73 %), including very good partial response in 19 cases, and complete response in 2 patients. After a median follow up of 27 months, 2 patients had died. In 23 patients with renal involvement, 11 (48%) had renal response, all of whom showed improved renal function. Two patients progressed to end stage renal disease. Out of 7 patients requiring hemodialysis dialysis at diagnosis, 1 died, and dialysis was withdrawn after BD in 1 case. Four patients had severe adverse effect including 1 encephalopathy.

**Conclusions:** BD-based regimens appear to be associated with high hematologic and renal response rates in MIDD. Further prospective studies are required to confirm these data.

### TH-PO1049

**Primary AL-Amyloidosis – Retrospective Study of 54 Patients, One Center Experience** Elena Zakharova. *Nephrology, City Clinical Hospital n.a. S.P. Botkin, Moscow, Russian Federation.*

**Background:** "Primary" AL-amyloidosis is a plasma-cell dyscrasia characterized by overproduction of monoclonal Ig light chains, most commonly affecting kidneys with nephrotic syndrome (NS) and renal failure (RF). Satisfactory treatment does not exist, current options include high-dose melphalan with autologous stem cell transplantation (TASC), melphalan-prednisone (MP), melphalan-dexamethasone (MD), bortesomib (B) containing regimens, and immunomodulators. We aimed to evaluate treatment results in our cohort.

**Methods:** Using electronic database for we searched patients with biopsy-proven "primary" AL-amyloidosis, treated in 1998-2013. Work-up included serum and urine immunochemistry, kidney biopsy with light microscopy and immunofluorescece ± electron microscopy, and bone marrow aspiration and/or biopsy with immunohistochemistry. Treatment regimens were TASC, MP, MD, B, and supportive treatment (ST) only.

**Results:** Study group included 54 patients, 29 (53.7%) male and 25 (46.3%) female, median age 57 [34;78] y.o. Clinical presentation and treatment are shown in table.

| | | |
|---|---|---|
| Duration before biopsy (months) | 12 | [1;92] |
| NS n | 46 | 85.1% |
| RF n | 29 | 53.7% |
| Creatinine µmol/l | 140 | [60;1200] |
| Kidneys only n | 15 | 27.7% |
| Kidneys+heart n | 14 | 25.9% |
| >2 organs n | 25 | 46.2% |
| TASC n | 9 | 16.6% |
| MP n | 13 | 24% |
| MD n | 6 | 11.1% |
| B n | 9 | 16.6% |
| 2 regimens n | 8 | 14.8% |
| ST n | 25 | 46.2% |
| Follow-up (months) | 5 | [1;94] |
| Alive not on dialysis n | 20 | 37% |
| Started dialysis n | 16 | 29.6% |
| Died n | 18 | 33.3% |

Among 29 patients, treated with chemotherapy, 14 (48.2%) achieved hematological remission, 11 (37.9%) – also organ remission, in 15 (51.7%) cases treatment failed, no significant differences between treatment groups was found.

**Conclusions:** Majority of patients in our cohort were diagnosed late and presented with nephrotic syndrome, notably about a half of them - with renal failure and multiorgan involvement, which limited chemotherapy choice and was associated with 33% of mortality. Treatment results in chemotherapy subgroup showed 48% of hematological and 38% of organ remissions, and did not depended on chemotherapy regimen.

## TH-PO1050

**Alchemy – A Large Prospective Study of Chemotherapy in Systemic AL Amyloidosis** Jennifer H. Pinney, Helen J. Lachmann, Ashutosh Wechalekar, Philip N. Hawkins, Julian D. Gillmore. *UK National Amyloidosis Centre, Div of Medicine, Royal Free Hospital, London, United Kingdom.*

**Background:** There are no large prospective clinical trials in AL amyloidosis.

**Methods:** ALchemy is a prospective observational study of chemotherapy in patients with AL amyloidosis. All patients with newly diagnosed AL amyloidosis requiring chemotherapy in the UK were eligible for study entry from September 2009. Study participants underwent assessment of their disease at baseline, after 3 cycles of chemotherapy and 6, 12, 18 and 24 months from baseline. Clonal disease was assessed after each cycle of chemotherapy and monthly thereafter. Details about tolerability and toxicity of chemotherapy were collected via a case record form.

**Results:** This the largest prospective study in AL amyloidosis worldwide; recruitment is ongoing. Here we present data from the first 616 patients. A primary renal presentation was seen in 49% and 24% had isolated renal disease. Median survival was best in patients with primary renal disease (median undefined) and worst in those with cardiac disease (median 9.3 months). There was no difference in patient survival when stratified for stage of CKD or amount of proteinuria at baseline. Intention to treat analysis of clonal response at 6 months showed that 20% achieved a CR, 23% a VGPR, 17% a PR, and 14% had no clonal response. 24% had died within 6 months of follow-up. In sub group analyses of patients with renal involvement, 59% of patients who presented with CKD stage 1-3 died or were on RRT by 24 months vs 91% of those with CKD stage 4-5 ($P < 0.01$). Renal progression or response occurred within the first 6 months in the majority of cases. By 24 months 46% of patients had renal progression, 26% were unchanged and 27% had a renal response. More patients were in CR/VGPR in the renal progression group compared to the renal response group (80% vs 50%, $P < 0.05$).

**Conclusions:** ALchemy is the largest prospective study in AL amyloidosis worldwide, and has provided a wealth of data to facilitate validation of clinical endpoints, to determine efficacy and toxicity of chemotherapy. Inclusion of all patients with all stages of disease indicates a persistently poor prognosis among a substantial proportion.

## TH-PO1051

**Glomerular Toxicity of Two Therapies Targeting the Vascular Endothelial Growth Factor Result from Distinct Mechanisms** Mario Ollero,[1] Hassane Izzedine,[2] Melanie Mangier,[1] André Pawlak,[1] Djillali Sahali.[1] *[1]INSERM, U 955, Equipe 21, Univ Paris-Est Creteil Val-de-Marne, Créteil, France; [2]Pitie-Salpetriere Hospital, Paris, France.*

**Background:** Renal toxicity constitutes a dose-limiting side effect of anticancer therapies targeting the vascular endothelial growth factor (VEGF), including anti-VEGF ligands and receptor tyrosine kinase inhibitors (RTKI).

**Methods:** We studied 29 patients having followed this kind of treatment. Eight of them developed minimal change nephropathy (MCN)/focal segmental glomerulopathy (FSG)-like lesions and 13 thrombotic microangiopathy (TMA). MCN/FSG-like lesions developed mainly under RTKI, whereas TMA complicated anti-VEGF therapy. We performed immunohistochemical and immunoultrastructural studies on kidney biopsies displaying TMA or MCN/FSG-like lesions and compared them with idiopathic forms. In parallel, we investigated the molecular mechanisms underlying these glomerular syndromes. The RTKI Sorafenib was tested in vitro on wild-type and RelA-deficient mouse embryonic fibroblasts (MEF), on a podocyte cell line, and on lymphocytes from healthy donors.

**Results:** TMA glomeruli exhibited high RelA expression in endothelial cells and podocyte nuclei, while c-mip was undetectable. Conversely, c-mip was highly abundant in MCN/FSG-like lesions, whereas RelA was scarcely detected. Electron microscopy showed major alterations in TMA glomeruli, including duplication of glomerular basement membrane, loss of fenestrations, detachment of endothelial cells and marked effacement of visceral epithelial cell foot processes in some areas. RelA gold particles where increased in podocyte nuclei, as well as in endothelial cells as compared with controls. Sorafenib upregulated c-mip at both transcript and protein levels in vivo and in vitro, at least partly due to inhibition of NF-kB activity. Notably, Sorafenib induced a profound cytoskeleton disorganization with depletion of stress fibers and impressive production of F-actin-rich membranes.

**Conclusions:** These results suggest that renal toxicity of anti-VEGF and RTKI therapies results from distinct mechanisms operating in podocytes and endothelial cells, in which RelA and c-mip play an antagonistic and mutually exclusive role.

*Funding:* Private Foundation Support, Government Support - Non-U.S.

## TH-PO1052

**Care Gaps and Barriers to Guideline-Based Management of Glomerulonephritis: A Survey of Nephrologists** Sean Barbour,[1,2] Monica C. Beaulieu,[1,2] Jagbir Gill,[1,2] Heather N. Reich,[3] Adeera Levin.[1,2] *[1]Div of Nephrology, Univ of BC; [2]BC Provincial Renal Agency; [3]Div of Nephrology, Univ of Toronto.*

**Background:** There is substantial variability in the treatment of glomerulonephritis (GN) that contributes to poor patient outcomes and historically may be due to a lack of accepted guidelines. As such, we sought to better understand the need for and barriers to knowledge translation (KT) of the recent KDIGO GN guidelines into clinical practice.

**Methods:** We surveyed nephrologists in British Columbia, Canada, using a 40 question survey addressing physician characteristics, GN exposure, care gaps, barriers to guideline use and support for a regional GN registry.

**Results:** The response rate was 64% (47 of 73 nephrologists). Biannually a median of 6 (IQR 5,10) new cases of idiopathic GN are seen per physician, which is similar in urban vs rural and academic vs private practices. Self-reported treatment of GN is shown in the table. Most treat ANCA and membranous GN as per KDIGO guidelines; however 19% treat FSGS and 2g/d proteinuria with immunosuppression and only 56% treat FSGS and 5g/d proteinuria with prednisone (less often in those with >15 vs fewer years in practices, 21% vs 64-73% p=0.03). Over 90% feel that standardized care tools would improve patient care yet they are available to only 19-27%. Patient education tools and decision support are unavailable to 93% and 57%. Insurance for immune therapies is poorly accessible to 86% yet 98% feel this would improve care. Almost all physicians support a regional GN registry that would provide achievable benchmarks in GN clinical care.

| Immune Therapies | | | | | |
|---|---|---|---|---|---|
| | **No Immune Therapy** | **Prednisone Alone** | **Calcineurin inhibitor** | **Cyclophosphamide** | **Azathioprine or MMF** |
| MN with 8g/day | 2% | 0% | 33% | 63% | 2% |
| FSGS with 5g/day | 7% | 56% | 27% | 11% | 0% |
| FSGS with 2g/day | 81% | 14% | 5% | 0% | 0% |

| Conservative Management | | | | | |
|---|---|---|---|---|---|
| | **Never** | **Rarely** | **Some of the time** | **Most of the time** | **All of the time** |
| ACEI to reduce proteinuria | 0% | 0% | 0% | 35% | 65% |
| Combination RAS blockade to reduce proteinuria | 23% | 42% | 30% | 5% | 0% |
| Calcium / Vit D to prevent osteoporosis in those on steroids | 0% | 2% | 5% | 23% | 70% |
| Bisphosphonates to prevent osteoporosis in those on steroids | 5% | 16% | 44% | 28% | 7% |
| PCP prophylaxis in those on high dose immunosuppression | 0% | 2% | 0% | 49% | 49% |

**Conclusions:** We describe significant care gaps in the management of GN, emphasizing the need to promote KT of the GN guidelines. We identify barriers to guideline implementation and physician support for initiatives that address these barriers potentially improving patient outcomes.

## TH-PO1053

**Proteinuria Does Not Need to Be Standardized to Body Surface Area in Adults with Glomerulonephritis** Sean Barbour,[1,2] Daniel C. Cattran,[3] Gabriela Espino-Hernandez,[2] Michelle A. Hladunewich,[3] Adeera Levin,[1,2] Heather N. Reich.[3] *[1]Div of Nephrology, Univ of BC; [2]BC Provincial Renal Agency; [3]Div of Nephrology, Univ of Toronto.*

**Background:** Baseline proteinuria (Prot) is an important but poorly defined determinant of renal outcome in glomerulonephritis (GN). While it is conventional in children to adjust proteinuria to body surface area (ProtBSA) this is not common in adults. We sought to determine if ProtBSA is more closely associated with the risk of kidney failure than traditional unadjusted proteinuria.

**Methods:** We analyzed an adult cohort with IgA nephropathy (IgAN N=445), focal segmental glomerulosclerosis (FSGS N=472) and membranous nephropathy (MN N=434) from the Toronto GN Registry followed for a median of 54 months. The primary outcome (ESRD or 50% drop in eGFR N=385) was analyzed using Cox regression to compare model fit between Prot and ProtBSA at biopsy, which were log-transformed due to non-linearity.

**Results:** The median baseline Prot was 3.7g/d and ProtBSA was 3.5g/d/1.73m$^2$. As shown in the table, in MN and IgAN both Prot and ProtBSA were associated with a similar and increased risk of renal progression ($p<0.001$ for all HR). The $R^2$, AIC, and C-statistic were similar between Prot and ProtBSA and the continuous (c)NRI and IDI were very

small or not different from zero. As in previous studies neither baseline Prot nor ProtBSA were associated with renal progression in FSGS (HR=1.11 95%CI 0.94-1.32, HR 1.12 95%CI 0.95-1.33 both p=0.2).

| | HR | $R^2$ | AIC | C statistic | Δ C statistic | cNRI | IDI |
|---|---|---|---|---|---|---|---|
| **IgAN** | | | | | | | |
| Prot | 1.66 (1.36, 2.02) | 0.062 | 1343 | 0.65 (0.60, 0.71) | | | |
| ProtBSA | 1.71 (1.41, 2.08) | 0.071 | 1339 | 0.66 (0.61, 0.72) | 0.01 (0.001, 0.02) | 0.37 (0.046, 0.65) | 0.006 (-0.0005, 0.02) |
| **MN** | | | | | | | |
| Prot | 1.89 (1.39, 2.56) | 0.048 | 920 | 0.63 (0.56, 0.70) | | | |
| ProtBSA | 1.92 (1.40, 2.63) | 0.048 | 920 | 0.63 (0.55, 0.70) | -0.0004 (-0.01, 0.01) | 0.20 (-0.34, 0.52) | -0.0006 (-0.005, 0.005) |

**Conclusions:** In a large cohort of adults with GN, Prot and ProtBSA similarly predict the risk of renal outcome. BSA adjustment does not improve the prognostic value of baseline proteinuria measurements.

## TH-PO1054

**Immunohistochemical Staining of IgG4 in Glomeruli for a Range of Renal Biopsies** Stacy C. Wolforth,[1] Xu Zeng,[2] Michele T. Rooney,[1] Wei Li,[1] Ping L. Zhang.[1] *[1]Anatomic Pathology, William Beaumont Hospital, Royal Oak, MI; [2]Bostwick Laboratories, Orlando, FL.*

**Background:** Immunohistochemical (IHC) staining for IgG4 became available in our lab due to the discovery of a systemic autoimmune inflammatory disease. Other labs have used immunofluorescent (IF) methods to stain IgG4 to differentiate idiopathic membranous glomerulopathy (MGN) from lupus membranous nephritis (LMN). In this study, we used IHC methods to stain IgG4 for a range of renal biopsies with known IgG staining by IF method to determine the presence of IgG4 in various glomerulopathies.

**Methods:** Monoclonal IgG4 antibody was purchased from Cell Marque (dilution 1:100). Four control groups including normal renal tissue (C1 normal renal tissue n= 5), LMN (C2, n =9), monoclonal light chain nephropathy without heavy chain deposition (C3, n = 24), and ANCA associated crescentic glomerulonephritis (CGN) (C4, n = 8) . Four study groups were composed of MGN (S1, n = 14), heavy chain nephropathy with or without monoclonal light chain (S2, n = 3), mixed group (S3, post-infectious glomerulonephritis, n = 2, thrombotic microangiopathy, n =5 , membranoproliferative glomerulonephritis n =2), and anti-glomerular basement membrane (anti-GBM) CGN (S4 n =13). All cases were stained for IgG4 and their expression in each was graded from 0 to 3+ depending on staining intensity.

**Results:** All 4 control groups (C1 – C4, total n = 46) are entirely negative for IgG4 in glomeruli. In group S1, 64 % (9/14) of MGN showed granular membranous staining for IgG4. One of three from group S2 (33%) revealed linear IgG4 (3+) along glomerular loops and along tubular basement membranes, similar to its IgG pattern by IF method. Group S3 stained negatively for IgG4. In one of 13 cases in group S4 (7.7%), linear IgG4 (2+) was identified in all 7 glomeruli, similar to the pattern of IgG linear staining by IF method.

**Conclusions:** Our data using IHC staining for IgG4 has confirmed specific IgG4 staining in the glomeruli of a majority of MGN cases as reported by others using IF methods. In addition, heavy chain deposition disease and anti-GBM CGN can be IgG4 positive in the glomeruli but with differing staining patterns as compared to MGN.

*Funding:* Clinical Revenue Support

## TH-PO1055

**Histopathological Analysis of IgG4-Related Kidney Disease: Hints from an Autopsy Series of 5 Cases** Ichiro Mizushima,[1] Mitsuhiro Kawano,[1] Takako Saeki,[2] Yoshifumi Ubara,[2] Nobuya Ohara,[2] Yasuharu Sato,[2] Kazunori Yamada,[1] Hitoshi Nakashima,[2] Shinichi Nishi,[2] Yutaka Yamaguchi,[2] Satoshi Hisano,[2] Michio Nagata,[2] Takao Saito.[2] *[1]Rheumatology, Kanazawa Univ Hospital, Japan; [2]'IgG4-Related Kidney Disease' Working Group, Japan.*

**Background:** IgG4-related disease (IgG4-RD) is a systemic disease characterized by marked lymphoplasmacytic infiltrates with abundant IgG4-positive plasma cells (PCs), fibrosis, and obstructive phlebitis. Plasma cell-rich tubulointerstitial nephritis is a typical renal manifestation of this disease. However, histopathological evaluation of the whole kidneys in autopsy cases has not been previously reported.

**Methods:** We analyzed 5 autopsy cases using Hematoxylin and eosin, Periodic acid-Schiff, Periodic acid methenamine silver, and elastic Van Gieson stains. Immunohistochemical staining was performed using anti-IgG4 antibodies (Abs) and anti-CD138 Abs.

**Results:** Two patients died of associated cancer and they had undergone chemotherapy without corticosteroid (CS). Two patients were receiving maintenance CS treatment (Tx), and the remaining one was not. All patients had typical extrarenal involvement by IgG4-RD. Four patients fulfilled kidney infiltrating IgG4 counts (mean 78; range 38-116) and IgG4:CD138 ratios (mean 81; range 48-110) proposed by the consensus statement on the pathology of IgG4-RD [IgG4+ > 30/high power field (HPF); IgG4/CD138 > 40%], while one patient, who underwent long-term CS Tx, showed few lymphoplasmacytic infiltrates but marked periarterial fibrosis of interlobular arteries. Three patients without CS Tx or with only short-term CS Tx had bird's eye pattern fibrosis, dense lymphoplasmacytic infiltrates around renal or interlobular artery segments (width 200-500μm) and vein. In contrast, another patient with long-term CS Tx had mild patchy infiltration of lymphocytes and PCs, but had a large fibrotic area with disappearance of almost all tubules with scattered glomeruli and arteries remaining.

**Conclusions:** Periarterial and perivenous lesions with marked lymphoplasmacytic infiltrates are additional characteristic features of IgG4-related kidney disease.

## TH-PO1056

**Diffuse Effacement of Foot Processes of Podocytes in Stage I Membranous Nephropathy** Kayori Tsuruoka, Yusuke Kajimoto, Seiichiro Higo, Go Kanzaki, Shinya Nagasaka, Akira Shimizu. *Analytic Human Pathology, Nippon Medical School, Tokyo, Japan.*

**Background:** Idiopathic membranous nephropathy (MN) is widely characterized pathologically by the spike formation in glomerular basement membrane in light microscopy (LM), glomerular capillary pattern of IgG and C3 deposition in immunofluorescence study (IF), and glomerular subepithelial electron dense deposits (EDD) in electron microscopy (EM). However, in stage I (Ehrenreich T and Churg J) of MN, we sometimes experience the cases that did not have typical features of these MN findings.

**Methods:** In the present study, in order to clarify the clinicopathological characteristics of MN stage I, we selected 33 cases (22.3%) of stage I of MN from 148 cases of idiopathic MN that we diagnosed in our department from 2001 to 2013.We assessed clinical and pathological characteristics including LM, IF, EM, and immuneno-EM.

**Results:** The 33 cases of stage I of MN were consisted of 22 males and 11 females. Ages at the time of biopsy ranged from 3 to 80 years (56.0 ± 20.1 years). Renal dysfunction was not detected in all cases. In addition, stage I MN was characterized by the presence of nephrotic rage proteinuria (4.84 ± 2.57g/day), nephrotic syndrome in 24 cases (72.7%), and short interval from disease onset (3.6 ± 4.1 months). In the pathology, the formation of spike on GBM was not detected in all cases. In EM, segmental subepithelial EDD was detected in all MN cases, but only a segmental and small subepithelial EDD was noted on GBM in 13 cases (39.4%). In these 13 cases, weak IgG deposition was evident with the degree of deposition of IgG > C3 in IF. The IgG subclass showed the predominant deposition of IgG4 > IgG1. In addition, IgG was only noted on subepithelial EDD on GBM in immuno-EM. Interestingly, diffuse effacement of foot process of podocytes was evident in stage I MN, even in the segmental and small subepithelial EDD on GBM.

**Conclusions:** In the stage I MN, diffuse effacement of foot process of podocytes was noted, even in the segmental and small subepithelial EDD on GBM. Subepithelial EDD and podocyte injury may be mediated heavy proteinuria in stage I MN.

## TH-PO1057

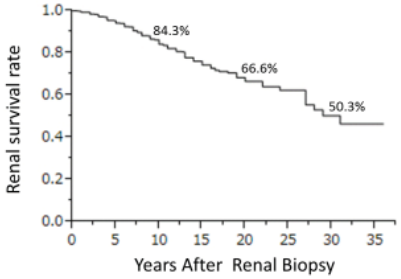
**Prognosis in IgA Nephropathy: 30-Year Analysis of 1,012 Patients at a Single Center in Japan** Takahito Moriyama, Kayu Tanaka, Chihiro Iwasaki, Yasuko Oshima, Takashi Takei, Kosaku Nitta. *Medicine, Tokyo Women's Medical Univ, Shinjyuku-ku, Tokyo, Japan.*

**Background:** Little is known about the long-term prognosis of patients with IgA nephropathy (IgAN). We therefore assessed the prognosis over 30 years of 1,012 patients with IgAN treated at our center since 1974.

**Methods:** This retrospective cohort analysis evaluated clinical and histological findings at the time of renal biopsy, initial treatment, patient outcomes over 30 years, and risk factors associated with progression.

**Results:** Of the 1,012 patients, 40.5% were male. Mean patient age was 32.9±12 years and mean blood pressure was 122±17/75±13 mmHg. Mean serum albumin was 3.9±0.5 g/dL, mean uric acid was 5.7±1.6 mg/dl, mean serum creatinine was 0.89±0.42 mg/dL, and mean estimated glomerular filtration rate (eGFR) was 71.1±23.5 ml/min/1.73m$^2$. Mean proteinuria was 1.19±1.61 g/day, and number of mean urinary red blood cells was 36.6±35.3 per high powered field. Histologically, mesangial hypercellularity was present in 47.6% of patients, endothelial hypercellularity in 44.3%, segmental sclerosis in 74.6%, and tubular atrophy/interstitial fibrosis in 28.8% by Oxford classification. Initial treatment consisted of corticosteroids in 26.9% of patients, immunosuppressive agents in 1.5%, RAS inhibitors in 28.9%, and tonsillectomy plus steroids in 11.7%. The 10-, 20-, and 30-year renal survival rates were 84.3, 66.6, and 50.3%, respectively.

*Cumulative renal survival rate from renal biopsy until ESRD in all 1,012 patients with IgAN.*



Cox multivariate regression analysis showed that higher proteinuria(HR 1.28, 95%CI 1.02-1.62, P=0.0372), lower eGFR (HR 1.86, 95%CI 1.43-2.43, P<0.0001), and higher uric acid concentration (HR 1.28, 95%CI 1.05-1.62, P=0.0372) at the time of renal biopsy were independent risk factors for the development of end stage renal disease (ESRD).

**Conclusions:** IgAN is not a benign disease, with over 50% of patients progressing to ESRD within 30 years despite treatment.

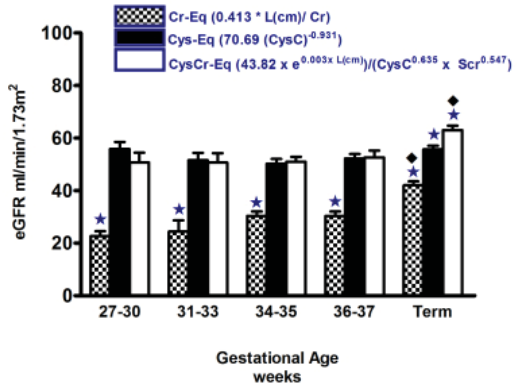
**TH-PO1058**

**Neonatal Kidney Size and Function in Preterm Infants: What Is a True Estimate of Glomerular Filtration Rate?** Carolyn L. Abitbol,[1] Wacharee Seeherunvong,[1] Marta G. Galarza,[2] Marissa J. Defreitas,[1] Teresa C. Cano,[1] Chryso P. Katsoufis,[1] Alcia D. Edwards- Richards,[1] Vimal Master Sankar Raj,[1] Jayanthi Chandar,[1] Shahnaz Duara,[2] Salih Y. Yasin,[3] Gaston E. Zilleruelo.[1] *[1]Pediatric Nephrology, Univ of Miami/ Holtz Children's Hospital, Miami, FL; [2]Neonatology, Univ of Miami/ Holtz Children's Hospital, Miami, FL; [3]Obstetrics & Perinatology, Univ of Miami/ Holtz Children's Hospital, Miami, FL.*

**Background:** Preterm birth is associated with early and late renal insufficiency that may be related to low nephron mass and altered maturation of renal function.

**Methods:** Sixty preterm and 40 term infants were enrolled at birth. Serum creatinine(Cr) and cystatin-C(CysC) were used to calculate estimated glomerular filtration rate (eGFR). Renal ultrasounds assessed kidney dimensions with calculation of total kidney volume (TKV) as a surrogate of nephron mass. Multiple regression analysis was applied to assess the relative impact of neonatal parameters on eGFR including TKV, gestational age (GA) and mean arterial pressure (MAP).

**Results:** Renal lengths correlated with GA and were within reference values for fetal ultrasounds at each GA. Estimation equations for GFR based on Cr, CysC and combined CysC+Cr demonstrated that Cr-based equations underestimated GFR; whereas, CysC and combined equations were consistent with the reference inulin clearance studies. TKV, GA and MAP correlated positively with eGFR; though, only MAP and GA remained significant when other measures were held constant.



**Conclusions:** Primary determinants of GFR in preterm infants are gestational age and mean arterial blood pressure. Serum creatinine is unreliable as a marker of renal function in preterm infants. Until more reliable markers are available, CysC should be used as the primary assessment of GFR in preterm infants.

**TH-PO1059**

**Birthweight Predicts Postnatal Kidney Function** Suad Ma Hannawi,[2] Issa A.L. Salmi.[1] *[1]The Renal Medicine Dept, The Royal Hospital; [2]The Medical Dept, AlBaraha Hospital, Dubai, United Arab Emirates.*

**Background:** Under nutrition in middle &late gestation programmes for later chronic diseases(CKD) or most importantly its risk factors.

**Methods:** A questionnaire about birthweight(BW) data was given to 11,247 participants,aged ≥25 years that were enrolled during a previous study. Children of VLBW due to prematurity were assessed for kidney function. This cohort &Control group were enrolled.Also, 412 CKD patients filled the questionnaire. Control, matched for gender &age, were selected for CKD patient(Salmi et al).

**Results:** O7,157 responded to our questionnaire &4,502(63%), reported BW data. BW ranged from 0.4 to 7.0kg & mean(SD) of 3.37(0.7). BW was lower for females, 3.28(0.6), compared to males, 3.5(0.7)kg. The eGFR strongly and positively associated with BW, & lowest sex-specific BW quintiles having the lowest mean eGFR. OR for eGFR<10$^{th}$ percentile,(<61.4 ml/min for females &<73.4 for males) for people in the lowest vs. the higher BW was 2.19(95% CI 1.14-4.2) in females &2.37(1.1-5.3) in males, after adjustment for other factors.

37 premature(PM) 23 fullterm children(FT). Gestational age for PM cohort was 26.7(2.6) &ranged from 23-35 weeks. Their BW was 867(248) g vs3433(285) for FT. The age of PM children was 12.1(3.8) years vs.11.5(3.5) years for FT. PM had lower kidney volumes (99.7 ml (89.3,110) vs131(111,151), P=0.01 and lower eGFR(87.0 (78.5,113) vs. 113(99.1,128), p<0.001.

Among CKD; mean BW was 3.27(0.62) vs3.46(0.6) kg for controls, p<0.001 and the proportions with BW<2.5 kg were 12.17% and 4.44%, p<0.001. Among CKD patients,22.8%, 21.7%, 8% &37.6% were in CKD stages 2,3,4 and 5 respectively. BW by CKD stage &their controls were as follows: 3.38(0.52) vs3.49(0.52), p=0.251 for CKD2; 3.28(0.54) vs3.44(0.54), p=0.121 for CKD3; 3.19(0.72) vs3.43(0.56), p= 0.112 for CKD4 and 3.09(0.65) vs3.47(0.67), p=<0.001 for CKD5.

**Conclusions:** LBW people were predisposed to higher rates of renal dysfunction in later stages of life. The awareness of the effect of LBW on development of renal dysfunction is of vital importance. A proactive public health strategy towards a better management of this group of population that are increasingly surviving into adulthood is of great importance.

**TH-PO1060**

**Tubular Dysfunction in Extremely Low Birth Weight Survivors** Kazuya Matsumura, Mariko Hida, Midori Awazu. *Dept of Pediatrics, School of Medicine, Keio Univ, Tokyo, Japan.*

**Background:** Extremely low birth weight (ELBW) survivors are known to develop glomerulosclerosis due to low nephron number. Microalbuminuria is regarded as an early marker of glomerular injury. Tubular damage may also occur, but little is known other than increased urine calcium excretion. We therefore studied tubular function of ELBW survivors.

**Methods:** Fifty-three subjects (30 boys and 23 girls, aged 7 months-19 years, median 42 months) were studied. The median gestational age and birth weight were 26 (22-32) weeks and 745 (316-999) g, respectively. Normal values were defined as urine calcium:creatinine ratio (Ca/Cr) <reference values by age, ß2 microglobulin:creatinine ratio (ß2M/Cr) <0.3 mg/g, N-acetyl-ß-d-glucosaminidase:creatinine ratio (NAG/Cr) <5 U/g), glucose:creatinine ratio (glu/Cr) <250 mg/g, uric acid:creatinine ratio (UA/Cr) <reference values by age, and microalbumin:creatinine ratio (malb/Cr) <30 mg/g. We assessed the association between urine markers and factors thought to predict renal injury such as asphyxia, nephrotoxic drugs, chronic lung disease etc. Univariate and logistic regression analyses were used to compare variables.

**Results:** Three subjects who had overt proteinuria were excluded. Ninety percent of subjects had at least one tubular dysfunction. Frequencies of elevated values were; NAG/Cr 75.5%, UA/Cr 53.1%, ß2m/Cr 38.2%, malb/Cr 28.2%, Ca/Cr 21.1%, and glu/Cr 20.5%. Urine ß2M/Cr and glu/Cr were negatively correlated with the gestational age. No association was observed between urine markers and the birth weight. There was a significant negative correlation between the current age and Ca/Cr, NAG/Cr, glu/Cr, and UA/Cr, suggesting a maturation of tubular function. On the other hand, ß2M/Cr and malb/Cr did not correlate with the current age, which may indicate persistent kidney injury. Significant correlations were observed between malb/Cr and ß2M/Cr, and malb/Cr and NAG/Cr. There was no association between urine markers and putative risk factors for renal injury.

**Conclusions:** Tubular dysfunction is quite common in ELBW survivors. Microalbuminuria is paralleled by increases in urine ß2M and NAG, which may suggest that it is, at least in part, tubular in origin.

**TH-PO1061**

**Epidemiology of Acute Kidney Injury in Hospitalized Children: A Comparison of ICU and Non-ICU Patients** Elizabeth A.K. Hunt,[1,2] Michael A. Ferguson,[1,2] Sushrut S. Waikar.[2,3] *[1]Div of Nephrology, Boston Children's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Renal Div, Brigham and Women's Hospital, Boston, MA.*

**Background:** Acute kidney injury (AKI) in children has been primarily studied in intensive care units and following cardiac surgery. Less is known about the epidemiology of AKI in hospitalized, non-critically ill children.

**Methods:** We obtained clinical, demographic, and laboratory data from all children hospitalized at a large pediatric tertiary care center in 2011 who had at least one serum creatinine (Scr) measurement. We excluded critically ill neonates, patients aged ≥24, and those with ESRD. Estimated creatinine clearance (eCCl)was calculated using the modified Schwartz formula. AKI was defined and stratified using the pRIFLE criteria (risk (R)= eCCl decrease by 25%, injury (I) = decrease by 50%, failure (F) = decrease by 75%). We used pre-hospital Scr measurements or the nadir inpatient Scr to determine baseline eCCl.

**Results:** We studied 12,090 admissions of 8,706 patients. 5,699 patients had no Scr measurement and 5,485 had one Scr measurement. The incidence of AKI in ICU patients was 53% (23% R, 7% I and 23% F); 3.3% of patients with pRIFLE F required renal replacement therapy (RRT). Overall mortality in ICU patients was 2.8%, and ranged from 0.9% with no AKI to 8.6% in pRIFLE F. Length of stay (LOS) increased with higher stages of AKI. In non-ICU patients, the incidence of AKI was 25% (13% R, 3% I and 9% F); 2.7% of patients with pRIFLE F required RRT. Overall mortality was 0.15%, and ranged from 0.07% with no AKI to 0.97% in pRIFLE F**.** LOS increased with higher stages of AKI.

| | No AKI | pRIFLE R | pRIFLE I | pRIFLE F | p Value |
|---|---|---|---|---|---|
| ICU | (n =1101) | (n =535) | (n =166) | (n =545) | |
| Inicidence % | 47 | 23 | 7 | 23 | |
| LOS days (IQR) | 3 (1-5) | 5 (2.5-7.5) | 6 (2-10)) | 14 (1-27) | <.001 |
| RRT % | 0 | 0 | 0 | 3.3 | |
| Mortality % | 0.91 | 0.93 | 2.4 | 8.6 | <.001 |
| non-ICU | (n=7036) | (n=1237) | (n=313) | (n=826) | |
| Incidence % | 75 | 13 | 3 | 9 | |
| LOS days (IQR) | 2 (0.5-3.5) | 5 (1.5-8.5) | 7 (2-12) | 16 (2.5-29.5) | <.001 |
| RRT% | 0 | 0 | 0 | 2.7 | |
| Mortality % | 0.07 | 0.08 | 0 | 0.97 | <.001 |

**Conclusions:** AKI is common in both ICU and non-ICU patients. The incidence and outcomes of children with AKI outside of the ICU deserve further study.

*Funding:* Other NIH Support - T32 training grant

**TH-PO1062**

**Applying the KDIGO AKI Definition to a Pediatric Critical Care Population** David T. Selewski, J. Troost, Susan M. Hieber, Brett Ehrmann, Michael Heung, Timothy Cornell, Neal B. Blatt, Kera E. Luckritz, David B. Kershaw, Robert J. Gajarski, Thomas P. Shanley, Debbie S. Gipson. *Univ of Michigan.*

**Background:** The Kidney Disease: Improving Global Outcomes (KDIGO) Acute Kidney Injury working group has proposed a standardized definition of acute kidney injury (AKI). We evaluated the KDIGO AKI criteria and the relationship of AKI with relevant

outcomes in a single center tertiary pediatric intensive care (PICU) and cardiothoracic unit (PCTU) population.

**Methods:** Electronic health records for all discharges (N=3213) from 07/2011-02/2013 were extracted, validated and analyzed. The KDIGO creatinine (Cr) based criteria (Cr must be greater than 0.5 mg/dL) were used to stage AKI. Outcomes were ICU length of stay (LOS) and ICU mortality. Exclusion: ESRD, renal transplant or missing PRISM score (N=199). Univariate analysis utilized Chi Squared tests (N,%) for count and Kruskal-Wallis (Median, IQR) tests for continuous variables. Multivariate analysis were performed controlling for mechanical ventilation (yes/no), vasopressors (yes/no), age, and PRISM III score (severity of illness).

**Results:** AKI occurred in 560 (19%) of 3014 discharges (PICU N=1931, PCTU N=1083) among 2393 patients, staged as I=153, II=143, and III=264. Overall ICU mortality was 2.7%. Univariate results are presented in Table 1. On multivariate analysis AKI stage was associated with an increase in ICU LOS (Stage I β=49hrs, p=0.018, II β=80hrs, p<0.001, and III β=280hrs, p<0.001). AKI Stage III was associated with increased odds of ICU mortality (OR 4.2, 95% CI 2.4-7.6.)

**Conclusions:** Using the KDIGO criteria to define AKI we show there is a high prevalence of AKI, AKI is associated with increased ICU LOS and stage III AKI is associated with increased mortality. The KDIGO criteria adequately describes clinically meaningful AKI in a broad pediatric critical care population.

| | No AKI(N=2454) | AKI(N=560) | *p* |

## TH-PO1063

**Acute Kidney Injury (AKI) in Non-Cardiac Neonates in the Pediatric Intensive Care Unit (PICU)** Disha S. Kriplani, James Schneider, Daniel E. Leisman, Christine Sethna. *Pediatrics, Div of Nephrology, Cohen Children's Medical Center of New York, New Hyde Park, NY.*

**Background:** AKI is common in neonates undergoing cardiac surgery. The incidence of AKI in non-cardiac neonates is unknown. The objectives were to define the incidence, assess independent risk factors and outcome of AKI in non-cardiac neonates in the PICU.

**Methods:** A retrospective study of neonates (age ≤28 days) admitted to a single, tertiary PICU from 2008-2012 was conducted. The incidence of AKI was determined based on the pRIFLE criteria. Logistic and linear regression were used to evaluate risk factors and outcomes related to AKI.

**Results:** 80 neonates, gestational age(GA) 38 (32-42) weeks (62.5% males) were reviewed. AKI was reported in 37 (46.2%) neonates. 5.4% reached pRIFLE category F. Neonates with AKI were born to diabetic mothers (13% vs 0%), were younger (6.1±7.8 vs 14.4±9.2), had higher max sodium values (146.9±6.2 vs 143±6), required umbilical catheter placement (64% vs 32%) and had longer duration of mechanical ventilation (15.6±21 vs 6.9±9.9), compared to those without AKI, (p < 0.05). On univariate analysis, variables of ECMO (p <0.001, OR 6.1, 95% CI 2.3 -16.1), max sodium value (p = 0.01, OR 1.12, 95% CI 1.02-1.23) and umbilical lines (p = 0.02, OR 3.6, 95% CI 1.2-10.7) were significantly associated with AKI; however, the associations did not hold after multivariate adjustment. Younger age was found to be an independent risk factor for AKI in a multivariate model (p <0.001, OR 0.89, 95% CI 0.85 – 0.95). Gender, ethnicity, GA, birth weight, sepsis and asphyxia were not associated with AKI. There was a significantly higher mortality rate in neonates with AKI compared to those without AKI (26% vs 7%, p = 0.02). In univariate analysis, AKI was associated with increased risk of mortality (p = 0.03, OR 6.2 95% CI 1.2-18.4) and longer duration of mechanical ventilation (ß 6.9, CI 1.9-11.9, p = 0.007); however, AKI was not an independent predictor of these variables after adjustment for age. AKI was not associated with hospital length of stay.

**Conclusions:** AKI is common in non-cardiac neonates in the PICU and is associated with increased morbidity and mortality. Age is an independent predictor of AKI.

## TH-PO1064

**Survival to Discharge after ECMO in Neonates with Preexisting CKD** Aaron G. Wightman,[2] Miranda Bradford,[3] Jordan M. Symons,[2] Thomas V. Brogan.[1] *[1]Pediatric Critical Care, Univ of Washington School of Medicine, Seattle, WA; [2]Pediatric Nephrology, Univ of Washington School of Medicine, Seattle, WA; [3]Children's Core for Biomedical Statistics, Seattle Children's Research Institute, Seattle, WA.*

**Background:** Little is known about the outcomes of neonates with preexisting chronic kidney disease (CKD) who receive ECMO (Extracorporeal Membrane Oxygenation) support. Limited data indicates some neonates with CKD have acceptable outcomes. We sought to investigate the rates and survival of children with preexisting kidney disease after placed on ECMO support.

**Methods:** We analyzed the ELSO (Extracorporeal Life Support Organization) registry of neonates (<30 days of age) with CKD noted at time of initiation of ECMO for survival to discharge from hospitalization. We compared survival to published norms and performed logistic regression to assess covariate associations with survival.

**Results:** 423 neonates (ECMO indication: 266 pulmonary, 130 cardiac, 27 ECPR) with preexisting CKD were identified in the ELSO registry from 1991-2012. Dialysis was required in 47% of neonates with pulmonary indication and 55% of neonates with a cardiac indication. Survival to discharge was lower in neonates with CKD compared to previously published norms of neonates for both pulmonary (42% vs. 85%, p<.001) and cardiac (20% vs. 40%, p<.001) indications for ECMO. Among infants with a pulmonary indication for ECMO, increased survival to discharge was associated with increased gestational age, increased weight at ECMO onset, treatment after 2000, VV vs. VA ECMO, and not having elevated creatinine or requiring dialysis. Survival was not associated with kidney diagnosis, ECMO duration, or age at ECMO onset. For neonates with a cardiac indication for ECMO, survival to discharge was not significantly associated with any covariates in logistic regression.

**Conclusions:** Neonates with preexisting CKD who require ECMO support have poorer chance of surviving to discharge than other neonates who require ECMO. This suggests that preexisting CKD should be considered when making ECMO initiation decisions.

## TH-PO1065

**Quality of Life after Renal Transplantation in Children** Aaron G. Wightman,[1] Kathryn B. Whitlock,[2] Marrie T. Ketchum,[1] Kristin L. Stockard,[1] Jodi M. Smith,[1] Ruth McDonald.[1] *[1]Pediatric Nephrology, Seattle Children's Hospital, Seattle, WA; [2]Core for Biomedical Statistics, Seattle Children's Research Institute, Seattle, WA.*

**Background:** Renal transplantation is the goal for children with end stage kidney disease providing them with the best opportunity for growth and development. Previous studies of quality of life (QOL) after renal transplant have yielded conflicting results. We sought to assess the impact of renal transplant on QOL.

**Methods:** We administered the PedsQL 3.0 ESRD module to patients and their parents following renal transplantation. The overall scores of transplant recipients were described and MANOVA analysis, accounting for correlation between parent and patient responses and among subscales, was used to analyze the association of demographic covariates with QOL scores. Where available, patient and parent pre-transplant QOL scores were collected. For those with pre and post transplant values within a year of transplant, the linear changes related to transplant were assessed.

**Results:** 32 patients and their parents were included in the analysis. Using MANOVA analysis, recipients who were white had higher scores on the "Treatment Problems" subscale of the module than non-white recipients (p<.015). Parents of children with living donor transplants had higher scores on the "Worry" and "Family and Peer Interaction" subscales than parents of children with deceased donor transplants (p<.005, p<.012). Parents of children who received a preemptive transplant had higher scores on the "Family and Peer Interaction" subscale than parents of children who did not receive a preemptive transplant (p<.019). Pre and post transplant QOL scores were available for 11 patients and their parents. In this subset, no significant changes were found over time in either the patient or parental total or subscale QOL scores.

**Conclusions:** Our study found that pediatric kidney transplant recipients score QOL differently depending on race. Parents of recipients score their child's QOL differently based on type of transplant. These differences in perceived QOL may provide opportunities for further study and implementation of targeted strategies to improve QOL in children after renal transplant.

## TH-PO1066

**Hyperuricemia Is Associated with Hypertension and Progression of Chronic Kidney Disease in Children** George J. Schwartz,[1] Michael F. Schneider,[8] Kyle Rodenbach,[1] Vikas R. Dharnidharka,[2] Donald J. Weaver,[3] Sahar A. Fathallah-Shaykh,[4] Marva M. Moxey-Mims,[5] Bradley A. Warady,[6] Susan L. Furth,[7] Mark Mitsnefes.[9] *[1]U. Rochester, Rochester, NY; [2]St. Lou. Child. Hosp., St. Lou., MO; [3]Levine Child. Hosp., Charleston, NC; [4]UAB, Birmingham, AL; [5]NIDDK, Bethesda, MD; [6]Child. Mercy Hosp., KC, MO; [7]Child. Hosp. Phila., Phila., PA; [8]J. Hopkins Sch. P. Hlth., Baltimore, MD; [9]Cin. Child. Hosp., Cincinnati, OH.*

**Background:** There is little data on the relationship of uric acid [Ur] to pediatric CKD.

**Methods:** We quantified the relationship between [Ur] and GFR, hypertension (Htn), and obesity among 617 subjects of the CKiD study. Htn was defined as systolic or diastolic BP>95$^{th}$ %ile and was separated from those whose BP was <95$^{th}$%ile on antiHtn meds. GFR was measured by iohexol plasma disappearance or estimated from CKID-published formulas. From [Ur] distributions subjects were divided into 2 groups: 1) girls and boys<13 years old, and 2) boys ≥13 years. 432 kids with >2 GFR measurements were studied by multivariate analysis of the effect of initial [Ur] on risk of a ≥30% GFR decline.

**Results:** Cross-sectional: Group 1: Hypertensives (n=73) or those on antiHtn meds (n=234) had mean [Ur] that was 0.35 [95% CI: -0.04, 0.73] and 0.50 [95% CI: 0.21, 0.78] mg/dL higher, respectively, than those with BP <95th %ile and on no antiHtn meds. A 5 mL decrease in GFR was associated with an increase of 0.15 mg/dL in [Ur]; this relationship was not modified by Htn. Obesity was associated with a 0.64 mg/dL (95% CI: 0.29, 0.98) greater [Ur]. Group 2: Hypertensives had comparable [Ur] to those with normal BP without antiHtn meds; those on antiHtn meds had marginally higher [Ur]. Obesity and low GFR were associated with higher [Ur]. Longitudinal: Group 1: [Ur] >7 mg/dL, SBP or DBP >95$^{th}$ %ile, and 5 mL/min lower initial GFR were associated with 2.16 [95% CI: 0.95, 4.90], 4.37 (95% CI: 2.04, 9.38), and 1.18 (95% CI: 0.99, 1.41) times greater risk for ≥30% GFR decline, respectively. Group 2: only initial GFR predicted ≥30% decline in GFR.

**Conclusions:** [Ur] is associated with Htn, obesity, and lower GFR in pediatric CKD. High [Ur] results in increased risk of 30% decline in GFR in girls and young boys with CKD, independent of other factors.

**TH-PO1067**

**Prediction of Chronic Kidney Disease (CKD) Progression in Children by Urinary Neutrophil-Associated Lipocalin (NGAL)** Anke Doyon,[1,2] Aysun Karabay Bayazit,[2] Daniela Kracht,[2] Rene Zeller,[2] Ali Anarat,[2] Anja Christine Sander,[2] Anette Melk,[2] Uwe Querfeld,[2] Franz S. Schaefer.[1,2] *[1]Pediatric Nephrology, Center for Pediatrics and Adolescent Medicine, Heidelberg, Germany; [2]4C Study Group.*

**Background:** NGAL, a novel biomarker of acute kidney injury, has been suggested in animal studies and work in adult patients to be predictive also of CKD progression. The aim of this work was to evaluate whether NGAL povides useful information about progression risk in children with CKD.

**Methods:** Urinary NGAL was measured in 385 children with CKD (mean age 12.5±3.3 yrs, eGFR 31±10 ml/min/1.73m²) followed in the 4C Study for a mean of 20±7 months. NGAL/creatinine ratio was calculated and log-transformed (NGAL-log). Short-term CKD progression was defined as either attainment of end-stage renal disease (ESRD) or >10% eGFR loss within the first year of follow-up. Long-term CKD progression was defined as ESRD or >50% eGFR loss at any time during the observation period.

**Results:** NGAL-log was correlated inversely with eGFR (r= -0.4, p<0.0001) and positively with albuminuria (r=0.3, p<0.0001) and CRP (r=0.2, p<0.0001). There was no association to age, BMI or blood pressure (BP).

Short-term CKD progression was noted in 187 patients (49%). These patients were not different from stable patients in age or baseline eGFR, but had higher BP and CRP levels. NGAL-log was a strong predictor of short-term CKD progression by both univariate and multivariate Cox regression (HR 1.11, p<0.02, adjusted for baseline GFR, BP, age, albuminuria and CRP).

Long-term progression was evident in 81 patients (21%) during the whole follow-up period. While NGAL-log significantly predicted long-term progression by univariate analysis, this association was not sustained when correcting for baseline GFR, BP, albuminuria, age and CRP in the multivariate analysis.

**Conclusions:** Urinary NGAL is an independent predictor of short-term progression of CKD in children, independent of baseline eGFR and other classic risk factors. There was no additional impact of NGAL on prediction of long-term CKD progression.

**TH-PO1068**

**Serum Hepcidin Is a Superior Indicator of Functional Iron Status in Children with Chronic Kidney Disease (CKD)** Anke Doyon,[1,2] Franz S. Schaefer.[1,2] *[1]Pediatric Nephrology, Univ of Heidelberg, Germany; [2]4C Study Group.*

**Background:** Hepcidin inhibits intestinal iron uptake as well as release from internal iron stores. It is upregulated in CKD and may thereby contribute to functional iron deficiency and anemia. Little is known about the distribution of serum hepcidin in pediatric CKD. The aim of this work was to evaluate the range and determinants of serum hepcidin concentrations observed in children and adolescents with CKD and to assess its usefulness in the evaluation of anemia in pediatric CKD.

**Methods:** Serum hepcidin, hemoglobin (Hb), and measures and determinants of iron status were measured in 130 children and adolescents with CKD (age 6 - 17 years, eGFR 10 - 60 ml/min/1.73 m²) followed in the 4C Study. Current use and dosage of erythropoetin stimulating agents (ESA, administered in 47% of patients) and iron supplements (prescribed to 10 %) was recorded. Hepcidin, ferritin and CRP levels were log-transformed for multivariate regression analysis.

**Results:** Median (IQR) serum hepcidin was 26.2 (37.6) ng/ml in boys and 28.0 (20.9) ng/ml in girls (p=n.s.). Hepcidin was correlated inversely with eGFR (r=-0.45, p<0.0001) and age (r=-0.18, p<0.05), and positively with serum ferritin (r=0.70, p<0.0001) and CRP (r=0.2, p<0.05) by univariate and multivariate analysis. No significant association with transferrin saturation (TSAT) was found. Also, serum hepcidin levels were not affected by iron supplementation or ESA therapy according to multivariate analysis.

A multivariate model adjusting for age, eGFR, gender, ESA and iron therapy identified hepcidin but not TSAT, ferritin or CRP as a significant predictor of Hb levels (p<0.05). High hepcidin levels were the only significant associate of Hb levels in non-ESA treated patients (p<0.01), whereas none of the parameters of iron status was predictive of Hb in patients receiving ESA.

**Conclusions:** Serum hepcidin increases in proportion to renal failure in children with CKD. It is linked to CRP and ferritin but not TSAT in children with CKD, suggesting its usefulness as a marker of functional iron deficiency in CKD associated anemia. Hepcidin appears superior to traditional indicators of iron status and inflammation in predicting Hb levels.

**TH-PO1069**

**Renal Hyperfiltration and Urinary Cytokines/Chemokines in Adolescents with Type 1 Diabetes Mellitus** Ronnie Lok-Hang Har,[1] James W. Scholey,[1] Denis Daneman,[2] Farid H. Mahmud,[2] Rahim Moineddin,[3] Masha Ostrovsky,[2] Livia Deda,[2] Laura Motran,[2] Yesmino Elia,[2] Etienne Bertrand Sochett,[2] Heather N. Reich,[1] David Cherney.[1] *[1]Univ Health Network, Univ of Toronto, Canada; [2]Hospital for Sick Children, Univ of Toronto, Canada; [3]Univ of Toronto, Canada.*

**Background:** In adults with type 1 diabetes (T1D), renal hyperfiltration is associated with high intraglomerular pressure, and with high levels of urinary cytokines/chemokines, which may contribute to the initiation of diabetic nephropathy. In children with T1D, the interaction between hyperfiltration and inflammation remains unknown. Our objective was to determine whether renal hyperfiltration is associated with increased levels of urinary cytokines/chemokines in adolescents with T1D.

**Methods:** Blood pressure, estimated glomerular filtration rate using cystatin C and a panel of 41 urine cytokines/chemokines using a Luminex platform were measured in individuals recruited to the Adolescent Type 1 Diabetes Cardio-Renal Intervention Trial (AdDIT). T1D patients with hyperfiltration (DM-H, n=81, GFR ≥135 ml/min/1.73m²) or normofiltration (DM-N, n=88, GFR<135 ml/min/1.73m²) were compared to a group of healthy controls (n=59).

**Results:** Compared to controls and after correcting for age, gender and weight, DM-H and DM-N exhibited elevated levels of urinary FGF-2, Flt-3, IL-12, -13 and -15, TNFα and TNFb (p≤0.042). These factors were not different in the two T1D groups. In contrast, some markers were higher in control vs. DM-H and DM-N, including eotaxin, GM-CSF, IL-7 and -17, PDGF-AA and PDGF-AB/BB, RANTES, VEGF and MCP-3 (p≤0.031). Other interleukins, IFN, IP-10, MCP-1, TGF, MDC and MIP1α were similar in the three groups.

**Conclusions:** Normotensive, normoalbuminuric T1D children exhibit differences in urinary cytokines/chemokines compared to healthy controls. In contrast with previous work in adults, hyperfiltration in T1D children is not associated with increased urinary cytokine/chemokine excretion. Further work is warranted to determine 1) if this early renal biomarker profile changes over time; 2) whether these factors respond to drug therapy; 3) the correlation between these factors and longer term outcomes.

*Funding:* Private Foundation Support

**TH-PO1070**

**Response to Standard Vitamin D Treatment among Children with Chronic Kidney Disease and Primary Hypertension** Bandana Paudyal, Gail Prado, Morris J. Schoeneman, Manoj Kumar Nepal, Valeriya M. Feygina, Vaishali Bansilal, Hanan K. Tawadrous, Anil K. Mongia. *Pediatrics Nephrology, SUNY Downstate Medical Center, Brooklyn, NY.*

**Background:** Children with vitamin D deficiency are treated with either ergocalciferol or cholicalciferol. Vitamin D treatment is standard fixed dose and duration as per serum 25 (OH) D levels, irrespective of age and weight. That means, the same dose might be sub therapeutic for some patients and toxic for other patients. However, limited studies are available looking at response of 25(OH) D level post treatment.

**Methods:** We enrolled 144 patients aged 2 to 19 yrs, 34 Primary Hypertension(PH), 95 Chronic kidney disease (CKD) 23 Control(C). Among CKD, 58 were (CKD I-IV), 16(Transplant), 21(Dialysis). We collected retrospective data on age, sex,race, cause of kidney disease, eGFR, Ht, Wt, BMI, BP z-scores, lipid panel, 25(OH) D level, PTH, Calcium, Phosphorus, Magnesium, type and dosing of Vitamin D Supplements and post treatment 25(OH) D level.

**Results:** Mean age (yrs) was (13.02±4.73). 76% African american. eGFR (ml/min/1.73m2 was significantly lower among CKD (61.23±44.10) than PH and C. SBP z-score (0.7±1.8) was higher among PH (2.1 ±1.9) than CKD (0.26±1.75), p=0.001 and controls (0.39±1.27), p=0.01. BMI z-score) was significantly higher among PH (1.61±1.22) and Control (1.20±1.21) than CKD (0.37±1.58) p= 0.04.Prevalence of Vitamin D deficiency was (91%); 60% had level <20 ng/ml. Mean pretreatment 25(OH) D (ng/ml) was (19.07±10.44), no significant difference among PH (18.5±9.7), CKD (18.8± 11.33) and Control (20.6±7.5). Pretreatment 25(OH) D didn't correlate with PTH, eGFR, BMI, SBP/DBP Z-score, serum cholesterol. Mean post treatment 25(OH) D (ng/ml) was (24.5±911.16). After completion of standard treatment almost 76 % patients had 25 (OH) D level <30 ng/ml, mean 25 (OH) D (24.5±11.16); PH (24.57±11.7) and CKD (24.9±9.9) and control (21.8±5.67). None were in toxic range.

**Conclusions:** The standard treatment dose of Vitamin D doesn't normalize 25(OH) D level in majority of patients. Newer treatment guidelines may be needed to optimize the treatment.

**TH-PO1071**

**Prevalence and Determinants of 25-Hydroxyvitamin D Deficiency in the Chronic Kidney Disease in Children Cohort** Juhi Kumar,[1] Lisa Aronson Friedman,[3] Alison G. Abraham,[3] Valerie L. Johnson,[1] Frederick J. Kaskel,[3] Bradley A. Warady,[3] Susan L. Furth,[3] Michal L. Melamed,[2] Anthony A. Portale.[3] *[1]Pediatrics, Weill Cornell Medical College, New York, NY; [2]Medicine, Albert Einstein College of Medicine, Bronx, NY; [3]Chronic Kidney Disease in Children(CKiD) Investigator.*

**Background:** Deficiency of 25-hydroxyvitamin D (25OHD) is highly prevalent in healthy children. Children with chronic kidney disease (CKD) are at higher risk for 25OHD deficiency, although the risk factors are poorly defined.

**Methods:** We measured 25OHD levels at baseline and after 1.5 years and 3.5 years of follow-up in 504 children with CKD stages 2-4 enrolled in the Chronic Kidney Disease in Children (CKiD) study. We used generalized estimating equations to determine the associations of demographic, nutritional, anthropometric and biochemical factors with 25OHD deficiency, defined as level <20 ng/ml; 25OHD sufficiency was defined as level ≥30 ng/ml.

**Results:** Median participant age was 12.2 years, and 22 % were African-American. Overall, 64 % of participants were 25OHD deficient at one or more visits. The prevalence of deficiency decreased with subsequent visits; 28% were deficient at baseline, 24% at 1.5 and 23% at 3.5 years of follow-up. Nutritional vitamin D supplement use was low, 1.5% at baseline, 3% at 1.5, and 15% at 3.5 years of follow-up. By multivariable analysis, 25OHD deficiency was significantly associated with older age (OR=1.1, p <0.05), African-American race (OR=4.4, p <0.001), higher BMI (OR=1.1, p <0.001), less than daily milk intake (OR=2.6, p <0.001), insufficient sunlight exposure (winter season/higher latitude of blood draw, OR=2.8, p<0.001), lower serum albumin (OR=2.5, p <0.01), baseline vs. 1.5 year follow up visit (OR=2.0, p<0.05) and absent use of nutritional vitamin D supplements (OR=6.6, p<0.01). Gender, maternal education, income, history of low birth weight, GFR, proteinuria, albumin-corrected calcium, PTH, and FGF 23 levels were not associated with 25OHD deficiency.

**Conclusions:** Risk factors for 25OHD deficiency in children with CKD are similar to those in normal children with age, race, BMI, sunlight exposure, milk intake, and use of nutritional vitamin D supplements being significant predictors.

## TH-PO1072

### Trends in Control of Hypertension (HTN) in Childhood Chronic Kidney Disease (CKD), 2005-13

Joseph T. Flynn,[1,2] Christopher B. Pierce,[2] Mark Mitsnefes,[2] Gina-Marie Barletta,[2] Joshua A. Samuels,[2] Susan L. Furth,[2] Bradley A. Warady.[2] *[1]Seattle Children's Hospital; [2]CKiD Investigators.*

**Background:** Early data from the chronic kidney disease in children (CKiD) cohort study demonstrated poor control of HTN. Enrollment of a second CKiD cohort allows examination of whether HTN control has improved over time.

**Methods:** Baseline casual and ambulatory blood pressure (BP) data were compared between participants enrolled in 2005-09 (cohort1) and those enrolled in 2011-13 (cohort2). Using auscultatory casual BP (CBP), we examined the prevalence of pre-HTN and HTN, as well as the prevalence of controlled (<90th %tile) and uncontrolled (90th %tile) CBP among those on antihypertensive medications. Ambulatory BP data were used to classify subjects as having confirmed normotension, WCH, ambulatory HTN or masked HTN. Cumulative logistic regression with adjustment for glomerular filtration rate (GFR), race, sex, age and body mass index was performed to examine the effect of cohort on BP status. Analyses were stratified by CKD diagnosis (glomerular and non-glomerular).

**Results:** Cohort characteristics were similar except for significantly higher GFR in cohort2. Unadjusted BP results are displayed in the table.

| | | Glomerular | | | Non-glomerular | |
|---|---|---|---|---|---|---|
| BP status, % | cohort1 | cohort2 | P | cohort1 | cohort2 | P |
| Systolic CBP | | | 0.05 | | | NS |
| Normotensive | 64 | 77 | | 78 | 73 | |
| Pre-HTN | 18 | 16 | | 10 | 11 | |
| HTN | 17 | 17 | | 12 | 17 | |
| Diastolic CBP | | | 0.049 | | | NS |
| Normotensive | 77 | 90 | | 78 | 80 | |
| Pre-HTN | 10 | 6 | | 9 | 9 | |
| HTN | 13 | 5 | | 13 | 11 | |
| Ambulatory BP | | | NS | | | NS |
| Normotensive | 47 | 63 | | 45 | 37 | |
| WCH | 2 | 5 | | 5 | 0 | |
| Masked HTN | 33 | 21 | | 35 | 36 | |
| Ambulatory HTN | 19 | 11 | | 14 | 15 | |

Rates of uncontrolled CBP in those on antihypertensive medications were similar in the two cohorts. After adjustment, no effect of cohort on BP status could be demonstrated.

**Conclusions:** HTN remains unrecognized and under-treated in children with CKD. Interventions to improve the recognition and treatment of HTN in pediatric CKD are urgently needed.

*Funding:* NIDDK Support, Other NIH Support - NHLBI, NICHD

## TH-PO1073

### The Contributions of Glomerular versus Non-Glomerular Diagnoses and Marked Proteinuria to Neurocognitive Outcomes in Children and Adolescents with CKD

Stephen R. Hooper,[1] Arlene C. Gerson,[2] Marc Lande,[3] Matthew Matheson,[2] Christopher Cox,[2] Bradley A. Warady,[4] Susan L. Furth.[5] *[1]U. North Carolina; [2]Johns Hopkins; [3]U. Rochester; [4]Children's Mercy; [5]CHOP.*

**Background:** The presence of pediatric chronic kidney disease may be associated with abnormal neurocognitive function. The type of kidney disease (glomerular [G] vs. non-glomerular [NG]) and marked proteinuria are two potential risk factors we have considered in assessing functional outcomes. Marked proteinuria has previously been shown to be related to lower neurocognitive functioning. However, to date, there are no available data to show how these two factors (diagnosis and proteinuria) interact to affect neurocognitive outcomes. This study investigated (1) the group differences between those with G versus NG, with and without marked proteinuria; and (2) how this interaction contributes to neurocognitive functioning.

**Methods:** Cross-sectional data from the NIDDK/NHLBI/NICHD-funded CKiD Study were employed for both questions. The G group included 43 subjects with marked proteinuria (uP/C>2) and 123 without, while the NG group included 39 with marked proteinuria and 460 without. Median Iohexol-based GFR for the sample was 50.44 ml/min/1.73m$^2$. Measures at study entry included IQ, inhibitory control, attention regulation, problem solving, working memory, and ratings of overall executive functioning at study entry.

**Results:** In comparing G vs NG groups with and without proteinuria at study entry, univariate results showed the 4 groups to be significantly different only for IQ ($p < .009$), with the groups having marked proteinuria having the lowest IQ scores. After adjusting for demographic and disease-related variables, neither diagnosis nor proteinuria was predictive of neurocognitive outcomes, although there was a trend for proteinuria to be associated with IQ ($p < .088$). The interaction between diagnosis and marked proteinuria was nonsignificant.

**Conclusions:** While a diagnosis of G vs. NG does not seem to affect neurocognitive outcomes cross-sectionally, proteinuria does show a modest effect on IQ regardless of diagnosis. A diagnosis X marked proteinuria interaction on neurocognitive functions was not detected.

*Funding:* NIDDK Support

## TH-PO1074

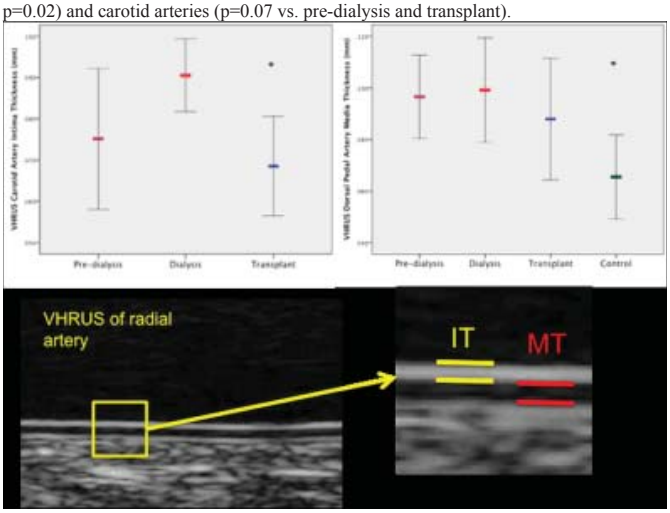
### Very High Resolution Ultrasound Reveals Peripheral Arterial Changes in Both Intima and Media in Children with Chronic Kidney Disease

Frida Dangardt,[1] Rukshana Shroff,[2] Marietta Charakida,[1] John E. Deanfield.[1] *[1]Vascular Physiology, Univ College London, London, United Kingdom; [2]Dept of Nephrology, Great Ormond Street Hospital for Children, London, United Kingdom.*

**Background:** Children with chronic kidney disease (CKD) have multiple risk factors for vascular damage that will contribute to the very high cardiovascular morbidity and mortality seen in this group. We hypothesize that children with CKD develop changes in their arterial intima and media, associated with different risk factors and that varies between vascular beds.

**Methods:** Intimal (IT) and medial (MT) thickness of the carotid, radial and dorsal pedal arteries were measured using very high resolution ultrasound (VHRUS) (40-55MHz) in 22 children with CKD (14.6 ± 3.0 years) (n=9 pre-dialysis CKD stages 4-5, n=7 dialysis, n=6 post transplant) and compared to radial and dorsal pedal arteries from 17 matched healthy controls. Results were compared with conventional carotid intima-media thickness (cIMT) and biochemical data in CKD patients.

**Results:** In CKD children, there was widespread medial thickening, most marked in dorsal pedal arteries (0.095±0.03 vs. 0.065±0.03 in controls; p=0.004). In children on dialysis, increased IT was also seen in radial arteries (0.060±0.01 vs. 0.056±0.01 in controls; p=0.02) and carotid arteries (p=0.07 vs. pre-dialysis and transplant).



Radial IT and carotid MT were both associated with serum calcium in these patients (r=0.42, p=0.05 and r=0.89, p=0.02). Intimal and medial changes could not be distinguished by conventional cIMT.

**Conclusions:** VHRUS reveals changes of both intima and media, not only in the central, but also in peripheral arteries. These changes are more pronounced in children on dialysis, and associated with calcium levels. This suggests that, in CKD children, strategies to target both metabolic and atherosclerosis risk factors should be initiated from an early age.

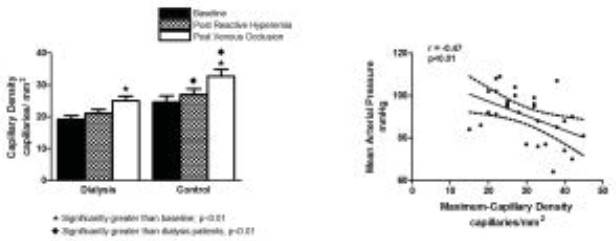
**TH-PO1075**

**Carotid Intima Media Thickness and Nailfold Capillary Density in Pediatric Hemodialysis Patients** Alcia D. Edwards-Richards,[1] Nao Sasaki,[2] Chryso P. Katsoufis,[1] Wacharee Seeherunvong,[1] Vimal Master Sankar Raj,[1] Marissa J. Defreitas,[1] Jayanthi Chandar,[1] Michael Freundlich,[1] Gaston E. Zilleruelo,[1] Carolyn L. Abitbol.[1] *[1]Pediatric Nephrology, Univ of Miami/ Holtz Children's Hospital, Miami, FL; [2]Pediatric Cardiology, Univ of Miami/ Holtz Children's Hospital, Miami, FL.*

**Background:** Pediatric patients with chronic kidney disease (CKD) on hemodialysis (HD) are at increased risk of cardiovascular disease (CVD) and cardiac death. Early detection of microvascular abnormalities may prompt timely therapeutic interventions to reduce these risks.

**Methods:** Nailfold capillary density (NCD), an early marker of microvascular disease, was assessed by capillaroscopy in 19 pediatric HD patients (aged:16.6±3.5 years) and 16 age-matched controls. Carotid intima media thickness (cIMT) and left ventricular mass index (LVMI) were measured by echocardiography and compared to healthy adolescent controls. Laboratory assessments included demographics of ethnicity and gender, dialysis vintage, mean pre-dialysis and post-dialysis blood pressures and cardiac biochemical markers such as pro-Brain natriuretic peptide (pro-BNP) and high sensitivity C-reactive protein (hsCRP).

**Results:** NCD was significantly lower in HD patients and correlated significantly with mean arterial pressures (Figure A & B). LVMI was greater than that of controls (36.5±19 versus 29.2±27 g/m$^{2.7}$; p<0.01) and cIMT was significantly less (0.37±.05 versus 0.41±.07 mm; p=0.03). All other biochemical markers of CVD injury were elevated above normal limits but did not correlate with NCD or echocardiographic measures.



**Conclusions:** In the present cross-sectional pilot study, pediatric HD patients had significantly lower NCD measurements than age-matched controls. NCD appears to be a valuable non-invasive tool to detect early subclinical CVD risk in young hemodialysis patients. Further studies are very much warranted.

**TH-PO1076**

**Peritoneal Membrane Transformation: Results from the International Pediatric Peritoneal Biopsy Study** Bradley A. Warady,[1] Betti Schaefer,[2] Stephan Macher-Goeppinger,[2] Maria Bartosova,[2] Benjamin L. Laskin,[3] Stefan Holland-Cunz,[2] Franz S. Schaefer,[2] Claus P. Schmitt.[2] *[1]The Children's Mercy Hospital, Kansas City; [2]Univ of Heidelberg, Heidelberg, Germany; [3]The Children's Hospital of Philadelphia, Narberth.*

**Background:** The peritoneal membrane has not yet been studied systematically in healthy children and adults, and age dependent differences are unknown. In adults, acidic PD fluids with abundant glucose degradation products (GDP) induce major alterations of the peritoneum. The impact of exposure to these same fluids or to "biocompatible PD fluids" in children is unknown.

**Methods:** Standardized peritoneal specimens were obtained from 56 healthy children (0.1-16.6 yrs), 9 healthy adults (19-62 yrs), 56 children at time of PD catheter insertion (0.1-19.6 yrs) and 51 children on PD (0.3-20.1 yrs) from 26 centres in 14 countries. 46 patients had low GDP fluids.

**Results:** In controls, the mesothelial cell layer was mostly intact, but in young children calretinin negative, indicating immaturity. Submesothelial compact zone was absent in 95% of samples, and submesothelial fat was missing in children under 2 yrs of age. Total submesothelial zone thickness was 269(207-370) µm. Capillaries were located in 3 layers 56(19-88), 162(69-301) and 323(157-774) µm below the mesothelial surface, depending on age and submesothelial thickness. Capillary surface area decreased with age. In patients, the mesothelial cell layer was intact in 68/58/21% at onset, after 0-2 and after > 2 yrs of PD. Submesothelial thickness increased to 250(90-700), 430(350-700) and 625(600-650) µm after 0-2, 2-4 and > 4 yrs of PD, despite low GDP fluid. Whereas capillary density increased in a subgroup of patients, vessel morphology remained unaltered. ASMA+ fibroblasts and CD45/CD68+ leucocytes were present in 23/11% of controls, in 31/26% at PD onset and in 55/69% of children on chronic PD. VEGF/TGF-ß abundance increased with PD. No biopsy related complications were reported.

**Conclusions:** Our findings reflect major, age dependent differences in peritoneal structure in non-uremic controls, as well as substantial time dependent peritoneal membrane transformation, despite low GDP fluid usage.

**TH-PO1077**

**The Bioelectric Impedance Analysis Using a Body Composition Monitor Allows Adequate Determination of Body Fluid Volume in Children and Adolescents following Peritoneal Dialysis** Rainer Büscher. *Univ Hospital Essen, Dept of Pediatrics II, Essen, Germany.*

**Background:** The adequacy of body fluid volume in children requiring dialysis is difficult to assess and a gold standard for the best method of measurement is missing. Chronic overhydration or hypovolemia are serious side effects of an inadequate dialysis treatment and a major risk for cardiovascular sequelae. This study was performed to determine whether body composition monitoring (BCM) or sonographic measurement of the inferior vena cava diameter (IVCD) is a valid means to study overhydration in children following peritoneal dialysis (PD).

**Methods:** Fourteen children (7 male) undergoing PD (CCPD n=11, CAPD n=3), mean age 14.5±3.1 years (male) and 12.2±1.2 years (female), age at onset of dialysis 11.7± 5.8 (male) and 11.1 ± 3.4 years (female) were included. Using a BCM device (Fresenius, Bad Homburg, Germany) we determined resistance (Ω) as well as sonographic IVCD (mm) in supine position before and following a CCPD interval. In addition, SDS-blood pressure was monitored using a 24-h ambulatory blood pressure monitor (ABPM). Data are presented as mean±SD.

**Results:** Resistance as a marker of fluid reduction increased significantly following a CCPD interval (male: mean 545±79 Ω before dialysis, 605±76 Ω after dialysis; female: mean 523±76 Ω before dialysis, 593±62 Ω after dialysis). Accordingly, IVCD significantly decreased following a CCPD-interval (male: mean 12.1±3.4 mm before dialysis, 10.2±3.0 mm after dialysis; female: mean 11.1±1.8 mm before dialysis, 8.8±2.2mm after dialysis). ABPM revealed a significant reduction of SDS-blood pressure following a CCPD-interval (male: 2.2±1.7 before dialysis, 0.4±1.1 after dialysis, p<0.0001; female: 2.1±1.2 before dialysis, 0.9±1.2 after dialysis, p<0.0001).

**Conclusions:** Bioelectric impedance analysis is an easy and reproducible method in children undergoing PD to determine body fluid volume on a daily basis. In contrast, determination of the IVCD is more laborious and combined with a greater observer variance. Although both methods simplify the assessment of fluid balance in children, the uncritical use of normograms leads to false high dry weights with subsequent overhydration.

**TH-PO1078**

**Current Achievement of the PD Adequacy Target in the Pediatric ESRD Population** Sylvia Paz B. Ramirez,[1] Alissa Kapke,[1] Natalie Scholz,[2] Bradley A. Warady.[3] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Univ of Michigan, Ann Arbor, MI; [3]The Children's Mercy Hospital.*

**Background:** Clinical practice guidelines in the pediatric (age<18) peritoneal dialysis (PD) population recommend a target weekly Kt/V of 1.8. While this target is based on prior studies in the pediatric and adult PD populations, there is consensus that greater solute clearance may be associated with improved outcomes in the pediatric PD population. We sought to examine the current achievement of this Kt/V target in the population.

**Methods:** Medicare claims data submitted for pediatric PD patients from 2011-2012 were assessed to determine how often patients achieved a weekly Kt/V ≥1.8 at the patient and facility-level.

**Results:** Claims were submitted for a total of 675 pediatric PD patients over two years resulting in 4,009 monthly observations (patient-months). A total of 140 patients (21%; 2,630 patient-months) did not have a single Kt/V reported. Among patient-months with Kt/V, 76% had a Kt/V ≥1.8 but this was 48% when patient-months without reported Kt/V were included. On facility-level analysis, the median %patient-months with weekly Kt/V ≥1.8 was 52% (interquartile range [IQR]:16%-78%). Facilities with <10 pediatric PD patients had a higher percentage with Kt/V ≥1.8 (median=56%;IQR:17%-79%), compared to facilities with >10 patients (median=49%;IQR:7%-71%). Better achievement was observed in urban facilities, hospital satellite facilities, and independent facilities [Table 1].

**Conclusions:** Many pediatric PD patients do not report Kt/V. When including patient-months without reported Kt/V, over 50% of patient-months did not meet the target. Facilities with more PD pediatric patients, rural facilities, hospital or freestanding facilities, and chain-associated facilities were less likely to meet the Kt/V target.

**Table 1. Percent patient-months with Kt/V>=1.8 by facility characteristics**

| Category | # Facilities | Median % with Kt/V>=1.8 (Q1-Q3) |
|---|---|---|
| **# PD pediatric pts** | | |
| 1-10 | 125 | 56 (17, 79) |
| 11+ | 19 | 49 (7,71) |
| **Urban/Rural** | | |
| Urban | 124 | 56 (15, 79) |
| Rural | 12 | 44 (8, 73) |
| **Facility Type** | | |
| Hospital-Based | 50 | 57 (15, 79) |
| Free-Standing | 80 | 50 (16, 78) |
| Hospital-Satellite | 10 | 63 (29, 85) |

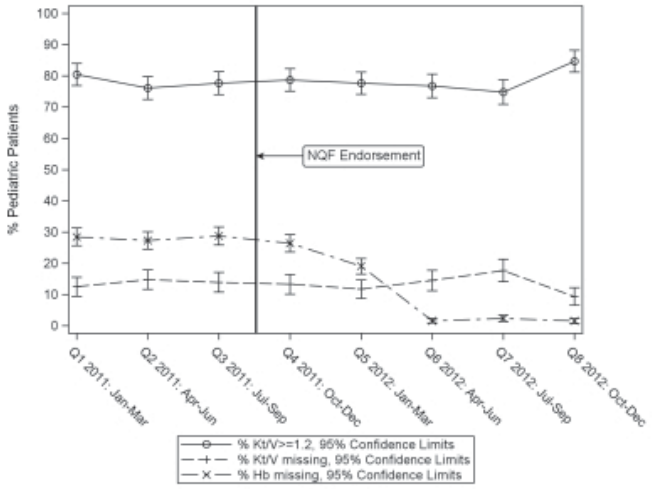
**Performance of Quality Measures for Pediatric Hemodialysis Patients**
Sylvia Paz B. Ramirez,[1] Alissa Kapke,[1] Jeffrey Pearson,[1] Jordan Jahnke,[1] Bradley A. Warady.[2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]The Children's Mercy Hospital, Kansas City, MO.*

**Background:** Published studies suggest improvement in mortality among pediatric patients receiving maintenance dialysis over time but mortality remains high; improved quality of dialysis care in this fragile patient group may further improve survival. Several pediatric ESRD quality measures received endorsement from the National Quality Forum (NQF) in August 2011 and in June 2012 were proposed for inclusion the CMS ESRD 2015 QIP. This study aims to examine the change in performance of these measures between 2011 and 2012.

**Methods:** Monthly hemoglobin (Hb) and dialysis adequacy measurements, and the achievement of spKt/V ≥1.2 were evaluated using Medicare claims data from 2011-2012. Monthly claims were aggregated by quarter for reporting purposes.

**Results:** Performance for the adequacy measures remained stable from Q1 through Q7. In Q8, the %spKt/V ≥1.2 increased nearly 5% over all other quarters to 85%, while the %monthly Kt/V not measured decreased by 5% to 11.5%. The %patients whose monthly Hgb was not reported remained over 25% through 2011 and decreased to 19% after August 2011. In April 2012, Medicare claims reporting instructions changed to require facilities to enter a Hgb value or 99.99 if Hgb was not reported, which appeared to be associated with a marked increase in reporting of Hgb levels (approximately 98% reporting). Figure 1. Quarterly performance of pediatric ESRD quality measures.



**Conclusions:** The pediatric ESRD quality measures analyzed in this study show some improvement in clinical performance over a two year period when several important steps were undertaken to implement the quality measures. Future analyses are needed to evaluate whether improvement in clinical performance measures is associated with improved health outcomes.

**TH-PO1080**

**Inpatient Citrate Based Hemodialysis in Pediatric Patients**
Rita D. Sheth, Cheryl P. Sanchez, Drew C. Cutler, Shobha Sahney. *Pediatric Nephrology, Loma Linda Univ, Loma Linda, CA.*

**Background:** Heparin use in inpatient hemodialysis is limited in critically ill or perioperative patients. Citrate based dialysate allows heparin avoidance.

**Methods:** Pediatric inpatient hemodialysis treatments (HDRx) were performed at a single institution over 1 year with a citrate based dialysis solution. Ica were monitored hourly for initial 3 HDRx. Rates of catheter malfunction, dialyzer and chamber clotting were monitored. HDRX characteristics and iCa levels were compared between AKI & CKD patients.

**Results:** 18 inpatients (10 male, ages: 0.01-18.13 yrs, 4.5 -57 kgs) were dialyzed with Citrasate®: 6 AKI, 2 new & 10 established CKD 5 pts. 119 HDRx over 21 admissions were performed;1-16 HDRx per patient. 10 pts (64 HD Rx) had a cuffed semi-permanent HD catheter, 8 pts (54 HDRx) had a temporary HD catheter and 1 pt (1 HDRx) an AVF. 10 HD Rx done with a blood prime. All patients were dialyzed heparin-free.

| | Overall | AKI | CKD | p value |
|---|---|---|---|---|
| Lost Circuit /Clotted | 3/119 (2.5%) | 3/54 HD Rx (5.6%) | 0/65 HD Rx (0%)* | <0.01* |
| Catheter malfunction | 2/119 (1.7%) | 2/54 D Rx (3.7%) | 1/65 HD Rx (1.5%) | NS |
| Decreased HD time | 7/119 (5.9%) | 5/54 HD Rx (9.3%) | 2/65 HD Rx (3.1%)* | <0.01* |
| Chamber clots | 62/119 (52.1%) | 32/54 (59.2%) | 32/65 (49.2%) | NS |
| Dialyzer clots | 50/119 (42.0%) | 28/54 (51.9%) | 23/65 (35.4%)* | <0.01 |
| Mean iCa hour 1 (mmol/L) | 0.97±0.12 | 0.92±0.11 | 1.0±0.11 | <0.05 |
| Mean iCa hour 2 (mmol/L) | 0.98±0.13 | 0.95±0.15 | 0.98±0.10 | NS |
| Mean Δ iCa hour 2 (mmol/L) | -0.01±0.17 | -0.03±0.22 | -0.02±0.12 | NS |
| Single iCa <1.0 (mmol/L) | 40/49 (81.6%) | 13/16 (81.1 %) | 25/33 (75.8%)* | <0.01 |
| ICa <1.0 entire HD Rx | 22/49 (44.9%) | 11/16 (68.8%) | 12/33 (36.4%)* | <0.01 |

* p<0.05

No patients had symptomatic hypocalcemia, lowest iCa was 0.76, 0.72 mmol/L at hour 1 and 2 respectively.

47% vs. 40% HDRX with a chamber clot had a iCa > 1 mmol/L, p=0.04; 56% vs. 55% HDRx with dialyzer clot had a iCa > 1 mmol, p=NS.

**Conclusions:** Citrate based acute HD is a safe and useful alternative and allows the avoidance of heparin in sick hospitalized patients. Risk for significant circuit loss is low. Most patients had mild asymptomatic hypocalcemia with no adverse reactions. Higher iCa values >1 mmol/L increased the risk for clotting.

**TH-PO1081**

**The Use of Nafamostat Mesilate as an Anticoagulant in Pediatric Continuous Renal Replacement Therapy**
Heeyeon Cho, Sang Taek Lee. *Pediatrics, Samsung Medical Center, Seoul, Korea.*

**Background:** Nafamostat mesilate, a synthetic serine protease inhibitor, has been used as an anticoagulant during continuous renal replacement therapy (CRRT) for the patients with high risk of bleeding. However, there is little data about its clinical utility in pediatric patients. The aim of this study was to evaluate the ideal dosage, efficacy and safety of nafamostat mesilate in CRRT among critically ill pediatric patients.

**Methods:** We conducted a retrospective study in pediatric patients who received CRRT from January 2011 to January 2013. Thirty seven patients were enrolled in this study (22 males with the median age at the initiation of CRRT of 8.3 years). The median duration for CRRT was 12.9 days and the survival rate 37.8 %. In the 6 pediatric patients without the risk of bleeding, heparin was used during CRRT. In the 31 patients with the risk of bleeding, we started CRRT without anticoagulation, and nafamostat mesilate was used if hemofilter lifespan was less than 12 h or the activated clotting time (ACT) was less than 200. The starting dosage of nafamostat mesilate was 0.25 mg/kg/h and titrated according to ACT.

**Results:** Of the 31 patients with the risk of bleeding, 14 (45.2 %) patients received nafamostat mesilate and the average hemofilter lifespan was improved from 7.8 h to 28.6 h after the use of nafamostat mesilate ($p < 0.001$). The average hemofilter life span with nafamostat mesilate was significantly greater than heparin (28.6 h vs. 11.3 h, $p<0.001$). The average hemofilter lifespan was 42.1 h in patients without anticoagulation. No patients experienced major bleeding, agranulocytosis, hyperkalemia or anaphylaxis while treated with nafamostat mesilate.

**Conclusions:** These data suggest that nafamostat mesilate is a good alternative as an anticoagulant in critically ill pediatric patients with high risk of bleeding who require CRRT.

**TH-PO1082**

**Long-Term Hemodialysis Therapy in Neonates and Infants with End Stage Renal Disease**
Shirley Pollack,[1,2] Israel Eisenstein,[1,2] Daniella Magen,[1,2] Mahdi Tarabeih,[1] Israel Zelikovic.[1,2] *[1]Pediatric Nephrology, Rambam Medical Center; [2]Faculty of Medicine, Technion - Israel Institute of Technology, Haifa, Israel.*

**Background:** Peritoneal dialysis (PD) is the preferred mode of renal replacement therapy (RRT) in infants with end stage renal disease (ESRD). Hemodialysis (HD) is seldom used in neonates and infants because of the major complications of this procedure in the very young.

**Methods:** We analyzed demographic, clinical, laboratory and imaging data in all infants younger than 12 months with ESRD who received HD therapy in our Pediatric Dialysis Unit between 1997-2013. RRT- primarily HD- is performed in all infants with ESRD admitted to our service without exclusion.

**Results:** Eighteen infants (M:F 6/12; Arabs/Jews 14/4) with ESRD (median age, 5 months ; median wt, 3.8 kg) received HD through a tunneled central venous catheter (CVC) for a total of 16,292 days. Seven (39%) were neonates (< 1 month of age ; group 1) and 11 (61%) were infants (1-12 months; group 2) who received HD for a cumulative 7141 days (44% of total) and 9151 days (56%), respectively. In 6 of the patients, the initial mode of RRT was PD for 1-3 months. Five (28%) of the patients had serious comorbidities. Thirty eight CVC were inserted (34 angiographically). There were 5 episodes of CVC infection- a rate of 0.3/1000 CVC days. Median catheter survival time was 428 days. Five (28%) of the infants (2 in group 1) underwent renal transplantation and 6-10 year graft survival was 80%. Seven (38%) of the patients died. Most infants had good oral intake and only 4 (22%) required gastric tube. Thirteen (72%) of the infants displayed normal growth. Eight (44%) of the patients (5 in group 1) had delayed psychomotor development. Of these infants, 5 (3 with comorbidities) had abnormal brain imaging, 4 had seizures, and 3 had sensorineural deafness.

**Conclusions:** Long term HD in neonates and infants with ESRD, performed in the appropriate setting, is technically feasible, can be implemented without major complications, carries a very low rate of CVC infection and malfunction, and results in good nutrition, growth and survival. Future efforts should aim to improve neurodevelopmental outcome and lower mortality rate, especially in treated neonates.

**TH-PO1083**

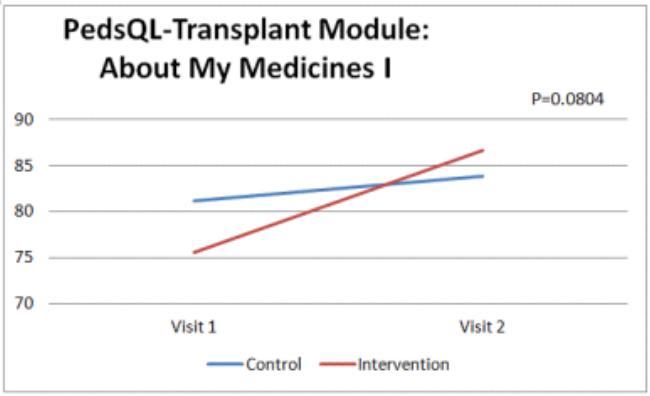
**Peers4PATH: Testing Peer Support as a Mechanism to Improve Transplant Outcomes among Adolescents with Solid Organ Transplants**
Sandra Amaral,[1,2] Nina Foster,[1] Amy Yang,[2] Justine Shults,[1,2] Susan L. Furth.[1,2] *[1]Pediatrics, Children's Hosp of Phila, Phila, PA; [2]Biostatistics and Epidemiology, Univ of Pa, Phila, PA.*

**Background:** Medication nonadherence contributes to inferior allograft outcomes among adolescents with solid organ transplants (SOT). Factors intrinsic to adolescence such as wanting to feel "normal" like peers may impact medication taking behavior. Peers4PATH

is an NIDDK-sponsored randomized clinical trial to examine peer mentoring as a means to improve medication taking behavior and health-related quality of life (HRQOL) among adolescents with SOT.

**Methods:** SOT recipients 14-23 years old at a single center are randomized to receive a gender- and race-matched peer mentor vs. usual care. Mentors meet in-person with mentees at 1, 6 and 12 months and communicate with mentees by phone, text, email or FaceBook at least once weekly. Mentors provide social support and positive role modeling. Primary outcomes are 1) change in percent medication adherence (by pharmacy refill data) and 2) change in HRQOL (PedsQL3.0 Transplant Module) over one year. Target enrollment is 60 subjects. This interim analysis examines initial feasibility and acceptability.

**Results:** Since April 2012, 30 subjects have enrolled: 17 kidney, 7 liver, and 6 heart transplant recipients. 14 subjects have completed six months of the study (5 intervention, 9 control). Thus far, mentees report that: "my mentor understands me", "is there for me" and "makes me feel important." Mentees (vs. controls) also report greater interim improvements in HRQOL related to problems with medication taking.



**Conclusions:** Peers4PATH is one of the first clinical trials to examine peer support as a means to improve medication adherence and HRQOL among adolescents with SOT. In its early phase, this study has shown feasibility and good acceptability by subjects. Further data are needed to assess the efficacy of the intervention.

## TH-PO1084

**Health Literacy in Caregivers of Children and Adolescents with Renal Transplant – Association with Adherence** Smitha R. Vidi, Tamar Y. Springel, Nataliya Zelikovsky, Susan L. Furth. *Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA.*

**Background:** Health literacy in caregivers and patients is associated with poor outcomes in multiple medical conditions. Little is known about health literacy in pediatric kidney transplant recipients and their parents. As poor adherence is linked to poor graft function and graft loss in solid organ transplant recipients, we sought to determine the association between lower health literacy and markers of poor adherence.

**Methods:** In this cross sectional study, we assessed the health literacy of 24 participants using validated measures; S-TOFHLA (Short Test of Functional Health Literacy in Adults), and REALM (Rapid Estimate of Adult Literacy in Medicine)-Teen & Transplantation. We compared the health literacy levels of adolescent patients and their parents based on S-TOFHLA and REALM scores. Adherence was measured both by self-report using MAM (Modified Adherence Module) and by calculating variability of immunosuppressant levels over a period of 6 months, by retrospective chart review. We used >2.5 standard deviation (SD) and >30% co-efficient of variation (CV) of immunosuppressant levels as markers of poor adherence, as shown in previous studies.

**Results:** Among 17 caregivers and 7 transplant recipients with median age 16.9 (IQR 15.7-19.7) yrs, all participants had adequate functional health literacy with S-TOFHLA scores >23. Five out of 24 participants (20%) had 7th/8th grade equivalent level of health literacy (REALM score:45-60) although they had higher levels of education. All participants had a MAM score of >20%, which indicated good adherence by self-report. Lower health literacy levels (REALM scores ≤ 61) was associated with >2.5 SD of immunosuppressant level in 4/7 and >30% CV in 5/7 participants. Comparing 5 adolescent patients and their parents, lower health literacy levels of either of them, is associated with significant variability in immunosuppressant levels (SD>2.5 and CV%>30).

**Conclusions:** Lower health literacy of both caregivers and adolescent kidney transplant recipients are associated with poorer adherence. Improving health literacy and using targeting interventions in this population may improve transplant outcomes.

*Funding:* Pharmaceutical Company Support - Fellowship support from an unrestricted educational grant from Amgen.

## TH-PO1085

**Transfer from Pediatric Nephrology to Adult Nephrology Goes along with Deterioration of Transplant Function** Christina Taylan, Michaela Gessner, Gesa Schalk, Rasmus J.C. Ehren, Lutz Thorsten Weber. *Pediatric Nephrology, Univ Hospital of Cologne, Cologne, Germany.*

**Background:** The transfer to adult nephrology implies a decisive turning point in the medical life of a patient in most cases.

**Methods:** We present data of 24 renal transplant recipients (21 ±4 years of age) who had been transferred to adult nephrologists between 2010 and 2012 (follow-up 24 – 3 months). Mean follow-up after renal transplantation (RTx) was 31 (6-113) months. The following parameters directly before transfer and the most recent follow-up were analyzed: retention values, number of rejections, blood pressure, change of medication, personal contentment with the actual situation, obtained through telephone survey.

**Results:** In 20/24 patients plasma creatinine levels had increased 0,65 (0,24 - 4,32) mg/dl. Five patients had to be hemodialyzed intermittently following the transfer, four of which were admitted back to the dialysis program. One patient died 1,5 years after the transfer from a PTLD. 7/24 patients had to be treated for acute rejection after transfer versus 4/24 before. Medication changes were numerous due to newly occurred acidosis, followed by changes in blood pressure medication. 19/24 patients were content, but reported a temporary sense of insecurity after the transfer.

**Conclusions:** Deterioration of renal function and increased risk of acute rejection after transfer underline the need for optimization of the transition process. The potential reasons for the described problems after transfer are manifold and comprise lower consultation frequency, higher expected self-reliance, limited team support, larger patient numbers etc. A refinanced standardized program for young adult chronic kidney patients might help the patients to reveal deficits in coping with their condition and prepare better for the transition to adult patient care.

## TH-PO1086

**Adherence to Cysteamine Therapy and Renal Outcomes in Cystinosis** Larry A. Greenbaum,[1] Ben Cadieux.[2] *[1]Pediatric Nephrology, Emory Univ, Atlanta, GA; [2]Raptor Pharmaceuticals, Novato, CA.*

**Background:** Early initiation and adherence to cysteamine therapy are essential in delaying progression to ESRD in cystinosis. Immediate-release cysteamine (IR-C) requires chronic, lifelong Q6H dosing. Objective measures of long-term adherence are challenging to quantify. Adherent patients are believed to significantly delay the onset of ESRD (beyond 10 yrs observed prior to cysteamine).

**Methods:** We examined 12 years (7/1/97 to 6/30/09) of Florida Medicaid claims to characterize IR-C adherence among cystinosis patients (ICD-9 270 and ≥1 IR-C claim).

**Results:** Among more than 7 million Florida Medicaid enrollees, we identified 12 pts (8 male) ages 1 to 22 years with cystinosis. Of these, 9 pts were born after FDA approval of IR-C: median age of diagnosis was 18 mos (range 11-42 mos). The majority (8/9) initiated IR-C within 3 mos of dx (delayed 14 mos in 1 pt). Duration of IR-C follow-up ranged from 11 mos to more than 11 yrs in 3 pts (total of 729 mos). Monthly refills for IR-C were skipped 296 times (41% of eligible months; ranged from 0 to 93%). Number of refill gaps averaged 1.3/yr (no gaps in 1 pt; <4 gaps in 4 patients; 12-25 gaps in 4 pts). Two pts appeared to have discontinued IR-C (gaps of 33 and 117 mos from last refill to last non-IR-C claim). Two pts reached ESRD at 9 and 11 years (skipped refill rates of 41 and 93%, respectively). Two pts reached CKD stage IV, each at 13 years (skipped refill rates of 22% and 53%, and each with an extended gap of 12 and 17 months, respectively).

**Conclusions:** Retrospective claims analysis provides a means of assessing adherence to cysteamine in patients with cystinosis. Adherence with IR-C in this small group of Florida Medicaid recipients with cystinosis is poor, and is associated with adverse renal outcomes. Future analysis will correlate adherence with health outcomes, and analyze changes in adherence following the recent introduction of delayed release cysteamine (q12h dosing formulation). Ongoing studies of adherence in this population are warranted.

*Funding:* Pharmaceutical Company Support - Raptor Pharmaceuticals

## TH-PO1087

**Trends in Hospitalizations, Emergency Room Visits and Economic Burden of Pediatric Nephrolithiasis** Kirsten A. Kusumi, Brian Becknell, Andrew L. Schwaderer. *Pediatric Nephrology, Nationwide Children's Hospital, Columbus, OH.*

**Background:** Nephrolithiasis poses a significant health burden with an approximately 10% lifetime risk and over 2 billion dollars in annual hospital charges for adults. The goal of this study was to examine national trends in hospitalization, emergency room utilization, secondary diagnoses, and charges associated with pediatric nephrolithiasis.

**Methods:** Nationally weighted data from the Kids' Inpatient Database of the Healthcare Costs and Utilization Project (HCUP) were evaluated from 1997-2009 for the total number of discharges, age, gender, length of stay, and hospital charges associated with nephrolithiasis. Secondary diagnoses were available on the basis of clinical classification software codes from 2003-2009. Data were also collected from the HCUP National Emergency Room Sample from 2006-2010 to yield the total number of pediatric Emergency Department (ED) visits associated with nephrolithiasis.

**Results:** The average number of pediatric discharges over the past 12 years with a primary diagnosis of nephrolithiasis increased by 30%. Mean hospital charges increased by 155% over this time frame, with aggregate hospital charges of $24,911,605 in 2009. 60% of patients were female, 47.5% were 15-17 years old, and length of stay was constant over this time period (2.3-2.7 days). Likewise, the number of pediatric ED visits increased by 13% from 359,771 in 2006 to 407,430 in 2010. The most common associated secondary diagnoses associated with nephrolithiasis between 2003-2009 were: urinary tract infections (628/4473, 14%); asthma (314/4473, 7%); epilepsy (180/4473, 4%); paralysis (178/4473, 4%). In 2009, secondary diagnoses of mood disorders and attention-deficit, conduct, and disruptive behavior disorders each occurred in 4% of children with nephrolithiasis.

**Conclusions:** Hospitalizations and inpatient health care charges associated with pediatric kidney stone disease continue to rise. Pediatric nephrolithiasis is associated with comorbid diagnoses of UTI, asthma, epilepsy, ADHD, disruptive behaviors and mood disorders. This raises the possibility that some of these conditions and/or medications used in their management may contribute to increased kidney stone frequency.

## TH-PO1088

**Urinary Stone Risk Factors in Pediatric Patients in Eastern North Carolina** Axita C. Patel,[2] Basema I. Dibas,[1] Guillermo Hidalgo,[1] Leonard Curtis Hymes,[1] Hsiao L. Lai.[1] *[1]Pediatrics, Div of Pediatric Nephrology, East Carolina Univ, Greenville, NC; [2]Undergraduate Honors College, East Carolina Univ, Greenville, NC.*

**Background:** The incidence of pediatric stone disease is rising. We hypothesized that the current trend of BMI elevation may be linked to increased urinary stone risk. Using Litholink 24-hr urinary analysis we identified stone risk distribution within pediatric patients in eastern North Carolina.

**Methods:** 143 consecutive Litholink collections from 100 patients obtained over a 2-year period from a single pediatric nephrology practice were analyzed with respect to BMI, gender and race. Indications for Litholink were history of kidney stone or findings of hematuria, hypercalciuria or crystalluria on spot urinary testing.

**Results:** The average age was 11 ± 4.2 years, 50% female, 56% White, 13% Black, and 27% Hispanic. 108 collections met volume adequacy criteria and were included in analysis. Prevalence of 3, 4, or 5 plus urinary risk factors were 32.4%, 15.7%, and 9.3%. BMI did not correlate with number of stone risk factors although male patients with BMI >85$^{th}$ percentile did have higher prevalence of uric acid supersaturation (17.6 vs 5.5%) compared to lean counterparts. Predominant risks were high urinary sodium excretion (69.4%), low urine volume (45.4%) and supersaturation of calcium phosphate (31.5%). Low urinary citrate was found in 38% of females and 22.2% of males, with especially high rate in Hispanic females (62.1%). Hispanic patients in general had lower supersaturation rates of calcium oxalate and calcium phosphate.

**Conclusions:** A high incidence of multiple urinary risks was observed, however we did not find the expected correlation of BMI with high urinary stone risk. The results of this study emphasize raising urine volume and lowering dietary sodium intake for all patients with stone risk. Hispanic patients appeared to have some protection against stone formation with lower urine saturation levels, but this was balanced by low urinary citrate levels. In female patients, especially Hispanic females, addressing low urinary citrate is a good strategy.

## TH-PO1089

**The Agony and the Ecstasy of a Career in Pediatric Nephrology** William A. Primack,[1] Larry A. Greenbaum,[2] Holly S. Ruch-Ross,[5] Suzanne Kirkwood,[3] Carrie Radabaugh,[3] Kevin E.C. Meyers.[4] *[1]UNC Kidney Center, Univ of North Carolina School of Medicine, Chapel Hill, NC; [2]Emory Children's Center, Emory School of Medicine, Atlanta, GA; [3]American Academy of Pediatrics, Evanston, IL; [4]Nephrology, Children's Hospital of Philadelphia and Univ of Pennsylvania, Philadelphia, PA; [5]Self Employed, Chicago, IL.*

**Background:** There is a shortage of pediatric nephrologists in the U.S., and close to 20% of trained pediatric nephrologists no longer practice pediatric nephrology (PN). Defining the perceived strengths and weakness of a career in PN may help to address this critical manpower shortage.

**Methods:** The AAP in collaboration with the ASPN sent an 88 item electronic survey in the Spring of 2013 to all physicians who are either working as pediatric nephrologists or were ever American board eligible in PN. One area of interest explored was: "How would you rate the following aspects of pediatric nephrology?" with completely positive rating=7 and completely negative=1.

**Results:** 500 responses were received (response rate 65.8%). 445 respondents provided data for this question.

| | mean | SD |
|---|---|---|
| intellectual stimulation | 6.53 | 0.76 |
| teaching opportunity | 6.03 | 0.98 |
| transplantation | 5.94 | 1.10 |
| critical care nephrology | 5.94 | 1.04 |
| academic setting | 5.59 | 1.27 |
| chronic dialysis | 5.59 | 1.24 |
| leadership opportunity | 5.07 | 1.38 |
| research opportunity | 5.04 | 1.51 |
| job opportunities | 4.81 | 1.54 |
| prestige | 4.71 | 1.41 |
| administrative | 4.64 | 1.29 |
| geographic distribution | 4.27 | 1.50 |
| hours worked | 4.06 | 1.74 |
| work-life balance | 3.85 | 1.65 |
| compensation | 3.61 | 1.56 |

**Conclusions:** Intellectual stimulation, the opportunity to teach, and the clinical areas of transplantation and critical care nephrology are the perceived strengths of a career in PN. However, cirtical lifestye issues such as work-life balance, compensation and hours worked are potent detractors. Efforts to address these issues may help to alleviate the shortage of pediatric nephrologists.

## TH-PO1090

**First-in-Man Study with BAY 85-3934 – A New Oral Selective HIF-PH Inhibitor for the Treatment of Renal Anemia** Michael-Friedrich Boettcher,[1] Silvia Lentini,[1] Andreas Kaiser,[2] Ingo Flamme,[3] Dagmar Kubitza,[1] Georg Wensing.[1] *[1]Clinical Sciences, Bayer Pharma AG, Wuppertal, Germany; [2]Global Biostatistics, Bayer Pharma AG, Berlin, Germany; [3]GTR-CH Acute Care Research, Bayer Pharma AG, Wuppertal, Germany.*

**Background:** Renal anemia is mostly caused by insufficient erythropoietin (EPO) synthesis in CKD patients. BAY 85-3934, a selective hypoxia-inducible factor prolylhydroxylase (HIF-PH) inhibitor, has shown to increase EPO dose-dependently in animal models thereby stimulating erythropoiesis.

**Methods:** This first-in-man study was a randomized, single-blind, placebo-controlled, group-comparison dose escalation study in healthy male subjects (18-45 years). Single oral doses of 5, 12.5, 25, 37.5 and 50 mg BAY 85-3934 PEG solution were administered to 12 subjects each (9 active, 3 placebo) to investigate safety, tolerability, pharmacokinetics and pharmacodynamics (EPO, reticulocytes, hemoglobin, and packed cell volume (PCV)).

**Results:** 59 (45 active, 14 placebo) subjects participated in the study. All 5 dosages were well tolerated. 14 subjects experienced 23 treatment-emergent adverse events (AE). 14 AEs were considered drug-related and all of mild intensity. The most common AEs were throat irritation (n=5) and headache (n=3). Frequency and quality of AEs were not related to dose. BAY 85-3934 was rapidly absorbed. Mean $C_{max}$ and AUC of BAY 85-3934 increased dose-proportional. Mean terminal half-lifes ($t_{1/2}$) ranged from 4.6 to 10.4 hours. The dose-dependent EPO increase resulted in a reticulocyte rise after 37.5 and 50 mg BAY 85-3934, whereas changes in hemoglobin and PCV were not measurable. Peak EPO values of 14.8 U/L (placebo; geo. mean) and of 39.8 U/L (50 mg) were observed about 12 hours post dose and reached baseline after approx. 24 hours. Vital signs, ECG and clinical laboratory parameters were not influenced.

**Conclusions:** The HIF-PH inhibitor BAY 85-3934 was well tolerated in healthy male subjects and EPO increased EPO dose-dependently, with a time course resembling the physiological diurnal variation of EPO. Therefore, it promises to be a valuable new treatment option for patients with renal anemia.

## TH-PO1091

**Effect of Different Doses of GQ-16, a Novel Partial Peroxisome Proliferator Activated Receptor Gamma Ligand, on Metabolic Parameters in Mice with Obesity and Insulin Resistance Induced by High Fat Diet** Alexandre Martini, Michela Soares Coelho, Francisco R. Neves. *Pharmaceutical Sciences Laboratory of Molecular Pharmacology, Univ of Brasilia, Brasilia, DF, Brazil.*

**Background:** Thiazolidinediones (TZDs) were used for the treatment of type 2 diabetes (T2D), and they act by activation of peroxisome proliferator-activated receptor γ (PPARγ). Despite their clinical efficiency, their use is limited by side effects such as weight gain and edema. This has prompted the search for novel PPARγ agonists with reduced side effects. We have previously described a novel partial PPARγ ligand (QG-16) with similar anti-diabetic efficacy as ROSI, yet in the absence of weight gain, in obese and insulin-resistant mice treated with GQ-16.

**Methods:** Mice were fed a normal-fat diet (NFD, 10% kcal fat) or HFD (60% kcal fat) since weaning. At the age of 16 wk, mice were randomly assigned into six groups and received GQ-16 (5, 10 or 20mg/kg/d), ROSI (4mg/kg/d) or vehicle by gavage daily for 2 weeks (groups: NFD, HFD, HFD+ROSI, HFD+QG+5, HFD+GQ+10 or HFD+GQ+20). Body weight (BW), BW gain, food, water and energy intake, metabolic efficiency, and fasting blood glucose were measured daily or weekly. Serum aspartate (AST) and alanine (ALT) transaminase levels were evaluated in adulthood. White adipose tissue (WAT) fat pad was excised and weighed for adiposity determination.

**Results:** BW, BW gain, WAT fat mass content, blood glucose and food intake were greater in the HFD group (BW: 67.4±2.2) compared to the NFD group (BW: 51.8±2.6g). AST and ALT transaminase levels did not differ among the six groups. GQ-16 treatment reduced BW and WAT fat pads in the HFD+GQ+20 group (BW: 45.9±3.2g), whereas ROSI treatment increased it (HFD+ROSI group, 74.1±3.6g). In HFD group, weight gain was reduced in all groups that treated with GQ-16, but increased by ROSI treatment. GQ-16 decreased blood glucose similarly to ROSI in the HFD+GQ+10 (91.3±1.4) and HFD+GQ+20 groups (85±5.5), when compared to the HFD group (123±6.4mg/dL).

**Conclusions:** Our results indicate that GQ-16 decrease blood glucose and visceral adiposity, modify body weight in mice with obesity and insulin resistance, with more favorable effects on weight, as compared to ROSI.

## TH-PO1092

**Therapeutic Monitoring of Serum Mizoribine (MZ) Concentration Is Effective for Preventing Adverse Events and Successive Engraftment in Renal Transplant Recipients** Kazufumi Iwata,[1] Kentaro Ueda,[1] Keiji Aizawa,[1] Kazuki Shimoishi,[1] Sachiko Jingami,[1] Eiko Fukunaga,[1] Hideyuki Saito.[2] *[1]Depts of Pharmacy, Japanese Red Cross Kumamoto Hospital, Kumamoto, Japan; [2]Dept of Pharmacy, Kumamoto Univ Hospital, Kumamoto, Japan.*

**Background:** MZ is an oral immunosuppressive agent for the prevention of rejection in renal transplantation. MZ exhibits a low incidence of cytomegalovirus (CMV) infection and severe adverse events, such as myelosuppression, hyperuricemia and hepatotoxicity, making it useful in long-term immunosuppression therapy. MZ is excreted predominantly in the urine (>80%), and its therapeutic window is considered to be set at 1.0 - 3.0 μg/mL

of trough serum concentration. However, the effectiveness of therapeutic monitoring of serum MZ has not been evaluated in practice. This study was to investigate retrospectively the relationship between serum MZ levels and adverse events in patients with renal transplantation.

**Methods:** Serum MZ concentration was determined in 12 male and 6 female recipients with renal transplantation, in those MZ was administrated once a day at an average dosage of 145 mg. The toxicity grade was evaluated by CTCAE version 4.0 criteria.

**Results:** The mean trough serum concentration of MZ in the whole recipients was2.5±1.7μg/mL. The significant relationship was found between the trough MZ level and serum creatinine (r=0.83), eGFR (r=0.65) and hemoglobin (r=0.63), whereas there was no correlation between the MZ levels and the data of white blood cell, platelet, uric acid, AST and ALT. The average trough level (3.7 μg/mL) of MZ in the recipients with >Grade 2 anemia was significantly higher than the level (2.3 μg/mL) in those with Grade 1/0 anemia. There was no recipient that experienced rejection or severe adverse events except for anemia. Two recipients with Grade 3 anemia was recovered by reducing the dosage or discontinue of MZ considering serum MZ levels.

**Conclusions:** In conclusion, therapeutic monitoring of the serum MZ level is suggested to be effective for maintaining the adequate serum levels to prevent both adverse events and rejection, as a clinical tool for personalized therapy in renal transplantation.

## TH-PO1093

### Analysis of 424 NEPharm Database Consultations on Drug Dose Adjustment in Kidney Patients

Belal Awad, Frieder Keller. *Internal Medicine 1, Nephrology, Univ Hospital, Ulm, Germany.*

**Background:** Half of all drugs and their metabolites are excreted renally and approximately 30 % of all adverse effects have a renal cause or a renal consequence [Arch Intern Med. 2005;165:790]. However, 70 % of all drugs lack any recommendation for dose adjustment in the case of renal dysfunction [Clin Pharmacol Ther. 2000;67:196].

**Methods:** We have been building up the NEPharm database since 1978 and have extracted 12,000 PubMed citations [Clin J Am Soc Nephrol. 2010;5:314]. Based on NEPharm, we have developed tables for dose recommendations (http://www.uni-ulm.de/nephrologie/fkd.html) and regularly receive consultant queries on drug doses which were evaluated here. The dose we recommend is generally targeting the peak level, for pharmacodynamic reasons. This was compared with the dose resulting from the proportionality rule according to Dettli [Ann Oncol. 2010;21:1395] where the individual dose (D) is obtained from the normal dose, the renally eliminated fraction (fren) and the individual glomerular filtration rate (GFR).

**Results:** In the period between 2002 and 2013, there was a total of 424 queries, 286 concerned cytostatic and anti-cancer drugs (68 %), 26 concerned anti-infective agents (6 %), 47 concerned other drugs (11 %) and 65 concerned the dosage table (15 %). Overall, queries came from 76 hospitals and from 130 physicians, of which 20 hospitals (26 %) and 30 physicians (19 %) also posed repeat queries. The number of queries increased by 8.6 times, from 8 in 2002 to 77 in 2012. Of the 359 queries regarding dose recommendations, 280 queries were for patients requiring hemodialysis (78 %), 9 queries for patients with peritoneal dialysis (2.3 %), 60 queries for patients with chronic renal failure (17 %) and a mean GFR of 45 +/- 19 ml/min. Compared with 100 % of the standard dose, our dose recommendation is 92 ± 16 %; by contrast, according to Dettli, it is only 69 % ± 19 % ($p < 0.0001$).

**Conclusions:** Based on pharmacodynamic considerations, we made individual dose recommendations which were higher than the porportional dose adjustment according to Dettli. Because of the increasing and repeated queries, it can be assumed, however, that the recommendations given were helpful.

## TH-PO1094

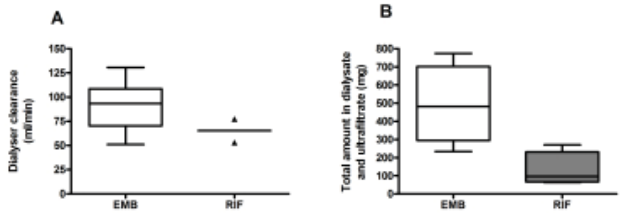
### Single and Multiple Dose Pharmacokinetics of Ethambutol and Rifampin in a Patient Undergoing Extended Daily Dialysis and ECMO

Ann-Kathrin Strunk, Julius Schmidt, Olaf Boenisch, Eva Schönenberger, Jan T. Kielstein. *Dept of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

**Background:** ARDS in tuberculosis is associated with an almost 100 % mortality, if acute kidney injury ensues. Dosing of tuberculostatic drugs is limited to outpatient dialysis. PK data for ICU patients receiving extended dialysis ED and ECMO are missing. We report single and multiple dose pharmacokinetics of ethambutol - EMB (renally cleared 80 %) and rifampin RIF under combined ED and ECMO.

**Methods:** A 42 year-old male (62 kg) i.v. drug user was admitted with progressive dyspnea and fever. Respiratory failure lead to intubation and ventilation. As adequate paO2 could not be achieved the patient was transferred to our center for ECMO support. Due to acute kidney injury extended daily dialysis (1.3 m² polysulfone dialyser, blood and dialysate flow of 230 ml/min, 10 hrs per day) was initiated. A bronchalveolar lavage yielded mycobacterium tuberculosis. Treatment with RIF (600 mg/d), EMB (1000 mg/d), pyrazinamid and moxifloxacin was started. Single and multiple dose PK were obtained. Diialyzer clearances were calculated. Amount of both drugs in the collected spent dialysate as well as pre and post the ECMO oxygenator were measured.

**Results:** EMB trough levels at 1000 mg/d were 1.5 mg/l, subtherapeutic (2-5 mg/l), promting the doubeling of the dose to 2000 mg/d. This lead to therapeutic levels of EMB (2.8-3.1 mg/l). Dialyser clearance of EMB was 91 ml/min, i.e. higher than previously reported A.



About 25% of EMB could be recovered in the spent collected Dialysate. There were no detectable effects of the ECMO membrane on the removal of both drugs.

**Conclusions:** Therapeutic drug monitoring is recommended for patients with mycobacterium tuberculosis infection undergoing renal replacement therapy as adherence to outdated dosing recommendations yields subtherapeutic plasma levels.

## TH-PO1095

### Optimized Dosing of Cefazolin in Patients on Nocturnal Home Hemodialysis

Marisa Battistella,[1,2] Robert M. Richardson,[1,2] Christopher T. Chan.[1,2] *[1]Univ Health Network, Toronto, Canada; [2]Univ of Toronto, Toronto, Canada.*

**Background:** The uptake of Nocturnal Home Hemodialysis (NHD) use is increasing; however the dosing of antimicrobials with this modality has not been described. We hypothesize that intensive hemodialysis will augment dialytic clearance of cefazolin, consequently, the dosing of cefazoin may need to be titrated appropriately. Subtherapeutic dosing may lead to treatment failure and microbiological resistance, while high concentrations of cefazolin may cause seizures. Our objective was to determine the pharmacokinetics of cefazolin during NHD and propose an appropriate dosing regimen.

**Methods:** We conducted a prospective, single arm pharmacokinetic study of cefazolin in 15 patients on NHD. Both blood and dialysate flow rates were set at 300ml/min. Patients received an intravenous dose of 2 grams of cefazolin over 30 minutes after their NHD. The following day patients were dialyzed at the NHD unit for 6 hrs and blood samples were drawn pre HD, 60, 180, and 360 (end of HD). Patients then received a second dose of 2 grams of cefazolin after HD and blood samples were drawn at the end of the 30 minute infusion, 30 and 60 minutes post infusion; dialysate samples were also drawn pre- HD, at 3 hours and then at the end of HD. Cefazolin levels were measured by HPLC.

**Results:** The mean age of the study population was 46+7.8 years; 9 males and 6 females were enrolled in the study. The mean percentage cefazolin removal by 6hrs of HD was 70±10% and clearance of cefazolin was 1.7±0.57 L/h while on dialysis; off HD, the clearance was 0.26±0.09 L/hr. Mean t½ of cefazolin on HD was 3.8±1.33h, while off HD, mean t1/2 was 23.2±4.5h. The volume of distribution was 9.0±2.9L.

**Conclusions:** Although 70% of the drug was removed during a 6 hour NHD session, serum drug concentrations remained above the target interval for microbiological eradication. Our study validates that 1 g of cefazolin dosed at the end of each dialysis is an appropriate approach to antimicrobial dosing in NHD. Monte Carlo simulation can now be utilized to design empirical dosing regimens that ensure the greatest probability of achieving the pharmacodynamic targets associated with maximal antimicrobial response.

### Gentamicin Dosing Protocol for Empirical Therapy in Hemodialysis Patients

Lavern M. Vercaigne,[1,2] Robert E. Ariano,[3,1] Sheryl Zelenitsky.[1,3] *[1]Faculty of Pharmacy, Univ of Manitoba, Winnipeg, Canada; [2]Manitoba Renal Program, Winnipeg Regional Health Authority, Winnipeg, Canada; [3]St. Boniface General Hospital, Winnipeg, Canada.*

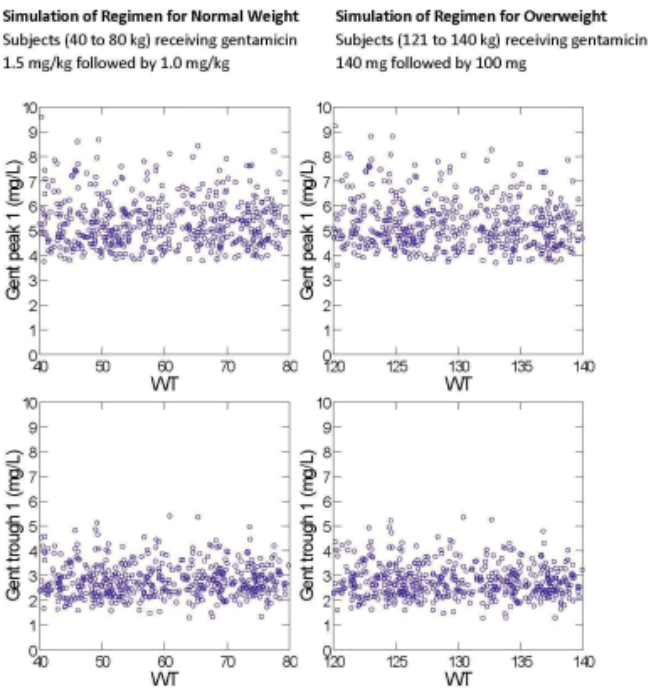
**Background:** Gentamicin is an important antibiotic for empirical treatment of Gram-negative infections in hemodialysis (HD) patients.

The goal of this study was to determine an effective and convenient empirical dosing strategy which avoids inadequate or excessive gentamicin exposure in overweight patients.

**Methods:** Monte Carlo simulation methods were used similar to those described previously *(Clin Infect Dis 2012;55:527) us*ing pharmacokinetics estimated from a population-pharmacokinetic model developed in the HD population *(Clin Pharmacokinet 2004;43:205).* The dosing regimen used by the Manitoba Renal Program (1.5 mg/kg load followed by 1.0 mg/kg post-dialysis) was tested as the baseline in subjects with normal body weights (40-80 kg). A dosing strategy to achieve similar gentamicin concentration profiles and exposures in patients with heavier body weights was determined (Table 1). Table 1.

| BODY WEIGHT (kg) | LOADING DOSE | SECOND DOSE (after next dialysis session) |
|---|---|---|
| 40-80 | 1.5 mg/kg | 1 mg/kg |
| 81-100 | 120 mg | 80 mg |
| 101-120 | 130 mg | 90 mg |
| 121-140 | 140 mg | 100 mg |

**Results:** The proposed dosing protocol provided very similar predicted peaks and troughs in patients ranging from 40-140 kg. Figure 1 shows first dose results for 500 simulated patients in the lower and upper weight categories. Figure 1.



As an index of gentamicin exposure, the $AUC_{0\text{-}48}$ (mg*h/L) was similar in the 40-80 kg group (180 ± 37 mg*h/L) compared with the 121-140 kg group (182 ± 38 mg*h/L).

**Conclusions:** The proposed dosing protocol provides similar predicted peak and trough gentamicin values in patients with body weights ranging from 40-140 kg. The protocol is suitable for empiric dosing of gentamicin over the first two HD sessions.

## TH-PO1097

**Clearance of Drugs for Multiple Myeloma Therapy during *In Vitro* High Cut-Off Hemodialysis** Detlef H. Krieter,[1] Eric Devine,[2] Christoph Wanner,[1] Markus Storr,[3] Bernd Krause,[3] Horst-Dieter Lemke.[2] *[1]Nephrology, Univ Hospital, Würzburg; [2]eXcorLab GmbH, Obernburg; [3]R&D, Gambro, Hechingen, Germany.*

**Background:** Current chemotherapy in multiple myeloma is based on bortezomib (BOR), dexamethasone (DEX) and thalidomide (THA). Purpose of the present study was to study their clearance during high cut-off (HCO) hemodialysis and to accordingly apply the results on the dialytic removal of protein-bound substances in general.

**Methods:** During *in vitro* hemodialysis with human blood (blood/dialysate/ultrafiltration flow rate 250, 500 and 5 mL/min, resp.) comparing a highly permeable HCO (Theralite™, 2.1 m²) to a high-flux dialyzer (HFHD; 2.1 m²), ultrafiltered volume was replaced by infusion of saline containing 30 g/L urea. After recirculation for equilibration, BOR was injected and arterial and venous samples were drawn after 10, 11 and 12 min to measure the plasma clearance (K) of both urea and BOR. The same procedure was performed with THA and DEX. By mathematical simulation, the influence of varying plasma albumin concentrations ($C_{HSA}$) on the protein bound drug fraction (PBF) and K was assessed.

**Results:** Plasma K of HCO and HFHD for THA, BOR, and DEX were about 40% (80±7 vs. 65±6 mL/min; P<0.05), 70% (40±8 vs. 33±4 mL/min; P<0.05), and 65% (47±11 vs. 38±7 mL/min; P<0.05), resp., lower (P<0.0001) compared to urea (125±7 vs. 122±5 mL/min). K was highest (P<0.0001) for THA. K negatively correlated with $C_{HSA}$ ($C_{HSA}$, THA, $r^2$=0.58, P<0.001; BOR, $r^2$=0.24, P<0.05; DEX, $r^2$=0.22, P<0.05). $C_{HSA}$ continually decreased (P<0.05) over time only with HCO resulting in lower calculated PBF. Compared to BOR and DEX (minimum 72 and 56%, resp.), the PBF of THA (37%) was much lower (P<0.001). Mathematical simulation based on K of urea and drug reliably estimated PBF ($r^2$=0.886, P<0.001).

**Conclusions:** Drugs for multiple myeloma therapy are significantly removed with both HCO and HFHD. This has important implications on the dosing and timing of application particularly in patients with cast nephropathy receiving extended dialysis. When knowing $K_{urea}$ of a dialyzer and the PBF of any given drug $K_{drug}$ can be reliably estimated by mathematical simulation.

*Funding:* Pharmaceutical Company Support - Gambro Dialysatoren

## TH-PO1098

**A Meta-Analysis of Extracorporeal Ultrafiltration versus Intravenous Loop Diuretics in Patients with Acute Decompensated Heart Failure (ADHF)** Fahad S. Alqahtani,[1] Khagendra Dahal,[2] Ioannis Koulouridis,[2] Maher Abulfaraj,[2] Paweena Susantitaphong,[3] Bertrand L. Jaber.[2] *[1]Robert C. Byrd Health Sciences Center, West Virginia Univ, Morgantown, WV; [2]Kidney and Dialysis Research Laboratory, Div of Nephrology, Dept of Medicine, St. Elizabeth's Medical Center, Boston, MA; [3]Extracorporeal Multiorgan Support Dialysis Center, Div of Nephrology, Dept of Medicine, King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

**Background:** The efficacy of ultrafiltration in patients with ADHF has been evaluated in several randomized controlled trials (RCTS) with conflicting results. We conducted a meta-analysis to assess the efficacy and safety of ultrafiltration compared to intravenous diuretics in hospitalized patients with ADHF.

**Methods:** We searched MEDLINE and EMBASE (through March 2013) and prior meta-analyses for RCTs comparing ultrafiltration/hemofiltration versus intravenous loop diuretic regimens. Random-effect model meta-analyses were used to examine several endpoints, including mean difference in fluid removal and weight loss, hospital length of stay and readmission, worsening of kidney function, and mortality.

**Results:** We identified 7 RCTs (578 patients). Fluid loss was significantly greater among patients receiving ultrafiltration compared to diuretics (-1998 mL; 95% confidence interval [CI] -3099, -897; P=0.0004). Weight loss was also significantly greater in among patients receiving ultrafiltration (-2.45 kg; 95% CI -4.01, -0.90; P=0.002). There was a non-significant trend toward a decrease in hospital length of stay (-2.4 days; 95% CI -5.12, 0.31; P=0.08), but there was no effect on more meaningful endpoints such as all-cause mortality (pooled risk ratio 1.05; 95% CI 0.68, 1.61; P=0.83), hospital readmission (P=0.86), and worsening of kidney function (P=0.39).

**Conclusions:** While extracorporeal ultrafiltration resulted in greater fluid and weight loss among hospitalized patients with ADHF compared to loop diuretics, other potential short- and long-term benefits of this invasive therapy could not be demonstrated.

## TH-PO1099

**Membrane Therapeutic Plasma Exchange (mTPE) Performed by Nephrologists: Early Technical and Clinical Experience** Casey N. Gashti. *Rush Univ Medical Center, Chicago, IL.*

**Background:** Separation of plasma using a highly permeable filter, referred to as mTPE, has undergone considerable investigation in Europe and Japan. Since nephrologists are well-trained in the management of extracorporeal blood purification and the advancement in technology has allowed performing mTPE using dialysis equipment, mTPE is gaining popularity in the US. We report our early single-center technical and clinical experience using hollow fiber plasma separator with dialysis equipment.

**Methods:** Data was prospectively collected on all pts receiving mTPE since program inception in January of 2013. Procedures used the Asahi Plasmaflo™ OP filter with the NxStage® System One™ machine. The mTPE was performed by dialysis technicians in cooperation with nursing staff. Albumin, Fresh Frozen Plasma (FFP) or a combination were used as replacement fluid (RF). Central venous access with targeted blood flow (QB) rate of 200 mL/min was obtained. The Filtration Fraction (FF) was monitored (RF/QB). Anticoagulation was not used for the significant majority of the procedures.

**Results:** A total of 200 mTPE procedures were performed in 41 pts over a five month period. The patients were 50±14 years old with a F:M ratio of 1.6:1. The pts had neurologic (44%), nephrologic including renal transplant (32%) and hematologic (17%) indications for therapy. RF was albumin in 57%, FFP in 38% and a combination of the two in the remaining treatments. Mean acheived QB was 179 mL/min. An average of 3746±909 mL of plasma was exchanged over 117±46 minutes (exchange rate of 35±10 mL/min). The average FF was 25%. Filter clotting was observed in 6% of treatments without the use of anticoagulation. This rate was similar (7%) in the small number of treatments that used anticoagulation (2 in 28 treatments). Paresthesia and cramping associated with FFP infusion was observed in 2% of all treatments. Hypotension was rare (1%). There were no central line-associated blood stream infections.

**Conclusions:** Nephrologists can safely and efficiently perform mTPE as an alternative to centrifuge-based therapeuic plasma exchange (cTPE). Advantages over cTPE include lack of anticoagulation and faster exchange rates, which could allow for shorter treatment time.

## TH-PO1101

**The Effect of N-Acetylcysteine on Methotrexate-Induced Nephrotoxicity: In Vitro Study in Renal Tubular Cells** Rikin Kartikbhai Shah, Ruchi Singh, Sudha P. Chennasamudram, Grant C. Weinheimer, Curtis W. Turner, Osvaldo Regueira, Tetyana L. Vasylyeva. *Dept of Pediatrics, Texas Tech Univ Health Science Center, Amarillo, TX.*

**Background:** High Dose Methotrexate (HDMTX) is effective treatment of childhood and adult cancers including acute lymphocytic leukemia, lymphoma and osteosarcoma (OS). Despite aggressive use of alkaline fluids and Leucovorin, renal dysfunction is a common side effect of the therapy. Mechanism of methotrexate(MTX) induced renal damage is unclear. MTX has been shown to increase the oxidative stress in rat kidney tissues. N-acetylcystiene(NAC) is a known antioxidant used in acetaminophen toxicity.Our objective is to evaluate the effects of N-acetylcysteine (NAC) on MTX induced toxicity in renal tubular cells and on MTX antitumor activity on the B- cell lymphoma cells.

**Methods:** Renal tubular cells (MDCK) and B-Lymphoma cells were exposed to MTX (10μM) alone and with NAC (2.5 mM). Reactive oxygen species (ROS) generation was measured by 2',7' –dichlorofluorescein diacetate (DCFDA) and flow cytometer. Percentage apoptosis was also measured using flow cytometer. Calorimetric measurement of GSH production was assayed by glutathione assay kit (Cayman Chemicals) as per manufacturer's instructions.

**Results:** Results are summarized in table below.

| Treatment | ROS generation in MDCK cells at 4 hrs | GSH generation in MDCK cells at 4 hrs | Apoptosis in MDCK cells at 24 hrs | Apoptosis in B-cell lymphoma cells at 24 hrs |
|---|---|---|---|---|
| MTX 10 μM | Increases | Increases | Increases | Increases |
| MTX 10 μM + NAC 2.5 mM | Significantly decreases then MTX alone | Significantly increases then MTX alone | Significantly decreases then MTX alone | No significant change |

**Conclusions:** NAC may prevent MTX induced renal tubular cytotoxicity by reducing ROS and increasing GSH production. Using NAC for kidney protection might not interfere with the anti-tumor activity of MTX. Further preclinical and clinical studies should be conducted to check this effect.

## TH-PO1102

### Safety, Tolerability and Efficacy of Febuxostat in Patients with Hyperuricemia and Severe Renal Impairment: A 24-Week Prospective, Open-Label, Non-Controlled Study

Yugo Shibagaki,[1] Iwao Ohno,[2] Tatsuo Hosoya,[2] Kenjiro Kimura.[1] *[1]Div of Nephrology and Hypertension, St. Marianna Univ Hospital, Kawasaki, Japan; [2]Div of Nephrology and Hypertension, Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** Hyperuricemia (HU) is a very common comorbid condition in patients with chronic kidney disease (CKD). The novel xanthine oxidase inhibitor, febuxostsat, has been shown to be efficacious and well tolerated in patients with HU. However, safety, tolerability and efficacy of febuxostat are not well determined in patients with HU and severe renal impairment.

**Methods:** We conducted a 24-week prospective, non-controlled study to investigate the safety, tolerability and efficacy of febuxostat in patients with HU and moderate to severe CKD (stage 3b to 5). 71 prevalent adult outpatients (55 males with average age of 66.3 years, N=18, 33, and 19 in stage 3b, 4, and 5, respectively) at two tertially care hospitals who met the inclusion criteria [serum urate > 8 mg/dl, estimated GFR (eGFR) < 45 ml/min/1.73m$^2$, non-use of urate lowering drug in the previous month] were recruited from November 2011 to April 2012. All the participant received febuxostat. Starting dose of febuxostat was 10 mg qd, increased to 20 mg, 40mg qd in week 4, and week 8, respectively. We observed during the study period the adverse events and adherence as a primary outcome and levels of serum urate as a secondary outcome.

**Results:** Baseline serum urate level (mg/dl) were 9.9, 10.6, and 9.8, in stage 3b, 4, and 5, respectively. 14 out of 71 participants (19.7%) were dropped out of the study. 8 adverse events (constipation, chest pain, edema, gout attack, palpitation, numbness, neuropathic pain, skin rash) occurred in 6 patients (8.5%). Out of 8 adverse events, 1 occurred in CKD stage 3b (5.6%), 5 in stage 4 (9.1%), and 2 in stage 5 (10.5%). Most adverse events were mild without permanent sequelae. Average serum urate in each stage of CKD reached below the target of 6 mg/dl by 8 weeks in stage 5, and by 12 weeks in stage 3b and 4. More than 70% of participants reached this target by 24 weeks.

**Conclusions:** Treatment of hyperuricemia with febuxostat was safe, tolerable and efficacious in patients with CKD stage 3b to 5.

## TH-PO1103

### Carcoxylesterase1 (CES1) Single Nucleotide Polymorphism (SNP) Significantly Reduces Mycophenolic Acid (MPA) Associated Leucopenia in Renal Transplant Recipients (RTR)

Natalie L. Borman,[1] Anthony Marinaki,[2] Gopalakrishnan Venkat-Raman.[1] *[1]Wessex Renal and Tranplantation Unit, Portsmouth; [2]Guy's and St. Thomas, London.*

**Background:** Mycophenolic acid precursors(MPAP) are widely used in transplantation. Leucopenia is a common side effect predisposing to severe infection. CES1/2 are thought to play a role in hydrolysis of MPAP to MPA and hence SNP in the genes may play an important role in activation/ tolerability of MPA. **Aim:**Examine associations of SNPs in CES gene and clinical response to MPAP following renal transplant(RTx).

**Methods:** 287 RTR were studied in first year post RTx for primary outcome measure of leucopenia defined as reduction in white cell count to<3.0 x10$^9$/L on 2 or more consecutive blood tests or a single test if resulted in change of MPA dose. Secondary outcome measure was time to leucopenia. Exome sequencing was carried out using Illumina Human exome Beadchip. Associations were sought between SNP's in CES gene and leucopenia.

**Results:** All participants received CNI(64.1% CyA, 35.9% Tac) and MPAP(91.3% MMF 8.7% MPS), 60.9% male, 93.4% Caucasian, mean age at RTx 47 years (range 17-79). Primary outcome frequency- 25.8%. Results were analysed using Fisher's exact test for allele frequency, dominant and recessive models. Logistical regression used to correct for potential confounders. Kaplan-Meier survival plot was produced for time to event analysis and Cox regression analysis to correct for confounders.

| Gene | Dom/rec | p value | P value post logreg | Exp(B) | 95%CI | %↓odd of event |
|---|---|---|---|---|---|---|
| CES1 | Dom | 0.02 | 0.008 | 0.46 | 0.26-0.82 | 54.2 |
| CES1 | Rec | 0.015 | 0.038 | 0.34 | 0.12-0.94 | 66.5 |
| **Time to Leucopenia KM Log rank** | **Coxreg Homozy vs wild** | **% risk reduction** | **Coxreg hetrozy vs wild** | **% risk reduction** | **Coxreg wild vs non-wild** | **% risk reduction** |
| p=0.008 | p=0.008 Exp(B)0.27 (95% CI 0.1-0.7) | 73 | P=0.02 Exp(B)0.55 (95% CI 0.33-0.91) | 44.9 | p=0.02 Exp(B)0.48 (95% CI 0.3-0.76) | 52.5 |

**Conclusions:** This SNP in CES1 is significantly associated with leucopenia in MPA treated RTR. Non wild phenotype significantly reduced risk of leucopenia and time to leucopenia. This SNP would appear to have important clinical implications in this cohort.

## TH-PO1104

### Influences of Single Nucleotide Polymorphisms (SNP) on Mycophenolic Acid Tolerance and Side Effects in Renal Transplant Recipients (RTR)

Natalie L. Borman,[1] Anthony Marinaki,[2] Gopalakrishnan Venkat-Raman.[1] *[1]Wessex Renal and Transplantation Unit, Portsmouth; [2]Guy's and St Thomas, London.*

**Background:** Mycophenolic Acid precursors(MPAP) are widely used in transplantation. Adverse drug reactions are dose dependent and improve with reduction/cessation, but with increased rejection risk and poorer long-term graft survival. Genetic variability accounts for 20-90% of the individual variation in response to immunosuppression. Given these challenges, interest is growing in the use of pharmacogenetics to individualise drug regimens **Aim:**To identify and investigate associations of SNP's with clinical response to MPAP in RTR.

**Methods:** 287 RTR were studied for primary outcome measures of biopsy proven acute rejection(BPAR) leucopenia(wcc<3) anaemia(Hb<10) gastro-intestinal side effects(GISE) and infection in the first year post transplant. Exome sequencing was carried out using Illumina Human exome Beadchip. Associations were sought between SNP's and primary outcome measures. Extensive clinical data was collected.

**Results:** All participants received CNI(64.1% Cyc A, 35.9% Tac) and MPAP(91.3% MMF 8.7% MPS) 60.9% male, 93.4% Caucasian, mean age at transplant 47 years(range 17-79). Primary outcome event rates were between 10.8 % and 34.5%. Results were analysed for associations between SNP's in candidate genes and primary outcomes. Fisher's exact test was used for allele frequency, dominant and recessive model analysis. Logistical regression was used to correct for confounders. 20 statistically significant results(P<0.05) were found in 13 SNP's across 3 genes(UGT, SLCO1B1, CES1). Associations were with SNP's and GISE, BPAR, anaemia, leucopenia and MPAP reduction. Example results are shown below, full results to be presented at conference.

| Gene | SNP | Event | P value | P value(log reg) | Exp(B) | 95% CI |
|---|---|---|---|---|---|---|
| UGT1A9 | 1 | GISE | 0.027 | 0.025 | 0.54 | 0.31-0.92 |
| SLCO1B1 | 2 | BPAR | 0.005 | <0.0001 | 4.37 | 1.93-9.89 |
| CES1 | 3 | WCC<3 | 0.02 | 0.036 | 0.46 | 0.26-0.82 |

**Conclusions:** This study has shown several SNP's in genes known to be associated with MPA metabolism/excretion have a significant and important impact on clinical outcome after renal transplantation.

## TH-PO1105

### Effect of Erythropoietin on Hepatic Expression and Function of Cytochrome P450 Drug Metabolizing Enzymes in an Adenine-Fed Model of Chronic Kidney Disease

David A. Feere,[1] Thomas Velenosi,[1] Anzel Hennop,[1] Brad Urquhart.[1,2,3] *[1]Schulich School of Medicine and Dentistry, Dept of Physiology and Pharmacology, Western Univ, London, Canada; [2]Lawson Health Research Institute, London, Canada; [3]Medicine (Clinical Pharmacology/Nephrology), Western Univ, London, Canada.*

**Background:** Chronic kidney disease (CKD) causes decreased hepatic drug metabolism secondary to a decrease in expression of drug metabolizing enzymes (DMEs). As kidney function declines, it loses the ability to produce erythropoietin (EPO) leading to anemia. Consequently, CKD patients are treated with recombinant EPO and the effect of this on hepatic drug metabolism is unknown.

**Methods:** Male Wistar rats were placed on an adenine (n=16) or chow diet (n=16) for 4 weeks prior to receiving 150U/kg IP injections of EPO or vehicle saline every other day for 2 weeks. Hepatic DME expression was determined by real-time PCR. Rat liver microsomes were isolated to assess enzymatic activity of cytochrome P450 DMEs. Testosterone was used as a probe substrate for CYP activity and resulting metabolites were quantified by ultra-performance liquid chromatography with PDA detection.

**Results:** CYP3A2 expression was significantly decreased in EPO treated rats relative to controls (P<0.01). Significant reduction in CYP3A2 expression was also seen in CKD and CKD EPO treated rats relative to both control and control EPO injected animals (P<0.05). CYP2C11 expression was significantly decreased, relative to control, in CKD and CKD EPO but not in EPO control animals (P<0.001). Maximal enzyme velocity of CYP3A was significantly decreased (P<0.05) in control EPO, CKD and CKD EPO groups relative to control (67%, 49% and 39% of control, respectively). CYP2C11 mediated metabolism of testosterone was significantly decreased (P<0.001) in the CKD and CKD EPO groups relative to control and control EPO (13% and 8% vs. 100% and 89% of control, respectively).

**Conclusions:** EPO administration causes a significant decrease in CYP3A2 mRNA expression and enzyme activity. Our data suggest that EPO and CKD both decrease hepatic drug metabolism and that EPO administration to manage anemia in CKD could affect drug metabolism and clearance of CYP3A substrates.

### TH-PO1106

**Expression and Function of Hepatic Drug Metabolizing Enzymes and Transport Proteins in End-Stage Renal Disease (ESRD)** David A. Feere,[1] Thomas Velenosi,[1] Melisa Gaspar,[1] Brad Urquhart.[1,2,3] *[1]Schulich School of Medicine and Dentistry, Dept of Physiology and Pharmacology, Western Univ, London, Canada; [2]Lawson Health Research Institute, London, Canada; [3]Medicine (Clinical Pharmacology/Nephrology), Western Univ, London, Canada.*

**Background:** Pharmacokinetics of several drugs are altered in end-stage renal disease (ESRD). Non-renal drug clearance pathways such as altered expression/activity of drug metabolizing enzymes and transporters have been implicated in rodent models of kidney disease however human data is controversial. In this study we assessed expression and function of hepatic drug metabolizing enzymes and drug transport proteins in liver samples from human patients with ESRD.

**Methods:** Liver samples were collected from ten recently deceased patients with ESRD and eleven recently deceased controls. Relative gene expression of drug metabolizing enzymes, transport proteins and nuclear receptors were determined by real-time PCR.

**Results:** P-glycoprotein, OATP1B1, BCRP and CYP2E1 expression were significantly decreased ($P<0.05$) in ESRD livers compared to control. Hepatic OATP1B3 expression was significantly increased in ESRD livers relative to controls ($P<0.05$). Significant decreases in nuclear receptor expression were observed for farnesoid X receptor, hepatocyte nuclear factor 4$\alpha$ and retinoid X receptor $\alpha$ ($P<0.05$).

**Conclusions:** Our results demonstrate that select drug metabolizing enzymes and transport proteins are down-regulated in ESRD. Current studies are evaluating protein expression and enzymatic activity of hepatic microsomes from ESRD patients using specific P450 probe substrates. Our results suggest that drug transporter activity may be especially impacted in ESRD and likely explains the decrease in non-renal drug clearance observed in patients with ESRD.

### TH-PO1107

**Midazolam and Fexofenadine Pharmacokinetics Are Altered in Patients with Chronic Kidney Disease** Brad Urquhart,[1,2] Benjamin Ka Thomson,[2] Thomas D. Nolin,[3] Thomas Velenosi,[1] David A. Feere,[1] Michael J. Knauer,[1] Linda J. Asher,[2] Andrew A. House.[2] *[1]Physiology & Pharmacology, Western Univ; [2]Medicine (Clinical Pharmacology/Nephrology), Western Univ; [3]Univ of Pittsburgh.*

**Background:** To clarify the impact of chronic kidney disease (CKD) on drug disposition, we investigated the pharmacokinetics (PK) of the CYP3A4 probe midazolam (MDZ) and the transporter substrate fexofenadine (FEX).

**Methods:** Healthy controls (HC, n=8), CKD patients with an eGFR of <40 ml/min/1.73m$^2$ (CKD, n=8), hemodialysis patients (HD, n=10) and nocturnal automated peritoneal dialysis patients (PD, n=8) were recruited. Patients were given 1 mg of MDZ IV and 120 mg of FEX PO. Serial blood samples were collected over 8 hours for determination of PK parameters.

**Results:** MDZ clearance (Cl) and volume of distribution (Vd) were significantly decreased in CKD (190.9+/-90.3 mL/min, 12.5+/-7.7 L) and HD (95.7+/-68.5 mL/min, 5.0+/-6.3 L), compared to control (283.3+/-77 mL/min, 31.5+/-22.2 L), respectively (Figure 1a, $P<0.05$). In PD patients the Cl (434.3+/-169.9 mL/min) and Vd (53.8+/-18.3 L) were significantly greater than HC, CKD and HD. There was no change in MDZ half-life or terminal elimination rate. FEX Cl and and half-life were significantly different in HD, PD and CKD patients compared to the HC group (Figure 1b, $P<0.05$).

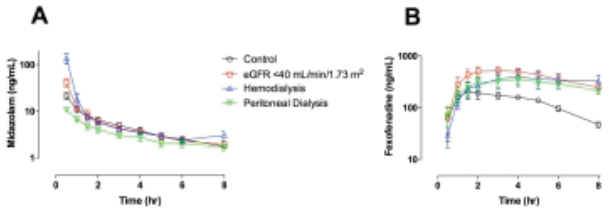


**Figure 1**

**Conclusions:** We show a significant reduction in MDZ Cl and Vd without changes in half-life suggesting decreased Vd and not hepatic intrinsic Cl alter MDZ PK in CKD. In addition, we show that the PK of MDZ is significantly different between HD and PD patients indicating that dialysis modality plays an underappreciated role in the PK of some drugs. In contrast, FEX pharmacokinetics are similarly altered in CKD, HD and PD patients. Collectively, our data indicate that dose adjustment for drugs that are not predominantly renally cleared warrants consideration in CKD.

### TH-PO1108

**Hepatic Drug Metabolizing Enzymes Are Downregulated by the Uremic Toxin Indoxyl Sulfate** Thomas Velenosi,[1] David A. Feere,[1] Andrew Kai Cheong Wong,[1] Brad Urquhart.[1,2] *[1]Physiology and Pharmacology, Western Univ, London, Canada; [2]Medicine (Clinical Pharmacology/Nephrology), Western Univ, London, Canada.*

**Background:** Patients with chronic kidney disease (CKD) require many medications to treat their CKD and associated co-morbidities. The majority of prescribed medications are metabolized by the drug metabolizing enzymes CYP3A and CYP2C. CYP3A and CYP2C expression is decreased in CKD; however the factors causing this downregulation are unclear. As kidney function declines, organic waste products accumulate in the blood resulting in uremia. It has been suggested that these waste products affect drug metabolizing enzyme function and expression. The objective of this study was to screen various uremic toxins to determine which toxin(s) affect hepatic drug metabolizing enzyme downregulation in CKD.

**Methods:** Huh7 human hepatoma cells were treated with selected uremic toxins as well as a cocktail of all selected toxins and CYP3A4 mRNA expression was determined. Male Wistar rats were given 0.1% indoxyl sulfate in their drinking water for 4 weeks. Hepatic drug metabolizing enzyme function and expression was determined in these rats.

**Results:** CYP3A4 mRNA expression was decreased when cells were treated with a cocktail of selected uremic toxins ($P<0.05$). Indoxyl sulfate (300 $\mu$M) was the only uremic toxin in the cocktail to independently decrease CYP3A4 expression resulting in a 51% decrease ($P<0.05$). Cell viability was unaffected at indoxyl sulfate concentrations routinely observed in CKD patients. Indoxyl sulfate treated rats had approximately 3-fold greater plasma indoxyl sulfate level than controls. Hepatic CYP3A2 and CYP2C11 mRNA levels were decreased 49% and 34%, respectively compared to controls. Results for the rat study are represented as n = 3 and are currently ongoing.

**Conclusions:** We demonstrate for the first time that the uremic toxin, indoxyl sulfate, causes downregulation of CYP3A and CYP2C hepatic drug metabolizing enzymes. Our results show that indoxyl sulfate causes a dose dependent decrease in CYP3A4 mRNA expression in human liver cells and may also affect hepatic drug metabolizing enzymes *in vivo*.

### TH-PO1109

**Tacrolimus Dose Requirement Based on the CYP3A5 Genotype in Renal Transplant Patients** Jianghua Chen. *Zhejiang Univ.*

**Background:** To determine CYP3A5*1 and CYP3A5*3 genotype could be the predictive index of tacrolimus dose requirement.

**Methods:** We tested archival peripheral blood of 69 kidney recipients for CYP3A5 genotyping with PCR-SSP. We measured the dose-normalized blood concentrations of tacrolimus at 1 and 2 months after the renal transplantation.

**Results:** The frequency of CYP3A5*1/*1 was 6/69, CYP3A5*1/*3 was 22/69, and CYP3A5*3/*3 was 41/69. CYP3A5*1 was associated with significant lower tacrolimus dose adjusted concentration at 1 and 2 months after transplantation. Hepatic and renal function showed no significant effect on tacrolimus dose adjusted concentration at 1 and 2 months after transplantation. Gender did not show a significant impact on tacrolimus dose. Carriers of CYP3A5*1 allele had lower predicted measures for tacrolimus dose adjusted concentration and higher predicted measures for volume of distribution.

**Conclusions:** These results indicate that CYP3A5*1 carriers need higher tacrolimus dose than CYP3A5*3 homozygote to achieve the target blood concentration. CYP3A5 genotyping is a new approach for detecting tacrolimus dose requirement in kidney recipients.

### TH-PO1110

**Influence of Kidney Function on Overanticoagulation Related Hemorrhage Risk in Warfarin Users** Nita A. Limdi,[1] Sarah Booth,[2] Thomas D. Nolin,[3] Marisa B. Marques,[1] Michael R. Crowley,[1] Michael Allon,[1] Timothy Mark Beasley.[1] *[1]Univ of Alabama at Birmingham; [2]Tufts Univ; [3]Univ of Pittsburgh.*

**Background:** Patients with chronic kidney disease (CKD) require lower warfarin dose, have poor anticoagulation control and a higher hemorrhage risk than those without CKD. Herein we evaluate if CKD patients have a differentially higher risk of hemorrhage associated with the episodes of over-anticoagulation (INR>4); and slower over-anticoagulation reversal rate.

**Methods:** We evaluated the influence of kidney function on over-anticoagulation and hemorrhage in 1270 warfarin users. Reversal of over-anticoagulation was evaluated in a subset of 79 patients. Warfarin and metabolite concentrations, clotting factors (II, VII, IX and X), and prothrombin induced in vitamin K antagonism (PIVKA-II) and INR levels were assessed at presentation with high INR and after reversal. The influence of the CKD-INR interaction on hemorrhage risk was assessed by Cox proportional hazards regression. The influence of CKD on anticoagulation reversal (rate of INR decline) was assessed using linear regression and path analysis. Multivariable analysis accounted for clinical (age, BMI, vitamin K dose) and genetic factors (CYP2C9, VKORC1, CYP4F2, GGCX) known to affect warfarin response.

**Results:** CKD patients experienced more frequent episodes of over-anticoagulation ($p<0.0001$) and a higher risk of hemorrhage ($p<0.0001$). The risk of hemorrhage was similar among patients with eGFR>60 and those with eGFR=45-59 ml/min/1.73 m$^2$, and was not modified by the INR at the time of the event ($p=0.79$). In contrast, the risk of hemorrhage was higher if the INR was >4 (vs. <4) for patients with eGFR 30-44 (HR 2.7; 95%CI 1.1-

6.9; p=0.03) and eGFR <30 ml/min/1.73m² (HR 5.2; 95%CI 2.6-10.7; p<0.0001) after adjustment for clinical and genetic factors. Finally, the adjusted rate of anticoagulation reversal was slower in CKD patients (p=0.018).

**Conclusions:** Impaired kidney function is associated with more frequent episodes of over-anticoagulation (INR>4) and a higher risk of hemorrhage in warfarin users. Moreover, reversal of over-anticoagulation is slower in patients with CKD, thereby prolonging their hemorrhagic risk.

*Funding:* Other NIH Support - RO1HL092173-S2; RO1HL092173, Pharmaceutical Company Support - Stago Diagnostica provided test reagents/ kits and consumables for analysis of clotting factors and Protein Induced by Vitamin K Antagonism-II (PIVKA-II)

### TH-PO1111

**Anti-Depressant Dose and Adverse Outcomes in Chronic Kidney Disease**
Varun Dev,[1] Stephanie Dixon,[1,2,3,4] Jamie L. Fleet,[2] Sonja Gandhi,[1,2,3] Amit X. Garg,[1,2,3,4] Ziv Harel,[7] Arsh Jain,[1,2,3] Salimah Z. Shariff.[1,4] *[1]Schulich School of Medicine, Western Univ, London, Canada; [2]Div of Nephrology, Western Univ, London, Canada; [3]Dept of Epidemiology and Biostatistics, Western Univ, London, Canada; [4]Institute for Evaluative Sciences, Canada; [5]Leslie Dan Faculty of Pharmacy, Univ of Toronto, Toronto, Canada; [6]Keenan Research Centre, Li Ka Shing Knowledge Institute, Toronto, Canada; [7]Div of Nephrology, Univ of Toronto, Toronto, Canada.*

**Background:** A lower dose of certain anti-depressants is recommended in patients with chronic kidney disease (CKD) to prevent drug accumulation from reduced elimination. In routine care this recommendation is often ignored.

**Methods:** We conducted a retrospective population-based cohort study to describe the 30-day risk of delirium and mortality in older adults from Ontario, Canada who initiated a higher vs. lower dose of three anti-depressants (paroxetine, mirtazapine or venlafaxine). We defined delirium using the proxy of hospitalization with an urgent head computed tomography (CT) scan. We also determined if CKD status modified the risk of delirium and examined 30-day all-cause mortality.

**Results:** We identified older adults (mean age 75 years) who started a new study anti-depressant at a higher dose (n=36,651; 31%) or a lower dose (n = 81,160; 69%) between 2002 and 2011. Initiating a higher vs. lower anti-depressant dose was not associated with a higher risk of hospitalization with head CT (incidence 1.09% vs. 1.27%; adjusted relative risk 0.90; 95% CI 0.80 to 1.02). This relative risk was not modified by the presence of CKD (interaction P value = 0.16). Initiating a higher vs. lower anti-depressant dose was associated with a lower risk of all-cause mortality (incidence 0.76% vs. 0.97%; adjusted relative risk 0.82; 95% CI 0.71 to 0.95). This relative risk was not modified by the presence of CKD (interaction P value = 0.68).

**Conclusions:** We did not observe an increase in adverse outcomes when study anti-depressants were initiated at a higher dose in patients with CKD. Contrary to our hypothesis, the 30-day risk of mortality was lower in patients initiating a higher dose.

### TH-PO1112

**Exposure-Response Relationship for Atrasentan in Patients with Diabetic Nephropathy**
Nael M. Mostafa, Chih-Wei Lin, Aksana Kaefer, Blai Coll, Dennis L. Andress, John J. Brennan, Cheri E. Klein, Walid Awni. *AbbVie, North Chicago, IL.*

**Background:** The pharmacokinetics (PK) and efficacy of atrasentan (ATR) in patients (pts) with diabetic nephropathy (DN) was studied in Phase 2 clinical trials (2 in Western and 1 in Japanese pts). The objective of this analysis was to characterize the exposure-response (ER) relationship between ATR concentration ($C_{ATR}$) and the decrease in urinary albumin to creatinine ratio (UACR).

**Methods:** A population pharmacokinetic (PPK) model for ATR was developed in NONMEM and utilized in the ER analysis using data (947 $C_{ATR}$ and 4709 UACR values) from pts with DN (N=257) who received ATR or placebo. The $C_{ATR}$ vs UACR ER model had additive terms for placebo (exponential) and drug effects (direct $E_{max}$). Likelihood ratio test was used for nested models comparison and visual predictive check (VPC) was employed for model qualification. Covariates were tested for their potential effect on ATR PK or ER.

**Results:** A two-compartment PPK model with first order absorption and elimination, fixed effects for weight on clearance (CL/F) and volume of distribution of the central compartment (V/F) and exponential inter-individual variability terms best described ATR PK. Mean estimates for CL/F and V/F were 17.5 L/hr and 1210 L, respectively. Structural parameters were well estimated with 5-48% relative standard errors (RSE) except for Ka. For the ER model, both $E_{max}$ and $EC_{50}$ for the $C_{ATR}$ vs UACR ER were well estimated (RSE 10-39%). The estimated $E_{max}$ corresponded to 46% drop in UACR and mean predicted $EC_{50}$ was 0.58 ng/mL. VPC for both PPK and ER models showed model adequacy as the majority of observations were within the 90% prediction interval of the simulated datasets. Study effect was not a significant covariate for PPK or ER models indicating that PK and ER are consistent between Western and Japanese pts.

**Conclusions:** A PPK model was developed for ATR PK and a statistically significant ER relationship between $C_{ATR}$ and UACR was characterized. ER analyses confirmed the efficacy of ATR in reducing UACR in DN pts with an estimated $E_{max}$ of 46% drop in UACR and mean predicted $EC_{50}$ of 0.58 ng/mL. ATR PK and ER relationship were similar between Western and Japanese pts.

### TH-PO1113

**Identification of SULF-2 by Transcriptome-Wide Sequencing as a Candidate Nephrosis Factor in Childhood Nephrotic Syndrome**
Richard F. Ransom,[1,3,4,8] Milan Popovic,[1,3] Audrey Carol Papp,[6,7,8] Amy Webb,[5,8] Saraswathi Sundararajan,[2,3] Shipra Agrawal,[1,3] Juan Luis Fernandez Martinez,[9] Rainer Benndorf,[1,3,4,8] Andrzej Kloczkowski,[2,3] Wolfgang Sadee,[6,7,8] William E. Smoyer.[1,3,4,8,10] *[1]Center for Clinical and Translational Research; [2]Battelle Center for Mathematical Medicine; [3]The Research Institute at Nationwide Children's Hospital; [4]Pediatrics; [5]Biomedical Informatics; [6]Pharmacology; [7]Program in Pharmacogenomics, Spain; [8]The Ohio State Univ; [9]Dept of Mathematics, Univ of Oviedo, Spain; [10]The Midwest Pediatric Nephrology Consortium.*

**Background:** Glucocorticoids (GC) induce remission of nephrotic syndrome (NS) in most children, though ~20% present with or develop GC resistance. This study was designed to identify candidate genes (nephrosis factors) that are associated with NS by comparing gene expression in circulating leukocytes between children with steroid-sensitive (SSNS) and steroid-resistant nephrotic syndrome (SRNS).

**Methods:** cDNA libraries were produced from mRNA from leukocytes collected at presentation (S1) and after the ~8 weeks of GC therapy (S2) from children with SSNS and SRNS. Deep sequencing yielded whole transcriptome sequencing data over a wide range of transcript expression. The collected complex data sets were then analyzed by statistical, 'Extreme Learning Machine' (ELM), and 'Particle Swarm Optimization' (PSO) approaches to obtain candidate nephrosis factors.

**Results:** Transcriptome-wide deep sequencing identified numerous known GC-regulated genes. Expression analyses by the ELM and PSO algorithms identified the gene "extracellular endoglucosamine-6-sulfatase 2" (SULF2) to be associated with clinical responsiveness to GC in these children. The biological relevance of these findings to NS was then confirmed by demonstration that the plasma SULF2 enzyme activity ratio (S2/S1) was greater in children with SSNS vs. SRNS.

**Conclusions:** SULF2 is a secreted enzyme necessary for full activity of a variety of growth factors, and known to be crucial for podocyte homeostasis. Our findings suggest that SULF2 may act as a "positive" nephrosis factor, where a deficiency in circulating SULF2 activity may result in the development of NS.

*Funding:* Other NIH Support - Supported in part by NIGMS U01 GM092655

### TH-PO1114

**Transcriptome Profile from Leukocytes of Children with Steroid Sensitive and Resistant Nephrotic Syndrome**
Shipra Agrawal,[1] Amy Webb,[2] Richard F. Ransom,[1] Audrey Carol Papp,[3] Milan Popovic,[1] Rainer Benndorf,[1,4] Wolfgang Sadee,[5,6] William E. Smoyer.[1,4,7] *[1]Center for Clinical & Translational Research, The Research Institute at Nationwide Childrens Hospital; [2]Biomedical Informatics; [3]Pharmacology; [4]Pediatrics; [5]Pharmacy; [6]Program in Pharmacogenomics, The Ohio State Univ; [7]The Midwest Pediatric Nephrology Consortium.*

**Background:** RNA-sequencing is emerging as a powerful tool for transcriptome analysis and identification of disease biomarkers. The present study aims to generate the transcriptome landscape from children with steroid sensitive and resistant nephrotic syndrome (SSNS and SRNS) and to explore its potential in identifying biomarkers for SRNS. This is important because ~20% of NS cases present with or develop resistance to steroid therapy, due to largely unknown reasons.

**Methods:** RNA-sequencing was performed with SOLiD™ technology from SRNS and SSNS leukocytes collected at disease presentation and after ~8 weeks of steroid therapy. After alignment with Lifescope, transcript expression was measured with Cufflinks. The Mann-Whitney U test was used to obtain candidate genes for expression differences associated with SRNS. Alternative transcripts were identified by splice junction alignment, SNPs detected by Samtools and AEI calculated. Databases and genes for steroid sensitivity/resistance in leukocytes and of relevance to NS are being integrated into the transcriptome data.

**Results:** Of 23,080 gene transcripts (including non-coding) studied, 4018 showed >1.4 fold ratio change between SRNS and SSNS. These included *PTGS2* and *CNTNAP3* (type of Neurexin), potentially relevant to NS, and *FKBP5* and *BMPRII,* which are associated with steroid sensitivity. 1109 genes were identified with alternative transcript expression, and 1908 SNPs were detected from 1234 genes with AEI >1.5 in >2 samples. The Mann-Whitney U test identified candidates associated with nephropathy or actin polymerization.

**Conclusions:** Generation of the transcriptome landscape for SSNS and SRNS has identified numerous differences among these groups along the varied parameters (i.e. expression, AEI, splice variants) and provides the potential to identify novel biomarkers for SRNS.

*Funding:* Other NIH Support - Supported in part by NIGMS U01 GM092655

### TH-PO1115

**Intravital Multiphoton Microscopic Imaging of the Effect of Chronic Kidney Disease on Hepatocellular Transport**
Brian S. Decker, Jennifer Ryan, Ken Dunn. *Indiana Univ School of Medicine.*

**Background:** Animal studies have shown that the uremic solutes of chronic kidney disease (CKD) attenuate CYP450 enzyme and hepatocyte transporter activity. These animal studies incubated hepatocytes with uremic serum and measured the extent of mRNA transcription of the specific CYP450 enzyme or drug transport protein. Though the cultured cells provide a reproducible system, they cannot duplicate the cellular interactions

that occur in living organisms. A more powerful research tool is intravital multiphoton microscopy (IVM) which provides direct visualization of drug transport and anatomic detail in live animals in a real-time fashion. The purpose of this study was to investigate the effect of uremia on hepatic drug transport in a validated animal model of CKD using intravital multiphoton microscopy.

**Methods:** Chronic kidney disease was induced in six Sprague-Dawley rats using a two-staged, five-sixths nephrectomy. Three Sprague-Dawley rats received sham surgeries and served as controls. On day 42 post surgery, the CKD and control rats were prepared for IVM. The IVM procedure consisted of anesthetizing the animals and exteriorizing the liver. Subsequently, each animal was placed on the microscope stage and injected intravenously with sodium fluorescein (Na-F) which is a probe for the OATP1 and MRP2 transporters. Intravital multiphoton fluorescence microscopy was then conducted using a Bio-Rad MRC-1024MP laser scanning multiphoton scanner. Hepatocyte uptake of Na-F was assayed using 3D imaging of two liver lobules in time series immediately after intravenous injection of Na-F. Uptake was quantified as the increase in fluorescence in the cytosol and secretion as the increase in fluorescence of the canaliculi over time.

**Results:** Six CKD rats and 3 control rats completed the study. We found no significant difference between the CKD and control rats in the mean fluorescence of sodium fluorescein over time in the hepatocyte cytosol and canaliculi.

**Conclusions:** We successfully utilized IVM to study the effect of uremia on hepatic drug transport in an animal model of CKD. CKD does not decrease the function of OATP1 and MRP2 transporters.

*Funding:* NIDDK Support

## TH-PO1116

**Renal Tissue Engineering Based on Decellularized Matrix Scaffolds** Barbara Bonandrini,[1] Marina Figliuzzi,[1] Evangelia Papadimou,[1] Marina Morigi,[1] Fabio Sangalli,[1] Ariela Benigni,[1] Giuseppe Remuzzi,[1,3] Andrea Remuzzi.[1,2] *[1]IRCCS - Mario Negri Institute, Bergamo, Italy; [2]Univ of Bergamo, Dalmine, Italy; [3]Papa Giovanni XXIII Hospital, Bergamo, Italy.*

**Background:** Chronic kidney disease is a leading cause of mortality and morbidity. New strategies to replace function of severely damaged kidneys are needed due to limited regenerative capacity and organ donor shortages. The concept of using decellularized animal kidneys for engineering a functional organ is a potential future treatment option. The aim of the present study was to produce three-dimensional whole-kidney scaffolds by a decellularization process and to recellularize the scaffolds with mouse embryonic stem (mES) cells under physiological perfusion condition.

**Methods:** We obtained whole organ scaffolds with intact 3D geometry and vasculature by decellularization of rat and porcine kidneys, as shown by histological examination. TEM and SEM analysis confirmed the preservation of kidney architecture. Micro-CT scan established integrity, patency and connection of the vascular network. Immunohistochemistry demonstrated preservation of native expression patterns of extracellular matrix proteins, including collagen IV, laminin and fibronectin.

**Results:** We repopulated acellular rat kidneys with mES cells seeding the cells through the renal artery and perfusion of cell medium for up to 3 days. Seeded cells were completely retained into the organ and uniformly distributed in arterial tree and in glomerular capillaries, without major signs of apoptosis. mES cells lined the luminal surface of arterial vessels and express endothelial markers. Occasionally mES cells reached peritubular capillaries and tubular compartment.

**Conclusions:** Our findings indicate that rat and porcine kidneys can be successfully decellularized to produce intact renal extracellular matrix scaffolds. These scaffolds maintain their basic components and show intact vasculature. We also demonstrated the ability of the decellularized matrix to support the engrafment of mES cells in a continuos perfusion system. This is an important step toward development of a tissue engineered kidney.

## TH-PO1117

**Aqp2 Is the Missing Progenitor Cell Marker of Renal Principal and Intercalated Cells** Lihe Chen,[1] Zhou Xiao,[1,2] Qiaoling Zhou,[2] Wenzheng Zhang.[1] *[1]Univ of TX Medical School at Houston; [2]Central South Univ.*

**Background:** While the renal principal and intercalated cells regulate the electrolyte/fluid and acid-base balance, respectively, the progenitors of these cells remain mysterious, because a specific lineage-tracing marker is still not available.

**Methods:** We developed an Aqp2-lineage tracing mouse model. These mice harbor a targeted mutation of the Gt(ROSA)26Sor locus with a loxP-flanked STOP cassette preventing transcription of a CAG promoter-driven red fluorescent protein (Rosa-RFP). They also carry an Aqp2Cre transgene that permits Cre expression under the control of Aqp2 regulatory elements. A series of double immunofluorescence staining experiments were performed.

**Results:** In adult mice, RFP labeled almost all of principal cells (Aqp2$^+$and Calbindin-D28k$^+$), and vast majority of intercalated cells (CAII$^+$, V-ATPase B1B2$^+$, AE1$^+$,and Pendrin$^+$) throughout the whole kidney. However, RFP was detected in none of cells positive for proximal tubule markers (Aqp1 and Megalin) and thick ascending limb marker (uromodulin); 2) At E14.5, Aqp2$^+$ cells were occasionally observed, with no or weak RFP expression; 3) At E16.5, RFP$^+$ cells formed tubular structures. In these tubules, most of RFP$^+$ cells expressed Aqp2, others lost Aqp2 and gained B1B2 and CAII expression. No RFP$^+$ Pendrin$^+$ or RFP$^+$ AE1$^+$ were found; and 4) At day 7 after birth, most of Pendrin$^+$ and AE1$^+$ cells in the cortex were RFP$^+$.

**Conclusions:** 1) RFP faithfully recapitulates the temporal and spatial expression pattern of the endogenous Aqp2; 2) Expression of Aqp2 is detectable at E14.5; 3) Aqp2-lineage cells give rises to Aqp2$^+$ principal cells and intercalated cells (V-ATPase B1B2+ and CAII$^+$) at E16.5; 4) Most of α-IC (AE1$^+$) and β-IC (Pendrin$^+$) are derived from Aqp2-lineage cells around day 7 after birth; 5) Aqp2 is the missing progenitor cell marker of renal principal and intercalated cells; and 6) The double transgenic mice (Rosa-RFP Aqp2Cre) is a valuable model to study cell differentiation under normal and pathological conditions.

**Activated Omentum Slows Progression of Chronic Kidney Disease** Ignacio Garcia-Gomez,[2,3] Nishit Pancholi,[2] Jilpa Patel,[2] Krishnamurthy P. Gudehithlu,[1] Perianna Sethupathi,[2,3] Peter D. Hart,[1,2,4] George Dunea,[1,2,3] Jose A.L. Arruda,[1,2,3] Ashok K. Singh.[1,2,3] *[1]Div of Nephrology, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL; [2]Hektoen Institute of Medicine, Chicago, IL; [3]Section of Nephrology, Univ of Illinois Medical Center at Chicago, Chicago, IL; [4]Internal Medicine, Rush Univ Medical College, Chicago, IL.*

**Background:** We examined whether attaching the omentum (a source of mesenchymal stem cells) to a subtotally nephrectomized kidney could slow the progression of chronic kidney disease.

**Methods:** Two groups of rats were studied, an experimental group which underwent 5/6 nephrectomy (removing left kidney and 2/3 of the remaining kidney), and a control group that underwent 5/6 nephrectomy as well as complete omentectomy. Polydextran gel particles were added intraperitoneally only in the experimental group in order to activate the omentum and facilitate its attachment to the injured kidney. Control omentectomized rats did not receive polydextran particles.

**Results:** After 12 weeks the experimental rats having omentum attached to the remnant kidney had 30% lower plasma creatinine and 50% lower urea nitrogen levels, 30% less glomerulosclerosis, 30% less tubulointerstitial injury, and reduced extracellular matrix and thickening of basement membranes. A fusion zone formed between the injured kidney and the omentum abounded in mesenchymal stem cells positive for sca-1, Wt-1 and CD 34, suggestive of an active and healing tissue. Kidney extracts showed a four-fold increase in VEGF levels at 1-4 weeks as well as significant increases of HGF and IGF-1 levels, increased number of proliferating cells especially at the injured edge, 2-fold increase of Wt-1 cells in the glomeruli and 5-fold increase in the gene expression for Wt-1.

**Conclusions:** These results suggest that the activated omentum attached to the injured kidney slowed the progression of chronic kidney disease. The effect appears to be brought about by the presence of stem cells and their secretory products in the vicinity of the injured kidney.

## TH-PO1119

**Stem Cells in the Repair of the Damaged Mesangium: An Ultrastructural Study** Jiamin Teng, Elba Turbat-Herrera, Guillermo A. Herrera. *Pathology, LSU Health, Shreveport, LA.*

**Background:** In previous studies our group has shown the role of stem cells in repairing the damaged mesangium in a model of light chain-mediated mesangial injury. Mechanistically, the stem cells selectively home to the damaged mesangial areas and proceed to repair them.

**Methods:** Rat kidneys (n=10) were procured and maintained physiologically intact using a perfusion model previously described by us. Using this ex-vivo renal perfusion system, the renal artery was perfused with purified glomerulopathic light chains (GLC) obtained from the urine of patients with renal biopsy-proven AL-amyloidosis and light chain deposition disease. 10 um/ml of purified light chains were used to perfuse the renal artery. The perfused GLC reached the mesangium and were allowed to interact with mesangial cells and surrounding matrix for 24 hours. Subsequently, mesenchymal stem cells were perfused through the renal artery. Tissue for light microscopic, immunofluorescence, and ultrastructural evaluation was obtained at different time frames up to 96 hours post-stem cell perfusion.

**Results:** Using transmission electron microscopy, stem cells were observed in glomerular capillaries and in the neighborhood of damaged mesangial areas where there was either amyloid or increased extracellular matrix. Furthermore, the light chains engaged in phagocytosis of amyloid and altered mesangial constituents, as they cleaned the damaged areas. With time, stem cells which normally have a very small amount of cytoplasm essentially devoid of organelles, were transformed into primitive mesangial cells as they acquired cytoplasm with contractile elements.

**Conclusions:** This study provides conclusive evidence of the crucial action of stem cells in the repair of the damaged mesangium. Stem cells are attracted to the damaged areas, clear the damaged mesangium, and differentiate into mesangial cells eventually laying down new mesangial matrix.

## TH-PO1120

**Repair and Regeneration of the Diabetic Kidney** Tariq Javed, Kuntal Mohare, Himanshu Vashistha, Leonard G. Meggs. *Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

**Background:** The adult kidney retains intrinsic regenerative potential, but the identity of adult stem cells remains in question. Src homology transforming protein 1 (p66) controls mitochondrial metabolism and cellular responses to oxidative stress, aging and apoptosis. Our working hypothesis is kidney mesenchymal stem cells (MSC) genetically deficient in p66 (p66$^{-/-}$MSC) will be resistant to senescent and apoptosis phenotype(s) associated with diabetes, participating in organ maintenance and repair through self renewal, autocrine/paracrine mechanisms and regenerative properties.

**Methods:** Akita ($Ins2^{+/C96Y}$) diabetic mice were crossed with $p66^{-/-}$ (KO) mouse to generate p66 KO-Akita mice. Kidney MSC were isolated and expanded in culture. By immunocytochemistry 90% of MSC expressed stem cell antigen-1 (Sca-1 ) but did not express hematopoietic markers c-kit, CD31,CD34, CD45, CD106.

**Results:** $p66^{-/-}$ MSC show no increase in ROS metabolism, when maintained at high ambient glucose (HG), whereas wild type (WT) MSC show robust ROS signal. Growth curves for WT MSC at HG, were markedly attenuated by day 6. By contrast, $p66^{-/-}$ MSC remained in active growth phase up to 12 days. Consistent with this analysis, WT MSC show upregulation of senescent associated proteins (p21, p53 and $p^{16INK4a}$), DNA damage and apoptosis; all of which were suppressed $p66^{-/-}$MSC. We identified $Sca\text{-}1^{+}CD45^{-}lin^{-}$ MSC and $Ki67^{+}$ cells in kidneys of p66 KO Akita, but these cells were rarely encountered in WT and Akita. Senescent phenotypes associated with diabetes (glomerulosclerosis; interstitial fibrosis; tubular atrophy), were barely detectable in p66 KO Akita, with near normalization of urine albumin excretion (UAE), whereas in Akita, kidney lesions and UAE were substantially increased.

**Conclusions:** Kidney MSC genetically enhanced by p66 null mutation offer a potential strategy to repair and regenerate the diabetic kidney.

### Bone Marrow-Derived Mesenchymal Stem Cells Transplantation Repairs Glomerular Podocytes in Mouse with Puromycin Aminonucleoside-Induced Nephrosis

Jian-Xin Wan. *Nephrology, The First Affiliated Hospital of Fujian Medical Univ, Fuzhou, Fujian, China.*

**Background:** To investigate the effects of bone mesenehymal stem cells (BMSCs) on nephropathy of glomeruli in puromycin amino nuclear glucoside (PAN) nephritic mice models.

**Methods:** Isolating bonemesenehymal stem cells from the bone of mice. The model of mice was established by PAN. Then the mice were randomly divided into three groups: Control group, PAN group and BMSCs group. The 24-hour urinary protein was obtained from each group after modeling, and urinary protein excretion was determined. The mice were killed for the blood samples and kidney specimens after the tenth day of modeling. The blood sample were collected for measuring Scr and Bun. The one part of kidney specimens was taken for observing the pathological changes by HE staining and electronmicroscope and the other part is for detecting the expression of the protein and mRNA of Nephrin, CD2AP, synaptopodin, TRPC6 by the methods of real-time quantitative PCR, western-blot and immunohistochemistry.

**Results:** After tail vein injection of PAN (0.5 mg/g) into the BALB/C mice, foot process fusion phenomenon was detected by electron microscopy, and the 24hr urinary protein excretion increased significantly than control mice on day3, day7 and day10 ($P<0.05$). The fusion of foot processes in glomerulus was ameliorated after the transplantation of BMSCs, and the 24hr urinary protein decreased ($P<0.05$). The expression of nephrin, CD2AP, synaptopodin in the glomerular slit diaphragm (SD) were up-regulated than PAN nephropathy model mice ($P<0.05$) while TRPC6 was down-regulated ($P<0.05$).

**Conclusions:** Administration of PAN induced foot process fusion and proteinuria, thus successfully established minimal change nephropathy models. BMSCs transplantation could reduce foot process fusion and urine protein, and protect the podocyte damage caused by PAN.

## TH-PO1122

### Methodology for Decellularization and Cell Seeding of Pig Kidneys for Tissue Regeneration

Edward A. Ross,[1] Bradley J. Willenberg,[1] Jose Antonio Oca Cossio,[1] William L. Clapp,[1] Naohiro Terada,[1] Dale R. Abrahamson,[2] Gary W. Ellison,[1] Chris Batich.[1] *[1]Univ of Florida, Gainesville, FL; [2]Univ of Kansas, Kansas City, KS.*

**Background:** Models in our and most investigations of seeding cells into acellular whole organ scaffolds for tissue regeneration have used rodent kidneys. For human applications, however, there is a paucity of research decellularizing swine kidneys, which due to their larger size present logistic difficulties. The vasculature and collecting systems need to be kept intact so that they can be populated separately without leakage and mixing of cells of different lineages.

**Methods:** We tested modifications of rat decellularization techniques in pigs using ranges of: ages and weights; ionic and nonionic detergent concentrations; positive and negative pressures; and flow rates. Antegrade arterial and retrograde ureteral seeding was studied to optimize pressure flow parameters using red and green fluorescent microspheres (10 μm polystyrene) or cells (HeLa and mouse lung fibroblasts). Architecture preservation and seeding efficacy were studied by fluorescence and light imaging using fresh and fixed tissue samples.

**Results:** Histology showed optimal decellularization was obtained using a 3 day protocol with serial 1% Triton X100 and 0.75% SDS, water rinses and DNase. Larger organs needed further time to remove residual detergents. Fluid limited to approx 40 mm Hg and 800 ml/hr was safe and effective for pig ages 2 wk (5kg), 8 wk (15 kg) and adults (45 kg). Particulate seeding was accomplished with positive pressure of 60 mm Hg, but was improved by applying 80 mm Hg vacuum: imaging proved that they could reach (antegrade) the glomerular tufts and (retrograde) Bowman's space. Histology confirmed preservation of architecture and did not show leakage from the vascular and collecting system compartments nor mixing of those constituents with these pressure and flow parameters.

**Conclusions:** With the ultimate goal of xenotransplantation using swine scaffolds and human cell seeding, we have developed techniques for decellularization that preserve delicate architecture and allow the vascular and collecting systems to be repopulated separately, and then incubated for cell growth.

## TH-PO1123

### Role of AT1 and AT2 Receptors in AFSC Mediated Podocyte Preservation

Sargis Sedrakyan, Astgik Petrosyan, Stefano Da Sacco, Roger E. De Filippo, Laura Perin. *Urology, Children's Hospital Los Angeles, Los Angeles, CA.*

**Background:** Emerging evidence strongly support the notion of podocyte depletion as a major mechanism driving glomerulosclerosis. We have previously demonstrated that stem cells derived from amniotic fluid (AFSC) significantly slow down chronic kidney disease progression in x-linked alport syndrome (XLAS) mice via preservation of podocyte numbers among other mechanisms. We hypothesize that AFSC protect podocyte injury through blockade of angiotensin II (Ang II) actions in podocytes acting through Ang II receptors types I (AT1) and II (AT2) with involvement of integrin linked kinase (ILK) and downstream elements of Wnt/b-catenin signaling pathway.

**Methods:** Primary cultures of glomerular cells, mainly podocytes were subjected to Ang II exposure for 4 hours then treated with AFSC. Cell characterization and gene expression were evaluated by Immunohistochemistry and qPCR. In vivo, $Col4a5^{-/-}$ XLAS mice were injected with AFSC. Whole kidneys, glomeruli and glomerular cells derived from injected mice were harvested and analyzed by qPCR, immunohistochemistry and western blotting.

**Results:** Ang II upregulated Glycogen synthase kinase-3 (GSk3b) and b-catenin in glomerular cells and downregulated tight junction proteins heavily present in podocytes such as nephrin and p-cadherin which was mitigated in the presence of AFSC. **Activation of this pathway involved both AT1 and AT2 receptors and blockade of one or the other resulted in a dampening of the response.** In vivo, injection of AFSC in Alport mice resulted in a significant downregulation of ILK protein levels at 10 weeks post treatment. More specifically, in glomeruli injected with AFSC lower expression of ILK was detected when compared to a non-treated sibling, indicating that AFSC regulates ILK expression in glomerular cells including the podocyte. Treated kidneys also had less presence of b-catenin at protein level.

**Conclusions:** AT1 and AT2 receptors play a significant role in mediating Ang II induced podocyte injury. Taken together our data suggest that AFSC contribute to podocyte preservation by preventing the activation of Ang II receptors, which trigger injurious mechanisms that result in podocyte depletion.

## TH-PO1124

### Development of Renal Regeneration with Human Renal-iPS Cells Using Epigenetic Memory

Osamu Takase, Keiichi Hishikawa. *Dept of Advanced Nephrology and Regenerative Medicine, Graduate School of Medicine, Univ of Tokyo, Tokyo, Japan.*

**Background:** We have investigated about the renal regeneration with human Renal-iPS (R- iPS) cells using epigenetic memory. Recently as epigenetic memory, it has been suggested that iPS cells derived from specific tissue is easy to differentiate into the original cells. We have already established original three R-iPS cells derived from tubular cells, mesangial cells, and proximal tubular cells. On DNA-methylation analysis in epigenetics, these R-iPS cells were different DNA-methylation from Fibroblastic-iPS (F-iPS) cells.

**Methods:** Here we investigated whether R-iPS cells were tendency to differentiate toward kidney of the source. As the differentiated-iPS cells, cells were cultured on conditional DMEM medium without basic-FGF and feeder cells. We studied the undifferentiated and differentiated makers in each iPS cells. Further to modify epigenetics, iPS cells were pre-treated with HDAC inhibitor (TSA). As application to in vivo, each iPS cells were injected into renal surface of SCID mouse.

**Results:** All R-iPS cells were not change the colony formation and increased in undifferentiation markers such as ALP staining, Oct3/4, and NANOG expression as compared with F-iPS cells. Differentiated-iPS cells lost undifferentiation character and expressed differentiation markers, especially Tubular-iPS cells expressed strongly the kidney-associated markers such as Pax-2, Sall-1, and AQP1. Further to pre-treat with TSA, Pax-2 and Sall-1 expression were further induced in Tubular-iPS cells. Interestingly in teratoma formation into the kidney, the injected Tubular-iPS cells differentiated into the renal component like glomerulus, and were increased in the expressions of AQP1, nephrin, and Epo, which are the specific kidney-associated markers.

**Conclusions:** Our results have suggested that the R-iPS cells differentiated advantageously toward kidney. We expect that R-iPS cells can treat to various CKDs and end-stage renal failure. Also the research with iPS cells using epigenetic memory may bring new strategy for various regenerative medicines.

**TH-PO1125**

**Developmental Expression of Stem Cell Factor Receptor c-kit Is Lost in Adult Renal Cortex, but Detected following Renal Injury in Glomerular Cells** Jan Sradnick,[1] Anika Luedemann,[1] Vladimir T. Todorov,[1] Michael Kotlikoff,[2] Christian Hugo,[1] Bernd Hohenstein.[1] *[1]Div of Nephrology, Internal Medicine III, Univ Hospital CGC, TU Dresden, Germany; [2]Biomedical Sciences Dept, College of Veterinary Medicine, Cornell Univ, Ithaca.*

**Background:** Stem cell factor receptor c-kit is a central marker of hematopoietic stem cells (HSC) and we previously showed that HSC are recruited to the kidney upon injury. c-kit was described as a marker of resident stem cells in the heart. c-kit expression has been studied in prenatal mice and can be detected in the renal medulla (collecting duct). Less is known about the localization and fate of c-kit expressing cells after birth and during renal injury. We now used c-kit eGFP transgenic mice to investigate expression patterns of c-kit positive cells in the kidney and after endothelial injury.

**Methods:** We studied c-kit eGFP transgenic mice during late renal development in healthy adult mice and after selective endothelial injury. Mice were sacrificed 4-6 days post-partum, and control and injured 10 week old mice were examined 1, 3 and 5 days after selective endothelial injury using the ConcanavallinA (conA)/anti-conA model. Kidneys were perfused with PFA and harvested for further assessment.

**Results:** Around day 5, a large set of cortical renal cells demonstrated c-kit expression. Many c-kit+ cells could be found in the medulla, which was described before in renal development. Tubules as well as cells of Bowman's capsule and many glomerular cells expressed c-kit, while adult mice lack c-kit+ cells in the cortex and glomeruli (except collecting duct cells). Following renal injury, c-kit positivity could be detected in tubules and glomeruli, localized in endothelial and podocytic positions. In addition, c-kit+ cells were also detected outside tubules along peritubular capillaries.

**Conclusions:** Many renal cells express c-kit during development, while adult mice virtually lack c-kit+ cortical cells. After injury, c-kit+ cells increased, which is consistent with our previous data on c-kit+ HSC using FACS analysis. Whether these c-kit+ cells immigrate from outside or consist of c-kit expressing resident renal cells needs to be clarified.

**TH-PO1126**

**Endothelial Progenitor Cells Recruited to the Kidney Do Not Originate from Bone Marrow** Jan Sradnick, Anika Luedemann, Lisa Maria Magyar, Charlotte Starke, Vladimir T. Todorov, Christian Hugo, Bernd Hohenstein. *Div of Nephrology, Internal Medicine III, Univ Hospital CGC, TU Dresden, Germany.*

**Background:** Recent literature implies that bone marrow (BM) derived endothelial progenitor cells (EPC) might participate in repair upon renal injury. Most of this data are based on *in vitro* experiments. We have previously shown that mainly endothelial outgrowth cells (EOC, ECFC) can be detected in the kidney after selective endothelial injury. To investigate the origin of such cells *in vivo*, we induced chimeric mice via BM transplantation to trace these cells.

**Methods:** BM cells were isolated from 8-10 week old ubiquitous tdTomato expressing reporter mice. Recipients were C57Bl6 mice of the same age. Endothelial injury was induced 6-8 weeks later in 20 of the 25 chimera. 5 mice were used as controls. Kidney, spleen, blood and BM were harvested on days 1, 3, 5 and 7 (n=5 per group) and analyzed using multicolor FACS-analysis and histology. EPC/ECFC (CD34, Flk-1, CD31, CD105, CD146, CD45, CD133, CD115, CD14), hematopoietic stem cells (c-kit+ Sca-1+ lin-), macrophages (F4_80+ CD11b+ CD11c- GR1-), dendritic cells (CD11c+ CD11b+ GR1-), B-cells and T-cells were measured using FACS-analysis.

**Results:** In injured kidneys the percentage of macrophages (d3: 0.5% vs ctrl: 0.1%), dendritic cells (4.4% vs 1.5%) and T-cells (CD4 0.7% vs 0.2%; CD8 0.3% vs 0.05%) increased significantly on d3 ($p<0.05$). B-cells were unchanged. ECFC were increased on d3 (1.7% vs 0.4% $p<0.001$) and HSC on d1 (0.6% vs 0.2% $p<0.05$). Compared to controls, significantly more tdTomato positive cells were recruited to injured kidneys (d1-d7: 4.3-8.3% vs 2.0%. Almost all macrophages (94.4%±6.4), dendritic cells (96.6%±1.5), neutrophils (99.7%±0.4) and B-cells (99.2%±0.7) were tdTomato positive, while only the minority of T-cells (CD4 34.5%±12.3; CD8 42.0%±11.0) and HSC (14.7%±11.0) were tdTomato positive. Basically none of the ECFC (0.3%±0.7) recruited to the kidney were tdTomato positive.

**Conclusions:** The present study demonstrates that EPC recruited to the kidney are not of BM origin, while HSC might partially emanate from BM. Further studies will have to define the niche for these stem cells in or outside the kidney.

**TH-PO1127**

**Sequential Activation of mTOR Network Components Determines Progression of Vascular Calcification** Theres Schaub,[1] Bjoern Hegner,[1] Claudia Lange,[2] Tobias B. Huber,[3] Duska Dragun.[1] *[1]Charité Universitätsmedizin Berlin; [2]Univ Medical Center Hamburg; [3]Univ Medical Center Freiburg.*

**Background:** Conversion of mesenchymal stromal cells (MSC) towards osteoblast like phenotype is instrumental for the development of uremic calcifying vasculopathy. mTOR kinase contained in mTOR complex 1 (mTORC1) and mTOR complex 2 (mTORC2) translates microenvironmental signals into cell differentiation responses and controls cell fate including authophagy and apoptosis. We hypothesized distinct roles of mTORC1 and mTORC2 during osteoblastic transformation of MSCs and examined temporal sequence of mTOR signaling operative in cell fate programs. In addition, we studied when and how pharmacologic mTOR targeting with Rapamycin (rapa) may interfere with these processes.

**Methods:** Human MSC were cultured in osteoblast induction medium with or without rapa. Osteoblastic differentiation, calcium deposition, induction and modulation of mTORC1 and mTORC2 signaling, cellular senescence, autophagy, and apoptosis were assessed every 3rd day.

**Results:** Induction of cellular senescence as indicated by elevated levels of p16INK4a in parallel to dormant autophagy was the earliest events accompanied by increased mTORC1 (Thr389pp70S6) and low mTORC2 (Ser473pAkt) activity. Alkaline phosphatase, a key enzyme of osteoblast differentiation, rose to a peak after 15 days paralleled by deposition of calcified extracellular matrix starting at day 6. Rapa treatment blocked mTORC1 activity while increasing mTORC2 activity resulting in inhibition of senescence and apoptosis and induction of autophagy. Rapa attenuated and delayed osteoblast differentiation with calcium deposition. Abrogation of mTORC2 by lentiviral shRNA transfer reversed protective effect of rapa by induction of apoptosis and increased extracellular calcium content.

**Conclusions:** Our findings reveal induction of mTORC1 and deregulation of mTORC2 signaling as early events closely linked to activation of different cell fate programs operative during osteoblastic MSC transformation. Modulation of mTOR signaling with rapa may evoke induction of alternative cell fate sequences and confer protection from accelerated osteoblastic transformation occurring during uremic vasculopathy.

**TH-PO1128**

**Cellular Characterization of Nephron Regeneration after Acute Kidney Injury in the Zebrafish** Kristen K. McCampbell, Rebecca A. Wingert. *Dept. of Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

**Background:** Acute kidney injury (AKI) is a devastating and often lethal condition in which kidney nephron cells are destroyed by damage from ischemia or toxin exposure. While nephron epithelial cells can regenerate after some forms of damage, there is currently a poor understanding of the cellular and molecular events that mediate nephron regeneration.

**Methods:** The zebrafish is an attractive and viable system to study the molecular pathways responsible for nephron regeneration, as its nephrons are simple, yet they maintain the biological complexity inherent to that of higher organisms including mammals. Previous studies have demonstrated that gentamicin-based chemical injury in zebrafish mimics human AKI, but detailed analysis of the cellular events associated with damage was not reported. We generated a novel toolkit of cellular and molecular protocols to perform this analysis in the zebrafish.

**Results:** Next, we extensively characterized the cellular changes resulting from gentamicin injury in the adult zebrafish using our platform of histology and immunohistochemistry techniques. This work has established the timing of renal cell death after injury, identified proliferative compartments within the kidney, and led to the assessment of gene expression changes associated with the regenerative response of proliferating cells.

**Conclusions:** Taken together, these data have provided a greater understanding of the full cycle of regenerative events. Insights from this work can be applied in future studies toward the design of chemical genetics screens in the adult and/or embryonic zebrafish to identify renal regeneration pathways and provide novel insights into the signals that orchestrate kidney epithelial regeneration.

**TH-PO1129**

**Amniotic Fluid Kidney Progenitors as a Tool to Study the Glomerular Filtration Barrier In Vitro** Stefano Da Sacco, Astgik Petrosyan, Sargis Sedrakyan, Kevin V. Lemley, Roger E. De Filippo, Laura Perin. *Children's Hospital Los Angeles, Los Angeles, CA.*

**Background:** The glomerular filtration barrier (GFR), essential for blood ultrafiltration, is formed by three major components: the podocyte, the glomerular basement membrane (GBM) and the fenestrated endothelial cell. While podocytes are the only cell in the glomerulus to produce collagen IV, endothelial cells play an important role in the formation of the GBM. However, the possibility to recapitulate the formation of a human GFR in vitro to study diseases and possible treatments, is still lacking. We have previously shown that human amniotic fluid progenitor cells (hAKPC) can differentiate into mature podocytes producing collagen IV alpha3-4-5 chains in vitro. In this study, we have evaluated the ability of hAKPC and glomerular endothelial cells to form in vitro a functional filtration barrier in vitro.

**Methods:** hAKPC were differentiated in VRADD media for 20 days. Immunofluorescence, qPCR, SEM and TEM were performed to confirm formation of slit diaphragm (SD) structures. Selective filtration of hAKPC seeded on transwells was tested by dextran permeability assay. To study their ability to form a functional GBM in vitro, hAKPC were co-cultured with human glomerular endothelial cells in 2D and 3D systems and analyzed by various means including PCR, Western Blotting, immunofluorescence, TEM and SEM.

**Results:** Upon differentiation, hAKPC express a full range of SD proteins and are capable of selective filtration. When co-cultured with human glomerular endothelial cells in 2D systems they depose collagen IV, laminin and other essential GBM components. When co-cultured with endothelial cells in 3D hanging drops, hAKPC are forming spheroids, express kidney and podocyte specific markers and form peculiar morphological structures.

**Conclusions:** In conclusion, hAKPC can be induced to differentiate into mature podocytes in vitro and exhibit the ability to form a functional SD capable of filtration. Moreover, they form, together with endothelial cells, a GBM-like structure. Based on these results, hAKPC might prove useful for a future cellular therapy aimed at understanding the mechanisms underlying recover of GBM in chronic kidney disease.

**TH-PO1130**

**C-kit+ Cells Restore Podocyte Function in a Model of Acute Glomerulonephritis** Erika B. Rangel,[1] Samirah Abreu Gomes,[1] Rosemeire Kanashiro-Takeuchi,[1] Phillip Ruiz,[1] Jochen Reiser,[2] Joshua M. Hare.[1] *[1]Univ of Miami; [2]Rush Univ.*

**Background:** C-kit-kidney derived cells exhibit the properties of stem cells and regenerate epithelial tubular cells following ischemia-reperfusion injury. We hypothesize that c-kit$^+$ cells have the capacity to improve podocyte function in a model of acute glomerulonephritis induced by puromycin aminonucleoside (PAN).

**Methods:** A single dose of PAN (15 mg/100g) was administered intraperitoneally into rats. After 5 days, animals were injected with saline or c-kit cells. Metabolic parameters (serum creatinine, blood urea nitrogen [BUN] and urinary ratio of albumin/creatinine), and histologic and gene expression analyses were performed at 10 and 21 days. A single dose of PAN (15 mg/100g) was administered intraperitoneally into rats. After 5 days, animals were injected with saline or c-kit$^+$ cells. Metabolic parameters (serum creatinine, blood urea nitrogen [BUN], urinary ratio of albumin/creatinine), histologic and gene expression analyses were performed at 10 and 21 days.

**Results:** C-kit treated animals exhibited lower values of BUN after 10 days compared to the saline group (92 mg/dL vs 58.2 mg/dL, P<0.001). At 21 days, kidney weight was lower in c-kit-treated animals (0.5 g/100 g body weight [BW]) compared to saline treated animals (0.54 g/100 g BW, P=0.024). Urinary ratio of albumin/creatinine was lower in c-kit treated animals (0.77±0.46 g/mg) compared to the saline group (1.15±0.77 g/mg). A few c-kit$^+$ cells were engrafted into the tubule-interstitial compartment. Expression of CD2AP and α-actin 4 (involved in podocyte cytoskeleton) and mTOR (mammalian target of rapamycin) were up-regulated after 21 days in the c-kit treated group. Of importance, Raptor/Rictor ratio was lower in c-kit treated animals compared to the saline group (1.17 vs 1.78, P = 0.029). Rictor expression was comparable between c-kit treated animals and normal kidneys, but was higher than the expression observed in the saline treated group (P<0.05). Autophagy was less efficient in the saline group compared to the c-kit treated group when the number of autophagosomes/autophagolysosomes was analyzed (4.3±0.6 vs 7.2±0.8, respectively, P=0.0088).

**Conclusions:** C-kit$^+$ stem cells preserve podocyte cytoskeleton in a model of PAN-induced glomerulonephritis apparently by up-regulating the mTOR-Rictor pathway and modulating the autophagic pathway. Taken together, these results suggest that c-kit$^+$ stem cells may have important biological and therapeutic properties. C-kit$^+$ cells preserve podocyte cytoskeleton in a model of PAN-induced glomerulonephritis apparently by up-regulating the mTOR-Rictor pathway and modulating the autophagic pathway. Taken together, these results suggest that c-kit$^+$ cells may have important therapeutic implications.

**TH-PO1131**

**Evaluation of Adipose Tissue-Derived Mesenchymal Stem Cells for Kidney Regeneration in Long-Term Dialysis Patients** Shuichiro Yamanaka,[1] Shinya Yokote,[1] Luna Izuhara,[2] Yuichi Jimmy Katsuoka,[2] Makoto Ogura,[1] Tetsuya Kawamura,[1] Takashi Yokoo.[1] *[1]Div of Kidney and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Shinbashi, Minato-ku, Japan; [2]Div of Regenerative Medicine, Jikei Univ School of Medicine, Shinbashi, Minato-ku, Japan.*

**Background:** We previously demonstrated that mesenchymal stem cells (MSCs) differentiate into kidney cells with glomerular filtration function and erythropoietin production capacity. Therefore, MSCs may potentially be used for kidney regeneration. However, in patients on long-term dialysis, MSCs may have been exposed to uremic toxins, which can decrease their viability and differentiation capacity. In this study, MSCs from patients with end-stage kidney disease (ESKD) and individuals with normal renal function were compared in terms of gene expression profiles, differentiation capabilities, proliferation potential, and senescence.

**Methods:** MSCs were isolated from adipose tissues of ESKD patients (MSC-KD) and controls for phenotypic and functional comparisons. All ESKD patients were on long-term dialysis (mean duration, 58.1 ± 41.0 months). After confirming MSC surface marker expression, data regarding comprehensive gene expression profiles, proliferation potential, and senescence were obtained using real-time polymerase chain reaction array, Western blotting, population doubling time, and senescence assays. MSCs were differentiated into adipocytes, osteoblasts, and chondrocytes, following which histological analyses and/or functional assays were performed.

**Results:** A significant difference in gene and protein expression of transforming growth factor beta-3 (Tgfb3; upregulated) and p300/CBP-associated factor (PCAF; down-regulated) was observed between MSC-KD patients and controls. Meanwhile, no significant differences were observed in MSC differentiation, proliferation potential, or senescence.

**Conclusions:** Some differences in gene expression of stemnessmarkers were noted in MSC-KD patients. Therefore, long-term exposure of MSCs derived from adipose tissues to uremic toxins may render them inappropriate asa source of cells for regenerative therapy.

**TH-PO1132**

**Differentiation of Human Embryonic Stem Cells into Kidney Specific Protein Positive Cells** Shintaro Yamaguchi, Koichiro Homma, Toshiaki Monkawa, Ryuji Morizane, Sayuri Suzuki, Shizuka Fujii, Shu Wakino, Koichi Hayashi, Hiroshi Itoh. *Dept of Internal Medicine, Keio Univ School of Medicine, Shinjyuku, Tokyo, Japan.*

**Background:** Kidney specific protein (KSP) is expressed in the ureteric buds, developing nephrons, mesonephric tubules, Bowman's capsules, proximal tubules, loops of Henle, distal tubules and collecting tubules. Recently, we succeeded in isolating mouse embryonic stem (ES) cells derived KSP-positive cells that could be differentiated into renal tubular lineage cells through tubular formation. Human ES cells possess many characteristics distinct from those of mouse ES cells, and the investigation of human ES cells is indispensable to clarify the kidney differentiation process in humans. In the present study, we utilized KSP as a marker to investigate the ability of human ES cells to differentiate into renal tubular lineage cells.

**Methods:** We performed monolayer multistep culturing of the human ES cell line KhES-1 on collagen substrate. As a first step, human ES cells were induced to differentiate into mesodermal lineage cells using a GSK-3β inhibitor. As a second step, further differentiation was induced under the low serum and several growth factors. Then the KSP-positive cells were sorted by flow cytometry at day 10.

**Results:** Quantitative RT-PCR analysis showed that significant amounts of intermediate mesoderm markers were expressed in human ES cells cultured with a GSK-3β inhibitor. Western blotting, immunocytochemistry, and flow cytometry showed that human ES cells cultured with a GSK-3β inhibitor were positive for KSP at day 10. On the other hand, human ES cells cultured without a GSK-3β inhibitor showed less protein expression of KSP, indicating that GSK-3β inhibition is essential to produce KSP-positive cells in this differentiation technique. Furthermore, the KSP-positive cells were able to form tubular-like structures when grown in a 3D culture in Matrigel.

**Conclusions:** We showed that human ES cells have the potential to differentiate into KSP-positive cells. Although the characteristics of KSP-positive cells should be investigated, the present technique is a promising step to obtaining renal tubular lineage cells from human ES cells.

**TH-PO1133**

**Early Endothelial Outgrowth Cells (eEOCs) in Murine Diabetic Nephropathy** Daniel Patschan, Susann Patschan, Gerhard A. Mueller. *Nephrology & Rheumatology, Univ Hospital of Göttingen, Göttingen, Niedersachsen, Germany.*

**Background:** Early Endothelial Outgrowth Cells (eEOCs), a major subpopulation of EPCs (Endothelial Progenitor Cells) have reliably been shown to protect mice from acute ischemic renal failure. These effects can significantly be improved by BMP-5. Chronic diabetic nephropathy is characterized by renal fibrosis during later stages of the disease, a process which partly results from mesenchymal transition of mature endothelial cells (EnMT). Aim of the current study was to analyze consequences of eEOC treatment of diabetic nephropathy in the context of BMP-5 actions on the cells.

**Methods:** Male C57/Bl6N mice were repeatedly injected with STZ. Animals received either untreated or BMP-5 pretreated syngeneic murine eEOCs at 2 and 7 days after the last STZ administration. Renal function, proteinuria, renal fibrosis and EnMT were analyzed 8 weeks later.

**Results:** STZ treatment induced significant and persistent increases of blood glucose levels, the animals additionally displayed renal dsyfunction and proteinuria at 8 weeks after the last STZ administration. Renal function and proteinuria significantly improved after injection of untreated and BMP-5 pretreated eEOCs. Reduction of proteinuria was more pronounced with BMP-5 treated eEOCs. Renal fibrosis was diminished by eEOCs as well. All experimental groups were characterized by increased expression of aSMA by CD31+ endothelial cells, indicating mesenchymal transition of the endothelium. BMP-5 treated eEOCs diminished aSMA expression in a statistically significant manner.

**Conclusions:** Early Endothelial Outgrowth Cells protect mice from diabetic nephropathy. In this situation BMP-5 augments antiproteinuric and antimesenchymal cell effects.

**TH-PO1134**

**Pretransplant Dialysis Duration Is a Risk Factor for Death after Kidney Transplantation also in the Current Era** Ilkka Helanterä,[1] Kaija Salmela,[2] Lauri Kyllönen,[2] Petri Koskinen,[1] Carola Gronhagen-Riska,[1,3] Patrik Finne.[1,3] *[1]Dept of Medicine, Div of Nephrology, Helsinki Univ Central Hospital, Helsinki, Finland; [2]Dept of Transplant Surgery, Helsinki Univ Central Hospital, Helsinki, Finland; [3]Finnish Registry for Kidney Diseases, Helsinki, Finland.*

**Background:** Although longer pretransplant dialysis has been associated with poor kidney transplant outcome, no data about this association exist from the current era or Europe. We studied the association of pretransplant dialysis duration with outcomes after kidney transplantation across different time periods.

**Methods:** All recipients of first kidney transplantation between 1964 and 2010 in Finland were included (N=5205) in this observational follow-up study of an inception cohort. Pre- and posttransplant data, and outcome data were collected from the Finnish Registry for Kidney Diseases. The association of the duration of pretransplant dialysis with patient and graft survival after transplantation was analyzed with multivariable Cox

regression and competing risk analyses. The association of pretransplant dialysis duration with the risk of specific causes of death (cardiovascular, infectious, or other causes) was analyzed using competing risk analysis.

**Results:** Longer duration of pretransplant dialysis was an independent risk factor for patient death after transplantation (Risk ratio 1.14 per one year increase) in the whole study population, but not for graft loss. Risk of death was increased in patients with more than 12 months of pretransplant dialysis. Longer duration of dialysis was an independent predictor of death due to cardiovascular diseases (RR 1.13 per one year increase), but not for other causes. After further adjustment in patients transplanted in 2000-2010, longer duration of dialysis remained an independent risk factor (RR 1.23 per one year increase). After stratification according to the era of transplantation, the risk of death associated with dialysis duration did not decrease over time.

**Conclusions:** Dialysis duration remains an independent predictor of patient death after kidney transplantation also in the current era, because of increased risk of death due to cardiovascular diseases.

## TH-PO1135

**Associations of Pre-Transplant Narcotics Use with Death and Graft Loss after Kidney Transplantation** Krista L. Lentine,[1] David A. Axelrod,[2] Daniel C. Brennan,[3] Vikas R. Dharnidharka,[3] Mark Schnitzler.[1] *[1]Saint Louis Univ; [2]Dartmouth Univ; [3]Washington Univ.*

**Background:** Limited data are available on the implications of narcotics use for outcomes after kidney transplantation (KT).

**Methods:** We examined a novel database wherein OPTN identifiers for KT recipients were linked to pharmacy fill records from a large U.S. pharmaceutical claims clearinghouse (2005 to 2010). For this study, we selected adult KT recipients with 1yr of captured pre-transplant pharmaceutical fill records (N=29,882). Pharmacy fills for narcotics in the year prior to KT were normalized to Morphine Equivalents (ME), and expressed as average mg/kg/d exposures. Associations of ME with post-transplant graft and patient survival (adjusted hazards ratio, aHR) were quantified by multivariate Cox regression including recipient, donor and transplant clinical factors in the OPTN registry.

**Results:** 28.9% of the sample filled narcotics in the year before KT. Among narcotic users, the 25th, 50th and 75th percentiles of ME were: 0.01, 0.02, and 0.06 mg/kg/d, respectively. 3-yr survival of deceased donor (DD) recipients declined with higher quartiles of ME exposure, from 88.9% among non-users to 87.6% (Q2), 85.3% (Q3), 83.2% (Q4) (P<0.0001). After multivariate adjustment, the risks of post-transplant death and graft loss in DD recipients with the highest quartile ME exposure were 1.6-times and 1.4-times that of narcotic non-users, respectively (Table). Patterns were similar among live donor KT recipients, with the upper quartile of pre-transplant narcotic exposure predicting 2.4 times the risk of death (P<0.0001) and 1.8 times the risk of all-cause graft loss (P<0.0001) (Table).

**ADJUSTED ASSOCIATIONS of PRE-TRANSPLANT NARCOTIC USE with 3yr PATIENT & GRAFT SURVIVAL after DECEASED DONOR KT**

*Based on Cox's regression, adjusted for recipient, donor and transplant factors in the SRTR transplant survival equations. †P<0.05 . KT, kidney transplant; ME, morphine equivalents

**Conclusions:** While these associations may in part reflect underlying conditions that require pain management, KT recipients who use chronic narcotics should be identified as a high risk group.

## TH-PO1136

**Pre-Transplant Geriatric Nutritional Risk Index (GNRI) and Outcomes after Kidney Transplantation** Mikiko Yoshikawa, Kentaro Nakai, Yuriko Yonekura, Hideki Fujii, Shinichi Nishi. *Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Hyogo, Japan.*

**Background:** Malnutrition is a prevalent condition in chronic dialysis patients and seems to be a risk factor for mortality. The association between pre-transplant nutritional assessments andpost-transplant outcome is unclear. Geriatric nutritional risk index (GNRI: 1.489×albumin (g/dL)+41.7×body weight/ ideal body weight)is a simple nutritional assessment tool for chronic dialysis patients. We hypothesized that pre-transplantlower GNRI might be associated with the worse post-transplant renal outcomes.

**Methods:** We studied a retrospective cohort of 79patients who received first kidney transplantation at our center from April 2003 to March 2011 and surveyed their clinical courses for 12 months after transplantation. Chi-squared test,t-test (Mann-Whitney test), Pearson correlation coefficient, and multivariate logistic regression model were used to analyze the data.

**Results:** The GNRI was significantly correlated with eGFR changes at 12 months. (r= 0.281, p=0.012) Patients were divided into two groups; "High-GNRI group">99 and "Low-GNRI group" = or <99. Low-GNRI group did not predict delayed graft function and acute rejection, but were independently associated with eGFR deterioration (HR=3.00, [95% confidence interval: 1.168-7.706]), and every graft failure in Low-GNRI group developed within 5 years. There was no significant relationship betweenthe episodes of post-transplant complications such as infection and cardiovascular events.

**Conclusions:** Lower pre-transplant GNRI is an independent risk factor for the deteriorating post-transplant graft function.

## TH-PO1137

**Left Ventricular Systolic and Diastolic Dysfunction and Mitral Regurgitation Are Key Determinants of Pulmonary Hypertension in Chronic Kidney Disease Patients** Aditi Puri, Randal K. Detwiler, Abhijit V. Kshirsagar, Hubert James Ford, Alan L. Hinderliter. *Univ of North Carolina Chapel Hill.*

**Background:** Pulmonary hypertension (PH) is common in patients with chronic kidney disease (CKD), and is associated with reduced survival in patients who undergo renal transplant. The exact mechanism of PH in CKD patients is unclear. Potential contributing factors include high cardiac output due to anemia and the presence of a graft or fistula; chronic inflammation or other adverse effects of hemodialysis (HD); and a high left atrial (LA) pressure due to mitral regurgitation (MR) or left ventricular (LV) systolic or diastolic dysfunction.

**Methods:** To gain insight into mechanisms underlying PH in CKD patients, we examined clinical, laboratory, and echocardiographic characteristics of 349 patients who were referred for cardiac evaluation prior to kidney transplant at UNC. A diagnosis of PH was based on measurement of tricuspid regurgitant jet velocity (TRV) by Doppler echocardiography, and defined as TRV ≥ 2.8 m/s.

**Results:** The average age of our patients was 56±10 years. Most (75%) had end-stage renal disease (ESRD); 60% were on HD. The prevalence of PH was 17%. LV systolic dysfunction (ejection fraction ≤ 40%) (odds ratio 4.12, 95% confidence interval 1.73-9.81), moderate or severe LA dilation (OR 3.53, 95% CI 1.89-6.56), ≥ grade 2 LV diastolic dysfunction (OR 3.09, 95% CI 1.68-5.67), and moderate or severe MR (OR 9.85, 95% CI 2.78-34.9) were significant predictors of PH. Age, race, gender, body mass index, ESRD, HD, hematocrit, C-reactive protein, and LV hypertrophy were not associated with PH. Diastolic dysfunction and MR remained significant independent predictors in a multivariable model.

**Conclusions:** There was a high prevalence of PH in our cohort of patients with CKD undergoing kidney transplant evaluation. LV systolic and diastolic dysfunction, LA dilation, and MR were predictors of PH. These findings suggest that LV systolic and diastolic dysfunction and MR may play important roles in development of PH in CKD patients. PH may be associated with poor outcomes in part because it is a marker of advanced left heart disease.

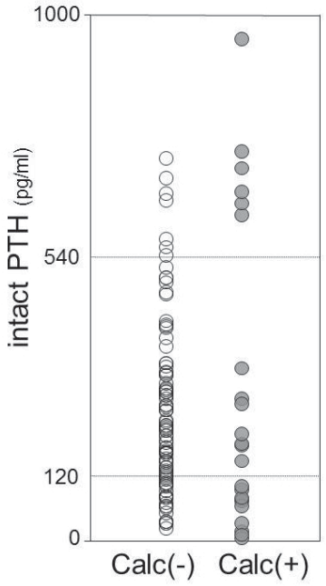
## TH-PO1138

**Preoperative Recipient Parathyroid Function Affects Intratubular Calcification in Transplanted Kidney Grafts** Junichiro J. Kazama,[1] Emiko Kono,[1] Michihiro Hosojima,[1] Suguru Yamamoto,[1] Kazuhide Saito,[2] Ichiei Narita.[1] *[1]Clinical Nephrology and Rheumatology, Niigata Univ, Niigata, Japan; [2]Urology, Niigata Univ, Niigata, Japan.*

**Background:** Intratubular calcification is occasionally found in transplanted kidney grafts. Its clinical significance remains unknown.

**Methods:** Among adult CKD patients who received kidney transplantation in Niigata University Medical and Dental Hospital between 2006 and 2012, those in whom the absence of intratubular calcification had been confirmed in the biopsied kidney graft tissue obtained immediately after the operation were retrospectively studied. The second biopsy of kidney graft was performed 4 weeks after the first biopsy.

**Results:** Of the 116 patients (M70F46, 43.4 ± 12.7yo, dialysis vintage 82.0 ± 97.3M) analyzed, intratubular calcification was found in 23 (19.8%) in the second biopsy specimen.



Those with calcification showed a significantly lower inulin clearance level than those without calcification at the time of second biopsy (50.6 ± 15.2 vs 40.4 ± 8.8 ml/min, p<0.05). Compared to the incidence of intratubular calcification among patients whose preoperative intact PTH level was within the KDIGO guideline's standard range of 120-540 pg/ml, both of those with intact PTH more than 540 pg/ml and with less than 120 pg/ml showed a significantly higher incidence of postoperative intratubular calcification (9.7 *vs* 46.2%, p<0.01 and 9.7 *vs* 32.3%, p<0.01, respectively). Hypercalcemia developed in patients with intratubular calcification with high PTH, but not in those with low PTH.

**Conclusions:** Intratubular calcification is a potential harm for a transplanted kidney graft. Both hyperactivated and suppressed preoperative parathyroid functions are associated with increased risk of the incidence of intaratubular calcification.

**TH-PO1139**

**Utility of Thrombophilia Screening in Children Awaiting Kidney Transplantation** Margret E. Bock,[1] Amy Bobrowski,[1] Rukhmi Bhat.[2] *[1]Kidney Diseases, Northwestern Univ; [2]Hematology, Northwestern Univ, Chicago, IL.*

**Background:** Vascular thrombosis is one of the more common causes of early allograft loss in children after kidney transplantation (KTx). The utility of screening for acquired & inherited thrombophilia is controversial. We posited that universal pre-transplant screening for thrombophilia was of low predictive value for post-operative outcomes.

**Methods:** We reviewed 84 children, aged 1-18 years, who underwent comprehensive thrombophilia evaluations prior to KTx & were then followed longitudinally.

**Results:** Pre-operative screening demonstrated thrombophilia in over 90% of patients (76/84). Low protein C, S & anti-thrombin 3 (AT) were found in 22.5%, 10.7% & 9.5% patients, respectively. Homocysteine was elevated in 25.8%. Plasminogen activity was abnormal in 16.5%. Antiphospholipid antibodies & lupus anticoagulant were positive in 20.8% & 62.1%, respectively. Heterozygosity for Factor V Leiden (FVL) & prothrombin gene mutations were found in 7.6% & 1.3% children, respectively. 14.5% patients had homo- & 36.8% patients had heterozygous MTHFR mutations. Patients were followed on average 4.2 yrs (SD: 1.8) after KTx. In 10/84 (11.9%) children a bleeding (5/84, 6%) or clotting (7/84, 8.3%) event occurred after KTx. Of the 5 bleeding events, 3 occurred during peri-operative anti-coagulation. A pre-KTx thromboembolic (TE) event occurred in 8/84 patients (9.5%). Post-operative events were associated with history of pre-KTx TE events (p = 0.019), FVL mutation (p = 0.002) & low AT level (p = 0.016). History of a pre-KTx TE event was associated with poorer graft survival at 3 yrs (p < 0.0001); FVL mutation was associated with poorer graft survival at 3 mos (p < 0.0001); low AT levels were associated with poorer graft survival at both 1 & 3 yrs (p < 0.0001 for both). Two of 84 grafts were lost to TE events.

**Conclusions:** Analysis of long-term follow-up data demonstrates that the value of universal comprehensive thrombophilia evaluation before KTx is low. Focused universal investigation, however, in addition to more detailed testing in those with a previous TE event, may be advisable, as these children may benefit from tailored peri-operative anti-coagluation.

*Funding:* Other NIH Support - Margret Bock is supported in part by Grant Number K12 HD055884 from the Eunice Kennedy Shriver National Institute of Child Health and Human Development

**TH-PO1140**

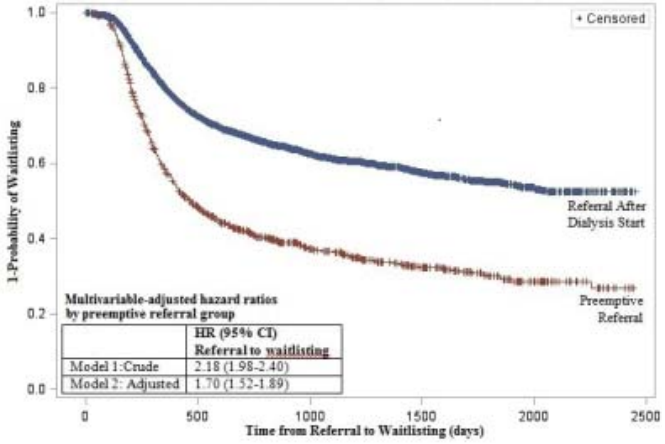
**Impact of Preemptive Referral for Kidney Transplant Evaluation on Waitlisting and Transplant** Mohua Basu, Brendan P. Lovasik, Justin D. Schrager, Stephen O. Pastan, Rachel E. Patzer. *Emory Univ School of Medicine.*

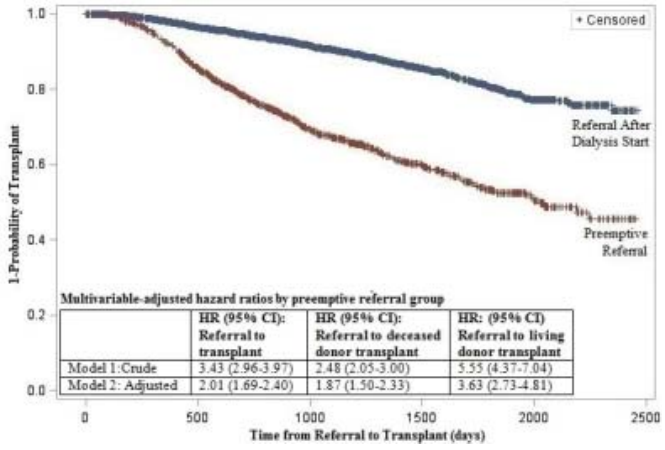
**Background:** Little is known about how preemptive referral, or referral for kidney transplant (KTx) evaluation prior to initiating dialysis, is associated with access to waitlisting and KTx in ESRD (end-stage renal disease) patients.

**Methods:** KTx center-level data for 4,914 patients with no previous transplant referred to a Southeastern transplant center for KTx evaluation from 2005-2010 were linked with United States Renal Data System baseline and follow-up data through September 2011. Patient addresses were geocoded and linked with 2009 Census poverty data. Cox models were used to examine the association between preemptive referral and access to 1) waitlisting and 2) KTx.

**Results:** Of 4,914 referred patients, 934 (19.0%) were preemptively referred. Among referred patients, 1,977 (40.2%) were waitlisted (62.8% of preemptively referred patients and 34.9% of patients referred after dialysis start), and 725 (14.8%) patients received KTx (35.0% preemptively referred and 10.0% referred after dialysis start). In analyses adjusted for demographic factors (age, sex, race, distance to KTx center), clinical factors (ESRD etiology, body mass index, tobacco use, cardiovascular disease, cancer, pre-ESRD nephrology care, erythropoietin use, hemoglobin and albumin levels), and SES factors (insurance and poverty), preemptively referred patients had a significantly higher rate of waitlisting (HR=1.70; 95% CI: 1.52-1.89) and KTx (HR=2.01; CI=1.69-2.40) compared to patients referred after initiating dialysis (Figure). Preemptive referral was associated with improved access to both deceased (HR=1.87; 95% CI: 1.50-2.33) and living donor KTx (HR=3.63; 95% CI: 2.73-4.81).

**Figure: Kaplan-Meier Curves for Access to Waitlisting and Transplant by Preemptive Referral Group**





**Conclusions:** Preemptive referral for KTx evaluation is associated with improved access to waitlisting and both deceased and living donor KTx. Interventions to increase early referral may improve access to KTx.

## TH-PO1141

**Knowledge and Attitudes toward Kidney Transplantation among Non-Physician Dialysis Providers: An Opportunity to Improve Kidney Transplantation Education and Access** Fidel Barrantes,[1] Elizabeth Evans,[1] Akeela Oaris,[2] Milagros D. Samaniego-Picota,[3] Fu L. Luan.[3] *[1]Renal Medicine Associates, Albuquerque, NM; [2]Internal Medicine, Presbyterian Health System, Albuquerque, NM; [3]Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

**Background:** Non-physician dialysis staff (NPDS) are the primary sources of education for patients with end stage renal disease (ESRD). However, many feel uncomfortable answering questions related to kidney transplantation (KT) and thus hinder early referral.

**Methods:** This survey was designed to evaluate NPDS knowledge and attitudes toward KT referrals. Survey was validated before implementation.

**Results:** We surveyed 259 providers nationwide. Amongst, 75% worked for for-profit dialysis organizations, 19.3% locally owned , and 5% were university affiliated ; 51% dialysis nurses, 18.5% nurse practitioners, and 11.4% technicians. The average dialysis working years was 12.5 . Only 58.1% stated that KT was the best renal replacement therapy option for ESRD patients , whereas 15.4% opted daily home hemodialysis, 11.8% peritoneal dialysis, 8.1% in-center nocturnal (3/week), and 8.1% intermittent hemodialysis. One third of participants thought kidneys from young living donors last 5-10 years. About 50% thought that kidneys from young deceased donors last 5-10 years and those from older donors <5 years.

NPDS identified two main reasons for non-referral: “patient too sick for transplant” or “non adherent to dialysis”. They identified that older patients, multiple co-morbidities and non-adherence to hemodialysis affect transplant outcomes; and reported that infection , non-compliance, failed cardiac clearance, morbid obesity, >3 co-morbidities and cancer as reasons transplant centers decline candidates. Only 40% of NPDS encouraged their patients to pursue evaluation once in the last 6 months.

Survey showed one third of NPDS never received KT education or had it >10 years ago.

**Conclusions:** NPDS displayed inadequate knowledge about KT, and identified factors that are associated with lack of referrals. Education in KT for NPDS may have the potential to avoid misinformation to patients with ESRD and to improve referral access to transplantation.

## TH-PO1142

**Achieving Preemptive Living Donor Kidney Transplantation in the United States for End Stage Renal Disease** Kevin C. Mange,[1] Francis L. Weng.[2] *[1]Barnabas Health, West Orange, NJ; [2]Saint Barnabas Medical Center, West Orange, NJ.*

**Background:** Preemptive living donor kidney transplantation (PLDKT) has been associated with survival advantages. However, the likelihood of preemptively wait-listed patients with ESRD in the US to undergo successfully PLDKT instead of initiating dialysis prior to LDKT is unknown.

**Methods:** To determine the likelihood of preemptively listed patients to undergo PLDKT, we examined UNOS data from 23,061 patients ≥18 years old who received a LDKT between 2000-12 where the transplant occurred either 1) preemptively or 2) within 90 days of starting dialysis yet the patient was preemptively listed. Estimates of income were obtained from 2011 American Community Survey by US Census Bureau. Univariate descriptive analyses were conducted to examine potential associations for logistic regression modeling.

**Results:** Potential PLDKTs represented 8.4% of all living donor transplants in the US. During 2000-12, PLDKT has become more frequent, and there was a 3-fold increased frequency of being listed before PLDKT (P<0.0001). Several factors have unadjusted associations. However, even though listed preemptively, Black or Hispanic race was more likely to get a non-PLDKT vs Caucasians (OR 1.40;OR 1.53, P<0.0001 for both).

| | Listed Preemp & PLDKT (N=21,123) | Listed Preemp & Non-PLDKT by <90 Days (N=1,938) | |
|---|---|---|---|
| Mean (SD) Days on Dialysis Pre-Transplant | ---- | 44.3 (25) | |
| Mean Recipient Age (SD) | 48.3 (13.6) | 47.1 (13.1) | <0.0001 |
| Female (%) | 41.0 | 38.9 | .08 |
| Recipient Ethnicity (%)<br>Caucasian<br>Black<br>Hispanic<br>Asian | <br>76.6<br>9.6<br>9.1<br>3.7 | <br>72.2<br>11.6<br>11.5<br>3.7 | <0.0001 |
| Cause of ESRD (%)<br>Diabetes<br>Hypertension<br>Glomerulonephritis<br>Chronic Interstitial Nephritis | <br>19.0<br>14.1<br>28.8<br>4.5 | <br>20.6<br>15.0<br>32.3<br>3.3 | <0.0001 |
| Primary Payer at Transplant<br>Private<br>Public<br>Other | <br>76.6<br>22.1<br>1.3 | <br>75.5<br>24.2<br>0.35 | <0.0001 |
| Median Household Income (2011 $) | 57,426 | 57,479 | 0.748 |
| Donor Relationship (%)<br>Parent<br>Child<br>Full Sibling<br>Spouse<br>Other | <br>6.9<br>18.1<br>26.9<br>16.0<br>32.1 | <br>7.1<br>15.1<br>22.6<br>15.8<br>39.4 | <0.0001 |

**Conclusions:** Based on US national data, PLDKT has become a more frequent treatment for ESRD. Even though listed preemptively, there are barriers to ultimately undergo PLDKT and realize a potential increase in allograft survival, especially among Blacks and Hispanics.

## TH-PO1143

**The Effect of Donor Service Area (DSA)-Specific Median Waiting Time on Waitlist Outcomes** Alireza Mehrnia, Mandana Kamgar, Marcelo Santos Sampaio, Edmund Huang, Suphamai Bunnapradist. *Medicine - Nephrology, UCLA - David Geffen School of Medicine, Los Angeles, CA.*

**Background:** Waiting time for deceased donor kidney transplant is increasing, but waiting time varies considerably in each DSA. We studied the impact of DSA waiting time on waitlist outcomes.

**Methods:** Primary adult kidney transplant candidates waitlisted from 2003 to 2012 were included. The cumulative incidence (CI) of a) receiving a transplant, b) being delisted, and c) dying was calculated using competing risks methods and is presented below. 201,937 candidates were included and followed for 5. DSA’s were stratified into quartiles by median waiting time calculated by the Kaplan-Meier method (Q1-Q4). Data was obtained from the OPTN/UNOS as of 31 December 2012.

**Results:** By 5 years, the CI of receiving a transplant was higher in Q1 (68.4%) compared to Q4 (35.1%). The CI of death was 10.8% in Q1 and 18.7% in Q4. The CI of delisting was mostly similar across quartiles. The CI of death was higher than delisting in the highest quartile (Q4).

**Conclusions:** Among 58 DSA’s, median waiting time varied considerably from 12 to 102 months. Death rate was higher among patients who were listed in centers with longer median waiting time, and was almost double in the quartile with the highest median waiting time (Q4) compared to the lowest (Q1).

| Quartiles by median DSA waiting time (min-max) | Transplanted (95% Confidence Interval) | Death (95% Confidence Interval) | Delisted (95% Confidence Interval) |
|---|---|---|---|
| **Q1** (12-31) | 68.4 (67.9-68.9) | 10.8 (10.5-11.1) | 13.5 (13.1-13.9) |
| **Q2** (32-43) | 59.2 (58.7-59.8) | 12.7 (12.3-13.0) | 13.8 (13.5-14.2) |
| **Q3** (44-50) | 50.7 (50.1-51.2) | 15.0 (14.6-15.4) | 14.8 (14.4-15.2) |
| **Q4** (51-102) | 35.1 (34.6-35.5) | 18.7 (18.3-19.1) | 13.8 (13.7-14.2) |

## TH-PO1144

**Access to Transplantation in the Elderly: Defining the Unmet Need** Elizabeth Hendren,[1] Elke Schaeffner,[2] Jagbir Gill,[1] John S. Gill.[1] *[1]Univ of British Columbia; [2]Charité Univ Medicine.*

**Background:** To what extent the low use of transplantation in the elderly is justified because of a high burden of comorbid disease and limited life expectancy is unclear.

The objectives of this USRDS analysis were:

1)To determine the proportion of incident ESRD patients ≥ 65 years that are transplant eligible (TE) and examine their access to transplantation (defined as wait-listing or transplantation).

2) To determine if the Medicare and Medicaid Services (CMS) requirement to report discussion of transplant treatment options at dialysis initiation (implemented in May 2005) was associated with an increase in access to transplantation.

**Methods:** We defined transplant eligibility using the following conservative criteria: 1) ESRD Survival ≥ 5 years, 2) no relative contraindications to transplantation, 3) no comorbid conditions and 4) no inability to ambulate or transfer.

**Results:** Overall 8.5% of elderly incident ESRD patients met our TE criteria, and 15.9% of these patients were ever wait-listed or transplanted. Among 65-9 year olds, 14% were transplant eligible and 30% of these patients gained access to transplantation. Among patients ≥ 70 years, 7% were TE but only 9% gained access to transplantation.

| Age (years) | All incident patients in USRDS 2000-2 | Survived 5 years | No contraindications or comorbid conditions | Access to transplantation (wait-listed or transplanted) |
|---|---|---|---|---|
| All ≥ 65 | 131,926 | 25,531 | 11,108 (8.5%) | 1772 (15.9%) |
| 65-69 | 25,107 | 8004 | 3627 (14%) | 1069 (30%) |
| 70-75 | 41,047 | 9561 | 4211 (10%) | 597 (14%) |
| 76-80 | 32,550 | 5129 | 2134 (7%) | 96 (4.1%) |
| ≥80 | 33,222 | 2837 | 1136 (3%) | 10 (1%) |

In a separate analysis, the proportion of TE elderly patients who gained access to transplantation within one year of first ESRD treatment increased by 100% in the two years after the implementation of the CMS requirement.

**Conclusions:** We conclude that 85% of TE elderly ESRD patients never gain access to transplantation. However, simple interventions such as required reporting of transplant discussions at dialysis initiation may increase access to transplantation among elderly patients.

## TH-PO1145

**Incorporating Uncertainties and Contingencies in a Paired Donation Program** Mathieu Bray,[1] Wen Wang,[1] Peter X.K. Song,[1] Alan B. Leichtman,[1] Michael A. Rees,[2] John Kalbfleisch.[1] *[1]Univ of Michigan, Ann Arbor, MI; [2]Univ of Toledo, Toledo, OH.*

**Background:** A kidney paired donation (KPD) pool consists of transplant candidates and their incompatible donors along with altruistic donors (ADs). In a match run, exchanges are arranged among pairs in the pool and chains created from ADs. A problem of importance is how best to arrange exchanges and chains to optimize the number of transplants performed. This study examines allocation schemes in a realistic model of a KPD system, incorporating into the scheme probabilities (PR) that chosen transplants may not be completed, as well as allowing for contingency plans (CON) when the optimal solution fails.

**Methods:** The simulations use data from the Alliance for Paired Donation and the University of Michigan KPD program. Simulations compared optimization schemes in 200

replications over 8 months, with 30 pairs and 1 AD added each month. A virtual crossmatch was used to identify potential donations; PRs were specified from the literature. At each match run, the optimal set of cycles and chains was determined for each scheme, with and without PR and with and without CON, and the number of realized transplants was then obtained. Cycles of size 2 and 3 were considered and simulations were done for chains of length 2 to 6. Two schemes for contingencies (CON1 and CON2) were used. Calculations for longer chains were too complex with present algorithms for the CON options.

**Results:** Table 1 compares the allocation schemes in terms of ratios of average number of transplants to a standard where chains are of length 2, without PRs or CONs. Approaches that aim to maximize the number of transplants without allowing for PRs are suboptimal and deliver diminishing returns for longer chain lengths. On average, 17-18% more transplants are realized based on chains of size 3 or 4 that account for PRs and CONs.

| Chain Length | No PR No CON | PR No CON | PR CON1 | PR CON2 |
|---|---|---|---|---|
| 3 | 1.06 | 1.11 | 1.17 | 1.18 |
| 4 | 1.08 | 1.13 | 1.17 | - |
| 5 | 1.07 | 1.11 | - | - |
| 6 | 1.03 | 1.11 | - | - |

**Conclusions:** It is advantageous to consider clinically relevant uncertainties and contingency plans in allocation schemes in KPD.

## TH-PO1146

**Feasibility and Benefit of Kidney Paired Donation between Pools of Ethnic Difference** Kyung Sun Park, Dae Joong Kim. *Div of Nephrology, Internal Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine.*

**Background:** Kidney paired donation (KPD) is an established method to overcome ABO incompatibility and positive cross-match in living kidney transplantation. We hypothesized that the opportunities and quality of matching in KPD may be enhanced by using KPD pools of ethnic difference.

**Methods:** To identify the feasibility and effectiveness of international KPD, we analyzed ABO blood type and HLA-A,B, DR data of 2 donor-recipient pools (DRP) of USA (1 from Allied Paired Donation (APD), another from Methodist San Antonio (SA) and 1 DRP of Korea (KR). The calculated panel reactive antigen (cPRA) was defined as the proportion of donors who have same HLA as the recipient's anti-HLA antibodies.

**Results:** In APD, SA and KR DRPs, 627, 298 and 369 donors, and 515, 237, 369 recipients were registered respectively. Blood type of donors (P<0.001) and of recipients (P<0.001) were significantly different between USA and KR DRPs. The distribution of HLA typing of donors (P<0.001 for A, P<0.001 for B and P<0.001 for DR) and of recipients (P<0.001 for A, P<0.001 for B and P<0.001 for DR) were also different significantly. Mean cPRA of APD recipients (75.3% with APD donors) decreased significantly when calculated with KR donors (69.4%, P<0.001) in comparison with SA donors (75.8%). In SA recipients (80.7% with SA donors), cPRA decrease was more evident with KR donors (75.0%, P<0.001) than with APD donors (80.2%).

**Conclusions:** Our data showed that the distributions of blood type and HLA type were different between USA and KR DRPs and cPRA of US patients decreased significantly in pools of different country. Considering ethnic differences, the feasibility and efficacy of KPD could be improved by using international kidney exchange network.

## TH-PO1147

**Impact of Human Leukocyte Antigen-DR Mismatches on Poor Outcome of Living Unrelated Kidney Transplantation in Comparison with Living Related Kidney Transplantation** Kyung Sun Park, Hye Ryoun Jang, Jung Eun Lee, Wooseong Huh, Yoon-Goo Kim, Ha Young Oh, Dae Joong Kim. *Div of Nephrology, Dept of Internal Medicine, Samsung Medical Center Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea.*

**Background:** Living-unrelated donors (LURD) have been widely used for kidney transplantation (KT). We compared clinical outcomes of KT from LURD and from concurrent living-related donors (LRD), and identified risk factors associated with acute rejection, graft and patient survival in living KT.

**Methods:** We retrospectively reviewed 779 patients who underwent living donor KT (264 from LURD, 515 from LRD) at Samsung Medical Center from January 2000 to December 2012.

**Results:** Median follow-up was 67 months. Mean age (43.2 vs. 38.4 years, P<0.001), mean number of total HLA mismatches (4.1 vs. 2.5, P<0.001) and HLA-DR mismatches (1.2 vs. 0.8, P<0.001) were higher, and mean estimated glomerular filtration rate (eGFR) was lower (87.6 vs. 90.9 ml/min, P=0.007) in LURD. Acute rejection-free survival (64.9% vs. 72.7% at 5 years, P=0.018) and graft survival (92.9% vs. 96.5% at 5 years, P=0.025) were lower for LURD than LRD whereas patient survival rate was comparable (97.9% vs. 98.7% at 5 years, P=0.957). Cox-regression analysis showed that HLA-DR mismatches (OR 1.77, 95% CI 1.20-2.62, P=0.004 for 1 mismatches; OR 2.63, 95% CI 1.64-4.20, P<0.001 for 2 mismatches), donor eGFR (OR 1.33, 95% CI 1.02-1.73, P=0.033) and delayed graft function (OR 2.16, P=0.033) were significant risk factors for acute rejection. For graft survival, delayed graft function (OR 4.87, P=0.009), acute rejection (OR 2.84, P<0.001) and donor eGFR (OR 1.87, 95% CI 1.04-3.35, P=0.035) were significant. We also identified significant impact of diabetes (OR 3.61, P=0.012) and delayed graft function (OR 5.60, P=0.023) for patient survival. However, genetic relation was not significant for acute rejection (P=0.889), graft survival (P=0.205) and patient survival (P=0.745).

**Conclusions:** Our data suggest that HLA-DR mismatches and donor eGFR are independent risk factors for clinical outcomes of living KT. In living KT, these factors should be considered to prevent acute rejection and improve graft survival.

## TH-PO1148

**Addressing U.S. National Geographic Disparity in Kidney Transplantation by Creating Sharing Partnerships** Sanjay Mehrotra,[1] Ashley E. Davis,[1] John J. Friedewald,[2] Michael Abecassis,[2] Daniela Ladner.[2] *[1]Industrial Engineering, Northwestern Univ; [2]Surgery, Div of Organ Transplantation, Northwestern Univ.*

**Background:** In 1998, the Department of Health and Human Services' Final Rule requested the elimination of geographic disparities in organ allocation. Despite this action, geographic disparity persists for kidney transplantation. We aim to develop an alternative kidney sharing strategy to reduce geographic disparity over time without greatly altering current kidney allocation.

**Methods:** Kidney transplant patient and standard criteria donor kidney allocation dynamics were obtained from 2000 to 2009 at Donor Service Area (DSA) precision from Organ Procurement and Transplant Network data. Our kidney sharing strategy establishes regional and national sharing partnerships between DSAs to prioritize the offering of non-locally used kidney organs. Using simulation optimization techniques, we determine the optimal sharing partners for each DSA to best reduce geographic disparity over time. Local allocation levels are not affected. Geographic disparity is represented by the range in blood type specific DSA median waiting times to transplantation, transplant rates, and waitlist mortality rates.

**Results:** After ten years of use, our alternative kidney sharing strategy reduces geographic disparity significantly for all blood types. This reduction occurred when only 40% of shared kidney organs were redirected following our alternative strategy. Compared to actual 2009 kidney allocation, the range in DSA waiting times to transplantation fell by 31%, 38%, 27%, and 27% for blood types A, AB, B, and O kidney allocation, respectively. The range in DSA transplant rates also fell by 32%, 43%, 19%, and 26% for blood types A, AB, B, and O kidney allocation, respectively. Approximately 400 (9%) less waitlist mortalities took place each year over all blood types.

**Conclusions:** Alternative kidney allocation strategies are necessary to reduce geographic disparities in kidney transplantation. We provide a simple change to current kidney allocation policy that reduces geographic disparity over time without affecting current local kidney allocation levels.

## TH-PO1149

**An Evaluation of the ECD Classification in Canadian Kidney Transplant Recipients** Ann Young,[1,2] Charmaine E. Lok,[1,2] Stephanie Dixon,[2] Greg A. Knoll,[2] Amit X. Garg,[2] Joseph Kim.[1,2] *[1]Univ Health Network, Toronto, Canada; [2]Institute for Clinical Evaluative Sciences, Canada.*

**Background:** Although outcomes of kidney transplant recipients in Canada have been shown to be superior to their U.S. counterparts, a critical evaluation of the Expanded Criteria Donor (ECD) classification system has not been undertaken in a Canadian kidney transplant population.

**Methods:** This retrospective, population-based cohort study followed deceased kidney allograft recipients from Ontario, Canada from Jan/2005 to March/2011. Subjects were identified through a transplant database and linked to large administrative healthcare databases in Ontario (www.ICES.on.ca). ECD status was ascertained based on age, serum creatinine, history of hypertension, and death due to stroke. Outcomes were defined using reliable ICD codes compared to chart review. Multivariable survival analysis assessed total graft loss (i.e., graft loss or death), death-censored graft loss, graft loss with death as a competing event, and all-cause mortality.

**Results:** We studied 1,470 deceased donor kidney transplants, of which 286 were from ECD and 1136 from non-ECD. The median age was 64 vs. 46 years for ECD vs. non-ECD, respectively. There were significantly more donors in the ECD group with hypertension (62% vs. 24%) and death due to stroke (22% vs. 10%). Pre-terminal serum creatinine was not significantly different (71 vs. 74 µmol/L). Recipients of ECD kidneys were older (median: 62 vs. 54 years). The five-year cumulative incidence of total graft loss was 28.8% vs. 21.1% in ECD vs. non-ECD kidney transplants, respectively. There was an increased relative hazard for total graft loss (HR 1.42 [95% CI: 1.04, 1.94]) and death-censored graft loss (1.63 [95% CI: 1.05, 2.52]) in the ECD vs. non-ECD kidney transplants. Similar trends were observed for graft loss with death as a competing risk and total mortality.

**Conclusions:** The ECD classification identifies deceased donor kidneys at increased risk of graft failure among Canadian kidney transplant recipients. The performance of more granular measures of donor risk (e.g., KDRI) and its impact on allocation or organ utilization in Canadian patients requires further study.

## TH-PO1150

**Benefits of Pre-Emptive Kidney Transplantation in the Elderly Using Deceased Donor** Enrique Morales, Eduardo Gutierrez-Martinez, Manuel Praga, Amado Andres. *Nephrology, Hospital 12 Octubre, Spain.*

**Background:** During the last two decades we have seen a substantial increase in the incidence of elderly patients who require replacement therapy. In these patients, renal transplantation (RT) should be considered a treatment option. There are a large number of kidneys from elderly patients that are not used. The cadaveric pre-emptive RT has a better survival (SV) -graft and patient- in comparison to the patient on dialysis. The aim of our study was to analyze the evolution of elderly patients on end stage renal disease non-dialysis (ESRDND) after receiving a first RT.

**Methods:** Prospective observational study (years 2007-2012) analyzing pre-emptive RT from a cadaveric donor in our hospital unit. (ESRDND) aged 65 years with a glomerular

filtration rate (GFR) <15 ml / min at the time of inclusion. We established a control group of patients of the same age in hemodialysis (HD) of which 50% of the cases shared the same donor.

**Results:** We included 26 patients (ESRDND) patients (57.7% women) of mean age 74.3 ± 2.9 years, nephrosclerosis (38.5%) as the main cause of nephropathy. RT received a first donor mean age was 73 ± 7.2 years. Cerebral hemorrhage was the most common cause of death (76.9%) and had a GFR of 90.4 ± 19 ml / min at the time of extraction. The cold ischemia time was 21.4 ± 5.3 hours. Immunosuppression was basiliximab induction, tacrolimus, mycophenolate mofetil and steroids (96.2%) in both groups. All baseline characteristics were identical for both groups. At the end of follow-up time 35.5 (5-67) months, the GFR was similar in both groups (42.2 ± 11.7 vs 41.7 ± 11.2 ml / min, p0.72), delayed graft function was higher in the group HD (4 vs. 39.1%, p 0.03) and acute rejection was higher in the PRD group (23.1 vs. 3.8%, p 0.04). The patient SV was similar in both groups (78 vs 83%, p 0.79), however the SV graft was higher in the group ESRD non-dialysis or censoring death (100 vs 77, p 003 and 92 vs. 64%, p 0.03).

**Conclusions:** In conclusion, our study suggests that pre-emptive kidney transplant is an interesting alternative for elderly patients with ESRD non-dialysis. However, it is necessary to perform studies with more patients and longer follow-up to establish a stronger conclusion.

## TH-PO1151

**Long Term Outcomes of Kidney Transplants and Risk of Infection Transmission from High-Infectious Risk Donors** Mili Jay Shah,[1] Gaurav Gupta,[1] Martha Behnke,[2] Marc P. Posner,[2] Amit Sharma,[2] Adrian Cotterell,[2] Robert Fisher,[2] Anne L. King.[1] *[1]Nephrology, Virginia Commonwealth Univ, Richmond, VA; [2]Transplant Surgery, Virginia Commonwealth Univ, Richmond, VA.*

**Background:** The use of kidneys from deceased donors considered at high infectious risk based upon CDC criteria (CDCHR) represents a strategy to increase the limited donor pool. Concern over transmission of viral infections is reported to result in a higher discard rate of these kidneys. Prospective studies on virawl transmission rates are lacking. We report our experience with CDCHR kidneys.

**Methods:** All patients signed an informed consent to receive CDCHR kidneys. Nucleic acid testing (NAT) for HIV, hepatitis B virus (HBV), and hepatitis C virus (HCV) was performed on all CDCHR donors before kidney transplant (KTx). Per protocol, viral transmission testing using HBV surface antigen, HIV ELISA and HCV PCR was performed at least once during the first year and then annually post-KTx.

**Results:** There were 89 CDCHR KTx and 533 Non-high risk (NHR) KTx during the study period from June 2004 to Dec 2011. Although median waiting time was shorter for the CDCHR group (14.8 mths) as compared to the NHR group (20 mths), these results were not statistically significant. Nearly all patients underwent post-KTx screening for HIV (79/89; 89%), HCV (83/89; 93%) and HBV (82/89; 92%). Among patients tested, there was a 0% rate of viral transmission. When compared to the NHR group, CDCHR kidneys were more likely (26% vs. 40%; p<0.01) to be imports. Fewer CDCHR kidneys were from expanded-criteria donors (3/89; 3% vs. 129/533; 24%; p<0.01). CDCHR KTx were more likely to be HCV positive (34% vs 11%; p<0.01) and receive a HCV positive organ (28% vs. 7%; p<0.01). Graft and patient survival at 1, 3 and 5 years were similar between the two groups.

**Conclusions:** In this till date largest single-center report with prospective screening we demonstrate that CDCHR donor kidneys can be used safely with achievement of excellent renal function and graft survival. This data can guide counseling of potential kidney transplant recipients about the benefits of CDCHR kidneys which might also include shorter waiting times.

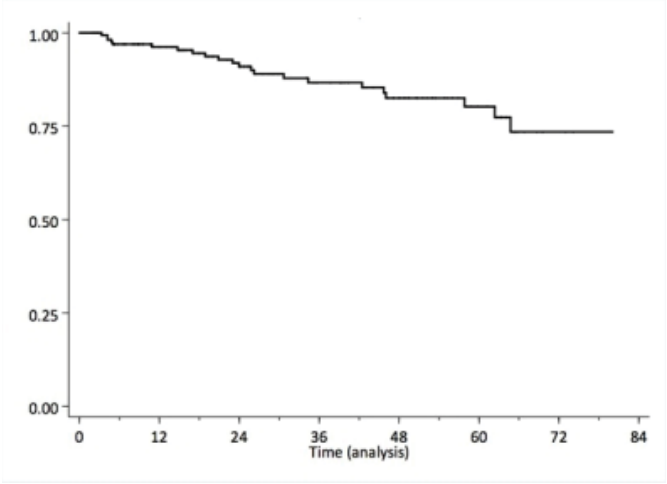
## TH-PO1152

**CDC High Risk Designation for Deceased Kidney Donors Is a Misnomer** Moya B. Gallagher, Demetra Tsapepas, Travis L. Samuels, Shefali Patel, Yael J. Coppleson, David J. Cohen, Lloyd Ratner, Sumit Mohan. *Columbia Univ Medical Center.*

**Background:** Approximately 10% of deceased donor kidneys meet the CDC criteria as "high-risk" for infection (HIV, HCV, HBV) and disease transmission. While this designation may lead to lower organ utilization by some centers, the risk of not detecting infection with modern nucleic acid testing appears low.

**Methods:** Since 2004, 170 patients received kidneys that meet CDC high-risk criteria at Columbia University Medical Center. In addition to standard pre-transplant serologic screening for HIV, HCV, and HBV these patients are also screened by antibody and PCR testing at 6, 12 and 24 weeks post transplant. All patients received our standard of care immunosuppressive protocol.

**Results:** Recipients were predominantly male (69.4%), Hispanic or White (68.8%), receiving a first transplant (80%) after waiting 1.7±1.2yrs and 27.7% experienced delayed graft function. Donors were 37±11.5yrs (10% extended criteria donors) and predominantly male (72.7%). Donor organs had 29.2±10.6hrs of cold ischemia, with a terminal creatinine of 2±1.7mg/dL. Among these donors, 57.1% had a history IVDU, 25.9% had high risk sexual behavior, 11.8% were incarcerated, 7.1% were men who had sex with men, and 4.7% had received multiple blood transfusions resulting in hemodilution. The majority (77.8%) were imported from other OPOs suggesting that other centers declined to use these organs. After a median of 2.4yrs of follow up, 86.5% of allografts were functioning (figure 2) with the most recent creatinine of 1.62±0.87mg/dL and no evidence of infectious seroconversion.



**Conclusions:** Our single center experience of 170 high-risk criteria organs demonstrates the relative safety of this important pool of deceased donor organs when screened by current methods. These organs should probably be labeled as "identified risk"; "high-risk" appears to be a misnomer.

## TH-PO1153

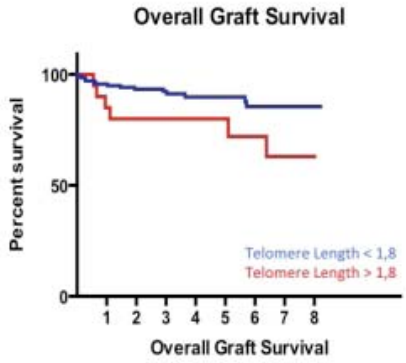
**The Discrepancy between Biological Age and Calendar Age: A Large Histology Study in Pre-Implantation Biopsies** Katrien De Vusser,[1] Nicky Pieters,[3] Evelyne Lerut,[2] Bjorn Meijers,[1] Dirk R. Kuypers,[1] Maarten Naesens.[1] *[1]Nephrology and Renal Kidney Transplantation, UZ Leuven, Leuven, Belgium; [2]Pathology, UZ Leuven, Leuven, Belgium; [3]Center for Environmental Science, U Hasselt, Hasselt, Belgium.*

**Background:** Replicative senescence (biological aging), associated with telomere shortening, plays an important roll in tissue aging. The relationship between calendar age, telomere length, markers of replicative senescence and renal histology is currently unknown.

**Methods:** DNA was extracted from a peripheral blood sample in 300 deceased kidney donors. Telomere length was measured by real-time PCR. All 300 kidneys were biopsied prior to implantation, and the histology was evaluated using the Banff classification. Kidney donor demographics and transplant outcome data were recorded prospectively. IHC was performed for p16, p53, KI-67 and Beta-galactosidase.

**Results:** Telomere length correlated with donor calendar age (p=0.0002). Older donor calendar age associated with IFTA grade and gs (both p<0.006), independent of the other donor characteristics. Telomere length predicted overall graft survival (p=0.02), but not death censored graft survival. Telomere length associated independently with intragraft arteriosclerosis (p<0.0001), independent of the other donor characteristics. Positive staining for p16 correlated (p=0,03) with longer telomere length, while intrarenal KI-67 expression with shorter telomere length. Thus, both molecules consistitute the renal senescent phenotype.

Figure 1: Overall graft survival Telomere Lenght.



**Conclusions:** This study indicates that biological aging and calendar age associate with different histological lesions, and likely represent different senescence pathways. We are currently expanding these studies in native kidney biopsies prior to transplantation, to investigate the molecular mechanisms underlying these observed discrepancies between calendar age and biological aging.

## TH-PO1154

**Peritubular Capillary (PTC) Number in Pre-Implantation Biopsies of Living Donors Is Associated with Cardiovascular Risk Factors and Later Graft Function** Floortje Steegh,[1] Marielle Gelens,[2] Marnix Van Agtmaal,[1] Elly Van Duijnhoven,[2] Mat Daemen,[3] Ernest Van Heurn,[4] Maarten H.L. Christiaans,[2] Carine Peutz-Kootstra.[1] *[1]Pathology, MUMC, Netherlands; [2]Nephrology, MUMC, Netherlands; [3]Pathology, AMC, Netherlands; [4]Surgery, MUMC, Netherlands.*

**Background:** Chronic transplant dysfunction (CTD) is a major cause of renal allograft loss and is associated with PTC loss and fibrosis in the renal biopsy (Bx). Recently we showed that PTC no. in the implantation Bx (M0 Bx) of postmortal and living donors (LDs) predicts PTC loss and graft function after transplantation (Tx). In this study we investigate the prognostic role of PTC no. in relation to CVD risk factors in an extended cohort of patients receiving kidneys from well characterized LDs.

**Methods:** 70 patients with representative protocollar Bx taken at implantation (M0) and 3 mo (M3) after kidney Tx with a LD kidney were included. All patients were treated with TAC-based immunosuppression. PTC no. per tubule at M0 and M3 was counted by 2 blinded observers (ICCs resp. 0.826 and 0.647). Statistical analysis was performed by T-test, Pearson correlations and multivariate analysis.

**Results:** In multivariate analysis we found that donor sex (women>men), positive family history for CVD and smoking of donor, are associated with higher PTC no. at M0. In contrast, high fasting glucose level of donor was associated with low PTC no. (r<sup style="font-family: Calibri; line-height: 17px;">2[/sup]=.327; p<.001, multiregression analysis). In this extended cohort we confirm our earlier finding that PTC no. is not significantly decreased after Tx for LDs. However, low PTC no. at M0 is associated with increased PTC loss the first 3 mo after Tx. Furthermore, PTC loss the first 3 mo after Tx is correlated with MDRD score at resp. 3 mo, and 1, 2 and 3 years after Tx (resp. r=.346,p<.001; r=.288,p=.028; r=.285,p=.030; r=.314,p=.025).

**Conclusions:** We confirm that low PTC no. in the M0 Bx is associated with more PTC loss the first months after Tx which is associated with renal function decline. Furthermore, we show that donor sex, but also CVD risk factors are associated with altered PTC density in the M0 Bx. Our findings indicate that CVD risk factors may affect PTC no. which can contribute to the progression of early CTD.

## TH-PO1155

**Glomerular Size on Time Zero Kidney Allograft Biopsies and Change in Kidney Function after Live Kidney Donation** Howard Hao Yan,[1] Elizabeth Hendren,[1] James Dong,[1] Michael Mengel,[2] John S. Gill.[1] *[1]Div of Nephrology, Univ of British Columbia, Vancouver, Canada; [2]Alberta Transplant Applied Genomics Centre, Univ of Alberta, Edmonton, Canada.*

**Background:** Identification of predictors of kidney function after live kidney donation may help expand the living donor pool or identify donors for long-term clinical follow-up.

**Methods:** In this study, we determined the association of demographic factors (donor age at transplantation, gender, race, body mass index), pre-donation kidney function (eGFR), and kidney allograft biopsy findings (glomerular diameter and volume as determined by Weibel-Gomez method) at time of transplantation (time zero) with change in kidney function (% decrease in eGFR 1 year after live kidney donation) among n=60 live kidney donors in our centre from 2000-2009.

**Results:** Mean±std pre- and post-donation eGFR were 93±14 and 61±15 ml/min/1.73m$^2$, respectively. Mean±std percent change in eGFR after donation was 34±12%, with 91% having ≥ 30% decrement in eGFR. Mean glomerular diameter was 163±17 µm, while mean glomerular volume was 2.81±0.98•10$^6$ µm$^3$. No donors had glomerulomegaly (defined as volume ≥6.81•10$^6$ µm$^3$). In regression analyses, contrary to previous reports, glomerular volume was not associated with donor age, gender, race or BMI. Donor age and overweight BMI were associated with percent decrease in kidney function after donation (3% decrement in pre-donation eGFR for each decade older, p=0.018; 6% decrease in overweight compared to normal BMI, p=0.04), but there was no significant association with pre-donation eGFR, glomerular diameter or volume, donor race or gender.

**Conclusions:** We conclude that eGFR percent decrement post-kidney donation is highly variable, and associated with donor age and overweight BMI at transplantation. eGFR decline in donors with increased BMI is independent of glomerular size. The absence of an association between glomerular diameter and volume with change in kidney function after donation in this study may be due to conservative donor selection. These parameters may still prove useful in the screening of higher-risk donors with other co-morbidities or more marginal levels of pre-donation kidney function.

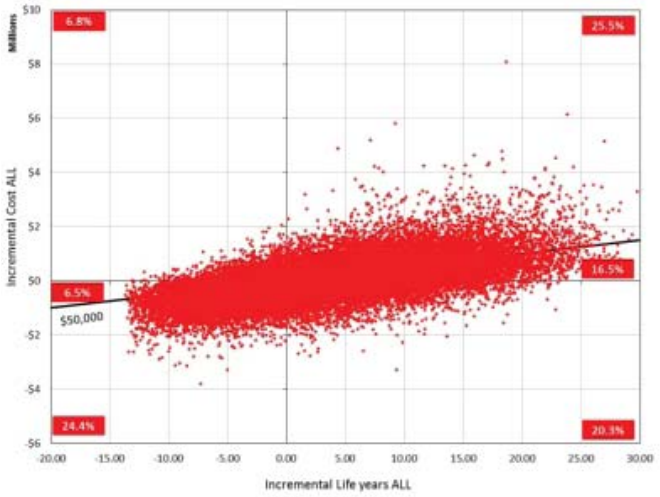
## TH-PO1156

**Is Deceased Donor Kidney Transplantation Cost-Effective across All End Stage Kidney Disease Patients?** Bekir Tanriover, Sumit Mohan, David J. Cohen. *Div of Nephrology, Columbia Univ College of Physicians & Surgeons, New York, NY.*

**Background:** Allocation of deceased donor kidneys is primarily based on waiting time in the US. The current system causes unnecessarily high re-transplantation and death with functioning graft resulting from survival mismatch between donor and recipient.

**Methods:** The United States Renal Data System (USRDS) linked Medicare database was analyzed to obtain real life outcomes, health care utilization related cost of wait-listed end stage kidney disease (ESRD) patients between 2000 and 2008. A probabilistic model was developed to simulate the natural history of a group of potential kidney transplant candidates (n = 100,000), stratified based on their underlying co-morbidities (low risk recipient –RL, defined as age <60 and no co-morbidities and high risk recipient – RH described as old age >60, diabetes, prior history of cardiovascular events including CABG, PTCA/stent, stroke, and peripheral arterial stent and bypass) and deceased donor categorized based on the Kidney Donor Risk Index-KDRI (low risk donor –DL, KDRI<1.6 and high risk donor –DH, KDRI ≥1.6) score.

**Results:** Under current waiting time for deceased donor transplantation, a potential recipient-donor pair achieves an average incremental cost-effectiveness ratio (ICER) of less than $50,000/LYG, except RH-DH group. In overall model, of all renal transplant recipients, 37.7% had worse survival and 38.8% cost more compared to matched wait-listed dialysis patients.



**Conclusions:** Our analysis suggests that renal transplantation is not cost-effective in all pairs compared with dialysis from third party-payers perspective and utilitarian grounds.

## TH-PO1157

**Outcomes of Kidney Transplantation from Older versus Younger Living Donors: Expanding the Donor Pool** Himanshu V. Patel,[1] Pankaj R. Shah,[1] Aruna V. Vanikar,[2] Vivek Balkrishna Kute,[1] Manoj R. Gumber,[1] Hargovind L. Trivedi.[1] *[1]Nephrology and Transplantation, IKDRC-ITS, Ahmedabad, Gujarat, India; [2]Pathology, India, Ahmedabad, Gujarat, India.*

**Background:** The disparity between donor kidney availability and demand has increased utilization of kidneys from older living donors (OLD). We compared outcome of OLD kidney transplants (group-1) with younger live donor (YLD) (<60 years) kidney transplants (group- 2).

**Methods:** Outcome of renal transplants performed between 2007 to 2012 was compared in terms of demographics, survival and graft function.

**Results:** Out of 1457 transplants, 147(10.1% ) belonged to group-1 and 1310 (89.9% ) belonged to group-2. Mean donor/recipient age was 62.7/36.6 years in group-1 and 43.5/33.8 years in group-2 and HLA-match was 3.12 and 2.46 respectively. Post-transplant immunosuppression consisted of calcineurin inhibitor based regimen in both groups. Patient survival at 1, 3 and 5-years was 95.7% , 89.4% and 82.6% in group-1 and 93.8% , 89.1% and 83.1% in group-2 (P=0.785). Death-censored graft survival at 1, 3 and 5-years was 98.5% , 94.8% and 94.8% in group-1 and 96.1% , 92.9% and 89% in group-2(P=0.166). Biopsy proven acute rejections were and 21% and 16.8% (P=0.206) and chronic rejections 5.03% and 3.4% respectively (p= 0.542).

**Conclusions:** Patient, graft survival and immune injuries were comparable for recipients of OLD kidneys and YLD kidneys. This study suggests that in organ availability crisis, OLD kidneys can be utilized without compromising the recipient 5-year patient or graft survival. This facilitates in decreasing the transplantation waiting lists.

## TH-PO1158

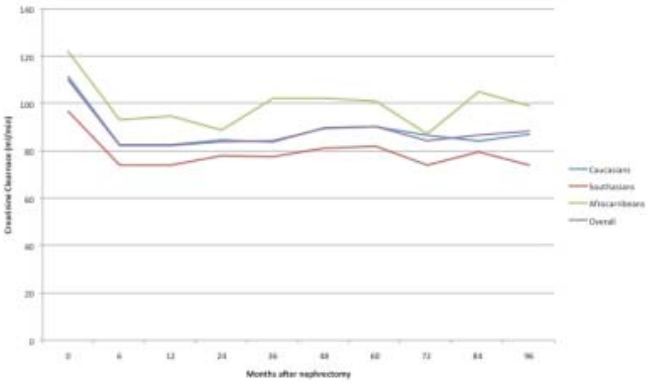
**Ethnicity Does Not Determine Long-Outcome after Donor Nephrectomy** Dimitrios Anestis Moutzouris, Rawya Charif, Jack W. Galliford, Jen McDermott, Harvinder Dulku, Honeylet Orr, David Taube, Marina Loucaidou. *Imperial College Kidney and Transplant Centre, Hammersmith Hospital, London, United Kingdom.*

**Background:** Living kidney donor transplantation is the treatment of choice for ESRD. Although long term data suggests that survival and chronic kidney disease risk in living donors (LD) is similar to general populations, data is limited regarding ethnic groups, particularly South Asian(SA) and Afro-Caribbean(AC) populations. We previously reported 5-year data on LD from different ethnic groups in our centre.

**Methods:** We prospectively collected data on consecutive LD(2000-2012). We analyzed follow-up data for 24-hour Creatinine Clearance(CrCl) and protein excretion, and blood pressure control. We included LD with at least one year of follow-up. We used one-way and repeated measures ANOVA for analysis.

**Results:** We studied 555 LD. 424 completed 12-month,170 had 60-month and 52 had 96-month follow-up. 338(56.8%) were caucasian (CA),113(19%) were SA, 53(8.9%) were AC. There were 51 LD with history of hypertension (HTN). 48 donors developed HTN during the follow up period. AC patients were at increased risk for developing HTN(CA=30(10.2%),AC=9(21.4%) and SA=6(6.9%)(p<0.05).

The mean CrCl (mls/min) at baseline, 60 and 96 months was 110, 95 and 89 (CA=111±32, 90±26 and 87±27, SA=97±25, 82±17 and 74±9, AC=122±36, 101±40 and 99±23 (p<0.01, but for the rate of CrCl change p=NS).



There was significant ethnic group age difference (CA=48±12, SA=43±13 and AC=38±9 years,p<0.01). There was no difference in the degree of proteinuria at baseline and at five years (011±0.1 vs 012±0.1g/24h,p=NS),even in patients with pre-existing HTN (0.21±0.2 vs 0.18±0.1 g/24h,p=NS).

**Conclusions:** Donor nephrectomy in high risk ethnic groups is safe and not associated with poorer outcomes. Kidney function was preserved and proteinuria was minimal over time. AC population is at increased risk for developing HTN.

## TH-PO1159

**Impact of Donor Glomerular Filtration Rate on Post Transplant Donor and Recipient Renal Function** Aneesha A. Shetty, Eric Soukup, Emilio D. Poggio. *Dept of Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH.*

**Background:** A glomerular filtration rate (GFR) greater than 80 ml/min/1.73m$^2$ independent of age and gender is considered suitable by certain living kidney donor selection guidelines. We studied the association of pre-transplant donor GFR with donor and recipient renal function post transplant to the impact of this screening criteria.

**Methods:** Pre-transplant $^{125}$I-iothalamate GFR was measured and pertinent demographic data was captured in 570 living kidney donors as part of donor evaluation. Follow up donor and recipient estimated GFR (eGFR) was calculated using the MDRD equation at 1, 2 and 3 years post-transplant.

**Results:** Mean pre-transplant donor BSA adjusted GFR (iGFR) was 106+/-23 ml/min/1.73m$^2$ and unadjusted GFR (uGFR) was 116+/-21 ml/min. Mean age was 43.5+/-11.6 years with 41.4% males and 14.4% African Americans. Mean donor eGFR was 63.8+/-12.3 ml/min, 66.4+/-15.8 ml/min and 68.7+/-10.6 ml/min, and mean recipient eGFR was 58.4+/-21.9 ml/min, 56.6+/- 24.5 ml/min and 55.1+/-23.5 ml/min at 1, 2 and 3 years of follow up.

Donor iGFR was a significant univariate predictor of donor eGFR at 1 and 2 years (p <0.05), but not at 3 years. Donor iGFR less than 90 ml/min/1.73m$^2$ was associated with lower donor eGFR at 1 year (p=0.01) but not at 2 or 3 years. In multivariate analyses donor iGFR was a significant predictor of donor eGFR at 1 year only (p = 0.003), while donor age remained a significant predictor of donor eGFR at 1 year (p=0.006) and 2 years (p=0.03). Gender and race were not significant predictors.

On recipient outcomes analyses donor uGFR was not associated with recipient eGFR over 3 years. In the multivariate model, however, donor age was negatively associated with recipient eGFR at 1 and 2 years (p<0.0001) but not at 3 years.

**Conclusions:** Recipient renal function up to 3 years post-transplant is independent of pre-transplant donor GFR. On the other hand, while donor GFR at 1 year post donation is lower for older donors with pre-transplant GFR less than 90 ml/min/1.73m$^2$, long term donor GFR appears to be independent of pre-donation GFR. Importantly, the compensatory effects of the remaining donor kidney GFR appears to be sustained or even increased over time.

## TH-PO1160

**Kidney Biopsy in Potential Donors with Non Visible Haematuria Is a Valuable Component of Donor Work-Up** Emma O'Lone, Abigail Lee, Ravindra Rajakariar, Raj C. Thuraisingham, Mark Blunden. *Nephrology, Barts and The London Hospitals, United Kingdom.*

**Background:** BTS guidelines recommend renal biopsy if non-visible haematuria (NVH) is >1+ on dipstick. Glomerular pathology precludes donation with the possible exception of thin basement membrane (TBM) disease. The level of evidence for these guidelines is graded as"moderate"; little data exists to support them. All biopsies performed on potential living kidney donors with NVH were reviewed.

**Methods:** A single centre review of prospectively collected data of patients between Jan 2008 and June 2013. Patients with undiagnosed NVH underwent biopsy. Percutaneous biopsy was performed under direct ultrasound (US) guidance using an 18 or 16 gauge needle. Samples were examined by a consultant histopathlogist by light microscopy (LM), immuno-histochemistry and electron microscopy (EM).

**Results:** 148 living donor transplants were performed in the 5 year period. 15 renal biopsies were done for undiagnosed NVH in 14 potential donors. Work-up included urine cytology, flexible cystoscopy, US and CT examination of urinary tract. Of those patients biopsied: Mean age 41.5 years and 33% male. Mean eGFR (by MDRD) of 94.5mls/min and mean corrected EDTA clearance 93.7mls/min. 11 (68.8%) biopsies had normal LM and immuno-histochemistry. Of these EM was normal in 6; TBM was diagnosed in 2 and minor paramesangial deposits seen in 2. 1 patient was found to have Zebra bodies on EM, Fabry's disease was excluded and the patient had previous exposure to chloroquine so donation went ahead. 4 biopsies precluded donation; 2 showed significant scarring, 1 a granulomatous TIN consistent with TB and repeat biopsy after treatment showed IgA nephopathy. Overall 11 patients were deemed suitable for donation and 4 biopsies (25%) precluded donation in 3 patients. All biopsies were performed as a day case and no complications were seen.

**Conclusions:** Biopsy for investigating NVH in potential donors is a safe and helpful investigation. It led to rejection of 25% of potential donors, despite acceptable EDTA GFR results but re-assured the transplanting team in 75% of cases. The long term significance of TBM disease and minor paramesangial deposits is uncertain in this scenario.

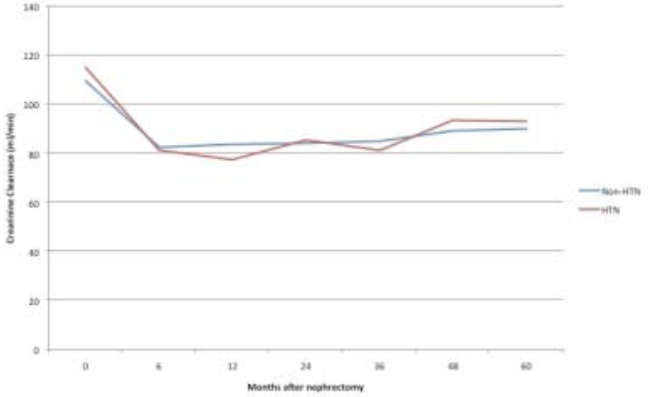
## TH-PO1161

**Hypertension Is Not a Contraindication to Living Kidney Donation** Rawya Charif, Dimitrios Anestis Moutzouris, Jack W. Galliford, Jen McDermott, Honeylet Orr, Harvinder Dulku, David Taube, Marina Loucaidou. *Imperial College Kidney and Transplant Centre, Hammersmith Hospital, London, United Kingdom.*

**Background:** The increasing numbers of patients with ESRF on waiting list for a kidney transplant has been the main driving force for expanding the donor pool. We undertook living kidney donor transplantation from hypertensive donors after initial reports that short-term outcomes are safe. We report 5-yr data in this group and compare these with the outcomes of non-hypertensive donors from our centre.

**Methods:** Data were prospectively collected on 555 consecutive live donors(LD) from 2000-2012. The hypertensive group consists of LD presenting with a pre-existing diagnosis of hypertension(HTN), well-controlled on at least one antihypertensive agent and without evidence of end-organ damage. We analysed 5-yr follow-up data for 24 hr Creatinine Clearance(CrCl) and protein excretion as well as blood pressure (BP) control.

**Results:** 51 LD were hypertensive(H) and 504 non-hypertensive(NH). In the NH group 302(59.9%) were Caucasian (C), 104(20.6%) South Asian(SA), 49(9.7%) Afrocaribbean (AC) and 49(9.7%) of other ethnicity. There was a higher percentage of C in the H group (70.6%) but similar of SA and AC. Mean age was 45.5 years(yrs) (H=54.6, NH=44.6, p<0.001) with a mean weight of 75.6 Kg(H=78.6, NH=75.0, p=0.01). The mean CrCl (ml/min) was 110.1 (H=115.2, NH=109.6, p=0.26) at time 0 and 90.4 (H=93.0, NH=90.0, p=0.17) at 5 yrs.



We did not find evidence of developing proteinuria in with 24-hour protein excretion of 0.12 (H=0.17, NH=0.10, p=0.03) g/24hrs at 5 yrs. BP remained well-controlled in the H group at 5 yrs at 139/85 vs 135/81 in the NH group (p=0.25). 48 donors in the NH group developed HTN post donation.

**Conclusions:** Donor nephrectomy in well-controlled hypertensive donors with no evidence of end-organ damage is safe and does not result in poorer outcomes compared to non-hypertensive donors.

## TH-PO1162

**Screening for Adequate GFR in Obese Potential Kidney Donors** Sanjeev Akkina, Mahvesh K. Mahmud, Ignatius Yun-Sang Tang. *Medicine, Univ of Illinois at Chicago, Chicago, IL.*

**Background:** As organs become scarce, more obese donors are being considered for kidney donation. Assessment of glomerular filtration rate (GFR) is critical in the evaluation of these potential donors. Accurate measurement of GFR using exogenous markers is expensive and time-consuming which complicate the medical evaluation of potential kidney donors. The objective of this study is to identify potential obese donors that need formal measurements of GFR.

**Methods:** This is a single-center, retrospective analysis of potential kidney donors between 2009-2012. Estimation of GFR was by 24 hour urine collection (CrCl) or by using the Modification of Diet in Renal Disease (MDRD) and the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations. Measured GFR (mGFR) was either by camera-based technetium clearance or iohexol clearance. Sensitivity and specificity was calculated for mGFR > 80 and 90mL/min/1.73m2 using estimated cutoffs 10mL/min/1.73m2 above the corresponding measured cutoff to increase specificity. Groups were divided by BMI (<35, >35).

**Results:** There were 250 potential kidney donors with a mGFR. The average age was 38.0±11.9 years with 60% female and a racial composition of 44% Black, 26% White, and 20% Hispanic. The sensitivity/specificity analysis is shown in the table. Pre-donation proteinuria was similar between the groups as was post-donation microalbuminuria (n=135) and prevalence of those with eGFR < 60mL/min/1.73m2 (n=151) with median follow up time of 6 months (3-12 months).

| | BMI < 35 (n=176) | BMI > 35 (n=74) |
|---|---|---|
| | Sensitivity/Specificity | Sensitivity/Specificity |
| mGFR > 80, eGFR > 90 | | |
| 24hr CrCl* | 67/33 | 96/25 |
| MDRD | 47/94 | 59/62 |
| CKD-EPI | 71/61 | 85/50 |
| | | |
| mGFR > 90, eGFR > 100 | | |
| 24hr CrCl* | 56/46 | 91/33 |
| MDRD | 33/92 | 46/86 |
| CKD-EPI | 49/92 | 67/64 |

*72 individuals with a BMI < 35, 31 with a BMI > 35.

**Conclusions:** The MDRD equation with a cutoff of 10mL/min/1.73m2 higher than the required mGFR may identify both obese and non-obese potential kidney donors needing a mGFR. Results should be validated in an independent cohort before screening potential kidney donors.

*Funding:* NIDDK Support

## TH-PO1163

### The Change of Single Kidney Function in Kidney Donor after Uninephrectomy

Ji Hyun Yu,[2,3] Keun Suk Yang,[2,3] Seun Deuk Hwang,[2,3] Jong Hoon Lee,[3] Eun Nim Kim,[1,2,3] Cheol Whee Park,[1,2,3] Yong-Soo Kim,[1,2,3] Chul Woo Yang,[1,2,3] Bum-Soon Choi.[1,2,3] *[1]Transplant Research Center; [2]Div of Nephrology; [3]Dept of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

**Background:** It was not fully investigated that how reserved capacity of single kidney for healthy kidney donor changes after unilateral nephrectomy. The aim of this study was to assess the change of remaining single kidney function after kidney donation and to evaluate predictive pre-donation factor for reserved single kidney capacity in donors.

**Methods:** Total 74 kidney donors who underwent $^{99m}$Tc-DTPA Scintillation-Camera renography before and after kidney donation were included in this study. By the renography, we measured single-kidney glomerular filtration rate (sk-GFR) of both kidney before donation and post-donation GFR of remaining kidney during 12 months. We investigated the factors that are associated with reserved capacity of remaining single kidney after donation.

**Results:** After uninephrectomy the mean of serum creatinine increased significantly (P=0.000, from 0.77 to 1.07 mg/dL) and the mean GFR measured by the renography declined (P=0.000, from 112.9 to 74.9 ml/min/1.73m$^2$). Nevertheless the mean of serum creatinine and mGFR was stabilized during 12 months follow-up period (mGFR at Post-donation, P=0.165 [6 month 74.9 ± 18.2 vs 12 month 81.4 ± 14.8 ml/min/1.73m$^2$]). The sk-GFR of remaining kidney significantly increased by 33.6 % after uninephrectomy (sk-GFR, P < 0.01 [Pre-nephrectomy 57.9 vs Post-nephrectomy 77.5 ml/min/1.73m$^2$]). By univariate linear regression, BMI, total mGFR, sk-GFR of remaining kidney and total kidney volume at pre-donation were included as independent predictors of change of sk-GFR. Among these, BMI (P=0.013) and sk-GFR of remaining kidney at pre-donation (P=0.019) were statistically related to reserved single kidney capacity in multivariate regression analysis.

**Conclusions:** After kidney donation, reserved single kidney capacity shows significant increase due to adaptive hyperfiltration. Especially in donor with lower BMI and lower sk-GFR of remaining kidney at pre-donation shows more compensatory response.

## TH-PO1164

### Kidney Transplant Outcomes among prior Live Organ Donors

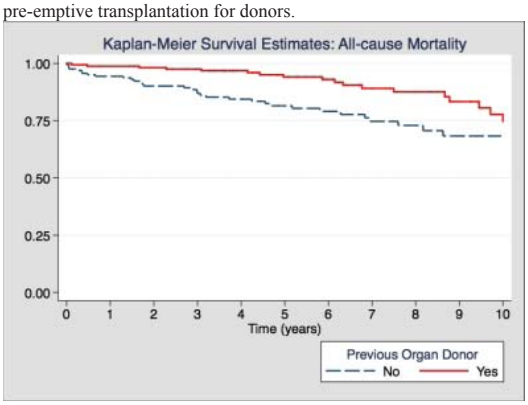
Vishnu S. Potluri, Meera Nair, Francis P. Wilson, Roy D. Bloom, Peter P. Reese. *Renal Div, Univ of Pennsylvania, Philadelphia, PA.*

**Background:** OPTN gives high priority in organ allocation to wait-listed candidates who are previous organ donors. However, information about waiting time for kidney transplant, organ quality and post-transplant outcomes among former live donors has not been reported.

**Methods:** We assembled a cohort of candidates listed for a kidney transplant from 1996 to 2010 using Scientific Registry of Transplant Recipients data. We used multivariable Cox regression to examine the association of prior kidney donor status to time to kidney transplant. Among candidates who received a kidney transplant, we used a 1:1 propensity score approach to compare allograft quality as measured by the kidney donor risk index (KDRI) and post-transplant outcomes among prior organ donors to recipients with similar demographic and clinical characteristics.

**Results:** During the study period, there were 407,212 listings for a kidney transplant, of which 268 were prior organ donors. Among listed candidates, 82% (n=214) of donors received a deceased donor kidney transplant as compared to 34% (n=140,046) of non-donors. The median time to transplant for organ donors was 174 days (HR for transplant associated with prior organ donor status 4.8, p<0.001). Most prior donors received dialysis by the time of listing (68% vs 65%, p=.56). Compared to matched recipients, prior organ donors received higher quality allografts (Median KDRI 0.72 for donors vs 0.82 for non-donors), p<.001. Donors did not have better all-cause graft survival than non-donors (HR 1.3, p=.3), but had lower mortality (HR .32, p=.003).

**Conclusions:** OPTN policy has enabled transplant candidates who are previous organ donors to have a brief waiting time for kidney transplantation. However, >60% of donors had dialysis by wait-listing. Early nephrology referral and transplant evaluation may enable pre-emptive transplantation for donors.



## TH-PO1165

### Hypothermic Machine Perfusion versus Cold Storage for Deceased-Donor Organ Preservation – Systematic Review and Meta-Analysis

Manvir Kaur Hayer, Adnan Sharif. *Institue of Renal Medicine, Queen Elizabeth Hospital, Birmingham, West Midlands, United Kingdom.*

**Background:** Organ preservation helps optimise outcomes from deceased kidney donors, with hypothermic machine perfusion (HMP) thought to reduce the noxious effects of ischaemic reperfusion injury. However there is conflicting evidence on the benefit of HMP versus cold storage (CS). We performed a systematic review and meta-analysis of all prospective randomised controlled trials (RCTs) comparing HMP versus CS for preservation of deceased kidney donors.

**Methods:** Medline, Embase and the Cochrane Register of Controlled Trials were searched from 1966 to 2013 for relevant studies in English. We included all prospective RCTs. 2 reviewers independently extracted study data. RevMan 5 program was used to perform the meta-analysis with the odds ratio (OR) calculated for dichotomous data. Fixed-effect models were chosen for non-heterogeneous analyses ($I^2$<30%), assuming a similar treatment effect across studies. Where heterogeneity persisted ($I^2$ ≥30%), results from random-effect models are reported, assuming that treatment effect varies across studies.

**Results:** We identified 22 studies with data for 2236 kidney allograft recipients. 21 studies were original data; 1 was an extraction of extended criteria donor kidney allografts from a previously published study. Significant heterogeneity existed across studies on donor type and machine perfusion logistics. Delayed graft function (DGF) was lower with HMP than CS in all studies (OR 0.63 [95% CI 0.48-0.81] p=0.004) but there was no difference in graft loss (OR 0.81 [95% CI 0.52-1.25] p=0.35). Analysing the 5 studies using DCD kidneys only showed lower DGF rates (OR 0.54 [95% CI 0.35-0.82], p=0.004) but no difference in graft survival (OR 1.56 [95% CI 0.69-3.55], p=0.29). Analysing the 7 documented prospective RCTs showed similar reduction in DGF (OR 0.70 [95% CI 0.56-0.88] p=0.002) and a reduction in graft loss (OR 0.62 [95% CI 0.42-0.93] p=0.02).

**Conclusions:** HMP significantly reduces DGF rates but it is unclear if this results in lower kidney allograft attrition rates in the long term post transplantation. Further well designed, adequately powered trials are needed to ultimately investigate the benefits of HMP.

**FR-PO001**

**Spit It Out to Check Your Kidneys: Saliva Urea Nitrogen Dipstick as a New Bedside Diagnostic Tool of Acute Kidney Injury**

Viviane Calice da Silva,[1,2] Marcos Alexandre Vieira,[1] Jochen G. Raimann,[3] Mary Carter,[3] John Callegari,[3] Nathan W. Levin,[3] Peter Kotanko,[3] Roberto Pecoits-Filho.[2] *[1]Pró-rim Foundation, Brazil; [2]School of Medicine, Pontificia Universidade Católica do Paraná, Brazil; [3]Renal Research Institute.*

**Background:** Kidney dysfunction can be identified non-invasively using a dipstick that semi-quantitatively determines saliva urea nitrogen (SUN) levels The SUN dipstick may be useful in areas with limited access to clinical chemistry facilities. Here, we evaluated the performance of SUN dipstick in patients with acute kidney injury (AKI; as per AKIN criteria).

**Methods:** Unstimulated saliva from hospitalized patients with pre-renal (PrR), renal (R) or post-renal (PoR) suspected AKI; blood urea nitrogen (BUN) was measured concomitantly. After collected, saliva was transferred to the SUN dipstick (Integrated Biomedical Technology, IN) and SUN's levels were read within one minute. The color of the test pad was compared to 6 standardized test pads indicating SUN concentrations: 5–14 (#1), 15–24 (#2), 25–34 (#3), 35–54 (#4), 55–74 (#5), and 75 (#6) mg/dL. Spearman's correlation test (Rs), areas under receiver operating characteristic curves (AUC ROC) and 95% confidence intervals evaluated the performances of SUN and BUN to diagnose AKIN 3. Youden's Index was used to compute thresholds to discriminate AKIN 3 from earlier AKI stages.

**Results:** 44 AKI patients (59.5±18 years, 58% female) (PrR: 67%; R: 24%; PoR: 9 %) with AKIN stage 1(33 %), 2 (27%), and 3 (40%) were enrolled. SUN and BUN levels were correlated (Rs= 0.77; p<0.001) irrespective of AKIN stage and AKI etiology. The diagnostic performance of SUN (AUC ROC: 0.76 (95% CI 0.61-0.91) and BUN (AUC ROC: 0.69 (95% CI 0.51-0.87) was comparable. Optimal diagnostic threshold levels were 72 mg/dL for BUN and 25-34 mg/dL (test pad #3) for SUN.

**Conclusions:** Our study indicates that SUN dipsticks discriminated AKIN 3 from earlier AKI stages which carry a lower probability to require dialysis. This low-resource technology may help to improve the diagnosis of advanced AKI and aid triaging patients in areas with limited access to healthcare facilities and may improve outcomes.

**FR-PO002**

**Biomarker Panels Can Predict and Classify Acute Kidney Injury**

Rajit K. Basu,[1] Catherine D. Krawczeski,[1] Lakhmir S. Chawla,[2] Derek Wheeler,[1] Stuart Goldstein.[1] *[1]Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Anesthesia and Critical Care, George Washington Univ, Washington, DC.*

**Background:** The ability to classify AKI severity or category of AKI (functional change or kidney damage) using biomarkers, a key directive from the 10th Acute Dialysis Quality Initiative (ADQI) conference, has yet to be demonstrated.

**Methods:** We retrospectively studied 359 children following cardiopulmonary bypass (CPB) surgery (pts) to determine if a biomarker panel taken 12 hours after CPB could differentiate the following AKI 'signatures': 1) severity of AKI or 2) AKI type: functional change or kidney damage. Severe AKI was defined as pRIFLE I-F (by creatinine) within the first seven days after CPB. AKI lasting only 1-2 days was deemed functional change. The functional change biomarker used was plasma Cystatin C (pCysC) while the kidney damage biomarker was urinary neutrophil gelatinase associated lipocalin normalized to creatinine (uNGAL/uCr). Sensitivity analyses identified cut-off values for both pCysC and uNGAL/uCr ("+").

**Results:** AKI occurred in 62 pts (17.3%). Pts with dual marker positivity were highly likely to develop severe AKI (likelihood ratio (+LR):24.6) while pts with dual marker negativity were highly unlikely (-LR:6.12). Pts with only (+)functional marker demonstrated a negligible increase in likelihood of severe AKI (+LR:1.04). In pts with AKI, a (+) functional/(-)damage panel carried a higher likelihood of functional injury (reversible), than any other biomarker combination and were unlikely to have persistent severe AKI (+LR:0.76). Addition of a positive damage marker (both positive) predicted a persistent AKI.

| **Outcome:** AKI ≤ 2 days (Reversible AKI) | | Damage Marker (uNGAL/uCr) | |
|---|---|---|---|
| | | Negative | Positive |
| Functional Marker (pCysC) | Negative | (+)LR: 0.00<br>(-)LR: 0.94<br>*No functional changes or damage* | (+)LR: 0.88<br>(-)LR: 1.04<br>*Damage without loss of function* |
| | Positive | (+)LR: 1.32<br>(-)LR: 0.97<br>*Functional AKI* | (+)LR: 0.92<br>(-)LR: 1.17<br>*Damage and loss of function* |

*Biomarker panel with ADQI-X phenotyped italicized.*
*Likelihood Ratios (LR) are for the outcome of AKI ≤ 2 days.*

**Conclusions:** Our data operationalizes the primary ADQI-X goal, combining functional and damage biomarkers into a panel which affords categorization of AKI severity and duration, predicting an AKI phenotype.

**B-Type Natriuretic Peptide Reduces Acute Kidney Injury: A Meta-Analysis**

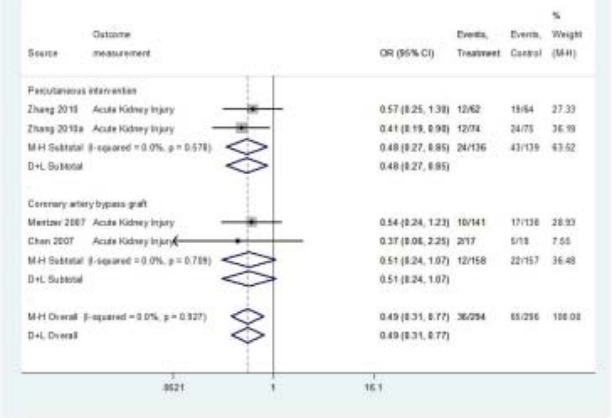
Sayyad F. Kyazimzade,[1] Daniel M. Pearlman,[1] Jeremiah R. Brown,[1] Alex L. Yerukhimov.[2] *[1]The Dartmouth Institute for Health Policy and Clinical Practice at the Geisel School of Medicine, Lebanon, NH; [2]Dartmouth College, Hanover, NH.*

**Background:** B-type natriuretic peptide (BNP) has been shown to improve renal function in individual clinical trials. However no systematic review or meta-analysis has been performed to determine whether BNP prophylaxis prevents acute kidney injury (AKI) in multiple randomized clinical trials involving coronary artery bypass graft (CABG) or primary percutaneous intervention (PCI). We hypothesized prophylactic treatment with BNP reduces the risk of AKI in cardiac procedures.

**Methods:** We conducted a meta-analysis for published randomized clinical trials involving treatment of BNP in percutaneous interventions or cardiac surgery procedures and reporting renal function. Our search identified 71 records, of which 5 RCTs, including 839 patients, met our pre-specified eligibility criteria. One article was excluded because BNP was administered after AKI was established. We calculated a random effects summary estimate for all trials and stratified by procedure type.

**Results:** Overall, only 12.2% of patients receiving BNP developed AKI compared 22.0% in controls with an odds ratio of 0.49 (95% confidence interval: 0.31 to 0.77, $P$ = 0.002 see figure). After stratifying this analysis by procedure type, risk of AKI remained significantly decreased for PCI (17.6% vs. 30.9%; OR, 0.48; 95% CI, 0.27 to 0.85; $P$ = 0.011) but not CABG (7.6% vs. 14.0%; OR, 0.51; 95% CI, 0.24 to 1.07; $P$ = 0.074). There was no observed heterogeneity (I-squared 0.0%; $P$ > 0.50).

**Conclusions:** Perioperative administration of BNP reduces the risk of AKI for patients undergoing PCI but not CABG surgery.



**FR-PO004**

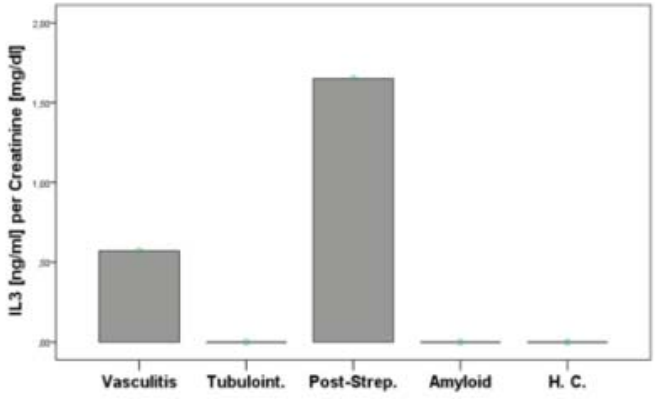
**Biomarker Profile in Biopsy-Proven Renal Diseases**

Natalie M. Otto,[1] Volker Schmitz,[1] Stephan Wolfgang Hanschke,[1] Joe F. Keenan,[2] Ralf Schindler.[1] *[1]Nephrology and Intensive Care, Charite, Berlin, Germany; [2]EKF Diagnostics Limited, Trinity Technology Campus, Dublin, Ireland.*

**Background:** The major tool to assess renal disease is the kidney biopsy. Efforts have been made to identify non-invasive markers to predict the type of renal damage. We investigated a variety of serum biomarkers to predict the category of renal histology obtained by biopsy.

**Methods:** 140 consecutive patients underwent renal biopsy as clinically indicated. Serum and urinary samples were prospectively collected and analyzed for 46 biomarkers. Serum levels of biomarkers were adjusted for serum creatinine. Biopsy results were categorized in 8 disease entities and biomarker levels compared in each category.

**Results:** Biopsy results were: minimal change/FSGS (n=38), vasculitis (n=19), IgA-nephropathy (n=20), membraneous nephropathy (n=19), diabetic nephropathy (n=11), hypertensive nephropathy (n=19), post-streptococcal nephritis (n=2), amyloidosis (n=4) and tubulointerstitial lesions (n=8). 10 healthy subjects without biopsy served as controls. There was a characteristic pattern of biomarker elevation for certain histological entities. For instance, IL-3 was elevated only in vasculitis and post-streptococcal nephritis (figure).



Several biomarker such as IL-6, IL-7, IL-8 were exclusively elevated in post-streptococcal nephritis. In contrast, tubulointerstitial disease was characterized by elevated levels of KIM-1 but marked decreased levels of biomarkers such as IL-23 or MMP-9. Hypertensive- and IgA-nephropathy did not show characteristic profiles of the investigated markers. Urinary biomarker results will also be presented.

**Conclusions:** In some types of renal disease serum levels of certain biomarkers are significantly different from controls. There appears to be a characteristic biomarker pattern for several disease entities that could help predicting the renal disease by straightforward and non-invasive analysis.

## FR-PO005

**Urine Microscopy – A Golden Tool in Diagnosis of Acute Kidney Injury**

Pinaki Mukhopadhyay,[1] Piyali Banerjee,[2] Gautam Mukherjee.[3] *[1]Nephrology, NRS Medical College & Hospital, Kolkata, West Bengal, India; [2]Medicine, Bagnan Rural Hospital, Howrah, West Bengal, India; [3]Gynaecology & Obstretics, North Bengal Medical College, Siliguri, West Bengal, India.*

**Background:** Urine microscopy is very important diagnostic modality.The aim of the study was to review the role of urine microscopy and urine sediment examination in the differential diagnosis and outcome prediction of acute kidney injury (AKI ).

**Methods:** All patients admitted with AKI (RIFLE criteria) were included and urine was tested for different cast, including granular cast(GC),renal tubular epithelial cell(RTEC). AKI cause (pre renal/acute tubular necrosis ,ATN) was evaluated by nephrologist two times before urine testing and at discharge. A scoring system {Scoring 1(RTEC & GC=0),2(RTEC=0&GC=1to5 or RTEC=1to5 &GC=0),3(RTEC=1to5&GC=1to5 orRTEC=0 &GC 6to 10 orRTEC=6to20 & GC=0 )} was created based on casts and RTEC and evaluated its accuracy for differentiating ATN from prerenal AKI . Likelihood ratios (LR) were calculated for a diagnosis of both ATN and prerenal AKI.

**Results:** The urinary sediment scoring system was highly predictive of the final diagnosis of ATN. The odds ratio (OR) for ATN incrementally increased with an increase in severity of the scoring system (all compared with score 0; score 1: OR 9.7, 95% CI 5.3 to 18.6; score ≥2: OR 74.0, 95% CI 16.6 to 329.1; In patients with a high pretest probability of ATN (initial diagnosis of ATN), any granular casts or RTEC (score ≥2) resulted in very high Positive Predictive Value (100%) and low NegetivePredictiveValue (44%) for a final diagnosis of ATN. In patients with a low pretest probability of ATN (initial diagnosis of prerenal AKI), the lack of granular casts or RTEC on urinary sediment examination had a sensitivity of 0.73 and a specificity of 0.75 for a final diagnosis of ATN. The NPV of lack of granular casts or RTEC in patients with low pretest probability of disease was 91%.

**Conclusions:** urine microscopy on the day of nephrology consultation is a valuable diagnostic tool for strengthening the probability of a diagnosis of ATN. Furthermore, an ATN scoring system is useful for improving the differential diagnosis of ATN *versus* prerenal AKI.

## FR-PO006

**Urinalysis (UA) Dipstick Proteinuria (DP) at ICU Admission Predicts Mortality in Sepsis**

John Manllo, Javier A. Neyra, Fabrizio Canepa, Ghassan Bandak, Jerry Yee, Lenar T. Yessayan. *Dept of Medicine, Henry Ford Hospital, Detroit, MI.*

**Background:** Sepsis is one of the most common causes of admission to the ICU, with a high degree of mortality, early predictors for mortality are helpful in clinical practice, to ensure prompt intervention. The purpose of our study is to assess the utility of UA DP as a predictor of clinical outcome in patients with sepsis.

**Methods:** 5,558 consecutive patients admitted to the ICU between October 2007 and April 2012 with severe sepsis (N=4,032) or septic shock (N=1,826) were screened for DP within 24 h of admission. Exclusion criteria:>100 RBC/hpf on microscopic UA; bacteriuria; urinary tract infection diagnosed by 24 h of admission; and within 3 months pre-admission, absence of UA testing, UA DP, or documented proteinuria by other means.

**Results:** 229 patients fulfilled study criteria. Bivariate analysis revealed that UA DP was associated with ICU mortality OR=3.91 (1.72-8.86), p=0.001 and hospital mortality OR=3.65, (1.77-7.53), p=0.001. Associations persisted in a Multivariate model that adjusted for ICU severity score (APACHE II), vasopressor use, age, and level of creatinine in the first 24 h post-admission.

| | Odds Ratio of ICU Mortality | | Odds Ratio of Hospital Mortality | |
|---|---|---|---|---|
| Parameter | Odds Ratio (95 CI%) | P-value | Odds Ratio (95 CI%) | P-value |
| Proteinuria on admission | 2.62 (1.08- 6.37) | 0.034 | 2.27 (1.04-4.97) | 0.040 |
| Vasopressor use | 3.17 (1.48 6.79) | 0.003 | 2.94 (1.46- 5.91) | 0.002 |
| APACHE II | 1.04 (0.97-1.10) | 0.282 | 1.03 (0.97-1.09) | 0.366 |
| Creatinine (*mg/dl*) | 1.16 (0.85- 1.58) | 0.349 | 1.16 (0.87-1.55) | 0.508 |
| Age (years) | 0.98 (0.95- 1.00) | 0.084 | 0.992 (0.97-1.02) | 0.319 |

**Conclusions:** In severe sepsis or septic shock ICU patients UA DP bear significant mortality risk for ICU and/or hospital mortality.

## FR-PO007

**Urinary Biomarkers and Differential Diagnosis of Acute Kidney Injury in Patients with Cirrhosis**

Justin Miles Belcher,[1] Guadalupe Garcia-Tsao,[1] Arun Sanyal,[2] Joseph K. Lim,[1] Mark A. Perazella,[1] Aldo J. Peixoto,[1] Chirag R. Parikh.[1] *[1]Yale Univ; [2]Virginia Commonwealth Univ.*

**Background:** Acute kidney injury (AKI) is common in patients with cirrhosis and carries a poor prognosis. Effective treatment relies upon accurate differential diagnosis of the cause of AKI but distinguishing acute tubular necrosis (ATN) from hepatorenal syndrome (HRS) is challenging. HRS is a hemodynamically mediated disease not associated with significant tubular injury. Utilizing rigorous clinical adjudication as a gold standard, biomarkers of structural AKI may therefore identify ATN in these patients.

**Methods:** 76 prospectively enrolled patients with cirrhosis and progressive AKI were blindly adjudicated by three physicians. A diagnosis of HRS, ATN or prerenal azotemia (PRA) was retrospectively made upon review of medical records, including AKI outcome. Urine samples collected upon meeting AKIN criteria were measured for neutrophil gelatinase-associated lipocalin (NGAL), interleukin-18 (IL-18), kidney injury molecule-1 (KIM-1), liver-type fatty acid binding protein (L-FABP), fractional excretion of sodium (FENa) and albumin.

**Results:** 39 (53%) patients were diagnosed with ATN, 19 (26%) with PRA and 16 (22%) with HRS. Median values for NGAL, L-FABP and albumin were significantly higher in patients with ATN while IL-18 demonstrating a strong trend. While FENa was significantly higher in patients with ATN compared to HRS, it did not reach overall statistical significance.

| | PRA N=19 | HRS N=16 | ATN N=39 | P Overall | P ATN vs HRS |
|---|---|---|---|---|---|
| *Tubular injury markers* | | | | | |
| **NGAL (ng/ml)** | 78 (16-206) | 115 (51-373) | 565 (76-1000) | 0.001 | 0.01 |
| **IL-18 (pg/ml)** | 46 (15-106) | 37 (15-90) | 124 (15-325) | 0.06 | 0.05 |
| **KIM-1 (ng/ml)** | 4.6 (2.6-12.7) | 7.6 (4.5-10.1) | 8.4 (4.1-18.3) | 0.13 | 0.40 |
| **L-FABP (ng/ml)** | 10 (3-20) | 14 (6-20) | 27 (8-103) | 0.05 | 0.17 |
| *Tubular function marker* | | | | | |
| **FENA (%)** | 0.28 (0.04-0.43) | 0.10 (0.02-0.23) | 0.31 (0.12-0.065) | 0.10 | 0.03 |
| *Glomerular injury marker* | | | | | |
| **Albumin (mg/dL)** | 21 (5-65) | 24 (13-129) | 92 (44-253) | 0.004 | 0.06 |

**Conclusions:** Multiple urinary biomarkers including NGAL, IL-18, L-FABP, albumin and FENa may distinguish ATN from HRS in patients with cirrhosis. Further studies are needed to determine if such biomarkers can guide treatment decisions.

## FR-PO008

**Insulin-Like Growth Factor-Binding Protein 7 and Tissue Inhibitor of Metalloproteinases-2 Provide Superior Risk Assessment for Acute Kidney Injury in Critically Ill Patients**

Azra Bihorac, Lakhmir S. Chawla, Jay L. Koyner, Michael Heung, Luis M. Ortega, George E. DeMuth, John A. Kellum. *On behalf of All Astute Medical Topaz Investigators.*

**Background:** In the multi-center Sapphire study we demonstrated excellent performance of the combination of two urinary biomarkers, insulin-like growth factor-binding protein 7 and tissue inhibitor of metalloproteinases-2 (TIMP2•IGFBP7), for risk assessment for acute kidney injury (AKI) in critically ill patients (area under the receiver operating characteristic curve (AUC) 0.80, 95% confidence interval (CI) 0.76-0.83).

**Methods:** We report on a new clinical trial, Topaz, in which we validated an optimal cutoff for urinary TIMP2•IGFBP7 for AKI risk assessment among 408 prospectively enrolled critically ill patients in 23 hospitals in the United States. The high-sensitivity cut-off of 0.3 ((ng/ml)$^2$/1000) was pre-selected from the Sapphire cohort. Urinary TIMP2•IGFBP7 was measured at admission to the ICU using a clinical assay platform (NephroCheck® Test, Astute Medical Inc, San Diego, CA, not available in the US). The diagnosis of AKI was established by a Clinical Adjudication Committee (CAC) of three expert nephrologists. We also compared the performance of TIMP2•IGFBP7 with that of paired serum creatinine (sCr) measurements.

**Results:** The prevalence of AKI diagnosed by the CAC was 17.4% in the Topaz cohort. Urinary TIMP2•IGFBP7 was superior (AUC 0.82, 95% CI 0.76-0.88) to paired sCr measurements (AUC 0.63, 95% CI 0.56-0.70) in detecting risk for AKI (p<0.0001). The cutoff of 0.3 was validated with high sensitivity, negative predictive value, and relative risk. The majority (~90%) of patients that manifested AKI was identified as being high risk using the cutoff of 0.3.

| Cut-Off | Study | Sensitivity (95% CI) | Negative predictive value (95% CI) | Relative Risk (95% CI) |
|---|---|---|---|---|
| 0.3 (ng/ml)$^2$/1000 | Sapphire | 0.89 (0.82-0.94) | 0.97 (0.96-0.99) | 7 (4-14) |
| 0.3 (ng/ml)$^2$/1000 | Topaz | 0.92 (0.85-0.98) | 0.96 (0.93-0.99) | 7 (4-22) |

**Conclusions:** The Topaz study confirms excellent performance of urinary TIMP2•IGFBP7 and externally validates a clinical cutoff for AKI risk assessment among critically ill patients.

**FR-PO009**

**Evaluation of New Urine Biomarker TIMP-2 in Intensive Care Unit**

Tetsushi Yamashita, Kent Doi, Maki Tsukamoto, Yoshifumi Hamasaki, Masaomi Nangaku, Naoki Yahagi, Eisei Noiri. *The Univ of Tokyo, Tokyo, Japan.*

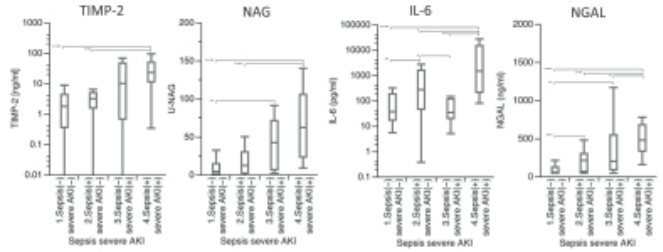
**Background:** Tissue inhibitor of metalloproteinases-2 (TIMP-2) was recently reported as a novel for predicting severe AKI in critical ill patients. We evaluated the performance of urine TIMP-2 in our adult mixed intensive care unit (ICU).

**Methods:** This study enrolled 98 patients who were admitted to the adult mixed ICU of The University of Tokyo Hospital from July 2011 to October 2011 by consecutive sampling. Urine TIMP-2 and NAG, and plasma NGAL and IL-6 were measured on ICU admission. This study was aimed to evaluate whether these biomarkers could predict AKI and its severity, and mortality by ROC analysis.

**Results:** AKI occurred in 42 (42.9%) patients including 27 (27.6%) severe AKI (KDIGO stage 2 or 3). The area under the ROC curve for each marker was shown in Table 1.

| AUROC | TIMP-2 | NAG | NGAL | IL-6 |
|---|---|---|---|---|
| AKI | 0.74 (0.63-0.83) | 0.84 (0.74-0.90) | 0.84 (0.74-0.91) | 0.72 (0.60-0.81) |
| Severe AKI | 0.80 (0.66-0.90) | 0.89 (0.78-0.94) | 0.87 (0.76-0.93) | 0.69 (0.59-0.80) |

Forty one (41.8%) patients was complicated with sepsis, including 19 (19.4%) severe AKI. In accordance with previous reports, plasma NGAL and IL-6 were increased by sepsis, however urine TIMP-2 and NAG was increased not by sepsis but by the presence of severe AKI.



In-hospital mortality was 15.3% in this cohort and urine TIMP-2 and NAG, and plasma NGAL were significantly higher in the non-survivors than the survivors, whereas plasma IL-6 was not significantly associated with mortality.

**Conclusions:** A new urine biomarker of TIMP-2 is increased especially in severe AKI and associated with mortality. Sepsis appeared to have a smaller impact on urine TIMP-2 and NAG compared with plasma NGAL and IL-6. This distinct feature of biomarkers will enable to evaluate the contribution of sepsis to the development of AKI.

**FR-PO010**

**Biomarkers for Acute Kidney Injury in the Emergency Department**

Martin Kimmel,[1] Jing Shi,[2] Joerg Latus,[1] Niko Braun,[1] Mark Dominik Alscher.[1] *[1]Dept of Internal Medicine, Div of Nephrology, Robert-Bosch Hospital, Stuttgart, Germany; [2]Walker Bioscience, Carlsbad, CA.*

**Background:** There is a growing role of emergency departments (ED) for hospital admissions but there are only few studies addressing acute kidney injury in ED. Two novel urinary biomarkers of acute kidney injury (AKI) were recently reported for risk stratification for AKI and the combination of these biomarkers (TIMP2•IGFBP7) was found to be superior to other known biomarkers of AKI in critically ill hospitalized patients. We have performed an analysis of TIMP2•IGFBP7 in patients presenting to the emergency department.

**Methods:** We enrolled 397 patients in the Emergency Department at Robert-Bosch-Krankenhaus, Stuttgart. Daily serum creatinine values and urine output were recorded for AKI staging by KDIGO criteria (302 patients had urine output data). Biomarkers were analyzed in samples collected during the first day (at 0, 6 and 24h) after enrollment. Cystatin C, KIM-1, L-FABP and NGAL were measured in blood and urine and IGFBP7, TIMP2, and IL-18 were measured in urine samples. We examined the association between these biomarkers and KDIGO stage 2 or 3 within 12 hours of sample collection using univariate and multivariate generalized estimating equation (GEE) logistic regression.

**Results:** All urinary biomarkers tested had a statistically significant ($p<0.05$) univariate odds ratio for KDIGO stage 2 or 3 within 12 hours. Of the markers measured in blood, only serum creatinine and plasma cystatin C had a significant univariate odds ratio. In a multivariate GEE logistic regression model including all the urine markers and serum creatinine, only TIMP2•IGFBP7 and serum creatinine had statistically significant adjusted odds ratios (standardized odds ratio=2.4 (95% CI,1.4-4.4) and 1.9 (95% CI,1.3-2.9), respectively) for patients with urine output data.

**Conclusions:** In conclusion, our study is the first to report TIMP2•IGFBP7 in urine from a cohort of emergency department patients. Our results show that TIMP2•IGFBP7, associated with mechanisms recently implicated in the pathogenesis of AKI, provides valuable information for risk assessment in the emergency department.

*Funding:* Pharmaceutical Company Support - Astute Medical, Private Foundation Support

**FR-PO011**

**Diagnostic Utility of Biomarkers of Acute Kidney Injury in Critically Ill Patients**

Claire Hannon,[1] Patrick T. Murray.[2] *[1]Dept of Nephrology, Mater Univ Hospital, Ireland; [2]Univ College Dublin, Ireland.*

**Background:** Acute kidney injury (AKI) occurs in 5-10% of hospitalized patients, with a mortality of approximately 50% in a critical care setting. Diagnosis is based on changes in serum creatinine, a late marker of injury. Development of AKI biomarkers may permit earlier detection of AKI and allow improvements in its prevention and therapy.

**Methods:** All patients admitted to the intensive care unit (ICU) were screened for inclusion in this prospective cohort study. Clinical information and urine was collected daily for 7 days. Urine biomarkers analysed were neutrophil-gelatinase associated lipocalin (NGAL), $\alpha$ and $\pi$ glutathione-S-transferase (GST), albumin and creatinine. AKI was defined by KDIGO criteria using ICU admission creatinine as reference. ROC curves were generated for admission biomarkers and AUC's calculated for prediction of AKI and a composite endpoint of death and need for renal replacement therapy (RRT). Admission biomarkers were collected at enrolment, within 24 hours of ICU admission.

**Results:** 201 patients were enrolled, 90 patients (45.3%) developed AKI. AKI stages: stage 1 (19.9%, n=40), stage 2 (6%, n=12) and stage 3 (18.9%, n=38). Patients with AKI were significantly older (67 v 59 years, p=0.003), had a higher incidence of chronic kidney disease (24.4 v 7.3%, p=0.001) and a higher mortality (44.4 v 28.8%, p=0.011). 40% of patients with AKI needed RRT. Moderate to good AUC's for AKI prediction were seen with urine NGAL (0.723, $p<0.0001$) and albumin (0.689, $p<0.0001$). The AUC's of urine creatinine, $\alpha$ and $\pi$ GST were non-significant. Combination of admission urine NGAL and urine albumin and APACHE II score improved prediction of AKI with an AUC of 0.770 ($p=0.04$). Prediction of a composite end-point of death or dialysis using admission urine albumin and NGAL was moderate, with AUCs of 0.639 ($p=0.0008$) and 0.596 ($p=0.0186$) respectively.

**Conclusions:** Admission urine NGAL and albumin showed moderate to good ability at AKI prediction**,** combination with a clinical severity score further improved this. Biomarkers and clinical model combinations may improve AKI diagnosis and prediction.

**FR-PO012**

**Positive Fluid Balance (PFB) and Hospital Mortality in Severe Septic Patients with or without Acute Kidney Injury (AKI)**

Javier A. Neyra,[1] Fabrizio Canepa,[2] John Manllo,[2] Beverley Adams-huet,[1] Robert D. Toto,[1] Jerry Yee.[2] *[1]Univ of Texas Southwestern Medical Center, Dallas, TX; [2]Henry Ford Hospital, Detroit, MI.*

**Background:** Severe sepsis causes increased capillary permeability, impaired renal excretion of exogenous sodium and slow vascular refilling, thereby promoting interstitial edema and adverse outcomes. AKI occurs in up to 70% of those with severe sepsis and intravenous fluid therapy is directed at restoring organ hypoperfusion. The aim of this study is to evaluate the relationship between PFB and hospital mortality by AKI status in non-CKD patients admitted to the ICU with severe sepsis.

**Methods:** A population-based linked administrative database of 2,786 septic patients was analyzed for the association of PFB (> 5 L) within the first 72 h of ICU admission and death. Our study group comprised 1,854 non-CKD patients (SCr < 1.5 mg/dL within 3 mo prior to admission) stratified by AKI status. Severe sepsis was defined by *Angus et al* criteria and AKI by Acute Kidney Injury Network. Multivariable logistic regression models were adjusted for age, gender, race, baseline SCr, comorbidities, vasoactive drugs, diuretic exposure, blood transfusion, and SOFA and APACHE II scores.

**Results:** Mean age (SD) was 65 (16) years: 39% were African American and 39% Caucasian. At time of admission, 47% (867/1,854) had AKI (Group A), 12% (232/1,854) developed AKI (Group B), and 41% (755/1,854) had no AKI within 72 h of admission (Group C). The mean cumulative fluid balance (SD) was 5.3 L (7.3) in Group A, 5.2 L (8.1) in Group B, and 2.8 L (5.4) in Group C. During hospitalization, 398 (21%) died: Group A, 219/867 (25%); Group B, 74/232 (32%); and Group C, 105/755 (14%). In stratified, adjusted models, PFB was significantly associated with hospital mortality in all groups: Group A, OR (95% CI) 2.4 (1.7, 3.4); Group B, 2.3 (1.2, 4.6); and Group C, 1.8 (1.1, 2.9).

**Conclusions:** In this study population of non-CKD patients with severe sepsis, PFB (> 5 L) was an independent predictor of hospital mortality in patients with or without AKI. These findings highlight the importance of individualized response-based fluid therapy, even in patients without significant increases in SCr within the first 72 h of ICU admission.

*Funding:* Clinical Revenue Support

**FR-PO013**

**Impact of Fluid Balance after Initiation of Renal Replacement Therapy (RRT) on Mortality in Critically Ill Patients with Acute Kidney Injury (AKI)**

Yee Lu,[1] Puja Goswami,[1] Robin L. Sands,[2] Michael Heung.[1] *[1]Dept of Medicine, Univ of MI, Ann Arbor, MI; [2]Univ of MI, Kidney Epidemiology and Cost Center, Ann Arbor, MI.*

**Background:** In critically ill patients with AKI, fluid overload (FO) at RRT initiation has been associated with increased mortality. However, the impact of fluid management during RRT is less clear. We examined fluid balance following RRT initiation for an association with hospital mortality.

**Methods:** Retrospective chart review of adult patients admitted to an intensive care unit (ICU) requiring RRT for AKI from January 2011 to January 2012 at a tertiary academic center. Patients initiated on RRT prior to ICU admission or for toxic ingestions were excluded. FO was defined as the cumulative fluid balance from ICU admit to RRT initiation expressed as a percentage of admit weight. Time-dependent Cox regression was used to assess the association between FO in the first eight days of RRT and hospital mortality, adjusted for sequential organ failure assessment score and history of malignancy.

**Results:** 149 ICU patients were included: mean age 54 ± 15y, 60% male, 74% white, mean baseline eGFR 81 ± 35 ml/min/1.73m$^2$ and mean SOFA score prior to RRT 13 ± 4. Hospital mortality was 56%. Mean FO at RRT start was 9.5 ± 11.3% and was correlated with FO on last day of RRT (r=0.83, p<0.0001). In unadjusted analysis, FO at RRT start was associated with an 80% higher risk among patients with FO>10.4% (3$^{rd}$ quartile) compared to patients with FO ≤ 3.4% (1$^{st}$ quartile; p=0.03); this association was not significant after adjustment. FO over the first eight days of RRT, adjusted for FO at RRT start, was significantly associated with risk of mortality in both unadjusted and adjusted analysis ($HR_{per\ 10\%}$=1.81; 95% CI 1.77-1.85, p<0.0001).

**Conclusions:** We found that FO at RRT initiation was associated with increased mortality, but this relationship was not significant after adjusting for severity of illness. Conversely, the ability to achieve a negative fluid balance following the initiation of RRT was associated with lower hospital mortality. Further studies are required to determine whether this finding represents an opportunity to positively intervene in this population.

## FR-PO014

### A New Urinary Scoring System for Differential Diagnosis of Acute Renal Injuries

Rong Chu,[1] Hua Xiao Liu,[1,2] Zi Jing Li,[1] Li Yang.[1] *[1]Renal Div, Peking Univ First Hospital, Beijing, China; [2]Renal Div, NingDe Hospital, NingDe, Fujian, China.*

**Background:** AKI is a clinical syndrome encompassing various etiologies that involve any of the renal tubules, interstitium, glomerulus or vasculatures. We developed a prospective cohort study to explore a new urinary scoring system that may help locate the pathogenic lesions of parenchymal acute renal injuries.

**Methods:** 165 AKI patients (2012-KDIGO) who were histologically proven as parenchymal acute renal injuries from Jun 2011 to June 2013 were enrolled. Urinary sediment examination was performed in the morning of renal biopsy by two independent nephrologists. 24hr-urinary protein was tested. A urinary scoring system was made from 50 AKI patients and validated in the following 115 AKI cases using histology as gold standard.

**Results:** The urinary scoring system originated from 15 cases with acute tubular necrosis (ATN, 13 with glomerular nephropathy, GN), 18 cases with acute tubulointerstitial nephritis (ATIN, 8 with GN), 15 cases with diffuse acute glomerular nephritic lesions (AGN, cellular crescentic GN etc) and 2 cases with vascular injuries.

| Pathological lesions | urinary indices | semiquantitative scores | scoring system |
|---|---|---|---|
| Glomerular (G) | RBC/HP | 0: <3<br>1: 3-10<br>2: 11-30<br>3: >30 or RBC casts | $G_{RBC}$+$G_{PRO}$<br>>=3: with GN<br><3: w/o GN |
| | Protein (g/24hr) | 0: <0.3<br>1: 0.3-2.0<br>2: 2.1-3.5<br>3: >3.5 | |
| Tubular injury (T) | Tubular epithelial cells /HPF | 0: <1<br>1: 1-5<br>2: >5<br>3: tubular epithelial cell casts | T<br>>=3: with ATN<br><1: w/o ATN |
| Inflammation (I) | WBC/HPF | 0: <5<br>1: 5-10<br>2:10-20<br>3: >20 or WBC casts | I<br>>=2: with inflammation<br><1: w/o inflammation |

Validation was performed in 35 ATN cases, 33 ATIN cases, 35 AGN cases and 12 vascular injuries cases. The urinary scoring system recognized 76.9% of ATN, 66.7% of ATIN and 91.2% of diffuse AGN. Patients with vascular injuries including TMA and malignant hypertension had "clean" urinary sediment examination and did not fit the scoring system.

**Conclusions:** Urinary scoring system may help differentiate acute renal parenchymal injuries. More cases are collecting to enlarge the sample size of the study. Urinary biomarkers, including NAG, a1-MG, KIM-1, NGAL, MCP-1 and IL-18, were tested. Analysis of combining the scoring system and biomarkers is processing.

## FR-PO015

### Glycosylated Protein CD147 Reflects Renal Dysfunction in Patients with Acute Tubular Necrosis

Hiroshi Kojima, Tomoki Kosugi, Mayuko Maeda, Kayaho Maeda, Yuka Sato, Hiroki Hayashi, Waichi Sato, Seiichi Matsuo, Shoichi Maruyama. *Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan.*

**Background:** Acute tubular injury (ATN) describes a form of intrinsic acute kidney injury (AKI) that results from persistent hypoperfusion and subsequent inflammation in the kidney. A glycoprotein CD147 contributes to cell survival and cancer invasion. Recently, we demonstrated that CD147 is responsible for chronic inflammation in the kidney, using CD147 knockout mice. In addition, hypoxia induced CD147 expression in TECs. We therefore investigated whether plasma and urinary CD147 could reflect disease activity of ATN.

**Methods:** Experiment (Exp.) 1: Plasma and spot urine samples were collected from the 24 patients, who underwent renal biopsy between 2008 and 2012. They included pathological control (n=12) and ATN (n=12). Exp. 2: 40 patients are registered undergoing open surgery to treat abdominal aortic aneurysms (AAA) in 2004 at our hospital. We collected 160 urine samples from 7 and 33 patients with and without AKI, respectively. In both experiments, plasma and urinary CD147 levels were measured, and its expression in kidneys was examined by immunostaining. We further examined urinary L-fatty acid binding protein (L-FABP), ATP and 8-OHdG levels.

**Results:** Exp. 1: CD147 expression, mainly detected in TECs of healthy kidneys, was extremely lower in injured tubules of ATN patients. CD147 induction was found in macrophages and fibroblasts around damaged tubules and vessels. Both plasma and urinary CD147 values strikingly increased in ATN patients compared to control. Both levels were correlated with serum creatinine (Cre) and ischemia-related factors, including L-FABP, ATP and 8-OHdG. Surprisingly, plasma CD147 showed greater correlations with pathological injuries and renal dysfunction compared with L-FABP. Experiment 2: While there was no differences in CD147 values and Cre before AAA operation between patients with or without AKI, mean CD147 level in patients with AKI was significantly higher than those with non-AKI towards post-operative day 1.

**Conclusions:** CD147 may be a prime candidate for developing a new procedure for the evaluation of AKI.

## FR-PO016

### Urinary Excretion of Kidney Injury Molecule 1 Predicts the Need for Extra-Renal Replacement Therapy in Cirrhotic Patients Admitted to the Intensive Care Unit

Justine Devos,[1] Francois Jouret,[2] Yvan Fleury,[1] Pierre-françois Laterre,[1] Diego Castanares-zapatero.[1] *[1]Cliniques Universitaires Saint-Luc (UCL, Brussels); [2]Univ of Liege Hospital (ULg CHU, Liege).*

**Background:** Detecting acute kidney injury (AKI) requiring extra-renal replacement therapy (ERRT) remains challenging in cirrhotic patients admitted to the Intensive Care Unit (ICU). Still, AKI is associated with an increased mortality. Here, we prospectively investigated the usefulness of the urinary biomarker of kidney damage, kidney injury molecule 1 (uKIM-1), in predicting the need for ERRT in ICU patients with decompensated cirrhosis.

**Methods:** Consecutive patients admitted to the ICU of Cliniques Universitaires Saint-Luc, Brussels, for cirrhosis-related complications were prospectively enrolled. Patients with chronic kidney disease were excluded. Serum creatinine levels (sCr) and urinary excretion of KIM-1 were measured at 24h and 48h post admission. A multiple logistic regression for ERRT prediction was performed after adjustment for age, gender, sepsis, MELD score.

**Results:** The cohort included 109 patients. Main causes of admission were gastro-intestinal bleeding (38.5%) and sepsis (33.2%). Twenty-seven patients (24.7%) developed AKI requiring ERRT. No ERRT was initiated before day 2. Mortality rate (74.1% vs 35.3%, p<0.05) and MELD score (27.8 vs 20.1, p<0.05) were significantly higher in ERRT-treated patients. No correlation was found in these patients regarding the evolution of sCr and uKIM-1 within the first 48h. Indeed, sCr decreased over time, whereas uKIM-1 further increased. At day 2, uKIM-1 was significantly higher in patients who required ERRT (17.1 vs 9.7 ng/ml, p=0.027). In logistic regression analysis, uKIM-1 > 10 ng/mL at day 2 predicted the need for ERRT.

**Conclusions:** At day 2 post ICU admission, uKIM-1 helps better identify patients with decompensated cirrhosis at risk for ERRT.

## FR-PO017

### The Monomer Is the Major Form of NGAL in Urine and Plasma in Severe Sepsis

Kristian Bangert,[1] Alexandra Baer,[1] Peter Buhl Hjortrup,[2] Anders Perner,[2] Lars O. Uttenthal.[1] *[1]BioPorto Diagnostics A/S, Denmark; [2]Rigshospitalet, Denmark.*

**Background:** Neutrophil gelatinase-associated lipocalin (NGAL) is a marker of acute kidney injury (AKI), but is also released from neutrophils on phagocytosis of bacteria and as part of the inflammatory response. It has been reported that the injured kidney releases NGAL in its monomer form. In contrast, the neutrophils are claimed to release NGAL primarily as homodimer. Patients with severe sepsis have both a high release of NGAL from the neutrophils and a high risk of AKI. We have measured the levels of NGAL monomer and homodimer in urine and plasma samples from patients suffering from severe sepsis.

**Methods:** NGAL monomer and homodimer were measured with specific ELISAs in sets of urine and EDTA plasma samples from 151 patients suffering from severe sepsis and compared with NGAL measured with a fully automated particle-enhanced turbidimetric immunoassay (The NGAL Test™, BioPorto Diagnostics A/S). AKI was defined as a 50% increase in plasma creatinine levels.

**Results:** AKI occurred in 83 of the 151 patients. The NGAL levels and the area under the receiver operating characteristics curve (AUROC) for the diagnosis of AKI are shown in the table:

| | NGAL immunoassay | Median value ng/mL | 25$^{th}$ and 75$^{th}$ percentiles ng/mL | AUROC | 95% confidence interval |
|---|---|---|---|---|---|
| **Urine** | Homodimer (% of total* NGAL) | 8.5 (1.2%) | 1.2 - 31.4 (1.0% - 2.6%) | 0.70 | 0.62 – 0.79 |
| | Monomer | 320 | 79.6 - 1914 | 0.75 | 0.67 – 0.82 |
| | The NGAL Test™ | 341 | 79.9 - 2012 | 0.74 | 0.66 – 0.82 |
| **EDTA plasma** | Homodimer (% of total* NGAL) | 31.5 (6.0%) | 17.2 - 51.4 (3.3% - 11.3%) | 0.59 | 0.50 – 0.68 |
| | Monomer | 455 | 230 - 850 | 0.78 | 0.70 – 0.85 |
| | The NGAL Test™ | 484 | 247 - 839 | 0.78 | 0.71 – 0.85 |

*Total NGAL = Monomer + Homodimer values.

**Conclusions:** NGAL monomer is the major form of NGAL found in urine and plasma from patients with severe sepsis. The occasional presence of low levels of NGAL homodimer has little impact on the interpretation of results obtained with monomer-reactive, homodimer cross-reactive NGAL assays in samples from patients with severe sepsis.

### FR-PO018

**Urine and Plasma Neutrophil Gelatinase Associated Lipocalin (NGAL), the Novel Biomarkers for Leptospirosis Associated Acute Kidney Injury (AKI): Result from the Multicenter Study** Nattachai Srisawat,[1,3] Kearkiat Praditpornsilpa,[1] Khajohn Tiranathanagul,[1] Sarinya Kumpunya,[1] Somchai Eiam-ong,[1] Kriang Tungsanga,[1] Visith Sitprija,[1,2] John A. Kellum.[3] *[1]Dept of Medicine, King Chulalongkorn Memorial Hospital, Thailand; [2]Queen Saovabha Memorial Institute, Thai Red Cross, Thailand; [3]The CRISMA Center, Dept of Critical Care Medicine, Univ of Pittsburgh School of Medicine.*

**Background:** AKI is one of the most serious complications of leptospirosis, an important zoonosis in the tropics. NGAL which represents as an early biomarker AKI has never been explored in this specific setting. In this multicenter study, we aimed to study the role of NGAL as an early marker and an outcome predictor of leptospirosis associated AKI.

**Methods:** Patients who presented with clinical suspiciousness of leptospirosis were prospectively enrolled in 11 centers. Blood and urine samples were serially collected on the first three days. We used three standard techniques (microscopic agglutination test, direct culture, and PCR technique) to confirm the diagnosis of leptospirosis. KDIGO criteria was used as the standard criteria for AKI diagnosis. Recovery was defined as alive and not requiring dialysis during hospitalization or having a persistent KDIGO staging at hospital discharge.

**Results:** Of the 89 recruited patients, 54 subjects were diagnosed as leptospirosis. Forty five percent had AKI. Median uNGAL and pNGAL levels in AKI group were significantly higher than non-AKI group [187.8 (51.7,724.6) vs 10.7 (2.2,35.9) ng/ml, $p < 0.001$] and [1300 (348,1300) vs 173 (86,238) ng/ml, $p < 0.001$], respectively. uNGAL and pNGAL levels predicted AKI with AUC-ROC of 0.89, and 0.90, respectively). Median uNGAL level in recovery group was significantly lower than non-recovery group [156.7 (38.0,551.2) vs 843.7 (256.8,922.2) ng/ml, $p = 0.039$], while pNGAL level was comparable. uNGAL and pNGAL predict renal recovery with AUC-ROC of 0.893 and 0.59, respectively).

**Conclusions:** From this multicenter study, uNGAL and pNGAL provided the promising result to be a marker for leptospirosis associated AKI. However, only uNGAL showed the potential role to be the predictor of renal recovery in this specific setting.

### FR-PO019

**The Renal Klotho Expression Is Associated with the Severity of Human AKI** Myung-gyu Kim, Sang-Kyung Jo, Won-Yong Cho. *Nephrology, Korea Univ Anam Hospital, Seoul, Republic of Korea.*

**Background:** Klotho is highly expressed in the kidney and known to have multiple functions including renoprotection from a variety of insult. Especially, its diagnostic and therapeutic roles in acute kidney injury (AKI) have been demonstrated recently in animal models. However, to date, there is no human study to determine renal Klotho in AKI. Therefore, here we examined renal Klotho expression in AKI patients and its clinical value.

**Methods:** We retrospectively collected kidney specimen and clinical data of AKI patients who underwent renal biopsy between January 2001 and December 2012 at Korea university hospital.The protein expression of Klotho was determined by immunohistochemical staining and clinical-pathological correlation was examined.

**Results:** Among 34 patients who were diagnosed with acute tubular necrosis or acute tubulointerstitial nephritis, a total of 21 patients without chronic histological lesion were included in the study. The mean age was 37.3±18.5years, and the causes of AKI were ischemic in 1 case(4.8%), infection in 7(33.3%), drug in 2(9.5%), rhabdomyolysis in 4(19.0%) and the others in 7(33.3%). Their peak creatinine level was 8.16±5.54mg/dL and 10 patients(47.6%) have received renal replacement therapy(RRT) temporarily. However, most of patients(81%) had functional recovery with creatinine level below 1.3mg/dL 3months after their discharge. When the Klotho expression was scored according to the percentage of area of positive cells, its low level was correlated to severe AKI. In addition, when the patients were divided into three groups according to the Klotho score (low, mid, high), the low group had the highest peak creatinine level, the longest hospital stay and the more RRT treatment significantly. In multivariate analysis, low Klotho score was also an independent factor associated with the development of severe AKI. However, Klotho score was not significant as a predictor for renal recovery or progression to chronic kidney disease.

**Conclusions:** This is a first human study which demonstrated that human renal Klotho expression was decreased significantly according to the severity of AKI regardless of etiology, and their low expression was associated with poor short-term outcome.

### FR-PO020

**Urinary NGAL (Neutrophil Gelatinase Associated Lipocalin) Excretion at Birth Is Predictive of Susceptibility to Acute Kidney Injury (AKI) in Very Low Birth Weight Infants** Licia Peruzzi,[1] Federica Chiale,[1] Roberta Camilla,[1] Giuliana Guido,[1] Claudio Martano,[2] Enrico Bertino,[2] Rosanna Coppo.[1] *[1]Nephrology Dialysis Transplanation, Regina Margherita Hospital, Italy; [2]Neonatology, Univ of Turin.*

**Background:** Preterm infants are susceptible to acute kidney injury (AKI); closure of patent ductus arteriosus (PDA) with prostaglandin inhibitors is a risk factor. Novel AKI biomarkers have not been assessed in their predictive value in very preterm infants.

We evaluated in very low birth weight (VLBW) infants the urinary excretion of NGAL as early AKI biomarker during treatment with ibuprofen for PDA.

**Methods:** We evaluated 50 VLBW (≤1500 g and/or gestational age ≤32 w) without congenital nephropaties, 19 treated with ibuprofen. Renal function was assessed by creatinine (sCr) (IDMS method) within 72 hours from birth, at 7 and 14 days and post ibuprofen (standard 3 doses). eGFR was calculated (Schwartz formula, k=0.413). uNGAL was measured with immunoassay (ARCHITECT®, Abbott) at the same time of sCr and 12-24h after each ibuprofen dose.

**Results:** Newborns with PDA had lower gestational age (28.37±2.79w. vs 30.61±2.17w, p 0.0045), lower APGAR score (6.63±1.83. vs 8.16±0.97, p 0.0009), required more ventilatory support (74% vs 16%, p<0.001) than untreated. At birth sCr and uNGAL were similar (sCr:1.02±0.34 mg/dl vs 0.91±0.19; uNGAL:81.65 ng/ml (4-1109) vs 41.40 ng/ml (13.30-215.1). p ns). In treated infants uNGAL rose significantly after first dose of ibuprofen (from 81.65 ng/ml to 188 ng/ml p 0.0067) and decreased after 7 days to 52.96 ng/ml (2.5-1046) (p 0.03), significantly higher than in untreated (52.96 vs 18.50 ng/ml,p 0.027).

9 children (7 treated, 2 untreated developed AKI according to AKIN criteria modified by Jetton2012: 4 stage 0, 3 stage 1, 2 stage 3 within the first week). uNGAL at birth was predictive of AKI, being higher in those who developed AKI (401.1±405ng/ml vs 41.60±52.3; p 0.03), while sCr was not predictive. ROC analysis showed a cut-off of 122.4 ng/ml discriminating infants at risk for AKI with specificity 76.92%, sensibility 75% and AUC values 0.75 (p 0.03).

**Conclusions:** uNGAL is a sensible and specific biomarker to monitor AKI in preterm infants treated with ibuprofen.

### FR-PO021

**Perioperative Plasma NGAL Measurement in LVAD Implantation Surgery** Maki Tsukamoto, Kent Doi, Minoru Ono, Naoki Yahagi, Masaomi Nangaku, Eisei Noiri. *The Univ of Tokyo.*

**Background:** Implantation of left ventricular assist device (LVAD) has recently been conducted for the treatment of severe heart failure. Perioperative complication of end-organ injury including acute kidney injury (AKI) is a frequent and serious problem in LAVD implantation. We evaluated an emerging biomarker plasma neutrophil gelatinase-associated lipocalin (NGAL), which can detect AKI before serum creatinine elevation, in a LVAD implantation cohort.

**Methods:** We prospectively studied 31 severe heart failure patients underwent LVAD implantation during the period of July 2011 to March 2013 at the University of Tokyo Hospital. Diagnosis of AKI was determined by the KDIGO creatinine criteria. Plasma NGAL was measured at pre-operation, just after operation (0 hr), and post-operative day (POD) 1, 7, 14, and 28. For severe AKI patients, plasma NGAL was continuously measured until discontinuation of dialysis or death.

**Results:** Causes of severe heart failure in this cohort were as follows; idiopathic dilated cardiomyopathy (n=20), ischemic cardiac disease (n=5), hypertrophic cardiomyopathy (n=3) and severe myocarditis (n=3). Seventeen (55%) patients were diagnosed as AKI and dialysis was required in 6 patients. Plasma NGAL values in the dialysis-requiring AKI group were significantly higher than the other patients at all the measurement time points, whereas the non-dialysis-requiring AKI group showed similar levels of plasma NGAL to the non-AKI group. AKI measured at pre-operation and ICU arrival after surgery (0 hr) could discriminate the dialysis-requiring AKI group from the non-dialysis-requiring AKI and the non-AKI groups (AUC-ROC 0.83 [95%CI 0.54-0.95] and 0.86 [0.66-0.95]). Dialysis could be discontinued in 4 of 6 severe AKI patients and their plasma NGAL levels decreased to 300 ng/ml or lower at termination of dialysis.

**Conclusions:** Measurement of perioperative plasma NGAL in LVAD implantation surgery will be useful for predicting severe AKI that requires dialysis and may potentially be used for predicting discontinuation of dialysis.

### FR-PO022

**Value of Plasmatic NGAL Levels in Assessing Severity and Outcomes in Acute Kidney Injury** Eva Rodriguez, Marta Riera, Maria Jose Soler, Clara Barrios, Julio Pascual. *Nephrology, Parc de Salut Mar-IMIM, Barcelona, Spain.*

**Background:** Plasmatic Neutrophil Gelatinase-Associated Lipocalin (NGAL) could be a good tubular biomarker for the diagnosis of Acute Kidney Injury (AKI), before creatinine elevation. Our aim was to assess if plasmatic NGAL at the time of AKI diagnosis is a good marker for identification of those patients who will develop a more severe form of AKI.

**Methods:** In a prospective cohort study in a tertiary hospital, 134 patients with different conditions known to be at high risk of AKI were included. One plasma-EDTA sample was collected at diagnosis, Four groups were pre-specified: septic patients (septic model of AKI, n=27,,52% with AKI vs 48% non-AKI), patients under colistin treatment (nephrotoxic model, n=50, 46% AKI vs 54% non-AKI), renal allograft recipients (ischemia-reperfusion model, n=40, 72.5% AKI vs 27.5% non-AKI), elderly patients with dehydration and ACE-I treatment (multifactorial-AKI, n=17). Plasmatic NGAL was measured by means of inmunofluorescence assay. Results were expressed in mean ± standard error.

**Results:** In our patient population, 52% had AKI and 48% normal kidney function. Plasmatic NGAL levels were significant higher in AKI patients (582 ± 44ng/mL vs 316± 41 ng/mL; $p<0.001$). NGAL levels were significantly higher in AKI-patients who needed renal replacement therapy during hospitalization compared with those who did not need such treatment (715±73 ng/mL vs 499±48 ng/mL; $p=0.014$) and significantly higher in AKI-patients who died (793±111 vs 442 ng/mL; $p<0.001$). Finally, NGAL levels were significantly lower in those AKI-patients who recovered renal function at time of discharge (258 ±48 ng/mL vs 336 ± 73 ng/mL, p=0.01). The receiver operating characteristic (ROC)

curve assessing the NGAL plasmatic value accuracy for the need of renal replacement treatment showed an AUC of 0.80 (CI 95% 0,57-0,87, p=0,03) and for the accuracy of death during AKI an AUC of 0,89 (CI 95% 0,54-0,90, p=0,01).

**Conclusions:** : Plasmatic NGAL could be useful to distinguish AKI patients who are at high risk for renal replacement therapy or will die during the event, and also to identify those patients who will recover renal function.

## FR-PO023

**Urine Stability Studies for Novel Biomarkers of Acute Kidney Injury** Chirag R. Parikh,[1] Isabel Butrymowicz,[1] Angela Yu,[1] Vernon M. Chinchilli,[5] Meyeon Park,[3] Chi-yuan Hsu,[3] William Brian Reeves,[5] Prasad Devarajan,[7] Paul L. Kimmel,[6] Edward D. Siew,[4] Kathleen D. Liu.[3] *[1]Yale School of Medicine; [2]Penn State College of Medicine; [3]Univ of California: San Francisco; [4]Vanderbilt Univ Medical Center; [5]NIDDK/NIH; [6]Cincinnati's Children's Hospital Medical Center, For the ASSESS-AKI Study.*

**Background:** The effect of variation in storage conditions on biomarker assays may affect accuracy and reliability of measurements. We examined how variations in short-term storage/processing affect measurement of urine Neutrophil Gelatinase-Associated Lipocalin (NGAL), Interleukin-18 (IL-18), Kidney Injury Marker-1 (KIM-1), Liver Fatty Acid Binding Protein (L-FABP) and Cystatin C in ASSESS-AKI, a multi-center study of hospitalized patients with and without AKI.

**Methods:** The impact of 3 processing conditions were tested: a) centrifugation and storage at +4°C for 48h before freezing at -80°C, b) centrifugation and storage at +25°C for 48h before freezing, and c) uncentrifuged samples immediately frozen. Biomarker values were log-transformed, and agreement with a reference standard of immediate centrifugation, aliquoting, and storage at -80°C was compared using concordance correlation coefficients (CCC).

**Results:** There was excellent CCC (>0.9) for all biomarkers for all processes, except IL-18 at +25°C.Good agreement was observed for IL-18 between samples stored at +25°C for 48h and the reference standard (0.81 (95% CI 0.66,0.96)).

| Processes | IL-18 | NGAL | KIM-1 | L-FABP | Cystatin C |
|---|---|---|---|---|---|
| A (Initial 48 hours: + 4ºC vs -80ºC) | 0.92 (0.85, 0.98) | 0.99 (0.98, 1.00) | 0.99 (0.99, 1.00) | 0.99 (0.98, 1.00) | 0.94 (0.89, 0.99) |
| B (Initial 48 hours: + 25ºC vs -80ºC) | 0.81 (0.66, 0.96) | 0.99 (0.98, 1.00) | 0.99 (0.99, 1.00) | 0.95 (0.92, 0.99) | 0.93 (0.87, 0.99) |
| C (Centrifuge vs No Centrifuge) | 0.98 (0.96, 1.00) | 0.99 (0.98, 1.00) | 0.99 (0.99, 1.00) | 0.99 (0.98, 1.00) | 0.99 (0.99, 1.00) |

**Conclusions:** All candidate markers tested showed high stability with short-term storage at +4°C or without centrifugation prior to freezing. For optimal fidelity, urine for IL-18 measurement should not be stored at +25°C before long-term storage.

## FR-PO024

**No Increase in Kidney Injury Molecule-1 and Neutrophil-Gelatinase Associated Lipocalin Excretion following Intravenous Contrast Enhanced-CT** Judith Kooiman,[1] Wilke R. Van de Peppel,[1] Yvo W.J. Sijpkens,[2] Harald Brulez,[3] Jean-paul P.M. De Vries,[4] Mioara Alina Nicolaie,[1] Hein Putter,[1] Menno V. Huisman,[1] Sandra W. Van der Kooij,[1] Cees van Kooten,[1] Ton J. Rabelink.[1] *[1]Leiden Univ Medical Center; [2]Bronovo Hospital; [3]St. Lucas Andreas Hospital; [4]St. Antonius Hospital.*

**Background:** Although intra-arterial contrast injections have been associated with increased Kidney Injury Molecule-1 (KIM-1) and Neutrophil-Gelatinase Associated Lipocalin (N-GAL) excretion, it is unclear whether intravenous contrast enhanced-CT (CE-CT) is also accompanied by damage of tubular epithelial cells. We analyzed KIM-1 and N-GAL excretion post CE-CT in patients with chronic kidney disease (CKD).

**Methods:** Patients were enrolled in a trial on contrast induced-acute kidney injury (CI-AKI) preventing hydration. Blood and urine samples were taken at baseline, 4-6 and 48-96 hours post CE-CT. Urinary KIM-1 and N-GAL values were measured by ELISA, normalized for urinary creatinine levels, and presented as medians with 2.5-97.5 percentiles.

**Results:** 511 patients were included of whom 10 (2%) where lost to follow-up. CI-AKI, (serum creatinine increase >25% or >44 umol/L 48-96 hours post CE-CT) occurred in 3.9% of patients (20/501, 95%CI2.6-6.1%). Median KIM-1 values were 1.2 (0.1-7.7) at baseline, 1.3 (0.1-8.6) at 4-6 hours, and 1.3 ng/mg (0.1-8.1) at 48-96 hours post CE-CT (P=0.39). Median N-GAL values were 41.0 (4.4-3174.4), 48.9 (5.7-3406.1), and 37.8 ug/mg (3.5-3200.4), respectively (P=0.07).The amount of KIM-1 and N-GAL excretion in follow-up was similar for patients with and without CI-AKI (P-value KIM-1 = 0.08 and for N-GAL 0.73). In a linear regression analysis, baseline estimated glomerular filtration rate (eGFR) was associated with KIM-1 and N-GAL excretion in follow-up (estimates for log translated values -0.006, $p < 0.001$ and -0.012, $p < 0.001$, respectively).

**Conclusions:** KIM-1 and N-GAL excretion were unaffected by CE-CT in both patients with and without CI-AKI suggesting that CI-AKI was not accompanied by tubular injury.

*Funding:* Private Foundation Support

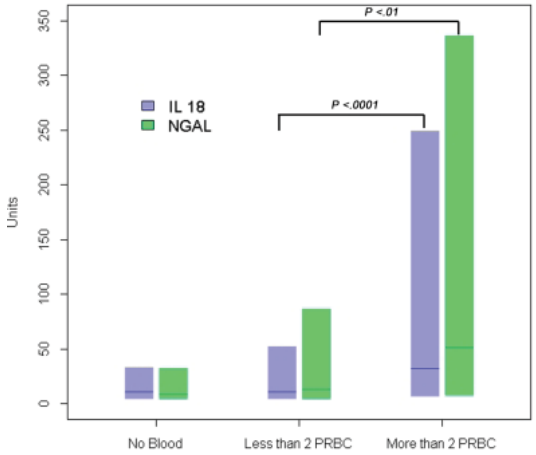
## FR-PO025

**Blood Transfusions Associate with New Biomarkers of Kidney Injury in Cardiac Surgery** Usman Ahmed Khan, Steven G. Coca, Kwangik Adam Hong, Jay L. Koyner, Amit X. Garg, Cary Steven Passik, Madhav Swaminathan, Susan Garwood, Uptal D. Patel, Mackenzie A. Quantz, Chirag R. Parikh. *Translational Research Investigating Biomarker Endpoints in Acute Kidney Injury (TRIBE-AKI) Consortium.*

**Background:** Blood transfusion is common in cardiac surgery and is associated with clinical acute kidney injury (AKI). We examined the effect of blood transfusion on biomarkers of kidney injury and serum creatinine in a clinical AKI in a large multicenter (TRIBE-AKI) cohort undergoing cardiac surgery.

**Methods:** 1210 adults underwent cardiac surgery and were divided into three groups based on the receipt of intraoperative packed red blood cell units: no blood (n=894), ≤ 2 PRBC (n=206) and > 2 PRBC (n=110). AKI was defined as: i) Doubling of serum creatinine from the baseline; ii) first post-operative urinary interleukin (IL)-18 and urinary neutrophil gelatinase-associated lipocalin (NGAL) in the 5th quintile. We determined the relative risk for AKI outcome according to PRBC group after adjusting for pre-operative and surgical variables. Using the Sobel test for mediation analysis, we also evaluated the role of biomarkers in causing AKI through indirect pathways.

**Results:** Urinary IL-18 and NGAL were higher in those who received >2 PRBC.



In patients receiving > 2 PRBC, the adjusted RRs were 2.3 (95% CI 1.2-4.4), 1.4 (95% CI 1.0-1.9), and 1.3 (95% CI 1.0-1.8) for doubling of serum creatinine, urinary IL-18 in the 5th quintile (>60 pg/ml), and urinary NGAL in the 5th quintile (>102 ng/ml), respectively. Furthermore, 17% of the effect of PRBC transfusion on AKI was mediated by IL-18 (P value for mediation 0.02).

**Conclusions:** Receipt of two or more PRBC during cardiac surgery is associated with a greater risk of AKI defined by serum creatinine and kidney injury biomarkers. Moreover, in part this effect is mediated by IL-18.

*Funding:* Other NIH Support - RO1HL085757 (CRP)

## FR-PO026

**Incidence, Risk Predictive Factors, and Clinical Outcomes of Acute Kidney Injury after Gastric Surgery for Gastric Cancer** Chang Seong Kim, Ha Yeon Kim, Yong Un Kang, Joon Seok Choi, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Dept of Internal Medicine, Chonnam National Univ Hospital, Gwangju, Republic of Korea.*

**Background:** Postoperative acute kidney injury (AKI), is a serious surgical complication in known to be common after cardiac surgery, however, reports on AKI after noncardiac surgery are limited. We sought to determine the incidence and predictive factors of AKI after gastric surgery for gastric cancer and its effects on the clinical outcomes.

**Methods:** We conducted a retrospective study of 4718 patients with normal renal function who underwent partial or total gastrectomy for gastric cancer between June 2002 and December 2011. Postoperative AKI was defined by serum creatinine change, as per the Kidney Disease: Improving Global Outcomes guideline.

**Results:** Of the 4718 patients, 679 (14.4%) developed AKI. Length of hospital stay and intensive care unit admission rates, and in-hospital mortality rate (3.5% versus 0.2%) were higher in patients with AKI than in those without. AKI was also associated with requirement of renal replacement therapy. Multivariate analysis revealed that male gender [odds ratio (OR) 1.75, 95% confidence interval (CI) 1.37-2.23], hypertension (OR 1.27, 95% CI 1.04-1.54), chronic obstructive pulmonary disease (OR 1.64 95% CI 1.15-2.35), hypoalbuminemia (< 4 g/dl) (OR 1.40 95% CI 1.11-1.77), use of diuretics (OR 2.39 95% CI 1.98-2.88), vasopressor (OR 1.87 95% CI 1.28-2.72) and contrast agent (OR 1.60 95% CI 1.29-2.00), and packed red blood cell transfusion (OR 1.72 95% CI 1.38-2.15) were independent predictors for AKI after gastric surgery. Postoperative AKI and vasopressor use entailed a high risk of 3-month mortality after multiple adjustments.

**Conclusions:** AKI was common after gastric surgery for gastric cancer and associated with adverse outcomes. We identified several factors associated with postoperative AKI; recognition of these predictors may help reduce the incidence of AKI after gastric surgery. Furthermore, postoperative AKI in patients with gastric cancer is an important risk factor for short-term mortality.

## FR-PO027

**Urine Angiotensinogen to Creatinine Ratio, a Marker of Intravascular Volume Depletion in Patients with Acute Kidney Injury** Line Malha, Joseph Alge, Nishant M. Bhensdadia, Morganne Phillips, Julie Teuber, Nithin Karakala, Christine M. Carr, John M. Arthur. *Medical Univ of South Carolina.*

**Background:** Intravascular volume depletion is a major risk factor for the development of acute kidney injury (AKI); its prompt identification may prevent the development of AKI. Urinary angiotensinogen/creatinine ratio (uAnCR) has been associated with worsening AKI. We hypothesized that uAnCR correlates with intravascular volume status.

**Methods:** 39 adult subjects were recruited in the emergency department. Volume status was determined by the examining physician's clinical impression. Patients were divided into two groups: intravascularly depleted (n=13) and non-depleted (n=26). The study is ongoing with a goal recruitment of 150 patients and a 1-year follow up chart review. Urinary angiotensinogen was measured by ELISA and corrected for urine creatinine in ng/mg.

**Results:** There was no difference in frequency between the intravascularly depleted and non-depleted groups by age, gender, use of Renin-Angiotensin System (RAS) blockade or AKI at the time of urine collection. 8 patients had AKI, 18 patients did not have AKI and 13 patients could not be assessed because they did not have a serum creatinine measurement. In the entire group, patients with volume depletion had a significantly higher uAnCR of 4.31±11.65ng/mg (median±interquatrile range) compared to 1.57±2.55ng/mg for the non-depleted patients (p=0.003). uAnCR accurately identified volume depleted patients, with an area under the receiver operating characteristic curve (AUC) of 0.793 (p= 0.003) for volume depletion. In the subgroup analysis, by AKI status, AUC was 1.0 (p=0.046) for the patients with AKI at presentation compared to an AUC 0.583 for the patients without AKI (p=0.57).

**Conclusions:** Intravascular volume depletion is associated with a higher UAnCR despite similar incidence of AKI at presentation and use of RAS blockade. The subgroup analysis suggests that the differences are driven entirely by patients with AKI. Larger numbers of patients will be required to determine if uAnCR can be used clinically to assess volume status among patients with AKI.

## FR-PO028

**Serum Cystatin C for Defining Acute Kidney Injury in Children Undergoing Cardiac Surgery** Michael Zappitelli,[1] Jason Henry Greenberg,[2] Steven G. Coca,[2] Catherine D. Krawczeski,[3] Simon Li,[4] Heather Thiessen Philbrook,[5] Gang Han,[2] Michael R. Bennett,[3] Prasad Devarajan,[3] Chirag R. Parikh.[5] *[1]McGill U.; [2]Yale U.; [3]U. Cincinnati; [4]Maria Fareri Child. Hosp.; [5]U. Western Ontario; [6]Yale U., Translational Research Investigating Biomarkers and Endpoints for AKI Consortium.*

**Background:** In theory, acute serum CysC change can be used to define acute kidney injury(AKI). If CysC, with its fewer limitations, defines AKI more accurately than serum creatinine(SCr) then AKI-biomarker associations will be stronger with CysC *vs.* SCr-AKI definition.

**Methods:** Three-center prospective study of children(1 mth-18 yrs) post-cardiac surgery. We measured pre and postop SCr, CysC and urine biomarkers(Fig.). We defined AKI based on KDIGO, using SCr- and CysC-AKI. We compared biomarker prediction of SCr and CysC-AKI (regression, diagnostic characteristics) and SCr- *vs.* CysC-AKI outcome associations.

**Results:** 287 children were included. There was poor agreement for SCr- and CysC-AKI Stage(St) 1(κ=0.38); good agreement for St 2 AKI(κ= 0.78). SCr- and CysC-AKI predicted longer hospital stay (SCr-AKI:7 *vs.* 4 d;CysC-AKI:7 *vs.* 5 d, adjusted[adj] p<0.001) and longer ventilation (SCr- and CysC-AKI:2 *vs.* 1 d, adj p<0.01). In general, 5th quintile (relative to 1st) 0-6hr postop biomarker concentrations predicted St 1 or worse CysC-AKI similarly or better than SCr-AKI (Fig, left, regression OR's); however, prediction was better for St 2 or worse SCr-AKI (Fig, right). Except for NGAL, 0-6hr postop biomarker AUCs were higher to predict St 1 or worse CysC-AKI (Fig, left); conversely, AUCs were higher to predict St 2 or worse SCr-AKI (Fig, right).

| AKI Definition | Urine Biomarker | Stage 1 AKI or worse | | Stage 2 AKI or worse | |
|---|---|---|---|---|---|
| | | Adj OR [95% CI] 5th vs 1st quintile | AUC ( SE) | Adj OR [95% CI] 5th vs 1st quintile | AUC ( SE) |
| SCr-AKI | IL-18 | 3.6 [1.3-9.7] | 0.66 (0.03) | 15.5 [1.8-135.8] | 0.75 (0.04) |
| | NGAL | 3.3 [1.1-9.6] | 0.69 (0.03) | 15.7 [1.7-145.7] | 0.76 (0.04) |
| | KIM-1 | 1.5 [0.6-3.5] | 0.58 (0.03) | 4.9 [1.2-20.6] | 0.69 (0.04) |
| | L-FABP | 3.4[1.2-9.6] | 0.66 (0.03) | 3.2 [0.8-13.5] | 0.73 (0.04) |
| | | | | | |
| CysC-AKI | IL-18 | 11.9 [2.3-62.2] | 0.74 (0.03) | 8.5 [0.9-81.8] | 0.72 (0.04) |
| | NGAL | 3.3 [0.9-13.5] | 0.66 (0.04) | 9.0 [0.9-90.8] | 0.72 (0.04) |
| | KIM-1 | 6.1 [1.5-25.2] | 0.65 (0.04) | 3.8 [0.8-17.7] | 0.67 (0.05) |
| | L-FABP | 5.3[1.4-19.9] | 0.68 (0.04) | 5.6 [0.8-36.8] | 0.70 (0.05) |

Biomarkers: Urine interleukin 18 (IL-18), neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule-1 (KIM-1), fatty acid binding protein (FABP), measured 0-6 hours postoperatively. Odds Ratios are adjusted for age, gender, white race, cardiopulmonary bypass>120 min, surgical severity score, baseline eGFR percentile, site. AUC (area under the curve); SE (standard error).

**Conclusions:** AKI biomarkers predicted mild CysC-AKI better than mild SCr-AKI. For more severe AKI prediction, associations were stronger using SCr-AKI. Implications are relevant for future studies using CysC for AKI definition.

*Funding:* NIDDK Support

## FR-PO029

**Diagnosis of Acute Pyelonephritis in Renal Allograft: A Possible Role for MicroRNAs** Anjali A. Satoskar,[1] Steve Oghumu,[1] Uday S. Nori,[2] Sergey V. Brodsky,[1] Ronald Pelletier,[3] Tibor Nadasdy.[1] *[1]Pathology, Ohio State Univ Wexner Medical Center, Columbus, OH; [2]Internal Medicine, Ohio State Univ Wexner Medical Center, Columbus, OH; [3]Surgery, Ohio State Univ Wexner Medical Center, Columbus, OH.*

**Background:** Acute pyelonephritis (APN) versus acute rejection (AR) is a frequently encountered diagnostic and therapeutic dilemma in clinical transplantation. Biopsy and urine culture are important diagnostic tools, but they may not always correlate. Variable culture results, overlapping histologic features with AR, persistent graft dysfunction despite antibiotics are frequently encountered. We explored the utility of intragraft microRNA profiles to distinguish between allograft APN and AR.

**Methods:** Between 2003 and 2011, we identified 49 patients with features of APN on biopsy, performed within the first two years post-transplant. MicroRNA profiling was performed on 20 biopsies (normal kidney, n=4; unequivocal AR, n=5; features of APN, n=11).

**Results:** Only 32% (16/49) of the patients had concomitant positive urine cultures at biopsy and in 8/16 patients colony count was less than $10^5$ CFU/ml. In 14/49 patients, positive urine culture did not coincide with the biopsy and in 19/49 patients, cultures were negative. On microRNA profiling, good clustering was seen among the normal kidneys and among AR biopsies. Among the eleven biopsies with features of APN, four biopsies showed good clustering and a pattern distinct from AR; (these four patients recovered graft function with antibiotics); 7/11 biopsies with features of APN showed heterogeneity in microRNA profiles. Three of these seven patients recovered only after steroid treatment, three lost their grafts within one month of the biopsy despite antibiotics and one patient expired. We identified a panel of 21 microRNAs showing significant difference in expression between AR and APN. MiR-99b, miR-23b and miRs from let-7, miR-30 family, show promise as markers to distinguish APN from AR.

**Conclusions:** Allograft pyelonephritis can be a diagnostic and therapeutic challenge. In addition to histology and cultures, differential intragraft microRNA expression may prove helpful to distinguish APN from AR in renal allografts.

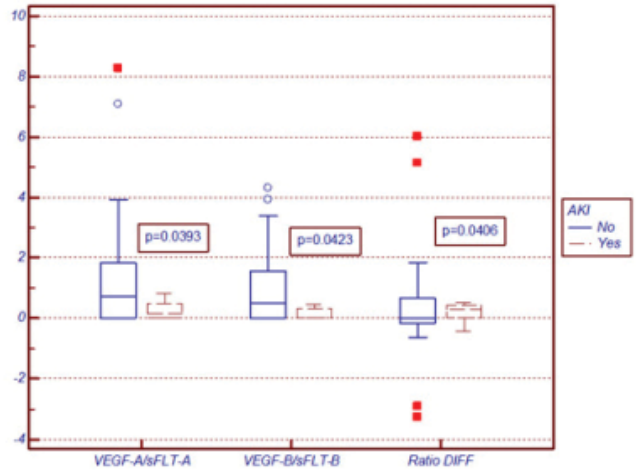
## FR-PO030

**Low VEGF/sFlt Ratio on Admission May Portend the Development of AKI in Critically Ill Patients with Sepsis** Arghya Majumdar, Aditi Jain. *Nephrology, AMRI Hospitals, Kolkata, India.*

**Background:** Microvascular alterations in the form of endothelial dysfunction and capillary leak play a key role in sepsis induced AKI.

**Methods:** To see whether VEGF/sFlt ratio on admission has a correlation with the development of AKI, in critically ill patients with sepsis. Methodology: Prospective observational study,conducted in a multi-specialty ICU, in a tertiary care hospital (AMRI), in Kolkata, India, for 1 year. Included: Adult patients with features of SIRS/sepsis admitted to ICU. Excluded: Patients‹18yrs old, brought in from other health facilities or transferred from wards after more than 24 hours of in-hospital stay, post-surgical patients, those anuric (for the first 6 hours after admission), with macroscopic hematuria, hemoglobinuria, pregnant or menstruating women, patients with neoplasm, known cases of CKD and macroalbuminuria. Within 6 hours of admission (A) and at 24 hours (B), VEGF and sFlt levels were measured from blood and microalbuminuria from urine samples. Clinical data was collated.

**Results:** An increase of microalbuminuria was noted in the first 24 hours,in the patients who went on to develop AKI, shock (requiring vasopressors) and organ dysfunction, more so in patients with sepsis, despite the fact that both the sepsis and SIRS group had similar APACHE IV and APS scores. The ratio of VEGF/sFlt had a significant correlation with AKI. In patients who developed AKI,VEGF/sFlt at (A) and 24 hours (B),after admission were lower than those who did not.



**Conclusions:** Endothelial dysfunction and capillary leak plays a pivotal role in pathogenesis of septic AKI. The ratio VEGF/sFlt on admission was inversely proportional to development of AKI. VEGF plays a key angio- protective role. Low VEGF levels may lead to endothelial cell apoptosis, capillary leak and AKI. Conclusion: Low VEGF/sFlt ratio may identify the septic patients at risk of developing AKI, on admission to ICU.

## FR-PO031

**Performance of Urinary Kidney Injury Molecule-1 (KIM-1) in Acute Kidney Injury (AKI): A Systematic Review** Paweena Susantitaphong,[1,2] Fouad Chebib,[1] Bertrand L. Jaber.[1] *[1]Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

**Background:** Urinary KIM-1 is a proximal tubular cell injury marker that has been proposed as a biomarker for early detection of AKI. We conducted a systematic review of diagnostic studies that examined the performance of urinary KIM-1 in AKI.

**Methods:** We searched MEDLINE (through December 2012), Scopus, Google Scholar, Cochrane Central Register of Controlled Trials and ClinicalTrials.gov for human studies investigating the diagnostic and prognostic performance characteristics of urinary KIM-1 for predicting development of AKI, dialysis requirement, and mortality. We performed bivariate-model and random-effects model meta-analyses.

**Results:** Of the 41 cohort studies and 8 case-control studies, only 9 prospective cohort studies could be meta-analyzed (2,647 patients). For the diagnosis of AKI, the estimated sensitivity of urinary KIM-1 was 64.7% (95% CI (50.9, 76.5%) and the specificity 81.6% (95% CI 76.0, 86.1%), with a diagnostic odds ratio DOR of 1.83 (95%CI, 1.04, 3.25; $P$=0.04). For prediction of dialysis requirement (2 studies, 545 patients), the estimated sensitivity of urinary KIM-1 was 42.6% (95% CI 25.7, 61.5%), and the specificity 91.0% (95% CI 49.2, 99.1%). For prediction of mortality (2 studies, 577 patients), the estimated sensitivity of urinary KIM-1 was 71.5% (95% CI 6.4, 98.9%), and the specificity 77.9% (95% CI 62.0, 88.4%).

**Conclusions:** Although KIM-1 is a promising urinary biomarker in AKI, its potential role needs to be examined in large cohort studies and across a broad range of clinical settings.

## FR-PO032

**Kidney Injury Molecule-1 and Monocyte Chemotactic Protein-1 as Sensitive Biomarkers for Detecting Cisplatin-Induced Nephrotoxicity in Patients with Lung Cancer** Haruka Shinke,[1] Yasuaki Ikemi,[2] Masami Tadehara,[2] Kazuo Matsubara,[1,2] Yosuke Togashi,[3] Young Hak Kim,[3] Michiaki Mishima,[3] Takaharu Ichimura,[4] Joseph V. Bonventre,[4] Satohiro Masuda.[1,2] *[1]Dept of Clinical Pharmacology and Therapeutics, Kyoto Univ Hospital, Kyoto, Japan; [2]Dept of Pharmacy, Kyoto Univ Hospital, Kyoto, Japan; [3]Dept of Respiratory Medicine, Kyoto Univ Hospital, Kyoto, Japan; [4]Renal Div, Brigham and Women's Hospital, Boston.*

**Background:** Acute kidney injury (AKI) is a common and serious adverse event after cisplatin-based chemotherapy. To identify urinary biomarkers for the accurate detection of cisplatin-induced AKI, we examined whether the recently discovered urinary biomarkers for AKI can detect cisplatin-induced nephrotoxicity in patients with lung cancer.

**Methods:** A total of 50 patients were enrolled in this study after providing written informed consent. Patients diagnosed with AKI lacking urine samples at day 3 after treatment were excluded. The urine samples were collected the day before cisplatin (80 mg/sqr) administration and at days 3, 7, and 14. The diagnoses of AKI were based on our hospital's criteria. This study was approved by the institutional ethics committee.

**Results:** A comparison of the urinary biomarker concentrations between the AKI (+) group (n = 30 samples) and AKI (-) group (n = 12 samples), revealed that kidney injury molecule-1 (KIM-1) and monocyte chemotactic protein-1 (MCP-1), but not neutrophil gelatinase-associated lipocalin (NGAL), were significantly higher in AKI (+) than that in AKI (-). Composite area under the receiver operating characteristics curve (AUC-ROC) analysis showed that KIM-1 (AUC = 0.858, $p < 0.01$) and MCP-1 (AUC = 0.828, $p < 0.01$), but not NGAL (AUC = 0.552, $p > 0.05$), had high sensitivity for detecting cisplatin-induced AKI. Moreover, AUC-ROC of the combined estimation of KIM-1 and MCP-1 was higher than that of either one alone (AUC = 0.871, $p < 0.001$). The cutoff values of KIM-1 and MCP-1 were calculated as 2.45 and 0.25 ng/mg creatinine, respectively.

**Conclusions:** Bothurinary KIM-1 and MCP-1 provide sensitive and specific detection of cisplatin-induced nephrotoxicity in patients with lung cancer.

*Funding:* Government Support - Non-U.S.

## FR-PO033

**Urinary Kidney Injury Molecule-1 (KIM-1) Levels Immediately after Surgery Predict the Development of Tacrolimus-Related Chronic Kidney Disease in Liver Transplantation Recipients** Haruka Shinke,[1] Ayami Tsuchimoto,[1] Venkata Sabbisetti,[2] Miwa Uesugi,[1] Emina Hashimoto,[1] Kazuo Matsubara,[1] Yasuhiro Fujimoto,[3] Toshimi Kaido,[3] Shinji Uemoto,[3] Motoko Yanagita,[4] Takaharu Ichimura,[2] Joseph V. Bonventre,[2] Satohiro Masuda.[1] *[1]Dept of Clinical Pharmacology and Therapeutics, Kyoto Univ Hospital, Kyoto, Japan; [2]Renal Div, Brigham and Women's Hospital, Boston; [3]Dept of Surgery, Kyoto Univ Hospital, Kyoto, Japan; [4]Dept of Nephrology, Kyoto Univ Hospital, Kyoto, Japan.*

**Background:** The aim of the present study was to examine whether the urinary KIM-1 levels immediately after surgery associates with the occurrence of tacrolimus-related post-liver transplant chronic kidney disease (CKD).

**Methods:** Twenty-three patients who received de novo living-donor liver transplantation (LDLT) with tacrolimus as a primary immunosuppressant were enrolled after providing written informed consent. Urine samples were collected at postoperative day (POD) 1, immediately before the first administration of tacrolimus. Development of CKD was defined by a Scr level that was 1.5-fold higher than the preoperative level for 3 consecutive months between PODs 1 and 180 (KDOQI CKD guidelines).

**Results:** Urinary KIM-1 concentrations at POD 1 after LDLT were significantly higher than those of healthy subjects. The levels of urinary KIM-1 at POD 1 in patients who ultimately developed CKD were significantly higher than those who did not develop CKD ($P < 0.001$ by Student-t test). The median value of urinary KIM-1 at POD 1 of all patients was found to be 2.85 ng/mg creatinine. The risk of post-transplant CKD was greater in patients whose urinary KIM-1 values at POD 1 were higher than that median value in comparison with to patients with lower urinary KIM-1 level at POD 1 ($P = 0.0325$ by Fisher's exact test). However, the frequency of post-transplant CKD was similar when the patients were categorized by the median value of the urinary neutrophil gelatinase-associated lipocalin levels at POD 1 (29.4 ng/mg creatinine, $P = 0.582$).

**Conclusions:** Urinary KIM-1 on POD 1 is a prognostic biomarker for the development of tacrolimus-related CKD after liver transplantation.

*Funding:* Government Support - Non-U.S.

## FR-PO034

**Is Kim-1 Is a Valuable Diagnostic Tool for Early Diagnosis of Contrast Induced Nephropathy?** Derya Akdeniz,[1] Huseyin Tugrul Celik,[2] Hakki Yilmaz,[3] Fatmanur Kazanci,[2] Ayse Mukadder Bilgic,[3] Nuket Bavbek,[3] Ali Akcay.[3] *[1]Internal Medicine, Turgut Ozal Univ Faculty of Medicine, Ankara, Turkey; [2]Biochemistry, Turgut Ozal Univ Faculty of Medicine, Ankara, Turkey; [3]Nephrology, Turgut Ozal Univ Faculty of Medicine, Ankara, Turkey.*

**Background:** Contrast-inducednephropathy (CIN) is a common complication of diagnostic/therapeutic procedures. Serum creatinin levels are sensitive but often lead to diagnostic delays for acute kidney injury (AKI) and potential misclassification of actual injury status. Kidney injury molecule (KIM-1) is a novel early marker of AKI. The aim of our study was to evaluate KIM-1 levels in patients with CIN. We performed a single center, nested case-control study.

**Methods:** Four hundred eighty six patients who undergone coronary angiography were included into the study.Thirty patients were diagnosed CIN. The diagnosis of CIN was done according to KDIGO 2012 Acute Kidney Injury Guideline criteria.Urinary KIM-1 is measured by enzyme-linked immunosorbent assay before, 6$^{th}$ and 48$^{th}$ hours post contrast. Serumcreatinine was measured before, 24$^{th}$ and 48$^{th}$ hours postcontrast.

**Results:** We showed that KIM-1 levels were significantly increased in the patients with CIN significantly in 6$^{th}$ hour when compared to baseline ($p<0.01$; median levels 48 and 101.8 mg/dL).

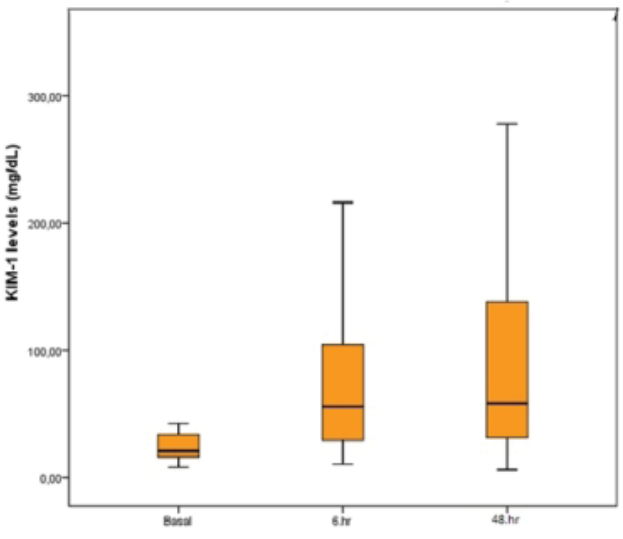


Figure 1 Comparison urinary corrected KIM-1 levels at baseline, 6th and 48th hour.

Pre-contrast and 48th hour KIM-1 levels were median levels were also significantly different(p= 0.001, median levels were 25, 101.8 respectively).

**Conclusions:** Because creatinine is a sensitive but a late marker of CIN, KIM-1 may be used for early diagnosis, early initiation of treatment and reduced risk of morbidity.

## FR-PO035

**Correlation of Increase in Urinary β2-Microglobulin and CD133 Staining in Renal Biopsy** Xu Zeng,[1] Guillermo A. Herrera,[1] Ping L. Zhang,[2] David G. Bostwick,[1] Deloar Hossain.[1] *[1]Nephrocor, Bostwick Laboratories, Orlando, FL; [2]Pathology, William Beaumont Hospital, Royal Oak, MI.*

**Background:** After filtration through the glomeruli, **β2-microglobulin is** reabsorbed by renal proximal tubules. Increase in urine **β2-microglobulin** indicates tubular injury, and measurement in urine sediment **is** useful to determine the source of kidney injury. CD133 has recently been characterized as a progenitor cell marker in the kidney, and also a marker for injured epithelial cells in proximal and distal nephron tubules. This study was designed to evaluate the correlation of urinary **β2-microglobulin and** CD133 with tubular injury.

**Methods:** Between 2009 and 2012, 47 patients with renal biopsies had prior RenalVysion™ analysis. Among these, 30 patients had increase in urinary **β2-microglobulin. The remainder 17 had normal urinary β2-microglobulin.** Immunohistochemical staining for CD133 (1:50 Miltenyi Biotec Inc.) was performed in corresponding renal biopsy specimens. CD133 staining in both proximal and distal tubules was considered positive. We evaluated the correlation of increase in urinary **β2-microglobulin** with positive CD133 staining in renal biopsy.

**Results:** 30 patients with increase in **β2-microglobulin** in the urine, and 25 of these also had CD133 staining positive proximal and distal tubules. In patients with normal **β2-microglobulin** in the urine, 11 of 17 patients were negative for CD133 staining. Using positive staining for CD133 as the end point for this analysis, sensitivity was 80.6%, specificity was 68.8%, positive predictive value was 83.3%, and negative predictive value was 64.7%.

| | CD133 (+) | CD133 (-) |
|---|---|---|
| β2-Microglobulin Increase | 25 | 5 |
| β2-Micorglobulin Normal | 6 | 11 |

**Conclusions:** Detection of **β2-microglobuline** in urine is a sensitive test of tubular injury, largely paralleled with CD133 upregulation in injured renal tubules. Due to low specificity, this finding should be utilized in conjunction with the patient's clinical history, urine cytology findings (including casts, tubular cells, and inflammatory cells), urine and serum chemistry.

## FR-PO036

**Plasma Cystatin C Should Not Be Used to Diagnose AKI after Cisplatin Therapy** Timothy J. Pianta,[1,2] Philip Peake,[1,2] Nicholas Buckley,[1] John W. Pickering,[3] Melvin Chin,[1] Zoltan H. Endre.[1,2,33] *[1]Prince of Wales Clinical School, Univ of New South Wales, Sydney, NSW, Australia; [2]Dept Nephrology, Prince of Wales Hospital, Sydney, NSW, Australia; [3]Dept Medicine, Univ of Otago, Christchurch, New Zealand.*

**Background:** Increased plasma cystatin C (pCysC) has been proposed as an alternative to serum creatinine (sCr) for diagnose AKI. We assessed theutility of plasma cystatin C (pCysC) to diagnose AKI after cisplatin-based chemotherapy.

**Methods:** Plasma and urinary biomarkers were measured at 8 time-points before and for 2 weeks after chemotherapy in 26 patients without CKD. All patients also received dexamethasone, aprepitant and palonosetron antiemetics.

**Results:** pCysC increased in all patients between 3 and 7 days after cisplatin. pCysC increased by more than 50% (AKI) in 9 patients (35%) whereas only 2 (8%) showed a 50% increase in sCr (p=0.04). pCys increased more than 25% in 16 patients (61%) whereas only 3 (12%) had a greater than 25% increase in sCr ($p < 0.001$). The mean difference between the percentage increase in pCysC and sCr was 25.0% (95% CI: 15.8% to 34.3%). Kidney injury molecule (KIM)-1, clusterin, interleukin-18 and neutrophil gelatinase-associated lipocalin (NGAL) increased above baseline 3 to 7 days after cisplatin ($p<0.05$). Peak KIM-1 and clusterin correlated with peak rise in sCr (r=0.43, p= 0.03; and r=0.40, p=0.04 respectively) suggesting the observed modest increases in sCr represented renal injury. Increases in pCysC did not correlate with increases in any other urinary biomarker ($0.80<p<0.88$).

**Conclusions:** After cisplatin chemotherapy, pCysC concentrations increase independently of sCr and kidney injury biomarkers in patients treated with contemporary antiemetics. This suggests significant interference, possibly by corticosteroids, neurokinin-1 receptor antagonists or serotonin antagonists warranting further study.

## FR-PO037

**Mean Daily Fluid Balance and Outcome in Acute Kidney Injury** Anup Chaudhari, Hemant J. Mehta. *Nephrology, Lilavati Hospital, Mumbai, Maharashtra, India.*

**Background:** Acute Kidney Injury (AKI) in critically ill patients carry high mortality. Fluid overload with oliguria leads to increased need for dialysis support and ventilation. The aim of this study is to evaluate the impact of mean daily fluid balance (MDFB) on outcomes in adult ICU patients with AKI.

**Methods:** This was a prospective study, from January 2009 to December 2010; included 130 patients. Inclusion criteria: Age > 18 years with AKI, admitted to ICU. APACHE II and SAPS II scores were calculated. Diagnosis of AKI was based on RIFLE criteria. MDFB was calculated for each day during ICU stay. Outcome was analyzed as survived or dead. Statistical analysis was done.

**Results:** Males/females = 89/49 (62.3%/37.7%). Mean age group 57.9 years (range 20-95 years), 46/130 (35.4%) had sepsis as the cause of AKI, 19 (14.6%) malaria, 17 gastrointestinal cause, 16 cardiac cause, 8 had dengue, 6 (4.6%) contrast induced nephropathy. Staging by RIFLE showed 9 cases (6.9%) in Risk group, 54 (41.5%) in Injury group, 60 (46.2%) in Failure group and 7 (5.4%) in Loss group. Comparison of various variables between recovered and expired cases at each stages of R, I, F and L for ventilation days, ICU days, inotropic support days, number of inotropes, APACHE II score and SAPS II score showed significant difference. Comparison between positive and negative MDFB showed significant difference for mechanical ventilator therapy, inotrope support, and survival v/s death such that patients in negative MDFB had a significant survival benefit. Overall survival was seen in 57.95% and mortality was 42.1%.

**Conclusions:** There appeared to be a step wise increase in relative risk of death, going from risk to failure in AKI. A negative MDFB was independently associated with a significant reduction in mortality. Even though we have invasive monitoring for fluid status, a simple calculation of MDFB by calculating intake and output can be useful, easy to calculate and very helpful for developing countries where such facilities of invasive monitoring may not be available. A recent multicentre study in Critical care by NEFROINT group has also shown that higher fluid balance and lower urine volume were both important factors associated with 28 days mortality of AKI patients.

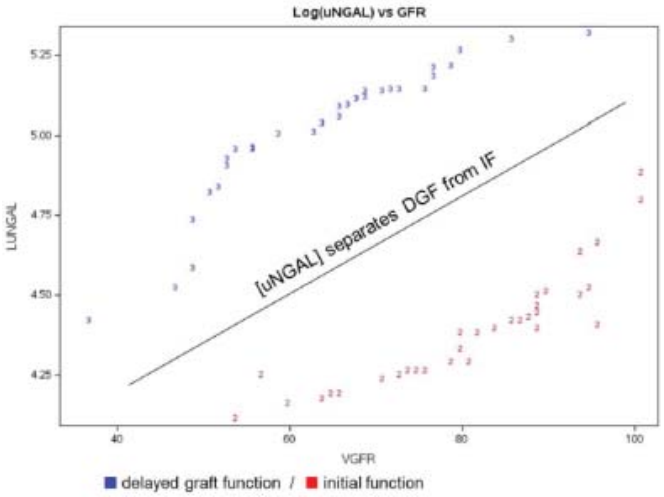
## FR-PO038

**Donor Neutrophil Gelatinase-Associated Lipocalin (NGAL) Concentration Predicts Post-Transplant Allograft Function after Kidney Tx** G. Junge, Wolfgang Arns. *The NGAL Study Group.*

**Background:** The donor pool for KTx has plateaued worldwide. Expansion of the pool by including LR-donations and donors who previously were not accepted is the only way to increase numbers. Data on specific parameters to predict success/failure of KTx are limited. It has been suggested that NGAL may serve as an early marker for renal injury, but have not as yet been investigated in kidney donors(KD). Therefore, it was the objective to evaluate NGAL in KD as a predictor of early allograft function after KTx.

**Methods:** This study prospectively evaluated NGAL (urine, serum) in healthy volunteers (n=30) to compare results with (1) brain dead organ donors (BDOD) before organ procurement (n=58), (2) living related (LR) KD (n=15), (3) KTx recipients who received an allograft from a BDOD (n=58) and (4) KTx recipients who received an allograft from LR donor (n=15). In addition, the study analyzed allograft function in associated kidneys in correspondent recipients that were classified into 2 groups depending on allograft function after KTx: initial function (IF) vs delayed graft function (DGF). The primary objective was to evaluate the predictive value of NGAL for post Tx allograft function. Secondary objectives were: (1) To compare NGAL levels in BDOD and CKD stage V patients on HD to healthy volunteers, (2) to evaluate NGAL evolution post (LR)KTx by visit, etc.

**Results:** Study results demonstrate that urine (and serum) NGAL levels in corresponding KD correlate with post transplant allograft function where higher NGAL levels where predictive for DGF.



**Conclusions:** In summary, our data indicates that NGAL represents a novel, sensitive and non-invasive urinary (and serum) biomarker predictive for primary graft function after KTx. Even in cases where our classical diagnostic parameters do not allow further differentiation of potential KD (marginal donors), NGAL seems to remain a stable and significant indicator.

## FR-PO039

### Effect of GFR Impairment on the Accuracy of BNP and NGAL as Markers of Cardiac and Renal Failure in Chronic Kidney Disease Patients

Carlo Donadio. *Clinical and Experimental Medicine, Univ of Pisa, Pisa, Italy.*

**Background:** Cardio-renal syndromes are characterized by the impairment of cardiac and renal functions. Plasma and urinary Neutrophil Gelatinase-Associated Lipocalin (NGAL), and plasma B-type natriuretic peptide (BNP) are markers of acute kidney injury (AKI) and heart failure (HF), respectively.

The aim of this study was to assess, in stable chronic kidney disease (CKD) patients in the different functional stages of CKD, the effect of the reduction of GFR on plasma BNP and on plasma and urinary NGAL concentrations.

**Methods:** GFR ($^{99m}$Tc-DTPA), plasma BNP, and plasma and urinary concentrations of NGAL and LMWP were measured in 310 CKD patients, clinically stable, at functional stages from 1 to 5. Serum and urinary low-molecular-weight proteins (LMWP), and urinary tubular enzymes (Enz) were measured for comparison. Plasma BNP, NGAL and LMWP were measured in 31 maintenance hemodialysis (MHD) patients.

**Results:** Plasma NGAL increased with the reduction of GFR in CKD patientsfrom stage 2. In the different CKD stages modest differences were found for BNP values. Urinary NGAL slightly but significantly increased in patients at CKD stages 4&5, similarly to urinary LMWP. In MHD patients, plasma NGAL and BNP were markedly increased, and high-flux hemodialysis decreased significantly their plasma concentrations.

**Conclusions:** Plasma NGAL increases markedly the with reduction in GFR, generating a very high number of false positive diagnosis of AKI in stable CKD patients. GFR impairment and etiology of kidney disease have a lower effect on urinary NGAL and on plasma BNP. In any case, specific reference values of NGAL and BNP should be used in CKD patients, according to their functional stage, when assessing AKI, HF, and cardio-renal syndromes in patients with impaired GFR.

### Is Mean Arterial Pressure or Use of Norepinephrine, during Cardiopulmonary Bypass, Associated with Acute Kidney Injury?

Kristian Kandler,[1] Mathias Ebbesen Jensen,[1] Christian Holdflod Møller,[1] Jens C. Nilsson,[2] Daniel Steinbrüchel.[1] *[1]Dept of Cardiothoracic Surgery, Rigshospitalet, Copenhagen, Denmark; [2]Dept of Cardiothoracic Anesthesia, Rigshospitalet, Copenhagen, Denmark.*

**Background:** Acute kidney injury (AKI) after cardiac surgery is common and associated with increased mortality. We wanted to investigate if the mean arterial pressure (MAP) or use of norepinephrine during cardiopulmonary bypass (CPB) were associated with AKI.

**Methods:** A retrospective analysis of patients who underwent elective or subacute CABG with or without concomitant procedures during the year 2012 was conducted. Exclusion criteria were baseline creatinine > 2.3 mg/dl (200 µmol/l), previous nephrectomy, selective cerebral perfusion and acute procedures within 24 hours of coronary angiography. AKI was defined, using the AKIN criteria, as a total increase in serum creatinine of ≥ 0.3 mg/dl (27 µmol/l) or > 50% compared to the baseline value, within the first 48 hours postoperative. Average MAP during CPB was gathered and calculated from electronic perfusion charts and entered in a binary logistic regression model together with pre- and intraoperative data.

**Results:** A total of 623 patients were included in the study of which 80% underwent isolated CABG. Mean age was 68.3 ± 9.7 years and 81% were males. AKI was observed in 177 patients (28.4%). Average MAP was 47 ± 6 mm Hg and 45 ± 6 mm Hg (p=0.003) in the AKI- and no-AKI group respectively. Norepinephrine was used, during ECC, in 19% of the AKI patients and 12% of no-AKI patients (p=0.024). Independent factors increasing the risk of AKI were higher age, body surface area, duration of CPB, Euroscore and hemodilution. Preoperative use of renin-angiotensin-aldosterone system inhibitors, hypertension and use of norepinephrine when leaving the operating room were also independently increasing the risk of AKI.

**Conclusions:** Although norepinephrine was used more frequently and the MAP was higher in the AKI group during ECC, the association was not found to be independent, using binary logistic regression analysis.

## FR-PO041

### Diagnostic Value of Cystatin C in Contrast-Induced Nephropathy after Percutaneous Cardiovascular Intervention

Peng Li,[1] Wong Ka tong,[2] Chan Wai Hun,[1] Wong Ka Nam.[3] *[1]Internal Medicine, Kiang Wu Hospital, Macau, Macau; [2]Nephrology Association of Macau, Macau, Macau; [3]Emergancy Dept, Centro Hospitalar Conde de Sao Januario, Macau, Macau.*

**Background:** Contrast-induced Acute Kidney Injury (CIAKI) is one of most common complications in the patients undergoing percutaneous cardiovascular intervention(PCI) using contrast media (CM)[1]. Many researchers have illustrated that cystatin C was a more sensitive marker of kidney injury since it was less influenced by sex, race, age, protein intake and muscle mass compared with serum creatinine(SCr)[2], and also found that cystatin C might have a better diagnotic accuracy in CIAKI than SCr[3]. We investigated the variation of cystatin C in the patients undergoing PCI in order to further determine the diagnostic value of cystatin C in CIAKI.

**Methods:** SCr and cystatin C were measured at baseline before contrast exposure, 24 hours and 48 hours after contrast exposure,respectively.Cystatin C levels were detected by particle-enhanced turbidimetric immunoassay (PETIA).Serum creatinine increased >= 25% within 48 hours is defined as the criteria for the diagnosis of CIAKI[1]. ROC curve analysis was performed for the 24hr and 48hr serum cystatin C.

**Results:** Among 196 study patients (61 female,135 Male, mean age: 70.7±11.3yr), 29 patients developed CIAKIaccording to the creatinine criteria.The prevalence of CIAKI was 14.8% .The area under the ROC curve (AUC) of the vari ation of cystatin C at 48hr showed a better performance than the variation of cystatin C at 24hr [AUC: 0.783(95% confidence interval (CI): 0.701–0.865, P=0.000)vs 0.661(95% confidence interval (CI): 0.548–0.774, P=0.006). In the ROC curve of cystatin C at 48hr, the 10% elevation of cystatin C yielded 48.3% diagnostic sensitivity, 83.2% specificity and 90.3% negative predictive value. 25% elevation of cystatin C yielded 27.6% diagnostic sensitivity, 96.4% specificity and 88.5% negative predictive value respectively.

**Conclusions:** The variation of cystatin C at 48hr presents a better diagnostic value in CIAKI than that of cystatin C at 24hr. Meanwhile, 25% elevation of serum cystatin C at 48hr seems to acquire an excellent specificity for the diagnosis of CIAKI.

## FR-PO042

### Clinical Adjudication Confirms TIMP2*IGFBP7 Results for Acute Kidney Injury

Mitchell H. Rosner,[1] Kathleen D. Liu,[2] Anitha Vijayan,[3] John A. Kellum.[4] *[1]Nephrology, Univ of Virginia, Charlottesville, VA; [2]Nephrology and Critical Care, Univ of California San Francisco, San Francisco, CA; [3]Renal Div, Washington Univ, St. Louis, MO; [4]Critical Care Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

**Background:** We showed that the combination of two biomarkers (TIMP2•IGFBP7) was predictive of AKI as defined by KDIGO stages 2 and 3 (Kashani et al. Critical Care 2013, 17:R25). However, AKI is a clinical diagnosis that does not solely rely on consensus definitions. To further assess the performance of TIMP2•IGFBP7, we assembled a committee of 3 expert nephrologists to adjudicate moderate and severe AKI events.

**Methods:** Adjudiication was done in a cohort of 408 subjects using clinical judgement and consensus definitions. In cases of discordance, the final adjudication was determined by the majority (2 out of 3).

**Results:** The committee adjudicated 337 (83%) subjects as No AKI and 71 (17%) subjects as AKI. Concordance among adjudicators was 94% (97% for No AKI subjects and 79% for AKI subjects). The KDIGO 2-3 rate (18%) was similar to adjudicated AKI rate, and the agreement between KDIGO staging and adjudication was 97% (98% for No AKI and 92% for AKI subjects). Of the 13 subjects for whom the adjudication and KDIGO staging differed, concordance among the adjudicators was 38% compared to 96% for those subjects for whom the adjudication and KDIGO staging agreed. Adjudication (blinded to biomarker values) agreed more with TIMP2•IGFBP7 levels than did KDIGO staging. The median TIMP2•IGFBP7 value was significantly ($p<0.01$) higher for the 6 patients who were adjudicated as AKI but did not reach KDIGO 2-3 ($2.78x10^3$ (ng/mL)$^2$</a>) compared to the 7 patients who were adjudicated as No AKI but reached KDIGO 2-3 ($0.52x10^3$ (ng/mL)$^2$). The TIMP2•IGFBP7 area under the receiver operating characteristic curve was 0.82 for detection of AKI as adjudicated by the committee.

**Conclusions:** Clinical adjudication showed differences compared to non-adjudicated KDIGO staging. This result has important implications for the evaluation of biomarkers and stresses the importance of independent adjudication in biomarker performance trials.

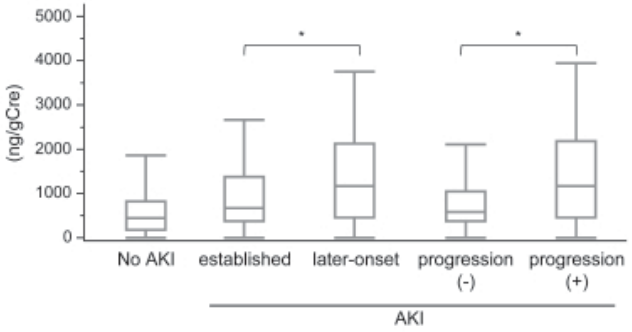
**FR-PO043**

**Urinary Semaphorin 3A Predicts the Progression of Acute Kidney Injury in an Adult Mixed Intensive Care Unit** Kent Doi,[1] Eisei Noiri,[1] Naoki Yahagi,[1] Calpurnia Jayakumar,[2] Ganesan Ramesh.[2] *[1]The Univ of Tokyo; [2]Georgia Health Sciences Univ.*

**Background:** Predicting the development of acute kidney injury (AKI) in critical care setting is challenging. Although several biomarkers showed moderately good performance for detecting established AKI even in heterogeneous disease oriented population, identification of new biomarkers that predict accurately the development of AKI is urgently required.

**Methods:** A single center prospective observational cohort study that was undertaken to evaluate for the first time the reliability of newly identified biomarker semaphorin 3A for AKI diagnosis in heterogeneous intensive care unit populations. Three hundred thirty-nine adult critically ill patients were recruited and urine samples were obtained at ICU admission.

**Results:** One hundred thirty one patients (39%) were diagnosed as AKI by the RIFLE criteria; 66 patients were diagnosed as AKI not at ICU admission but eventually within one week after (later-onset AKI). Eighty four AKI patients showed worsening the severity during one week observation (AKI progression). In addition to five urinary biomarkers of L-type fatty acid-binding protein (L-FABP), neutrophil gelatinase-associated lipocalin (NGAL), IL-18, albumin, and N-acetyl-β-D-glucosaminidase (NAG), urinary semaphorin 3A was measured at ICU admission. Although other five biomakers showed higher AUC-ROC values in detecting established AKI compared with detecting later-onset AKI or progression of AKI, semaphorin 3A was able to detect later-onset AKI and AKI progression better than established AKI (AUC-ROC for established AKI 0.64, later-onset AKI 0.71, AKI progression 0.71). Finally, sepsis did not have any impact on semaphorin 3A, while other urinary biomarkers were increased with sepsis.



**Conclusions:** A new AKI biomarker semaphorin 3A have a distinct predictive use for AKI progression from other AKI biomarkers.

**FR-PO044**

**Identification of Superoxide Dismutase [Cu-Zn] as a Prognostic AKI Biomarker** Joseph Alge,[1] Nithin Karakala,[1] Benjamin Neely,[1] Michael G. Janech,[1] James A. Tumlin,[2] Lakhmir S. Chawla,[3] Andrew Shaw,[4,5] John M. Arthur.[1,6] *[1]Medical Univ of South Carolina; [2]Univ of Tennessee College of Medicine in Chattanooga; [3]George Washington Univ; [4]Duke Univ; [5]Durham VA Medical Center; [6]Ralph H Johnson VA Medical Center.*

**Background:** Prognostic biomarkers could be valuable tools for risk assessment during the early phases of AKI. We identified candidate prognostic biomarkers using the combined results of 5 discovery phase proteomics studies (3 human, 1 mouse, 1 rat).

**Methods:** Thirteen urinary proteins that appeared predictive of AKI across 5 proteomic analyses were measured by parallel reaction monitoring mass spectrometry in urine samples from 157 post cardiac surgery patients who were classified as AKIN stage 1 at the time of sample collection, 21 of whom met the primary outcome of AKIN stage 3 or death. Prediction of the primary outcome was evaluated using the area under the ROC curve.

**Results:**

| Table 1. Results of Parallel Reaction Monitoring Assay for Prediction of AKIN stage 3 or Death | | | |
|---|---|---|---|
| **Protein** | **AKIN 1 or 2/Survivedc** | **AKIN 3/Deathc** | **AUC** |
| Superoxide dismutase [Cu-Zn]a | 9.9 (4.9-20.3) | 22.0 (13.9-104.8)* | 0.74* |
| Angiotensinogenb | 75.4 (40.4-193.4) | 312.3 (122.0-493.8)* | 0.73* |
| L-FABPa | 12.1 (5.7-21.4) | 19.7 (15.0-58.4)* | 0.72* |
| Nonsecretory ribonucleasea | 8.2 (5.4-2.7) | 11.2 (7.2-20.7) | 0.62 |
| Uromodulina | 14.6 (8.5-24.1) | 19.9 (12.9-31.2) | 0.60 |
| Pigment epithelium derived proteinb | 14.3 (4.4-145.3) | 67.2 (8.9-354.9) | 0.60 |
| Antithrombin IIIb | 96.0 (27.1-270.5) | 92.6 (56.3-430.4) | 0.58 |
| Complement C4Bb | 6.4 (3.3-28.3) | 8.0 (4.7-17.7) | 0.57 |
| ProEGFb | 77.2 (8.8-240.5) | 40.7 (10.0-160.4) | 0.51 |
| Apo A-IV# | ND | ND | ND |
| CD59# | ND | ND | ND |
| Myoglobin# | ND | ND | ND |
| KIM-1# | ND | ND | ND |

afmol/μg creatinine; battomol/μg creatinine; cmedian (IQR); AUC, area under the receiver operator characteristic curve; *P<0.05; #>90% of samples were below limit of detection; ND, Not determined

**Conclusions:** We identified superoxide dismutase [Cu-Zn] as a new biomarker of worsening AKI and confirmed angiotensinogen and L-FABP as prognostic AKI biomarkers. Several other candidates had marginal prognostic ability. No conclusions could be drawn regarding Apo A-IV, CD59, and myoglobin due to the large number of patients with undetectable protein concentrations.

**FR-PO045**

**Fibroblast Growth Factor 23 Is a Potential Biomarker of Development of Acute Kidney Injury in Rats and Patients: Preliminary Results** Luis F. Michea,[1] Luis Toro.[1,2] *[1]Centro Estudios Moleculares de la Celula, Facultad de Medicina Universidad de Chile, Santiago, Chile; [2]Critical Care Unit, Hospital Clinico Universidad de Chile, Santiago, Chile.*

**Background:** Acute kidney injury (AKI) is a condition of high incidence in Critical Care Units (CCU). Retrospective studies have shown association between serum Fibroblast Growth Factor 23 (sFGF-23) and AKI in hospitalized patients. The objective of the study is to evaluate in prospective clinical studies and murine models whether sFGF-23 is a predictor of AKI.

**Methods:** 1) Prospective cohort of patients admitted in the CCU of our hospital with severe sepsis or septic shock. sFGF-23 was measured at admission, 24 and 48 hours after hospitalization, plus clinical and biochemical parameters. Primary outcomes evaluated were the development and severity of AKI, defined by AKIN criteria. 2) Rat model of AKI through unilateral nephrectomy (U-NPX), with measurement of sFGF-23 and biochemical parameters at baseline, 1, 2, 3 and 4 hours after intervention, with a sham surgery control group.

**Results:** 1) Preliminary results with 11 patients. 7 (64%) developed AKI during hospitalization. 4 of them developed AKIN 1, 2 had AKIN 2 and 1 had AKIN 3. sFGF-23 was significantly increased in patients with AKI, compared to non-AKI patients, where the difference was most relevant at admission (AKI: 70.8±31.7 pg/mL; non-AKI: 14.9±6.1 pg/mL; $p<0.01$). The variation of sFGF-23 in AKI patients compared to non-AKI patients was more pronounced that changes in serum creatinine (sCr). Also, sFGF-23 at admission was significantly higher in patients with AKIN 2 and 3, compared to AKIN 1 patients (AKIN 2+3: 80.4±24.6 pg/mL; AKIN 1: 36.3±8.0 pg/mL; $p<0.01$). 2) sFGF-23 increased significantly after U-NPX, compared to control rats and baseline values. The increase was detected as early as 3 hours after U-NPX (10.6x higher than Sham, $p<0.01$), with a more pronounced variation in sFGF-23 compared to sCr.

**Conclusions:** Serum FGF-23 is correlated with the presence and severity of AKI in rats and CCU patients. Due to its early increase and magnitude, it may potentially be useful as a more sensitive biomarker to evaluate AKI.

*Funding:* Pharmaceutical Company Support - FONDECYT 1130550,1090223, IMII P09/016F, Government Support - Non-U.S.

**FR-PO046**

**Utility of Fractional Excretion of Sodium (FeNa) Compared with the Old-Fashion Clinical History and Urinalysis in the Evaluation of Acute Kidney Injury** A.C. Ortiz-Guerrero,[1] R.R. Malchira,[1] C.S. Huang,[1] E. McCann,[1] A. Jittirat,[1] P.T.T. Pham,[2] P.C. Pham.[1] *[1]Nephrology, Olive View MC; [2]Kidney & Pancreas Transplant, UCLA, Los Angeles, CA.*

**Background:** Traditionally, it is taught that FeNa can be used in the evaluation of non-oliguric acute kidney injury (AKI) to differentiate the prerenal state from acute tubular necrosis. Accordingly, primary care physicians (PCPs) oftentimes solely focus on obtaining FeNa prior to consulting nephrology for AKI, but not necessarily a complete clinical history or urinalysis (UA) that could be of great diagnostic value. We compared the diagnostic value of FeNa versus those obtained from routine clinical history and UA in the AKI setting.

**Methods:** This is a prospective study. All consults involving AKI evaluated by the lead author from July 2012-June 2013 were included. Data collected: Age, gender, ethnic background, presenting laboratory findings including Na, K, Cl, HCO3, blood urea nitrogen, creatinine, FeNa, UA, clinical history, and final diagnosis of AKI, recorded as prerenal or "other." FeNa <1%, presence of hyaline casts, urine specific gravity >1.015, or BUN to creatinine ratio (BUN:Cr) = of > 20, were considered to be consistent with prerenal state. Sensitivity and specificity of using FeNa, clinical history, UA, either positive clinical history or UA, and BUN:Cr for identifying a prerenal cause of AKI were calculated.

**Results:** There were 35 cases: 17 females, 17 Hispanics, 11 Caucasians, 7 others, mean age: 51+/-14, estimated glomerular filtration rate (MDRD-4): 24+/-15 mL/min/1.73m$^2$.

| | FeNa | Clinical history | UA | Either Clinical history or UA | BUN:Cr ≥ 20 |
|---|---|---|---|---|---|
| Sensitivity (%) | 62 | 62 | 77 | 85 | 38 |
| Specificity (%) | 68 | 82 | 54 | 59 | 86 |

**Conclusions:** While many PCPs heavily rely on FeNa to evaluate AKI, we suggest that FeNa does not provide greater sensitivity or specificity in identifying prerenal state compared to the basic clinical history and urinalysis. Emphasis on obtaining a thorough clinical history and routine UA rather than the sole reliance on FeNa for AKI evaluation among PCPs is warranted. Of interest, BUN:Cr > 20 traditionally taught to indicate a prerenal state has low sensitivity but high specificity.

## FR-PO047

**Assessing Fractional Excretion of Urea for Early Diagnosis of Cardiac Surgery Associated Acute Kidney Injury** Federico Varela, Angel Medina Ayala, Gustavo Cristian Greloni, Matilde Josefina Navarro, Guillermo Javier Rosa diez. *Nephrology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.*

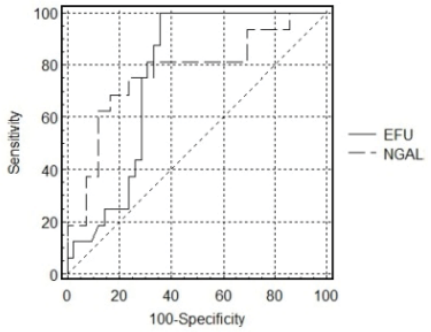
**Background:** AKI is a common complication after Cardiac Surgery (CS). Fraction Excretion of Urea (EFU) has been cited as a precise method to discriminate between early prerrenal and established AKI. The aim of our study is evaluate sensitivity and specificity of the EFU, in the early diagnosis of AKI in patients undergoing CS.

**Methods:** Prospective study of adult patients undergoing CS. AKI was defined by AKIN criteria. CKD patients were excluded. EFU sensitivity and specificity on predictive AKI diagnosis were tested on 1, 6 and 24 hours after CS. Same evaluation was conducted for urinary NGal. Comparation of AUC (ROC curve) for both methods was made.

**Results:** Sixty patients, 68 ± 11 years, 25% female. AKI prevalence 26.23%, mortality 3.28%. Staging AKI: 56% was AKIN I, 25% was AKIN II and was 19% AKIN III. Thirty-five of patients received diuretics during the first 48 hours. Patients with AKI had significantly lower EFU compared with normal kidney function group (13.3 ± 2.7 vs. 31.6 ± 3.4%, p<0.05) only at 6 hours after CS . N-Gal values also showed statistical difference between both groups at same period.

| | N Gal µg/l Hour 1 | EFU% Hour 1 | NGal µg/l Hour 6 | EFU% Hour 6 | NGal µg/l Hour 24 | EFU% Hour 24 |
|---|---|---|---|---|---|---|
| No AKI | 97.9 ± 43.1 | 31.5 ± 23.5 | 33.8 ± 38.9* | 31.6 ± 22** | 118.1 ± 279.4 | 40.9 ± 57 |
| AKI | 108.9 ± 59.7 | 25.9 ± 22.5 | 103.5 ± 104* | 13.3 ± 10** | 104.36 ± 127.88 | 16 ± 15 |

EFU showed sensitivity of 100%, specificity 65%, AUC of 0.768 and Yunden point of 28.04%. Comparision of AUC of both methods not showed statistical difference.



**Conclusions:** The results of this study support that EFU measured early after CS, predicts AKI in these patients.

## FR-PO048

**Renal Outcomes after Liver Transplantation in Fulminant Hepatitis A with Acute Kidney Injury: Comparison with Hepatorenal Syndrome** Jae-yoon Park,[1] Jung Pyo Lee,[2] Hyung Jung Oh,[3] Dong Ki Kim,[1] Chun Soo Lim,[2] Yon Su Kim.[1] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [2]Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea; [3]Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

**Background:** Liver transplantation (LT) is the treatment of choice for hepatorenal syndrome (HRS). However, the outcome of LT is not well established in acute hepatitis A accompanied by acute kidney injury (AKI). We investigated the outcomes of LT in patients with AKI associated with acute hepatitis A compared with patients with HRS due to other causes.

**Methods:** We reviewed 1940 consecutive adult recipients undergoing LT at three liver transplantation centers in Korea between 2005 and 2012. 20 patients with acute hepatitis A and AKI (HAV group) were compared with 76 patients with HRS from other causes (HRS group).

**Results:** There was no difference in the model for end-stage liver disease (MELD) score between groups. Pretransplant estimated glomerular filtration rate (eGFR) was lower in the HAV group compared with the HRS group (20.6 ± 12.7 *vs.* 28.2 ± 12.8 mL/min/1.73m$^2$, p=0.021). Posttransplant patient and graft survival rates were similar between groups. More patients in the HAV group required posttransplant hemodialysis compared with the HRS group (65.0% *vs.* 38.2%, p=0.043). However, eGFR had been significantly higher in HAV group since posttransplant month 2 (p<0.05). In addition, the HAV group had superior recovery rate of kidney function (eGFR ≥60ml/min/1.73m$^2$) after adjustment for pretransplant renal function or liver function. No patients required long-term renal replacement therapy in either group.

**Conclusions:** Pre- and immediate posttransplant kidney function is worse in patients with AKI due to acute fulminant hepatitis A, compared to those with HRS due to any cause. However, posttransplant long-term renal outcomes may be better in the HAV group.

## FR-PO049

**GFR Distributions among Scheduled Contrast-Enhanced Computed Tomography before and after eGFR Self-Report** Yoshinari Yasuda, Kanako Shibata, Shoichi Maruyama, Seiichi Matsuo. *Nephrology/CKD Initiatives, Nagoya Univ, Nagoya, Japan.*

**Background:** Renal insufficiency is the most important risk factor for contrast induced nephropathy (CIN), however it is difficult to assess renal function only by serum creatinine (sCr). Estimated glomerular filtration rate (eGFR) is globally recommended for evaluation of renal function, and eGFR self-report may affect clinical decision making to prevent CIN. Since Nagoya University Hospital (NUH) started eGFR self-report in December 2009, we analyzed GFR distributions in out-patients prior to scheduled contrast-enhanced computed tomography (CE) in NUH before and after eGFR self-report.

**Methods:** Study subjects were 6,108 and 6,308 out-patients who were examined by scheduled CE in NUH in 2008 and 2011. Patients under 18 years of age and emergency CE cases were excluded. Age, gender and sCr before CE (until 4 months before) were collected from medical record and eGFR was calculated by Japanese eGFR equation. Implementation rates of sCr measurements and distributions of age, gender and eGFR categories (G1: 90 and above, G2: 60-89, G3a: 45-59,G3b: 30-44 ,G4: 15-29 and G5: less than 15 mL/min/1.73m2) were compared before and after eGFR self-report. And implementation rates preventive hydration were analyzed among CKD patients with eGFR below 45 mL/min/1.73m$^2$.

**Results:** Age and gender distributions were not different in 2008 and in 2011. Implementation rates of sCr measurements were 78.5% in 2008 and 78.4% in 2011. Proportion of G3b to G5 patients in 2011 was significantly smaller than that in 2008. Implementation rate of preventive hydration was dramatically increased in 2011 (86.7%) compared to 2008 (31.8%) , however hydration regimen was not appropriate in some cases.

**Conclusions:** Distributions of eGFR categories and implementation rate of preventive hydration among patients examined by scheduled CE were different before and after eGFR self-report in NUH, suggesting its preferable effect to prevent CIN.

## FR-PO050

**SIRS, ALI, and AKI Are Established by Four Hours in Experimental Sepsis and Are Not Improved by Post-Sepsis Administration of TNF-α Antibodies** Sarah Faubel, Chris Altmann, Ana Andres-hernando, Rhea Bhargava, Kayo Okamura. *U of CO.*

**Background:** Acute kidney injury (AKI) and acute lung injury (ALI) are complications of sepsis, and the presence of either increases mortality. AKI is often viewed as a late complication of sepsis and some studies have suggested that AKI occurs as a result of ALI. Notably, the onset of AKI relative to ALI is unclear as routine measures of kidney function (BUN, creatinine) are insensitive and increase late. In this study, we hypothesized that AKI and ALI would occur simultaneously due to a shared pathophysiology (i.e., TNF-α mediated systemic inflammatory response syndrome [SIRS]), but that sensitive markers of kidney function would be required to identify AKI.

**Methods:** Sepsis was induced in male C57B/6 mice with 4 different one time doses of intraperitoneal (IP) endotoxin (LPS) (0.0001, 0.001, 0.01, or 0.25 mg). SIRS was assessed by serum inflammatory cytokines (TNF-α, IL-1β, CXCL1, IL-6), ALI was assessed by lung inflammation (lung MPO activity), and AKI was assessed by serum creatinine, BUN, and glomerular filtration rate (GFR) (FITC-labeled inulin clearance) at 4 hours. 20 µgs of TNF-α antibody (Ab) or vehicle was injected IP 2 hours before or 2 hours after LPS.

**Results:** Serum cytokines and lung MPO activity increased with all 4 doses of LPS; creatinine did not increase with any dose; BUN increased with 0.01 and 0.25 mg. Remarkably, GFR was reduced with all 4 doses of LPS and was 50% reduced in the 0.001 mg dose, demonstrating that dramatic loss of kidney function can occur in sepsis without a change in BUN or creatinine. Prophylactic TNF-α Ab reduced serum cytokines, lung MPO activity, and BUN; however, post-sepsis administration had no effect.

**Conclusions:** ALI and AKI occur together after sepsis and TNF-α plays a role in the pathogenesis of both. Although failure of anti-TNF-α therapy in clinical trials has generated doubt regarding the role of TNF-α in the pathophysiology of sepsis and called into the question the value of animal models, our data demonstrate that TNF-α mediated ALI and AKI are established early and not amenable to anti-TNF-α treatment; thus, even after just 2 hours, anti-TNF-α therapy cannot be expected to be successful in patients with sepsis.

**Activation of Type 1 Angiotensin II Receptors on T Lymphocytes Limits TNF-α-Mediated Acute Kidney Injury** Jiandong Zhang, Mehul B. Patel, Jose Gomez, Matthew A. Sparks, Steven D. Crowley. *Duke Univ.*

**Background:** Although blockade of type 1 angiotensin ($AT_1$) receptors is a cornerstone of therapy for patients with chronic kidney disease, the role of the renin-angiotensin system (RAS) in the pathogenesis of acute kidney injury remains unclear. In the present experiments, we examined the actions of $AT_1$ receptors specifically on T lymphocytes during acute kidney injury in the cisplatin (CIS) nephropathy model.

**Methods:** To this end, we intercrossed mice carrying a floxed gene for the $AT_{1A}$ receptor (*Agtr1a*$^{flox/flox}$) with mice harboring *Cre recombinase* under the control of the CD4 promoter to remove $AT_{1A}$ receptor-mediated responses from T lymphocytes alone (*Cre*$^{+}$ *Agtr1a*$^{flox/flox}$ = TKO). Compared to *Cre*$^{-}$ *Agtr1a*$^{flox/flox}$ littermates (WT), the TKOs had a ~90% reduction in $AT_{1A}$ receptor mRNA expression solely in T lymphocytes ($p<0.0001$). We also generated CD4-Cre mT/mG (T cell GFP) mice in which T cells fluoresce green to trace renal infiltration of T lymphocytes.

**Results:** When we subjected T cell GFP mice to CIS injection (30mg/kg), we detected green signals in the kidney out to 72 hrs**,**confirming the renal infiltration of T lymphocytes during the window of nephrotoxicity. At 72hrs, BUN in CIS-treated WTs increased dramatically to 185±20mg/dL, compared to vehicle-treated WTs (25±0;,$p<0.001$), but CIS-treated TKOs had 30% higher BUNs than WTs (244±20; $p=0.008$). Similarly, CIS-treated TKOs had 50% higher serum creatinines (Scr) (1.85±0.21 vs. 1.24±0.23 mg/dL; $p=0.02$). Moreover, compared to CIS-treated WTs, TKOs had augmented renal mRNA expression for the injury marker NGAL (683±203 vs. 1796±645 au; $p=0.006$). TNF- α mediates CIS nephropathy and is produced by several cell lineages including T cells. Renal mRNA expression of TNF-α was increased in CIS- vs. vehicle-treated WTs (13.3±3.4 vs. 1.0±.21au), but even more profoundly in CIS-treated TKOs (30.8±5.2, $p=0.01$). By ELISA, protein levels of TNF- α were also higher in CIS-treated TKOs in the kidney (342±36 vs. 233±20 pg/mg protein, $p=0.004$) and the serum (169±52 vs. 59±20 pg/mL, $p<0.04$).

**Conclusions:** We concludethat $AT_1$ receptor stimulation on T lymphocytes ameliorates acute kidney injury by limiting the production of TNF-α.

**Selective Deletion of Endothelial Sphingosine-1-Phosphate Receptor 1 Exacerbates Kidney Ischemia-Reperfusion Injury** H. Thomas Lee,[1] Vivette D. D'Agati,[2] Mihwa Kim.[1] *[1]Dept of Anesthesiology, Columbia Univ, New York, NY; [2]Dept of Pathology, Columbia Univ, New York, NY.*

**Background:** Acute kidney injury (AKI) is a devastating clinical problem without effective therapy and renal ischemia reperfusion (IR) injury is a major cause of AKI. Although the renal protective effects of proximal tubule sphingosine-1-phosphate receptor 1 ($S1P_1R$) are well known, the role for endothelial $S1P_1R$ in AKI remains unclear as germline endothelial $S1P_1R$ deletion is embryonically lethal.

**Methods:** To test whether endothelial $S1P_1Rs$ play a protective role against AKI due to renal IR injury, we generated conditional endothelial $S1P_1R$ deficient mice by crossing mice with floxed $S1P_1R$ ($S1P_1R^{f/f}$) with mice that express a tamoxifen-inducible form of Cre recombinase (iCreER) under the transcriptional control of the Platelet-derived growth factor-b (Pdgfb) gene. We subjected tamoxifen-treated adult $S1P_1R^{f/f}$ $Pdgfb^{iCreER}$ mice as well as wild type ($S1P_1R^{f/f}$) mice to mild (20 min) renal IR injury.

**Results:** Mice with tamoxifen-induced deletion of endothelial $S1P_1R$ developed significantly worse kidney injury with large increases in plasma Cr (2.81+0.21 mg/dL, N=5) 24 hr after 20 min renal ischemia when compared to wild type $S1P_1R^{f/f}$ mice (Cr=0.95+0.22 mg/dL, N=5, $P<0.001$). Mice with conditional deletion of endothelial $S1P_1R$ ($S1P_1R^{f/f}$ $Pdgfb^{iCreER}$ mice) also had ~3 fold increase in kidney vascular permeability as well as increased renal tubular necrosis, neutrophil infiltration, pro-inflammatory cytokine expression and renal tubular apoptosis after ischemic AKI when compared to wild type mice. Moreover, conditional endothelial $S1P_1R$ deficient mice subjected to 20 min renal IR had increased hepatic injury (plasma ALT=160+20 U/L, N=5) compared to wild type mice (ALT=95+18 U/L, N=5, $P<0.05$). As a potential mechanism for exacerbated renal injury, conditional endothelial $S1P_1R$ null mice had markedly reduced (~90%) endothelial HSP27 expression compared to wild type mice.

**Conclusions:** Taken together, our studies demonstrate a protective role for endothelial $S1P_1R$ against ischemic AKI most likely by regulating endothelial barrier integrity and endothelial HSP27 expression.

**Prior Splenectomy Increases the Susceptibility of Mice to Renal Ischemia-Reperfusion Injury** Joseph C. Gigliotti,[1] Liping Huang,[1] Eric Mace,[1] Amandeep Bajwa,[1] Hong Ye,[1] Alexander L. Klibanov,[2] Mark D. Okusa.[1] *[1]Div of Nephrology and CIIR; [2]Div of Cardiology, Univ of Virginia, Charlottesville, VA.*

**Background:** Several preventative therapies for acute kidney injury (AKI) in mice require an intact spleen. However, the interaction of the spleen with AKI is unknown. Therefore the objective of the current study was to determine how prior splenectomy (SPLX) modulates the susceptibility of mice to AKI.

**Methods:** Male 8-12 wk old C57BL/6 or $Rag1^{-/-}$ mice underwent SPLX or sham operation 7d prior to subthreshold, bilateral renal ischemia-reperfusion injury (subIRI). After 24h of reperfusion, AKI was assessed by plasma creatinine and histology. Renal inflammation was determined by FACS, immunohistochemistry, and renal CXCL1 and IL-6 mRNA expression. In separate experiments, phagocytic splenocytes were labeled by i.v. injection of fluorescently labeled liposomes 24h prior to unilateral IRI. Tissue samples were collected 1, 3, and 7d following reperfusion.

**Results:** 5d after SPLX, no difference ($P\geq0.25$) was observed in circulating leukocytes or total hematocrit compared to sham-operated mice. Plasma creatinine (mg/dL) in mice receiving subIRI alone was similar (0.4) to controls (0.3). However, SPLX+subIRI resulted in higher plasma creatinine (1.2, $P=0.001$) and acute tubular necrosis (15% of kidney section area) compared to subIRI alone (5%, $P<0.001$). SPLX+subIRI resulted in increased circulating ($P=0.009$) and infiltrating neutrophils ($P<0.001$) and renal mRNA expression of CXCL1 and IL-6 ($P\leq0.003$). SPLX $Rag1^{-/-}$ mice were also more susceptible to IRI ($P<0.001$), suggesting the effect of SPLX is not dependent upon T or B-cells. Fluorescently labeled cells were observed 3d after reperfusion and persisted only in the ischemic kidney through 7d, suggesting phagocytic cells originating from the spleen localize to ischemic renal tissue following AKI.

**Conclusions:** The spleen mediates the susceptibility of mice to IRI. Prior SPLX results in increased renal inflammation and damage following IRI. Trafficking of splenic phagocytes does not appear to influence AKI, since fluorescently labeled cells were not observed in the ischemic kidney until 3d after reperfusion.

**Prior Ultrasound Exposure Improves Survival and Modulates the Early Inflammatory Response to Ischemia-Reperfusion Injury in Mice** Joseph C. Gigliotti,[1] Liping Huang,[1] Alexander L. Klibanov,[2] Diane L. Rosin,[1,3] Kambiz Kalantari,[1] Mark D. Okusa.[1] *[1]Div of Nephrology and CIIR; [2]Div of Cardiology; [3]Dept of Pharmacology, Univ of Virginia, Charlottesville, VA.*

**Background:** Inflammation mediates the tissue injury that occurs during acute kidney injury (AKI). We have shown prior ultrasound (US) exposure reduces AKI and inflammation in mice. How US modulates inflammation is unknown. Therefore, the objective of the current study was to determine if prior US exposure modulates the initial inflammatory response to AKI.

**Methods:** Male C57BL/6 mice were anesthetized and exposed to US (7MHz, MI = 1.2) using Siemens Acuson Sequoia 512 system with a 15L8w transducer. 24h after US exposure, mice were subjected to bilateral renal ischemia-reperfusion injury (IRI). For survival studies, mice were maintained for 7d after IRI. For acute studies, mice were euthanized and tissue samples were collected after 0h (no reperfusion) and 0.5h after IRI. AKI was assessed by measuring plasma creatinine. Neutrophils were quantified by FACS and renal IL1β mRNA expression was determined by RT-PCR.

**Results:** Exposure to US 24h prior to IRI significantly improved 7d survival as compared to IRI alone (mortality of 25% vs 87%, $P=0.004$). The protective effect of US was observed 0.5h after reperfusion, where mice pretreated with US had a 67% reduction ($P=0.02$) in plasma creatinine compared to mice receiving IRI alone. IRI resulted in a 3-fold increase in renal neutrophils, a phenomenon prevented with prior US exposure ($P=0.05$). However, prior US did not influence ($P=0.99$) circulating neutrophils 0.5h after reperfusion, suggesting that US modulates trafficking of neutrophils into the kidney. US reduced ($P=0.05$) kidney IL1β mRNA expression by 50% after ischemia alone (no reperfusion), suggesting prior US exposure modulates the response of the kidney to ischemic damage.

**Conclusions:** The results demonstrate that prior US exposure decreases the mortality associated with IRI in mice. This could be due to an US-induced reduction in ischemic tissue damage, which in turn reduced neutrophil accumulation following reperfusion. Identifying the mechanism responsible will shed light on new therapeutic targets for AKI.

**Macrophage-Specific Deletion of Transforming Growth Factor-β1 Does Not Prevent Renal Fibrosis after Severe Ischemia-Reperfusion Injury** Sarah C. Huen, Gilbert W. Moeckel, Lloyd G. Cantley. *Yale Univ School of Medicine, New Haven, CT.*

**Background:** The persistence of macrophages is associated with tubulointerstitial fibrosis and progression of chronic kidney disease. Macrophages are known to be major producers of transforming growth factor-β1 (Tgf-β1). Tgf-β1 has long been implicated as a central mediator of kidney fibrosis. To determine the fibrogenic role of macrophage-derived Tgf-β1 we deleted *Tgfb1* from myeloid cells by establishing a *LysM-Cre;Tgfb1*$^{f/n}$ transgenic mouse and induced severe unilateral ischemic renal injury.

**Methods:** *LysM-Cre* mice were bred with *Tgfb1*$^{f/n}$ (*loxP* sites flanking exon 1 of the *Tgfb1* gene on one allele with the second allele being *Tgfb1* null) mice. Wild-type (*Tgfb1*$^{f/+}$) and whole body *Tgfb1* heterozygous with macrophage specific *Tgfb1* knockout (*LysM-Cre;Tgfb1*$^{f/n}$) male mice 8-10 weeks old were subjected to 35 minutes of unilateral renal ischemia. Kidneys were harvested 28 days after ischemia/reperfusion (I/R) for mRNA and protein analysis as well as histology for blinded fibrosis and tubular injury scoring.

**Results:** Both bone marrow derived macrophages and macrophages isolated from the kidney 28 days after I/R injury from *LysM-Cre;Tgfb1*$^{f/n}$ mice showed significantly decreased *Tgfb1* expression compared to macrophages from wild-type mice. Whole kidney *Tgfb1* mRNA expression increased by 6-fold after I/R injury in wild-type mice, while injured kidneys from *LysM-Cre;Tgfb1*$^{f/n}$ mice exhibit an overall reduction of *Tgfb1* by 75.5%. Consistent with the sustained increase in *Tgfb1* mRNA expression in wild-type kidneys, Smad2/3 was highly activated. In contrast, Smad2/3 activation was eliminated in injured kidneys from *LysM-Cre;Tgfb1*$^{f/n}$ mice. *LysM-Cre;Tgfb1*$^{f/n}$ injured kidneys showed a trend toward less fibrosis that did not reach statistical significance compared to wild-type injured kidneys. Markers of extracellular matrix and fibrogenic genes remain elevated in *LysM-Cre;Tgfb1*$^{f/n}$ kidneys and were only modestly decreased compared to wild-type kidneys.

**Conclusions:** Targeting macrophage-derived Tgf-β1 does not appear to be an effective therapy for attenuating progressive renal fibrosis after ischemic kidney injury.

### RGS4 Inhibits Angiotensin II Signaling and Macrophage Localization during Renal Reperfusion Injury Independent of Vasomotor Tone

Paul Pang, Padsawan Khamlue, Joseph V. Bonventre, Andrew M. Siedlecki. *Medicine, Brigham and Women's Hospital, Boston, MA.*

**Background:** Vascular inflammation is a major contributor to the severity of acute kidney injury. The anti-inflammatory effect of RGS4 in angiotensin II-induced atherosclerosis is known (PNAS, 105:4277, 2008) but has not been studied in the setting of reperfusion injury in the kidney. We hypothesized that RGS4 expression in vascular smooth muscle cells is protective to the kidney after vascular injury.

**Methods:** We used RGS4 overexpressing (R4OX) and smooth cell-specific RGS4 deleted mice in a model of acute renovascular kidney injury. RGS4-dependent cell signaling was studied in vascuar smooth muscle cell (VSMC) culture.

**Results:** 18 hours after 10-minute unilateral renal artery clamping we observed: no tubular injury, normalized ET-1 levels, and reduced calponin-1 expression.
