KIDNEYWEEK 2013
Atlanta, GA | Nov 5 - 10

# JASN Abstract Supplement

**Abstract Publication**
More than 4,300 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date*, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined. For the poster sessions, the publication numbers and poster board numbers are the same.

**Abstract Author Index**
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

**Abstract Keyword Index**
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

**Abstract Reference Format**
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 24, 2013: Page(s).

For example: Hsu CW, Mukherjee P, Kestenbaum BR, Himmelfarb J, Wurfel MM: The Association between Single Nucleotide Polymorphisms in the FAS Pathway with Acute Kidney Injury [Abstract]. J Am Soc Nephrol 24, 2013: 1A.

**Abstract Experts**
Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The *Onsite Program* lists all abstract experts.

**Abstract Disclaimer and Copyright**
The Abstract Issue of JASN® contains proprietary information belonging to the American Society of Nephrology (ASN). It is published as a service for the personal, noncommercial, and informational use only of its members and Kidney Week participants. Any commercial use is strictly prohibited. ASN's program materials and publications facilitate scientific discourse for educational purposes. ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such material within Kidney Week and other ASN publications, or online postings does not constitute an endorsement by ASN.

**ASN General Information**

Kidney Week Program and Presentations
The Kidney Week 2013 program, which can be found in the *Onsite Program*, includes:

- Early Programs' content
- Plenary Sessions
- Basic and Clinical Science Symposia
- Clinical Nephrology Conferences
- Special Sessions
- Educational Symposia
- Oral Abstract Sessions
- Poster Sessions

Disclosure Statement
ASN requires all individuals in a position to control content for Kidney Week 2013 to complete a disclosure form. Responses are listed in the Kidney Week 2013 *Disclosure Digest*, which is available to each meeting participant.

Program Builder
All abstracts and the complete Kidney Week 2013 program are viewable online through the Program Builder at www.asn-online.org/KidneyWeek with features including keyword search and PDA download.

*Support provided by Mitsubishi Tanabe Pharma.*

Posters On-Demand™
Fully paid participants can access electronic versions of the Kidney Week 2013 posters at no additional cost. Search and locate posters easily by authors, categories, or keywords during and after the meeting. Posters can be accessed online at www.asn-online.org/KidneyWeek/PostersOnDemand.

*Support provided by Mitsubishi Tanabe Pharma.*

**TH-OR001**

**The Association between Single Nucleotide Polymorphisms in the FAS Pathway with Acute Kidney Injury** Christine W. Hsu,[1] Paramita Mukherjee,[1] Bryan R. Kestenbaum,[1] Jonathan Himmelfarb,[1] Mark M. Wurfel.[2] *[1]Div of Nephrology, Univ of Washington, Seattle, WA; [2]ARDSNet Investigators, Div of Pulmonary & Critical Care Medicine, Univ of Washington, Seattle, WA.*

**Background:** Inflammation and apoptosis of renal tubular cells may be central to the pathophysiology of acute kidney injury (AKI). The Fas/Fas ligand pathway is a key initiator of both inflammation and apoptosis. Fas is a transmembrane protein in the tumor necrosis factor family that can induce inflammation and apoptosis upon binding Fas ligand.

**Methods:** We performed a retrospective cohort study of 401 patients who provided consent for genotyping while enrolled in the NHLBI ARDSNet Fluid and Catheter Trial (FACTT) from 2000-2005. We genotyped 376 single nucleotide polymorphisms (SNPs) on 45 genes of the Fas/Fas ligand pathway, and then used logistic regression, assuming an additive genetic model to identify associations between SNPs in Fas pathway genes and the development of AKI by day 2 after enrollment in FACTT. We classified levels of AKI using the Acute Kidney Injury Network (AKIN) criteria. In the primary analysis, we compared patients with AKI (AKIN stage 1 and above) to those without AKI (AKIN stage 0). In a sensitivity analysis, we compared patients with severe AKI (AKIN stage 2 and 3) to those without AKI (AKIN stage 0). Analyses were performed separately by race (Caucasian vs. African-American).

**Results:** In Caucasian patients, we identified associations between two SNPs and the incidence of AKI: rs1050851 and rs2233417. Both are found within the gene for nuclear factor of kappa light polypeptide gene enhancer in B-cells inhibitor, alpha (*NFKBIA*). For rs1050851 and rs2233417, the odds ratios (ORs) were 2.34 (95% confidence interval (CI)=1.58-3.46;p=$1.06x10^{-5}$) and 2.46 (CI=1.61-3.76;p=$1.81x10^{-5}$) for each minor allele, respectively. The associations were stronger still for AKIN stage 2-3 (severe AKI), with ORs 4.00 (CI=2.10-7.62;p=$1.05x10^{-5}$) and 4.03 (CI=2.09-7.77;p=$1.88x10^{-5}$) for each minor allele of rs1050851 and rs2233417, respectively.

**Conclusions:** In critically ill Caucasian patients with ALI, the presence of minor alleles in two SNPs in *NFKBIA* was strongly associated with the development of AKI.

**TH-OR002**

**Explaining the Temporal Trend in Dialysis-Requiring Acute Kidney Injury in the U.S.** Raymond K. Hsu, Charles E. McCulloch, Chi-Yuan Hsu. *Univ of California, San Francisco.*

**Background:** The U.S. population incidence of dialysis-requiring acute kidney injury (AKI-D) has increased rapidly, but reasons for this temporal trend are incompletely understood.

**Methods:** We analyzed data from the 2006-2010 Nationwide Inpatient Sample, a nationally representative sample of hospitalizations, and identified cases of AKI-D using validated ICD9 codes. To explore potential reasons for the temporal trend in risk of AKI-D among hospitalized patients, we identified the top 15 diagnoses and the top 15 procedures most strongly associated with AKI-D. We then used multivariate logistic regression to examine the degree to which accounting for the 15 diagnoses or for the 15 procedures attenuated observed temporal trends in AKI-D.

**Results:** From 2006-2010, the odds of developing AKI-D among hospitalized patients in the U.S. increased by 9% per year (unadjusted OR 1.09, 95% CI 1.07-1.11). After adding in sex, age, race, and the 15 top medical diagnoses as covariates, the temporal trend was completely accounted for (fully adjusted OR 0.97, 95% CI 0.95-0.98). Using backward selection, we determined that the increase in incidence of AKI-D appears to be driven by increases in both acute diagnoses (respiratory failure, septicemia, shock) and chronic diagnoses (chronic kidney disease, liver disease, hypertension) among hospitalized patients. In the second analysis, temporal trends in the top 15 procedures (such as cardiac and vascular surgeries) did not correlate well with changes in the risk of AKI-D.

**Conclusions:** Increasing rates of AKI-D observed in the U.S. appear to correlate with higher burden of acute and chronic conditions (such as infectious and cardiovascular disease) among hospitalized patients but not with increases in surgeries and procedures. This suggests that AKI prevention efforts should target these high-risk populations with multiple co-morbidities.

**TH-OR003**

**Pre-Operative Angiotensin Converting Enzyme Inhibitors and Angiotensin Receptor Blocker Use and Acute Kidney Injury in Patients Undergoing Cardiac Surgery** Steven G. Coca, Amit X. Garg, Madhav Swaminathan, Heather Thiessen Philbrook, Cary Steven Passik, Jay L. Koyner, Chirag R. Parikh. *TRIBE-AKI Consortium.*

**Background:** Using either an angiotensin converting enzyme inhibitor (ACEi) or an angiotensin receptor blocker (ARB) the morning of surgery may lead to 'functional' post-operative acute kidney injury (AKI), measured by an abrupt increase in serum creatinine. Whether the same is true for 'structural' AKI, measured with urinary biomarkers for tubular damage, is unknown.

**Methods:** The TRIBE-AKI study was a prospective cohort study of 1594 adults undergoing cardiac surgery at 6 hospitals between July 2007 and December 2010. We classified the degree of exposure to ACEi/ARB into three categories: "none" (no exposure prior to surgery), "held" (on chronic ACEi/ARB but held on the morning of surgery), or "continued" (on chronic ACEi/ARB and taken the morning of surgery). The co-primary outcomes were "functional" AKI based upon changes in pre to post-operative serum creatinine, and "structural AKI", based upon peak post-operative levels of 4 urinary biomarkers of tubular damage.

**Results:** Across the three levels (none, held and continued) of ACEi/ARB exposure, there was a graded-increase in functional AKI, as defined by a the incidence in a rise in creatinine of 50% or 0.3 mg/dL; (31%, 34%, 42%, p for trend 0.03) and by mean percentage changes in serum creatinine from pre to post-operative (25%, 26%, and 30%, p for trend 0.03). In contrast, there were no differences in structural AKI across the strata of ACEi/ARB exposure, as assessed by concentrations of four AKI biomarkers (NGAL, KIM-1, IL-18, or L-FABP; p for trend NS for all).

**Conclusions:** Pre-operative ACEi/ARB usage was associated with more functional but not more structural acute kidney injury. As AKI from ACEi/ARB in this setting is unclear, interventional studies testing different strategies of peri-operative ACEi/ARB use are warranted.

*Funding:* NIDDK Support, Other NIH Support - NHLBI

**TH-OR004**

**Using e-Alerts for AKI – Recording Incidence, Measuring Outcomes and Guiding Education** Christopher J. Mulgrew, Allie Wilson, Barbara A. Flower. *Dept of Renal Medicine, Royal Devon and Exeter NHS Foundation Trust, Exeter, United Kingdom.*

**Background:** AKI is common and complicates ~15% of hospital admissions. The UK NCEPOD report 'Adding Insult to Injury' evidenced suboptimal care given to some patients who died with AKI - 20% of AKI post-admission being predictable and avoidable. Accurate data on AKI in our hospital was unknown. Changes to antimicrobial prescribing resulting in a higher usage of gentamicin also led to reports of an increase in AKI. Two audits (one as part of a national audit) were then initiated.

**Methods:** Prospective data on all renal referrals over a six month period was collected, reviewing source of referral, AKI stage, if the AKI occurred pre- or post-admission and potential causes, length of stay and 90-day mortality. An e-alert was also added to our pathology system, generating AKI 'flags' for all cases of AKI, graded according to stage following the KDIGO AKI definition. Monthly reports were run and data analysed by AKI stage, location and clinical speciality.

**Results:** In the prospective audit, most referrals had AKI3 (76.7%), an average of 4 AKI risk factors and ~70% occurring pre-admission. Length of stay was significantly increased, from a hospital average of 5 days, to 14d for AKI3. AKI post-admission increased length of stay further to 22d (AKI3). Overall in-hospital mortality of those referred was around 15%. e-alerts from Aug 2012-Apr 2013 recorded 50-60 cases of AKI3 per month, 50% occurring pre-admission. Overall mortality was 32.3%, usually due to hypotension and/or sepsis. Analysis of AKI1-3 showed up to 500 cases/month, the majority being AKI1. 2/3 of the cases of AKI1 were post-admission, occurring where co-morbidities and sepsis were often seen.

**Conclusions:** AKI increases hospital length of stay and overall morbidity is high. The use of e-alerts increased awareness of the prevalence of AKI in our hospital. We can now target areas where AKI occurs most frequently, using local guidelines and our AKI outreach nurses to increase awareness of AKI amongst junior medical and nursing staff. The impact of these interventions will need to be re-audited but as reported elsewhere (e.g. Selby *et al* in Derby, UK), they can be effective at reducing mortality and cost.

*Funding:* Government Support - Non-U.S.

**TH-OR005**

**Acute Kidney Injury prior to End-Stage Renal Disease Predicts Poor Dialysis Outcomes** Timmy C. Lee,[1,2] Anthony Leonard,[1] Pratik Parikh,[3] Charuhas V. Thakar.[1] *[1]Internal Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Medicine, Univ of Alabama at Birmingham, Birmingham, AL; [3]Biomedical, Industrial and Human Factors Engineering, Wright State Univ, Dayton, OH.*

**Background:** Previous studies have not evaluated the role of pre-end stage renal disease (ESRD) acute kidney injury (AKI) on major clinical outcomes at or after hemodialysis (HD) initiation.

**Methods:** We evaluated 47,327 adult incident hemodialysis patients (age ≥ 18) from the United States Renal Data System (USRDS) who initiated HD from January 1, 2008 to December 31, 2008 and had pre-ESRD Medicare claims during the two calendar years prior to incident HD. Using administrative records, pre-ESRD AKI was assessed as a risk factor for two separate outcomes: type of vascular access [catheter versus arteriovenous (AV) access] at HD initiation and one-year mortality after HD. Both unadjusted risks, and risks adjusted (by logistic regression) for demographic and comorbidity factors were calculated.

**Results:** Mean age at HD initiation was 72 years, 54% were male, 70% were white, and mean BMI was 29. 18% of patients initiated hemodialysis with an AV access (14% with AV fistula) and 82% with a catheter/others. 32% of patients died within 12 months of HD initiation. 53% of total patients had an AKI event, during inpatient stay in the pre-ESRD period. Patients with pre-ESRD AKI event were more likely to initiate HD with catheter compared to those without pre-ESRD AKI event (87% vs 74 %; p<0.0001) and less likely with an AVF (8% vs 20%; p<0.0001); the adjusted risk of starting HD with a catheter was higher in pre-ESRD AKI group [odds ratio (OR) = 2.2, 95% confidence interval (CI) = (2.1, 2.3)] After adjusting for access type and other covariates, pre-ESRD AKI was associated with higher risk of 1-year mortality in HD (OR = 1.6, 95% CI = (1.5, 1.6)).

**Conclusions:** AKI events prior to ESRD predict higher rates of catheter use in HD patients, and higher one year mortality when adjusted for access type. Preventing AKI and improving processes of care after AKI may improve dialysis outcomes. Biological and process-of-care relationships between these events need further analyses.

## TH-OR006

**De Novo Acute Kidney Injury and Subsequent Chronic Kidney Disease: Analysis of a National Sample of Veterans** Michael Heung,[1] Diane Steffick,[1] Tanushree Banerjee,[2] Neil R. Powe,[2] Meda E. Pavkov,[3] Desmond Williams,[3] Vahakn B. Shahinian.[1] *[1]Univ of Michigan, Ann Arbor; [2]Univ of California San Francisco; [3]Centers for Disease Control and Prevention, Atlanta, GA.*

**Background:** Acute kidney injury (AKI) is a risk factor for chronic kidney disease (CKD). We compared the odds of developing CKD within 1 year of discharge in patients with & without in-hospital AKI and also stratified by AKI type.

**Methods:** Patients with 1+ outpatient visit in 2005 and 1+ hospitalizations of >1 day with 2+ inpatient serum creatinine (SCr) tests in 2005-8 were selected from a 5% sample of national Veterans Affairs data. Baseline was the SCr closest to 1 week before admission but <1 year; if not available, then a SCr <7 days before admission or the first inpatient SCr was used. Patients with baseline MDRD-eGFR <60 ml/min/1.73m$^2$ and those who died within 1 year of discharge were excluded. CKD by 1 year was defined as: ICD9 codes, dialysis, transplant, or eGFR closest to 1 year <60. AKI was defined as a 0.3 mg/dL increase in SCr from baseline to peak. Subgroups of AKI were: pre-renal (SCr decrease within 2 days of peak), recovered AKI (last inpatient eGFR >60) or non-recovered AKI (eGFR <60). Logistic models estimated the association of AKI with CKD within 1 yr, after adjusting for age, race, sex, diabetes, and hypertension.

**Results:** Of the 13,563 patients in the sample, 1,937 (14.3%) had CKD by 1 year; 26.3% of those with AKI & 11.5% without AKI. Those with AKI had 2.5 times the odds of having CKD as those without. All AKI subgroups had elevated odds of CKD compared with those without.

Association of Acute Kidney Injury (AKI) with Development of Chronic Kidney Disease Within 1 Year, N=13,563

| | N | Adjusted OR | 95%CI | p-value |
|---|---|---|---|---|
| Model 1: | | | | |
| No acute kidney injury | 11,048 | 1.00 | ref | ref |
| AKI | 2,515 | 2.51 | 2.25-2.80 | <0.001 |
| Model 2: | | | | |
| No acute kidney injury | 11,048 | 1.00 | ref | ref |
| Pre-renal AKI | 1,425 | 2.14 | 1.87-2.46 | <0.001 |
| AKI with hospital recovery | 667 | 1.63 | 1.31-2.01 | <0.001 |
| AKI without hospital recovery | 423 | 6.32 | 5.15-7.76 | <0.001 |

Adjusted for age, race, sex, diabetes and hypertension.

*Chronic kidney disease within 1 year= serum creatinine (SCr) closest to 1 year post-discharge yielding MDRD eGFR<60, diagnosis of CKD by ICD-9-CM codes, maintenance dialysis, or transplant.*
*Acute kidney injury=rise in SCr > 0.3 mg/dL from baseline to peak inpatient level.*
*Pre-renal AKI=AKI with sCr decreasing in hospital to < baseline sCR+0.3 mg/dL within 2 days of peak inpatient level.*
*AKI with hospital recovery=AKI with last inpatient SCr yielding MDRD eGFR > 60 ml/min/1.73m$^2$*
*AKI without hospital recovery=AKI with last inpatient SCr yielding MDRD eGFR < 60 ml/min/1.73m$^2$*

**Conclusions:** De novo AKI is a strong risk factor for CKD. This relation persisted for AKI patients with rapid resolution of kidney function, suggestive of pre-renal AKI, often considered benign, and also for patients who appeared to recover from AKI during that hospitalization.

*Funding:* Other U.S. Government Support

## TH-OR007

**Community-Acquired Acute Kidney Injury: Hospital Admissions and Outcomes** Adil Hazara, Sunil Bhandari. *Hull and East Yorkshire Hospitals NHS Trust, United Kingdom.*

**Background:** Hospital-based emergency services are often the first point of contact for patients who develop Acute Kidney Injury (AKI) in the community. We have reviewed patterns of AKI presentation and their relationship with length of hospital stay, re-admissions and mortality.

**Methods:** Admissions with AKI were identified using a computerized algorithm developed in accordance with Acute Kidney Injury Network (AKIN) criteria. Baseline, admission, peak and final SCr values were reviewed retrospectively along with data relating to patient demographics, reasons for admission and outcomes.

**Results:** 172 patients were identified to have AKI in one month (1.8% of all hospital attendances). Mean age: 72 (range 19–100) years; Males: 76 (44%). Of these, 99 (58%), 50 (29%) and 23 (13%) patients had stage 1, 2 and 3 AKI respectively.

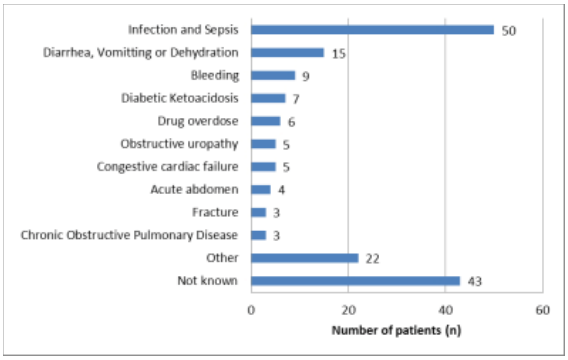

**Fig 1. Reasons for admission in patients with community-acquired AKI**

54 (31%) patients died within 30 days of admission. Mortality in AKI stage 1 (n=99), 2 (n=50) and 3 (n=23) groups was 23%, 42% and 43% respectively. Length of hospital stay also increased with AKI stage. After excluding deceased patients, mean length of stay for all (n=123), stage 1 (n=78), 2 (n=32) and 3 (n=13) patients were 10.2 +/-1.7, 9.1 +/-1.2, 10.7 +/-2.4 and 16.2 +/-5.3 (days +/-standard error) respectively.

AKI resolution (SCr return to 120% of baseline) was in-complete in 60 (49%) cases at the time of discharge. Of these, 21 (35%) were re-admitted or died within 30 days. The relative risk for '30-day re-admission or mortality' was 2.2 (95% confidence intervals 1.1 to 4.3, p=0.02) when compared to those whose AKI resolved.

**Conclusions:** Community-acquired AKI is associated with diverse range of medical presentations. Its severity can be a marker of increased length of hospital stay and mortality. Non-resolution of AKI at the time of discharge significantly increases risk of further re-hospitalization or death.

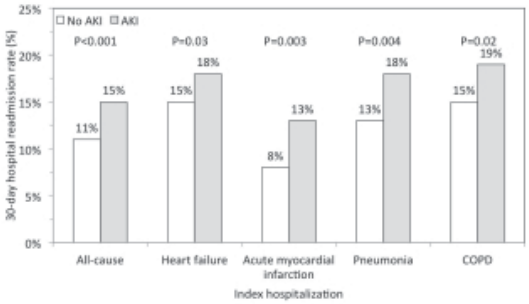
## TH-OR008

**Hospital-Acquired Acute Kidney Injury (AKI) and Early Readmission: A Cohort Study** Ioannis Koulouridis,[1,2] Lori Lyn Price,[3] Nicolaos E. Madias,[1,2] Bertrand L. Jaber.[1,2] *[1]Dept of Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Dept of Medicine, Tufts Univ School of Medicine, Boston, MA; [3]Clinical Research and Health Policy Studies, Tufts Medical Center & Tufts CTSI, Tufts Univ, Boston, MA.*

**Background:** AKI is associated with increased mortality and resource consumption. We examined whether survivors of hospital-acquired AKI are at an increased risk for early hospital readmission.

**Methods:** This was a single-center retrospective cohort study of 22,001 adults hospitalized for the first time (index) at an acute care facility and discharged alive. The nadir-to-peak serum creatinine difference during the index hospitalization was used to define AKI according to the AKI network criteria. Multivariable logistic regression analyses examined the association of AKI with 30-, 60-, and 90-day hospital readmission adjusting for age, sex, race, Charlson-Deyo comorbidity index, acute hospital-related factors, and baseline eGFR.

**Results:** The incidence of AKI was 15.2%. The 30-day hospital readmission rate was higher among patients with AKI for all-cause and condition-specific index hospitalizations (Figure).



Survivors of AKI episodes had 1.21 higher adjusted odds for 30-day hospital readmission (95% CI 1.08, 1.36), which persisted at 60 (OR 1.15; 95% CI 1.03, 1.27) and 90 (OR 1.13; 95% CI 1.02, 1.25) days. AKI was associated with higher odds for 30-day hospital readmission in patients originally hospitalized on medical services (OR 1.29; 95% CI 1.14, 1.46), younger patients (OR 1.54; 95% CI 1.26, 1.89), those with fewer comorbidities (OR 1.34; 95% CI 1.16, 1.56), and higher baseline eGFR (OR 1.20; 95% CI 1.04, 1.39).

**Conclusions:** Survivors of hospital-acquired AKI experience a higher risk of early hospital readmission. Transitions of care services may be warranted for such patients to prevent readmissions and reduce healthcare costs.

**TH-OR009**

**Acute Kidney Injury (AKI) Epidemiology in Very Low Birth Weight (VLBW) Infants** Neha Patil, Rajesh Koralkar, Susan Keeling, Namasivayam Ambalavanan, David J. Askenazi. *Pediatrics, Univ of Alabama at Birmingham, Birmingham, AL.*

**Background:** AKI is associated with mortality in neonatal and pediatric critically ill populations, but the true incidence, risk factors and outcomes in VLBW are yet fully known.

**Objective:** To determine incidence, risk factors and outcome of development of AKI in first two weeks of life in VLBW Infants.

**Methods:** Between Feb 2012 to Feb 2013, 91 VLBW Infants (birth weight <=1200 gm. or gestational age <31 weeks) were prospectively followed. Serum creatinine (SCr) values collected on days 1,2,3,4,and 14; and combined with clinically measured SCr were used to determine AKI status according to KDIGO. Stage 1 AKI was defined as SCr ≥ 0.3 mg/dl or ≥ 150-200% from lowest previous value. Stage 2: SCr > 200-300% from previous value and Stage 3 AKI: SCr > 2.5 mg/dl or SCr > 300% from previous value. Bronchopulmonary dysplasia (BPD) was defined if an infant was oxygen dependent at 28 days. Those who were alive at 36 weeks post-conception or discharged home were deemed survivors.

**Results:** Cumulative incidence of AKI over first two weeks of life was (27/87) 31%. Differences in infant and maternal demographics and co-morbidities and outcomes between AKI and No AKI showed that female, white race, lower gestational age, lower 5 minute Apgar and UAC were risk factors for AKI (p value <0.05), while pre-eclampsia was inversely associated with AKI (p value <0.001). AKI group had higher BPD, trend towards longer hospital stay, and lower survival.

| Cumulative Incidence of AKI by day of life | | | |
|---|---|---|---|
| **AKI Stage** | **Day 3** | **Day 7** | **Day 15** |
| **AKI 1** | 14 (16%) | 21 (24%) | 22 (25%) |
| **AKI 2** | 1 (1%) | 1 (1%) | 2 (2%) |
| **AKI 3** | 1 (1%) | 2 (2%) | 3 (4%) |
| **AKI Incidence** | 16 (18%) | 24 (27%) | 27 (31%) |
| **No AKI** | 75 (82%) | 65 (73%) | 60 (69%) |
| | | | |
| **Outcome for those with and without AKI at day 15** | | | |
| **Outcome** | **No AKI (N=60)** | **AKI (N=27)** | **P value** |
| **BPD** | 21 (37%) | 17 (71%) | 0.005 |
| **Survivor** | 58 (97%) | 22 (81%) | 0.01 |
| **Length of stay (days)** | 77 (15-232) | 92 (6-209) | 0.2 |

**Conclusions:** AKI is common in VLBW infants. Development of AKI in first two weeks of life can result in higher incidence of BPD and lower survival.

**TH-OR010**

**The Daily Burden of Acute Kidney Injury: A World Kidney Day Survey of U.S. Nephrologists** Jay L. Koyner,[1] Jorge Cerda,[1] Stuart Goldstein,[1] Bertrand L. Jaber,[1] Kathleen D. Liu,[1] Judy A. Shea,[2] Sarah Faubel.[1] *[1]AKI Advisory Group of the American Society of Nephrology; [2]General Internal Medicine, Univ of Pennsylvania.*

**Background:** This year, World Kidney Day (WKD, March 14, 2013) focused on raising awareness of the short- and long- term consequences of AKI.

**Methods:** To estimate the extent of in-hospital and outpatient nephrology effort devoted to the care of patients with AKI, we conducted an internet-based survey of all (n=4957) US-based ASN physician members, on WKD.

**Results:** We received survey responses from 598 nephrologists (12% response rate). 49% worked in a teaching hospital with a median of 398 beds. Nephrologists were asked about patients seen on WKD. Respondents saw a median (25th, 75th percentile) of 12 (5, 18) patients in the hospital compared to 8 (5, 12) patients seen in clinic. A median of 4 (1, 6) patients seen in the hospital had pre-existing ESRD while 5 (2, 8) patients had AKI (p=0.002). In total, most patients seen in the hospital had AKI, comprising 46% (n=1500) of the sample, followed by ESRD (38%; n=1233). Among patients seen in the hospital for AKI, a median of 2 (1, 3) were critically ill, and 1 (0, 2) required renal replacement therapy (RRT). The delivered dose of intermittent hemodialysis was measured in only 17%. Among patients seen in clinic, a median of 1 (0, 1) patient was seen for follow-up of in-hospital AKI; 55% reported that in the prior year, <10% of patients seen in clinic were for follow-up of in-hospital AKI.

**Conclusions:** AKI is the most common in-hospital diagnosis seen by US nephrologists. Patients with AKI are often critically ill and receive RRT. However, the delivered dose of intermittent hemodialysis is infrequently measured, and survivors of in-hospital AKI do not comprise a large part of outpatient clinic encounters, and might be lost to nephrology follow-up. These findings call for continued efforts to promote excellence in the delivery of RRT to patients with AKI, and reliable transition of care services following hospital discharge from an AKI episode.

**TH-OR011**

**Id Proteins Regulate Capillary Repair and Perivascular Cell Proliferation following Ischemia-Reperfusion Injury** Matthew D. Plotkin, David H. Lee, Shantheri S. Shenoy, Yezina T. Nigatu. *Medicine, New York Medical College, Valhalla, NY.*

**Background:** Acute kidney injury (AKI) results in microvascular damage that may lead to fibrosis. The Id1 and 3 proteins promote angiogenesis during development and tumor growth by functioning as dominant negative regulators of bHLH transcription factors. The goal of this study was to determine if Id proteins regulate microvascular repair and if increased Id1 expression reduces capillary loss following AKI.

**Methods:** The effect of changes in Id expression *in vivo* on microvascular repair following ischemia-reperfusion injury (IRI) was examined using Id1 -/-, Id3RFP/+ (Id1/3 KO) and Tek (Tie2)-rtTA, TRE-lacz/TRE Id1 (TRE Id1) mice with doxycycline inducible endothelial Id1 and β-galactosidase expression.

**Results:** Id1 and 3 were co-localized in endothelial cells in adult kidneys and protein levels were increased at day 3 following IRI. In comparison with WT littermates, Id1/3 KO mice had decreased baseline capillary density and pericyte coverage and increased tubular damage following IRI but no fibrosis. TRE Id1 mice had no capillary rarefaction and dilated medullary peritubular capillaries. Following IRI, X-gal positive interstitial cells were located in areas of collagen deposition in doxycycline treated TRE Id1/ TRE-lacz mice while positive cells from doxycycline treated single transgenic TRE-lacz mice were confined to capillary lumens. TRE Id1 mice had increased proliferation of Id1/PDGFRβ positive interstitial cells and medullary collagen deposition. These differences were associated with increased Angiopoietin 1 (Ang1) and decreased Ang2 expression in TRE Id1 mice. Examination of gene expression in microvascular cells isolated from WT, Id1/3 KO and TRE Id1 mice showed increased Ang1 and αSMA in Id1 overexpressing cells and decreased endothelial and pericyte markers in cells from KO mice.

**Conclusions:** Transgenic endothelial Id1 expression resulted in reduced capillary rarefaction and increased perivascular fibroblast proliferation and matrix deposition following IRI. Id1 was expressed in perivascular cells in areas of fibrosis and was associated with increased Ang1 levels, suggesting a role in abnormal microvascular remodeling following injury.

**Differentiated Kidney Epithelial Cells Repair Injured Proximal Tubule without Evidence for Intratubular Progenitors** Tetsuro Kusaba, Matthew A. Lalli, Akio Kobayashi, Benjamin D. Humphreys. *Renal Div, Brigham and Women's Hospital, Boston, MA.*

**Background:** Whether kidney proximal tubule harbors a scattered progenitor population is a major unsolved question. Lineage-tracing studies, histologic characterization and ex vivo functional analysis results conflict.

**Methods:** To address this controversy, we analyzed the lineage and clonal behavior of terminally differentiated proximal tubule epithelial cells after injury. We knocked in a Cre-ERt2 cassette into the sodium-dependent inorganic phosphate transporter SLC34a1 locus, which is expressed only in fully differentiated proximal tubule.

**Results:** After crossing this new CreERt2 line to a reporter (R26Tomato), we validated that tamoxifen-dependent recombination was absolutely specific to proximal tubule. In vivo clonal analysis after injury and repair showed that the bulk of labeled cells proliferate after injury with increased clonal expansion after severe compared to moderate injury. For example, clone size-frequency analysis before and after injury revealed that the fraction of clones 5 cells or larger increased from 0 before injury to 24.1 +/- 8.5 % after injury,avg +/- SE, $p < 0.01$. Single labeled proximal tubule cells not only expressed injury (KIM-1) and proliferation (Ki67) markers but also transiently expressed vimentin and Pax-2, markers thought to identify intratubular epithelial progenitors in other species. This finding was recapitulated by ex vivo proximal tubule culture. After complete labeling of proximal tubule followed by injury and repair, there was no dilution of the fate marker despite substantial proliferation, strongly arguing against an undifferentiated intratubular progenitor. When single proximal tubular cells were labeled at e14.5, clone size expanded by P14, suggesting a similar mechanism of tubule elongation during growth as in adult repair.

**Conclusions:** These findings provide no evidence for a scattered intratubular progenitor population in mouse proximal tubule epithelia but indicate that fully differentiated epithelia re-express apparent progenitor markers during injury-induced dedifferentiation and repair.

**TH-OR013**

**Exploring the Origin and Limitation of Kidney Regeneration** Motoko Yanagita,[1] Tomomi Endo,[1] Tomohiko Okuda,[1] Jin Nakamura,[1] Misako Asada,[1] Masayuki Takase,[1] Ryo Yamada,[1] Sato Yuki,[1] Koji Takaori,[1] Akiko Oguchi,[1] Taku Iguchi,[1] Eri Muso.[2] *[1]Nephrology, Kyoto Univ, Japan; [2]Nephrology, Kitano Hospital, Osaka, Japan.*

**Background:** Recent epidemiological data indicates that acute kidney injury (AKI) increases the risk for chronic kidney disease (CKD), however the molecular mechanism remains unknown.

Genetic fate mapping experiments recently demonstrated that kidney tubular epithelial cells are repaired by surviving nephrons after AKI. However, the cell population in the nephron that repairs damaged kidneys has not been identified. It is also unknown whether there are repair capacity limitations in the kidney.

**Methods:** To answer these questions, we generated new transgenic mouse strain (*NDRG1*$^{CreERT2/+}$ mice) in which more than 90 % of mature proximal tubule, the segment mostly damaged during AKI, can be genetically labeled at desired time points by the administration of tamoxifen.

**Results:** Genetic fate mapping using this mouse strain showed the massive proliferation of mature proximal tubule cells during repair, with no dilution of genetic label being observed in the proximal tubules even after repeated repair processes. These results indicated that proximal tubules repair themselves by their own proliferation. We further demonstrated that repeated kidney injuries lead to significant shortening of the proximal tubules, renal atrophy and renal dysfunction, and clarified the limitations in the kidney's capacity to repair.

**Conclusions:** Our current findings demonstrate for the first time that repeated AKI leads to the shortening of proximal tubules, renal atrophy and renal dysfunction, and clarify the limited regenerative capacity of mature proximal tubule cells. These results indicate that

repaired kidney is, although similar, non-identical to healthy kidney, and these findings might explain, at least in part, why reversible episodes of AKI leads to the progression of CKD.

**KIM-1-Mediated Phagocytosis Induces Autophagy and MHC Antigen Presentation in Epithelial Cells** Craig R. Brooks,[1] Hui Chen,[2] Joel M. Henderson,[2] Takaharu Ichimura,[1] Joseph V. Bonventre.[1] *[1]Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Dept of Pathology, Boston Univ, Boston, MA.*

**Background:** Phagocytosis of apoptotic cells (AC) by both professional and semi-professional phagocytes is required for resolution of organ damage and maintenance of immune tolerance. KIM-1 is the most up-regulated proximal tubule protein following kidney injury. KIM-1 is a phosphatidylserine receptor which transforms renal proximal tubule epithelial cells (PTC) into phagocytes. Here, we describe that KIM-1-mediated phagocytosis induces autophagy and antigen presentation on MHC in PTCs.

**Methods:** LLC-PK1 cells and primary PTCs expressing KIM-1 or phagocytosis-deficient KIM-1 mutants were exposed to AC. LC3 localization to the phagosome was measured by live cell imaging, phagosome isolation and western blotting. Activation of ULK1 and other autophagy proteins was also measured by immunoblots. MHC presentation in primary PTCs was measured by flow cytometry and activation of CD4+ and CD8+ T cells.

**Results:** Following uptake of AC, KIM-1 phagosomes localized to LC3-positive autophagosomes. The presence of KIM-1 phagosomes within double membrane bound autophagosomes was confirmed by electron microscopy. KIM-1-mediated phagocytosis induced activation of the essential autophagy protein ULK1. Autophagy induction was necessary for degradation of phagocytosed AC. Primary cultured PTCs expressing KIM-1 were found to have a high level of basal autophagy as measured by LC3 punctae formation and LC3 II formation. LC3 II formation was reduced in PTCs derived from mice expressing phagocytosis-deficient mutant KIM-1 and in primary PTCs from wild-type mice treated with shRNA to knockdown KIM-1 expresssion. Antigens phagocytosed by KIM-1 were processed and presented on MHC II and cross-presented on MHC I. Incubation of OVA liposomes with PTCs resulted in activation of OVA-reactive CD4+ and CD8+ T cells, which was inhibited by KIM-1 shRNA and/or autophagy inhibition.

**Conclusions:** These data reveal a novel mechanism linking a specific epithelial cell receptor (KIM-1) to phagocytosis, autophagy, antigen presentation and regulation of the inflammatory response.

**TH-OR015**

**KIM-1 Interacts with Gα12 and Suppresses Its Activity to Mediate Efferocytosis** Ola Ziyad Ismail, Xizhong Zhang, Lakshman Gunaratnam. *Western Univ, London, Canada.*

**Background:** The phagocytic clearance of apoptotic cells (efferocytosis) serves to attenuate inflammation and enable tissue repair following injury. Kidney injury molecule-1 (KIM-1) is a type I transmembrane protein that is upregulated on renal proximal tubular epithelial cells (PTECs) following acute kidney injury (AKI). It is a phagocytic receptor that specifically recognizes phosphatidylserine (PS), an "eat me" signal, displayed on the surface of apoptotic cells. The signalling mechanism by which KIM-1 converts PTECs into non-professional phagocytes is not known.

Previously we identified Gα12 as a novel KIM-1-interacting protein in PTECs using co-immunoprecipitation and mass spectrometry. Gα12 belongs to the G12 family of heterotrimeric G proteins that regulates multiple cellular responses, including proliferation, apoptosis, permeability and actin cytoskeleton reorganization. We hypothesized that KIM-1 interacts with Gα12 to mediate efferocytosis.

**Methods:** To test our hypothesis, we used porcine (LLC-PK1) PTECs overexpressing HA-tagged human KIM-1, and human embryonic kidney (HEK293) cells expressing high levels of endogenous Gα12 and overexpressing GFP-tagged human KIM-1.

**Results:** First, we established that Gα12 interacts with the cytosolic domain of KIM-1 via co-immunoprecipitation and GST-Gα12 pull-down assays. Using confocal microscopy, we observed the co-localization of KIM-1 with GFP-tagged Gα12 in PTECs. Next, using an active Gα12 (GST-TPR) pull-down assay, we determined that Gα12 activity (GTP-binding) is significantly reduced in PTECs upon exposure to apoptotic cells. To determine the impact of Gα12 activity on KIM-1-mediated efferocytosis, we overexpressed a constitutively active mutant of Gα12 in KIM-1-expressing PTECs and found a significant decrease in their phagocytic efficiency. Conversely, we found an increase in the uptake of apoptotic cells when Gα12 expression was silenced using siRNA in HEK293 cells stably expressing KIM-1. Finally, we observed that KIM-1 inhibited Gα12 activation in HEK293 cells loaded with non-hydrolyzable GTP in the absence of apoptotic cells.

**Conclusions:** Taken together, our experiments suggest that KIM-1 interacts with and inhibits Gα12 activation in PTECs to mediate efferocytosis.

**Elucidating the Mechanisms of Therapeutic Augmentation of Kidney Repair after Acute Kidney Injury** Lauren Brilli,[1] Takuto Chiba,[3] Nataliya Skrypnyk,[4] Lee McDermott,[2] Mark P. De Caestecker,[3,4] Neil A. Hukriede.[1] *[1]Developmental Biology, Univ of Pittsburgh, Pittsburgh, PA; [2]Pharmaceutical Sciences, Univ of Pittsburgh, Pittsburgh, PA; [3]Cell and Developmental Biology, Vanderbilt Univ Medical Center, Nashville, TN; [4]Medicine, Vanderbilt Univ Medical Center, Nashville, TN.*

**Background:** Acute kidney injury (AKI) is a serious disorder for which there is no targeted clinical treatment. A promising approach to improve treatment options lies in developing novel post-AKI therapies that enhance innate renal regenerative processes. Our lab has used zebrafish to identify small molecules that enhance renal tubular epithelial cell (RTEC) regeneration after AKI. Using this approach we identified methyl-4-phenylthiobutanoate (m4PTB), an HDAC inhibitor that promotes renal progenitor expansion in zebrafish embryos and accelerates recovery after AKI in zebrafish and mice. The ability of m4PTB to expand the renal progenitor cell population in zebrafish embryos depends on intact retinoic acid (RA) signaling, but the mechanisms underlying how m4PTB accelerates recovery after AKI are unknown.

**Methods:** We utilize a nephrotoxic model of gentamicin-induced AKI in zebrafish larvae that demonstrates the same hallmarks of renal injury and regeneration post-AKI as the mammalian kidney. *Tg(12XRARE:GFP)* transgenic larvae are used to assess RA signaling, and heat shock is used to induce expression of a dominant negative RA receptor (RAR) in *Tg(hsp70:dnRARa)* larvae.

**Results:** Live imaging of *Tg(12XRARE:GFP)* larvae post-AKI shows that m4PTB stimulates RA signaling in the larval zebrafish kidney RTECs. m4PTB also increases expression of the RA pathway components *Aldh1a2* and *Ret* by qRT-PCR in a mouse model of ischemia reperfusion AKI. Finally, we show that reducing RA signaling by heat shock in *Tg(hsp70:dnRARa)* larvae abrogates m4PTB-stimulated RTEC proliferation and impairs larval survival post AKI.

**Conclusions:** These studies indicate that m4PTB activates RA signaling and that m4PTB-dependent renal regeneration requires intact RA signaling post-AKI. This work suggests that m4PTB action is mediated by activating RA-dependent regenerative responses after AKI. Funding support: R01 DK069403, RC4 DK090770.

**Retinoic Acid Signaling Promotes Epithelial Cell Repair after Acute Kidney Injury** Takuto Chiba,[1] Lauren Brilli,[2] Nataliya Skrypnyk,[1] Neil A. Hukriede,[2] Mark P. De Caestecker.[1] *[1]Medicine, Vanderbilt Univ, Nashville, TN; [2]Developmental Biology, Univ of Pittsburgh, Pittsburgh, PA.*

**Background:** Restoration of tubular integrity is essential for functional recovery and reduction in post injury fibrosis after acute kidney injury (AKI). However the mechanisms promoting tubular epithelial cell (TEC) repair are poorly understood. We have used zebrafish and mouse model systems to explore the regulation and role of retinoic acid (RA) signaling in mediating regenerative TEC repair after AKI.

**Methods:** We used gentamicin-induced AKI in zebrafish larvae, and ischemia reperfusion AKI (IR-AKI) in mice; QRT-PCR to quantify RA target mRNAs in mouse kidneys, as well as mouse and zebrafish transgenic RA reporter lines to assess localization and kinetics of RA signaling post AKI. We also used heat shock to induce dominant negative RA receptor (DN RAR) expression in Tg(hsp70:dnRARa) larvae, and the RA antagonist BMS493 and agonist all-trans RA (ATRA) in mice.

**Results:** RA signaling is activated in de-differentiated, regenerating proximal TECs (PTEC) in the mouse and larval zebrafish kidneys post AKI. Inhibition of RA in zebrafish larvae and mice impairs functional recovery post AKI. In mice this is associated with a marked reduction in PTEC proliferation and increased post injury fibrosis. In addition, treatment with ATRA enhances recovery when administered 24 hours after injury in mouse IR-AKI, and enhances activation of RA reporters in zebrafish and mouse kidneys.

**Conclusions:** These studies show that RA signaling is activated in PTECs post AKI, and inhibition of RA impairs recovery and inhibits PTEC repair. Since high levels of RA signaling during kidney development are repressed postnatally, our findings suggest a novel molecular mechanism whereby reactivation of a conserved embryonic signaling pathway drives regenerative repair post AKI. Our data also indicate that RA agonists can be given post injury to enhance this intrinsic repair mechanism after AKI.

**TH-OR018**

**Extracellular Adenosine Controls the Kidney Microenvironment and Regulates Acute and Chronic Kidney Injury** Li Li,[1] Liping Huang,[1] Hong Ye,[1] Diane L. Rosin,[2] Mark D. Okusa.[1] *[1]Div of Nephrology, CIIR, Univ of Virginia, Charlottesville, VA; [2]Dept of Pharmacology, Univ of Virginia, Charlottesville, VA.*

**Background:** CD73, or ecto-5'-nucleotidase, is critical for generation of extracellular adenosine, which increases during organ ischemia/reperfusion injury (IRI).We hypothesized that regulation of the kidney adenosine microenvironment by CD73 could play a role in shaping both acute and chronic kidney injury.

**Methods:** To investigate kidney IRI inflammation, both (or one) kidney pedicles were clamped for 26 (or 28) min and then released for 24 hr.

**Results:** Acute kidney injury (AKI) after IR was the same in CD73$^{-/-}$ and WT (B6) mice (plasma creatinine, PCr; P>0.05). Because discrete tissue localization of CD73 may be important in regulating the adenosine microenvironment, we deleted CD73 on proximal tubule cells by generating PEPCK-CreCD73$^{fl/fl}$ mice and these mice had higher PCr than PEPCK-Cre controls (P<0.05) after IRI. Interestingly, conditional knockout of CD73 on CD11c+ dendritic cells (DCs) (CD11c-CreCD73$^{fl/fl}$) also resulted in more kidney inflammation compared with CD11c-Cre mice following IRI (P<0.05). These studies indicate that the expression of CD73 on hematopoietic and kidney epithelial cells is important for AKI.

Locally produced adenosine may activate its receptors. Our previous studies using CD11c-CreAdora2a$^{fl/fl}$ mice showed that activation of adenosine 2A receptors (A2aR) on DCs has a critical role in suppressing the immune response in kidney IRI . In this study to further investigate the downstream effects of CD73 in chronic kidney injury, we examined and demonstrated that CD11c-CreAdora2a$^{fl/fl}$ mice also have more kidney fibrosis with higher PCr (P<0.01; as revealed by contralateral nephrectomy on day 14) compared with CD11c-Cre mice 15 d after unilateral IRI.

**Conclusions:** Our studies reveal that hematopoietic and renal CD73 promote the production of adenosine that is important for AKI, and activation of A2aRs on DCs attenuate kidney IRI and fibrosis. Activation of CD73 or A2aR provides novel therapeutic targets for the disease.

## TH-OR019

### Sustained EGFR Activation Mediates Postischemic Acute Kidney Injury Progression to Chronic Kidney Disease

Shougang Zhuang. *Dept of Medicine, Rhode Island Hospital, Alpert Medical School of Brown Univ, Providence, RI.*

**Background:** Acute kidney injury (AKI) is frequently accompanied by maladaptive repair and renal fibrogenesis, however, the molecular mechanisms that mediate progression from acute kidney injury to chronic kidney disease remain poorly understood.

**Methods:** Here we examined the role of epidermal growth factor receptor (EGFR) in this process using waved-2 (Wa-2) mice, which have reduced EGFR activity, and their wild type (WT) littermates after renal ischemia.

**Results:** Renal EGFR phosphorylation was induced within 2 days after ischemia, increased over time, and remained elevated at 28 days in WT mice, but this was diminished in Wa-2 mice. At the early stage of post-ischemia (2 days), Wa-2 mice developed more severe acute renal tubular damage with less reparative responses as indicated by enhanced tubular cell apoptosis, and reduced dedifferentiation and proliferation as compared to WT animals. At the late stage of postischemia (28 days), Wa-2 mice exhibited less severe renal interstitial fibrosis as shown by reduced activation/proliferation of renal myofibroblasts and decreased deposition of extracellular matrix proteins. EGFR activation also contributed to cell cycle arrested at G2/M phase, a cellular event associated with production of profibrogenetic factors, in the injured kidney. Collectively, these results indicate that severe ischemic AKI results in sustained activation of EGFR, which is required for progression of AKI to CKD.

**Conclusions:** Thus, blockade of EGFR holds a novel therapeutic potential for attenuating or halting initiation/progression of CKD following ischemia/reperfusion injury.

## TH-OR020

### The Role of M2 Macrophage in the Progression of Chronic Kidney Disease following Acute Kidney Injury

Myung-Gyu Kim, Sang-Kyung Jo, Won-Yong Cho, Hyoung-Kyu Kim. *Dept of Internal Medicine, Korea Univ Anam Hospital, Seoul, Republic of Korea.*

**Background:** Acute kidney injury (AKI) is a major risk factor for progression of chronic kidney disease (CKD). However, the mechanism that link AKI to CKD remains unclear. Recently, macrophages were shown to shift their phenotype from M1 to M2 and these M2 macrophages facilitate recovery. In this study, we examined the alteration of macrophage phenotype during the extended period of recovery phase following ischemia/reperfusion injury (IRI) and tried to verify their roles in the development of renal fibrosis in a mouse model of I/R-CKD.

**Methods:** Renal pedicle was clamped unilaterally for 40 minutes and on day 7, 14 and 28 after IRI, phenotype of monocyte/macrophage, cytokine expression, renal fibrosis were assessed. To determine the role of monocyte/macrophage subset in renal fibrosis, liposome clodronate (LC) was injected or CD11c-DTR transgenic mice were used. Depletion was initiated on day 3 following IRI.

**Results:** Throughout the recovery phase of IRI, mRNA expression of M2 marker (Arginase-1) in kidney was markedly increased compared to M1 marker (iNOS). Flow cytometric analysis also revealed the predominant macrophage subset was F4/80$^{+}$CD206$^{+}$ M2-phenotype macrophages but not F4/80$^{+}$CD206$^{-}$ M1-phenotype macrophages during the recovery phase. On day 28 after IRI, renal fibrosis was clearly shown with increased type IV collagen and TGF-ß. Injection of LC resulted in preferential depletion of M2 macrophages and it was associated with significant reduction of kidney IL-6, type IV collagen, TGF-ß and ultimately improved renal fibrosis. Additionally, we found that TGF-ß were about 2.5 fold highly expressed in M2 macrophages than M1 macrophages, suggesting the important contribution of M2 macrophage in the development of renal fibrosis. On the other hand, injection of diphtheria toxin to CD11c-DTR transgenic mice resulted in depletion of CD11c-high cells with relatively preserving M2 macrophages and had minimal impact on renal fibrosis as well as tissue level of cytokines.

**Conclusions:** Although known to be important in facilitating recovery, M2 macrophages are thought to be main culprit in the development of renal fibrosis following IRI.

## TH-OR021

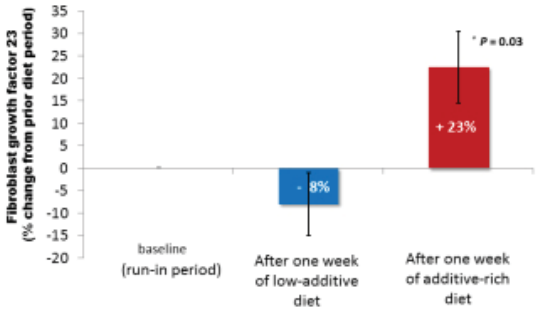
### Impact of Phosphorus-Based Food Additives on Bone and Mineral Metabolism in Healthy Volunteers

Orlando M. Gutierrez,[1] George R. Beck.[2] *[1]UAB; [2]Emory.*

**Background:** Phosphorus-based food additives substantially increase phosphorus intake in westernized diets. Few studies examined the impact of these additives on bone and mineral metabolism in humans.

**Methods:** 10 healthy volunteers participated in the study. Subjects needed to be 19-45 years old. Exclusion criteria included kidney disease, BMI ≥30 kg/m$^2$, or intake of medications known to affect phosphorus metabolism. After a two-week run-in period during which baseline biochemical data were obtained, subjects were fed standardized diets prepared by the metabolic kitchen over the following 2 weeks. During the 1st week, they were fed a diet designed to provide ~2,000 kcal and 900 mg of phosphorus (Pi) per day using foods known to be free of Pi additives. During the 2nd week, they consumed a diet containing the same food items as the low-additive diet only the foods contained Pi additives. Blood and urine specimens were collected at regular intervals throughout the intervention period.

**Results:** The mean age of subjects was 32±8 years old, 30% were male, and 70% black. The measured Pi content of the high-additive diet was ~617 mg higher than the low-additive diet, and the measured sodium content was ~1.3 grams higher; there were no other differences in the measured content of the two diets. There were no statistically significant changes in serum Pi, calcium, PTH, CTX, or P1NP during the dietary intervention period. FGF23 concentrations declined after one week of the low-additive diet, then significantly increased after 1 week of the high-additive diet (Figure).



Further, osteopontin levels significantly increased and sclerostin levels significantly decreased after one week of the high-additive diet.

**Conclusions:** One week of eating a diet rich in Pi additives significantly increased FGF23 and osteopontin concentrations, and significantly decreased sclerostin concentrations in healthy volunteers.

## TH-OR022

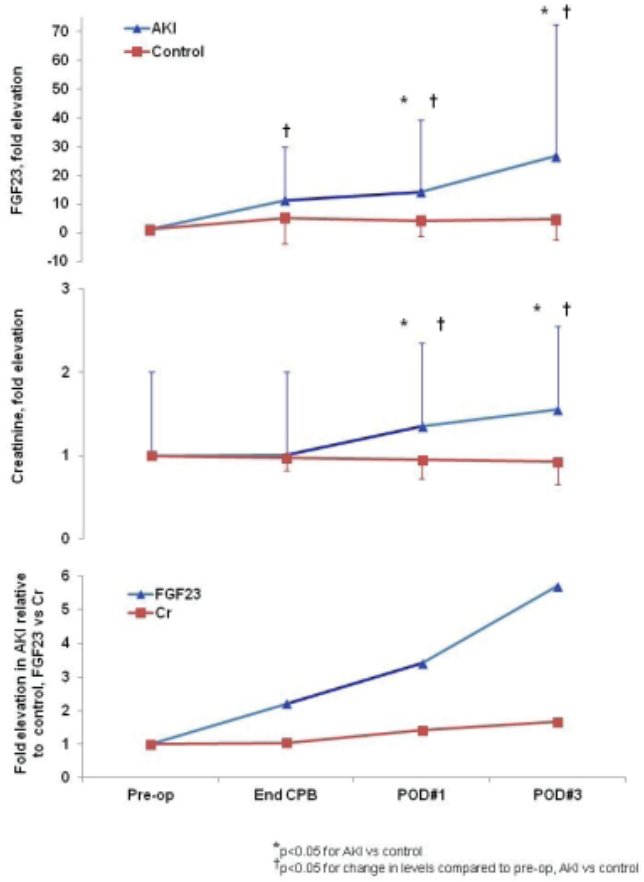
### Fibroblast Growth Factor 23 Rises Early in Acute Kidney Injury after Cardiac Surgery and Predicts Adverse Outcomes

David E. Leaf,[1] Marta Christov,[2] Harald Jüppner,[2] Myles S. Wolf,[3] Sushrut S. Waikar.[1] *[1]Brigham and Women's Hospital; [2]Massachusetts General Hospital; [3]Univ of Miami Miller School of Medicine.*

**Background:** FGF23 levels increase as CKD progresses and are strongly associated with increased mortality in both CKD and ESRD. The kinetics and prognostic value of FGF23 among patients with acute kidney injury (AKI), however, have not been well characterized. We hypothesized that FGF23 rises early in AKI and is associated with the composite outcome of hospital mortality or need for renal replacement therapy (death/RRT).

**Methods:** We performed a nested case-control study of 100 participants with and without AKI after cardiac surgery (N=50 in each group). Controls were matched based on age and eGFR. Plasma FGF23 and creatinine levels were measured at four timepoints: pre-op, end of cardiopulmonary bypass, and postoperative days 1 and 3. Logistic regression was used to assess the association between FGF23 area under the curve (AUC), calculated by the trapezoid method, and death/RRT among AKI cases. Secondary outcomes included post-op sepsis and post-op vasopressor requirement beyond 24 hours.

**Results:** FGF23 levels were significantly higher among cases than controls (figure1).



Among cases, FGF23 levels rose early in the course of AKI, becoming significantly elevated (11.3-fold) by the second timepoint (end of cardiopulmonary bypass). FGF23 AUC was significantly associated with death/RRT [OR 1.82, 95% CI 1.10-3.00, p=0.02] and remained significant after adjustment for baseline eGFR. FGF23 AUC was also significantly associated with post-op sepsis and post-op vasopressor requirement.

**Conclusions:** FGF23 levels are elevated in AKI after cardiac surgery, rise early in the course of AKI, and are associated with greater risk of death/RRT. Additional work is needed to determine potential mechanisms underlying these findings.

## TH-OR023

### Cinacalcet Decreases FGF23 Levels in Prevalent Dialysis Patients Compared to Placebo

Sharon M. Moe,[1] On Behalf of EVOLVE Investigators.
[1]*Indiana Univ, Indpls, IN.*

**Background:** Fibroblast Growth Factor 23 (FGF23) levels are associated with increased mortality in ESRD patients and FGF23 is a direct cardiac toxin in rodents. FGF23 is a phosphaturic hormone that is stimulated by 1,25(OH)2 vitamin D, parathyroid hormone (PTH), and elevated phosphorus (Pi), and inhibited by calcium (Ca). We hypothesized that treatment of hemodialysis patients with cinacalcet (which lowers PTH, calcium and phosphorus) would lower FGF23.

**Methods:** To test this hypothesis, we analyzed FGF23 in serum samples from 200 subjects in the EVOLVE trial (NEJM 2013). Subjects in the trial were randomized to treatment with cinacalcet or placebo, on a background of standard of care with calcitriol or its analogs and phosphate binders. In this study, 100 subjects in each arm were randomly selected from all subjects with baseline and week 20 blood samples and FGF23 was measured using a Millipore intact FGF23 assay.

**Results:** The demographics and baseline laboratory values in this cohort were reflective of the larger study: median age of 53 yrs; dialysis vintage median of 43.2 months (range 7.3 to 159); 37.5% female, 94% with cardiovascular disease; 61.5% receiving vitamin D sterols and 87% on phosphate binders. The baseline median PTH was 648 pg/ml (369-1602 p10, p90), Ca 9.8 mg/dl (9.1, 10.6), Pi 6.2 mg/dl (4.9, 8.2). The mean± SD baseline FGF23 levels were 8469 ± 9549 pg/ml in the cinacalcet patients and 8029 ± 8043 pg/ml in the placebo patients and was significantly greater in men and those patients with higher Pi or Ca (Odds ratio 4.55, 5.28, 7.28 respectively). After 20 weeks, FGF23 levels decreased by 25 ± 76% (mean ± SD) in the cinacalcet treated patients but increased by 31 ± 120% in the placebo treated patients ($p < 0.001$). These changes were similar in patients on or off vitamin D. The change in FGF23 was not related to PTH but correlated with change in Ca ($r = 0.34$) and Pi ($r = 0.33$, both $p < 0.001$).

**Conclusions:** In a secondary analysis of the EVOLVE study, patients treated with cinacalcet compared to placebo had significant lowering of FGF23. An analysis of whether the lowering of FGF23 leads to improved outcomes is ongoing.

## TH-OR024

### No Decrease in Albuminuria with Cholecalciferol in a Randomized Placebo Controlled Trial in Older Patients with Heart Failure

Amanda Gomes,[1] Brian Schmotzer,[3] Lavinia A. Negrea,[1] Rebecca S. Boxer.[2] [1]*Nephrology and Hypertension, Univ Hospitals Case Medical Center, Cleveland, OH;* [2]*Cardiovascular Medicine, Univ Hospitals Case Medical Center, Cleveland, OH;* [3]*Center for Clinical Investigaion, Case Western Reserve Univ, Cleveland, OH.*

**Background:** Proteinuria is an established risk factor for cardiovascular morbidity and mortality and adverse renal outcomes. Both microalbuminuria and macroalbuminuria are prevalent in heart failure. The mainstay for treatment of proteinuria is inhibition of the renin-angiotensin system. In vitro and animal studies have shown vitamin D to have a suppressive role on RAS. Activated vitamin D has been shown to reduce albuminuria in patients with type 2 diabetes and with chronic kidney disease. Oral cholecalciferol has also been shown to reduce albuminuria in type 2 diabetic nephropathy. The study objective is to determine the effect of oral cholecalciferol (D3) on urine albumin creatinine ratio (ACR) in an older adults with heart failure.

**Methods:** Single center, double blind, randomized placebo-controlled trial among 64 patients with heart failure greater than 50 years of age and low or low normal 25OH vitamin D were randomly assigned to receive 6 months of weekly treatment of 50,000 units of oral cholecalciferol (D3) (n=31) or placebo (n=33), both groups received calcium citrate 800mg daily. We measured change in ACR between 0 and 6 months.

**Results:** Treatment with 50,000 units of cholecalciferol resulted in an increase in serum 25OH vitamin D of 42 ± 16 ng/mL and was unchanged in the placebo group (0 ± 7 ng/mL) from baseline to 6 months. ACR levels were not associated with Vitamin D level at baseline ($r=0.08$, $p=0.56$). The treatment group did not demonstrate a reduction in urine ACR relative to the placebo group ($p=0.18$) from baseline to 6 months (treatment group change = 6 ± 52 mg/gm, placebo group change = -3 ± 32 mg/gm). There was also no difference in reduction in ACR between diabetics and non-diabetics ($p=0.54$).

**Conclusions:** 6 months of treatment with 50,000 units of weekly cholecalciferol did not result in reduction in albumin creatinine ratio in older patients with heart failure.

## TH-OR025

### Fasting Status, Serum Phosphorus, and Mortality: Results from NHANES III

Alex Chang, M. Grams. *Nephrology, Johns Hopkins Univ.*

**Background:** Most but not all studies have found associations between elevated serum phosphorus levels and mortality; negative studies tend to use single random measurements. Since serum phosphorus levels may be affected by dietary phosphorus intake, we hypothesized that fasting status modifies the association between serum phosphorus and mortality.

**Methods:** The interaction between fasting status (≥12 hours without food or drink other than water), serum phosphorus, and all-cause and cardiovascular mortality was evaluated using participants from NHANES III (1988-1994). Cox proportional hazards models were adjusted for age, sex, race/ethnicity, time of examination, cardiovascular risk factors, eGFR, low vitamin D, and urine albumin/creatinine ratio.

**Results:** Fasting participants had lower serum phosphorus levels than non-fasting participants (3.3 vs. 3.6; $p<0.001$). Serum phosphorus was significantly associated with all-cause mortality among fasting participants (adjusted hazard ratio (aHR) per 1mg/dL:1.48; 95% CI 1.23-1.78) but not non-fasting participants (aHR 1.10; 95% CI 0.95-1.27; p for interaction=0.01). Similarly, serum phosphorus was significantly associated with cardiovascular mortality among fasting participants (aHR per 1mg/dL:1.67; 95% CI 1.28-2.17) but not non-fasting participants (aHR 1.25; 95% CI 0.98-1.61).

**Conclusions:** Fasting serum phosphorus levels have a stronger relationship with all-cause and cardiovascular mortality than non-fasting levels. This may explain the heterogeneity in previous studies regarding the association between serum phosphorus and mortality.

**Cardiac FGF23 Expression Is Associated with Left Ventricular Hypertrophy in Pediatric Patients with Chronic Kidney Disease** Maren Leifheit-Nestler,[1] Kathrin Flasbart,[1] Robert Grosse Siemer,[1] Dagmar-Christiane Fischer,[2] Michael Klintschar,[3] Jan U. Becker,[4] Tomas Seeman,[5] Christoph Aufricht,[6] Dieter Haffner.[1] *[1]Dept of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany; [2]Dept of Pediatrics, Univ Hospital Rostock, Rostock, Germany; [3]Institute for Forensic Medicine, Hannover Medical School, Hannover, Germany; [4]Institute of Pathology, Hannover Medical School, Hannover, Germany; [5]Div of Pediatric Nephrology, Univ Children´s Hospital Motol, Prague, Czech Republic; [6]Div of of Pediatric Nephrology, Univ Children´s Hospital Vienna, Vienna, Austria.*

**Background:** Left ventricular hypertrophy (LVH) is an important cause of cardiovascular disease (CVD) in patients with chronic kidney disease (CKD). Experimental and clinical studies demonstrated an association between elevated serum levels of fibroblast growth factor 23 (FGF23) and LVH in CKD.

**Methods:** We conducted a retrospective study in 19 deceased pediatric patients with end-stage renal disease (age 11±8y) and 23 age- and sex-matched healthy controls. Myocardial autopsy samples of the left ventricle (LV) were evaluated by immunohistochemistry and qPCR with respect to FGF23 expression, and signaling involved in calcineurin-NFAT associated pathway of hypertrophy. Expression of brain natriuretic peptide (BNP) served as a marker of LVH.

**Results:** FGFR1 was expressed in all samples to the same extent. Cardiac FGF23 protein expression tended to be enhanced in samples of CKD patients compared to controls. Cardiac FGF23 mRNA was 3-fold increased in LV of CKD patients versus controls ($p<0.05$), and associated with the duration of CKD ($r=0.636$, $p<0.05$). Cardiac BNP mRNA levels were enhanced in samples of CKD patients compared to controls, and associated with cardiac FGF23 gene expression ($r=0.982$, $p<0.05$). In line with a causative role of FGF23 in LVH, calcineurin mRNA expression was 19-fold higher in hypertrophic heart tissue compared to healthy tissue.

**Conclusions:** FGF23 expression as well as the FGF23-dependent calcineurin pathway is upregulated in heart tissue samples of pediatric CKD patients and significantly associated with duration of CKD and marker of LVH.

**TH-OR027**

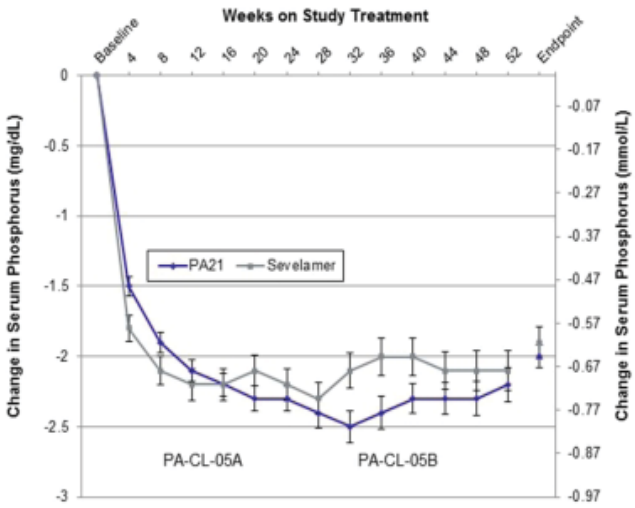
**Efficacy of PA21, a Novel Iron-Based Phosphate Binder, Maintained to 52 Weeks in Dialysis Patients with Hyperphosphatemia** Stuart M. Sprague,[1] Jürgen Floege,[2] Adrian Covic,[3] Markus Ketteler,[4] Anjay Rastogi,[5] Edward M.F. Chong,[6] Bruce S. Spinowitz.[7] *[1]NorthShore Univ Health System; [2]RWTH Univ Hosp Aachen; [3]Gr.T. Popa Univ of Med and Pharm; [4]Coburg Clinic and KfH-Dialysis Center; [5]Univ of California; [6]Vifor Pharma; [7]New York Hosp Queens.*

**Background:** A phase 3, open-label study investigated 1-year efficacy and safety of PA21, a novel polynuclear iron(III)-oxyhydroxide phosphate binder, vs sevelamer carbonate (SEV).

**Methods:** 1059 patients were randomized to PA21 (1.0–3.0 g/day; n=710) or SEV (2.4–14.4 g/day; n=349) for 12 weeks' dose titration then 12 weeks' maintenance; 99 hemodialysis patients receiving PA21 were re-randomized to evaluate PA21 maintenance-dose vs low-dose control (250 mg/day) from Weeks 24–27 (primary endpoint). Patients completing treatment, excluding those on low-dose PA21, were enrolled in a 28-week extension study. Secondary endpoints included change in serum phosphorus (sP; baseline–Week 12) to assess non-inferiority of PA21 vs SEV; long-term safety and efficacy of PA21 and SEV.

**Results:** Primary and Week 12 secondary efficacy endpoints were met (shown at ASN 2012). 658 patients were treated; 549 completed the extension. PA21 and SEV efficacy were maintained: mean [SD] change in sP concentration from baseline (7.6 [1.69] mg/dL and 7.4 [1.76] mg/dL) is shown (full analysis set, FAS; Figure). Mean daily tablet number over 52 weeks was lower for PA21 (3.3) vs SEV (8.7). Serum ferritin and transferrin saturation increased with PA21 over the first 24 weeks (mean change from baseline [SD]: 135.0 [340.33] ng/mL and 4.9 [16.12]%, respectively) then stabilized, with no evidence of iron accumulation with PA21 over 52 weeks. PA21 and SEV were well tolerated, with no notable difference in safety between groups.

**Figure:** Change (± standard deviation) in sP from baseline (FAS; N=1,041).



**Conclusions:** PA21 efficacy was maintained long-term, with a lower pill burden than SEV and similar safety profile.

**TH-OR028**

**Cinacalcet Induces Apoptosis of Parathyroid Cells through Increased Expression of FGF Receptor 1 in Hyperplastic Parathyroid Glands from Uremic Patients** Keiichi Sumida, Yoshifumi Ubara, Koki Mise, Masahiro Kawada, Tatsuya Suwabe, Junichi Hoshino, Kenmei Takaichi. *Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

**Background:** Decreased expression of both fibroblast growth factor receptor 1 (FGFR1) and its co-receptor Klotho was demonstrated in uremic parathyroid hyperplasia, particularly in nodular hyperplasia. However, the effect of cinacalcet hydrochloride (cinacalcet) on the expression of FGFR1 and Klotho in association with parathyroid cell proliferation and apoptosis remains unclear.

**Methods:** Four normal parathyroid glands and 71 hyperplastic parathyroid glands from 18 hemodialysis patients with refractory secondary hyperparathyroidism treated with ($n = 10$; cinacalcet group) or without ($n = 8$; conventional group) cinacalcet were examined immunohistochemically. The expressions of FGFR1 and Klotho, proliferative activity marker (Ki67), and apoptosis marker (M30 CytoDEATH) were analyzed semiquantitatively according to the areas of diffuse or nodular hyperplasia.

**Results:** Compared with normal glands, the immunohistochemical expressions of both FGFR1 and Klotho were decreased significantly in both the cinacalcet and conventional groups. In the cinacalcet group, the expression of FGFR1 was increased significantly only in areas of diffuse hyperplasia ($0.97 \pm 0.09$ vs. $0.25 \pm 0.11$, $P < .001$), but not in nodular areas, compared with the conventional group. The expression of Klotho was not different between the two groups or the two areas. In the cinacalcet group, Ki67 labeling indexes in both diffuse and nodular areas were significantly smaller than in the conventional group ($2.41 \pm 0.33$ vs. $3.94 \pm 0.54$ and $15.7 \pm 2.51$ vs. $23.4 \pm 2.64$, per 1000 cells, $P< .01$, respectively). The M30 labeling index was significantly higher in the cinacalcet group, particularly in areas of diffuse hyperplasia, than in the conventional group ($6.44 \pm 0.62$ vs. $3.65 \pm 0.57$, per 1000 cells, $P < .01$).

**Conclusions:** These results suggest that cinacalcet suppresses parathyroid cell proliferation and induces apoptosis in hyperplastic parathyroid cells through the increased expression of FGFR1, particularly in glands with diffuse hyperplasia.

**Temporal Trends in the Incidence, Treatment, and Outcomes of Hip Fracture after First Kidney Transplantation in the United States** Sumi Sukumaran Nair,[1] Colin R. Lenihan,[1] Maria E. Montez-Rath,[1] Glenn M. Chertow,[1,2] Wolfgang C. Winkelmayer.[1,2] *[1]Div of Nephrology, Dept of Medicine, Stanford Univ School of Medicine; [2]Dept for Health Research and Policy, Stanford Univ School of Medicine.*

**Background:** Kidney transplant recipients are at increased risk of hip fracture. Post-transplant bone disease is influenced by multiple pre- and post-transplant factors. The modern era has seen numerous changes in kidney transplant demographics, co-morbidities, wait-time and immunosuppression. It is currently unknown whether any secular trends exist in the hip fracture incidence, its treatment and case-fatality in kidney transplant recipients (KTR).

**Methods:** We identified first-time KTR (1997-2010) who had >1 year of Medicare coverage and no recorded history of hip fracture and followed them for 3 years. New hip fractures were identified from corresponding diagnosis and surgical procedure codes in

claims. Outcomes studied included time to hip fracture, type of surgery received (internal fixation; partial, or total hip replacement), and 30-day mortality. Cox and modified Poisson regressions were used to describe trends in study outcomes.

**Results:** Of 72,682 KTR transplanted in 1997-2010, 620 experienced a hip fracture event during 162,351 person-years of follow-up for an incidence rate of 3.81 per 1,000 person-years. While unadjusted hip fracture incidence did not change over 14 years, strong confounding by changes in case mix was present. Using year of transplantation as a continuous variable, the demographic-adjusted hazard ratio (HR) for hip fracture in 2010 compared with 1997 was 0.67 (95%CI: 0.50-0.89), further magnified with adjustment for dialysis and comorbid factors (HR=0.55; 95%CI: 0.41-0.74). No obvious trends in hip fracture treatment were noted. The 30-day mortality was lower than that of the general population at 2.09 per 100 events.

**Conclusions:** Adjusted post-transplant hip fracture rates declined substantially between 1997 and 2010 for reasons that further research will need to identify.

## TH-OR030

**Reduced VEGFA Expression in Bone Marrow Cells Is Associated with Altered Bone Formation in CKD** Neal X. Chen,[1] Kalisha O'Neill,[1] Matthew R. Allen,[1] Christopher Newman,[1] Vincent H. Gattone,[1] Sharon M. Moe.[1,2] *[1]Indiana Univ School of Medicine, Indpls, IN; [2]VAMC.*

**Background:** Over suppression of osteoblastic bone formation is considered an adverse effect of aggressive management of elevated PTH in CKD-MBD. Osteoblasts, critical in bone formation, derive from bone marrow mesenchymal stem cells (MSC), a process in part regulated by vascular endothelial growth factor (VEGFA). Therefore, an alternative hypothesis is that CKD leads to impaired bone formation due to reduced VEGFA that is overcome in the setting of high PTH.

**Methods:** To test this hypothesis, we analyzed bone marrow cells (BMC) from CKD (Cy/+ rats) for expression of VEGFA and transcription factors of MSC differentiation pathways and determined the relationship to histomorphometry indices of bone turnover (BFR) and mineralization (MS/BS), and bone volume (%BV) by microCT. Normal (NL) rats were compared to CKD rats (CKD; high PTH and high BFR), CKD treated with calcium (CKD-Ca; low PTH and low BFR), and CKD treated with zoledronic acid, known to have anti-VEGFA activity (CKD-Zol; high PTH and low BFR).

**Results:** The expression of VEGFA was reduced in the BMC from CKD vs NL animals, and further reduced by both Ca and Zol ($p < 0.04$). In contrast, there was no difference in the VEGF-receptor expression between the groups. In CKD BMC VEGFA expression was correlated with BFR, MS/BS, and BV ($r = 0.80$, 0.65 and -0.85, respectively, all $p<0.01$). VEGFA is known to increase the differentiation towards osteoblast (RUNX2) rather than adipocyte lineage (PPARγ). The expression of these factors was strongly correlated with VEGFA expression, and the RUNX2 expression was equivalent in CKD animals compared to NL, but decreased in both CKD-Ca and CKD-Zol($p<0.001$). Similar results were obtained with PPARγ but CKD was slightly lower than NL.

**Conclusions:** We conclude that CKD is associated with decreased VEGFA expression in BMC. These results suggest that in untreated CKD animals, the elevated PTH could overcome the low VEGFA and increase RUNX2 and BFR. In contrast, the induction of low BFR and suppression of PTH with Ca is associated with reduced VEGFA and RUNX2 expression to levels similar to Zol treatment, a known VEGFA inhibitor.

## TH-OR031

**LPA-LPA$_1$ Signaling Drives Renal Fibrosis by Inducing Fibroblast Accumulation through MRTF-SRF-Dependent Epithelial CTGF Expression** Norihiko Sakai,[1,3] Takashi Wada,[3] Andrew M. Tager.[2] *[1]Div of Rheumatology, Massachusetts General Hospital, Boston, MA; [2]Div of Pulmonary and Critical Care Unit, Massachusetts General Hospital, Boston, MA; [3]Div of Nephrology, Kanazawa Univ, Kanazawa, Ishikawa, Japan.*

**Background:** Renal fibrosis is a common pathway of progressive renal diseases and results in renal failure, but the mechanisms driving this pathway remain to be fully identified. We previously implicated the lipid mediator lysophosphatidic acid (LPA) and one of its receptors, LPA$_1$, in lung and skin fibrosis. Recently, we have demonstrated that LPA and LPA$_1$ drive peritoneal fibrosis by inducing connective tissue growth factor (CTGF)–dependent fibroblast accumulation. LPA signaling through LPA$_1$ on peritoneal mesothelial cells drives CTGF production in these cells by activating myocardin-related transcription factor (MRTF)-serum response factor (SRF)-dependant transcription. We therefore examined the role of this LPA-LPA$_1$-MRTF-SRF-CTGF pathway in renal fibrosis induced by unilateral ureteral obstruction (UUO).

**Methods:** Type I pro-collagen promoter-driven green fluorescent protein (GFP) mice were crossed with LPA$_1$-deficient mice (LPA$_1$ KO-GFP) or wild-type mice (WT-GFP).

**Results:** UUO-induced increases in renal hydroxyproline content were significantly attenuated in LPA$_1$KO-GFP compared with WT-GFP animals. Renal accumulation of a-smooth muscle actin$^+$ myofibroblasts and GFP$^+$ fibroblasts was also significantly reduced in LPA$_1$ KO-GFP mice. Renal CTGF expression was mainly detected in renal epithelial cells, and the levels of renal CTGF expression were suppressed in LPA$_1$ KO-GFP compared with those in WT-GFP mice. We also found that LPA directly induced CTGF expression dependent on an LPA$_1$-MRTF-SRF axis in mouse primary renal epithelial cells. Finally, supernatants of renal epithelial cells stimulated with LPA were found to contain CTGF protein, and to enhance fibroblast proliferation.

**Conclusions:** Our results suggest that LPA and LPA$_1$ drive renal fibrosis by inducing fibroblast accumulation through epithelial CTGFproduction, by activating MRTF-SRF-dependent transcription in epithelial cells.

## TH-OR032

**A Cationic-Independent Mannose 6-Phosphate Receptor Inhibitor (PXS64) Ameliorates Kidney Fibrosis Independent of Smad, AKT and ERK Signaling Pathways** Jie Zhang, May Yw Wong, Muh Geot Wong, Carol A. Pollock, Sonia Saad. *Kolling Institute of Medical Research, Univ of Sydney, St. Leonards, NSW, Australia.*

**Background:** Agents which completely inhibit transforming growth factor-β (TGFβ) have limited clinical use due to unwanted side effects. The cationic-independent mannose 6-phosphate receptor (CI-MPR) is a multifunctional protein which inhibits the activation of latent TGFβ1 without complete inhibition. We have previously shown that PXS25, has anti-fibrotic properties in human proximal tubular cells (HK-2) but is limited by its bioavailability. We aim to determine the role of PXS64, a pro-drug of PXS-25, in renal fibrosis and in HK-2 cells.

**Methods:** A 7 day unilateral ureteric obstruction (UUO) model was examined in 6-8 week old male C57BL/6 mice (20–25g, n=5) in the following groups: (i) Sham operated; (ii) UUO control; (iii) PSX64 (10mg/kg; by daily intraperitoneal injection) and (iv) Telmisartan (3mg/kg; in drinking water). Semiquantitative morphometric analyses of glomerulosclerosis and tubulointerstitial fibrosis were performed. Kidney tissue was analysed for fibrotic and inflammatory markers. HK-2 cells were exposed to TGFβ1 (1ng/ml) with or without PXS64 (10 μmol/L) for 24 hours. The mRNA expression of Collagen IV (ColIV) and Fibronectin (FN) was assessed by real time PCR. Phosphorylated and total protein expressions of signaling pathways downstream of TGFβ1 were assessed by western blot.

**Results:** The mRNA expression of ColIV and FN in kidney tissue was lower in animal treated with PXS64 as compared to the vehicle control (PBS) ($p<0.05$). The mRNA expression of TGFβ1 and MCP1 were suppressed by PSX64 and Telmisartan ($p<0.05$, both) compared to the vehicle. Mice treated with PXS64 had lower tubulointerstitial fibrosis score, FN and ColIV protein expression. In the *in vitro* study, PXS-64 inhibits TGFβ1-induced mRNA and protein expression of ColIV and FN compared to controls ($P < 0.05$) but did not inhibit TGFβ1-induced Smad2/3, AKT or ERK1/2.

**Conclusions:** PSX64 is as effective as Telmisartan as an antifibrotic agent in kidney fibrosis. PXS64 attenuates TGFβ1-induced matrix production independent of Smad2/3, AKT and ERK1/2 signaling pathways.

## TH-OR033

**MicroRNA Regulation of the Cell Cycle in Aristolochic Acid Nephropathy** Robert H. Jenkins,[1] Donald Fraser,[1] Luke C. Davies,[2] Philip R. Taylor,[2] Timothy Bowen.[1] *[1]Institute of Molecular and Experimental Medicine, Cardiff Univ, Cardiff, Wales, United Kingdom; [2]Institute of Infection, Immunity and Biochemistry, Cardiff Univ, Cardiff, Wales, United Kingdom.*

**Background:** Aristolochic acid nephropathy (AAN) is characterised by rapidly progressive tubulointerstitial nephritis culminating in end stage renal failure. A recent study causally links epithelial cell $G_2$M cell cycle arrest to fibrosis, following acute ischaemic, aristolochic acid (AA), and obstructive injuries (Yang L et al. Nat Med 2010; 16(5) 535). We have previously characterised microRNA expression in response to AA, including the induction of cell cycle associated microRNAs, miR-192, -194, -450a, and -542-3p. The purpose of this study was to investigate the mechanism of microRNA regulation of cell cycle arrest in AAN.

**Methods:** An in vitro study in proximal tubular epithelial cells in a model of AAN, using stable-expression cell lines, TaqMan RT-qPCR, Flow Cytometry, Western Blots, and Immunofluorescence.

**Results:** AA induced profound $G_2$/M arrest in proximal tubular cells via p53-mediated downstream inactivation of the maturation promoting complex CDK1/Cyclin-B1. This was associated with the formation of RNA stress granules, termed processing-bodies, indicative of translational repression. The enforced expression of miR-192 recapitulated the $G_2$/M arrest and translational repression. The mechanism of $G_2$/M arrest was due to miR-192 repression of the E3 ubiquitin ligase MDM2, a negative regulator of p53. The subsequent increase in p53 transcriptionally induced $p21^{cip1}$ and the growth arrest and DNA damage 45 (GADD45) proteins, which phosphorylated, inactivated and disassociated the maturation promoting complex CDK1/Cyclin-B1.

**Conclusions:** These data define a mechanism by which microRNAs control cell cycle arrest in epithelial cells in a model of AAN. This is of mechanistic importance in the recently described pro-fibrotic $G_2$/M arrest seen following a range of acute renal injuries.

## TH-OR034

**Nlrp3 Regulates Apoptosis in Renal Tubular Epithelial Cells** Akosua Vilaysane, Daniel A. Muruve. *Medicine, Univ of Calgary, Calgary, Canada.*

**Background:** Tubular cell apoptosis contributes to the pathogenesis of progressive chronic kidney disease (CKD). Caspases play an important role in this process that result in tubular atrophy, tubulointerstitial inflammation and fibrosis. Previous work from our lab showed reduced apoptosis in the renal epithelium of Nlrp3-/- mice undergoing unilateral ureteric obstruction when compared to wild-type controls. The mechanism behind this distinction in Nlrp3-/- renal cells is unknown but does not appear to be simply due to classical Nlrp3 inflammasome activation involving the adaptor protein ASC and caspase-1 that mediates the maturation of pro-inflammatory cytokines such as IL-1β.

**Methods:** Apoptotic responses were analyzed in primary mouse tubular epithelial cells from wild type and Nlrp3-/- mice.

**Results:** Mouse tubular epithelial cells (mTECs) were found to express Nlrp3 and ASC proteins, however active caspase-1 subunits and IL-1β were undetectable suggesting

inflammasome independent roles for Nlrp3 and ASC in these cells. Primary Nlrp3-/- mTECs displayed reduced caspase-8, -3 and -7 activation and reduced poly-ADP ribose polymerase (PARP) cleavage after incubation with extrinsic cell death ligands, TNFα and Fas ligand. The reduction in apoptosis in Nlrp3-/- cells occurred independent of ASC since apoptotic responses in these cells were comparable to wild type mTEC. Differences in cell death between Nlrp3 deficient and wild-type mTECs appear to be independent of death inducing signaling complex (DISC) mRNA and protein levels and NF-κB pro-survival signaling. Likewise, tumor necrosis factor receptor 1 (TNFR1) protein levels remained similar between both cell types. Consistent with these findings, overexpression of NLRP3 in HeLa cells increased levels of active caspase-8 over GFP controls. Initial experiments have localized NLRP3 to mitochondria in renal tubular epithelial cells suggesting that NLRP3 may modulate cell death by sensing or regulating mitochondrial function.

**Conclusions:** Taken together, these results support an inflammasome-independent role for Nlrp3 in renal cell death, which in addition to its roles in cytokine maturation and inflammation, identify this protein as a potential therapeutic target in progressive CKD.

*Funding:* Government Support - Non-U.S.

## TH-OR035

### Fibroblast αv Integrins Are Key Mediators of Renal Fibrosis – Potential Novel Targets for Anti-Fibrosis Therapy

Yongen Chang,[1] Dean Sheppard.[2] *[1]Medicine/Div of Nephrology, Univ of California San Francisco, San Francisco, CA; [2]Medicine/Div of Pulmonary and Critical Care, Univ of California San Francisco, San Francisco, CA.*

**Background:** Renal fibrosis is the common pathway of chronic kidney disease. So far, its molecular mechanism is not entirely clear. While epithelial αv integrins, i.e. αvβ6, were identified as key pro-fibrotic factors through activation of transforming growth factor β (TGFβ), the role of fibroblast αv integrins is not established.

**Methods:** Platelet-derived growth factor receptor β (PDGFRβ) is highly expressed in activated pericytes, a main source of fibroblasts. Using a PDGFRβ promoter driven Cre system, we deleted αv integrins specifically in activated pericytes in mice while turning on Tdtomato reporter fluorescence in these cells. We then performed unilateral ureteral obstruction (UUO) surgery to induce interstitial fibrosis in these mice. We isolated Tdtomato positive wild type or αv null renal fibroblasts using fluorescence-activated cell sorting. For TGFβ activation assays, isolated fibroblasts were co-cultured with mink lung epithelial cells expressing firefly luciferase downstream of a TGFβ sensitive portion of the plasminogen activator inhibitor 1 promoter. The assays were also performed in the presence of blocking antibodies or small molecule inhibitors specific for each αv integrin.

**Results:** We found that renal fibroblasts express several αv integrins including αvβ1, αvβ3 and αvβ5. Deletion of αv integrins in renal fibroblasts protected mice from interstitial fibrosis after UUO as evidenced by decreased collagen deposition in conditional αv null mice compared to wild type. Furthermore, isolated wild type renal fibroblasts are able to activate TGFβ in vitro. Specific small molecule inhibitors against αvβ1 inhibited TGF beta activation by renal fibroblasts. Similarly, function blocking antibodies against αvβ3, but not αvβ5, also impaired the ability of fibroblasts to activate TGFβ.

**Conclusions:** We found that specific fibroblast αv integrins, namely αvβ1 and αvβ3, mediate renal fibrosis through direct activation of TGFβ. Small molecule inhibitors or blocking antibodies against αv integrins may emerge as potential anti-fibrotic therapeutic agents.

## TH-OR036

### Impact of Connective Tissue Growth Factor (CCN 2) on Hypoxia Inducible Factor-1alpha (Hif-1α) Responsiveness

Leighton R. James,[1,3] Catherine Le.[2,3] *[1]Dept of Medicine, Nephrology Div, Univ of Florida, Jacksonville, FL; [2]Cell and Molecular Biology, Colorado State Univ, Fort Collins, CO; [3]Dept of Medicine, UT Southwestern Medical Center, Dallas, TX.*

**Background:** CTGF is implicated in the pathogenesis of diverse fibrotic conditions. Hif-1α mediates cellular adaptation to hypoxia, vasculogenesis, glucose disposal and intermediary metabolism. However, the interaction between CTGF and Hif-1α is contradictory. Hypoxia may induce CTGF via hif-1α in lungs, but inhibit CTGF expression in proximal tubular epithelial cells (protective effect of hypoxic preconditioning), while in some systems CTGF may regulate HiF1 stability. Recently, we have observed that *ctgf* expression may influence blood pressure in a mice model. The objective of the current study was to examine effect of *ctgf* gene dose on Hif-1α expression and downstream Hif-1α targets.

**Methods:** CTGF knockout and CTGF gene-duplicated mice, as well as, mouse embryonic fibroblasts (MEFs) derived from these lines, were studied. Expression analysis was also performed with Mouse Array Chip (Illumina). Expression of constructs containing Hif-1α responsive elements (HRE-Luc) and pro-apoptotic Nip3 promoter and Endothelin-1(Et-1) protein levels were assessed. Blood pressure was assessed using automated tail-cuff method.

**Results:** Disruption of *ctgf* gene enhances MEF growth. Expression array analysis revealed that relative to wildtype, there was increased expression of Hif-1α-responsive genes including stem cell growth factor, fifty percent reduction in Et-1 and, concurrently enhanced expression of Hif-1α antagonistic factors necdin and claudin 1. Expression of HRE-Luc and Nip3 were increased in ctgf-null MEF under normal oxygen conditions. Nip3 promoter mutation abrogated expression in wildtype MEF, but marginally influenced expression in ctgf-null MEFs. Et-1 protein was reduced in ctgf-null MEF and, in parallel with elevated blood pressure in mice, enhanced CTGF expression accentuated Et-1 levels.

**Conclusions:** Variation in *ctgf* expression impacts HiF-1α and potentially influences normal physiologic processes as well as cellular responses to perturbation and injury.

*Funding:* NIDDK Support, Private Foundation Support

## TH-OR037

### Systemic Deletion of CTGF Ameliorates Anti-Glomerular Basement Membrane Nephritis with Reduction of Macrophage Infiltration

Naohiro Toda,[1] Hideki Yokoi,[1] Masato Kasahara,[1] Kiyoshi Mori,[1] Takashige Kuwabara,[1] Hirotaka Imamaki,[1] Akira Ishii,[1] Kenichi Koga,[1] Keita P. Mori,[1] Yukiko Kato,[1] Shoko Ohno,[1] Akira Sugawara,[1] Taiji Matsusaka,[2] Kazuwa Nakao,[1] Masashi Mukoyama.[1] *[1]Dept of Medicine and Clinical Science, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [2]Dept of Internal Medicine, Tokai Univ School of Medicine, Kanagawa, Japan.*

**Background:** Connective tissue growth factor (CTGF/CCN2) regulates signaling of other growth factors and promotes fibrosis. Although we previously showed that drug-inducible systemic CTGF knockout mice attenuated anti-glomerular basement membrane (anti-GBM) nephritis, the molecular mechanism how systemic deletion of CTGF ameliorated nephritis was unclear. To address these questions, we generate podocyte-specific CTGF knockout (pod-CTGF cKO) mice and drug-inducible systemic CTGF knockout (Rosa-CTGF cKO) mice.

**Methods:** CTGF floxed mice were crossed with RosaCreER$^{T2}$ mice, which ubiquitously express a tamoxifen-inducible Cre recombinase, to generate Rosa-CTGF cKO mice. Nephrin-Cre mice were used to create pod-CTGF cKO mice. We evoked anti-GBM nephritis and investigated the progression of glomerular injury including macrophage infiltration for 28 days.

**Results:** Rosa-CTGF cKO mice and pod-CTGF cKO mice showed normal renal appearance and no proteinuria without nephritis. After induction of anti-GBM nephritis, severe proteinuria and glomerular injury were developed in control mice. Pod-CTGF cKO mice showed similar renal injury and proteinuria. In contrast, Rosa-CTGF cKO mice exhibited reduced proteinuria by half at day 7 with ameliorated histological changes. The number of MAC2-positive cells in glomeruli was reduced in Rosa-CTGF cKO mice but not in pod-CTGF cKO mice. Glomerular expressions of TGF-β1, fibronectin and F4/80 were upregulated in control mice, and these increments were significantly reduced in Rosa-CTGF cKO mice, but not in Pod-CTGF cKO mice.

**Conclusions:** These results indicate that systemic deletion of CTGF, but not podocyte-specific inhibition of CTGF, can reduce proteinuria and macrophage infiltration to ameliorate glomerular injury in anti-GBM nephritis.

## TH-OR038

### Molecular Mechanism for Asymmetric Dimethylarginine Dysregulation in Patients with Chronic Kidney Disease

Crystal A. Gadegbeku,[1,5] Subhasish Bose,[1] Wenjun Ju,[2] Louis G. D'alecy,[2] Kalyani Perumal,[3,5] Zeenat Yousuf Bhat,[4,5] Matthias Kretzler.[2,5] *[1]Temple Univ; [2]Univ of Michigan; [3]John H. Stroger Hospital; [4]Wayne State Univ; [5]Michigan O'Brien Renal Center (P30).*

**Background:** Endothelial dysfunction is implicated in accelerated atherosclerosis in patients with chronic kidney disease (CKD). Plasma asymmetric dimethylarginine (ADMA), an endogenous competitive inhibitor of nitric oxide synthase, is linked to cardiovascular morbidity and mortality and reaches high levels in CKD. ADMA is generated by protein methyltransferase 1 (PRMT1) and metabolized by dimethylarginine dimethylaminohydrolase (DDAH). This study was designed to characterize intra-renal molecular markers of ADMA metabolism in patients that have been implicated in experimental studies.

**Methods:** Renal biopsy tissue stored in the Michigan O'Brien Renal Center biobank from 29 consented individuals underwent gene expression analysis using Affymetrix 133 plus GeneChips®. Steady state gene expression levels of PRMT1, DDAH, and oxidative stress markers, cytochrome b-245 beta polypeptide (CYBB), neutrophil cytosolic factor 2 (NCF2), and superoxide dismutase 2 (SOD2), were measured from the micro-dissected tubulo-interstitial compartment of cortical samples. Estimated GFR (eGFR, CKD-EPI equation) at the time of biopsy was used for analysis. To explore relationships between molecular markers and eGFR, Pearson correlations were used with adjustment for multiple comparisons.

**Results:** Tubulo-interstitial gene expression of PRMT1 was inversely correlated with eGFR (-0.49, p=0.02) and DDAH1 (-0.65, p=0.0002) but not DDAH2. Also, positive correlations were observed with oxidative stress markers, CYBB and NCF2 (R=0.43; R=0.44, both p=0.04) and marginally, with SOD2 (R=0.41, p=0.06). Additionally, DDAH1 was inversely correlated with NCF2 (R=-0.59, p=0.001) and SOD2 (R=-0.44, p=0.04).

**Conclusions:** For the first time in humans, we demonstrate a potential mechanism for ADMA dysregulation that may contribute to CVD burden in CKD. These findings support animal model data demonstrating up-regulation of PRMT1 and down-regulation of DDAH1 associated with oxidative stress in CKD.

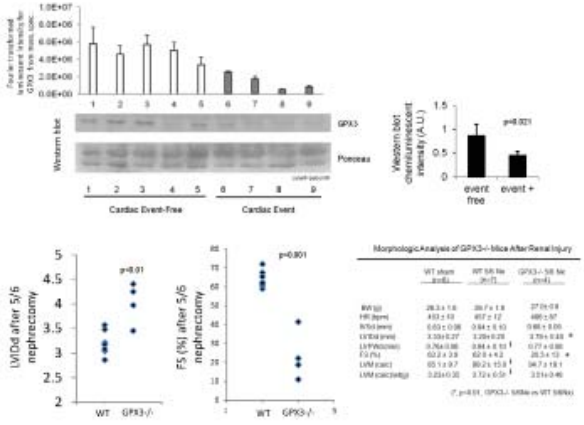
**Uremic Cardiomyopathy Is Associated with Glutathione Peroxidase 3 Deficiency** Paul Pang, Rafael Kramann, Joseph Loscalzo, Joseph V. Bonventre, Andrew M. Siedlecki. *Medicine, Brigham and Women's Hospital, Boston, MA.*

**Background:** Glutathione peroxidase 3 (GPX3) is synthesized primarily in the kidney. Patients with chronic kidney disease (CKD) have deficient levels of circulating GPX3. This may lead to a form of cardiomyopathy due to the accumulation of reactive oxygen species that exacerbate inflammatory signaling in the myocardium.

**Methods:** 9 patients with CKD, had serum collected, were followed prospectively, and monitored for cardiac endpoints. Proteomic analysis was performed by LC-tandem mass spectrometry. GPX3-/- and wild type mice underwent 5/6 nephrectomy followed by echocardiography 4 weeks and 8 weeks after injury.

**Results:** We identified several circulating proteins of interest based on plasma proteomic analysis of patients with CKD and cardiac endpoints.



GPX3 showed the greatest absolute decrease in protein expression. Patients with an incident cardiac event on average had a 66.4% decrease in GPX3 plasma levels measured by mass spectrometry. This finding was validated by western blot analysis where GPX3 protein levels were decreased by 47.6±15.7% in CKD patients with a cardiac event (p=0.021) compared to CKD patients without a cardiac event. GPX3-/- mice underwent 5/6 nephrectomy compared to wild-types + 5/6nephrectomy. At 4 weeks after injury, LVIDd was increased, 4.02±0.42mm (n=4) vs 3.33±0.27mm (n=7) respectively (p<0.01). At the same time point fractional shortening was decreased to 23.5±11% in GPX3-/- compared to 62.0%±4 in injured wild-types (p<0.001).

**Conclusions:** For the first time we show that the mechanism of renal-induced cardiac disease is dependent on GPX3 deficiency. This was evident by the dramatic worsening of cardiac function after subtotal nephrectomy in GPX3-/- animals. GPX3 deficiency is also associated with increased frequency of cardiac events in patients with CKD and may offer a targeted therapy for renal-induced cardiomyopathy.

**Activation of Aryl Hydrocarbon Receptor Mediates Suppression of Hypoxia Inducible Factor-Dependent Erythropoietin Expression by Indoxyl Sulfate** Hirobumi Asai, Junya Hirata, Sayaka Seki, Mie Watanabe-Akanuma. *Kureha Corporation, Tokyo, Japan.*

**Background:** Uremic toxins are considered to have a role in renal anemia which is caused by inadequate renal erythropoietin (EPO) production. Indoxyl sulfate (IS), a representative uremic toxin, has been reported to suppress the activation of hypoxia inducible factor (HIF) and subsequent EPO production. In this study, we investigated the involvement of aryl hydrocarbon receptor (AHR) on the suppressive effect of IS. Besides, effect of the other uremic toxins, p-cresyl sulfate (PCS) and phenyl sulfate (PhS), on EPO expression was also examined.

**Methods:** HepG2 cells were treated with cobalt chloride (50 μM) to induce hypoxic response in the presence or absence of IS, PCS, PhS or an AHR agonist 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). For the inactivation of AHR, cells were treated with an AHR antagonist CH-223191 or transfected with the specific siRNA prior to the IS treatment. EPO gene expression was examined by real time RT-PCR, and HIF transcriptional activity was assessed by hypoxia responsive element (HRE) luciferase reporter assay.

**Results:** IS significantly inhibited cobalt chloride-induced elevation of EPO expression at 100 μM or more. PhS slightly inhibited the EPO expression at relatively higher concentration (1.5 mM), whereas PCS (up to 1.5 mM) had no effect. IS also significantly inhibited the HIF activation at 20 μM or more, while PCS had no inhibitory effect. Inactivation of AHR by either CH-223191 or the specific siRNA completely abolished the inhibitory effect of IS. Similar to IS, TCDD also significantly inhibited the HIF activation.

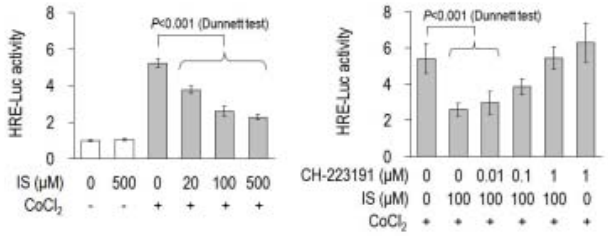

**Figure.** *Left*, effect of IS on cobalt chloride ($CoCl_2$)-induced HIF activation. *Right*, effect of CH-223191, an AHR antagonist, on the suppression of HIF activation by IS.

**Conclusions:** IS but not PCS and PhS suppresses HIF-dependent EPO expression at a concentration relevant to the serum levels in patients with chronic kidney disease, and AHR plays a crucial role in the suppressive effect of IS.

**TH-OR041**

**Impact of Genetic TNFR1 Modulation on Diabetic Nephropathy Course in a Murine Model of Diabetes** Roberto Bassi,[1] Andrea Vergani,[1] Masami Ikehata,[3] Jung Eun Lee,[2] Melissa Chin,[1] William Walker,[2] Moufida Ben Nasr,[1] Jackson Jeong,[2] Irene Garcia,[4] Maria Pia Rastaldi,[3] Paolo Fiorina,[1] Monika A. Niewczas.[2] *[1]Boston Children's Hospital, Boston; [2]Joslin Diabetes Center, Boston; [3]Ospedale Maggiore Policlinico, Milan, Italy; [4]Univ of Geneva, Switzerland.*

**Background:** Circulating TNFR1 was identified as a strong predictor of diabetic nephropathy (DN) progression in the Joslin Kidney Study. Aim of this work was to evaluate whether TNFR1 contributes to the injury of the diabetic kidney. We tested our hypothesis in a murine model of DN in which hyperglycemia was chemically induced with streptozotocin (STZ) and TNFR1 expression was genetically modulated.

**Methods:** Tnfrsf1atm1Imx knockout ($TNFR1^{-/-}$), TNFR1 transgenic (TNFR1tg) and control WT (WT) mice all in the C57BL/6 background (n=8 per group of 8 weeks of age) were used in our study. We confirmed their TNFR genotype with RT-PCR and their protein expression with ELISA. Repeated measurements of glycemia and albumin excretion rate (AER) were performed over a 12 week period following STZ injection.

**Results:** Serum TNFR1 levels were undetectable in $TNFR1^{-/-}$ mice, 1408±1634ng/ml in TNFR1tg mice and 0.89±0.16ng/ml in WT mice. Albuminuria course over time was significantly different among the 3 groups of mice, AER values were lower in $TNFR1^{-/-}$ and higher in TNFR1tg compared to the control group, respectively (p=0.007, significance obtained with mixed effect model). Survival of TNFR1tg mice was significantly reduced compared to the other groups (deaths: TNFR1tg: 5/8, vs. $TNFR1^{-/-}$: 2/8; WT: 2/8).

| **AER (mg/24hrs):** median (25th, 75th percentile) | | | |
|---|---|---|---|
| | **WT** | **$TNFR1^{-/-}$** | **TNFR1tg** |
| baseline | 7 (5-10) | 15 (8-18) | 7 (5-9) |
| 4 weeks | 17 (14-21) | 13 (11-13) | 13 (12-26) |
| 8 weeks | 17 (13-25) | 11(11-18) | 27 (20-32) |
| 12 weeks | 24 (19-44) | 13 (10-17) | 22 (18-32) |

**Conclusions:** We demonstrated that the modulation of TNFR1 expression impacts albuminuria course in an experimental model of murine DN. Our data suggest that TNFR1 may play a causative role in DN progression and warrants its consideration for therapeutic applications.

**TH-OR042**

**Tissue Transcriptome-Driven-Approach Facilitates Discovery of Non-Invasive Biomarkers for Chronic Kidney Disease** Wenjun Ju,[1] Viji Nair,[1] Shahaan Smith,[1] Jennifer Joyce Hawkins,[1] Ivan Formentini,[2] Maria Bobadilla,[2] Maria Chiara Magnone,[2] Crystal A. Gadegbeku,[3] Matthias Kretzler.[1] *[1]Univ of Michigan; [2]Hoffmann-La Roche; [3]Temple Univ, for the ERCB, C-PROBE and NEPTUNE Consortium.*

**Background:** Defining intra-renal molecular mechanism associated with CKD is critical for identification of therapeutic targets and molecular marker definition. We have employed a gene expression profiling study in renal biopsies of the European Renal cDNA Bank (ERCB) and identified a set of 68 intrarenal transcripts that was able to predict degree of CKD in ERCB training (n=164) and test cohorts (n=55), as well as in 42 patients of the Michigan O'Brien Renal Center C-PROBE cohort.

**Methods:** In this study we investigate if proteins encoded by the intrarenal CKD associated transcripts can be discovered in urine, if urinary proteins correlate with intrarenal transcript level and if they maintain their association with eGFR. Epidermal growth factor (EGF) was selected from the transcript panel as a proof of principle study.

**Results:** Intrarenal EGF mRNA correlates with eGFR in the ERCB test cohort (r=0.66) and C-PROBE cohort (r=0.42). In C-PROBE, matching urine samples at time of biopsy (n=34) were evaluated for EGF and demonstrated a significant correlation with intra-renal EGF mRNA (r=0.7, p<0.0001). Urinary EGF retained its correlation with eGFR in 93 C-PROBE patients irrespective of underlying disease type, stage, age, gender or race (r=0.82, p<0.0001). Robustness of the EGF-eGFR association in proteinuric patients was demonstrated in 213 patients from the Nephrotic Syndrome Study Network (NEPTUNE) (r=0.83, p<0.0001, urine protein level ranges from 0.01 to 66.8 g/g creatinine).

**Conclusions:** In conclusion, intrarenal transcripts with strong associations to eGFR can be used to define urinary protein markers for non-invasive stratification of CKD patients according to their intrarenal pathophysiology.

### TH-OR043

**In Vitro Human Renal Primary Cells for Studies of Mineral Ion Homeostasis**

Rebecca M. Wadey,[1] Lydia E. Searchfield,[1] Sally A. Price,[2] Daniela Riccardi.[1]
*[1]Cardiff Univ, United Kingdom; [2]AstraZeneca, United Kingdom.*

**Background:** FGF23, PTH and Vitamin D play important roles in mineral ion homeostasis. The complex interactions between these hormones are difficult to investigate *in vivo*. We have characterised a human primary renal cell model in an attempt to specifically dissect out the role the kidney plays within the FGF23, PTH and Vitamin D axis.

**Methods:** Primary renal cells were isolated from ethically-consented kidney cortical tissue from patients undergoing nephrectomy. Cell monolayers were cultured on transwells without passaging and characterised in terms of viability (proliferation/apoptosis), morphology (electron microscopy) and expression of proximal and distal markers, N- and E-cadherin, respectively. Expression of NaPiIIa (type 2a $Na^+$-Pi cotransporter), NCX1 ($Na^+$-$Ca^{2+}$ exchanger), PMCA1 (plasma membrane $Ca^{2+}$ ATPase), FGFr1-4 and Klotho were determined by immunohistochemistry (on kidney sections) and western blotting (of kidney lysate) and then confirmed in isolated cells. Functional readouts included Pi-dependent NaPiIIa upregulation, ERK activation, 1-hydroxylase activity and Pi-induced mineralisation.

**Results:** Cell proliferation rates were high and apoptosis rates low throughout culture. Dual N- and E-cadherin immunostaining revealed that primary cultures consisted of 70% proximal and 30% distal cells after 5 days. When cultured on transwells, NaPi2a expression was present up to day 8 and NCX1, PMCA1, FGFr1-4 and Klotho proteins up to day 15. Proximal tubule brush border membranes were visible by electron microscopy at day 5. NaPiIIa expression was upregulated following 24h exposure to Pi-free medium. FGF23 treatment induced ERK activation, which could be blocked by inhibiting MEK. MEK inhibition also increased Pi-dependent mineralisation.

**Conclusions:** Primary human kidney cells retain the morphological and functional properties of kidney cells *in vivo* and express key proteins involved in mineral ion homeostasis. These observations suggest great potential for this preparation as a model for investigating the interplay between FGF23, PTH and Vitamin D in mineral ion homeostasis, and for understanding how mineral ion dysregulation occurs in chronic kidney disease.

### TH-OR044

**Urinary Proteomics: The Development of a Diagnostic Biomarker Panel for Pre-Eclampsia**

Kate Bramham,[1] Hiten Mistry,[1] Marta Hentschke,[1] Steven Lynham,[2] Malcolm Ward,[2] Lucilla Poston,[1] Lucy C. Chappell.[1] *[1]Div of Women's Health, King's College London, London, United Kingdom; [2]Centre of Excellence for Mass Spectrometry, King's College London, London, United Kingdom.*

**Background:** Early detection/diagnosis of pre-eclampsia allows appropriate monitoring and targeting of therapeutic strategies. Urinary proteomics is a rapidly developing field that allows detection and identification of individual proteins. Our hypothesis is that a distinctive pre-eclampsia urinary proteome profile can be identified.

**Methods:** A proteome profile for time-of-disease urine samples from twelve pre-eclamptic and twelve gestation-matched controls was established using a validated workflow, involving selective immunodepletion, 1D SDS-PAGE gel fractionation, in-gel digestion of gel sections, LC-MS/MS analysis, spectral analysis and selection of candidate proteins for Selective Reaction Monitoring (SRM) verification and quantification.

**Results:** 981 proteins were identified using minimal stringency in Scaffold, and 8 proteins were differentially expressed between cases and controls. Subsequent SRM area-under-curve peak analysis revealed 7 proteins which were present in significantly higher levels in pre-eclamptic urine samples than controls and 1 protein was significantly lower in pre-eclamptic samples. An example of spectral peaks are shown in Figure 1.

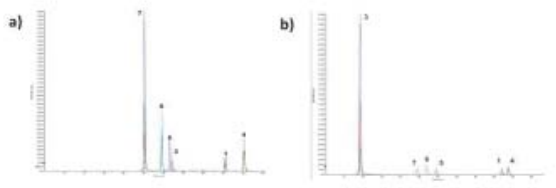

Figure 1: SRM peaks in a) one pre-eclampsia sample and b) one control sample for a single peptide from each of the seven proteins shown to be increased in 12 pre-eclampsia patients and one only present in the 12 controls

For protection of intellectual property protein identities are omitted.

**Conclusions:** A urinary proteomic signature can be identified in the urine of women with pre-eclampsia samples. Validation of this differential proteomic profile using a larger number of samples, including women with CKD and superimposed pre-eclampsia, chronic and gestational hypertension is currently underway. The use of a diagnostic urinary biomarker will be invaluable in low socioeconomic countries where facilities for blood taking and processing are limited.

### TH-OR045

**P-Cresol (PC) and P-Cresyl Sulfate (PCS) Stimulate Chemoattractant Protein-1 (MCP-1) Expression in Human Vascular Smooth Muscle Cells (VSMC)**

Rayana Ariane Pereira Maciel,[1] Lisienny Campoli Tono Rempel,[1] Alessandra Becker Finco,[1] Wesley M. Souza,[1] Roberto Pecoits-Filho,[2] Andréa Marques Stinghen,[1] Bruna Bosquetti.[1] *[1]Universidade Federal do Paraná, Curitiba, Brazil; [2]Pontifícia Universidade Católica do Paraná, Curitiba, Brazil.*

**Background:** Uremic toxins such as PC and its conjugate PCS are responsible for many of the uremia clinical consequences, such as atherosclerosis in CKD patients. In this study we investigate the *in vitro* role of PC and PCS in MCP-1 expression via transcription factor NF-κβ p65 in VSMC.

**Methods:** PCS was synthesized by PC sulfatation. VSMC were extracted by enzymatic digestion of umbilical cord vein and characterized by immunofluorescence against α-actin antibody. The cells were treated with PC and PCS in a kinetics of 0 and 3 h in their normal (PC1 0.60 and PCS1 2.87 mg/L), minimum (PC2 20.10 and PCS2 15.6 mg/L) and maximum uremic concentrations (PC3 40.7 and PCS3 47.20 mg/L). Cell viability was assessed by MTT. MCP-1 expression was investigated by ELISA in cells supernatant after toxins treatment in the presence or absence of NF-κβ p65 inhibitor.

**Results:** No significant difference was observed in cell viability after toxins treatment for all concentrations tested. After 3h there was a significant increase in MCP-1 expression in cells treated with PC2 (150±16 pg/mL, $P<0.001$), PC3 (144±28 pg/mL, $P<0.05$), PCS1 (145±24 pg/mL, $P<0.005$), PCS2 (150±13 pg/mL, $P<0.001$) and PCS3 (160±8 pg/mL, $P<0.001$), compared with control cells (37±3 pg/mL). When VSMC were treated with NF-κβ p65 inhibitor, we observed after 3h a pronounced decrease in MCP-1 levels, especially to PC2 (150±16 pg/mL *vs* 36±10 pg/mL, $P<0.001$) and PC3 (160±8 *vs* 50±18 pg/mL, $P<0.05$) treatment, but no difference was observed when the inhibitor was adding with PCS.

**Conclusions:** VSMC are involved in atherosclerosis lesion formation and cytokines production such as MCP-1, which contributes to the inflammatory response initiation and propagation to lipid. Our results suggest for the first time that PC mediates MCP-1 production in VSMC, probably through NF-κβ p65 pathway, although we hypothesize that PCS acts through a different subunit pathway since NF-κβ p65 inhibitor was not able to inhibit MCP-1 production.

### TH-OR046

**Targeting the CRBN/DDB1/Cul4A E3 Ubiquitin Ligase Prevents Kidney Fibrosis**

Yuanyuan Shi,[1] Yanlin Wang,[2] William E. Mitch,[2] Zhaoyong Hu.[2] *[1]Nephrology Div, Second Hospital of Shanxi Medical Univ, Taiyuan, Shanxi, China; [2]Nephrology Div, Baylor College of Medicine, Houston, TX.*

**Background:** Cereblon (CRBN) interacts with damaged DNA binding protein 1 (DDB1) and Cullin 4A (Cul4A), forming an E3 ubiquitin ligase complex, the first step towards degradation by proteasomes (UPS). CRBN is the critical element that recognizes substrate proteins leading to their conjugation with ubiquitin and ultimately, UPS degradation. Notably, the CRBN/DDB1/Cul4A is activated by inflammation, in stress response and it can influence cell growth. Since CRBN is stimulated by inflammation, etc. we investigated whether blocking CRBN would ameliorate the progression of kidney fibrosis. The mechanisms of fibrosis are pertinent because the degree of fibrosis is closely associated with progression of chronic kidney disease (CKD). Unfortunately, there are few therapies that effectively block or suppress kidney fibrosis. We investigated whether blocking CRBN would ameliorate the progression of kidney fibrosis.

**Methods:** In mice with genomic or pharmacological inhibition of CRBN, we evaluated inflammatory mediators and the degree of kidney fibrosis following unilateral ureteral obstruction (UUO).

**Results:** At 7 days after UUO in wild type mice, there was increased expression of collagen, fibronectin and SMAa, as demonstrated by many investigators. Mice with CRBN knockout exhibited reduced expression of collagen I (60%), fibronectin (>80%) and SMAa (>50%). Importantly, there also was suppression of the tubulointerstitial fibrosis caused by UUO. Inhibition of CRBN suppressed TGFb1 mRNA expression as well as phosphorylation of Smad3. In cultured kidney fibroblasts and wild-type UUO mice, we found that thalidomide, a CRBN inhibitor, suppressed ubiquitin conjugation to SnoN, this results in an increase in SnoN with inhibition of TGFb1 expression. These responses reduced fibrosis in the kidney despite UUO.

**Conclusions:** The ubiquitin E3 ligase of the CRBN/DDB1/CUL4A E3 complex regulates the kidney expression of TGFb1 and ultimately, fibrosis. We have identified a molecular basis for an anti-fibrotic effect of blocking CRBN and this could become a treatment strategy for the fibrosis that damages the kidney in CKD.

*Funding:* NIDDK Support

### TH-OR047

**Resistance Exercise Prevents Muscle Wasting in Mice with Chronic Kidney Disease by Increasing microRNA-23**

Cong Zhang,[1] Li Hu,[1] Janet D. Klein,[1] Russ Price,[1,2] Xiaonan H. Wang.[1] *[1]Renal Medicine, Emory Univ, Atlanta, GA; [2]Renal Medicine, Atlanta VAMC, Decatur, GA.*

**Background:** There are 23 individual microRNAs that are significantly changed in muscle of chronic kidney disease (CKD) mice (Wang et al, JASN 2010). We previously showed that exercise improves muscle protein synthesis and prevents accelerated protein degradation in muscle of CKD mice (Wang at al, KI 2009). This study identifies In silico

analysis and other reports suggested that microRNA-23 (miR-23) targets several proteins associated with muscle atrophy. In this study, we evaluated whether exercise increases the level of miR-23 (miR-23) in CKD mice.

**Methods:** CKD was induced in 20-25g mice by 5/6th nephrectomy. Muscle overloading, produced by removing the gastrocnemius and soleus muscles from both hindlimbs of control and CKD mice, was used as an exercise model.

**Results:** Since atrogin-1, MuRF-1, YY1 and PTEN are putative targets of miR-23, and each of them can impact muscle wasting, we verified whether miR-23 changes the expression of each target using 3'-UTR-luciferase reporter assays. Overexpression of miR-23 in cultured muscle cells inhibits the reporter gene activities of atrogin-1 and MuRF1, suggesting that miR-23 attenuates the expression of its predicted targets. Exercise significantly increased the level of miR-23 in muscle of CKD mice vs. unexercised CKD mice. Consistent with the response, exercise decreased PTEN protein and increased Akt phosphorylation (2.3-fold, P<0.001) which would limit muscle atrophy. Exercise increased MyoD, myogenin and eMyHC, myogenic proteins that are linked to YY1 transcription factor in CKD mice. Finally, mRNAs for the muscle-specific E3 ubiquiin ligases, atrogin-1 and MuRF-1, were attenuated by exercise in CKD mice. Other muscle-specific miRs (i.e., miR-1, miR-133b and miR-206) were unchanged by exercise in muscle of CKD mice, indicating specificity of the miR-23 response.

**Conclusions:** Resistance exercise can prevent CKD-induced muscle loss by increasing miR-23. This leads to a suppression of multiple atrophy-related target proteins that may contribute to the muscle-sparing effects of exercise in CKD.

## TH-OR048

**GFR Decline as an Endpoint for Clinical Trials in CKD – A Meta-Analysis of Treatment Effects from Randomized Trials: Report of an NKF-FDA Workshop** Lesley Inker,[1] Hiddo Jan Lambers Heerspink,[4] Hasi Mondal,[1] Josef Coresh,[2] Tom Greene,[3] Andrew S. Levey.[1] *[1]Tufts Medical Center; [2]Johns Hopkins Univ; [3]Univ of Utah; [4]Univ Medical Center Groningen.*

**Background:** The FDA accepts doubling of serum creatinine (Scr) (halving of GFR), as a surrogate endpoint for kidney failure in trials of CKD progression. Substantial time is often required to reach this endpoint. Lesser declines in GFR could reduce the length of trials, increasing feasibility of RCTs. The NKF and FDA sponsored a workshop to examine data supporting alternative definitions of GFR decline as endpoints in RCT's.

**Methods:** Using a pooled dataset of 12821 patients from 43 CKD studies, we compared the treatment effect using established endpoints (EE) of dialysis, GFR<15 or 2XScr over the entire trial period to the alternative endpoints (AE) of a decline in GFR of 20, 30 or 40% over the entire period or 12, 18 and 24 months. Cox analyses were performed within study, followed by random effects analyses summarizing results across studies of same intervention.

**Results:** The table compares percent differences in hazard ratios for the treatment effect on AE's compared to the EE.

**Percent difference in HR of the AE relative to the HR of the EE**

| Intervention | All | | | 24 months | | | 18 months | | | 12 months | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | 40% | 30% | 20% | 40% | 30% | 20% | 40% | 30% | 20% | 40% | 30% | 20% |
| RASB | 4 | 12 | 25 | -4 | 6 | 19 | -6 | 2 | 19 | -2 | 6 | 18 |
| RASB vs CCB | 15 | 22 | 43 | 9 | 24 | 39 | 4 | 34 | 49 | 10 | 39 | 65 |
| BP | -2 | 4 | 9 | -8 | 3 | 12 | -8 | -5 | -2 | 17 | 11 | 7 |
| LPD | -14 | -19 | -18 | -12 | -21 | -18 | -16 | -23 | -22 | -8 | -20 | -29 |
| IS | 24 | 32 | 47 | 46 | 52 | 45 | 83 | 98 | 68 | 94 | 86 | 70 |

Renin angiotension system blockade, RASB; Calcium channel blocker, CCB; intensive blood pressure, BP; low protein diet, LPD; immunosuppressive therapy, IS

Higher values indicate greater HR for the AE (less strong treatment effect) than HR of the EE. Pooled results may not apply to each studies. Solid shading: differences in HR of ≤± 10% (white), ±10-15% (gray), or >±15% (dark gray). Hatched shading: confounded results as intervention effected by nonGFR determinants of Scr.

**Conclusions:** For some interventions, 40 or 30% decline in GFR, appears to be a reasonable alternative endpoint for CKD trials, especially for shorter time periods. Studies in patients with high GFR, such as IS studies, may not show benefit due to the short duration. Scr based AE should not be used to evaluate interventions that effect nonGFR determinants of Scr.

*Funding:* Private Foundation Support

## TH-OR049

**GFR Decline as an Alternative Endpoint for Kidney Failure – Meta-Analysis of CKD Prognosis Consortium Cohorts: A Report from an NKF FDA Workshop** Josef Coresh, Kunihiro Matsushita, Yingying Sang, Shoshana Ballew, Lawrence J. Appel, Jamie Alton Green, Gunnar H. Heine, Lesley Inker, Areef Ishani, Angharad Marks, Tanvir Chowdhury Turin, Kunitoshi Iseki, Andrew S. Levey. *CKD Prognosis Consortium.*

**Background:** The NKF and FDA convened a workshop to evaluate the evidence for using a change in GFR smaller than doubling (2x) of serum creatinine as an alternative endpoint to kidney failure in studies of CKD progression.

**Methods:** eGFR (CKD-EPI creatinine) % change from the first to last eGFR in a 2-year baseline period was related to subsequent ESRD in adjusted Cox Regression using splines. Random effects meta-analyses combined results across studies stratified by first eGFR (<60 & ≥60). Absolute ESRD risk is based on a pooled baseline risk.

**Results:** 21 cohorts with 722,221 participants reported 7,529 ESRD cases during 2.4 years average follow-up after 2-year baseline period. Log hazard ratio (HR) of ESRD increased linearly with % eGFR decline adjusted for baseline eGFR, age, sex, race, diabetes, history of CVD, cholesterol and blood pressure (Figure; eGFR<60 HR 5.1; eGFR 60+ HR 6.2 for -30% eGFR change). Association was strong and consistent even for modest, more common reductions in eGFR as well as length of baseline (1, 2 and 3 years), eGFR, age, diabetes, or ACR and slope of eGFR decline. Pooled absolute ESRD risk 10-years after baseline adjusted for covariates and competing mortality risk for eGFR changes of -57% (2x serum creatinine), -40%, -30% and 0% were 100%, 92%, 78%, vs. 28% respectively at baseline eGFR of 35.

**Conclusions:** Declines in eGFR, smaller than doubling of serum creatinine, are strongly and consistently associated with the risk of ESRD adjusted for the baseline eGFR and covariates supporting alternative endpoints for CKD progression.

**Figure**: Adjusted hazard ratio (HR) of ESRD vs. 2-year % change in eGFR: Baseline eGFR<60

## TH-OR050

**Serum Level of Soluble (Pro)renin Receptor Is Modulated in Chronic Kidney Disease (CKD) and a Novel Valuable Biomarker for Progression of CKD: A Longitudinal Follow-Up Study** Kazu Hamada,[1] Yoshiko Shimamura,[1] Koji Ogata,[1] Kosuke Inoue,[1] Yoshinori Taniguchi,[1] Masayuki Ishihara,[1] Taro Horino,[1] Kenji Yuasa,[2] Yoshio Terada.[1] *[1]Dept of Endocrinology, Matabolism and Nephrology, Kochi Medical School; [2]Kochi-Takasu-Hospital.*

**Background:** Prorenin, the precursor of renin, binds to the (pro)renin receptor ([P]RR) and triggers intracellular signaling. The ligand binding sites of (P)RR are disconnected and are present in the soluble form of the receptor in serum. Given that the clinical significance of serum prorenin and soluble (P)RR in chronic kidney disease (CKD) is unclear, no longitudinal follow-up studies have been reported to evaluate soluble (P)RR as a biomarker for renal prognosis. We investigated the relation between serum prorenin, soluble (P)RR, and various clinical parameters in patients with CKD.

**Methods:** A total of 374 patients with CKD were enrolled. Serum creatinine (Cr), blood urea nitrogen (BUN), uric acid (UA), hemoglobin (Hb), soluble secreted α-Klotho, and the urine protein/Cr ratio were also measured. Similarly, clinical parameters were also evaluated using serum and urine sample collected after 1 year (n = 204).

**Results:** Soluble (P)RR levels were positively associated with serum Cr, BUN, UA levels CKD stage and urine protein/Cr ratio. Soluble (P)RR levels were lower in patients treated with an angiotensin II receptor blocker (ARB) than in those without ARB therapy. Soluble (P)RR levels were slower in CKD patients with diabetes mellitus or primary hypertension than in those without these conditions. Soluble (P)RR levels did not correlate with prorenin levels.Finally, with respect to the relationship between basal soluble (P)RR levels and the progression rates of kidney function, soluble (P)RR levels were positively associated with ΔCr and inversely associated with ΔeGFR.

**Conclusions:** Serum levels of soluble (P)RR correlated with the stage of CKD, and had a positive correlation with the decline rate of eGFR. Our findings suggest that soluble (P)RR may be involved in renal injury and influence progression of CKD and become a novel valuable biomarker to predict the prognosis of kidney diseases.

## TH-OR051

**Elevated NT-proBNP and Kidney Function Decline** Meyeon Park,[1] Eric Vittinghoff,[1] Michael Shlipak,[1] Mary Whooley,[1] Nisha Bansal.[2] *[1]Univ of California, San Francisco; [2]Univ of Washington, Seattle.*

**Background:** Venous congestion may be an important contributor to kidney function decline even in patients without clinical heart failure (HF). N-terminal pro-brain natriuretic peptide (NT-proBNP) is released from cardiac myocytes in response to pressure or volume overload. We evaluated associations of NT-proBNP with longitudinal changes in kidney function among patients with stable coronary heart disease and without clinical HF.

**Methods:** Participants in the Heart and Soul Study had NT-proBNP measured from baseline serum samples. We excluded individuals with baseline HF and categorized NT-proBNP into quartiles, comparing the highest (>396 pg/mL) to the lowest (<72 pg/mL) quartile. We evaluated associations of NT-proBNP with longitudinal changes in estimated

glomerular filtration rate (eGFR), defined as a percent loss per year and as rapid eGFR loss (>3% eGFR loss per year). We adjusted for cardiovascular disease risk factors, echocardiography measures, and baseline kidney function.

**Results:** Among 810 participants without HF, mean age was 67 (SD 11); 82% were male; 60% were white. Median NT-proBNP was 150 pg/mL (IQR 67-377). Mean eGFR was 72 (SD 21) ml/min/1.73m$^2$. After multivariable adjustment, the highest quartile of NT-proBNP was associated with a 1.7% (0.5-3) faster loss in eGFR per year (p=0.007) compared with the lowest quartile. Participants in the highest quartile also had >5 times the odds of rapid eGFR loss compared with those in the lowest quartile (Table); findings were similar when restricted to participants with eGFR>60 ml/min/1.73m$^2$ at baseline (N=550).

| | Unadjusted OR (95% CI) | | Fully adjusted OR | | eGFR>60 only Fully adjusted OR | |
|---|---|---|---|---|---|---|
| Q1Odds of rapid eGFR loss by quartile of NT-proBNP | ref | p | ref | p | ref | p |
| Q2 | 3.0 (1.4-6.8) | 0.04 | 2.6 (1.1-6.3) | 0.04 | 2.8 (1.1-7.6) | 0.04 |
| Q3 | 3.7 (1.7-8.3) | 0.01 | 3.1 (1.2-7.7) | 0.02 | 2.6 (0.9-7.5) | 0.08 |
| Q4 | 7.8 (3.5-17.5) | <0.001 | 5.5 (2-15.1) | 0.001 | 7.4 (2.1-26.1) | 0.002 |

**Conclusions:** NT-proBNP is strongly associated with accelerated kidney function loss in individuals without HF, suggesting that venous congestion may be an important contributor to adverse kidney outcomes.

### Changes in Mortality Rates among Patients with End-Stage Renal Disease (ESRD) and Changes in Incident Rates of ESRD before and after the Great East Japan Earthquake and Tsunami 2011

Masaki Ohsawa. *Hygiene and Preventive Medicine, Iwate Medical Univ, Iwate Prefecture, Japan.*

**Background:** The Great East Japan Earthquake and Tsunami (March 11th 2011) caused significant damage to people in Iwate Prefecture (North-east area in Japan). Patients with end-stage renal disease (ESRD) are thought to be vulnerable for disasters and prolonged sedentary lifestyle during evacuation may contribute to worsening diabetic and hypertensive status of the refugees living in shelters. It is hypothesized that mortality rates in patients with ESRD increased and incident rates of ESRD increased in disaster area.

**Methods:** The Iwate ESRD registry program based on inventory survey was initiated in 2010 and this program has been continued to the present. We obtained data from the database of Iwate ESRD registry program from Iwate Medical Association. We counted total annual number of deaths in ESRD patients and total annual number of incident ESRD in Iwate Prefecture across the sea coast area (Tsunami disaster area) and inland region, respectively, in 2010 and 2011 (disaster year).

**Results:** The results are shown in the table. There were 4 ESRD patients who were missing and feared dead after Tsunami disaster in sea coast area.

| | 2009/12/31 | 2010/01/01-2010/12/31 | 2010/12/31 | 2011/01/01-2011/12/31 | 2011/12/31 |
|---|---|---|---|---|---|
| sea coast area total population | 128,635 | | 128,873 | | 124,982 |
| ESRD (prevalence /Million) | 318 (2472) | | 329 (2553) | | 360 (2880) |
| deaths | | 36 | | 27 | |
| incident of ESRD | | 47 | | 58 | |
| annual mortality (/1000 person-years (pys)) | | 113.2 | | 82.1 | |
| annual incidence (/1000 pys) | | 0.365 | | 0.450 | |
| inland region total population | 440,296 | | 439,762 | | 440,611 |
| ESRD (prevalence/Million) | 1,056 (2398) | | 1,074 (2442) | | 1,096 (2487) |
| deaths | | 121 | | 106 | |
| incident of ESRD | | 139 | | 128 | |
| annual mortality (/1000 pys) | | 114.6 | | 98.7 | |
| annual incidence (/1000 pys) | | 0.316 | | 0.291 | |

**Conclusions:** Mortality rates in patients with ESRD did not increase after The Great East Japan Earthquake and Tsunami. Incident rates of ESRD increased in Tsunami disaster area after the disaster.

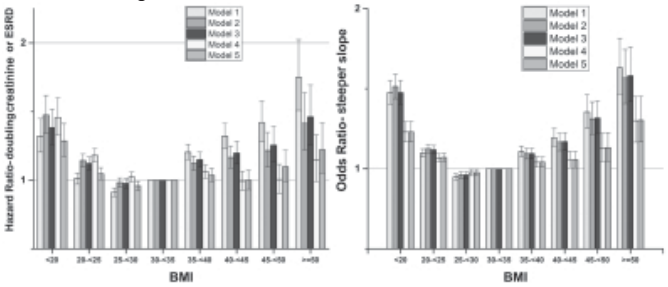
### Association of Body Mass Index with Progression of Kidney Disease in Patients with Non-Dialysis Dependent CKD

Jun Ling Lu,[1] Kamyar Kalantar-Zadeh,[2] Jennie Z. Ma,[3] Leigh Darryl Quarles,[1] Csaba P. Kovesdy.[1,4] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Harold Simmons Center for Chronic Disease Research and Epidemiology, Univ of California Irvine, Orange, CA; [3]Univ of Virginia, Charlottesville, VA; [4]Memphis VA Medical Center, Memphis, TN.*

**Background:** The association of obesity with progression of kidney disease in patients with non-dialysis dependent chronic kidney disease (NDD-CKD) is unclear.

**Methods:** We examined the association of BMI with CKD progression in a national cohort of 453,946 US veterans with estimated glomerular filtration rate (eGFR) <60ml/min/1.73m$^2$. CKD progression was defined as the incidence of the composite of doubling of serum creatinine or End Stage Renal Disease (ESRD), and as the risk of slopes of eGFR <-4 ml/min/1.73m$^2$/year. Associations were examined in crude (Model 1) and in multivariable adjusted Cox models and logistic regression models. Adjustments were made for age (Model 2), race (Model 3), comorbidities and medications (Model 4), and baseline estimated GFR (Model 5).

**Results:** The mean age (Standard Deviation [SD]) was 73.9(9.3) years, 9.1% were African American, and the mean estimated GFR (SD) was 47.8 (9.9) ml/min/1.73m$^2$. 148,276 patients died (mortality rate: 73.9/1000 Patient-Year (95% confidence interval [CI]:73.5-74.3)). BMI showed U-shaped association with both the incidence of the composite renal end point (Figure 1), and the risk of steeper slopes (Figure 2). Patients with BMI 25-30 kg/m$^2$ had the best outcomes.



**Conclusions:** The association of BMI with kidney disease is complex, with both relatively low and high BMI showing increased risk of progressive CKD. Overweight patients with CKD appear to have the best renal outcomes.

## TH-OR054

### Percutaneous Coronary Intervention versus Optimal Medical Therapy for Stable Angina in Late-Stage Chronic Kidney Disease: A Decision Analysis

Ernest I. Mandel,[1] Matthew R. Reynolds,[2] David M. Charytan.[1] *[1]Renal Div, Dept of Medicine, Brigham and Women's Hospital, Boston, MA; [2]Dept of Cardiovascular Medicine, Lahey Clinic Medical Center, Burlington, MA.*

**Background:** Performing percutaneous coronary interventions (PCI) in the setting of stable symptomatic angina is often deferred in late-stage chronic kidney disease until necessitated by a more acute indication or until dialysis has been initiated. Whether immediate PCI or deferral of PCI in favor of optimal medical management (MM) improves quality of life or survival is uncertain.

**Methods:** Quality-adjusted life-years (QALYs) following PCI vs. MM in late-stage CKD and stable symptomatic angina were compared in a decision analysis. A Markov model was created to capture the possible disease states taking into account successful relief of symptomatic angina from the chosen intervention, dialysis-dependence as a result of CKD progression or contrast-induced nephropathy (CIN) from PCI, and procedural morbidity and mortality. Utilities and transition probabilities were derived from previous studies, literature review, and USRDS data. The Markov model was run in 3-month cycles for a total of three years of follow-up. Probabilistic sensitivity analyses on the likelihood of dialysis-dependent CIN and other transition probabilities were conducted using Monte Carlo simulation with 10,000 trials.

**Results:** The PCI strategy yielded a mean (SD) of 1.44 (0.04) QALYs over three years of follow-up while the MM strategy yielded a mean of 1.40 (0.04) QALYs (p<0.0001). The difference (95% CI) in QALYs between the two strategies was 0.038 (0.037 to 0.039). The probability of dialysis-requiring CIN at which the advanced CKD patient would be indifferent between MM and PCI, or over which would prefer MM, was 0.42.

**Conclusions:** A strategy of PCI for relief of stable symptomatic angina yielded higher expected QALYs than MM. The probability of CIN at which the decision would be indifferent or above which MM would be preferred is significantly higher than the observed probability of dialysis-requiring CIN in any previous studies. PCI should be considered despite concern over CIN in carefully selected late-stage CKD.

## TH-OR055

### Monogenic Forms of Nephrotic Syndrome Occur in Diverse Genes across the Lifespan in North American Subjects

Matthew G. Sampson,[1,2,3] Edgar Otto,[1] J Troost,[1,2,3] Crystal A. Gadegbeku,[2,3,4] Matthias Kretzler.[1,2,3] *[1]Univ of Michigan, Ann Arbor, MI; [2]Nephrotic Syndrome Study Network (NEPTUNE); [3]The Michigan O'Brien Renal Center; [4]Temple Univ, Philadelphia, PA.*

**Background:** The frequency of causal mutations in children and adults with nephrotic syndrome (NS) in North American nephrology practices is unknown. This is in part because genetic and phenotypic heterogeneity of NS, and cost, precludes sequencing all known NS genes in all affected patients. To address this, we sequenced 21 monogenic NS genes in 103 unselected NS subjects from two prospective, multi-center glomerular disease cohorts.

**Methods:** NEPTUNE (n=67) enrolls at time of initial clinical biopsy and CPROBE (n=36) enrolls incident and prevalent patients. Recruitment is not based on age, suspicion of genetic NS, or steroid resistance. Subjects had either minimal change disease or FSGS on biopsy. All exons of 21 NS-associated genes were analyzed by microfluidic PCR paired with Next-Gen sequencing. After mapping and comparison to the Exome Variant Server, variants with minor allele frequency <1% (and *NPHS2* R229Q variant) were validated by Sanger sequencing. Variants deemed causal were based on previous reports of pathogenicity, <0.3% frequency or absence in control populations, and cross species conservation.

**Results:** 8/103 (8%) of NS subjects had a probable monogenic cause (5/8 > age 21; 0/8 with family history of NS). Variants were found in *NPHS2* (3), *ACTN4*, *CD2AP*, *LMX1B*, *MYO1E*, and *WT1*. These included a person in their 60's with compound heterozygosity of *MYO1E*, their 40s with an *LMX1B* variant, and a teen with a *CD2AP* variant. The five adult-onset subjects had variants in five different genes.

**Conclusions:** High-throughput sequencing reveals a diverse set of genetic forms of NS in 8% of this phenotypically varied cohort. This suggests that in sporadically affected subjects, targeting only subsets of genes based on age or other characteristics may result in missing genetic causes of NS. Discovery of additional monogenic NS genes will increase the prevalence of mongenic forms of NS. More frequent, or functional non-coding, NS-associated risk variants may explain a portion of the remaining heritability.

## TH-OR056

**Mutation-Dependent Recessive Inheritance in *NPHS2*-Associated Steroid-Resistant Nephrotic Syndrome** Kalman Tory,[1,2,3] Dora K. Menyhard,[4] Fabien Nevo,[1,3] Olivier Gribouval,[1,3] Andrea Kerti,[2] Pal Straner,[4] Christelle Arrondel,[1,3] Evelyne Huynh Cong,[1,3] Stephanie Woerner,[1,3] Tivadar Tulassay,[2,5] Geraldine Mollet,[1,3] Andras Perczel,[4] Corinne Antignac.[1,3] *[1]Inserm U983, Necker Hospital, Paris, France; [2]Ist Dept of Pediatrics, Semmelweis Univ, Budapest, Hungary; [3]Institut Imagine, Univ Paris Descartes, Paris, France; [4]MTA-ELTE Protein Modeling Research Group, Eötvös Loránd Univ, Budapest, Hungary.*

**Background:** *NPHS2*, encoding podocin, is the most frequently mutated gene in steroid-resistant nephrotic syndrome (SRNS). Patients who are compound heterozygous for an *NPHS2* mutation and the R229Q polymorphism ([R229Q];[mutation]) are expected to develop late-onset SRNS with a complete penetrance.

**Methods:** Based on epidemiological data, we hypothesized that the penetrance of late-onset SRNS in patients with [R229Q];[mutation] is incomplete. Therefore, we (1) screened 129 parents of affected children with *NPHS2* mutations for the R229Q variant, (2) compared the position of the *NPHS2* mutations between patients with two mutations and patients with [R229Q];[mutation], (3) coexpressed different R229Q-associated podocin mutants with podocin$^{R229Q}$ and podocin$^{wt}$ in human podocytes and (4) calculated the structure of different podocin dimers based on a homology model of P. horikoshii stomatin.

**Results:** Six of 129 unaffected parents carried [R229Q];[mutation], proving that the penetrance of late-onset SRNS is indeed incomplete. Though missense mutations of exons 7 and 8 are rare among *NPHS2* mutations (34/498, 6.8%), we found these mutations to be associated to R229Q in the vast majority of patients with late-onset SRNS (56/71, 78.9%, $p=1.4 \times 10^{-39}$). These podocin mutants retained podocin$^{R229Q}$ but not podocin$^{wt}$ in the cytoplasm and formed an abnormal heterodimer with podocin$^{R229Q}$. Podocin mutants that were non-pathogenic with R229Q did not change the subcellular localization of podocin$^{R229Q}$.

**Conclusions:** The R229Q variant is only pathogenic when associated to specific mutations. This is secondary to an altered dimerization and mislocalization of podocin dimers. The normal structure and localization of podocin$^{R229Q}$ homodimer explains the late-onset nature of SRNS in patients with [R229Q];[mutation].

## TH-OR057

**MiR-17-92 Is Required for Nephrogenesis and Renal Function** April Marrone,[1] Sheldon Bastacky,[3] Donna Beer Stolz,[2] Andrew J. Bodnar,[1] Jacqueline Ho.[1] *[1]Div of Nephrology, Dept of Pediatrics, School of Medicine, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Cell Biology, Univ of Pittsburgh, Pittsburgh, PA; [3]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA.*

**Background:** MicroRNAs (miRNAs) are small non-coding RNAs that act as novel regulators of gene expression through the repression of their target mRNAs. Although deletion of miRNAs in nephron progenitors demonstrates a critical role for miRNAs in progenitor survival, the specific miRNAs responsible have not been identified. Deletions in the *MIR17HG* cluster (*miR-17~92* in mice) represent the first miRNA mutations to be associated with a developmental defect in humans, leading to Feingold syndrome. While *MIR17HG* is expressed in the developing kidney, and a subset of patients with Feingold syndrome have renal anomalies, it remains unclear to what extent *MIR17HG* contributes to renal development and function.

**Methods:** To define the role of *miR-17~92*, we generated a conditional deletion of *miR-17~92* in nephron progenitors and their derivatives in mice, resulting in renal hypodysplasia.

**Results:** The nephron progenitor population is preserved; however, there are decreased developing nephrons. Cell division analyses throughout embryogenesis suggests that progenitors and their progeny divide less in the absence of *miR-17~92*, providing a possible mechanism causing low nephron endowment. Postnatally, the mice develop signs of renal disease by six weeks with albuminuria, and then focal podocyte foot process effacement and glomerulosclerosis at three months.

**Conclusions:** Taken together, these data support the first role for a single miRNA cluster in renal development, specifically in the regulation of nephron development, with subsequent consequences for renal function in adult mice.

## TH-OR058

**A Novel Variant of the Mitochondrial Heavy Strand Promoter Causes Renal Disease and Reduced Oxygen Consumption** Thomas Michael Connor,[1] Daniel P. Gale,[1] Phillippa J. Carling,[2] Gavin Hudson,[2] Patrick F. Chinnery,[2] Patrick H. Maxwell.[1] *[1]UCL Centre for Nephrology, Univ College London, London, United Kingdom; [2]Institute of Genetic Medicine, Univ of Newcastle, Newcastle, United Kingdom.*

**Background:** In the past few years, mitochondrial dysfunction has become a focus of research in human disease. Disorders of mitochondrial DNA (mtDNA) are an important cause of genetic disease and produce highly variable clinical features. There is a renal phenotype associated with a number of complex mitochondrial disorders, and evidence of an increased frequency of single nucleotide polymorphisms and deletions in end-stage renal disease. To date, the majority of pathogenic mutations have involved coding regions of the mitochondrial genome. We investigated a large Caucasian pedigree that included 17 individuals affected with adult-onset renal disease in the maternal line. There were no extra-renal signs in any of the affected individuals.

**Methods:** DNA was genotyped using the Illumina 300K chip. The mitochondrial genome was sequenced using Big Dye Terminator cycle sequencing and compared with the reference sequence. Primary dermal fibroblasts were cultured from four affected individuals and three healthy controls. Cybrids were created by fusion with 143B rho zero cells. Mitochondrial respiration was measured using the Seahorse XF bioanalyser.

**Results:** Linkage analysis demonstrated extra-chromosomal inheritance in this family. Mitochondrial sequencing showed the presence of a novel polymorphism located within the heavy strand promoter 1 (HSP1) and expressed at homoplastic levels. Primary fibroblasts showed a reduction in the ratio of transcripts from the HSP1 and a reduced rate of oxygen consumption. These findings were confirmed in mitochondrial cybrids, which showed an even greater reduction in HSP1 transcription and mitochondrial protein synthesis.

**Conclusions:** This is the first description of familial nephropathy due to a mutation in the mitochondrial heavy strand promoter. Reduced promoter function results in decreased transcription, and causes reduced oxygen consumption with a compensatory increase in glycolysis. These findings confirm the importance of mitochondrial function in renal disease.

*Funding:* Government Support - Non-U.S.

## TH-OR059

**Mutation Analysis in 30 Mouse Model Candidate Genes in 790 Humans with Isolated CAKUT** Stefan Kohl,[1] Gabriel C. Dworschak,[1,5] Alina Hilger,[2,5] Pawaree Saisawat,[2] Elijah O. Kehinde,[3] Radovan Bogdanovic,[4] Heiko M. Reutter,[5] Velibor Tasic,[6] Friedhelm Hildebrandt.[1,7] *[1]Dept of Nephrology, Boston Children's Hospital, Boston; [2]Dept of Pediatrics, Univ of Michigan, Ann Arbor; [3]Dept of Surgery, Kuwait Univ, Safat, Kuwait; [4]Medical Faculty, Univ of Belgrade, Belgrade, Serbia; [5]Institute of Human Genetics, Univ of Bonn, Bonn, Germany; [6]Dept of Pediatric Nephrology, Children's Hospital, Skopje, Macedonia, The Former Yugoslav Republic of; [7]Howard Hughes Medical Institute, Chevy Chase.*

**Background:** Congenital anomalies of the kidney and urinary tract (CAKUT) account for ~50% of the ESRD-cases in children. In order to identify single-gene causes of CAKUT, we performed exon resequencing in 790 children (690 families) with non-syndromic CAKUT examining 30 genes that (i) cause unilateral renal agenesis in mice and (ii) previously have not been implicated in pathogenesis of human CAKUT.

**Methods:** The coding sequences of 30 genes were re-sequenced using a high-throughput mutation analysis by array-based PCR (Fluidigm®) and next-generation sequencing (1). (1) Halbritter, J Med Genet, 49: 756, 2012.

**Results:** We detected homozygous or compound heterozygous variants in six genes. In the Fraser syndrome-causing genes, *FRAS1*, *FREM2*, and *GRIP1*, we detected recessive hypomorphic mutations in 17 unrelated individuals with isolated CAKUT. Furthermore, we identified a homozygous missense mutation in *GLI3* (c.316G>C, p.G106R) in an individual with left duplex ureter and UPJO. In *LHX1*, we found a homozygous missense mutation (c.159C>G, p.N53K) in an individual with left multicystic dysplastic kidney. A homozygous spice site mutation in *ITGA8* (c.2982+2T>C) was present in an individual with ureter duplex.

**Conclusions:** Our results indicate that in genes known to cause Fraser syndrome if truncating alleles are present, hypomorphic mutations cause isolated CAKUT. In 690 families with CAKUT we can molecularly "solve" ~2.5% with recessive hypomorphic mutations in *FRAS1*, *FREM2*, and *GRIP1*. Furthermore, we identified in 3 genes that cause CAKUT in mice mutations in 3 families, thereby making them candidates for mutation analysis in future studies.

## TH-OR060

**Copy-Number Variation in Children with a Solitary Functioning Kidney – The KIMONO-GENE Study** Rik Westland,[1,2] Brittany J. Perry,[1] Miguel VERBITSKY,[1] Michiel Schreuder,[3] Petra Jg Zwijnenburg,[4] Ali G. Gharavi,[1] Joanna Van Wijk,[2] Simone Sanna-Cherchi.[1] *[1]Div of Nephrology, Columbia Univ, New York City, NY; [2]Dept of Pediatric Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [3]Dept of Pediatric Nephrology, Radboud Univ Nijmegen Medical Centre, Nijmegen, Netherlands; [4]Dept of Clinical Genetics, VU Univ Medical Center, Amsterdam, Netherlands.*

**Background:** Rare genic copy-number variations (CNVs) have been associated with congenital renal malformations. We investigated the role of rare CNVs in children with a solitary functioning kidney derived from the KIMONO study.

**Methods:** Genome-wide genotyping for CNV analysis was performed with the Illumina OmniExpress platform (730k markers). PennCNV was used to determine the CNV calls using generalized genotyping methods. To identify rare pathogenic CNVs, we compared data to 23,362 controls. Criteria for pathogenic CNVs were: 1) CNV-size ≥100kb, 2) confidence score ≥30 and 3) frequency of <1:5,000 in controls.

**Results:** 64 children with a solitary functioning kidney were included. Clinical phenotypes were renal hypodysplasia (48%), unilateral renal agenesis (30%), vesicoureteric reflux (14%) and obstructive nephropathy (8%). A total of 99 large, high-quality CNVs were identified (mean 1.55 per case), of which 58 (59%) were duplications and 41 (41%) were deletions. Median CNV-size was 173kb (IQR 133–250kb). CNVs overlapping significantly with known genomic disorders were identified in 6 (9%) patients (e.g. 3p29 microdeletion syndrome, 16p13.11 duplication and 16p12.1 distal deletion). Furthermore, 6 (9%) children were found to carry CNVs that were larger than 250kb, disrupting coding segments and absent or extremely rare in controls, representing potential novel genomic disorders. The identified genomic disorders occurred in all phenotypes.

**Conclusions:** The KIMONO-GENE study demonstrates that genomic disorders can be identified in almost one in five children with a solitary functioning kidney. As our findings underline the pivotal role of copy-number disorders in congenital kidney malformations, the identification of pathogenic CNVs should be considered in order to establish a molecular diagnosis in these patients.

## TH-OR061

**A Novel Mutation Specific Cause of Fanconi Syndrome and Nephrocalcinosis in *HNF4A*** Alexander J. Hamilton,[1,2] Coralie Bingham,[2] Sian Ellard,[1] Andrew Hattersley.[1] *[1]Univ of Exeter Medical School, Exeter, Devon, United Kingdom; [2]Renal Unit, Royal Devon and Exeter Hospital, Exeter, Devon, United Kingdom.*

**Background:** We have identified 5 individuals from 3 families with an *HNF4A* R76W mutation that co-segregates with Fanconi syndrome and nephrocalcinosis. *HNF4A* mutations cause maturity onset diabetes of the young (MODY), but are not among the 8 genes known to cause proximal tubulopathy. We aimed to describe this new phenotype and establish if this was a generalised or mutation specific effect by comparison with a cohort of patients with other HNF4A mutations.

**Methods:** We measured fasted urines in the R76W group and in 20 patients with other *HNF4A* mutations. Renal ultrasounds were performed in 15 patients. Results were compared using the independent samples median test or Z scores.

**Results:**

| | R76W (n=5) | Other *HNF4A* (n=20) | |
|---|---|---|---|
| Urinary α1-microglobulin mg/l, median | 264.0 | 6.0 | *p=0.005* |
| Urinary β2-microglobulin mg/l, median | 66.4 | 0.3 | *p<0.0001* |
| Urinary retinol binding protein mg/l, median | 128.0 | 2.0 | *p<0.0001* |
| Urinary glucose mmol/l, median | 62.3 | 0.3 | *p=0.005* |
| Serum urate umol/L, median | 102.0 | 268.0 | *p=0.002* |
| Serum magnesium mmol/l, median | 1.11 | 0.82 | *p=0.03* |
| Serum calcium mmol/l, median | 2.11 | 2.39 | *p<0.0001* |
| Urinary calcium:creatinine mmol(Ca)/m, median | 1.04 | 0.5 | *p=0.6* |
| Serum creatinine mg/dl, median | 1.33 | 0.95 | *p=0.004* |
| Nephrocalcinosis on ultrasound | 5/5 | 0/10 | |
| Amino acids, mean Z score | 24.3 | -0.16 | |

**Conclusions:** Patients with the *HNF4A* R76W mutation have a novel and specific phenotype of proximal tubulopathy and nephrocalcinosis characterised by aminoaciduria, massive low molecular weight proteinuria and glycosuria. These features were not seen in 20 patients with other *HNF4A* mutations. *In silico* modelling suggests that the R76 residue is involved in DNA binding to promoters and we hypothesize that the mutation may affect target specificity. This is the first description of a mutation specific effect in the MODY genes, hitherto not known to be related to renal tubular dysfunction or renal tract calcification.

*Funding:* Government Support - Non-U.S.

## TH-OR062

**Mutations in PAX2 Cause Adult-Onset Familial Focal and Segmental Glomerulosclerosis** Moumita Barua,[1] Emilia Stellacci,[2] Lorenzo Stella,[5] Astrid Weins,[3] Giulio Genovese,[4] Valentina Muto,[2] Hakan R. Toka,[1] Victoria Charoonratana,[1] Martin R. Pollak.[1] *[1]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Dipartimento di Ematologia, Istituto Superiore di Sanità, Rome, Italy; [3]Pathology, Brigham and Women's Hospital, Boston, MA; [4]Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA; [5]Dipartimento di Scienze e Tecnologie Chimiche, Università di Roma Tor Vergata, Rome, Italy.*

**Background:** FSGS is a histologically defined kidney injury characterized by sclerosis of some but not all glomeruli. Mutations in the transcription factor gene, *PAX2*, have been shown to cause congenital abnormalities of the kidney and urinary tract (CAKUT) as part of an autosomal dominant condition named papillorenal syndrome. We show that *PAX2* mutations leads to FSGS and demonstrate the mechanisms of disease.

**Methods:** Exome sequencing in a family with adult-onset FSGS revealed a suspicious *PAX2* variant. *PAX2* was sequenced in 175 FSGS families and 85 CAKUT individuals. *In silico* analysis and functional assays consisting of DNA binding and transactivation studies were performed. Immunohistochemistry to evaluate the impact of dysregulated PAX2 on expression of a target, WT1, was done.

**Results:** Six and seven heterozygous non-synonymous private variants were found in the familial FSGS and CAKUT cohort, respectively. There was an enrichment of rare variants in the patient groups compared to controls ($p<0.05$). In the CAKUT group, most variants localized within the transactivation domain while those in the FSGS group localized to outside of this region. As predicted, the PAX2 paired domain variant impaired DNA binding and transactivation activity while the PAX2 octapeptide variant resulted in enhanced repressor activity without affecting DNA binding. Immunohistochemical staining revealed reduced WT1 expression in both sclerosed and non-sclerosed glomeruli.

**Conclusions:** *PAX2* mutations leads to FSGS and CAKUT. Functional studies suggest that mutations lead to haploinsufficiency or dominant negative effects. Dysregulation of PAX2 targets expressed in the podocyte such as WT1 may lead to FSGS by disruption of this cell critical for filtration.

## TH-OR063

**IQCJ Podocytopathy Causes Primary Renal Failure and De Novo Membranous Nephropathy Post Transplantation** Rachel Lennon,[1] Edward A. McKenzie,[1] Sarah B. Daly,[1] Helen Mary Stuart,[1] Jill Clayton-Smith,[1] Shelly Harris,[2] Lorna J. McWilliam,[2] Colin Short,[2] Laurence R. Solomon,[3] Ian Roberts,[4] Ron Korstanje,[5] Mario Schiffer,[6] Paul E. Brenchley.[1] *[1]Univ of Manchester, United Kingdom; [2]Central Manchester NHS Trust, United Kingdom; [3]Lancashire Teaching Hospitals, Preston, United Kingdom; [4]Univ of Oxford, Oxford, United Kingdom; [5]Jackson Labs, Bar Harbor; [6]Univ Medical School, Hannover, Germany.*

**Background:** We describe a novel podocytopathy causing primary renal failure in two siblings identified following "de novo" membranous nephropathy (MN) in their allografts.

**Methods:** A consanguineous family where parents and two children suffered CKD was investigated genetically following the post transplant development of de novo MN in both siblings resulting in allograft loss within two years. Autozygosity mapping identified a novel gene deletion of 129kb, near IQ Domain-Containing Protein J (IQCJ) on chr 3. Exome sequencing excluded known podocytopathies. Native kidney biopsy of an affected sibling showed a podocytopathy and excluded MN. In vitro and in vivo experimental systems were used to investigate the biological function of IQCJ.

**Results:** Parents were heterozygous and affected siblings homozygous for the gene deletion. Both affected cases became seropositive for anti-IQCJ antibodies detected by ELISA post transplantation. Immunostaining of normal kidney for IQCJ showed podocyte specific staining. In cultured normal podocytes, mRNA transcript for IQCJ was detected by PCR and immunostaining with anti-IQCJ located the antigen in transport vesicles with a distribution from perinuclear to cell membrane showing colocalisation with known transport proteins.Transient knock down of IQCJ mRNA in zebrafish caused edema consistent with a glomerular phenotype.

**Conclusions:** Alloimmunization post transplantation can reveal abnormal gene/protein expression causing the primary renal disease e.g. Alports Disease. Such a mechanism may explain two different rare phenotypes (in native and allograft kidney) occurring in this family and caused by a single podocyte gene, IQCJ. This gene may play a wider role in primary glomerulopathies and as a target for "de novo" MN post transplantation.

## TH-OR064

**Mutations in *DGKE* Cause a Novel Form of Recessive Atypical Hemolytic-Uremic Syndrome without Complement Activation** Mathieu Lemaire,[1,2] Veronique Fremeaux-Bacchi,[3,4] Franz S. Schaefer,[5] Murim Choi,[1,2,6] Jack Tang,[1] Moglie Le Quintrec,[4] Fadi Fakhouri,[7] Sophie Taque,[8] Francois Nobili,[9] Weizhen Ji,[1,2] John Overton,[1,6] Shrikant M. Mane,[1,6] Gudrun Nürnberg,[10] Denis Morin,[11] Véronique Baudouin,[12] Brigitte Llanas,[13] Eva Simkova,[14] Peter Nuernberg,[10,15] Gilbert W. Moeckel,[1] John Hwa,[1] Chantal Loirat,[12] Richard P. Lifton.[1,2,6] *[1]Yale Univ; [2]Howard Hughes Medical Institute; [3]Hôpital Européen Georges-Pompidou; [4]Centre de Recherche des Cordeliers; [5]Heidelberg Univ; [6]Yale Center for Mendelian Genomics; [7]CHU Nantes; [8]CHU Rennes; [9]CHU Besançon; [10]Univ of Cologne; [11]CHU Montpellier; [12]Hôpital Universitaire Robert-Debré; [13]CHU Bordeaux; [14]Dubai Hospital; [15]ATLAS Biolabs GmbH.*

**Background:** Atypical Hemolytic-uremic syndrome (aHUS) is caused by pathological complement activation due to hereditary or acquired factors. Renal outcomes have improved since eculizumab (anti-C5) was introduced. Half of cases remain unexplained.

**Methods:** We performed exome sequencing on samples from two unrelated families each with 2 affected children. Bioinformatics analysis yielded a list of variants shared by each sibling set: gene(s) present in both lists were sequenced to find mutations in other aHUS patients. Expression of candidate genes in human and rodent tissues was tested with protein blotting and immunohistochemistry.

**Results:** We identified rare recessive damaging and missense mutations in *DGKE* (diacylglycerol kinase ε): mutations co-segregated with disease in 13 subjects from 9 unrelated kindreds. All patients presented before age 1, none had overt complement abnormalities, many developed chronic kidney disease with age, transplantation was uneventful in 3, and one had a HUS relapse while on eculizumab. DGKE protein is found in glomerular endothelium, podocytes, and platelets. DGKE terminates signaling by arachidonic acid-containing diacylglycerols, a potent activator of protein kinase C.

**Conclusions:** We infer that loss of *DGKE* function causes a novel form of renal thrombotic microangiopathy that does not require complement activation. The limited benefits of eculizumab for patients with *DGKE* nephropathy may lead to revision of aHUS treatment guidelines.

## TH-OR065

**Differential Role of IL-6 Classical and Trans-Signaling in Crescentic Nephritis** Yoshikuni Nagayama,[1] Gerald S. Braun,[1] Claudia R.C. van Roeyen,[1] Luigi Villa,[1] Barbara Mara Klinkhammer,[1] Stefan Rose-John,[2] Tammo Ostendorf,[1] Jürgen Floege.[1] *[1]Div of Nephrology, RWTH Univ, Aachen, Germany; [2]Institute for Biochemistry, Christian-Albrechts-Univ, Kiel, Germany.*

**Background:** The role of IL-6 signaling in renal diseases remains controversial with data describing both anti- and pro-inflammatory effects. IL-6 can act via classical signaling engaging its two membrane receptors gp130 and IL-6R (anti-inflammatory potential). Alternatively, trans-signaling employs the soluble IL-6R (sIL-6R) to act on IL-6R negative cells (mostly pro-inflammatory). The aim of this study was to characterize the differential role of both pathways in crescentic nephritis (CN).

**Methods:** Human sera and urine samples from CN patients were analyzed. Nephrotoxic nephritis (NTN) was induced in Balb/c mice. Time-dependent IL-6 signaling was characterized. Specific blocking or activation of classical and trans-signaling was performed.

**Results:** Patients with CN had significantly elevated levels of serum IL-6 and of urinary IL-6, sIL-6R, and the endogenous trans-signaling inhibitor, sgp130. Consistent with this, NTN mice showed an early peak of both serum IL-6 and urinary IL-6, sIL-6R, and sgp130 levels. Serum sIL-6R and renal downstream signals (pSTAT-3, SOCS-3 mRNA) increased over time, suggesting increased trans-signaling. Simultaneous inhibition of both IL-6 signaling pathways using anti-IL-6 antibody did not impact on NTN severity when compared to treatment with isotype IgG. By contrast, specific inhibition of trans-signaling using recombinant sgp130fc (3 mg/kg) resulted in milder disease when compared to PBS-treated controls (crescents 4 ±6 vs. 10±7%, means±SD, $p<0.05$; necrosis score 0.5±0.6 vs. 1.2±0.8, $p<0.05$). Vice versa, specific activation of trans-signaling using a recombinant IL-6-sIL-6R fusion molecule ("hyper-IL-6") significantly aggravated NTN. This correlated with an increased synthesis of renal IL-17 mRNA.

**Conclusions:** Collectively our data suggest a central role for trans-signaling in crescentic nephritis. Global inhibition of IL-6 signaling was not beneficial during a model of NTN in Balb/c mice. On the other hand, specific antagonism of trans-signaling may represent a novel therapeutic approach.

## TH-OR066

**Plasticity of Th17 Cells in Crescentic Glomerulonephritis** Christian Franz Krebs, Jan-Eric Turner, Hans-Joachim Paust, Sonja Kapffer, Sabrina Bianca Bennstein, Anett Peters, Rolf A. Stahl, Ulf Panzer. *UKE Hamburg, Nephrology, Hamburg, Germany.*

**Background:** $CD4^+$ T cells play a pivotal role in the pathogenesis of autoimmune disease, including human and experimental crescentic glomerulonephritis, by their ability to differentiate into pathogenic effector $T_H1$ and $T_H17$ cells or protective Treg cells. Classically, these $CD4^+$ T cell subsets have been viewed as terminally differentiated lineages with limited flexibility. The aim of the present study was to analyze the potential plasticity of $CD4^+$ $T_H17$ cells in experimental crescentic GN (nephrotoxic nephritis, NTN).

**Methods:** To study the fate of $CD4^+$ T cells during the course of NTN we performed three different approaches: (i) the adoptive transfer of in vitro polarized $T_H0$ or $T_H17$ cells in nephritic Rag-1-deficent mice; (ii) the use of a fluorescent acute activity reporter mice to directly detect, sort, and transfer IL-17A$^+$ ($T_H17$) $CD4^+$ T cells and (iii) the use of a IL-17A fate reporter mice to analyze renal 'ex-Th17' cells by flow cytometry.

**Results:** In vitro polarized 'bulk' $T_H17$ and $T_H0$ cells were transferred into Rag-1$^{-/-}$ mice, subsequently NTN was induced. As expected 10 days after nephritis induction renal tissue injury was aggravated in mice that received $T_H17$ cells. Interestingly, > 50 % of the transferred $T_H17$-polarized cells started to express IFN-gamma, a feature of $T_H1$ cells. To acquire a highly pure $T_H17$ population we FACS sorted IL-17A$^+$ cells from fluorescent acute reporter mice after $T_H17$ polarization in vitro (>95 % purity) and transferred them into nephritic Rag-1-deficient mice. The majority (>90%) of transferred $T_H17$ cells lost their IL-17A production and 25 % expressed IFN-γ. Furthermore, analysis of fate-mapped 'ex-$T_H17$' cells in IL-17A fate reporter mice (IL-17A Cre x Rosa26eYFP mice) with NTN showed that only a minor proportion of $T_H17$ cells (~15%) lost IL-17A production during the course of the nephritis, indicating that in vivo derived $T_H17$ cells are stable in NTN.

**Conclusions:** Here we show that in vitro polarized $T_H17$ cells have a high degree of plasticity during the course of the nephritis, whereas in vivo acquired $T_H17$ cells have a more stable phenotype in experimental crescentic glomerulonephritis.

## TH-OR067

**Inhibition of IL-6 Receptor Attenuates Autoimmunity and Glomerulonephritis in Experimental ANCA Vasculitis** Sharon Lee Ford,[1] Michael Mülleneisen,[2] Stefan Rose-John,[3] Stephen R. Holdsworth,[1] Shaun A. Summers,[1] Oliver M. Steinmetz.[2] *[1]Centre for Inflammatory Diseases, Monash Medical Centre, Melbourne, Australia; [2]III. Med. Klinik, Univ of Hamburg, Germany; [3]Biochemistry, Univ of Kiel, Germany.*

**Background:** The pleiotropic cytokine IL-6, critically required for Th17 immunity, is elevated in patients with ANCA vasculitis. IL-6 signaling occurs via the classic pathway using membrane bound IL-6 receptor (mIL-6R) and the trans-pathway via soluble IL-6 receptor (sIL-6R). Anti-IL-6R therapy has recently been established as treatment for rheumatoid arthritis while the role in renal disease remains unclear.

**Methods:** We induced autoimmune anti-myeloperoxidase (MPO) glomerulonephritis (AIaMPOGN) by immunising C57BL/6 mice with murine MPO. Renal injury was triggered after 14 days by administration of a sub-nephritogenic dose of nephrotoxic serum. Effects of IL-6 inhibition administered during the induction phase (days -1 and 7) or during the effector phase (day 14) of injury were assessed using antibodies targeting IL-6, mIL-6R (classical and trans pathway), or sIL-6R (trans pathway only).

**Results:** mIL-6R blockade during the induction phase attenuated humoral and cellular autoimmunity. Anti-MPO IgG levels as well as spleen sizes and proliferative activity were significantly reduced. In line, MPO-stimulated splenocyte IL-17A and IFNγ production was impaired in anti mIL-6R treated mice. Importantly, renal injury was also attenuated in terms of histological damage and albuminuria. To clarify the role of IL-6 as effector cytokine, we also studied IL-6 pathway blockade in the effector phase of AIaMPOGN. However, neither systemic autoimmunity nor renal injury was altered by effector phase blockade of either IL-6, mIL-6R or sIL-6R.

**Conclusions:** IL-6 critically directs development of cellular and humoral autoimmunity in ANCA associated glomerulonephritis but does not seem to play a major role as effector cytokine. Early mIL-6R blockade significantly attenuated glomerulonephritis and therefore offers exciting therapeutic potential for ANCA vasculitis.

*Funding:* Government Support - Non-U.S.

## TH-OR068

**Functionally Active C3 and Other Complement Components Are Secreted by Human Podocytes** Anne Katrin Dettmar,[1] Isabell Kopka,[2] Christoph Licht,[3] Markus J. Kemper,[1] Peter F. Zipfel,[2] Jun Oh.[1] *[1]Univ Hamburg-Eppendorf, Hamburg, Germany; [2]Hans-Knöll-Institut, Jena, Germany; [3]The Hospital for Sick Children, Toronto, Canada.*

**Background:** The activation of the complement system plays an important role in various kidney diseases. The majority of the circulating complement components are produced in the liver. But in the last decade the local production of complement components by other cells is highly debated. The aim of our study was to proof the ability of human podocytes to produce and secrete complement components and the functionality of these produced components.

**Methods:** Immortalized human podocytes were analyzed by Western Blot (WB), immunofluorescence (IF) and PCR for their ability to produce components (C1/ C1q, C2, C3, C4, C5, C7, C9) inhibitors (factor H, CD46, CD55, CD59) and activators (factor B, properdin, factor D) of the complement system. Secretion of components was measured in the medium, hemolytic activity was tested in a hemolysis assay and functionality of C3 was tested in a specific C3-convertase assay. Stimulation of the cells was done with either interferon-γ or interleukin 6.

**Results:** PCR-studies revealed that human podocytes express on mRNA level the components C1, C2, C3, C4, C5, the inhibitors factor H, CD46, CD55 and CD59, and the activators properdin and factor B. Cells expressed CD55 and CD59 on protein level. In addition, we could show that podocytes secrete the factors C2, C3, C4, C5, C7 and factor H into the medium. As expected, because of the missing secretion of factor D and B, there was no functionally active complete complement cascade resulting in hemolysis of rabbit-erythrocytes, but the secreted C3 was clearly functionally active.

**Conclusions:** This is the first study showing the potential of human podocytes to secrete active complement components. These data suggest that podocytes might contribute to local complement activation and modify complement mediated renal diseases.

## TH-OR069

**Complement Pathway Inhibition by Antisense Oligonucleotide for Treatment of Renal Diseases** Tamar R. Grossman, Lisa A. Hettrick, Robert Benjamin Johnson, Brett P. Monia, Michael McCaleb. *Antisense Drug Discovery, Isis Pharmaceuticals, Carlsbad, CA.*

**Background:** Activation of the complement system plays a key role in normal inflammatory response to injury but may cause substantial injury when activated inappropriately. Complement contributes to injury in several forms of glomerulonephritis, chronic humoral rejection after renal transplantation and ischaemia/reperfusion injury. Genome-wide association studies have shown that polymorphisms at the complement factor H-related gene locus are associated with over activation of the alternative complement pathway and subsequent susceptibility to IgA nephropathy and systemic lupus erythematosus. Rare mutations in these genes and other complement genes are associated with familial forms of C3 glomerulopathy and hemolytic uremic syndrome.

**Methods:** Using second generation antisense technology, we identified and characterized Antisense oligonucleotides (ASO) to murine complement component 5 (C5) and complement factor B (CFB) and tested their efficacy in NZB/W and MRL/lpr mouse models for Lupus Nephritis as a representative of human renal disease.

**Results:** Systemic Treatment with CFB ASO (100 mpk/wk) resulted in 75-90% mRNA knockdown in the liver and 40-60% in the kidney, which led to improved survival, proteinuria, renal C3 accumulation and renal pathology in mouse models for lupus nephritis. In addition plasma C3 level, which is dramatically reduced by C3 turnover in the disease models, was corrected to normal level with treatment. Similarly, systemic treatment with C5 ASO (25 mpk/wk) resulted in 95% mRNA knockdown in the liver and 80% in the kidney and improved renal pathology and reduced renal C3 accumulation in MRL/lpr mice.

**Conclusions:** Our results suggest that the amplification of complement activation by the alternative pathway is necessary for glomerular C3 deposition and progression of proteinuria and that factor B and C5 play important roles for disease progression and pathology in lupus nephritis mouse models. Treatment with ASO to CFB or C5 may offer a novel treatment strategy to treat lupus nephritis and other complement related renal diseases, such as C3 glomerulopathy, hemolytic uremic syndrome and dense deposit disease.

## TH-OR070

**IgM Contributes to Glomerular Disease Progression in Complement Induced Glomerulopathy** Sarah E. Panzer,[1] Brandon Renner,[1] Danica Ljubanovic,[2] Dorin-Bogdan Borza,[3] Joshua M. Thurman.[1] *[1]Renal Div, Univ of Colorado Denver, Aurora, CO; [2]Dept of Pathology, Univ Hospital Dubrava, Zagreb, Croatia; [3]Renal Div, Vanderbilt Univ, Nashville, TN.*

**Background:** While glomerular IgM deposition is reported in a variety of glomerular diseases the mechanism of its deposition and the clinical significance of its presence remain controversial. Recent research demonstrates IgM binds damaged glomeruli. Clinical studies associate IgM deposition with more severe manifestations of nephrotic syndrome. We hypothesized natural IgM binds neo-epitopes exposed after insults to the glomerulus and exacerbates disease progression.

**Methods:** We used mice deficient in the complement regulatory protein factor H to model a non-sclerotic and non-immune-complex glomerular disease and assessed the contribution of glomerular IgM to disease expression. To test the functional importance of IgM in this model we crossed factor H deficient mice with mice that lack B cells and therefore do not produce IgM. We also injected B cell deficient mice with IgM from wild type mice to determine whether it has nephritogenic properties.

**Results:** We demonstrated glomerular IgM deposition occurred consistently in factor H deficient mice and progressed from a mesangial distribution into the basement membrane of capillary loops as mice aged. In contrast, glomerular IgG deposition was not observed. Factor H deficient mice lacking B cells were protected from renal damage, as evidenced by milder histologic lesions on electron microscopy and a trend towards reduced albuminuria. IgM from wild-type mice, but not IgG, bound to cultured murine mesangial cells. Injection of purified IgM into mice lacking B cells bound within the glomeruli and induced albuminuria ($P < 0.05$ by ANOVA, N=3).

**Conclusions:** These results suggest IgM plays an active role as a contributing factor to the development of glomerular damage in a non-sclerotic and non-immune complex model of glomerular disease. Natural IgM and complement may offer new therapeutic targets for slowing the progression of glomerular disease.

*Funding:* NIDDK Support

## TH-OR071

**Inflammasome in Renal Collecting Duct Cells Contributes to Inflammation and Fibrosis after Unilateral Ureteral Obstruction** Takanori Komada,[1,2] Shigeaki Muto,[1] Eiji Kusano,[1] Masafumi Takahashi.[2] *[1]Dept of Nephrology, Jichi Medical Univ, Tochigi, Japan; [2]Div of Inflammation Research, Jichi Medical Univ, Tochigi, Japan.*

**Background:** The inflammasome is a multiple protein complex containing Nod-like receptors (NLRs), ASC, and caspase-1. It regulates interleukin-1β (IL-1β) and contributes to the development of CKD. However, the role of each inflammasome component in the renal parenchymal cells remains unclear. We investigated the role of ASC using a murine unilateral ureteral obstruction (UUO) model and evaluated the localization of ASC.

**Methods:** C57BL/6J-background wild type (WT) and ASC-knockout (ASC-KO) mice underwent UUO. Primary mouse collecting duct (CD) cells were used in in vitro study.

**Results:** ASC-KO showed a significant reduction in tubulointerstitial injury and fibrosis histologically. On the 5 days after UUO, flow cytometric analysis showed that leukocyte infiltration was abolished in ASC-KO compared with WT, indicating that inflammatory response was remarkably suppressed in ASC-KO. The mRNA expressions of *IL1b*, *Ccl2*,*Col1a1*, *Col3a1*, and *Tgfb* showed less increase in ASC-KO. Immunohistochemistry showed that ASC expression was upregulated in the renal tubules after UUO. Double immunofluorescence analysis revealed that most ASC positive tubules were co-stained with AQP2, collecting duct marker. In *in vitro* study, we identified the presence of NLRP3 and ASC in primary mouse CD cells using western blotting. After 5mM ATP stimulation, IL-1β secretion and active caspase-1 were observed. This response in IL-1ß secretion was prevented significantly by $P2X_7$ inhibitor (A-438079), by blocking the $K^+$ efflux, by glibenclamide, or by antioxidant *N*-acetyl cysteine (NAC).

**Conclusions:** ASC was upregulated in CD cells after UUO and related to inflammation and fibrosis. Extracellular ATP stimulated inflammasome activation in CD cells, through $P2X_7$-potassium efflux and ROS-dependent pathways. These findings suggest that ASC in the CD cells contributes to kidney inflammation as a major component of the inflammasome.

## TH-OR072

**Macrophage $A_{2A}$ Adenosine Receptors Are Essential to Protect from Progressive Kidney Injury** Gabriela E. Garcia,[1] Luan D. Truong,[2] Jessica Helen Trostel,[1] Richard J. Johnson,[1] Lili Feng.[3] *[1]Medicine, Univ of Colorado Denver, Aurora, CO; [2]Pathology, The Methodist Hospital, Houston, TX; [3]Medicine, Baylor College of Medicine, Houston, TX.*

**Background:** $A_{2A}$ adenosine receptor ($A_{2A}R$) activation attenuates inflammation and induces tissue repair. Macrophages (Mφ) that are key effectors of kidney disease progression express $A_{2A}R$.

**Methods:** We investigated the role of Mφ $A_{2A}R$ in the progression of kidney injury in a model of severe, macrophage-mediated anti-glomerular basement membrane glomerulonephritis (anti-GBM GN) using CD11b-DTR transgenic mice. In these mice, tissue Mφ can be selectively depleted by injection of diphtheria toxin (DT). GN was induced in CD11b-DTR mice and Mφ were selectively depleted in the established phase of the disease and reconstituted with Mφ from WT or $A_{2A}R$ deficient mice and then treated with an $A_{2A}R$ agonist and euthanized at day 8. Mice reconstituted with WT Mφ but not treated with $A_{2A}R$ agonist were used as a control.

**Results:** Mφ were tracked in vivo labeling them with PKH -26GL and found that Mφ were distributed in nephritic kidneys. In mice that received WT Mφ and were treated with $A_{2A}R$ agonist the glomerular cellularity, crescent formation, sclerotic glomeruli and tubulointerstitial (TIN) injury were significantly reduced compared with the control group. In contrast, mice reconstituted with $A_{2A}R$ deficient Mφ and treated with $A_{2A}R$ agonist, the kidney injury was worst with increased crescent formation, enhanced sclerotic glomeruli and higher TIN injury compared with the control group. In addition, collagen (Col)-I, Col-III and Col-IV deposition were increased in mice receiving Mφ deficient in $A_{2A}R$ compared with the control group. Importantly, the antigen-specific humoral immune response and the glomerular immunoglobulin G deposition were not affected by DT, Mφ depletion, or Mφ reconstitution. In vitro studies, higher levels of TGF-β2 and tissue inhibitor of matrix metalloproteinase-1 were induced in Mφ from $A_{2A}R$-deficiente mice compared with Mφ from WT mice.

**Conclusions:** These findings suggest that absence of Mφ $A_{2A}R$ increases Mφ pro-fibrotic activity and that endogenous Mφ $A_{2A}Rs$ are essential to protect from progressive kidney fibrosis.

*Funding:* NIDDK Support

## TH-OR073

**NLRP3 Is a Predictor of Renal Tubular Injury in Human IgA Nephropathy** Justin Chun, Xiangyu (Wendy) Wang, Hyunjae Chung, Matthew T. James, Kiril Trpkov, Brenda Hemmelgarn, Daniel A. Muruve. *Medicine, 1, Calgary, Canada.*

**Background:** Despite efforts to identify biomarkers to classify and prognosticate kidney disease, current markers are non-specific and unable to predict disease outcome. Our previous studies have demonstrated significant expression of a family of NOD-like receptors called NLRPs in various human kidney diseases. NLRP3 gene expression is increased in biopsies of patients with IgA nephropathy (IgAN), a slowly progressing form of CKD that is associated with tubulointerstitial fibrosis. Although NLRP3 mRNA expression has been linked with IgAN, little is known about the relationship between NLRP3 expression with IgAN progression.

**Methods:** Biopsies from a total of 67 patients with IgAN were selected for analysis of NLRP3 mRNA expression by quantitative real-time PCR. Patients with advanced renal failure (GFR≤15 ml/min) were excluded from the analysis to avoid patients with ESRD. Therefore, a total of 57 cases of IgAN were analyzed. NLRP3 gene expression was analyzed as a logarithmic variable due to its non-normal distribution, and displayed as tertiles in a survival curve. We used immunohistochemistry (IHC) and Western blot to study NLRP3 protein expression with correlation to a kidney injury molecule (KIM-1).

**Results:** Our results demonstrate that lower levels of NLRP3 gene expression is associated with a worse outcome in patients with IgAN. NLRP3 and KIM-1 had strong positive correlation both with high expression in IgAN tissue compared with normal tissue. With disease progression, there was increased tubular atrophy and fibrosis with a concomitant reduction of NLRP3 and KIM-1 in kidney tissue samples. Consistent with our IHC results, proximal tubular epithelial cells had an initial increase of NLRP3 and KIM-1 protein levels that diminished after prolonged treatment with TGFβ, a major profibrotic cytokine known to induce the expression of NLRP3.

**Conclusions:** NLRP3 is a promising marker of epithelial burden that can be used to predict IgAN progression. Higher levels of NLRP3 mRNA and protein expression are associated with earlier manifestation of IgAN. The presence of high levels of NLRP3 in IgAN may provide an opportunity to identify reversible or treatment responsive inflammation.

## TH-OR074

### Transcriptional Regulation of Endothelial Cell Proliferation Induced by Simultaneous Antibody Targeting of $AT_1$- and $ET_A$ Receptors

Aurélie Philippe, Rusan Catar, Philine Wagner, Duska Dragun. *Nephrology and Intensive Care Medicine, Univ Hospital Charité, Berlin, Germany.*

**Background:** Patients with systemic sclerosis (SSc) suffer from severe obliterative autoimmune vasculopathy affecting various vascular beds including kidney. Activating autoantibodies simultaneously targeting G-protein coupled receptors (GPCR) Angiotensin II type 1 receptor ($AT_1R$) and Endothelin-1 type A receptor ($ET_AR$) may predict velocity of vascular complications by mechanisms which remain to be clarified. We hypothesized that both activating antibodies may induce vascular dysfunction independent from receptor natural ligands, Angiotensin II and Endothelin-1.

**Methods:** Affinity purified IgG fraction derived from serum of SSc patients positive for $AT_1R$-/$ET_AR$-Abs (SSc P-IgG) served for functional, signaling and transcriptional regulation studies in human microvascular endothelial cells (HMEC-1). Mice were passively transferred with SSc P-IgG.

**Results:** Both autoantibodies induced ERK1/2 phosphorylation to a similar extent as natural ligands, indicative of their biologic activity, and induced further down-stream phosphorylation of the transcription factor Ets-1. SSc P-IgG transfer induced expression of Ets-1 in kidney arteries of mice. $AT_1$-/$ET_AR$ autoantibodies, but not natural ligands Ang II or ET-1 were able to induce endothelial cell proliferation. Respective receptor antagonists attenuated endothelial proliferation emphasizing receptor specific effect of both activating antibodies. These effects were attributed to GPCR since pharmacologic targeting of ERK1/2 achieved similar results. Same anti-proliferative effects could be achieved by siRNA mediated blockade of Ets-1. SSc P-IgG also induced increased DNA binding to Tissue factor (TF) promoter, which contains Ets-1 binding site, in EMSA and ChIP assays. Moreover, inhibition of TF obviated endothelial cell proliferation, illustrating that antibodies activating $AT_1R$ and $ET_AR$ contribute to pathogenesis of proliferative obliterative vascular lesion via enhanced Ets-1 mediated transcriptional regulation of TF.

**Conclusions:** Targeting pathways induced by $AT_1R$ and $ET_AR$ antibodies may offer new prospects in treating obliterative vascular lesions in autoimmune vasculopathies.

## TH-OR075

### Increased Hedgehog-GLI Signaling Causes Stromal Cell-Mediated Ureteropelvic Junction Obstruction

Norman D. Rosenblum,[1] Lijun Chi,[1] Brian Nieman,[3] Steven Potter.[2] *[1]Div Neph, Prog DSCM, Hosp Sick Child, U Toronto, Toronto, Canada; [2]Dev Biol, Child Hosp Med Centre, Cincinnati; [3]Toronto Centre Phenogenomics, Toronto, Canada.*

**Background:** Hedgehog (HH)-GLI signalling is required during kidney morphogenesis. While increased HH-GLI signalling causes cancer in nonrenal tissues, its pathogenic role in the embryonic kidney is undefined.

**Methods:** We generated and analyzed mice with a constitutive increase in HH-GLI signalling activity in the metanephric mesenchyme by genetically inactivating *Patched1* (*Ptch1*), that encodes a cell surface protein that constitutively inactivates HH signaling in the absence of ligand, using *Rarb2-Cre* and $Ptch1^{loxP}$ mouse strains.

**Results:** *Ptch1*-deficient (*Rarb2-Cre;*$Ptch1^{loxP/-}$) mice were characterized by hydronephrosis after E15.5. Dye injection into the renal pelvis revealed obstruction of dye passage beyond the ureteropelvic junction (UPJ). Serial 2 µm histologic sections revealed cells obstructing the UPJ. Analysis of *Ptch-lacZ* expression, a reporter of HH signaling activity, in *Ptch1*-deficient;*Ptch1-lacZ and Ptch1*-deficient;*Ptch2-lacZ* mice, revealed increased *Ptch1* and ectopic expression of *Ptch2* in the cells obstructing the UPJ. A 2-fold rescue of hydronephrosis, measured by MRI, was observed in *Ptch1*-deficient mice with constitutive expression of the $Gli3^{\Delta 699}$ allele that encodes GLI3 repressor, demonstrating that UPJO in *Ptch1*-deficient mice is GLI-dependent. *Ptch2*-positive cells (3 distinct batches of 2000 cells) were isolated distinct from *Ptch2*-negative cells in the region of the UPJ by tissue dissection and flow sorting and analyzed by RNAseq. In comparison to *Ptch2*-negative cells, *Ptch2*-positive cells exhibited a 2-9-fold increase in genes expressed in renal stromal cells or ureteric smooth muscle progenitors, or that promote smooth muscle development. Validation of these results using qPCR and double in situ hybridization with *Ptch2* mRNA established the stromal cell identify of obstructing *Ptch2*-positive cells.

**Conclusions:** Increased HH-GLI signaling in the metanephric mesenchyme causes UPJO due to ectopic stromal cells. Our results provide a basis to investigate human UPJO, presently understood only at the level of histopathology.

## TH-OR076

### Wnt7b Signals to Pericytes/Perivascular Fibroblasts and Regulates Microvasculature Development in the Renal Medulla

LaToya Ann Roker, Jing Yu. *Cell Biology, Univ of Virginia, Charlottesville, VA.*

**Background:** Wnt7b is expressed in the ureteric trunk epithelium and essential for renal medulla formation. It elicits canonical Wnt signaling in interstitial cells of the prospective renal medulla, which is also vital for renal medulla formation. However, the identity of the Wnt7b target cells remains elusive. Determining the identity of these cells may help us to better understand *Wnt7b* functions in renal medulla development.

**Methods:** Therefore, we employed mouse genetics, Immunohistochemistry, and Transmission Electron Microscopy (TEM) to determine the identity of *Wnt7b* target interstitial cells and the effect of *Wnt7b* signaling on this cell population.

**Results:** We found that the in the nascent renal medulla, *Wnt7b*/canonical Wnt signaling target cells do not constitute the entire prospective medullary interstitium; rather, they are confined to 1-3 cell layers adjacent to the prospective medullary collecting ducts. Moreover, we found that they express pericyte markers and are intimately associated with endothelial cells of the microvasculature lining the prospective medullary collecting ducts, demonstrating that these cells are pericytes/perivascular fibroblasts. We further found that differentiation of this population of pericytes/perivascular fibroblasts did not depend on *Wnt7b* signaling from ureteric trunks; instead, ablation of *Wnt7b* signaling in the kidney led to their reduced *Pdgfrβ* expression and increased cell proliferation. Furthermore, *Wnt7b* mutants displayed an increase in the density of vascular coverage of prospective medullary collecting ducts and in endothelial cell proliferation. Further analysis identified a defect in endothelial cell flattening and lumen formation of this population of the microvasculature.

**Conclusions:** Taken together, our study revealed a novel function of *Wnt7b* in kidney development, that *Wnt7b* regulates peri-ureteric trunk microvasculature development in the developing renal medulla, most likely through its signaling to pericytes/perivascular fibroblasts lining the microvasculature.

### Wnt5a Is Crucial for Kidney Development

Liwei Huang, Soo Young Choi, Maria F. Chacon-Heszele, Weibin Zhou, Sarah McKenna, Xiaofeng Zuo, Yun Kyoung Ryu, Rejji Kuruvilla, Joshua H. Lipschutz. *Dept of Medicine, Univ of Pennsylvania, Philadelphia, PA.*

**Background:** Wnt5a is a non-canonical secreted glycoprotein of the Wnt family that plays an important role in the development of various organs and postnatal cellular function. Little is known regarding the role of Wnt5a during kidney development.

**Methods:** The objective of the present study is to determine the role of Wnt5a during nephrogenesis using zebrafish and murine models.

**Results:** By Real-time RT-PCR and whole mount ISH (wmISH), wnt5a expression occurs in the zebrafish pronephros. Wnt5a knockdown by antisense wnt5a morpholinos results in abnormal glomerular structure and dilated renal tubules in zebrafish. In wt1-GFP fish, the pronephros can be visualized with fluorescence microscopy. Dilations are visualized at 48 hours post fertilization (hpf) in the glomerular and proximal tubular region of the wt1-GPF fish injected with wnt5a antisense morpholinos. Wnt5a knockdown resulted in decreased wt1 expression detected by wmISH and in the wt1-GFP fish detected by fluorescence microscope. Rescue with a mouse Wnt5a mRNA showed that this was not due to off-target effects. In the Wnt5a global knockout mouse, by wmISH, Wnt5a expression is localized to the entire intermediate mesoderm at embryonic day (E) 10.5, and its expression level is increased further at E11.5. At E13.5, Wnt5a is weakly expressed in the mesenchymal region of the metanephros. Wnt5a global knockout mice showed pleiotropic kidney phenotypes, including bilateral or unilateral kidney agenesis, hydronephrosis and fused kidneys. Further histologic examination, when kidney tissue was present, revealed reduced kidney tubules, glomeruli, and medullary zones in the Wnt5a -/- embryos.

**Conclusions:** A strength of this study is that we utilized two different animal models each of which has specific advantages that could be exploited to investigate the role of Wnt5a in nephrogenesis. In zebrafish and mice, Wnt5a was expressed very early in nephrogenesis. Disrupted Wnt5a resulted in abnormal glomerular and tubular growth and cyst formation. Our data indicate that Wnt5a is centrally involved in kidney development.

### The WNT-Calcium Pathway Controls c-Ret Expression during Ureteric Bud Branching Morphogenesis

Diana Iglesias,[1] Jeremy A. Saban,[2] Rachel Corsini,[1] Paul R. Goodyer.[1,2] *[1]Pediatrics, Montreal Children's Hospital Research Institute, Montreal, Canada; [2]Human Genetics, Montreal Children's Hospital Research Institute, Montreal, Canada.*

**Background:** Normal nephrogenesis requires reciprocal signaling between the invading ureteric bud (UB) and the condensing metanephric mesenchyme (MM). Here, we examine the role of the non-canonical WNT/ $Ca^{2+}$/calcineurin (WNT-$Ca^{2+}$) signaling pathway in kidney development.

**Methods:** We used a transgenic mouse that carries a luciferase reporter downstream of an NFAT binding sensitive promoter.

**Results:** We found that WNT-$Ca^{2+}$ signaling peaks at embryonic days E13-E16 in wildtype embryonic mouse kidney and is downregulated perinatally as nephrogenesis comes to an end. The *Nfat*-luciferase reporter was responsive in vitro and ex vivo to non-canonical WNTs such as WNT5a and WNT11, but not to the canonical WNT3a. The effect of non-canonical WNTs is abrogated by cyclosporin-A (CsA) treatment in explants, which also causes reduced UB branching. *Nfat*-luciferase activity was significantly reduced in kidneys from E16 embryos when CsA was administered by gavage to pregnant mice between E13-E16. *In situ* hybridization for the luciferase transcript shows that WNT-$Ca^{2+}$ signaling activity is located in the outer nephrogenic zone. *Nfat*-luciferase activity was highest in *Hoxb7*/GFP-tagged UB cells isolated by FACS from E15 kidneys of mice bearing the reporter transgene. This unexpected finding suggests that WNT11 expressed in UB tips may play an autocrine role in branching morphogenesis. To ascertain whether the pathway regulates UB expression of RET (a receptor for MM-secreted GDNF) we treated E13 kidney explants with CsA vs control conditions for 48 hours and examined the levels of *Ret* and *Gdnf* by quantitative RT-PCR and IF microscopy. Inhibition of the WNT-$Ca^{2+}$ pathway by CsA caused striking reduction of explant *Ret* expression despite addition of excess soluble GDNF, which is proposed to activate *Ret* expression in response to paracrine WNT11 activity.

**Conclusions:** We propose a spatio-temporal regulatory role for the WNT-$Ca^{2+}$ pathway that ensures the expression of *Ret*, thereby mediating UB branching morphogenesis.

## TH-OR079

### Gene-Environment Interactions in the Ureteric Bud Lineage Cause CAKUT

Lei Yan, Xiao Yao, Zubaida R. Saifudeen, Samir S. El-Dahr. *Pediatrics, Tulane Univ School of Medicine, New Orleans, LA.*

**Background:** Polymorphisms in the bradykinin B2 receptor (*BDKRB2*) are associated with susceptibility to human hypertension. In mice, targeted disruption of *Bdkrb2* predisposes to hypertension, senescence, and diabetic nephropathy. *Bdkrb2*$^{-/-}$ embryos are prone to congenital anomalies of the kidney and urinary tract (CAKUT) following gestational salt stress. We hypothesized that *Bdkrb2* inactivation in the ureteric bud (UB) lineage increases the susceptibility to CAKUT in mice.

**Methods:** 1. We generated mice harboring a conditional *Bdkrb2* allele; 2. To delete *Bdkrb2* in the UB lineage, Bdkrb2$^{f/f}$;R26R$^{tdTomato}$ were bred to *Hoxb7-Cre:GFP* mice, and females were placed on 5% NaCl diet during gestation; 3. GFP$^{+}$/tdTomato$^{+}$:Bdkrb2$^{UB-/-}$ and GFP$^{+}$:Bdkrb2$^{UB+/+}$ cells were isolated by FACS. RNA expression was analyzed by microarray hybridization, QPCR and ISH. Apoptosis was assessed by TUNEL and active caspase 3 IF. Double-stranded DNA breaks were assessed by γH2AX staining.

**Results:** 1. FACSorted *Bdkrb2*$^{UB-/-}$cells lack *Bdkrb2* DNA and mRNA.

2. Salt stressed *Bdkrb2*$^{UB-/-}$ kidneys exhibit hypoplastic papillae, dilated medullary collecting ducts, and occasional cortical cyst of UB origin.

3. The medullary collecting ducts of *Bdkrb2*$^{UB-/-}$ kidneys show a marked downregulation of Pax2, E-Cadherin, *Wnt7b, Wnt9b, and Wnt11.*

*4. Bdkrb2*$^{UB-/-}$ medulla exhibits extensive histone γH2AX phosphorylation, accumulation phosphorylated p53 (p-p53$^{Ser23}$), and upregulation of TUNEL/Caspase3-positive cells.

5. *Bdkrb2*$^{UB+/+}$ and *Bdkrb2*$^{UB-/-}$ cells exhibit d ifferential expression of 300 genes ($p<0.05$; >2-fold). The major categories of downregulated gene clusters are cell adhesion/ tight junction (claudin 4/7, E-cadherin, occludin), Wnt signaling (Wnt7b, Wnt10a, NFAT, cyclinD2), apoptosis (Caspase 4, Apaf1), transcriptional regulators of distal nephron fate (Irx2, Brn1), and collecting duct receptors/transporters/channels (ET1Rb, EP1, AVPR2, AQP3, AE1, UT-1).

**Conclusions:** 1. This study provides a proof-of-concept that gene-environment interactions act cell-autonomously to disrupt organogenesis.

2. *Bdkrb2* signaling opposes deleterious pathways leading to DNA damage, p53 activation, apoptosis, and impaired terminal epithelial differentiation.

## TH-OR080

### Heterochronic Transplantation of Mid- and Late-Gestation Metanephric Mesenchyme Revealed Age Related Differences

Shuang Chen, Raphael Kopan. *Developmental Biology, Washington Univ in St. Louis, Saint Louis, MO.*

**Background:** During development mammals build kidneys with a large surplus of nephrons from the cap mesenchyme (CM). Although stem-like in many respects, these embryonic progenitors differentiate en mass before or shortly after birth. It is unclear at present whether progenitor lifespan is regulated by progenitor-extrinsic signals (loss of niche cytokine, a powerful pulse of inductive signal) or intrinsic mechanisms (limited self-renewal capacity of progenitor cells).

**Methods:** To ascertain if there is an intrinsic difference in the self-renewal and differentiation capacity of young and old CM cells, we co-injected FACS sorted Six2+ cells from E12.5 (young) and P1 (old) kidneys at a 1:1 ratio into the CM of E12.5 recipient kidneys. To allow fate mapping of the injected progenitors, we collected young and old Six2+ cells from Six2$^{TGC+/tg}$; Rosa +/tdTom (red) and Six2$^{TGC+/tg}$; CAG-eCFP $^{+/tg}$ (blue) animals, respectively. Pax2Cre$^{+/tg}$, Rosa +/eYFP (green) kidneys were used as recipients to ensure positioning of injected cells into the CM. We then cultured the recipients for 4 days and compared the number of young and old cells within the CM and in epithelial compartment by immunostaining. In parallel, cells from the same sort were cultured in the presence of Fgf9 and BMP7 and the distribution of red and blue cells within cell aggregates were analyzed.

**Results:** Both young and old Six2+ cells readily integrate into the CM and/or the differentiating nephron epithelia when injected into the host kidneys. Interestingly, at the end of 4-day culture, most of the P1 progenitors have differentiated with few remaining in the CM. In contrast, 3-5 fold more E12.5 progenitor remained in the CM. When cultured in vitro, young and old progenitors sort away from each other, with the young cells in the periphery and old cells at the center. Switching the lineage label (red and blue) in young and old Six2+ cells does not alter these results.

**Conclusions:** These data suggest that young and old Six2+ CM cells are intrinsically different and the young niche did not "rejuvenate" older cells. This conclusion is further supported by their differential adhesion properties in vitro.

*Funding:* NIDDK Support

## TH-OR081

### Genetic Analysis of Nephron Segmentation Using the Zebrafish

Rebecca A. Wingert, Gary F. Gerlach. *Dept of Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

**Background:** The zebrafish pronephros, or embryonic kidney, has become an increasingly popular model to study renal development and disease. Zebrafish form a pronephros comprised of two nephrons that consist of a series of proximal and distal functional segments, similar to mammals. How nephron segment cell types arise remains a major outstanding question in the field of nephrology.

**Methods:** We have performed a novel forward genetic screen to identify nephrogenesis genes using zebrafish. We screened approximately 700 genomes and observed 45 mutations that cause nephron cell type defects. To date, 15 recessive mutations have been recovered, and ongoing complementation suggests that these represent at least 12 different nephrogenesis genes.

**Results:** The kidney phenotypic classes include models of podocyte deficiency, as well as expansions or reductions in the domains of individual proximal and distal tubule segments. Thus far, we have characterized 5 mutant lines that evince podocyte formation defects. Mutants ND172 and ND233 have absent and reduced podocytes, respectively, and display normal development until 3-4 days, when they exhibit renal failure. These data suggest that ND172 and ND233 play specific roles in podocyte formation, while the other podocyte mutants have widespread defects suggesting a disruption in genes with pleiotropic functions. We have also recovered 5 mutant lines with tubule patterning defects that exhibit alterations in proximal or distal segment formation. For example, kidney mutant ND161 displays an abrogation of distal tubule formation, exhibiting a loss of romk gene expression. This finding suggests that ND161 may be a useful system relevant to the study of Barttner's syndrome. Ongoing efforts are aimed at further phenotypic characterization of ND161, and identification of the genetic lesion underlying this distal tubule mutant.

**Conclusions:** Taken together, our collection will provide a useful resource to delineate the genes that direct nephrogenesis pathways, and may provide new models to study human congenital kidney defects.

## TH-OR082

### Unraveling the Role of Podocyte Regeneration for Glomerular Homeostasis and Aging

Nicola Wanner,[1,2,3] Bjorn Hartleben,[1] Markus Gödel,[1] Natalie Stickel,[2,3,4] Gerd Walz,[1] Marcus J. Moeller,[5] Florian Grahammer,[1] Tobias B. Huber.[1,2,6] *[1]Renal Div, Univ Medical Center Freiburg; [2]Spemann Graduate School of Biology and Medicine (SGBM), Albert Ludwigs Univ Freiburg; [3]Faculty of Biology, Albert Ludwigs Univ Freiburg; [4]Dept of Hematology and Oncology, Univ Medical Center Freiburg; [5]Div for Nephrology and Immunology RTWH Aachen; [6]BIOSS Centre for Biological Signalling Studies, Albert-Ludwigs-Univ, Freiburg, Germany.*

**Background:** Podocyte loss is a major determinant of progressive chronic kidney disease. Although recent studies have shown that a subset of parietal epithelial cells can serve as podocyte progenitors, the role of podocyte regeneration in aging and nephron loss remains unclear.

**Methods:** Here we combined genetic fate mapping with highly efficient podocyte isolation protocols to precisely quantify podocyte turnover.

**Results:** We demonstrate for the first time that parietal epithelial cells can give rise to fully differentiated visceral epithelial cells indistinguishable from resident podocytes, and found that limited podocyte renewal occurs during glomerular development as well as in a diphtheria toxin-model of acute podocyte ablation. In contrast, the compensatory programs in response to nephron loss mainly evoke podocyte hypertrophy, but not podocyte regeneration. In addition, under physiological conditions no turnover of podocytes could be detected in aging mice. In the absence of podocyte replacement, progressive accumulation of oxidized proteins, deposits of protein aggregates, loss of podocytes and glomerulosclerosis were characteristic features of aging mouse kidneys.

**Conclusions:** In summary, quantitative investigation of podocyte regeneration *in vivo* provides novel insights into the mechanism and capacity of podocyte regeneration in mice. Our data reveal that podocyte generation is mainly confined to glomerular development and occurs after acute glomerular injury, but fails to regenerate podocytes in aging kidneys or in response to nephron loss.

**TH-OR083**

**A Transposon-Mediated System for the Generation of Nephron Progenitors from Adult Somatic Cells** Jessica May Vanslambrouck,[1] Lauren Elizabeth Woodard,[2] Norseha Suhaimi,[1] Matthew H. Wilson,[2] Melissa H. Little.[1] *[1]Institute for Molecular Bioscience, Univ of Queensland, Australia; [2]Dept of Medicine, Baylor College of Medicine, TX.*

**Background:** Novel treatments for chronic kidney disease are desperately needed and cellular reprogramming may represent one such option. As all nephrons in the human kidney form prior to birth, their regeneration may require the recreation of embryonic nephron progenitors (NPs). Using a lentivirus-mediated screen, we identified 6 transcription factors sufficient to re-impose a NP-like state when co-expressed in adult human proximal tubule cells (Hendry et al., JASN, 2013). Here we report the preliminary de-replication of this gene set and development of a multicistronic transposon construct to improve this reprogramming.

**Methods:** De-replication involved removal of individual lentiviral constructs from HK2 cell transductions. A transposon-mediated system was generated by engineering all 6 genes into a *piggyBac* construct with intervening 2A sequences, a tetracycline response element for doxycycline inducibility and a reporter (mCherry) for cell enrichment. FuGENE6 was used to co-transfect HK2 cells with this transposon, a tetracycline activator transposon and a *piggyBac* transposase construct. Gene expression was induced with 2μg/mL doxycycline. Reprogramming was assessed via morphological change (epithelial-to-mesenchymal transition) and expression of key NP genes.

**Results:** A NP-like state was achieved without *EYA1* or *HOXA11*. Transposon integration into HK2 cells was most efficient with the hyperactive *piggyBac* transposase (m7pB). Following integration, HK2 cells displayed tightly regulated doxycycline-inducible mCherry expression and NP-like characteristics, including increased expression of key NP markers. The expression of these genes was influenced by the length of doxycycline exposure.

**Conclusions:** These results further refine the genes required for NP reprogramming and demonstrate the feasibility of a transposon-based approach for inducible reprogramming to a NP. In the long term, this approach will facilitate patient-specific reprogramming to NP cells. Such cells may also prove invaluable for bioengineering and nephrotoxicity screening.

*Funding:* Government Support - Non-U.S.

**TH-OR084**

**Rapid and Efficient Differentiation of Human Pluripotent Stem Cells into Intermediate Mesoderm Cells That Form Tubules and Express Proximal Tubule Markers** Albert Q. Lam,[1,2] Benjamin S. Freedman,[1] Ryuji Morizane,[1] M. Todd Valerius,[1,2] Joseph V. Bonventre.[1,2] *[1]Renal Div, Brigham and Women's Hospital, Boston, MA; [2]Harvard Stem Cell Institute, Cambridge, MA.*

**Background:** Human pluripotent stem cells (hPSCs) have the capacity to generate the wide diversity of human cell types, making them ideal starting substrates for generating cells of the kidney lineage. Here we report a highly efficient system to differentiate human embryonic stem cells (hESCs) and induced pluripotent stem cells (hiPSCs) into cells of the intermediate mesoderm (IM), the embryonic tissue which gives rise to the adult kidneys.

**Methods:** hPSCs were cultured in mTeSR1 medium until they reached 50% confluence, then differentiated into mesendoderm using serum-free media supplemented with the GSK-3β inhibitor CHIR99021 (CHIR). To identify conditions to induce IM differentiation, we screened several growth factors at varying doses for the ability to induce expression of the IM markers PAX2 and LHX1.

**Results:** Treatment of hPSCs with CHIR induced BRACHYURY$^+$MIXL1$^+$ mesendoderm differentiation with nearly 100% efficiency. In the absence of additional exogenous factors, CHIR-induced mesendodermal cells preferentially differentiated into lateral plate mesoderm with minimal IM differentiation. Screening multiple growth factors for the ability to promote IM differentiation identified FGF2 and retinoic acid (RA) as potent inducers of the IM markers PAX2 and LHX1, respectively. The sequential treatment of hPSCs with CHIR followed by FGF2 and RA generated PAX2$^+$LHX1$^+$ cells after 3 days of differentiation with 70-80% efficiency as determined by immunocytochemistry and flow cytometry. These putative IM cells expressed other IM markers, including OSR1, PAX8, and WT1, without significant expression of lateral plate or paraxial mesoderm markers. After an additional 6 days of differentiation, these PAX2$^+$LHX1$^+$ cells gave rise to tubular structures co-expressing the proximal tubule markers LTL and Kidney-specific protein.

**Conclusions:** Our findings establish a system whereby hPSCs can be rapidly and robustly differentiated into PAX2$^+$LHX1$^+$ intermediate mesoderm cells which form tubules and express proximal tubule markers.

**TH-OR085**

**Contrasting Roles for M1 and M2 Type Macrophages in Childhood IgA Nephropathy** Yohei Ikezumi,[1] Toshiaki Suzuki,[1] Takeshi Yamada,[1] Hiroya Hasegawa,[1] David J. Nikolic-Paterson,[2] Akihiko Saitoh.[1] *[1]Dept of Pediatrics, Niigata Univ Medical and Dental Hospital, Niigata, Japan; [2]Monash Univ Dept of Medicine, Monash Medical Centre, Clayton, Victoria, Australia.*

**Background:** We have previously shown that M2-type macrophages (MQ) are dominant in chronic lesions, such as glomerular matrix expansion and interstitial fibrosis, in IgA nephropathy (IgAN). However, the role of M1-type activated MQ has not been elucidated. Therefore, we examined activated M1-type MQ in biopsies of childhood IgAN.

**Methods:** Biopsies taken from 81 cases of childhood IgAN (11±3 years) were examined for histologic changes and by immunofluorescence staining for activated M1-type MQ (CD86$^+$ cells) and M2-type MQ (CD163$^+$ cells). Nine biopsies from children with thin basement membrane disease (TBMD) were used as control.

**Results:** Histopathologic assessment of IgAN revealed significant accumulation of both M1 and M2 type MQ in glomeruli, while most interstitial MQ were CD163$^+$ (M2-type). CD86$^+$ M1-type MQ correlated with: endocapillary proliferation and cellular crescent formation (both $p<0.001$); the degree of hematuria ($p<0.001$) and proteinuria ($p=0.014$), but did not correlate with glomerular matrix expansion or interstitial fibrosis. In contrast, CD163$^+$ M2-type MQ correlated with glomerular matrix expansion ($p<0.01$) and interstitial fibrosis ($p<0.001$).

**Conclusions:** We have identified contrasting roles for M1 and M2 type MQ in childhood IgAN. Activated M1-type MQ appear to be involved in the development of acute lesions (endocapillary proliferation and cellular crescents), whereas M2-type MQ are involved in chronic lesions such as mesangial matrix expansion and interstitial fibrosis. The prognostic significance of these findings warrants further study.

**TH-OR086**

**Mycofenolate Mofetil Therapy in IgA Nephropathy: Histological Changes after Treatment** Hannah Kate Sarah Beckwith, Nicholas R. Medjeral-Thomas, Jack W. Galliford, Megan Griffith, Jeremy B. Levy, Andrew B.D. Palmer, Candice A. Roufosse, H. Terence Cook, Tom Cairns. *Imperial College Kidney and Transplant Institute, London, United Kingdom.*

**Background:** Endocapillary hypercellularity independently predicts renal outcome in IgA Nephropathy (IgAN)[1]. Mycophenolate mofetil (MMF) treatment is offered to patients presenting to the Imperial College Kidney and Transplant Institute with IgAN and histological evidence of endocapillary inflammation. Clinical trials of MMF in IgAN have been inconclusive. Evidence of histological improvement following MMF treatment would support its therapeutic use. We therefore reviewed histological changes after MMF therapy in a cohort of IgAN patients.

**Methods:** Eleven IgAN patients with repeat native renal biopsies before and after MMF treatment were identified. Patients were excluded if they had received any other immunosuppression therapy, including corticosteroids. Based on the Oxford classification of IgAN[1], we reviewed histological changes after MMF treatment.

**Results:** Seven patients (60%) were male. At diagnostic renal biopsy, median age was 42 (range 19-67), serum creatinine was 127umol/L (56-233), and urine protein creatinine ratio (UPCR) was 157 mg/dl (67-224). The median time between biopsies was 29 months (14-41).

Following MMF treatment, repeat biopsy demonstrated statistically significant improvement in the mean percentage of glomeruli showing endocapillary hypercellularity and cellular/fibrocellular crescents. A significant reduction in IgA deposition ($p=0.04$) and a trend towards improved mesangial hypercellularity ($p=0.05$) was also demonstrated. There was no change in tubular atrophy. Median serum creatinine remained stable at 3 years follow-up at 110umol/L (59-421).

| | Biopsy 1 | Biopsy 2 | p-value |
|---|---|---|---|
| Glomeruli with endocapillary hypercellularity, mean % (SD) | 11.0 (14.3) | 1.60 (4.03) | <0.01 |
| Tubular atrophy, mean % (SD) | 21.8 (11.9) | 18.1 (16.4) | 0.23 |
| Glomeruli with crescents, mean % (SD) | 7.69 (8.77) | 1.60 (3.25) | <0.01 |

**Conclusions:** MMF treatment is associated with histopathological improvement in IgAN.

**References** 1.Cattran D, Coppo R, Cook T et al. The Oxford classification of IgA nephropathy: Rationale, clinicopathological correlations and classification. Kidney Int 2009;76:546-556.

**TH-OR087**

**Abnormal STAT3 Signaling Enhances Production of Autoantigen in an Autoimmune Disease, IgA Nephropathy** Colin Reily,[1] Koshi Yamada,[1,5] Zhi Qiang Huang,[1] Milan Raska,[1,4] Hitoshi Suzuki,[1,5] Bruce A. Julian,[1,2] Christopher D. Willey,[3] Jan Novak.[1] *[1]Microbiology, Univ of Alabama at Birmingham; [2]Medicine, Univ of Alabama at Birmingham; [3]Radiation Oncology, Univ of Alabama at Birmingham; [4]Palacky Univ in Olomouc; [5]Juntendo Univ Faculty of Medicine.*

**Background:** IgA Nephropathy (IgAN) is an autoimmune disease characterized by IgA1-containing mesangial immunodeposits. These deposits are likely derived from circulating immune complexes formed from IgA1 with galactose-deficient *O*-glycans (Gd-IgA1; autoantigen) and antiglycan autoantibodies. Disease activity (macroscopic hematuria) frequently manifests after an upper-respiratory-tract infection, suggesting that immune activation via cytokines may be involved in disease exacerbation. This concept is supported by the observation that serum IL-6 levels are elevated in some IgAN patients. Using immortalized IgA1-secreting cells derived from the circulation of IgAN patients and healthy controls (HC), we characterized signaling mechanisms involved in Gd-IgA1 production induced by IL-6.

**Methods:** IgA1-secreting cells were stimulated with IL-6, and IgA1 production and *O*-glycosylation were assessed. siRNA knock-down (k/d) and specific kinase inhibitors confirmed the role of IL-6-STAT3 pathway in Gd-IgA1 production. Association of a possible co-factor, HDAC6, with STAT3 was assessed by using immunoprecipitation and Western blot assay.

**Results:** IgA1-producing cells from IgAN patients but not HC stimulated with IL-6 secreted more Gd-IgA1 ($P<0.05$). IL-6 stimulation induced more robust and prolonged STAT3 phosphorylation in cells from IgAN patients than from HC. siRNA k/d and kinase

inhibitors confirmed the central role of STAT3 activation in the enhanced production of Gd-IgA1 in response to IL-6 (P<.05). HDAC6 showed no association with STAT3 regardless of IL-6 stimulation.

**Conclusions:** IL-6-mediated activation of STAT3 plays an important role in the enhanced production of Gd-IgA1 in IgAN. Further analysis is needed to determine a potential role of acetylation in STAT3 activation. STAT3 signaling is exacerbated in IgAN patients and may offer a future target for disease-specific therapy.

## TH-OR088

**Tonsillar Cells in Patients with IgA Nephropathy Produce Aberrantly Glycosylated IgA1 and Anti-Glycan Antibodies** Hitoshi Suzuki,[1] Yusuke Suzuki,[1] Yuko Makita,[1] Bruce A. Julian,[2] Jan Novak,[2] Yasuhiko Tomino.[1] *[1]Nephrology, Juntendo Univ Faculty of Medicine, Tokyo, Japan; [2]Medicine and Microbiology, Univ of Alabama at Birmingham, Birmingham, AL.*

**Background:** IgA1 in circulating immune complexes and mesangial deposits of patients with IgA nephropathy (IgAN) is aberrantly glycosylated, galactose-deficient in *O*-glycans (Gd-IgA1), and is bound to anti-glycan IgG/IgA autoantibodies. However, the origin of cells producing Gd-IgA1 and the autoantibodies is not certain. Upper respiratory tract infections and tonsillitis are frequently associated with clinical flares of IgAN, suggesting a link with disease pathogenesis. Levels of gene transcription for specific glycosyltransferases are dysregulated in tonsillar B cells from patients with IgAN, resulting in production of Gd-IgA1. In some patients, tonsillectomy and glucocorticoids (TSP) may slow disease progression in early clinical stages. Therefore, we assessed whether tonsillar cells produce Gd-IgA1 or anti-glycan IgG.

**Methods:** Tonsillar cells obtained from 29 patients with IgAN were cultured 72 hours. Gd-IgA1 and anti-glycan IgG secreted by these cells were measured by ELISA. Proteinuria and hematuria, and serum levels of Gd-IgA1, Gd-IgA1-specific IgG and IgA, and IgG-IgA immune complexes (IC) were measured before and after TSP.

**Results:** Proteinuria and hematuria improved after TSP (P<0.05). Eighteen of 29 patients had proteinuria less 0.3 g/g and 5 red blood cells/HPF after TSP (Remission group). Eleven patients did not clinically improve (non-Remission group). Serum levels of Gd-IgA1, Gd-IgA1-specific autoantibodies, and IgG-IgA IC decreased during glucocorticoid therapy after tonsillectomy (P<0.01). The rates of decrease in the levels of Gd-IgA1, Gd-IgA1-specific antibodies and IgG-IgA IC were greater in the Remission group (P<0.01). Tonsillar cells from Remission group produced more Gd-IgA1 and anti-glycan IgG than those from non-Remission group (P<0.01).

**Conclusions:** Tonsillar cells may contribute to the circulating Gd-IgA1 and anti-glycan IgG in patients with IgAN. These biomarkers may be useful for guiding therapy of IgAN.

*Funding:* NIDDK Support

## TH-OR089

**Understanding the Structure of PLA2R: Insights into Formation of the Immunodominant Epitope Recognised by Autoantibodies in Patients with Idiopathic Membranous Nephropathy** Maryline Fresquet, Thomas A. Jowitt, Jennet O. Gummadova, Edward A. McKenzie, Rachel Lennon, Paul E. Brenchley. *Faculty of Human and Medical Sciences, Univ of Manchester, Manchester, United Kingdom.*

**Background:** 75% of patients with idiopathic membranous nephropathy (IMN) have autoantibodies against the phospholipase A2 receptor (PLA2R). The epitope(s) within PLA2R and its 3D structure are unknown. The objective is to understand how autoantibodies to PLA2R interact with the target receptor.

**Methods:** To identify the dominant epitope, PLA2R was trypsin digested, separated on unreduced gels and peptides reacting to patient sera were identified by western blotting. Bands of 16, 20 and 37kDa were excised, reduced and analysed by MS. The structure of both PLA2R and an immunoreactive PLA2R fragment, NCTLD3, were investigated using sedimentation, SAXS and 3D electron tomography. A SPR method was developed to assess binding kinetics of patient antibodies to PLA2R and NCTLD3.

**Results:** MS analyses suggest 3 peptides constitute part of the PLA2R epitope. The distribution of these peptides is discontinuous on the linear sequence but could be in proximity within the folded molecule.

Hydrodynamic experiments showed PLA2R exists in two distinct pH-dependent conformations similar to other mannose receptor family members. Low resolution *ab initio* structures from SAXS and EM have enabled us to construct a model of both full-length and NCTLD3 PLA2R.

SPR analysis of patient sera revealed equivalent autoantibody binding kinetics to both full-length PLA2R and NCTLD3. Antibody affinity was similar in all five patient sera tested.

**Conclusions:** We identified a specific region on PLA2R as the potential immunodominant epitope involved in the interaction with its autoantibody. This epitope appears to be solely within the N-terminal CTLD3 region as shown by SPR, and there appears to be no difference in affinity between patients. PLA2R fluctuates between an extended conformation at neutral pH and a bent conformation at lower pH possibly involved in the regulation of ligand recognition or receptor oligomerization. This has implications for formation of neo-epitopes that may become immunogenic and induce autoimmunity.

## TH-OR090

***APOL1* Risk Variants in PLA2R-Positive Membranous Glomerulopathy** Christopher Patrick Larsen, Patrick D. Walker, Josephine M. Ambruzs, Nidia Cordeiro Messias. *Nephropath, Little Rock, AR.*

**Background:** The APOL1 disease spectrum includes non-diabetic ESKD, FSGS and collapsing glomerulopathy (CG) associated with HIV and SLE. It is currently unknown if the presence of *APOL1* risk alleles modify the morphologic phenotype of other glomerulonephritides. We sought to determine if there were any morphologic alterations correlated with the presence of *APOL1* risk alleles in a homogeneous cohort of patients with PLA2R-positive membranous glomerulopathy (PLA2rMG).

**Methods:** 118 renal biopsies were identified in the case file of our institution from AA patients with PLA2rMG. A blinded morphologic evaluation was performed to evaluate for changes associated with the presence of 2 *APOL1* risk alleles. Features examined include global and segmental glomerulosclerosis, subtype of FSGS, degree of interstitial fibrosis and tubular atrophy, subtype of tubular atrophy, degree of interstitial inflammation, degree of arteriosclerosis, evidence of acute tubular injury, and the presence of microcystic tubular dilatation (MCTD). DNA was genotyped for *APOL1* risk alleles using TaqMan assays.

**Results:** Six (6) cases of CG were identified including 4/18 in the group with 2 risk alleles, 2/45 in the group with 1 risk allele, and 0/40 in the group with no risk alleles. *APOL1* associated with CG such that in a recessive model, *APOL1* risk alleles conferred 11.9 fold higher odds of developing CG ($P<0.01$, Odds ratio $CI_{95}=2.0\text{-}79.0$). *APOL1* risk alleles were also found to be associated with MCTD ($P<0.04$), interstitial inflammation ($P<0.03$), and segmental sclerosis ($P<0.01$). The cases with 2 risk alleles also showed a trend toward more interstitial fibrosis and tubular atrophy. Other morphologic features were not found to be associated with *APOL1*.

**Conclusions:** Collapsing glomerulopathy is an aggressive nephropathy with no currently available efficacious treatment. We have evaluated the changes associated with *APOL1* risk alleles in a cohort of patients with PLA2R-positive MG and found that there is significantly more CG with the presence of 2 *APOL1* risk alleles. These results raise the possibility that *APOL1* risk alleles modulate and potentially accelerate glomerular diseases though the development of collapsing lesions.

## TH-OR091

**The Prevalence of Circulating Monoclonal Protein in Proliferative Nephropathy with Monoclonal Deposits** Gauri Bhutani,[1] Fernando C. Fervenza,[1] Sanjeev Sethi,[2] Samih H. Nasr,[2] Nelson Leung.[1] *[1]Nephrology & Hypertension, Mayo Clinic; [2]Anatomic Pathology, Mayo Clinic, Rochester.*

**Background:** Monoclonal gammopathy of 'Renal' significance (MGRS) was recently described as a new classification of monoclonal gammopathy which results in renal disease but is not diagnostic of multiple myeloma. MGRS is defined as a kidney disease with monoclonal protein deposits or where the monoclonal protein acts as a C3 nephritic factor. This study was undertaken to evaluate the hematologic characteristics of these patients.

**Methods:** The pathology database at Mayo Clinic was reviewed for patients with MGRS associated proliferative kidney diseases from 2008 to 2012. Circulating monoclonal protein testing included serum protein electrophoresis with immunofixation (SPEP/IF) and serum free light chain assay (FLC). Methods to detect the pathological clone included bone marrow biopsy and PET scan. Fisher's exact test was used for statistical analysis.

**Results:** In a total 56 patients, biopsy displayed mesangioproliferative (8 = 14%), membranoproliferative (MPGN) (22 = 40%), diffuse proliferative (DPGN) (11 = 20%), a mixed MPGN- DPGN (10 = 18%) and proliferative GN with membranous features (5 = 9%). Monoclonal deposits were IgGK in 59%, IgGγ in 25% and IgAK / γ or IgMK / γ in the remaining 10%. IgG subtyping showed IgG3 in 14 (64%), IgG1 in 5 (22%) and IgG2 in 3 (14%) out of 22 biopsies. Table 1 notes pertinent diagnostic workup.

| All proliferative glomerulonephritides (56) | | | | | | |
|---|---|---|---|---|---|---|
| | Positive SPEP/IF (14 = 25%) | | Negative SPEP / IF (42 = 75%) | | | |
| FLC Ratio (0.37 – 3.1) | Clone detected (11 = 79%) | No clone detected (3 = 21%) | Clone detected (1 = 1.5%) | No clone detected (23 = 55%) | Unrelated clone (2 = 3.5%) | Clone not checked (16 = 38%) |
| Abnormal | 0 | 1 | 1 | 0 | 0 | 1 |
| Normal | 10 (91%) | 1 | 0 | 18 | 2 | 8 |
| Not known | 1 | 1 | 0 | 5 | 0 | 7 |

**Conclusions:** Majority of patients with a proliferative nephropathy and monoclonal deposits lack a detectable serum monoclonal gammopathy. Detection of a serum monoclonal protein is associated with significantly high detection rate of the pathologic clone ($p < 0.01$) and, hence, a more directed treatment. Serum free light chain ratio is normal in most patients and an abormal result does not appear to increase the likelihood of finding a pathologic clone.

## TH-OR092

**Toward a Working Definition of C3 Glomerulopathy by Immunofluorescence** Jean Hou, Glen S. Markowitz, Andrew S. Bomback, Gerald B. Appel, Leal C. Herlitz, Michael B. Stokes, Vivette D. D'Agati. *Columbia Univ Medical Center, New York, NY.*

**Background:** An impediment to the diagnosis of C3G is the lack of a working IF definition developed and validated in a disease cohort. While "C3 only" is applied as a theoretical construct, its practicality is untested. We aimed to test hierarchical IF criteria with varying stringency for C3G using dense deposit disease (DDD) as gold standard; determine if "C3 only" is a practicable criterion; apply these criteria to analyze the incidence of C3G in MPGN types 1 and 3; and explore clinical correlates.

**Methods:** A total of 807 biopsies (bx) diagnosed as MPGN from 1999-2012 were retrospectively reviewed. Excluding cases with known etiology (e.g. hepatitis C), we identified 319 cases of primary MPGN types 1-3. We analyzed IF reports and coded bx as glomerular deposits of: C3 only (Criterion 1); C3 dominant and ≤1+ IgM only (Criterion 2); C3 dominant and ≥2 orders of intensity stronger than any combination of IgG, IgM, IgA, C1q (Criterion 3); C3 dominant and >1+ IgG or IgM (Criterion 4).

**Results:** On analysis of initial bx in 319 patients (200 MPGN1, 42 DDD and 77 MPGN3), the most restrictive criterion of "C3 only" captured only 50% of DDD (compared to 8% MPGN1 and 10.4% MPGN3), whereas criterion 3 identified 88.1% of DDD (compared to 30.5% MPGN1 and 39% MPGN3). Broadening to criterion 4 added only 4.8% of DDD cases but added 26.5% MPGN1 and 13% MPGN3 cases, suggesting loss of specificity. Therefore criterion 3 was chosen as working definition of C3G. Among MPGN3, 90% of C3G cases were Strife and Anders variant. Repeat bx in C3G revealed a change in IF criterion class in 10 of 23 cases, indicating fluidity between subgroups. The prevalence of low serum C3 and/or C4 at bx did not significantly differ among the 3 proposed IF criteria. A nephritic presentation was more common in criterion 1 cases.

**Conclusions:** "C3 only" is an impractical definition of C3G. We propose a less restrictive definition of C3 dominant and at least 2 orders of magnitude more intense than any other immune reactant. These criteria provide a framework for identifying renal biopsies most likely to benefit from investigations into alternative pathway dysregulation.

## TH-OR093

**Biomarker Profiling of Dense Deposit Disease and C3 Glomerulonephritis** Yuzhou Zhang, Tara Maga, Bertha Martin, Nicole Meyer, Dingwu Shao, Xue Xiao, Carla M. Nester, Richard J. Smith. *Univ of Iowa, Iowa City, IA.*

**Background:** Dense Deposit Disease (DDD) and C3 Glomerulonephritis (C3GN) are prototypical C3 Glomerulopathies (C3G). On renal biopsy, both are C3-dominant by immunofluorescence while on electron microscopy DDD is defined by intramembranous glomerular basement membrane dense deposits while C3GN is associated with some combination of subepithelial, subendothelial and/or less dense, discontinuous intramembranous deposits. The pathophysiological basis of both diseases is dysregulation of the complement cascade at the level of the C3 and C5 convertases.

We sought to define the relative degrees of proximal and distal complement pathway dysregulation in a cohort of DDD and C3GN patients to test the hypothesis that these two diseases can be differentiated by biomarker profiling.

**Methods:** We examined a panel of biomarkers that are reflective of alternative and terminal complement pathway activity in 17 DDD patients and 17 C3GN patients.

**Results:** As compared to controls, in both DDD and C3GN patients, serum levels of C3, factor B, properdin and C5 are significantly reduced ($p<.005$) while levels of C3d are significantly elevated ($p<.005$). In C3GN patients but not in DDD patients, sMAC is elevated ($p<.005$) and C7 is reduced ($p<.01$) as compared to controls. Significant biomarkers differences between DDD and C3GN include a significant reduction in both properdin ($p<.005$) and C7 ($p<.01$) in C3GN and a significant elevation of sMAC ($p<.05$) in C3GN.

**Conclusions:** Biomarker profiling distinguishes DDD and C3GN and is a valuable metric for defining the degree of complement dysregulation that is present. These results have clinical implications and can be used to guide and follow response to different anti-complementherapies.

## TH-OR094

**Recurrent C3 Glomerulonephritis: Clinicopathological Findings and Outcomes** Ladan Zand,[1] Elizabeth C. Lorenz,[1] Fernando G. Cosio,[1] Fernando C. Fervenza,[1] Samih H. Nasr,[1] Richard J. Smith,[2] Sanjeev Sethi.[1] *[1]Mayo Clinic, Rochester, MN; [2]Carver College of Medicine, Iowa City, IA.*

**Background:** C3 glomerulonephritis (GN) is a proliferative glomerulonephritis characterized by bright C3 staining and the absence of significant Ig staining on IF microscopy. C3GN results from abnormalities in the alternative pathway of complement. In a significant number of C3GN patients, the disease progresses to end-stage renal disease (ESRD). The clinical, pathology findings and outcome of C3GN patients receiving a kidney transplant is largely unknown.

**Methods:** We identified 22 C3GN patients between 1996 and 2010 at our institution who received a kidney transplant.

**Results:** Fourteen of the 22 patients had recurrence of C3GN (63.6%). 6 were male and 8 were female patients. The median age at time of initial diagnosis of C3GN on native kidney biopsy was 23 years. Median time from diagnosis to ESRD was 82.6 months. Twelve patients received living donor transplants, 2 received deceased donors. Four transplants were pre-emptive. Median time to recurrence of disease was 9.2 months, with failure of 50% of the grafts (n=7), with a median of 16.6 months to graft failure. Majority of patients (n=11) had hematuria and/or proteinuria at time of recurrence; 3 patients had low C3 levels. Three patients (23%) of 13 tested were positive for a monoclonal gammopathy. All 3 patients had early recurrence of disease (within 3 months) with loss of graft in two patients. Kidney biopsy at time of diagnosis of recurrence showed mesangial proliferative GN in 8 patients and a membranoproliferative GN in 6 patients. All biopsies showed bright C3 staining (2-3+), 6 also showed trace-1+ staining for IgM and/or IgG. EM showed only mesangial deposits in 3 patients, mesangial and subendothelial deposits in 9 patients, 3 also showed subepithelial deposits. In 2 cases, EM studies were not done.

**Conclusions:** This is the first study of recurrent C3GN. Almost 2/3rds of C3GN recur. Despite standard therapy (combination of calcineurin inhibitors, mycophenolate mofetil and prednisone), the course is progressive and results in graft loss in 50% of patients. C3GN recurs early, particularly in patients with monoclonal gammopathy.

## TH-OR095

**Small Molecule Agonists of CD11b Reduce Leukocyte Activation and Recruitment to Promote Kidney Allograft Survival** Samia Khan,[1] Mohd Hafeez Faridi,[1] Anupam Agarwal,[2] James George,[2] Vineet Gupta.[1] *[1]Dept of Internal Medicine, Rush Univ Medical Center, Chicago, IL; [2]Biochemistry & Molecular Genetics, The Univ of Alabama at Birmingham, Birmingham, AL.*

**Background:** Graft loss remains a major obstacle in kidney transplantation and the severity of allograft rejection is often associated with inflammatory infiltrates of leukocytes including myeloid cells expressing β2 integrin CD11b/CD18. Recently, we reported that activation of CD11b/CD18 by a small molecule compound, leukadherin-1 (LA-1), increases leukocyte cell adhesion to the inflamed endothelium, prevents transmigration and inhibits leukocyte tissue recruitment, which resulted in improved kidney function in a murine model of experimental nephritis.

**Methods:** Here we tested whether targeting of CD11b/CD18 using LA-1 prolongs kidney allograft survival in a mouse model of fully major histocompatibility complex-mismatched orthotopic kidney transplant, where C57BL/6J (H-2b) recipients receive a kidney allograft from a Balb/c animal (H-2d) along with daily cyclosporine for 2 weeks to sustain the transplant (control group). In addition to standard cyclosporine therapy, the recipient C57BL/6 mice in the test group were administered LA-1 injections daily during week 1 and every other day from weeks 2-8 after receiving the transplant. Renal allograft rejection was considered at the time animals displayed signs of ill health and high serum creatinine levels.

**Results:** Combination therapy with LA-1 and cyclosporine resulted in a significant prolongation of median graft survival from 28 days (cyclosporine only) to 60 days (cyclosporine and LA-1). At week 5 after transplantation, cyclosporine treated controls had serum creatinine values near 0.6 mg/dl while LA-1 and cyclosporin treated mice had baseline values near 0.2 mg/dl. The mice in the combination therapy group showed significantly reduced leukocyte infiltration and neointimal hyperplasia.

**Conclusions:** These findings indicate a crucial role for CD11b/CD18 in the control of leukocyte migration to transplanted kidney and identify leukadherins as potential, novel therapeutics for use in renal allotransplantation.

## TH-OR096

**Myeloid Derived Suppressor Cells Induced by Apoptotic Donor Cells Suppress Transplant Rejection via Indolamine 2,3-Dioxygenase** Jane Bryant,[1] Nadine M. Lerret,[1] Jiaojing Wang,[2] Zheng Jenny Zhang,[2] Xun-Rong Luo.[1,2] *[1]Medicine, Northwestern Univ Feinberg School of Medicine; [2]Surgery, Northwestern Univ Feinberg School of Medicine.*

**Background:** We have previously shown that pre- and post-transplant infusions of apoptotic donor splenocytes induced by 1-ethyl-3-(3'-dimethylaminopropyl)-carbodiimide treatment (ECDI-SPs) provide significant donor-specific protection to full MHC-mismatched donor cardiac allografts, and with a short course of rapamycin provides indefinite cardiac allograft survival in 100% of the recipients. The mechanisms of protection are not fully elucidated.

**Methods:** The current study focuses on the role of apoptotic donor ECDI-SPs in the induction of myeloid derived suppressor cells and their mechanism of suppression of subsequent transplant rejection in a murine cardiac transplant model. BALB/c cardiac grafts are transplanted to C57BL/6 recipients treated with infusions of donor (BALB/c) ECDI-SPs, and cells from the graft and the spleen are examined.

**Results:** We show that infusions of donor ECDI-SPs induce a significant increase of both the $CD11b^{+}Gr1^{hi}Ly6C^{int}$ and the $CD11b^{+}Gr1^{-}Ly6C^{hi}$ populations in the spleen in a PGE-2 dependent manner, and that depletion of these cell populations abolishes graft protection induced by donor ECDI-SPs infusions. Interestingly, both splenic $CD11b^{+}Gr1^{hi}Ly6C^{int}$ and the $CD11b^{+}Gr1^{-}Ly6C^{hi}$ populations suppress T cell proliferation *in vitro*, with more robust suppression towards $CD8^{+}$ T cells, whereas the same populations when trafficking to the cardiac allograft become less suppressive. Furthermore, the suppression by these myeloid-derived suppressor cells (MDSCs) is mediated through an interferon-γ dependent induction of the tryptophan metabolizing enzyme indolamine 2,3-dioxygenase (IDO). Consequently, treatment with the IDO inhibitor 1-MT abolishes T cell suppression *in vitro* as well as cardiac graft protection *in vivo*.

**Conclusions:** These findings reveal a novel link between apoptotic donor cell infusions and the induction of IDO-producing MDSCs as a mechanism for transplant graft protection, and provide several targets amenable to therapeutic manipulations for tolerance induction for cardiac transplantation.

*Funding:* NIDDK Support

## TH-OR097

**Protection from Apoptosis during Extreme Cold Ischemia and Reperfusion Is Mediated by XIAP and Akt** Swati Jain, Daniel Keys, Charles L. Edelstein, Alkesh Jani. *UC Denver.*

**Background:** Cold ischemia (CI) followed by warm reperfusion (WR) during hibernation is a natural model we have used to understand DGF. Hibernating ground squirrel (GS) kidneys survive CI for *several days* in torpor (LT) followed by WR in Arousal (IBA) without AKI or tubular cell (RTEC) apoptosis seen in mouse & human kidneys after CI/WR. The molecular mechanism of protection against apoptosis & AKI during hibernation has long been sought. We hypothesized that upregulation of anti-apoptotic proteins XIAP, pAkt & pBAD during hibernation prevents RTEC apoptosis.

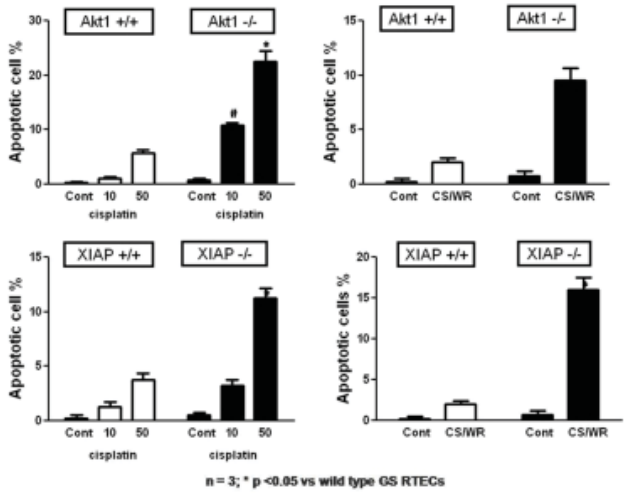
**Methods:** XIAP, pAkt & pBAD were examined: a)*in vivo* in LT & IBA GS kidneys (b)*in vitro* in GS & mouse RTEC under 2 apoptotic stimuli:1) cisplatin 2) cold storage followed by rewarming (CS/WR) to simulate IBA.

**Results:** XIAP, pAkt & pBAD increased after WR in IBA vs. LT kidneys, while cleaved caspase-3 (CC3) & apoptosis did not. Similarly, GS RTEC treated with cisplatin or CS/WR had less apoptosis, no CC3, & increased XIAP, pAkt & pBAD vs. mouse.

| | Mouse RTECs | | Squirrel RTECs | |
|---|---|---|---|---|
| | Cont | CS/WR | Cont | CS/WR |
| XIAP | +++ | + | +++ | +++ |
| pAkt | +++ | ++ | ++ | +++ |
| pBAD | + | - | ++ | ++++ |
| CC3 | + | ++++ | - | - |
| TUNEL + cells | 2.7±0.4 | 26±2.2* | 0.25±0.2 | 2.0±0.4 |

n = 3; * p <0.05 vs GS RTECs

To determine the mechanism of protection GS RTEC were treated with Akt1 shRNA & XIAP siRNA. GS RTEC deficient in Akt1 & XIAP had increased apoptosis & CC3.



**Conclusions:** We have shown for the first time a mechanism used by hibernators to survive prolonged CI/WR far in excess tolerable by human kidneys, using survival factors Akt1 & XIAP. Upregulation of anti-apoptotic factors may prevent apoptosis & AKI in donor kidneys subjected to prolonged CI/WR.

*Funding:* NIDDK Support

## TH-OR098

### Autoimmune Targeting of Protease Activated Receptor-1 (PAR-1) Deregulates VEGF and Disturbs Neoangiogenesis

Rusan Catar, Isa Annett Schramm, Michele Simon, Oskar Wischnewski, Aurélie Philippe, Angelika Kusch, Duska Dragun. *Univ Hospital Charite, Berlin, Germany.*

**Background:** Early loss of peritubular capillaries (PTC) with initiation of tubular atrophy and interstitial fibrosis is central to progressive nephron loss in native kidneys and transplants. VEGF is crucial for endothelial growth, differentiation and survival and mediates PTC homeostasis. Thrombin, a serin protease which elicits its cellular effects via the G-Protein Coupled Receptor (GPCR) PAR-1 is closely involved in VEGF regulation. Functional anti-GPCRs autoantibodies are able to induce endothelial dysfunction. We hypothesized that autoimmune GPCR targeting process may disturb VEGF induced angiogenesis and identified PAR-1 as a novel activating autoantibody target.

**Methods:** Human microvascular endothelial cells (HMEC-1) were stimulated with IgG isolated from patients' sera with transplant peritubular pathology (KTx-IgG). VEGF transcriptional regulation was studied by promoter deletion assay, transcription factor activation by qRT-PCR, western blot, EMSA and knockdown, VEGF secretion by ELISA. Tube formation on matrigel served to study endothelial neoangiogenic response.

**Results:** Treatment with KTx-IgG reduced ERK1/2 dependent VEGF secretion and tube formation. Upon treatment with several pharmacologic antagonists, VEGF secretion could be only normalized by pretreatment with specific PAR-1 inhibitor. Specificity was further confirmed by the use of PAR-1 2nd extracellular loop peptide which rescued endothelial tube formation. KTx-IgG increased cFos protein expression and its binding to VEGF-promoter contributing to deregulate neoangiogenesis by reducing VEGF-promoter activity. AP-1 inhibition or cFos siRNA-induced knockdown reconstituted VEGF levels and increased its promoter activity.

**Conclusions:** We identified the PAR-1 receptor as a new target for functional antibodies in the context of kidney transplantation with disturbed PTC homeostasis. We showed that KTx-IgG disturbs VEGF transcriptional regulation resulting in reduced VEGF secretion and inability of endothelial cells to form tubes. PAR-1 mediated VEGF regulation could offer new possibilities for treatment of kidney transplants to obviate loss of PTCs.

## TH-OR099

### Notch-2 Plays a Crucial Role in B Cell Development and Alloantibody Production

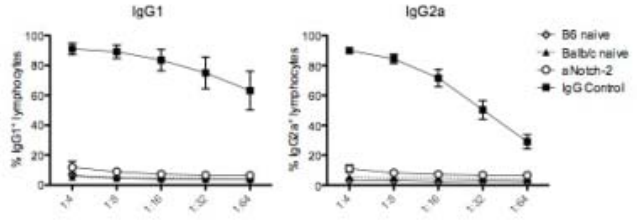
Ciara N. Magee, Tetsunosuke Shimizu, Kassem Safa, Nader Najafian, Leonardo V. Riella. *Transplantation Research Center, Brigham & Women's Hospital, Harvard Medical School.*

**Background:** The role of B cells in alloimmunity is increasingly recognized, while alloantibody production remains a major barrier to long-term graft survival. We have previously shown that Notch signaling critically affects T cell development; however, little is known about the influence of Notch in B cell differentiation and function in transplantation.

**Methods:** We examined the role of Notch-2 therein using a novel, selective antibody against the Notch-2 receptor (aNotch-2; Wu *et al.* Nature 2010) in a full MHC-mismatch cardiac transplant model (Balb/c->B6). B6 recipients treated with aNotch-2 for 6 days had significant, albeit modest, prolongation of graft survival compared to IgG-treated controls (MST 10 *vs* 7 days; $p$=0.0023).

**Results:** Treatment with aNotch-2 effected a 10-fold reduction in marginal zone B cells ($p$<0.0001), while follicular (FO) B cells were increased (71.9±1.45%, $n$=31.29±0.8 x$10^6$ *vs* 50.5±5%, $n$=11.01±0.2 x$10^6$ in controls; $p$=0.046 & $p$=0.06, respectively). Interestingly, despite this, there was significantly less proliferation of FO B cells in mice treated with aNotch-2. The plasma cell subset (B220$^-$CD138$^+$) was significantly reduced in both the spleen and bone marrow of aNotch2-treated mice (0.46±0.03 & 0.2±0.004 *vs* 1.7±0.3 & 0.3±0.01% in controls; $p$=0.047 & $p$=0.01, respectively); furthermore, a greater proportion of splenic plasma cells isolated from aNotch-2-treated mice were immature (CD138$^+$IgM$^+$). Most remarkable, however, was the profound inhibition of alloantibody production following aNotch-2 treatment (Figure; IgG1 & IgG2a).

**Conclusions:** These data reveal a crucial role for Notch-2 in B cell development and function in transplantation, particularly in alloantibody production. Selective Notch-2 blockade may be a useful therapeutic strategy to prevent the antibody-mediated injury so resistant to current therapies.



## TH-OR100

### Erythropoietin Inhibits Human Alloreactive T Cell Response

Joaquin Manrique,[1] Paolo Cravedi,[1] Anita Mehrotra,[1] Jessica A. Reid-Adam,[1] Katherine E. Hanlon,[2] Peter S. Heeger.[1] *[1]Renal Div, Dept of Medicine, Recanati Miller Transplant Institute and Immunology Institute, Mount Sinai School of Medicine, New York, NY; [2]Hematology and Medical Oncology, Mount Sinai School of Medicine, New York, NY.*

**Background:** EPO therapy has been associated with improved transplant outcomes but the mechanisms are unknown. Published data in murine systems indicate EPO has immunomodulatory properties prompting us to test the effects of EPO on in vitro human alloresponses.

**Methods:** Naïve and memory CD4$^+$ and CD8$^+$ T cells, and CD14+ monocytes were isolated from buffy coats or PBLs using magnetic beads. Monocytes were cultured for 5 days with IL-4 and GMCSF to induce DCs and then matured with LPS. Immune cell phenotyping, T cell proliferation in response to allogeneic DCs (CFSE dilution), and intracellular signaling (phosphoflow) were quantified using flow cytometry.

**Results:** CD4$^+$, CD8$^+$, and DCs expressed both the classic EPO receptor (EPOR) and the alternative receptor CD131. Addition of EPO caused a dose dependent decrease in proliferation of naïve and memory CD4$^+$ and CD8+ T cells responding to allogeneic DCs (-61.3±20.2% to 65.2±31.9%, for naïve CD4 cells, p<0.001 vs control). EPO also inhibited anti-CD3/CD28 stimulated T cell proliferation (1000-2000U/mL:-36.5±20.9% to -90±4.37%; p<0.001), the latter indicating a direct effect of EPO on the T cells. Addition of EPO blocked allo-induced IFNg production (-43.3±22.4% p<0.05 vs control) without altering IL-4, IL-17 or Treg induction under appropriate cytokine-polarizing conditions. While EPO lowered DC expression of CD40 (-32.2±11.8 vs. control, p<0.05), it had no effect on CD80/86 expression and EPO-treated DCs induced T cell proliferation to the same degree as controls. EPO inhibited T cell receptor (TCR) induced AKT (CD4$^+$ MFI= -47.1±2.6, p<0.05 and CD8$^+$ MFI= -50.8±6.2, p<0.05) and ERK (CD4$^+$ pERK1/2 MFI= -59.7±14.6, p<0.05; CD8$^+$ pERK1/2 MFI= -35.5±2.7, p<0.05) phosphorylation, linking the above functional effects to known biochemical pathways downstream of the TCR.

**Conclusions:** EPO directly suppresses human alloreactive T cells providing one potential mechanism underlying the observed improved outcomes of EPO treated kidney transplant recipients.

## TH-OR101

**CTLA4 Is Required for Rapamycin-Induced Augmentation of the CD8+ T Cell Response to a Latent Viral Infection** David F. Pinelli, Mandy L. Ford. *Emory Univ.*

**Background:** Latent viral infections are a major concern among immunosuppressed transplant patients. Treatment with belatacept, a CTLA4-Ig fusion protein, was shown to reduce toxicity in kidney transplant recipients compared to CNI therapy, but is contraindicated in EBV- patients, due to an increased risk of PTLD associated with primary EBV infection. Therefore, strategies to improve patients' protective immunity without increasing alloreactivity would be beneficial in this setting. Recent reports have shown that treatment with rapamycin (rapa) paradoxically enhances CD8 T cell responses to certain pathogen infections, raising the enticing possibility that rapa could be used to enhance responses to EBV in belatacept-treated patients.

**Methods:** Mice were infected with gammaherpesvirus 68 (gHV), the murine homolog of EBV, treated with rapa +/- CTLA-4 Ig, and MHC tetramers were used to track virus-specific CD8 T cells. We also performed ex vivo restimulation with gHV peptide to assess CD8 T cell IFN-γ production.

**Results:** Rapa treatment alone enhanced the T cell response to gHV, with a significant increase in the number of gHV tetramer positive CD8 T cells per $10^6$ PBMCs at Day 20 compared to mice that received no treatment (4.5E4±9E3 vs. 2.4E4±9E3) and also led to an increase in the percentage of IFN-γ producing CD8 T cells. In contrast, CTLA4-Ig treatment prevented rapa from significantly enhancing CD8 T cell responses (CTLA4-Ig 2.0E4±8E3 vs. +Rapa 2.6E4±6E3). Interestingly, when an anti-CTLA4 blocking antibody was used, which leaves CD28 signals intact, rapamycin was also unable to augment the response to gHV (Anti-CTLA4 4.2E4±5E3 vs. +Rapa 4.6E4±5E3).

**Conclusions:** Taken together, these results suggest that the ability of rapamycin to enhance virus-specific memory T cell formation requires signals through the CTLA-4 coinhibitor. Further work is necessary to dissect the interactions of these two signaling pathways, and thus to determine the mechanism by which CTLA4 blockade diminishes the ability of mTOR inhibition to promote the generation of CD8 T cell memory.

## TH-OR102

**Gadolinium Accelerates Cardiac Allograft Rejection through Macrophage Activation and Blockade of Phagocytosis** Martina M. McGrath, Melissa Y. Yeung, Nader Najafian. *Renal Div, Brigham and Women's Hospital, Boston.*

**Background:** Phagocytosis is a crucial mechanism for the maintenance of self-tolerance. Defects in phagocytic mechanisms predispose to autoimmunity. Gadolinium has been used as a tool to impair macrophage phagocytosis in experimental models. In this study, we sought to examine the effect of blockade of macrophage phagocytosis by gadolinium, on allograft outcomes.

**Methods:** B6 recipients of fully mismatched heart transplants were treated with CTLA4-Ig 500ug on D0, ± 300ug gadolinium ip on D-2, D5 and D12 post transplant and assessed for survival and mechanistic studies.

**Results:** Treatment with gadolinium led to accelerated allograft rejection (MST 10d vs 30d, p<0.001). Mechanistic studies revealed increased AnnV+ apoptotic cells in spleens of gadolinium treated recipients (p<0.05). Furthermore, gadolinium treated recipients showed increased production of pro-inflammatory IFNg, IL4, IL6, IL17; and reduced IL10 levels in draining lymph nodes. Similarly, CD4+ and CD8+ T effector memory/T reg ratios were increased (p <0.05). [We next sought to more fully assess how gadolinium precipitated allograft rejection. In vitro and in vivo phagocytosis assays confirmed an incremental impairment in macrophage phagocytosis after treatment with gadolinium. DC phagocytosis was unaffected in vivo. Incubation with gadolinium increased macrophage expression of MHC Class II molecules and CD86. Macrophage production of pro-inflammatory TNFa, IL12 and IL17 also increased significantly in response to gadolinium treatment in vitro.

**Conclusions:** These data indicate that gadolinium promotes an activated macrophage phenotype with impaired phagocytosis, increased costimulatory molecule expression and proinflammatory cytokine production. In vivo treatment of recipients of fully mismatched cardiac allografts precipitates acute rejection, characterised by markedly increased pro-inflammatory T cell infiltrate in graft, spleen and draining lymph nodes and splenic accumulation of apoptotic cells. Further studies are required to fully elucidate the mechanisms of rejection induction and evaluate the translational significance of these findings in humans exposed to gadolinium.

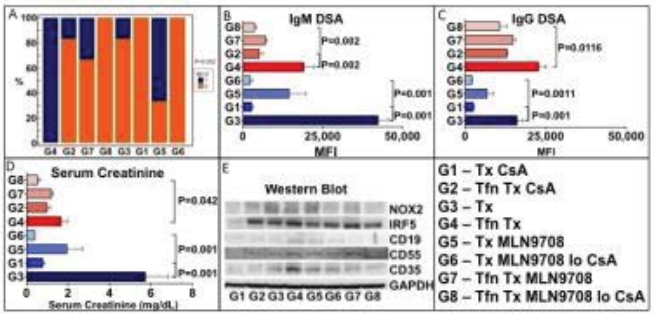
## TH-OR103

**Prevention of Acute Antibody Mediated Rejection by MLN9708, Alone and in Association with Low Dose Cyclosporine in Sensitized Rats** Shannon Reese,[1] Nancy A. Wilson Schlei,[1] Gengwen Huang,[1] Weixiong Zhong,[2] Arjang Djamali.[1] *[1]Medicine, Univ of Wisconsin; [2]Pathology, Univ of Wisconsin.*

**Background:** We designed a study to evaluate the activity of proteasome inhibitor Ixazomib Citrate (MLN9708) alone and in combination with low dose cyclosporine in the prevention of acute antibody mediated rejection (ABMR) in a rat kidney transplant model.

**Methods:** To develop a robust model of ABMR, full MHC mismatch (Brown Norway to Lewis) kidney transplants were performed in recipients that were sensitized to donors via blood transfusion 3 weeks prior to transplant (n=5-8 in all groups). Histopathological grading was performed in accordance with BANFF criteria using H&E, PAS and C4d staining. Flow-cytometry was used to evaluate the effect of treatment on circulating Donor Specific Antibody (DSA). The presence of graft infiltrating B cells, complement regulatory proteins (CD35 and CD55) and M1 macrophage transcription factor (IRF5) were assessed by western blot analysis. Serum creatinine was measured as an indicator of kidney function.

**Results:**



One week after transplant, MLN9708, alone or in combination with low dose CsA, was associated with a significant prevention of ABMR as evidenced by inhibition of microcirculation inflammation (MI score > 2), DSA (IgM and IgG) and improved kidney allograft function (Panels A,B,C & D). MLN9708 was also associated with reduced B-cell infiltration, lower levels of complement regulatory proteins, superoxide generating enzyme (Nox2) and IRF5 (Panel E).

**Conclusions:** Ixazomib citrate (MLN9708) + Low Dose CsA is effective in preventing acute ABMR in an experimental rat model. Further mechanistic studies are needed to understand the therapeutic synergy between proteasome inhibition and calcineurin inhibition in CNI minimization protocols.

## TH-OR104

**High Salt Intensifies Alloimmune Response** Kassem Safa, Tetsunosuke Shimizu, Ciara N. Magee, Anil K. Chandraker, Leonardo V. Riella. *Renal Div/ Transplantation Research Center, Brigham and Women's Hospital, Boston, MA.*

**Background:** Recent reports suggest that a high salt diet (HSD) exacerbates autoimmunity in mice (Nature, 2013). Whether HSD exerts a similarly deleterious effect in alloimmunity is unknown. Herein, we sought to examine the effect of NaCl on the alloimmune response both *in vitro* and *in vivo*, using mixed lymphocyte cultures (MLC) with allo-stimulation and a murine model of solid organ transplantation.

**Methods:** B6 mice were sensitized with fully MHC-mismatched BALB/c skin grafts; to perform MLCs, splenocytes were isolated from these mice and cultured with irradiated BALB/c splenocytes in media enriched with NaCl at gradual increments from 0 to 80 mM. To examine the effect of HSD *in vivo*, B6 mice were fed either HSD (3% Na chow, 0.9% saline) or normal salt diet (NSD; 0.3% Na chow, regular water) starting 3 days prior to receipt of a BALB/c cardiac graft; a single dose of CTLA-4-Ig was administered to control the initial alloimmune response.

**Results:** An increase in the *in vitro* [NaCl] from 5-10 mM effected a corresponding increase in IFNγ secretion, as measured by ELISPOT (311 vs 342 SFC; p=0.03); however, further increase in [NaCl] from 10-40 mM reduced IFNγ secretion (342 vs 275 SFC; p<0.001). Similarly, increased cellular proliferation, as measured by thymidine incorporation, was seen as [NaCl] increased from 0-20 mM (923 vs 1377 cpm; p=0.046), while further increase from 20-40 mM NaCl decreased proliferation (1377 vs 778 cpm; p<0.001).

*In vivo*, HSD-fed transplanted mice lost more weight than both NSD-fed transplanted mice and HSD-fed naïve controls (-7 vs +0.7 and -3.25g; p=0.002 and p=0.106, respectively). HSD precipitated earlier graft rejection compared to NSD (median survival 26 vs. 42 days; p=0.04). While the percentages of both CD4 and CD8 T cells increased in the HSD transplanted group (p<0.001), regulatory T cells (CD4+CD25+Foxp3+) were significantly reduced (5.9±0.4 vs 8.5±0.2% in NSD-fed recipients; p=0.006).

**Conclusions:** These results indicate that HSD may indeed influence the alloimmune response. Further mechanistic experiments will provide greater insight into this fascinating observation that has significant clinical implications in transplantation.

## TH-OR105

**Epigenetic Programing of Postnatal Renal Transcription Rates by Maternal Malnutrition** Oleg N. Denisenko,[1] Karol Bomsztyk,[1] Tom Patrick Fleming.[2] *[1]Medicine, Univ of Washington, Seattle, WA; [2]Univ of Southampton, Southampton, United Kingdom.*

**Background:** Adverse exposures during pregnancy result in intrauterine growth restriction, IUGR, and increased risk of chronic diseases later in life, a phenotype that can be transmitted through generations. A diversity of conditions that cause this phenomenon suggests that common mechanisms of programming may be operative. We recently reported that transcription rates were globally decreased in fetal kidneys in two animal models of IUGR, maternal protein restriction in pigs and placental insufficiency in sheep, together representing the two major causes of IUGR in humans. Here, we examined mechanisms of transcription changes in a mouse model of maternal malnutrition.

**Methods:** Pregnant animals were fed low protein (LPD, 9% protein) or normal protein (NPD, 18% protein) diets during the entire gestation period, after birth all offspring were fed normal diet. RNA and DNA purified from embryonic (17 dpc) and adult (6mo) kidneys were analyzed by RT qPCR and methylated DNA IP (MeDIP) respectively.

**Results:** We found that maternal LPD results in *increased* cellular RNA content in adult kidneys, in contrast to the *reduced* RNA levels in LPD fetal kidneys ($p<0.05$). Moreover, even brief exposure to LPD during the periconceptional period (0-3.5 dpc) was sufficient to consistently increase renal cellular RNA levels in kidneys after transition to normal diet. To explore epigenetic contribution, we examined levels of DNA methylation known to repress transcription. Ribosomal RNA transcribed from ribosomal DNA (rDNA) loci represents 80% of cellular RNA. Diet-induced changes in cellular RNA content inversely correlated with levels of rDNA methylation, and were matched by changes in expression levels of Rrn3, a key rDNA transcription factor.

**Conclusions:** These observations identify rDNA methylation and transcription factor Rrn3 as putative targets of dietary programming of rDNA transcription. Because ribosome production consumes up to 70% of cell resources, upregulation of rDNA transcription in LPD offspring may have adverse consequences for kidney function.

## TH-OR106

**Effect of N-3 Fatty Acids on Kidney Function after Myocardial Infarction: The Alpha Omega Trial** Ellen K. Hoogeveen,[1] Johanna M. Geleijnse,[2] Daan Kromhout,[2] Theo Stijnen,[3] Eugenie Gemen,[1] Ron Kusters,[1] Erik Giltay.[3] *[1]Nephrology, Jeroen Bosch Hospital, Den Bosch, Netherlands; [2]Human Nutrition, Wageningen Univ, Wageningen, Netherlands; [3]Medical Statistics and Bioinformatics, Leiden Univ Medical Center, Leiden, Netherlands.*

**Background:** Kidney function gradually decreases with age, and a myocardial infarction accelerates this deterioration.

**Methods:** We examined in an ancillary study the effect of marine n-3 fatty acids eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), and plant-derived alpha-linolenic acid (ALA) on kidney function in the Alpha Omega Trial: a multicenter, double-blind, randomized, placebo-controlled trial with a 2x2 factorial design.

**Results:** We randomly assigned free-living Dutch patients with a history of myocardial infarction, aged 60-80 years (79% men), to margarines supplemented with targeted additional intake of 400mg/day EPA and DHA, 2g/day ALA, EPA-DHA plus ALA, or placebo for 40 months. In 2426 patients the treatment effect parameters cystatin C-, creatinine- and creatinine-cystatin C-based eGFR were assessed with CKD-EPI equations. Patients consumed 19.8g margarine/day, providing an additional amount of 238mg/day EPA with 158mg/day DHA, 1.98g/day ALA, or both, in active-treatment groups. In the placebo-group, cystatin C-based eGFR was 5.57 ml/min/1.73m$^2$ (SE=0.44) lower after 40 months. Compared to placebo the decline (95%-CI) in cystatin C-based eGFR was reduced by 1.50 (+0.26 to +2.74) for EPA-DHA, 1.03 (-0.21 to +2.28) for ALA, and 1.28 (+0.04 to +2.51) ml/min/1.73m$^2$ for EPA-DHA plus ALA. Creatinine- and creatinine-cystatin C-based eGFR in the placebo-group declined by 10.33 (SE=0.39) and 8.22 (SE=0.39) ml/min/1.73m$^2$, respectively. Decline of creatinine- and creatinine-cystatin C-based eGFR was not affected by EPA-DHA and/or ALA treatment.

**Conclusions:** Supplementation with modest amounts of EPA-DHA, with or without ALA, significantly attenuated the decline of cystatin C-based eGFR in post-myocardial infarction patients. However, a beneficial effect was not observed for creatinine-based and creatinine-cystatin C-based eGFR.

## TH-OR107

**Effects of a Low Protein Diet on Skeletal Muscle Protein Synthesis and Degradation in Patients with Chronic Kidney Disease** Giacomo Garibotto, Antonella Sofia, Valeria Cademartori, Emanuele L. Parodi, Daniela Verzola. *Div of Nephrology, Dyalisis and Transplantation, Genoa Univ and AOU San Martino-IST, Genoa, Italy.*

**Background:** Chronic kidney disease (CKD) is characterized by progressive loss of muscle mass, an effect which could be accelerated by a low protein diet (LPD). However, to what extent skeletal muscle protein metabolism adapts to a LPD in CKD patients is still unexplored.

**Methods:** To assess the effect of LPD on muscle protein metabolism in CKD patients, forearm [2H]phenylalanine kinetics and amino acid balance were evaluated in six CKD patients( 4M/2F, age 54±5 yrs, eGFR 18±2 ml/min) assigned to a usual-protein diet (1.2 g/kg/day, 32 kcal/Kg/day) (4 weeks), followed by a 4- week LPD (0.55 g/kg, 32 kcal/Kg/day) period. Studies were performed after an overnight fast (post-absorptive state) and results express basal rates of protein turnover.

**Results:** After LPD: (a) whole body protein turnover declined only slightly (from 0.65±2 to 0.57 ±2 μmol/min/kg, usual protein diet vs, LPD, $p<0.06$) ; (b) forearm protein net balance, i.e. the difference between protein synthesis and degradation, decreased markedly (-41%, from -21±2 to.-12 ±2 nmol/min.100 ml, $p<0.02$), (c) the efficiency by which amino acids are cycled back from protein degradation into protein synthesis increased by 30% ( $p<0.05$), d)muscle protein degradation underwent a marked decline (from 65±4 to 48 ±4 nmol/min.100 ml , $p<0.02$), c) Protein synthesis was unchanged (from 43±4 to 37±4 nmol/min.100 ml, p= NS).

**Conclusions:** Our data show that CKD patients achieve muscle protein metabolism adaptation to a LPD through a marked decrease in muscle protein degradation and enhanced recycling of amino acid derived from catabolism. Protein synthesis appears to be remarkably preserved, which suggests that a 0.55 g/kg LPD is nutritionally safe.

## TH-OR108

**Effect of Potassium Supplementation with and without Neutralization of Endogenous Acid Production on Markers of Insulin Secretion, Insulin Sensitivity and Blood Pressure in Human Subjects with Combined Glucose Intolerance ("Prediabetics")** Reto Krapf,[4] Katrin Conen,[1] Roberto Scanni,[2] Henry N. Hulter.[3] *[1]Medicine, Univ Hospital Basel, Basel, Switzerland; [2]Medicine, Univ of Basel, Bruderholz, Switzerland; [3]Medicine, Klinik St. Anna Hirslanden, Lucerne, Switzerland.*

**Background:** Potassium (K) depletion is known to inhibit insulin secretion, while metabolic acidosis is reported to decrease insulin sensitivity. Modern Western diets are characterized by comparatively low K and high acid loads. The effect of K supplements on beta cell function in the absence of overt K depletion and the effect of alkali on insulin metabolism without overt acidosis have not been reported.

**Methods:** Double-blind, randomized crossover design: 11 patients with CGI (fasting glucose > 5.7 to < 7.0 mmol/L and glucose levels >7.8 but < 11.1 mmol/L, 2h after 75 gr glucose) were supplemented with 90 meq K as KCl or Kcitrate or placebo daily for 14 days prior to measurements of insulin secretion (HOMA-Beta) and insulin sensitivity (HOMA-IR), oral glucose tolerance (oGTT) and 24 hour ambulatory blood pressure (ABPM) profiles. Washout periods of 2 weeks were interposed between the experimental periods.

**Results:** K supplementation significantly increased HOMA-Beta compared to placebo (from 74 + 7 % to 85 + 8% for KCl and to 84 + 7% for Kcitrate, p= 0.02 each). Only Kcitrate significantly decreased HOMA-IR from 2.76 + 0.23 to 2.41 + 0.19 (p = 0.03), while KCl induced a non-significant increase to 3.17 + 0.39. During Kcitrate, subjects significantly lost 1.5 kg + 0.4 kg (p = 0.18) bw (no change during KCl) and decreased their mean 24 hour BP by - 4.0 + 0.9 (syst) and – 2.7 + 0.4 (diast) mm Hg ($p < 0.02$ compared to KCl and placebo). Quantitative insulin sensitivity check index (Quicki) and measures of the insulin/glucose response after oGTTs confirmed the HOMA findings.

**Conclusions:** In prediabetic subjects, K supplementation improves beta-cell function even without overt K depletion. Only Kcitrate (alkali therapy) and not KCl improves insulin sensitivity and 24h ABPM. These novel results suggest for the first time, that K and/or alkali supplements may play a role in epidemic T2DM prevention or treatment.

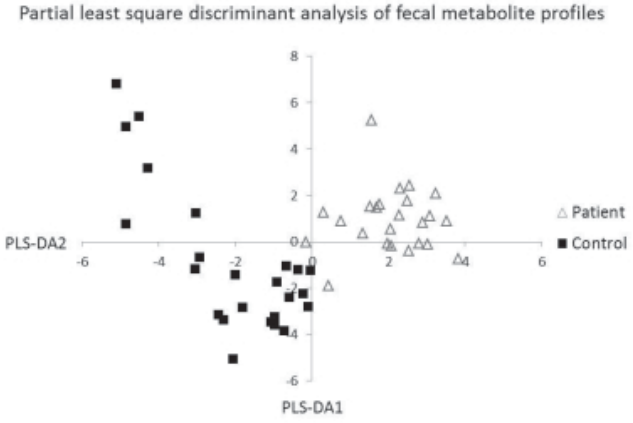
## TH-OR109

**Uremia Is Associated with a Distinct Gut Microbial Metabolism** Ruben Poesen,[1] Karen Windey,[2] Vicky De Preter,[2] Pieter Evenepoel,[1] Kristin Verbeke,[2] Bjorn Meijers.[1] *[1]Nephrology, Univ Hospitals Leuven, Belgium; [2]Translational Research in GastroIntestinal Disorders, Belgium.*

**Background:** The gut microbial metabolism contributes substantially to the human metabolome and is a well-known source of uremic retention solutes. Mounting evidence indicates that the gut microbial metabolism can be disease-specific. Whether uremia is associated with a different gut microbial metabolism has not been studied to date.

**Methods:** Fecal samples of patients on maintenance hemodialysis were collected (NCT01874210). A control group was composed of household contacts to minimize environmental differences. Subjects with gastro-intestinal disease were excluded. Untargeted fecal metabolic fingerprinting with characterization of individual volatile organic compounds was performed with a dedicated gas chromatography-mass spectrometry method. Differences in fecal metabolite profiles were examined with partial least square discriminant analysis.

**Results:** Fecal samples of 25 hemodialysis patients (median age 75y, IQR 64-81) and their household contacts (median age 70y, IQR 65-76) were included for analysis. There were no significant between-group differences in baseline demographics (age, gender, body mass index and presence of diabetes mellitus). A total of 228 different metabolites were identified. Partial least square discriminant analysis demonstrated a clear distinction between fecal metabolite profiles of hemodialysis patients and household contacts (see figure).



**Conclusions:** Uremia is associated with a distinct fecal metabolic fingerprint. Identification of discriminating metabolites is ongoing. Whether the different gut microbial metabolism is secondary to or also (partly) contributing to the syndrome of uremia needs further examination. The potential beneficial effect of therapeutics targeting the gut microbiota (e.g. prebiotics) in patients with renal disease has to be awaited.

*Funding:* Government Support - Non-U.S.

**TH-OR110**

**Effect of Restriction of Foods Containing Phosphorus Additives on the Phosphatemia of Patients with End-Stage Renal Disease**
Margareth Fornasari, Yvoty As Sens. *Santa Casa de São Paulo - School of Medical Sciences, Sao Paulo, SP, Brazil.*

**Background:** Hyperphosphatemia control in chronic renal disease involves restriction of foods which naturally contain phosphorus. However, this restriction must also be extended to processed foods with phosphorus additives, the percentage of which varies from country to country. The purpose of the study is to verify the effect of restricting foods containing phosphorus additives on the serum phosphorus in patients on hemodialysis.

**Methods:** This study was done on adults with end-stage renal disease on hemodialysis for ≥6 months at a single center in Sao Paulo, Brazil. A total of 248 patients with phosphorus > 5.5 mg/dL were evaluated, and 134 were selected according to the inclusion criteria and randomized into 2 groups: intervention (n=67) and control (n=67). Clinical-laboratorial, nutritional status, calories, protein, phosphorus intakes and nPNA evaluations were made at the beginning of the study and after 90 days. The intervention group received orientation to substitute processed foods with phosphorus additives for foods without these additives, but having similar nutritional value. The control group maintained the nutritional orientation given prior to the study. The prescription of phosphorus binders was not modified for either group.

**Results:** There was no initial difference between the groups for serum phosphorus, nutritional status, protein and calories intakes and nPNA. After 3 months, there was a decline in phosphorus levels in the intervention group (from 7.2±1.4 mg/dL to 5.0±1.3 mg/dL, $p<0.001$), while there was no significant difference in the control group (from 7.1±1.2 to 6.7 ±1.2 mg/dL, $p=0.650$). In the intervention group 65.7% of the patients reached the target of ≤5.5 mg/dL serum phosphorus versus 18.5% in the control group ($p<0.001$). There was no difference between groups for nutritional status, protein intake and nPNA.

**Conclusions:** The restriction of food with phosphorus additives reduced the serum phosphorus without interfering in the nutritional status of end-stage renal disease patients on hemodialysis.

**TH-OR111**

**Safety and Efficacy of Bariatric Surgery in Obese Patients with CKD: The London Renal Obesity Network (LonRON) Experience**
Helen L. MacLaughlin,[1] Iain C. Macdougall,[1] Ahmed R. Ahmed,[2] Ameet G. Patel,[1] Avril Chang,[1] Aine Burns,[3] Nick Finer,[4] Harvinder Chahal,[2] George Tharakan,[2] Andrea Pucci,[4] Frederick W.K. Tam,[2] Lina Johansson,[2] Jan Flint,[3] Andrew H. Frankel.[2] *[1]King's College Hospital, United Kingdom; [2]Imperial College Healthcare, United Kingdom; [3]Royal Free London, United Kingdom; [4]Univ College London Hospitals, United Kingdom.*

**Background:** Bariatric surgery is currently the most effective treatment for obesity. Recent evidence suggests the complication rate may be higher in those with CKD, than without.

**Methods:** We report a retrospective study of all obese patients with CKD (eGFR <60ml/min, or eGFR >60ml/min with evidence of kidney damage & under the care of a nephrologist) undergoing laparoscopic bariatric surgery in 3 major London teaching hospitals from 2007-2012. Patient demographics, surgery type, length of stay (LOS), weight loss, adverse events & mortality, were extracted from medical records during Oct 2012-Mar 2013.

**Results:** Of 74 patients (33M;41F), age (mean±SD) 52(±10)years, eGFR 48(±19)ml/min, pre-operative BMI 44.5(±5.7)kg/m$^2$, 38% underwent Roux-en-Y bypass (RYGB), 57% sleeve gastrectomy (SG), & 5% adjustable gastric banding (AGB). 11% were classified as CKD stages 1-2, 59% CKD stage 3, 12% CKD stage 4/stage 5 non-dialysis, & 18% were on haemodialysis at the time of surgery. Mean (95% CI) LOS for SG was 6 days (5, 7), 4 days (3, 5) for RYGB, & 3 days (0, 6) for AGB. Across all forms of surgery, excess BMI loss (>25kg/m$^2$) was 61% (55, 68), & BMI was 33.2 kg/m$^2$ (31.5, 34.8) 12 months post-surgery. There were 16 adverse events (16/74, 22%), including 2 deaths (3%) related to surgical complications. Acute kidney injury was most frequent (4%), followed by leak (3%), acidosis & hyperkalaemia (3%), post-operative chest infection (3%), B12/Fe deficiency (3%), fistula/graft failure (3%), & myocardial infarction (1%). A further 4 deaths occurred during the study period, including 2 related to cancer.

**Conclusions:** While bariatric surgery is effective for weight loss in obese patients with CKD, the adverse event and mortality rates are high. Identification of risk factors for adverse events & investigation of non-surgical alternatives remain priorities.

*Funding:* Government Support - Non-U.S.

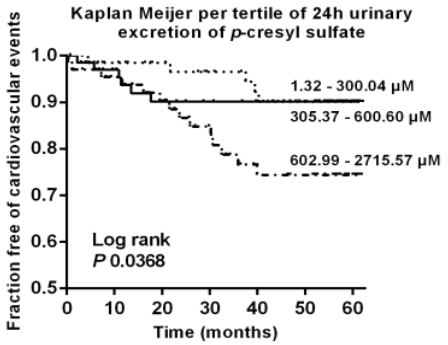
**TH-OR112**

**Cardiovascular Disease Relates to Intestinal Uptake of p-Cresol in Patients with Chronic Kidney Disease**
Ruben Poesen, Liesbeth Viaene, Bert Bammens, Kathleen Claes, Pieter Evenepoel, Bjorn Meijers. *Nephrology, Univ Hospitals Leuven, Leuven, Belgium.*

**Background:** Serum p-cresyl sulfate (PCS) associates with cardiovascular (CV) disease in patients at different stages of chronic kidney disease (CKD). PCS concentrations are determined by intestinal uptake of p-cresol (PC), human metabolism to PCS and renal clearance. Whether intestinal uptake itself is associated with CV disease in patients with CKD has not been studied to date.

**Methods:** We performed a prospective study in patients with CKD stage 1-5 (NCT00441623). Intestinal PC uptake, under steady state conditions, was estimated from 24h urinary excretion of PCS. Primary endpoint was time to first CV event, i.e. cardiac death, myocardial infarction/ischemia, ventricular arythmia, CV surgery, cerebrovascular accident or symptomatic peripheral arterial disease. Statistical analysis was done using Kaplan Meier estimates and Cox proportional hazard analyses.

**Results:** In a cohort of 200 patients, median 24h urinary excretion of PCS was 457.47 µM (IQR 252.68-697.17). After a median follow-up of 52 months, 25 patients reached the primary endpoint (tertile 1/2/3: 5/6/14 events, see figure). Higher urinary excretion of PCS was related with CV events (univariate HR per 100 µM increase: 1.112, P 0.0015). In multivariate analysis, urinary excretion of PCS remained a predictor of CV events, independent of markers of renal function (HR 1.120, P 0.0022) and in different models with other CV risk factors (Framingham, CV history, diabetes mellitus and biochemical parameters). The independent association between urinary excretion of PCS and outcome persisted after correction for serum PCS.



**Conclusions:** Intestinal uptake of PC associates with CV disease. Insights into mechanisms governing intestinal generation and absorption of PC may lead to identification of novel therapeutic targets to reduce CV disease risk in patients with CKD.

*Funding:* Government Support - Non-U.S.

**TH-OR113**

**Sagittal Abdominal Diameter Is an Independent Predictor of Mortality in Incident Peritoneal Dialysis Patients**
Mi Jung Lee,[1] Shin-Wook Kang,[1] Hyung Jung Oh,[1] Sung Jin Moon,[2] Tae Ik Chang,[3] Dae-Suk Han,[1] Tae-Hyun Yoo.[1] *[1]Brain Korea 21; Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea; [2]Internal Medicine, Kwandong Univ, Gyeonggi-do, Korea; [3]Internal Medicine, NHIC Ilsan Hospital, Gyeonggi-do, Korea.*

**Background:** Visceral fat plays a crucial role in the development and progression of cardiovascular (CV) disease. However, the impact of sagittal abdominal diameter (SAD), as an index of visceral fat, on clinical outcomes has never been explored in dialysis patients. In this prospective observational study, therefore, we elucidated the prognostic value of SAD in incident peritoneal dialysis (PD) patients.

**Methods:** SAD was determined by lateral abdominal X-ray at PD initiation in 418 incident PD patients. SAD was defined as the anterior-posterior distance, from skin to skin, at the L4-L5 intervertebral disc level. Cox proportional hazard analysis was performed to ascertain the independent prognostic values of SAD for all-cause and CV mortality.

**Results:** The mean SAD was 24.5±4.3 cm. During a mean follow-up duration of 39.4±21.3 months, 97 patients (23.2%) died. SAD was a significant independent predictor of all-cause [HR (hazard ratio) = 1.081, 95% CI (confidence interval) = 1.015-1.151, P=0.015] and CV mortality (HR = 1.119, 95% CI = 1.022-1.225, P=0.015). In addition, SAD provided significantly higher predictive values for all-cause (AUC: 0.691 vs. 0.547, P<0.001) and CV mortality (AUC: 0.644 vs. 0.483, P<0.001) than body mass index (BMI). Subgroup analysis revealed that higher SAD (≥24.2 cm) was significantly associated with all-cause mortality in men, women, younger patients (<65 years), and patients with lower BMI (<22.3 kg/m$^2$).

**Conclusions:** SAD on lateral abdominal X-ray at the time of PD start was a significant independent predictor of all-cause and CV mortality in incident PD patients, suggesting that estimating visceral fat by SAD could be useful to stratify mortality risk in these patients.

*Funding:* Government Support - Non-U.S.

**Relationship between Body Composition Evaluated by Whole Body Bioimpedance and Survival in Hemodialysis Patients**
Daniele Marcelli,[1] Len A. Usvyat,[2,3] Cristina Marelli,[4] Michael Etter,[5] Jeroen Kooman,[6] Aileen Grassmann,[1] Laura Scatizzi,[1] Inga Bayh,[1] Peter Kotanko,[3] Bernard Canaud.[1] *[1]Fresenius Medical Care, Germany; [2]Fresenius Medical Care North America; [3]Renal Research Institute, N.Y.; [4]Fresenius Medical Care, Argentina; [5]Fresenius Medical Care Asia Pacific; [6]Maastricht Univ Medical Centre, Netherlands.*

**Background:** It is unknown which components of body composition contribute to the reported protective effect of high body mass index (BMI) in chronic HD patients. This international observational study explores the independent and joint associations of fat and lean tissue mass (FTM, LTM) with mortality.

**Methods:** The MONDO consortium comprises HD databases from 26 countries (Usvyat, Blood Purif 2013). Use of the Body Composition Monitor (BCM) (Fresenius Medical Care, Germany) in EMEA NephroCare clinics allowed analysis of data from 17 countries. Lean and Fat Tissue Index (LTI, FTI) were computed as the respective tissue masses normalized to height in $m^2$. The relationship between LTI, FTI and all-cause mortality was assessed by Cox regression adjusted for age, gender, and BMI.

**Results:** For the 10,331 HD patients (age 62.6±14.7; 57% male), baseline median (IQR) LTI and FTI were 12.3 (10.6-14.4) and 9.4 (6.8-12.2) $kg/m^2$, respectively. Analysed jointly, a 1 $kg/m^2$ increment of LTI or FTI was associated with a mortality reduction of 31% or 26%, respectively. Analysed separately, a 1 $kg/m^2$ increment of LTI and FTI was associated with a 13% decrease and a 9% increase in mortality, respectively. A 1-unit higher FTI/LTI ratio yielded a 70% increase in mortality (Table).

| | Hazard Ratio | 95% CI | | p-value |
|---|---|---|---|---|
| LTI independent of FTI (per 1 $kg/m^2$) | 0.87 | 0.84 | 0.90 | <0.001 |
| LTI jointly with FTI (per 1 $kg/m^2$) | 0.69 | 0.65 | 0.74 | <0.001 |
| FTI independent of LTI (per 1 $kg/m^2$) | 1.09 | 1.04 | 1.14 | <0.001 |
| FTI jointly with LTI (per 1 $kg/m^2$) | 0.74 | 0.68 | 0.80 | <0.001 |
| FTI / LTI ratio (per 1 unit) | 1.70 | 1.44 | 2.00 | <0.001 |

**Conclusions:** LTM, not FTM, seems to be the main determinant of the inverse relationship between BMI and mortality. FTM seems to be only protective if accompanied by an appropriately higher LTM. Patients with low LTM relative to FTM appear to be at highest risk.

## TH-OR115

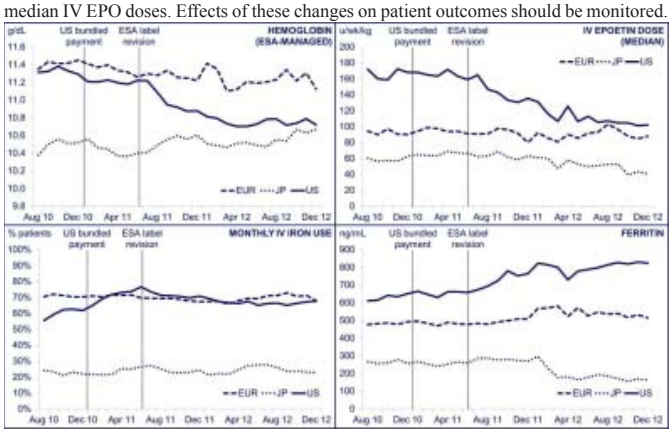
**International Comparisons Illustrate Effect of Payment and Regulatory Changes on Anemia Practice in U.S. Hemodialysis Patients: The Dialysis Outcomes and Practice Patterns Study** Douglas S. Fuller,[1] Bruce M. Robinson,[1] Brian Bieber,[1] Hal Morgenstern,[2] Tadao Akizawa,[3] Stefan H. Jacobson,[4] Francesco Locatelli,[5] Ronald L. Pisoni.[1] *[1]Arb Res Collab Hlth, Ann Arbor; [2]Univ of MI, Ann Arbor; [3]Showa Univ, Tokyo; [4]Danderyd Hosp, Stockholm; [5]Hosp A Manzoni, Lecco.*

**Background:** In the US in 2011, an erythropoiesis-stimulating agent (ESA) label change and Quality Incentive Program (QIP) update removed the 10 g/dL lower hemoglobin (Hb) target, and a new dialysis payment system began. To assess the impact, we compared recent anemia management practices in the US to Europe (EUR) and Japan (JP).

**Methods:** Linear spline regression adjusted for age, black race, sex, vintage, and catheter use was used to assess trends from Aug 2010 to Dec 2012 for ESA-managed Hb ($Hb^{ESA}$), serum ferritin, TSAT, and ESA and IV iron use in US, EUR, and JP.

**Results:** In Aug '10, mean $Hb^{ESA}$ in US (11.3 g/dL) was similar to that in EUR but then diverged after Jun '11 US ESA label change. By Dec '12, mean $Hb^{ESA}$ was 10.7, 10.7, and 11.1 g/dL in US, JP, and EUR. ESA use (any time over 3 months) changed from 95% to 89% in US, 91% to 89% in EUR, and 87% to 91% in JP. Median prescribed IV epoetin (EPO) dose fell 41% in US to 102 u/wk/kg (Dec '12) vs little change in EUR and JP (92 and 63 u/wk/kg, Dec '12). US monthly IV iron use over the study rose from 55 to 68% while stable in EUR and JP. US mean ferritin rose 35% to 825 ng/mL (Dec '12; median: 794), with an 8% rise in EUR to 514 ng/mL and no rise in JP. Higher ferritin in US may be due to higher mean IV iron doses used in US vs most other countries.

**Conclusions:** Recent US trends of lower ESA doses and Hb and higher ferritin levels have not been seen in EUR or JP, suggesting a large impact of payment and/or regulatory changes. In the US, mean Hb is lower than in EUR for first time in >10 yrs with similar median IV EPO doses. Effects of these changes on patient outcomes should be monitored.



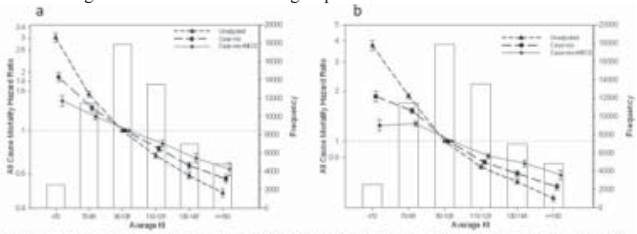
## TH-OR116

**Linear Relationships between Non-Volume-Scaled Dialysis Dose and Mortality Risk among Male and Female Hemodialysis Patients** Connie Rhee,[1] Vanessa A. Ravel,[1] Jongha Park,[4] Elani Streja,[1] Allen R. Nissenson,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Orange, CA; [2]DaVita Inc, El Segundo, CA; [3]Memphis VA Medical Center, Memphis, TN; [4]Univ of Ulsan College of Medicine.*

**Background:** Dialysis dose has typically been defined as the dialyzer clearance of urea multipled by dialysis duration (**Kt**) scaled to the volume of distribution of urea in the body (**V**). Using this classic metric (**Kt/V**), prior observational studies have shown that women receiving lower dialysis doses have higher mortality than women receiving higher doses, whereas men receiving higher doses have slightly increased mortality. However, **V** may have been a proxy for body size, which is associated with mortality independent of urea clearance. **KT** (dialysis dose non-scaled to **V**), may be a more optimal approach to examining the association between dialysis dose and hemodialysis (HD) patient mortality.

**Methods:** Using DaVita clinical data, we identified 104,219 maintenance HD patients who underwent treatment from 2001-2009. Associations between time-averaged **KT** and all-cause mortality were examined in the overall cohort and within subgroups of males (n= 57,156) and females (n=47,063) using Cox regression models.

**Results:** In the overall cohort, there was a graded inverse association between higher time-averaged **KT** levels and mortality risk in unadjusted, case-mix, and case-mix and malnutrition-inflammation-complex syndrome adjusted analyses (reference **KT**=90-109). A similar pattern of association between increased **KT** level and decreased mortality was observed among both male and female subgroups.



Death hazard ratios (and 95% CI) of 8-year average Kt levels for (a) 47,063 female and (b) 57,156 male HD patients (2001-2009)

**Conclusions:** Higher non-volume scaled dialysis dose defined by **KT** is associated with decreased mortality in HD patients, and contrary to findings in prospective randomized controlled trials, our results found no effect differences ascribable to gender.

## TH-OR117

**Effect of Medicare Part D Plan on Adoption on Renal Medications by Dialysis Patients on Renal Transplant Wait List** Marie D. Philipneri, Krista L. Lentine, Mark Schnitzler. *Saint Louis Univ, Saint Louis, MO.*

**Background:** Medicare Part D Prescription Drug Benefit Program came into effect on January 1, 2006. There is **l**imited data on the adoption of renal medications post Medicare Part D implementation among dialysis patients.

**Methods:** A novel database wherein OPTN identifiers for kidney transplant (KT) wait list patients were linked to pharmacy fill records from a large U.S. pharmaceutical claims clearinghouse (2005 to 2010) was evaluated. For this study, we selected dialysis patients with at least one Medicare pharmaceutical fill per quarter in 2006 and at least one pharmaceutical fill per quarter in 2005 (N=1,648).

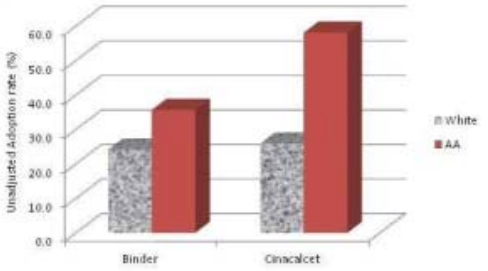
**Results:** 34.0% of the sample did not have pharmacy fills for any binder in 2005 and of these 27.8% filled at least one binder in 2006. African American patients were 1.65 times more likely to adopt binders after the start of Medicare Part D compared to Caucasians after adjusting for gender, education level, and employment status ($p<0.05$). 82.2% of the sample did not have pharmacy fills for cinacalcet in 2005 and of these 15.7% filled cinacalcet at least once in 2006. African American and middle-aged (31-65 year old) patients were more likely to adopt cinacalcet use compared to Caucasian and older (over 65 years) patients after adjusting for gender, level of education, and employment status. The patients who attained college education were 40% less likely to adopt use of cinacalcet compared to those who did not receive college education ($p< 0.05$).

**Association of Demographic Factors with Adoption of Phosphate Binders and Cinacalcet among Dialysis Patients after Medicare Part D Prescription Plan in 2006**

| Variable | Any Binder* [aOR (95% CI)] | Cinacalcet [aOR (95% CI)] |
|---|---|---|
| Age (years): >65 | Reference | Reference |
| 46-65 | 1.22 (0.67-2.23) | 2.10 (1.18-3.73)* |
| 31-45 | 1.36 (0.71-2.61) | 1.98 (1.09-3.63)* |
| 19-30 | 0.99 (0.43-2.28) | 1.01 (0.39-3.69) |
| 0-18 | 0.30 (0.04-2.53) | 0.45 (0.06-3.59) |
| Race: White | Reference | Reference |
| African Americans | 1.65 (1.06-2.58)* | 1.54 (1.09-2.16)* |
| Hispanics | 1.27 (0.65-2.49) | 1.11 (0.70-1.75) |
| Other | 1.46 (0.60-3.52) | 1.33 (0.72-2.43) |
| Female | 1.03 (0.70-1.51) | 1.30 (0.96-1.75) |
| Attained college education | 0.69 (0.46-1.03) | 0.60 (0.42-0.85)* |
| Employed | 0.82 (0.43-1.55) | 1.12 (0.69-1.84) |

*p<0.05

**Unadjusted Adoption Rates for Phosphate Binders and Cinacalcet by African Americans compared to Caucasians after Medicare Part D Prescription Plan in 2006**



**Conclusions:** The results of this study suggest that Medicare Part D Plan was particularly helpful for the African American, middle-aged, and those without college education among dialysis patients on renal transplant wait list. Future studies are needed to see if this trend is sustained and the findings could help policy makers focus their efforts on special populations in the implementation of new health care reforms.

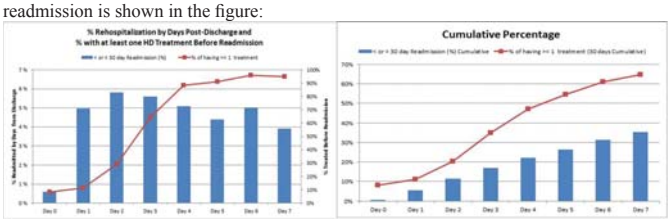
## TH-OR118

**Outpatient Dialysis Treatments in the Week Post-Discharge and Readmissions** Eduardo K. Lacson, Weiling Wang, Franklin W. Maddux. *Fresenius Medical Care, North America, Waltham, MA.*

**Background:** 30-day hospital readmissions in dialysis patients are thought to be influenced by outpatient dialysis facility care. Contact with facility staff to draw labs and implement interventions are necessary to influence outcome. Laboratory results are often received by the second (or third) treatment and could be acted upon. We evaluated the frequency of hemodialysis (HD) treatments within the 1st week post-discharge, before readmission events.

**Methods:** All adult in-center HD patients treated 3x/ week as of 1/1/2011 in Fresenius Medical Care, North America facilities with at least one hospital discharge in 2011 were included. Days to readmission and the number of HD treatments before readmission were recorded until 12/31/2011.

**Results:** There were 164,258 hospital events in 64,128 patients in 2011. 50,380 (30.7%) 30-day readmissions occurred in 23,575 patients. 17,797 (35.3%) out of 50,380 readmissions were within 7 days post-discharge, with only 5,810 (32.6%) of them having 1 treatment prior to readmission and 5,723 (32.2%) having at least 2 treatments. Within the first 3 days, only 34.8% (2975 of 8541 readmissions) received a treatment in the facility. The day-to-day (left) and cumulative (right) rate of treatments provided prior to readmission is shown in the figure:



**Conclusions:** The first week post-discharge from the hospital represents a critical actionable period for outpatient HD facilities to potentially impact 30-day readmission rates. However, over 35% of 30-day readmissions occur within the first week and may not be actionable, particularly since more than two-thirds of these readmissions did not have sufficient contact time to draw and result lab tests as well as respond with clinical intervention(s). Unlike hospitals, outpatient dialysis facilities should not be held accountable for hospital readmissions that occur in the first week post-discharge.

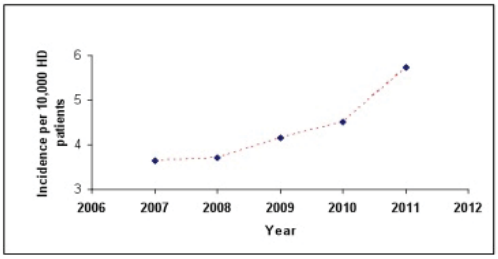
## TH-OR119

**Evaluation of Calciphylaxis Incidence in the United States Renal Data System** Sagar U. Nigwekar,[1] Craig Solid,[2] Elizabeth D. Ankers,[1] Ravi I. Thadhani,[1] Charles A. Herzog.[2] *[1]Massachusetts General Hospital; [2]CVSSC, US Renal Data System, Minneapolis, MN.*

**Background:** Exact incidence of calciphylaxis, a highly fatal condition seen in maintenance hemodialysis (MHD) patients, is unknown. This study is designed to develop a strategy to accurately identify calciphylaxis cases in the United States Renal Data System (USRDS) and to examine calciphylaxis incidence.

**Methods:** Using the USRDS database, we identified those receiving MHD during 2007-2011 (n=1,203,240). ICD-9 code 275.49 refers to *Other Disorders of Calcium Metabolism* with calciphylaxis included along with other diagnoses such as nephrocalcinosis, chondrocalcinosis, etc. Since accurate diagnosis of calciphylaxis requires a skin biopsy and other disorders covered under 275.49 do not require a skin biopsy for diagnosis, we theorized that applying ICD-9 code 275.49 plus skin biopsy procedure codes simultaneously to claims in the USRDS will accurately identify calciphylaxis cases. We planned a systematic validation of this strategy in Partners Healthcare System's Research Patient Data Registry (RPDR) that contains 11,451 MHD patients using natural language processing and by an independent query of pathology department records.

**Results:** Application of surrogate strategy to RPDR identified 69 calciphylaxis cases. Chart review confirmed 66 cases to be true positives. An independent query of pathology records identified 8 calciphylaxis cases missed by the surrogate strategy. This yielded sensitivity 87%, specificity 99%, and C statistic 0.96 for the surrogate strategy. Application of this validated strategy to the USRDS database identified 527 calciphylaxis cases. Annual incidence of calciphylaxis increased over the study period from 3.7 per 10,000 HD patients to 5.7 per 10,000 HD patients.



**Conclusions:** Calciphylaxis is rare but its incidence is rising. Further research is needed to investigate reasons for this rise.

*Funding:* Private Foundation Support

## TH-OR120

**Provider Characteristics and Hemodialysis Patient Outcomes** Yelena Slinin,[1] Haifeng Guo,[2] Suying Li,[2] Jiannong Liu,[2] Areef Ishani.[1,2] *[1]Veterans Administration Health Care System, Minneapolis, MN; [2]Chronic Disease Research Group, Minneapolis, MN.*

**Background:** Physician characteristics are associated with differential performance on quality measures and patient outcomes in several medical fields. We aimed to determine whether hemodialysis provider characteristics were associated with patient morbidity, mortality, and quality of care (defined by influenza vaccination and wait-listing for kidney transplant).

**Methods:** Using USRDS data for patients who initiated in-center hemodialysis 10/01/2003-9/30/2006 (n = 91,276), we defined patient characteristics and identified physicians from Part B Medicare claims for outpatient dialysis submitted during months 4-6 of hemodialysis. We obtained physician characteristics from the AMA Physician Master File. We determined associations of physician characteristics with 1-year patient mortality and first hospitalization using Cox proportional hazards analysis, and with vaccination and wait-listing using logistic regression.

**Results:** Physician characteristics were not associated with patient mortality. After adjustment for patient and other provider characteristics, longer practice duration (AHR 1.03(1.01-1.05) for 9-21 years in practice compared with 0-8), and administrative, research, or teaching practice (1.08(1.00-1.16) compared with office-based practice) were associated with greater risk of patient hospitalization. Practice in smaller metropolitan service areas (MSAs) was associated with lower risk of hospitalization (0.95(0.92-0.97)). Longer practice duration was associated with higher chance of wait-listing for kidney transplant (AOR(1.15(1.05-1.25) for ≥ 22 years in practice compared with 0-8), and practice in smaller MSAs was associated with lower chance (0.89(0.79-0.99) for population 100,000-249,999 and 0.84(0.74-0.95) for < 100,000, compared with ≥ 1,000,000). Graduation from a foreign medical school was associated with higher odds of influenza immunization (1.07(1.00-1.14)), as was practice in smaller MSAs (AOR 1.29(1.20-1.38) for population 100,000-249,999).

**Conclusions:** Several characteristics of physicians following patients for outpatient hemodialysis were associated with patient hospitalizations and quality of care.

## TH-OR121

**Comparison of Hospitalization between For-Profit and Nonprofit Dialysis Facilities** Lorien S. Dalrymple,[1] Kirsten L. Johansen,[2,3] Patrick S. Romano,[1] Glenn M. Chertow,[4] Yi Mu,[1] Julie H. Ishida,[3] Barbara A. Grimes,[3] George A. Kaysen,[1] Danh V. Nguyen.[5] *[1]UC Davis; [2]San Francisco VAMC; [3]UCSF; [4]Stanford; [5]UC Irvine.*

**Background:** The vast majority of US dialysis facilities are for-profit and profit status has been associated with processes of care and outcomes in patients on dialysis. Our study examined whether dialysis facility profit status was associated with the rate of hospitalization in patients starting dialysis.

**Methods:** We conducted a retrospective cohort study of Medicare beneficiaries starting dialysis between 2005 and 2008 using data from the United States Renal Data System. We examined and compared all-cause hospitalization between for-profit and nonprofit dialysis facilities through 2009 using Poisson regression. We conducted companion analyses of cause-specific hospitalization that are likely to be influenced by dialysis facility practices including hospitalizations for heart failure and volume overload, access complications, or hyperkalemia.

**Results:** The cohort included 150, 642 patients. Of these, 12,985 (9%) were receiving care in nonprofit dialysis facilities. In adjusted models, patients receiving hemodialysis in for-profit facilities had a 15% (95% CI 13 - 18%) higher relative rate of hospitalization compared to those in nonprofit facilities. Among patients receiving peritoneal dialysis, adjusted analyses showed a non-significant trend toward higher rate of hospitalization in for-profit facilities (RR 1.07, 95% CI 0.97 - 1.17). Patients on hemodialysis receiving care in for-profit dialysis facilities had 37% (95% CI 31 - 44%) higher rates of hospitalization for heart failure or volume overload and 15% (95% CI 11 - 20%) higher rates of hospitalization for vascular access complications.

**Conclusions:** Hospitalization rates were significantly higher for patients receiving hemodialysis in for-profit dialysis facilities.

## TH-OR122

**Primary Care Nephrology versus Subspecialist Care for ESRD Patients: The Southern California Kaiser Permanente Experience** Dean A. Kujubu,[1] Miwa Takayanagi,[2] Jean Q. Wang,[2] Antoine C. Abcar,[1] Scott A. Rasgon.[1] *[1]Nephrology, Kaiser Permanente, Los Angeles, CA; [2]Research and Evaluation, Kaiser Permanente, Pasadena, CA.*

**Background:** Since most dialysis patients see their nephrologists more often than their generalists, many nephrologists serve as *de facto* primary care physicians. Alternatively, other nephrologists prefer to manage ESRD issues only and defer non-dialysis issues to the patients' primary care physicians. Which practice pattern results in better clinical outcomes, more efficient use of medical resources, or higher patient satisfaction is unclear.

**Methods:** We reviewed the number of emergency room (ER) visits, hospitalizations, hospital days, ambulatory visits, and mortality of ESRD patients in the Southern California Kaiser Permamente (SCKP) Health System from 1999-2009. In 2 of the 13 medical centers, nephrologists serve as primary care physicians (PC) for ESRD patients; in the other 11 medical centers, ESRD patients see nephrologists who do not provide primary care (NPC). Demographic data and the presence of co-morbidities (CAD, CHF, HTN, DM, cirrhosis) were collected.

**Results:** From 1999-2009, there were 1932 ESRD patients in the PC group and 9192 patients in the NPC group. The PC group had more PD patients (10.9% vs 9.1%), more men (60.2% vs 57.1%), fewer Blacks (14.5% vs 23.7%), more Asians (15% vs. 8.7%), and more cirrhotics (5.8% vs 3.7%) compared to NPC group. Age and the presence of other co-morbidities were not significantly different. Compared with NPC patients, PC patients had fewer ER visits/yr (4.0 v 4.7, p=.001), fewer hospitalizations (2.8 v. 3.1 p=.03), and fewer clinic visits (10.7 v 11.4, p<.0001). Hospitalization days, death rate, and time to death were not significantly different. Nephrologists who provided PC received higher patient satisfaction scores (9.55 v 9.46, p=.01).

**Conclusions:** Within SCKP, patients of PC nephrologists had significantly fewer ER and clinic visits, fewer hospitalizations, and better satisfaction with their physicians compared with those ESRD patients whose nephrologists who did not provide PC. An ESRD patient-centered medical home with nephrologists serving as primary care physicians may improve both patient care and patient satisfaction.

## TH-OR123

**Cost Analysis of Provider-Patient Visit Frequency during In-Center Hemodialysis** Benjamin R. Morgan,[1] Suying Li,[3] Jiannong Liu,[3] Areef Ishani,[1,2,3] Yelena Slinin,[1,2] Haifeng Guo.[3] *[1]Univ of Minnesota, Minneapolis, MN; [2]Veterans Administration Health Care System, Minneapolis, MN; [3]Chronic Disease Research Group, Minneapolis, MN.*

**Background:** Beginning in 2004, CMS linked physician payment for HD services to the number of times/month providers see their patients. It is unknown whether increased HD provider visit frequency is associated with Medicare cost savings.

**Methods:** Using USRDS data, a retrospective cohort of 130,892 in-center HD patients was created, including patients starting HD between October 31st, 2003 & September 30th, 2006. During a 3 month run-in phase, provider visit frequency was defined as the average number of provider visits/month, and expressed as ≥4 or <4 provider HD visits/month. Total individual Medicare costs, inpatient Medicare costs, and hospital length of stay (LOS) were summed over the course of a 12 month observational phase. A multi-linear regression model was constructed to estimate the association of provider visit frequency on total Medicare monthly costs accounting for other patient demographics and comorbidities. For inpatient Medicare costs and LOS, a two step statistical model was generated to account for both the probability of hospitalization and the incurred inpatient costs and LOS.

**Results:** Using a multi-linear regression model, provider visit frequency corresponded to a non-significant 0.01% reduction in total Medicare monthly expenditures for patients with ≥4 provider visits a month. Logistical regression models showed a 4% reduction (C.I. 0.93-0.98) in the odds of incurring any inpatient costs or LOS among the ≥4 provider visits/month group as compared to <4 visits/month. On average, patients with <4 visits/month, incurred $232/month higher expenses and stayed in the hospital 0.21 days/month longer than patients with ≥4 provider visits/month.

**Conclusions:** A non-significant difference in total expenditures along with the observed reduction in hospitalization rates among the higher provider frequency group support the current CMS dialysis provider reimbursement policy strategy.

*Funding:* NIDDK Support

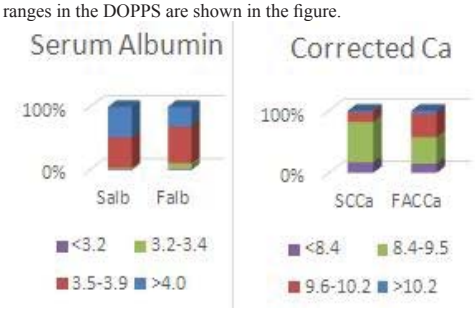
## TH-OR124

**Can We Compare Laboratory Results from Different Dialysis Units?** Panupong Lisawat,[1] Jeffrey M. Rimmer.[1] *[1]FAHC/UVM.*

**Background:** Calcium and albumin concentrations are important in management of hemodialysis patients and may be used as quality indicators. Difficulty achieving targets for serum calcium and albumin in our patients led to the hypothesis that differences in laboratory measurements influence assessment of population outcomes.

**Methods:** All patients at the our dialysis unit were offered inclusion in the study. Specimens were collected on the day of monthly testing in the usual manner. After routine testing was complete, the remaining sample in each specimen was divided equally into 2 plastic transport tubes. These samples were stored and then analyzed the same day at Fletcher Allen Laboratory (FAL) and Spectra Laboratories (SL). Both laboratories use similar indicator techniques for albumin and calcium but different analytic instruments and formulae for corrected calcium.

**Results:** Samples were obtained from 66 patients. Results for paired values of serum albumin, calcium and corrected calcium were significantly different between laboratories with p values of <0.001, 0.001 and <0.001. Bland-Altman analysis showed the systematic bias between laboratories for albumin, calcium and corrected calcium to be 0.08 g/dl, 0.24 mg/dl and -0.26 mg/dl. Albumin and corrected calcium values categorized according to the ranges in the DOPPS are shown in the figure.



Distributions of SL (Salb) and FAL (Faalb) albumin values are different (p=0.02) as are distributions of values for SL corrected calcium (SCCa) and FA corrected calcium (FACCa) (p=0.002).

**Conclusions:** Measurements of serum albumin, calcium and calculated calcium made on the same serum sample differ significantly between laboratories. A small systematic bias results in significant differences in categorized laboratory outcomes. Differences in quality of care may be mistakenly inferred from differences resulting from laboratory measurement.

## TH-OR125

**In Vivo Modulation of Per1 Target Gene Expression in the Kidney by Pharmacological Blockade of Circadian Clock-Regulatory Kinases CK1δ/ε** Jacob Richards, Sean All, Kit-Yan Cheng, Michelle L. Gumz. *Medicine, Univ of Florida, Gainesville, FL.*

**Background:** Mounting evidence suggests that the circadian clock plays an important role in the regulation of renal function and blood pressure (BP). We previously showed that the circadian clock protein Per1 coordinately regulates expression of several genes encoding products that function in the regulation of sodium (Na) reabsorption in the kidney. Per1 positively regulates the alpha subunit of the renal epithelial Na channel (αENaC) and Fxyd5, a gamma-like subunit of the $Na^+ K^+$ ATPase. Per1 negatively regulates the lipid raft protein Caveolin-1 (Cav-1) and Endothelin-1 (ET-1), a potent inhibitor of ENaC channel activity. This coordinate regulation of Na transport genes predicts that knockdown of Per1 would result in renal Na wasting and subsequent decreased blood volume and BP. Indeed, we have shown that Per1 KO mice have significantly lower BP than control mice (Stow et al. *Hypertension* 2012). In order to enter the nucleus, Per1 must be phosphorylated by casein kinase 1 δ/ε (CK1δ/ε). Our previous *in vitro* data demonstrated that pharmacological inhibition of CK1δ/ε resulted in decreased αENaC expression and decreased ENaC Channel activity (Richards et al. *AJP Renal* 2012).

**Methods:** Wild type 129/sv mice were injected with vehicle or the CK1δ/ε inhibitor PF670462 every 12 hr for 2.5 days, a previously reported effective dose and time. Mice were euthanized at midnight and kidneys were harvested RNA was isolated, and real time PCR was used to assess changes in gene expression of αENaC, Fxyd5, Cav-1, and ET-1 in the renal inner medulla and cortex.

**Results:** Because the BP phenotype of Per1 KO mice suggests that Per1 is a viable target for the treatment of hypertension, we tested the *in vivo* effects of pharmacological inhibition of Per1 nuclear entry on the expression of Per1 target genes in the kidney. CK1δ/ε inhibition led to decreased αENaC and Fxyd5 and increased Cav-1 and ET-1 in the inner medulla and cortex, consistent with our previous *in vitro* data.

**Conclusions:** These results support the use of PF670462 for *in vivo* inhibition of Per1 activity and may have implications for the treatment of hypertension.

## TH-OR126

**A Novel Mouse Model Expressing Cre Recombinase along the Entire DCT** Juliette Hadchouel,[1,2] Christelle Soukaseum,[1,2] James A. McCormick,[3] Nicolas Picard,[1,2] David H. Ellison.[3] *[1]INSERM U970, Paris Cardiovascular Research Center, Paris, France; [2]Univ Paris-Descartes, Paris Sorbonne Cité, Paris, France; [3]Oregon Health and Science Univ, OR.*

**Background:** The distal nephron, composed of the cortical Thick Ascending Limb (cTAL), the Distal Convoluted Tubule (DCT), the Connecting Tubule (CNT) and the Collecting Duct (CD), is a key player in maintaining $Na^+$, $K^+$ and $Cl^-$ homeostasis. Since many important regulators of ion transport are expressed in several segments, the development of segment-specific models is critical. While transgenic mouse lines expressing Cre recombinase along the CNT and CD have been generated, only one transgenic line allowing targeting of the DCT is available, using the *parvalbumin* promoter. However, this model only targets the proximal part of the DCT. Our goal was to develop a transgenic line expressing Cre along the whole DCT, using the promoter of the Na-Cl cotransporter, NCC.

**Methods:** Our previous attempt with an NCC-based transgene was unsuccessful. We therefore chose to introduce the iCre cDNA into the endogenous *Slc12a3* locus, encoding NCC. In order to preserve NCC expression and activity, we used the viral 2A peptide, introduced between the iCre cDNA and the first coding amino acid of NCC. Using homologous recombination in ES cells, we have generated two independent mouse lines with the iCre-2A cassette targeted into the *Slc12a3* locus.

**Results:** Immufluorescence showed that iCre recombinase is expressed along the DCT in $NCC^{+/iCre}$ mice. We further demonstrated by RT-PCR that iCre is expressed only in the kidney. We are currently assessing whether the knock-in of iCre into the *Slc12a3* locus affects NCC activity by measuring NCC expression and phosphorylation, and by performing thiazide-response tests in $NCC^{iCre/iCre}$ mice.

**Conclusions:** Many studies have highlighted the crucial role of the DCT in the maintenance of normal sodium balance. However, characterization of the mechanisms regulating DCT function has been hampered by several issues, such as the lack of a good cellular model and the difficulties of microperfusing this segment *in vitro* in mice. The generation of NCC-iCre mice provides the first tool to specifically target the entire DCT.

## TH-OR127

**A Western Diet Activates NCC to Promote Sodium Retention** Andrew Terker, Chao-Ling Yang, David H. Ellison. *Nephrology & Hypertension, Oregon Health & Science Univ, Portland, OR.*

**Background:** To maintain blood pressure homeostasis, the thiazide-sensitive Na-Cl cotransporter (NCC) is suppressed by diets that are high in salt, promoting natriuresis. NCC also plays a key role in potassium ($K^+$) homeostasis. Diets that are low in $K^+$ increase NCC abundance, reducing distal sodium delivery, and suppressing sodium-dependent potassium secretion along the distal nephron. A Western diet is typically high in salt and low in potassium. To determine the effects of a typical Western diet on NCC, we analyzed effects of opposing sodium and K+ signals.

**Methods:** Several models were used to generate opposing sodium/potassium signals: 1) Fludrocortisone (F) was administered via drinking water at a dose of 17 mg/L for one week; 2) Amiloride (A) was administered via drinking water at a dose of 50 mg/L for one week. 3) Indicated diets were administered for 7-10 days; high salt/normal K+ (HS/NK, 6% NaCl/0.8% K+); high salt/low $K^+$ (HS/LK, 6% NaCl/0% $K^+$).

**Results:** 1) We confirmed that F (to model primary aldosteronism/Liddle syndrome) increased total and phosphorylated NCC; when NCC activation could not occur (NCC knockout (KO)), F caused profound hypokalemia. 2) Surprisingly, A (to model psedohypoaldosteronism type I, PHA I), which caused hyperkalemia as expected, decreased total and phosphorylated NCC significantly. 3) HS/LK dramatically increased total and phosphorylated NCC, compared with HS/NK. Further, HS/LK increased WNK4 and SPAK, and redistributed WNK4 in DCT to cytoplasmic punctae. These effects were preserved in SPAK and angiotensin II receptor 1a (AT1a) KO mice. Lastly, a HS/LK diet decreased urinary sodium compared with a HS/NK diet in WT, but not in NCC KO mice.

**Conclusions:** Increased NCC caused by F attenuates $K^+$ wasting. Decreased NCC caused by A likely results from hyperkalemia; a similar effect may contribute to salt-wasting in PHA I. On a HS diet, LK greatly increases NCC, compared with NK, independent of SPAK or AT1aR. Changing from a HS/NK to a HS/LK diet promoted sodium retention, an effect that requires NCC. Lastly, HS/LK moves WNK4 into cytoplasmic punctae. The results suggest that a Western diet promotes hypertension in an NCC-dependent manner; this hypothesis should be tested in humans.

## TH-OR128

**The Application of a Novel Phosphoprotein Technology to Study the WNK Kinase Signaling Network** Jesse Rinehart, Natasha L. Pirman. *Cellular and Molecular Physiology, Systems Biology Institute, Yale Univ, New Haven, CT.*

**Background:** Recent work has identified phosphorylation sites in the WNK kinases and has shown that mechanistic insight into WNK kinase phosphorylation will be a key to understanding their role in renal sodium transport and hypertension.

**Methods:** While many of the phosphorylation sites on mammalian proteins have been identified, and most others are within reach via phosphoproteomics; there remains a substantial knowledge gap in the connections between kinases and substrates. We have recently made substantial progress in transforming phosphoprotein research by introducing a new technology that enables site-specific incorporation of phosphoserine into proteins. Our technology adds phosphoserine to the genetic code of E. coli by using the rare TAG stop codon (Amber codon). Phosphoproteins can then be synthesized and studied without the corresponding upstream kinase.

**Results:** We have an new optimized version of our technology that enables robust production of stoichiometricly phosphorylated proteins at single or multiple sites. This new technology was used to produce and study WNK4 with its physiologically relevant phosphorylation sites and a combinatorial library of WNK1 variants with phosphoserine introduced at activation loop residues. Previous work showed that phospho-mimetic aspartate substitutions in these same positions produced an inactive WNK1. In contrast, our technology introduced native phosphoserines and produced fully activated WNK1. We used these activated WNK1 proteins to reconstitute the WNK-SPAK-NKCC sub-network which showed robust WNK1 dependent SPAK activation. Quantitative phosphoproteomic analysis of this network and WNK1 auto-phosphorylation have been investigated and suggest new functional roles for WNK phosphorylation.

**Conclusions:** Our technology provides unprecedented resolution into the role of protein phosphorylation in WNK kinase function, as well as recapitulates physiologically relevant signaling networks. Our study provides the basis for a general strategy to study the role of protein phosphorylation in kidney physiology and a novel platform to develop targeted therapies.

## TH-OR129

**WNK4 Modulates the WNK1/WNK3-Mediated Activation of the NaCl Cotransporter** Maria Chavez-Canales,[1] Christelle Soukaseum,[2] Chao-Ling Yang,[3] Erika Moreno,[1] Diana Pacheco-Alvarez,[4] Emmanuelle Vidal-Petiot,[2] Maria Castañeda-Bueno,[1] Norma Hilda Vázquez,[1] Lorena Leonor Rojas,[1] Xavier Jeunemaitre,[5] David H. Ellison,[3] Gerardo Gamba,[1] Juliette Hadchouel.[2] *[1]Molecular Physiology Unit, INNSZ-IIB, UNAM, Mexico City; [2]INSERM, Paris; [3]Oregon Health and Science Univ, Portland; [4]Universidad Panamericana, Mexico City.*

**Background:** Increased renal salt reabsorption is a key pathogenic factor in the development of Arterial Hypertension. Familial Hyperkalemic Hypertension (FHHt) is a monogenic form of salt-sensitive hypertension caused by mutations in genes encoding WNK1, WNK4, Cullin 3 or kelch-like 3 that belong to the same salt reabsorption regulatory cascade. However, the precise mechanisms by which WNK1 and WNK4 affect target transporters remain unclear. In the kidney, the most abundant WNK1 isoform lacks only exon 11, WNK1-Δ11.

**Methods:** We used *Xenopus* oocytes, HEK 293 cells and genetically altered mice.

**Results:** In oocytes and in HEK 293 cells transfected with NCC, WNK1-Δ11 increased NCC activity and phosphorylation, as previously shown for WNK3. In oocytes, the disruption of the WNK1-SPAK interaction, by removing a SPAK-binding motif in WNK1 (WNK1-Δ11-F316A), prevented WNK1-Δ11 stimulation of NCC and showed a dominant-negative effect on NCC activity, suggesting that activation of NCC occurs through a SPAK dependent pathway. We also demonstrated that WNK4 inhibited both the WNK1 and WNK3 activation of NCC and angiotensin II prevented this WNK4 inhibitory effect. These results suggest that WNK4 acts upstream of WNK1 and WNK3. To test whether WNK1 lies downstream from WNK4 in vivo, we crossed a $WNK1^{+/FHHt}$ mice, generated by deletion of the first intron of WNK1, with $WNK4^{-/-}$mice. $WNK1^{+/FHHt}$:$WNK4^{-/-}$ animals retained the full FHHt phenotype, caused by an increased in NCC expression and phosphorylation, as seen in $WNK1^{+/FHHt}$ mice.

**Conclusions:** Our results revealed that WNK kinases signalling cascade in the distal nephron is mastered by WNK4, which modulates the activity of WNK1 and WNK3 towards SPAK and NCC, an effect modulated by angiotensin II.This model of WNKs interaction provides a molecular understanding of blood pressure and distal salt reabsorption regulation.

## TH-OR130

**WNK Regulates NKCC in the Fly Tubule through a SPAK Intermediate** Aylin R. Rodan, Chou-Long Huang. *Dept of Medicine, UT Southwestern, Dallas, TX.*

**Background:** The main segment of the *Drosophila melanogaster* renal tubule is $K^+$-secreting. We have previously shown that the fly NKCC, Ncc69, mediates approximately 1/3 of normal $K^+$ flux. In the mammalian nephron, the WNK/SPAK kinase cascade regulates the Ncc69-related transporters NCC and NKCC2. Here, we examined whether this pathway is conserved in the fly tubule.

**Methods:** We genetically manipulated the fly WNK and SPAK kinases in wild-type and *Ncc69* mutant flies and measured $K^+$ flux in isolated tubules. We measured *wnk* transcript levels using quantitative RT-PCR.

**Results:** Knockdown of *wnk* with RNAi in the cation-secreting cells of the fly renal tubule decreased $K^+$ flux (80±5 pmol/min/tubule in control vs 49±5 in *wnk* knockdown tubules, $p<0.0001$). Similarly, expression of $WNK^{D420A}$, a kinase-dead isoform with dominant-negative effects, also decreased $K^+$ flux (68±4 in control vs. 50±4 in kinase-dead WNK tubules, $p<0.05$). Fray is the fly SPAK homolog. Expression of constitutively active $Fray^{T206E}$ in *wnk* knockdown tubules restored $K^+$ flux to wild-type levels (control, 89±9; *wnk* knockdown 60±8; *wnk* knockdown with $fray^{T206E}$, 94±9, $p<0.05$ for *wnk* knockdown vs. control and $fray^{T206E}$ groups). Activated Fray expression on its own did not change $K^+$ flux (57±6 in control vs 68±8 in $fray^{T206E}$-expressing tubules; NS). *Wnk* knockdown in an *Ncc69* null mutant background did not result in decreased $K^+$ flux (65±5 in controls, 62±4 in *Ncc69* mutant tubules with *wnk* knockdown, NS). *Wnk* transcript levels were similarly decreased by *wnk* knockdown in both the wild-type and *Ncc69* mutant backgrounds, to 37±9% and 50±17% of control (NS).

**Conclusions:** Decreasing WNK activity in the fly renal tubule impairs $K^+$ flux. This phenotype is rescued by expression of constitutively active Fray (fly SPAK), suggesting that Fray acts downstream of WNK and that WNK activates Fray. Ncc69, the fly NKCC, appears to be the target of WNK/SPAK signaling, as the *wnk* knockdown phenotype is abolished in *Ncc69* mutant tubules. We have thus established that the WNK/SPAK/NKCC pathway is conserved in the fly renal tubule, laying the groundwork for further dissection of the mechanisms by which this occurs, as well as the discovery of new genes in this regulatory pathway.

## TH-OR131

### SPAK-Independent Activation of Na-(K)-Cl Cotransport by WNK4 Requires Cab39 as an Adaptor Protein

José Ponce-Coria,[1] Paul A. Welling,[2] Eric J. Delpire.[1] *[1]Anesthesiology, Vanderbilt Univ, Nashville, TN; [2]Physiology, Univ of Maryland, Nashville, TN.*

**Background:** SPAK (STE20/SPS1-related proline alanine rich kinase), OSR1 (oxidative stress kinase 1) and WNK (with no K-lysine) kinases modulate distal $Na^+$ transport by affecting the activities of the thick ascending limb of Henle Na-K-2Cl cotransporter (NKCC2) and of the distal convoluted tubule Na-Cl cotransporter (NCC). WNK4 is thought to affect the cotransporters through two different pathways: 1) by regulating their trafficking to the plasma membrane; and 2) by phosphorylating and activating SPAK which then phosphorylates and activates the cotransporters. Here, we demonstrate a third mode of action consisting of a direct stimulatory effect of WNK4 on the cotransporters.

**Methods:** We measured $K^+$ influx in *Xenopus* oocytes injected with cotransporter, wild-type and mutant kinase, and Cab39 cRNAs to assess the role of the kinases and adaptor protein in modulating cotransporter activity.

**Results:** When Cab39 or Cab39l cRNA was injected with WNK4 and NKCC1, we observed a significant increase in the level of $K^+$ influx. This increase was bumetanide-sensitive indicating that the flux was mediated by the cotransporter. We show that this stimulation requires the catalytic activity of WNK4 and is not affected by overexpressing dominant negative SPAK, suggesting that WNK4 is able to phosphorylate and activate the cotransporter in a SPAK-independent manner. When we mutated a phenylalanine residue in a WNK4 domain that resembles the SPAK/OSR1 binding domain, we prevented the Cab39/WNK4 activation of the cotransporter. When we mutated Cab39 residues known to promote interaction between Cab39 and Ste20 kinases, we observed WNK4 activation. Finally, we demonstrate that the WNK4 PHAII mutation, E599K, does not affect the ability of WNK4 to activate SPAK, whereas it completely abrogates the activation of NKCC1 by WNK4. These data were reproduced using a chimeric transporter consisting of the N-terminal regulatory tail of NCC fused to NKCC1, indicating that NCC is similarly activated by the Cab39/WNK4 interaction.

**Conclusions:** Our data demonstrate that WNK4 interact and activate the NaCl cotransporters in the absence of SPAK or OSR1.

## TH-OR132

### Af9 Targets Ring Finger Protein 2 (Rnf2) to the αENaC Promoter to Regulate Basal and Aldosterone-Stimulated αENaC Transcription

Zhiyuan Yu, Qun Kong, Bruce C. Kone. *The Univ of Texas Medical School at Houston, Houston, TX.*

**Background:** Af9 is an aldosterone-sensitive regulator of αENaC transcription required for enhanced renal tubular Na transport. Af9 binds to a cis-element in the αENaC promoter to recruit histone methyltransferase Dot1a to epigenetically repress basal αENaC transcription in collecting duct cells. Aldosterone downregulates this repressor complex to de-repress αENaC transcription. Rnf2, a central component of Polycomb repressive complex 1 involved in epigenetic silencing of target genes, lacks DNA-specific binding activity, so that other factors must mediate its site-specific chromatin recruitment. We tested the hypotheses that Af9 interacts with and recruits Rnf2 to the αENaC promoter and contributes to basal αENaC repression and aldosterone de-repression of αENaC transcription in mIMCD3 cells.

**Methods:** Immunofluorescence microscopy, co-immunoprecipitation, and GST pull-down assays were used to identify Af9-Rnf2 interactions in mIMCD3 cells. Chromatin immunoprecipitation (ChIP)/qPCR and re-CHIP assays, promoter-luciferase assays, overexpression and siRNA knockdown of Rnf2 were used to assay functionally relevant interactions of Rnf2 with the αENaC promoter in vehicle and aldosterone-treated mIMCD3 cells.

**Results:** Rnf2 and Af9 co-localized in the nucleus, and they interacted in co-immunoprecipitation and GST-pull-down assays. Rnf2 knockdown enhanced basal and aldosterone-stimulated αENaC mRNA levels and αENaC promoter activity. Conversely, Rnf2 overexpression inhibited aldosterone-stimulated αENaC mRNA expression and αENaC promoter activity. ChIP/re-ChIP assays showed that Af9 and Rnf2 co-occupy the R3 subregion (-57/+494) of the αENaC promoter. Aldosterone inhibited Rnf2 occupancy of the αENaC promoter and trimethylation of histone H3K27, a chromatin mark of repressed genes, coincident with induction of αENaC transcription.

**Conclusions:** We conclude that Af9 mediates site-selective physical and functional recruitment of Rnf2 to the αENaC promoter to constrain basal αENaC transcription. Aldosterone de-represses αENaC transcription by inhibiting Dot1a, Af9, and Rnf2 association and action at the αENaC promoter.

## TH-OR133

### Renal SGK1 Plays a Crucial Role in the Control of Potassium Homeostasis, by NEDD4-2 Dependent Regulation of ENaC and NCC

Lama Al-Qusairi,[1] Matteo Stifanelli,[1] Anne Debonneville,[1] Nourdine Faresse,[1] Johannes Loffing,[2] Olivier Staub.[1] *[1]Univ of Lausanne; [2]Univ of Zurich.*

**Background:** Dietary $K^+$ load results in increased kalemia, leading to aldosterone (aldo) release thereby stimulating $K^+$ secretion in the ASDN. However, the mechanisms of this regulation are unclear.

**Methods:** Here, we identified the specific role of the aldosterone inducible SGK1 kinase in the tight regulation of potassium secretion using an inducible nephron specific SGK1 KO ($SGK1^{Pax8/LC1}$) mouse model.

**Results:** We find that lack of SGK1 has no obvious effect on potassium homeostasis under normal diet. However, under high $K^+$ diet for 48 hours, mutant mice exhibit a 35% decrease in urinary $K^+$ excretion, accompanied with sever hyperkalemia and increased plasma aldo levels. At the molecular level, we observe a decrease in cleavage of alpha and gamma ENaC, indicating that ENaC activity is reduced. Moreover, phosphorylation of the Na-Cl-cotransporter NCC is strongly reduced under these conditions, indicating reduced NCC activity. The ubiquitin-protein ligase NEDD4-2, a well-known substrate of SGK1 kinase, and implicated in the positive regulation of both ENaC and NCC, is less phosphorylated on the SGK1-dependant phosphorylation sites S222 and S328, as evidenced by immunoblotting.

**Conclusions:** Our data indicate that renal SGK1 is a key regulator of potassium homeostasis in the kidney, which affects the activity of both NCC and of ENaC, likely via regulation of NEDD4-2.

## TH-OR134

### Calveolin-1 Is Required for Src-Family Protein Tyrosine Kinase (SFK)-Induced Regulation of the Basolateral K Channel in the Early Distal Convoluted Tubule (DCT1)

WenHui Wang. *Pharmacology, New York Medical College, Valhalla, NY.*

**Background:** The basolateral K channels in the DCT1 play an important role in determining the membrane potential which is essential for sustaining Cl exit across the basolateral membrane and Na-K-ATPase activity.

**Methods:** We performed the whole-cell recording to measure the $Ba^{2+}$-sensitive K currents in the DCT1 which represents the basolateral K channel activity since no apical K channel activity has been detected.

**Results:** The whole K currents in DCT1 are inwardly-rectifying and inhibited by blocking SFK with PP1. However, the effect of PP1 on K currents was absent in calveolin-1 knockout (KO) mice. Moreover, the K currents in KO mice were significantly lower than those in wt mice. This suggests that calveolin-1 is critically involved in modulating the effect of SFK on basolateral K channels in DCT1. This hypothesis was tested by investigating the effect of PP1 on K channel activity in HEK293T cells transfected with KCNJ10+KCNJ16 which are known to form heterotetramer K channel in the DCT1. We detected a 40 pS K channel in KCNJ10/16-transfected cells and a 20 pS K channel in the cells transfected with KCNJ10 alone. The whole cell recording demonstrated that K currents in KCNJ10/16-transfected cells were significantly larger than those in KCNJ10-transfected cells. However, inhibition of SFK had no effect on K currents in both KCNJ10/16- and KCNJ10-transfected cells. Co-transfection of calveolin-1 with KCNJ10/16 or KCNJ10 did not alter the K currents in comparison to those without calveolin-1 cotransfection. However, Inhibition of SFK significantly decreased the whole cell K currents in the cells transfected with KCNJ10/16+calveolin-1 or with calveolin-1+KCNJ10. Immunostaining showed that calveolin-1 and KCNJ10 are colocalized in the distal nephrons.

**Conclusions:** We conclude that SFK plays an important role in regulating the basolateral K channel activity and calveolin-1 is critically involved in modulating the effect of SFK on the basolateral K channels in DCT1.

## TH-OR135

**The Rapidly Growing Global Burden of End-Stage Renal Disease – An Analysis of the Change in Maintenance Dialysis Prevalence between 1990 and 2010** Bernadette A. Thomas,[1] Sarah Wulf,[2] Rajnish Mehrotra,[1] Jonathan Himmelfarb,[1] Mohsen Naghavi,[2] Christopher Jl Murray.[2] *[1]Kidney Research Institute, Univ of Washington, Seattle, WA; [2]Institute for Health Metrics and Evaluation, Univ of Washington, Seattle, WA.*

**Background:** Rapidly rising global rates of chronic diseases portend a consequent rise in end-stage renal disease (ESRD). However, the change in global burden of treated ESRD has never before been quantified. This study was undertaken to accurately report the trajectory of treated prevalent ESRD rates at the global and regional level between 1990 and 2010.

**Methods:** We extracted data from the Global Burden of Disease database, the largest existing database for global causes of morbidity and mortality. The prevalence estimates were calculated from data from national and regional ESRD registries and a structured literature review for years 1990 and 2010. Data from 26 countries that lack routine access to dialysis were excluded. Data from twenty-three countries providing 100% dialysis access and 138 countries providing partial dialysis access were included. A negative binomial Bayesian regression tool was used to estimate the prevalence of chronic dialysis in 161 countries stratified by year and sex.

**Results:** Within the past two decades, there has been a global increase in maintenance dialysis of 165%. The global prevalence of treatment with maintenance dialysis for countries with universal dialysis access increased by 134% after population growth and aging adjustment; 145% in women versus 123% in men. For countries whose populations lack universal dialysis access, adjusted prevalence increased by 102%; 116% for women versus 90% for men. The five world regions not experiencing substantial increase in maintenance dialysis prevalence include Oceania, South Asia, central sub-Saharan Africa, eastern Europe, and tropical Latin America.

**Conclusions:** The significant growth in maintenance dialysis therapy far out of proportion to population growth for a majority of regions in the world. This emphasizes the need for early chronic kidney disease detection and treatment targeting ESRD prevention, since continued rise in prevalence of maintenance dialysis may not be sustainable.

*Funding:* Private Foundation Support

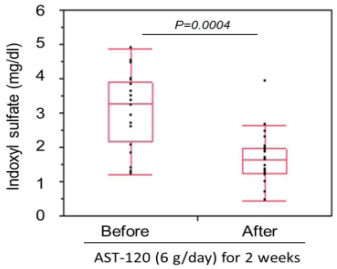
## TH-OR136

**Oral Activated Charcoal Adsorbent, AST-120, Induced Continuous Reduction of Protein-Bound Uremic Toxins in Maintenance Hemodialysis Patients: A Randomized Cross-Over Trial** Suguru Yamamoto,[1] Kentaro Omori,[2] Koji Matsuo,[1] Kazuko Kawamura,[1] Minako Wakasugi,[1] Hiroki Maruyama,[1] Junichiro J. Kazama,[1] Ichiei Narita.[1] *[1]Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Omori Clinic, Niigata, Japan.*

**Background:** An accumulation of protein-bound uremic toxins (PBUT) is one of the reasons why patients undergoing dialysis treatment have high risk of cardiovascular events. Oral activated charcoal adsorbent, AST-120, has been shown to decrease serum indoxyl sulfate in non-dialysis CKD patients. The aim of this study is to examine whether AST-120 decreases PBUT in maintenance hemodialysis patients.

**Methods:** Twenty maintenance hemodialysis patients were individually randomized in a crossover design between treatment with 6 g/day of AST-120 and non-treatment for 4-week periods. Ten participants followed the AST-120 treatment first for 2 weeks and then switched to non-treatment for another 2 weeks; the other 10 subjects followed the same treatment in reverse order. Serum level of indoxyl sulfate at pre/post dialysis session before and after the AST-120 treatment was measured by mass spectrometry. Data were presented as medians (interquartile range: IQR). Wilcoxon signed-rank test was used for the statistical analysis.

**Results:** At the baseline, serum levels of indoxyl sulfate were 3.27 (2.17 to 3.89) and 2.20 (1.38 to 2.89) mg/dl in pre- and post-dialysis sessions respectively while it returned to the previous level before the next dialysis sessions. However, AST-120 treatment for 2 weeks dramatically decreased serum indoxyl sulfate levels in both pre- [1.64 (1.25 to 1.98) mg/dl, P=0.0004 vs. baseline] and post- [1.24 (0.87 to 1.49) mg/dl, P= 0.002 vs. baseline] dialysis treatment.



**Conclusions:** Use of AST-120 showed a continuous and powerful effect to remove protein-bound uremic toxins in maintenance hemodialysis patients.

*Funding:* Government Support - Non-U.S.

## TH-OR137

**Prevalence and Predictors of Blood Pressure Variability in Hemodialysis Patients** Talal S. Alzahrani, Fangtang Yu, Samir S. Patel, Dominic S. Raj. *Dept of Medicine, Div of Renal Diseases & Hypertension, The George Washington Univ, Washington, DC.*

**Background:** Blood pressure variability (BPV) predicts cardiovascular mortality in general population and patients with kidney disease. We hypothesized that variation in pre-dialysis systolic blood pressure (Pre-SBP) and mean BP change are independent predictors of mortality in hemodialysis patients.

**Methods:** We used clinical and biochemical data derived from the DaVita database. The study population (N=420,255) included subjects undergoing hemodialysis in DaVita facilities across the US during the period of 2004 to 2011. Pre-SBP variability is described by the SD of SBP examined before every dialysis during a month; mean BP change during dialysis is described by the mean of the difference between post-dialysis mean BP and pre-dialysis mean BP over a month. Repeated measurement model were built to examine the factors that influence SBP variability. Cox proportional hazard model with time-dependent covariates were fitted to test if SBP variability is a significant predictor of time to death and time to hospitalization.

**Results:** The mean pre-dialysis systolic blood pressure was 148±53 mm of Hg. Low, medium and high BP variability was found in 35%, 34%, and 30% of the patients respectively. Patients' gender, race, BMI, weight gain during dialysis, lack of insurance, exposure to heart disease or Diabetes mellitus are significant predictors to both SBP variability and mean BP change during dialysis (p<0.001). Both Pre-SBP variability and mean BP change during dialysis were significant predictor of time to death (HR (pre-SBP)=1.009 95% CI (1.0081,1.0102) p<0.001, HR (BP change)=1.028, 95% CI (1.0273,1.0287), p<0.001) and time to hospitalization (HR (pre-SBP)=1.005 95% CI (1.0046,1.0058) p<0.001, HR (BP change)=1.010, 95% CI (1.0092,1.0100), p<0.001).

**Conclusions:** Pre-SBP variability and mean BP change are very common and they are associated with distinct clinical predictors. Both SBP variability and mean BP change during dialysis are significant predictors of time to death and time to hospitalization. Further studies are needed to confirm our results and to find ways to decrease BP variability in patient with ESRD.

## TH-OR138

**Greater Endotoxin Level of Dialysis Fluid Associated with Increased Mortality of Hemodialysis Patients: A Nationwide Cohort Study** Takeshi Hasegawa,[1,2,3] Ikuto Masakane,[3] Kunitoshi Iseki,[3] Yoshiharu Tsubakihara,[3] Tadao Akizawa.[4] *[1]Div of Nephrology, Showa Univ Fujigaoka Hospital, Yokohama, Japan; [2]Dept of Epidemiology and Healthcare Research, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [3]Committee of Renal Data Registry, The Japanese Society for Dialysis Therapy, Tokyo, Japan; [4]Div of Nephrology, Showa Univ School of Medicine, Tokyo, Japan.*

**Background:** There has been wide variation in targeted endotoxin level of dialysis fluid among countries, however, evidences for the effectiveness of dialysis fluid purity for mortality of patients on hemodialysis (HD) are lacking. The aim of this research is to evaluate the impact of water quality by dialysis fluid endotoxin level (dET) on mortality of HD patients.

**Methods:** The design of this investigation is a cohort study using a nationwide annual survey of the Japan Renal Data Registry. We analyzed 130,781 patients on HD (at the end of 2006: on HD > half a year, three times session per week, during 2007: no changing facilities and treatment modalities). The main outcome measure was all-cause death. Main exposure to be tested was dET reported by 2,746 facilities at the end of 2006 (categorized into 5 groups: <0.001, 0.001 to 0.01, 0.01 to 0.05, 0.05 to 0.1, and 0.1< EU/mL). Cox regression was employed to estimate the hazard of all cause death adjusted for potential confounders.

**Results:** During one year follow-up, 8,978 (6.9%) patients died of all-causes. The rate of all-cause mortality at one year was the highest of patients in the greatest dET (0.1EU/mL<) category (88.0 deaths/1,000 person-years). After multivariable adjustment, patients who were exposed to the greatest dET (0.1EU/mL<) displayed a 28% (95% CI, 15%-41%) increased risk of all-cause death compared to those who with the lowest dET (<0.001EU/mL).

**Conclusions:** These results suggested that greater dET was related to increased risk of all-cause death in HD patients. Correcting this modifiable water management practice may improve outcomes of HD patients.

## TH-OR139

**Convective Therapies *versus* Low-Flux Hemodialysis for Chronic Kidney Failure: A Meta-Analysis of Randomized Controlled Trials** Paweena Susantitaphong,[1,2] Bertrand L. Jaber.[1] *[1]Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

**Background:** Convective therapies have gained popularity for the optimal removal of uremic solutes. However, their benefits and potential risks have not been fully elucidated. We conducted a meta-analysis of all randomized controlled trials (RCTs) comparing convective therapies vs. low-flux hemodialysis in patients with chronic kidney failure.

**Methods:** We searched MEDLINE (through December 2012), Cochrane Central Register of Controlled Trials, ClinicalTrials.gov, scientific abstracts from meetings, and bibliographies of retrieved articles for randomized controlled trials comparing the effects of convective therapies (including high-flux hemodialysis, hemofiltration, and

hemodiafiltration) versus low-flux hemodialysis were included. Random-effects model meta-analyses were used to compute absolute net changes in mean values for continuous outcomes, and relative risks (RRs) for binary outcomes.

**Results:** Compared to low-flux hemodialysis, convective therapies resulted in a decrease in all-cause mortality (pooled RR 0.88; 95% CI 0.76, 1.02, P = 0.09; $I^2$ = 18%), cardiovascular mortality (pooled RR 0.84; 95% CI 0.71, 0.98, P = 0.03; $I^2$ = 0%), all-cause hospitalization (pooled RR 0.91; 95% CI 0.82, 1.01; P = 0.06; $I^2$ = 77%) and therapy-related hypotension (pooled RR 0.61, 95% CI 0.42, 0.89, P = 0.01; $I^2$ = 99%). Convective therapies also resulted in a signifcant improvement in the clearance, reduction ratio and/or pre-therapy serum levels of several low-molecular-weight solutes (urea, creatinine, and phosphate), middle-molecular weight solutes (beta-2 microglobulin and leptin), and protein-bound solutes (homocysteine, advanced glycation end-products, and pentosidine). There was no impact of convective therapies on cardiac structure and function, blood pressure parameters, and anemia parameters.

**Conclusions:** Although convective therapies are associated with decreased morbidity and mortality and improved clearance of uremic solutes, the potential long-term benefits of specific modalities require further study.

## TH-OR140

**Trends in Medicare Costs for Hemodialysis Patients, 2001-2011, and Estimated Change in Medicare Costs Associated with the New Medicare Bundle Payment Policy** Allan J. Collins,[1,2] Suying Li,[1] Jiannong Liu,[1] David T. Gilbertson,[1] Robert N. Foley,[1,2] James P. Ebben,[1] Craig Solid,[1] Shu-Cheng Chen.[1] *[1]USRDS Coordinating Center, MMRF, Mpls, MN; [2]Medicine, Univ of MN, Mpls, MN.*

**Background:** Starting in January 2011, several outpatient dialysis services, including laboratory services performed by nephrologists and injectable medications, were incorporated into the new Medicare prospective payment system (PPS). We aimed to examine trends in Medicare costs 2001-2011 and estimate change in Medicare costs associated with the new PPS in hemodialysis (HD) patients.

**Methods:** Yearly cohorts, 2001-2011, included point prevalent HD patients on January 1, with a 90-day rule applied and Medicare Parts A/B eligibility required. Patients were followed from January 1 to December 31 each year and censored at transplant, change in modality, death, or loss to follow-up. Medicare payment per person-year (PPPY) consisted of inpatient (IP), outpatient (OP)/physician services, and other costs. Dialysis facilities were characterized as 100% bundle or 25% blend based on their decisions regarding the new PPS in 2011. We estimated change in Medicare costs associated with the new PPS using the difference-in-difference approach.

**Results:** Total PPPY increased from $57008 in 2001 into $79758 in 2010 and decreased to $78864 in 2011. The cost changes (PPPY) from 2010 to 2011 were -$238 for IP, -$880 for OP/physician, and $224 for others. Among the change in OP/physician cost, the reduction in categories related to the new PPS (HD and routine lab services, injectable medications, and lab services performed by nephrologists) was $1,106 (PPPY). The estimated change (2011 vs. 2010) in Medicare cost (PPPY) associated with new PPS (100% bundle vs. 25% blend) was -$215 (95% CI, -$1617 to $1187).

**Conclusions:** The $894 (PPPY) saving in Medicare costs in 2011 implies an approximate saving of $220 million in total Medicare costs for HD patients included in this study. This reduction may contribute to a low rate of growth in per capita general Medicare spending in 2011. Although the new PPS bundle associates with stabilization of Medicare total costs in 2011, providers may reduce their expenses, generating margins previously unrealized.

*Funding:* NIDDK Support

## TH-OR141

**Factors Influencing Hospital Admissions and Deaths over the Two Day Gap in Three Times a Week Hemodialysis** James Fotheringham,[1] Damian G. Fogarty,[2] Michael J. Campbell,[1] Meguid El Nahas,[3] Ken Farrington.[2] *[1]School of Health and Related Research, Univ of Sheffield, Sheffield, South Yorkshire, United Kingdom; [2]The UK Renal Registry, Bristol, United Kingdom; [3]Global Kidney Academy, Sheffield, United Kingdom.*

**Background:** Excess mortality and hospitalization has been identified after the 2 day gap in 3 times a week hemodialysis (HD) patients compared to 1 day intervals. Thus far additional risk factors and potential interventions have not been formally explored in dialysis scheduling related events. Greater understanding of mortality and hospitalisation events is required.

**Methods:** Incident renal replacement therapy patients starting treatment between 2002 and 2006 in England with available data until 2009 from the UK Renal Registry were analysed. Hospitalisation data was used to identify HD attendance patterns, admissions and comorbidity. Laboratory and clinical measurements were obtained from the nearest recorded period in the 6 months before the week of analysis. Rates were compared with rate ratios of events after the 2 day gap compared to the rest of the week (RR).

**Results:** 9,925 patient years were identified in 5790 patients across 36 centres. Compared to the rest of the week, excess emergency admissions were seen after the 2 day gap (2.29 vs 1.36 per patient year, P<0.001). Admission RR remained constant for the first 2 years of dialysis, the 2 years approaching death and across centres. Greatest admission increases were seen in heart failure (RR 1.82 vs 1.64 without, P=0.012), chronic obstructive pulmonary disease (RR 1.97 vs 1.65 without, P=0.002) and Pre-HD systolic blood pressure >150mmHg (RR 1.79 vs 1.62 <150mmHg, P=0.038). Excess all-cause mortality after the 2 day gap (21.3 vs 15.7 deaths per 100 patient years, P<0.001) was primarily due to the 32% of deaths occurring at home (out of hospital mortality RR 1.59, in hospital RR 1.06, P=0.001).

**Conclusions:** In England, comorbidity and volume overload/hypertension were associated with excess 2 day gap admissions in 3 times a week HD. Excess mortality was driven by deaths out of hospital. Interventions which reduce the risk of volume overload and sudden death in susceptible patients merit exploration.

## TH-OR142

**Risk of Under-Dialysis: Use of Scaling Parameters Reflecting Metabolic Activity** Sivakumar Sridharan,[1] Jocelyn Berdeprado,[1] Neil Ashman,[2] Andrew Davenport,[3] Michael K. Almond,[4] Anindya Banerjee,[5] Enric Vilar,[1,6] Justin Roberts,[6] Ken Farrington.[1,6] *[1]Lister Hospital; [2]Royal London Hospital; [3]Royal Free Hospital; [4]Southend Hospital; [5]Arrowe Park Hospital; [6]Univ of Hertfordshire.*

**Background:** Patients with small body size have reduced survival on haemodialysis (HD). This may be due to total body water being used as the normalising factor for HD dose prescription.We explored the use of alternative scaling parameters reflecting metabolic activity.

**Methods:** We recruited adult in-centre HD patients.Anthropometric, demographic and HD adequacy details were obtained from direct measurements and medical records.Body surface area (BSA) was estimated using Haycock formula. Resting energy expenditure (REE) was estimated using a novel equation, derived and validated in HD patients.Total energy expenditure (TEE) was calculated from physical activity data obtained using Recent Physical Activity Questionnaire (RPAQ). Kt/BSA, Kt/REE and Kt/TEE were estimated for all subjects.

**Results:** 1500 HD patients (910 males) were recruited.Median BSA was 1.85 $m^2$, median REE 1530 kcal/day and median TEE 1781 kcal/day. For Kt/V of 1.2, there was a wide range of equivalent doses expressed as Kt/BSA, Kt/REE and Kt/TEE. The equivalent dose ranges of Kt/BSA for women ranged from 21.15 to 23.06 (median 21.80) and for men 22.04 to 29.72 (median 25.33). For Kt/REE these were 0.0240 to 0.0314 (median 0.0263) for women and 0.0265 to 0.0345 (median 0.0304) for men. For Kt/TEE they were 0.0118 to 0.0286 (median 0.0234) for women and 0.0116 to 0.0321 (median 0.0259) for men. The median equivalent dose was significantly lower in women with all 3 parameters (p<0.001). Kt/BSA was lower for women in each weight quartile compared to those in highest quartile (p<0.001).There was no difference in Kt/REE or Kt/TEE for women in lowest quartile compared to the highest quartile.In men, all 3 parameters were significantly lower in each weight quartile compared to the highest quartile (p<0.001).

**Conclusions:** Our data suggest that current dosing practices risk under-dialysis in women and men of lower body size.Using BSA, REE or TEE based dialysis prescription would result in higher dose delivery in these settings.

## TH-OR143

**Determinants of Potassium Kinetics during Hemodialysis** Baris U. Agar,[1] J. Ken Leypoldt,[1] Richard J. Fluck,[2] Bruce F. Culleton.[1] *[1]Medical Products, Baxter Healthcare Corportation, Deerfield, IL; [2]Dept of Renal Medicine, Royal Derby Hospital, Derby, United Kingdom.*

**Background:** Both hyperkalemia and hypokalemia are associated with elevated mortality in hemodialysis (HD) patients, and low dialysate potassium (K) concentration (<2 mEq/L) during HD treatments are associated with a higher incidence of sudden cardiac arrest if predialysis serum K levels are ≤5 mEq/L. Improved control of serum K levels in HD patients, particularly those treated by frequent HD sessions, may benefit from improved understanding of K kinetics. We have recently shown (2013 ERA-EDTA Congress) that K kinetics during HD can be described using a pseudo one-compartment model and that K mobilization clearance ($K_M$) and predialysis K central distribution volume (V) are relatively independent of dialysate K concentration.

**Methods:** We determined $K_M$ and V from kinetic modeling sessions in 437 patients during the HEMO Study with a dialysate K concentration of approximately 2 (1.6-2.5) mEq/L by optimal fitting of pseudo one-compartment model predictions of serum K levels to those measured predialysis, after 1 hour of treament, postdialysis and 30 minutes after stopping the treatment. The determinants of these kinetic parameters were determined by univariate and multivariate linear regression.

**Results:** The patients were 59±14 (mean±standard deviation) years old with predialysis body weight (BW) of 72.6±15.1 kg; predialysis serum K concentration ($K_{pre}$) was 5.3±1.0 mEq/L and treatment time (T) was 206±29 minutes. Fifty-five percent of patients were female; 45% were diabetic and 34% were of black race. On univariate analyses, $K_M$ and V were associated (P<0.001) positively with BW and T but negatively with $K_{pre}$. $K_M$ was also lower for females than males (P=0.003). On multivariate analyses, $K_M$ and V were associated positively with BW and negatively with $K_{pre}$; only V was associated positively with T. In total, V was 27±19% of BW.

**Conclusions:** Faster K mobilization and a larger central distribution volume are expected for bigger patients, providing further support for the validity of a pseudo one-compartment model. The larger central distribution volume with longer treatment times may indicate more effective K removal.

## TH-OR144

**Potential Application of Exhaled Breath Monitoring in Renal Replacement Therapy** Kelly M. Paschke,[1] Sevag Demirjian,[2] Jaime T. Newman,[1] Lauren L. Chen,[1] Raed A. Dweik,[1,3] Robert J. Heyka.[2] *[1]Pathobiology/Lerner Research Institute, Cleveland Clinic, Cleveland, OH; [2]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; [3]Pulmonary, Allergy, and Critical Care Medicine/Respiratory Institute, Cleveland Clinic, Cleveland, OH.*

**Background:** Uremic retention solutes are a systemic consequence of Chronic Kidney Disease (CKD) and contribute to disease progression. Urea removal is used for monitoring adequacy of solute removal in hemodialysis (HD). However, this does not always correlate with symptoms of uremia or removal of retained solutes. In end stage renal disease (ESRD), the unique breath profile composed of volatile organic compounds and inorganic amines represents accumulations of end products of metabolic reactions, gut bacteria, and exogenous volatiles. However, no standardized breath test exists for monitoring CKD or the efficacy of HD.

**Methods:** Selected ion flow tube mass spectrometry (SIFT-MS) was used to quantify the exhaled breath of 15 ESRD patients before and after HD. An additional 15 healthy subjects were recruited as a baseline control. Selected ion monitoring of 21 known breath volatiles and mass scanning for high intensity peaks of unknown volatiles was applied.

**Results:** ESRD patients pre HD had elevated breath ethanol, ammonia, trimethylamine, 2-propanol, and acetone compared to healthy controls ($p<0.05$) and 43 peaks in the mass spectra ($p<0.01$). HD reduced breath trimethylamine, 2-propanol, acetaldehyde, acetone, benzene, dimethyl sulfide, pentane, 1-nonene, 3-methylhexane ($p<0.01$), and 13 peaks in the mass spectra ($p<0.01$). Breath ammonia, ethanol ($p<0.05$), and 21 peaks in the mass spectra ($p<0.01$) remained elevated post HD compared to healthy controls. Post HD breath composition more closely resembled healthy controls.

**Conclusions:** Breath testing may serve as a novel modality for CKD monitoring, in particular for HD adequacy. A potential advantage of breath tests is the ability to measure multiple volatiles simultaneously for a disease state which may provide a more robust method for monitoring CKD and HD.

## TH-OR145

**Gene-Targeted Deletion of the Angiotensin II Type 1 Receptor-Interacting and Functionally Modulating Protein Enhances Renal Sodium Reabsorption and Exacerbates Angiotensin II-Mediated Hypertension** Kouichi Tamura. *Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Japan.*

**Background:** The angiotensin II (Ang II) type 1 receptor (AT1R)-associated protein (ATRAP/Agtrap), a molecule which specifically interacts with the AT1R. We hypothesize that a down-regulation of ATRAP at local tissue sites that enhances the pathological activation of tissue AT1R signaling in response to certain stimuli without any evident effect on baseline physiological AT1R signaling. Functional significance of ATRAP in renal sodium handling and blood pressure (BP) regulation in response to pathological stimuli is not fully resolved.

**Methods:** We generated mice with a gene-specific disruption of ATRAP (ATRAP-KO mice). We examined the effects of chronic Ang II infusion on BP and renal sodium handling in ATRAP-KO mice and their littermate wild-type control mice (WT mice).

**Results:** Although ATRAP was abundantly distributed along the renal tubules in WT mice, there was no ATRAP expression in any of the nephron segments in ATRAP-KO mice. ATRAP-KO mice exhibited no apparent renal morphological alterations under baseline conditions and BP of ATRAP-KO mice was comparable to that of their littermate wild-type control mice (WT mice) at baseline. However, the Ang II-mediated BP elevation was significantly augmented in the ATRAP-KO mice. Consequently, the heart weight /body weight ratio and urinary albumin excretion in the Ang II-infused ATRAP-KO mice were significantly increased compared with those in Ang II-infused WT mice. Metabolic cage analysis disclosed the increased cumulative sodium balance during the Ang II infusion period in the ATRAP-KO mice, along with an increase in the expression of α-subunit of the epithelial sodium channel in the kidney of ATRAP-KO mice.

**Conclusions:** In summary, these results indicated that the gene-targeted deletion of ATRAP provoked the exacerbation of Ang II-mediated hypertension and its associated end-organ injury, along with an inhibition of natriuresis, without any evident influence on baseline physiological function. Therefore, ATRAP is a potential target of interest in the regulation of BP.

## TH-OR146

**Somatic and Germline *CACNA1D* Calcium Channel Mutations in Aldosterone-Producing Adenomas and a Mendelian Syndrome Featuring Primary Aldosteronism** Ute I. Scholl,[1] Gerald S. Goh,[1] Gabriel Stölting,[2] Regina Campos de Oliveira,[3] Murim Choi,[1] Annabelle L. Fonseca,[4] Erum A. Hartung,[5] Matthew Benson,[6] Carol J. Nelson-Williams,[1] Steven Libutti,[7] Shrikant M. Mane,[1] Per Hellman,[8] Peyman Björklund,[8] Tobias Carling,[4] Christoph Fahlke,[2] Patricia Hidalgo,[2] Richard P. Lifton.[1] *[1]Genetics, HHMI, Yale School of Medicine, New Haven, CT; [2]Institute of Complex Systems, Forschungszentrum Jülich, Germany; [3]Neurophysiologie, Medizinische Hochschule Hannover, Germany; [4]Surgery, Yale School of Medicine, New Haven, CT; [5]Children's Hospital of Philadelphia, Philadelphia, PA; [6]Nemours Children's Clinic, Jacksonville, FL; [7]Surgery, Albert Einstein College of Medicine, Bronx, NY; [8]Surgical Sciences, Uppsala, Sweden.*

**Background:** Adrenal aldosterone-producing adenomas (APAs) are benign, hormone-producing tumors found in ~5% of patients referred to hypertension specialists. ~40% of these tumors are caused by recurrent mutations in the potassium channel *KCNJ5*, resulting in sodium permeability, depolarization and calcium influx.

**Methods:** We here use exome and targeted sequencing to identify additional recurrent mutations in APAs and evaluate their functional impact by using patch clamp electrophysiology.

**Results:** We describe seven novel somatic mutations in the voltage-gated calcium channel *CACNA1D* in 43 non-*KCNJ5*-mutant APAs (16.3%). Four alter G403, and one each alter I770, F767 and V1373. Six of seven mutations are located within the S6 domains of the channel and are shown by electrophysiology or inferred to be gain-of-function, resulting in activation at less depolarized potentials. G403 mutations also impair inactivation. Remarkably, we identify *de novo* mutations at the identical residues in two patients with a novel Mendelian syndrome featuring primary aldosteronism and neuromuscular abnormalities, including seizures. *CACNA1D* is expressed in human adrenal cortex. Excess calcium influx through mutant channels is expected to result in aldosterone production and proliferation by activation of the same pathways upregulated in *KCNJ5*-mutant tumors.

**Conclusions:** These findings explain a significant fraction of primary aldosteronism and have diagnostic and therapeutic implications.

## TH-OR147

**Mutation of Anti-Aging Gene Klotho Causes Hypertension via Upregulation of Adrenal CYP11B2 Expression and Plasma Aldosterone Levels** Zhongjie Sun. *Physiology, Univ of Oklahoma Health Sciences Center.*

**Background:** Klotho is a recently discovered anti-aging gene. The purpose of this experiment is to assess if klotho deficiency affects blood pressure.

**Methods:** One group of KL mutant heterozygeous (+/-) mice and one group of wild-type mice were used.

**Results:** Interestingly, klotho (+/-) mice demonstrated a significant and persistent increase in blood pressure starting form 3-4 months of age, indicating that klotho deficiency causes hypertension. Plasma level of aldosterone was elevated in KL(+/-) mice. Two groups of KL(+/-) mice and 2 groups of wild-type mice were used. When BP was elevated in KL(+/-) mice, 1 group of KL (+/-) mice and 1 group of WT mice were treated with aldosterone receptor blocker, eplerenone (6 mg/kg/day), while the remaining groups received DMSO and serve as controls. Eplerenone decreased hypertension to the control level. Eplerenone also abolished KL deficiency-induced kidney damage (glomerulus collapse, fibrosis). Klotho deficiency causes renal inflammation as evidenced by significant increases in inflammatory cytokines (IL-6, TNFα and MCP-1) and T cell and macrophage infiltration in kidneys of KL (+/-) mice. Eplerenone significantly attenuated KL deficiency-induced inflammation. Notably, NCC and Sgk1 levels were increased in kidneys in KL(+/-) mice, which could be abolished by eplerenone. Further analysis indicated that klotho co-localized with CYP11B2, a key enzyme for aldosterone synthesis, in the adrenal cortex. Klotho deficiency upregulated CYP11B2 protein expression.

**Conclusions:** KL deficiency caused hypertension via upregulating adrenal CYP11B2 protein expression and plasma aldosterone levels which led to inflammation and upregulation of NCC signaling in kidneys.

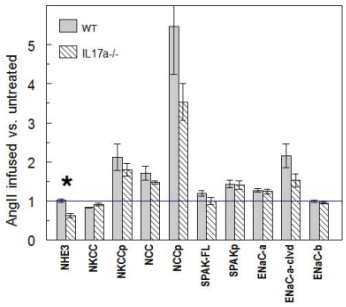
## TH-OR148

**Hypertensive Response to Angiotensin II (Ang II) Infusion Is Blunted in IL-17a$^{-/-}$ Mice Associated with Depressed Na/H Exchanger 3 (NHE3) Abundance** Nikhil Kamat,[1] David G. Harrison,[2] Alicia A. McDonough.[1] *[1]Cell and Neurobiology, Keck School of Medicine of USC, Los Angeles, CA; [2]Vanderbilt Vascular Biology Center, Vanderbilt Univ Medical Center, Nashville, TN.*

**Background:** Previous studies (Harrison lab), establish that CD8 T cells are essential for the hypertensive response to AngII infusion and that CD8 cells accumulate in the kidney of hypertensive animals where they produce the cytokine IL-17a. AngII infusion hypertension is blunted in IL-17a $^{-/-}$ mice compared to wild type (WT) mice (18 vs. 38 mmHg rise). The aims of this study were to test the hypothesis that the blunted hypertensive response to AngII infusion in IL17a$^{-/-}$ mice is associated with blunted renal $Na^+$ transporter stimulation, and to define the transporter(s) involved.

**Methods:** WT and IL17a$^{-/-}$ mice were infused with AngII (490 ng/kg/min x 14 days), homogenates subjected to quantitative immunoblot analysis of $Na^+$ transporters' abundance, phosphorylation and processing. Density values were normalized to values in WT sham infused mice, defined as 1.00; * = p <0.05.

**Results:** In both WT and IL17a$^{-/-}$ mice, Ang II infusion increased thick ascending limb NKCCp, distal convoluted tubule NCCp, cortical SPAKp and collecting duct ENaCa cleavage, all evidence of transporter activation. However, in IL17a$^{-/-}$, PT NHE3 abundance fell to 62% of that in uninfused IL17a$^{-/-}$.



**Conclusions:** Since depressing NHE3 transport is key to pressure natriuresis, we postulate that AngII infusion stimulates IL17a production in infiltrating CD8 cells which blunts pressure natriuresis and ↑ blood pressure, and that in the IL17a$^{-/-}$ mice pressure natriuresis is enhanced leading to blunted hypertension.

### Loss of Cilia Results in Increased Intra-Renal Angiotensinogen and Mislocalized Prorenin Receptor in the Collecting Duct of a Polycystic Kidney Disease Mouse Model

Takamitsu Saigusa,[1] Yujing Dang,[1] Marlene Amjad Bunni,[1] Stacy Steele,[1] P. Darwin Bell.[1,2] *[1]Nephrology/Medicine, Medical Univ of South Carolina, Charleston, SC; [2]Nephrology/Medicine, Ralph H. Johnson VA Medical Center, Charleston, SC.*

**Background:** The mechanism for early hypertension in polycystic kidney disease (PKD) has not been elucidated. Activation of the intra-renal renin-angiotensin-system (RAS) has been demonstrated from several human PKD studies. For example, angiotensinogen is primarily expressed in cysts of proximal tubule origin and may result in increased downstream intra-tubular Angiotensin II concentrations thus leading to increased distal tubular RAS activity, $Na^+$ reabsorption and elevated blood pressure. However, it is unknown whether primary cilium plays a role in intra-renal RAS in PKD. The purpose of this study was to determine whether loss of cilia results in increased intra-renal RAS in mouse model of PKD.

**Methods:** Adult *ift* 88 conditional floxed allele mice with or without cre were administered tamoxifen to induce cilia loss. Three weeks or 3 months after tamoxifen injection, kidney tissues were examined by histology, immunofluorescence, Western blot and mRNA to assess intra-renal RAS components. SV40 immortalized collecting duct cell lines from hypomorphic *ift*88 mouse were used to assess intra-renal RAS components in collecting duct cells.

**Results:** Loss of cilia significantly increased cyst formation, kidney angiotensinogen protein and mRNA levels but did not alter kidney renin, prorenin receptor, angiotensin-1 receptor expression. There was a trend in higher blood pressure in cilia (-) mice. Immunofluorescence revealed mislocalization of prorenin receptor to the basolateral membrane of principal cells in cilia (-) but not in cilia (+) kidneys. Prorenin was increased in cilia (-) collecting duct cell line and angiotensin II simulation resulted in increased levels of cAMP inhibited by losartan which may contribute to elevated prorenin levels in the collecting duct.

**Conclusions:** These data suggest that in the absence of cilia, there is an upregulation and mislocalization of intra-renal-RAS components, which may contribute to elevated blood pressure in PKD.

## TH-OR150

### Renal ACE Causes Salt Sensitivity in Response to Renal Inflammation

Jorge F. Giani,[1] Tea Janjulia,[1] Jorge E. Toblli,[2] Romer Andres Gonzalez-Villalobos.[1] *[1]Depts of Biomedical Sciences and Pathology, Cedars-Sinai Medical Center, Los Angeles, CA; [2]Laboratory of Experimental Medicine, Hospital Alemán, Buenos Aires, Argentina.*

**Background:** Studies emphasize the importance of renal inflammation in causing defective sodium handling by the kidneys, the central feature of salt-sensitive (SS) hypertension. Yet, exactly how inflammation impairs renal sodium excretion is not fully understood. Our previous data show that local Ang II synthesis by renal ACE is a master switch for sodium transport along the nephron. Accordingly, we hypothesized that activation of the renal ACE/Ang II pathway by renal inflammation causes SS hypertension.

**Methods:** We studied the responses of mice lacking renal ACE but with normal circulating ACE (10/10 mice) to post L-NAME hypertension; a model in which the transient exposure to L-NAME triggers substantial renal inflammation and SS hypertension [L-NAME (4 weeks) → Washout (1 week) → high salt diet (HS 4%, 3 weeks)].

**Results:** Wild-type (WT) mice (n=12), previously salt resistant, became salt sensitive after L-NAME exposure. L-NAME increased WT systolic blood pressure (SBP) from 110±2 to 135±3 mmHg ($p<0.01$). SBP returned to baseline during the washout and increased again in response to HS diet (131±3 mmHg; $p<0.01$). Remarkably, ACE 10/10 mice did not develop post L-NAME salt sensitivity. This was despite having equivalent to WT levels of SBP (133±1 mmHg) and renal inflammation (macrophage infiltration, TNFα and IL-6, all by IHC) in response to L-NAME. At the end of HS phase, SBP of ACE 10/10 mice was 106±5 mmHg (NS). In addition, basal renal Ang II level (by IHC) was similar between WT and ACE 10/10. However, sodium load induced an accumulation of renal Ang II that was greater in WT compared to ACE 10/10 (26±2 vs. 13±2 %/area; $p<0.01$). Finally, sodium balance studies revealed an enhanced natriuretic response of ACE 10/10 vs. WT during the HS diet. For instance, sodium excretion after day 1 (before returning to balance) was 1076±67 μmol/day in WT vs. 1353±52 μmol/day in ACE 10/10 mice ($p<0.01$).

**Conclusions:** These results demonstrate that renal ACE is required to increase local Ang II, trigger anti-natriuresis and to induce SS hypertension in response to renal inflammation.

## TH-OR151

### Role of Collecting Duct Renin in Blood Pressure Regulation

Nirupama Ramkumar,[1] Deborah Stuart,[1] Sara Rees,[1] Curt D. Sigmund,[2] Donald E. Kohan.[1] *[1]Nephrology and Hypertension, Univ of Utah, Salt Lake City, UT; [2]Univ of Iowa, Iowa City, IA.*

**Background:** Recent studies propose that collecting duct (CD) renin is an important modulator of blood pressure regulation, especially in conditions such as angiotensin-II infused hypertension.

**Methods:** We used gene targeting to generate a CD-specific renin knockout (KO) to assess if CD derived renin can regulate BP. Utilizing the Cre lox P system, exon 1 of the renin gene was ablated specifically in the CD. BP was recorded via telemetry and plasma and urine were collected in metabolic cages on normal, high and low Na diets.

**Results:** DNA recombination showed kidney specific recombination in KO mice. Compared to floxed mice, CD renin KO mice had 70 % lower medullary renin mRNA levels and 90% lower renin mRNA in micro-dissected cortical and inner medullary CD tubules. Urinary renin levels were significantly lower in the KO mice on normal and low Na diets (45% of floxed levels) but not with high Na intake. Plasma renin concentration was significantly higher in the KO mice on all three diets. While BP was similar between the two groups on all three diets, infusion of Ang-II delayed the increase in BP in the CD renin KO group for at least 4 days post-infusion.

**Conclusions:** These findings suggest that CD renin likely plays a role in normal BP regulation (evidenced by an increase in PRC) and in response to AngII infusion.

## TH-OR152

### Salt Overload Aggravates Hypertension and Promotes Severe Renal Injury in Rats Subjected to NF-κB Inhibition during Nephrogenesis

Victor F. Avila, Simone C.A. Arias, Orestes Foresto-Neto, Camilla Fanelli, Claudia R. Sena, Vivian L. Viana, Denise M.A.C. Malheiros, José E. Krieger, Roberto Zatz, Clarice K. Fujihara. *Univ of Sao Paulo, Brazil.*

**Background:** We showed recently that NF-κB inhibition by pyrrolidine dithiocarbamate (PDTC) during rat lactation leads to hypertension (HTN) in adult life, with no renal injury. Here we investigated whether challenging this new model with a high-salt diet (HS) would exacerbate HTN and promote renal damage.

**Methods:** Munich-Wistar dams were kept with their offspring (males only, n=49), receiving no treatment or PDTC, 280 mg/kg/day in drinking water during lactation only. The offspring underwent uninephrectomy (UNx) at 10 wks of age, and received normal salt diet (NS) until 12 wks of age, when they were divided into: **C+NS**, control (C); **C+HS**, C receiving 3.2% NaCl chow and 0.5% NaCl to drink; **PDTC$_{Lact}$+NS**, rats that had received neonatal PDTC; **PDTC$_{Lact}$+HS**, PDTC$_{Lact}$ on HS. Tail-cuff pressure (TCP, mmHg), glomerulosclerosis index (GSI), % cortical interstitium (% INT), % injured microvessels (%Vasc), INT macrophage infiltration (MΦ, cells/mm$^2$), plasma renin activity (PRA, ng/mL/h), and INT angiotensin II (AngII, cells/mm$^2$), were assessed 12 wks later.

**Results:**

| | TCP | GSI | %INT | %VASC | MΦ | PRA | AngII |
|---|---|---|---|---|---|---|---|
| C+NS | 144±2 | 3±1 | 1±1 | 0±0 | 33±3 | 2.7±0.6 | 2±1 |
| C+HS | 165±1$^b$ | 14±3 | 1±1 | 4±2 | 55±6 | 0.2±0.1$^b$ | 3±1 |
| PDTC$_{Lact}$+NS | 166±2$^a$ | 2±1 | 1±1 | 1±1 | 35±4 | 2.1±0.4 | 2±1 |
| PDTC$_{Lact}$+HS | 195±3$^{ab}$ | 55±21$^{ab}$ | 6±2$^{ab}$ | 16±6$^{ab}$ | 153±22$^{ab}$ | 0.2±0.1$^b$ | 5±1$^b$ |

Mean±SE, $^a p<0.05$ vs C; $^b p<0.05$ vs. NS)

Moderate HTN was seen in Groups C+HS and PDTC$_{Lact}$+NS, while Group PDTC$_{Lact}$+HS exhibited marked HTN, GS, glomerular thrombi and aneurysms, INT expansion, severe Vasc, intense MΦ infiltration, and INT AngII dissociated from PRA.

**Conclusions:** HS and UNx uncovered a renal dysfunction not apparent in PDTC$_{Lact}$ rats on NS, indicating that an intact NF-κB system is required to enable developing rat kidneys to avoid HTN and deal properly with salt excess in adult life.

**TH-OR153**

**The Endoplasmic Reticulum Stress Inhibitor, 4-Phenylbutyrate, Reduces Hypertension in the Spontaneously Hypertensive Rat Model of Essential Hypertension** Kaitlyn Werner,[1,2] Victoria Yum,[1,2] Chao Lu,[1,2] Jeffrey G. Dickhout.[1,2] *[1]Medicine, Div of Nephrology, McMaster Univ, Hamilton, Canada; [2]Nephrology, St. Joseph's Healthcare Hamilton, Hamilton, Canada.*

**Background:** We have shown that endoplasmic reticulum (ER) stress is important in angiotensin II-mediated hypertension, and that the low molecular weight chemical chaperone, 4-phenylbutyrate (4-PBA), can inhibit endoplasmic reticulum stress in the kidney via oral dosing. Therefore, we tested the ability of 4-PBA to lower blood pressure in the most frequently used animal model of essential hypertension, the spontaneously hypertensive rat (SHR).

**Methods:** 12 week old male SHRs with established hypertension were used and treated with 4-PBA (1g/kg/day, orally). Blood pressure was measured 1 week before treatment using tail cuff plethysmography and was 181/118 initially. These animals were randomized into either 4-PBA or vehicle treatment groups. Treatment with 4-PBA proceeded for 5 weeks. Aortas and mesenteric resistant vessels were collected after 5 weeks for functional and structural analysis. Final blood pressures were measured directly through carotid artery cannulation.

**Results:** We found 4-PBA treatment significantly lowered blood pressure in the SHR (Vehicle 206.1 ±4.4 vs. 4-PBA 179.0 ±3.1, systolic; vehicle 143.6 ±4.4 vs. 4-PBA 121.2 ±4.3, diastolic) at 5 weeks. This was reflected in both tail cuff and direct blood pressure measurement. Examination of aortic and mesenteric resistant artery contractility found 4-PBA diminished mesenteric resistant artery contractility but had no effect on that of the aorta. 4-PBA treatment also augmented endothelial vasodilation in the resistant vessels, but not the aorta. 4-PBA treatment had no effect on the ability of nitric oxide to evoke vasorelaxation in either mesenteric vessels or the aorta, as shown by sodium nitroprusside treatment. 4-PBA treatment did not change the structure of mesenteric resistant vessels, as shown by three dimensional volume reconstructions.

**Conclusions:** The ER stress inhibitor, 4-PBA, reduces hypertension in the spontaneously hypertensive rat by improving resistant blood vessel endothelial dependent vasodilation without changing smooth muscle mass or vessel structure.

**TH-OR154**

**Mesenchymal Stem Cells (MSC) Prevent the Progression of Renovascular Hypertension, Improved Renal Function and Architecture** Elizabeth B. Oliveira-Sales,[1] Edgar Maquigussa,[1] Patricia Semedo Kuriki,[1] Luciana Guilhermino Pereira,[1] Vanessa Meira Ferreira,[1] Niels O.S. Camara,[1] Cassia T. Bergamaschi,[2] Ruy Campos,[2] Mirian A. Boim.[1] *[1]Dept of Medicine, Federal Univ of Sao Paulo, Sao Paulo, Brazil; [2]Dept of Physiology, Federal Univ of Sao Paulo, Sao Paulo, Brazil.*

**Background:** Renovascular hypertension induced by 2 Kidney-1 Clip (2K-1C) is a renin-angiotensin-system (RAS)-dependent model, leading to renal vascular rarefaction and renal failure. RAS inhibitors are not able to reduce arterial pressure (AP) and/or preserve the renal function, and thus, alternative therapies are needed.

**Methods:** Three weeks after left renal artery occlusion, fluorescently tagged mesenchymal stem cells (MSC) ($2x10^5$ cells/animal) were injected weekly into the tail vein in 2K-1C hypertensive rats.

**Results:** Flow cytometry showed labeled MSC in the cortex and medulla of the clipped kidney. MSC prevented a further increase in the AP, significantly reduced proteinuria and decreased sympathetic hyperactivity in 2K-1C rats. Renal function parameters were unchanged, except for an increase in urinary volume observed in 2K-1C rats, which was not corrected by MSC. The treatment improved the morphology and decreased the fibrotic areas in the clipped kidney and also significantly reduced renal vascular rarefaction typical of 2K-1C model. Expression levels of IL-1β, TNF-α angiotensinogen, ACE, and Ang II receptor $AT_1$ were elevated, whereas $AT_2$ levels were decreased in the medulla of the clipped kidney. MSC normalized these expression levels.

**Conclusions:** In conclusion, MSC therapy in the 2K-1C model (i) prevented the progressive increase of AP, (ii) improved renal morphology and microvascular rarefaction, (iii) reduced fibrosis, proteinuria and inflammatory cytokines, (iv) suppressed the intrarenal RAS, iv) decreased sympathetic hyperactivity in anesthetized animals and v) MSC were detected at the CNS suggesting that the cells crossed the blood-brain barrier. This therapy may be a promising strategy to treat renovascular hypertension and its renal consequences in the near future.

**Loss of p47$^{phox}$ Ameliorates Kidney Fibrosis and Proteinuria** Xiwu Chen, Paisit Paueksakon, Ming-Zhi Zhang, Raymond C. Harris, Roy Zent, Ambra Pozzi. *Medicine, Vanderbilt Univ, Nashville, TN.*

**Background:** Reactive oxygen species (ROS) play an important pathogenic role in the development of various diseases, including kidney disease. The major generator of ROS in the glomerulus of the kidney is the NAPDH oxidase complex which consists of five different subunits. Among these subunits, the p47$^{phox}$ is a critical regulatory subunit of NADPH oxidase and its expression is upregulated in the course of renal injury. The contribution of p47$^{phox}$ has been widely investigated in diabetic nephropathy; however whether is also plays a role in non-diabetic-mediated glomerular injury is unclear.

**Methods:** To address this issue, we analyzed the contribution of the p47$^{phox}$ in glomerural disease since it is a critical regulatory subunit of NADPH oxidase. To this end, we crossed the p47$^{phox}$-null mice with integrin α1-null mice, a model of exacerbated NADPH-mediated ROS production and glomerulosclerosis after injury, to generate wild type, p47$^{phox}$-null, integrin α1-null, and p47$^{phox}$-null/integrin α1-null mice. These mice were then subjected to either ROS-dependent (adriamycin) or ROS-independent (partial renal ablation) renal injury and their proteinuria and kidney injury was analyzed over time.

**Results:** We provide evidence that in both models, deletion of p47$^{phox}$ significantly reduced proteinuria and kidney fibrosis, and these effects were more accentuated on the integrin α1-null background. This protection is accompanied by decreased production of free radicals, and consequent glomerular injury. Moreover, *in vitro* analysis of primary mesangial cells isolated from different types of mice revealed that loss of p47$^{phox}$ leads to reduced basal levels of superoxide and collagen production.

**Conclusions:** Our study suggests that the NADPH oxidase is major source of ROS in kidney glomeruli and contributes to kidney injury. Moreover, our study points to the p47$^{phox}$ a potential target for antioxidant therapy in fibrotic disease.

**miR-182 Inhibits FoxO3-Mediated Atrophic Signaling in Muscle, and Glucocorticoid Administration and Acute Diabetes Down-Regulate Muscle miR-182** Matthew B. Hudson,[1] Myra Woodworth-Hobbs,[1,2] Bin Zheng,[1] Jill Rahnert,[1] Harold A. Franch,[1] Russ Price.[1,3] *[1]Renal Div, Dept of Medicine, Emory Univ, Atlanta, GA; [2]Nutrition and Health Sciences Graduate Program, Emory Univ, Atlanta, GA; [3]Atlanta VA Medical Center, Decatur, GA.*

**Background:** Skeletal muscle atrophy occurs in response to a variety of conditions including chronic kidney disease, diabetes, metabolic acidosis, and elevated glucocorticoids. Previous studies demonstrate components of the Forkhead box O (FoxO) pathway are increased in multiple models of skeletal muscle wasting. FoxO transcription factors induce skeletal muscle atrophy by increasing the expression of components for the ubiquitin-proteasome and autophagy-lysosome systems.

**Methods:** To identify potential modulators of the atrophy process, an *in silico* target scan analysis of known microRNAs was performed. miR-182 was predicted to target the FoxO proteins. To test whether miR-182 regulates expression of the FoxOs, C2C12 myotubes were transfected with miR-182 and levels of FoxO1 and FoxO3 protein were evaluated.

**Results:** miR-182 reduced FoxO3 protein 64% ($P<0.05$ vs Con) whereas FoxO1 was unaffected. Treatment of C2C12 myotubes with dexamethasone (1 μM, 6 hr) to induce muscle atrophy decreased miR-182 expression by 46% ($P<0.05$ vs Con). Overexpression of miR-182 prevented the glucocorticoid-induced upregulation of FoxO3 gene targets including MAFbx/Atrogin-1, ATG12, Cathepsin L, and LC3. To determine if miR-182 is altered in an *in vivo* model of muscle atrophy, miR-182 was measured in the gastrocnemius muscle of rats with acute diabetes (3 d) induced by streptozotocin. miR-182 was suppressed by 43% in the gastrocnemius of diabetic mice ($P<0.05$ vs Con).

**Conclusions:** These data identify miR-182 is a new and important regulator of FoxO3-mediated signaling during muscle atrophy induced by catabolic disease states.

**The Paraoxonase PON2 Modifies Lipid Peroxidation at the Slit Diaphragm** Henning Hagmann,[1] Dontscho Kerjaschki,[2] Stuart E. Dryer,[3] Bernhard Schermer,[1] Thomas Benzing,[1] Paul T. Brinkkoetter.[1] *[1]Dept of Nephrology, Univ of Cologne, Cologne, Germany; [2]Dept of Clinical Pathology, Univ of Vienna, Vienna, Austria; [3]Dept of Biochemistry, Univ of Houston, Houston.*

**Background:** The mammalian slit diaphragm is a site of highly active intercellular signalling between adjacent podocytes. Signalling pathways e.g. via TRPC6 depend on the distinct lipid composition of the plasma membrane. Interestingly the signalling-complex at the slit diaphragm shares close homology with the neuronal mechanosensory complex of *C. elegans.* The Podocin homologue MEC-2 orchestrates protein-lipid supercomplexes in the plasma membrane of *C.elegans* touch neurons to allow for proper signalling via the degenerin cation channel MEC-4/-10. Part of the mechanosensory complex is also the lipid modifying enzyme MEC-6, which interacts with MEC-4/-10 and enhances its channel activity.

**Results:** We identified the mammalian homologue of MEC-6, the paraoxonase family protein PON2, as a novel slit diaphragm protein. PON2 localizes to the slit diaphragm in immuno-fluorescence and immunogold-labeling studies. In addition it not only co-fractionates with Podocin in cholesterol-rich detergent resistant membrane domains but also interacts directly with slit diaphragm proteins like Nephrin, Podocin and TRPC6 in pull-down experiments. We were able to show that PON2 is an integral transmembrane protein that localizes to the plasma membrane with its enzymatically active domain facing extracellular. To address the functional role of PON2 in the plasma membrane we employed in vitro enzyme assays with recombinant protein and analysed the lipid profile of PON2-proficient and –deficient cells using mass spectrometry. We found that PON2 affects the content of glycolipids and the overall peroxidation state of membrane lipids.

**Conclusions:** In conclusion we show that PON2 is a novel slit diaphragm protein which modifies the lipid content and peroxidation state of the plasma membrane. It is therefore well conceivable that it is an important regulator of signal transduction e.g. via the cation channel TRPC6.

**FR-OR004**

**Involvement of Nitric Oxide and Endothelin Systems in the Pathogenesis of Endothelial Dysfunction in Diabetic Nephropathy** Niroz Abu-Saleh,[1] Mogher Khamaisi,[2] Hoda Awad,[1] Suheir Assady,[3] Ravit Cohen,[1] Zaher Armaly,[4] Zaid Abassi.[1] *[1]Technion, Haifa, Israel; [2]Joslin Diabetes Center, Boston; [3]Rambam Medical Center, Haifa, Israel; [4]Nazareth Hospital-EMMS, Israel.*

**Background:** Endothelial dysfunction (ED) is a major cause of vascular complications characterizing diabetic nephropathy. Diabetic patients who also exhibit hyperlipidemia suffer from accelerated vascular complications. While the deleterious effects of hyperglycemia (HG) and hyperlipidemia alone on ED is well established, the effects of combined hyperlipidemia and HG has not been thoroughly studied.

**Methods:** We applied cultured human umbilical vein endothelial cell (HUVECs), and LDL receptor knockout mice ($LDLR^{-/-}$) to investigate the mechanisms underlying combined HG and hyperlipidemia-induced ED.Incremental doses of glucose in the presence or absence of oxidized LDL (oxLDL) were added to HUVECs. The status of nitric oxide (NO) and endothelin (ET)-1 systems as well as their signal transduction were assessed after 5 days of HG. The effects of chronic combination of HG and hyperlipidemia on endothelial integrity and function as well as alterations in NO and ET-1 systems in vascular, cardiac and renal tissues were examined in the $LDLR^{-/-}$ and wild type (BALB) mice.

**Results:** HUVEC exposed to HG and ox-LDL displayed enhanced ET-1 production, more than HG or Ox-LDL alone. Overproduction of ET-1 stems from upregulation of endothelin converting enzyme (ECE-1) immunoreactivity. Combination of HG and Ox-LDL dramatically decreased total and activated endothelial NO synthase (eNOS) and NRF2, a transcription factor for various antioxidant enzymes by ~50%. Likewise, $ET_B$ levels decreased by 64%. As compared with normoglycemic $LDLR^{-/-}$ and BALB mice, diabetic $LDLR^{-/-}$ mice displayed a higher blood pressure (135±2 vs. 113±4 and 97±4mmHg, respectively) plasma glucose (308±52.7 vs. 159.2±18.8 and 105±10.51mg%), ET-1 (14.9±0.9 vs. 12.31±2.097 and 9.57±0.497pg/ml) and NO2/NO3 levels (42.3±21.71 vs. 12.65±1.24 and 12.76±2.17μM).

**Conclusions:** Combined diabetes and hyperlipidemia activate the ET system and attenuate eNOS and Nrf2. These findings suggest that perturbations in these systems may contribute to diabetic nephropathy.

**FR-OR005**

**Human Kidney Proximal Tubular Epithelial Cells Are Not Protected against Oxidative Stress by PPARγ Agonists** David M. Small,[1] Christudas Morais,[1] David W. Johnson,[1,2] Glenda C. Gobe.[1] *[1]Centre Kidney Disease Research, Univ of Queensland; [2]Dept Nephrology, PA Hospital, Brisbane, Australia.*

**Background:** Peroxisome proliferator activated receptor-gamma (PPARγ) agonists are renoprotective in diabetic nephropathy but the mechanisms are not well-understood. Mitochondrial dysfunction and oxidative stress contribute to diabetic nephropathy. PPARγ upregulates proteins required for mitochondrial biogenesis. Our aim is to determine the role of PPARγ in protecting kidney proximal tubular epithelium (PTE) against mitochondrial destabilisation and oxidative stress.

**Methods:** HK-2 cells were treated with 0.2-1.0mM hydrogen peroxide ($H_2O_2$) for 2h and 18h. Treated and untreated cells were compared for: apoptosis, mitosis (morphology/biomarkers); cell viability (MTT); superoxide (dihydroethidium /DHE); mitochondrial function (MitoTracker Red; JC-1); ATP (luminescence); and mitochondrial ultrastructure (electron microscopy). Western immunoblotting was used to study PPARγ, phospho-PPARγ, PPARy-coactivator-1α (PGC-1α; mitochondrial biogenesis marker), and pak2, p62 and LC3-II (mitophagy markers). PPARγ agonists (rosiglitazone, pioglitazone, troglitazone) and the inhibitor (GW9662) were used to modulate PPARγ.

**Results:** At 2h and 18h, mitochondrial destabilisation increased with $H_2O_2$ concentration: MitoTracker Red and ATP decreased ($p<0.05$); JC-1 fluorescence altered red→green; and DHE increased (18h; $p<0.05$). Mitochondria were sparse and had disrupted cristae. Pak2 increased, p62 decreased (2h), and p62 and LC3-II increased (18h) (all $p<0.05$) indicating increased defective mitochondrial autophagy. PPARγ expression did not alter but phospho-PPARγ increased and PGC-1α decreased (2h) indicating aberrant PPARγ activation and reduced mitochondrial biogenesis. Cell viability decreased (18h; $p<0.05$), with further cell death when PPARγ agonists were used. PPARγ inhibition had negligible effect.

**Conclusions:** Oxidative stress promoted mitochondrial destabilisation in kidney PTE, in association with PPARγ activation. PPARγ agonists failed to protect the cells. Despite positive effects in other tissues, PPARγ activation appears to be detrimental to kidney PTE health when oxidative stress induces damage.

**FR-OR006**

**Circulating Oxidized Albumin Is a Mediator of Endothelial Dysfunction in Uremia** Faiga Magzal,[2,3,4] Snait Tamir,[3,5] Andrea Szuchman-Sapir,[3,5] Shifra Sela,[2,4] Batya Kristal.[1,2] *[1]Nephrology and Hypertension Dept, Western Galilee Hospital, Israel; [2]Faculty of Medicine in the Galilee, Bar Ilan Univ, Safed, Israel; [3]Laboratory of Human Health and Nutrition Science, Migal, Israel; [4]Eliachar Research Laboratory, Western Galilee Hospital, Israel; [5]Nutrition Dept, Tel Hai College, Israel.*

**Background:** Oxidative stress and inflammation prevalent among hemodialysis patients underly atherosclerosis and cardiovascular (CV) morbidity and mortality. We suggest that modified human serum albumin (HSA) mediate endothelial dysfunction, a process that may initiate CVD. Our study aims to characterize the modifications of uremic HSA, reveal their effects on endothelial function and establish a "finger-print" of modified HSA as a potential novel tool to predict CVD.

**Methods:** Albumin enriched fraction from 5 healthy controls (HC) and 5 Hemodialysis (HD) patients were evaluated by electrospray ionization mass spectrometry (Q-TOF LC/MS). Human umbilical vein endothelial cells (HUVEC) were exposed to albumin separated from sera of HC or HD. Endothelial mRNA was extracted to determine expression of Interleukin 6 (IL-6), TNF-alpha and e-NOS.

**Results:** We revealed the existence of reversible and irreversible post-translational modifications, present in HC and HD patients. Each group is characterized by an unique profile with some of the post-translational modifications present only in HD patients. Unmodified Albumin showed a molecular mass of 66440.64 ± 0.14 Da. The known post-translational modifications observed were: Cysteinylation (66558.60 ± 0.74 Da), Nytrosylation (664676.80± 2.55 Da), Nitration (66483.57±3.31), Glycation (66601± 0.70 Da) and Sulphenic Acid formation (66655.49 ± 1.49 Da). Exposure of endothelial cells to HAS separated from HD patients resulted in an increase in the cytokine and e-NOS expression by 1.2, 1.5 and 2.4 fold, respectively, in comparison to HAS of HC.

**Conclusions:** We suggest that modified albumin plays a pivotal role in endothelial dysfunction underlying atherosclerosis. Further studies are needed to enable the use of these exclusive modifications as a "finger-print" for evaluation and follow-up of the atherosclerotic process.

**FR-OR007**

**FGF23 Enhances Nitric Oxide Synthesis, and Reduces Production of Reactive Oxygen Species in Human Endothelial Cells *In Vitro*** Maren Leifheit-Nestler, Jacqueline Haller, Dieter Haffner. *Dept of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany.*

**Background:** Oxidative stress and uremic toxins are well known risk factors for cardiovascular diseases (CVD), associated with comorbidity of patients with chronic kidney disease (CKD). Patients with CKD exhibit excessive serum concentration of phosphaturic hormone fibroblast growth factor 23 (FGF23) as a result of disordered calcium and phosphate homeostasis. FGF23 binds primarily to FGF-receptor (FGFR) 1 and its cofactor klotho. Klotho is a transmembrane protein and after cleavage the extracellular domain acts as a humoral factor (soluble a-klotho) as well. Klotho has been associated with aging and bone loss and klotho-deficient mice indicate accelerated arteriosclerosis suggesting an influence of klotho on the cardiovascular system.

**Methods:** To examine the impact of FGF23 on endothelial function, human coronary artery endothelial cells (HCAEC) were stimulated with FGF23 in a time- and concentration-dependent manner. Cells were evaluated for protein expression and activation of FGF23, FGFR1-4, klotho and endothelial nitric oxide synthase (eNOS). To analyze endothelial function, the formation of reactive oxygen species (ROS) was detected by fluorescence microscopy and FACS analysis and FGF23 dependent nitric oxide (NO) production was quantified using modified Griess assays.

**Results:** FGF23 receptors 1 and 2 as well as klotho were detected in HCAEC. Incubation of HCAEC with FGF23 (10-100ng/ml) resulted in (i) decreased formation of ROS, (ii) increased NO production, and (iii) enhanced eNOS activity, demonstrated by enhanced phosphorylation of serin1177, in a time-dependent fashion. Incubation of HCAEC with FGF23 for 60 minutes induced the release of soluble a-klotho (3.6-fold; $p<0.05$) in conditioned medium.

**Conclusions:** Vascular endothelial cells are a target of FGF23 as HCAEC express receptors required for FGF23 signaling. FGF23 reduces oxidative stress (i.e. ROS production) and increases eNOS activity, and NO production in cultured HCAEC. This might be at least partly mediated by increased secretion of soluble a-klotho. Thus, FGF23 has a positive impact on oxidative stress in HCAEC in vitro.

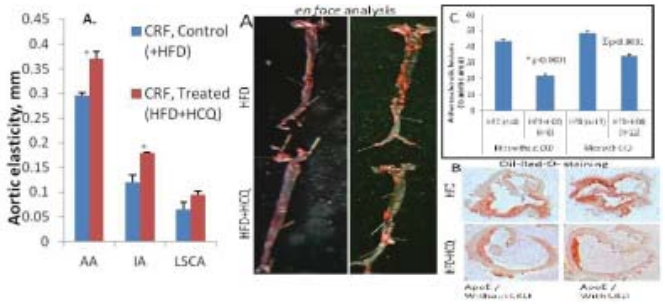
**FR-OR008**

**A Novel Approach for the Management of Cardiovascular Disease in CKD** Ashutosh M. Shukla,[1] Chhanda X. Bose,[2] Oleg K. Karaduta,[2] Sudhir V. Shah.[2] *[1]Div of Nephrology, Univ of Florida & NF/SG VA, Gainesville, FL; [2]Div of Nephrology, Univ of Arkansas for Med. Sci. & CAVHS, Little Rock, AR.*

**Background:** At the present time we lack an effective strategy to manage cardiovascular disease associated with chronic kidney disease(CKD). Atherosclerosis is an inflammatory process and hydroxychloroquine(HCQ) has multiple pleiotropic properties that are anti-inflammatory.

**Methods:** In the present study we examine the effects of HCQ in ApoE-/- mice with CKD. Males 6-8 weeks old ApoE-/- mice(C57BL/6 background) were grouped by 2 x 2 design into those with and without CKD, and those who received HCQ or placebo. CKD state was created by a two-step surgical technique. All mice remained on a high-fat diet for next 16 weeks and uremia was confirmed by serial lab values. Atherosclerosis was assessed through premortem(serial intravital ultrasound echography-IUE & cytokine studies), as well as postmortem studies(pathological-en face staining with Sudan IV of whole aorta and Oil Red O staining of aortic bulb; & immunohistochemical studies).

**Results:** In CKD model, HCQ reduced the progression of atherosclerosis and better preserved the vascular compliance for the aorta(0.37±0.01 Vs 0.29±0.01, $p<0.05$) and major vessels on serial IUE. Histopathological studies at the end of 16 weeks of therapy showed a significant reduction in the area of atherosclerosis(*en face* staining of whole aorta; treatment mice (34.1±3.1%), placebo (48.5±3.1%,$p<0.0001$) as well as the severity of atherosclerosis(Oil Red O examination).



Similar results were seen in non-CKD mice.

**Conclusions:** We conclude that HCQ reduces the extent & severity of atherosclerosis in CKD state & provide evidence for a novel approach toward the therapy of CKD-associated CVD. Additionally, detailed analysis of our data show the importance of nontraditional risk factors in the management of CVD, which may be important even in general population.

## FR-OR009

### Childhood Chronic Kidney Disease (CKD) Impairs Normal Vasoprotective Functions of High Density Lipoprotein (HDL)

Ryohei Kaseda, Kathy L. Jabs, Tracy E. Hunley, Deborah P. Jones, Valentina Kon. *Vanderbilt Univ.*

**Background:** HDL's beneficial effects encompass not only reverse cholesterol transport relevant to atherosclerosis but also modulation of inflammatory cells and protection of the endothelium relevant to vasculopathy. Since early intervention can impact CKD complications later in life, we evaluated if different degrees of CKD occurring in childhood disrupt these newly appreciated vasoprotective functions of HDL.

**Methods:** Inflammatory and chemotactic effects were assessed in THP-1 cells exposed to HDL isolated from children with end stage renal damage on peritoneal dialysis (ESRD-PD, n=14), CKD (stage III-IV, n=15) and normal kidney function (Control, n=7). Cytokine response of LPS-activated THP-1 cells ± HDL was assessed by mRNA expression of inflammatory markers. Chemotaxis of THP-1 cells to monocyte chemoattractant protein-1 (MCP-1) was assessed in a transwell chamber. THP-1 cells labeled calcein adhesion to HUVEC was assessed by fluorescence and microscopy.

**Results:** HDL of CKD and ESRD-PD heightened the inflammatory cytokine response: TNF-α: Control:0.47±0.04, CKD:1.03±0.08*, ESRD-PD:0.76±0.08*; MCP-1: Control:0.85±0.05, CKD:2.12±0.15*, ESRD-PD:1.70±0.19*; IL-1β: Control:1.41±0.20, CKD:2.60±0.24*, ESRD-PD:2.31±0.36#, (*P<0.01 and #P<0.05 vs Control). Control HDL reduced chemotaxis of THP-1 while HDL from CKD and ESRD-PD had no beneficial effect (ratio compared to medium: MCP-1:2.0±0.2, Control:0.9±0.2, CKD:1.9±0.2*, ESRD-PD:1.7±0.3#). HDL of CKD and ESRD-PD has reduced ability to protect HUVEC against macrophage adhesion (%decrease: Control:-7.9±2.3, CKD:-1.3±1.2*, ESRD-PD:-0.7±1.6*).

**Conclusions:** Even in the absence of long-standing concomitant diseases/risk factors prevalent in adults such as diabetes, obesity and smoking, children with CKD have HDL that dramatically increases the inflammatory and chemotactic response of macrophages while impairing its endothelial protective ability. The impairment is evident even pre-dialysis, in children with moderate CKD. The results indicate that CKD per se causes dysfunctional HDL. Dysfunctional HDL is thus an early therapeutic target that may forestall subsequent vascular complication of CKD.

## FR-OR010

### Podocyte B7-1 Inhibition as a Therapeutic Strategy for Diabetic Nephropathy

Roberto Bassi,[1] Andrea Vergani,[1] Monika A. Niewczas,[2] Marcus G. Pezzolesi,[2] Melissa Chin,[1] Maria Pia Rastaldi,[3] Jochen Reiser,[4] Andrzej S. Krolewski,[2] Peter H. Mundel,[5] Mohamed H. Sayegh,[1] Paolo Fiorina.[1] *[1]Boston Children's Hospital; [2]Joslin Diabetes Center, Boston; [3]Ospedale Maggiore Policlinico, Milan, Italy; [4]Rush Univ, Chicago; [5]Massachusetts General Hospital, Charlestown.*

**Background:** Glomerular podocytes, damaged during diabetic nephropathy (DN) progression, may express B7-1 under stress. We hypothesize that B7-1 upregulation leads to podocyte alteration and that B7.1-targeting (CTLA4-Ig) may protect podocytes from high glucose-mediated injuries.

**Methods:** Kidney biopsies were obtained from individuals with T2DN (n=30). 173 T2DN cases were screened for B7-1 single-nucleotide polymorphisms (SNPs). Epidemiologic studies were performed on the Joslin Clinic cohort of T2D and soluble (s) CD28 (B7-1 ligand) was measured by Platinum ELISA. Podocytes were cultured at 10mM (normal glucose) and 30 mM (high glucose) for 7, 14 days and treated with CTLA4-Ig at 100 μg/ml. Mice were treated with CTLA4-Ig using 500 μg at day 0 and 250 μg at day 2, 4, 6, 8, 10; 250 μg twice a week thereafter.

**Results:** Kidney biopsies from T2D patients showed glomerular B7-1 upregulation compared to controls. Two SNPs at the *B7-1* gene were associated with progression to end stage renal disease (ESRD; OR=1.56, p=0.008) and sCD28 serum baseline levels predicted ESRD progression in T2D patients. B7-1 was upregulated *in vitro* in murine podocytes when cultured in high-glucose and *in vivo* on glomerular podocytes of diabetic db/db and streptozotocined (STZ)-C57BL/6 mice. Pharmacological targeting of B7-1 with CTLA4-Ig, protected podocytes *in vitro* from high glucose-induced damage (deregulation of podocyte-specific cytoskeleton proteins) and CTLA4-Ig treatment of db/db and STZ-C57BL/6 mice was able to prevent urinary albumin excretion rise (UAE; db/db, STZ-C57Bl/6: untreated 7wks vs. 25wks; p<0.01, p<0.0001; CTLA4-Ig-treated 7wks vs. 25wks; p=ns) and glomerular alterations such as mesangial expansion and collagen I deposition.

**Conclusions:** Targeting B7-1 with CTLA4-Ig (clinically available as Abatacept) is a novel therapeutic strategy for diabetic nephropathy.

## FR-OR011

### A Randomized, Double-Blind, Placebo Controlled Trial of FG-4592 for Correction of Anemia in Subjects with Chronic Kidney Disease in China

Jia Qi Qian,[1] Nan Chen,[2] Jianghua Chen,[3] Chuanming Hao,[4] Hong Li Lin,[5] Dalvin Ni,[6] Cameron S. Liu,[6] Thomas B. Neff,[6] Kin-Hung Peony Yu,[6] Frank H. Valone.[6] *[1]Renji Hosp., Shanghai; [2]Ruijin Hosp., Jiaotong Univ, Shanghai; [3]Zhejiang Univ, Hangzhou; [4]Huashan Hosp., Shanghai; [5]Dalian Med. Univ, Dalian; [6]FibroGen, Inc., San Francisco, CA.*

**Background:** FG-4592 is an oral inhibitor of hypoxia-inducible factor degradation being developed for treatment of anemia. This Phase 2b study tested the efficacy and safety of FG-4592 in anemic chronic kidney disease (CKD) subjects.

**Methods:** CKD subjects not on dialysis with hemoglobin (Hb) <10 g/dL were randomized 1:1:1 to FG-4592 low or high dose or placebo orally 3 times a week (wk) for 8 wks. The primary efficacy endpoint was maximum change of Hb ($\Delta Hb_{max}$) from baseline (BL) by Wk 9.

**Results:** 91 subjects enrolled, 90 completed 8 wks dosing; 88 were evaluable for efficacy. BL characteristics for FG-4592 and placebo groups are comparable. In FG-4592-treated subjects, Hb increased from BL in a dose-related fashion. The proportion of Hb responders (ΔHb >1 g/dL from BL) and subjects achieving Hb ≥11.0 g/dL was significantly higher in FG-4592 vs placebo subjects (Table). Significant decreases in total and low-density lipoprotein cholesterol (ΔTC & ΔLDL-C) occurred in FG-4592 subjects. The incidences of treatment emergent adverse events (AEs) and serious AEs (SAEs) were nearly identical for FG-4592-treated and placebo subjects. AEs were generally mild or moderate and typical for CKD patients.

| Cohort | 1 | 2 | FG-4592 | Placebo |
|---|---|---|---|---|
| N | 30 | 31 | 61 | 30 |
| Mean (SD) dose, mg/kg/Wk | 4.16 (0.52) | 5.03 (0.67) | 4.60 (0.74) | - |
| BL Hb, g/dL | 8.82 | 8.84 | 8.83 | 8.93 |
| Hb @9 wks, g/dL | 10.74# | 11.38# | 11.07# | 9.4 |
| $\Delta Hb_{max}$, g/dL | 1.75# | 2.69# | 2.22# | 0.57 |
| Hb responders (%) | 24 (80)# | 27 (93.1)# | 51 (86.4)# | 7 (24.2) |
| Subjects with Wk 9 Hb ≥11.0 g/dL (%) | 15 (50)^ | 22 (75.9)# | 37 (62.7)# | 2 (6.9) |
| ΔTC, mg/dL (%) | -32 [-19.7]# | -35 [-17.5]# | -33.9 [-18.5]# | +8 (+5.5) |
| ΔLDL-Cmg/dL, (%) | -23.7[-23.2]# | -32[-23.2]# | -27.9[ -23.2]# | +4 |
| Subjects w/ AEs (%) | 17 (56.7) | 19 (61.3) | 36 (59.0) | 19 (63.3) |
| Subjects w/ SAEs (%) | 4 (13.3) | 5 (16.1) | 9 (14.8) | 4 (13.3) |
| Subjects w/ cardiovascular SAE (%) | 0 | 0 | 0 | 1 (3.3) |

^p<0.01, #p < 0.0001

**Conclusions:** This study suggests that FG-4592 effectively corrects CKD anemia and is well-tolerated in CKD patients. FG-4592 may also lower cholesterol. P3 trials of FG-4592 in CKD patients are underway.

## FR-OR012

### Association between Sleep Quality and Cardiovascular Damage in Pre-Dialiysis Patients with Chronic Kidney Disease

Jun Zhang.[1] *[1]Div of Nephrology, Dept of Medicine, 3rd Hospital of Sun Yat-sen Univ, China.*

**Background:** Poor sleep quality, a novel risk factor of cardiovascular diseases (CVD), is highly prevalent in patients with chronic kidney disease (CKD). However, the association between poor sleep quality and cardiovascular damage is unclear. This study aimed to determine the relationship between sleep quality and cardiovascular damage and assess the prevalence and related risk factors of sleep disturbance among in Chinese patients with pre-dialysis CKD.

**Methods:** A total of 427 pre-dialysis CKD patients (mean age = 39±15 years, 260 male/167 female) were recruited in this study. Demographics and clinical correlates, including BMI and eGFR etc, were collected. The sleep quality was measured by Pittsburgh Sleep Quality Index (PSQI), while cardiovascular damage indicators (E/A ratio and left ventricular mass index (LVMI)) were determined by echocardiographic examination.

**Results:** 77.8% of the CKD patients were poor sleeper as defined by a PSQI score > 5. Logistic regression analysis revealed that left ventricular hypertrophy (LVH) were independently associated with PSQI score (OR = 1.092, 95% CI = 1.011-1.179, p=0.025), after adjustment for age, sex, and clinic systolic blood pressure, diastolic blood pressure, P, iPTH, HGB, eGFR. Linear regression analysis showed that E/A ratio were independently associated with PSQI score (β=-0.118, P=0.014) after adjusted for a series of potential confounding factors.

**Conclusions:** Poor sleep quality, which is commonly found in pre-dialysis CKD patients, is an independent correlated factor of cardiovascular damage in CKD patients. Our finding implies that the association between poor sleep and CVD might be mediated by cardiac remodeling and improvement of sleep quality might reverse this abnormality and subsequent CVD event.

**FR-OR013**

**A Systematic Exploration of Individual Haemodialysis Patient Prefrences for Treatment Outcome: Symptoms or Survival** Zoe C.L. Pittman,[1] Chris W. McIntyre.[1,2] *[1]Royal Derby Hospital, United Kingdom; [2]Univ of Nottingham, United Kingdom.*

**Background:** In many chronic diseases, patients treatment outcome preferences vary between symptom control and survival. This has not been formerly investigated in kidney disease. We therefore aimed to systematically explore haemodialysis (HD) patients' outcome preferences, utilising established methodology to compare and quantify the subconscious trade off in decision making.

**Methods:** Prevalent HD patients completed a full profile conjoint analysis outcome preference data set comprising 25 proposed treatment outcome profiles each scored for overall acceptability. All profiles contained the same 6 attributes (pain, tiredness, breathlessness, depression, survival and treatment burden (TB)), variable across 4 levels of severity. Standard conjoint analysis techniques were used to derive part worths (utilities) and importance weights for each attribute, allowing the relative contribution of each attribute to be determined per individual. Additional demographic data were collected.

**Results:** 22 patients were studied, mean age 63±15 years, 59% male, 52% diabetic. Overall importance weights (%) were higher for survival (20.6), pain (20.3) and breathlessness (18.2), than for tiredness (14.4), depression (13.7) or TB (12.8). Pain ranked 1st or 2nd in 15/22, survival 8, breathlessness 6, tiredness 5, depression 4, and TB 3. Reverse utility scores (indicating little or no influence over the decision), occurred for TB (9), depression (5), pain (3), survival (2) and breathlessness (2) but not for tiredness. There was clear separation in preference patterns between aversion to worsening symptoms with indifference to survival and/or indifference to increased TB compared to those patients that had a predominant preference for survival.

**Conclusions:** There are a variety of different outcome preferences in this cohort however the majority of patients showed a preference for symptom control, as opposed to survival, and were able to consider increased treatment burden in order to achieve this. Understanding of individual patient preferences for treatment outcome may allow a more informed discussion about changes to therapy, including potential for increased uptake of more intensive therapy.

**FR-OR014**

**Cross-Sectional Study of Hyponatremia Associated with Prescribed Medications in Chronic Kidney Disease** Diana Chiu, Darren Green, Smeeta Sinha, Philip A. Kalra. *Salford Vascular Research Group, Univ of Manchester, United Kingdom.*

**Background:** Medications prescribed to patients with Chronic Kidney Disease(CKD) may contribute to hyponatremia.We sought to explore which prescribed medication is most frequently associated with hyponatremia in this setting.

**Methods:** Cross-sectional baseline analysis of hyponatremia(<135mmol/l) and concomitant medication of patients enrolled in the Chronic Renal Insufficiency Standards Implementation Study(CRISIS),a prospective observational outcome study in all-cause CKD stages 3-5,managed in secondary care,was undertaken.We examined the association of drugs known to cause hyponatremia in a multivariate logistic regression(LR)adjusting for diabetes,eGFR,history of heart failure and liver disease.

**Results:** From 2093 patients,63% male,32% diabetic and mean eGFR was 33±16ml/min/1.72m$^2$.Mean sodium was 140±3mmol/l and 4.6% had hyponatremia(mean sodium was 132±2mmol/l,range 125-134mmol/l).Diuretics were associated with hyponatremia(OR 1.56,P=0.04),but when separated into loop(OR 1.20,P=0.40),thiazide(OR 1.31,P=0.36) and potassium sparing diuretics(spironolactone and amiloride),only the latter were statistically significant(OR 3.67,P<0.01).Proton pump inhibitors and Angiotensin receptor blockers were associated with hyponatremia whilst ACE inhibitors were not (OR 0.77, P=0.22). Significant predictors in the final LR model, are shown in the table.

| Medication | No. on medication | Odds Ratio | 95% CI | P value |
|---|---|---|---|---|
| Potassium sparing diuretic | 88 | 3.67 | 1.92-7.08 | <0.01 |
| Proton pump inhibitor | 538 | 1.67 | 1.08-2.56 | 0.02 |
| Angiotensin receptor blocker(ARB) | 550 | 1.72 | 1.11-2.65 | 0.01 |

Loop diuretics,thiazides,SSRIs,tricyclics,ACE inhibitors,sulphonylurea,sodium valproate and lamotrigine,benzodiazepines and thiazolidinediones were not statistically significant in the final model.

**Conclusions:** Potassium sparing diuretics,proton pump inhibitors and ARBs have important associations with hyponatremia in CKD.It is well known that spironolactone,amiloride and ARBs are associated with hyperkalemia,but their association with hyponatremia should not be ignored.The validity and nature of these relationships needs to be explored further.

**FR-OR015**

**Proteomic Analysis of the Plasma in Chronic Kidney Disease Related with Cardiovascular Disease** Maria Wanic-Kossowska,[3] Magdalena Luczak,[1] Dorota Formanowicz,[2] Elzbieta Pawliczak,[3] Lidia Koziol.[3] *[1]Institute of Bioorganic Chemistry, Polish Academy of Sciences, Poznan, Poland; [2]Dept of Clinical Biochemistry, Poznan Univ of Medical Sciences; [3]Dept of Nephrology, Transplantology and Internal Medicine, Poznan Univ of Medical Sciences.*

**Background:** Atherosclerosis is the most serious complications in chronic kidney disease (CKD) and the risk of cardiovascular events increase with degree of reduced renal function. However, molecular mechanisms that enhance the formation of plaque in CKD patients are still unclear. The major goal of this study was global analysis of plasma proteome to better understanding of molecular mechanisms of relation between cardiovascular disease (CVD) and chronic kidney disease (CKD).

**Methods:** We used 2DE and MS methods to study changes in the profiles of plasma protein accumulation during development of CKD. Study involved healthy volunteers and four group of patients: patients in stage 1-2CKD; 3-4CKD and 5CKD and patients with classical CVD with unstable coronary artery disease and after myocardial infarction, but without clinical signs of renal dysfunction. We analyzed three different plasma protein sets: high-abundant, low-abundant proteins and also low molecular proteins (?5kDa) to find differentially expressed proteins. The proteins were identified by MALDI/TOF-TOF mass spectrometry. Differentially expressed proteins were confirmed by selected reaction monitoring (SRM) analysis.

**Results:** Identified 13 proteins were used to analyze the functional interactions of all identified differential proteins. Created on this basis network revealed that at least three functional nodes are related with CKD and CVD: blood coagulation cascade, metabolism of lipoproteins and inflammatory processes.

**Conclusions:** Differential concentration of identified proteins in CKD and CVD indicate that different molecular mechanisms are involved in the development of CKD- and CVD-related atherosclerosis. These results suggest that CKDA is highly accelerated by the inflammatory processes compare to classical CVD which seems to be more affected by defects in cholesterol transport or metabolism.

**FR-OR016**

**Effects of Resistance Exercise on Akt Signalling and Protein Degradation in Chronic Kidney Disease** Emma Watson, Neil J. Greening, Nichakarn Ruttanaporn, Jonathan Barratt, Alice C. Smith. *Leicester Kidney Exercise Team, Univ of Leicester, United Kingdom.*

**Background:** Resistance exercise (RE) is anabolic in healthy individuals but its potential to overcome muscle wasting in Chronic Kidney Disease (CKD) has not been well studied. Akt is an important regulator of cellular survival via promotion of protein synthesis and inhibition of protein breakdown. In health, skeletal muscle Akt phosphorylation and protein synthesis are upregulated for 48 hours after RE. MAFbx and MuRF-1 are E3 ligases playing a key role in the regulation of muscle protein degradation. This study investigated molecular responses to RE in pre-dialysis CKD.

**Methods:** 18 patients CKD3b-4 (mean eGFR 23, range 16-36ml/min/1.73m$^2$; mean age 63, range 45-77years) were randomised to RE (3 sets 10-12 leg extensions at 70% maximum, 3/week for 8 weeks;n=11), or control (usual activity;n=7). Quadriceps cross-sectional area (CSA) was measured by ultrasonography at baseline (BL) and 8 weeks. Muscle biopsies were obtained at BL and 8 weeks in controls, and BL, 24h post first training session (PRE-RT) and 24h post final training session (POST-RT) in exercisers. Akt phosphorylation, MAFbx and MuRF-1 mRNA expression were analysed by Western blotting and RT-PCR.

**Results:** No changes were seen in the controls. In exercisers, 8 weeks RE significantly increased quadriceps CSA (P=0.001). After the first RE session, the normal Akt phosphorylation response failed to occur. In contrast, the expected increase was seen after the final RE session (BLvsPOST-RT P=0.04). Of the protein breakdown regulators, MuRF-1 initially increased in response to RT (BLvsPRE-RT P=0.02). However, after 8 weeks of RE, MAFbx fell below BL (BLvsPOST-RT P=0.004).

**Conclusions:** This study reveals a previously unknown failure of RE-stimulated Akt phosphorylation in CKD, which may be a novel contributor to muscle wasting. However, eight weeks RE restored Akt signalling, suppressed mRNA expression of E3 ligases MAFbx and MuRF-1, resulting in significant muscle hypertrophy. These results demonstrate that RE is effective in modifying molecular abnormalities in skeletal muscle in CKD and can overcome muscle wasting, which has important clinical implications in this population.

**FR-OR017**

**Increased Urine SEMAPHORIN 3A Is Associated with Renal Damage in Hypertensive and Diabetic Patients with Chronic Kidney Disease** Ganesan Ramesh,[2] Calpurnia Jayakumar,[2] Francesca Viazzi,[1] Giovanna Leoncini,[1] Debora Garneri,[1] Roberto Pontremoli.[1] *[1]Medicine, Univ of Genoa, Italy; [2]Vascular Biology Center, Georgia Regents Univ, Augusta, GA.*

**Background:** Semaphorins are guidance proteins that influence cellular morphology and function, and have been implicated in several pathophysiological processes such as angiogenesis, organogenesis, tumourogenesis, cell migration, cytokine release and immune modulation. Semaphorin3a (SEMA3A) administration in animals induces acute and transient massive proteinuria through distruption of podocyte foot process. However,its role in human disease has not been investigated so far.

**Methods:** To determine the role of sema3A in CKD, we performed a cross-sectional, nested, case-control study on a group of 151 age, gender, and body mass index (BMI) matched hypertensive patients with and without chronic kidney disease (CKD) or diabetes mellitus. SEMA3A was quantified in the urine by ELISA. CKD and its components, i.e., estimated glomerular filtration rate (eGFR) and albuminuria were measured by CKD EPI formula and albumin creatinine ratio (ACR), respectively. Data are expressed as mean ± SD. Statistical analysis was done using Statview for Windows.

**Results:** USEMA3A levels were positively correlated with urine albumin creatinine ratio (UACR) (P= 0.0038) and serum creatinine (P= 0.0013). USEMA 3A was significantly higher in patients with both components of renal damage as compared to those with only one and those with normal renal function (P<0.008 and <0.0001, respectively). In a logistic multiple regression analysis the presence of increased urine SEMA3A levels (i.e. top quartile) entailed a 14 fold (OR 95% CI 3.2-63, P <0.0005) higher risk of combined renal damage and at least a 5 fold higher risk of macroalbuminuria or of reduced eGFR even taking into consideration potential confounding factors such as serum uric acid (P<0.0079 and 0.0034, respectively).

**Conclusions:** This study demonstrates that USEMA 3A is significantly associated with renal damage both in diabetic and non diabetic hypertensive patients. USEMA 3A levels appear to be a marker of renal dysfunction, independent of eGFR, albuminuria and serum uric acid.

## FR-OR018

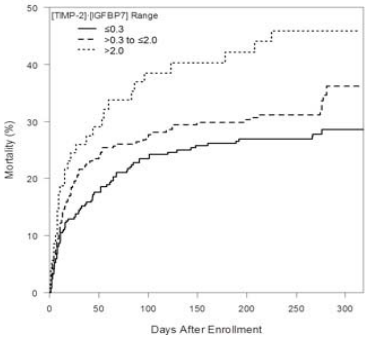
### Increased TIMP2•IGFBP7 Is Associated with Increased 9 Month Mortality in ICU Patients at Risk for AKI

Jay L. Koyner, Andrew Shaw, Lakhmir S. Chawla, Eric Hoste, Azra Bihorac, Kianoush Banaei-Kashani, Jing Shi, John A. Kellum. *On behalf of All Astute Medical Sapphire Investigators.*

**Background:** We recently reported a 728 patient multicenter study (Sapphire) where Insulin-like growth factor-binding protein 7 (IGFBP7) and tissue inhibitor of metalloproteinases-2 (TIMP-2), were validated for risk stratification for moderate to severe Acute Kidney Injury (AKI, KDIGO stages 2 and 3).

**Methods:** We prospectively selected 2 clinical cutoffs for the TIMP2•IGFBP7 panel from the Sapphire dataset, one (0.3) with high sensitivity, 89% (specificity=50%) and one (2.0) with high specificity, 95%, (sensitivity 42%) for the development of KDIGO 2/3 within 12 hours of study enrollment. We then compared 9-month all cause mortality stratified by these cutoffs using a log rank test. A Cox proportional hazards model was used in which both TIMP2•IGFBP7 and serum creatinine were included as continuous variables.

**Results:** Baseline TIMP2•IGFBP7 results were available for 715 patients. KDIGO 2/3 occurred in 9 of 342 (2.6%) patients in the ≤ 0.3 cohort; 31 of 302 (10%) patients in the 0.3-2.0 cohort and 28 of 71 (39%) patients in the >2.0 cohort. Nine months following study enrollment 208 patients (29% of total) had died.



Nine-month mortality was significantly increased as TIMP2•IGFBP7 increased across the 3 strata (p=0.013). In the Cox model after adjusting for baseline creatinine, TIMP2•IGFBP7 remained significantly associated with 9 month mortality (p=0.018). Similarly, the >2.0 cohort had an increased risk of mortality compared to the ≤0.3 cohort, with a hazard ratio (95% CI) of 1.84(1.21-2.78), p=0.004. This risk was only slightly attenuated after adjusting for serum creatinine, HR=1.68(1.10-2.58), p=0.017.

**Conclusions:** We conclude that the TIMP2•IGFBP7 biomarker combination stratifies AKI severity and identifies patients with increased risk of mortality over the next 9 months.

## FR-OR019

### Renal Angina in the Pediatric Intensive Care Unit: The CHERUB Prospective Study

Shina Menon, Stuart Goldstein, Rajit K. Basu. *Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

**Background:** Delay in recognition of acute kidney injury(AKI) and inability to predict severe AKI delays institution of optimal therapy. We previously showed that fulfillment of renal angina(ANG) by renal angina index(RAI), a composite of AKI risk and early signs of injury, stratifies patients (pts) at risk for persistent AKI. In our multi-center retrospective study, RAI>8 (ANG+) in first 24 hours of pediatric intensive care unit(PICU) admission showed greater precision to identify pts with severe persistent AKI(doubling of serum creatinine) 3 days after assessment (Day3-AKI) than risk factors or signs of injury alone. We aimed to determine if fulfillment of ANG on PICU admission had greater predictive precision for Day 3–AKI than absence of ANG in this study of AKI in critically ill CHildren Evaluated by Renal angina and Urinary Biomarkers(CHERUB).

**Methods:** ANG was assessed in pts admitted to the PICU. 'Day0' was defined as the first 8 hours for admission after 12 pm or first 24 hours for admission prior to 12pm. RAI was calculated as previously described. Our primary outcome was Day 3–AKI.

**Results:** 94 pts(age 8.8+7 yrs) were enrolled from Sept 2012 to May 2013. 36 pts(38%) were ANG+ on Day 0.The incidence of Day 3-AKI was 30%. Day 3-AKI was higher for ANG+ pts and the area under the curve(AUC-ROC) for Day 3-AKI was 0.75(0.64-0.85). Negative predictive value for ANG+ was 80%(69-89). ANG+ pts had higher morbidity and mortality than ANG-.

| | ANG-(n=58) | ANG+(n=36) | p |
|---|---|---|---|
| Day 3-AKI | 12 (20%) | 16 (44%) | 0.01 |
| +LR for Day3-AKI | 0.51(0.29-0.87) | 1.89(1.16-3.07) | |
| -LR for no Day3-AKI | 2.21(1.38-3.54) | 0.61(0.39-0.97) | |
| ICU LOS | 8.2+6.6 | 10.2+9.8 | 0.07 |
| Organ Failure Days | 3.7+4.2 | 6.2+6.1 | 0.03 |
| RRT provision | 2(3%) | 6(17%) | 0.03 |
| ICU mortality | 1(2%) | 7(21%) | 0.001 |

**Conclusions:** In our initial analysis of the first prospective CHERUB study, ANG+ discrimination for subsequent severe AKI was superior to ANG-. Given a high negative predictive value of ANG for not progressing to severe persistent AKI, we suggest using ANG as a clinical adjunct to target biomarker testing. We plan to enroll more patients and incorporate biomarkers to validate our results and determine if biomarkers add to the prediction of AKI.

## FR-OR020

### Insulin-Like Growth Factor-Binding Protein 7, and Tissue Inhibitor of Metalloproteinases-2 Are Significantly Associated with 18 Month Decline in eGFR

Kianoush Banaei-Kashani,[1] John A. Kellum.[2] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Critical Care Medicine, Univ of Pittsburgh, School of Medicine, Pittsburgh, PA.*

**Background:** We recently reported Insulin-like growth factor-binding protein 7 (IGFBP7) and tissue inhibitor of metalloproteinases-2 (TIMP-2) as validated markers for risk stratification for moderate to severe Acute Kidney Injury. We now report the 18-month follow up outcomes of the Mayo Clinic discovery cohort.

**Methods:** We enrolled 285 critically ill patients without known AKI and followed this cohort for 18 months for mortality and eGFR. Enrollment TIMP2•IGFBP7 was measured by immunoassay and was analyzed with respect to outcomes in a Cox proportional hazards model.

**Results:** In this cohort of 285 patients 162 (57%) were male, 267 (94%) were Caucasian and median age was 66 years (IQR 56-76). Incidence of moderate to severe AKI (RIFLE I-F) was 53 (19%) and 6 (2%), respectively. Eighty (28%) patients died within 18 months and 105 patients had at least one follow-up serum creatinine value measured between 3 and 18 months after enrollment. Of these patients with follow-up creatinine, 23 (22%) had at least a 25% drop in eGFR compared with baseline. Hazard ratio (HR) for incurring a 25% or greater decline in eGFR for the patients who had at least one serum creatinine measured more than three months after enrollment was significant with (HR, 2.52; 95% CI, 1.1-5.75, p 0.03) or without (HR, 2.49; 95% CI, 1.17-5.34, p=0.018) adjustment for enrollment sCr for each unit increment in the enrollment TIMP2•IGFBP7. HR for mortality was in the same direction but did not reach significance with (HR, 1.44; 95% CI 0.97-2.11, p 0.067) or without (HR, 1.42; 95% CI 0.97-2.08, p=0.074) adjustment for enrollment sCr.

**Conclusions:** TIMP2•IGFBP7 predicts worsening of renal function in 18 month follow up. These results show that TIMP2•IGFBP7 provides valuable information about kidney status in acutely ill hospitalized patients that is relevant to long-term health outcomes.

*Funding:* Pharmaceutical Company Support - Astute medical Inc.

## FR-OR021

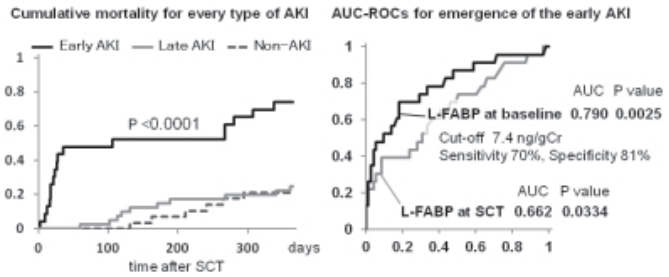
### Acute Kidney Injury prior to the Stem-Cell Engraftment Is a Harbinger of Short-Term Mortality in Hematopoietic Stem Cell Transplantation

Taku Morito,[1,2] Minoru Ando,[1,2] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Renal Div, Dept of Medicine, Tokyo Metropolitan Cancer Center, Komagome Hospital, Bunkyo-ku, Tokyo, Japan; [2]Dept IV of Internal Medicine, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan.*

**Background:** AKI that occurs before the stem-cell engraftment may be fatal in allogeneic hematopoietic stem cell transplantation (SCT). Prediction of such AKI may contribute to the improvement of prognosis in SCT recipients.

**Methods:** One-year prospective cohort study was conducted in 94 allogeneic SCT recipients, who had normal kidney function at baseline. Urinary Liver-type fatty acid binding protein (L-FABP) level was measured as a marker of tubular damage before conditioning therapy (baseline), and at days 0 (the morning of SCT). The "AKI prior to the stem-cell engraftment" was defined as the "early AKI" and the subsequently-occurred AKI was as the "late AKI". Cumulative mortality was analyzed by the Kaplan–Meier method. Discriminative ability of L-FABP for emergence of the early AKI was evaluated using AUC-ROC. Multivariate Cox hazards analysis was used to ascertain an association between the "early AKI" and the mortality.

**Results:** The early and late AKI developed in 23 patients (24.5%) and 41 patients (43.6%), respectively. The cumulative mortality of patients with the early AKI was the highest among the 3 groups: 73.9% in the early AKI; 24.7% in the late AKI; and 21.2% in the non-AKI. The emergence of the early AKI was the significant risk for the 1-year mortality (HR 4.02; 95% CI 1.50–12.0; P = 0.0051). The urinary L-FABP level at baseline had good discriminative ability for the early AKI.



**Conclusions:** The early AKI emerges in one-quarter of allogeneic SCT recipients, which has the significant impact on their short-term mortality. Potentially-existing tubular damage, which is identified by urinary L-FABP concentration, may be involved in the emergence of the early AKI.

## FR-OR022

**Development and Standardization of a Furosemide Stress Test to Predict the Severity of Acute Kidney Injury** Ermira Brasha-Mitchell,[1] Danielle Davison,[1] Jay L. Koyner,[2] Andrew Shaw,[3] John M. Arthur,[4] Divya M. Chalikonda,[1] Sharon A. Trevino,[2] Paul L. Kimmel,[5] James A. Tumlin,[6] Michael Seneff,[1] Lakhmir S. Chawla.[1] *[1]George Washington Univ; [2]Univ of Chicago; [3]Duke Univ; [4]Medical Univ of South Carolina; [5]NIH; [6]Univ of Chattanooga.*

**Background:** In the setting of early acute kidney injury (AKI), no test has been shown to definitively predict the progression to more severe stages.

**Methods:** We investigated the ability of a furosemide stress test (FST) (one-time dose of 1.0 or 1.5 mg/kg depending on prior furosemide-exposure) to predict the development of AKIN Stage-III in 2 cohorts of critically ill subjects with early AKI. Cohort 1 was a retrospective cohort who received a FST in the setting of AKI in critically ill subjecs as part of Southern AKI Network. Cohort 2 was a prospective multicenter group of critically ill patients who received the FST in the setting of early AKI.

**Results:** We studied 77 subjects; 23 from cohort 1 and 54 from cohort 2; 25 (32.4%) met the primary endpoint of progression to AKIN-III. Subjects with progressive AKI had significantly lower urine output following FST in each of the first 6 hours (p<0.001). The area under the receiver operator characteristic curves for the total urine output over the first 2 hours following FST to predict progression to AKIN-III was 0.87 (p=0.001). The ideal-cutoff for predicting AKI progression during the first 2 hours following FST was a urine volume of less than 200mls(100ml/hr) with a sensitivity of 87.1% and specificity 84.1%. Furosemide Stress Test Effect on Urine Flow:

| | Combined | Non-Progressors | Progressed to AKIN III | p |
|---|---|---|---|---|
| | *n=77* | *n=52* | *n=25* | |
| **Hour 1 (ml)** | 251(35.2) | 329(46.0) | 89(33.0) | .001 |
| **Hour 2 (ml)** | 296(35.8) | 392(42.2) | 96(46.6) | .001 |
| **Hour 3 (ml)** | 246(26.6) | 311(31.7) | 109(35.4) | .001 |
| **Hour 4 (ml)** | 207(24.1) | 265(31.1) | 88(23.4) | .001 |
| **Hour 5 (ml)** | 175(18.6) | 219(22.8) | 83(23.7) | .001 |
| **Hour 6 (ml)** | 155(17.4) | 194(22.3) | 75(17.4) | .001 |

**Conclusions:** The FST in subjects with early AKI serves as a novel assessment of tubular function with robust predictive capacity to identify patients with severe and progressive AKI. Future studies to validate these findings are warranted.

*Funding:* NIDDK Support

## FR-OR023

**Plasma Kidney Injury Molecule-1 Is a Sensitive and Specific Biomarker of Kidney Proximal Tubule Injury** Venkata Sabbisetti,[1] Sushrut S. Waikar,[1] Daniel J. Antoine,[2] Joseph V. Bonventre.[1] *[1]Dept of Medicine, Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston; [2]Dept of Molecular & Clinical Pharmacology, Univ of Liverpool, Liverpool, United Kingdom.*

**Background:** Kidney Injury Molecule-1 (KIM-1) is highly upregulated in dedifferentiated proximal tubular cells following kidney injury. The ectodomain of KIM-1 is shed and serves as a urinary biomarker of kidney injury. We report that shed KIM-1 is also leaked into the systemic circulation and serves as a sensitive and specific plasma biomarker of kidney proximal tubule injury.

**Methods:** Human and rodent plasma KIM-1 assays were developed. Mice were subjected to I/R injury for 10, 20, & 30 min and urine, plasma, and tissue specimens were collected for 14 days. Rats were given saline, 50, or 200 mg/kg of gentamicin i.p daily for 10 days. In humans, KIM-1 and creatinine were evaluated in spot urine and corresponding plasma samples from healthy control (HC), patients undergoing cardiac surgery with cardiopulmonary bypass (CPB), and patients admitted to the surgical ICU. To determine the time course of biomarker changes in prospective studies, plasma and urine samples were collected prior to surgery, at the end of CPB, then at 4h, 12h and then daily for 5 days after CPB. Urine and plasma samples were also collected from individuals with chronic kidney disease (CKD).

**Results:** In mice, plasma KIM-1 levels were elevated in a graded fashion with increasing periods of ischemia. In rats, plasma KIM-1 levels increased with gentamicin dose. In humans, plasma KIM-1 levels were higher in patients with acute kidney injury (AKI) than in HC or patients admitted to the ICU without AKI with AUC-ROC of 0.96. Plasma KIM-1 levels were elevated within 2 days (P = 0.008) after surgery in CPB in patients who developed AKI. Plasma KIM-1 levels were also elevated in patients with CKD and correlated positively with stage of CKD.

**Conclusions:** Plasma KIM-1 concentration is elevated in both acute and chronic kidney disease and serves as a novel plasma biomarker of kidney injury. To our knowledge, this is the first demonstration of a plasma biomarker with high specificity for kidney proximal tubule injury in rodents and humans.

## FR-OR024

**Effects of ABT-719 on Incidence of Acute Kidney Injury during Cardiac Surgery Procedures** Samina Khan,[1] Soren Nielsen,[2] Michael Beckert,[3] Mark T. Houser,[1] Deli Wang.[1] *[1]AbbVie; [2]Aarhus Univ, Denmark; [3]CaRACS, Germany.*

**Background:** Patients undergoing on-pump cardiac surgery are at increased risk for ischemia reperfusion (I/R)-induced acute kidney injury (AKI). ABT-719 is a novel melanocortin receptor agonist in development for prevention of I/R-induced AKI. We report here the proportion of patients developing postoperative AKI injury by surgical procedure.

**Methods:** In a double-blind study, patients undergoing on-pump cardiac surgery were randomized to placebo (PBO; n=26), ABT-719 given at either 600μg/kg (n=25), or 800μg/kg (n=26). Each dose was divided into 3 bolus infusions at fixed intervals. AKI was determined according to the AKIN and RIFLE scores.

**Results:** Baseline characteristics were: mean age, 71yrs; males, 64%; pre-existing kidney disease, 53%. Mean overall bypass duration was 2.3hrs and the majority of patients (53%) underwent combined CABG and valve surgery. ABT-719 (800μg/kg) reduced the incidence of AKI, compared with PBO, for the following surgery types: combined CABG and valve, multiple valve, and CABG with chronic kidney disease.

**Conclusions:** 800μg/kg dose of ABT-719 reduced the incidence of AKI in patients undergoing various cardiac surgeries compared to PBO. However, since the sample size of the study is limited, additional studies are in development to further evaluate ABT-719 in patients with a high risk of I/R-induced AKI.

**Table: % of patients with AKI based on AKIN and RIFLE scores with various cardiac surgery procedures**.

| Type of Surgery | PBO | PBO | ABT-719 (600 μg/kg) | ABT-719 (600 μg/kg) | ABT-719 (800 μg/kg) | ABT-719 (800 μg/kg) |
|---|---|---|---|---|---|---|
| | AKIN | RIFLE | AKIN | RIFLE | AKIN | RIFLE |

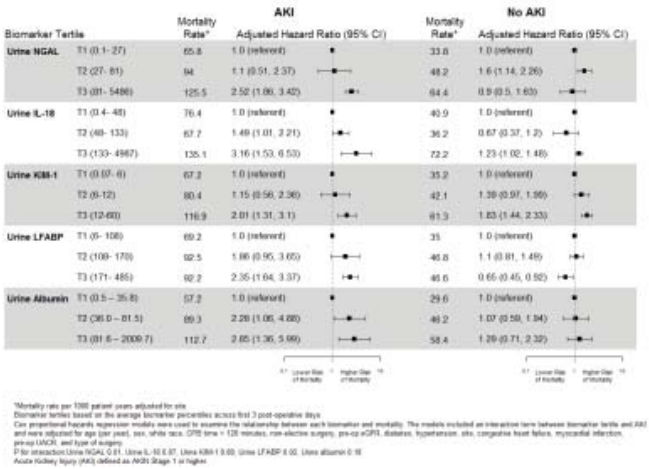
**Urinary Biomarkers of Acute Kidney Injury and Mortality 3-Years after Cardiac Surgery** Steven G. Coca, Amit X. Garg, Heather Thiessen Philbrook, Jay L. Koyner, Uptal D. Patel, Harlan M. Krumholz, Michael Shlipak, Chirag R. Parikh. *TRIBE-AKI Consortium.*

**Background:** The association between urinary biomarkers of acute kidney injury (AKI) and outcomes beyond hospital discharge is unknown.

**Methods:** 1199 patients that were discharged aliver after hospitalization for cardiac surgery in the TRIBE-AKI cohort study were followed prospectively for the occurence of death. The primary exposures were peak concentrations of five urinary biomarkers on post-operative days 1-3: neutrophil gelatinase-associated lipocalin (NGAL), interleukin(IL)-18, kidney injury molecule-1 (KIM-1), liver fatty acid binding protein (L-FABP), and albumin. Hazard ratios (HRs) of mortality according to tertiles of the five urinary biomarkers were adjusted for pre-operative clinical variables, cardiopulmonary bypass time, and change in serum creatinine from baseline.

**Results:** During a median follow-up of 3.0 years (IQR 2.2-3.6), 139 (11.6%) participants died (50 per 1000 person-years). Among patients with clinical AKI (serum creatinine change of 50% or 0.3 mg/dL), the upper tertiles of urinary NGAL, IL-18, KIM-1, L-FABP, and albumin were independently associated with a 2.0-3.1-fold higher risk for mortality compared with the lowest tertiles.



In patients without clinical AKI, the upper tertiles of IL-18 and KIM-1 were independently associated with long-term mortality and yielded a continuous net reclassification improvement of 26% and 37%, respectively, for the prediction of 3-year mortality.

**Conclusions:** Urinary biomarkers of kidney injury in the post-operative period provide additional prognostic information beyond that of changes in serum creatinine and clinical variables for risk of 3-year mortality.

## FR-OR026

**The SAFE-T Approach to Collaborative Kidney Biomarker Qualification**

Patrick T. Murray,[3] Joe F. Keenan,[1] Frank Dieterle.[2] *[1]SAFE-T Consortium, EKF Diagnostics Ltd, Dublin; [2]SAFE-T Consortium, Novartis AG, Basel; [3]SAFE-T Consortium, UCD Mater Hospital, Dublin; [4]SAFE-T Consortium, Charite Hospital, Berlin, Germany; [5]SAFE-T Consortium, AstraZeneca, Wilmington, DE; [6]SAFE-T Consortium, Pfizer Inc, Cabmbridge, MA.*

**Background:** A European consortium (SAFE-T) was established in 2009 with the objective of providing a data submission package to the Health Authorities (FDA & EMA) to allow for the qualification of human kidney biomarkers to monitor drug induced kidney injury. The consortium has performed a first phase exploratory study of a larger list of candidate biomarkers through a number of healthy volunteer and drug induced kidney injury (DIKI) cohorts. Following statistical assessment of these exploratory studies SAFE-T will dismiss certain candidates that do not meet performance criteria and then perform a larger confirmatory DIKI study, the results of which are intended to serve as a convincing submission package for the qualification of a number of key kidney markers with the health authorities.

**Methods:** SAFE-T have established a candidate shortlist of 22 kidney biomarkers assembled from an extensive literature search of 50 biomarkers which were graded using a number of variables (including clinical publications, preclinical evidence, Marker stability, IP, etc.). Assays have been validated at 3 testing sites (the top 10 graded markers using dual technology i.e. both microtitre ELISA and Luminex). A healthy volunteer cohort of samples has already been assessed to establish marker variation and normative ranges. Clinical samples from three clinical studies have been collected and assessed: 1. Cisplatin Nephrotoxicity; 2. Acute Glomerulonephritis (GN); 3. Contrast Media.

**Results:** Performance of all 22 markers in an interim analysis of the key Cisplatin, acute GN and Contrast Media study cohorts as well as the healthy volunteer cohort will be assessed, presented and discussed. SAFE-T will also discuss critical aspects of this biomarker qualification including outlining the decision process for advancing successful biomarkers.

## FR-OR027

**Does Choice of Renal Replacement Therapy Modality Impact Renal Recovery and Clinical Outcomes in Acute Kidney Injury in the Intensive Care Unit?**

Kelly V. Liang,[1] Raghavan Murugan,[2] Florentina E. Sileanu,[2] Paul M. Palevsky,[1,3] John A. Kellum.[2] *[1]Renal, Univ of Pittsburgh; [2]Critical Care, Univ of Pittsburgh; [3]Renal Section, VA Pittsburgh Healthcare System.*

**Background:** Observational evidence has suggested that renal replacement therapy (RRT) modality may affect renal recovery after acute kidney injury (AKI). However, the Kidney Disease Improving Global Outcomes (KDIGO) guideline recommends choosing RRT modality based on hemodynamics. It is unclear whether initial modality of RRT [intermittent (IRRT) or continuous (CRRT)] affects renal recovery, post-discharge survival, or development of end-stage renal disease (ESRD) in critically ill patients when modality choice is made primarily on hemodynamics.

**Methods:** We examined adults (≥18 years) admitted to University of Pittsburgh Medical Center intensive care units from 2000 to 2008 using the High Density Intensive Care (HiDenIC) electronic database. We defined AKI using the KDIGO definition. We analyzed patients who received RRT for AKI based on initial modality (IRRT vs. CRRT). We used propensity covariate adjustment with model selection and multivariable logistic regression. Renal recovery was being alive and free of RRT. Survival was analyzed from initiation of RRT. ESRD was determined by matching to United States Renal Data System.

**Results:** Out of 37,627 total patients, 22,953 (61.6%) had AKI of whom 5,282 (23.0%) were KDIGO Stage 3 and 1,397 (26.4% of stage 3 patients and 6.1% of all AKI) received RRT. 612 (43.8%) RRT patients survived to hospital discharge (293 CRRT and 319 IRRT). After adjusting for propensity score for CRRT and other covariates, there was no difference in recovery from AKI at 90 or 365 days between CRRT and IRRT (OR 0.88, 95% CI 0.56-1.39, p=0.58 at 90 days; OR 0.92, 95% CI 0.60-1.41, p=0.71 at 365 days). Among survivors, at one year, 31.1% vs. 32.0% (p=0.79) had died and 9.6% vs. 7.8% (p=0.43) were alive with ESRD.

**Conclusions:** There was no increased hazard for non-recovery, mortality or ESRD with IRRT vs. CRRT. These results suggest that when initial RRT modality is chosen based on hemodynamic stability per KDIGO guidelines, renal recovery and clinical outcomes are similar between IRRT and CRRT.

## FR-OR028

**Measuring Glomerular Filtration Rate. A Systematic Review**

Inga Soveri,[1] Ulla B. Berg,[2] Jonas Björk,[6] Carl Gustaf Elinder,[7] Anders O. Grubb,[4] Ingegerd Anne Mejàre,[5] Gunnar Sterner,[3] Sten-Erik Bäck.[4] *[1]Dept of Medical Sciences, Uppsala Univ, Uppsala, Sweden; [2]Dept of Clinical Science, Intervention and Technology, Div of Pediatrics, Karolinska Institutet, Stockholm, Sweden; [3]Dept of Nephrology, Skåne Univ Hospital, Malmö, Sweden; [4]Dept of Clinical Chemistry, Lund Univ Hospital, Lund, Sweden; [5]Swedish Council on Health Technology Assessment, Stockholm, Sweden; [6]Dept of Occupational and Environmental Medicine, Lund Univ, Lund, Sweden; [7]Dept of Clinical Science, Intervention and Technology, Div of Renal Medicine, Karolinska Institutet, Stockholm, Sweden.*

**Background:** The accuracy of methods to measure GFR was assessed.

**Methods:** Original studies and systematic reviews comparing endogenous creatinine clearance, renal or plasma clearance of $^{51}$CrEDTA, DTPA, iohexol and iothalamate, and plasma clearance of inulin to renal inulin clearance measured under continuous inulin infusion and urine collection were included. Two reviewers assessed the quality of each study. When raw data was unavailable, individual clearance data were assessed from enlargements of index-reference method scatterplots. Bias, P30 and P10 were calculated. The quality of evidence across studies was rated (GRADE).

**Results:** Renal clearance of iothalamate measured GFR with sufficient accuracy (strong scientific evidence). Renal and plasma clearance of $^{51}$CrEDTA and plasma clearance of iohexol were sufficiently accurate to measure GFR (moderately strong scientific evidence). Renal clearance of DTPA, renal clearance of iohexol and plasma clearance of inulin had sufficient accuracy (limited scientific evidence). Endogenous creatinine clearance was an inaccurate method (strong scientific evidence) as was plasma clearance of DTPA (limited scientific evidence). There was insufficient scientific evidence to determine the accuracy of plasma iothalamate clearance.

**Conclusions:** Accurate methods to measure GFR are renal clearances of iothalamate and $^{51}$CrEDTA and plasma clearances of $^{51}$CrEDTA and iohexol. Endogenous creatinine clearance is an inaccurate method. The conclusions are supported by moderately strong to strong scientific evidence.

*Funding:* Government Support - Non-U.S.

## FR-OR029

**Relevance of Correction for Day-To-Day Variation in Cystatin C Measurement**

Priya Vart,[1] Stephan J.L. Bakker,[2] Hiddo Jan Lambers Heerspink,[3] Dick de Zeeuw,[3] Sijmen A. Reijneveld,[1] Ute Bültmann,[1] Ron T. Gansevoort.[2] *[1]Health Sciences; [2]Nephrology; [3]Clinical Pharmacology, UMC Groningen.*

**Background:** For epidemiological research it is important to obtain the most reliable measurement of filtration markers to estimate GFR. Despite standard laboratory quality control day-to-day variability in cystatin C (cysC) measurements can be observed. We investigated whether correction for day-to-day variation might help in obtaining more optimal cysC based GFR estimates.

**Methods:** Plasma samples of the PREVEND study (a general population-based observational cohort study, 8,592 subjects) were used to re-measure cysC (Gentian assay) over a period of 243 days (March 2010 to October 2012). Each measurement day two aliquots of a plasma pool were included ("controls"). First, we calibrated controls against the international reference standard for cysC. Second, using these control samples, we calculated for each measurement day a correction factor to adjust individual cysC values for day-to-day variation in cysC measurement. Estimated GFR with the cysC CKD-EPI equation.

**Results:** Coefficient of variation of cysC in control samples was 6.9%. Mean±SD eGFR using non-corrected cystatin C ($eGFR_{cysC}$) was 92.8±19.3 and using corrected cystatin C ($GFR_{cysC\ corr}$) 94.9±19.0 ml/min./1.73m$^2$. Subjects were categorized in 6 strata of $eGFR_{cysC}$ as reference:≥120, 90–119, 75–89, 60–74, 45–59 and <45 ml/min/1.73 m$^2$. Use of $GFR_{cysC\ corr}$ resulted in upward reclassification to a higher eGFR stratum in 0%, 4%, 36%, 30%, 31% and 25% of subjects and downward in 26%, 6%, 7%, 6%, 2% and 0%, respectively. Participants re-classified upward had significantly lower age, BMI, blood pressure, cholesterol, glucose and albuminuria, whereas opposite was true for participants reclassified downward. Renal risk factors explained more variance in $eGFR_{cysC\ corr}$ than in $eGFR_{cysC}$ ($p<0.001$). Importantly, $eGFR_{cysC\ corr}$ had a better association with incident cardiovascular events (n=789, follow-up 9.3±2.7 yrs.) than $eGFR_{cysC}$ (NRI 0.102, p=0.006).

**Conclusions:** In the absence of a gold standard measurement of GFR, these epidemiological data suggest that correction for day-to-day variation in cysC measurements improves GFR estimation using cysC.

**FR-OR030**

**Non-Glomerular Filtration Rate (GFR) Factors and Cystatin C**
Krishna Pothugunta,[1] Holly J. Kramer,[1] Lara Dugas,[1] Pascal Bovet,[2] Terrence Forrester,[3] Vicki Lambert,[4] Jacob Plange-Rhule,[5] Dale Schoeller,[6] Ramon Durazo,[1] Wolfgang Korte,[7] Amy Luke,[1] Franziska Lohrer.[7] *[1]Loyola Univ Chicago; [2]Lausanne Univ Hospital; [3]Univ of the West Indies; [4]Univ of Cape Town; [5]Kwame Nkrumah Univ of Science and Technology; [6]Univ of Wisconsin; [7]Centre of Laboratory Medicine St. Gallen.*

**Background:** Non-GFR factors may influence cystatin C variance but data on potential non-GFR factors among healthy adults remain limited.

**Methods:** The Modeling the Epidemiologic Transition Study is a cohort study of adults with African ancestry aged 25-44 years living in five different countries across the African Diaspora [Chicago (n=502), Jamaica (n=499), Ghana (n=500), South Africa (n=504) and Seychelles (n=500)]. Baseline exam was conducted during January 2010 –December 201; fasting blood samples were collected along with demographic and medical information using standardized surveys. Cystatin C was measured via nephelometry (Siemens). Characteristics were compared using ANOVA for continuous variables and Chi-square test for categorical variables by site. Spearman rank correlations coefficients were calculated to assess the correlation between c-reactive protein (CRP), thyroid stimulating hormone (TSH), waist circumference (WC) and Cystatin C by site. Linear regression was used to determine the amount of variance in cystatin C due to WC, CRP, age, gender and site.

**Results:** The mean age ranged from 33.4 years in South Africa to 35.3 years in Chicago. The mean BMI ranged from 24.1 kg/m$^2$ in Ghana to 31.9 kg/m$^2$ in Chicago. The mean CRP ranged from 0.47 mg/L in Ghana to 7.85 mg/L in South Africa and mean serum cystatin C level ranged from 0.57 mg/L in Seychelles to 0.70 mg/L in Ghana. In the pooled sample, age, gender, BMI, WC and CRP accounted for less than 3.1% of the total variance of cystatin C. Findings were similar when stratified by site. In the pooled sample, the Spearman correlation coefficient between cystatin C and CRP, TSH and WC was -0.17, 0.10 and 0.06, respectively. Results were similar across all sites.

**Conclusions:** Non-GFR factors account for only 3% or less of the total vairance of cystatin C in this young population with African ancestry regardless of site.

**FR-OR031**

**FAST Determination of Measured GFR (mGFR) in Normal Subjects: A Phase One Study**
Erinn Sheridan,[1] Daniel J. Meier,[1] James S. Strickland,[1] Ruben M. Sandoval,[2] Bruce A. Molitoris.[2,3] *[1]FAST Biomedical, Indianapolis, IN; [2]Medicine/Nephrology, IU School of Medicine, Indianapolis, IN; [3]Roudebush VAMC, Indianapolis, IN.*

**Background:** Development of a rapid technique to measure GFR (mGFR) has been a goal for many years as an aide in diagnosing AKI, determining severity of injury, drug dosing, CVVH initiation and discontinuation and determining risk for radiocontrast studies.

**Methods:** We have now conducted a prospective single blinded placebo controlled dose escalation (5 to 150mg, 0.3 to 3.0 ml injectate) study in 32 normal subjects. We used a patented technique employing large (150kDa-2-sulfohexamine rhodamine) and small (7kDa-fluorescein) fluorescent dextrans, optical quantification of plasma clearance, and two compartment modeling. Fluorescent dextrans were extremely water soluble and allowed for a high conjugation ratio with fluorescent molecules thus minimizing the milligram dose and administered volume when compared to other markers such as inulin.

**Results:** All doses were safe and well tolerated. Plasma volumes, determined by large dextran dilution 15 min post IV injection, were dose independent and consistent with standardized formula calculations. GFRs calculated by both continuous monitoring and four plasma sample optical determinations were agreeable and within the predicted range. The t1/2 for the 5kDa was as expected GFR dependent and for the 150kDa dextran marker 110 hours.

**Conclusions:** In summary, the technique provided a safe and rapid, less than 120 minute, determination of mGFR suitable for a wide variety of patients and purposes. This technique represents an important step in development of a reliable bedside mGFR technique for use in-hospital and in outpatient settings. Supported by a NIH SBIR phase II grant to FAST Biomedical and an NIH P-30 both to BAM.

*Funding:* Other NIH Support - SBIR phase and NIH P-30 both to Bruce A Molitoris

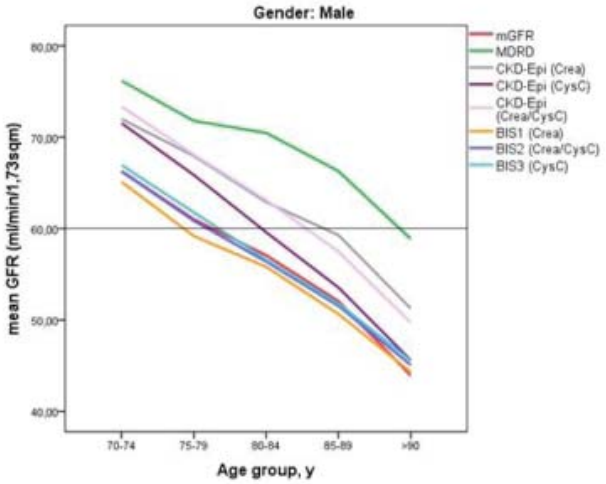
**FR-OR032**

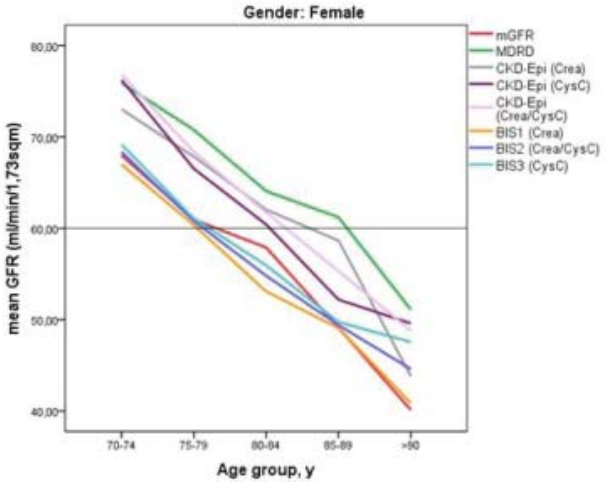
**Comparison of Current eGFR Equations with Measured GFR in an Elderly Population**
Natalie Ebert,[1] Olga Jakob,[2] Peter Martus,[3] Elke Schaeffner.[1] *[1]Nephrology, Charité, Berlin, Germany; [2]Biostatistics and Clin Epidemiology, Charité, Berlin, Germany; [3]Clin. Epidemiology and Medical Biostatistics, Eberhard Karls Univ, Tübingen, Germany.*

**Background:** Equations to estimate GFR have limitations, especially among older adults. The aim of this analysis was to compare current creatinine- and cystatin C-based equations with a gold standard in a subsample of the Berlin Initiative Study, a cohort of older adults.

**Methods:** We measured iohexol clearance in a non CKD-population of 570 participants of the Berlin Initiative Study (BIS) with a mean age of 78.5 yrs and compared the most recent 7 creatinine and/or cystatin C-based estimating equations to our measured GFR (mGFR). For iohexol clearance measurement blood samples were taken after 30, 60, 90, 120, 150, 180, 240, and 300 min (5h) after injection of 5 ml of iohexol. All comparisons were done separately for male and female patients and dependent on age.

**Results:** Compared to the mGFR (red line) the MDRD overestimates GFR by appr. 10-15 ml/min/1.73m$^2$ in all age groups, followed by the CKD-EPI equation and the new combined CKD-EPI$_{(Crea/CysC)}$ equation. The CKD-EPI$_{(CysC)}$ equation performs closer to the gold standard. The BIS-equations are the closest to the mGFR. The zig-zag-pattern of lines beyond the age of 85 in females might be due to the small numbers in that age group (n= 34). Overall the bias was largest for the MDRD equation (mean 11.2 ± 11.4 SD) followed by the CKD-EPI$_{(crea)}$ equation (mean 8.9 ± 10.1 SD) and CKD-EPI$_{(crea/cysC)}$ (mean 7.4 ± 9.2 SD). The BIS1$_{(crea)}$, BIS2$_{(crea/cysC)}$, and BIS3$_{(cysC)}$ and the CKD-EPI$_{(CysC)}$ showed lowest bias (mean -0.9, 0.1, 0.5, 4.8; SD ± 9.2, 8.1, 8.9, 10.7, respectively).





**Conclusions:** Clinicians and researchers should be aware of the fact that eGFR results differ considerably in older adults depending on the equation used. Current eGFR-equations mostly overestimate GFR in older adults.

*Funding:* Private Foundation Support

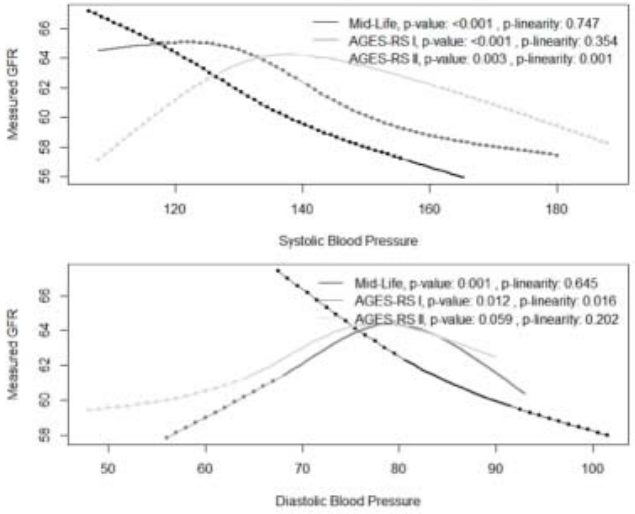
**FR-OR033**

**Kidney Function in the Elderly: A Population Based Study of Measured GFR**
Lesley Inker,[1] Aghogho A. Okparavero,[1] Hocine Tighiouart,[1] Margret B. Andresdottir,[2] Thor Aspelund,[3] Gudny Eiriksdottir,[3] Hrefna Gudmundsdottir,[2] Vilmundur Gudnason,[3,4] Tamara Harris,[4] Olafur S. Indridason,[2] Lenore J. Launer,[4] Gary F. Mitchell,[5] Hjalmfridur Lilja Nikulasdottir,[3] Runolfur Palsson,[2] Johanna Eyrun Sverrisdottir,[3] Andrew S. Levey.[1] *[1]Tufts Medical Center; [2]National Univ Hospital of Iceland; [3]Icelandic Heart Association; [4]National Institute of Aging; [5]Cardiovascular Engineering.*

**Background:** GFR declines with age, leading to a high prevalence of CKD in the elderly. Causes of this decline are not well understood due in part to absence of reliable information about GFR in a representative elderly population and its associations with midlife factors.

**Methods:** We measured GFR (mGFR) using plasma clearance of iohexol in 805 people participating in a community based prospective cohort study, Age, Gene/Environment Susceptibility Reykjavik Study (AGES-RS). We examined the associations of mGFR with age and systolic (SBP) and diastolic (DBP) blood pressure at 3 visits: midlife [mean(SD) age 51.0(5.8)], AGES-RS I [74.7(3.9)] and AGES-RS-II [79.4(3.8)].

**Results:** Mean mGFR was 62.3 (16.6, range 4-112) ml/min/1.73m$^2$. mGFR was 1.38 (1.09-1.66) ml/min /1.73m$^2$ lower per 1-y older age. The figure shows the relationships of mGFR at AGES-RS-II with SBP and DBP at the 3 visits. These relationships persisted after adjusting for age and creatinine at midlife, concurrent treatment, or BP at the other times.



Curves are cubic splines with 4 knots. Dots represent significant differences as compared to the reference point of SBP=140 and DBP=80. P-linearity <0.05 indicates nonlinearity of the curve. P-value < 0.05 indicates a significant association between BP and GFR.

**Conclusions:** Many elderly people have normal levels of GFR, suggesting decline in GFR may be secondary to pathological processes rather than aging. The strong associations of higher levels of SBP and DBP at midlife even less than 140/90 with lower mGFR in late life, suggest a possible mechanism for GFR related decline and may provide some directions for prevention of CKD in the elderly.

*Funding:* NIDDK Support, Government Support - Non-U.S.

## FR-OR034

### Chronic Kidney Disease Diagnosis and Referral Patterns by International Classification of Diseases-9 Codes

Anju A. Oommen, Lynn E. Schlanger, James L. Bailey, Jeff M. Sands, Janice P. Lea. *Nephrology, Emory Univ School of Medicine, Atlanta, GA.*

**Background:** There are an estimated 20 million persons with CKD in the U.S., which is associated with significant morbidity and mortality. Patients at high risk for CKD require screening including those with diabetes, hypertension, family history of CKD, and African Americans. The estimated glomerular filtration rate (eGFR) reporting has become standard practice in most labs to help identify persons with CKD stage 3-5. Despite having access to eGFR measurements, oftentimes ICD-9 CM codes may not reflect accurately the level of CKD.

**Methods:** We used cross-sectional analysis to evaluate the accuracy of renal related ICD-9 coding for CKD in our outpatient clinic populations across Emory Healthcare. Using the modified creatinine based eGFR, CKD was defined as having two or more eGFR values< 60ml/min/1.73m$^2$ at least 90 days apart. Exclusion criteria were ESRD patients, renal transplants, and presumed acute kidney injury.

**Results:** Of the 93,938 patients in our clinical data warehouse meeting criteria for CKD, 55% were males, 54% Caucasians and 33% African Americans. Of those 93,938 clinic patients, 17,584 (18.7%) had one or more specific renal diagnosis codes on record while 76,354 (81.3%) did not have any. Of those patients (17,584) with CKD by eGFR and ICD-9 coding reflecting a CKD diagnosis, 35.3% had been seen in nephrology clinic as compared to those patients (76,354) with CKD but no ICD-9 coding, only 0.8% was seen in nephrology clinic, p value< 0.0001. There were no differences observed according to race or sex in diagnosis or referral patterns.

**Conclusions:** In summary, ICD-9 codes used in clinic settings do not completely identify persons with all forms of CKD. Those patients with a CKD diagnosis reflected in ICD-9 coding are seen by nephrology more often than others, however, the majority of persons with CKD defined by eGFR are not identified by ICD-9 codes and are not under care of a nephrologist. More education is needed to emphasize importance of identifying all stages of CKD in order to provide proper risk stratification and interventions to improve outcomes.

## FR-OR035

### A Comparison of Slopes in Measured and Estimated GFRs: The CRIC Study

Dawei Xie, Wei Yang, Amanda Hyre Anderson, Harold I. Feldman. *Biostatistics and Epidemiology, Univ of Pennsylvania, Philadelphia, PA.*

**Background:** This study compared the slopes in measured GFR (mGFR) and three estimated GFRs (eGFRs) from CRIC, MDRD and CKD-EPI equations.

**Methods:** Included were 1009 CRIC participants with >=2 mGFRs. Linear regression models estimated the slopes. Spearman correlations were calculated among the slopes. The slope difference of CRIC eGFR vs mGFR was regressed on baseline covariates.

**Results:** Mean length of follow up was 3.5 years (range=1.6-8.9). The Spearman correlations were >0.9 among the three eGFR slopes, and 0.59, 0.53, and 0.53 between mGFR and CRIC, MDRD, CKD-EPI eGFR slopes. Mean slope difference between CRIC eGFR and mGFR was 0.56 (SD=3.84, median=0.41, IQR: -1.33 to 2.37) ml/min/1.73m2/year. Model estimates which were the eGFR versus mGFR slope difference per unit change in the predictor were shown in Table.

| Baseline Predictors | Age, gender, race, center adjusted (95% CI) | p | Final multivariable model (95% CI) | p |
|---|---|---|---|---|
| CRIC eGFR-mGFR | -0.19 (-0.21, -0.17) | <.0001 | -0.19 (-0.21, -0.17) | <.0001 |
| mGFR | 0.04 (0.03, 0.06) | <.0001 | | |
| Log HOMA insulin sensitivity | -0.29 (-0.54, -0.04) | .03 | -0.26 (-0.47, -0.04) | .02 |
| Log TNF alpha | 0.31 (0.03, 0.60) | .03 | 0.27 (0.04, 0.51) | .02 |
| Log BNP | -0.29 (-0.57, -0.01) | .04 | | |
| Log urine urea nitrogen | 0.29 (0.02, 0.57) | .04 | | |
| Log Cystatin C | 0.26 (-0.01, 0.53) | .06 | | |
| Log IL-6 | 0.27 (-0.01, 0.55) | .06 | | |
| Log IL-1RA | -0.26 (-0.54, 0.02) | .07 | -0.38 (-0.60, -0.15) | .001 |
| Log fibrinogen | 0.20 (-0.06, 0.46) | .1 | | |
| Serum urea nitrogen | 0.20 (-0.06, 0.47) | .1 | | |
| CRIC eGFR | -0.01 (-0.03, 0.00) | .1 | | |
| Log hsCRP | 0.19 (-0.08, 0.46) | .2 | | |
| Log plasma homecysteine | 0.19 (-0.09, 0.47) | .2 | | |
| Wasit circumference | 0.18 (-0.09, 0.44) | .2 | | |
| Log Urine creatinine excretion | 0.19 (-0.10, 0.48) | .2 | -0.25 (-0.47, -0.04) | .02 |

**Conclusions:** The ability of eGFR slopes to approximate mGFR slope in the setting of CKD is impaired by inflammation, insulin sensitivity, creatinine generation, and poor agreement between baseline eGFR and mGFR.

*Funding:* NIDDK Support

## FR-OR036

### National Impact of Cystatin C on Safe and Appropriate Utilization of Metformin among Patients with Type 2 Diabetes

Delphine S. Tuot,[1] Michael Shlipak,[1] Jerry Yee,[2] Rajiv Saran,[3] Neil R. Powe.[1] *[1]Univ of California, San Francisco, San Francisco, CA; [2]Henry Ford Hospital, Detroit, MI; [3]Univ of Michigan.*

**Background:** Metformin may be underused among persons with diabetes (DM) and chronic kidney disease (CKD) because of concerns of side effects at low glomerular filtration rates (GFR). eGFRcr-cys correlates better with measured GFR than other measures and may be a more reliable measure on which to base medication dosing. We examined the potential impact of eGFRcr-cys on guiding safe and appropriate utilization of metformin among US adults with DM.

**Methods:** Self-reported metformin use was assessed among 397 diabetic adults using 1999-2002 National Health and Nutrition Examination Survey data. DM was defined by self-report or a glycosylated hemoglobin > 6.5mg/dL. eGFRcr was measured by the 4-variable MDRD equation; eGFRcr-cys by the CKD-EPI 2012 equation. We used proportions to reclassify: (1) the percentage of diabetics with eGFRcr >45ml/min not on metformin who could presumably safely be on metformin because a eGFRcr-cys >45ml/min and (2) the percentage of diabetics with eGFRcr < 45ml/min on metformin, who should presumably not be on metformin because of an eGFRcr-cys < 45ml/min. Results are weighted to the US population.

**Results:** Overall, 28% of patients with DM reported a metformin prescription, of whom 97% had an eGFRcr-cys <60ml/min. Nearly 16% of patients with DM and eGFRcr < 45ml/min not on metformin could safely be on metformin (Table 1) and 23% of persons with DM and eGFRcr >45ml/min on metformin should use the drug with caution based on eGFRcr-cys <45ml/min (Table 2).

Table 1: Percentage of patients with DM not on metformin who could safely use metformin by reclassification using eGFRcr-cys.

| | eGFRcr-cys ≥45 | eGFRcr-cys <45 |
|---|---|---|
| eGFRcr ≥45 | 94.1 | 6 |
| eGFRcr <45 | 15.7 | 84.3 |

Table 2: Percentage of patients with DM on metformin whose safety with metformin is concerning, by reclassification using eGFRcr-cys.

| | eGFRcr-cys ≥45 | eGFRcr-cys <45 |
|---|---|---|
| eGFRcr ≥45 | 77 | 23 |
| eGFRcr <45 | 14 | 86 |

**Conclusions:** eGFRcr-cys may help clinicians better identify individuals for whom metformin prescription is safe and appropriate. Prospective studies should further clarify the role of eGFRcr-cys for evaluation of safety and efficacy of medication dosing among CKD patients.

**FR-OR037**

**GFR Decline as an Endpoint for Clinical Trials in CKD: Report of an NKF-FDA Workshop** Andrew S. Levey,[1] Josef Coresh,[2] Aliza M. Thompson,[3] Edmund J. Lewis,[4] Dick de Zeeuw,[5] Alfred K. Cheung,[6] Kerry Willis,[7] Norman Stockbridge.[3] *[1]Tufts Medical Center; [2]Johns Hopkins Univ; [3]Food and Drug Administration; [4]Rush Univ Medical Center; [5]Univ Medical Center Groningen; [6]Univ of Utah; [7]National Kidney Foundation.*

**Background:** The FDA accepts halving of GFR, assessed as doubling of serum creatinine (Scr) level, as a surrogate end point for the development of kidney failure in clinical trials of kidney disease progression. A Scr doubling is generally a late event in CKD and takes a long time to develop. There is great interest in considering alternative endpoints for clinical trials to shorten their duration and to extend their application to earlier stages of CKD. However, there is uncertainty about the associations of lesser declines in GFR with subsequent development of kidney failure. The NKF and FDA sponsored a scientific workshop to exam critically data that might new definitions of GFR decline as endpoints in clinical trials of CKD-related therapies. The anticipated outcome of the workshop was the identification of new definitions of GFR decline with sufficiently strong associations with important clinical outcomes of CKD so that they can be used as endpoints in CKD clinical trials.

**Results:**

Summary of performance of alternative time-to-event endpoints for 2-3 year trial*

| Acute effects** | Baseline GFR high Stage 2 | | Baseline GFR medium Stage 3 | | Baseline GFR low Stage 4 | |
|---|---|---|---|---|---|---|
| | 40% decline | 30% decline | 40% decline | 30% decline | 40% decline | 30% decline |
| Large negative | | | | | | |
| Moderate negative | | | | | | |
| None | | | | | | |
| Moderate positive | | | | | | |
| Large positive | | | | | | |
| Key** * | Type 1 error not acceptable (false positive for benefit) | Type 1 error not acceptable (false positive for harm) | Type 1 error acceptable but power not improved | Type 1 error acceptable and power improved | | |

*Acute effect refers to an initial GFR decline opposite in direction to the hypothesized long-term beneficial effect. **Assumptions: treatment effect is mixed proportional/uniform; acute effect attenuates to 0 at ESRD; trial duration 3 years for high GFR and 2 years for medium and low GFR. ***Key: acceptable type 1 error = 10% or less; improved power = smaller samples size for alternative vs. 57% decline (equivalent to a Scr doubling) in a trial of the same duration.

**Conclusions:** Based on a series of meta-analyses of 21 cohorts and 43 clinical trials and simulations of trial designs and analytic methods, the workshop concluded that a confirmed decline in eGFRcr of >30 or >40% may be an acceptable surrogate endpoint (acceptable type 1 error and power improved) in some circumstances, based on baseline GFR, magnitude of acute effects, duration of follow-up.

**FR-OR038**

**Lower Creatinine Clearance Is Associated with Reduced Walking Speed and Muscle Atrophy among Older Adults** Baback Roshanravan,[1] Cassianne Robinson-Cohen,[1] Ian H. de Boer,[1] Ann M. O'Hare,[1] Jonathan Himmelfarb,[1] Kushang V. Patel,[2] Bryan R. Kestenbaum.[1] *[1]Nephrology, Univ of Washington, Seattle, WA; [2]Anesthesiology & Pain Medicine, Center for Pain Research on Impact, Measurement & Effectiveness, Seattle, WA.*

**Background:** CKD promotes malnutrition and inflammation that may lead to loss of skeletal muscle and reduced physical performance. Associations of kidney function with human skeletal muscle structure and longitudinal measures of physical performance are unknown.

**Methods:** We tested associations of 24hr creatinine clearance (CrCl) with physical function in the InCHIANTI study, a community-based cohort of adults ≥65yrs. We included 826 participants without stroke or disability who completed a 24hr urine collection. Linear regression was used to assess cross-sectional associations of CrCl with gait speed over 7 and 400 meters, and knee extension strength. We adjusted for age, sex, ht, wt, study site, smoking, education, diabetes, and CAD. We tested associations of CrCl with muscle and fat areas of the calf muscle by CT. Mixed effects models to estimate associations of baseline CrCl with longitudinal physical performance measures over 9yrs.

**Results:** Mean age was 74 ±7yrs. Mean CrCl was 79 ±25ml/min with 206 participants with CrCl<60ml/min. In cross-sectional analysis each 10ml/min lower CrCl was associated with an adjusted mean difference of -0.01m/s (95% CI: -0.014, -0.003; P=0.002) in usual gait speed and -0.009m/s (95% CI: -0.015, -0.004; P=0.004) in 400m gait speed. No difference was seen with knee strength at baseline (P=0.8). Each 10ml/min lower CrCl was associated with an adjusted mean difference of -30mm$^2$(95% CI: -58, -2; P=0.03) in calf muscle area and -0.16 mg/cm$^3$ (95% CI -0.27, -0.05; P=0.005) in muscle density. In longitudinal analysis each 10ml/min lower CrCl was associated with an adjusted difference of -0.025kg/year in knee strength (95% CI: -0.04, -0.01; P=0.001) but no difference in gait speed.

**Conclusions:** Lower CrCl is associated with slower 7m usual gait speed and 400m gait speed and diminished calf muscle area and muscle density. Knee extension strength declined more rapidly among those with lower CrCl.

**FR-OR039**

**Effects of Aging on Renal Arteriolar Hyaliosis in Autopsies: The Hisayama Study** Toshiharu Ninomiya,[1] Michiaki Kubo,[2] Masaharu Nagata,[1] Yoshinao Oda,[3] Takanari Kitazono,[1] Yutaka Kiyohara.[4] *[1]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [2]Laboratory for Genotyping Development, RIKEN Yokohama Institute, Yokohama, Japan; [3]Dept of Anatomic Pathology, Kyushu Univ, Fukuoka, Japan; [4]Dept of Environmental Medicine, Kyushu Univ, Fukuoka, Japan.*

**Background:** There were limited studies addressing the effect of aging on renal arteriolar hyalinosis by considering the status of other cardiovascular risk factors.

**Methods:** In 839 consecutive population-based autopsy samples, which were obtained between 1962 and 1994, the effect of aging on advanced renal arteriolar hyalinosis was examined, taking the status of other cardiovascular risk factors into account. The advanced renal arteriolar hyalinosis was determined based on the 95 percentile values of arteriolar hyalinosis index among subjects who had no clinical sign of kidney disease. The risk estimates were computed using a logistic regression analysis.

**Results:** Aging was significantly associated with the likelihood of advanced renal arteriolar hyalinosis after adjusting for other cardiovascular risk factors, being 1.00 (reference), 1.66 (95% confidence interval, 0.60-4.60), 2.03 (0.79-5.24), and 3.11 (1.21-7.98) for 40-59, 60-69, 70-79, and ≥80 years. In the analysis stratified by hypertensive status, however, the multivariate-adjusted odds ratios of the presence of advanced renal arteriolar hyalinosis increased significantly with aging in hypertensives, whereas there was no evidence of the association in normotensives: 1.00 (reference), 2.23 (0.64-7.72), and 1.97 (0.54-7.19) for 40-69, 70-79, and ≥80 years in normotensives: 3.37 (1.18-9.61), 4.35 (1.62-11.71), and 7.33 (2.75-19.49) in hypertensives. In the multivariate analysis, aging, hypertension, glucose intolerance, and proteinuria were significant risk factors for the presence of advanced renal arterial hyalinization, where hypertension had the greatest odds ratio.

**Conclusions:** Our findings suggest that aging is a significant risk factor for renal arterial hyalinization, but its magnitude of effect is less than that of hypertension.

**FR-OR040**

**Incidence of Dementia Based on Dialysis Modality** Dawn F. Wolfgram,[1] Qun Xiang,[2] Aniko Szabo.[2] *[1]Medicine, Medical College of Wisconsin and Zablocki VA Medical Center, Milwaukee, WI; [2]Biostatistics, Medical College of Wisconsin, Milwaukee, WI.*

**Background:** Dementia prevalence is increasing in our ESRD population. Although this may reflect their overall higher risk of vascular disease, dementia increases substantially after initiation of dialysis. This suggests that hemodialysis itself, with its rapid fluctuations in blood pressure and osmolality, contributes to initial cognitive changes. Currently, there is no data on the incidence of dementia in the peritoneal dialysis (PD) population. Since PD lacks the fluctuations seen in HD, we hypothesize that that persons on PD would be less likely to develop dementia than those on HD.

**Methods:** Using linked Medicare - United States Renal Data System data, we identified persons who initiated dialysis during 2006-2008 and did not have a dementia diagnosis code during the two years preceding dialysis initiation. We followed this cohort for up to 3 years to identify new dementia diagnoses. We estimated cumulative dementia incidence rates overall and for persons receiving HD vs PD using Nelson-Aalen estimators, censoring for mortality, and at December 31, 2008. We used Cox proportional hazards models to determine the independent effect of initial modality.

**Results:** We identified 144,244 eligible patients; PD was the initial modality in 6.2%. The overall mortality was 62.3% in 3 years. The cumulative incidence of dementia at 3 years was 6.1% overall; 6.8% and 3.5%, respectively, among those whose first modality was HD and PD. In bivariable analyses, African American race, older age, female sex, and hypertension or diabetes as primary ESRD cause were associated with increased risk for dementia. After adjusting for potential confounders, persons initiating dialysis with PD remained significantly less likely to develop dementia (HR 0.60, 95% CI 0.53-0.68).

**Conclusions:** Initial modality of PD is associated with lower risk of incident dementia than HD. Analysis taking into account further risk factor adjustment and time on dialysis modality is ongoing. These results suggest a need for more research regarding the potential risks of intradialytic events, including fluctuations in BP and osmolality.

**FR-OR041**

**Cognitive Impairment in Moderate Chronic Kidney Disease: The Brain IN Kidney Disease (BRINK) Study** Anne M. Murray,[1,2,3] Yelena Slinin,[2] Sarah L. Pederson,[3] Elizabeth Amiot,[3] David Tupper.[1,2] *[1]Hennepin County Medical Center, Minneapolis, MN; [2]Univ of MN; [3]MMRF.*

**Background:** In the longitudinal BRain IN Kidney disease (BRINK) study we are characterizing burden of cognitive impairment (CI) in 350 CKD and 100 non-CKD subjects. We describe the frequency of domain-specific CI in CKD and non-CKD cohorts after one year of recruitment.

**Methods:** Pts with CKD Stages 3b-5 (eGFR < 60 mL/min; dialysis pts exclude</a>d) and age, race, and education-matched controls (eGFR ≥ 60 mL/min) were recruited from three Minneapolis urban clinics. Domain- specific neuropsychological testing was performed at baseline using the following tests: 1) 3MS (Modified Mini-Mental State Exam) for global cognition, 2) Hopkins Verbal Learning Test-Revised (HVLT-R, Immediate and Delayed; verbal memory), 3) Controlled Oral Word Association Test (COWAT, semantic memory/language), 4) Color Trails 1 and 2 (executive function) (CTT2), 5) Symbol-Digit-

Modality Test (SDMT) (executive function), and 6) Brief Visuospatial Memory Test-Revised (BVMT-R, Immed and Delayed; visualspatial/memory) and the PHQ Depression Scale. We compared raw scores and T-scores using published norms.

**Results:** 201 participants (CKD N = 124, Control N = 77) were recruited. Mean ages of CKD and control groups were 67.5 ± 9.7 years and 65.1 ± 10.8 yrs, respectively (p=0.11). Baseline eGFR among CKD subjects was 29.8 ± 10.4 mL/min (Stage 4 CKD). CKD pts had a higher prevalence of HTN than controls (93.5% vs. 75.3%, p<0.01) but similar prevalence of prior stroke (15.3% vs. 13.0%, p=0.65) and diabetes (59.3 vs. 51.9%, p=0.30). CKD pts scored significantly worse on the 3MS (92.5 ± 6.5 vs. 94.4 ± 6.0, p = 0.04), HVLT-R delayed (6.9 ± 3.2 vs. 8.3± 2.7 words, p<.01), and SDMT (36.5 ± 12.2 vs. 42.2 ± 11.3, p<.01); associated T-scores were also significantly different. There were no significant differences on the CTT2, COWAT, Digit span, BVMT-R or PHQ9 </ a>depression scale between cohorts.

**Conclusions:** CKD pts had significantly lower levels of global cognitive function, verbal memory, and executive function/processing speed, consistent with possible mixed neurodegenerative and vascular cognitive impairment. Further analyses will measure factors associated with domain- specific CI.

## FR-OR042

### Dizziness and Vestibular Disorders Are Associated with Falls in Chronic Kidney Disease (CKD)

Premila Bhat,[1,2] Ashok Valluri.[2] *[1]Atlantic Dialysis Management Services, LLC, Ridgewood, NY; [2]Wyckoff Heights Medical Center, Brooklyn, NY.*

**Background:** CKD is associated with increased risk of falls and fracture but the factors contributing to fall risk in CKD are not fully known. We hypothesize that vestibular disorders, including disorders of balance and dizziness, contribute to fall risk in CKD. To examine this association cross-sectional analysis of the continuous National Health and Nutrition Examination Survey (NHANES) was conducted.

**Methods:** Subjects ≥40 yrs of age and enrolled in NHANES 2001-2004 (n=21,161) were included. Screening for problems with dizziness, balance, or falls and results of a modified Romberg test were ascertained from the NHANES Balance Questionnaire and Exam. Uni- and multivariate logistic regression were used to compare the prevalence of balance associated symptoms or Romberg test failure across CKD categories. Continuous and categorical data are presented as means±SD and percents (%), respectively.

**Results:** Of the 4,878 subjects, 48.9% were female, 16.9% black, mean age was 60.7±13.4 yrs, mean BMI 28.2±5.3, 42.2% with HTN, 13.0% DM. Prevalence of CKD was: Stages 1-2 (eGFR≥60), 88.5%; 3A (45≤eGFR<60), 7.8%; 3B (30≤eGFR<45), 2.5%; and 4-5 (eGFR<30), 1.2%. Of 23.3% who reported dizziness, balance or falling problems, 24.2% reported falls. Compared to those with eGFR≥60, for CKD Stage 3A, 3B, and 4-5 unadjusted OR's for balance symptoms were 1.818 (95%CI: 1.452, 2.277), 2.475 (95%CI:1.709, 3.584), and 3.069 (95%CI: 1.829, 5.148), respectively. The relationship between advanced CKD (Stages 3B and 4-5) and balance symptoms was seen even after adjustment for age, gender, race, DM, HTN and BMI, with OR's 1.706 (95%CI: 1.151, 2.530) and 2.141 (95%CI:1.204, 3.808), respectively. Failure to pass level 2 or 3 Romberg exam remained predictive of falls after adjustment for CKD (level 2 OR=1.839, 95%CI: 1.224, 2.762; level 3 OR=2.575, 95%CI: 1.486, 4.463).

**Conclusions:** Problems with balance and dizziness are common in CKD. There is a graded relationship between CKD stage and balance symptoms. Among those with CKD, falls are associated with failure to pass sequential Romberg tests, suggesting that the Romberg test can identify individuals with CKD at high risk for falls.

*Funding:* Clinical Revenue Support

## FR-OR043

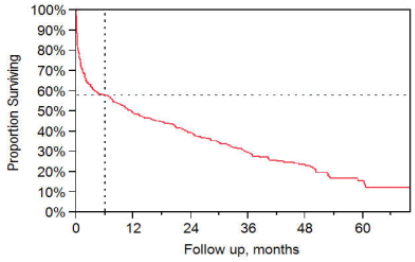
### Starting Dialysis at Age 75 Years or Older – Outcomes Data to Help in Shared Decision Making

Bjoerg Thorsteinsdottir,[1] Hanna L. W. Larson,[2] LaTonya J. Hickson,[1] Molly A. Feely,[1] Amy W. Williams.[1] *[1]Medicine, Mayo Clinic, Rochester, MN; [2]Univ of San Diego, San Diego, CA.*

**Background:** The intensity of medical care for the oldest old has escalated beyond population growth in the past decades driven by powerful moral and technological imperatives to treat. Many elderly patients and their families feel that they have no choice but to start renal replacement therapy (RRT) with several expressing regret of having initiated therapy. High HD withdrawal rates have been found in this group. Shared decision making regarding RRT in the elderly is hampered by the lack of evidence to guide practice in this age group.

**Methods:** Review of the medical record for all patients 75 years and older, initiating any form of RRT at Mayo Clinic Jan 1, 2007 - Dec 31, 2011.

**Results:** Of 390 patients, 66% were male, 94% were Caucasian, and mean age was 81.3 years (Interquartile range (IQR) 77.5-84.4), 40% had diabetes, and 27% had congestive heart failure. The mean Charlson comorbidity index was 7.9 (IQR 6-10). The majority, 290 (74%), started RRT in hospital. 147 (57%) began with continuous RRT in the ICU. Of 210 hospital-initiated patients admitted from independent living, only 70 (33%) were discharged home. Mean follow up was 17 months (range 0-74). Early mortality was high with 104 (27%) dying in less than 30 days and 140 (36%) dying in less than 90 days. The 6-month survival rate was 58% and 12 month survival 49% (Figure 1). Among hospital starters, 110 of 290 (38%) died during the index hospitalization.



**Conclusions:** This cohort study of elderly incident RRT patients suggests that most initiate RRT in the hospital following an illness or an event. Loss of independent living is frequently observed following hospitalization. Early and overall mortality is high. Patient awareness of these outcomes may allow for better informed discussions at time of RRT consideration.

## FR-OR044

### Determinants of Outcome of Conservatively Managed CKD Stage 5 Patients: Single Centre Review

Muhammad Nauman Hashmi, Mohammed Awais Hameed, Arvind Ponnusamy, Vijay Sundaram Thanaraj, Ajay Prabhakar Dhaygude. *Renal Medicine, Royal Preston Hospital, Preston, United Kingdom.*

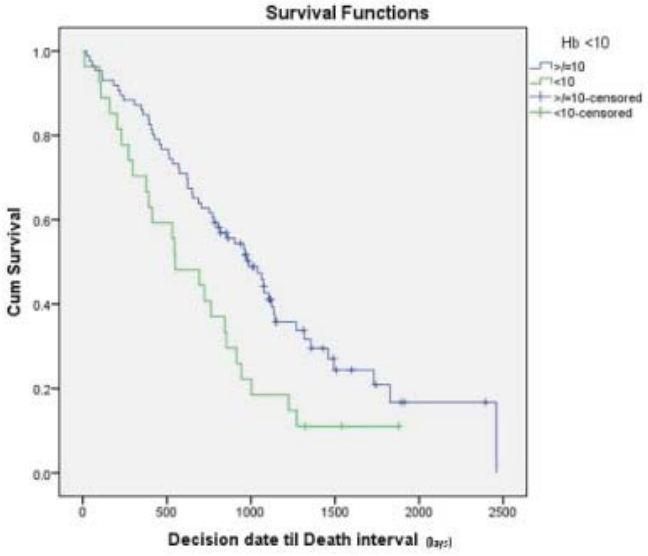
**Background:** Conservative treatment has become a recognized modality of treatment in end stage renal disease (ESRD) in selected group of chronic kidney disease (CKD) patients. These patients are managed in a multidisciplinary setting. However, there is lack of data regarding outcome of these patients.

**Methods:** This is a retrospective analysis of conservatively managed patients CKD stage 5 (Total number 119) patients followed up in a single centre from January 2005 till December 2010. Residual renal function (eGFR), laboratory parameters (calcium, phosphate, albumin & haemoglobin) were recorded from the time of decision to manage conservatively. These parameters were co-related.

**Results:** Median age of the study population was 85.5 years. The most common co-morbidity was hypertension. Mean haemoglobin at baseline was 11.3g/dl, calcium 2.30mmol/l, phosphate 1.31mmol/l and albumin 39 g/l. Median overall survival was 816 days.

| | Registration to death interval (days) | Decision date to death to interval (days) |
|---|---|---|
| Mean | 1660 | 825 |
| Median | 1531 | 816 |
| Mode | 1092 | 98 |

The number of patients died were 87. Haemoglobin >10 g/dl at presentation was associated with greater survival (p<0.001). Median survival of patients with haemoglobin >10 g/dl was 1116.5 days compared to 705.3 days for those with haemoglobin <10 g/dl.



Interestingly, other parameters did not predict outcome.

**Conclusions:** Conservative management in ESRD has become one of the modality in RRT. Increasing proportion of CKD patients, particularly the elderly, opt for conservative care. There should be a multidisciplinary approach to the management of such patients. Haemoglobin appears to be important predictor of survival in our cohort of patients.

## FR-OR045

**Non-Dialysis Management in the Elderly: Survival, Symptom Control and Quality of Life** Mark A. Brown, Gemma Collett, Elizabeth A. Josland, Frank Brennan. *Renal Medicine, St. George Hospital & Univ of NSW, Sydney, NSW, Australia.*

**Background:** Decisions concerning appropriateness of dialysis in the elderly require knowledge of expected survival and whether reasonable life can be maintained without dialysis. We compared prospectively symptom control, Quality of Life(QOL) and survival between ESKD patients managed without dialysis (NFD) and those planned for dialysis (Pre-Dx).

**Methods:** In a single centre *prospective observational study* over 4 years 290 Pre-Dx patients had usual nephrology care and 135 NFD patients also received Renal Supportive Care(RSC) adding the skills of a Palliative Medicine team. Patients were recommended a NFD pathway based upon co-morbidity, frailty, poor functional status or nutrition and their nephrologist's view that survival would be poor. Symptoms were measured using the validated MSAS survey and QOL using the SF-36 survey.

**Results:** NFD patients were older than the Pre-Dx group (median 83 vs. 69 yrs, $p<0.001$);median eGFR at 1st clinic visit was 16ml/min in both. 126(43%) of Pre-Dx patients commenced dialysis over the 4 years. Mean survival was greater in Pre-Dx (44 vs. 23 months, $p<0.001$). 71(53%) of NFD and 28(10%) of Pre-Dx patients died ($p<0.001$); death rates for patients > 75 yrs were 63/115(55%) and 15/99(15%) respectively ($p<0.001$). 48%(21/44) of NFD and 47%(46/97) of Pre-Dx patients had stable or improved symptoms over the 1st 6 months and 52%(12/23) vs.45%(23/52) at 12 months. Physical QOL was maintained or improved at 6 and 12 months in 38%(15/39) and 43%(9/21) of NFD and 51%(53/104) and 46%(25/54) of Pre-Dx patients.Mental QOL was maintained or improved at 6 and 12 months in 51%(20/39) and 52%(11/21) of NFD and 57% (59/104 and 31/54) of Pre-Dx patients.

**Conclusions:** As expected, elderly patients carefully selected for dialysis survive longer than those treated conservatively. However, a RSC service utilising the skills of palliative medicine ensures symptom control and QOL without dialysis to the level of those receiving usual nephrology care including dialysis. These data support a role for palliative (supportive) care and can assist nephrologists counselling elderly patients regarding appropriateness and likely outcomes if dialysis is not employed.

*Funding:* Pharmaceutical Company Support - Amgen Australia

## FR-OR046

**Preexisting Do Not Resuscitate Status Reduces Hospital-Centered Morbidity and Mortality at the End of Life in a University Hospital-Based Dialysis Population** Marc Richards,[1] Len A. Usvyat,[2] Philip J. Klemmer.[1] *[1]UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC; [2]Renal Research Institute, New York, NY.*

**Background:** Medical advances have extended life spans, but at the expense of more complex illnesses and comorbidities. This is particularly the case for end stage renal disease patients who have a 25% annual mortality, four times that of age-matched patients without kidney disease. Previous studies have suggested that end of life care in ESRD patients is often aggressive and expensive, yet frustratingly futile.

**Methods:** Records were obtained from the Renal Research Institute (RRI) detailing all patients who left one of three suburban or rural dialysis units affiliated with the UNC Kidney Center. 287 adult patients died or withdrew from dialysis. Data was compiled from an electronic medical record and the dialysis units to determine demographic data, comorbidities, aggressiveness of care at the end of life, advanced directives, and implementation of palliative measures.

**Results:** Please see table. Of note, black, ESRD onset age <70, and PD patients were more likely to receive aggressive end-of-life care (data not shown).

| N=287 | Hospitalization (last month of life) | ICU admission (last month of life) | CPR or CRRT or Intubation or Pressors (last month of life) | In-Hospital Death | Hospice Referral | With-drawal of dialysis as inpt. | With-drawal of dialysis as outpt. |
|---|---|---|---|---|---|---|---|
| Preexisting DNR/DNI prior to 1 month before death OR last admission (n=52, 22.1%) | 36 (69.2%) | 8 (15.4%) | 7 (13.5%) | 9 (17.3%) | 27 (51.9%) | 12 (23.1%) | 16 (30.8%) |
| No Preexisting DNR/DNI (n=235, 77.9%) | 196 (83.4%) | 106 (45.1%) | 115 (48.9%) | 135 (57.4%) | 37 (15.7%) | 24 (10.2%) | 10 (4.2%) |
| p-values -> | 0.009 | <0.001 | <0.001 | <0.001 | <0.001 | 0.006 | <0.001 |

**Conclusions:** Dialysis patients with established DNR/DNI orders were more likely to avoid aggressive intervention at the end of life, establish hospice care, and voluntarily withdraw from RRT. A prospective trial is warranted to see if earlier initiation of advanced directives in the ESRD population results in more compassionate, less costly care.

## FR-OR047

**Dignity and Quality of Life in End Stage Renal Disease Patients, Close to the End of Life** James M. Zacharias,[1] Sara N. Davison,[2] Harvey M. Chochinov.[3] *[1]Dept of Medicine, Section of Nephrology, Univ of Mantitoba, Winnipeg, Canada; [2]Dept of Medicine, Univ of Alberta, Edmonton, Canada; [3]Dept of Psychiatry, Univ of Manitoba, Winnipeg, Canada.*

**Background:** Maintaining dignity of patients in end-of-life (EOL) situations has been a foundation of palliative care. An empirical model of dignity (Chochinov et al, 2002), has been used to explore dignity in EOL cancer populations, but no work has yet been done to identify sources of dignity related distress in the End Stage Renal Disease (ESRD) population.

**Methods:** Entry criteria: ESRD patients on dialysis >3 months and between 65 and 80 years of age and their caregivers were consented. Demographics were collected and the disposition of the patient followed for up to two years. Various instruments measuring psycosocial and existential distress including the Patient Dignity Inventory (PDI), Structured Interview for Symptoms and Concerns. (SISC) and KDQOL, were administered at the onset of the study and 3 months later.

**Results:** 103 patients on dialysis a median of 1-3 years from two sites in Canada were enrolled. Sixty percent were male, 52% diabetic, mean age 72.5 years. Eighty-two percent had never had counseling or treatment for an emotional problem. SISC indicated 18.8% patients felt some loss of dignity; 51.6% some degree of suffering, 50.5% feelings of hopeless. 53.5% endorsed one of more items of the PDI. However more malignant expressions of distress such as; desire for death (9.9%) and thoughts of suicide (14.9%) were less frequent, comparable to terminal ill cancer populations.

**Conclusions:** Suffering and existential distress appears to be quite prominent in this patient population. However, more severe expressions of marked distress are less common. Further research must explore the full experiential landscape of distress, in order to determine appropriate therapeutic approaches.

*Funding:* Government Support - Non-U.S.

## FR-OR048

**Phospholipase $A_2$ Receptor Antibody Levels Predict Clinical Outcome and Therapeutic Response in Patients with Primary Membranous Nephropathy** Elion Hoxha, Ina Ellen Thiele, Gunther Zahner, Ulf Panzer, Sigrid Harendza, Rolf A. Stahl. *III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

**Background:** The prediction of clinical outcome and the decision for an immunosuppressive treatment in patients with Membranous Nephropathy (MN) currently relies on prolonged follow-up measurements of proteinuria. Yet, changes in proteinuria do not necessarily reflect the activity of immunologic disease. A marker which would reflect immunologic and clinical activity in real time and predict clinical outcome could substantially improve the care of patients with MN.Phospholipase $A_2$ Receptor antibody ($PLA_2R$-Ab) levels may serve as such a biomarker.

**Methods:** The correlation of $PLA_2R$-Ab levels with proteinuria and their predictive value for clinical response was analyzed in a prospective multicenter study including 133 patients with primary MN. The patients were followed for up to 24 months. $PLA_2R$-Ab levels were assessed at the time of inclusion in the study and at 3 months intervals.

**Results:** During the time of observation 101 patients were treated with immunosuppressants, 32 patients received supportive care only. Following immunosuppression $PLA_2R$-Ab level fell rapidly (81% in 3 months), while the decrease in proteinuria was protracted (39% after 3 months). Immunosuppressive regimens (calcineurin inhibitors, alkylating agents or rituximab) did not show differences in the efficacy to reduce $PLA_2R$-Ab levels. In patients with spontaneous remission of proteinuria, $PLA_2R$-Ab levels fell (from 197±279 U/ml at study start to 7±6 U/ml at 15 months) but remained high in patients who did not show a reduction in proteinuria (from 193±184 U/ml at study start to 98±88 U/ml at 15 months). At the time of inclusion in the study there was a significant difference in the $PLA_2R$-Ab levels between patients who experienced remission of proteinuria after 12 months and those with no remission of proteinuria (Remission: 179±207 U/ml; No remission: 311±297 U/ml).

**Conclusions:** $PLA_2R$-Ab levels reflect clinical disease activity and predict clinical response in patients with primary MN. $PLA_2R$-Ab are reliable real time markers of disease activity in patients with primary MN and may affect clinical outcome.

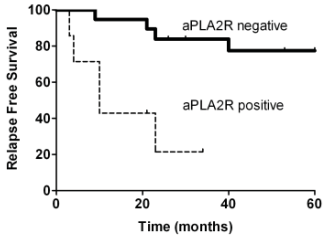
## FR-OR049

**Measurement of AntiPLA2R Antibodies Predicts Relapse Rate after Immunosuppressive Therapy in Patients with Idiopathic Membranous Nephropathy** Julia M. Hofstra,[1] Anneke Bech,[1] Paul E. Brenchley,[2] Jack F. Wetzels.[1] *[1]Nephrology, Radboud Univ Nijmegen Medical Center, Nijmegen, Netherlands; [2]Nephrology, Manchester Institute of Nephrology and Transplantation, Manchester, United Kingdom.*

**Background:** Antibodies against the phospholipase A2 receptor (PLA2R-ab) are present in 70% of patients with idiopathic membranous nephropathy (iMN). During immunosuppressive therapy a decrease of PLA2R-ab precedes remission of proteinuria. The clinical value of repeated PLA2R-ab measurements is unknown. Aim of this study is to evaluate if PLA2R-ab levels at the end of immunosuppressive treatment predict relapse rate in iMN.

**Methods:** We evaluated patients with iMN, and positive PLA2R-ab, who were treated with immunosuppression, and developed a remission. PLA2R-ab levels were measured with ELISA (Kanigicherla et al, 2013, KI) in serum samples collected at baseline and at the end of treatment.

**Results:** In total 26 patients were included (18 male). Treatment consisted of cyclophosphamide (n=11), MMF (n=8 ), or ACTH (n=7). At the start of treatment, the median eGFR was 59 ml/min/1.73m² (IQR 49-74), serum albumin 25 g/l (IQR 19-30) and PLA2R-ab 201 U/l (IQR 122-314). At the end of therapy, 27% of patients still were PLA2R-ab positive. During follow-up 35% of all patients developed a relapse of proteinuria (> 3.5 g/day with ≥ 50% increase from lowest level during remission) within 5 years after therapy. The risk of relapse in patients with PLA2R-ab positivity at end of treatment was significantly higher when compared to patients in whom PLA2R-ab had disappeared (relapse rate 21% versus 71%, p =<0.01).



**Conclusions:** PLA2R-ab remained elevated in a significant number of patients with iMN treated with immunosuppressive therapy. The persistence of antibodies was associated with a higher relapse rate. Our observations suggest that measurement of PLA2R-ab may guide duration of therapy in patients with iMN.

## FR-OR050

**Changes in Plasma Soluble Urokinase-Type Plasminogen Activator Receptor (suPAR) Levels Correlate with Naive T-Regulatory and Monocyte Subset Populations in Nephrotic Children with Focal Segmental Glomerulosclerosis (FSGS) following Rituximab Therapy** Wee Song Yeo,[1] Chang Yien Chan,[1] Changli Wei,[2] Jochen Reiser,[2] Subhra K. Biswas,[3] Hui Kim Yap.[1] *[1]Pediatrics, National Univ of Singapore, Singapore; [2]Internal Medicine, Rush Univ, Chicago, IL; [3]Singapore Immunology Network, A*STAR, Singapore.*

**Background:** Recent studies suggest suPAR as the plausible circulating factor in FSGS. In recent years, rituximab has been used in patients with nephrotic syndrome who have failed therapy with conventional immunosuppressants. This study aimed to examine the effect of rituximab in children with FSGS on plasma suPAR levels and identify the source of suPAR by correlating suPAR trends with various immunological subsets.

**Methods:** Eleven nephrotic children with FSGS were given 2-weekly doses of rituximab (375 mg/m²) for 1-4 doses. Urinary/blood biochemistry and immunological subsets (T-, B-, NK cells, and monocytes) with corresponding plasma suPAR levels were monitored throughout the study. Statistical analysis was done using Mann-Whitney U test and Spearman's correlation.

**Results:** Five (45%) patients achieved complete response defined as urine protein:creatinine ratio of <0.02 g/mmol and ability to wean off at least 2 immunosuppressants post-rituximab. Plasma suPAR levels did not differ significantly between complete responders (2622.02±298.10 pg/ml) and incomplete responders (3205.18±481.34 pg/ml) prior to initiation of rituximab therapy (p=0.47). Complete responders showed a negative mean-fold change in plasma suPAR levels (ΔsuPAR) (-0.033 ±0.077 pg/ml) compared to incomplete responders (0.436±0.173 pg/ml) (p=0.045). Significant correlation was shown between ΔsuPAR and mean change in naïve T-regulatory cells (CD25+CD45RA+CD4+) (ΔNTregs) (r=-0.85, p<0.001), as well as mean change in monocyte subsets (CD14dimCD16+ and CD14+CD16+)(Δmonocytes) (r=0.65, p=0.042). ΔNTregs also demonstrated a significant negative correlation with Δmonocytes (r=-0.75, p=0.013).

**Conclusions:** Our study suggested that the efficacy of action of rituximab in FSGS may be mediated via decrease in plasma suPAR levels, and this may be related to monocyte subset changes, regulated by naïve T-regulatory cells.

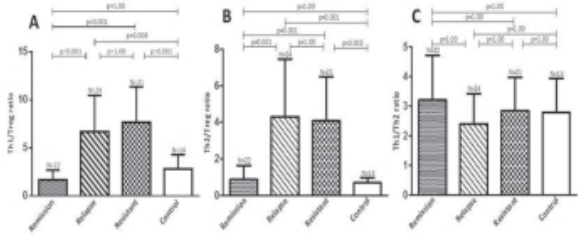
## FR-OR051

**Expression of Permeable Glycoprotein on Peripheral Blood T Lymphocytes with Regulatory and Effectors T Cells Imbalance Determines Steroid Response in Childhood Nephrotic Syndrome** Narayan Prasad,[1] Akhilesh Jaiswal,[1] Vikas Agarwal,[2] Brijesh Yadav,[1] Deepak Tripathi,[2] Amit Gupta,[1] Raj K. Sharma.[1] *[1]Nephrology, SGPGIMS, Lucknow, UP, India; [2]Immunology, SGPGIMS.*

**Background:** Permeable glycoprotein (Pgp) expression on lymphocytes may be related to cell mediated immune response and steroid response in Nephrotic syndrome (NS).We aimed to study the expression of Pgp on CD4+IFN-γ+ Th1, CD4+IL-4+ Th2 and CD4+CD25+FoxP3+ regulatory T lymphocyte (Treg) with their imbalance in steroid response in NS.

**Methods:** From patients of NS, 22 patients in sustained remission, 24 in relapse, and 21 steroid resistant patients and 14 healthy controls were included in the study .Circulating Treg, Th1 and Th2 lymphocytes and P-gp Expression on these T reg , Th1 and Th2 lymphocytes in patients in sustained remission, relapse,steroid resistant (SRNS) and healthy control were measured.

**Results:** The absolute expression of Pgp was greater in relapsed (83.51±37.22, P=0.001) and SRNS (101.72±44.91, P=0.001) compared to that of patients in remission (33.16±23.97) and controls (33.38±17.05). Th2 cells(%) in patients with remission (5.18±3.12) was significantly less than that of relapsed (9.89±5.23; P=0.006) or SRNS patients (10.74±5.91; P=0.001); and similar to that of control subjects (4.91±1.24) p=1.0. The % of Th1 cells was significantly lesser in patients with sustained remission (10.37±3.49) compared to that of patients during relapse (16.18±7.19; P=0.008); SRNS patients (20.24±7.01; P=0.001); and in controls (18.38±3.28; P=0.006). The Treg cells was significantly higher in controls and remission compared to that of SRNS and relapsed patients. The ratio of Th1/ Tregs, Th2/Tregs and Th1/ Th2 are shown in Figure 1 indicate that imbalance between Treg and Teff is responsible for remission and SRNS state.



**Conclusions:** The imbalance of Treg and Teff cells with expression of P-gp plays role in steroid response in NS.

*Funding:* Government Support - Non-U.S.

## FR-OR052

**Soluble Urokinase Receptor (suPAR) Is Not a Clinical Marker for Focal Segmental Glomerulosclerosis** Bjorn Meijers,[1] Ruben Poesen,[1] Markus Storr,[2] Kathleen Claes,[1] Dirk R. Kuypers,[1] Pieter Evenepoel.[1] *[1]Nephrology, Univ Hospitals Leuven, Belgium; [2]Gambro Dialysatoren GmbH, Hechingen, Germany.*

**Background:** Soluble urokinase receptor (suPAR) promotes proteinuria and induces glomerular focal segmental glomerulosclerosis (FSGS)-like lesions in mice. Furthermore, a serum suPAR concentration cut-off of 3000 pg/mL has been proposed as clinical biomarker for FSGS patients. Interestingly, several studies in patients with glomerulopathy demonstrated an inverse correlation between the eGFR and suPAR concentrations. As patients with FSGS present at different eGFR, we studied the relationship between eGFR and suPAR in a large cohort of non-FSGS patients.

**Methods:** We measured suPAR concentrations in patients with chronic kidney disease (CKD) from the Leuven mild-to-moderate CKD study (Clinical trials protocol NCT00441623) using the human uPAR enzyme-linked immune sorbent assay (ELISA, R&D systems). Variables determining suPAR concentrations were identified using multivariate regression analysis.

**Results:** We determined suPAR concentrations in 486 patients with known non-FSGS CKD (controls), and in 18 patients with biopsy-proven FSGS (cases: 6 active disease, 2 partial remission and 10 complete remission). In multivariate analyses, eGFR was the strongest determinant of suPAR concentrations (P<0.0001, $R^2$ 0.46). suPAR concentrations exceeded the proposed cut-off for FSGS of 3000 pg/mL in 17%, 39% and 88% in patients with eGFR of more than 60, 45-60 and 30-45 ml/min/1.73 m², respectively. In patients with eGFR of less than 30, suPAR concentrations exceeded the proposed cut-off in 95% of patients. suPAR levels of patients with biopsy-proven FSGS were interspersed with non-FSGS controls and for any given eGFR did not discriminate FSGS cases from non-FSGS controls.

**Conclusions:** This study does not support an absolute, i.e. eGFR independent, suPAR concentration cut-off as biomarker for FSGS. Our data moreover question the validity of relative, i.e. eGFR-dependent, suPAR cut-off values.

## FR-OR053

**Randomized Controlled Trial of Low-Dose Intravenous Cyclophosphamide versus Oral Mycophenolate Mofetil in Treatment of Lupus Nephritis** Ajay Goyal,[1] Manish Rathi,[1] Vivekanand Jha,[1] Aman Sharma,[2] Kusum Joshi,[3] Ritambhra Nada,[3] Vinay Sakhuja.[1] *[1]Nephrology, PGIMER, Chandigarh, India; [2]Internal Medicine, PGIMER, Chandigarh, India; [3]Pathology, PGIMER, Chandigarh, India.*

**Background:** Several recent controlled trials establish Mycophenolate Mofetil (MMF) as one of the first-choice drugs for inducing a remission in lupus nephritis. However, in most of these trials MMF was compared with either oral or high dose monthly pulses of intravenous cyclophosphamide (CYC). The current study was aimed at comparing the efficacy and safety of MMF with low-dose intravenous CYC (Euro-Lupus regimen) in these patients.

**Methods:** The study was an open label, prospective, randomized, two-arm study which included patients who had a kidney biopsy diagnosis of lupus nephritis (Class III/ IV/V). Out of 94 patients who were screened for inclusion, 53 patients were randomized to receive either low dose intravenous CYC (6 fortnightly pulses at a fixed dose of 500 mg) or MMF (target dosage 3g/day) as induction treatment for a period of 24 weeks in addition to steroids. The primary end point was a pre-specified decrease in proteinuria and

stabilization or improvement in serum creatinine. Secondary end points included complete renal remission, systemic disease activity (by Safety of Exogenous Estrogens in Lupus Erythematosus National Assessment/Systemic Lupus Erythematosus Disease Activity Index) and adverse events.

**Results:** At the end of 24 weeks, both groups had similar response rates. In the intention-to-treat analysis, 19 of the 26 patients (73.1%) who received CYC and 19 of the 27 patients receiving MMF (70.4%) showed a response (primary end point) (95% CI, 0.34 - 3.78%; *p*=0.83). Complete remission was achieved in 13 of the 26 patients (50.0%) and 13 of the 27 patients (48.1%), respectively (*p*=0.89). Gastro-intestinal symptoms and infections occurred in significantly lesser number of patients in CYC group as compared to MMF group. Four patients (1 in CYC group and 3 in MMF group) died during the study period.

**Conclusions:** MMF had similar efficacy in comparison to low dose intravenous CYC in terms of response and remission rates, however, it was associated with more adverse events.

## FR-OR054

### Long Term Follow Up of Patients Who Received Repeat Dose Rituximab as Maintenance Therapy for ANCA Associated Vasculitis (AAV)

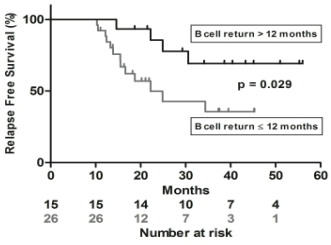
Federico Alberici, Rona M. Smith, Rachel B. Jones, David R.W. Jayne. *Vasculitis and Lupus Clinic, Addenbrooke's Hospital, Cambridge, United Kingdom.*

**Background:** Rituximab (RTX) is an established induction agent in AAV. We previously showed that repeat dose RTX for two years is a potential maintenance strategy. Relapse risk after repeat dose RTX discontinuation is not known.

**Methods:** We report long term follow up of patients who received a two year repeat dose RTX regimen for relapsing/refractory AAV (1g x 2, then 1g/6 months x 4).

**Results:** Sixty-nine patients completed the two year RTX course, during the treatment course 9 (13%) relapsed. Median post-treatment follow-up was 22.7 months (IQR12.5-38.6). 25 relapsed after a median of 30.6 months (95%CI 18.4-42.7). For relapse treatment, 20 received RTX and five other agents. By 6 months, 21/25 (88%) had regained remission.

54/69 were ANCA negative at the end of the RTX course. 12 (22%) became ANCA positive during follow-up, of which 9 (75%) relapsed a median of 1.6 months (0.5-4.6) after. 15 remained ANCA positive after the RTX course, of which 3 (20%) relapsed. Thus,12/25 (48%) had detectable ANCA at relapse. Switch of ANCA to positive conferred an 11.81 fold increased risk of relapse compared to those whom maintain their ANCA status (p=0.001). Of 56 patients (81%) with available B-cell counts, 42 (75%) had B-cell return a median of 11 months (IQR 9-13) after the RTX course. 17/25 (68%) had detectable B cells at relapse, and in 11/17 (65%) B cells had returned in the 6 months preceding relapse. The patients experiencing B-cell return within 12 months had a significant shorter relapse free survival compared to the ones whose B-cell returned after 12 months.



**Conclusions:** Following a two year RTX course, relapse risk was lower than that seen following a single RTX course for relapsing GPA. A switch from ANCA negativity to positivity and earlier B cell return were relapse predictors.

## FR-OR055

### Rituximab and Cyclophosphamide Decreases Dialysis and Death Rates in Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis

JulieAnne G. McGregor,[1] Susan L. Hogan,[1] Elizabeth Studstill,[1] Caroline J. Poulton,[1] Yichun Hu,[1] Roberto Negrete-Lopez,[2] Jason M. Kidd,[1] Suzanne L. Katsanos,[1] Donna O. Bunch,[1] Patrick H. Nachman,[1] Ronald J. Falk.[1] *[1]UNC Kidney Center, Chapel Hill, NC; [2]Hospital Universitario-UANL, Monterrey, Nuevo Leon, Mexico.*

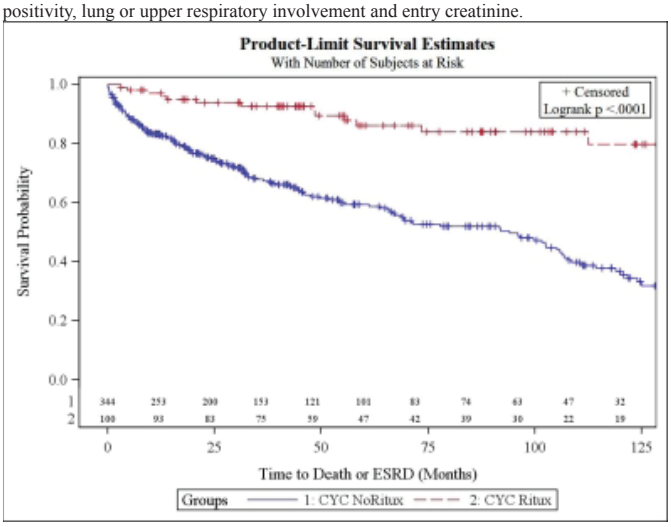
**Background:** Current evidence for use of rituximab (RTX) in Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis (AAV) has not shown improvement in hard outcomes including dialysis or death.

**Methods:** 100 patients with AAV (1991-2011) who received RTX, cyclophosphamide (CYC) and corticosteroids at any time were compared to 351 patients who received CYC and corticosteroids without RTX for treatment. End-stage renal disease (ESRD) at onset was excluded. Comparisons were done by Fisher's exact test for categorical and Kruskal-Wallis test for continuous variables. Multivariable Cox Regression was used. Incidence per person-year of follow-up was calculated.

**Results:** 166 RTX courses were given to 100 patients who had previously or concurrently received CYC. 4 patients had RTX at induction, 18 for resistance to CYC, 123 for relapse and 21 for remission maintenance.

Incidence of infection was higher in patients treated with CYC alone than patients also treated with RTX (0.20 95% CI [0.19, 0.21]; (0.13 95% CI [0.12, 0.15], respectively, p=<0.0001); likewise for severe infection (0.24 95% CI [0.21, 0.28], 0.17 95% CI [0.13, 0.22], respectively p=0.0150).

Those treated with RTX and CYC were less likely to reach death or dialysis than those treated with CYC alone which remained significant controlling for age, MPO/PR3 ANCA positivity, lung or upper respiratory involvement and entry creatinine.



HR for death or ESRD among patients who at some point received RTX was 0.27, 95% CI: 0.15-0.48, p=<0.0001.

**Conclusions:** Patients treated with RTX and CYC were 3.7 times less likely to reach ESRD and death, and had a lower incidence of infections and severe infections.

## FR-OR056

### Genetic Analysis of the Coagulation Pathway in Atypical Hemolytic Uremic Syndrome

Richard J. Smith, Fengxiao Bu, Nicole Meyer, Kai Wang, Carla M. Nester. *Univ of Iowa.*

**Background:** Atypical Hemolytic Uremic Syndrome (aHUS) is a complement-driven disease. Approximately 40% of patients carry single mutations in CFH, C3, CFI, CFB or CD46; multiple mutations are identified in 3% of patients. We hypothesized that additional genetic risk factors for aHUS could be identified by screening all genes in the coagulation pathway. We used targeted genomic enrichment and massively parallel sequencing (TGE+MPS) to screen all coding exons of the 85 genes that comprise the complement and coagulation pathways.

**Methods:** 47 patients with sporadic aHUS patients were included in this study. TGE was performed using an RNA-bait panel and MPS of captured libraries was completed on a HiSeq 2000 and a MiSeq. Data were analyzed using a local installation of the open-source Galaxy software running on a high-performance computing cluster at the University of Iowa.

**Results:** Mean total reads per sample approximated 9,000,000, with >97% mapping to the reference genome and >50% mapping to targeted regions. Average coverage-per-targeted-base was larger than 1600 reads; 99% of targeted regions had 30x coverage. Of the 9,966 variants identified, 9,424 (94.56%) passed quality control. After filtering by frequency and predicted functionality, 25 novel and 101 non-synonymous rare variants (nsRVs) remained. 55 of these variants were known or predicted to be deleterious and were carried by 32 patients. 27 of these 55 variants were found in previously reported aHUS genes, 18 were found in other complement-related genes, and 16 were found in coagulation pathway genes. The greatest number of deleterious variants was found in *CFH* and the second greatest number was found in *PLG*. Rare variants in *CFB* (rs143259927, Fisher Exact P = 0.001) and *PLAU* (rs55744193, Fisher Exact P = 0.01) were also significantly correlated with the disease.

**Conclusions:** As expected, most deleterious variants (39 of 55) were found in complement genes implicated in the pathogenesis of aHUS. However, variants in coagulation pathway genes, especially in antithrombotic genes *PLAU*, *PLG*, *PROC* and *ADAMTS13*, were also found in aHUS patients implicating this pathway in the pathogenesis of aHUS.

## FR-OR057

### Eculizumab (ECU) Inhibits Thrombotic Microangiopathy (TMA) and Improves Renal Function in Adult Atypical Hemolytic Uremic Syndrome (aHUS) Patients (Pts)

Fadi Fakhouri, Maryvonne Hourmant, Josep M. Campistol, Spero R. Cataland, Mario Espinosa, A. Osama Gaber, Jan Menne, Enrico E. Minetti, Francois Provot, Eric Rondeau, Piero Ruggenenti, Laurent E. Weekers, Masayo Ogawa, Camille L. Bedrosian, Christophe M. Legendre. *The C10-004 Study Group.*

**Background:** aHUS is a rare, severe, genetic, life-threatening disease of chronic complement-mediated TMA. ECU, a terminal complement inhibitor, is approved for the treatment of aHUS. Here, we report safety and efficacy results of ECU in adult pts from the largest prospective study performed in aHUS.

**Methods:** This was a single-arm, Phase 2 trial of ECU in adult pts (≥18 yrs) with aHUS and platelets <LLN at screening. Prior plasma exchange or infusion (PE/PI) was not required for inclusion. The primary endpoint was the proportion of pts with complete TMA response at 26 wks.

**Results:** 41 pts enrolled and 38 (93%) received 26 wks of treatment. 30 pts (73%) were newly diagnosed (median duration to treatment initiation of 2 weeks). Six pts had no PE/PI during the current clinical manifestation. At wk 26, 30 pts (73%) achieved the primary endpoint.

| Table: Wk 26 ITT Results (N=41) | |
|---|---|
| **Baseline Demographics and Disease Characteristics** | |
| Age (years) – mean (SD) | 40.3 (15.3) |
| Female sex – n (%) | 28 (68) |
| Identified complement regulatory protein mutation or auto-antibody – n (%) | 21 (51) |
| Time from aHUS diagnosis until screening (months) – median (range) | 0.8 (0–311) |
| Newly diagnosed pts – n (%) | 30 (73) |
| Duration of current clinical manifestation of aHUS (months) – median (range) | 0.5 (0.0–19.1) |
| PE/PI during current clinical manifestation of aHUS – n (%) | 35 (85) |
| Dialysis at baseline – n (%) | 24 (59) |
| Prior renal transplant – n (%) | 9 (22) |
| Platelet count <150x10⁹/L – n (%) | 27 (66) |
| LDH >ULN – n (%) | 32 (78) |
| eGFR ≤60 mL/min/1.73 m² – n (%) | 41 (100) |
| **Efficacy Outcomes** | |
| Complete TMA response – n (%) | 30 (73) |
| Hematologic normalization– n (%) | 36 (88) |
| Platelet count normalization – n (%) | 40 (98) |
| Platelet count increase (x10⁹/L) – mean (95% CI) | 119 (94; 145) *P*<0.0001 |
| eGFR increase from baseline ≥15 mL/min/1.73 m² – n (%) | 22 (54) |
| eGFR increase from baseline (mL/min/1.73 m²) – mean (95% CI) | 26.1 (19.8; 32.4) *P*<0.0001 |
| CKD improvement ≥1 stage from baseline – n (%) | 26 (63) |
| **Complete TMA response**: normalization of platelets and LDH, and <25% increase in serum Cr from baseline on 2 consecutive measurements ≥4 wks apart. **Hematologic normalization:** platelet and LDH normalized for ≥2 consecutive measurements ≥4 wks apart. **Platelet count normalization:** platelet count ≥150x10⁹/L ≥2 consecutive measurements ≥4 wks apart. | |

24/41 pts (59%) were on dialysis at BL, 20 of whom discontinued by wk 26. Mean (95% CI) eGFR increase from baseline was 26.1 mL/min/1.73 m² (19.8; 32.4: *P*<0.0001). Two pts who were not on dialysis at baseline initiated during the treatment period and remained on dialysis through 26 wks. QoL significantly improved. ECU was generally safe and well tolerated. Two pts had meningococcal infections; one pt continued ECU. No pts died.

**Conclusions:** ECU normalized hematologic parameters and significantly improved renal function and QoL. 83% of pts on dialysis at baseline were able to discontinue by wk 26. The results of this prospective study confirm that ECU inhibits complement-mediated TMA in adult aHUS pts. The study is ongoing.

## FR-OR058

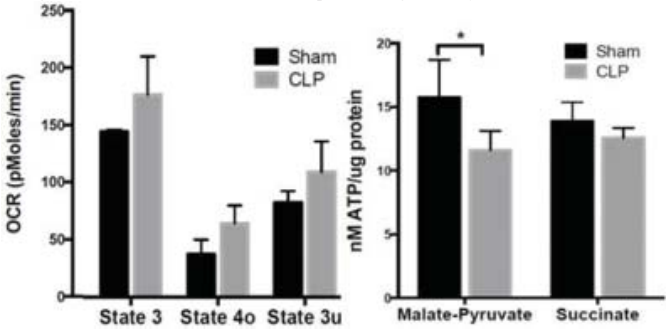
### Mitochondrial Dysfunction in Sepsis-Associated Acute Kidney Injury

Prabhleen Singh, Koji Aoyama, Joanna Thomas. *Medicine, UCSD & VASDHS, San Diego, CA.*

**Background:** Sepsis-associated AKI is frequently observed and has poor prognosis. The lack of complete understanding of its pathogenesis is a significant barrier to progress and fresh insights into its pathogenesis are critically needed.

**Methods:** We examined renal oxygenation (oxygen delivery and consumption) and mitochondrial function in the cecal ligation and puncture (CLP) model of sepsis in rats. RBF, GFR, and kidney oxygen consumption (QO2) were measured at 6 and 24 hours post CLP or sham surgery. Mitochondrial QO2, ATP generation, HIF1α expression and response to HIF-1α activation by DMOG was assessed. Data presented as mean±sem.

**Results:** At 6 and 24 hours, GFR was significantly lower in CLP (2.5±0.4 vs. 3.6±0.2 ml/min, p=0.03 at 6 hours and 1.2±0.3 vs. 3.3±0.2 ml/min, p<0.001 at 24 hours). While RBF and $O_2$ delivery was largely unchanged in CLP, renal $O_2$ extraction factored for GFR was higher compared to shams, (0.023±0.002 vs. 0.01±0.001 vol%ml/min, p=0.001) as was renal $QO_2$/GFR (0.11±0.01 vs. 0.05±0.01 ml/min, p=0.04). HIF-1a expression was seen in cortical and medullary tubules indicating hypoxia due to oxygen demand-supply mismatch. There was a trend for improvement in GFR at both 6 and 24 hours. In CLP mitochondria, we found elevated rates of both coupled and uncoupled respiration. However, ATP generation measured in the same samples was significantly lower.



**Conclusions:** We demonstrate increased renal oxygen utilization in the CLP rats sespite lower GFR and reabsorptive load leading to hypoxia. We also demonstrate dissociation between excess oxygen consumption and ATP generation in CLP mitochondria, which can explain the inefficiency in oxygen utilization. We are investigating alterations in mitochondrial dynamics which could explain mitochondrial dysfunction and tubular injury, and the role of HIF-1α pathway in ameliorating mitochondrial dysfunction and consequently global renal function.

## FR-OR059

### Even Delayed Therapy with the Mitochondria-Targeted Antioxidant Mito-TEMPO Ameliorates Sepsis-Induced Acute Kidney Injury

Naeem K. Patil, Lee Ann MacMillan-Crow, Philip R. Mayeux. *Pharmacology and Toxicology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

**Background:** Sepsis is characterized by severe systemic inflammatory response to a microbial infection. Acute kidney injury (AKI) is a frequently encountered complication of sepsis and leads to a high mortality rate ~70%. Human and animal studies suggest that mitochondrial dysfunction plays an important role in sepsis induced multi-organ failure, but the importance of mitochondrial dysfunction in renal injury during sepsis has not been well studied.

**Methods:** We used a clinically relevant cecal ligation and puncture (CLP) murine model of sepsis to assess renal mitochondrial function. High resolution respirometry was used to measure mitochondrial complex respiration. Intravital video microscopy was used to study oxidant generation and renal microcirculation.

**Results:** As early as 4h after CLP, the activity of manganese superoxide dismutase (MnSOD) was decreased by 50% and inhibition was sustained through 36h. This was associated with increased mitochondrial superoxide levels, implying compromised mitochondrial antioxidant defense. CLP also caused a time-dependent decrease in renal mitochondrial complex I and II/III respiration and a reduction in renal ATP levels. *Thus, we hypothesized that a mitochondrial specific antioxidant Mito-TEMPO (MT) could protect renal mitochondria and attenuate sepsis-induced AKI.* Dose-response studies with 3, 10 and 30mg/kg ip showed that 10mg/kg was the lowest most efficacious dose that decreased renal mitochondrial superoxide levels after CLP. Thus, this dose was used in a clinically relevant delayed dosing paradigm. MT given at 6h post CLP decreased mitochondrial superoxide levels, protected complex I and II/III respiration, restored MnSOD activity and improved renal microcirculation by 18h. Importantly, delayed therapy with MT significantly increased the 96h survival rate from 40% in untreated septic mice to ~83%.

**Conclusions:** Mitochondrial dysfunction is a critical event in sepsis induced AKI and even delayed therapy with mitochondria-targeted antioxidant MT represents a promising approach to treat septic AKI. Supported by NIH DK075991 (PRM) and AHA 12PRE12040174 (NKP).

## FR-OR060

### Enhanced Glycolytic Activity and Mitochondrial Dysfunction in a Mouse Model of Sepsis-Induced Acute Kidney Injury

Joshua Andrew Smith, L. Jay Stallons, Rick G. Schnellmann. *Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.*

**Background:** Sepsis is a common cause of acute kidney injury (AKI), accounting for approximately half of AKI cases in the ICU. Recent evidence indicates that septic AKI results in renal mitochondrial dysfunction. Because the mechanisms by which renal cortical ATP is maintained in the presence of mitochondrial dysfunction are unknown, we investigated glycolysis as a source of ATP production in a mouse model of sepsis-induced AKI.

**Methods:** Male C57BL/6 mice were treated with lipopolysaccharide (LPS, 10 mg/kg, i.p.) and kidneys harvested (3, 6, and 18 h post-LPS). Renal function was determined by measuring blood urea nitrogen (BUN) and urine output. Mitochondrial electron transport chain and glycolytic mRNAs and proteins in the renal cortex were assessed by qRT-PCR and immunoblot analysis. Standard biochemical assays were used to determine renal cortical hexokinase (HK), phosphofructokinase (PFK), and pyruvate kinase (PK) activities.

**Results:** LPS administration resulted in AKI with increased BUN and reduced urine output 18 h post-LPS. Transcript levels of mitochondrial markers (PGC-1α, ATPSb, NDUFS1, and COX1) were reduced >50% 18 h post-LPS treatment. Expression of HK2 mRNA increased (~2-fold) in these mice, while expression of other glycolysis-related mRNAs remained unchanged (glut1, pfkl, pkm, and ldha) or decreased (pfkm, pgk1, and pdk1). Immunoblot analysis revealed no changes in protein levels of glycolytic enzymes (HK1, HK2, PFKP, PKM1/2, and LDHA). However, a ~3-fold increase in HK activity was observed 3 h after LPS exposure and was maintained over 18 h.

**Conclusions:** Renal hexokinase activity rapidly increases in conjunction with the loss of mitochondrial function following LPS exposure. These findings suggest that glycolysis may be induced to maintain ATP levels and renal function in sepsis-induced AKI.

**Muc1 Is Protective in a Mouse Model of Acute Kidney Injury** Rebecca P. Hughey,[1] Sheldon Bastacky,[3] Kenneth R. Hallows,[1] Nuria M. Pastor-Soler,[1] Timothy A. Sutton.[2] *[1]Dept of Medicine, Renal-Electrolyte Div, Univ of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Dept of Medicine, Div of Nephrology, Indiana Univ School of Medicine, Indianapolis, IN; [3]Div of Anatomic Pathology, Dept of Pathology, Univ of Pittsburgh School of Medicine, Pittsburgh, PA.*

**Background:** Ischemia-reperfusion injury (IRI) due to hypotension or sepsis is the most common cause of acute kidney injury (AKI). Human MUC1 is an apical transmembrane protein expressed in the distal tubules and collecting ducts of the adult kidney. MUC1 is induced by hypoxia and directly interacts with both HIF-1 and β-catenin in the nucleus where MUC1 transactivates these protective pathways and modulates metabolic adaptations and promotes cell survival.

**Methods:** To assess the function of Muc1 during AKI, we used a model of IRI in Muc1 knockout (KO) and congenic control C7BL/6 mice. Both renal pedicles of mice were clamped for 19 min prior to recovery periods of 0, 4, 24 and 72 h when blood and kidneys were recovered.

**Results:** Profiles of serum creatinine and BUN were significantly higher in the profile from Muc1 KO than control mice consistent with increased kidney damage and delayed recovery of kidney function in the absence of Muc1. This difference was readily apparent in the microscopic analysis of kidney morphology after H&E staining and scoring of tubule damage. Immunoblot analysis of kidney extracts revealed a significant increase in Muc1 levels consistent with its induction by hypoxia. We observed Muc1-dependent changes in glycolytic enzymes (e.g., LDHA) and kinases (e.g., PDK1 and PKM2) involved in the hypoxia-induced switch of glucose metabolism from oxidative to glycolytic, consistent with Muc1 transactivation of the HIF-1 pathway. This was supported by finding an accentuated and prolonged activation of AMPK in the kidneys of Muc1 KO mice after IRI when compared to controls, reflecting energy stress. As PKM2 also transactivates the β-catenin pathway we discovered significant Muc1-dependent increases in β-catenin and its downstream target consistent with a role for Muc1 in cell survival.

**Conclusions:** Altogether the data indicate that Muc1 is required for both efficient adaptation of glucose metabolism in response to IRI to avoid energy stress and for promoting tubule survival and recovery.

**Increasing cGMP-Dependent Protein Kinase I Activity Attenuates Cisplatin Induced Kidney Injury through Protection of Mitochondria Function** Shuxia Wang. *Nutritional Sciences, Univ of Kentucky, Lexington, KY.*

**Background:** Cisplatin is widely used to treat malignancies. However, its major limitation is the development of dose-dependent nephrotoxicity. The precise mechanisms of cisplatin-induced kidney damage remain unclear, and the renoprotective agents during cisplatin treatment are still lacking.

**Methods:** Both in vitro proximal tubular cell culture and in vivo ischemia-reperfusion induced acute kidney injury mouse model were utilized. In adidiiton, genetic as well as pharmacological approach was used to increase cGMP-dependent protien kinase activity in mice and the development of acute kidney injury in these mice was determined.

**Results:** We demonstrated that the expression and activity of cGMP-dependent protein kinase-I (PKG-I) was reduced in cisplatin treated renal tubular cells in vitro as well as in the kidney tissues from cisplatin treated mice in vivo. Increasing PKG activity by both pharmacological and genetic approaches attenuated cisplatin-induced kidney cell apoptosis in vitro. This was accompanied by decreased Bax/Bcl2 ratio, caspase 3 activity, and cytochrome c release. Cisplatin-induced mitochondria membrane potential loss in the tubular cells was also prevented by increased PKG activity. All of these data suggest a protective effect of PKG on mitochondria function in renal tubular cells. Importantly, increasing PKG activity pharmacologically or genetically diminished cisplatin-induced tubular damage and preserved renal function during cisplatin treatment in vivo. Mitochondria structural and functional damage in the kidney from cisplatin treated mice was inhibited by increased PKG activity. In addition, increasing PKG activity enhanced ciaplatin induced cell death in several cancer cell lines.

**Conclusions:** These results suggest that increasing PKG activity may be a novel option for renoprotection during cisplatin-based chemotherapy.

**Conditional Proximal Tubule Mitofusin 2 Knockout (cPT-MFN2 KO) Accelerates Renal Recovery and Improves Survival after Ischemia** Zhiyong Wang, Jonathan M. Gall, Ramon G. Bonegio, Andrea Havasi, John H. Schwartz, Steven C. Borkan. *Renal Section, Boston Univ Medical Center, Boston, MA.*

**Background:** Elimination of MFN 2, a major mitochondrial elongation protein, sensitizes proximal tubule (PT) cells to Bax-mediated death after *in vitro* stress. To assess its role in the intact kidney, the effect of cPT-MFN2 KO was evaluated after renal ischemia *in vivo.*

**Methods:** cPT-MFN2 KO mice were generated by crossing MFN2 floxed mice ($MFN2^{ff}$) with animals harboring a testosterone activated, PT-specific KAP2-Cre. These mice were supplemented with exogenous testosterone to enhance conditional PT MFN2 knockout prior to ischemia induced by bilateral renal pedicle occlusion. Testosterone treated parental line mice served as control. MFN2 KO in cultured cells was achieved by exposing primary PT cells harvested from $MFN2^{ff}$ mice to Cre expressing adenovirus.

**Results:** Compared to control, testosterone exposure in $MFN2^{ff}$–MFN2 KO mice selectively decreased PT MFN2 expression and resulted in short, punctate mitochondria in renal cortical PT cells. After transient renal ischemia induced AKI, only 28% of testosterone-treated control mice survived (n=18). In contrast, 86% of cPT-MFN2-KO animals survived (n=22; $P<0.001$). Enhanced survival in cPT-MFN2 KO mice was associated with a significantly lower peak BUN on days 1-2 post injury. Although histologic injury score did not differ between groups, cPT-MFN2-KO mice exhibited a four-fold increase in cell proliferation restricted to the renal cortex, the region targeted by the conditional MFN2 KO ($P<0.05$). Preliminary studies in primary PT cells suggest that MFN2 KO enhances proliferation by increasing RAS-dependent, ERK-1/2 activation. MFN2 binds p21 RAS, linking cell MFN2 to ERK-1/2 mediated PT cell proliferation.

**Conclusions:** These results support the hypothesis that PT MFN2 exerts independent, dual roles on: (1) mitochondrial morphology that regulates Bax-mediated apoptosis and; (2) ERK-1/2 dependent PT cell proliferation during renal recovery from ischemia. We speculate that MFN2 KO enhances survival by simultaneously increasing the removal of damaged PT cells by apoptosis and accelerating repair of injured tubular epithelium after ischemic AKI.

**Activation of AMP-Activated Protein Kinase Contributes to Cisplatin-Induced Acute Kidney Injury** Yanlin Wang, Xiaogao Jin. *Deaprtment of Medicine, Div of Nephrology, Baylor College of Medicine, Houston, TX.*

**Background:** Cisplatin, a commonly used anti-cancer drug, has been shown to induce acute kidney injury, which limits its clinical use in cancer treatment. Emerging evidence has suggested that AMP-activated protein kinase (AMPK), which functions as a cellular energy sensor, is activated by various cellular stresses. However, the potential role of AMPK in cisplatin-induced acute kidney injury has not been studied.

**Methods:** We used mouse renal tubular epithelial cells to examine the role of AMPK signaling in cisplatin-induced apoptosis in vitro and we treated mice with Compound C, a selective AMPK inhibitor, to determine the role of AMPK in cisplatin-induced acute kidney injury in vivo.

**Results:** Our results demonstrated that cisplatin activated AMPK (Thr172 phosphorylation) in cultured renal tubular epithelial cell in a dose- and time-dependent manner, which led to p53 phosphorylation, Bax induction, caspase 3 activation, and apoptosis. Compound C, a selective AMPK inhibitor, abolished cisplatin-induced AMPK activation and p53 phosphorylation and apoptosis. Furthermore, silence of AMPK expression by siRNA attenuated cisplatin-induced apoptosis through inhibiting p53 phosphorylation, Bax induction, and Caspase 3 activation. Conversely, AICAR, a selective AMPK activator, dose-dependently induced p53 phosphorylation and subsequent Bax induction and apoptosis. AMPK is activated in the kidney in cisplatin treated mice. Cisplatin-induced renal dysfunction and tubular epithelial cell apoptosis in vivo were attenuated by treatment with Compound C.

**Conclusions:** Our results indicate that AMPK signaling plays a pivotal role in the development of cisplatin-induced renal injury through regulation of P53-Bax apoptosis pathway. These findings suggest that inhibition of AMPK signaling could be a novel target for the prevention and treatment of acute kidney injury.

**Preconditioning Mouse Proximal Tubular Cells with Pharmacologic Activators of AMP-Activated Protein Kinase Ameliorates Apoptosis Induced by Subsequent Metabolic Stress** Wilfred Lieberthal,[1] Leiqing Zhang,[1] Jerrold S. Levine.[2] *[1]Medicine, Stony Brook Medical Center, Stony Brook, NY; [2]Medicine, Univ of Chicago at Illinois, Chicago, IL.*

**Background:** We have previously reported that AMP-activated protein kinase **(**AMPK) is activated when mouse proximal tubular (MPT) cells are subjected to metabolic stress, and plays a role in ameliorating stress-induced apoptosis of these cells (Lieberthal et. al.: AJP, 301:F1177, 2011). We now test the hypothesis that preconditioning MPT cells with pharmacologic activators of AMPK, can reduce apoptosis induced by subsequent metabolic stress. We also compare the efficacy of two novel AMPK activators (A768662 and RSVA314) with that of AICAR, an AMPK activator used for many years to elucidate the functions of AMPK.

**Methods:** MPT cells were preconditioned with AICAR, A-769662, or RSVA314. After preconditioning, the cells were subjected to metabolic stress by inhibiting mitochondrial function using antimycin A.

**Results:** Preconditioning MPT cells with AMPK activators was found to: 1) increase the expression of Glut1 and hexokinase II; 2) stimulate lactate production; 3) reduced the fall in cell ATP levels induced by metabolic stress and 4) ameliorate stress-induced apoptosis of MPT cells. All these effects of preconditioning were substantially greater with A769662 and RSVA314 than with AICAR.

**Conclusions:** Preconditioning MPT cells with AMPK activators substantially ameliorates apoptosis induced by subsequent metabolic stress. This beneficial effect of preconditioning appears due to the stimulation of glycolysis, and to a consequent conservation of cell energy stores during metabolic stress. Furthermore, A769662 and RSVA314 are more effective preconditioning agents than AICAR.

**Deleterious Role of the Polyol Pathway and Fructokinase Activation in the Proximal Tubule in Mice Undergoing Ischemic Acute Kidney Injury**
Miguel A. Lanaspa, Ana Andres-Hernando, Christina Cicerchi, Shinichiro Inaba, Sarah Faubel, Richard J. Johnson. *Medicine, Div of Renal Disease and Hypertension, Univ of Colorado Denver, Aurora, CO.*

**Background:** Despite important discoveries in the pathophysiology of acute kidney injury, no clinically applicable treatment to accelerate kidney recovery has emerged and new targets are needed. Our published data show that the metabolism of dietary fructose by fructokinase (KHK) results in ATP depletion and the generation of uric acid and oxidants causing acute tubulointerstitial injury. Here we show that besides dietary intake, fructose is endogenously produced from glucose by the polyol pathway in the renal cortex of mice undergoing ischemic acute kidney injury (iAKI). The aim of this study is to determine the specific role of this endogenous fructose and its metabolism by KHK in iAKI.

**Methods:** iAKI was induced by renal pedicle clamping in wild type (WT) or KHK knockout (KHK-KO) mice. Sham operation referred to renal pedicle exposure without clamping. iAKI was assessed by determination of parameters of renal function (serum creatinine and BUN), inflammation (serum and renal IL-6), and kidney tubular injury was assessed by NGAL urinary excretion and histology.

**Results:** Mice undergoing iAKI demonstrated a significant activation of the polyol pathway in the kidney cortex as noted by high levels of aldose reductase, sorbitol and fructose accumulation. Compared to sham, mice undergoing iAKI developed significantly higher serum creatinine and BUN as well as urinary NGAL. Also, iAKI induced elevated serum and renal levels of the pro-inflammatory cytokine IL6. Of interest, WT but not KHK-KO mice demonstrated renal ATP depletion, oxidative stress and uric acid generation. Furthermore, KHK-KO mice undergoing iAKI had improved renal function compared to WT mice with lower serum creatinine and BUN levels, reduced NGAL levels and improved proximal tubule histology.

**Conclusions:** Our data demonstrate that fructose generated and metabolized by KHK in proximal tubules during iAKI may have a deleterious role in the pathogenesis of this condition. Therefore, fructokinase (KHK) is a novel potential target for the prevention and treatment of iAKI.

**Hypoxia-Inducible Factor-2 in Endothelial Cells Mediates Protection and Recovery from Ischemic Kidney Injury**
Pinelopi P. Kapitsinou,[1] Hideto Sano,[1] Timothy A. Sutton,[2] Volker H. Haase.[1] *[1]Nephrology, Vanderbilt Univ, Nashville, TN; [2]Nephrology, Indiana Univ, Indianapolis, IN.*

**Background:** Key mediators of cellular adaption to hypoxia are hypoxia-inducible factor (HIF)-1 and -2, which are regulated by the prolyl hydroxylases (PHDs). Although the PHD/HIF pathway has been shown to promote tolerance to acute ischemia, little is known about their cell type-specific functions in this context. Here, we used a genetic approach to specifically dissect the functions of endothelial HIF-1 and HIF-2 in renal ischemia-reperfusion injury (IRI).

**Methods:** To delete HIF-1 and -2 in endothelial cells (EC), Vecadherin (Cdh5)-Cre transgenic mice were crossed to mice carrying conditional HIF-1 and/or HIF-2 alleles. Systemic HIF activation was induced by a proly-hydroxylase-inhibitor (PHI), while EC specific HIF activation was achieved by crossing Cdh5-Cre transgenics to Phd2 floxed mice. IRI was induced by uni-/bilateral renal artery clamping.

**Results:** While at 2hrs and day1 post IRI, Hif1Hif2$^{-/-}$ showed similar injury to controls, at day3 they demonstrated impaired recovery as shown by higher morphologic injury score, an 1.6-fold increase in *Kim1* mRNA and a 47% increase in BUN levels compared to controls.Time course analysis of leucocyte infiltration by CD45 staining revealed an 8.5-fold increase in CD45$^{+}$area in Hif1Hif2$^{-/-}$ at day3 post IRI, which correlated with enhanced *VCAM1* expression. Renal IRI on single Hif1$^{-/-}$ or Hif2$^{-/-}$showed that Hif2$^{-/-}$ but not Hif1$^{-/-}$ mirror the changes observed in Hif1Hif2$^{-/-}$. To test whether EC-Hif-2 is required in PHI-mediated cytoprotection, wild type (WT) and Hif2$^{-/-}$mice were treated with PHI or vehicle, exposed to renal IRI and analyzed on day3 post IRI. In contrast to WT mice, PHI-induced cytoprotection was abolished in Hif2$^{-/-}$. Finally, EC-Phd2$^{-/-}$were protected from renal IRI as shown by a 2.2-fold reduction in *Kim1* mRNA compared to controls (n=3-4, P<0.01).

**Conclusions:** Our data establish a critical role for endothelial HIF-2 a) in the regulation of IRI-associated inflammation and recovery from kidney injury b) in the PHI-induced cytoprotection. Our findings identify the PHD2/HIF2 axis as a potential target for renoprotective therapies.

**Tankyrase/β-Catenin Signaling: A Novel Regulatory Signaling Pathway for Vasopressin-Induced AQP2 Expression in Kidney Collecting Duct Cells**
Hyun Jun Jung, Eunjung Kim, Tae-Hwan Kwon. *Biochemistry and Cell Biology, School of Medicine, Kyungpook National Univ, Taegu, Korea.*

**Background:** Water channel aquaporin-2 (AQP2) mediates arginine vasopressin (AVP)-induced water reabsorption in the kidney collecting ducts. AVP increases the expression of AQP2 mainly via Gsα/cAMP/PKA signaling. Tankyrases, members of PARP family, are known to mediate Wnt/β-catenin signaling-induced transcription of Wnt-targeting genes. We aimed to examine as to whether tankyrase/β-catenin signaling play a role in AVP-induced AQP2 expression in kidney collecting ducts.

**Methods:** We performed 1) semiquantitative immunoblotting for AQP2 expression; 2) pull-down assay of ADP-ribosylated proteins using biotin-NAD$^{+}$; 3) live cell FRET imaging analysis for PKA activity; 4) siRNA-mediated β-catenin knockdown; and 5) laser scanning confocal microscopy for subcellular localization of phosphorylated β-catenin (S552).

**Results:** RT-PCR and immunoblotting showed expression of tankyrases in rat kidney and mpkCCDc14 cells. Tankyrase inhibitor XAV939 significantly decreased the AQP2 induction in response to dDAVP in mpkCCDc14 cells. ADP-ribosylation assay exhibited that ADP-ribosylated Gsα expression was increased by dDAVP treatment for 24 h or 48 h, whereas it was not observed in the presence of XAV939 co-treatment. FRET imaging analysis, however, revealed that XAV939 did not affect the dDAVP- or forskolin-activated PKA levels during 20 min-stimulation. Phosphorylation of β-catenin (S552) was significantly increased in response to dDAVP, but it was unchanged by XAV939 co-treatment. Importantly, siRNA-mediated knockdown of β-catenin was associated with attenuation of the dDAVP-induced AQP2 up-regulation.

**Conclusions:** We revealed that Gsα is a novel substrate protein of tankyrases in kidney collecting duct cells. Decrease of dDAVP-induced AQP2 up-regulation by tankyrases inhibition is not likely due to the decreased ADP-ribosylated Gsα expression, but possibly due to decreased β-catenin signaling to induce AQP2 transcription. Thus, tankyrase/β-catenin signaling could be a novel regulatory signaling for vasopressin-regulated AQP2 expression in kidney collecting duct cells.

**High Throughput Screening for Novel Drugs to Treat Nephrogenic Diabetes Insipidus by Stimulating Vasopressin-Independent Aquaporin-2 Membrane Trafficking**
Naohiro Nomura, Paula Nunes, Richard Bouley, Stanley Shaw, Hua Ann Jenny Lu, Dennis Brown. *Program in Membrane Biology, Massachusetts General Hospital, Boston, MA.*

**Background:** Nephrogenic diabetes insipidus (NDI) is characterized by loss of urine concentration with no response to vasopressin (VP). In most cases, NDI is caused by loss of plasma membrane accumulation of AQP2 in kidney principal cells due to defective VP signaling through the VP receptor (V2R). The amount of AQP2 on the plasma membrane is increased by VP, and is determined by a balance of exocytosis and endocytosis. To find novel therapeutic approaches for NDI treatment, we performed high throughput screening (HTS) for chemicals that stimulate AQP2 exocytosis independently of VP/V2R signaling.

**Methods:** HTS was performed with an exocytosis assay using LLCPK1 cells expressing soluble secreted YFP (ssYFP) and AQP2. We evaluated exocytosis of AQP2 by quantifying fluorescent ssYFP in the medium, and then tested whether identified compounds also induced AQP2 membrane accumulation by immunofluorescence in cell cultures, and rat kidney slices in vitro. Positive compounds were injected intraperitoneally into VP-deficient Brattleboro rats, and urine volume and osmolality were measured over 24 h.

**Results:** We screened 4000 compounds and identified 34 candidate exocytosis enhancers. Finally, 20 "novel" AQP2 enhancers were tested further. Three compounds increased AQP2 membrane accumulation in LLCPK1 cells and two were also effective in MDCK cells and rat kidney slices. Then we treated Brattleboro rats with each compound. One of them, AG490, a JAK2 kinase and EGFR inhibitor, decreased urine volume and increased urine osmolality significantly in the first few hours after a single injection.

**Conclusions:** By HTS screening and subsequent assays, we identified one compound that stimulates AQP2 exocytosis, induces AQP2 membrane accumulation, and stimulates urine concentration in a VP-independent manner. These data show that our chemical screening is effective in identifying novel and unsuspected strategies for the potential treatment of water balance disorders. Its mechanism of action is now under investigation.

**FR-OR070**

**Modulation of cAMP Signaling, AQP2 Phosphorylation and Osmotic Water Permeability in Response to DDAVP or FK under Tolvaptan Treatment in Renal Cells**
Grazia Tamma,[1] Annarita Di Mise,[1] Marianna Ranieri,[1] Peter M.T. Deen,[2] Maria Svelto,[1] Giovanna Valenti.[1] *[1]Dept of Biosciences, Biotechnologies and Biopharmaceutics, Univ of Bari, Bari, Italy; [2]Dept of Physiology, Univ, Nijmegen, Netherlands.*

**Background:** The vasopressin receptor antagonist tolvaptan has emerged as tool in the management of hyponatremia. However, no direct evidence that the aquaretic effect of tolvaptan is based on impairment of vasopressin stimulated AQP2 phosphorylation and targeting to the plasma membrane has been provided.

**Methods:** MDCK stably expressing hAQP2 or rat kidney slides were exposed to DDAVP or forskolin (FK) stimulation in the presence or in the absence of tolvaptan (10nM). The effect of these treatments on cAMP levels, AQP2 phosphorylation, intracellular calcium concentration and osmotic water permeability was analyzed.

**Results:** In MDCK cells, DDAVP treatment significantly increased cAMP levels paralleled by an increase in p256AQP2. Pretreatment with tolvaptan significantly reduced both effects. Surprisingly, tolvaptan pretreatment strongly reduced the increase in p256AQP2 elicited by FK, a direct activator of adenylyl cyclase. Similar results were obtained in rat kidney slides. In line, tolvaptan prevented the increase in the osmotic water permeability promoted by either DDAVP or FK in MDCK. We therefore analyzed whether tolvaptan had, *per se*, a cellular effect. Calibration of cellular calcium in MCDK cells revealed that tolvaptan caused a significant increase in intracellular calcium (tolvaptan 64.0±2 nM; ctr 32±1.7 nM). Since p256AQP2 can be de-phosphorylated by PP2A, a calcium depended serine/threonine phosphatase, rat kidney slides were pretreated with tolvaptan and exposed

to FK in the presence or absence of caliculyn (5pM) a specific inhibitor of PP2A. Under these conditions tolvaptan failed to prevent FK-induced increase in p256AQP2 suggesting that tolvaptan, activates PP2A.

**Conclusions:** Tolvaptan prevents vasopressin induced increase in p256AQP2, AQP2 trafficking and increase in osmotic water permeability. Moreover tolvaptan increases basal intracellular calcium, which might have relevant consequences in modulating p256AQP2 levels and therefore the clinical response to the drug.

## FR-OR071

### Aquaporin2 (AQP2) Expression and Phosphorylation in Rats with Severe Salt Wasting and Volume Depletion

Kamyar A. Zahedi,[1] Sharon L. Barone,[1] Manoocher Soleimani.[1,2] *[1]Internal Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Administration, Cincinnati, OH.*

**Background:** Concomitant ablation of Na-Cl co-transporter (NCC) and pendrin leads to salt wasting, profuse diuresis and severe volume depletion. The carbonic anhydrase inhibitor acetazolamide (ACTZ) inhibits salt absorption in the proximal tubule and down regulates pendrin and is a mild diuretic. Hydrochlorothiazide (HCTZ), a specific inhibitor of NCC, is the most commonly used diuretic for control of mild hypertension. Our studies indicate that similar to the above mouse model, ACTZ pre-treated rats when given a combination of HCTZ and ACTZ develop severe salt wasting and diuresis. We propose that the increase in urine output in ACTZ/HCTZ treated animals that display severe salt wasting and volume depletion is due to AQP2 dysfunction.

**Results:** Compared to vehicle, ACTZ or HCTZ treated rats, ACTZ pre-treated rats given ACTZ and HCTZ excrete high amounts of salt and have significantly elevated urine output. The increased urine output in these rats was associated with decreased urine osmolality despite severe volume depletion. The latter alterations point to impaired water reabsorption. Therefore, we examined the expression of AQP2 in vehicle and ACTZ/HCTZ treated rats. Western blot analyses of kidney extracts from the vehicle and ACTZ/HCTZ treated animals revealed that the levels of total AQP2 and $^{Ser256}$p-AQP2 were significantly reduced while those of $^{Ser261}$p-AQP2 were only marginally affected in the ACTZ/HCTZ treated animals. These results were confirmed by immunofluorescent studies.

**Conclusions:** ACTZ/HCTZ treated animals have reduced levels of total and surface bound/cycling AQP2 ($^{Ser256}$p-AQP2, $^{Ser256-261}$p-AQP2) while their cytosolic AQP2 levels are significantly elevated. The inability to conserve water in ACTZ/HCTZ treated animals in the face of volume depletion mimics the situation in NCC/pendrin dKO mice and is due to reduced expression of AQP2, its diminished surface expression and impairment of water salvage mechanism. Despite being considered mild agents individually, we propose that the combination of ACTZ and HCTZ is a powerful diuretic regimen.

## FR-OR072

### Abolished Renal Glucose Reabsorption in Euglycemic Mice Lacking SGLT1 and SGLT2

Volker Vallon,[1] Maria Gerasimova,[1] David R. Powell,[2] Hermann Koepsell,[3] Timo M. Rieg.[1] *[1]Div of Nephrology, UC San Diego & VA San Diego Healthcare System, La Jolla, CA; [2]Lexicon Pharmaceuticals, Inc., The Woodlands, TX; [3]Anatomy & Cell Biology, Univ of Wurzburg, Germany.*

**Background:** Gene knockdown of the sodium-glucose cotransporter (SGLT) 2 (Sglt2-/-) increases fractional renal glucose excretion (FGE) to ~55% in euglycemic mice (Vallon 2011), whereas deletion of SGLT1 (Sglt1-/-) increases FGE to ~3% (Gorboulev 2012). To further define the role of SGLT1 or of a possible non SGLT1/SGLT2 glucose transporter for renal glucose reabsorption, we generated and characterized mice lacking both SGLT2 and SGLT1 (Sglt1/2-/-).

**Methods:** All mice were fed a glucose-free diet to prevent glucose/galactose malabsorption and subsequent diarrhea due to complete absence of SGLT1. Food and fluid intake were determined in regular cages. Plasma glucose and urinary glucose to creatinine ratios (UGCR) were determined in non-fasted mice. Renal $^3$H-inulin clearance studies with precise determination of GFR/filtered and excreted glucose were performed under terminal anesthesia in Sglt1/2-/- to determine FGE. * P<0.05 vs WT.

**Results:** Absolute urinary glucose concentrations and UGCR were increased in Sglt1/2-/- compared with wild-type mice (WT)(402±34* vs 1.0±0.1mM; 4906±573* vs. 4±1µmol/mg; n=9/group; all male); previous studies reported UGCR in Sglt1-/- and Sglt2-/- of 87±5 and 1847 ± 119µmol/mg, respectively. Sglt1/2-/- had lower blood glucose levels vs WT (83±3* vs 115±5mg/dL), greater food and fluid intake (0.16±0.01* vs 0.10±0.01 g/[24h*g bw]; 0.57±0.02* vs 0.20±0.01 mL/[24h*g bw]), and higher values for hematocrit (49.8±0.3* vs 48.1±0.5%), plasma concentrations of sodium (158±2* vs 153±1mM) and aldosterone (1311±133* vs 276±42pg/mL), as well as urine vasopressin/creatinine ratios (192±34* vs 110±20nmol/mmol). Clearance studies revealed that fractional renal glucose reabsorption was not different from zero in euglycemic Sglt1/2-/-, which had a FGE of 110±7 % (n=4 female and 6 male mice).

**Conclusions:** The results indicate that in euglycemic mice 1) SGLT2 and SGLT1 account for renal glucose reabsorption, and 2) SGLT1 reabsorbs about half of the filtered glucose when SGLT2 is deleted.

## FR-OR073

### S100A11, an EF Hand Calcium Binding Protein, Is a Novel NEDD4-Specific Substrate Protein in Kidney Inner Medulla

Eunjung Kim, Tae-Hwan Kwon. *Dept of Biochemistry and Cell Biology, Kyungpook National Univ, Taegu, Korea.*

**Background:** E3 ubiquitin-protein ligases confer the specificity to ubiquitylation by recognizing target substrates. Ubiquitylation by HECT E3 ligase, NEDD4, has gained interests as a central mechanism for understanding the regulation of the epithelial sodium channel (ENaC) in the kidney. Although NEDD4 is most abundantly expressed in the kidney inner medullary collecting ducts, most studies on NEDD4-mediated ubiquitylation to date are focused on NEDD4-specific substrate protein ENaC mainly expressed in the cortical collecting ducts. Herein, we aimed to identify novel substrate proteins of NEDD4 in rat kidney inner medulla.

**Methods:** All three WW domain-containing fragment protein of rat NEDD4 was made for substrate binding. Interactions between the WW domains and the rat kidney inner medullary homogenates were induced with post-chemical crosslinking (Sulfo-SMCC) and these were subjected to LC-MS/MS analysis. In vitro ubiquitylation assay of S100A11 was done.

**Results:** LC-MS/MS analysis identified nineteen candidate substrate proteins of NEDD4 in kidney inner medulla. Among them, S100A11, an EF hand calcium binding protein, was selected as a novel NEDD4 WW domain-binding protein. Immunohistochemistry revealed that S100A11 was abundantly localized at the inner medullary collecting duct cells. In vitro ubiquitylation assay showed that S100A11 was monoubiquitylated by NEDD4. When in vitro ubiquitylation reactions were carried out with increasing calcium concentrations, significant decreases in NEDD4-mediated monoubiquitylation of S100A11 as well as NEDD4 auto-ubiquitylation were detected.

**Conclusions:** We demonstrated that S100A11, an EF hand calcium binding protein, is a novel substrate protein for NEDD4-mediated ubiquitylation, which is affected by calcium levels. Further studies are needed to examine the role of monoubiquitylation of S100A11 by NEDD4 in translocation of S100A11 to the plasma membrane or to the nucleus for the regulation of water channel protein AQP2 and osmotic water permeability in the collecting ducts.

## FR-OR074

### Protein Kinase C (PKC) Increases UT-A1 Urea Transporter Glycan Sialylation, Membrane Expression and Urea Transport Activity

Xuechen Li,[1] Janet D. Klein,[2] Jeff M. Sands,[1,2] Guangping Chen.[1] *[1]Physiology, Emory Univ, Atlanta, GA; [2]Renal Medicine, Emory Univ, Atlanta, GA.*

**Background:** UT-A1 urea transporter was initially identified as a vasopressin-regulated urea transporter and plays an important role in the urine concentration mechanism. However, accumulating evidence demonstrates that protein kinase C (PKC) also regulates urea permeability in the rat inner medullary collecting duct (IMCD). PKC particularly mediates hypertonicity-stimulated urea transport in kidney. In this study, we investigated the role of PKC alpha in UT-A1 protein membrane expression and glycosylation structure change.

**Methods:** UT-A1 MDCK cells, HEK293 cells and rat kidney IMCD suspension were used for PKC activator PDBu treatment or PKC alpha gene (pcDNA3-PKC alpha) transfection. Crude cell membrane from PKC alpha knockout mouse was isolated by sucrose gradient ultracentrifuge. Cell surface UT-A1 was measured by biotinylation and the glycan structure change of UT-A1 was examined using sugar-specific binding lectins.

**Results:** Treatment with 2 µM of the PKC activator PDBu significantly increases UT-A1 protein abundance in UT-A1 MDCK cells. Interestingly, activation of PKC by PDBu markedly increases UT-A1 glycan sialic acid. Consistently, activation of PKC increased UT-A1 sialylation from kidney inner medulla (IM). Functionally, increased UT-A1 sialylation has enhanced urea transport activity when the UT-A1 MDCK cells were incubated with 2 mM sialic acid for 24 h. To exclude the possible non-specific effect of the PKC activator, the PKC alpha gene was transfected into UT-A1 HEK293 cells. Cell surface biotinylation assay showed that PKC alpha directly increased UT-A1 membrane expression and the increased UT-A1 is highly sialylated as judged by SNA lectin pulldown assay. A PKC alpha knockout mouse has impaired urine concentrating ability. We examined UT-A1 glycosylation change and found that the UT-A1 sialylation is impaired from PKC alpha knockout mouse.

**Conclusions:** Our study revealed a novel, important mechanism of PKC-mediated UT-A1 membrane expression and bioactivity via enhancement of UT-A1 glycan sialylation.

## FR-OR075

### Transgenic Mice That Express UT-A1 but Lack UT-A3 Have Increased AQP3 and Normal Urine Concentrating Ability

Janet D. Klein,[1,2] Abinash C. Mistry,[1] Patrick A. Molina,[1] Priya Datta,[1] Richard T. Rogers,[1] Mitsi A. Blount,[1,2] Jeff M. Sands.[1,2] *[1]Renal Div, Dept of Medicine, Emory Univ; [2]Dept of Physiology, Emory Univ, Atlanta, GA.*

**Background:** Mice lacking the inner medullary collecting duct (IMCD) urea transporters, UT-A1 and UT-A3, are unable to concentrate their urine. To determine whether this defect results from the absence of UT-A1 (located intracellularly and at the apical membrane), UT-A3 (active at the basolateral membrane), or both, we made a mouse that expresses UT-A1 but not UT-A3 (UT-A1$^{+/+}$/A3$^{-/-}$). Since AQP3 has been reported to transport urea across the basolateral membrane, we assessed AQP3 levels and cellular location in the UT-A1$^{+/+}$/A3$^{-/-}$mice.

**Methods:** We generated a UT-A1 gene that could not be spliced to produce UT-A3, behind its original UT-A promoter. We introduced this transgene into UT-A1/A3 knock-out (KO) mice to yield a mouse expressing only UT-A1 (UT-A1$^{+/+}$/A3$^{-/-}$). Western blot and immunohistochemistry were used to assess transport and channel proteins in the UT-A1$^{+/+}$/A3$^{-/-}$ mice.

**Results:** Western blot demonstrated 1) UT-A1 protein in inner medulla (IM) of UT-A1$^{+/+}$/A3$^{-/-}$ and wild-type (WT) mice, but not in UT-A1/A3 KO mice and 2) UT-A3 absent from both mice. UT-A1 protein was not detected in extra-renal tissues from UT-A1$^{+/+}$/A3$^{-/-}$ mice. Immunohistochemisty showed negative UT-A3 staining and positive UT-A1 staining present only in the IM of the UT-A1$^{+/+}$/A3$^{-/-}$ mice. Basal urine osmolalities in WT (2844 mOsm) and UT-A1$^{+/+}$/A3$^{-/-}$ mice (2508 mOsm) increased upon overnight water restriction to 4469 mOsm in WT and 3656 mOsm in UT-A1$^{+/+}$/A3$^{-/-}$ mice. Both WT and UT-A1$^{+/+}$/A3$^{-/-}$ urine osmolalities were significantly higher than in UT-A1/A3 KO (basal: 920 mOsm; dehydrated: 1365 mOsm) mice. AQP3 was increased 61±13% (n=11, $p<0.05$), but its basolateral location was unchanged in the UT-A1$^{+/+}$/A3$^{-/-}$ mice compared with WT mice.

**Conclusions:** Mice expressing UT-A1, but not UT-A3, are able to concentrate their urine to similar levels as WT mice. This suggests that UT-A3 may not be essential for urine concentration. The increase in AQP3 suggests a potential role moving urea across the basolateral membrane to compensate for the lack of UT-A3.

## FR-OR076

### A Small Molecule Screen Identifies Selective Inhibitors of Urea Transporter UT-A1

Cristina Esteva-Font,[1] Puay Wah Phuan,[1] Marc O. Anderson,[2] Alan S. Verkman.[1] *[1]Depts of Medicine and Physiology, Univ of California San Francisco, San Francisco, CA; [2]Dept of Chemistry and Biochemistry, San Francisco State Univ, San Francisco, CA.*

**Background:** Urea transporter (UT) proteins, including UT-A in kidney tubule epithelia and UT-B in vasa recta microvessels, facilitate urinary concentrating function. UT-A1/A3 double knock-out mice have reduced urine-concentrating ability. We previously identified small-molecule UT-B inhibitors with low nanomolar potency using an erythrocyte lysis-based screen assay. UT-A is of greater importance in urinary concentration, with UT-A1 as the principal target. The goal of this study is to identify UT-A1 inhibitors for application as diuretics ('urearetics') with a novel mechanism of action.

**Methods:** A robust screen for UT-A1 inhibitors was developed in MDCK cells expressing UT-A1, aquaporin-1, and fluorescent chloride sensor YFP-H148Q/V163S. Changes in cell volume alter intracellular chloride concentration, producing a near-instantaneous change in YFP-H148Q/V163S fluorescence. Creation of an inwardly directed urea gradient produces rapid cell shrinking due to osmotic water efflux (decreased fluorescence), followed by UT-A1-dependent cell swelling due to water and urea entry (increased fluorescence).

**Results:** Screening of 100,000 synthetic small molecules yielded UT-A1 inhibitors of four chemical classes with low micromolar $IC_{50}$. The compounds fully and reversibly inhibited UT-A1-facilitated urea transport. Structure-activity analysis of analogs of the active compounds revealed compounds with high UT-A1 selectivity and compounds with comparable potency for UT-A1 and UT-B inhibition. Docking computations based on a homology model of UT-A1 suggested binding modes of the inhibitors into the hydrophobic channel region. Optimization of in vivo inhibitor pharmacology and testing in rodent models is in progress.

**Conclusions:** Small-molecule UT-A1 selective and non-selective inhibitors were identified by high-throughput screening. UT-A1 inhibitors may be useful as diuretics that may be effective in high-vasopressin, fluid-retaining conditions in which conventional salt transport-blocking diuretics have limited efficacy.

## FR-OR077

### Urea Transport in the Collecting Duct, Regulated by an Endothelin/Nitric Oxide Signaling Pathway, Is Required for Sodium Reabsorption

Richard T. Rogers, Sara K. Redd, Seongun M. Hong, Mitsi A. Blount. *Dept of Medicine - Renal Div, Emory Univ, Atlanta, GA.*

**Background:** Through several regulatory mechanisms, the kidney modifies blood pressure by controlling fluid homeostasis. Nitric oxide (NO) production in the collecting duct regulates sodium and water reabsorption to stabilize blood volume by regulating transporter function. Ablation of the collecting duct urea transporters, UT-A1 and UT-A3, induces polyuria in UT-A1/A3 null (KO) mice. The inability of these mice to reabsorb water leads us to speculate that NO production is altered.

**Methods:** We collected serum and 24-h urine samples then harvested renal medullary tissue from UT-A1/A3 KO mice and corresponding control littermates (WT). Samples were subjected to ELISA, qRT-PCR, Western, and electrolyte analysis accordingly. Blood pressure was measured in UT-A1/A3 KO and WT mice via tail cuff following 4 days of training.

**Results:** In corroboration with previous reports, urinary nitrate/nitrite levels were increased 3-fold in UT-A1/A3 KO mice. Investigation of nitric oxide synthase (NOS) mRNA expression levels revealed that NOS2 and NOS3 expression were unchanged in UT-A1/A3 KO medulla compared to WT; however, NOS1 expression was increased 40-fold in inner medulla of UT-A1/A3 KO mice. Because collecting duct endothelin (ET-1)/NO signaling pathway modulates pressure-natriuresis, we investigated this pathway in the inner medullary collecting ducts of UT-A1/A3 KO mice. We found that serum aldosterone levels and mineralocorticoid receptor protein expression, regulators of ET-1 concentration, were increased and endothelin type-B (ETB) receptor protein expression, the target of ET-1, was also increased in UT-A1/A3 KO mice compared to WT. Urinary sodium excretion in UT-A1/A3 KO was increased 57% and blood pressure was slightly lower in these mice compared to WT in accordance with the natriuretic and antihypertensive effects of ET-1 and ETB expression.

**Conclusions:** Renal handling of sodium and water has always been linked processes in regulation of blood volume. The present studies suggest that urea handling in the collecting duct, acting through endothelin-simulation of NOS1, also regulates sodium reabsorption.

## FR-OR078

### Nephrology Curriculum Moving Forward in the Era of Team Based Learning

Rupal Mehta, James J. Paparello. *Nephrology, Northwestern Univ, Feinberg School of Medicine, Chicago, IL.*

**Background:** Team Based Learning (TBL) is an approach to medical education that focuses on active learning and application of knowledge in group collaboration. There are few studies to date that show correlations between how students perform on their TBL exercises to their own standardized final exam scores.

**Methods:** After being given preparation material, 162 first year medical students were given 10 acid base and 9 renal pathology questions as the individual readiness assurance test (IRAT). In groups of 10-12, students were then given the same questions as the group readiness assurance test (GRAT), followed by application to more complex clinical scenarios. The final exam given 2 weeks later consisted of 109 questions, 78 of which were related to the TBL material.

**Results:** The preliminary data suggests an improvement between IRAT and final examination scores with the average percentile on the IRAT score of 66% compared to 80.21% on the final exam. The average acid base physiology percentage was 64% vs 70% on the renal pathology component. This does not prove causation but shows that TBL can be a component of teaching nephrology.

**Conclusions:** TBL is an effective teaching tool in medical education. Ongoing steps include analyzing individual scores on the 78 questions testing TBL material and compare this to the 31 questions taught by other methods. This has the ability to show that TBL can be more successful than standard models. We are looking to identify subsets of students who benefited the most by TBL with qualifers such as baseline IRAT score percentile or gender. These groups can then be the focus of TBL exercises. Students identified the renal curriculum as ideal for the TBL model and this will broaden its use at Northwestern University. Team based learning is a rapidly growing educational strategy and the implementation will likely be seen throughout many levels of training.

## FR-OR079

### Palliative Care Training during Fellowship: National Survey of Second-Year U.S. Nephrology Fellows

Sara A. Combs,[1] Stacey Culp,[3] Jean L. Holley,[2,4] Alvin H. Moss.[3] *[1]Univ of Colorado, Aurora, CO; [2]Carle Physicians Group, Urbana, IL; [3]West Virginia Univ, Morgantown, WV; [4]Univ of Illinois, Urbana-Champaign, IL.*

**Background:** Dialysis patients have a high symptom burden and a limited life expectancy. Nephrologists are responsible for their care.

**Methods:** In 2013 we surveyed US second-year nephrology trainees to assess their attitudes toward and the quality of teaching in palliative care received during fellowship and their perceived preparedness to care for patients at end of life (EOL). 326 trainees were surveyed with a 64% response rate. These responses were compared to results from a similar fellows' survey in 2003.

**Results:** More fellows thought it was moderately to very important to learn to provide care to dying patients (95% in 2013, 54% in 2003, $p<0.001$). 99% of fellows in both surveys believed physicians have a responsibility to help patients at the EOL. On a 10-point scale in which 0 is "no teaching" and 10 is "a lot of teaching", fellows reported more teaching in managing a patient on dialysis (mean 9.0 ± 1.4) than a patient at the EOL (mean 4.5 ± 2.5) or with distal RTA (mean 6.5 ± 2.3), all $p<0.001$. On a similar 10-point scale for preparedness, fellows' self-assessments in managing a patient at the EOL (mean 6.1 ± 2.5) and with distal RTA (mean 7.3 ± 2.0) were also lower than managing a patient on hemodialysis (mean 8.9 ± 1.2), all $p<0.001$. Ranking of quality of teaching during fellowship in all areas (mean 4.1 ± 0.8 on a scale of 0-5 where 0 is poor and 5 is excellent) and specific to EOL care (mean 2.4 ± 1.1) did not change between 2003 and 2013, but knowledge of annual gross mortality rate for dialysis patients was worse in 2013, only 57.4% answered correctly ($p=0.048$). 86% reported that no palliative care rotation was offered during fellowship. To an open-ended question about what would most improve fellows' EOL care education, the most common response was a required palliative medicine rotation during fellowship.

**Conclusions:** The amount of teaching specific to palliative care has not improved over the last decade, but fellows increasingly believe that they should learn how to provide this care during fellowship.

**FR-OR080**

**Use of Simulated Patients for Teaching Core Communication Skills to Nephrology Trainees** Robert A. Cohen,[1] Jane O. Schell.[2] *[1]Dept of Medicine Nephrology Div, Beth Israel Deaconess Medical Center (BIDMC)/Harvard Medical School, Boston, MA; [2]Section of Palliative Care and Section Renal-Electorlyte, Univ of Pittsburgh School of Medicine/UPMC, Pittsburgh, PA.*

**Background:** Nephrologists face challenging conversations with patients about dialysis decision-making and end of life. Yet minimal training of nephrology fellows for how to engage in these discussions occurs. Other specialties have employed simulated patients to assist fellows in practicing communication skills for delivering bad news and discussing end of life transitions. We present a communication workshop for nephrology fellows using standardized patients to teach and practice key communication skills.

**Methods:** First-year nephrology fellows from the BIDMC, Brigham and Women's Hospital, and Massachusetts General Hospital and UPMC participated in a full-day interactive communication skills workshop for delivering serious news and promoting discussions about dialysis decision-making and end of life. This consisted of didactics followed by practice sessions. Simulated patients role-played cases giving each fellow an opportunity to practice newly learned skills. Faculty facilitated sessions, providing formative feedback. Surveys were completed prior to and at end of each workshop. Fellows' perceptions of preparedness for engaging in these discussions were rated on a Likert scale prior to and after the workshop.

**Results:** Nineteen fellows (9 females; 10 males) participated at two sites (13 in Boston and 6 in Pittsburgh). Each fellow had an opportunity to participate in facilitated role play with simulated patients at least once during the workshop. Perception of preparedness for engaging in these conversations increased for all fellows following the workshop.

**Conclusions:** Using nephrology specific cases, we report the use of simulated patients for teaching nephrology fellows communication skills for addressing dialysis decision-making and end of life issues. Simulated patients provide a novel approach to communication education in nephrology training. Future efforts include increasing the number and location of such workshops in an effort to train more nephrology fellows in core communication skills.

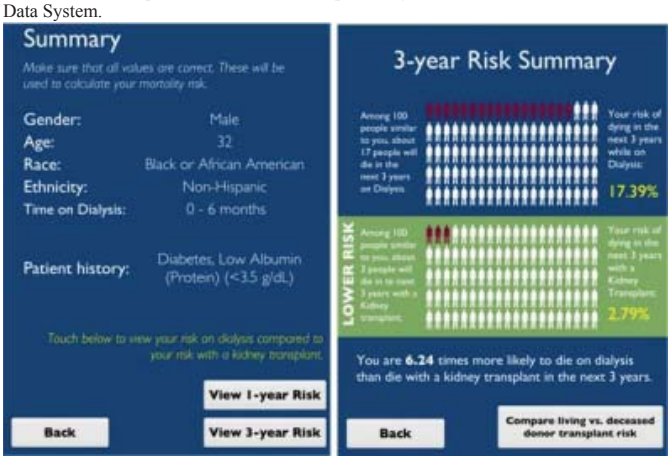
**FR-OR081**

**Dialysis or Transplant: Use of a Shared Decision Making Tool for Treatment Options** Rachel E. Patzer,[1] Mohua Basu,[1] Janice P. Lea,[2] William M. McClellan,[2] David H. Howard,[3] Kimberly Arriola.[4] *[1]Emory Transplant Center, Atlanta, GA; [2]Dept of Medicine, Emory Univ, Atlanta, GA; [3]Dept of Health Policy and Management, Rollins School of Public Health, Atlanta, GA; [4]Dept of Behavioral Sciences and Health Education, Rollins School of Public Health, Atlanta, GA.*

**Background:** The decision to choose kidney transplantation (KTx) over dialysis is a life-altering decision that patients with end stage renal disease (ESRD) make with minimal and subjective data. Shared decision support tools may improve patients' decision-making.

**Methods:** In March 2013, we conducted a feasibility study of a decision support iPad Application tool (iChoose Kidney) that provided risks of death on dialysis compared to KTx based on risk prediction models developed using data from the United States Renal Data System.



The study was conducted at an urban dialysis center comprised primarily of African American (AA) patients, who historically have reduced KTx access.

**Results:** A total of 21 patients received standard education about treatment options plus iChoose Kidney (100% AA, mean age 54 yrs, 61.9% <high school education, 71.4% had income <$20,000, and all were within 1-year of ESRD). Patient knowledge and opinions were examined pre- and post-assessment. Nearly half (42.9%) of patients had never had a physician discussion about KTx. The majority (85.7%) agreed or strongly agreed the tool was useful in making treatment decisions, 90.5% said they learned something new, 71.4% said the tool encouraged them to speak with family about treatment, and 85.7% said they would recommend iChoose Kidney to other patients.

**Conclusions:** This study demonstrated the feasibility of iChoose Kidney to improve shared decision-making about treatment options for AA ESRD patients. A future randomized trial to assess clinical effectiveness is warranted.

*Funding:* Other NIH Support - National Center for Advancing Translational Sciences (NCATS)

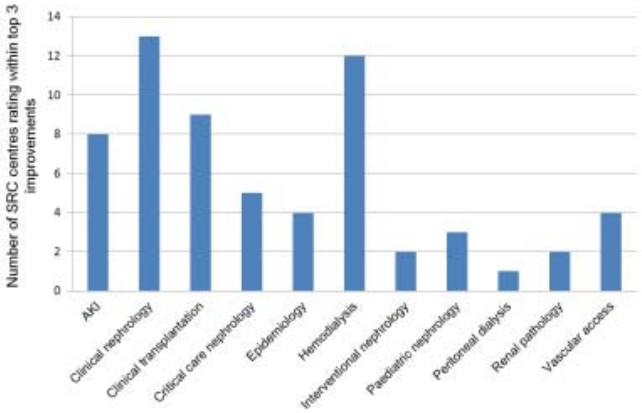
**FR-OR082**

**Successful Development of Worldwide Nephrology through the ISN Sister Renal Centre Programme** Matthew O. Brook,[2] Paul N. Harden.[1,2] *[1]International Society of Nephrology, Brussels, Belgium; [2]Oxford Kidney Unit, Oxford, United Kingdom.*

**Background:** The International Society of Nephrology (ISN) sister renal centre (SRC) programme seeks to advance nephrology by linking emerging centres (EC) in the developing world with supporting centres (SC) in the developed world.

**Methods:** Of 34 active links in 2012, 26 (76%) responded to a survey investigating each links focus for development and success.

**Results:** ECs were distributed throughout 4 continents and 19 countries whilst SCs originated from 11 countries. Developing general clinical nephrology (16/34 links), haemodialysis (12/34) and acute kidney injury (11/34) services were the three most prolific areas of activity although significant diversity was evident. The most improved aspects of nephrology were identified as general clinical nephrology (13/21 responding links), Haemodialysis (12/21) and transplantation services (9/21) (Figure).



SRC links had a positive impact on clinical training (mean impact rating 8.7/10), clinical services (8.1/10) and research (7.3/10) within the Ecs. SCs noted increased global health awareness and interest in global health issues (both 7.9/10) among staff.

Establishing new clinical services, education through training exchanges and direct interactions between SC and EC staff were identified as providing the greatest contribution to successful EC development.

The SRC link between Oxford, U.K. and Minsk, Belarus is a good example of sustained success. A new paediatric programme contributed to a >20 fold increase in transplantation in Belarus. The Minsk team have since used their experience to support the first ever paediatric transplants in Khazakstan and living donor transplants in Krygykstan.

**Conclusions:** The SRC programme provides a template that may be adopted by other specialities for substantial and sustained improvement in healthcare tailored to the demands and resources of the emerging unit.

**FR-OR083**

**NephMadness: Social Media Campaign to Promote Nephrology Education and Interest** Joel Topf,[1] Matthew A. Sparks,[3] Kenar D. Jhaveri.[2] *[1]Medicine, St. John Hospital and Medical Center, Detroit, MI; [2]Medicine, Hofstra North Shore LIJ School of Medicine, Great Neck, NY; [3]Medicine, Duke Univ Medical Center, Durham, NC.*

**Background:** In order to increase interest in nephrology we constructed an online social media campaign specifically designed to encourage an interactive educational experience of nephrology concepts called NephMadnes.

**Methods:** One of the cornerstones of social media is the rapid ability to share information and interact with colleagues. In March to April 2013 we created an online educational tournament coined NephMadness on the website http://www.ajkdblog.org" consisting of 64 nephrology achievements. The concept was to parody the NCAA men's Division 1 Basketball Tournament. We mirrored the traditions, language and structure of the basketball tournament to generate interest in our tournament of nephrology ideas.

**Results:** 64 nephrology concepts and achievements arranged in brackets were introduced on the initial day. Descriptions and educational material of all 64 achievements were divided across 8 blog posts and spanned 11,534 words. The achievements were divided into 8 groups: programs, drugs, research techniques, discoveries, learning tools, equations/lab values, diagnostics, and studies. Over the ensuing 4 weeks the field of 64 was narrowed until a winner was declared. While the first two rounds were scripted by the editors, subsequent narrowing was decided by the users through online voting. NephMadness generated 34 seperate blog posts. 40% (14/34) were posted from blogs other than eAJKD. Twitter was a primary source of interactivity in which 77 individuals tweeted about the project 473 times and generated 519,323 impressions using the hashtag #NephMadness.

**Conclusions:** To our knowledge this is the first educational social media campaign performed of this magnitude in medicine. The campaign was successful in drawing many people to interact and learn about nephrology. Traffic to the originating blog was the highest in it's history by a wide margin. Use of interactive campaigns are possible and deserve formal study. Such interactive games could spark interest in nephrology, at a time when interest in declining.

## FR-OR084

**Two Novel Educational Interventions to Navigate the Challenges of CKD Care** Stacey Jolly, Sankar D. Navaneethan, Jesse D. Schold, Susana Arrigain, Victoria Konig, Yvette K. Burrucker, Barbara H. Tucky, John W. Sharp, Joseph V. Nally. *Cleveland Clinic.*

**Background:** There is a scarcity of translational research in CKD that incorporates educational tools. We are 1 of 5 NIDDK R34 grants whose focus is improving outcomes for CKD patients through T2 research. We describe the development of two interventions, a CKD Patient Navigator program and a CKD specific enhanced personal health record (PHR).

**Methods:** To accomplish our specific aims, we assembled key members from our multidisciplinary CKD Team and enlisted new members from information technology and data management. Creation of the CKD Navigator Program encompassed three phases: hiring, training, and implementing. We hired a navigator who could provide "individual guidance, support, education, coordination of care, and other assistance to patients". For training, there were three key areas a) Harold Freeman Patient Navigator Institute b) CKD education and c) electronic health record (EHR) training. For implementation, we defined barriers of care, ensured randomization, and created EHR templates for which pertinent study data could be extracted. Enhanced PHR creation was a multi-step process. We selected educational materials specific to CKD Stage 3b/4 patients, developed a user guide for potential participants who may not be familiar with our PHR, and pilot tested including verifying our ability to collect PHR use data among participants.

**Results:** We created a CKD Patient Navigator program adapting the use of patient navigators successfully employed in other fields with the well-established chronic care model. We developed an EHR-based enhanced PHR that allows for CKD stage-specific education disseminated electronically and utilized many publicly available NKDEP and NKF education materials. We're performing an RCT to determine the effect of these interventions alone and in combination on CKD outcomes. Recruitment is underway and we have enrolled over half of our target population (n=208) and await future analyses.

**Conclusions:** CKD research that uses novel educational approaches is pressing and will require technology, stakeholders, and a multidisciplinary team to translate frameworks into adaptable interventions.

*Funding:* NIDDK Support, Other NIH Support - S.D.N. was supported by National Center for Research Resources, Multidisciplinary Clinical Research Career Development Program Grant RR024990

## FR-OR085

**Changes in Endothelial and Smooth Muscle Cells Morphology by Patient-Specific Disturbed Flow Patterns Derived from Autologous Arteriovenous Fistulae** Andrea Remuzzi,[1,2] Bogdan Ene-Iordache,[1] Marco Franzoni,[1] Irene Cattaneo.[1] *[1]IRCCS - Mario Negri Institute, Bergamo, Italy; [2]Univ of Bergamo, Dalmine, Italy.*

**Background:** Radial-cephalic arteriovenous fistula (AVF) is the first choice for haemodialysis ascular access. AVF surgery has significant early failure rates due to vessel stenosis in the draining vein. It has been proposed that oscillating wall shear stress (WSS) acting on endothelial cells (EC), is a trigger of intimal hyperplasia (IH), vessel stenosis and AVF failure. We investigated whether WSS acting on EC in regions of disturbed flow, that develop in AVF, may influence EC function.

**Methods:** We used magnetic resonance images obtained in two patients, 40 d post-surgery, to reconstruct 3D models of AVF and to estimate the blood flow field by computational fluid dynamics. We localized areas of disturbed flow using oscillatory shear index [He, 1996], and we derived time changes in WSS in these regions, and in regions exposed to pulsatile flow far from the anastomosis. We then exposed human umbilical EC (HUVEC) in vitro to oscillating and pulsatile WSS, using a cone-and-plate device, and exposed vascular smooth muscle cells (SMC) to culture media conditioned by HUVEC under different flow conditions.

**Results:** HUVEC exposed to pulsatile WSS (1.24 to 2.23 Pa, n=4) for 48 hrs elongated and aligned in the flow direction, while HUVEC exposed to oscillating WSS (1.28 to -1.62 Pa, n=4) did not align nor elongate. Morphology of SMC was importantly affected by medium pre-conditioned by oscillating WSS on HUVEC, while medium conditioned by HUVEC under pulsatile flow did not affect SMC phenotype.

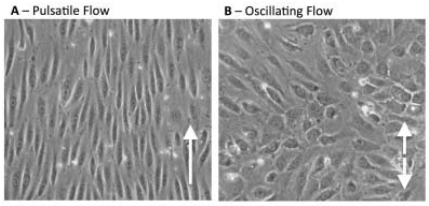


**Figure 1** – HUVEC after in vitro exposure to fluid flow for 48 hrs.

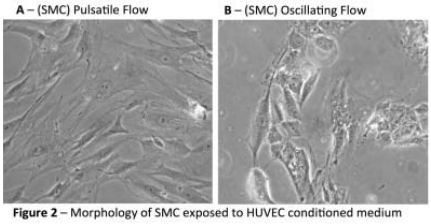

**Figure 2** – Morphology of SMC exposed to HUVEC conditioned medium

**Conclusions:** Our data demonstrate that exposure of EC to oscillating WSS that develop in the venous site in side-to-end AVF importantly affect EC and SMC function. These results confirm that disturbed flow conditions acting on EC may be responsible for IH and AVF stenosis.

## FR-OR086

**Pancreatic Elastase (PRT-201) Improves Radiocephalic Arteriovenous Fistula (AVF) Maturation and Patency** Bradley S. Dixon,[1] Robert J. Hye,[2] Michael R. Jaff,[4] Pamela Gustafson,[5] Francesca Lindow,[5] Marco D. Wong,[5] Laura M. Dember,[3] Steven K. Burke.[5] *[1]U Iowa; [2]Kaiser Permanente; [3]UPenn; [4]Mass General; [5]Proteon Therapeutics.*

**Background:** Over 50% of AVFs lose primary unassisted patency within one year of creation. A pilot study suggested PRT-201 is safe and may prolong AVF patency.

**Methods:** We conducted a randomized double-blind, placebo controlled trial of PRT-201 on primary unassisted patency (time from AVF creation to thrombosis or an intervention to maintain patency) of a new AVF. Secondary outcomes included secondary patency (time from AVF creation to fistula abandonment), and unassisted maturation assessed by duplex ultrasound (blood flow ≥ 500 mL/min and vein lumen diameter ≥ 4 mm).

**Results:** 169 patients were randomized and 151 patients treated with PRT-201 (10 µg, n=51 or 30 µg, n=49) or placebo (n=51) applied topically to the exposed artery and vein immediately following surgery. Primary unassisted patency at one year was 47% in placebo compared to 59% for PRT-201 (10 µg and 30 µg dose groups combined; p=0.11). In a Cox model adjusting for baseline covariates, the hazard ratio for time to primary unassisted patency loss was 0.76 (95% CI 0.43-1.35; p=0.35) for 10 µg and 0.59 (95% CI 0.32-1.10; p=0.10) for 30 µg. Unassisted maturation at 12 weeks was 67% for placebo compared to 87% (p=0.03) for 10 µg and 92% (p<0.01) for 30 µg. Stratifying by AVF location (Table 1), 30 µg PRT-201 significantly improved primary unassisted patency and unassisted maturation in radiocephalic but not brachiocephalic AVFs.

| Table 1 | Radiocephalic AVF (n=67) | | | Brachiocephalic AVF (n=84) | | |
|---|---|---|---|---|---|---|
| | Placebo | 10 µg | 30µg | Placebo | 10µg | 30µg |
| Primary Unassisted Patency (%) | 33 | 52 | 65* | 59 | 64 | 55 |
| Unassisted Maturation (%) | 47 | 74 | 93** | 80 | 83 | 77 |
| Secondary Patency (%) | 67 | 83 | 90† | 89 | 82 | 79 |
| *p=0.03; **p=0.009; †p=0.08 | | | | | | |

**Conclusions:** PRT-201 improved primary unassisted patency and unassisted maturation in radiocephalic AVFs.

*Funding:* Pharmaceutical Company Support - Proteon Therapeutics

## FR-OR087

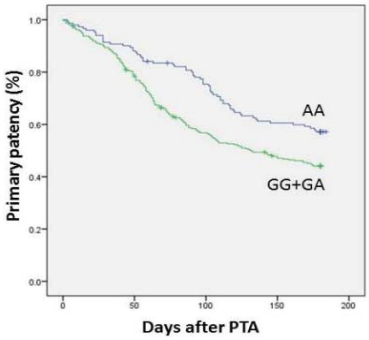
**Genotype Polymorphisms of Dimethylarginine Dmethyl Aminohydrolase 1 (DDAH1) Predict Restenosis of Vascular Access after Angioplasty in Hemodialysis Patients** Chih-Ching Lin. *Div of Nephrology, Dept of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.*

**Background:** Elevated plasma asymmetric dimethylarginine (ADMA) has been reported to be associated with restenosis after percutaneous transluminal angioplasty (PTA) of AVF in hemodialysis (HD) patients. Dimethylarginine dimethylaminohydrolase 1 (DDAH1) is the major enzyme eliminating ADMA, but the effect of genetic variations in DDAH1 on the outcome of vascular access after PTA in HD patients remained unknown.

**Methods:** We assessed the association between polymorphisms in DDAH1 and vascular access outcome in 473 maintenance HD patients, who were prospectively followed up for one year after PTA for vascular access dysfunction. Eleven single nucleotide polymorphisms (SNPs) in endothelial function related genes were analyzed and plasma ADMA levels were determined at baseline.

**Results:** After adjustment of demographic, access, and risk factors, individuals with high baseline plasma ADMA (>0.9µM) levels had higher rates of re-intervention at 3 and 6 months after PTA (three months, 56% vs. 36%, p=0.08; six months:74% vs. 53%, p=0.05). DDAH1 rs233112 was significantly associated with increased levels of plasma ADMA levels. Compared with individuals with rs233112 AA genotypes, individuals with rs233112 GA or GG genotypes had higher risks for re-intervention (58% vs. 45%, p=0.003) after

PTA at 6 months. In the same multivariate- adjusted model, the clinical factors predicting higher risk of re-intervention at 6 months include current smoker, graft access, and rs233112 GG+GA genotypes of DDAH1 gene (HR 2.302, 95% CI 1.557-3.407).



**Conclusions:** Our results provide the first evidence that rs233112 GG+GA genotypes of DDAH1 gene predict early and frequent restenosis of vascular accesses after PTA in HD patients.

## FR-OR088

**The Impact of Arterial Micro-Calcification of Vascular Access on Early Access Failure in Hemodialysis Patients** Su Jin Choi,[1] Yu-Seon Yun,[2] Young Soo Kim,[1] Sunae Yoon,[1] Young Ok Kim.[1] *[1]Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea; [2]Gyeonggi Province Geriatric Hospital of Dongducheon.*

**Background:** Vascular calcification is common in hemodialysis (HD) patients, and it is a significant predictor for cardiovascular mortality in HD patients. Also, vascular access calcification identified by plain radiography was reported as a risk factor for cardiovascular mortality in HD patients. But the relationship between arterial micro-calcification (AMiC) by pathologic study and patency of vascular access has been rarely reported. The aim of this study was to determine the impact of AMiC of vascular access on access patency in HD patients.

**Methods:** One-hundred six HD patients (Mean age; 59.6 ± 12.9 years, Male/Female; 66/40, Percent of diabetes mellitus; 73%) receiving vascular access operation were included in this study. During the operation, we obtained partial arterial specimen and performed pathologic examination by von Kossa stain to identify AMiC. We investigated early access failure (complete obstruction of blood flow or severe stenosis requiring radiologic intervention or surgical correction of AVF within 1 year after the operation) between the patients with AMiC and those without AMiC.

**Results:** Mean duration of follow-up was 42.5 ± 33.8 months and the incidence of AMiC was 38.7% (n=41). The form of vascular calcification is arterial medial calcification. Early access failure was occurred in 45 patients (42.5%), and mean time between the operation and access failure was 4.1 ± 3.1 months (range, 1 to 12 months). The access failure was associated with older age (62.7 ±11.8, 57.3 ± 13.2, p-value = 0.032) and low BMI (23.3±2.9, 24.5 ± 3.5, p-value = 0.043). The early AVF failure rate was higher in patients with AMiC than those without AMiC (56.1%, n=23/41, vs. 33.8%, n=22/65, p-value = 0.024). Diabetes, cardiovascular disease and cardiovascular death were not related to access patency. Kaplan-Meier analysis showed that the presence of AMiC significantly increased the risk for the access failure (Log rank = 4.98, p-value = 0.026).

**Conclusions:** This study demonstrates that AMiC of the vascular access is associated with early access failure in HD patients.

## FR-OR089

**Liposomal Delivery of Prednisolone Improves Outward Remodeling in Murine Arteriovenous Fistulas** ChunYu Wong,[1] Carolien Rothuizen,[1] Josbert Metselaar,[2] Floris Verbeek,[3] Erik Stroes,[4] Anton Jan Van Zonneveld,[1] Ton J. Rabelink,[1] Paul Quax,[3] Joris I. Rotmans.[1] *[1]Nephrology, Leiden Univ Medical Center, Leiden, Netherlands; [2]MIRA Institute, Univ of Twente, Enschede, Netherlands; [3]Surgery, Leiden Univ Medical Center, Leiden, Netherlands; [4]Vascular Medicine, Amsterdam Medical Center, Amsterdam, Netherlands.*

**Background:** Arteriovenous fistulas (AVFs) have a 1-year primary patency of only 60%, mainly as a result of maturation failure that is caused by insufficient outward remodeling (OR) and intimal hyperplasia (IH). The exact pathophysiology remains unknown, but the locally augmented inflammatory response is thought to play a role. Corticosteroids (CS) are powerful inhibitors of inflammation but result in adverse side effects when given systematically at a higher dose. In this study we evaluated the effect of CS combined with a targeted delivery method using liposomes in a murine AVF model.

**Methods:** AVFs between the jugular vein and common carotid artery were created in an end-to-side manner in C57bl6 mice. Subsequently, the animals were injected i.v. (dose 10 mg/kg) with either liposomal prednisolone phosphate (LPP), empty liposomal vehicle, prednisolone phosphate or PBS at days 0,2,5 and 10 after surgery. At 14 days, the labeled liposomes were visualized in mice *in vivo* by near infrared fluorescent imaging whereupon the animals were sacrificed for histomorphometric and immunohistochemical analysis.

**Results:** Liposomes accumulated in the anastomotic area of the AVF. Treatment with LPP resulted in a 27% increase in venous circumference and 47% increase in lumen ($p<0.01$;$p<0.03$) when compared to the PBS group. No significant difference in intimal hyperplasia was observed. Furthermore, we observed a 83% reduction in leukocyte infiltration in the anastomotic area in the LPP group ($p<0.01$).

**Conclusions:** Liposomal CS targeting proved to be an effective and selective method to ameliorate venous remodeling in AVFs by increasing the luminal area that was caused by augmented OR, rather than the reduction of IH formation. Treatment with liposomal prednisolone phosphate could be a valuable strategy to reduce the peri-anastomotic inflammatory response and improve maturation of AVFs.

## FR-OR090

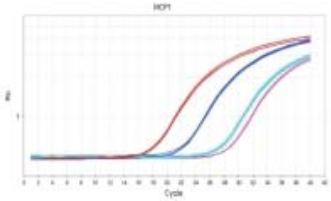
**Genomics of Arteriovenous Fistula Maturation** Timmy C. Lee,[1,2] Jing Chen,[1] Prabir Roy-Chaudhury,[1] Begoña Campos,[1] Mario Medvedovic.[1] *[1]Internal Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Medicine, Univ of Alabama at Birmingham, Birmingham, AL.*

**Background:** Studies that evaluate the progressive effects of vascular injury and biological mechanisms leading to venous neointimal hyperplasia development and arteriovenous fistula (AVF) non-maturation have yet to be performed in vascular access. The objective of this study was to evaluate gene expression changes from vein specimens from subjects without chronic kidney disease, advanced chronic kidney disease (CKD) receiving new vascular access, advanced CKD subjects during second stage of basilic vein transposition, and stenotic early AVF failure.

**Methods:** Vein samples were isolated for RNA from non-CKD deceased donors (n=2), advanced CKD subjects receiving new vascular access (n=2), subjects at the time of second stage basilic vein transposition (n=2), and stenotic early AVF failure (n=2). We performed differential gene expression analysis using high throughput RNA-seq to compare gene expression at these various time points. We also performed qRT-PCR for selected genes of interests.

**Results:** We found significant and progressive increases in expression of genes regulating cellular proliferation, cell adhesion, chemokine and cytokine signaling, and extracellular matrix production with increased vascular injury to the vein. qRT-PCR for monocyte chemoattractant protein-1 (MCP-1), showed significantly progressive gene expression from non-CKD vein to stenotic AVF ($p<0.005$) (see figure).

**Conclusions:** Our results show significant and progressive increases in gene expression in pathways regulating inflammation, oxidative stress, and endothelial function from the non-CKD period to the time of venous stenosis. Future studies are needed to evaluate in greater detail the effect of different vascular injuries (uremia and hemodynamics) at different time points in the natural history of AVF maturation.



**qRT-PCR of MCP-1 from Vein Specimens.** MCP-1 expression curves of non-CKD veins (purple), CKD vein at time of AVF creation (aqua blue), vein from 2nd step of BVT (dark blue), and stenotic AVF vein (red). Note progressive increased expression of MCP-1 with vascular injury.

*Funding:* NIDDK Support

## FR-OR091

**Notch/FSP-1 Signaling Contributes to CKD-Induced Neointima Formation in AV Fistula** Jizhong Cheng,[1] William E. Mitch,[1] Yun Wang,[1] Anlin Liang.[1] *[1]Dept of Medicien/Nephrology, Baylor College of Medicine; [2]Dept of Medicien/Nephrology, Baylor College of Medicine; [3]Dept of Medicien/Nephrology, Baylor College of Medicine; [4]Dept of Medicien/Nephrology, Baylor College of Medicine.*

**Background:** Functional arteriovenous fistulas (AVF) are critical for hemodialysis patients but neointima formation causes 60% of AVF's to fail in 2 years. The migration and proliferation of smooth muscle cells (SMCs) are the major resources of neointima formation. Fibroblast specific protein 1 (FSP-1) regulate cell migration and could be associated with CKD-induced AVF failure.

**Methods:** AVFs were created in WT and FSP-1 KO mice with or without CKD, the neointima foramtion in AVFs was evaluated. The expression of FSP-1 and the underlying mechanism were investigated in cultured SMCs.

**Results:** FSP-1 expression was significantly increased in neointima area of AVFs from patient and CKD mice compared with that of WT mice. SMCs treated with FSP-1 showed enhanced potential of migration and proliferation. FSP-1 promoter contains RBP-Jk (a downstream transcription factor of Notch) consensus sites. Notch ligand, Jagged 1, increased FSP-1 expression and its promoter activity. Deletion of the RBP-Jkbinding sites inhibited Jagged 1-induced FSP-1 promoter luciferase activity. Moreover, CHIP and electrophoretic mobility shift assay (EMSA) analysis showed that Jagged 1 stimulated direct interactions of RBP-Jk with FSP-1 promoter sequences. Knockout of RBP-Jk in SMCs abolished these interactions. Similar responses were detected by using Notch inhibitor, DAPT. FSP-1-mediated migration and proliferation in SMCs were also suppressed by Notch inhibitor and by RBP-Jkknock out. Finally, AVFs created in mice with KO FSP-1 suppressed CKD-induced neointima formation. In these mice, neointima formation was ~ 40% below that in wild type, uremic mice.

**Conclusions:** Thus, uremia enhances FSP-1 expression through activation of Notch RBP-Jk signaling in SMCs and causes migration and proliferation of neighboring SMCs which accelerates neointima formation and AVF failure. FSP-1 could become a therapeutic target for suppressing neointima in AVFs.

*Funding:* NIDDK Support

## FR-OR092

**Preclinical Dataset Supports Initiation of Clinical Trials for Bioengineered Vascular Access Grafts** Shannon L.M. Dahl,[1] Jeffrey Lawson,[2] Heather L. Prichard,[1] Roberto J. Manson,[2] William Tente,[1] Alan P. Kypson,[3] Shawn Michael Gage,[2] Juliana Blum,[1] Laura E. Niklason.[4] *[1]Humacyte, Inc.; [2]Duke Univ; [3]East Carolina Univ; [4]Yale Univ.*

**Background:** End stage renal disease (ESRD) patients who require hemodialysis access would benefit from an alternative to synthetic grafts, which have high rates of thrombosis and venous intimal hyperplasia. Our bioengineered vascular graft is comprised of human extracellular matrix and is similar in strength to native human vein and artery. This acellular graft may be stored in a regular refrigerator, making it readily available for off-the-shelf surgical use. This graft is currently in clinical studies for evaluation of safety and efficacy for use as hemodialysis vascular access in patients with ESRD.

**Methods:** Banked smooth muscle cells were cultured in bioreactors in vitro to produce bioengineered tissue grafts, and a decellularization process was subsequently employed to remove cellular antigens and render grafts non-immunogenic. Canine-derived grafts were implanted as carotid artery bypass grafts in dogs, which provided directional guidance for evaluation of human grafts. Human-derived grafts were implanted as arteriovenous grafts in baboons. Evaluations included patency, durability, cannulation, immunogenicity, intimal hyperplasia, and remodeling.

**Results:** The mechanical integrity of these acellular grafts was retained throughout 1-year of refrigeration. Canine studies demonstrated long-term (1-year) safety and function of engineered tissues. Baboon studies showed that bioengineered grafts were safe, well tolerated, and functioned as intended. No significant intimal hyperplasia was observed in the graft or outflow vein in any recipient. Histologic analysis demonstrated evidence of host vascular cell migration into the graft.

**Conclusions:** These bioengineered grafts demonstrated high patency, could be cannulated repeatedly, and did not show significant intimal hyperplasia. These preclinical results support the evaluation of the grafts to provide dialysis access in patients with end stage renal disease.

## FR-OR093

**Taurolidine-Citrate-Hepatin Lock Solution Significantly Improves Inflammatory Profile in Hemodialysis Patients with Tunneled Catheters** Javier Donate,[1] Néstor Fontseré,[2] Celia Cardozo,[3] Mercedes Muros,[4] Alex Soriano,[3] Mercedes Pons,[5] Josep Mensa,[3] Josep M. Campistol,[1] Francisco Maduell,[1] Juan F. Navarro-Gonzalez.[1,6] *[1]Research Unit, HUNSC, S/C Tenerife; [2]Nephrology, Hosp. Clinic, Barcelona; [3]Infectious Diseases, Hosp. Clinic, Barcelona; [4]Clinical Analysis, HUNSC, S/C Tenerife; [5]CETIRSA, Barcelona; [6]Nephrology, HUNSC, S/C Tenerife.*

**Background:** The taurolidine-citrate-heparin lock solution (TCHLS) effectively eradicates pathogens from nontunneled and tunneled catheter biofilms and helped to maintain catheter lumen sterility. We aimed to evaluate the potential beneficial effect of this solution on the inflammatory profile of hemodialysis (HD) patients.

**Methods:** Thirty-one chronic patients, 18 males and 13 female, with a mean age of 72 years, and a mean time on HD of 82 months, were included in the study. All patients were on maintenance HD with tunneled catheters locked with a heparin filling were subsequently converted to a TCHLS. Serum concentration of inflammatory parameters [high-sensitive C-reactive protein (hsCRP), tumor necrosis factor-alpha (TNFa), interleukin (IL)-6 and IL-10], as well as mRNA expression levels of TNFa, IL6 and IL10 in peripheral blood mononuclear cells (PBMC) were analysed at baseline and after 6 months of TCHLS.

**Results:** Serum concentrations of hsCRP and IL-6 experienced a significant reduction (2.1±0.5 and 14.8±3.9 vs 1.5±0.4 and 10.6±2.7, respectively, p=0.01), whereas serum TNFa and IL10 did not change. Regarding inflammatory cytokine gene expression in PBMC, after 6 months of TCHLS, mRNA levels of IL-6 and TNFa significantly decreased by 20% and 19%, respectively ($p<0.05$), without changes in the expression levels of IL-10.

**Conclusions:** The use of TCHLS in maintenance HD patients with tunneled catheters resulted in an improvement of the inflammatory profile, with a significant decrease in the serum levels of hsCRP and IL-6, as well as a reduction in the mRNA gene expression levels of TNFa and IL-6 in PBMC.

## FR-OR094

**Safety of Small Bore Tunneled Central Venous Catheters in Chronic Kidney Disease Population** Gauri Bhutani,[1] Mireille El Ters,[1] Joe L. Klunder,[2] Sandra J. Taler,[1] Andrew Stockland,[2] Marie C. Hogan.[1] *[1]Nephrology & Hypertension, Mayo Clinic; [2]Interventional Radiology, Mayo Clinic, Rochester.*

**Background:** There is accumulating evidence that peripherally inserted central venous catheters (PICCs) are associated with high rates of venous thrombosis, remnant vascular injury and in the dialysis population, subsequent lack of functioning AV fistulas. Data from our center shows a PICC prevalance rate of 30% in the chronic hemodialysis population. A potential strategy to reduce vascular injury to arm veins may be to employ central neck veins for venous access.

**Methods:** Radiology database enquiry identified patients who received small bore tunneled central venous catheters (STCCs) at our center between January 1st 2010 and 31stMarch 2013. Demographics and line related characteristics from all available data are shown in table 1 below. Complication rate assessment is currently underway using chart audit.

**Results:** A total of 70 STCCs were placed in 62 adult patients under ultrasound guidance by interventional radiologists.

| | n = 62 patients ; 70 STCCs | Results |
|---|---|---|
| Age (years) | 62 patients | 21 to 84 (mean = 56.5) |
| Catheter diameter (Fr) | 48 lines (22 unknown) | 4 to 6 (4 Fr = 35.4% ; 5 Fr = 62.5% ; 6 Fr = 2.1%) |
| Number of lumens | 63 lines (7 unknown) | 1 to 3 (1 = 44.4% ; 2 = 52.4% ; 3 =3.2% ) |
| Site of placement | 67 lines (3 unknown) | Right Internal Jugular = 34 (50.7%)<br>Right External Jugular = 9 (13.4%)<br>Left Internal Jugular = 20 (29.8%)<br>Others = 4 (6 %)<br>(includes neck collaterals & subclavian veins) |

93 % lines were inpatient and for 72%, the indication was antibiotic administration (n=35). No placement complications were noted. Indwelling days ranged from 1 - 175 (mean 32). Follow up ranged from 4 - 1165 (mean 255) days. 69% of patients receiving these 35 STCCs had CKD, renal transplant or ESRD. There were no observed superficial or deep venous thrombosis sequelae.

**Conclusions:** We have observed a zero incidence of venous thrombosis over 918 indwelling days with STCCs.This is significantly lower than the 20 - 30% rate reported for PICCs in the current literature. STCCs may be a safer option in CKD patients in order to protect their arm veins for future dialysis access.

## FR-OR095

**Polycystic Kidney Disease without Apparent Family History (AFH)** Vinusha Kalatharan,[1] Alessia C. Borgo,[1] Young-Hwan Hwang,[1] Kairong Wang,[1] Jamie L. Sundsbak,[2] Christina M. Heyer,[2] Peter C. Harris,[2] York P. Pei.[1] *[1]Div of Nephrology, Univ Health Network, Toronto, Canada; [2]Dept of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

**Background:** The absence of a positive family history in 15-20% of patients poses a diagnostic challenge for autosomal dominant polycystic kidney disease (ADPKD) and may be due to multiple causes.

**Methods:** In the Toronto Genetic Epidemiology Study of PKD (TGESP), 220 unrelated probands prospectively underwent renal function and imaging testing as well as a comprehensive *PKD1* and *PKD2* mutation screen. From this cohort, we identified all cases without AFH, examined their parental medical records, and performed renal imaging in any available parents of unknown disease status. From these results, we re-classified our cases into: (i) *de novo* disease (DND); (ii) positive family history (PFH) in retrospect; and (iii) indeterminate family history (IFH).

**Results:** We found that 53/220 (24%) of the TGESP probands did not have AFH. Among this patient subgroup, 26/53 (49%) had DND, 4/53 (8%) had a PFH in retrospect, and 23/53 (43%) had an IHF. Their re-classified family history and mutation types are shown below:

| Type of Mutation | *De Novo* Disease (n=26) | Positive Family History in Retrospect (n=4) | Indeterminate Family History (n=23) |
|---|---|---|---|
| Truncating PKD1 | 26.9% | 0% | 21.7% |
| Hypomorphic PKD1 | 26.9% | 75% | 30.4% |
| Truncating PKD2 | 3.9% | 0% | 8.7% |
| No mutation detected (NMD) | 42.3% | 25% | 39.1% |
| *% denotes column percent of n | | | |

Among the cases with *de novo* disease, we found one family (with two affected siblings and unaffected parents) suggestive of germline mosacism and 5 other with asymmetrical PKD suggestive of somatic mosacism. PKD1 and PKD2 mutation screen of the latter patients by Sanger sequencing was negative in all but one case (with a PKD1 frameshift mutation affecting the proband and her daughter).

**Conclusions:** PKD patients without AFH comprise a heterogeneous group resulting from *de novo* mutations, germline and/or somatic mosacism, mild disease from both hypomorphic *PKD1* and *PKD2* mutations, and unavailable parental medical records. Additionally, in ~1/3 of the cases, no pathogenic mutations could be found despite a comprehensive screen of both *PKD1* and *PKD2*.

## FR-OR096

**Identification of Mosaic Mutations in Mild, Mutation Negative ADPKD Patients Using Next-Generation Sequencing** Katharina Hopp,[1] Sandro Rossetti,[2] Maria V. Irazabal,[1] Binu M. Paul,[1] Jamie L. Sundsbak,[1] Christina M. Heyer,[1] Peter C. Harris.[1] *[1]Mayo Clinic; [2]Cardio-Renal Dept Otsuka Pharm.*

**Background:** In ~10% of ADPKD patients no *PKD1*/*PKD2* mutation is detected by conventional Sanger sequencing, and evidence for a third locus is not strong. The majority of these patients have mild disease and often a negative family history. An explanation consistent with these findings is mosaicism, which has rarely been described in ADPKD but might often be undetected since it is difficult to identify by Sanger sequencing.

**Methods:** We have combined imaging, family, and sequencing analysis to identify ~80 mild, mutation negative ADPKD patients with a negative/uncertain family history. Using next-generating sequencing we developed a protocol to deep sequence (>5000x) the *PKD1/PKD2* loci that reliably detects variants at the >3% level. This protocol takes into account equal read start site, additional allele call, and vicinity mismatch penalties, For/Rev read balance scores, and common false positive filters gathered from next-generation sequencing data of >200 ADPKD samples.

**Results:** In the first test run of 8 ADPKD probands we detected two promising variants, *PKD1* c.7006T>TG, p.Y2336D (6.6%, read depth 7911x) and *PKD1* c.12682C>CT, p.R4228X (7.4%, read depth 5601x). The first variant scored as highly likely pathogenic in the ADPKD Mutation Database and was found in a proband with only ~25 small cysts at 76 years of age and an unclear family history. The second variant was found in a patient with negative family history, who was diagnosed at 34 years with a few renal cysts and now at 73 years has a TKV of 1,417ml and serum creatinine of 1.5mg/dl. This variant was confirmed by allele specific PCR and Sanger sequencing, where the c.12682C>CT peak could be seen just above the background level.

**Conclusions:** We hypothesize that mosaicism explains a significant portion of ADPKD mutation negative patients with mild disease and the incidence is likely underestimated due to the lack of a protocol that allows reliable detection of these variants. Here, we have developed such a protocol using next-generation sequencing technologies and have shown its efficacy in an initial test run.

## FR-OR097

**Prediction of GFR Endpoints in Early Autosomal Dominant Polycystic Kidney Disease** Michal Mrug,[1] Sylvie Mrug,[1] Doug Landsittel,[2] Vicente E. Torres,[3] Kyongtae Ty Bae,[2] Peter C. Harris,[3] Lisa M. Guay-Woodford,[4] Michael F. Flessner,[5] William M. Bennett,[6] Jared J. Grantham,[7] Arlene B. Chapman.[8] *[1]U AL Birmingham; [2]U Pittsburgh; [3]Mayo Clinic; [4]Children's Nat Med Ctr; [5]NIH; [6]Legacy Good Samaritan Hosp; [7]Kansas U; [8]Emory U.*

**Background:** There are no reliable formulas for predicting renal function over time in early autosomal dominant polycystic kidney disease (ADPKD).

**Methods:** We developed multivariable logistic models for reaching progression endpoints of CKD stage 3a and 3b and GFR decline by 30% and 50%. We developed the models and assessed their utility (with 10-fold cross-validation) using data collected by the Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease (CRISP), a prospective, observational, longitudinal, multicenter study of 241 ADPKD adults with preserved renal function. Demographic, physical, laboratory and imaging data were collected at baseline and during follow up visits.

**Results:** After a mean follow-up of 8.7 years, mean iothalamate clearance (GFR) decreased from 97.8 to 74.0 ml/min/1.73m$^2$. Baseline GFR alone was a poor predictor of GFR outcomes. However, prediction of the GFR endpoints has improved when ten baseline variables were used in multivariable models. GFR outcomes were significantly predicted by baseline age, BMI, hypertension, GFR, serum calcium and alkaline phosphatase, hemoglobin, white blood cell count, urinary MCP-1 and total kidney volume (TKV). Predicting the development of CKD stages 3a and 3b or GFR decline by 30% and 50% within 8.7 yrs using ROC analyses demonstrated an area under the curve (AUC) of 0.92, 0.93, 0.87 and 0.86, respectively for multivariable models. Similar AUCs were obtained using 10-fold cross-validation. The GFR-based modeling was repeated with MDRD-GFR, yielding similar outcomes.

**Conclusions:** Multivariable logistic models using routine clinical data predicted mild-moderate GFR decline endpoints in patients with early ADPKD. Such models may also facilitate the development of ADPKD therapies by informing selection of study participants with the highest risk for reaching FDA favored end-points.

*Funding:* NIDDK Support

## FR-OR098

**A New Algorithm to Predict Renal Outcome in Autosomal Dominant Polycystic Kidney Disease** Emilie Cornec-Le Gall,[1] Maryvonne Hourmant,[3] Marie-Pascale Morin,[4] Regine Perrichot,[6] Christophe Charasse,[7] Pascale Siohan,[5] Marie-Pierre Audrezet,[2] Claude Ferec,[2] Yannick Le Meur.[1] *[1]CHRU BREST, France; [2]INSERM 1078, CHRU Brest; [3]CHU Nantes; [4]CHU Rennes; [5]CH Quimper; [6]CH Vannes; [7]CH Saint-Brieuc.*

**Background:** As targeted therapies are under development in Autosomal Dominant Polycystic Kidney Disease (ADPKD), the selection of patients who should be treated is crucial. Herein, we present a new prognostic model to target patients at risk of poor renal outcome.

**Methods:** In a population of 1017 patients from 755 pedigrees, we studied the influence of 26 clinical, biological and genetic variables on renal outcome. We then built a model and tested it in a sub-population of 255 patients over 60 years or having reached ESRD before that age.

**Results:** The association of hypertension and at least one urologic complication (macroscopic hematuria, cysts infection or flank pain) before 35 yrs (group (g) 1) is associated with the poorest renal outcome (median age at ESRD=48 yrs, HR=3.8), the presence of either hypertension or urologic complication (g2) is of intermediate severity (54.4 yrs, HR=1.9), while patients without these characteristics (g3) have the best renal survival (67.9 yrs, $p<0.05$). Molecular data were available for 806 patients: truncating mutations (TM) of *PKD1* are associated with poorer renal outcome (53.9 yrs, HR=5.2) than non truncating (NTM) ones (62.6 yrs, HR=2.2) and *PKD2* patients have the the best renal survival (79.7 yrs, $p<0.05$). In a subgroup of patients over 60 yrs or having reached ESRD before that age, 96.3% of the patients belonging to g1 vs 79% of g2 and 44% of g3 reached ESRD before 60 yrs ($p<0.05$). Integrating molecular genetic and clinical data, we show that in g2 and g3, the proportion of patients reaching ESRD before 60 yrs is significantly higher in case of *PKD1* TM (g2:90.2%, g3:62%) than *PKD1* NTM (g2:62.9%, g3:37.1%) or *PKD2* mutations (g2:25%, g3:9.4%, $p<0.05$).

**Conclusions:** Based on the integration of simple clinical features with molecular genetic data, this algorithm might contribute to the development of a tailored approach of the therapeutic decision in ADPKD patients.

*Funding:* Government Support - Non-U.S.

## FR-OR099

**Novel Imaging Classification to Predict Functional Disease Progression in Autosomal Dominant Polycystic Kidney Disease (ADPKD)** Maria V. Irazabal, Laureano J. Rangel, Eric J. Bergstralh, Amber J. Harmon, Marie C. Hogan, Ziad El-Zoghby, Peter C. Harris, Bernard F. King, Vicente E. Torres. *Mayo Clinic, Rochester, MN.*

**Background:** CRISP showed that height adjusted total kidney volume (HtTKV) measured by stereology (TKVs) predicts eGFR decline in ADPKD. TKV can be used (1) as outcome measure in clinical trials and (2) for selection of patients more likely to exhibit treatment effect in a trial or benefit from an effective treatment. High precision but time consuming TKVs is essential for (1), but not for (2). Also, TKV and renal function correlate poorly in some patients. Our goal was to develop and validate a fast method to measure HtTKV that can be used for (2).

**Methods:** 590 ADPKD patients with CT/MR images and ≥3 eGFR measurements ≥6 months apart were classified as Atypical (class 1) or Typical (class 2) using pre-specified criteria (Figure 1 A). Class 2 patients were randomly partitioned into development and validation sets. TKV was calculated by stereology and ellipsoid formula (TKVe). Patients from the development set were subclassified (a-e) by age and HtTKV. A longitudinal mixed effects regression model was used to model eGFR decline.

**Results:** Figure 1 A shows baseline characteristics. TKVe correlated well with TKVs ($R^2$=0.98) without systematic bias (95% CI: -20.7%,19.6%) (Figure 1 B). HtTKV predicted eGFR decline in class 2 patients ($p<0.0001$), but not in class 1 ($p=0.07$). In the development set, patient subclasses showed significant differences in eGFR decline, with an average predicted error of=13.3 mL/min/1.73m$^2$ for the validation set (Figure 1C).

**Conclusions:** TKVe by CT/MR is an excellent predictor of TKVs and a fast way of estimating TKV for classifying class 2 ADPKD patients. The classification provides a practical tool for selecting the most appropriate patients for clinical trials and identifying patients with progressive disease likely to benefit from therapy.

## FR-OR100

**A Novel Agent That Inhibits Disease Progression in Models of Autosomal Dominant Polycystic Kidney Disease (ADPKD)** Sorin V. Fedeles,[1] Bogdan I. Fedeles,[2] Seung H. Lee,[1] Stefan Somlo.[1] *[1]Internal Medicine, Yale School of Medicine, New Haven, CT; [2]Biological Engineering, MIT, Cambridge, MA.*

**Background:** ADPKD is a common monogenic cause of end-stage kidney disease for which no effective therapy exists. We examined the role of the novel antitumor agent 11**β** (Fedeles, et al., J Biol Chem, **286**:33910) in ADPKD. 11**β** has been shown to induce apoptosis in prostate cancer cells in vitro and to prevent growth of xenograft tumors in nude mice.

**Methods:** We used the orthologous Pkd1 model, Pkd1$^{fl/fl}$;Pkhd1-Cre. Mice were given daily intraperitoneal injections of 11**β** from P10 to P24. We determined kidney to body weight (KW/BW) ratio, cystic index, BUN, apoptosis, and proliferation at P24 in treated and control animals.

**Results:** 11**β** administration resulted in a decrease in KW/BW ratio as compared to vehicle injected controls (6.3+/-0.4 vs.15.1+/-2;***p,0.001); the body weight of treated animals was not statistically lower than controls. These changes were accompanied by a decrease in th cystic index (50%+/-1.1 vs. 70%+/-1.2;***p.0.001) and a decrease in BUN levels (41+/-1.4 vs. 76+/-1.5;***p<0.001). 11**β** specifically increased apoptosis as assessed by the cell-titer blue viability assay in cultured Pkd1 null cells compared to control (***p<0.001). The in vivo apoptotic index by TUNEL staining also showed significant decrease in treated mice (***p<0.001). Importantly, the effect of the drug was specific in vivo, as the vast majority of apoptotic cells stained positive were of collecting duct origin where the Cre is active; proximal tubule cells did not exhibit increased apoptosis. Interestingly, 11**β** did not have a statistically significant effect on the proliferation of Pkd1 null cells in vivo, as measured by Ki67 staining.

**Conclusions:** Our data show that 11**β** is a potent and specific inducer of apoptosis of Pkd1 null cells both in vitro and in vivo. In previous work 11**β** has been shown to have a pleiotropic effect on several cellular signaling pathways including mTOR, the unfolded protein response (UPR), and MAP kinase. Further studies are needed to elucidate the role of 11**β** in the apoptotic response seen on a Pkd1 knockout background.

## FR-OR101

**Inhibition of DNMT1 Delays Cyst Growth in Autosomal Dominant Polycystic Kidney Disease** Xia Zhou,[1,2] James P. Calvet,[2,3] Xiaogang Li.[1,2,3] *[1]Dept of Internal Medicine; [2]Kidney Institute; [3]Dept of Biochemistry and Molecular Biology, Univ of Kansas Medical Center, Kansas City, KS.*

**Background:** Aberrant expression of DNA (cytosine-5)-methyltransferases (DNMTs) leads to promoter hypermethylation and the transcriptional silencing of a variety of tumor suppressor genes. Epigenetic alterations that result in dysregulated intracellular signaling pathways are proposed to promote cyst formation in ADPKD animal models. However, it is unknown whether DNMTs have a role in renal cyst formation.

**Methods:** To functionally test the role of DNMTs in renal cyst growth *in vivo*, *Pkd1* conditional knockout mice were treated with the DNMT inhibitor 5-azacytidine. To investigate how DNMTs might regulate cystic renal epithelial cell proliferation and apoptosis, cystic cells were treated with either DNMT1 siRNA or the inhibitor 5-azacytidine.

**Results:** We found that DNMT1 mRNA was upregulated in *Pkd1* mutant renal epithelial cells and tissues of *Pkd1*$^{flox/flox}$:Ksp-Cre mice vs *Pkd1* wild-type mice.Administration of 5-azacytidine to *Pkd1*$^{flox/flox}$:Pkhd1-Cre mice was found to significantly delay renal cyst growth *in vivo*. Knockdown of DNMT1 with siRNA or inhibition with 5-azacytidine in *Pkd1* mutant renal epithelial cells 1) decreased cystic epithelial cell proliferation as analyzed by the MTT assay, and induced G1 phase arrest as detected by FACS; and 2) decreased expression of Cyclin D1, phospho-Stat3, EGFR, and phospho-ERK, which were aberrantly upregulated and contribute to cystic epithelial cell proliferation in ADPKD. These results suggest that DNMT1 regulates cystic epithelial cell proliferation through these pathways. We also found that treatment with 5-azacytidine 1) induced cystic epithelial cell apoptosis as analyzed by Annexin V and PI double staining and TUNEL assay; and 2) increased the expression of p53, Bax and cleaved PARP, which suggested that the p53-Bax signaling pathway was involved in 5-azacytidine induced cystic renal epithelial cell death.

**Conclusions:** Inhibition of DNMT1 produces a potent anti-proliferative and pro-apoptotic effect in cystic renal epithelia and delays cyst formation in vivo, which suggests that targeting DNMT1 may function as a potential therapeutic strategy in ADPKD.

## FR-OR102

**Lanreotide Halts Polycystic Liver and Kidney Growth in Patients with Autosomal Dominant Polycystic Kidney Disease** Tom JG Gevers,[1] Jeroen C. Hol,[1] René Monshouwer,[3] Helena Dekker,[4] Jack F. Wetzels,[2] Joost P.H. Drenth.[1] *[1]Gastroenterology and Hepatology, Radboud Univ Nijmegen Medical Centre, Netherlands; [2]Nephrology, Radboud Univ Nijmegen Medical Centre, Netherlands; [3]Radiation Oncology, Radboud Univ Nijmegen Medical Centre, Netherlands; [4]Radiology, Radboud Univ Nijmegen Medical Centre, Netherlands.*

**Background:** We showed that the somatostatin analogue lanreotide reduced liver volume in patients with polycystic livers. However, this trial included patients with autosomal dominant polycystic kidney disease (ADPKD) and with isolated polycystic liver disease (PCLD). The aim of the present study was to assess the efficacy of lanreotide treatment in ADPKD patients with symptomatic polycystic liver disease.

**Methods:** This open-label clinical trial evaluated the effect of 6 months of lanreotide 120 mg subcutaneously every 4 weeks. Exclusion criteria were eGFR (MDRD) < 30 ml/min/1.73m2, use of oral contraceptives and PCLD. The primary outcome was change in liver volume determined by computerized tomography-volumetry. Secondary outcomes were changes in total kidney volume, eGFR and symptom relief. The severity of gastro-intestinal symptoms was measured with a 7-points scale questionnaire, and were dichotomized for absence or presence.

**Results:** We included 43 ADPKD patients with polycystic liver disease (84% female, mean age 51 years, eGFR 63 ml/min/1.73m2). Median liver volumes decreased from 4859 ml to 4595 ml (-3.2%, p<0.01). Lanreotide significantly relieved postprandial fullness (p<0.01), shortness of breath (p<0.012) and abdominal distension (p<0.01). Patients previously treated with somatostatin analogues had similar reductions in liver volumes as treatment-naïve patients. Although median kidney volumes decreased from 1023 ml to 1012 ml (-1.6%, p<0.01), this reduction did not improve eGFR.

**Conclusions:** Lanreotide reduces polycystic liver and kidney volumes and decreases symptoms in ADPKD patients with polycystic livers. Previous treatment with somatostatin analogues does not impair efficacy.

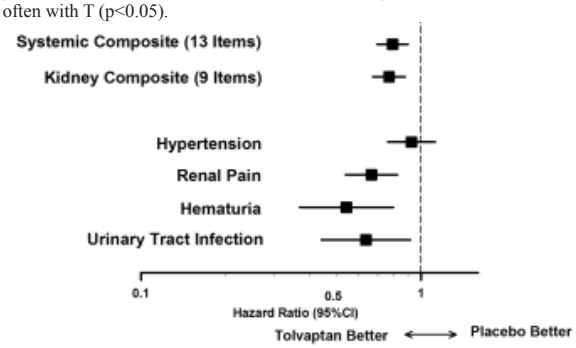
### Clinical Outcomes in ADPKD: Results from the TEMPO 3:4 Trial

Frank S. Czerwiec,[1] Arlene B. Chapman,[2] Olivier Devuyst,[3] Ron T. Gansevoort,[4] Eiji Higashihara,[5] Holly Krasa,[1] John Ouyang,[1] Ronald D. Perrone,[6] Vicente E. Torres.[7] *[1]Otsuka, USA; [2]Atlanta, USA; [3]Zurich, Switzerland; [4]Groningen, Netherlands; [5]Mitaka, Japan; [6]Boston, USA; [7]Rochester, USA.*

**Background:** ADPKD is a hereditary disease of progressive kidney destruction by cysts associated with systemic complications. The effect of tolvaptan (T) on systemic aspects of ADPKD was prospectively assessed in the TEMPO trial.

**Methods:** Clinical outcomes related to ADPKD were collected at each study visit and were analyzed by incidence and time to multiple events as a 13- (systemic) and 9-item (kidney) composite and the 4 most frequently observed events.

**Results:** Tolvaptan (T) subjects had less ADPKD-related outcomes in both disease composites (p<0.05). Of the most common events renal pain, hematuria, and UTI occurred less often with T (p<0.05).



For each of these events, T subjects reported less medical resource use (healthcare visits and/or medical procedures) and lost productivity due to the event. All 9 kidney-related events occurred less often with T.

| Event Type | Tolvaptan (N=961) % | Placebo (N=484) % |
|---|---|---|
| Hypertension* | 34.9 | 35.7 |
| Renal pain* | 26.2 | 38.0 |
| Urinary tract infection* | 9.8 | 14.6 |
| Hematuria* | 7.5 | 13.8 |
| Vascular/Cardiac Abnormalities | 4.6 | 4.7 |
| Anemia* | 2.2 | 4.5 |
| Abdominal/inguinal hernia* | 3.1 | 3.7 |
| Nephrolithiasis* | 1.7 | 3.5 |
| Other Cysts | 1.5 | 2.0 |
| Hepatic Cysts | 1.7 | 1.6 |
| Albuminuria* | 0.5 | 1.4 |
| Renal Function (eg, Dialysis)* | 0.9 | 1.0 |
| Colonic Diverticuli | 0.4 | 0 |
| * *Part of Kidney Composite* | | |

**Conclusions:** T treated subjects demonstrated fewer kidney related complications in an exploratory endpoint. These results support the impact of T beyond kidney cyst growth and functional decline.

*Funding:* Pharmaceutical Company Support - Otsuka Pharmaceuticals

## FR-OR104

### Effect of Tolvaptan on Urine Osmolality versus Outcome in ADPKD: Results from the TEMPO 3:4 Trial

Olivier Devuyst,[1] Arlene B. Chapman,[2] Ron T. Gansevoort,[3] Jared J. Grantham,[4] Eiji Higashihara,[5] Ronald D. Perrone,[6] Vicente E. Torres,[7] Holly Krasa,[8] John Ouyang,[8] Susan E. Shoaf,[8] Xiaofeng Wang,[8] Frank S. Czerwiec.[8] *[1]Zurich, Switzerland; [2]Atlanta; [3]Groningen, Netherlands; [4]Kansas City; [5]Mitaka, Japan; [6]Boston; [7]Rochester; [8]Otsuka PDC.*

**Background:** The TEMPO 3:4 trial indicated that the vasopressin V2-receptor (V2R) antagonist tolvaptan (T) slowed the increase in total kidney volume (TKV) and the decline in kidney function (eGFR) over 3 years in ADPKD patients with preserved eGFR. We investigated whether this beneficial effect could be predicted by changes in urine osmolality (Uosm).

**Methods:** Post-hoc, exploratory analyses of a prospective, blinded RCT. Trough morning spot urine samples were collected at baseline (BL), and months (M) 12, 24 and 36. By protocol, water intake was encouraged and use of diuretics discouraged.

**Results:** Baseline Uosm was similar in placebo (N=333) and T (N=668) subjects (515 vs 497 mOsm/kg, respectively). It correlated with age, eGFR, and TKV. Placebo treated subjects had mean changes from BL Uosm ranging between -26 and -85 mOsm/kg over M36, reflecting increased water intake. A lower average Uosm during the trial was associated with a lesser increase in TKV. T treatment significantly reduced Uosm vs. placebo (by 249 mOsm/kg at week 3 and by 190 mOsm/kg at M36), with no loss of effect over time. T subjects with a greater suppression in Uosm had a 2-fold reduction in the occurrence of clinical progression events (severe renal pain and worsening kidney function) vs. those with less Uosm suppression (12.1% vs. 23.3%, highest vs. lowest quartile of Uosm change from BL, respectively), as confirmed by Kaplan-Meier analysis. T subjects with the greatest mean changes from BL Uosm were more likely to achieve no change in renal function.

**Conclusions:** These data in T treated patients (i) support the link between vasopressin V2R signalling and progression in ADPKD; (ii) suggest that monitoring Uosm could guide T titration and maintenance; and (iii) indicate that greater renoprotective effect may be achieved when Uosm is reduced by 300 mOsm/kg.

## FR-OR105

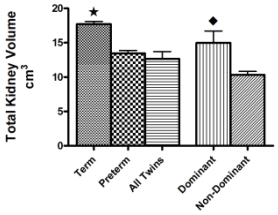
### Nephron Mass and the Intrauterine Environment: Twins from the Gerber Infant Kidney Study

Marissa J. Defreitas,[1] Teresa C. Cano,[1] Wacharee Seeherunvong,[1] Marta G. Galarza,[2] Chryso P. Katsoufis,[1] Vimal Master Sankar Raj,[1] Alcia D. Edwards- Richards,[1] Salih Y. Yasin,[3] Jayanthi Chandar,[1] Shahnaz Duara,[2] Gaston E. Zilleruelo,[1] Carolyn L. Abitbol.[1] *[1]Pediatric Nephrology, Univ of Miami/ Holtz Children's Hospital, Miami, FL; [2]Neonatology, Univ of Miami/ Holtz Children's Hospital, Miami, FL; [3]Obstetrics/Perinatology, Univ of Miami/ Holtz Children's Hospital, Miami, FL.*

**Background:** Nephrogenesis is active until 36 weeks' gestation. Preterm birth interrupts nephrogenesis and predisposes to a reduction in the total number of nephrons. Total Kidney Volume (TKV) is a surrogate for nephron mass. Multiple gestation imposes increased competition and provides a venue for studying a shared intrauterine environment.

**Methods:** Of 155 infants enrolled in the Gerber Infant Kidney Study, 53 were term infants (>37 weeks' gestational age) (GA), 86 were preterm (<37 weeks' GA) and 16 were preterm twins. Renal function was assessed by estimated glomerular filtration rate (eGFR) calculated from reference equations using serum creatinine and cystatin C. Renal length and volume were measured by ultrasound.

**Results:** eGFR was similar in twins and singletons of similar GA. Renal length and TKV were significantly less in preterm infants compared to term controls and correlated to GA (r=0.52; p<0.001). Among twin pairs, their was a significant discrepancy in TKV (15±5 versus 10±1 $cm^3$; p<0.01). One twin was dominant for kidney mass which was independent of gender or birth weight or length (p>0.5).



★ Significantly greater than others in same group; p<0.01

◆ Sigificantly greater than the non-dominant twin; p<0.05

**Conclusions:** Preterm birth imposes a restriction on nephron mass. Multiple gestation appears to impose an additional restriction in one of the twins that may predispose to adult cardiovascular and renal disease risks. Prospective longitudinal studies are needed to better understand the impact of twinning on nephron mass.

## FR-OR106

**Mortality and Length of Stay Increase with Acute Kidney Injury (AKI) Severity Stage in Critically Ill Children** Scott M. Sutherland,[1] John James Byrnes,[2] Manish Kothari,[2] Pablo Garcia,[2] Stuart Goldstein.[3] *[1]Pediatrics, Stanford Univ, Stanford, CA; [2]SRI International, Menlo Park, CA; [3]Center for Acute Care Nephrology, Cincinnati Children's Hospital, Cincinnati, OH.*

**Background:** Recently, standardized AKI definitions have been developed (pRIFLE, AKIN, and KDIGO). These consensus definitions have not been correlated with outcomes in pediatric patients on a large scale.

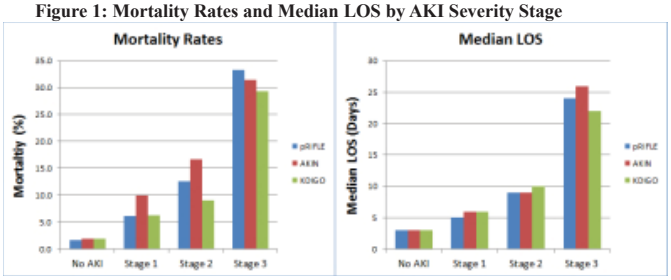
**Methods:** Patient data including age, height, and serial serum creatinine values were extracted anonymously from the electronic medical record. Mortality rates and length of stay (LOS) distributions were calculated for each stage of each definition. Likelihood ratios were calculated to assess the mortality risk associated with incremental AKI severity stages.

**Results:** 2365 intensive care unit (ICU) hospitalizations were analyzed. The median age was 6.0 (IQR 2.0-14.0). AKI rates varied between the pRIFLE (39%), AKIN (30%), and KDIGO (35%) definitions; across all three, AKI severity stage was associated with increased mortality rates and LOS (Figure 1). Compared to patients without AKI, patients with AKI experienced a greater likelihood of death; more severe AKI was associated with a greater mortality risk (Table 1, all p-values < 0.001).

**Table 1: Likelihood Ratio (LR) of Death by AKI Severity Stage**

| | Stage 1 vs. No AKI | Stage 2 vs. No AKI | Stage 3 vs. No AKI |
|---|---|---|---|
| **pRIFLE** | 3.8 | 7.8 | 20.5 |
| **AKIN** | 5.0 | 8.4 | 15.8 |
| **KDIGO** | 3.3 | 4.8 | 15.4 |

**Figure 1: Mortality Rates and Median LOS by AKI Severity Stage**



**Conclusions:** Within a large pediatric ICU cohort, AKI was significantly associated with poorer outcomes. Mortality rates and LOS increased incrementally as AKI severity increased. All three AKI definitions demonstrated strong outcome association. Further analysis is required to determine which definition is optimal.

## FR-OR107

**Microalbuminuria in Children with Chronic Kidney Disease** Dana F. Work,[1] Michael F. Schneider,[2] Susan L. Furth,[3] Jeffrey M. Saland,[4] Tom D. Blydt-Hansen,[5] Bradley A. Warady,[6] Marva M. Moxey-Mims,[7] George J. Schwartz.[1] *[1]Peds., Univ Rochester Med. Center, Rochester, NY; [2]Epi., J. Hopkins Bloom. Sch. Pub. Health, Baltimore, MD; [3]Peds., Child. Hosp. Phila., Phila., PA; [4]Peds., Mt. Sinai Sch. Med., New York, NY; [5]Peds., Univ Manitoba, Winnipeg, MB; [6]Peds., Child. Mercy Hospital, Kansas City, MO; [7]NIDDK, NIH, Bethesda, MD.*

**Background:** Children are generally screened for proteinuria by measurement of urine protein/creatinine ratio (Up/c). By this screening method those with microalbuminuria (urine albumin:creatinine between 30 and 300 mg/g) are classified as having clinically insignificant proteinuria. We sought to examine microalbuminuria, in the absence of elevated Up/c, as a potential marker for lower GFR in children with CKD.

**Methods:** We used data collected in the Chronic Kidney Disease in Children (CKiD) study. Linear regression was used to quantify the association of initial spot urine microalbuminuria, as well as Up/c, on GFR while controlling for age, diabetes, gender, hypertension, race and cause of CKD. GFR was measured by iohexol disappearance or estimated using CKiD-published formulas. Hypertension was defined as systolic or diastolic BP>95$^{th}$ percentile or on BP medication.

**Results:** In 682 subjects 1-21 years old, those with microalbuminuria did not have a significant difference in mean GFR (3.4±3.0 ml/min per 1.73m$^2$, p=0.64) when compared to subjects without microalbuminuria (64.9±23.7 vs. 69.5±24.5 ml/min per 1.73m$^2$). Individuals with elevated Up/c and > 300 mg albumin/g creatinine (albuminuria) had a mean GFR that was 19.0±2.2 ml/min per 1.73 m$^2$ less than those without proteinuria or microalbuminuria (p<0.001). Of 183 subjects who had Up/c < 0.2 and had >1 GFR value over a mean of 2 years of follow-up, 9 (5%) (7 without microalbuminuria) had a decline in GFR of at least 30%; this is compared to 307 subjects with Up/c>0.2 of which 74 (24%) had a decline in GFR of at least 30%.

**Conclusions:** While screening for microalbuminuria may be useful in some patient populations, our analysis suggests that when monitoring proteinuria in children with CKD, Up/c is sufficient. Urine albumin does not appear to provide additional information for the management of CKD in children.

## FR-OR108

**Does Nephrectomy of Failed Renal Transplant Affect Outcome in Pediatric Patients with a Second Transplant?** Marta Monteverde,[1] Alicia Beatriz Chaparro,[1] Liliana Margarita Briones,[1] Juan Carlos Ayus.[2] *[1]Hospital Garrahan, Bs As, Argentina; [2]Renal Consultants of Houston, Texas.*

**Background:** Patients with a failed renal allograft who return to dialysis have significant increase in morbidity and mortality, most likely related to chronic inflammation(Lopez JM;JASN 2004). Transplant nephrectomy in these patients is associated with decreased mortality (Ayus JC JASN 2010). However, a possible drawback of transplant nephrectomy could be an increase in transplant failure in retransplantation.**Purpose:** To evaluate the difference in outcome between pediatric patients who had a second transplant (STX) after nephrectomy of the failed allograft and patients with a first transplant (FTX), as no information regarding allograft nephrectomy and retransplantation exists in children.

**Methods:** We compared patient and graft survival and eGFR at last visit of follow-up between F TX and S TX children with allograft nephrectomy.

**Results:** Between December 1988 and March 2013, 696 TX were performed at a public tertiary pediatric referral center, 659 first renal TX **(FTX)** and 37 second TX **(STX)**. Thirty-one children from the STX group had their first failed graft removed. In 15, nephrectomy was early (<90 days post TX) and in 16 late. Median time of follow up after transplantation of patients in both FTX and STX groups was 5 years (IQR: 2-7.4). Except for panel reactive antibodies (PRA) levels pre-TX (<10% in 98% vs. 87%, 10 to 40% in 2.2% vs. 8.7%, and > 40% in 0% vs. 4% of FTX vs. ST X; p=0.004), and recipient age (FTX: 11.1 ±4.3 years, STX: 12.9±3 years; p=0.02), there were no other differences at baseline between both groups. Patient survival at 6 years was 95% for FTX and STX. Graft survival at 1 and 6 years was 93% vs. 90.3 % and 77% vs. 81% for FTX and STX patients with allograft nephrectomy (p= 0.82). Six-year graft survival was not different in those with late vs. early nephrectomy (78% vs. 86%; p=0.40). eGFR at last visit was 43±26 vs. 40±23 ml/min/1.73m2 (p=0.58).

**Conclusions:** Nephrectomy of the failed renal allograft did not affect either patient or graft survival and final eGFR in their second transplant.

## FR-OR109

**The Antimicrobial Activity of Ribonuclease 7 Is Blocked by an Endogenous Ribonuclease Inhibitor in the Human Urinary Tract** John David Spencer, Tad Eichler, David S. Hains. *Center for Clinical and Translational Research, The Research Institute at Nationwide Children's, Columbus, OH.*

**Background:** Although urine is considered sterile, little is known how the kidney defends against infection. We have previously demonstrated that the collecting duct produces antimicrobial peptides (AP). The collecting duct produce RNase7, one of the most potent human APs. To date, the regulation of RNase7's antimicrobial activity is not defined. Other research groups have demonstrated that an endogenous Ribonuclease Inhibitor (RI) binds to Ribonuclease A proteins and alters their function. The expression of RI in the urinary tract has not been previously evaluated and its on RNase7 in the urinary tract are unknown.

**Methods:** RNA from non-infected and pyelonephritic human kidney was used to quantify *RNASE7* and *RI* via real-time PCR. IF localized RNase7 and RI production. Western blot (WB) quantified RNase7/RI in kidney and urine samples. Native gel assays assessed RI-RNase7 binding. Bacterial binding and Live/Dead kill assays assessed the antimicrobial function of RNase7 on *E.coli* (UPEC) in the presence and absence of RI.

**Results:** With pyelonephritis, RNASE7 mRNA expression increased while RI mRNA expression decreased (p<0.05). IF localized RNase7 production to the apical surfaces of intercalated cells (ICs) in the renal collecting ducts and RI to the basolateral surfaces of ICs. WB demonstrated that kidney and urinary RNase7 peptide production increase with infection while RI peptide decreased with pyelonephritis. Recombinant RNase7 kills UPEC at micromolar concentrations. Protein binding assays demonstrate that RI tightly binds to RNase 7. In the presence of equal concentrations of RI, the antimicrobial effects of RNase7 significantly decrease against UPEC. RI blocks the binding of RNase 7 to LPS of Gram-negative uropathogens.

**Conclusions:** The renal epithelium is important in maintaining sterility of the urinary tract as it produces potent APs like RNase7. It also produces regulatory proteins like RI, which binds RNase7 and abrogates its antimicrobial effects. Further elucidation of the factors that regulate production/function of APs like RNase7 may lend insight into the UTI pathogenesis.

*Funding:* NIDDK Support

## FR-OR110

**Nephroprotective Efficacy of RAS Blockade in Mice Carrying R140Q Podocin Mutation** Tanja Wlodkowski,[1] Helga Denc,[1] Ivana Simic,[1] Mansoureh Tabatabaei Far,[1] Geraldine Mollet,[2] Corinne Antignac,[2] Franz S. Schaefer.[1] *[1]Pediatric Nephrology Div, Heidelberg Univ, Germany; [2]Inserm U983, Hopital Necker, France.*

**Background:** NPHS2 mutations cause hereditary nephrotic syndrome and progressive renal failure. We recently generated an inducible knock-in mouse model carrying R140Q, the analogue of the most common human mutation R138Q. These mice develop FSGS with nephrotic syndrome and progressive renal failure. Here we tested the efficacy of early and delayed RAS blockade in this model of hereditary podocyte disease.

**Methods:** In C57BL/6 mice with Nphs2$^{Flox/R140Q}$,Cre$^{+}$ genotype hemizygosity for mutant podocin was induced by tamoxifen injection. Animals received combined high-dose ACE inhibition and AT1 receptor blockade (ramipril+candesartan 10 mg/kg each,R+C) or

remained untreated. Treatment was started either prophylactically (P) at time of induction or with a two-week delay (D). Animals were sacrificed after 4 wks or observed open-end.

**Results:** RAS blockade reduced proteinuria to 6%(P,p<0.005) and 33%(D,p<0.05) of untreated animals 5 wks after induction. At this time point, the R+C animals retained normoalbuminemia(31 v.19 g/l), lower serum creatinine(0.14 v.0.16 mg/dl), a higher number of podocytes per glomerulus(73 v.39), and a lower glomerular sclerosis index(0.91 v.1.47). Podocin protein abundance was almost totally lost in both untreated and treated animals, despite preserved or even increased mRNA expression. At wk 9, proteinuria had gradually increased to 75% of controls in D(n.s.) but remained low in P animals(10% of controls,p<0.005). Three-month graft survival was 50.1% in the untreated animals, but 100% in all animals with RAS blockade(p<0.05).

**Conclusions:** In mice carrying the most common human podocin mutation, RAS blockade attenatues proteinuria, podocyte loss and glomerulosclerosis despite persistently increased degradation of mutant podocin protein. Renal failure is delayed and survival prolonged. Treatment is more effective when applied prophylactically than when started after 2 wks, the time when histopathological lesions first become detectable. Our findings indicate that early RAS blockade provides effective nephroprotection in this hereditary podocytopathy.

## FR-OR111

**Adeno-Associated Virus 9 Expression of GFP in Mice Using a Truncated Nephrin Promoter** Melissa A. Muff-Luett, Di Wu, Jason L. Picconi, Erik Bunchman, Patrick D. Brophy. *Div of Pediatric Nephrology, Univ of Iowa Children's Hospital, Iowa City, IA.*

**Background:** Structural renal diseases such as nephrotic syndrome have no specific curative therapy. Gene therapy offers the possibility of therapeutic intervention for diseases with single gene mutations. The kidneys especially glomeruli have proven difficult to target with previous experimental vectors. Recently the adeno-associated virus 9 (AAV2/9) has been shown to have broad tissue tropism in mice including the kidneys. A truncated 1.25kb promoter of NPHS1, the gene which encodes nephrin, has been shown to have renal specific expression. We developed a novel AAV2/9 with the truncated minimal nephrin promoter (MNP) to direct kidney specific gene expression and potential therapy. Our goal was to characterize GFP expression in mice after systemic tail vein injection with the AAV2/9-MNP-GFP vector.

**Methods:** We designed an AAV2/9-MNP-GFP vector with the 1.25kb nephrin promoter to drive GFP gene expression. A CMV promoter (AAV2/9-CMV-GFP) was used as the positive control vector and saline as a negative control. Eight-week old female C57 mice were injected with 3x10^11 viral particles of each vector. Tissue was harvested 8 weeks after injection. Kidney, brain, liver and heart were analyzed for the presence of viral DNA copies, GFP RNA expression and GFP protein expression.

**Results:** AAV2/9-MNP-GFP transfected kidneys showed 6 fold higher viral copy numbers than CMV controls with a similar trend in the other tissues. Renal GFP RNA expression was 5 fold higher in the AAV2/9-CMV-GFP transfected controls compared to the AAV2/9-MNP-GFP mice. AAV9-MNP-GFP livers showed GFP RNA expression but no protein expression. GFP RNA expression was absent in brain and heart of AAV9-MNP-GFP mice. AAV2/9-MNP-GFP transfected mice demonstrated sustained glomerular GFP protein expression within the kidneys by immunofluorescence with no protein expression in the liver, brain and heart.

**Conclusions:** The AAV2/9 vector utilizing the 1.25kb nephrin promoter provides a safe, viable tool for renal directed gene therapy in mice. These experiments provide a novel method for the investigation and potential therapy for congenital renal diseases in mice.

*Funding:* Private Foundation Support

## FR-OR112

**Chronic Epithelial Kidney Injury Molecule-1 Expression in Mice Causes Inflammation, Fibrosis and Kidney Failure** Benjamin D. Humphreys, Venkata Sabbisetti, Fengfeng Xu, Ivica Grgic, Said Movahedi Naini, Ningning Wang, Guochun Chen, Sheng Xiao, Dhruti D. Patel, Joel M. Henderson, Takaharu Ichimura, Shan Mou, Savuth Soeung, Andrew P. McMahon, Joseph V. Bonventre. *Renal Div, Brigham and Women's Hospital, Boston, MA.*

**Background:** Acute kidney injury predisposes to future CKD and ESRD but the molecular details underlying this clinical association are unknown. We report that chronic expression of Kidney Injury Molecule-1 (KIM-1), an epithelial phosphatidylserine receptor expressed during acute injury and in fibrotic renal disease, promotes kidney fibrosis.

**Methods:** We generated a transgenic mouse line for conditional overexpression of KIM-1 in a cell specific manner. The KIM-1 conditional mouse line was crossed with a tubular Cre driver and we examined kidney phenotype over time. We also evaluated susceptibility to unilateral ureteral obstruction (UUO)-induced fibrosis in mice with a targeted deletion of the mucin domain of KIM-1, resulting in a mutant, KIM-1 polypeptide with markedly diminished phagocytic function.

**Results:** Mice with transgenic overexpression of KIM-1 in tubule epithelia, but no other cell type, developed spontaneous and progressive interstitial kidney inflammation with fibrosis leading to renal failure. Mice developed anemia, proteinuria, hyperphosphatemia, hypertension, cardiac hypertrophy and died of renal disease, analogous to progressive kidney disease in humans. KIM-1-transgenic kidneys had elevated expression of the pro-inflammatory chemokine monocyte chemoattractant protein-1 (MCP-1) at early time-points. Heterologous expression of KIM-1 in an immortalized proximal tubule cell line triggered MCP-1 secretion and increased MCP-1-dependent macrophage chemotaxis. In KIM-1 mutant mice, experimental kidney fibrosis, secondary to UUO, was ameliorated and levels of MCP-1 were reduced, consistent with a pro-fibrotic role for native KIM-1.

**Conclusions:** Sustained KIM-1 expression, a characteristic of chronic kidney disease in humans, promotes kidney inflammation and fibrosis and provides a molecular link between acute injury and progressive chronic kidney disease.

## FR-OR113

**Myofibroblastic Transformation of Renal Erythropoietin-Producing Cells Governs Fibrosis but Is Reversible in Early Injury Stage** Tomokazu Souma,[1] Shun Yamazaki,[1] Takashi Moriguchi,[1] Norio Suzuki,[1] Sadayoshi Ito,[2] Masayuki Yamamoto.[1] *[1]Dept of Medical Biochemistry, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan; [2]Dept of Medicine, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan.*

**Background:** Myofibroblasts are the culprit of renal fibrosis, and anemia develops along with scaring due to insufficient erythropoietin (Epo). We have recently characterized renal Epo-producing cells (REPs) as fibroblast-like cells with neural characters. They transform into myofibroblasts when injured, while exact contributions of REPs to the total myofibroblasts pool, mechanisms underlying this process and phenotypic reversibility are still unclear.

**Methods:** To analyze the myofibroblastic transformation process, we generated efficient monitoring and cell-fate tracing systems for REPs utilizing transgenic (Tg) complementary rescue method and Cre-loxP system. Genetically induced severe anemia in Tg-rescued mice enabled maximal recruitment and isolation of REPs. Transgenic Cre expressions, which are driven by full regulatory region of Epo, enabled tracking of cells with history of Epo expression.

**Results:** By adopting unilateral ureteral obstruction, we discovered that almost all myofibroblasts in cortex and outer medulla are derived from REPs. Transformed REPs were isolated by flow cytometry, and were found to lose their Epo-producing potential by 90%. On the contrary, they produced not only extracellular matrix, but also inflammatory mediators (such as Ccl2, Il6, and so on). By removing the obstruction in early injury stage, myofibroblasts reverted to physiological status, regaining normal Epo-producing ability, and stopped producing excess collagens. Microarray analysis showed inflammatory signaling cascades were the top canonical pathways induced in injured kidneys during the transformation process. Thereby, anti-inflammatory therapy accelerated the reversion of myofibroblasts to normal REPs.

**Conclusions:** Our findings demonstrate that REPs are the major source of myofibroblasts, and possess profound plasticity. Modulation of cellular status of REPs is an important strategy to control the balance between beneficial repair/regeneration and deleterious scaring of kidneys.

## FR-OR114

**Multiple Genes of the Renin-Angiotensin System Are Novel Targets of Wnt/β-Catenin Signaling in Kidney Injury** Li Li Zhou,[1,2] Yingjian Li,[1] Dong Zhou,[1] Roderick J. Tan,[3] Jing Nie,[2] Fan Fan Hou,[2] Youhua Liu.[1] *[1]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA; [2]Div of Nephrology, Nanfang Hospital, Southern Medical Univ, Guangzhou, Guangdong, China; [3]Dept of Medicine, Univ Pittsburgh, Pittsburgh, PA.*

**Background:** Activation of the renin-angiotensin system (RAS) plays an essential role in the pathogenesis of chronic kidney and cardiovascular diseases. However, current anti-RAS therapy only displays limited efficacy, partly because of compensatory upregulation of renin expression. Therefore, developing a strategy to simultaneously target multiple RAS genes is necessary for the effective treatment of chronic kidney and cardiovascular diseases.

**Methods:** The promoter region of all RAS genes were analyzed by bioinformatics tool. The expression of RAS genes in cultured cells and kidney tissues were examined by qRT-PCR, Western blot, and immunostaining.

**Results:** By bioinformatics analyses, we uncovered that all RAS genes contained putative TCF/LEF-binding sites in their promoter regions, and β-catenin induced the binding of LEF-1 to these sites in kidney tubular cells. Over-expression of either β-catenin or different Wnt ligands induced the expression of all RAS genes. Conversely, a small molecule β-catenin inhibitor ICG-001 abolished RAS induction. In a mouse model of nephropathy induced by adriamycin, either transient therapy or late administration of ICG-001 was able to abolish an established proteinuria and kidney lesions. ICG-001 inhibited renal expression of multiple RAS genes in vivo, and abolished the expression of other Wnt/β-catenin target genes. As a result, ICG-001 therapy attenuated myofibroblast activation, repressed matrix expression, and inhibited renal inflammation and fibrosis.

**Conclusions:** Collectively, these studies identify all RAS genes as novel downstream targets of Wnt/β-catenin. Our results also indicate that blockade of Wnt/β-catenin signaling can simultaneously repress multiple RAS genes, thereby leading to the reversal of an established proteinuria and kidney injury.

**FR-OR115**

**Blocking the TGF-Beta Type II Receptor in Interstitial Cells Does Not Ameliorate Renal Fibrosis** Leslie S. Gewin,[1,2] Roy Zent.[1,2,3,4] *[1]Dept of Research, Veterans Affairs Hospital, Nashville, TN; [2]Div of Nephrology, Dept of Medicine, Vanderbilt Univ, Nashville, TN.*

**Background:** TGF-beta exerts strong pro-fibrotic effects following injury, but the target cell responsible for mediating these effects is unclear. TGF-beta activates fibroblasts and induces their production of collagen I in vitro, but how TGF-beta signaling in fibroblasts modulates injury in vivo has not been examined.

**Methods:** To address this, we deleted the TGF-beta type II receptor in interstitial cells using two different tamoxifen-inducible Cre: COL1A2-Cre and TenascinC-Cre. The mT/mG reporter mouse localized Cre activity, and recombination after tamoxifen administration in vivo was confirmed using PCR. Characterization of these interstitial cells was performed by FACS analysis.

**Results:** Surprisingly, both $Tgfbr2^{floxed}$xCOL1A2-Cre and $Tgfbr2^{floxed}$xTenascin C-Cre mice had equivalent amounts of tubulointerstitial fibrosis compared to their $Tgfbr2^{floxed}$ littermate controls at 7 and 14 days after unilateral ureteral obstruction (UUO). Fibrosis was measured by picosirius red staining, immunohistochemistry for collagen I, IV, and fibronectin, and by immunoblotting renal tissue lysates for collagen I. Cells were isolated from both $Tgfbr2^{floxed}$xCOL1A2-Cre and $Tgfbr2^{wildtype}$xCOL1A2-Cre mice after UUO using FACS to sort out EGFP+ cells. Primary cells from both mice expressed markers typical for fibroblasts. Cells isolated from $Tgfbr2^{wildtype}$xCOL1A2-Cre mice had markedly increased collagen I expression after stimulation with TGF-b1 but those from $Tgfbr2^{floxed}$xCOL1A2-Cre mice had less collagen I at baseline and no significant response to TGF-b1.

**Conclusions:** These results suggest that interstitial cells with the type II receptor isolated from injured mice do upregulate collagen I expression in response to TGF-b1 in vitro, and this response is not observed in cells lacking the TGF-beta type II receptor. However, the absence of the TGF-beta type II receptor in interstitial cells does not protect against renal injury, implying that in vitro data may not reliably predict in vivo responses and that TGF-beta signaling in medullary interstitial cells may not be important in modulating UUO-induced tubulointerstitial fibrosis.

**FR-OR116**

**Exploring the Function of Renal Fibroblasts of Extra-Renal Origin** Jin Nakamura, Akiko Oguchi, Motoko Yanagita. *Nephrology, Kyoto Univ, Graduate School of Medicine, Kyoto, Japan.*

**Background:** We previously reported that most fibroblasts in the renal cortex and outer medulla are myelin protein zero-Cre (*P0-Cre*) lineage-labeled cells (P0 cells)of extra-renal origin, and that some of them are erythropoietin (EPO) producing cells in the healthy kidney. In the diseased kidney, P0 cells transdifferentiate into myofibroblasts and predominantly contribute to fibrosis, with concomitant loss of EPO production. In this study, we further investigated the function of P0 cells and the crosstalk between the fibroblasts and tubular epithelial cells.

**Methods:** We utilized *P0-Cre* inducible simian diphtheria toxin receptor (DTR) transgenic mice (*P0-Cre:iDTR* mice). The binding of DT to DTR halts protein synthesis within P0 cells, inhibiting the crosstalk between fibroblasts and tubular epithelial cells.

**Results:** First we confirmed that renal fibroblasts were successfully labeled with DTR in *P0-Cre:iDTR* mice. DT administration ablated the expression of DTR and fibroblast markers, indicating the effective cessation of protein synthesis in P0 cells. Simultaneously, the expression of EPO was significantly reduced, and did not increase even after the induction of severe anemia. In addition, the expression of tubular injury markers, as well as the proliferation of proximal tubule cells was induced. The administration of DT to *P0-Cre:iDTR* mice with unilateral ureteral obstruction reduced the expression of fibrosis markers, and enhanced the expression of tubular injury markers in diseased kidney. Unlike the results of healthy kidney, tubular proliferation in diseased kidney was attenuated.

**Conclusions:** Cessation of protein synthesis in P0 cells reduced the expression of EPO in healthy kidney and the fibrosis markers in diseased kidney, supporting our previous findings. And this also induced the tubular injury and influenced the tubular proliferation, suggesting that fibroblasts inhibit tubular proliferation and injury in healthy kidney, while support the repair of injured tubule by promoting tubular proliferation in diseased kidney. These results indicate the possible interactions between the fibroblasts and tubular epithelial cells. We are currently searching for the molecules responsible for the interactions.

**FR-OR117**

**Tracing Tubular Cells' Fate in Folic Acid Induced Kidney Injury Model by Lineage Tagging** Jianling Tao,[1,2] Peng Guo,[3] Katalin Susztak.[1] *[1]Renal Electrolyte and Hypertension Div, Dept of Medicine, Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA; [2]Div of Nephrology, Peking Union Medical College Hospital, Peking Union Medical College & Chinese Academy of Medical Sciences, Beijing, China; [3]Analytical Imaging Facility, Albert Einstein College of Medicine, Yeshiva Univ, Bronx, NY.*

**Background:** Tubulointerstitial fibrosis (TIF) is the final common pathway leading to ESRD. Folic acid (FA) induced acute/chronic TIF model was used to follow the fate of different cell types in the kidney to address which tubule segment is injured and the origin of activated myofibroblast (epithelial, pericyte).

**Methods:** The tomato/GFP mouse model (mT/mG) and different cre recombinases were used. Tomato fluorescence turns to GFP (mG) after cre-mediated recombination. Tubule cells were traced by the Pax8rtTA/TREcre, proximal tubule epithelial cells by PEPCKCre, distal tubule epithelial cells by KSPCre and pericytes by Foxd1cre. GFP positive cells were followed by flourescence and FACS analysis. To detect activated myofibroblasts kidney was stained with alpha smooth muscle actin (aSMA).

**Results:** Pax8 positive cell number was decreased after FA injection. The proliferating cells re-expressed Pax8 and they were different from the original Pax8 expressing cells. KSP positive distal tubule cell number decreased on day 7(D7) and remained lower for 4 weeks, they proliferated and number increased at 12 weeks and returned to baseline by 20 weeks. PEPCK positive epithelial cell number did not significantly change on D7. Foxd1 positive pericyte number significantly increased on D7. aSMA, did not colocalize with epithelial lineage markers (PEPCK, KSP, PAX8). aSMA failed to fully colocalize with pericyte marker foxd1, indicating pericyte might not be the only origin of myofibroblast.

**Conclusions:** The collecting ducts and thick ascending limb of loop of Henle appear to be a key site in folic acid induced epithelial injury. Majority of activated myofibroblasts are not of epithelial origin and pericytes only partially contribute to the myofibroblast pool.

**FR-OR118**

**Laminin 211-Mediated Focal Adhesion Kinase Activation Triggers Alport Glomerular Pathogenesis** Dominic E. Cosgrove, Brianna Johnson, Daniel T. Meehan, Duane C. Delimont, Marisa Zallocchi, Linda Cheung. *Genetics, Boys Town National Research Hospital, Omaha, NE.*

**Background:** It has been known for some time that laminins 211 and 111, normally restricted to the mesangial matrix, accumulate in the glomerular basement membranes (GBM) of Alport mice, dogs, and humans. Whether these abnormal laminins contribute to Alport glomerular pathology has remained unknown.

**Methods:** A double knockout mouse for laminin $\alpha$2 and COL4A3, and a podocyte-specific conditional FAK knockout Alport mouse were compared with wild type and Alport mice. SiRNA knocdown for FAK in glomerular pododytes was performed. The small molecule inhibitor for FAK, TAE226 was used in both podocyte cell cultures and *in vivo*. TAE226-treated Alport mice were assessed for glomeruloschlerosis, fibrosis, proteinuria and uremia. FAK activation for podocyte cultures on different laminin substrates was performed. Real time RT-PCR analysis for MMP-9, -10, and -12 as well as IL-6 and NFkappaBIA was assessed for RNA from both isolated glomeurli and cultured podocytes.

**Results:** Laminin 211, but not laminin 111, activates focal adhesion kinase (FAK) on glomerular podocytes *in vitro* and *in vivo*. Alport glomeruli showed significant induction of MMP-9, MMP-10, MMP-12 and IL-6. SiRNA knockdown of FAK in cultured podocytes significantly reduced expression of MMP-9, MMP-10 and IL-6, but not MMP-12. Glomerular mRNA analysis of podocyte-specific conditional FAK-null Alport mice also showed reduced expression of MMP-9, MMP-10, and IL-6 mRNA relative to age/strain matched Alport mice. MMP-12 expression was not affected. Treatment of Alport mice with TAE226, a small molecule inhibitor of FAK activation, ameliorated fibrosis and glomerulosclerosis, significantly reduced proteinuria and blood urea nitrogen levels, and partially restored GBM ultrastructure. Glomerular expression of MMP-9, MMP-10 and MMP-12 mRNAs was significantly reduced in TAE-226 treated animals.

**Conclusions:** This work identifies laminin 211-mediated FAK activation in podocytes as an important early event in Alport glomerular pathogenesis and suggests that FAK inhibitors might be employed as a novel therapeutic approach for treating Alport renal disease in its early stages.

**Uromodulin Regulates Renal Calcium Channel TRPV5 via a Mechanism Synergistic with Secreted Klotho** Matthias Wolf,[1] Chou-Long Huang.[2] *[1]Pediatric Nephrology, Univ of Texas Southwestern Medical Center, Dallas, TX; [2]Internal Medicine, Univ of Texas Southwestern Medical Center, Dallas, TX.*

**Background:** Uromodulin (UMOD) is the most abundant urinary protein and protects against nephrolithiasis. We recently reported that UMOD acts extracellularly to upregulate TRPV5 by impairing its endocytosis. Secreted Klotho (sKL) cleaves the terminal sialic acid of TRPV5 N-glycan to allow the channel binding to galectin-1, which decreases endocytosis and increases surface abundance of the channel. We examined the mechanism of UMOD regulation of TRPV5, particularly the potential interaction with sKL.

**Methods:** TRPV5 surface abundance and activity were studied by biotinylation and whole-cell patch-clamp recording in HEK cells expressing TRPV5, UMOD and/or sKL.

**Results:** Coexpression of UMOD increased current density (pA/pF) of wild-type TRPV5 (446±37, -UMOD vs 802±45, +UMOD, $p<0.0001$), but not N-glycan deficient (N358Q) TRPV5 (453±45, -UMOD vs 422±43, +UMOD). Similarly, UMOD increased surface abundance of WT-TRPV5, but not N358Q mutant, supporting that UMOD upregulation of TRPV5 requires N-glycosylation. Upregulation of TRPV5 by UMOD was prevented by dominant-negative dynamin or by deletion of caveolin-1 in cells, as was the regulation by sKL. To examine the relationship between UMOD and sKL regulation of TRPV5, we showed that coexpression with sub-threshold dose of sKL or UMOD had no effect on TRPV5 whereas sub-threshold dose of sKL and UMOD in combination markedly increased its surface abundance and current density. The above finding was confirmed using application of purified UMOD and/or purified sKL to the culture medium, supporting the action of UMOD or sKL from the cell exterior. Similar to that for sKL, knockdown of galectin-1 by siRNA, but not control oligo, prevented UMOD regulation of TRPV5.

**Conclusions:** UMOD and sKL increase TRPV5 channel activity synergistically. UMOD forms polymers in urine. One potential mechanism for synergism between UMOD and sKL is stabilization and enhanced galectin-1 binding to TRPV5 on the apical membrane by UMOD, leading to decreased endocytosis of TRPV5. The effect of UMOD and sKL on TRPV5 may contribute to protection against nephrolithiasis.

## FR-OR120

**Mice with Kidney-Specific Deletion of the Sodium/Calcium Exchanger 1 Have Increased Intestinal Calcium Absorption** Olivier Bonny,[1,2] Candice Stoudmann,[1] Vlasta Zavadova,[1] Donald W. Hilgemann,[3] Orson W. Moe.[3] *[1]Dept of Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland; [2]Service of Nephrology, Lausanne Univ Hospital (CHUV), Lausanne, Switzerland; [3]Depts of Internal Medicine and Physiology, Jane and Charles Pak Center of Mineral Metabolism, Univ of Texas Southwestern Medical Center, Dallas, TX.*

**Background:** Hypercalciuria constitutes a key risk factor in kidney stone formation and the role of the renal sodium/calcium exchanger 1 (NCX1/SLC8A1) in this process is not known. We established a mouse model in which we deleted NCX1 in the distal part of the nephron and showed that these mice are hypercalciuric, have higher urine volume and lower urine pH compared to their WT littermates. Their levels of $1,25(OH)_2$-vitamin D are elevated, but iPTH levels are normal. These mice displayed normal bone architecture at one year of age. We asked how these mice maintain calcium balance while being continuously hypercalciuric and we studied intestinal calcium absorption.

**Methods:** We used 8 wildtype (WT) littermates and 8 NCX1-kidney-specific KO (NCX1-KSKO) mice and performed $^{45}$Ca-absorption assay. The contribution of intestinal calcium load in hypercalciuria was studied by challenging the mice with a low calcium diet (0.12%) for one week and by measuring calcium balance in metabolic cages.

**Results:** We compared mRNA levels of the calcium transporters TRPV6, PMCA and NCX1 in the duodenum of NCX1-KSKO and WT mice and found increased TRPV6 expression in NCX1-KSKO mice. Then, we performed $^{45}$Ca absorption assay and found that NCX1-KSKO mice have significant increased intestinal calcium absorption (41% increase, 12 minutes after gavage). We finally exposed the mice to a low calcium diet and looked at complete calcium balance. Both WT and NCX1-KSKO mice stayed in balance even when challenged with low calcium diet.

**Conclusions:** In summary, we showed that NCX1-KSKO mice have increased intestinal calcium absorption due to higher 1,25(OH)2 vitamin D levels and are able to compensate for chronic hypercalciuria and maintain calcium balance.

*Funding:* NIDDK Support, Government Support - Non-U.S.

## FR-OR121

**Expression of the Calcium-Sensing Receptor in Mouse, Rat and Human Kidney** Joao Z. Graca,[1,2] Martin Schepelmann,[2] Rebecca M. Wadey,[2] Sarah C. Brennan,[2] Simon Brocklehurst,[1] Daniela Riccardi,[2] Sally A. Price.[1] *[1]AstraZeneca, Macclesfield, United Kingdom; [2]Cardiff Univ, Cardiff, United Kingdom.*

**Background:** The calcium sensing receptor (CaSR), a key GPCR for calcium homeostasis, was cloned and characterized in kidney nearly two decades ago. Nevertheless, there is still no consensus in the literature regarding the renal expression pattern and discrepancies have been reported between species. This work aims to elucidate the localisation of the CaSR in mouse, rat and human kidney and thus allow a better understanding of its physiological role.

**Methods:** CaSR expression was analysed by *in situ* hybridization (ISH) using a branched-DNA methodology and by immunohistochemistry (IHC) using four antibodies raised against different CaSR epitopes [ADD (Thermo/Abcam); N-term (Anaspec); C-term (custom made, mouse/rat), whole protein (Novus, human)]. These antibodies were selected from a panel of seven antibodies by assessing CaSR immunofluorescence pattern in CaSR-HEK cells. The specificity of the selected antibodies was further confirmed by western blotting in mouse, rat and human kidney. The expression of CaSR along the nephron was assessed by dual labeling with specific markers for the descending thin limb (DTL, aquaporin 1), thick ascending limb (TAL, Tamm-Horsfall), distal tubule (DT, $Na^+$-$Cl^-$ cotransporter) and collecting duct (CD, aquaporin 2).

**Results:** By ISH, CaSR mRNA was detected in the TAL, and to a lesser extent in the DT and CD. By IHC, CaSR immunoreactivity was comparable in mouse, rat and human kidney with the four selected antibodies; generally CaSR immunoreactivity was stronger in the medulla/medullary rays and weaker in the cortex. Moreover, CaSR immunoreactivity was detected in proximal tubule (identified by the brush border), TAL, DT and CD, but not in the DTL.

**Conclusions:** Our data show that the CaSR is expressed along the nephron, including TAL, CD and DT, with the strongest expression being seen in the TAL. These findings clarify the renal CaSR expression pattern in mouse, rat and human, and therefore enable the determination of its full pathophysiological role.

## FR-OR122

**Elucidation of the Distal Convoluted Tubule Transcriptome Identifies New Candidate Genes Involved in Renal Magnesium Handling** Jeroen H.F. De Baaij,[1] René J. Bindels,[1] Joost Hoenderop.[1] *[1]Dept of Physiology, Radboud Univ Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Molecular Cancer Research, UMC Utrecht, Utrecht, Netherlands.*

**Background:** The kidney plays a key role in the maintenance of the magnesium ($Mg^{2+}$) homeostasis. Specifically, the distal convoluted tubule (DCT) is instrumental in fine-tuning of the renal $Mg^{2+}$ handling. In recent years hereditary $Mg^{2+}$ transport disorders have helped to identify important players in DCT $Mg^{2+}$ homeostasis. Nevertheless, several proteins involved in DCT-mediated $Mg^{2+}$ reabsorption remains to be discovered and a full expression profile of this complex nephron segment may facilitate the discovery of new $Mg^{2+}$-related genes.

**Methods:** Transgenic mice expressing eGFP under a DCT-specific parvalbumin promoter were subjected to $Mg^{2+}$-deficient or $Mg^{2+}$-enriched diets. Subsequently, the Complex Object Parametric Analyzer and Sorter (COPAS) allowed for the first time isolation of eGFP-positive DCT cells. RNA extracts thereof were analyzed by DNA microarrays comparing high vs. low $Mg^{2+}$ to identify $Mg^{2+}$ regulatory genes.

**Results:** Here, we report the $Mg^{2+}$-sensitive expression of the DCT transcriptome. Several known magnesiotropic genes, such as *Trpm6* and *Parvalbumin*, were upregulated under low dietary $Mg^{2+}$. First, examination of the $Mg^{2+}$ sensitive expression of all putative $Mg^{2+}$ transporters identified *Slc41a3* as potential $Mg^{2+}$ extrusion mechanism in the DCT. Additonally, based on statistical significance and a fold-change of at least two, 46 genes showed differential expression. Among these, *Pcbd1*, *Tbc1d4* and *Umod* were identified to be potentially involved in renal $Mg^{2+}$ handling. To confirm that the selected candidate genes were regulated by dietary $Mg^{2+}$ availability, the expression levels of *Slc41a3*, *Pcbd1*, *Tbc1d4* and *Umod* were determined by RT-PCR analysis. Indeed, all four genes show significant upregulation in the DCT of mice fed the $Mg^{2+}$-deficient diet. Furthermore, GO-term enrichment analysis identified 'EGF pathway' and 'Bone mineralization' among the enriched pathways in low $Mg^{2+}$-fed mice.

**Conclusions:** By elucidating the $Mg^{2+}$-sensitive DCT transcriptome new candidate genes in renal $Mg^{2+}$ handling have been identified.

*Funding:* Government Support - Non-U.S.

## FR-OR123

**New Missense Mutations Linked to Hypomagnesemia with Secondary Hypocalcemia** Joost Hoenderop,[1] René J. Bindels,[1] Sergio Lainez Vicente,[1] Karl P. Schlingmann,[2] Martin Konrad.[2] *[1]Physiology, Radboud Univ Nijmegen Medical Centre, Nijmegen, Netherlands; [2]General Pediatrics, Univ Hospital Münster, Münster, Germany.*

**Background:** Despite recent progress in our understanding of renal magnesium ($Mg^{2+}$) handling, the molecular mechanisms accounting for transepithelial $Mg^{2+}$ transport are still poorly understood. Mutations in the *TRPM6* gene, encoding the epithelial $Mg^{2+}$ channel TRPM6 (transient receptor potential melastatin 6), have been proven to be the molecular cause of hypomagnesemia with secondary hypocalcemia (HSH). HSH manifests in the newborn period being characterized by very low serum $Mg^{2+}$ levels (<0.4 mmol/L) accompanied by low serum calcium ($Ca^{2+}$) concentrations. A proportion of previous described *TRPM6* mutations lead to a truncated TRPM6 protein resulting in a complete loss-of-function of the channel.

**Methods:** The study cohort comprises five families from different ethnic origin with seven individuals with HSH and at least one missense mutation leading to a non-conservative amino acid exchange in TRPM6. Human embryonic kidney (HEK) 293 overexpressing wild-type and mutant TRPM6 were analyzed by patch clamp analysis. Cell surface expression of TRPM6 was addressed by biotinylation assays.

**Results:** The aim of this study was to complement the current clinical picture by adding molecular data from six new missense mutations found in five patients with HSH. To this end, wild-type and mutated TRPM6 channels were expressed in HEK293 cells. Subsequently, patch-clamp analysis and cell surface measurements were performed to assess the effect of the various mutations on TRPM6 channel function. To determine the functional implications of the mutations on TRPM6 channel activity, HEK293 cells were transiently transfected with either mock, WT TRPM6 or the different TRPM6 mutants ($L^{708}P$, $E^{872}G$, $Y^{1053}C$, $L^{1143}P$, $Q^{1663}R$, $S^{1754}N$). All mutant channels, except $Q^{1663}R$, expressed in HEK293 cells, showed loss-of-function, while no significant trafficking impairment to the plasma membrane surface was observed.

**Conclusions:** We conclude that the new *TRPM6* missense mutations affect gating and permeation properties of the ion channel, leading to dysregulated intestinal/renal $Mg^{2+}$ (re)absorption.

*Funding:* Government Support - Non-U.S.

## FR-OR124

**Hepatectomy Hypophosphatemia: A Novel Phosphaturic Factor in the Liver-Kidney Axis** Kengo Nomura, Sawako Tatsumi, Atsumi Miyagawa, Yuji Shiozaki, Shohei Sasaki, Hiroko Segawa, Ken-Ichi Miyamoto. *Institution of Health Bioscience, The Univ of Tokushima, Japan.*

**Background:** Inorganic phosphate (Pi) absorption in the renal proximal tubules and small intestine is important for Pi homeostasis.

The incidence of liver transplantation has steadily increased, and, as a consequence, the incidence of partial hepatectomy (PH) has also increased. Marked hypophosphatemia is common after major hepatic resection, but the pathophysiologic mechanism remains unknown.

**Methods:** We used PH model rats to investigate the molecular basis of hypophosphatemia. PH rats exhibited hypophosphatemia and hyperphosphaturia.

**Results:** In renal and intestinal brush border membrane vesicles isolated from PH rats, The $Na^+$-dependent Pi (Na/Pi) uptake was decreased by 50% to 60%. PH rats also exhibited significantly decreased levels of renal and intestinal Na/Pi transporter proteins (NaPi-IIa, NaPi-IIb, and NaPi-IIc). Parathyroid hormone was elevated at 6 h after PH. Hyperphosphaturia persisted, however, even after thyroparathyroidectomy in PH rats. Moreover, DNA microarray data revealed elevated levels of nicotinamide phosphoribosyltransferase (Nampt) mRNA in the kidney after PH. Nampt catalyzes the first rate-limiting step in converting nicotinamide (NAM) to nicotinamide adenine dinucleotide (NAD). In addition, Nampt protein levels and the total NAD were significantly increased in the proximal tubules. PH rats also exhibited markedly increased levels of urinary NAM and NAM catabolites. In vitro analyses using opossum kidney cells revealed that NAM alone did not affect endogenous NaPi-IIa (NaPi-4) levels, but Nampt expression with the addition of its substrate (NAM) led to a marked decrease in the NaPi-4 protein levels. FK866, a specific Nampt inhibitor, completely blocked this reduction in Nampt-induced NaPi-4. Further, FK866-treated mice showed elevated renal Pi reabsorption and hypophosphaturia.

**Conclusions:** The findings of the present study indicate that hepatectomy-induced hypophosphatemia is due to abnormal NAM metabolism, including Nampt activation in the renal proximal tubular cells. The present study also suggests that NAM metabolism though the liver-kidney axis is important in Pi homeostasis.

## FR-OR125

### Regulation of Renal Type IIa Sodium Phosphate Cotransporter (Npt2a) Trafficking by Na-H Exchanger Regulatory Factor 1 (NHERF1)

Eleanor D. Lederer,[1,2] Rebecca Murray,[2] Nina W. Lesousky,[2] Syed J. Khundmiri,[2] Edward J. Weinman.[3] *[1]Medical Services, Robley Rex VA Medical Center, Louisville, KY; [2]Medicine/Physiology, Univ of Louisville, Louisville, KY; [3]Medicine, Univ of Maryland, Baltimore, MD.*

**Background:** The PDZ domain protein NHERF1 plays a critical role as an anchor in the apical membrane (AM) for Npt2a, a proximal tubule transporter critical role for regulation of phosphate homeostasis. We and others have previously demonstrated that NHERF1 deficiency results in defective glycosylation and intracellular accumulationof Npt2a.

**Methods:** We hypothesized that NHERF1 associates with Npt2a prior to AM insertion and facilitates glycosylation. To test this hypothesis, we examined Npt2a-NHERF1 association in Golgi (G) by density gradient centrifugation of opossum kidney (OK) cells, a model of renal proximal tubule. Cells transfected with GFP-Npt2a wild type or C terminal –TRL deletion mutant constructs were treated with PTH to eliminate expression of surface Npt2a followed by exposure to low phosphate medium to stimulate Npt2a production for 8h. Cells were fractionated by sucrose gradient density centrifugation and the fractions representing G or plasma membrane identified by specific markers.

**Results:** Npt2a or GFP immunoprecipitation of G and PM fractions from cells expressing wild type GFP-Npt2a showed positive immunoblot for NHERF1. GFP-Npt2a lacking the terminal –TRL motif demonstrated failure to undergo complete glycosylation, associate with NHERF1 in the G, integrate into a membrane compartment, or traffic to the AM. Confocal imaging confirmed the diffuse intracellular distribution of the TRL deletion mutant.

**Conclusions:** We conclude that Npt2a associates with NHERF1 in the G through the C-terminal PDZ binding domain and that this association is essential for Npt2a glycosylation, membrane incorporation, and AM trafficking. These findings suggest a novel chaperone function for NHERF1 in Npt2a regulation.

## FR-OR126

### Egr-1 Mediates FGF23-Induced Hypophosphatemia but Does Not Inhibit Renal 1,25 (OH)$_2$D Synthesis

Farzana Perwad, Martin Y.H. Zhang, Anthony A. Portale. *Pediatrics, Univ of California San Francisco, San Francisco, CA.*

**Background:** The transcription factor, early growth response 1 (egr-1), is a biomarker for activation of the MAP kinase/extracellular signal regulated kinase 1/2 (ERK1/2) signaling pathway by fibroblast growth factor 23 (FGF23). In *Hyp* mice, excess circulating FGF23 constitutively activates ERK1/2 signaling in the kidney, resulting in increased egr-1 expression, hypophosphatemia and 1,25-dihydroxyvitamin D (1,25(OH)$_2$D) deficiency. These abnormalities are reversed by blockade of FGF23-dependent ERK1/2 signaling.

**Methods:** To test whether egr-1 itself mediates the renal actions of FGF23, we administered FGF23 to wild-type (WT) and egr-1 null *(egr-1$^{-/-}$)* mice. To explore the molecular mechanisms by which egr-1 mediates renal actions of FGF23, we performed chromatin-immunoprecipitation sequencing (ChIP-seq) with anti-egr-1 antibody.

**Results:** In WT mice, FGF23 induced hypophosphatemia and suppressed renal Npt2a and Npt2c mRNA expression. In FGF23-treated *egr-1$^{-/-}$* mice, hypophosphatemic effect was blocked and NPT2a/2c mRNA were not suppressed. In contrast, FGF23 induced equivalent suppression of renal Cyp27b1 mRNA and stimulation of Cyp24a1 mRNA expression in both WT and *egr-1$^{-/-}$* mice. Thus, downstream of FGF receptor binding and ERK1/2 signaling, we can distinguish the effector pathway that mediates inhibition of renal Pi reabsorption from the pathway that mediates inhibition of 1,25(OH)$_2$D synthesis. In kidneys from FGF23-treated WT mice, we demonstrate rapid binding of egr-1 to regulatory DNA elements in proximity to genes that encode key participants in renal Pi cotransport, specifically: renal Na/Pi cotransporters, Npt2a and Npt2c, scaffolding proteins (Nherf-1, Nherf-2, Ezrin, GABARAP and pdzk1IP), and vesicle trafficking proteins (Rab37 and sytl3). *In silico* gene network analyses identified the following significant functional pathways in the egr-1 ChIP-seq dataset; cytoskeleton remodeling, TGF/WNT signaling and FGFR signaling pathways.

**Conclusions:** These data suggest that the phosphaturic effect of FGF23 is mediated, atleast in part, by activation of the transcription factor, egr-1. We have thus identified the FGF23-dependent egr-1 cistrome in the kidney.

## FR-OR127

### PTH Increases FGF23 Transcription by Activating the Orphan Nuclear Receptor Nurr1 Both In Vitro and in Experimental CKD and This Is Prevented by the Calcimimetic R568

Tomer Meir,[1] Karina Durlacher,[1] Oded Volovelsky,[1] Gili Cohen,[1] William G. Richards,[2] Justin Silver,[1] Tally Naveh-Many.[1] *[1]Nephrology, Hadassah Hospital, Jerusalem, Israel; [2]Amgen, Thousand Oaks, CA.*

**Background:** PTH increases FGF23 mRNA and protein levels in vivo and in vitro. In experimental CKD parathyroidectomy both prevents and corrects the high levels of FGF23. We report that the effect of PTH to increase FGF23 is mediated by the orphan nuclear receptor Nurr1.

**Methods:** Adenine high Pi induced CKD rats were given the calcimimetic R568 to study calvaria FGF23 and Nurr1 mRNA and protein levels. UMR-106 rat osteoblast-like cells were incubated with PTH and transfected with Nurr1 expression plasmid to study the effect on endogenous FGF23 mRNA levels and on FGF23 promoter-luciferase expression. Chromatin immunoprecipitation (CHIP) using a Nurr1 antibody was performed on cell lysates.

**Results:** Nurr1 mRNA and protein levels were increased in calvaria from CKD rats together with the high PTH and FGF23 levels. Calcimimetics decrease PTH and FGF23 levels in CKD. Importantly, in CKD rats the calcimimetic R568 decreased PTH expression, calvaria Nurr1 mRNA and protein levels and FGF23 mRNA, suggesting that the decrease in Nurr1 by the calcimimetic mediates the decrease in FGF23. Nurr1 binds to cis-acting sequences in the promoter of its target genes and regulates their transcription. In UMR-106 cells PTH increased FGF23 transcription. Significantly, PTH increased Nurr1 mRNA levels at 30 min, before the increase in FGF23 mRNA levels. Nurr1 over-expression increased FGF23 mRNA levels also in the absence of PTH. Reporter gene experiments using different fragments of the FGF23 promoter showed that PTH and/or Nurr1 over-expression increased FGF23 promoter activity. Bioinformatic analysis identified several Nurr1 potential binding sites in the FGF23 promoter. The functionality of these response elements was demonstrated by FGF23 promoter-luciferase assays. CHIP analysis confirmed the binding of Nurr1 to the functional regions in the FGF23 promoter.

**Conclusions:** PTH increases Nurr1 to induce FGF23 transcription. In SHP the decrease in FGF23 by a calcimimetic is mediated by decreased PTH and Nurr1 levels.

### Phosphate Transport-Dependent and -Independent Functions of the Sodium Dependent Phosphate Transporter, PiT-1, in Vascular Smooth Muscle Cell Mineralization

Nicholas W. Chavkin, Matthew H. Crouthamel, Cecilia M. Giachelli. *Bioengineering, Univ of Washington, Seattle, WA.*

**Background:** Elevated serum phosphate is associated with increased vascular calcification in patients with chronic kidney disease. *In vitro*, elevated phosphate induces vascular smooth muscle cell (VSMC) mineralization, and this can be blocked by knocking down PiT-1. In this study, we aimed to determine the contribution of phosphate transport-dependent and-independent functions of PiT-1 on VSMC mineralization.

**Methods:** Wildtype (WT) and PiT-1 mutants containing three different point mutations of amino acids proposed to be required for phosphate uptake (E74K, S132A, and S623A) were generated and stably expressed in PiT-1 deficient mouse VSMCs derived from PiT-1 fl/fl SM22α Cre transgenic mice. Cell lines were characterized for gene and protein expression by Q-PCR and immunocytochemistry. Sodium-dependent phosphate uptake, ERK1/2 phosphorylation, and VSMC calcification were analyzed using published analytical methods.

**Results:** WT and mutant PiT-1 mRNAs were similarly expressed, and protein localized to cell membranes in transduced VSMCs. VSMCs containing the PiT-1 mutations had reduced sodium-dependent phosphate uptake compared with those containing WT PiT-1, with S132A and S623A having intermediate levels and E74K exhibiting the lowest levels. Phosphate-induced ERK1/2 phosphorylation was elevated to a similar extent in PiT-1 WT and E74K expressing VSMCs compared to vector control. SM22α mRNA levels were decreased to a similar extent in PiT-1 WT and E74K VSMCs compared to vector control. Phosphate-induced matrix mineralization was much higher in VSMC expressing WT PiT-1 compared to E74K, and extent of matrix mineralization correlated with transport uptake activity.

**Conclusions:** ERK1/2 phosphorylation and loss of SM22α expression are phosphate uptake-independent activities of PiT-1, whereas stimulation of VSMC matrix mineralization by PiT-1 is predominantly phosphate uptake-dependent. Together, the data suggest that both phosphate uptake-dependent and -independent functions of PiT-1 contribute to processes important for matrix mineralization.

## FR-OR129

**Genetic Loss of Function Mutations in Zebrafish and Human CRB2, a Regulator of Epithelial Polarity, Are Associated with Podocyte Foot Process Effacement and Focal Segmental Glomerulosclerosis** Arindam Majumdar,[1] Shazia Ashraf,[2] Svjetlana Lovric,[2] Heon Yung Gee,[2] Friedhelm Hildebrandt.[2] *[1]Immunology, Genetics, and Pathology, Uppsala Univ, Uppsala, Sweden; [2]Div of Nephrology, Harvard Medical School, Boston Children's Hospital, Boston, MA.*

**Background:** Podocytes are polarized epithelial cells, a central component of the glomerular filtration barrier, and a major pathological target in kidney glomerular disease. In published work, we identified a requirement for zebrafish *crb2b*, a conserved regulator of epithelial polarity, in podocyte morphogenesis. The Crb proteins are EGF-like domain transmembrane proteins which lie at the intersection of epithelial polarity, cell signaling, and membrane biogenesis.

**Methods:** We study podocyte polarity in zebrafish *crb2b* mutants and we ask whether the CRB2 gene may be affected in human nephrotic syndromes.

**Results:** We present a null allele in zebrafish, *crb2b*$^{zm}$, which phenocopies our published morpholino results and independently confirms a role for *crb2b* in podocyte differentiation. In the absence of *crb2b*, Nephrin protein is mis-targeted to apical membranes. Biochemically, co-immunoprecipitation shows that Crb2b associates with Nephrin. Both Crb2b and Nephrin co-localize to vesicles in transient cell culture transfection assays.

We than extended our zebrafish Crb2 studies into nephrotic syndrome in humans. Podocyte Crb2 expression is conserved from zebrafish to humans. A combination of SNP homozygosity mapping and exome re-sequencing were used to screen for mutations in human CRB2 FSGS families. Analysis of the CRB2 sequence in 30 consanguinous sibling pairs identified a homozygous 1859 G > C missense mutation resulting in Cys 620 > Ser. The conserved Cys residue lies in an extracellular EGF like-repeat. The functional consequence of this mutation was tested in zebrafish *crb2b* mutants.

**Conclusions:** Our genetic analyses in both zebrafish and humans indicate a requirement for Crb2 function in podocyte cell structure and function. These results suggest that some nephrotic syndromes may be due to fundamental misregulation of podocyte apical basal polarity.

*Funding:* Government Support - Non-U.S.

## FR-OR130

**Gene-Gene Interactions in APOL1-Associated Nephropathy** Jasmin Divers, Nicholette D. Palmer, Lingyi Lu, Carl D. Langefeld, Michael V. Rocco, Pamela J. Hicks, Mariana Murea, Lijun Ma, Donald W. Bowden, Barry I. Freedman. *Wake Forest School of Medicine, Winston-Salem, NC.*

**Background:** Two APOL1 nephropathy variants confer risk for non-diabetic end-stage kidney disease (ESKD) in African Americans (AAs). Modifying factors likely contribute as not all genetically high-risk individuals develop ESKD.

**Methods:** We tested variants from a prior discovery GWAS aimed at detecting single nucleotide polymorphisms (SNPs) that potentially interact with *APOL1* to alter ESKD risk in 864 AA cases with non-diabetic ESKD and 612 non-nephropathy controls. The top 42 discovery interactive SNPs were re-examined in DNA from two new AA cohorts: 503 additional unrelated non-diabetic ESKD cases and 892 non-nephropathy controls (combined discovery + replication sample had 1,367 ESKD cases and 1,504 controls) and an independent family-based cohort including 608 1st degree relatives of non-diabetic ESKD probands. Logistic regression and mixed models were fitted to test for interaction effects with APOL1 on risk of ESKD and albuminuria/eGFR in families.

**Results:** Fourteen SNPs replicated *APOL1-interaction with ESKD in the same direction as the discovery GWAS analysis with interaction p-values <0.05 in combined replication + discovery ESKD samples. The strongest interactions were rs16854341 in podocin (NPHS2, odds ratio [OR] 0.5; p=5.0x10-4), rs2802723 in serologically defined colon cancer antigen 8 (SDCCAG8, OR 1.8; p=5.0x10-4), rs9533534 (ENOX, OR 0.7; p=8.0x10-4), and rs8014363 (near BMP4, OR 1.6; p=1.0x10-3).* Several SNPs demonstrated the same directions of *APOL1 interaction with nephropathy in family-based samples, including NPHS2 and SDCCAG8 for albuminuria (p=0.05 and 0.03, respectively).*

**Conclusions:** Variants in NPHS2 and SDCCAG8, and SNPs in other regions appear to interact with APOL1 to modulate risk for non-diabetic ESKD.

## FR-OR131

**Whole Exome Sequencing (WES) for Disease Gene Discovery in Familial IgA Nephropathy** Xuewen Song,[1] Nicole M. Roslin,[2] Bushra Joarder,[1] Meng Yi Xu,[1] Amirreza Haghighi,[1] Melody Ren,[1] Mitchell Li Cheong Man,[1] Andrew D. Paterson,[2] York P. Pei.[1] *[1]Div of Nephrology, Univ Health Network, Toronto, Canada; [2]Program in Genetics and Genomic Biology, Hospital for Sick Children, Toronto, Canada.*

**Background:** Multiple rare disease genes with high effect size have been implicated by genome-wide linkage analysis of familial IgAN (fIgAN) but none has been identified.

**Methods:** To identify disease genes for fIgAN, we performed WES using AB Solid 5500xL platform in 21 patients from 15 well-characterized families (each with at least one biopsy-proven case and one or more affected individuals with persistent hematuria/proteinuria). For 2 multiplex families each with 5 affected, we also performed genome-wide linkage scans and focused WES on regions of positive linkage signals. Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare putative deleterious variants of high and moderate impact as predicted by PolyPhen-2, Sift, and Provean.

**Results:** On average, our exome sequencing provided coverage for 99.8% of all the exons with a mean depth of 100X. We cataloged 19 regions with LOD >1 under a dominant model from our two moderately large families. From these studies, we identified a total of 24 rare deleterious variants from the following candidate disease genes: ITGA4, TNFRSF6B, CD81, FASLG, ITGB2, TNIP1, MSH6, MLH6, LIG4, LCP1, KIAA1704, TMEM52, TFRC, FCAR, DFFA4, OSM, MPDU1, CD68, CFH, and CFHR3. Five of these variants affected two or more independent families.

**Conclusions:** Our preliminary results are consistent with the notion of an underlying genetic heterogeneity in fIgAN with the possibility of multiple disease genes each only accounting for a small proportion of cases. To validate our findings, we are currently conducting exome sequencing in 12 more unrelated families. Future studies to identify deleterious mutations from the same candidate gene in multiple unrelated families as well as within-family segregation analysis will help to narrow a short list of most promising candidate disease genes for functional studies. Identification of disease genes for fIgAN has the potential to improve diagnosis and treatment.

## FR-OR132

**A CFHR2-CFHR5 Hybrid Protein Causes Complement Deregulation and Reveals a Novel Pathogenic Mechanism for Dense Deposit Disease** Christine Skerka,[1] Qian Chen,[1] Michael Sean Wiesener,[2] Hannes Uwe Eberhardt,[1] Kerstin U. Amann,[2] Maike Julia Buettner,[2] Tim Goodship,[3] Christian Hugo,[4] Peter F. Zipfel.[1] *[1]Leibniz Institute for Natural Product Research and Infection Biology; [2]Univ Erlangen-Nuremberg; [3]Univ Newcastle upon Thyne; [4]Univ Hospital Dresden.*

**Background:** Dense Deposit Disease (DDD) is a severe renal disorder that is caused by complement dysregulation. There is no effective treatment and patients often progress to end-stage renal failure. For a small fraction of DDD patient's genetic causes in form of *Factor H-* or *C3* gene mutations have been reported.

**Methods:** Gene copy number variations, genetic breakpoint amplification, gene sequencing. Complement activation assays, immune precipitation, recombinant expression.

**Results:** Genetic analysis of two DDD patients identified a chromosomal deletion in the *CFHR* gene cluster leading to the expression of a hybrid CFHR2-CFHR5 plasma protein, that has domains 1-2 (SCRs1-2) of CFHR2 fused to SCRs1-9 of CFHR5. The recombinant and the native hybrid protein stabilized the complement C3 convertase and also reduced Factor H mediated decay of the C3 convertase. Thus explaining why plasma addition to the patient *in vivo* enhanced complement activation and why the patient was refractory to plasma therapy. I*n vitro* assays performed with diverse complement inhibitors and C3 and Factor B supplemented serum of the patient revealed that the soluble complement inhibitor sCR1 was able to neutralize the C3 convertase stabilizing effect of the hybrid protein, but neither a tagged version of Compstatin nor the established C5 convertase inhibitor Eculizumab did restore the defective regulation of the C3 convertase.

**Conclusions:** Our findings provide first evidence that chromosomal rearrangements in the *CFHR* gene cluster leads to hybrid CFHR proteins that act as activators of the C3 convertase leading to DDD. Thus monitoring sequence variations in *CFHR2* and *CFHR5* genes is recommended for patients with DDD. Because of the permanently active C3 onvertase plasma infusion therapy is critical for these patients.

*Funding:* Government Support - Non-U.S.

## FR-OR133

**Genomic Disorders in the Chronic Kidney Disease in Children (CKiD) Cohort** Miguel Verbitsky,[1] Simone Sanna-Cherchi,[1] Krzysztof Kiryluk,[1] Brittany J. Perry,[1] Frederick J. Kaskel,[2] Susan L. Furth,[3] Bradley A. Warady,[4] Craig S. Wong,[5] Ali G. Gharavi.[1] *[1]Nephrology, Columbia Univ, New York, NY; [2]Pediatric Nephrology, Children's Hospital at Montefiore, Bronx, NY; [3]Pediatric Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA; [4]Pediatric Nephrology, Children's Mercy Hospital, Kansas City, MO; [5]Pediatric Nephrology, Univ of New Mexico, Albuquerque, NM.*

**Background:** Previous studies reported a high prevalence of pathogenic copy number variants (CNVs) in children with Renal Hypodysplasia (RHD). We followed up these data in the Chronic Kidney Disease in Children (CKiD) cohort, an observational study of pediatric nephropathy.

**Methods:** PennCNV was used to determine CNV calls in 420 CKiD samples genotyped on the Illumina Omni2.5 beadarrays (N=420). To identify rare pathogenic CNVs, we compared data to 23,362 controls.

**Results:** Participants were phenotypically classified into Congenital Abnormalities of the Kidney and Urinary Tract (CAKUT; N=216), which includes Renal Hypodysplasia (RHD=69) and non-CAKUT (N=204, e.g. glomerular disorders). CNVs were diagnostic of 12 known syndromes in 15 individuals (3.6%): 10 (4.6%) in CAKUT and 5 (2.5%) in non-CAKUT participants, compared to 318 (1.4%) controls. Recurrent CNVs included 17q12 (*HNF1B*) and 16p11.2 deletions. Additionally, 20 large, likely pathogenic CNVs were identified in another 19 children (4.5% of cohort): 9 (4.2%) in CAKUT, and 10 in (4.9%) non-CAKUT. Genomic imbalances were most common in RHD patients (10.1% with known and 4.3% with likely pathogenic CNVs). In several cases, the microarray data indicated an alternative renal diagnosis.

**Conclusions:** As significant number of children with CKD have an unsuspected genomic imbalance, particularly those with RHD. Moreover, most of the identified genomic disorders have a known association with neurodevelopmental phenotypes. The diagnosis of CNV disorders has clinical implication for risk stratification, prediction of complications and personalized management of pediatric patients with CKD.

*Funding:* NIDDK Support

## FR-OR134

**Mutations in a Large VNTR of MUC1 Are Frequent in Autosomal Dominant Medullary Cystic Kidney Disease (MCKD)** Vincent Moriniere,[1] Simon Hollebecque,[1] Said Lebbah,[2] Andre Megarbane,[7] Andreas Gnirke,[3] Brendan Blumenstiel,[3] Anthony J. Bleyer,[5] Andrew Kirby,[6] Bertrand Knebelmann,[2] Corinne Antignac.[4] *[1]Genetic Dept, Necker Hospital, Paris, France; [2]Nephrology Dept, Necker Hospital, Paris, France; [3]Broad Institute, Cambridge, MA; [4]INSERM U983, Univ Paris Descartes, Paris, France; [5]Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; [6]Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA; [7]Genetic Medical Unit, Saint Joseph Univ, Beirut, Lebanon.*

**Background:** MCKD is a rare autosomal dominant tubulo-interstitial kidney disease, sometimes associated with renal cysts and gout/hyperuricemia. UMOD mutations have been described in patients with hyperuricemia (MCKD2). Mutations in the MUC1 gene encoding mucin 1 were very recently identified in MCKD1 patients (Kirby et al, Nature Genet, 2013) using a sophisticated approach associating cloning of the genomic region, capillary sequencing and de novo assembly since next generation sequencing failed to identify them. All patients harbor a single cytosine insertion in one copy of the 60-base repeat unit of the long CG-rich coding VNTR of MUC1. The frameshift is predicted to result in a mutant protein which is expressed in the distal tubule and collecting duct.

**Methods:** Using an approach coupling PCR amplification of patient DNA cleaved by MwoI (that selectively cleaves the unmutated repeat sequence) and probe-extension assay (SNAPshot), we tested 26 new families.

**Results:** We detected the presence of the cytosine insertion in 14/26 families. In addition, we detected a new 5pb deletion, which is predicted to result in the same mutant protein as the cytosine deletion. Among 14/15 families with mutations, 101 individuals were affected, with detailed clinical information available for 75 patients. 58 reached ESRD at a mean age of 46 yrs (20-82 yrs) with high intrafamilial variability. Early gout occurred in only 1 case and hyperuricemia in 3 (2 from the same family). Renal cysts were present in 10/40 pts.

**Conclusions:** These results show that MUC1 mutations represent a frequent cause of MCKD.

## FR-OR135

**Functional Annotation of Single Nucleotide Polymorphisms Associated with Chronic Kidney Disease** Yi-An Ko, Katalin Susztak. *Renal Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia, PA.*

**Background:** The eukaryotic transcription unit includes the promoter enhancer interaction, which is essential for transcription. Enhancers can be upstream or downstream of the transcription start site. What separate the transcript units are the insulators. These are the important regulatory elements in the genome. Each regulatory element is associated with certain specific histone tail modifications. Epigenetic modifications are characterized by their cell type specificity. We used different combination of histone modifications ChIP-seq data to annotate the single nucleotide polymorphisms (SNPs) that are associated with kidney function and chronic kidney disease (CKD).

**Methods:** The human kidney epithelial cell epigenome was generated from ChIP-seq using H3K4me1/2/3, H3K9me3, H3K27ac, H3K27me3, and H3K36me3 to targetthe human kidney epithelial cells (HKC8). The sequencing results were analyzed with the algorithm *ChromHMM*. The annotated human kidney epigenome map with annotated regulatory elements were used for mapping CKD associated SNPs (n=37) published in three different studies.

**Results:** Kidney specific epigenome was generated from HKC8 cell ChIP-seq. The outputs of the *ChromHMM* were states and patterns of regulatory elements, which are enhancers, promoters, transcribed regions, insulators, and repressed regions. Next, we compared the SNPs annotated with the kidney regulatory elements to nine cell types published in ENCODE project. The results revealed that CKD associated SNPs have strong cell type specificity enriched in human kidney enhancers. Furthermore, to exclude the possibility that all the SNPs are enriched in kidney specific enhancers, we used 36 control SNPs from unassociated studies. These SNPs did not show cell type specific gene regulatory region pattern.

**Conclusions:** CKD SNPs are enriched in the kidney specific gene regulatory regions, especially in the enhancers. This approach can potentially be used for prioritizing SNPs found in genome-wide association studies.

*Funding:* NIDDK Support

## FR-OR136

**The 4D Study: 11 Years of Follow-Up, Effects on Mortality and Morbidity of 4 Years Atorvastatin Treatment in 1255 Patients with Diabetes Mellitus on Hemodialysis, a Randomized, Controlled Trial** Vera Krane,[1] Kay-Renke Schmidt,[1] Lena Johanna Gutjahr-Lengsfeld,[1] Britta Stahl,[1] Monika Mehling,[1] Susanne Kempf,[1] Winfried März,[2] Christoph Wanner.[1] *[1]Dept of Medicine I, Div of Nephrology, Univ Hospital, Univ of Würzburg, Würzburg, Germany; [2]Synlab Academy, Synlab Services GmbH, Mannheim, Germany.*

**Background:** Findings of large randomized trials of lowering LDL-cholesterol in dialysis patients have shown controversial results, limited evidence exists about the long-term effects. The aim of this follow-up of the German Diabetes Dialysis Study (4D Study) is to assess long-term effects of atorvastatin treatment in hemodialysis (HD) patients.

**Methods:** 1255 patients with type 2 diabetes mellitus on HD were randomly allocated to either 20 mg atorvastatin daily or placebo, median follow-up was 4 years. Post trial statin treatment was at the discretion of the patients´ nephrologists. The primary outcome of the 4D study was a composite of death from cardiac causes, nonfatal myocardial infarction (MI) and stroke. Analysis was by intention to treat.

**Results:** In and post-trial follow-up yielded a mean duration of 11.5 years in both groups. Overall, 90% of patients died. Post-trial statin use (51% and 48%) and LDL levels were similar in both groups. Allocation to atorvastatin during the in-trial period yielded an average reduction in LDL cholesterol of 42%. Over the entire time period, a proportional non-significant 9% decrease in the combined endpoint of cardiac death, MI and stroke (95% CI, 0.78 to 1.07) was detected. However, the risk of all cardiovascular events combined was significanty reduced (RR 0.83, 95% CI 0.70-0.97) whereas the incidence of all cerebrovascular events combined did not differ between groups (RR 0.94, 95% CI 0.72-1.23). No significant effect of atorvastatin on fatal infection (RR 0.97, 95% CI, 0.76-1.23), or all-cause death (RR 0.93, 95% CI 0.82-1.04) was detected. No case of rhabdomyolysis was reported.

**Conclusions:** After 4 years of atorvastatin treatment, no significant effect on the 11 year endpoint of cardiac death, MI and stroke was detected. However, there was a significant 17% relative risk reduction in all cardiovascular events combined and no evidence of emerging hazards.

*Funding:* Government Support - Non-U.S.

## FR-OR137

**Unchanged Heart Function and Blood Pressure after Cholecalciferol Treatment–A Randomized Controlled Trial** Frank H. Mose,[1] Henrik Vase,[3] Thomas Larsen,[1] Anne Sophie Pinholt Kancir,[1] Renata Kosierkiewicz,[2] Bartlomiej B.J. Jonczy,[2] Anna Ewa Oczachowska-Kulik,[2] Ingrid Moeller Thomsen,[2] Jesper N. Bech,[1,2] Erling B. Pedersen.[1,2] *[1]Dept of Medical Research, Holstebro Hospital and Aarhus Univ, Denmark; [2]Dept of Medicine, Holstebro Hospital, Denmark; [3]Dept of Cardiology, Aarhus Univ Hospital, Denmark.*

**Background:** In dialysis patients vit-D3 improved biochemical endpoints, but the effect of vit-D3 supplementation on cardiovascular function and BP is unknown. The aim of this study was to test the hypothesis that vit-D3 supplementation improves cardiac function and reduces BP and pulse wave velocity (PWV) in patients on chronic dialysis.

**Methods:** In a randomized, placebo-controlled, double-blind study, we investigated the effect of 75 µg vit-D3 per day for 6 months, in patients on chronic dialysis. We performed two-dimensional echocardiography, with doppler and tissue-doppler imaging, 24-h ambulatory BP (24-h BP), PWV, augmentation index (AIx), central BP (cBP) and brain natriuretic peptide (BNP) at baseline and after 6 months.

**Results:** Sixty-four patients were allocated to the study, and 50 patients (42 on hemodialysis and 8 on peritoneal dialysis) completed the trial (25 in vit-D3 and 25 in placebo group). Mean age 68 years (range 46 to 88), 32 were men, BMI 23.9±4.4 kg/m$^2$ and baseline plasma 25-hydroxyvitamin D (p-25[OH]D) 28 (29;53) nmol/l. Age, sex, BMI and p-25(OH)D were not significantly different between groups at baseline. After 6 months, Vit-D3 had no impact on left atrial or ventricular structure. LV systolic and diastolic function was not changed by vit-D3. 24-hour BP decreased significantly in placebo group and in-significantly in vit-D3 group, but with no difference between treatments (p=0.314 for systolic BP and p=0.344 for diastolic BP). PWV, cBP, Aix and BNP were not changed in placebo or vit-D3 group at follow-up. P-25(OH)D increased significantly compared to placebo (88 (67;125) vs. 34 (21;56), p<0.001).

**Conclusions:** In conclusion, 6 months vit-D3 treatment in patient on chronic dialysis did not improve 24-h BP, arterial stiffness or cardiac function.

*Funding:* Private Foundation Support, Government Support - Non-U.S.

## FR-OR138

**Warfarin Initiation after Newly-Diagnosed Atrial Fibrillation Associates with Better Outcomes in U.S. Patients on Hemodialysis** Jenny I. Shen, Maria E. Montez-Rath, Tara I. Chang, Wolfgang C. Winkelmayer. *Div of Nephrology, Stanford School of Medicine, Palo Alto, CA.*

**Background:** Atrial fibrillation (AF) is increasingly common in patients on hemodialysis (HD). Although warfarin is indicated to prevent ischemic strokes in most patients with AF, evidence for its use in HD patients is limited and conflicting. In this observational cohort study, we examined the net safety of initiating warfarin for incident AF in a large, nationally-representative cohort of patients on chronic HD.

**Methods:** We identified from the USRDS all adult HD patients who were newly diagnosed with AF during a hospitalization from 2007-10, who participated in the low income subsidy program of Medicare Part D, and who had no history of warfarin use in ≥6 months prior to admission. Patients who filled a first prescription for warfarin within 30 days of discharge were considered users; all others were non-users. We excluded patients who died within 30 days of discharge. We applied Cox regression to a propensity-score matched cohort of warfarin users and non-users to estimate the hazard ratios (HR) for all-cause mortality and the combined outcome of gastrointestinal bleeding (GIB), any stroke, or death.

**Results:** Among 9316 patients, 1330 (14%) initiated warfarin. We matched 1329 warfarin users to 1329 non-users whose observed baseline characteristics were exquisitely balanced. Over 3163 person-years of follow-up, we observed 1083 deaths, 109 GIB, and 149 strokes. Warfarin initiation was associated with a decreased risk of both all-cause mortality [HR 0.85; 95% confidence interval (CI): 0.75-0.95] and the composite outcome (HR: 0.87, 95% CI: 0.78-0.98).

**Conclusions:** In HD patients with hospitalized incident AF, warfarin use was associated with a decreased risk of both all-cause mortality and a composite outcome of GIB, any stroke, and death, indicating net benefits of warfarin use in this indication. This is at odds with several previous studies that have suggested an increased risk of adverse outcomes in users. Given the uncertainty surrounding warfarin for AF in HD patients, further clinical trials are warranted.

*Funding:* NIDDK Support

## FR-OR139

### Irbesartan Shows No Beneficial Blood Pressure Independent Effects on Intermediate Cardiovascular Risk Markers in Hemodialysis Patients

Christian D. Peters,[1] Krista D. Kjaergaard,[1] J Dam Jensen,[1] Kent L. Christensen,[2] Charlotte Strandhave,[3] I. N. Tietze,[4] Marija K. Novosel,[5] Bo M. Bibby,[6] Erik Sloth,[7] Bente Jespersen.[1] *[1]Dept of Renal Medicine, Aarhus Univ Hospital (AUH), Denmark; [2]Dept of Cardiology, AUH, DK; [3]Dept of Nephrology, Aalborg Univ Hospital, DK; [4]Dept of Medicine, Region Hospital Viborg, DK; [5]Dept of Medicine, Fredericia Hospital, DK; [6]Dept of Biostatistics, Aarhus Univ, DK; [7]I-Research, AUH, DK.*

**Background:** Angiotensin II receptor blockers are frequently used in end-stage renal disease patients but it is unclear if they exert beneficial cardiovascular (CV) effects beyond blood pressure (BP) reduction. The aim of this study was to determine whether irbesartan improves well-established intermediate CV risk markers in hemodialysis (HD) patients.

**Methods:** A multicenter randomized placebo-controlled double-blinded trial initiated by the investigators with 1 year follow-up. A pre-defined systolic BP (SBP) target of 140 mmHg was used in all patients. ClinicalTrials ID: NCT00791830.

**Results:** Of the 82 patients randomized (placebo n=41/irbesartan n=41), 56 completed 1 year. Baseline mean±SD: Males 26/30, age 62±14/61±16 years, SBP 145±19/148±21 mmHg, HD vintage 168±95/171±93 days, HD time 10±2/11±3 hr/week, urine output 1.3±0.7/1.5±0.8 L/24 h. Comorbidity, antihypertensive drugs and HD parameters were comparable at baseline. Brachial SBP decreased significantly during the study but there was no significant difference between the groups (p=0.418). Mean decrease in SBP (baseline-1 year) was 8.2±4.1 mmHg, p=0.04 (placebo) and 10.0±4.3, p=0.02 (irbesartan). Use of additional antihypertensive drugs, ultrafiltration volume and HD dosage were similar during follow-up. Intermediate CV risk markers such as central aortic BP, carotid-femoral pulse wave velocity, left ventricular (LV) mass index, NT-proBNP, heart rate variability and plasma catecholamines were not significantly affected by irbesartan. Changes in SBP during the study period correlated significantly with changes in LV mass index (p=0.02) and arterial stiffness (p<0.001).

**Conclusions:** Effects of irbesartan on intermediate CV endpoints beyond BP reduction are absent in HD patients.

## FR-OR140

### Association of Intradialytic Hypotension (IDH) with Interdialytic Weight Gain (IDWG) and Cardiovascular (CV) Disease

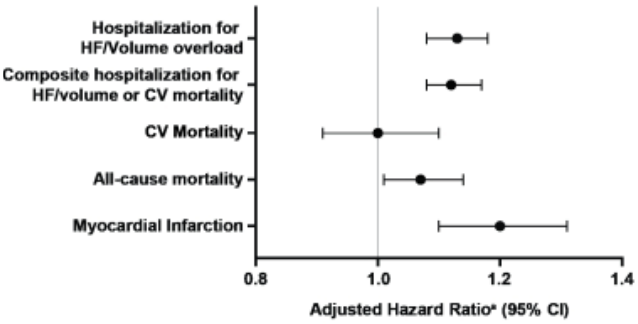
Claudia S. Cabrera,[1] Steven M. Brunelli,[2] David P. Rosenbaum,[3] Emmanuel A. Anum,[2] Karthik Ramakrishnan,[2] Donna E. Jensen,[2] Nils-Olov Stalhammar,[1] Bergur V. Stefansson.[1] *[1]AstraZeneca, Molndal, Sweden; [2]DaVita Clinical Research, Minneapolis, MN; [3]Ardelyx Inc, Fremont, CA.*

**Background:** Patients undergoing hemodialysis (HD) have elevated risk of CV disease-related morbidity and mortality compared to the general population. This burden may relate in part to episodic tissue hypoxia resulting from IDH. The aims of this study were 1) to estimate the associations of IDH with CV events/mortality and 2) to determine whether patients with greater IDWG (who require more ultrafiltration) are predisposed to IDH.

**Methods:** Patients incident to in-center HD (1 Jan 07–31 Dec 08) who remained on this modality for ≥181 days and had Medicare or Medicaid as primary insurer were assessed. IDWG and IDH were assessed over HD days 91-180. Outcomes were identified through US Renal Data Systems claims data, and were considered as those occurring on/after dialysis day 181 until death, care transfer, modality change or study end (31 Dec 09). IDH was defined as fall in systolic blood pressure of >20 mmHg from pre-dialysis to nadir intradialytic levels with at least 2 responsive measures (reduced ultrafiltration rate, reduced HD blood flow rate, saline administration, premature cessation of dialysis).

**Results:** The study included 39,497 patients; 35.7% of patients experienced IDH at least once during the baseline period. Cross-sectional analysis demonstrated a potent and statistically significant association between IDH and IDWG (p<0.001). IDH was independently associated with increased risk of heart failure (HF), composite HF/CV mortality, all-cause mortality and myocardial infarction.

**Adjusted Associations of Intradialytic Hypotension with Incident Clinical Outcomes**
(reference = IDH absent)



Abbreviations: CI, confidence intervals; CV, cardiovascular; HF, heart failure; IDH, intradialytic hypotension

*Hazard ratios were adjusted for age, race, sex, etiology of ESRD, prior renal transplant, access type, and baseline diabetes, uncontrolled hypertension, heart failure, myocardial infarction, atrial fibrillation, and ischemic/hemorrhagic stroke or transient ischemic attack.

**Conclusions:** These data show a significant association between IDWG and IDH; IDH was independently associated with CV events. Mitigating IDWG may reduce IDH and thereby improve CV outcomes in ESRD patients.

## FR-OR141

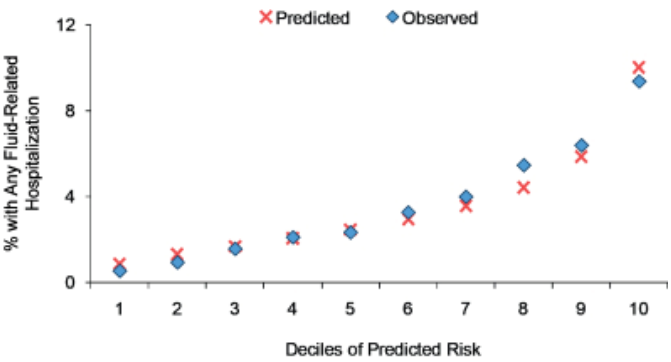
### Fluid Overload in Hemodialysis (HD) Patients: Development and Validation of a 'Big Data' Predictive Analytic

Steven M. Brunelli,[1] Karthik Ramakrishnan,[1] Scott Sibbel,[2] Irina Goykhman,[3] Chhaya B. Patel,[3] Robert Provenzano,[3] Stephen D. McMurray,[3] David B. Van Wyck,[3] Allen R. Nissenson,[3] Mahesh Krishnan.[1] *[1]DaVita Clinical Research, MN; [2]DaVita Labs, FL; [3]DaVita HealthCare Partners Inc, CO.*

**Background:** Fluid management is poor for many HD patients, with consequences that include increased morbidity, mortality, and utilization of healthcare resources. The ability to prospectively identify patients at high risk of imminent fluid-related hospitalization (FRH) would enable targeted implementation of avoidance strategies, and the more efficient allocation of resources. The aim of this study was to derive an empirical clinical risk algorithm using available clinical data to predict risk of FRH in the subsequent 3 months.

**Methods:** Demographic and clinical data were abstracted from the DaVita Clinical Data Warehouse. FRH events were identified from Centers for Medicare and Medicaid Services claims data. In the derivation set, predictor variables were considered as of Sept 2009 and used to predict risk of FRH in Q4 2009. In the validation set, predictors were considered as of June 2009; predicted and observed Q3 2009 FRH were compared.

**Results:** The derivation set contained 60,114 patients; the validation set contained 57,245 patients. Sixty-seven variables were identified and included in the model (C-statistic, 0.71). In the validation set, the model demonstrated excellent calibration over the 20-fold range of risk observed; patients in the highest decile of predicted risk demonstrated more than 3-fold greater risk of observed FRH (risk ratio, 3.2 [CI: 2.9, 3.7]; rate ratio, 3.4 [CI: 3.1, 3.8]).



**Conclusions:** The algorithm accurately and reproducibly predicts risk of FRH and can be tailored to accommodate more or less restrictive definitions of risk. Use of the algorithm will permit identification of high risk patients in whom to target interventions, and allow for the judicious allocation of resources.

## FR-OR142

**Plasma Long-Chain Acylcarnitines Predict Cardiovascular Mortality in Incident Dialysis Patients** Sahir Kalim,[1] Clary B. Clish,[2] Julia Beth Wenger,[1] Sammy Elmariah,[3] Robert W. Yeh,[3] Joseph James Deferio,[1] Kerry A. Pierce,[2] Amy Deik,[2] Robert E. Gerszten,[2,3] Ravi I. Thadhani,[1] Eugene P. Rhee.[1,2] *[1]Nephrology Div, Massachusetts General Hospital, Boston, MA; [2]Broad Institute, Cambridge, MA; [3]Cardiology Div, Massachusetts General Hospital, Boston, MA.*

**Background:** The marked excess in cardiovascular mortality that results from uremia remains poorly understood.

**Methods:** In two independent nested case-control studies, we applied liquid chromatography-mass spectrometry based metabolite profiling to plasma obtained from participants of a large cohort of incident hemodialysis patients.

**Results:** First, 100 individuals who died of a cardiovascular cause within one year of initiating hemodialysis (cases) were randomly selected along with 100 individuals who survived for at least one year (controls), matched for age, sex, and race. Four long-chain acylcarnitines achieved the significance threshold adjusted for multiple testing ($P<0.0003$), and remained associated with 1-year cardiovascular death after multivariable adjustment: oleoylcarnitine (odds ratio (OR) per SD 2.3 [95% confidence interval, 1.4-3.8]; $P=0.001$), linoleylcarnitine (OR per SD 2.4 [1.4-4.1]; $P=0.002$), palmitoylcarnitine (OR per SD 1.8 [1.2-2.8]; $P=0.006$), and steaorylcarnitine (OR per SD 1.6 [1.1-2.5]; $P=0.025$). The association between oleoylcarnitine and 1-year cardiovascular death was then replicated in an independent sample (n= 300, OR per SD 1.4 [1.1-1.9]; $P=0.008$). Addition of oleoylcarnitine to clinical variables improved net reclassification (NRI, 0.38 [95% CI 0.20-0.56]; $P<0.0001$). In physiologic profiling studies, we demonstrate that the fold change in plasma acylcarnitine levels from the aorta to renal vein and from pre- to post hemodialysis samples exclude renal or dialytic clearance of long-chain acylcarnitines as confounders in our analysis.

**Conclusions:** Our data highlight clinically meaningful alterations in acylcarnitine homeostasis at the time of dialysis initiation which may represent an early marker, effector, or both of uremic cardiovascular risk.

## FR-OR143

**Speckle Tracking Echocardiography Detects Uremic Cardiomyopathy Early and Predicts Cardiovascular Mortality in End-Stage Renal Disease** Rafael Kramann,[1] Vincent Brandenburg,[2] Thilo Krueger,[1] Jürgen Floege,[1] Georg Schlieper.[1] *[1]Nephrology, RWTH, Aachen, Germany; [2]Cardiology, RWTH, Aachen, Germany; [3]Clinical Epidemiology, Leiden Univ, Leiden, Netherlands.*

**Background:** Cardiovascular (CV) mortality in end stage renal disease is mainly driven by sudden cardiac death and recurrent heart failure due to uremic cardiomyopathy (UC). An early detection of UC might identify patients at risk and can have clinical impact in therapeutic decision-making. 2-dimensional strain echocardiography (**2DSE**) is a recently developed method to determine myocardial function in a multidimensional fashion.

**Methods:** In an animal study using two rat models of UC we tested whether 2DSE is superior to routine echocardiography to detect early changes in myocardial contractility. In a clinical study 2DSE parameters, ejection fraction (EF) and clinical characteristics were assessed in 171 ESRD patients, patients were followed up for 2.5 years. Primary endpoint was CV-mortality and secondary endpoint was all-cause mortality.

**Results: Animal study-**Using 2DSE in two rat models of UC early (4-6 weeks) after induction of kidney disease we observed that global radial and circumferential strain parameters were significantly decreased whereas fractional shortening (FS) and cardiac-output (CO) remained unchanged. Furthermore, compared to FS and CO, 2DSE parameters showed better correlations with histologic hallmarks of UC (grade of interstitial fibrosis and cardiomyocyte cross-sectional area). **Clinical study-** During the follow-up period, EF and various 2DSE parameters were significant risk factors for CV mortality in a multivariate cox model (EF hazard ratio-HR 0.97 95% confidence interval-CI 0.95-0.99, p=0.012, peak global longitudinal strain HR 1.17 95%-CI 1.07-1.28, p<0.001; peak systolic and late diastolic longitudinal strain rates HR 4.7, 95%-CI 1.23-17.64, p=0.023; HR 0.25, 95%-CI 0.08-0.79 p=0.019, respectively). Multivariate cox-regression analysis revealed circumferential early diastolic strain rate among others as an independent risk factor for all-cause mortality (HR 0.43; 95%-CI 0.25-0.74; p=0.002).

**Conclusions:** 2DSE can detect UC early in rats and predicts cardiovascular and all-cause mortality in ESRD patients.

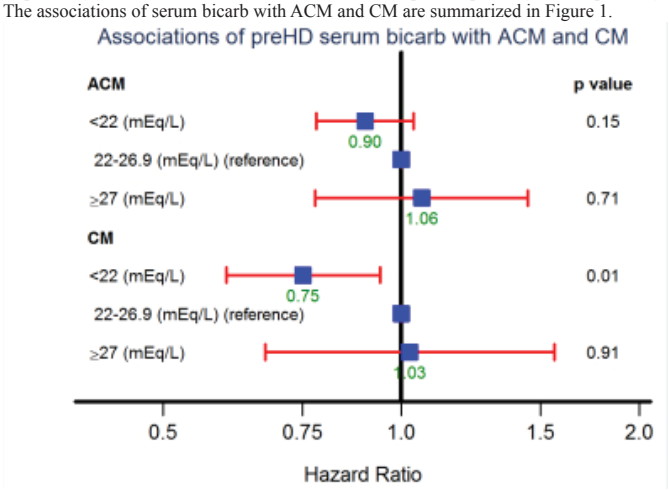
## FR-OR144

**Low Serum Bicarbonate Is Associated with Lower Cardiac Mortality (CM) in Hemodialyis (HD) Patients** Abinash C. Roy, G. Wei, R. Filipowicz, Tom Greene, Kalani L. Raphael, Alfred K. Cheung, Srinivasan Beddhu. *Dept of Medicine, Univ of Utah, Salt Lake City, UT.*

**Background:** Recent data suggest ↑ serum bicarbonate (bicarb) is associated with ↑ mortality. However, the associations of lower serum bicarb with mortality is controversial. Therefore, we examined the associations of lower than normal serum bicarb with mortality using the HEMO Study data.

**Methods:** The HEMO study was a 2X2 factorial design randomized controlled trial of dialysis dose and flux in 1846 prevalent HD pts. Patients were enrolled in the study from March 1995 until October 2000 and followed through December 2001. Causes of deaths were adjudicated by an outcomes committee. The associations of baseline pre-dialysis serum bicarb with all-cause mortality (ACM) and cardiac mortality (CM) were examined in Cox proportional hazard regression models adjusted for age, gender, race, diabetes, duration of dialysis, ICED score, Ktv group, flux group, enPCR, arrhythmia, pre HD dialysis serum albumin, K, Ca and P.

**Results:** Mean age was 58±14 yrs, 56% were female , 63 % were black and 69% had diabetes. Serum bicarb , Ca and K levels were 21.5±3.6, 9.29±.97 and 4.86±.77 mEq/L respectively. There were 16.6 ACM and 9.0 CM events per 100 patient years, respectively. The associations of serum bicarb with ACM and CM are summarized in Figure 1.



Interaction terms of serum bicarb with serum K and serum Ca were non-significant when added to the above models.

**Conclusions:** Elevated serum bicarb was not associated with ACM or CM in this study. Surprisingly, pre-HD serum bicarb below the normal range was associated with lower CM. Further studies are warranted to examine the mechanisms for the observed lower CM in those with lower serum bicarb.

*Funding:* NIDDK Support

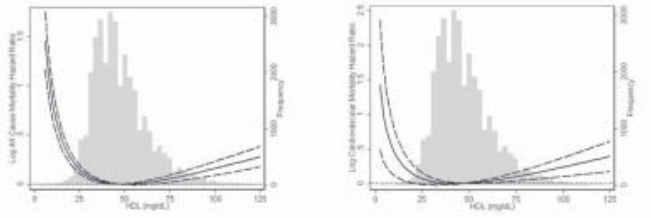
## FR-OR145

**Elevated Serum High Density Lipoprotein Cholesterol Level Is Paradoxically Associated with Increased Overall and Cardiovascular Mortality in Patients on Hemodialysis** Hamid Moradi,[1,2] Elani Streja,[1,2] Nosratola D. Vaziri,[2] Moti L. Kashyap,[2] Gregg C. Fonarow,[3] Kamyar Kalantar-Zadeh.[1,2] *[1]Harold Simmons Center, Orange, CA; [2]Univ of California, Irvine, CA; [3]Univ of California, Los Angeles, CA.*

**Background:** High density lipoprotein (HDL) confers protection against atherosclerosis by several different mechanisms. Although in the general population, increasing levels of HDL are associated with reduced cardiovascular (CV) mortality, this association is not well known in patients with chronic disease states such as end stage renal disease. We hypothesize that the association of serum HDL concentration with all-cause and CV mortality in hemodialysis patients is different from the general population.

**Methods:** We examined the survival impact of serum HDL level in a 3-year (6/2004-6/2007) cohort of 33,109 maintenance hemodialysis patients being treated in clinics of a large dialysis organization using Cox models adjusted for demographics and case-mix variables and cubic splines were plotted.

**Results:** In this cohort the mean age (mean + SD) was 60+15 years old and included 45% women, 33% African-Americans, and 61% diabetics. In the fully adjusted models, higher HDL concentrations up to 50 mg/dL were associated with better overall survival, while HDL above 60 mg/dL was associated with a rise in all-cause and cardiovascular mortality. All-cause and CV mortality HR was 1.28 (1.20-1.38) and 1.08 (1.01-1.16) for HDL <30 mg/dL and 1.05 (1.00-1.10) and 1.08(1.00-1.16) for HDL≥60 mg/dL, respectively (reference: HDL 30-<60 mg/dL).



**Conclusions:** A U-shaped association between serum HDL cholesterol level and all-cause and CV mortality exists in HD patients with HDL around 50 mg/dL exhibiting the best survival. The underlying mechanisms responsible for these seemingly paradoxical associations await further investigation.

*Funding:* NIDDK Support

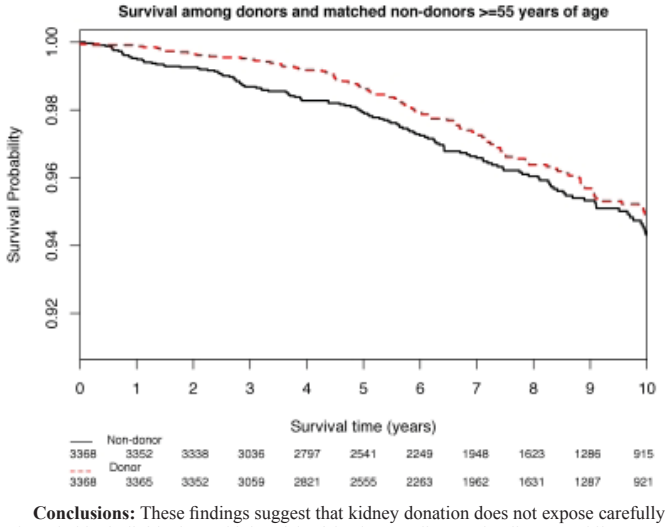
## SA-OR001

**Mortality, Cardiovascular and End-Stage Renal Disease Outcomes among Older Live Kidney Donors** Peter P. Reese,[1] Roy D. Bloom,[1] Harold I. Feldman,[1] Paul Rosenbaum,[1] Wei Wang,[2] Philip Saynisch,[2] Nicole Tarsi,[2] Nabanita Mukherjee,[2] Amit X. Garg,[3] Adam S. Mussell,[1] Orit Even-Shoshan,[2] Raymond R. Townsend,[1] Jeffrey H. Silber.[2] *[1]Univ of Pennsylvania; [2]Children's Hospital of Philadelphia; [3]Univ of Western Ontario.*

**Background:** Older individuals (≥55 y/o) have been accepted for live kidney donation more commonly over the past two decades. Given strong associations of both older age with worse renal function and cardiovascular (CV) disease, nephrectomy could make older donors vulnerable to death, CV events and end-stage renal disease (ESRD).

**Methods:** We performed a matched cohort study of older individuals who underwent nephrectomy between the years 1996–2006 and participants in the Health and Retirement Study (HRS). Each donor was matched to an HRS participant who was free of important comorbidities close to the date of the donor's nephrectomy. Among 5152 donors, 3368 (65%) were matched to healthy comparators using demographics, economic environment and body mass index. The primary outcome was death, ascertained from death registries. Secondary outcomes ascertained for pairs with Medicare claims were a) death/CV diagnoses, and b) ESRD.

**Results:** In each group, the mean age was 59 y/o and 6% were African-American. In median follow up of 7.8 years, mortality was not significantly different between donors and matched non-donors (p=0.21). The rate of death and CV events was not different for donors and matched non-donors (p=0.70). Among pairs in Medicare, the risk of ESRD was higher for donors (HR 7.4; 95% CI 2.91, 18.8; p<0.001), although the number of donors with ESRD was small (n=20).



**Conclusions:** These findings suggest that kidney donation does not expose carefully selected older individuals to a higher risk of death or cardiovascular disease. While ESRD was rare, older donors have an elevated risk of this outcome.

*Funding:* NIDDK Support, Private Foundation Support

## SA-OR002

**Donor Tubular Phosphate Handling Independently Predicts Recipient Outcomes after Living Kidney Donation** Marco van Londen, Jelmer Kor Humalda, Johannes S. Sanders, Stephan J.L. Bakker, Gerjan Navis, Martin H. De Borst. *Dept of Nephrology, Univ Medical Center Groningen, Netherlands.*

**Background:** Identification of pre-transplantation (pre-Tx) donor factors associated with recipient outcomes may help to improve prognosis after kidney transplantation. Tubular injury leads to reduced expression of NaPi cotransporters and reduced phosphate (Pi) transport. We investigated whether pre-Tx parameters of Pi metabolism in living donors are associated with recipient outcomes after transplantation (post-Tx).

**Methods:** In 130 donors, pre-Tx $^{125}$I-iothalamate GFR, serum and urinary Pi, plasma fibroblast growth factor 23 and parathyroid hormone, fractional Pi excretion and TmP-GFR (tubular maximum Pi reabsorption per GFR) were determined. In corresponding recipients GFR was measured 1 year post-Tx, and follow-up data documented. Associations between pre-Tx donor factors and recipient post-Tx GFR were tested by linear regression. Next, a multivariate Cox regression model for a composite endpoint of rejection, graft failure or recipient mortality was built using pre-Tx donor factors, recipient factors, and transplant characteristics.

**Results:** Pre-Tx GFR in donors (age 52±10 yrs, 48% men) was 118±24 ml/min. GFR one year post-Tx in recipients (age 48±19 yrs, 61% men) was 60±19 ml/min. In multivariate regression, pre-Tx donor TmP-GFR (standardized β 0.30, P=0.003) and donor age (st. β -0.28, P=0.01) were independent determinants of recipient 1-yr post-Tx GFR (final model $R^2$=0.20). During follow up of 2.4 [1.2-3.2] yrs, 29 recipients had rejection, 3 graft failure and 9 died. Donor pre-Tx TmP-GFR was independently associated with the composite endpoint (HR 0.25 [95% CI 0.08-0.72] per 1 mg/dL TmP-GFR, P=0.01), along with age, cold ischemia time and recipient gender. Other Pi-related factors were not associated with recipient outcome.

**Conclusions:** A lower donor pre-Tx TmP-GFR, indicating a reduced maximum tubular Pi reabsorption capacity, independently predicts a lower recipient GFR one year post-Tx and an increased risk of rejection, graft failure or recipient mortality. These data are the first to link donor tubular function to recipient outcomes, and warrant further dissection of underlying mechanisms.

*Funding:* Government Support - Non-U.S.

## SA-OR003

**New K/DIGO Guidelines and Kidney Transplantation: Is the Cystatin-C Based Recommendation Relevant?** Ingrid Masson,[1] Nicolas Maillard,[1] Pierre Delanaye.[2] *[1]Nephrology Dialysis Renal Transplantation, Univ Hospital, Saint-Etienne, France; [2]Dialysis, Univ Hospital, Liege, Belgium.*

**Background:** In 2013, K/DIGO guidelines published recommendations for evaluation and management of chronic kidney disease (CKD). These guidelines propose a new framework for the evaluation of CKD, especially in patients with altered glomerular filtration rate (GFR) .They suggest measuring cystatin C in adults with GFR estimated by the CKD-EPI creatinine-based equation (eGFRcreat) 45–59 ml/min/1.73 m² to confirm the diagnosis of CKD. Although derived from studies unrelated to kidney transplantation, the K/DIGO guidelines aim to target the transplant population as well. Herein, we sought to determine whether the new K/DIGO strategy to detect decreased GFR might be applicable in renal transplantation.

**Methods:** In 670 kidney transplant recipients (KTR), we analyzed the performance of the combined CKD-EPI equation (eGFRcreat-cys) to reclassify KTR in comparison with inulin clearances (mGFR) by using the analytical methodology developed in these guidelines. Serum creatinine was measured by an IDMS traceable enzymatic method; cystatin C by IFCC-traceable nephelometric method.

**Results:** In the whole cohort, 192 patients had eGFRcreat 45-59 mL/min/1.73m² but mGFR was above 60 mL/min/1.73m² in 39 of them (20%). When using eGFRcreat-cys in these 192 patients, only 181 (94%) had also eGFR below 60 mL/min/1.73 m². In the 39 patients with eGFRcreat <60 but mGFR >60 mL/min/1.73 m², only 8 were correctly reclassified by the eGFRcreat-cys equation. Estimating GFR by eGFRcreat led to 20% (39/192) of errors in CKD classification. Following the strategy suggested by the guidelines, errors in classification were actually marginally corrected (18%, 34/192).

**Conclusions:** The K/DIGO guidelines recommend the use of the eGFRcreat-cys to improve the detection of CKD in patients whom eGFRcreat 45-59mL/min/1.73m². In the present study, we show that this recommendation cannot be extended to transplant recipients.

## SA-OR004

**Differential Diagnosis of Acute Kidney Allograft Dysfunction Using Urinary Cell mRNA Profiles** Thangamani Muthukumar, Marie Matignon, Catherine Snopkowski, Carol Y. Li, John R. Lee, Darshana Dadhania, Manikkam Suthanthiran. *Cornell Univ.*

**Background:** A noninvasive diagnostic test that distinguishes acute rejection (AR) from acute tubular injury (ATN) is an unmet need in clinical renal transplantation.

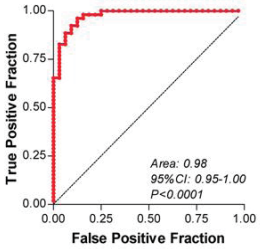
**Methods:** We tested the hypothesis that urinary cell mRNA profiles distinguish AR vs. ATN by profiling urine specimens collected at the time of allograft biopsy from 84 kidney transplant recipients with allograft dysfunction; 52 AR (ACR-26 and AMR-26) and 32 ATN. We measured absolute levels (copies/ug total RNA) of a mechanistically informative panel of 26-mRNAs using qPCR assays. We used discriminant analyses to develop a model to distinguish AR from ATN and validated it by a 10-fold cross-validation. We used decision curve analysis *(Vickers AJ. Med Decis Making 2006)* and determined whether the diagnostic test (urinary cell mRNA profile) is clinically useful.

**Results:** Neither s.creatinine nor tacrolimus levels differed between patients with AR or ATN. Urinary cell levels of 23 of the 26 mRNAs were statistically different (P<0.05) between AR and ATN. A urine composite score derived from a model of a combination of 6 of the 26 mRNAs assayed had a prediction accuracy of 94% (ROC-AUC: 0.98; 95%CI: 0.95-1.00).

| | | Predicted Category | |
|---|---|---|---|
| | | Acute Rejection | Acute Tubular Injury |
| Actual Category (N=84) | Acute Rejection (N=52) | 50 | 2 |
| | Acute Tubular Injury (N=32) | 3 | 29 |

Prediction Accuracy: 94.1%, Press's Q=65.2, P<0.0001
Acute rejection correctly classified: 96.2%
Acute tubular injury correctly classified: 90.6%

Hit ratio (percentage correctly classified) based on the discriminant function: 94.1%
Maximum chance criterion (MCC, predict everyone to be classified to the largest diagnostic category): 61.9%
Proportional chance criterion ($C_{pro}$, randomly classify proportionate to the two diagnostic categories): 52.8%



By 10-fold cross-validation, the prediction accuracy was 88.5% (ROC-AUC: 0.88, 95%CI: 0.78-0.97). The net benefit, over a wide range of physician's threshold probability for biopsy to diagnose AR, was higher when biopsy was done as informed by the urine composite score. By this approach, at 25% physician's threshold probability for biopsy, the number of biopsies avoided per 100 patients was 29.8, with resultant cost savings of about US$ 65,700.

**Conclusions:** In kidney transplant recipients with abnormal creatinine levels, urinary cell mRNA profile not only facilitates differential diagnosis of AR vs. ATN but also minimizes biopsy procedures and reduce health care costs.

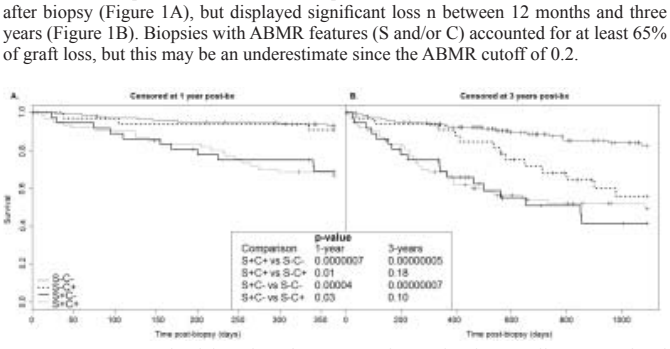
## SA-OR005

**Prediction of Failure in Antibody-Mediated Rejection Requires Molecular as Well as Conventional Assessment** Philip F. Halloran, Andre Barreto Pereira, Konrad S. Famulski. *Alberta Transplant Applied Genomics Centre, Edmonton, Canada.*

**Background:** Antibody-mediated rejection (ABMR) is the major determinant of transplant outcome but conventional assessment is problematic, particularly since the recognition of C4d negative ABMR.

**Methods:** We recently created and validated a microarray-based test for ABMR – the ABMR score - in 703 prospective indication biopsies in 579 patients. We now compared the ability of the conventional (C) tests – histology, C4d, HLA antibody - to the ABMR score (S>0.2) for predicting failure in the 342 patients undergoing late biopsies >1 year post transplant.

**Results:** Excluding glomerulonephritis and BK, there were four groups: 61 S+C+; 36 S+C-; 32 S-C+, and 144 S-C-. All 3 classes of classes of kidneys with ABMR features (S+C+, S+C-, S-C+) were at risk for failure, but only biopsies with positive scores (S+C- and S+C+) showed rapid deterioration. S-C+ biopsies showed no increased loss for 12 months after biopsy (Figure 1A), but displayed significant loss n between 12 months and three years (Figure 1B). Biopsies with ABMR features (S and/or C) accounted for at least 65% of graft loss, but this may be an underestimate since the ABMR cutoff of 0.2.



**Conclusions:** Optimal detection of ABMR requires molecular as well as conventional assessment. The molecular changes detect many missed cases and predict rapid deterioration after biopsy, and thus will be critical in developing new therapies and guiding their use.

## SA-OR006

**The Contribution of Post Transplant Disease Recurrence to Graft Failure in Glomerulonephritis** Maria Pippias,[1] Vianda S. Stel,[1] Fergus J. Caskey,[2] Kitty J. Jager.[1] *[1]On Behalf of the ERA-EDTA Registry Study Group, ERA-EDTA Registry, Amsterdam, Netherlands; [2]Richard Bright Renal Unit, Bristol, United Kingdom.*

**Background:** Glomerulonephritis (GN) continues to predominate as one of the leading causes of established renal failure and subsequent need for transplantation. Post-transplant disease recurrence (PTDR) is a significant cause of long term graft loss, however there is little consensus in the rate of graft loss due to PTDR. We studied the contribution of PTDR to graft failure in those with a primary renal diagnosis (PRD) of GN.

**Methods:** Data on all adult first kidney transplants (Tx) performed between 1991 and 2011 in 11 countries reporting to the ERA-EDTA Registry were used. In those with a PRD of GN [IgA, MPGN I, MPGN II, FSGS and membranous nephropathy (MN)] 5, 10 and 15 year death censored graft survival was studied using Kaplan Meier and Cox regression analysis whilst adjusting for gender, age at the start of RRT and age at Tx. Adult polycystic kidney disease (APKD) was the control group. Any additional risk of graft loss when compared to APKD was assumed to be due to PTDR.

**Results:** 12,646 individuals were included in the study, 6279 with GN and 6367 with APKD. Overall, 15 year adjusted graft survival was lowest in MN (56.3%) and highest in IgA (66.8%). No difference in 5, 10 or 15 year adjusted graft survival was found between APKD and IgA (15 year HR 1.04; 95% CI 0.92-1.16). Significantly worse graft survival was seen in all other GNs: MPGN II (HR 2.27; 95% CI 1.67-3.09), MPGN I (HR 1.88; 95% CI 1.58-2.23), MN (HR 1.4; 95% CI 1.18-1.67) and FSGS (HR 1.39; 95% CI 1.18-1.63).

**Conclusions:** This is the first study examining graft survival outcomes in a large European Tx population with various GNs over a 15 year period. We found no difference in graft survival in IgA compared to APKD but worse outcomes in other GNs. As short term graft function continues to improve further studies are required to understand the determinants of long term graft survival. Further analyses will focus on long term graft outcomes with different donor types as such information would aid the patient in Tx counselling particularly when considering donor type.

## SA-OR007

**Albuminuria and Cardiovascular Disease, Kidney Failure and Death in Stable Kidney Transplant Recipients** Alin A. John,[1] Andrew S. Levey,[1] Myra A. Carpenter,[2] Lawrence G. Hunsicker,[3] Roberto S. Kalil,[3] John W. Kusek,[4] Marc A. Pfeffer,[5] Scott D. Solomon,[5] Matthew R. Weir,[6] Daniel E. Weiner.[1] *[1]Tufts; [2]UNC; [3]Iowa; [4]NIDDK; [5]BWH; [6]Maryland.*

**Background:** Despite improvement in early graft loss, overall graft survival remains suboptimal. While albuminuria is a known risk factor for adverse outcomes in the general and CKD populations, the relationship between albuminuria and outcomes in kidney transplant recipients (KTRs) remains uncertain.

**Methods:** In a post-hoc analysis of the Folic Acid for Vascular Outcomes Reduction in Transplantation (FAVORIT) Trial, a large randomized trial of homocysteine lowering in stable KTRs, we evaluated the relationship between albuminuria and risk of cardiovascular disease, end-stage renal disease (ESRD) and all-cause death. Multivariable Cox proportional hazards models, adjusting for age, sex, race, treatment allocation, country, systolic and diastolic blood pressure, history of CVD, diabetes and smoking, cholesterol, BMI, eGFR, donor type, transplant vintage, and calcineurin inhibitor use, were used.

**Results:** In 3,460 participants with complete data, 1,912 (55%) had an albumin to creatinine ratio (ACR) <30 mg/g, 1,113 (32%) ACR of 30-299 mg/g, and 435 (12%) ACR of ≥300 mg/g at baseline. Median (IQR) ACR was 24 mcg/g (9-97) and mean eGFR 49 ± 18 ml/min/1.73m$^2$. Mean age was 52 ± 9 years, 17% were black, and 37% women; median graft vintage was 4.1 (1.7, 7.4) years and 57% received deceased donor kidneys. Variables associated with higher ACR included older graft vintage, deceased donor transplant, history of CVD and diabetes, higher blood pressure, and lower eGFR. Over mean follow-up of 4.0 ± 1.5 years, a total of 494 cardiac events, 281 kidney failure events and 395 deaths occurred. Following adjustment, each doubling of ACR was associated with significantly increased risk of cardiovascular outcomes [HR=1.05 (1.02, 1.09)], kidney failure [HR=1.43 (1.36-1.50)], and all-cause mortality [HR=1.14 (1.09-1.18)].

**Conclusions:** In stable KTRs, elevated baseline uACR was independently associated with risk of CVD, kidney failure and death. Future studies are needed to evaluate whether reducing albuminuria improves these clinical outcomes.

**5 Years Follow-Up on ZEUS: Improved Renal Function of an Everolimus/Enteric-Coated Mycophenolate Sodium Regimen after Calcineurin Inhibitor Withdrawal in De Novo Renal Transplant Patients** Wolfgang Arns,[1] Ute Eisenberger,[1] Oliver Witzke,[1] Claudia Sommerer,[1] Petra Reinke,[1] Martina Porstner,[2] Christoph May,[2] Eva-Maria Paulus,[2] F. Lehner,[1] Klemens Budde.[1] *[1]ZEUS Study Group, Germany; [2]Novartis Pharma, Germany.*

**Background:** Follow-up (FU) on renal function(RF), efficacy and safety after conversion to an Everolimus(EVR)/Enteric-Coated Mycophenolate Sodium(EC-MPS) regimen after cyclosporine A(CsA) withdrawal in *de novo* kidney allograft recipients at month (Mo)60 after transplantation (Tx).

**Methods:** In this prospective, open-label, controlled, multi-center study renal Tx patients (pts) were randomized (rdz) at Mo4.5 post Tx to an immunosuppressive (IS) regimen consisting of either EVR/EC-MPS or CsA/EC-MPS. After completion of 12Mo core-study pts were included in an observational FU.

**Results:** 300 pts were rdz to either EVR+EC-MPS(n=155) or CsA+EC-MPS(n=145). Mo60 visit was completed by 227(76%) pts. RF expressed as eGFR(Nankivell, ITT) was similar in both groups at baseline (4.5Mo post Tx) with an improvement by +3.6mL/min/1.73m2 (p=0.045) in favor of the EVE regimen at Mo60 (+9.8mL/min/1.73m2 at Mo12). All pts who remained on the assigned EVR regimen (on-therapy) had a higher improvement of RF, i.e.+7.3mL/min/1.73m2(p<0.001) at Mo60. An overall improved GFR was observed in 69% of EVR on-therapy pts at Mo60 vs 46% on CsA (p=0.007). 3deaths and 3graft losses were observed in CsA vs 4deaths and 4graft losses in EVR group (ITT). Number of pts with infections: 32(21%) in EVR, 21(15%) in CsA group; hospitalisation: 36(23%) in EVR, 21(15%) in CsA group between Mo48 and Mo60. No significant difference in BPAR was reported from rdz to Mo60 with 21(14%) in EVR vs. 11(8%) in CsA group (p=0.095).

| eGFR Nankivell (ml/min/1.73m²) | EVR | CsA | Difference EVR/CsA | P-Value |
|---|---|---|---|---|
| ITT population | n=99 | n=100 | Δ | |
| eGFR mean ±SD | 68.0±17.1 | 65.3±15.7 | +2.9 | 0.331[b] |
| eGFR change[a], mean ±SD | +5.1±13.7 | -0.4±12.9 | +5.5 | 0.003[b] |
| eGFR LS-mean[c] [95%CI] | 67.9 [63.7;72.1] | 64.2 [60.0;68.6] | +3.6 [0.1;7.2] | 0.045[c] |
| On-therapy population | n=71 | n=76 | Δ | |
| eGFR mean ±SD | 70.3±17.1 | 66.3±15.1 | +4.1 | 0.141[b] |
| eGFR change[a], mean ±SD | +8.3±13.1 | -0.9±11.8 | +9.2 | <0.001[b] |
| eGFR LS-mean[c] [95%CI] | 71.1 [66.4;75.9] | 63.8 [59.1;68.5] | +7.3 [3.4;11.3] | <0.001[c] |

[a]RandomizedTreatmentPeriod; [b]Wilcoxon Rank-Sum test; [c]ANCOVA

**Conclusions:** Early conversion to EVR in *de novo* KTx pts after CNI withdrawal maintains better RF over a period of 5years without compromising efficacy and safety.

## SA-OR009

### Prevalence and Clinical Significance of C1q Binding Anti-HLA Antibodies in Patients with Functioning Allografts More Than 10 Years after Kidney Transplantation

Sumeyye Calp Inal, Adriana Colovai, Michal L. Melamed, Enver Akalin. *Renal Div, Albert Einstein College of Medicine, Bronx, NY.*

**Background:** We aimed to investigate the prevalence and clinical significance of C1q binding anti-HLA antibodies in patients with functioning grafts more than 10 years post-transplantation.

**Methods:** All recipients had negative complement-dependent-cytotoxicity cross-match at the time of transplantation. HLA antibody identification was performed using Luminex Single Antigen Bead assay. The capacity of serum HLA antibodies to fix complement was tested using the C1q assay.

**Results:** Of the 176 patients studied, %23 (n=41) had donor-specific anti-HLA antibodies (DSA), and %20 of the DSA+ patients (n=8) had C1q binding capacity. Mean fluoresence intensity values of DSAs were higher in DSA+/C1q+ group (7282 vs 3472). Comparing to DSA negative and DSA+/C1q- patients, DSA+/C1q+ patients had more history of previous kidney transplantation, higher class II panel reactive antibody levels, acute antibody-mediated rejection and transplant glomerulopathy. There was no difference in terms of allograft function between the groups.

**Conclusions:** Positive C1q assay was seen in 20% of the DSA+ patients 10 years after transplantation and it is significantly associated with AMR and transplant glomerulopathy.

### Circulating MicroRNAs Correlate with Diabetic Nephropathy and Systemic Microvascular Damage and Normalize after Simultaneous Pancreas-Kidney Transplantation

Roel Bijkerk,[1,2] Meriem Khairoun,[1] Jacques Duijs,[1,2] Kristel C.J.H. ter Horst,[1] Aiko P.J. De Vries,[1] Eelco de Koning,[1] Johan W. De Fijter,[1] Ton J. Rabelink,[1,2] Anton Jan Van Zonneveld,[1,2] Marlies Reinders.[1,2] *[1]Nephrology, LUMC, Netherlands; [2]Einthoven Laboratory for Experimental Vascular Research, LUMC, Netherlands.*

**Background:** Simultaneous pancreas-kidney transplantation (SPK) is an advanced treatment option for type I diabetes (T1D) patients with extensive microvascular disease and nephropathy (DN). Circulating microRNAs (miRNAs) can be sensitive biomarkers and their functional properties could provide insight into disease state. By assessing miRNA profiles in healthy control subjects and T1D patients before and following SPK we aimed to identify differentially expressed subsets of miRNAs that associate with microvascular destabilization and disease state.

**Methods:** Circulating miRNA expression was determined using TaqMan® Human miRNA Array Card in plasma of DN (n=8) and SPK patients (n=8) and compared with healthy controls (n=3). In addition, the SPK patients were studied longitudinally before, 1, 6 and 12 months after SPK. Microvascular morphology and mean capillary density were visualized using sidestream darkfield imaging of the oral mucosa. Furthermore, circulating levels of angiogenic factors, including angiopoietin-1 (Ang1), angiopoietin-2 (Ang2), VEGF and soluble thrombomodulin (sTM) were measured using ELISA.

**Results:** In our study we identified miR-25, 27a, 126, 130b, 132, 152, 181a, 320 and 660 to have elevated expression levels in plasma of DN patients as compared to healthy controls, whereas miR-223 and 574-3p expression was decreased. After SPK, expression levels of these miRNAs normalized and positively correlated with GFR and Hba1c levels. Interestingly, the expression of miR-126, 130b and 132, which are known to be pro-angiogenic, correlated with Ang2 levels. In addition, miR-130b showed a strong correlation with microvascular tortuosity and sTM levels.

**Conclusions:** Circulating miRNAs profiles correlate with DN and systemic microvascular destabilization. Following SPK these profiles normalized concomitant with microvascular stabilization supporting the potential use of miRNA profiles to assess disease progression.

### Impaired KLHL3-Mediated Ubiquitination of WNK4 Activates OSR1 and SPAK Kinases-NaCl Cotransporter (NCC) Signaling and Causes Hypertension

Mai Wakabayashi, Takayasu Mori, Kiyoshi Isobe, Eisei Sohara, Koichiro Susa, Yuya Araki, Motoko Chiga, Eriko Kikuchi, Naohiro Nomura, Yutaro Mori, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Dept of Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan.*

**Background:** Mutations in two WNK kinase genes, WNK1 and WNK4, cause pseudohypoaldosteonism type II (PHA II) characterized by hypertension, hyperkalemia and acidosis. Recently, mutations in Kelch-like 3 (KLHL3) and Cullin3 were also identified to cause PHAII. However, the pathogenic role of the mutations of KLHL3 and Cullin3 genes was not well understood. In this study, we investigated how these three genes interacted each other and how they were involved in the pathogenesis of PHAII.

**Results:** Methods and Results: KLHL3 was co-immunoprecipitated with WNK4, but not with OSR1, SPAK, or NCC. PHAII-causing mutations in either KLHL3 or WNK4 decreased the binding of two proteins. Overexpression of KLHL3 and Cullin3 with WNK4 dramatically decreased WNK4 protein expression, and this decrease was blunted by the PHAII mutations in WNK4, KLHL3, or Cullin3. KLHL3 coexpression with WNK4 significantly induced the ubiquitination of WNK4, which was also impaired by the PHAII mutations in WNK4 and KLHL3. In vitro ubiquitination assay confirmed that WNK4 is a direct substrate of KLHL3-Cullin3 E3 ubiquitin ligase. Transgenic mice overexpressing WNK4 showed PHAII phenotypes and the activation of OSR1/SPAK-NCC signaling in the kidneys, and WNK4 protein was indeed increased in *Wnk4*$^{D561A/+}$ PHAII model mice. WNK4 protein was also increased in KLHL3-mutated PHAII patients.

**Conclusions:** WNK4 is a target for KLHL3/Cullin3-mediated ubiquitination, and the impaired ubiquitination of WNK4 is a common mechanism of PHAII.

## SA-OR012

### Analyses of KLHL3 Mutants That Cause Pseudohypoaldosteronism Type II

Yutaro Mori, Mai Wakabayashi, Takayasu Mori, Yuya Araki, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Dept of Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan.*

**Background:** Recently, we reported that WNK4 is a substrate of KLHL3-Cullin3 (CUL3) E3 ubiquitin ligase complexes, and that the impaired ubiquitination of WNK4 would be a common mechanism of pseudohypoaldosteronism type II (PHAII) caused by WNK4, KLHL3 and CUL3. Among various PHAII-causing KLHL3 mutants, we revealed that R528H mutant (a kelch domain mutant) showed less binding to WNK4, thereby causing less ubiquitination and increased abundance of WNK4 within cells. However, pathogenic mechanisms of other PHAII-causing KLHL3 mutants remained to be determined.

**Methods:** We transiently expressed four PHAII-causing KLHL3 mutants (E85A in BTB domain, C164F in BACK domain, S410L and R528H in kelch domains) in HEK293T cells. Stability of the KLHL3 mutants within cells was examined by cycloheximide chase assay. Immunoprecipitation and fluorescence correlation spectroscopy (FCS) were used to evaluate binding of the mutant KLHL3s with WNK4 or CUL3. In vitro and in vivo ubiquitination assays were performed to examine the ubiquitination of WNK4 by the KLHL3 mutants.

**Results:** The expression levels of the KLHL3 mutant proteins differed significantly. Especially, S410L expression was low even with increased amounts of the expression plasmid. Cycloheximide chase assay revealed that S410L was more rapidly degradated compared to wild-type KLHL3. E85A and C164F showed less binding to CUL3, and S410L as well as R528H showed less binding to WNK4. In both in vitro and in vivo ubiquitination assays, WNK4 was less ubiquitinated and increased within cells with all these mutant KLHL3s, compared with wild-type KLHL3.

**Conclusions:** PHAII-causing KLHL3 mutants examined in this study showed less ability to ubiquitinate WNK4 either by its own low stability and/or the decreased binding to CUL3 or WNK4.

*Funding:* Government Support - Non-U.S.

**SA-OR013**

**KLHL2 Interacts with and Ubiquitinates WNK Kinases** Daiei Takahashi, Takayasu Mori, Mai Wakabayashi, Yutaro Mori, Koichiro Susa, Moko Zeniya, Tatemitsu Rai, Eisei Sohara, Sei Sasaki, Shinichi Uchida. *Dept of Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan.*

**Background:** Mutations in the WNK1 and WNK4 genes result in an inherited hypertensive disease, pseudohypoaldosteronism type II (PHAII). Recently, the KLHL3 and Cullin3 genes were also identified as responsible genes for PHAII. We reported that WNK4 is a substrate for the KLHL3-Cullin3 E3 ligase complex, and that the impaired ubiquitination and subsequent increase of WNK4 in the kidney would be a common mechanism of PHAII caused by mutations of WNK4, KLHL3 and Cullin3. Since WNK isoforms are widely expressed in the body, it is not clear whether all of the WNK isoforms are regulated only by KLHL3. To explore the interaction of WNKs and other kelch-like proteins, we focused on KLHL2 (Mayven), a human homolog of drosophila kelch that shares the highest similarity with KLHL3 (86% amino acid identity with KLHL3 in Kelch domain).

**Methods:** To determine the interaction between KLHL2 and WNK kinases, we performed immunoprecipitation and fluorescence correlation spectroscopy. The effect of KLHL2 coexpression on the abundance of WNK kinases was determined by immunoblotting. Ubiquitination of WNK isoforms by KLHL2 was studied in vivo (HEK293T cells) and in vitro.

**Results:** We found that KLHL2, as well as KLHL3, was co-immunoprecipitated with all four WNK isoforms. The direct interaction of KLHL2 with WNKs was confirmed on fluorescence correlation spectroscopy. Co-expression of KLHL2 and Cullin3 decreased the abundance of WNK1, WNK3 and WNK4 within HEK293T cells, and a significant increase of WNK4 ubiquitination by KLHL2 and Cullin3 was observed both in HEK293T cells and in an *in vitro* ubiquitination assay.

**Conclusions:** We have identified the function of KLHL2 as an E3 ubiquitin ligase for WNK kinases. Different combinations of KLHL2 and KLHL3 with WNKs could regulate WNK kinase signaling in different kinds of cells.

*Funding:* Government Support - Non-U.S.

**SA-OR014**

**WNK3 Regulates Blood Pressure through the Regulation of Vascular OSR1/SPAK-NKCC1 Phosphorylation Cascade** Moko Zeniya, Eisei Sohara, Katsuyuki Oi, Motoko Chiga, Koichiro Susa, Takayasu Mori, Daiei Takahashi, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Dept of Nephrology, Graduate School of Medical and Dental Sciences, Bunkyo-ku, Tokyo, Japan.*

**Background:** NKCC1 is involved in the regulation of vascular smooth muscle cell contraction. The WNK-SPAK-NKCC1 phosphorylation cascade in vascular smooth muscle cells was found to be important in the regulation of vascular tone. Moreover, we have recently reported that WNK3 knockout mice showed lower blood pressure only when mice were fed low-salt diet, through extra-renal mechanisms. In this study, we investigated whether the WNK-SPAK-NKCC1 cascade in mouse aortic tissue is regulated by dietary salt intake, and the mechanisms responsible, focusing on WNK3.

**Methods:** The phosphorylations of SPAK and NKCC1 were examined in the aorta of wild-type and WNK3 knockout mice fed high-salt, normal or low-salt diet. In addition, the effects of angiotensinII (AngII) on their phosphorylations and blood pressure were also examined.

**Results:** Phosphorylation of SPAK and NKCC1 was significantly reduced in the aorta in high-salt fed mice, and was increased in the aorta in low-salt fed mice, indicating that the WNK-SPAK-NKCC1 phosphorylation cascade in the aorta was indeed regulated by dietary salt intake. Acute and chronic AngII infusion increased phosphorylation of SPAK and NKCC1 in the mouse aorta. In addition, valsartan, an antagonist of angiotensin II type 1 receptor, inhibited low-salt diet-induced phosphorylation of SPAK and NKCC1, demonstrating that AngII activates the WNK-SPAK-NKCC1 phosphorylation cascade in aorta through the AT1 receptor. However, low-salt diet and AngII together did not increase phosphorylation of SPAK and NKCC1 in the aorta of WNK3 knockout mice, indicating that activation of the WNK-SPAK-NKCC1 phosphorylation cascade induced by low-salt diet and AngII is dependent on WNK3. Indeed, increases in blood pressure by AngII infusion were diminished in WNK3 knockout mouse.

**Conclusions:** We demonstrated that dietary salt intake regulates the WNK3-SPAK-NKCC1 phosphorylation cascade in mouse aortic tissue through AngII. We clarified for the first time the physiological role of WNK3 in vivo.

**SA-OR015**

**mPGES-1 Deletion Increases Blood Lithium Concentration and Induces Colon Injury via Elevated Oxidative Stress** Zhanjun Jia,[1,2] Ying Sun,[1,2] Tianxin Yang.[1,2] *[1]Internal Medicine, Univ of Utah, Salt Lake City; [2]VA Medical Center, Salt lake City, UT.*

**Background:** It is well established NSAIDs including specific COX-2 inhibitors elevated blood lithium levels in lithium treated patients. However, a specific prostanoid involved in this phenomenon is unknown.Present study attempted to study the role of microsomal prostaglandin E synthase-1 (mPGES-1) in lithium metabolism and toxicity.

**Methods:** Lithium at a low dose of 4 mmol/kg/day for 2 weeks or a high dose of 32 mmol/kg/day for 1 week was administered to mPGES-1 WT and KO mice.

**Results:** During 2-week low dose lithium treatment, KO mice showed a significant elevation of plasma lithium level compared with the WT (KO: 0.18±0.01 vs WT: 0.12±0.02 mmol/L, $p<0.05$), accompanied with reduced urine lithium excretion (KO: 30.0±2.9 vs WT:41.5±4.3 umol/24h, $p<0.05$). Meanwhile, the polyuria induced by lithium was blocked by 80% compared with WT mice. Interestingly, the high dose treatment in KO not only further elevated blood lithium level ((KO: 0.9±0.19 vs WT: 0.4±0.04 mmol/L, $p<0.05$), but also caused severe hematochezia with 50% lethal rate during 7-day lithium treatment. HE staining showed severe hemorrhage lesions without inflammatory cells infiltration. By qRT-PCR, none of inflammatory cytokines including IL-1β, TNF-α, MCP-1, were induced in colon irrespective of the genotype. Interestingly, the lithium overload induced remarkable elevations of SOD1 (3.5 folds) and SOD2 (4.8 folds) in colon of WT mice contrasting to the significant reductions of both SOD1 (-45%) and SOD2 (-44%) in KO. In contrast, colon expression of NADPH oxidase subunits, including $p47^{phox}$, $gp91^{phox}$, was similarly induced in two genotypes. Consistent with the change of SOD, administration of tempol (50 mg/kg/day), a SOD mimic, remarkably diminished the hematochezia and colon damage without affecting the blood lithium (0.86±0.11 mmol/L). Finally, the colon PGE2 content in WT exhibited a 50% increase ($p<0.05$) after lithium treatment contrasting to a marked decrease in KO mice (KOLi: 8.5±0.2 vs KO cont: 3.9±0.46 ng/mg protein, $p<0.01$).

**Conclusions:** mPGES-1 deletion enhanced blood lithium accumulation and resulted in lethal colon injury via oxidative stress.

**SA-OR016**

**Acetazolamide: An Improved Treatment for Lithium-Induced Nephrogenic Diabetes Insipidus?** Theun de Groot,[1] Anne P. Sinke,[1] Marleen L.A. Kortenoeven,[1] Ruben Baumgarten,[2] Olivier Devuyst,[3] Johannes Loffing,[4] Jack F. Wetzels,[1] Peter M.T. Deen.[1] *[1]Radboud Univ Nijmegen Medical Centre, Netherlands; [2]St. Exp. Lab. Med, Netherlands; [3]Zurich Centre for Integr. Human Physiology, Switzerland; [4]Univ Zurich, Switzerland.*

**Background:** Lithium causes nephrogenic diabetes insipidus (Li-NDI) and hydrochlorothiazide (HCTZ) forms, together with amiloride, the mainstay treatment for Li-NDI patients. The antidiuretic action of HCTZ in Li-NDI is generally ascribed to increased proximal sodium and water uptake, compensating for sodium loss due to NaCl-co-transporter (NCC) inhibition. Earlier, we found that HCTZ also reduces Li-NDI in NCC knockout mice, coinciding with alkalinized urine, suggesting that inhibition of carbonic anhydrase by HCTZ plays a role. To test whether inhibition of only carbonic anhydrases could be a useful alternative therapy, the effect of acetazolamide (ACZ) in Li-NDI was tested.

**Methods:** Polarized mouse cortical collecting duct (mpkCCD) cells and mice were used to study the effect of ACZ on Li-NDI.

**Results:** Treatment of mpkCCD cells with ACZ attenuated the lithium-induced downregulation of endogenous AQP2. ACZ did not affect transcellular voltage, and, upon co-incubation with amiloride, resulted in significantly higher levels of AQP2, indicating that the action mechanism of ACZ differs from that of amiloride. Treatment of Li-NDI mice with ACZ revealed a significant antidiuresis and increased urine osmolality, which was indifferent from Li-NDI mice treated with HCTZ/amiloride. However, unlike HCTZ/amiloride, ACZ treatment did not result in hyponatremia, hyperkalemia, hypercalcaemia, metabolic acidosis and increased serum lithium concentrations. Moreover, ACZ rescued AQP2 expression over the entire length of the collecting duct, whereas HCTZ/amiloride only increased AQP2 levels in the renal papilla.

**Conclusions:** In conclusion, our data reveal that inhibition of carbonic anhydrases attenuates lithium-induced downregulation of AQP2 and NDI development. Moreover, as ACZ appeared as effective as the conventional treatment to rescue Li-NDI, but caused fewer side effects, ACZ may represent a better therapeutic agent than HCTZ/amiloride to treat Li-NDI.

**Mechanism of Acidosis-Induced Adaptive Proliferation of Collecting Duct Intercalated Cells** Lydie Cheval, Suresh K. Ramakrishnan, Christophe Klein, Alain Doucet. *Centre de Recherche des Cordeliers, Paris, France.*

**Background:** Kidneys adapt to acid load by increasing proton secretion by collecting duct a intercalated cells (AIC). This adaptation stems in part from increased number of AICs. We reported previously that acid loading induces proliferation of AICs in mouse outer medullary collecting duct (OMCD) and that this process depends on the production of growth and differentiation factor 15 (Gdf15), a member of TGFb super family (JASN, 19:1965-1974, 2008). Here we investigated the mechanisms of Gdf15 production and action in OMCDs.

**Methods:** Acidosis was induced by feeding mice a $NH_4Cl$-enriched diet (0.7M). OMCDs were microdissected from collagenase-treated kidneys. mRNAs were quantified by RT-quantitative PCR, number of AICs was counted after immunolabeling with an AE1 antibody. The angle of AICs doublets with the axis of the tubule was determined after confocal imaging of isolated OMCDs and 3D reconstruction.

**Results:** Within 2 days, acidosis induced a 3-fold over expression of p53. $NH_4Cl$-induced over expression of Gdf15 and cyclin D1 were abolished in $p53^{-/-}$ mice which, accordingly, developed stronger acidosis. Treatment with the pan-erbB tyrosine kinase inhibitor canertinib (60mg/Kg/day, IP) did not alter the over expression of Gdf15 but curtailed that of PCNA and cyclin D1, and accordingly mice developed stronger acidosis. In control mice, the angle of the doublets of AICs was evenly distributed from 0 to 90°. Conversely, in acidotic mice, the number of doublets increased and they were preferentially oriented in parallel with the tubule axis.

**Conclusions:** Gdf15 triggers axial proliferation of AICs through activation of ErbB receptor. This adaptive proliferation is dependent on p53 over expression.

**Multifunctional Role of the N-Terminal Variable (V1) Domain of the Sodium-Bicarbonate Cotransporter NBCe1-A: Patch Formation, Trafficking and Gating** Harry S. Gill,[1] Casey N. Watkins,[1] Anastas Popratiloff.[2] *[1]Dept of Medicine, The George Washington Univ & Div of Renal Diseases & Hypertension, Washington, DC; [2]Center for Microscopy & Image Analysis, The George Washington Univ, Washington, DC.*

**Background:** The electrogenic NBCe1-A is an integral membrane cotransporter that reabsorbs $Na^+$ and $HCO3^-$ across the basolateral membrane of the proximal tubule. Naturally occurring mutations (Q29X, R298S) in the cytoplasmic, N-terminal domain of NBCe1-A (Nt) lead to Type II acidosis. NBCe1 family members contain a large Nt with two variable regions, one at the extreme N terminus (V1).

**Methods:** The Nt structure was solved by X-ray crystallography. To investigate the role of the V1 domain, truncation mutants were rationally generated. Surface-plasmon-resonance (SPR) and light-scattering (MALS-SEC) techniques were used to evaluate pH-sensitive self-associations of the Nt. The mutants were also fused with the green fluorescent protein and expressed in cultured human proximal tubular (HK2) cells to evaluate self-associations at the plasma membrane by confocal microscopy.

**Results:** We present the Nt crystal structure at 2.4 Å resolution. The structure reveals that the Nt dimerizes by two-interlocking arms and that has two variable flexible regions, one at the extreme N terminus (V1) that gates substrate entry into the Nt and another large solvent accessible loop (V2) that extends ~20 A from the core Nt structure. The SPR and MALS-SEC experiments indicate that the V1 domain is responsible for Nt self-associations. In agreement, punctate clusters and large patches of full-length NBCe1-A are observed at the plasma membrane. Trafficking to the membrane is significantly affected in several Nt mutants.

**Conclusions:** We conclude that NBCe1-A molecules form patches in the plasma membrane of PT cells in the presence of intracellular $HCO3^-$. Secondly, we have discovered a novel role for V1 domain of NBCe1-A in cell membrane trafficking. These findings illuminate the role of the Nt of NBCe1-A in $HCO3^-$ sensing and transport and provide insight to the pathogenic processes observed in a subset of patients with truncating and point mutations in the gene encoding NBCe1-A.

**Missense Mutation T485S Alters NBCe1-A Electrogenicity Causing Proximal Renal Tubular Acidosis** Quansheng Zhu,[1] Xuesi Max Shao,[1] Liyo Kao,[1] Rustam Azimov,[1] Alan Mark Weinstein,[2] Debra Newman,[1] Weixin Liu,[1] Ira Kurtz.[1] *[1]Dept of Medicine, Univ of California, Los Angeles, Los Angeles, CA; [2]Dept of Physiology and Biophysics, Weill Medical College of Cornell Univ, New York, NY.*

**Background:** The electrogenic sodium-base cotransporter, NBCe1-A plays a critical role in reabsorbing filtered bicarbonate in the proximal renal tubule. Eight missense mutations in NBCe1-A have been reported to cause proximal tubular acidosis (pRTA), of which the Thr485 to Ser mutation minimally perturbs the transporter structure and retains 50% of base transport. The disease causing mechanism of T485S is intriguing because Thr and Ser are structurally and chemically similar.

**Methods:** We expressed human NBCe1-A in HEK 293 cells and explored the molecular mechanism of the T485S pRTA mutation using a combined approach of intracellular pH assays, whole cell patch clamping, computational molecule simulation and small molecule probing.

**Results:** Wild-type NBCe1-A mediates electrogenic sodium-base cotransport with a 1:2 charge transport stoichiometry. Using nitrate as a surrogate for carbonate, our data suggests that wild-type NBCe1-A mediates electrogenic sodium carbonate cotransport. T485S causes the transporter to become electroneutral with a loss of sodium-coupled nitrate transport. The underlying mechanism appears to involve a change of carbonate for bicarbonate as the preferred substrate in the anion interaction site. The location of Thr485 in the anion interaction site was determined from [$^{14}$C]NEM labeling experiments, functional characterization with MTS reagents, and studies showing that the adjacent pRTA causing mutation, G486R, alters the position of Thr485 significantly impairing transporter function.

**Conclusions:** Our findings indicate that NBCe1-A cotransports sodium and carbonate (rather than bicarbonate), with 1:2 charge transport stoichiometry. In patients, electroneutral T485S is predicted to transport sodium-bicarbonate from blood into proximal tubule cells thereby impairing transepithelial bicarbonate absorption representing a potentially new pathogenic mechanism for generating human pRTA.

**Epithelial Sodium Proton Exchanger, NHE3, Activity Is Enhanced by a Physical and Functional Interaction with Carbonic Anhydrase II, CAII** Deivshree Krishnan, Emmanuelle Cordat, R. Todd Alexander. *Univ of Alberta.*

**Background:** Seventeen hundred mg of NaCl is filtered by the glomerulus daily, more than two thirds is reabsorbed from the proximal tubule. The molecular determinants of proximal tubular $Na^+$ reabsorption are coupled to bicarbonate reabsorption and the cytosolic C-terminus of NHE3 contains a putative CAII binding site. We therefore hypothesize that NHE3 and CAII; molecules involved in the combined flux of $Na^+$ and $HCO_3^-$, physically and functionally interact to increase $Na^+$ reabsorption from the proximal tubule.

**Methods:** Physical interaction studies included: immunostaining of mouse kidney, a proximity ligation assay and a microtitre plate assay with NHE3 GST-fusion constructs and recombinant CAII. NHE3 was stably over-expressed in opossum kidney cells (OK-$NHE3_{38HA3}$) and activity measured as the rate of intracellular pH recovery, induced by an acid load and detected with the fluorescent ratiometric probe BCECF-AM. Acidification was induced by switching cells from a bicarbonate free medium, to one containing bicarbonate and 5% $CO_2$.

**Results:** Murine renal sections immunostained for CAII and NHE3 demonstrate colocalization in the brush border. That the two proteins were closer than 40 nm apart was revealed by a proximity ligation assay. A direct physical interaction was confirmed with GST fusion constructs. OK-$NHE3_{38HA3}$ cells demonstrate significantly greater recovery of intracellular pH than controls that is both $Na^+$ dependent and inhibited by 100 uM EIPA. Inhibition of endogenous CAII activity with acetazolamide significantly decreased NHE3 activity, an effect that was not observed when acidification was induced in the absence of $CO_2$ and $HCO_3^-$. To ascertain whether CAII binding per se activates NHE3, we over-expressed $NHE3_{38HA3}$ with: CAII, a catalytically dead CAII mutant (CAII-V143Y) or a binding mutant (CAII-HEX). These studies revealed an increase of NHE3 activity induced by CAII coexpression that was absent in the presence of the V143Y or HEX mutant.

**Conclusions:** These studies confirm that CAII binds to and increases NHE3 activity likely augmenting $Na^+$ and $HCO_{3[sup]-[/sup]}$ reabsorption from the proximal tubule.

**SA-OR021**

**Kruppel-Like Factor 6 Regulates Mitochondrial Function in Podocytopathy** Sandeep K. Mallipattu,[1] Ruijie Liu,[1] Vivette D. D'Agati,[3] Peter Y. Chuang,[1] Roel Sterken,[2] Natalia Papeta,[2] Ali G. Gharavi,[2] John C. He.[1] *[1]Nephrology, Mount Sinai Medical Center; [2]Nephrology, Columbia Univ; [3]Pathology, Columbia Univ.*

**Background:** Podocyte injury resulting from mitochondrial dysfunction has been implicated in glomerular disease. However, transcription factors mediating mitochondrial damage in podocyte injury have yet to be identified.

**Methods:** We performed quantitative trait loci (eQTL) analysis of recently identified HIVAN susceptibility loci. Kruppel-like Factor 6 (KLF6), a zinc-finger binding transcription factor, was highly predictive to be causal for glomerulosclerosis. KLF6 expression was compared in resistant and nonresistant murine models of HIVAN. Mice with podocyte specific loss of KLF6, $Cre^+$ podocin $KLF6^{flox/flox}$ (C57BL/6 background), were generated to assess the role of KLF6 in adriamycin (ADR)-induced nephropathy.

**Results:** First, we confirmed the eQTL findings by qPCR. KLF6 expression was reduced in HIVAN-sensitive Tg26 mice (FVB/n) as compared to HIVAN-resistant Tg26 mice (C57BL/6). $Cre^+$ podocin $KLF6^{flox/flox}$ mice exhibited a significant reduction in kidney weight with a 3-fold increase in proteinuria at 12 weeks of age. In addition, ADR-treated $Cre^+$ podocin $KLF6^{flox/flox}$ mice as compared to ADR-treated wild-typemice resulted in nephrotic range proteinuria with significant glomerulosclerosis, podocyte effacement, and structural mitochondrial defects in podocytes at 5 weeks post ADR treatment. Promoter analysis predicted multiple KLF6 promoter binding sites on mitochondrial genes. Genes involved in mitochondrial replication, transcription, and oxidative phosphorylation were reduced in isolated glomeruli from ADR-treated $Cre^+$ podocin $KLF6^{flox/flox}$ mice. These findings were confirmed in ADR-treated cultured murine podocytes with and without KLF6. Finally, KLF6 expression was reduced in human FSGS and HIVAN as compared to healthy donor biopsy specimens.

**Conclusions:** We showed a podocyte-specific loss of KLF6 resulted in podocyte injury and FSGS in a resistant mouse background of ADR-induced nephropathy. This was associated with mitochondrial injury specific to podocytes. Combined, this suggests a critical role of KLF6 in regulating mitochondrial function and protecting podocytes against injury.

**SA-OR022**

**The Regerative Potential of Parietal Epithelial Cells in Adult Mice** Marcus J. Moeller, Katja Berger, Kevin Schulte, Jürgen Floege, Bart Smeets. *Nephrology and Clinical Immunology, RWTH Univ of Aachen, Aachen, NRW, Germany.*

**Background:** Several years ago, we have shown in newborn PEC-rtTA transgenic mice that a small portion of podocytes is recruited from cells of Bowman's capsule. This finding has raised hope that parietal epithelial cells (PECs) might be a potential progenitor cell population for podocytes.

**Results:** To investigate whether PECs replenish podocytes, PECs were genetically labeled in an irreversible fashion in 5 weeks-old adult mice. No significant increase in labeled podocytes was observed even after more than one year.

In order to induce a relative podocytopenia, uninephrectomies or 5/6 nephrectomies were performed, which resulted in progressive glomerular hypertrophy. However, here also no significant recruitment of labeled PECs onto the glomerular tuft was observed.

Labeled PECs only invaded the glomerular tuft, when glomerulosclerosis was induced by 5/6 nephrectomy and DOCA/salt overload. Thus, in sclerotic lesions PEC invasion onto the glomerular tuft played a negative role, not a regenerative role.

To explain our findings of PEC recruitment in juvenile mice, these experiments were repeated. Again, we found significant recruitment of labeled cells from Bowman's capsule onto the glomerular tuft – confirming our initial findings. However, when we genetically labeled podocytes in juvenile newborn Pod-rtTA transgenic mice, cells on Bowman's capsule were also directly labeled. These labeled cells were later also recruited onto the glomerular tuft to become fully differentiated podoctes. This indicates that in newborn mice a fraction of the cells on Bowman's capsule is already committed to directly differentiate into podocytes. At this early stage, these cells are directly marked by the PEC-rtTA mouse as well as the Pod-rtTA mouse.

**Conclusions:** In summary, PECs do not differentiate into podocytes in models of glomerular hypertrophy or in aging mice. Instead, our findings further strengthen the notion that PECs play a major role in glomerular diseases, specifically in FSGS and crescentic glomerulonephritis.

*Funding:* Government Support - Non-U.S.

## SA-OR023

**Epigenetic Role of Wolf-Hirschhorn Syndrome Candidate 1-Like 1 in Glomerulogenesis** Yugo Ito,[1] Zentaro Kiuchi,[1] Yukino Nishibori,[1] Kunimasa Yan.[1] *[1]Pediatrics, Kyorin Univ School of Medicine, Tokyo, Japan; [2]Medical Biochemistry and Biophysics, Karolinska institute, Stockholm, Sweden.*

**Background:** We previously reported that Wolf-Hirschhorn syndrome candidate 1-like 1 (WHSC1L1) is a novel epigenetic molecule in the podocytes, which activates nephrin promoter through tri-methylating HistoneH3K4 (2012 ASN Kidney Week). The present study aimed to explore the functional role of WHSC1L1 in glomerulogenesis.

**Methods:** Zebrafish embryos depleted of WHSC1L1 by using the antisense morpholino oligonucleotides (MO) against the translation initiation site, the donor sites on exon1 and the acceptor sites on exon3 were established. The phenotypic changes of the WHSC1L1 morphants at 96 hpf were observed and compared with control zebrafish. PAS staining and electron microscopy were performed to verify the histological change of pronephros and morphology of the podocytes and their foot processes. RT-PCR was performed to compare the expression level of nephrin mRNA in WHSC1L1 morphants and control zebrafish. Dextran dye filtration assay with the WHSC1L1 morphants was used to evaluate the function of glomerular filtration barrier.

**Results:** Disruption of WHSC1L1 expression in MOs was confirmed by RT-PCR and Western blot study. Morphant embryos injected with WHSC1L1 MOs developed cardiac edema, dorsal body axis curvature and short stature in 89.9% of the translation initiatoion site MO, 59.2% of the exon1 MO and 65.5% of the exon3 MO compared with 5.3% of the control. Morphants lacking WHSC1L1 revealed collapsed glomeruli associated with dysgenesis of the podocytes and foot processes. Morphants lacking WHSC1L1 displayed the reduction of nepnrin mRNA. Finally, permeability studies of the glomerular filtration barrier demonstrated a disruption of the selective glomerular permeability filter in morphants.

**Conclusions:** The present study suggests that WHSC1L1 plays a pivotal role in glomerulogenesis.

## SA-OR024

**Regulation of Glomerular DAF by HO-1** Maria Detsika,[1] Pu Duann,[2] Elias A. Lianos.[2] *[1]Medicine, Univ of Athens, Greece; [2]Div of Nephrology, Univ of Medicine and Dentistry of New Jersey.*

**Background:** Rat glomeruli express Decay accelerating factor (DAF) exclusively in glomerular epithelial cells (GEC) attenuating complement (C) activation-mediated injury. C activation also induces Heme oxygenase (HO)-1. Although HO-1 induction affords cytoprotection via heme degradation products, an alternative mechanism may involve DAF regulation. This was explored in normal rat glomeruli.

**Methods:** hmox1$^{+/-}$ and hmox1$^{-/-}$ rats were obtained by Zinc Finger Nuclease (ZFN)-mediated HO-1 gene disruption. Rats with GEC targeted HO-1 overexpression (GEC$^{HO-1}$) were generated by Sleeping Beauty Transposon mediated transgenesis using a nephrin promoter. Glomeruli isolated from wild type (WT) or hmox1$^{+/-}$, hmox1$^{-/-}$ or GEC$^{HO-1}$ rats were treated for 18h with Metalloporphyrins (MPs): Heme or Cobalt Protoporphyrin (CoPP) (HO inducers), Zinc (ZnPP) or Tin (SnPP) (HO inhibitors). Co-incubations of Heme and cycloheximide (CHX, protein synthesis inhibitor) were also performed. HO-1 and DAF protein and mRNA levels were assessed by western blot analysis and Real-time PCR.

**Results:** A 60-70% reduction in constitutive HO-1 levels and complete HO-1 absence was observed in hmox1$^{+/-}$ and hmox1$^{-/-}$ glomeruli, respectively. Constitutive DAF levels decreased by 2-fold and 4-fold in hmox1$^{+/-}$ and hmox1$^{-/-}$ glomeruli, respectively. Heme and CoPP dose-dependently (50-800 μM) induced DAF in WT glomeruli. Heme-induced DAF in both WT and transgenic animals but DAF induction in hmox1$^{+/-}$ and hmox1$^{-/-}$ glomeruli was attenuated. In WT glomeruli co-incubated with Heme and CHX, heme-mediated DAF induction was also attenuated. In GEC$^{HO-1}$glomeruli, constitutive DAF expression was increased and heme-mediated DAF induction was augmented. ZnPP and SnPP, (5-100μM) increased DAF levels in WT glomeruli. In co-incubations with heme, ZnPP and SnPP had an additive effect on DAF induction.

**Conclusions:** Glomerular DAF expression is HO-1 dependent. As well as through HO-1, Heme induces DAF via a non-HO-1 mechanism. Non-heme HO inhibitory MPs upregulate DAF indicating a HO-activity independent mechanism. MP-mediated DAF induction may point towards novel therapeutic strategies in C-dependent glomerular forms of injury.

## SA-OR025

**TRPC5 Inhibition Protects the Kidney Filter by Preventing Podocyte Cytoskeletal Collapse** Thomas Schaldecker,[1] Sookyung Kim,[1] Constantine Tarabanis,[1] Samy Hakroush,[1] Philip M. Castonguay,[1] Lisa Maria Buvall,[1] Astrid Weins,[1,2] Anna Greka.[1] *[1]Dept of Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA; [2]Dept of Pathology, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

**Background:** Kidney filter damage results in urinary albumin loss, a hallmark of cardiovascular disease and kidney failure. However, the earliest molecular events leading to filter damage are not well understood. Our previous studies have implicated the ion channel TRPC5 in podocyte injury.

**Methods:** We utilized TRPC5 knockout mice and two models of acute podocyte injury to study the role of TRPC5 *in vivo*. Using a novel small molecule inhibitor of TRPC5, we also probed whether pharmacologic inhibition of the channel confers protection from albuminuria, filter barrier collapse, and podocyte injury. We developed a method for calcium imaging in isolated kidney glomeruli in addition to live imaging of podocyte actin dynamics to investigate the role of TRPC5 in the initiation of kidney filter damage.

**Results:** Loss of TRPC5 or its inhibition abrogates podocyte cytoskeletal collapse, by blocking Rac1 and stabilizing synaptopodin. Importantly, genetic deletion or pharmacologic inhibition of TRPC5 protects mice from filter damage.

**Conclusions:** This study reveals TRPC5 as the $Ca^{+2}$ permeable channel responsible for filter barrier collapse, and identifies TRPC5 inhibition as a therapeutic strategy for the prevention or treatment of albuminuric disease.

## SA-OR026

**Rac1 Activation in Podocytes Induces Rapid Foot Process Effacement and Proteinuria** Haiyang Yu,[1] Hani Suleiman,[1] Alfred Hyoungju Kim,[1] Jeffrey H. Miner,[3] Shreeram Akilesh,[4] Andrey S. Shaw.[1,2] *[1]Dept of Pathology and Immunology, Washington Univ in St. Louis, Saint Louis, MO; [2]Howard Hughes Medical Institute, Washington Univ in St. Louis, Saint Louis, MO; [3]Dept of Medicine, Washington Univ in St. Louis, Saint Louis, MO; [4]Dept of Pathology, Univ of Washington, Seattle.*

**Background:** The exact nature of foot process effacement is not known, but recent studies proposed that it might reflect the Rac1-induced actin reorganization. Here we inducible expressed constitutively active Rac1 specifically in podocytes in a transgenic mouse model, and observed rapid onset of foot process effacement and proteinuria after doxycycline induction, which was validated as a direct effect of active Rac1 by a super resolution imaging method.

**Methods:** Dox-inducible knock-in mouse model stochastic reconstitution optical microscopy (STORM).

**Results:** To test the effects of Rac1 activation *in vivo*, we generated a transgenic mouse with inducible expression of active-Rac1. The transgene was knocked into the *Hprt1* locus in ES cells by homologous recombination. Transgenic mice were generated and bred to the *Podocin*-rtTA strain and a new strain we generated, *Nephrin*-rtTA. Proteinuria was detectable after 2 days of doxycycline induction, peaked at day 4, and gradually decreased. The transgene were patchy-expressed, but the magnitude of proteinuria correlated with efficiency of transgene expression with the *Nephrin*-rtTA more broadly expressed. We validated focal foot process effacement by TEM and showed that the amelioration of proteinuria correlated with the loss of transgene-positive podocytes. The patchy expression of transgene allowed us to test whether areas of focal foot process effacement correlated with transgene expression. Correlating STORM with freeze-etch electron microscopy, we showed that only transgene positive podocytes were effaced.

**Conclusions:** Here we show that activation of Rac acutely induces foot process effacement. Our data support the hypothesis that foot process effacement is the *in vivo* correlate of Rac activation and that Rac activation may lead to podocyte loss.

## SA-OR027

**Brain Derived Nuerotrophic Factor (BDNF) Repairs Podocyte Damage by Inducing Actin Polymeryzation through Brain-Specific microRNAs** Maria Pia Rastaldi,[1] Min Li,[1] Silvia Armelloni,[1] Cristina Zennaro,[2] Alessandro Corbelli,[1] Masami Ikehata,[1] Anna Mondini,[1] Deborah Mattinzoli,[1] Changli Wei,[3] Jochen Reiser,[3] Piergiorgio Messa.[1] *[1]Renal Research Laboratory, Fondazione IRCCS Ospedale Maggiore Policlinico, Milano, Italy; [2]Laboratory of Renal Pathophysiology, Univ of Trieste, Trieste, Italy; [3]Dept of Internal Medicine, Rush Univ Medical Center, Chicago, IL.*

**Background:** Podocyte damage is the hallmark of focal segmental glomerulosclerosis (FSGS), a devastating glomerulopathy that needs better treatment. Podocytes are ramified cells sharing numerous properties with neurons and BDNF improves neuronal cell morphology and synaptic function upon TrkB binding.

**Methods:** BDNF was added to control and damaged (protamine sulfate, PS. Puromycin aminonucleoside, PA) podocytes. 3D endothelial-podocyte co-cultures were used for permeability tests. In D. Rerio larvae and Balb/c mice BDNF was administered after pericardial oedema and nephrotic proteinuria were induced by adriamycin (Adr). TrkB was silenced in vitro and in vivo.

**Results:** Increased number and length of processes, via LIMK-1 overexpression and cofilin phosphorylation, were observed in control podocytes after BDNF incubation. LIMK-1 protein increase was not paralleled by mRNA changes, leading to investigate

miRNA involvement, which demonstrated BDNF opposite actions on brain-specific miRNAs; reduced miRNA134 and increased miRNA132 directly and indirectly (by reducing p250GAP) alleviated the blockade on LIMK-1 translation. Double transfection experiments confirmed opposite effects on process formation, actin polymerization and cofilin phosphorylation.

In vitro, BDNF repaired podocyte damage due to PS or PA and reduced albumin permeability in 3D co-cultures.

In vivo, BDNF reduced pericardial oedema, restored podocyte morphology and nephrin and TrkB levels in D. Rerio larvae exposed to adriamycin. In Balb/c mice, adriamycin-induced glomerular damage was repaired by BDNF and proteinuria diminished. All effects were mediated by BDNF-TrkB interaction, being abolished by TrkB silencing.

**Conclusions:** On the whole, our results support the possibility that BDNF could be a promising option for treating proteinuric diseases characterized by podocyte injury.

*Funding:* Private Foundation Support, Government Support - Non-U.S.

## SA-OR028

**Loss of Prohibitin-2 in Podocytes Leads to Proteinuria and Renal Failure in Mice** Christina Ising,[1] Bernhard Schermer,[1] Andreas Linkermann,[2] Sebastian Braehler,[1] Dontscho Kerjaschki,[3] Christine E. Kurschat,[1] Thomas Benzing,[1] Paul T. Brinkkoetter.[1] *[1]1Dept II of Internal Medicine and Center for Molecular Medicine Cologne, Univ of Cologne, Cologne, Germany; [2]Div of Nephrology and Hypertension, Christian-Albrechts Univ, Kiel, Germany; [3]Clinical Institute of Pathology, Medical Univ of Vienna, Vienna, Austria.*

**Background:** SPFH domain-containing proteins support the formation of functional lipid microdomains within cellular membranes. Prohibitin-2 (PHB2), a member of this family, has recently been reported to control mitochondrial cristae morphogenesis and biogenesis of oxidative phosphorylation system complexes. Genetic deletion of *Phb2* in mice results in embryonic lethality.

**Results:** Here, we studied the role of PHB2 at the kidney filtration barrier by conditional deletion of *Phb2* gene expression in podocytes and demonstrate development of progressive proteinuria, glomerulosclerosis and endstage renal failure. In contrast to previous observations in proliferating fibroblasts this phenotype was not associated with mitochondrial apoptosis because we did not detect increased caspase-3 cleavage in post-mitotic podocytes, suggesting an additional, previously undefined function for PHB2 outside the apoptotic pathway. Immunofluorescence stainings and immunogold labeling localized PHB2 not only in mitochondria but also at the slit diaphragm, a specialized cell contact of podocytes at the kidney filter. Here, PHB1 and PHB2 interacted with podocin, another SPFH domain-containing protein essential for the assembly of the slit diaphragm complex. Given the structural similarity of the slit diaphragm complex in mammals and the mechanosensory complex in *C. elegans*, we studied localization and function of the PHB2 ortholog (PHB-2) in touch neurons of the nematode. Immunofluorescence stainings revealed co-localization of PHB-2 and the podocin ortholog MEC-2. Moreover, knockdown of either *phb-1* or *phb-2* impaired the function of the mechanosensory complex.

**Conclusions:** These data indicated that besides its well established role at the mitochondrial inner membrane, PHB2 may have an additional function at mechanosensory protein complexes.

## SA-OR029

**Increased Podocyte $[Ca^{2+}]_i$ Correlates with Cell Motility in an In Vivo Imaging Model of Kidney Fibrosis** James L. Burford, Karie G. Villanueva, Anne Riquier-Brison, Janos Peti-Peterdi. *Physiology and Biophysics, Univ of Southern California, Los Angeles, CA.*

**Background:** Recent genetic and cellular studies highlighted the role of podocyte calcium ($[Ca^{2+}]_i$) signaling and cell motility in the development of glomerulosclerosis. However, our mechanistic understanding of podocyte $[Ca^{2+}]_i$ dynamics is limited to a few calcium channels and knowledge learned from *in vitro* approaches. Recently, we developed a serial multiphoton microscopy (MPM) approach to directly visualize the changes in podocyte $[Ca^{2+}]_i$ in vivo in the intact kidney of mice with podocyte-specific $[Ca^{2+}]_i$ indicator GCaMP3. We used MPM to study the role of podocyte $[Ca^{2+}]_i$ in a disease state using the unilateral ureteral obstruction (UUO) model of progressive renal fibrosis.

**Methods:** Podocin Cre GCaMP3 mice were subjected to UUO and serial MPM at days 7-14 after UUO. Vasculature were labeled red with the plasma marker Alexa594-albumin. Specific glomeruli were imaged repeatedly every 24 hours using MPM and full z-scans to visualize podocyte $[Ca^{2+}]_i$, morphology, dynamics and glomerular architecture during disease progression.

**Results:** Intravital MPM imaging of Podocin Cre GCaMP3 mice found low baseline $[Ca^{2+}]_i$before UUO but heterogeneous increases in podocyte $[Ca^{2+}]_i$ between and within glomeruli after UUO. Some podocytes in different regions within the same glomeruli showed low baseline $[Ca^{2+}]_i$(average fluorescent intensity (Fi) of GCaMP3 Fi= 5.16), while regions where visceral-to-parietal adhesions and parietal podocyte layers developed due to podocyte migration/cell dedifferentiation showed >3-fold increases in podocyte $[Ca^{2+}]_i$(Fi =18.93, P<0.01). Podocyte $[Ca^{2+}]_i$ was significantly reduced by the iv administration of the purinergic receptor inhibitor suramin.

**Conclusions:** This study is the first time visual demonstration of the *in vivo* importance of podocyte $[Ca^{2+}]_i$ in glomerular pathology and provides evidence for the link between high podocyte $[Ca^{2+}]_i$ and increased cell motility, and their causative role in progressive glomerulosclerosis. P2 receptor-mediated purinergic $[Ca^{2+}]_i$ signaling in podocytes maybe an important new mechanism in podocyte injury and a promising new therapeutic target in glomerular disease.

## SA-OR030

**Podocyte Detachment Induced by PAI-1 and uPAR-Mediated β1 Integrin Internalization** Namiko Kobayashi,[1] Toshiharu Ueno,[1] Kumi Ohashi,[1] Kazuo Sakamoto,[1] Satoshi Hara,[1] Yasutoshi Takashima,[1] Taiji Matsusaka,[2] Toshio Miyata,[3] Michio Nagata.[1] *[1]Renal Pathology, Univ of Tsukuba, Tsukuba, Japan; [2]Internal Medicine, Tokai Univ School of Medicine; [3]United Centers, Tohoku Univ.*

**Background:** We previously reported that transgenic mice with podocyte-specific injury (NEP mice) showed microangiopathy at the site of podocyte injury, and plasminogen activator inhibitor-1 (PAI-1) was increased prior to the reduction of podocytes. Both PAI-1 and uPA bind to uPAR, and make complex with integrin on cell membrane. Internalization of the complex induces the cell detachment as a result of reduction of cell-matrix adhesion molecules. The present study was aimed to show that PAI-1 was involved in podocyte detachment through the complex with uPAR-integrin by using NEP mice and podocyte cell line.

**Methods:** Two groups of NEP mice, with or without PAI-1 inhibitor (PI) were induced podocyte injury by LMB2 injection on day 0. PI was administered from day 0 to 12. Histological and clinical parameters were analyzed on day 12. Then, we treated cultured podocytes either with PAI-1/uPA complex (P/U), uPA (control), or antibody for blocking uPAR with P/U (B-P/U). After incubation, attached cells were counted, and localization of β1 integrin and uPAR was detected by immunofluorescence. Cytoplasmic β1 integrin was analyzed by Western blot.

**Results:** Proteinuria (P) and Thronbi score (T) in PI group were lower than the control (P; 64.29 ± 23.30 vs. 161.12 ± 34.0; p <0.05, T; 0.01 ± 0.01 vs. 0.23 ± 0.07, p <0.05), and podocyte numbers were preserved (9.41 ± 0.45 vs. 2.67 ± 0.41, p <0.0001). Glomerular morphology in PI group was preserved. In vitro, attached cells in P/U were reduced compared with the control and B-P/U (p <0.01). Confocal microscopy showed that β1 integrin and uPAR were colocalized (Pearson's coefficient (PC) = 0.50) and shifted to cytoplasm in P/U. In contrast, β1 integrin remained on the membrane and was not colocalized with uPAR in the control and B-P/U (PC = 0.12, 0.06, respectively). In Western blot, β1 integrin expression was increased in P/U.

**Conclusions:** PAI-1/uPA complex may act on the podocytes detachment via internalization of β1 integrin through the uPAR mechanism.

## SA-OR031

**Blood Pressure and Mortality at Advanced CKD and Incident ESRD: The CRIC Study** Nisha Bansal,[1] Raymond R. Townsend,[2] Mahboob Rahman,[3] Charles E. McCulloch,[1] Alan S. Go,[4] Arnold B. Alper,[5] Amanda Hyre Anderson,[2] John W. Kusek,[6] Claudia M. Lora,[7] Eva Lustigova,[5] Chi-Yuan Hsu.[1] *[1]UCSF; [2]UPenn; [3]Case Western; [4]KPNC; [5]Tulane; [6]NIDDK; [7]UIC.*

**Background:** In observational studies of hemodialysis (HD) patients, lower blood pressure (BP), even within the "normal" range, is associated with higher mortality. Whether this paradoxical association is present in advanced CKD is unknown.

**Methods:** Participants of the Chronic Renal Insufficiency Cohort had standardized BP measures at yearly study visits. We studied the association between mortality and systolic BP (SBP) measured at the: 1) first study visit after reaching eGFR of <30 ml/min/1.73m$^2$ ("advanced CKD SBP") (N=1,705); 2) first study visit after starting HD ("HD study visit SBP")(N=404); and 3) HD unit ("pre-HD SBP")(N=404). We performed a survival analysis, fitting a quadratic term for BP.

**Results:** Among 1,705 participants with advanced CKD, mean eGFR was 25±4 ml/min/1.73 m$^2$ and SBP was 131 (±24) mm Hg. There were 390 deaths over 4.7 (±2.3) years. Adjusting for demographics, tobacco use, BMI, diabetes, and cardiovascular disease, there was a linear association between advanced CKD SBP and mortality. Among the 404 participants who subsequently started HD, mean pre-HD SBP was 152 (±22) mm Hg and HD study visit SBP was 132 (±25) mm Hg. There were 98 deaths after the start of HD over 2.8(±1.7) years. A U-shaped association between pre-HD SBP and mortality was observed. There was a linear association between HD study visit SBP and mortality (**Figure**).

**Conclusions:** At advanced CKD, higher SBP was associated with higher mortality. Among those who started HD, a U-shaped association between pre-dialysis SBP and mortality was observed. In contrast, there was a linear association between mortality and SBP measured outside the HD unit, which may be a more appropriate target for therapy.

**Masked and Sustained Hypertension Are Associated with Increases in Left Ventricular Mass and Pulse Wave Velocity in CKD – The CRIC Study**

Paul E. Drawz,[1,2] Arnold B. Alper,[2] Amanda Hyre Anderson,[2] Denise C. Babineau,[2] Carolyn S. Brecklin,[2] Jeanne Charleston,[2] Jing Chen,[2] Yonghong Huan,[2] Susan P. Steigerwalt,[2] Jonathan J. Taliercio,[2] Raymond R. Townsend,[2] Matthew R. Weir,[2] Mahboob Rahman.[2] *[1]Univ of Minnesota; [2]CRIC Investigators.*

**Background:** The goal of this study was to evaluate whether white-coat (WCH), masked (MH), and sustained hypertension (SH) are associated with increases in left ventricular mass index (LVMI) and pulse wave velocity (PWV).

**Methods:** In the Chronic Renal Insufficiency Cohort study, 24 hour ambulatory blood pressure (ABP) was measured between 2008 and 2012. Clinic blood pressure (BP) was measured in triplicate. WCH was defined by a clinic BP ≥140/90mmHg and daytime ABP <135/85mmHg; MH by a clinic BP <140/90mmHg and daytime ABP ≥135/85mmHg; and SH by a clinic BP ≥140/90mmHg and daytime ABP ≥135/85mmHg. Echocardiograms were obtained and left ventricular mass was indexed to height$^{2.7}$. PWV was measured in the supine position using the right carotid and femoral arteries. Creatinine was measured annually. Urine protein was measured in a 24 hour sample at baseline.

**Results:** ABP was obtained in 1439 participants; echocardiography was obtained in 1230 and PWV in 1345 of these participants. In adjusted linear models, both MH and SH were associated with increased LVMI and PWV (table). In adjusted logistic regression models, MH was associated with increased odds for a PWV >10m/sec and SH was associated with increased odds for both left ventricular hypertrophy (LVH) and a PWV >10m/sec.

| | LVMI | LVH | PWV | PWV > 10m/sec |
|---|---|---|---|---|
| BP category | Beta (95% CI) | OR (95% CI) | Beta (95% CI) | OR (95% CI) |
| Normotensive | l | l | l | l |
| WCH | -1.04 (-3.9 to 1.9) | 0.84 (0.5 to 1.4) | 0.50 (-0.2 to 1.2) | 1.49 (0.8 to 2.8) |
| MH | **1.61 (0.1 to 3.1)** | 1.12 (0.9 to 1.5) | **0.82 (0.4 to 1.2)** | **2.48 (1.7 to 3.5)** |
| SH | **4.22 (2.5 to 6.0)** | **1.96 (1.4 to 2.7)** | **1.22 (0.8 to 1.7)** | **2.04 (1.4 to 3.0)** |

**Conclusions:** In a large cohort of participants with CKD, both MH and SH were associated with vascular injury and target organ damage. Ambulatory BP may better characterize the relationship between BP and adverse outcomes in patients with CKD.

## SA-OR033

**The Clinical Impact of Renal Artery Denervation on Blood Pressure and Renal Function in Patients with Uncontrolled Hypertension: From the Global SYMPLICITY Registry**

Luis M. Ruilope,[1] Markus Schlaich,[2] Roland E. Schmieder,[3] Giuseppe Mancia,[4] Krzystof Narkiewicz,[5] Bryan Williams,[6] Felix Mahfoud,[7] Michael Böhm.[7] *[1]Universidad Autonoma, Madrid, Spain; [2]Baker IDI Heart and Diabetes Institute, Melbourne, Australia; [3]Univ of Erlangen-Nürnberg, Erlangen, Germany; [4]Univ of Milan-Bicocca, Milan, Italy; [5]Medical Univ of Gdansk, Gdansk, Poland; [6]Univ College London, United Kingdom; [7]Univ of Saarland, Homburg, Germany.*

**Background:** Renal artery denervation (RDN) has been demonstrated to safely lower blood pressure (BP) in controlled clinical trials. To further evaluate the safety and effectiveness of this minimally invasive treatment in "real world" patients with hypertension the Global SYMPLICITY Registry (GSR) was initiated.

**Methods:** The GSR is a prospective, multicenter (~200 sites), open-label study designed to evaluate the effect of RDN with the Symplicity™ renal denervation system in adults with uncontrolled hypertension. Data collected includes office BP measurements at each follow-up, renal function, procedural events and safety events possibly related to RDN.

**Results:** Baseline characteristics for 409 patients with baseline BP ≥160 mmHg (150 mmHg for diabetic patients) include mean age 60±12 yrs, 65% males, and 47% with diabetes. Mean baseline BP was 175.4± 17.6/ 94.3 ± 15.2 mmHg and baseline eGFR was 78±21 mL/min/1.73m$^2$; 97% of patients had an eGFR >45 mL/min/1.73m$^2$. BP dropped -16.5±21.5 /-7.1±13.3 mmHg (n=247) at 3 months and -17.1±19.5/-8.2±12.3 mmHg (n=134) at 6 months (p<0.001 for both). At 3 and 6 months post-RDN mean eGFR was 75±19 and 76±17 mL/min/1.73m$^2$. Patients with baseline eGFR 45-60 mL/min/1.73m$^2$ had similar significant drops in BP at 3 and 6 months (-15.6±20.5/-5.5±12.9 mmHg and -20.4±21.6/-9.3±13.2 mmHg) to those with baseline eGFR 60-90 (-13.8±21.5/-5.8±13.0 mmHg and -15.7±20.9/-7.7±12.0 mmHg). No serious procedural-related complications or adverse events related to RDN were reported.

**Conclusions:** RDN using the Symplicity catheter significantly and safely lowers BP in patients with uncontrolled hypertension. Renal function does not impact the drop in blood pressure.

## SA-OR034

**Apolipoprotein L1 Gene Variants Associate with Increased Systolic and Diastolic Blood Pressure in Younger African Americans Independent of Renal Function**

Girish N. Nadkarni, Erwin P. Bottinger. *Dept of Nephrology, Mount Sinai Icahn School of Medicine.*

**Background:** Polymorphisms at the APOL1 locus confer a substantial increase in risk of non-diabetic renal diseases in African Americans, including renal disease associated with hypertension. Little evidence has emerged to date, to suggest that APOL1 variants can increase hypertension risk independent of kidney disease. We aimed to assess the association of these variants and blood pressure in African Americans.

**Methods:** We utilized PCR and ASPE APOL1 G1/G2 genotype testing. The clinical and biochemical parameters were abstracted using the electronic health record (EHR) from consented Mount Sinai Biobank participants. The primary outcome variables of interest were systolic and diastolic blood pressures (SBP and DBP) averaged over a nine-year period. We utilized multivariable logistic regression to assess this association.

**Results:** We had data on 4765 participants. Of these, 36% were male, 36% had a history of diabetes mellitus and 42% had a history of antihypertensive medication use. The mean age was 53 years. Homozygous APOL1 risk genotype was present in 700(14.7%). With participants less than 50 years of age (n=1478), the APOL1 risk genotype was present in 206(14%). Both the SBP and DBP were significantly higher with homozygous risk genotype (126 vs. 124 mmHg; p=0.01 and 76 vs. 74 mmHg; p=0.04 respectively). These participants were 2.5 times as likely to have a SBP>160 mm Hg (OR 2.54; 95% CI 1.25- 5.19; p=0.01) and 2 times as likely to have a DBP>90 mm Hg (OR 2.01; 95% CI 1.26- 3.21; p=0.01). This association remained significant after adjusting for potential confounders including the mean estimated glomerular filtration rate (eGFR).

**Conclusions:** We describe a significant association between homozygous APOL1 risk genotype status and higher SBP and DBP in African Americans < 50 years independent of kidney function. Whether this relationship is causative or mediated by a yet unknown action of APOL1 warrants further investigation.

## SA-OR035

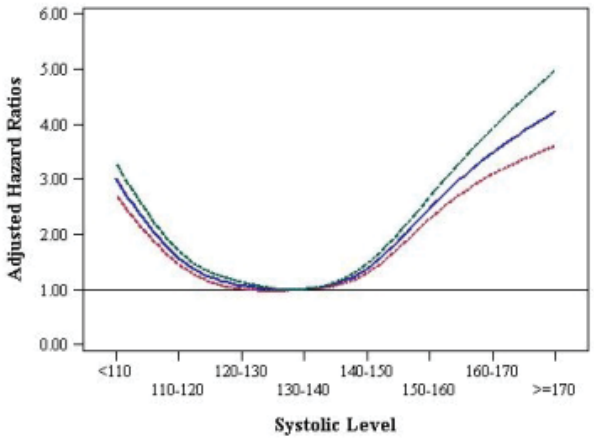
**Evaluation of Blood Pressure and Risk of ESRD/Mortality in Resistant Hypertension**

John J. Sim,[1] Jiaxiao Shi,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[3] *[1]Nephrology & Hypertension, Kaiser Permanente Los Angeles Med Ctr, Los Angeles, CA; [2]Memphis VA Med Ctr; [3]UC Irvine Med Ctr.*

**Background:** Blood pressure (BP) goals in hypertension (HTN) have been challenged. Even less is known about resistant hypertension (RH) in terms of the comparative risk of BP on clinical outcomes. RH likely has chronic physiologic compensations including vascular remodeling and higher threshold perfusion BP. We hypothesize that a similar J shaped curve exists within RH and furthermore the nadir BP associated with best ESRD and mortality outcomes are higher than what is observed in the general HTN population.

**Methods:** Retrospective longitudinal study of Kaiser Permanente Southern California health system (1/1/2006-12/31/2009) performed. RH defined as HTN individuals with uncontrolled BP on 3 meds or requiring >/= 4 meds. Demographic, co morbidity, laboratory, medication, and outcomes data extracted from the electronic medical records. ESRD defined as eGFR<15, dialysis, or renal transplant. Serial BP during and up to 4 years follow up averaged and multivariable hazard ratios (HR) calculated for every 10 mm Hg increment systolic BP (SBP) using 130-139mm as reference.

**Results:** The RH cohort of 50,020 was comprised of 43% females, 46% whites, 19% blacks, 18% Hispanics, and 6% Asians. Mean age was 70 yrs. Adjusted HR (95% CI) for combined ESRD/mortality compared to SBP 130-139mm group were 3.0 (3.7-3.3), 1.6 (1.5-1.7), 1.1 (1.0-1.1), 1.4 (1.3-1.5), 2.5 (2.3-2.7), 3.2 (3.1-3.9), & 4.2 (3.6-5.0) for SBP <110, 110-119, 120-129, 140-149, 150-159, 160-169, & >169 respectively. Males, blacks, CKD, & DM also had increased HR for ESRD/mortality (not shown).



**Conclusions:** Among a large ethnically diverse RH cohort, we found a J curve in BP and risk for ESRD/Mortality with the nadir systolic BP at 130-139. This was not different to what was observed in our general HTN population (not shown).

## SA-OR036

**Renal Artery Denervation Can Safely Lower Blood Pressure in Patients with Severe Treatment-Resistant Hypertension: Results from the Symplicity HTN Trials** Markus Schlaich,[1] Henry Krum,[2] Murray Esler,[1] Michael Böhm,[4] Roland E. Schmieder.[3] *[1]Baker IDI Heart and Diabetes Institute, Melbourne, Australia; [2]Monash Univ, Melbourne, Australia; [3]Univ Erlangen-Nürnberg, Erlangen, Germany; [4]Univ of Saarland, Homburg.*

**Background:** The sympathetic nervous system is an important contributor to the pathogenesis of hypertension. Renal artery denervation (RDN) via delivery of low power radiofrequency energy with the Symplicity™ RDN catheter reduces sympathetic nerve activity and blood pressure (BP). The Symplicity HTN-1 and Symplicity HTN-2 trials evaluated the safety and effectiveness of RDN in subjects with severe treatment-resistant hypertension (systolic BP >160 mmHg or >150 mmHg for subjects with diabetes while on ≥3 antihypertensive drugs, including a diuretic).

**Methods:** Inclusion criteria included an eGFR ≥45 mL/min/1.73 m$^2$. Renal imaging was performed pre-procedure and renal arteries <4mm in diameter or <20 mm in length or with significant abnormalities were excluded. Changes in office BP, serum chemistries, and all RDN-related safety events were followed every 6 months.

**Results:** A total of 239 subjects (mean age 57 yrs) were treated. Mean baseline BP was 178±18/98±15 mmHg and mean baseline eGFR was 82.7±19.9 mL/min/1.73 m$^2$. BP was significantly lower than baseline after RDN by -24±23/-10±13 mmHg at 6 months, -26±24/-12±13 mmHg at 1 yr and -30±24/-13±14 mmHg at 2 yrs (p<0.01 for all). Mean eGFR was 81.7±20.2 at 6 months and 80.8±18.6 mL/min/1.73 m$^2$ at 1 yr. Mean eGFR was 76.8 ± 22.8 mL/min/1.73 m$^2$ in 43 subjects followed through 2 yrs. Procedural complications included 2 renal artery dissections and 4 pseudoaneurysms all treated without further sequelae. Bradycardia required treatment during RDN in 10.7% of subjects. Transient acute renal failure deemed unrelated to RDN occurred in 3 patients. There was one progression of a pre-existing stenosis unrelated to RDN and one new moderate stenosis that did not require treatment.

**Conclusions:** RDN significantly lowers BP without adverse consequences on renal function. Further studies are warranted to assess a potential renoprotective role of RDN in patients with both normal and impaired renal function.

*Funding:* Pharmaceutical Company Support - Medtronic, Inc

## SA-OR037

**Preeclampsia and End-Stage Renal Disease: A United States Renal Data System Linkage Study** Andrea G. Kattah,[1] Sanket Agarwal,[1] Dawn C. Scantlebury,[4] Michelle M. Mielke,[2] Amy L. Weaver,[2] Wendy White,[3] Reem A. Asad,[1] Vesna D. Garovic.[1] *[1]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Div of Health Sciences Research, Mayo Clinic, Rochester, MN; [3]Dept of Obstetrics and Gynecology, Mayo Clinic, Rochester, MN; [4]Div of Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

**Background:** Preeclampsia has been implicated in the future development of hypertension (HTN) and renal disease. Recent data from registry-based studies suggest that preeclampsia is a risk factor for end-stage renal disease (ESRD). However, the magnitude of the association and the contributions of comorbidities remain unknown.

**Methods:** We performed a case-control study using a cohort of Olmsted County, MN residents who gave birth between 1976-1982 (n=8362). The ESRD cases were identified by linkage with the United States Renal Data System (USRDS); cases were matched to 2 controls based on maternal date of birth, age at first pregnancy, parity and length of follow-up. Medical records from all pregnancies were reviewed for evidence of preeclampsia, preeclampsia superimposed on HTN, or eclampsia and for comorbidities, including diabetes mellitus (DM) and HTN. Exclusion criteria were ESRD prior to pregnancy and refusal of research authorization.

**Results:** A total of 23 cases of ESRD were identified; 2 had ESRD prior to pregnancy and 1 denied authoriziation for medical record review, leaving 20 available ESRD cases for analyses. The mean (SD) age at diagnosis of ESRD was 52.6 (8.1) years. Per chart review, 8/20 (40%) cases vs. 5/40 controls (12.5%) had preeclampsia, preeclampsia superimposed on HTN or eclampsia (OR 4.5, 95% CI 1.1-21.4, p=0.04). DM and HTN were more common in cases than controls (50% vs. 15%, 80% vs. 45%, respectively). After adjusting for DM (OR 3.5, 95% CI 0.7-18.1, p=0.13) and HTN (OR 3.1, 95% CI 0.7-15.5, p=0.17), the OR for ESRD was attenuated.

**Conclusions:** Preeclampsia is associated with a higher odds of ESRD. However, after adjusting for DM and HTN, the association was attenuated and no longer significant. Larger population-based studies that rely on chart review or prospective studies are needed to confirm the association of preeclampsia and ESRD.

## SA-OR038

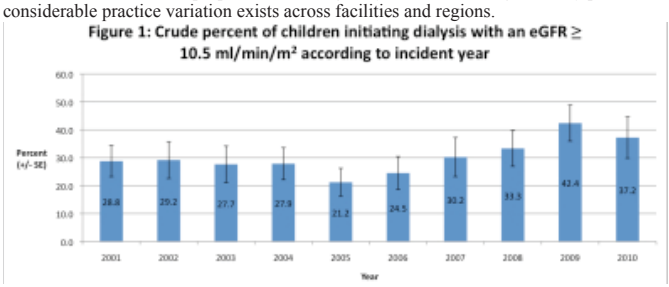
**Variability in Timing of Dialysis Initiation in Children** Allison Dart,[1,7] Susan M. Samuel,[2,7] Manish M. Sood,[1,7] R. Todd Alexander,[3,7] Steven Arora,[6,7] Robin L. Erickson,[4,7] Braden J. Manns,[2,7] Michael Zappitelli.[5,7] *[1]Univ of Manitoba; [2]Univ of Calgary; [3]Univ of Alberta; [4]Univ of Saskatchewan; [5]McGill Univ; [6]McMaster Univ; [7]Canadian Kidney Knowledge Translation and Generation Network (CANN-NET).*

**Background:** The benefits of initiating chronic dialysis in children must be balanced against increased complexity of care and potential complications. We assessed variability in eGFR at dialysis initiation and evaluated the association of patient, facility and regional factors with early vs. late dialysis initiation.

**Methods:** Incident Canadian dialysis patients <22 yo, between 2001-2010 from 9 Canadian provinces were identified from the Canadian Organ Replacement Registry. The outcome was early *vs.* late dialysis initiation (eGFR ≥ *vs.* < 10.5 ml/min/1.73m$^2$). We examined the associations of age at dialysis initiation, sex, ethnicity, ESRD etiology, distance from nearest pediatric facility, initial modality (peritoneal *vs.* hemodialysis), income quintile, era (2001-05 *vs.* 2006-10), pediatric *vs.* adult facility, and geographic region (West, Ontario, East), on the outcome using multiple variable logistic regression models.

**Results:** Thirty % of 540 children started dialysis with eGFR ≥10.5ml/min/1.73m$^2$ (21-31% across regions; 12-79% across facilities). This proportion increased from 29% in 2001 to 37% in 2010 (Figure 1). Mean eGFR at dialysis initiation by facility was also variable (7-15 ml/min/1.73m$^2$). Factors independently associated with early start were genetic cause of ESRD (OR=3.2; 95% CI 1.5-6.7) and later era (OR=1.5; 95% CI 1.0-2.3). Sensitivity analysis using eGFR threshold of 12 ml/min/1.73m$^2$ revealed similar results.

**Conclusions:** Approximately one third of children initiated dialysis with eGFR ≥ 10.5 ml/min/1.73m$^2$. The proportion initiating early increased during the study period and considerable practice variation exists across facilities and regions.



*Funding:* Private Foundation Support

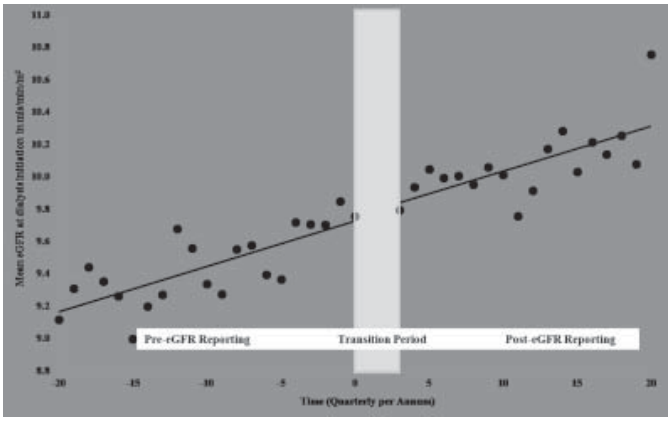
## SA-OR039

**The Impact of Estimated Glomerular Filtration Rate Reporting on the Timing of Dialysis Initiation** Manish M. Sood,[1] Paul Komenda,[2] Claudio Rigatto,[2] Brett M. Hiebert,[3] Navdeep Tangri.[2] *[1]Medicine, St. Boniface Hospital, Winnipeg, Canada; [2]Medicine, Seven Oaks Hospital, Winnipeg, Canada; [3]Cardiac Sciences, St. Boniface Hospital, Winnipeg, Canada.*

**Background:** Automatic reporting of the estimated glomerular filtration rate (eGFR) by laboratories has been widely implemented during the last decade. Concurrently, a steady increase in the eGFR at dialysis initiation has been reported. We hypothesize that automatic eGFR reporting may be leading to earlier dialysis initiation, based on level of eGFR, rather than clinical symptoms. The purpose of this study was to examine trends in the eGFR at dialysis initiation before and after eGFR reporting.

**Methods:** All incident dialysis patients from four Canadian provinces that implemented, province-wide, automatic laboratory reporting of eGFR were included in the study (N=27, 088). Data were obtained from the Canadian Organ Replacement Registry (CORR) from Jan 1, 2001 to Dec 31, 2010. The primary outcome was the mean eGFR level at dialysis initiation. An interrupted time series and adjusted multilevel models were used to determine the change in eGFR at dialysis initiation, pre- and post-reporting.

**Results:** We observed a linear increase in the mean eGFR at dialysis initiation from 9.1 to 10.8 mls/min during the study period. In an unadjusted interrupted time series analysis, there was no change in the trajectory of the eGFR at dialysis initiation, before or after eGFR reporting. In multi-level models, there was no change in the slope of the eGFR at dialysis initiation after adjustment for case-mix and facility characteristics (post-eGFR reporting X time interaction p=0.6).



**Conclusions:** Automatic laboratory-based eGFR reporting did not impact the eGFR at dialysis initiation in a large incident hemodialysis cohort. Concerns that widespread eGFR reporting leads to earlier dialysis initiation are not supported by this study.

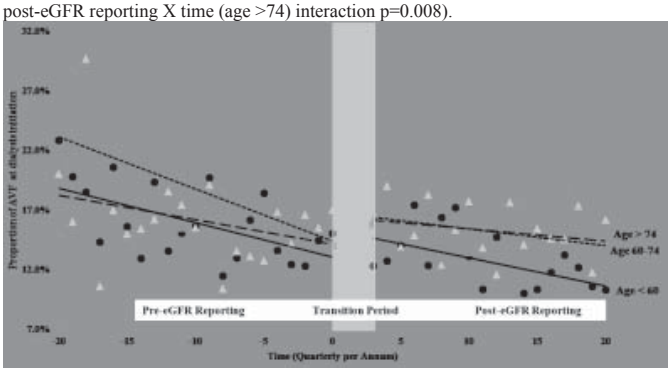
## SA-OR040

**The Impact of Estimated Glomerular Filtration Rate Reporting on the Initiation of Dialysis with an Arteriovenous Fistula** Manish M. Sood,[1] Paul Komenda,[2] Claudio Rigatto,[2] Brett M. Hiebert,[3] Navdeep Tangri.[2] *[1]Medicine, St. Boniface Hospital, Winnipeg, Canada; [2]Medicine, Seven Oaks Hospital, Winnipeg, Canada; [3]Cardiac Sciences, St. Boniface Hospital, Winnipeg, Canada.*

**Background:** The effect of automatic laboratory reporting of the estimated glomerular filtration rate (eGFR) on dialysis-related quality of care remains unknown. We set out to examine trends in the presence of an AVF at dialysis initiation before and after eGFR reporting.

**Methods:** All incident dialysis patients from four Canadian provinces that implemented province-wide, automatic laboratory reporting of eGFR with a known vascular access at dialysis initiation were included in the study (N=25,201). Data were obtained from the Canadian Organ Replacement Registry (CORR) from Jan 1, 2001 to Dec 31, 2010. The primary outcome was the proportion of AVF use at dialysis initiation. An interrupted time series and multilevel models adjusted for patient and facility characteristics were used to determine the change in AVF proportion pre- and post-reporting.

**Results:** The proportion of patients initiating hemodialysis with an AVF use decreased gradually over the study period from 19.0 to 14.6%. In an interrupted time series analysis, there was improvement in AVF usage at dialysis initiation after eGFR reporting, and this effect was predominantly seen in patients over 60 years. In multi-level models, there was improvement in the slope for AVF usage at dialysis initiation after adjustment for case-mix and facility characteristics, predominantly in patients over 60 (post-eGFR reporting X time (age < 60) interaction p=0.3, post-eGFR reporting X time (age 60-74) interaction p=0.01, post-eGFR reporting X time (age >74) interaction p=0.008).



**Conclusions:** Automatic laboratory-based eGFR reporting is associated with an increased likelihood of starting hemodialysis with an AVF in patients over 60.

## SA-OR041

**Early Nephrology Referral Reduces Economic Costs during the Period before and after Initiation of Renal Replacement Therapy: Comprehensive Prospective Study of the Clinical Research Center for End Stage Renal Disease in Korea** Jeonghwan Lee,[1] Jung Pyo Lee,[2] Hye Min Jang,[3] Ji-Young Choi,[4] Yong-Lim Kim,[4] Chul Woo Yang,[5] Shin-Wook Kang,[6] Yon Su Kim,[7] Chun Soo Lim.[2] *[1]Dept of Internal Medicine, Hallym Univ Hangang Sacred Heart Hospital, Seoul, Korea; [2]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea; [3]Dept of Statistics, Kyungpook National Univ, Daegu, Korea; [4]Dept of Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Korea; [5]Dept of Internal Medicine, The Catholic Univ of Korea College of Medicine, Seoul, Korea; [6]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; [7]Dept of Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea.*

**Background:** We evaluated the health care costs according to referral time of patients with CKD to a nephrology clinic.

**Methods:** A total of 941 patients who start dialysis from 2008 to 2011 were prospectively enrolled. Early referral was defined as patients who were referred to a nephrologist more than a year before dialysis and visited nephrology 2 or more times, and other patients whose referral time was less than a year were considered as late referral. Cost information was acquired from the claim data of Korea Health Insurance Review and Assessment Service.

**Results:** Total amount of medical costs during the first 12 months after initiation of dialysis was not different between the two groups. However, costs during the first 1 month of early referral patients were lower than those of late referral patients (3029 ± 2219 versus 3438 ± 2821 US dollars, P = 0.025). Total 12 months health care costs before initiation of dialysis were lower in the early referral group (6206 ± 5873 versus 8610 ± 7820 US dollars, P < 0.001). In multivariable analysis, early referral reduced significantly health care costs (2513 ± 443 US dollars, P < 0.001) during the 12 months before dialysis start and the first month (400 ± 182 US dollars, P = 0.028) after initiation of renal replacement therapy.

**Conclusions:** Early referral of CKD patients to a nephrologist is associated with decreased medical costs during the predialysis and early period of dialysis.

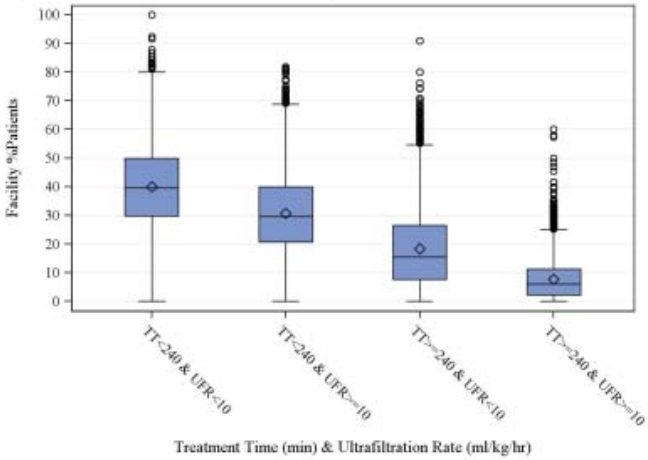
## SA-OR042

**Hemodialysis Facility and Patient Level Treatment Time and Ultrafiltration Rate Practices in the United States** Rajiv Saran,[1] Brett W. Plattner,[1] Chad M. Cogan,[2] Casey Parrotte,[1] Alissa Kapke,[2] Yi Li.[1] *[1]Univ of Michigan; [2]Arbor Research Collaborative for Health.*

**Background:** Longer dialysis treatment time(TT) and lower ultrafiltration rates(UFR) are associated with lower mortality in hemodialysis(HD) patients(pts). However, TT<240 min is still common in the US. We sought to examine US dialysis practice with respect to TT and UFR and characterizing pts receiving longer TT.

**Methods:** May 2012 CROWNWeb data on 235,629 pts from 4,313 dialysis facilities(≥10pts) were analyzed. 3x/week adult HD pts with residual urea clearance <2.0mL/min/1.73m² or not reported were included. TT was categorized: <180, 180-210, 210-240 and ≥240 min. UFR categories were <10, 10-13 and >13ml/kg/hr. A logistic regression model fitted via generalized estimating equations assessed the associations between pt characteristics and TT while adjusting for clustering in facilities.

**Results:** 66% of pts received TT <240 min. Based on the estimated regression coefficients, pt characteristics significantly associated with TT>240 min included younger age, men, African American race, shorter dialysis vintage, higher intradialytic weight loss, congestive heart failure, diabetes mellitus, higher BMI, and lower UFR.



The figure displays the variation in the distributions of clinically relevant TT/UFR combinations at the facility level. In a median US dialysis facility 15% of pts received TT>240 min and UFR<10. In contrast, 50% US dialysis facility had at least 40% pts receiving TT<240 min and UFR<10, and 30% pts receiving TT<240 min and UFR≥10.

**Conclusions:** In current US dialysis practice, the majority of pts on 3x/week dialysis have a TT<240 mins. Pt-level analysis suggests that longer TT in the US is utilized among pts with adverse prognostic factors. A proportion of facilities are able to provide TT>240 min and lower UFR to a sizable number of pts, demonstrating the potential feasibility of expanding this practice pattern.

*Funding:* Other U.S. Government Support

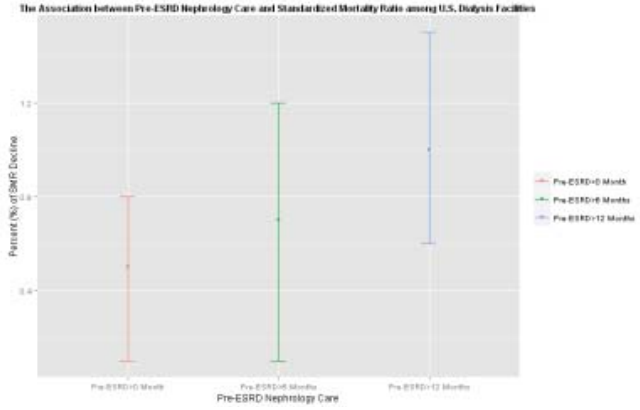
## SA-OR043

**Nephrology Care Influence Patient Mortality among United States Dialysis Facilities** Hua Hao,[1] Howard Chang,[2] Ritam Chowdhury,[1] Rachel E. Patzer.[3] *[1]Dept of Epidemiology, RSPH, Emory Univ; [2]Dept of Biostatistics and Bioinformatics, RSPH, Emory Univ; [3]Div of Transplantation, Emory Univ School of Medicine, Atlanta, GA.*

**Background:** Pre-ESRD nephrology care is important for better clinical outcomes for patients with end stage renal disease (ESRD). The aim of this study was to determine the association between pre-ESRD nephrology care and the standardized mortality ratio (SMR) among dialysis facilities in the US.

**Methods:** A total of 5,387 dialysis facilities were identified from the Dialysis Facility Report data 2007-2010. A marginal generalized estimating equation model assuming exchangeable covariance structure was used to estimate the association between pre-ESRD nephrology care, timing of pre-ESRD nephrology care, and facility level SMR.

**Results:** The percentage of patients who received pre-ESRD nephrology care within a facility was significantly associated with facility-level SMR. A 10% increase in pre-ESRD nephrology care was associated with a 0.50% (95% CI, 0.10%-0.80%, *P*=0.0067) decline in facility SMR. After considering the timing of pre-ESRD nephrology care, for every 10% increase in the percentage of patients who received pre-ESRD nephrology care within a dialysis facility, there was a 0.70% (95% CI, 0.10%-1.20%, *P*<0.0001) and 1.00% (95% CI, 0.60%-1.50%, *P*<0.0001) decrease in facility SMR for patients who received pre-ESRD care >6 months and >12 months prior to ESRD, respectively.



**Conclusions:** As the percentage of patients who received pre-ESRD nephrology care within a facility increased, the facility-level SMR decreased. The timing also played a significant role in mortality reduction where earlier access to nephrology care resulted in a steeper decline in the mortality. This suggests that targeted interventions to improve access to pre-ESRD nephrology care could reduce mortality among ESRD patients in dialysis facilities.

## SA-OR044

**2012 National Survey of Hemodialysis Infection Prevention and Vascular Access Practices** Priti Patel, Katelyn Coutts, Ann Goding Sauer, Alicia Shugart, Anna M. Melville, Matthew J. Arduino, Nicola D. Thompson, Alexander Kallen. *Centers for Disease Control and Prevention (CDC), Atlanta, GA.*

**Background:** Infections cause many dialysis patient hospitalizations and deaths. To better understand practices related to infection risk, CDC administers an annual survey to dialysis centers via the National Healthcare Safety Network (NHSN).

**Methods:** The Outpatient Dialysis Center Practices Survey, required for NHSN participation, includes self-reported center characteristics, infection prevention strategies, and vascular access practices. Surveys completed in 2012 by U.S. hemodialysis centers were analyzed. Chi-square test was used for comparisons.

**Results:** Of 5666 centers, 589 (10.4%) were hospital-affiliated centers (HAC). Adherence to CDC recommendations for hepatitis C screening (16.2%), and catheter (CVC) exit site care using chlorhexidine (27.7%) or antimicrobial ointment (15.1%) was low. These practices were more common in HAC than freestanding centers (FSC).

| **Percent of Centers Reporting Select Practices** | | | |
|---|---|---|---|
| | All (5666) | HAC (589) | FSC (5077) |
| **CDC-recommended** | | | |
| Hepatitis C screening* | 16.2 | 33.5 | 14.1 |
| Chlorhexidine for CVC exit site care* | 27.7 | 73.3 | 22.4 |
| Antimicrobial ointment at CVC exit site* | 15.1 | 22.4 | 14.2 |
| | | | |
| **Other** | | | |
| Vascular access nurse* | 88.7 | 64.7 | 91.7 |
| Nurse does CVC care* | 67.2 | 82.7 | 65.4 |
| Antimicrobial-impregnated CVCs* | 2.4 | 5.3 | 2.0 |
| Chlorhexidine-impregnated CVC dressings* | 14.5 | 46.7 | 10.8 |
| CVC closed connector devices* | 46.3 | 39.4 | 47.1 |
| Buttonhole cannulation** | 61.2 | 59.1 | 61.5 |
| HAC vs. FSC: *p<0.001; **p=0.26 | | | |

Sodium hypochlorite was most often used for CVC exit site (47.4%) and hub (48.2%) care, despite no recommendation for its use. More HAC reported that nurses did most CVC care, but FSC more often had a dedicated vascular access nurse. Most centers performed buttonhole cannulation.

**Conclusions:** Infection prevention strategies vary and recommended practices are underused. HAC may be more aware of CDC recommendations than FSC. Understanding implementation barriers among FSC is important to reducing infections.

## SA-OR045

**Targeted Medication Therapy Management (MTM) Improves Outcomes for Dialysis Patients and the Healthcare System** Joshua K. Howland, May Hoang, Maricela Lara Nevarez, Kelly K. Chillingworth, Tracy Furgiuele. *DaVita Rx, Coppell, TX.*

**Background:** The Affordable Care Act expanded MTM services to become a core component of the Medicare Part D program. Identification of medication-related problems and partnership with interdisciplinary healthcare teams to achieve resolution can improve clinical outcomes, reduce hospitalizations, and reduce costs. Given the large number of medications prescribed for dialysis patients, a pharmacist medication review program targeted to patients in transitions of care should improve clinical and systems costs for these patients.

**Methods:** Data from 212 patients (new to dialysis [<90 days] or ≤14 days since hospital discharge) who received a medication review were assessed by review of patient records. Each participant received a comprehensive medication review conducted via telephone by a pharmacist. Interventions which resulted in an avoided hospitalization/ER visit were determined and independently verified by pharmacists based on the clinical impact of the medication-related problem. Systems costs avoided were calculated using data from the Agency for Healthcare Research and Quality (AHRQ) H-CUP database and the Kaiser Family Foundation database on Medicare enrollees based on probable ICD-9 codes.

**Results:** 279 unique interventions were identified that resulted in potential avoidance of hospitalization/ER visit. Modeled mean cost savings for the healthcare system were $642,436; median cost savings were $440,911.

| | | |
|---|---|---|
| Incidence of probable hospitalizations | 0.257 | |
| All-cause hospitalization % for ESRD patients | 0.36 | |
| Interventions avoiding ER/hospitalization | 279 | |
| Study period | 05-Mar-12 to 13-May-13 | |
| | | |
| | Mean | Median |
| Modeled cost of all discharge diagnoses | $2,496,673 | $1,713,494 |
| Total modeled costs avoided | $642,436 | $440,911 |

**Conclusions:** These data suggest that a pharmacist medication review program for vulnerable patient populations has the potential to improve patient outcomes and lower overall healthcare costs through avoided hospitalizations. Assessment of actual hospitalization rates for patients receiving program interventions will be needed to validate these findings.

## SA-OR046

**Infrastructure for Patient Navigation and Timing of Referral and Evaluation for Kidney Transplant: A Survey of Nephrologists** Kevin C. Roe, Shahed Abbasi, Ahmad Aswad, Nasrollah Ghahramani. *Nephrology, Penn State College of Medicine, Hershey, PA.*

**Background:** Kidney transplant (KT) is the treatment of choice for majority of ESRD patients. Navigation of the evaluation process is a challenge, contributing to variations in timing for KT evaluation. We analyzed the association between the infrastructure for patient navigation and the timing of referral and evaluation for KT.

**Methods:** Invitations were sent to 3180 nephrologists in the eastern US. From 822 interested, 250 were randomly invited to complete a questionnaire about demographics, practice characteristics, and availability of infrastructure in their practice for patient navigation of the KT process. Excluding 9 with incomplete responses yielded 216 participants for a 2-step analysis: 1) association between practice characteristics and availability of infrastructure (formal protocol for KT referral, designated coordinator for KT workup, outreach activities by a transplant center (TC)); 2) association between infrastructure and timing of KT referral and evaluation. Chi-square and stepwise logistic regression were performed.

**Results:** A protocol (52%) was more likely among nephrologists in large groups (>10 members) (OR:3.08,p=0.003). Coordinator availability (46%) was more likely among academic nephrologists (OR:2.56,p=0.002) and those in large groups (OR:2.30,p=0.02). TC outreach was more likely for respondents (51%) attending transplant-related CME

(OR:2.37, p=0.004). Early referral (GFR:21-30) for KT evaluation (23%) was associated with coordinator availability (OR:2.09,p=0.04). A short (2 months or less) referral to evaluation time (52%) was more likely with TC outreach activities (OR:1.98,p=0.02). 44% indicated that the TC should only follow the KT patients 1 year; this was associated with coordinator availability (OR:1.87,p=0.04).

**Conclusions:** Availability of an infrastructure for patient navigation during the KT evaluation process is associated with referral at an earlier stage, a shorter referral to evaluation time and an earlier resumption of post-KT care by the primary nephrologist.

## SA-OR047

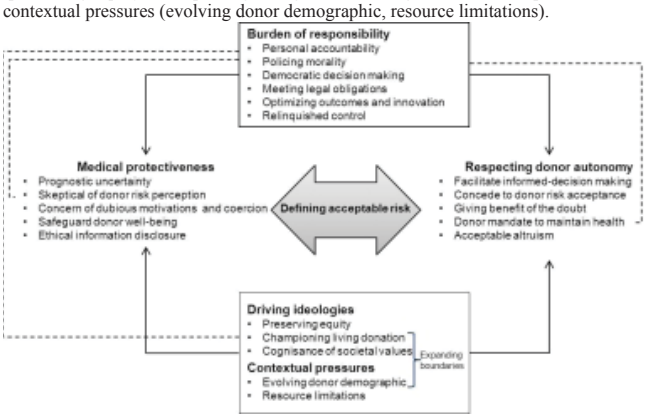
### Living Kidney Donor Assessment: Challenges, Uncertainties and Controversies among Transplant Nephrologists and Surgeons

Allison Tong,[1,2] Jeremy Chapman,[3] Germaine Wong,[1,2,3] Jonathan C. Craig.[1,2]
*[1]Sydney School of Public Health, The Univ of Sydney, NSW, Australia; [2]Centre for Kidney Research, The Children's Hospital at Westmead, NSW, Australia; [3]Centre for Transplant and Renal Research, Westmead Hospital, NSW, Australia.*

**Background:** The assessment of living kidney donors presents unique ethical challenges and complex psychosocial implications. We aimed to aimed ascertain the perspectives of transplant nephrologists and surgeons on living kidney donor assessment.

**Methods:** Semi-structured, face-to-face interviews were conducted with 110 transplant nephrologists and surgeons from 43 transplant units in 12 countries from Europe, Australasia, and North America.

**Results:** The challenge of defining acceptable risk to the donor was central to five themes identified: burden of responsibility (personal accountability, policing morality, democratic decision making, meeting legal obligations, optimizing outcomes and innovation, relinquished control); medical protectiveness (prognostic uncertainty, scepticism of donor risk perception, avoidance of undue coercion, concerns for dubious motivations and coercion, safeguard donor well-being, ethical information disclosure); respecting donor autonomy (facilitate informed-decision making, concede to donor risk acceptance, benefit of the doubt, donor mandate to maintain health, acceptable altruism); driving ideologies (preserving equity, championing living donation, cognisance of anti-paternalism); and contextual pressures (evolving donor demographic, resource limitations).



**Conclusions:** Living kidney donor assessment involves complex interactions between safeguarding the donors' welfare and respecting their autonomy. Authoritative and well-described transplant unit, hospital and public policy positions would make explicit the considerations which are often implicit, and reduce the uncertainty within which living donors are assessed today.

## SA-OR048

### Impact of Hypertension Management in Patients with Chronic Kidney Disease on Outcomes after End-Stage Renal Disease

Elaine Ku,[1] David V. Glidden,[1] Barbara A. Grimes,[1] Kirsten L. Johansen,[1] Mark J. Sarnak,[2] Hocine Tighiouart,[2] Chi-Yuan Hsu.[1] *[1]UCSF; [2]Tufts Medical Center.*

**Background:** There is controversy regarding whether strict blood pressure (BP) control (BP < 140/90 mm Hg) is indicated in patients with chronic kidney disease (CKD) since primary results of randomized controlled trials showed this strategy does not reduce rates of kidney function loss. However, it is possible that strict BP control has other beneficial effects beyond reducing risk of end-stage renal disease (ESRD), such as lowering mortality rates after onset of ESRD (a possible mechanism for this would be reduced cardiovascular disease burden at the start of ESRD).

**Methods:** The Modification of Diet in Renal Disease (MDRD) study is a well-known CKD trial conducted from 1989-1993 that randomized 840 CKD patients to strict (mean arterial pressure <92 or <98 mmHg depending on age) vs. usual BP control (<107 mm Hg). We extended follow-up of MDRD study enrollees via cross-linkage with US Renal Data System (USRDS) and National Death Index to ascertain ESRD onset and death (prior to ESRD) through 12/31/2007. Deaths after onset of ESRD were ascertained via USRDS through 12/31/2009.

**Results:** Of the 840 MDRD enrollees, 616 developed ESRD by 12/31/2007. There were 306 cases of ESRD in the strict BP arm and 310 cases of ESRD in the usual BP arm (unadjusted Cox models hazard ratio [HR] 0.93; 95% CI 0.79-1.08; p = 0.34). Prior to ESRD, there were 66 deaths in the strict BP arm and 40 deaths in the usual BP arm (HR 1.48; 95% CI 1.00-2.19; p = 0.05). After onset of ESRD, there were 132 deaths in the strict BP arm and 179 deaths in the regular BP arm (HR 0.68; 95% CI 0.54- 0.85; p = 0.001) in a Cox model of time to event since dialysis initiation. When considering all deaths regardless of timing relative to ESRD, mortality risk was lower in the tight blood pressure control group (HR 0.81; 95% CI 0.67-0.99; p = 0.04).

**Conclusions:** Although strict BP control may not delay progression of CKD to ESRD, this strategy appears to be associated (even years after end of active intervention) with reduced risk of death after onset of ESRD. Post-ESRD outcomes should be considered when formulating BP targets for CKD patients.

## SA-OR049

### Physical Activity and Risk of Kidney Failure in the Singapore Chinese Health Study

Tazeen H. Jafar,[1] Jin Ai Zhen,[2] Woon-Puay Koh,[1] Khuan Yew Chow.[2] *[1]Duke-NUS Graduate Medical School, Singapore; [2]National Registry of Diseases Office, Health Promotion Board, Singapore; [3]Saw Swee Hock School of Public Health, National Univ of Singapore, Singapore.*

**Background:** The relationship between physical activity and risk of kidney failure is not clear. We analyzed data from the Singapore Chinese Health Study to investigate whether physical activity reduces the risk of kidney failure.

**Methods:** The Singapore Chinese Health Study is a population-based cohort of 63,257 Chinese adults enrolled between 1993 and 1998. Self-reported information on habitual physical activity at baseline. Incidence of kidney failure was identified via record linkage with the nationwide Singapore Renal Registry until 2008, defined by one of the following: 1) serum creatinine level of more than or equal to 500 µmol/l (5.7 mg/dl), 2) estimated GFR of less than 15 ml/min/1.73m$^2$, 3) undergoing hemodialysis or peritoneal dialysis, 4) kidney transplantation. Multivariable models were built and cox proportional hazard regression analysis was performed to assess the association between physical activity with kidney failure after adjusting for age, education, dialect, herbal medications, body mass index, sex, physician-diagnosed hypertension and diabetes.

**Results:** Mean age of subjects was 55.6 years; 44% were men. A total of 671 incident cases of kidney failure occurred during a median follow-up of 13.3 years. Individuals who were physically active had significantly reduced adjusted risk of kidney failure [hazard ratio (HR): 0.70; 95% CI: 0.58-0.83] compared to those who were inactive. The risk reduced with increase in intensity from moderate to vigorous/ strenuous (p for trend=<0.0001), and with increase in duration of moderate physical activity to 4-6 hours/week (adjusted p for trend =0.01). Vigorous activity or strenuous of 30 minutes to 2 hour/week independently reduced the risk of kidney failure (HR = 0.63, CI: 0.42-0.94).

**Conclusions:** Physical activity is associated with decreased risk of kidney failure. The risk reduction appears to be dose- dependent with increase in intensity and duration of moderate physical acitivity. Even a short duration of vigorous physical acitivity predicts additional risk reduction.

## SA-OR050

### Race, Dietary Acid Load and Risk of ESRD among Low Income Americans with CKD

Deidra C. Crews,[1] Tanushree Banerjee,[2] Donald E. Wesson,[3] Hal Morgenstern,[4] Nilka Rios Burrows,[5] Rajiv Saran,[4] Desmond Williams,[5] Neil R. Powe.[2] *[1]Johns Hopkins Univ; [2]Univ of California, San Francisco; [3]Texas A&M College of Medicine; [4]Univ of Michigan; [5]Centers for Disease Control and Prevention.*

**Background:** Racial disparities in risk of ESRD are most profound among individuals of low socioeconomic status (SES). High dietary acid load (e.g., diet poor in base-producing fruits/vegetables) is positively associated with CKD progression to ESRD. Whether the effect of dietary acid load on risk of ESRD differs by race is unknown.

**Methods:** We examined data on 159 non-Hispanic black (NHB), and 760 non-Hispanic white (NHW) adults with CKD (eGFR=15-59 ml/min/1.73 m$^2$), aged >20 years, and with an annual household income <300% of the federal poverty guideline, from the 1999-2004 National Health and Nutrition Examination Survey. Dietary acid load was estimated using the net acid excretion (NAE) formula by Remer and Manz and 24h dietary recall data. ESRD events were ascertained via linkage with the Medicare ESRD registry through 2008. Cox regression was used to estimate the hazard ratio (HR) for ESRD, comparing NHBs with NHWs, adjusting for age, sex, diabetes, hypertension, baseline eGFR, urinary albumin:creatinine, daily caloric intake, and NAE. The modification of the NAE effect by race was examined by including an interaction term in the Cox model.

**Results:** Compared with NHWs at baseline, NHBs were younger, more likely to have diabetes and/or albuminuria and had greater NAE (49.1 vs. 45.3 mEq/d). Overall, 94 (12.4%) participants [36 (38.3%) NHWs and 58 (61.7%) NHBs] developed ESRD during an average of 6.4 years of follow up. NHBs had a higher risk of developing ESRD than NHWs with an unadjusted HR of 13.7 (95% CI 13.6-13.8) and adjusted HR of 3.04 (95% CI 3.02-3.07). On stratifying by race, each unit increase in NAE was more strongly associated with ESRD among NHBs [HR 1.035 (1.033-1.036)] than among NHWs [HR 1.018 (1.018-1.019)] in Cox models adjusted for age (P for interaction <0.001).

**Conclusions:** Among low SES adults with CKD, the detrimental effect of high dietary acid load on progression to ESRD appears to be greater for NHBs than for NHWs, and is worthy of further investigation in other populations.

**SA-OR051**

**Persistent Alkalosis Is Associated with High Risk of Heart Failure in Patients with CKD: A Report from the Chronic Renal Insufficiency Cohort (CRIC) Study** Mirela A. Dobre,[1] Wei Yang,[2] Lawrence J. Appel,[2] Keith A. Bellovich,[2] Harold I. Feldman,[2] Jing Chen,[2] Michael J. Fischer,[2] L. Lee Hamm,[2] Thomas H. Hostetter,[1] Bernard G. Jaar,[2] Radhakrishna Reddy Kallem,[2] Sylvia E. Rosas,[2] Julia J. Scialla,[2] Myles S. Wolf,[2] Mahboob Rahman.[1] *[1]Case Western Reserve Univ; [2]CRIC Study.*

**Background:** The aim of the study is to evaluate the effect of serum bicarbonate change over 1 year on clinical outcomes in a large cohort of participants with CKD.

**Methods:** Serum bicarbonate was measured at baseline and after 1 year in 3394 CRIC participants with CKD. Participants were divided in 4 groups of serum bicarbonate change: *Normal* [22-26mEq/L] at baseline and year 1, n=1288; *Improved* - abnormal at baseline who became normal at year 1, n=674; *Worsening/persistent acidosis* <22mEq/L at baseline and year 1, n=257 plus all who became <22mEq/L at year 1, n=349; *Worsening/persistent alkalosis* >26mEq/L at baseline and year 1, n=433 plus all who became >26mEq/L at year 1, n=393. Renal outcomes were defined as ESRD or 50% eGFR decline. Cardiovascular outcomes were defined as atherosclerotic (myocardial infarction, stroke, peripheral arterial disease) or CHF events. Multivariable Cox proportional hazards models were used to test the associations of interest.

**Results:** The risk of developing heart failure was 37% higher for participants in the alkalosis group (HR 1.37; 95%CI 1.02-1.84, p=0.04) compared to participants in the normal group, after adjusting for demographics, co-morbidities, medications including diuretics, eGFR and proteinuria.

| | Normal | Improved | | Worsening/persistent acidosis | | Worsening/persistent alkalosis | |
|---|---|---|---|---|---|---|---|
| | | HR(95%CI) | p | HR(95%CI) | p | HR(95%CI) | p |
| **CHF** | Ref | 1.12(0.81-1.53) | 0.50 | 0.93(0.68-1.29) | 0.70 | 1.37(1.02-1.84) | 0.04 |
| **Renal event** | Ref | 0.99(0.81-1.23) | 0.90 | 1.00(0.82 1.21) | 0.90 | 1.18(0.96-1.45) | 0.10 |
| **Death** | Ref | 0.87(0.64-1.18) | 0.40 | 1.01(0.75-1.34) | 0.90 | 1.00(0.75-1.32) | 0.90 |
| **Atherosclerotic event** | Ref | 1.17(0.84-1.63) | 0.30 | 0.88(0.62-1.25) | 0.50 | 1.02(0.73-1.42) | 0.90 |

**Conclusions:** In a cohort of participants with CKD, persistent alkalosis was an independent risk factor for heart failure events.

**SA-OR052**

**The Impact of a Mediterranean Style Diet on Kidney Function** Minesh Khatri,[1] Yeseon Park Moon,[2] Nikolaos Scarmeas,[3] Yian Gu,[2] Consuelo Mora-McLaughlin,[2] Hannah Gardener,[4] Clinton Wright,[4] Ralph L. Sacco,[4] Thomas L. Nickolas,[1] Mitchell S.V. Elkind.[2] *[1]Nephrology, Columbia Univ, New York, NY; [2]Neurology, Columbia Univ, New York, NY; [3]Sergievsky Center, Columbia Univ, New York, NY; [4]Neurology, Univ of Miami, Miami, FL.*

**Background:** Adherence to a Mediterranean diet has been associated with improved cardiovascular risk through improved endothelial function and blood pressure, and decreased inflammation. Whether these benefits extend to kidney function is unclear.

**Methods:** The Northern Manhattan Study is a prospective, community-based, multi-ethnic cohort that was stroke-free at baseline. Serum creatinine was measured at baseline and at follow-up (mean 6.9 years). A dietary questionnaire was administered at baseline, from which elements of a Mediterranean diet were extrapolated into a previously used nine point scoring system (MeDi) that was associated with cerebrovascular disease outcomes in this cohort. The primary outcome was incident CKD, defined as a follow-up MDRD estimated glomerular filtration rate (eGFR) of <60 mL/min among subjects with eGFR>60 mL/min at baseline. A secondary outcome was defined as the upper quartile of annualized eGFR decline within this cohort (≥2.5 mL/min/year). Models were adjusted for demographics and baseline vascular risk factors.

**Results:** A total of 900 subjects had requisite data. At baseline, mean age was 64, 59% were women, 65% were Hispanic, 19% had diabetes and 69% had hypertension. Mean baseline eGFR was 83.1 mL/min, with a mean annualized decline of 1.1 mL/min; incident CKD developed in 14%. In multivariate analysis, every one-point increase in adherence to MeDi was associated with a 17% decreased odds (p=0.015) of incident CKD and a 14% decreased odds (p=0.009) of being in the upper quartile of eGFR decline.

**Conclusions:** This prospective analysis suggests that a Mediterranean style diet is associated with a reduced risk of CKD and slows the rate of eGFR decline. Randomized trials are needed to confirm these findings, and mechanisms by which a Mediterranean style diet may protect against kidney disease progression need to be determined.

*Funding:* Other NIH Support - NINDS R37 29993

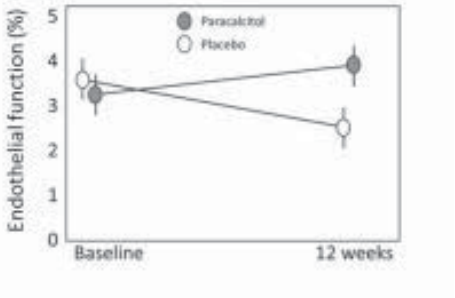
**SA-OR053**

**The Paricalcitol and ENdothelial FuNction in Chronic KidneY Disease (PENNY) Trial: Paracalcitol Improves Endothelium-Dependent Vasodilatation in Stage 3-4 CKD Patients** Carmine Zoccali,[1] Giuseppe Curatola,[1] Vincenzo Panuccio,[1] Rocco Tripepi,[1] Patrizia Pizzini,[1] Maria Carmela Versace,[1] Davide Bolignano,[1] Sebastiano Cutrupi,[1] Raffaele Politi,[1] Giovanni Tripepi,[1] Ravi I. Thadhani,[2] Francesca Mallamaci.[1] *[1]CNR-IBIM, Clin. Epid. and Physiopath. of Renal Dis. and Hypertens., CNR-IBIM, Reggio Calabria, Italy; [2]Massachusetts General Hospital, Harvard Medical Center, Boston.*

**Background:** An association between low vitamin D, endothelial dysfunction and atherosclerosis has been described in CKD pts but the effect of active forms of vitamin D on endothelial function has not been tested in a controlled trial in these pts.

**Methods:** PENNY is a double blinded RCT (Clinicaltrials.gov NCT01680198) testing the effect of paracalcitol (PCT, 2 µg/day x 12 weeks) on the forearm blood flow (FBF) response to ischemia (endothelium dependent vasodilatation) and to nitroglicerine (NTG, endothelium independent vasodilatation) by a standardized technique (JH 2012;30:1399) in 88 stage 3-4 CKD pts with PTH>65 pg/ml (PCT,n=44; Placebo,n=44).

**Results:** PCT reduced PTH from a median of 102 pg/ml (IQR:82-146 pg/ml) to 41 pg/ml (24-61 pg/ml). BP and HR remained unmodified in both study arms. PCT increased the FBF response to ischemia by 14% and the between groups difference in FBF changes across the trial (the primary end-point) was highly significant (P=0.01).



No effect of PCT on the response to NTG was registered indicating that PCT specifically affects endothelium dependent vasodilatation.

**Conclusions:** PCT improves endothelium dependent vasodilatation in stage 3-4 CKD pts. Such an effect indicates that endothelial dysfunction is a reversible phenomenon in this population. Since endothelial dysfunction is a strong predictor of death and CV events, findings in this study provide a rationale for designing randomized trials based on clinical end-points in CKD.

*Funding:* Pharmaceutical Company Support - AbbVie

**SA-OR054**

**The Effects of Allopurinol on Metabolic Acidosis and Endothelial Functions in the Hyperuricemic Patients with Stage 2-4 Chronic Kidney Disease** Mehmet T. Sezer,[1] Dilara Bayram,[2] Atila Altunta?,[1] Salih Inal,[1] Veysel Kidir.[1] *[1]Internal Medicine, Suleyman Demirel Univ School of Medicine, Isparta, Turkey; [2]Nephrology, Suleyman Demirel Univ School of Medicine, Isparta, Turkey.*

**Background:** An elevated serum uric acid level is reported to be associated with endothelial dysfunction which is common in chronic kidney disease (CKD). At the same time, endothelial dysfunction and metabolic acidosis have emerged as important risk factors for progression of kidney disease. In this study, we aimed to investigate the effects of allopurinol on metabolic acidosis and endothelial functions in hyperuricemic stage 2-4 CKD patients.

**Methods:** Thirty patients (14 male/16 female) with stage 2-4 CKD and serum uric acid levels over 5.5 mg/dL were included in the study group. They were prescribed 300 mg/day po allopurinol for 3 months. Age and gender matched CKD patients (n=30) with similar clinical characteristics (13 male/ 17 female) were taken as the control group and they were not given allopurinol. Endothelial functions were measured via flow mediated dilatation (FMD) over forearm. Additionally, pH and $HCO_3$ levels in venous blood, glomerular filtration rate (GFR) and proteinuria levels were calculated in all patients at the beginning and at the third month of follow up.

**Results:** Clinical and Laboratory findings were similar in both groups in the first visit. FMD was found to be significantly increased in allopurinol group (5,80 ± 2,56 vs 6,27 ± 2,70; p:0,006) whereas it decreased significantly in the control group (6,27 ± 1,62 vs 5,71 ± 1,90; p:0,005) between the two visits. When FMD variations within two groups were evaluated via the repeated ANOVA - general linear model, it was clearly significant. Additionally, uric acid levels were found to be inversely correlated with GFR and $HCO_3$ levels.

**Conclusions:** The primary finding in this study was that decreased uric acid levels with allopurinol in hyperuricemic CKD patients have beneficial effects over endothelial dysfunction and serum $HCO_3$ levels. We assume that decreasing uric acid levels seems to be helpful in order to restore endothelial functions, prevent metabolic acidosis and slow down the progression to end stage renal disease.

## SA-OR055

**Validation of the Kidney Failure Risk Equation in an International Consortium** Navdeep Tangri, Andrew S. Levey, M. Grams, Josef Coresh, Brad C. Astor, Allan J. Collins, Ognjenka Djurdjev, Carolyn Raina Elley, Stein I. Hallan, Lesley Inker, Csaba P. Kovesdy, Florian Kronenberg, Hiddo Jan Lambers Heerspink, Angharad Marks, Sankar D. Navaneethan, Robert G. Nelson, Mark J. Sarnak, Benedicte Stengel, Mark Woodward, Kunitoshi Iseki. *CKD Prognosis Consortium.*

**Background:** Predicting the progression of CKD can enable early and appropriate nephrology care. We previously developed and validated laboratory based kidney failure risk equations (KFREs) for the progression of CKD to kidney failure in patients referred for nephrology care in Canada. Evaluation in other countries and in non-referred CKD populations is needed.

**Methods:** We meta-analyzedindividual level data from 34,569 patients with CKD Stages 3-5 from 12 cohorts spanning 7 countries. We assessed models containing 3 (age, sex, estimated glomerular filtration rate [GFR]), 4 (+albuminuria) and 8 (+serum albumin, calcium, phosphorous, and bicarbonate) variables from the original publication. We compared hazard ratios for constituent predictors, discrimination, calibration, net reclassification index (NRI), and integrated discrimination index (IDI) for all models.

**Results:** The original 4- and 8-variable KFREs obtained similar hazard ratios for constituent predictors and achieved excellent discrimination (C statistic >0.84 – Table). Calibration of the original KFREs was adequate at 5 years, and improvements in NRI and IDI were observed in comparison with a 3-variable model (NRI 18%, IDI 5% for the 4-variable,and 25% and 6% for the 8-variable model). Performance in subgroups by age, race and diabetes status was similar.

**Conclusions:** The previously developed KRFEs accurately predict the progression of CKD Stages 3-5 to kidney failure across a wide range of studies. The abbreviated 4-variable equation is simple and highly accurate. Integration in routine clinical practice should be evaluated.

| Model | Difference of C Statistic | NRI with risk categories of 0-1%, 1-2%, 2%+ | IDI |

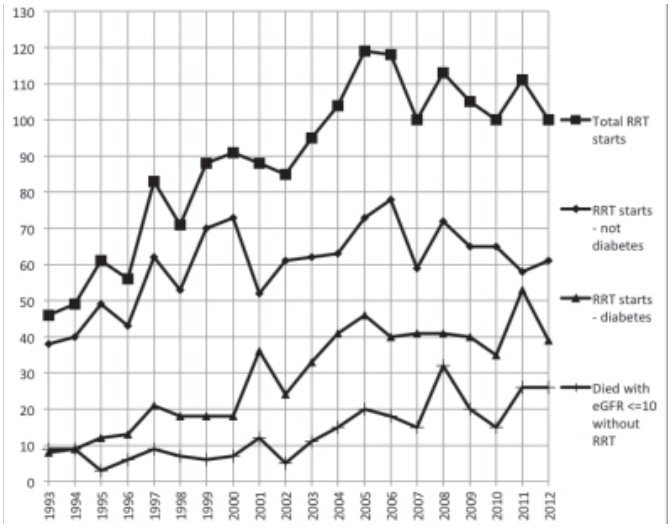
**CKD Management Program Improved Access to Nephrology Care and Stabilized Renal Replacement Therapy Incidence in Birmingham, UK** Hugh C. Rayner, Jyoti B. Baharani, Indranil Dasgupta, Vijayan Suresh, Robert Mark Temple, Mark E. Thomas, Stephen A. Smith. *Renal Medicine, Heart of England NHS Foundation Trust, Birmingham, West Midlands, United Kingdom.*

**Background:** Heart of England (HEFT) provides ESRD care for c.0.72m population with mixed ethnicity and large areas of deprivation. From 2001-11 the England unadjusted incident RRT rate increased 1.1% per year. In 2003/4, HEFT introduced a CKD management program with primary care education, multidisciplinary predialysis and conservative care (Nephron Clin Pract 2010;115:c283-8), routine eGFR reporting, and diabetes CKD surveillance (Rayner BMJ Qual Saf 2011). In 2006, national financial incentives for primary CKD care were introduced. We have studied access to nephrology care and trends in RRT and end of life care at HEFT.

**Methods:** Incident CKD5 patients >=75yrs (eGFR<15 x2 >3 mths apart Jan2010 - Jun2011) in HEFT pathology database linked with a nephrologist by UK Renal Registry. RRT = dialysis + pre-emptive transplant. Variation over time analyzed by statistical process control.

**Results:** In 2010/11 50/55 incident CKD5 patients >=75yrs were known to a nephrologist. From 1998, mean age at start of RRT (62 yrs) and eGFR at start of dialysis (7.8) were stable. From 2005 the unadjusted RRT incident rate stabilized (fig). RRT incidence at the neighboring centre was stable. Patients known to a nephrologist who died with eGFR <10 without dialysis increased (fig); mean age at death increased linearly from 70 in 1993 to 82yrs in 2012. From 2004, 105/189 patients (56%) who died with eGFR <10 without dialysis received multidisciplinary care; 67/189 (36%) received planned conservative care.



**Conclusions:** Following implementation of a CKD management program, >90% CKD5 patients aged >75 yrs were known to a nephrologist, the incident RRT rate stabilized and >50% patients dying with renal failure without dialysis received multidisciplinary care.

## SA-OR057

**Change in GFR and Subsequent Mortality: Meta-Analysis of 32 Cohorts in the CKD Prognosis Consortium** Tanvir Chowdhury Turin, Kunihiro Matsushita, Josef Coresh, Hisatomi Arima, Steven J. Chadban, Massimo Cirillo, Ognjenka Djurdjev, Jamie Alton Green, Fujiko Irie, Joachim H. Ix, Csaba P. Kovesdy, Takayoshi Ohkubo, Chi Pang Wen, Paul E. de Jong, Kunitoshi Iseki, Benedicte Stengel, Ron T. Gansevoort. *CKD Prognosis Consortium.*

**Background:** Change in estimated GFR (eGFR) is frequently used to track CKD progression in clinical practice, trials and cohort studies but its association with mortality has not been studied extensively.

**Methods:** Change in eGFR was estimated as % change from the first to last eGFR (CKD-EPI creatinine) in a 2-year baseline period. We modeled the hazard ratios (HRs) of subsequent mortality as a spline function of %change in eGFR after adjusting for age, sex, race, first eGFR, and co-morbid conditions. We used random effects meta-analyses to combine results stratified by first baseline eGFR (<60 & ≥60) across studies.

**Results:** Mortality follow-up of 910,660 participants from 32 cohorts for a mean of 4.2 years after the 2-year baseline period showed 91,398 deaths for baseline eGFR <60 (n=333,722) and 45,063 deaths for baseline eGFR ≥60 (n=576,938). Change in eGFR had a non-linear association with mortality (Figure for eGFR<60). A decline in eGFR was consistently associated with higher subsequent mortality risk (adjusted HR for -30% vs. 0% change in eGFR were: 1.8 at eGFR <60; and 1.5 at eGFR ≥60; p<0.001). Similar results were obtained for a 1- or 3-year change in eGFR. Hazards ratios were largely similar for those with eGFR ≥60 or when stratified by ACR levels.

**Conclusions:** Declines in eGFR are strongly and consistently associated with subsequent risk of mortality adjusted for the first eGFR and covariates. These findings support using smaller changes than -57% (equivalent to doubling of serum creatinine) in clinical research.

**Figure.** Adjusted mortality hazard ratio vs. % 2-year Change in eGFR: Baseline eGFR<60

**EGFR Deletion in Podocytes Attenuates Diabetic Nephropathy**
Jianchun Chen,[1] Jian-Kang Chen,[2] Raymond C. Harris.[1] *[1]Medicine, Vanderbilt Univ, Nashville, TN; [2]Experimental Medicine, Georgia Regents Univ, Augusta, GA.*

**Background:** The generation of ROS, specifically superoxide ($\cdot O_2^-$), by damaged or dysfunctional mitochondria, has been postulated to be a primary initiating event in the development of diabetes complications. The glomerulus is a primary site of diabetic injury, and podocyte loss is one of the classic hallmarks of diabetic glomerular lesions. The current studies were designed to determine the potential role EGFR activation in podocytes in diabetic glomerular injury.

**Methods:** We generated podocyte-specific EGFR knockout mice ($EGFR^{podKO}$) by crossing $EGFR^{flox/flox}$ mice with podocin-Cre mice and induced diabetes in $EGFR^{podKO}$mice and their wild type littermates (WT) by streptozotocin injections.

**Results:** $EGFR^{podKO}$ and their WT control mice on a 129SVJ background developed similar levels of hyperglycemia and polyuria, but $EGFR^{podKO}$ developed significantly less albuminuria(urinary albumin/creatinine ratio at 32 weeks of hyperglycemia WT vs $EGFR^{podKO}$: 170.80 ± 12.93 vs. 80.8 ± 6.14 µg/mg, P<0.001, n =5-7). More podocytes were lost in WT diabetic mice compared with the $EGFR^{podKO}$ diabetic mice (podocyte number/glomerulus: WT vs $EGFR^{podKO}$: 9.71 ± 0.56 vs 12.71 ± 0.42 podocytes/glomerular section, P<0.01, n=4-6). Furthermore, increased fibronectin deposition in glomeruli was attenuated in $EGFR^{podKO}$ diabetic mice. Immunoblotting of isolated glomerular lysates revealed that up-regulation of cleaved caspase 3 and down-regulation of $EGFR^{podKO}$ mice. Our studies also revealed up-regulation of phospho-EGFR, phospho-smad2/3, and TGFβ1 expression were markedly inhibited in $EGFR^{podKO}$ diabetic mice. Furthermore, in WT diabetic mice, administration of either a mitochondria-targeted antioxidant, mito-TEMPO, or a cell-permeable NADPH-oxidase inhibitor, apocynin, also attenuated up-regulation of phospho-EGFR, phospho-smad2/3 and TGFβ1 expression, and blunted the altered expression of cleaved caspase 3 and Bcl-2 expression in glomeruli.

**Conclusions:** This study demonstrates that EGFR plays an important role in oxidative stress-induced podocyte loss and glomerular ECM expansion in the pathogenesis of diabetic nephropathy.

**Podocyte VEGF-A and eNOS Loss of Function Lead to Diffuse Glomerulosclerosis in Mice**
Alda Tufro,[1] Pardeep Kumar Aggarwal,[1] Gilbert W. Moeckel.[2] *[1]Pediatrics/ Nephrology, Yale Univ, New Haven, CT; [2]Pathology, Yale Univ, New Haven, CT.*

**Background:** Vascular endothelial growth factor-a (VEGF-A) and nitric oxide (NO) are essential for glomerular filtration barrier homeostasis, and are disregulated in diabetic nephropathy. While NO availability is consistently low, both high and low VEGF-A have been reported in patients with diabetic nephropathy.

**Methods:** Here we examined the effect of inducible podocyte VEGF-A knockdown (podocin-rtTA:tet-O-siVEGF = VEGF-$A^{KD}$) in diabetic mice and in endothelial nitric oxide synthase knockout mice (eNOS KO). Diabetes was induced with streptozotocin (STZ) using the ADMCC protocol. Proteinuria was measured by albumin ELISA, VEGF-A and total NO were measured in plasma and urine by ELISA and colorimetric methods, respectively.

**Results:** Podocyte VEGF-$A^{KD}$caused diffuse glomerulosclerosis associated with small glomeruli, foot process effacement and GBM thickening in mice with streptozocin-induced diabetes and in non-diabetic eNOS KO mice. In addition, VEGF-$A^{KD}$:eNOS KO mice developed microaneurisms, arteriolar hyalinosis, massive proteinuria (>30 fold above eNOS KO and >5 fold above VEGF-$A^{KD}$ diabetic mice) and renal failure. Conversely, VEGF-$A^{KD}$ diabetic mice had milder proteinuria and normal GFR, associated to extremely high NO urinary excretion (~10-fold above non-diabetic controls and eNOS KO mice).

**Conclusions:** Collectively, data indicate that glomerular VEGF-A and eNOS deficiency are necessary and sufficient to induce diffuse glomerulosclerosis in mice, and that compensatory NO generation prevents severe proteinuria and GFR loss in diabetic mice with intact eNOS, whereas in eNOS KO mice VEGF-$A^{KD}$ leads to severe diffuse glomerulosclerosis and renal failure mimicking the progression of diabetic nephropathy in humans.

**Genetic Deletion and Pharmacological Inhibition of the NADPH Oxidase Nox4 Provides Renoprotection in Diabetes-Induced Nephropathy**
Jay C. Jha,[1,5] Stephen P. Gray,[1] Kirstin Wingler,[2] Cedric Szyndralewiez,[3] Freddy Heitz,[3] Rhian Touyz,[4] Mark E. Cooper,[1,5] Harald H. Schmidt,[2] Karin Jandeleit-Dahm.[1,5] *[1]Diabetic Complications Div, Baker IDI Heart & Diabetes Institute, Melbourne, Victoria, Australia; [2]Dept of Pharmacology, Cardiovascular Research Institute Maastricht (CARIM), Maastricht Univ, Maastricht, Netherlands; [3]Genkyotex SA, Geneva, Switzerland; [4]Ottawa Hospital Research Institute, Ottawa, Canada; [5]Medicine, Monash Univ, Melbourne, Victoria, Australia.*

**Background:** Chronic kidney disease is a major complication of diabetes.Oxidative stress could contribute to the development of diabetic nephropathy(DN). NADPH oxidases (Nox) are a major source of reactive oxygen species(ROS) production in the kidney and contribute to renal damage in diabetes. However, the role of specific Nox isoforms in DN remains unresolved. Thus,we aimed to examine the role of Nox1 and Nox4 in DN using genetic deletion and pharmacological inhibition approaches in diabetic mice.

**Methods:** $Nox1^{-/y}ApoE^{-/-}$or $Nox4^{-/-}ApoE^{-/-}$and their respective wild type or $ApoE^{-/-}$ mice were rendered diabetic via streptozotocin injection. $ApoE^{-/-}$ mice were treated with the specific Nox1/4 inhibitor *GKT137831*. Animals were culled after 20 weeks and kidneys were obtained for assessment of renal structure and function as well as ROS production. In vitro, Nox4 was silenced in human podocytes and exposed to high glucose and TGFβ for gene expression and ROS measurement.

**Results:** Deletion of Nox4, but not of Nox1 resulted in renal protection from glomerular injury as evidenced by attenuated albuminuria, preserved renal structure, reduced glomerular accumulation of extracellular matrix proteins and attenuated glomerular macrophage infiltration. Administration of *GKT137831* to diabetic $ApoE^{-/-}$ mice conferred a similar degree of renoprotection as did deletion of Nox4. In human podocytes, silencing of Nox4 gene resulted in reduced ROS production and down-regulation of profibrotic markers that are implicated in DN.

**Conclusions:** Collectively, these results identify Nox4 is a key source of ROS responsible for kidney injury in diabetes and provide proof of principle for an innovative small molecule approach to treat and/or prevent DN .

**Altered Metabolic Substrate Utilization and Mitochondrial Dysfunction Characterizes Diabetic Nephropathy**
Pradeep Kayampilly, Kelli Sas, Jaeman Byun, Hongyu Zhang, Charles Burant, Frank C. Brosius, Subramaniam Pennathur. *Univ of Michigan, Ann Arbor, MI.*

**Background:** Diabetic nephropathy (DN) is the most common cause of end-stage renal disease in the United States. While it is well-recognized that diabetes leads to altered carbohydrate, amino acid and fatty acid metabolism, the utilization and flux of these substrates *in vivo* has not been systematically studied.

**Methods:** We developed a comprehensive targeted metabolomic platform for simultaneous quantitative analysis of glycolytic, tricarboxylic acid (TCA) and fatty acid oxidation intermediates by liquid chromatography electrospray ionization tandem mass spectrometry (LC/ESI/MS/MS) and gas chromatography-mass spectrometry (GC/MS). Animals which exhibit characteristic pathological features of DN (BKS db/db) were used as a model system to examine the dynamic changes in substrate utilization.

**Results:** Static metabolite levels of several metabolites including acylcarnitines, glycolytic, and TCA cycle were markedly and statistically significantly increased in diabetic renal cortex and mitochondria from renal cortex (1.5 to 6-fold). Diabetic urine, but not plasma, showed similar increases suggesting that urinary metabolites reflect renal cortical metabolism. Metabolic flux analysis was performed following incubation or intraperitoneal administration of isotopically labeled substrates ($U^{13}C$ glucose and 2, 3-$^{13}C$ pyruvate) for *ex-vivo* proximal tubule and *in vivo* whole-animal flux respectively. Proximal tubule and *in vivo* flux analyses showed a significant elevation of labeled glycolytic and TCA intermediates in diabetic renal cortex at 12 and 24 weeks compared to controls, suggesting increased flux through these pathways. Mitochondria from diabetic renal cortex exhibited reduced ATP production and increased proton leak indicating diminished function and compromised membrane integrity.

**Conclusions:** Taken together, these results show a metabolic reprogramming in the diabetic kidney leading to mitochondrial dysfunction and oxidative stress. The altered metabolic profile in mouse diabetic kidney is mirrored in urine samples of DN patients, suggesting that a subset of these metabolites may serve as potential biomarkers of DN.

**SA-OR062**

**Autophagy Is Beneficial for Podocytes during Diabetes-Induced Nephropathy**
Olivia Lenoir,[1,2] Magali Jasiek,[1,2] Pierre-Louis F. Tharaux.[1,2] *[1]Paris Cardiovascular Research Centre - PARCC, INSERM, Paris, France; [2]Univ Paris Descartes, Sorbonne Paris Cité, Paris, France.*

**Background:** Diabetic nephropathy (DN) is the major microvascular complication of diabetes and the leading cause of ESRD in industrialized countries. The development of CKD in patients with diabetes can take several decades and may manifest despite tight glycemic and blood pressure control. With the current standard therapies only partial renal protection is obtained, thus, it is of particular importance to understand more about the pathogenesis of DN and to identify novel therapeutic targets. Recently, autophagy pathway as emerged as a survival signal in several cell types during stress-induced cellular lesions.

Recently, Huber and coll. demonstrated the importance of autophagy in podocytes in the preservation of glomerular cells functions during aging. Moreover, we found that high glucose induces autophagy in podocytes. Thus, we hypothetized that autophagy could be important for podocyte cell survival during diabetes-induced nephropathy.

**Methods:** We evaluated the effects of high glucose on mouse primary podocytes cell function and survival and on the induction of autophagy. We also studied the development of diabetic nephropathy in streptozotocin-treated diabetic mice with a podocyte-specific disruption of the autophagy pathway.

**Results:** In freshly isolated podocytes, we demonstrated that high glucose induced podocyte autophagy. Furthermore, high glucose-induced autophagy is associated with a decrease in podocin and WT1 expression. Next, autophagy pathway was disrupted in mice using a genetic deletion of Atg5 specifically in podocyte using the Cre-lox system (NPHS2Cre). We found that genetic deletion of autophagy in podocytes dramatically sensitized mice towards the development of diabetic nephropathy in mice. Indeed,

NPHS2Cre-Atg5$^{lox/lox}$ mice present advanced diabetic nephropathy with mesangial thickening, glomerulosclerosis, podocyte loss, foot process effacement and GBM thickening, while control mice present only mild glomerular lesions.

**Conclusions:** These results point to a critical role of autophagy for the development of diabetes-induced glomerular disease representing a novel putative target to ameliorate diabetic nephropathy.

## SA-OR063

**miRNA Profiling in Human Diabetic Nephropathy** Francesca Conserva,[1] Paola Pontrelli,[1] Matteo Accetturo,[1] Anna Maria Di Palma,[1] Salvatore Di Paolo,[3] G. Grandaliano,[2] Loreto Gesualdo.[1] *[1]Dept of Emergency and Organ Transplants - Nephrology Unit, Univ of Bari, Italy; [2]Dept of Biomedical Sciences - Nephrology Unit, Univ of Foggia, Italy; [3]Nephrology and Dialysis Unit, Hospital Dimiccoli, Barletta, Italy.*

**Background:** Diabetic Nephropathy (DN) is a clinical complication of Diabetes. Up to date there is still no cure for DN and this condition has rapidly become the primary cause of End Stage Renal Disease (ESRD). As widely acknowledged, microRNA expression is tightly connected to protein synthesis as each microRNA can induce translational repression of hundreds of targets. Aim of our study was to identify a pattern of differentially expressed microRNAs in kidney biopsies of patients with DN and analyze the role of their putative targets in the pathogenesis and progression of the disease.

**Methods:** Using microarray technology we assayed microRNA expression in formalin fixed kidney tissues from 8 DN patients showing increased proteinuria and decreased glomerular filtration rate (GFR), and 4 control patients with no histological signs of nephropathy. Selected microRNAs were then validated using quantitative PCR.

**Results:** 76 miRNAs were differentially expressed in DN, of which 18 were further validated using quantitative PCR. The microRNA/mRNA joint target analysis revealed three proteins whose reduction could be crucial in the context of glomerular filtration: vascular endothelial growth factor (VEGF-A), essential for podocytes survival and preservation of the glomerular microvasculature; membrane-associated guanylate kinase inverted 2 (MAGI2), a newly discovered component of the slit diaphragm; and sulfatase 1 (SULF1), an enzyme that modulates the interaction of heparan sulfate glycosaminoglycans with growth factors, cytokines, chemokines and adhesion molecules.

**Conclusions:** To our knowledge there is no previous study reporting the microRNA profile of human DN kidney. The validation of these microRNAs in biofluids along with further functional studies in terms of mRNA target validation will soon allow the identification of novel disease biomarkers and untangle novel key players in DN progression.

## SA-OR064

**Systems Biology Approaches in Understanding Diabetic and Non-Diabetic Kidney Disease Risk Loci** Nora Ledo, Yi-An Ko, Ae Seo Deok Park, Katalin Susztak. *Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA.*

**Background:** Recent genome-wide association studies (GWAS) have identified multiple loci associated with the risk of chronic kidney disease (CKD) development. The functional role of these loci and the nearby genes is largely unknown. The aim of our study is to map the expression of these genes in normal and disease human kidney samples using systems biology approaches.

**Methods:** We interrogated the expression and regulation of 86 different transcripts that was associated with 211 single nucleotide polymorphisms. Baseline transcript expression was examined by whole human kidney RNA-sequencing. In addition, expression arrays of 92 microdissected (glomeruli and tubules) control, diabetic and hypertensive human kidney samples were analyzed.

**Results:** Among the 86 different transcripts, 57 genes were expressed in the kidney based on the RNA-sequencing data. Only 6 genes showed significantly higher expression in glomeruli compared to tubules ($p<0.05$, fold change>1.5), while 8 genes were specific for tubules in normal human kidney samples. In hypertensive CKD 18 genes were down-regulated, 2 were up-regulated ($p<0.01$). In diabetic kidney disease (DKD) 13 transcripts were down-regulated and 2 were up-regulated ($p<0.01$). Down-regulation of SORT1, DACH1 and SETDB1 and up-regulation of ALMS1 and TBX2 were observed exclusively in DKD, not in hypertensive CKD. Furthermore, of the 57 kidney expressed transcripts, 27 showed strong statistically significant linear correlation with eGFR levels; these included UMOD, NAT8, LASS2, SLC34A1, SLC6A13, ANXA9, SLC7A9 ($p<1E-04$). Network analysis of these eGFR-associated genes highlighted the enrichment for kidney development related pathways.

**Conclusions:** An important part of the post-GWAS functional characterization of the CKD risk loci is the analysis of the gene expression of nearby genes. We found that GWAS-associated genes are enriched for kidney developmental pathways. Our study did not find significant compartmental enrichment of these GWAS related genes. The expression of almost a third of these transcripts showed a strong association with renal function.

*Funding:* NIDDK Support

## SA-OR065

**Systems Genetics Identifies Drivers of Early Diabetic Kidney Disease** Claudiu V. Komorowsky,[1] Viji Nair,[1] E. Jennifer Weil,[2] Ann Randolph,[1] Berne Yee,[3] Kevin V. Lemley,[4] Robert G. Nelson,[2] Benjamin J. Keller,[1] Matthias Kretzler.[1] *[1]Nephrology, Univ of Michigan, Ann Arbor, MI; [2]Diabetes Epidemiology & Clinical Research Section, NIDDK, NIH, Phoenix, AZ; [3]Southwest Kidney Institute, Phoenix, AZ; [4]Nephrology, Children's Hospital LA, Univ of Southern California, Los Angeles, CA.*

**Background:** Genetic variation contributes to the risk of development and progression of diabetic kidney disease (DKD). We sought to elucidate the framework by which SNPs are linked via tissue-specific endophenotypic intermediaries to clinical outcome of human DKD.

**Methods:** 65 participants in the "Renoprotection in Early Diabetic Nephropathy in PIMA Indians Trial (NCT00340678)" underwent SNP genotyping. Matching protocol kidney biopsies were microdissected and profiled on an Affymetrix platform (HG-U133A/Plus2). Stepwise integration of expression quantitative trait locus analysis (eQTL), with weighted co-expression network analysis, quantitative morphometric analysis of renal biopsies (light- and electron microscopy) and deep clinical phenotypic data were leveraged for association analysis.

**Results:** Consistent with previous studies, the majority of eQTLs are located in non-coding regions of the genome. Joint eQTL and co-expression module analysis suggests that gene expression alterations in inflammatory processes are genetically determined and are major drivers of human DKD. Moreover, phenotypic data (morphometry, prospective clinical outcome measurements) was leveraged as functional and clinically relevant framework for variant and gene prioritization. Top eQTLs linked to clinical traits (SNP–Gene–Trait triads: 66 unique SNPs, 83 transcripts and 3 clinical traits) involve genes regulating cellular growth and metabolic adaptation (*e.g. SIRT3*), and inflammatory processes (*e.g. CD48, CSF1R*). Furthermore, we implicate genes not previously linked to diabetes or its complications (*e.g. ADAM12*).

**Conclusions:** Structured integration of information across the genome-phenome continuum offers unique insight into the genetic architecture of DKD. Moreover, it facilitates a systems-based prioritization of variants and linked transcriptional processes for further functional studies in humans and model organisms.

## SA-OR066

**Inhibition of EGFR Activity Protects against Diabetic Nephropathy by Decreasing ER Stress and Augmenting Autophagy** Ming-Zhi Zhang, Bing Yao, Raymond C. Harris. *Medicine, Vanderbilt Univ School of Medicine, Nashville, TN.*

**Background:** Previous studies have indicated activation of renal epidermal growth factor receptors (EGFR) in models of diabetic nephropathy (DN). In the present studies, we examined the effect of treatment with erlotinib, an inhibitor of EGFR tyrosine kinase activity, in the development of DN.

**Methods:** Male eNOS-/- mice on BKS background received daily injections of streptozotocin (STZ; 50 mg/kg i.p.) for 5 consecutive days. The mice were divided into 3 groups: non-diabetes, diabetes with vehicle (water), and diabetes with erlotinib (80 mg/kg/day, daily gastric gavage, 24 weeks).

**Results:** Inhibition of renal EGFR activation by erlotinib was confirmed by decreased phosphorylation of EGFR. Increased ACR in diabetic mice was markedly attenuated by erlotinib treatment (ACR: μg/mg: non-diabetes: 473 ± 96; diabetes: 1516 ± 234, $P < 0.01$ vs. non-diabetes; diabetes + erlotinib: 576 ± 112, $P < 0.01$ vs. diabetes. $N = 4$ in each group). Erlotinib protection against diabetic nephropathy was also indicated by less histological glomerular injury as well as decreases in renal expression of fibronectin and collagen 1. The mammalian target of rapamycin (mTOR) pathway, a key factor in the development of DN, has been reported to be inhibited by AMPK activation. Erlotinib treatment led to activation of AMPK and inhibition of mTOR pathway as evidenced by decreased phosphorylation of mTOR and its downstream target, S6K. Autophagy plays an important role in the pathophysiology of diabetes mellitus, and impaired autophagy may lead to increased endoplasmic reticulum (ER) stress and subsequent tissue injury. In diabetic mice, erlotinib treatment led to activation of renal autophagy as indicated by increased expression and activity of LC3A, a hallmark of autophagy, and was associated with decreased ER stress as indicated by decreased expression of CHOP, BIP and PERK.

**Conclusions:** These studies suggest that inhibition of EGFR with erlotinib attenuates the development of DN in type I diabetes, mediated in part by inhibition of mTOR pathway and subsequent activation of autophagy and inhibition of ER stress.

## SA-OR067

**Role of Sirtuin-1 in Deacetylation of Transcription Factors during Diabetic Nephropathy** Yifei Zhong,[1] Ruijie Liu,[2] John C. He.[3] *[1]Nephropathy, Longhua Hospital, Shanghai Univ of Traditional Chinese Medicine, Shanghai, China; [2]Medicine, Mount Sinai School of Medicine, James J. Peters VAMC, New York City, NY; [3]Inst#2.*

**Background:** Acetylation and deacetylation of transcription factors such as NF-κB and STAT3 have been recognized as important events in pathogenesis of diabetic kidney disease (DKD). Sirtuin-1 (Sirt1) is an enzyme that mediates nicotinamide adenine dinucleotide-dependent deacetylation and can regulates several transcription factor's activity through deacetylation.

**Methods:** Diabetic db/db mice, podocyte-specific Sirt1 knockout diabetic db/db mice and human kidney biopsies were employed in the study. Kidney morphology and apoptosis were examined by PAS and TUNEL stainings respectively. Expression of acetyl-NF-kB and acetyl-STAT3 were examined by immnostaining.

**Results:** Acetylation of NF-κB and STAT3 were increased in the kidneys of both diabetic mice and patients.Moreover, when diabetic db/db mice were treated with pyridoxamine that restored Sirt1 expression, there were an increased level of Sirt1 and decreased acetylation of NF-kB and STAT3 in the kidney. In addition, pyridoxamine attenuated formation of proteinuria. It also improved kidney apoptosis. Furthermore, when Sirt1 was deleted in podocytes of db/db mice, there were aggravated proteinuria and kidney injury as compared to wild-type db/db mice. At the same time, acetylation of NF-kB and STAT3 was increased in podocte-specific Sirt1 knockout diabetic db/db mice.

**Conclusions:** Sirt1 could regulate acetylation of NF-kB and STAT3, which makes Sirt1 as a new therapeutic target for treatment of diabetic nephropathy.

## SA-OR068

### Gene Expression Differences in Skin Fibroblasts (SF) of Type 1 Diabetic (T1D) Patients (pts) with and without Diabetic Nephropathy (DN)

Maria Luiza A. Caramori,[1] Youngki Kim,[1] Jason H. Moore,[2] Stephen Rich,[3] Andrzej S. Krolewski,[4] Allison B. Goldfine,[4] Helen D. Nickerson,[5] Michael Mauer.[1] *[1]U of MN; [2]Dartmouth College; [3]U of VA; [4]Joslin Diabetes Center; [5]JDRF.*

**Background:** The in vitro behaviors of SF from pts with and without DN have been associated with DN risk.

**Methods:** We performed research skin biopsies in 100 former Genetics of Kidneys in Diabetes (GoKinD) pts. SF were grown in high glucose (HG, 25 mmol/L) for 3-4 passages until 90% confluence and gene expression determined by RNAseq in 40 DN controls (long-standing T1D duration and normoalbuminuria; C) and 60 DN cases (35 proteinuric [P] and 25 ESRD). Directional Exploratory Visual Analysis determined whether differentially expressed genes were over represented in KEGG pathways.

**Results:** Cases were older (56±7 vs. 48±11 years; p<0.001) and had longer T1D duration (44±8 vs. 35±7 years; p<0.001) than C. Systolic blood pressure (BP) was higher in ESRD (137±20) than in P (127±17 mmHg; p<0.02) or C (121±14; p<0.001). There were no differences in sex distribution, $HbA_{1c}$ or diastolic BP among groups. Spliceosome ($p=8.4^{e-17}$), Cell cycle ($p=3.7^{e-15}$), DNA replication ($p=1.8^{e-14}$), Proteasome ($p=8.9^{e-10}$), Pyrimidine metabolism ($p=5.4^{e-7}$), Purine metabolism ($p=9.1^{e-7}$), Mismatch repair ($p=3.9^{e-6}$), RNA degradation ($p=2.1^{e-5}$), Base excision repair ($p=5.1^{e-5}$), Ribosome ($p=8.4^{e-5}$), Terpenoid backbone biosynthesis ($p=8.6^{e-5}$), Propanoate metabolism ($p=1.4^{e-3}$), Cysteine and methionine metabolism ($p=2.4^{e-3}$), Fatty-acid metabolism ($p=4.0^{e-3}$), Glycolysis-Gluconeogenesis ($p=4.9^{e-3}$), Nucleotide excision repair ($p=6.1^{e-3}$), Homologous recombination ($p=7.2^{e-4}$), Pyruvate metabolism ($p=7.2^{e-3}$), and TCA-citrate cycle ($p=1.7^{e-3}$) were up-regulated in C vs. DN cases. The results were similar when C were compared to P or ESRD pts only.

**Conclusions:** There are robust differences in gene expression in SF grown in HG between pts with and without DN. T1D pts without DN despite long T1D duration show increased expression of genes in pathways predominantly related to cell cycle, cell cycle regulation and cell repair mechanisms. These findings are consistent with previous observations indicating protective mechanisms in T1D pts without DN.

## SA-OR069

### Renal Outcomes with Aliskiren in Patients with Type 2 Diabetes: A Pre-Specified Analysis from ALTITUDE

Hiddo Jan Lambers Heerspink,[1] Barry M. Brenner,[2] Frederik I. Persson,[3] Nish Chaturvedi,[4] Scott D. Solomon,[2] Marc A. Pfeffer,[2] Hans-Henrik Parving,[5] Dick de Zeeuw.[1] *[1]Clinical Pharmacology, Univ Medical Center Groningen, Netherlands; [2]Brigham Woman Hospital, Boston; [3]Steno Diabetes Center, Denmark; [4]Imperial College London, United Kingdom; [5]Aarhus Univ, Denmark.*

**Background:** The ALTITUDE (The Aliskiren Trial in Type 2 Diabetes Using Cardiorenal Endpoints) trial showed no benefit of aliskiren on renal outcomes (doubling of serum creatinine, ESRD or renal death) as an adjunct to angiotensin-converting-enzyme inhibitors or angiotensin receptor blockers. We performed a pre-specified analysis of the ALTITUDE trial analyzing the effects of aliskiren on intermediate renal outcomes.

**Methods:** In a double blind randomized controlled trial, 8561 patients were assigned to aliskiren 300 mg/day or placebo and followed for a median of 2.8 years. Intermediate renal endpoints were transitions in albuminuria-stages (i.e. normo-, micro, or macroalbuminuria) and rate of estimated glomerular filtration rate (eGFR) decline either calculated from baseline or from month 6, thus excluding the acute effect of aliskiren on eGFR.

**Results:** Aliskiren significantly decreased progression as well as increased regression of transitions in albuminuria classes by 14% (HR 0.86, 95%CI 0.77 – 0.95) and 27% (HR 1.27, 95%CI 1.17 – 1.37), respectively. Annual rate of eGFR decline was 3.1 ml/min/1.73m$^2$/year in the aliskiren and 3.0 ml/min/1.73m$^2$/year in the placebo group (p=0.52). However, subjects assigned to aliskiren had a significantly greater fall in eGFR during the first 6 months compared to placebo (2.5 vs. 1.4 ml/min/1.73m$^2$; p<0.001), but a slightly slower annual rate of eGFR decline thereafter (2.8 vs. 3.1 ml/min/1.73m$^2$/year; p=0.068).

**Conclusions:** Although the ALTITUDE showed no beneficial effect of aliskiren on hard renal outcomes, aliskiren did delay progression to micro- and macroalbuminuria, and improved regression to micro- and normoalbuminuria. In addition, aliskiren attenuated the (chronic) eGFR decline. The lack of renoprotection with aliskiren, as measured on hard clinical outcomes requires further examination.

### Protective Effect of Angiotensin Receptor Blockers on Stroke Attenuates with Lower Renal Function: A Post-Hoc Analysis of RENAAL, IDNT and LIFE

Jarno Hoekman,[1] Frank Holtkamp,[1] Hans Ibsen,[3] Hans-Henrik Parving,[2] Hiddo Jan Lambers Heerspink,[1] Dick de Zeeuw.[1] *[1]Dept Clinical Pharmacology, Univ Med Cent Groningen, Netherlands; [2]Dept Med Endocrinology, Rigshospitalet, Univ of Copenhagen, Denmark; [3]Div Cardiology, Holbæk Hospital, Holbæk, Denmark.*

**Background:** Recent clinical trials in type 2 diabetes and nephropathy assessing the effect of potential cardiorenal protective drugs, including dual Renin-Angiotensin-Aldosterone-System (RAAS) blockade, reported unexpected effects on stroke incidence. We performed a post-hoc analysis in three large trials to study whether specific baseline parameters modify the effect of RAAS-blockade on stroke.

**Methods:** Patients with type 2 diabetes were randomized to losartan or placebo (RENAAL), losartan or atenolol (LIFE), or irbesartan, placebo or amlodipine (IDNT). The total population comprised 4175 subjects. Median follow-up was 3.2 years. Stroke was part of a secondary endpoint in all trials. Homogeneity in treatment effect was tested by adding an interaction term (treatment*baseline parameter) to a multivariable Cox model that included age, sex, systolic blood pressure (BP), eGFR, and albuminuria. Treatment effects were compared in subgroups defined by thirds of the relevant baseline parameter.

**Results:** The effect of ARB therapy was modified by baseline eGFR (p for interaction = 0.03) and not by other baseline parameters. A total of 1215 had eGFR>60, 2267 had eGFR between 30 and 60, and 693 had eGFR <30 ml/min/1.73m$^2$. After 12 months, BP was reduced by 2.3 mmHg (95%CI -3.6 to -1.0) and albuminuria by 28% (35 to 20) in the overall population. Effects did not differ between baseline eGFR subgroups. The risk of stroke was reduced by 36% (-4 to 60) in patients with eGFR>60, reduced by 11% (-28 to 35) in those with eGFR 30 to 60 and increased by 38% (-31 to 174) in those with eGFR<30 ml/min/1.73m$^2$. The risk of other cardiovascular events did not differ between eGFR subgroups.

**Conclusions:** The protective effect of ARB therapy on stroke attenuates at lower eGFR in patients with type 2 diabetes despite similar reductions in BP and albuminuria. This suggests that other, yet unknown, mechanisms account for the lack of protection of ARB therapy in these patients.

*Funding:* Pharmaceutical Company Support - The RENAAL and LIFE trials were sponsored by Merck & Co. The IDNT trial was sponsored by Bristol-Meyers Squibb.

## SA-OR071

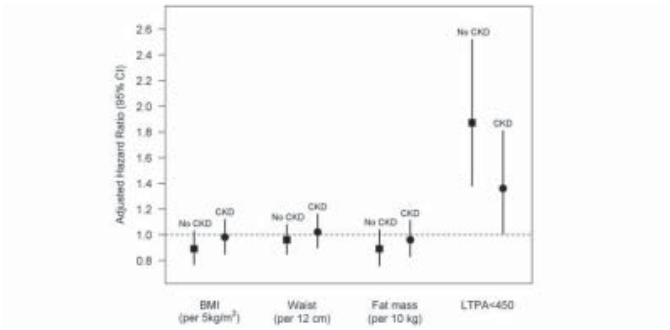
### Adiposity Measures, Physical Activity and Death in CKD: NHANES 1999-2004

Sankar D. Navaneethan,[1] John P. Kirwan,[2] Susana Arrigain,[3] Jesse D. Schold.[3] *[1]Nephrology; [2]Pathobiology; [3]Quantitative Health Sciences, Cleveland Clinic.*

**Background:** Few studies have examined the effects of various adipose tissue measures and leisure time physical activity (LTPA) on mortality.

**Methods:** Data from the National Health and Nutrition Examination Surveys (NHANES) 1999-2004 was used in this analysis. We studied the associations between adiposity measures (total fat mass measured by DEXA), waist circumference [WC], body mass index [BMI] and LTPA with all-cause mortality in those with and without CKD. LTPA was categorized into less than minimum goal (<450 MET/min/week) and at least meeting the minimum goal (>450 MET/min/week) as recommended by national guidelines. Multivariate models were adjusted for demographics, smoking, C- reactive protein, malignancy, eGFR and albuminuria.

**Results:** We included 2153 CKD participant and 9,433 non-CKD participants who had fat mass measured using DEXA, BMI, WC, LTPA and mortality data. After adjusting for covariates, there was no significant risk for death noted with higher WC, fat mass and BMI in those with and without CKD (Figure). When examining normal, overweight and obese groups based on BMI criteria, being overweight (BMI 25-29.9) was associated with lower risk of death in those without CKD (Hazard ratio 0.64, 95% CI 0.45, 0.92). There was a significantly higher risk for death among those who did not meet the minimum LTPA goals compared to those who met or exceeded the recommended activity levels in patients with and without CKD (CKD Hazard ratio: 1.36, 95% CI 1.01, 1.81; non-CKD HR 1.87, 95% CI 1.38, 2.52)(Figure).



**Conclusions:** Lower physical activity, but not adipose tissue measures is associated with higher mortality in those with and without CKD in the representative US population. Future studies should study the effects of improving physical activity levels particularly in the CKD population.

## SA-OR072

**Versican and Mortality in Type 2 Diabetic Patients** Bernt Johan Illum von Scholten,[1] Maria Lajer,[1] Diana Julie Leeming,[2] Anne-Mari Gall,[1] Hans-Henrik Parving,[3] Lars M. Rasmussen,[4] Morten Asser Karsdal,[2] Peter Rossing.[1] *[1]Steno Diabetes Center, Denmark; [2]Nordic Bioscience, Denmark; [3]Rigshospitalet, Denmark; [4]Odense Univ Hospital, Denmark.*

**Background:** Extracellular matrix remodelling (ECMr) is a central part in many diseases, in which matrix metallo protease (MMP) driven proteolytic tissue destruction is central in the pathogenesis, such as kidney failure and cardiovascular related diseases. When tissue proteins are degraded by proteases, small fragments are released into the circulation where they may be used as quantitative biomarkers. Versican (VCAN) is an anti-adhesive proteoglycan involved in inflammation and associated with cardiovascular diseases. MMP-12 degraded VCAN circulates in plasma. We aimed to investigate the prognostic value of plasma MMP degraded VCAN in relation to all-cause and cardiovascular mortality in a cohort of type 2 diabetic patients.

**Methods:** In a prospective observational follow-up study, 165 type 2 diabetic patients (101 men; aged 53.9 ± 8.8 years) were followed for a median of 16.8 years (range 0.2-23.0). Baseline plasma VCAN concentrations were determined by ELISA assay. The assay recognises exclusively MMP degraded VCAN, and not intact version nor other closely related proteins.

**Results:** During follow-up, 71 (43%) patients died. Elevated levels of VCAN was borderline associated with all-cause mortality (covariate-adjusted for urinary albumin excretion rate [UAER], estimated glomerular filtration rate, p-NT-proBNP, and conventional risk factors); hazard ratio (HR) 2.64 [95% CI 0.93-7.52] p=0.069. Within groups divided according to level of UAER (normo-, micro- and macroalbuminuria), VCAN was predictive of all-cause mortality in microalbuminuria HR 14.96 (1.23 to 181) and macroalbuminuria HR 250 (3.2 to 19437) but not normoalbuminuria.

**Conclusions:** Elevated plasma VCAN is an independent predictor of all-cause mortality in type 2 diabetic patients with elevated UAER. The effect of VCAN on all-cause mortality was independent of conventional cardiovascular risk factors, UAER, and p-NT-proBNP levels.

## SA-OR073

**Identification of Urine Biomarkers to Predict Early Renal Function Decline in Patients with Type 2 Diabetes** Nishant M. Bhensdadia,[1] Kelly J. Hunt,[1] Joseph Alge,[1] Benjamin Neely,[1] Michael G. Janech,[1,2] John M. Arthur.[1,2] *[1]Nephrology, Medical Univ of South Carolina, Charleston, SC; [2]Nephrology, Ralph H Johnson VA Medical Center, Charleston, SC.*

**Background:** Diabetic nephropathy accounts for 44% of End Stage Renal Disease in United States. We have previously shown urine haptoglobin to urine creatinine ratio could predict patients at risk of renal functional decline. Here we have measured additional candidate markers in urine.

**Methods:** Urine samples of 88 randomly-selected type 2 diabetic patients with eGFR≥60 ml/min and ACR<300 mg/g were used to measure 9 candidate markers (Ceruloplasm, Non-secretory ribonuclease, VIP 36, CD 59 glycoprotein, Nidogen-1, Albumin, Alpha-2HS glycoprotein, Syndecan 4, Beta-hexosaminidase alpha subunit) using LC-MS/MS (Liquid Chromatography Mass Spectrometry) based PRM (Parallel Reaction Monitoring) method. Early Renal Functional Decline (ERFD) was defined as ≥3.3% eGFR decline per year.

**Results:** 16 out of 88 type 2 diabetic patients had ERFD. Creatinine normalized concentration of five candidate biomarkers (Ceruloplasm, Non-secretory ribonuclease, VIP 36, CD 59 glycoprotein, Nidogen-1) had AUC values to predict ERFD which exceeded 0.65 with p value <0.05. Ceruloplasm had the highest AUC value of 0.69 and a p value of 0.017. For comparison creatinine normalized albumin had an AUC value of 0.65 with p value of 0.055.

**Conclusions:** We have identified urine ceruloplasm to creatinine ratio as a biomarker along with 4 other urinary proteins (Non-secretory ribonuclease, VIP 36, CD 59 glycoprotein, Nidogen-1) which can predict ERFD with AUC values which are higher than the AUC for albumin to creatinine ratio in type 2 diabetic patients prior to the development of macroalbumiuria or reduced eGFR.

*Funding:* NIDDK Support, Veterans Affairs Support

## SA-OR074

**Urinary Monocyte Chemotactic Protein-1 and Early Diabetic Nephropathy (DN) Lesions** Michael Mauer,[1] Brad H. Rovin,[2] Jon B. Klein,[3] Vasan S. Ramachandran,[4] Harold I. Feldman,[5] Paul L. Kimmel,[6] John W. Kusek,[6] Robert G. Nelson.[7] *[1]Pediatrics, Univ of Minnesota, Minneapolis, MN; [2]Medicine, Ohio State Univ, Columbus, OH; [3]Medicine, Univ of Louisville, Louisville, KY; [4]Medicine, Boston Univ, Boston, MA; [5]Medicine, Univ of Pennsylvania, Philadelphia, PA; [6]NIDDK NIH, Bethesda, MD; [7]NIDDK NIH, Phoenix, AZ.*

**Background:** MCP-1 is a key chemokine regulating monocytes/macrophages migration and infiltration. We asked whether urinary MCP-1 levels are associated with DN lesion severity or the rate of change in DN lesions over 5 yrs in serial biopsy samples in normoalbuminuric normotensive, normal GFR patients (pts) with type 1 diabetes (T1D, duration 3-20 years) in the Renin Angiotensin System Study (RASS).

**Methods:** The progression of DN lesions was not slowed by RAS blockade in the trial. MCP-1 levels were measured by ELISA in baseline urines stored at -80°C and adjusted for urinary creatinine (MCP-1/UCr); 166 of 246 pts had measurable MCP-1/UCr levels.

**Results:** There was no statistically significant association between baseline MCP-1/UCr and the baseline biopsy severity of DN lesions. Higher MCP-1/UCr was associated with greater increases over 5 years in interstitial fractional volume [Vv(Int/cortex)] and glomerular basement membrane (GBM) width but not mesangial fractional volume [Vv(Mes/glom)] (Table 1). However, adjusted for T1D duration, HbA1c, age and sex, only change in GBM width remained statistically significant.

**Conclusions:** We have previously shown that GBM width is a strong and independent predictor of progression from NA to proteinuria and ESRD in normoalbuminuric T1D patients, (Caramori *et al*, JASN, in press). In summary, MCP-1/UCr may be an early biomarker of the progression of important DN lesions in normoalbuminuric, normotensive, normal GFR T1D patients consistent with the notion that inflammatory processes may be involved in the pathogenesis of early DN structural changes. FOR THE BIOMARKER CONSORTIUM.

| Dependent Variable: Delta 5 years | Predictor Variable: Urine MCP-1/Cr* |
|---|---|
| GBM Width | 0.0364 (0.02) |
| Vv(Mes/glom) | 0.0000 (0.37) |
| Vv(Int/cortex) | <0.0001 (0.01) |

## SA-OR075

**Clinical Significance of Linear Immunofluorescent IgG Staining in Patients with Diabetic Nephropathy** Koki Mise, Junichi Hoshino, Yoshifumi Ubara, Masahiro Kawada, Rikako Hiramatsu, Toshiharu Ueno, Keiichi Sumida, Tatsuya Suwabe, Shigeko Hara, Kenmei Takaichi. *Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

**Background:** The kidneys of diabetic patients usually exhibit a characteristic pattern of linear immunofluorescent staining for IgG along the glomerular and tubular basement membranes. However, the association between linear IgG staining and the clinical outcome remains unclear.

**Methods:** Among 233 patients with diabetes mellitus who underwent renal biopsy from 1985 to 2010 and were confirmed to have pure diabetic nephropathy according to the classification of Tervaert et al., 159 patients (glomerular class I to III) were enrolled in this study. Immunofluorescent staining was classified into three categories (0=none, 1=weakly positive, 2= positive) according to its intensity. Cox proportional hazards regression analysis was used to calculate the hazard ratio (HR) and 95% confidence interval (CI) for death-censored renal death, with each regression analysis examining two levels of multivariate adjustment. Renal death was defined as commencement of dialysis due to end-stage renal disease.

**Results:** After adjustment for age, gender, estimated glomerular filtration rate, type of diabetes, urinary protein excretion, systolic blood pressure, body mass index, HbA1c, diabetic retinopathy, and red blood cells in urinary sediment at the time of renal biopsy, the HRs for death-censored renal death of patients with IgG staining scores of 1 or 2 were 3.12 (95% CI: 1.08-9.14) and 4.50 (1.60-12.68), respectively, compared with patients whose staining score was 0.

**Conclusions:** More intense linear IgG staining is associated with higher HRs for renal death. This suggests that linear immunofluorescent staining for IgG may be a prognostic pathological finding in patients with diabetic nephropathy.

**SA-OR076**

**Serum and Urinary Levels of TNFRs and Decreasing Renal Function in Type 1 Diabetes (T1D)** Jung Eun Lee,[1,2,3] Tomohito Gohda,[1,2,4] Jan Skupien,[1,2,5] William Walker,[1] Kevin P. McDonnell,[1] Rita R. Holak,[1] Adam Smiles,[1] Andrzej S. Krolewski,[1,2] Monika A. Niewczas.[1,2] *[1]Research Div, Joslin Diabetes Center, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Dept of Medicine, Saumsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea; [4]Dept of Internal Medicine, Juntendo Univ School of Medicine, Tokyo, Japan; [5]Dept of Metabolic Disease, Jagiellonian Univ Medical College, Krakow, Poland.*

**Background:** Increased circulating levels of soluble TNFR1 and TNFR2 are strong predictors of renal decline and progression to ESRD, however, the mechanism underlying this increase is unknown. This study aimed to determine serum and urinary patterns of TNFRs in subjects with T1D and various stages of diabetic nephropathy.

**Methods:** Study groups comprised T1D subjects with normo- or microalbuminuria (n=667), with proteinuria (n=412) and 78 healthy subjects. We determined serum and urinary concentrations of TNFR1 and TNFR2 and their respective fractional excretion (FE) in the study group.

**Results:** Subjects with T1D and proteinuria had higher levels of serum and urinary TNFRs compared with subjects without proteinuria ($P < 0.001$). In proteinuria group serum and urinary TNFRs concentrations and FE increased progressively with advanced chronic kidney disease (CKD) stages ($P < 0.001$ for trend). Findings for both TNFRs were similar, so TNFR1 data are shown.

| | Healthy (n=78) | T1D (n=667) No proteinuria CKD 1-2 | T1D (n=261) Proteinuria CKD 1-2 | T1D (n=151) Proteinuria CKD 3-4 |
|---|---|---|---|---|
| Serum TNFR1 (ng/mL) | 1.2 (1.0-1.4) | 1.4 (1.1-1.7) | 2.1 (1.9-2.6) | 4.5 (3.6-5.7) |
| Urinary TNFR1 (ng/mg Cr) | 0.7 (0.5-1.1) | 1.3 (0.9-1.9) | 2.2 (1.4-3.9) | 6.4 (2.7-12.0) |
| TNFR1 FE (%) | 0.5 (0.3-0.7) | 0.8 (0.5-1.2) | 0.9 (0.6-1.5) | 2.7 (1.1-5.2) |

**Conclusions:** Pattern of fractional excretion of TNFRs in our study suggests that increased levels of these receptors in serum and urine in TID subjects at high risk of renal decline and rapid progression to ESRD result from their increased systemic production rather than being a simple reflection of impaired glomerular filtration.

*Funding:* NIDDK Support

**SA-OR077**

**The Impact of Vitamin D Nuclear Receptor on Inflammation of Type 2 Diabetic Nephropathy Patients** Bin Yi, Hao Zhang, Xiao-Fang Hu, Jing Huang, Wei Li. *Dept of Nephrology, The Third Xiangya Hospital of Central South Univ, Changsha, Hunan, China.*

**Background:** The development of chronic inflammation is closely related with the progress of diabetic nephropathy(DN). Studies in vitro have shown that nuclear vitamin D receptor(nVDR) has anti-inflammatory effect. In order to investigate the impact of VDR on the inflammatory state of DN patients, we will detect the nVDR and NF-κB expressions of peripheral blood mononuclear cells and urinary chemokines excretion levels of MCP-1 and RANTES.

**Methods:** 143 subjects were enrolled, including 113 diabetic patients and 30 healthy subjects (NC group). According to the uACR, diabetics were divided into normal albuminuria group(DN0 group), microalbuminuria group(DN1 group), and macroalbuminuria group(DN2 group).Urine MCP-1 and RANTES levels were measured by ELISA. VDR and NF-κB expressions were detected by realtime qPCR and western-blotting. One-way analysis of variance, Pearson correlation analysis and multiple stepwise regression analysis were used for statistical analysis.

**Results:** VDR mRNA and nVDR protein expressions in diabetic groups were gradually decreased with the uACR increase, and significantly lower than those in NC group($p<0.05$). However, NF-κB levels of diabetic patients were gradually increased with the uACR, and NF-κB expressions in DN2 group were significantly higher than those in DN0 andDN1 group($p<0.05$). Urinary MCP-1/Cr and RANTES/Cr levels were significantly different between thegroups, and those in DN2 group were higher than the other three groups. Multivariate linear regression analyses showed that uACR was closed related with SBP, eGFR, VDR and NF-κBp65 levles, andurinary MCP-1 and RANTES excretion rate; the urinary MCP-1/Cr and RANTES/Cr were independently associated with eGFR,SBP and VDR levels.

**Conclusions:** The expression of nVDR were decreased in type 2 DN patients, and negatively related with uACR and urinary MCP-1/RANTES excretion rate. The down-regulation of nVDR may induce inflammation by over-expressed NF-κB, which may play a role in DN pathogenesis.

*Funding:* Government Support - Non-U.S.

**SA-OR078**

**Klotho Genomic Variants Impact on Serum Klotho and Patients Survival in Hemodialysis: The Arnogene Project** Denis Fouque,[1,2] Delphine Maucort-Boulch,[3] Jocelyne Drai,[4] Leslie Genet,[1] Guillaume Jean,[5] Christophe Marçais.[4] *[1]Nephrology, Centre Hospitalier Lyon Sud, Pierre Benite, France; [2]Carmen Cens, Univ de Lyon, Lyon, France; [3]Biostatistics, Centre Hospitalier Lyon Sud, Pierre Benite, France; [4]Biochimie, Centre Hospitalier Lyon Sud, Pierre Benite, France; [5]Dialysis, Nephrocare, Ste Foy, France.*

**Background:** Klotho (KL) is a recently discovered FGF23 cofactor involved in phosphorus metabolism. KL overexpression is associated with extended longevity, whereas KL-KO animals die prematurely.

**Methods:** We prospectively followed 769 hemodialysis (HD) pts between 2009 and 2012 and studied 3 KL genomic polymorphisms, serum KL protein and survival. KL polymorphisms (KL-VS, rs577912 and rs526906) were genotyped through dHPLC analysis and DNA sequencing. Serum α-KL was measured by Elisa (IBL, Japan, normal values 239-1266 pg/mL).

**Results:** Patients were 69±14 yr old, male (58%), diabetic (35%), smokers (37%), dialysis vintage was 6.0 yr, BMI 25.2. Serum phosphorus was 4.7±1.6mg/dL, calcium 8.9±0.7mg/dL, 25OH vit D 56 nmol/L. Median serum a-KL was 127.4 pg/mL (IQ 117-272), significantly lower than in controls. Overall mortality was 13.3% per year. Cox analyses adjusted on dialysis vintage showed that KL-VS homozygotes had a 12% better survival compared to patients without the KL-VS allele (non significant trend). By contrast, homozygotes for rs577912 minor allele had a survival reduced by 20% ($p=0.05$) compared to homozygotes for rs577912 major allele. There was no trend of rs526906 polymorphism on survival. Accordingly, KL-VS homozygocity was associated with a higher serum a-KL concentration (245 vs 116pg/mL), whereas the detrimental rs577912 minor allele homozygocity was associated with a lower serum a-KL (116 vs 130pg/mL).

**Conclusions:** This is the first long term study showing that KL polymorphisms may impact on HD patients survival. Furthermore, KL expression differed depending on KL-VS and rs577912 genotypes, and genotypes with better survival had higher serum a-KL. Whether attempts to increase serum a-KL will improve survival should be tested in future trials.

*Funding:* Government Support - Non-U.S.

**SA-OR079**

**Oral Nutrition Supplements and Readmission Rate in Hypoalbuminemic Dialysis Patients** Eduardo K. Lacson, Weiling Wang, Franklin W. Maddux. *Fresenius Medical Care, North America, Waltham, MA.*

**Background:** Our group has shown that intradialytic oral nutrition supplements (ONS) associated with reduced hospitalization risk in hemodialysis (HD) patients. We evaluated whether early start of ONS within 30 days post-discharge will decrease readmission rates.

**Methods:** All adult HD patients, treated 3x/week on 1/1/2011 in Fresenius Medical Care, North America facilities with their 1st hospital discharge in 2011 were followed for up to 30 days. Patients with post-discharge albumin of ≤3.5 g/dL without ONS use during the 90 days prior to the index hospital admission were eligible. Patients prescribed ONS thereafter were in the ONS group, else were controls. Case-mix (age, gender, race, diabetes mellitus, vintage, access type, BMI, and hospitalization history during 10/1 -12/31/10 plus 3-month means for albumin, hemoglobin, phosphorus, and eKt/V) was recorded as of 1/1/11. Odds ratios (OR) for 30-day readmission were calculated by logistic regression in the overall cohort and in a 2:1 case-mix-based propensity score plus "time-to-albumin result" matched cohort.

**Results:** From 64,128 patients with ≥1 hospital discharge in 2011, 14,435 (22.5%) had no albumin result within 30 days post-discharge, 44,214 (68.9%) had albumin >3.5 g/dL and the remaining 5,479(8.5%) patients had at least one albumin ≤3.5 g/dl. Among the latter, 1,420 (25.9%) ONS patients and 4,059 (74.1%) controls were analyzed. Albumin was resulted within 7.3 ± 6.4 days (IQR: 2-11; median: 5) for ONS vs. 9.9 ± 8.6 days (IQR: 3-16; median: 7) for controls. The mean time from discharge to readmission was 20.3±6.5 days (IQR: 15-16; median: 21) for ONS vs. 15.8 ± 7.6 days (IQR: 9-22; median: 15) for controls. Among ONS patients, the mean time from albumin result to first ONS taken was 16.4±7.2 days (IQR: 10.5-22; median: 16). Readmission OR=2.64 (unadjusted) and 2.27 (adjusted) for controls vs. ONS, and remained at 1.69 for the matched comparison of 1,848 controls with 950 ONS patients (all $p<0.0001$).

**Conclusions:** ONS use was significantly associated with reduced 30-day readmission rate in chronic HD patients. There could be residual confounding from unmeasured factors. These results require confirmation in prospective clinical trials.

## SA-OR080

**Resistance Exercise Program Improves Protein-Energy Wasting and Inflammation in Hemodialysis Patients** Cristiane Moraes,[1] Sandra Mara Silva de Azevedo Marinho,[2] Milena Barcza Stockler-Pinto,[3] Wellington Seguins da Silva,[4] Maria Thereza Baptista Wady,[4] Antonio Nobrega,[1] Denise Mafra.[1] *[1]Graduate Program in Cardiovascular Sciences, Fluminense Federal Univ, Niterói, RJ, Brazil; [2]Graduate Program in Medical Sciences, Fluminense Federal Univ, Niterói, RJ, Brazil; [3]Carlos Chagas Filho Biophysic Institute, Federal Univ of Rio de Janeiro, Rio de Janeiro, RJ, Brazil; [4]Immunology Institute, Oswaldo Cruz Foundation, Rio de Janeiro, RJ, Brazil.*

**Background:** Inflammation and protein-energy wasting (PEW) are highly prevalent in hemodialysis (HD) patients. We assessed the effects of reistance exercise (RE) on these conditions.

**Methods:** Patients (n=38,45.9±14.1yrs,61% men,BMI 23.8±4kg/m$^2$) underwent 6 months of RE (3x/week, intradialytic) with elastic bands and bilateral ankle loads. Adhesion molecules (ICAM-1, VCAM-1) were measured by EIA and, interleukin-6 (IL-6), C-reactive protein (CRP) and Tumor Necrosis Factor-Alpha (TNF-α) by ELISA. PEW was diagnosed if patient had simultaneously: BMI<23kg/m$^2$, albumin <4g/dL and,reduced mid-arm muscle circumference area.

**Results:** Adhesion molecules, CRP and, PEW reduced and, physical capacity improved significantly.

**Conclusions:** RE improved PEW and inflammation of HD patients.

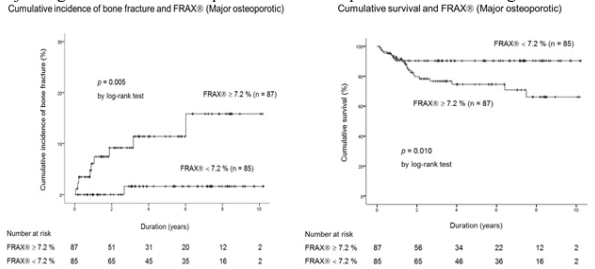
**Bone Fracture and Mortality Risk Prediction Using FRAX® in Male Japanese Hemodialysis Patients** Toshihide Hayashi, Nobuhiko Joki, Yuri Tanaka, Hiroki Hase. *Div of Nephrology, Toho Univ Ohashi Medical Center, Tokyo, Japan.*

**Background:** Individuals with bone fracture are at substantially increased risk of mortality. Recently, The World Health Organization Fracture Risk Assessment Tool (FRAX®) has been developed to estimate a 10-year absolute risk of major osteoporotic fracture among general population; however the evidence in CKD patients has been lacking. We, therefore, conducted this hospital-based prospective cohort study to evaluate the predictive ability of FRAX®, not only for fracture but also for mortality, in hemodialysis patients.

**Methods:** We studied a total 172 Japanese men (mean ± SD age; 67 ± 14 years), who had been instituted maintenance hemodialysis from March 2003 to November 2012. Patients were divided into two groups according to the median value of FRAX® for major osteoporotic fracture. The endpoint was defined as all-cause bone fracture and death. The Cox proportional hazard model was used to calculate the hazard ratio (HR) and 95% CI.

**Results:** The baseline mean (± SD) FRAX® for major osteoporotic fracture was 8.5 ± 5.4 %. Total 10 fractures during a mean (± SD) follow-up period of 4.1 ± 3.0 years, and 29 deaths during which of 4.3 ± 3.0 years were observed. Cumulative incidence of fracture in patients with FRAX® below and above the median was 1.2 and 10.3 % ($p$ = 0.005, log-rank test), and cumulative survival was 90.6 and 75.9 % ($p$ = 0.010, log-rank test), respectively. In multivariate Cox regression analysis, FRAX® was significantly associated with both fracture (HR 1.14, 95% CI 1.05 to 1.23) and mortality (HR 1.11, 95% CI 1.04 to 1.18), adjusting for covariates except for clinical component of FRAX® algorithm.



**Conclusions:** These results indicate that FRAX® predict bone fracture risk as well as general population, and mortality risk in hemodialysis patients.

## SA-OR082

**Soluble Ferric Pyrophosphate (SFP) Administered via Dialysate Reduces ESA Requirements in CKD-HD Patients with ESA Hypo-Response** Vivian H. Lin, Tasha M. Farmer, Carrie D. Guss, Raymond D. Pratt, Ajay Gupta. *Rockwell Medical Inc.*

**Background:** SFP added to bicarbonate concentrate crosses the dialyzer membrane and binds to apotransferrin during hemodialysis.

**Methods:** In this double-blind RCT, 103 iron replete, CKD-HD patients were randomized to either SFP dialysate (2 μM or 110 μg iron/L) or placebo, (premixed liquid bicarbonate). Two strata were prospectively defined (Table). ESA was managed by a centralized Anemia Management Center to facilitate consistent adherence to the hemoglobin target range of 95 to 115 g/L. IV iron administration was protocol defined.

**Results:** The primary end-point was change in prescribed ESA dose from baseline to end of treatment (EoT). The SFP group required 35% less prescribed ESA compared to placebo (p=0.045). The subgroup analysis examined the effect of SFP in patients with relative ESA resistance (baseline ESA doses ≥ 13,000 U/week)compared to those who were normo-responsive to ESA.

| | Stratum 1 (ESA< 13,000 U/wk) N=80 | | Stratum 2 (≥13,000 U/wk) N=23 | |
|---|---|---|---|---|
| | SFP N=40 | Placebo N=40 | SFP N=12 | Placebo N=11 |
| Hgb (g/L) BL | 109.2 | 111.3 | 110.7 | 110.2 |
| Hgb (g/L) EoT | 103.7 | 103.9 | 108.5 | 104.5 |
| ESA (U/wk) BL | 7083.2 | 7300.0 | 17,483 | 16,134 |
| ESA (U/wk)) EoT | 7913.6 | 9251.8 | 16,386 | 24,909 |
| LS Mean % change Mean ± SE | 7.6 ± 12.08 | 34.0 ± 12.08 | -8.5 ± 33.4 | 65.9 ± 34.83 |
| LS Mean Difference Mean ± SE (95% CI) | -26.4 ± 17.18 (-60.6, 7.8) | | -74.4 ± 48.23 (-175, 26.2) | |

SFP reduced ESA utilization in both subgroups, compared to placebo. Subgroup size was not suffiicient for statistical significance, however the results were similar in each group; a reduction in prescribed ESA favoring SFP. The effect was numerically larger in the hypo-responsive group. Reticulocyte Hgb was better maintained in the SFP group. The adverse events in the SFP group were similar in frequency and severity to placebo.

**Conclusions:** SFP, delivered via dialysate, reduces ESA dose approximately 75% in hypo-responders compared to placebo while maintaining Hgb and CHr. SFP is well-tolerated with a safety profile similar to that of placebo patients.

## SA-OR083

**Ferric Citrate, a Phosphate Binder, Increases Iron Stores but Is Not Associated with Evidence of the Malnutrition-Inflammation-Cachexia Syndrome** John Paul Middleton,[1] Balaji Padmanaban Athreya,[2] Olayiwola B. Ayodeji,[3] Rafael Burgos-Calderon,[4] Ingrid J. Chang,[5] A. Kaldun Kaldun Nossuli,[6] Juan Jose Olivero,[7] Mohammed Sika,[8] Kotagal Shashi Kant,[9] The Collaborative Study Group.[10] *[1]Duke Univ; [2]Pioneer Valley Neph; [3]Peninsula Kidney Assoc; [4]Univ Puerto Rico; [5]Western Neph; [6]Washington Neph Assoc; [7]Med Cent Dialysis; [8]Vanderbilt Univ; [9]Univ Cincinnati; [10]CMM.*

**Background:** A cornerstone of care in hemodialysis (HD) patients is controlling serum phosphorus (P) by use of oral binders. Oral iron in the form of ferric citrate (FC) can reduce serum P concentrations. However, elevated iron stores may create adverse clinical effects by favoring growth of invasive pathogens or by modulating immune pathways. The purpose of this study was to determine whether FC was associated with evidence for the malnutrition-inflammation-cachexia syndrome (MICS) in HD patients.

**Methods:** We conducted a multicenter, randomized, clinical trial of oral FC in 441 dialysis subjects. We did a 2-week washout period and a 52-week Safety Assessment Period (SAP). Subjects were randomized 2:1 to FC or active control (AC; sevelamer, calcium acetate, or both). Intravenous iron usage was at the discretion of the site, but IV iron was not administered if the serum ferritin was >1000 ng/mL or transferrin saturation (TSAT) was > 30%.

**Results:** 292 subjects received FC and 149 subjects received AC. During the SAP, serum P was similar between the FC and AC groups (mean difference at SAP end 0.036mg/dL; p=0.82). We examined laboratory markers associated with iron stores and MICS.

| Variable | | Ferric Citrate | Active Control | Rx Effect P Value |
|---|---|---|---|---|
| Serum Albumin (mg/dL) | Baseline | 4.02 ± 0.33 | 4.00 ± 0.33 | 0.7 |
| | Week 52 | 3.98 ± 0.41 | 3.98 ± 0.35 | |
| Serum Ferritin (ng/mL) | Baseline | 593 ± 293 | 609 ± 308 | <0.001 |
| | Week 52 | 896 ± 489 | 624 ± 361 | |
| TIBC (mcg/dL) | Baseline | 233 ± 40 | 227 ± 39 | <0.001 |
| | Week 52 | 225 ± 43 | 235 ± 39 | |
| Mean Periph WBCs (x10$^{-3}$) | Baseline | 6.7 ± 2.0 | 6.5 ± 2.2 | 0.9 |
| | Week 52 | 6.6 ± 2.0 | 6.5 ± 2.0 | |
| Lymphocytes (%) | Baseline | 22.4 ± 7.7 | 22.3 ± 8.6 | 0.5 |
| | Week 52 | 22.1 ± 7.9 | 21.7 ± 8.2 | |

**Conclusions:** Thus oral FC controls serum P concentrations and is associated with evidence of increased iron stores. However, FC is not associated with the appearance of markers of inflammation or malnutrition. These data suggest that FC will not predispose to MICS in HD patients.

*Funding:* Pharmaceutical Company Support - Keryx

## SA-OR084

**Intravenous Iron for Functional Iron Deficiency Anemia in Hemodialysis Patients: A Meta-Analysis**

Paweena Susantitaphong,[1,2] Fahad S. Alqahtani,[1] Bertrand L. Jaber.[1] *[1]Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

**Background:** Studies on benefits of intravenous iron therapy among hemodialysis patients with functional iron deficiency anemia have shown conflicting results. We conducted a meta-analysis to assess the efficacy and safety of intravenous iron in hemodialysis patients with functional iron deficiency anemia.

**Methods:** We searched MEDLINE (through December 2012), Cochrane Central Register of Controlled Trials, and ClinicalTrials.gov for single-arm studies and randomized controlled trials (RCTs) that examined the effect of intravenous iron for functional iron deficiency anemia in hemodialysis patients on anemia parameters and markers of oxidative stress and inflammation. Studies of absolute iron deficiency were excluded. Random-effect model meta-analyses were used to compute changes in outcomes of interest.

**Results:** We identified 41 studies (3,202 patients), representing 27 single-arm studies, and, 2 crossover and 12 parallel-arm RCTs. The results of the single arm studies are shown in the Table.

| Outcome variable | No. study arms | No. patients | Mean change (95%CI) | P-value |
|---|---|---|---|---|
| Hemoglobin, gm/dL | 32 | 3242 | 0.5 (0.3, 0.7) | <0.001 |
| Hematocrit, % | 16 | 1524 | 1.3 (0.4, 2.2) | 0.006 |
| Ferritin, ng/mL | 51 | 4798 | 138 (89, 186) | <0.001 |
| TSAT, % | 60 | 4880 | 15 (11, 18) | <0.001 |
| Erythropoietin dose, units/week | 29 | 2404 | -1506 (-2360, -653) | 0.001 |
| C-reactive protein, mg/dL | 10 | 652 | -0.01 (-0.02, 0.001) | 0.06 |
| Oxidized LDL, U/L | 5 | 152 | 9.1 (-11.4, 29.7) | 0.38 |
| Total anti-oxidant capacity, mmol/L | 4 | 156 | -0.4 (-0.6, -0.1) | 0.002 |
| MDA, µmol/L | 2 | 52 | 0.12 (0.01, 0.23) | 0.04 |
| Neutrophil respiratory burst, RLU | 2 | 28 | -453 (-736, -170) | 0.02 |

Similar trends were observed in RCTS.

**Conclusions:** Intravenous iron administered to hemodialysis patients with functional iron deficiency anemia results in an increase in hemoglobin and a decrease in erythropoietin dose. The observed effects on markers of oxidative stress are of unclear clinical significance. Studies with long-term clinical outcomes are needed.

**Hepatitis C Serostatus Modifies Anemia Control in Chronic Hemodialysis Patients: Results from an International Study**

Lim Paik Seong,[1] Len A. Usvyat,[2] Michael Etter,[4] Peter Kotanko.[4] *[1]Nephrocare and Tungs Taichung Metroharbour Hospital, Taiwan; [2]Fresenius Medical Care North America, Waltham, MA; [3]Fresenius Medical Care Asia Pacific, Hong Kong, Hong Kong; [4]Renal Research Institute, New York, NY.*

**Background:** Recent basic research indicates that hepatitis C core+1/ARFP, a novel protein produced by a second functional open reading frame within the core gene, decreases hepcidin expression in hepatoma cells (Kotta-Loizou, *J Gen Virol* 2013). Since hepcidin is a key regulator of iron availability, we hypothesized that hepatitis C positive chronic hemodialysis (HD) patients experience better anemia control and less resistance to erythropoietin (EPO) compared to their hepatitis C negative fellow patients.

**Methods:** We tested our hypothesis in two diverse large HD populations from December 2012, namely in patients treated in Nephrocare facilities in Taiwan, and in patients dialyzed in US Renal Research Institute (RRI) clinics. We extracted hepatitis C serology, indicators of anemia control, and iron status (RRI only). EPO resistance was calculated as EPO dose divided by hemoglobin level.

**Results:** We analyzed data from 14,589 Taiwanese and 6,238 US patients. In the cohort from Taiwan 16.8% of patients were hepatitis C positive, in the US cohort 9.3%. Hepatitis C positive patients in both populations showed higher hemoglobin levels (Taiwan: 10.5 vs. 10.4 g/dL; US: 10.9 vs. 10.8 g/dL) and lower EPO doses (Taiwan: 3637 vs. 4352 U/HD; US: 4978 vs. 5199 U/HD). Compared to hepatitis C positive patients, EPO resistance was increased in hepatitis C negative patients by 5% in the US and by 20% in Taiwan. In the US cohort the average iron dose per HD was lower in hepatitis C positive patients (73.9 vs. 77.0 mg/HD).

**Conclusions:** In two large diverse dialysis populations a positive hepatitis C serostatus is associated with improved anemia control and EPO responsiveness. This observation is possibly related to the recently described interaction between hepatitis C virus and hepcidin expression.

## SA-OR086

**Uremic Toxicity Induces Eryptosis and Atypical Monocyte Transformation: Erytrophagocytosis as a Novel Pathway to Renal Anemia**

Natalia Borges Bonan,[1] Thiago Maass Steiner,[1] Peter Kotanko,[2] Viktoriya Kuntsevich,[2] Roberto Pecoits-Filho,[1] Andrea Novais Moreno-Amaral.[1] *[1]PUCPR, Curitiba, Brazil; [2]RRI, New York.*

**Background:** Anemia is common in chronic kidney disease (CKD) and hemodialysis (HD). Uremia alters red blood cell (RBC) membrane resulting in increased phosphatidylserine (PS) exposure and increased RBC clearance (eryptosis). CD14+/CD16+ monocytes represent an atypical inflammatory phenotype that mimics a macrophage, potentially capable of erythrophagocytosis. Here we investigate the effects of uremic serum and p-Cresol (pC) on eryptosis, monocytes transformation and erythrophagocytosis.

**Methods:** Cells from CKD and HD patients and healthy controls (HC) (5 subjects each) were collected. HC cells were treated with RPMI, pC (concentrations of 10 and 50µg/ml) or uremic serum. Cells were stained with annexin V to detect PS expression, and anti-CD14-CD16 to detect monocyte transformation. Erythrophagocytosis was evaluated using control monocytes and RBC stained with anti-CD14 and antiGlycophirin-A, previously incubated with pC or uremic serum and after co-incubated with control cells for 2 hours: control monocytes against pretreated RBC or control RBC against pretreated monocytes.

**Results:** The fraction of annexinV+ RBC was increased in CKD (6%) and HD (6%) when compared to HC (1.9%). Incubation of HC RBC with uremic serum or pC 50µg/ml, resulted in 5.9% and 8.5% annexin V+ cells. The fraction of CD14+/CD16+ monocytes was greatly increased in CKD (40%) and HD (19%), when compared to controls (3.4%). We observed an increase in CD14+/CD16+ cells following addition of pC at concentrations of 10µg/ml (8%) and 50µg/ml (18%). Erytrophagocytosis was increased when RBC were pretreated with pC 50µg/ml (74%) and uremic serum (62%), and co-incubated with monocytes. HC monocytes pretreated with pC 50µg/ml or uremic serum, and co-incubated with RBC showed increased erythrophagocytosis ( 73% and 35%, respectively).

**Conclusions:** This is the first description that that uremic serum and pC can (a) increase RBC PS expression (and thus eryptosis); (b) transform monocyte phenotype; and (c) increase erythrophagocytosis. Taken together, our observations indicate a novel pathway in the pathogenesis of CKD anemia.

## SA-OR087

**Hypoxia Inducing Factor Prolyl Hydroxylase Inhibitor FG-4592 Corrects Anemia in Peritoneal Dialysis**

Anatole Besarab,[1] Daniel Tak Mao Chan,[3] Sohan L. Dua, Marietta Franco,[2] Eugenia Henry,[2] Robert Leong,[2] Lona Poole,[2] Ming Zhong,[2] Lynda Szczech,[2] Kin-Hung Peony Yu,[2] Thomas B. Neff.[2] *[1]Henry Ford Hosp; [2]FibroGen; [3]Univ of Hong Kong; [4]Valley Renal Medical Group.*

**Background:** FG-4592 inhibits prolyl hydroxylase and transiently stabilizes hypoxia-inducible factor being developed for CKD anemia treatment. Endogenous erythropoietin levels are transiently normalized to physiologic levels. The safety and efficacy of FG-4592 using various iron regimens was tested in a phase 2 study FGCL4592053 in hemo (HDP) and peritoneal (PDP) dialysis patients and reported. In that ~10% of patients with end stage renal disease (ESRD) globally receive PD, it is important to characterize the efficacy of FG-4592 in this group.

**Methods:** 48 ESA-naïve HDP were randomized to FG-4592 and no, oral or IV iron. All PDP (12) received FG-4592 with oral iron. The cohorts of PDP and HDP receiving oral iron were compared (n=24). Hb target was 11-13 g/dL.

**Results:** There were no clinically or statistically significant differences in demographics, medical history or baseline labs btw PDP and HDP. Among PDP, median age was 51.0 y (range 30-68). At baseline, Hb was 8.8 g/dL (0.7), ferritin level was 144.3 ng/mL (79.2) and TSAT was 19.4% (5.8) in the PD cohort. All PDP had hypertension while none had DM. PDP had a median baseline:peak change in Hb of 3.1 g/dL (range 2.4-4.7). All PDP and 11/12 HDP on oral iron responded (a change in Hb>1 g/dL from wks 3-13). Comparing PDP to HDP controlling for baseline Hb and iron stores, no difference in Hb change from baseline or in time to Hb response was detected btw groups (P=0.90 and 0.42, respectively). Median time to response was 4 wks (range 3-8). Adverse Event rates were similar between HDP and PDP and were generally mild-moderate and typical for ESRD patients.

**Conclusions:** While the power afforded by the number of patients receiving PD is limited, these data do not suggest a difference in efficacy or safety for FG-4592 among patients with ESRD based on modality. Given these data and safety signals demonstrated in trials of ESAs, FG-4592 could represent a safer and more convenient option for anemia treatment in ESRD.

**Validation of Rare Genetic Variants Associated with Focal Segmental Glomerulosclerosis by Using an ES Cell-Based RNAi Mouse Model**

Haiyang Yu,[1] Andrey S. Shaw.[1,2] *[1]Dept of Pathology and Immunology, Washington Univ in St. Louis, Saint Louis, MO; [2]Howard Hughes Medical Institute, Washington Univ in St. Louis, Saint Louis, MO.*

**Background:** We sequenced 2,500 podocyte genes in over 200 FSGS patients of European ancestry. Based on the distribution of variants, we identified candidate genes that have a variant pattern that is distinct from an ethnically matched control group. To validate potential FSGS disease genes in an animal model, we developed a mouse ES cell model, which will allow us to efficiently and physiologically test candidate genes.

**Methods:** A new ES cell line that is sensitized to FSGS, and express podocyte specific rtTA. Laser assisted micro-injection that facilitates generation of 100% chimeric mice. Inducible RNAi in podocytes to knock down candidate genes in podocyte *in vivo*.

**Results:** We developed a FSGS disease candidate gene list based on the statistical analysis of the sequences of 2500 podocyte genes that we sequenced in over 200 FSGS patients of European ethnicity. To efficiently validate these genes, we developed a mouse ES cell strategy to test individual genes. We first established a mouse ES cell line that is sensitized to the development of FSGS based on our previous finding that haploinsufficiency in both *Cd2ap* and *Synpo*, leads to FSGS over 6-12 months. We designed a Mir30 based shRNA expression cassette that allows tetracycline inducible expression of the shRNA and facilitates efficient homologous recombination into the *Hprt1* locus. The recombinant ES cells were then injected using a method that generates mice with near 100% chimerism. Chimeric mice were directly used for screening by doxycycline-induced shRNA expression. The method was validated by showing that a CD2AP shRNA can induce nephrotic syndrome. Using this method, we will test each of our candidate genes.

**Conclusions:** We established a mouse model to induce RNAi in podocyte in vivo, and validated that this method is applicable for screening gene candidates that were identified by the large-scale genomic analysis. Now we are screening for the genes that induces proteinuria when they are knocked down in the chimeric mice.

## SA-OR089

### Lack of Murine Double Minute (MDM)-2 in Podocytes Causes Dysregulation of Autophagy and Focal Segmental Glomerulosclerosis

Dana Thomasova,[1] Hauke A. Bruns,[1] Helen Liapis,[2] Hans J. Anders.[1] *[1]Renal Div, Medizinische Klinik und Poliklinik IV, Univ of Munich, Munich, Germany; [2]Dept of Pathology & Immunology, Washington Univ School of Medicine, St. Louis, MO.*

**Background:** Podocytes are terminal differentiated epithelial cells of the glomerular filtration barrier that can hardly be replaced upon loss. Like neurons, they seem to survive many decades and manage to stand the hemodynamic, toxic, and immunologic insults that occur during lifetime. The E3-ubiquitin ligase murine double minute (MDM)-2 is a non-redundant element of NF-kB signaling and the master negative regulator of tumor suppressor gene p53-mediated cell cycle arrest. MDM2 blockade can prevent adriamycin-induced podocyte loss by restoring p53 and preventing podocyte mitotic catastrophe, because podocyte mitosis leads to podocyte death. The role of the intense MDM2 expression in non-stressed podocytes, however, is unknown today. We hypothesized, that MDM2 would be required to prevent p53 overactivation, a state that may cause premature podocyte loss.

**Methods:** We generated and characterized podocyte-specific MDM2-knockout mice (Podocin-Cre/MDM2flox).

**Results:** Comparison of podo-MDM2 -/- mice with their heterozygous +/- littermates revealed lack of MDM2 in podocytes. Nephrin/WT-1+ podocyte counts were identical in 3 weeks old mice of both groups. The podocyte/glomerulus ratio increased with aging in the control mice while it declined in podo-MDM2 KO mice by week 14 of age. Relative podocytopenia in podo-MDM2 KO mice resulted in proteinuria and progressive FSGS. Electron microscopy of podo-MDM2-/- renal tissue displayed the typical abnormalities of glomerulosclerosis but also specific ultrastructural changes in the podocytes, such as massive vacuolization and ER abnormalities suggesting involvement of dysregulated autophagy. Upregulation of p53 expression concurrently with no increase of TUNEL staining in the podo-MDM2 KO podocytes indicates involvement of p53-dependent alternative, nonapoptotic programmed cell death mechanism in podocyte loss.

**Conclusions:** In contrast to the pathogenic role of MDM2 in podocyte injury, podocytes need MDM2 during homeostasis to avoid dysregulated autophagy and podocyte loss.

## SA-OR090

### Direction of Transdifferentiation between Podocytes and Parietal Epithelial Cells, and Its Role for Focal Segmental Glomerulosclerosis

Kazuo Sakamoto,[1,2] Toshiharu Ueno,[1] Namiko Kobayashi,[1] Satoshi Hara,[1] Taiji Matsusaka,[3] Michio Nagata.[1] *[1]Pathology, Univ of Tsukuba, Tsukuba, Ibaraki, Japan; [2]Nephrology, Iizuka Hospital, Iizuka, Hukuoka, Japan; [3]Medicine, Tokai Univ, Isehara, Kanagawa, Japan.*

**Background:** Although transdifferentiation (TD) between podocytes and parietal epithelial cells (PECs) has been suggested in focal segmental glomerulosclerosis (FSGS), its role for FSGS is still unknown. Using genetic tagging system combined with cell-marker staining, we are able to determine the direction of TD between two cells and its frequency/localization.

**Methods:** Mouse model of FSGS (LMB2-treated NEP25 mouse) carrying genetic tagging on podocyte (FSGS mice; n = 9) and NEP25 without LMB-2 (controls; n = 7) were analyzed. TD from podocyte to PEC was determined when cell expressed LacZ, a podocyte lineage-marker, and Pax-8, PEC marker, by double staining. TD from PEC to podocyte was estimated by comparison of frequency between Nestin, a podocyte marker, and Pax8-double positive (DP) cells, and that of LacZ-Pax8-DP cells. When frequency of each-DP cells are not different, majority of TD is podocyte to PEC. When Nestin/Pax-8 DP cells are more, some fraction of cells is supposed to be PEC to podocyte. We counted the number of DP cells per 100 glomeruli to examine the frequency. From localization of DP cells, we speculated role of epithelial TD in FSGS. Statistical analysis was done by Student's T test.

**Results:** Totally 795 glomeruli in FSGS and 546 glomeruli in control were analyzed. 1. The frequency of DP cells for Nestin/Pax8 was significantly increased in FSGS mice (1.6 ± 0.4% vs. 5.8 ± 0.5%, control vs. FSGS, P < 0.01) and those of LacZ/Pax8 were also significantly higher in FSGS mice (1.5 ± 0.6% vs. 4.3 ± 0.6%, control vs. FSGS, P < 0.01). 2. Incidence of Nestin/Pax8 and LacZ/Pax8-DP cells showed no difference. Suggesting majority was podocyte to PEC. 3. Most of DP cells were in glomerular tufts without sclerotic lesion of FSGS, and few (less than 1 %) of them were detected in extra-capillary hyperplasic lesions in FSGS mice.

**Conclusions:** Epithelial transdifferentiation in FSGS was much more likely from podocyte to PEC than PEC to podocyte in FSGS and its role is mimal in FSGS lesion.

## SA-OR091

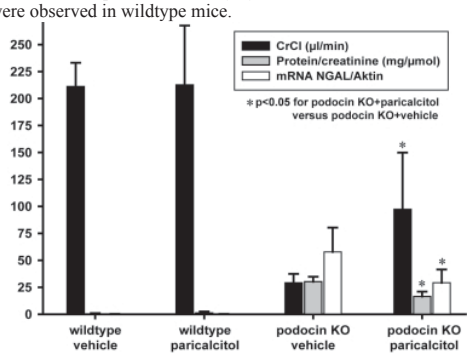
### Paricalcitol Reduces Proteinuria and Improves Renal Function in Podocin Deficiency and Nephrotic Syndrome

Henrik Birn,[1] Corinne Antignac,[2] Rikke Nielsen,[1] Erik I. Christensen,[1] Kathrin Weyer.[1] *[1]Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark; [2]Inserm U983, Hôpital Necker Enfants Malades, Paris, France.*

**Background:** Mutations in the podocin gene, *NPHS2*, have been shown in familial and sporadic forms of steroid-resistant nephrotic syndrome with focal segmental glomerulosclerosis (FSGS). Studies indicate that the vitamin D analog paricalcitol ameliorates proteinuria and prevents kidney injury in acquired podocyte injury. So far the renoprotective effect of vitamin D in genetic nephrotic syndromes has not been addressed. We examined the effect of paricalcitol in a genetic FSGS model caused by inactivation of podocin in the mouse kidney using the Cre-loxP technology.

**Methods:** Mature podocin knockout mice ($Nphs2^{lox/lox}$; $Cre^{+}$) and littermate controls ($Nphs2^{lox/lox}$; $Cre^{-}$) were induced by injection with tamoxifen. Subsequently, the knockout and control mice were receiving either paricalcitol (0.15 µg/kg BW) or vehicle using osmotic minipumps for 5 weeks. Plasma samples, 24-hour urine samples, and kidney tissue were collected.

**Results:** Paricalcitol attenuated weight-loss of the podocin knockout mice and reduced the urinary protein/creatinine ratio by 43 +/- 3% when compared to vehicle treated knockout mice. At 5 weeks creatinine clearance in vehicle treated podocin knockout mice was reduced to 29 +/- 8 µl/min or 13% of wildtype (211 +/- 22 µl/min, p<0.0001). Paricalcitol treated knockouts sustained a creatinine clearance of 97 +/- 53 µl/min (p=0.02 compared to vehicle treated knockout mice), and had a reduced renal expression of the injury marker NGAL and the pro-inflammatory cytokine IL-6. No renal effects of paricalcitol treatment were observed in wildtype mice.



**Conclusions:** Paricalcitol protects renal function and reduces proteinuria in a mouse model of genetic nephrotic syndromes involving mutations of the podocin gene. This may be be further explored in human disease.

*Funding:* Private Foundation Support, Government Support - Non-U.S.

## SA-OR092

### Induction of CCAAT/Enhancer-Binding Protein Delta (CEBPD) Links Inflammation and Hypoxia to Injury by Regulating Hypoxia-Inducible Factor 1 (HIF-1)

Junna Yamaguchi, Tetsuhiro Tanaka, Nobuaki Eto, Masaomi Nangaku. *Div of Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan.*

**Background:** Tubulointerstitial hypoxia is a critical determinant in the pathogenesis of ischemic kidney diseases. HIF-1 is a master regulator of defense against hypoxia, and we designed this study to identify novel HIF-1 regulators in kidney.

**Methods:** An shRNA library was created based on our microarray analysis of chronic kidney hypoxia model. The impact of candidate genes on HIF-1 was evaluated by immunoblotting and hypoxia-inducible reporter assays in vitro, leading to identification of a novel upregulator of HIF-1. Its canonical regulation of HIF-1 and the underlying mechanisms were investigated by real-time PCR, immunoblotting, HIF-1α promoter assay and chromatin immunoprecipitation (ChIP) in human proximal tubular cells (HK-2).

**Results:** An shRNA library experiment consisting of 150 genes identified CEBPD, a transcription factor, as a novel HIF-1 regulator. CEBPD was induced in kidneys subjected to systemic hypoxia, as well as in models of various acute and chronic ischemic kidney injuries (ischemia reperfusion injury, cisplatin nephrotoxicity, renal artery stenosis and 5/6 nephrectomy), with predominant expression in the nuclei of tubular cells. In vitro, CEBPD siRNA knockdown and overexpression mediated down- and upregulation of HIF-1α as well as its target genes, respectively. Mechanistically, CEBPD directly promoted the transcription of HIF-1α by binding to its promoter. Furthermore, we characterized the inflammatory nature of CEBPD and linked inflammation and the HIF response. CEBPD was rapidly inducible by inflammatory cytokines, such as interleukin-1β (IL-1β), in an NF-κB-dependent manner, and was indispensable for the non-hypoxic induction of HIF-1α.

**Conclusions:** These results demonstrate CEBPD as a novel HIF-1 regulator in kidney. CEBPD was up-regulated in tubular epithelial cells via NF-κB-dependent pathway and regulated HIF-1 expression and its transcriptional activity. Given the overall protective roles of HIF-1, modulation of CEBPD activity may offer a novel therapeutic strategy in kidney diseases characterized by co-existent hypoxia and inflammation.

## SA-OR093

**mTORC1 and -2 Induced Signalling Pathways Regulate Renal Proximal Tubular Endocytosis** Franziska Theilig,[1] Patricia Matthey,[1] Brigitte Scolari,[1] Florian Grahammer,[2] Tobias B. Huber.[2] *[1]Medicine, Anatomy, Fribourg, Switzerland; [2]Medicine, Nephrology, Freiburg, Germany.*

**Background:** Receptor-mediated endocytosis is a pivotal function of the renal proximal tubule (PT) to reabsorb proteins from the ultra filtrate. PT dysfunction occurring e.g. in nephrotic syndrome results in an impairment of this process. The regulation of endocytosis and signaling pathways involved remain unknown. The aim of the study was to identify possible kinase-induced signaling pathways involved in the regulation of endocytosis.

**Methods:** Therefore OK cells were incubated with various kinase inhibitors and endocytosis assays using rhodamine-coupled albumin were performed. Transgenic mutants of mTORC1 and -2 were used to elucidate their role in endocytosis.

**Results:** Inhibitors for mTORC1, mTORC2, PI3-kinase and PKC significantly inhibited receptor-mediated endocytosis, whereas Inhibitors for MAPK, JNK and ERK did not alter albumin uptake. To further elucidate the role of mTORC1and -2; Raptor $^{fl/fl}$ and Rictor $^{fl/fl}$ Pax8rtTa*TetOCre as well as double mutants were analyzed. Low molecular weight proteinuria was only observed in the double knockout. Injections of horse reddhish peroxidase demonstrated a significantly reduced uptake in PT of transgenic mice compared to the respective controls. Electron microscopic analysis revealed a diminished content of endocytic vesicles which was mostly pronounced in the Raptor$^{fl/fl}$/Rictor$^{fl/fl}$;Pax8$^{Cre}$. Silencing of S6-kinase 1 and rictor by adenoviral transduction strongly reduced early endosome formation, the actin cytoskeleton remained unaltered. Western blot analysis demonstrated a knockout degree of approx. 65 ± 11 % and reduced clathrin, EEA1 and Rab11 expression for clathrin vesicles, early endosomes and recycling endosomes, respectively. However, PI3-kinase and PKC were unchanged between groups and may not be involved as a downstream target of mTORC1/-and 2 to affect endocytosis.

**Conclusions:** In conclusion, mTORC1 and -2 are important regulators to alter PT endocytic functions.

## SA-OR094

**Anti-miR21 Protects Collagen 4A3 Deficient Mice from Progression of Alport Disease by Decreasing Oxidative Stress** Ivan G. Gomez,[2] Deidre Mackenna,[1] Allie M. Roach,[2] Bryce Gordon Johnson,[2] Tai-He Xia,[4] Vivek Kaimal,[1] Dorin-Bogdan Borza,[3] Jie Zhang,[4] Shiguang Liu,[4] B. Nelson Chau,[1] Jeremy Stuart Duffield.[2] *[1]Regulus Therapeutics; [2]Medicine, Univ of Washington, Seattle, WA; [3]Vanderbilt Univ; [4]Sanofi-Genzyme R&D Center.*

**Background:** Alport syndrome in humans is an inherited form of kidney disease caused by a mutation in the gene coding the capillary basement membrane collagen IV. The disorder is characterized by progressive glomerulonephritis, leading to glomerulosclerosis, tubulo-interstitial disease and organ failure. Col4a3$^{-/-}$ mice also spontaneously develop severe kidney disease highly similar to human disease. Recent studies have shown that miR-21 promotes interstitial kidney disease with fibrosis by silencing metabolic pathways, particularly fatty acid metabolism, and by promoting ROS formation. We hypothesized that treating Col4a3$^{-/-}$ mice with silencing anti-miR21 oligonucleotides would prevent progression of disease.

**Methods:** Col4a3$^{-/-}$ mice were given anti-miR21 (25mg/kg q4d) or control from wk3 to wk9. Urine, plasma and kidneys were harvested at the end of wk9. All samples were analyzed to determine changes in kidney function and fibrosis.

**Results:** Anti-miR21 treatment attenuated the loss of kidney function and development of albuminuria. Glomerulosclerosis and interstitial fibrosis were markedly attenuated, proximal tubules were preserved, and crescent formation reduced. Anti-miR21 reduced infiltrating macrophages, myofibroblast appearance, and tissue and urinary ROS production. Global transcriptional analysis confirms our previous observations implicating a role for PAPRa as a mediator of anti-miR-21 in models of chronic kidney disease; additional analyses are ongoing and will be discussed.

**Conclusions:** Anti-miR21 prevents progressive loss of kidney function in the Col4a3$^{-/-}$ mouse, attenuates both glomerular and tubulo-interstitial disease by reducing oxidative stress as one of the potential mechanisms. Anti-miR21 is a potential new therapy for Alport Syndrome.

## SA-OR095

**APOL1 Is an Innate Immunity Effector That Induces Stress Autophagy by Interacting with the SNARE Protein, VAMP8** John F. O'Toole,[1] Sethu M. Madhavan,[1] David B. Thomas,[2] L. Barisoni,[2] Leslie A. Bruggeman,[1] John R. Sedor.[1] *[1]Case Western Reserve Univ; [2]Univ of Miami.*

**Background:** Apolipoprotein L1 (APOL1) prevents African Sleeping Sickness, a trypanosomal disease. However, some species express a serum resistance associated protein (SRA) that binds and blocks APOL1 function. Genetic variants in APOL1 (variant APOL1s) that occur in the SRA-binding domain of APOL1 circumvent parasitic resistance, but associate with non-diabetic kidney diseases in African Americans. The mechanisms by which variant APOL1s promote nephropathy are unknown. We hypothesized that the SRA-binding domain of APOL1 interacts with a human protein(s) orthologous to SRA and that identification of APOL1's binding partner(s) would reveal its function(s).

**Methods:** APOL1 and VAMP8 localization and expression were examined in cultured cells and normal human kidney sections. Transfection, immunoblotting, immunoprecipitation (IP) and pull-downs were performed with standard methods.

**Results:** APOL1 localized in podocytes of normal human kidney. We used a bioinformatic structural homology search to identify human orthologs of the trypanosomal SRA protein and elucidate the function of the SRA-binding domain of APOL1. VAMP8, the cognate receptor for an autophagosomal SNARE protein, was the top hit; its interaction with wild type APOL1 was confirmed by pull-down and IP. APOL1 risk variants attenuated this interaction and deletion of the SRA-binding domain abolished it. APOL1 and VAMP8 colocalized in podocytes of normal kidney. Expression of wild-type APOL1 in cell lines stimulated autophagy, which was less when variant APOL1s were expressed. Expression of wild-type or variant APOL1s in VAMP8 knockdown cells also increased the appearance of LC3II on immunoblotting, but the small change with the addition of bafilomycin A with variant APOL1s suggests a block in autophagy maturation.

**Conclusions:** Wild-type APOL1 stimulates autophagy and interacts with VAMP8, a structural ortholog of the trypanosomal SRA protein. Variant APOL1s attenuate the APOL1-stimulated autophagy, as well as, the APOL1 interaction with VAMP8. The interaction of VAMP8 with the SRA-domain of APOL1 may promote autophagic maturation as a defense against environmental stress.

## SA-OR096

**Variants in Genes Encoding Complement Regulation Proteins CFH, CFHR3 and CFHR1 Affect the Complement Activation and Susceptibility of IgA Nephropathy** Li Zhu,[1,2,3] Yaling Zhai,[1,2,3] Fengmei Wang,[1,2,3] Jicheng Lv,[1,2,3] Damin Xu,[1,2,3] Sufang Shi,[1,2,3] Lijun Liu,[1,2,3] Feng Yu,[1,2,3] Minghui Zhao,[1,2,3] Hong Zhang.[1,2,3] *[1]Renal Div, Dept of Medicine, Peking Univ First Hospital; [2]Peking Univ Institute of Nephrology; [3]Key Laboratory of Renal Disease, Ministry of Health of China.*

**Background:** Complement activation was common in patients with IgAN and further associated with disease severity. Our recent GWAS study identified 1q23 as a IgAN associated locus, containing complement regulatory protein genes, CFH and the related CFHR3, CFHR1, CFHR4, CHFR2, CFHR5, with rs6677604 in CFH as the top signal SNP. But the underlying genetic mechanism was still unknown. In the present study, we explore the genetic pathogenesis of CFH, CFHR3 and CFHR1 in IgAN susceptibility.

**Methods:** In total, 428 IgAN patients and 902 healthy controls were enrolled. Genotyping of rs6677604 were detected by TaqMan SNP Genotyping Assay. The copy number variation of the CFH-CFHRs region were detected by multiplex ligation-dependent probe amplification (MLPA). Additionally, plasma levels of factor H, complement activation split products C3a and C5a, and sC5b-9 were detected by ELISA in IgAN patients with different copy number of CFHR3-1.

**Results:** In our present population, we confirmed the association of rs6677604 with IgAN susceptibility. Moreover, the linkage disequilibrium of A allele in rs6677604 with CFHR3-1Δ deletion were also confirmed. Furthermore, we found that IgAN patients with CFHR3-1Δ deletion presented with higher plasma factor H and lower complement activation split products C3a and C5a, compared to those without CFHR3-1Δ deletion (CFH: 425.94±137.12ug/ml Vs 337.49±101.87 ug/ml, p=0.002; C3a: 468.89 (276.41-687.59) ng/ml Vs 2469.53 1051.97-3556.53) ng/ml, p<0.001; C5a: 8.34 (6.24-10.42) ng/ml Vs 11.69 (6.56-20.18) ng/ml, p=0.037). However, Plasma sC5b-9 levels showed no difference.

**Conclusions:** Our findings implied a possible genetic mechanism of 1q23 in IgA nephropathy: genetic CFHR3-1Δ deletion, which tagged by A allele of rs6677604, was associated with up-regulation of factor H, and through its inhibition effect on complement activation, at last resulted in the protection to IgAN susceptibility.

*Funding:* Government Support - Non-U.S.

## SA-OR097

**Mesangial Cell Hypersensitivity to Galactose Deficient IgA, a Key to the Development of IgA Nephropathy** Kerstin Ebefors,[1] Peidi Liu,[1] Johannes Elvin,[2] Borje Haraldsson,[2] Jenny C. Nystrom.[1] *[1]Physiology, Neuroscience and Physiology, Gothenburg, Sweden; [2]Molecular and Clinical Medicine, Medicine, Gothenburg, Sweden.*

**Background:** The key feature of IgA nephropathy (IgAN) is deposition of galactose deficient IgA (gd-IgA) in the mesangial matrix. These depositions can also be found in asymptomatic individuals. There are also individuals who have gd-IgA in their circulation without developing the disease. We therefore hypothesize that patients developing IgAN have mesangial cells that are hypersensitive to gd-IgA. Since IgAN is a disease that can reoccur in the transplant (around 40% of cases), we also hypothesize that around half of the population have mesangial hypersensitivity. However, since most of us do not have gd-IgA in our circulation, we have no risk of developing the disease.

**Methods:** We developed a unique method for culturing mesangial cells from patients with IgAN and from controls. IgA1 was purified from serum from patients with IgAN and healthy controls using the method of jacalin purification. Mesangial cells were stimulated with purified IgA1 and the expression of matrix genes and release of cytokines were investigated.

**Results:** First, we investigated the gene expression of selected matrix genes in cells from patients and controls, and found that untreated cells from patients had a different expression profile compared to cells from controls. Stimulation of cells with purified IgA1 did not affect the expression of selected matrix genes further. Secondly, we investigated the release of cytokines after stimulation with IgA1 from patients and controls. We found that the cells responded with release of several cytokines and cells from patients with IgAN released more PDGF-bb than most controls. Stimulation with gd-IgA gave a significantly stronger response than control IgA. In line with our hypothesis we also found control cells (cells from 3 out of 8 control subjects) responding the same way as cells from patients with IgAN.

**Conclusions:** Mesangial cells from patients with IgAN are hypersensitive to gd-IgA, likely depending on their matrix composition (as shown previously by our group). We believe that this hypersensitivity is necessary for the IgA depositions to be pathogenic.

*Funding:* Private Foundation Support, Government Support - Non-U.S.

## SA-OR098

**Toll Like Receptor 9 on Regulatory T Cells Regulates Acute Kidney Injury** Shaun A. Summers, Joanna R. Ghali, A. Richard Kitching, Stephen R. Holdsworth. *Medicine and Nephrology, Monash Univ and Monash Health, Melbourne, Victoria, Australia.*

**Background:** Acute kidney injury (AKI) is a significant cause of renal disease. Cisplatin nephrotoxicity is mediated by leukocytes and cytokines. Toll like receptors (TLRs) are innnate immune cells which actively control inflammation.

**Methods:** We treated C57BL/6 wild type (WT) and TLR9-/- mice with cisplatin and assessed renal inflammation and injury. CD25 negative (-), effectors, and CD4+CD25+ splenocytes were isolated by magnetic bead separation. For reconstitution experiments effector cells and whole splenocytes, from WT or TLR9-/- mice were administered to recombinant activation gene deficient mice (RAG1-/-) which lack adaptive immune cells. Administration of diphtheria toxin to Depletion of Regulatory T cell (DEREG) mice successfully depleted endogenous regulatory T cells (Tregs), which were then reconstituted with CD4+CD25+ cells from WT or TLR9-/- mice.

**Results:** Renal injury and inflammation was enhanced in the absence of TLR9. Blood urea nitrogen (BUN) was increased (WT 43.6±11.1 vs. TLR9-/- 98.9±15.0 mmol/L, $P<0.01$), as was histological injury, interstitial neutrophil recruitment and kidney CXCL1 and CXCL2 expression. Kidney mRNA expression of FoxP3 was decreased in TLR9-/- mice. Renal injury was similar in RAG1-/- mice reconstituted with WT and TLR9-/- effectors and treated with cisplatin. However after reconstitution with whole splenocytes functional (BUN; WT recon 32.3±8.1 vs. TLR9-/- recon 63.6±11.6 mmol/L, $P<0.05$) and histological injury (Injury Score [0-4], WT recon 2.3±0.3 vs. TLR9-/- recon 3.0±0.2, $P<0.05$) was increased in RAG1-/- mice reconstituted with TLR9-/- splenocytes. Finally, we depleted endogenous Tregs in DEREG mice and reconstituted them with CD4+CD25+ cells from WT or TLR9-/- mice, followed by cisplatin. Compared to DEREG mice reconstituted with WT CD4+CD25+ cells functional renal injury was enhanced after reconstitution with TLR9-/-CD4+CD25+ splenocytes (BUN; WT recon 50.3±13.7 vs.TLR9-/- recon 93.8±11.3 mmol/L, $P<0.05$) as was histological injury (Injury Score [0-4] WT recon 2.6±0.3 vs. TLR9-/- recon 3.7±0.1, $P<0.01$).

**Conclusions:** Endogenous TLR9 regulates Treg mediated suppression of cisplatin induced acute kidney injury.

## SA-OR099

**Blockade of Death Ligand TRAIL Inhibits Renal Ischemia Reperfusion Injury** Takaomi Adachi,[1,3] Noriyuki Sugiyama,[2] Takahiko Yokoyama.[3] *[1]Dept of Nephrology, Kyoto Prefectural Univ of Medicine, Kyoto, Japan; [2]Dept of Anatomy and Cell Biology, Osaka Medical College, Takatsuki, Osaka, Japan; [3]Anatomy and Developmental Biology, Kyoto Prefectural Univ of Medicine, Kyoto, Japan.*

**Background:** Acute kidney injury (AKI) remains a significant clinical problem because of high mortality and morbidity rates. However, the mechanisms of AKI has not been fully elucidated. Tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) is a member of the tumor necrosis factor superfamily, and induces apoptosis and inflammation. In the field of nephrology, recent studies suggest that TRAIL plays a role in the pathogenesis of diabetic nephropathy. However, the role of TRAIL in renal ischemia reperfusion injury (IRI) is unclear.

**Methods:** To induce AKI, the left renal pedicle was occluded by clamping the left renal artery for 60 min, followed by reperfusion. Kidneys were collected and weighed at the indicated times after reperfusion and examined. Neutralizing anti-TRAIL monoclonal antibodies were given 24 hours before ischemia, and a half-dose booster injection was administered into the peritoneal cavity immediately after reperfusion.

**Results:** We observed that the expression of TRAIL and its receptors were highly upregulated in renal tubular cells in renal IRI. To clarify the function of TRAIL in renal IRI, we treated the IRI kidney with anti-TRAIL antibodies. We found that TRAIL blockade reduced tubular injury and inhibited tubular apoptosis. Moreover, TRAIL blockade reduced the accumulation of neutrophils and macrophages. Furthermore, TRAIL blockade abrogated renal fibrosis and atrophy after IRI.

**Conclusions:** We suggest that TRAIL plays a critical role in renal IRI, and that TRAIL blockade ameliorates renal IRI. Our findings may have clinical relevance and provide new insights into the pathogenesis of renal IRI. This study also suggests that targeting TRAIL may be a novel significant therapeutic approach to overcome renal IRI.

## SA-OR100

**Mesenchymal Stem Cells Ameliorates Rhabdomyolysis-Induced Acute Kidney Injury through Activation of M2 Macrophage** Xiang-Mei Chen, Li Zhang, Yanqiu Geng. *Dept of Nephrology, State Key Laboratory of Kidney Disease, State Key Laboratory of Kidney Disease, Beijing, China.*

**Background:** Acute kidney injury (AKI) associated with myoglobinuria is the most serious complication of rhabdomyolysis. The mortality of critical AKI is still high since there is no effective therapy. Several studies have shown that administration of bone marrow-derived mesenchymal stem cells (MSCs) leads to the amelioration of AKI, but the mechanisms are still unknown. It was showed that MSCs could induce macrophage both in vivo and in vitro, which mediates MSCs protection in other experimental inflammation related organ injury. However, whether macrophage is also involved in the protective effect of MSCs in rhabdomyolysis-induced AKI needs to be clarified. In this study, we investigated the effects of MSCs on macrophage activation in rhabdomyolysis-induced AKI.

**Methods:** Rhabdomyolysis-induced AKI was induced in male C57BL/6 mice by intramuscular injection with 50% glycerol solution following deprivation of water for 24 hours. Then, we administered MSCs ($10^6$ per mouse) via tail vein.

**Results:** We found that intravenously delived MSCs to Rhabdomyolysis- induced AKI may significantly decrease serum creatinekinase, creatinine and blood urea nitrogen levels, improve tubular injury and lowered acute tubular necrosis score. Serum proinflammatory cytokines TNF-$\alpha$ and IL-6 decreased and anti-inflammatory cytokines IL-10 increased. Immunofluorescence revealed that renal macrophages accumulation with an increasing percentage of "M2" ($CD206^+$) phenotype. Western Blot demonstrated that MSCs caused an advanced expression of CD206. We double labeled $CD206^+$ macrophages with the proliferation marker Ki67. The increases in M2 macrophages resulted largely from in situ proliferation in the kidney. Depletion of M2 macrophages with clodronate delayed the recovery of AKI.

**Conclusions:** This study demonstrates that MSCs-mediated expansion and activation of M2 macrophages is a novel and important mechanism in the protection of rhabdomyolysis-induced AKI.

## SA-OR101

**Myeloid Cells Are Essential Mediators of Renal Endotoxin Preconditioning** Takashi Hato, Rakesh Kumar, Pierre C. Dagher. *Medicine, Indiana Univ, Indianapolis, IN.*

**Background:** We have previously demonstrated that systemically administered endotoxin directly interacts with renal proximal tubules and results in severe tubular oxidative stress. Here we examined whether it is possible to precondition the kidney in vivo and curtail endotoxin-induced tubular injury.

**Methods:** We compared preconditioned (0.25 mg/kg followed by 5 mg/kg lipopolysaccharide ip) and non-preconditioned animals (single-dose 5 mkg/kg ip). A combination of tools was used including mutant and bone marrow chimeric mice, qPCR, flow cytometry, and intravital 2-photon microscopy.

**Results:** We found that preconditioning completely abolished tubular oxidative stress upon subsequent high-dose endotoxin challenges. Renal KIM-1 and NGAL mRNA expression levels were also markedly decreased in the preconditioned kidneys. While preconditioning did not affect the total number of infiltrating renal macrophages, it favored an M2 phenotypic switch. In addition, preconditioning upregulated cytoprotective heme oxygenase-1 and sirtuin-1 in infiltrating macrophages. In chimeric mice lacking hematopoietic TLR4, preconditioning failed to prevent tubular oxidative stress indicating that $TLR4^+$ hematopoietic cells are indispensable for successful preconditioning. Along with TLR4, CD14 is a co-receptor for endotoxin that is primarily expressed on myeloid cells and is essential for TRIF pathway signaling. Chimeric mice lacking hematopoietic CD14 also showed complete failure to exhibit tolerance after preconditioning suggesting that TRIF pathway is involved in endotoxin tolerance. Indeed, the administration of poly (I:C), which stimulates exclusively the TRIF pathway, significantly restored endotoxin tolerance in CD14KO/WT chimeras.

**Conclusions:** These data support a model in which myeloid cells are essential mediators of the protective effects of endotoxin preconditioning on the kidney. Understanding the mechanisms underlying endotoxin preconditioning can have important clinical applications in the prevention of sepsis-induced acute kidney injury.

## SA-OR102

**Forskolin, a Potent Cyclic-AMP Pathway Activator, Protect Mice from Acute Pyelonephritis Induced by Uropathogenic *Escherichia Coli*** Ke Li,[1] Yang Wei,[1] Wuding Zhou.[1,2] *[1]Core Research Laboratory, The Second Affiliated Hospital, Xi'an Jiaotong Univ, Xi'an, China; [2]MRC Center for Transplantation, King's College London, London, United Kingdom.*

**Background:** Pyelonephritis caused by uropathogenic Escherichia coli (UPEC) are very common infections that can cause severe kidney damage. Uncontrolled or dysregulated innate immune responses are well recognized as a contributor to the pathogensis. In this study, we investigated the effect of forskolin (a potent activator of cyclic-AMP pathway) on susceptibility/severity of acute pyelonephritis and innate immune responses to pathogen using an established experimental model of ascending UTI and primary cell cultures (i.e. renal tubular epithelial cells(RTEC), mono/macrophages).

**Methods:** Forkolin (10mg/kg) was given before the induction of infection by i.p. injection. Kidney infection was assessed in forskolin or control reagent treated mice at 6,

24, 48h after bladder inoculation of UPEC (J96). Bacteria load in kidneys was analyzed by the agar plate assay. Tissue damage was assessed by histopathology. Leukocytes infiltration was analysed by immunochemical staining, tissue MPO activity assay and flow cytometry.

**Results:** Administration of forskolin significantly reduced bacterial load in kidneys and protected tissue damage at different time points, this was associated with reduced intrarenal production of pro-inflammatory cytokines/chemokines (e.g. TNF-α, KC, MCP-1) and attenuated intrarenal infiltration and accumulation of leukocytes (i.e. CD45+. Gr-1+, F4/80+) as well as intrarenal MPO activity. In vitro, forskolin inhibited LPS or UPEC mediated pro-inflammatory cytokine/chemokine production by primary RTECs and monocytes/macrophages. Furthermore, forskolin reduced bacterial uptake by RTECs (a potential reservoir for bacteria), but had no apparent effect on phagocytosis by professional phagocytes.

**Conclusions:** These findings demonstrate that administration of forskolin is beneficial for controlling the development of UPEC mediated acute pyelonephritis in mice. The protective effect of forskolin (via cAMP activation) can be explained at least in part by limiting excessive inflammatory responses through acting on both renal parenchymal and inflammatory cells.

## SA-OR103

### DNA Methylation in Acute Kidney Injury and Kidney Repair

Zheng Dong.[1,2] *[1]GRU; [2]VA.*

**Background:** To evaluate the changes of DNA methylation in acute kidney injury (AKI) and kidney repair by a global methylation analysis.

**Methods:** To examine DNA methylation during AKI, B6 mice were treated with cisplatin ( i.p.) for 3 days or subjected to 30 minutes of bilateral renal ischemia followed by 48 hours of reperfusion. To study DNA methylation during kidney repair, B6 mice were subjected to 25 minutes of bilateral renal ischemia followed by 1 week or 1 month of reperfusion. Genomic DNA was purified from freshly frozen cortex tissue for Reduced representation bisulfite sequencing (RRBS) to evaluate DNA methylation changes during and after AKI.

**Results:** Totally 1.4-1.9 million of CpG sites in the sham and injured kidney genome were analyzed. Comparing the methylation profiles of sham control and AKI kidneys, there were 296-359 differentially methylated regions (DMRs). The numbers of hypermethylated DMRs and hypomethylated DMRs were similar between sham and cisplatin 3days, sham and 30 minutes ischemia /48 hours reperfusion, sham and 25 minutes ischemia/1week reperfusion groups., suggesting that the overall DNA methylation does not change under these conditions. In contrast, the 25 minutes ischemia/1month reperfusion group showed more hypermethylated DMRs than hypomethylated DMRs, indicating an increase of DNA methylation. The distribution of DMRs was very similar in the 4 AKI groups comparing with sham; relatively few (6-9%) DMRs were located in the promoter or 5'-UTR regions of genes, while most DMRs were intergenic. 381-491 genes showed significant DNA methylation changes from DMRs. These genes were enriched in several functional pathways including Wnt, Jak-stat and TGF-beta pathways. Several genes showing significant DNA methylation changes following AKI were chosen to for pyrosequencing to confirm the global methylation sequencing results for further functional study.

**Conclusions:** Collectively, the results demonstrate DNA methylation in specific genes during and after AKI.

## SA-OR104

### Telomerase Deficiency Delays Renal Recovery after Ischemia Reperfusion Injury (IR)

Huifang Cheng,[1] Xiaofeng Fan,[1] William E. Lawson,[1] Paisit Paueksakon,[2] Raymond C. Harris.[1] *[1]Medicine, Vanderbilt Univ Medical Center, Nashville, TN; [2]Pathology, Microbiology and Immunology, Vanderbilt Univ Medical Center, Nashville, TN.*

**Background:** Increasing morbidity and higher mortality of acute kidney injury (AKI) are reported in the aged populations. Aging may be directly linked to telomere shortening; both (TerT) and telomerase RNA (TerC) are essential to maintain telomere length.

**Methods:** To investigate molecular and genetic mechanisms underlying susceptibility of AKI in seniors, we induced renal IR in mice from three genotypes: wild type (Wt); and fourth generation (G4) mice with TerC or TerT deletion (TerC KO and TerT KO respectively) by clamping both renal pedicles for 25 mins., using sham operated mice with each genotype as control.

**Results:** Our results suggested that IR induced similar renal injury from day 1 in each genotype, indicated by plasma BUN (Wt: 112.9±2.6; TerC KO: 119.6±3.0; TerT KO: 122.6±6.0 mg/dl), albuminuria and acute tubular injury score (ATI) according to the percentage of damaged tubules (eg., loss of brush border, tubular dilation, "blebbing", cast formation and epithelial cell lysis), injury predominantly in proximal tubules. Increased apoptotic tubular epithelial cells detected by TUNEL Assay and renal Kim-1 were found in all mice by day 1 after IR. However, compared to Wt, both TerC KO and TerT KO mice had significantly delayed recovery, based on evaluation of BUN, albuminuria, ATI score and calculation of tubular epithelial cell apoptosis / proliferation (measured by Ki 67). Electron microscopy demonstrated that IR stimulated autophagosome formation in renal tubular epithelial cells from each group, but the peak in Wt was at day 3 post IR, while it was markedly delayed in TerC / TerT KO mice (peak at day 14). Immunoblotting and immunohistochemistry also demonstrated that the ratio of LC III-2/1 significantly increased at day 3 in Wt, but only at day 14 in TerC / TerT KO. Similar patterns were noted with up-regulation of P62 and ubiquitin.

**Conclusions:** Our study suggested that deletion of either TerC or TerT in mice led to delayed kidney recovery from IR, possibly via impairment of autophagy.

## SA-OR105

### Proximal Tubule Specific Deletion of p53 Reduces Ischemic Renal Injury in Mice

Yuan Ying, Babu J. Padanilam. *Cellular & Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE.*

**Background:** The key features of Ischemic renal injury (IRI) are vascular damage, inflammation and proximal tubular cell apoptosis and necrosis, particularly in the outer medulla. The transcription factor p53 plays an important role in conducting cell cycle arrest, apoptosis, and even necrosis after various types of cell stress. Although a key role for p53 is implicated in IRI, there are conflicting reports on its benevolent and malevolent effects. We hypothesize that specific deletion of p53 in the proximal tubule protects kidneys from ischemic injury.

**Methods:** Mice with the p53 gene specifically deleted in the proximal tubule underwent either sham surgery or clamping of the renal pedicle for 30 min followed by reperfusion for different time periods. Renal function was assessed by creatinine and blood urea nitrogen (BUN) assays, histological damage by Periodic acid-Schiff staining, inflammation by neutrophil and macrophage (F4/80) staining, and fibrosis by Sirius red staining. Apoptosis was measured by TUNEL staining and Western blot analysis for apoptotic proteins.

**Results:** Plasma levels of creatinine and BUN were significantly decreased 24 h after reperfusion in p53 knockout mice compared with wild type. Knockout mice had less renal histological damage, infiltration of leukocytes and apoptosis. Deletion of p53 attenuated the expression of its target gene, the cyclin-dependent kinase inhibitor, p21 after injury. Consistently, renal fibrosis was significantly reduced in p53 knockout mice 16 d after reperfusion.

**Conclusions:** Specific knockout of p53 in the proximal tubule protects kidneys from functional and histological deterioration after IRI by decreasing apoptosis, inflammation, and fibrosis.

*Funding:* NIDDK Support

## SA-OR106

### Primary Cilia-Dependent NOS1 in the Macula Densa (MD) Protects against Ischemia-Reperfusion-Induced Acute Kidney Injury (I/R-AKI)

Yan Lu, Luis A. Juncos, Ying Ge, Yiling Fu, Jin Wei, Richard J. Roman, Ruisheng Liu. *Univ of Mississippi Medical Center, MS.*

**Background:** The macula densa has prominent primary cilia that may be important in regulating NOS1 activity in the MD, and consequently renal function.

**Methods:** Animal: Tissue specific knockout mice: 1). NKCC2-cilia KO 2). NKCC2-NOS1 KO mice. Surgery:IRI was induced by bilateral renal pedicel clamping for 18 min at 37oC. NO measurement: fluorescent TGF was measured with micropuncture and microperfusion AKI marker: Serum Creatinine; Urine KIM-1; Histology (fluorescent H&E staining).

**Results:** Increasing flow across a MD cell-line increased NO (from 175 ± 22 to 276 ± 24) in the presence of intact primary cilia, but had no effect when the cilia were removed by siRNA (48.6 ± 17.5 vs. 62.7 ± 15.2). Similarly, increasing tubular flow in isolated JGA obtained from control mice, increased NO in the MD from 120±22 to 164±14. Subjecting C57BL/6 mice (WT) to 18 minutes of bilateral I/R-AKI decreased the number and length of primary cilia and prevented flow-induced increases in NO in isolated JGA (72±16 vs. 86±15). We then tested whether specifically inhibiting primary cilia-dependent NO production in the MD would exacerbate I/R-AKI. For this we developed 2 strains of NKCC2-tissue-specific KO mice (thus targeting the MD and thick ascending limb). In the first, the primary cilia was deleted in the MD and thick ascending limb, while the second resulted in MD specific deletion of all the splice variants of NOS1. Twenty-four hours post I/R-AKI, the plasma creatinine (mg/dl) was 0.075±0.03 in sham, 0.56±0.02 in WT, 1.25±0.05 in Cilia KO and 0.89±0.03 in NOS1 KO. Urine KIM-1(pg/24h) was 10.7±2.9 in sham, 31.2±5.5 in WT, 274.7±9.3 in Cilia KO and 1340.3±362.2 in NOS1 KO. Morphologically, we observed mild injury in WT and more severe cortical injury in both the Cilia KO and NOS1 KO while no injury in sham. Tubuloglomerular feedback (TGF) was enhanced (4.5±0.3 vs 8.4±0.7 mmHg) and NO in the MD was absent in the NOS1 KO compared to WT mice.

**Conclusions:** We conclude renal IRI damages cilia and reduces NO, and that reduction of primary cilia-dependent NO in the MD exacerbates I/R-AKI, perhaps via enhanced TGF.

## SA-OR107

### Polyamine Catabolism in Renal Ischemia/Reperfusion (I/R) Injury

Kamyar A. Zahedi,[1] Sharon L. Barone,[1] Tracy Murray-Stewart,[2] Yang Wang,[1] Prabir Roy-Chaudhury,[1] Robert A. Casero,[2] Manoocher Soleimani.[1,3] *[1]Univ of Cincinnati, Cincinnati, OH; [2]Johns Hopkins Univ, Baltimre, MD; [3]Veterans Administration, Cincinnati, OH.*

**Background:** The activity of Spermidine/Spermine-N[1]-Acetyltransferase (SSAT) increases in kidneys subjected to I/R injury. We propose that increased SSAT expression in proximal tubule epithelial cells (PTEC) contributes to I/R induced tubular injury.

**Methods:** The severity of renal I/R injury was compared in wild type (wt) and proximal tubule specific SSAT knockout (PT-SSAT-Cko) mice.

**Results:** The severity of renal I/R injury, as determined by renal histopathology and serum creatinine levels, is reduced in PT-SSAT-Cko compared to wt mice. The ablation of SSAT also leads to significant decreases in the expression of spermine oxidase (SMO), tumor necrosis factor-a, and monocyte chemoattractant protein 1 in the injured kidneys. Animals treated with MDL72527, an inhibitor of polyamine oxidases, had less severe renal injuries than those treated with vehicle only, suggesting that polyamine oxidation plays an

important role in the mediation of renal I/R injury. In order to assess the basis of SSAT-mediated cell injury, we examined the effect of its expression on HEK cells. Our results indicate that SSAT expression leads to the loss of mitochondrial integrity, activation of caspase3, cleavage of poly (ADP-ribose) polymerase 1 and apoptosis. In addition, SSAT expression leads to increased expression of high mobility group B 1 (HMGB 1) protein. Based on our in vivo and in vitro results we examined the effect of SSAT ablation on the onset of innate immune response and apoptosis. Our results indicate that, compared to wt mice, PT-SSAT-Cko animals had: 1) lower HMGB 1, toll-like receptor-2 and -4 levels; 2) increased serine 637 phosphorylated dynamin-related protein 1 levels, indicative of reduced mitochondrial fission; and 3) reduced cleaved caspase 3 levels.

**Conclusions:** 1) Enhanced polyamine catabolism by PTEC plays a maladaptive role in kidney I/R injury; 2) reduced tissue damage in PT-SSAT-Cko mice is in part due to the modulation of innate immune and apoptotic responses; 3) Enzymes involved in polyamine catabolism can be targets for the treatment of renal I/R injury.

**The Cystic Kidney Disease Protein ANKS6 Is a Novel Binding Partner and Substrate of the NEK8 Kinase**

Peter G. Czarnecki,[1,2,5] Danielle K. Manning,[3] Mikhail Sergeev,[2,5] Maija Garnaas,[3] Wolfram Goessling,[3] David Beier,[3,4] Jagesh V. Shah.[2,5] *[1]Div of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Renal Div, Brigham and Women's Hospital, Boston, MA; [3]Genetics Div, Brigham and Women's Hospital, Boston, MA; [4]Center for Developmental Biology and Regenerative Medicine, Children's Research Institute, Seattle, WA; [5]Dept of Systems Biology, Harvard Medical School, Boston, MA.*

**Background:** Cystic kidney disease is a consequence of mutations and knockouts of many ciliary genes. How these gene products exert their effect on kidney epithelium to promote cystogenesis remains unknown. Here we investigated the cystic kidney disease gene NEK8, which is mutated in the juvenile cystic kidney (*jck*) mouse and in a subset of patients with nephronophthisis (NPHP9).

**Results:** Analysis of NEK8 co-immunoprecipitates by mass spectrometry revealed ANKS6, the protein mutated in the cy/+ rat model of cystic kidney disease, as a novel binding partner of NEK8. The ANKS6-NEK8 interaction is mediated by the binding of the ankyrin domain of ANKS6 to the kinase domain of NEK8. The ankyrin domain of ANKS6 is also required for its localization to the Inversin compartment in ciliated cells. Morpholino mediated disruption of ANKS6 in zebrafish results in the formation of pronephric cysts and pericardial edema, a phenotype that is characteristic of many ciliopathy genes. However, unlike loss of function mutations in NEK8, INVS and NPHP3, three other core constituents of the Inversin compartment, defects in L/R asymmetry were not observed. We found ANKS6 to be readily phosphorylated by NEK8 and identified a number of phosphorylation sites in the C-terminal region including the SAM-domain. Deletion of the SAM domain results in enhanced oligomerization of ANKS6 and NEK8, and hyperaccumulation of these proteins in the Inversin compartment.

**Conclusions:** Our work reveals a novel interaction network between cystic kidney disease proteins that may represent the basis of a new cystogenic pathway.

## SA-OR109

**Defects in the IFT-B Component IFT172 Cause Nephronophthisis with Skeletal Abnormalities**

Jan Halbritter,[1,10] Jonathan Porath,[1,10] Albane A. Bizet,[2,10] Miriam Schmidts,[3,10] Daniela A. Braun,[1] Peter G. Czarnecki,[4] Emilie Filhol,[2] Heon Yung Gee,[1] Pauline Krug,[2] Rannar Airik,[1] Patrick Nitschke,[2] Christine Bole-Feysot,[2] Anna M. Lehman,[5] Edgar Otto,[6] Bertrand Knebelmann,[2] Stephane Burtey,[2] Attila J. Szabo,[7] Kalman Tory,[7] Markus Schueler,[1] Hulya Kayserili,[8] Dan Doherty,[9] Peter Scambler,[3] Philip L. Beales,[3] Jagesh V. Shah,[4] Hannah Mitchison,[3] Sophie Saunier,[2] Friedhelm Hildebrandt.[1] *[1]Med, BCH, Boston; [2]INSERM U983, NH Paris, France; [3]MMU, UCL, United Kingdom; [4]Med, BWH, Boston; [5]Med Gen, U BC, Vancouver, Canada; [6]Ped, U MI, Ann Arbor; [7]Ped, SW U, Budapest, Hungary; [8]Med Gen, Istanbul U, Turkey; [9]Ped, U WA, Seattle; [10]Equally Contributed.*

**Background:** Intraflagellar transport (IFT) is an evolutionarily conserved mechanism, essential for cilia assembly and maintenance. All components of IFT subcomplex A, have been implicated in human skeletal ciliopathies including Sensenbrenner, and Mainzer-Saldino syndrome (MSS). Additionally, the IFT B-component IFT80 and the IFT-A motor DYNC2H1 have been shown to cause Jeune syndrome (JATD) when mutated. The role of other IFT-B proteins in human disease remains obscure.

**Methods:** To identify additional IFT-B complex products as defective in ciliopathies, we performed array based multiplex PCR of 13 IFT-B components in 1,056 patients with nephronophthisis-related ciliopathies (NPHP-RC) and whole exome resequencing in 56 individuals with JATD.

**Results:** This approach led to the detection of 8 families with recessive mutations in the gene *IFT172*. All affected individuals showed NPHP and skeletal abnormalities of thorax and long bones, combined with hepatic or retinal involvement, consistent with the diagnosis of JATD or MSS. Injection of *ift172* or *ift80* antisense-morpholino in zebrafish resulted in formation of glomerular cysts. A similar phenotype resulted from injection of subphenotypic doses of *ift172* and *ift80* in combination, indicating genetic interaction.

**Conclusions:** We show that mutation of an additional IFT-B component, *IFT172*, is a novel cause of NPHP-RC with skeletal involvement, and we demonstrate genetic epistasis between *ift80* and *ift172*.

## SA-OR110

**Cdc42 Knockdown/Knockout Results in Ciliary Abnormalities and Cystic Kidneys**

Soo Young Choi,[1] Maria F. Chacon-Heszele,[1] Liwei Huang,[1] Sarah McKenna,[1] Francis P. Wilson,[1] Xiaofeng Zuo,[1] Joshua H. Lipschutz.[1,2] *[1]Dept of Medicine, Univ of Pennsylvania; [2]Philadelphia VAMC, Philadelphia, PA.*

**Background:** Primary cilia are found on renal tubule cells, and cilia dysfunction is linked to polycystic kidney disease (PKD). We previously demonstrated that the exocyst, a conserved eight-protein trafficking complex, is required for ciliogenesis and cystogenesis, most likely due to its role in trafficking ciliary proteins. We also showed, in culture, that Cdc42, a small GTPase, co-localizes with the exocyst at primary cilia, and biochemically interacts with Sec10, a crucial exocyst component. Knockdown of Cdc42 and Tuba, a Cdc42 GEF, inhibited ciliogenesis and resulted in MAPK pathway activation, something observed in cells with dysfunctional cilia.

**Methods:** Given the importance of Cdc42 for cell function, to study how *cdc42* affects ciliogenesis and cystogenesis *in vivo*, we used two different animal models and techniques: antisense morpholinos (MOs) to knockdown *cdc42* in zebrafish, and the Cre-Lox system to knockout Cdc42 in a kidney-specific manner in mice. Zebrafish embryos were injected with *cdc42* start-site MOs. Cdc42 renal tubule specific knockout mice were generated by breeding Cdc42 floxed and Ksp-cadherin Cre mice.

**Results:** We show cdc42 knockdown in zebrafish phenocopies many aspects of sec10 knockdown—including tail curvature, glomerular expansion, and MAPK activation. Other ciliary phenotypes include hydrocephalus and loss of photoreceptor cilia. We also observe a synergistic genetic interaction between zebrafish *cdc42* and *sec10*, suggesting that *cdc42* and *sec10* function in the same pathway. Cdc42 kidney-specific knockout mice died within weeks of birth of renal failure. Histology revealed cystogenesis in distal tubules and collecting ducts, decreased ciliogenesis in cyst cells, increased tubule cell proliferation, increased apoptosis, increased fibrosis, and MAPK activation, all features of PKD, especially nephronophthisis.

**Conclusions:** These data support a model in which Cdc42 localizes the exocyst to primary cilia, whereupon the exocyst targets and docks vesicles carrying ciliary proteins, and, if this does not occur, the result is abnormal ciliogenesis and PKD.

## SA-OR111

**Deletion of S6 Phosphorylation Exacerbates Renal Cystogenesis in Conditional Tsc1 Knockout Mice**

Huijuan Wu,[1] Jianchun Chen,[2] Jian-Kang Chen.[1] *[1]Experimental Medicine, Georgia Regents Univ, Augusta, GA; [2]Medicine, Vanderbilt Univ, Nashville, TN.*

**Background:** Tuberous sclerosis (TSC) is caused by *Tsc1* or *Tsc2* gene mutations and characterized by proliferative lesions in many organs, with kidney involvement being the leading cause of death in adult TSC patients. Phosphorylation of the40S ribosomal protein S6 is implicated in regulation of cell growth, but its role in the renal lesions of TSC has not yet been explored.

**Methods:** We generated renal proximal tubule-specific *Tsc1* knockout mice ($Tsc1^{ptKO}$) by crossing *Tsc1*-floxed mice with γGT-Cre mice. We then bred $Tsc1^{ptKO}$ with S6 knock-in mice carrying unphosphorylatable S6 ($S6^{P-/-}$) to produce $Tsc1^{ptKO}$ mice lacking S6 phosphorylation ($Tsc1^{ptKO}$; $S6^{P-/-}$).

**Results:** By 1 week of age, $Tsc1^{ptKO}$ mice developed enlarged kidneys, which were blunted in $Tsc1^{ptKO}$; $S6^{P-/-}$mice (kidney-to-body weight ratios (K/Bwt): 1.14±0.2 vs. 0.71±0.02%; p<0.01, n=5), with indistinguishable body weight. Surprisingly, by 2 weeks of age, $Tsc1^{ptKO}$; $S6^{P-/-}$ kidneys outgrew $Tsc1^{ptKO}$ kidneys (K/Bwt: 3.0±1.49 vs. 1.4±0.16%; p<0.05, n=5). By 4 weeks of age, $Tsc1^{ptKO}$;$S6^{P-/-}$ mice developed severe polycystic renal lesions, with increased BUN (74.29±12.36 vs. 25±3.38 mg/dl in $Tsc1^{ptKO}$; p<0.01, n=7). 67% of $Tsc1^{ptKO}$;$S6^{P-/-}$ mice died by 9 weeks of age when $Tsc1^{ptKO}$ mice were all alive, with far fewer renal cysts. Triple immunofluorescence staining confirmed that all cysts originated from proximal tubules. $Tsc1^{ptKO}$ mice showed increased S6 phosphorylation in involved renal tubules compared with WT littermates, but $Tsc1^{ptKO}$;$S6^{P-/-}$ mice and $S6^{P-/-}$mice showed no S6 phosphorylation. Compared with $Tsc1^{ptKO}$ mice, Ki67-positive renal cells in $Tsc1^{ptKO}$;$S6^{P-/-}$ mice were significantly fewer at 1 week of age but more by 2 weeks of age. Immunoblotting revealed aberrantly heightened phosphorylation of EGFR and STAT3 in $Tsc1^{ptKO}$;$S6^{P-/-}$ mice by 2 weeks of age.

**Conclusions:** This study, for the first time, reveals that blocking S6 phosphorylation transiently inhibits Tsc1 deletion-induced renal growth and then unexpectedly exacerbates cystogenesis and renal function. This may explain why recent clinical trials for treatment of polycystic kidney disease with mTOR inhibitors, which block S6 phosphorylation, failed.

## SA-OR112

**Loss of Cilia Suppresses Cyst Growth in Genetic Models of Autosomal Dominant Polycystic Kidney Disease** Ming Ma,[1] Xin Tian,[1] Mingfeng Li,[5] Christopher Y. Chen,[1] Yiqiang Cai,[1] Peter Igarashi,[2] Gregory J. Pazour,[3] Stefan Somlo.[1,4] *[1]Dept of Internal Medicine, Yale Medical School, New Haven, CT; [2]Dept of Medicine, Univ of Texas Southwestern Medical School, Dallas, TX; [3]Program in Molecular Medicine, UMass Medical School, Worcester, MA; [4]Dept of Genetics, Yale Medical School, New Haven, CT; [5]Dept of Neurobiology, Yale Medical School, New Haven, CT.*

**Background:** Inactivation of a single cilia membrane component protein, polycystin, in ADPKD or complete removal of cilia by inactivation of intraflagellar transport-related proteins in ciliopathies both give rise to kidney cysts, yet the interrelationship of these two mechanisms of cyst formation is not understood.

**Methods:** We combined inactivation of *Pkd1* and *Pkd2* with loss of *Kif3a* and *Ift20* in kidney and liver to investigate the role of cilia in ADPKD. We examined epithelial cell proliferation and activation of several known ADPKD associated pathways in polycystin-only and cilia/polycystin double mutants. We also defined genotype dependent changes in the transcriptome at the pre-cystic stage of inducible adult onset ADPKD models using RNASeq with loss of polycystin alone or of cilia/polycystin together.

**Results:** We found that loss of intact cilia suppresses cyst growth following inactivation of polycystins. The severity of cystic disease and the associated epithelial proliferation was directly related to the length of time between the initial loss of polycystins and the subsequent involution of cilia. This effect was not explained by activation of the MAPK/ERK, mTOR or cAMP pathways. RNASeq analysis of wild type and pre-cystic polycystin-1 (PC1) single and PC1/Kif3a double mutant kidneys 6 weeks after adult gene inactivation showed 407 transcripts whose expression was altered in the PC1-only mutants when compared to both wild type and PC1/Kif3a double mutants.

**Conclusions:** The data establish the existence of a novel signaling pathway showing polycystin-dependent inhibition and cilia-dependent activation that is central to the pathogenesis of ADPKD. Alterations in the transcriptome of polycystin-only mutants compared to cilia/polycystin double mutants should identify transcriptional targets which will help in defining these pathways and in identifying therapeutic targets.

## SA-OR113

**$Pkd1_{extra}$ Transgenic Mice Implicate Pc2 Gene Dosage as a Pathogenetic Mechanism** Marie Trudel, Almira Kurbegovic. *Molecular Genetics and Development, Institut de Recherches Cliniques de Montréal, Montreal, Canada.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is characterized by slow progression of multiple cysts in both kidneys that lead to renal insufficiency in mid-life or later. ADPKD is associated with mutations mainly in the PKD1 gene (encoding polycystin-1 or PC1) and less frequently in the PKD2 gene (encoding polycystin-2 or PC2).

**Methods:** To mimic naturally occurring human PKD1 mutations and gain insight into the PC1 extracellular domain function, four transgenic mouse lines were established with exclusively the extracellular domain of the Pkd1 gene ($Pkd1_{extra}$) under endogenous transcriptional regulation.

**Results:** Expression of the $Pkd1_{extra}$ transgene was 2- to 80-fold above endogenous levels. Strikingly, the $Pc1_{extra}$ protein was more abundant than expected based on proportion to the Pc1 endogenous levels. All four transgenic mouse lines consistently displayed progressive renal cystic phenotype. Consequently, these transgenic mice reproducibly developed altered renal function similar to human ADPKD with proteinuria, renal insufficiency, anemia and died of renal failure late in life. Substantial levels of $Pc1_{extra}$ protein were detected in exosomes from $Pkd1_{extra}$ MEFs and from urine of $Pkd1_{extra}$ mice. In precystic kidneys, the $Pkd1_{extra}$ transgene modulated Pc2 expression. Furthermore, we identified increased interaction of $Pc1_{extra}$/Pc1 with Pc2 in $Pkd1_{extra}$ kidneys relative to controls. This study uncovered a potential Pc1-mutant/Pc2 pathogenic crosstalk mechanism. Moreover, the pathophysiologic mechanism also implicates c-myc, a major modulator of cystogenesis.

**Conclusions:** Altogether, the novel $Pkd1_{extra}$ mouse model is the first Pc1 extracellular mutant that reproduces human ADPKD clinical progression and physiopathology.

*Funding:* Government Support - Non-U.S.

## SA-OR114

**Scattered Single-Cell Deletion of Pkd1 in Mouse Kidneys Recapitulates Human Polycystic Kidney Disease and Refines the Model of Cystogenesis** Wouter N. Leonhard,[1] Malu Zandbergen,[2] Kimberley Veraar,[2] Emile De Heer,[2] Martijn H. Breuning,[1] Dorien J.M. Peters.[1] *[1]Dept of Human Genetics; [2]Pathology, Leiden Univ Medical Center, Netherlands.*

**Background:** ADPKD patients carry a germline mutation in *PKD1* or *PKD2* which leads to the formation of thousands of kidney cysts. The relatively rapid progression of the disease is preceded by a lag-phase of several decades. Although the cause of this rapid progression is poorly understood, extensive research led to the presumption that somatic inactivation of the remaining allele initiates the formation of cysts, and the progression is further accelerated by renal injury. This hypothesis is based primarily on animal studies in which the gene is inactivated in large percentages of kidney cells. In this study we lowered this percentage to mimic human ADPKD more precisely.

**Methods:** To inactivate *Pkd1* in fewer renal cells in adult tamoxifen-inducible kidney-specific *Pkd1*-deletion mice, we lowered the tamoxifen dose. Quantification and visualization of $Pkd1^{del,del}$ cells was done by eMLPA and by crossbreeding to LacZ reporter mice. Renal injury was applied by nephrotoxicant (DCVC) injection, unilateral nephrectomy, or combinations. Western blot and IHC analysis was used to assess the expression of several PKD-related proteins.

**Results:** Interestingly, no pathological changes occurred for six months after scattered single-cell *Pkd1* deletion in adult mice and additional renal injury did not trigger rapid PKD. However, in the next few months (i.e. 6-10 months following *Pkd1*-disruption) the mice developed rapidly progressing PKD that was remarkably similar to human ADPKD. This shift was not caused by general aging but was preceded by increased pSTAT3, Ki-67 and LCN2 expression in the vicinity of the initial cysts.

**Conclusions:** Our data argue against the presumption that acute renal injury plays a major role in triggering cyst formation. We show that the initial cysts themselves, by imposing persistent stress on surrounding tissue, are the principal trigger for a 'snow-ball' effect driving the formation of new cysts. In addition, our approach is a suitable model for mimicking human ADPKD and will provide more accurate predictions of clinical outcome.

## SA-OR115

**A Human Pathogenic Single Amino Acid Deletion Affecting Polycystin-1 (PC1) G-Protein Signaling Prevents Activation of the Polycystin-2 (PC2) Channel** Stephen C. Parnell,[1] Tengis S. Pavlov,[2] Brenda S. Magenheimer,[1] Robin L. Maser,[1] Alexander Staruschenko,[2] James P. Calvet.[1] *[1]Kidney Inst, Univ of Kansas Med Ctr, Kansas City, KS; [2]Dept Physiol, Med Coll Wisc, Milwaukee, WI.*

**Background:** We previously reported that a single amino acid deletion in mouse polycystin-1 (PC1) disrupts the ability of PC1 to signal via heterotrimeric G-proteins while preserving the ability of PC1 to interact with PC2. Introduction of this mutation, which corresponds to human ADPKD-associated L4132Δ (ΔL, Afzal et al Hum Genet 1999 105:648), causes a severe PKD phenotype in Pkd1cond/ΔL knock-in mice. To determine if the ΔL mutation affects the ability of PC1 to regulate PC1/PC2 channel activity, we co-expressed PC1/PC2 and measured whole-cell macroscopic currents under voltage-clamp conditions.

**Methods:** HA-tagged human full-length wild-type, L4132Δ, or C-terminally truncated S4213X PC1 were co-transfected with human Myc-tagged PC2 and eGFP in CHO cells. S4213X lacks the PC2-interacting coiled-coil region. Whole-cell current recordings were made with eGFP-positive cells. Currents were elicited by test pulses of 20 mV steps from 80 to -80 mV from a holding potential of 0 mV to assess current–voltage (I-V) relationships and to measure current at -80 mV. After initial recordings cells were superfused with bath solution containing 0.5 mM $LaCl_3$ to block PC1/PC2 in order to determine $La^{3+}$-sensitive cation current density.

**Results:** As shown by co-immunoprecipitation, transfected wild-type PC1 and L4132Δ interacted equally well with PC2. However, compared to wild-type PC1, both L4132Δ and S4213X failed to elicit PC2-dependent channel activity in CHO cells (pA/pF: 30.9±8.6 vs 10.2±1.9 and 6.5±1.6; $P<0.05$).

**Conclusions:** Previous work showed that PC1/PC2 channel activity is stimulated by Gβγ subunits in a PC1-dependent manner (Kwon et al PNAS 2012 109:21462); and we showed that the PC1 L4132Δ mutation disrupts G-protein signaling and causes a severe PKD phenotype in mice. Here we show that this mutation inhibits PC1/PC2 channel activity, without affecting PC1/PC2 interaction, suggesting that PC1-dependent heterotrimeric G-protein signaling is critical for normal PC1/PC2 channel complex function.

## SA-OR116

**Polycystin Activity Is Regulated by Cellular Oxygen Sensing Pathways and Influences Mitochondrial Energy Production** Valeria Padovano, Ivana Y. Kuo, Benjamin J. Flaherty, Hans R. Aerni, Ming Ma, Stefan Somlo, Barbara E. Ehrlich, Jesse Rinehart, Michael J. Caplan. *School of Medicine, Yale Univ, New Haven, CT.*

**Background:** ADPKD is caused by mutation in the genes encoding polycystin-1 (PC1) and polycystin-2 (PC2). Loss of polycystin expression leads to perturbations in energy production, although the mechanisms responsible for this effect are unclear. We find that the activity and subcellular localization of the PC1-PC2 complex is sensitive to $O_2$ levels and that this $O_2$ sensitivity plays a role in regulating mitochondrial energy production.

**Methods:** Mitochondrial function was measured using Seahorse analysis. Mass spectrometry was used to identify proline hydroxylation. PC2 channel activity was studied by single channel recording in bilayer membranes.

**Results:** Seahorse analyses showed that $Pkd1^{-/-}$ cells have decreased $O_2$ consumption and oxidative phosphorylation (OXPHOS) rates. Moreover, pyruvate dehydrogenase (PDH), a key enzyme in OXPHOS regulation, is less active (higher pPDH/PDH ratio) in $Pkd1^{-/-}$ cells and in pre-cystic $Pkd1^{-/-}$ mouse kidneys, suggesting that OXPHOS reduction precedes cyst formation. $Ca^{2+}$ release from the ER positively regulates PDH and OXPHOS activity. Interestingly, we found that a cellular $O_2$ sensor, prolyl hydroxylase domain protein 3 (PHD3 or EGLN3), interacts with PC1 and that PHD3 knockdown led to increased PC1 localization at the cell surface; the same effect was also induced by hypoxia and the hypoxia-mimicking compound $CoCl_2$. Mass spectrometry revealed the presence of hydroxylated prolines in PC1, the extent of which was reduced by treatment with DMOG, a PHD inhibitor. Furthermore, DMOG induced a reduction in the activity and the $Ca^{2+}$ sensitivity of the PC2 channel. Finally, inhibition of PDH phosphorylation by dichloroacetate reduced the formation of cysts in 3D cultures of $Pkd1^{-/-}$ cells.

**Conclusions:** Our data suggest the intriguing possibility that changes in $O_2$ concentration alter the channel properties of the PC1-PC2 complex, leading to changes in ER calcium release that in turn affect mitochondrial function. This study also suggests that PDH may be a possible novel target for PKD pharmacotherapy.

## SA-OR117

### Transcriptional Targets of STAT6 in Polycystic Kidney Disease

Erin E. Olsan, Nicholas Doerr, Thomas Weimbs. *Molecular, Cellular and Developmental Biology, Univ of California, Santa Barbara, CA.*

**Background:** The majority of ADPKD patients have mutations in the PKD1 gene, encoding the large, multi-pass transmembrane protein polycystin-1 (PC-1). Previously, we showed that a soluble fragment of PC-1, consisting of the c-terminal cytoplasmic tail, interacts with STAT6 and co-activates STAT6-dependent reporter transcription. Additionally, we reported increased phosphorylated STAT6 in several PKD mouse models, and showed that genetic removal or pharmacological inhibition of STAT6 decreases disease severity. To understand how STAT6 activation may contribute to renal cyst growth we identified several potential transcriptional targets of STAT6 signaling in PKD including IL24, periostin and galectin-3. IL24 is an IL10 family cytokine that functions in wound healing and inflammation in the skin and has been shown to be transcriptionally regulated by STAT6 in immune cells. Periostin, an extracellular matrix protein, and galectin-3, a β-galactoside binding lectin, both have previously been implicated in PKD.

**Methods:** Kidney epithelial cells treated with IL4 or IL13 or transfected with the PC-1 cytoplasmic tail were analyzed by RT-PCR. Microarray analysis was performed on cells overexpressing the PC-1 cytoplasmic tail. Total RNA or protein extracts from normal or cystic mouse kidneys were analyzed using RT-PCR or Western blot.

**Results:** We found that treatment of human and mouse kidney epithelial cells with IL4 or IL13, cytokines that signal through STAT6, increases IL24 gene expression. Overexpression of the PC-1 cytoplasmic tail also increases IL24 transcript levels. Importantly, we show that IL24 is upregulated in kidneys from several cystic mouse models. As predicted, we found increased levels of periostin and galectin-3 in cystic mouse kidneys compared to normal, and their expression levels are diminished in STAT6 KO cystic kidneys, suggesting that gene regulation is dependent on STAT6. Overexpression of the PC-1 cytoplasmic tail increased transcript levels of a related protein, galectin-8.

**Conclusions:** STAT6 has been shown to be an important signaling molecule in PKD. Here we identify several genes involved in the pathogenesis of PKD that can be transcriptionally regulated by STAT6.

## SA-OR118

### Evidence for Abnormal Glucose Homeostasis in Idiopathic Calcium Stone Formers

Kristin J. Bergsland, Elaine M. Worcester, Fredric L. Coe. *Dept of Medicine, Nephrology Section, Univ of Chicago, Chicago, IL.*

**Background:** Calcium (Ca) stone formers with idiopathic hypercalciuria (IHSF) have an exaggerated calciuric response to glucose administration. We and others have found that the calciuric effect of insulin does not differ between IHSF and normal people, so what mediates this response is unclear.

**Methods:** In the General Clinical Research Center, we studied renal mineral handling and glucose homeostasis in 21 normal controls (C), 12 female, and 31 IHSF (20 calcium oxalate [ICSF], 7 female; 11 with stones >50% calcium phosphate [IPSF], 5 female). We collected 15 urines and 20 blood samples over a 15 hour day, both fasting and with 3 meals of known composition. Subjects were selected for hypercalciuria and were not diabetic.

**Results:** By ANOVA adjusted for age, sex and creatinine excretion (UCreat/hr), all IHSF were hypercalciuric, fasting and fed (Table). Adjusted for age, sex and BMI, all IHSF had elevated serum glucose vs C, fasting and fed. In the fed state, ICSF had increased serum insulin vs. IPSF. BMI did not differ by subject type (26.7±1.1, 25.9±1.1, and 24.4±1.4 kg/m$^2$ for C, ICSF and IPSF, respectively, all p, NS). Gender differences were not detected in any of the analyses.

| | Glucose (mg/dL) | | Insulin (pM) | | UCa (mg/hr) | |
|---|---|---|---|---|---|---|
| | Fast | Fed | Fast | Fed | Fast | Fed |
| C | 91.5 ± 1.3 | 103.7 ± 1.3 | 39 ± 3 | 245 ± 15 | 5.7 ± 0.4 | 11.0 ± 0.4 |
| ICSF | 96.5 ± 1.3* | 110.6 ± 1.3* | 48 ± 3 | 274 ± 14† | 9.0 ± 0.4* | 20.0 ± 0.5* |
| IPSF | 97.5 ± 1.8* | 111.5 ± 2.0* | 39 ± 5 | 194 ± 22 | 10.4 ± 0.6* | 19.4 ± 0.6* |

Mean ± SEM adjusted for age, sex and BMI (for glucose, insulin) or UCreat/hr (for UCa).*, differs from C;†, differs from IPSF; all p<0.05

**Conclusions:** Glucose homeostasis in both male and female IHSF is markedly different than in C. Higher glucose in all IHSF, and higher insulin in ICSF after eating, cannot be explained by differences in diet or body size, since subjects were non-diabetic, ate the same meals, and analyses were corrected for BMI. Alterations in insulin sensitivity or pancreatic function in IHSF may contribute to Ca stone disease, and possibly to differences in stone type, and will be the subject of future research.

## SA-OR119

### Distinguishing Characteristics of Idiopathic Calcium Oxalate Kidney Stone Formers with Low Amounts of Randall's Plaque

Xiangling Wang,[1] Amy E. Krambeck,[1] James Williams,[2] Andrew D. Rule,[1] Eric J. Bergstralh,[1] Loren Paola Herrera Hernandez,[1] John C. Lieske.[1] *[1]Mayo Clinic, Rochester, MN; [2]Indiana Univ School of Medicine, Indianapolis, IN.*

**Background:** Overgrowth of calcium oxalate on Randall's plaque, composed of apatite that extends from the medullary interstitium to the papillary surface, has been hypothesized to be the main mechanism of stone formation among idiopathic CaOx stone formers (ICSF). However, it is less clear how stones form in ICSF that have little or no plaque.

**Methods:** In the current study a cohort of ICSF who underwent percutaneous nephroscopic papillary mapping and papillary tip biopsy during a stone removal procedure were divided into those with high (>5%; mean 10.5%) versus low (<5%; mean 1.5%) amounts of Randall's plaque coverage per papillum. Demographic and laboratory features were compared between these two groups.

**Results:** Low plaque ICSF were more likely to be female and obese and had a significantly lower 24-hr urine calcium excretion (Table). Their stones were more likely to have a positive bacterial culture and to have an atypical morphology by micro CT (lacked a CaP core consistent with origin upon plaque). Papillary biopsies of low plaque patients had less severe interstitial and basement membrane punctate crystallization (P<0.05).

| | High Plaque ICSF (n=10) | Low Plaque ICSF (n=31) | P value |
|---|---|---|---|
| Age (yr) | 61±7 | 62±10 | 0.76 |
| Female | 4 (40%) | 25 (74%) | 0.05 |
| Body Mass Index>30 | 4 (10%) | 15 (48%) | 0.03 |
| History of prior stone event | 9 (82%) | 15 (43%) | 0.04 |
| 24-hr Urine Volume (L) | 2.5±0.06 | 1.9±0.8 | 0.03 |
| 24-hr Urine Calcium (mg) | 291±99 | 196±87 | 0.01 |
| Positive Stone Culture | 0 (0%) | 6 (19%) | 0.06 |
| Atypical Stone Morphology | 0 (0%) | 9 (29%) | 0.04 |

**Conclusions:** These findings suggest that the pathogenesis of CaOx stone formation differs in patients with low amounts of Randall's plaque. Those ICSF with low plaque lack hypercalciuria, more commonly have stones with atypical morphology, and appear to have distinct clincial features (more likley to be female, obese, and have infected stones). Thus, there may be differnt pathways to stone formation amongst ICSF with and without abundant plaque.

## SA-OR120

### Modulators of Urinary Stone Formation: Transcriptional Study in an Animal Model of Hyperoxaluria

Saeed R. Khan, Sunil Joshi, Wei Wang, Ammon B. Peck. *Pathology, Univ of Florida, Gainesville, FL.*

**Background:** Role of macromolecular modulators (MMs) in stone formation has been investigated in animal models, one MM at a time. We used an unbiased approach of gene expression profiling to determine differential gene expression of all MMs shown to be involved in stone formation, in hyperoxaluric rats, with and without treatment with NADPH oxidase inhibitor apocynin.

**Methods:** Male Sprague-Dawley rats were fed rat chow or chow supplemented with 5% w/w hydroxy-L-proline (HLP) with or without apocynin-supplemented water. After 28 days, rats were euthanized, kidneys explanted and dissected to separate cortex and medulla. Total RNA was isolated and microarray analysis was conducted on the renal cortical and medullary tissues using the Illumina bead array reader™ . Gene ontology (GO) analysis and the pathway analysis of the genes was done using DAVID (Database for Annotation, Visualization of Integrated Discovery) enrichment analysis tool. Immunohistochemistry was used to confirm expressions of selected gene products.

**Results:** Administration of HLP led to crystal deposition in the kidneys. Deposits ranged from few scattered crystals to heavy deposit in the cortical tubules. Apocynin treatment resulted in near complete absence of crystals, despite showing similar levels of hyperoxaluria. Genes encoding for alpha-1and alpha-2-microglobulin, fibronectin, CD 44, osteonectin, fetuin, osteopontin, and matrix-gla protein, were up-regulated in both cortex and medulla. On the other hand, genes encoding for inter-alpha-inhibitor 1, 3 and 4, calgranulin B, prothrombin, and Tamm-Horsfall protein were down-regulated in both cortex and medulla. HLP-fed rats receiving apocynin had a significant reversal in gene expression profiles, those that were up-regulated came down while those that were down-regulated stepped up.

**Conclusions:** Our study provides a unique introspection into oxalate induced metabolic pathways in the cortex and medulla of hyperoxaluric kidneys. It appears that NADPH oxidase is involved in regulation of MM gene expression. Clearly, there are two distinct types of MMs, one is down-regulated and the other up-regulated during hyperoxaluria and crystal deposition in the kidneys.

## SA-OR121

### High Prevalence of CKD among Genetic Stone Formers

Lada Beara Lasic,[1] Vidar O. Edvardsson,[2] Runolfur Palsson,[2] David S. Goldfarb,[1] Eric J. Bergstralh,[3] Ramila A. Mehta,[3] John C. Lieske,[3] Dawn S. Milliner.[3] *[1]New York Harbor VAMC, New York, NY; [2]Landspital Univ Hospital, Reykjavik, Iceland; [3]Mayo Clinic, Rochester, MN.*

**Background:** Kidney stone disease is a multisystem disease associated with reduced kidney function. Patients with primary hyperoxaluria (PH), cystinuria (Cys), APRT deficiency (APRTd), and Dent disease (DD) have lifelong recurrences of stones. Due to their rarity, understanding of the impact of these disorders on kidney function is limited. We performed a cross-sectional study of estimated glomerular filtration rate (eGFR) in patients with each of these disorders.

**Methods:** A total of 380 patients with PH, 223 with Cys, 46 with APRTd, and 108 with DD were enrolled in the observational registries of the Rare Kidney Stone Consortium. Serum creatinine at first presentation was used for calculation of first eGFR by the MDRD equation in adults and modified Schwartz equation in children. The prevalence of CKD at presentation and end stage renal disease (ESRD) ever was compared between diseases.

**Results:** Stage 3 CKD was common at presentation, in 21-35% of patients. Stage 4 CKD was also common at presentation in PH, APRTd and DD (14-19%), but less so in Cys (3%). ESRD was documented in 0% (Cys) to 42% (PH) of the patients.

**Conclusions:** Stage 3 and 4 CKD is common at presentation of patients with PH, Cys, APRTd and DD. Development of ESRD at any time during registry follow up is common in all but Cys. Whether kidney damage is related to crystal nephropathy, stone burden or to other factors remains to be determined.

| | APRT deficiency (n=46) | Dent disease (n=108) | Cystinuria (n=223) | PH (n=380) |
|---|---|---|---|---|
| Age at first eGFR (yrs) | 37.2 ± 18.9 | 12.2 ± 10 | 37.4 ± 18.1 | 15.7 ± 17.1 |
| Age at last follow up (yrs) | 42.5 ± 19.4 | 18.5 ± 13.9 | 41.8 ± 18.7 | 26.1 ± 19.9 |
| Stones at diagnosis | 0.6 ± 0.8 | 3.0 ± 3.6 | 1.7 ± 1.5 | 3.9 ± 8.3 |
| N (First eGFR available) | 42 | 80 | 58 | 220 |
| First eGFR ml/min/1.73 $m^2$ | 73.4 | 74.4 | 78.8 | 71.9 |
| eGFR < 60 ml/min/1.73 $m^2$ | 14 (33%) | 27 (34%) | 12 (21%) | 78 (35%) |
| eGFR < 30 ml/min/1.73 $m^2$ | 8 (19%) | 12 (15%) | 2 (3%) | 30 (14%) |
| Patients with ESRD | 9 (20%) | 11 (10%) | 0 | 159 (42%) |
| Age at ESRD | 38.0 ± 18.8 | 34.3 ± 11.4 | - | 29.8 ± 18.5 |

## SA-OR122

### Proximal Tubule Is a Site of Injury in Oxalate Nephropathy

Dawn S. Milliner, Eric J. Bergstralh, Ramila A. Mehta, John C. Lieske. *Mayo Clinic, Rochester, MN.*

**Background:** Loss of kidney function leading to kidney failure occurs in most patients with primary hyperoxaluria (PH). Oxalate (ox)-induced parenchymal kidney injury is felt responsible. Plasma ox (Pox) is freely filtered, concentrated in tubular fluid, and may also be secreted by the proximal tubule (PT), leading to high levels in the S3 segment where nephrocalcinosis could occur. Patients with higher Pox will have higher PT ox concentrations, favoring injury by ox ion or Caox crystals. We thus examined the relationship between Pox, PT ox, and markers of PT injury (urinary retinol binding protein (RBP) and alpha 1 microglobulin (A1M)). Urine supersaturation (SS) was used as a marker for Caox crystal formation in the collecting duct.

**Methods:** 110/276 patients enrolled in the PH Registry of the Rare Kidney Stone Consortium had Pox prior to ESKD and were included for study. eGFR was estimated by modified Schwartz equation in children and MDRD in adults. RBP and A1M were measured in 24 hr urine collections. Urine SS was by EQUIL2. Maximal PT ox was estimated assuming an average 75% PT fluid reabsorption. Associations with Pox, PT ox, and eGFR were assessed by Spearman's rank correlation.

**Results:** Age at PH diagnosis was 12.8 (3.3,16.7) yrs, mean (25th, 75th %ile), eGFR 88 (66,105) ml/min/BSA, Pox 6.7 (2.1, 8.2) umol/L, PT ox 47 (29,72) umol/L, and Uox 1.56 (0.94, 2.06) mmol/24 hrs/BSA.

| Spearman rank correlations: * .01<p< 05, **p<= 01 | Pox, umol/L (n=110) | PT ox, umol/L (n=88) | eGFR ml/min/BSA (n=98) |
|---|---|---|---|
| Uoxalate, mmol/24 hrs/BSA (n=89) | 0.51** | 0.81** | -0.13 |
| UCaox SS (n=58) | -0.03 | 0.10 | 0.24 |
| Pox, umol/L (n=110) | n/a | 0.67** | -0.47** |
| RBP, ug/gm creat (n=21) | 0.76** | 0.65** | -0.38 |
| A1M, mg/gm creat (n=21) | 0.55** | 0.32 | -0.12 |
| PT ox,umol/L (n=88) | 0.67** | n/a | -0.54** |

**Conclusions:** Uox and Caox SS, reflecting distal tubule events, did not correlate with eGFR. However, the correlation of Pox with A1M (p=0.0093), and both Pox and PT ox with RBP (p<0.001) and eGFR (p<0.001) suggest that ongoing PT injury could mediate loss of kidney function in PH.

## SA-OR123

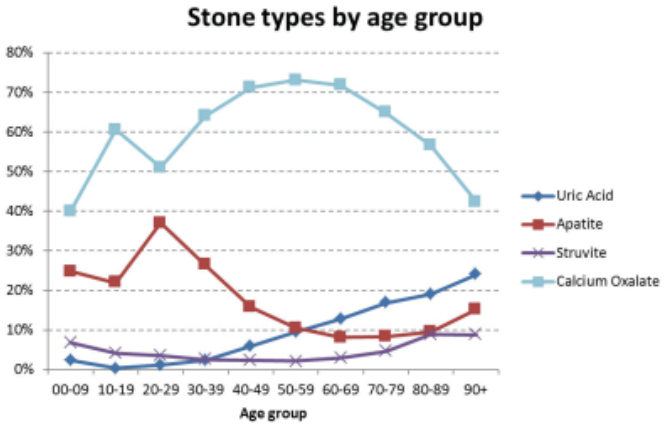
### Characteristics Associated with Stone Composition in a Large Referral Laboratory

John C. Lieske, Eric J. Bergstralh, Xujian Li, Thomas P. Moyer, Andrew D. Rule. *Mayo Clinic, Rochester, MN.*

**Background:** The prevalence of stone disease appears to be rising in the United States. We examined the case mix of stone composition in a large referral laboratory in order to discern characteristics that may explain this trend.

**Methods:** There were 48,446 stones submitted for analysis in the Mayo Clinic metals laboratory for the year 2010, but analysis was restricted to the first stone submitted per person (n=43,545). Each stone former was classified into mutually exclusive groups using the following order: any struvite (ST), any cystine (Cy), any uric acid (UA), any brushite (BR), majority (≥50%) Calcium oxalate (CaOx), or majority (≥50%) hydroxyapatite (HA).

**Results:** CaOx (67%) were most common, followed by HA (16%), UA (8%), Struvite (3%), BR (0.9%) and cystine (0.35%). Women were more likely to have a HA (65%) or ST (65%) stone, while men were more likely to have a CaOx (64%) or UA (72%) stone (P< 0.001). There were striking age trends in stone type, with HA stones being more common among those 20-29 yrs old, CaOx among those 40-70 yrs old, and UA among those 70+ yrs old (P<0.001, Figure). More CaOx and UA stones occurred in July and August (P<0.001), while calendar month did not influence other stone types.



**Conclusions:** Overall, CaOx stones are the most common, as is generally accepted. However, age and gender have marked influence on the type of stone formed. The change in composition amongst the elderly favoring UA has not previously been appreciated. These data also suggest a summer effect of increased stone risk, although this is restricted to CaOx and UA stones.

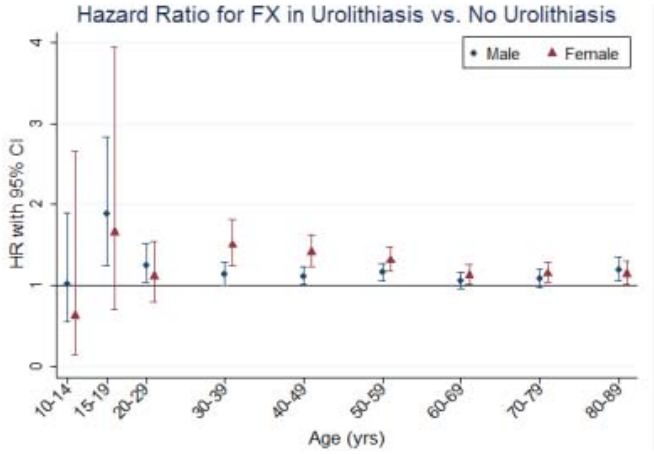
### Urolithiasis and Fracture Risk over the Lifespan: A Population-Based Study Using the Health Improvement Network (THIN)

Michelle Denburg,[1,2] Lawrence A. Copelovitch,[1,2] Kevin Haynes,[1] Shamir Tuchman,[3] Gregory Edward Tasian,[2] Mary B. Leonard.[1,2] *[1]Perelman School of Medicine at the Univ of Pennsylvania; [2]Children's Hospital of Philadelphia; [3]Children's National Medical Center.*

**Background:** Studies have shown decreased bone mineral density in patients with urolithiasis, but the fracture (FX) burden is unclear. The objectives of this study were to determine if urolithiasis is associated with increased FX risk and to explore age, sex and site-related differences.

**Methods:** In a retrospective cohort study using THIN, a primary care electronic medical records database, we identified 60,629 subjects with urolithiaisis and randomly selected 605,264 age, sex, and practice-matched subjects (10:1). Cox regression analysis was used to estimate the hazard ratio (HR) for first FX.

**Results:** Median age was 51 yrs, and 68% were male confirming their 2-fold greater urolithiasis burden. Over a median follow-up of 5 yrs (IQR 2-10), 4321 first FX events occured in those with urolithiasis (113/10,000 person-yrs) vs. 36,367 FX events (98/10,000 person-yrs) in those without urolithiasis. Distribution of FX site was comparable between groups with forearm/wrist, hand, and lower leg/ankle being the most common sites in both. Median time from initial urolithiasis diagnosis to FX was 10 yrs (IQR 4-19). The effect of urolithiasis on FX risk differed by sex and age (p for interactions ≤0.003). Urolithiasis was associated with significantly increased FX risk in women after age 30 and in young, middle-aged and elderly men, with the greatest risk in the 3rd decade for females and late adolescence for males.



**Conclusions:** Urolithiasis was associated with increased FX risk, and the distribution of FX sites did not differ from that of the general population. While the HR was greatest in young adults, the significantly increased risk in the elderly has important public health implications.

## SA-OR125

**Metabolic Acidosis as a Risk Factor for Mortality in Peritoneal Dialysis Patients** Tae Ik Chang,[1] Seung Hyeok Han,[2] Hyung Jung Oh,[2] Tae-Hyun Yoo,[2] Dae-Suk Han,[2] Shin-Wook Kang.[2] *[1]Dept of Internal Medicine, NHIC Ilsan Hospital, Gyeonggi-do; [2]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

**Background:** Metabolic acidosis is common in patients with end-stage renal disease (ESRD) and is associated with increased mortality in hemodialysis (HD) patients. Given the continuous provision of dialysis treatment with PD, PD is more effective in correcting metabolic acidosis than HD, and thus the impact of metabolic acidosis on clinical outcomes may differ between the two dialysis modalities. However, there have been few studies on the relationship between serum bicarbonate levels and the risk of death in PD patients.

**Methods:** This prospective observational study included a total of 441 incident ESRD patients who started PD from Jan 2000 to Dec 2005. Using time-averaged serum bicarbonate levels (TA-Bic), we elucidated whether metabolic acidosis could predict all-cause mortality in these patients.

**Results:** Multivariable linear regression analysis revealed that serum bicarbonate concentrations were positively associated with hemoglobin levels ($\beta = 0.187$; $P < 0.001$) and residual renal function (RRF) ($\beta = 2.038$; $P = 0.042$), while they were negatively associated with serum albumin ($\beta = -0.235$; $P < 0.001$) and C-reactive protein (CRP) levels ($\beta = -2.804$; $P = 0.005$). During a median follow-up duration of 34.8 months, 149 deaths were recorded. After adjustment for age, diabetes, coronary artery disease, serum albumin, ferritin, CRP, RRF, normalized protein catabolic rate, and percentage of lean body mass, TA-Bic levels were associated with a significantly lower risk for mortality (HR per 1 mEq/L increase, 0.83; 95% CI, 0.76-0.90; $P < 0.001$). In addition, compared to patients with TA-Bic concentrations of 24-26 mEq/L, TA-Bic levels < 22 and 22-24 mEq/L groups conferred 15.9- and 2.1-folds increased risk of death, respectively. Similar findings were observed for cardiovascular mortality.

**Conclusions:** Metabolic acidosis was an independent risk factor for mortality in incident PD patients. This relationship between low bicarbonate levels and adverse outcome might be partly related to enhanced inflammation associated with metabolic acidosis.

## SA-OR126

**The PD-Biosensor: A New, Quick and Easy Method to Assess the Functions of the Peritoneal Membrane** Giuseppe Pontoriero, Vincenzo La Milia, Francesco Locatelli. *Nephrology and Dialysis, A. Manzoni Hospital, Lecco, Italy.*

**Background:** During peritoneal dialysis (PD) glucose (G) is absorbed from dialysate (D) to blood (B) and the others solutes as urea, creatinine (Cr), etc, diffuse from B to D. During a dwell with a high osmolarity PD solution (S) a marked reduction in the D sodium concentration ($\Delta$Na) may occur. To evaluate the functions of peritoneal membrane (PM) we use the peritoneal equilibration test (PET). The PET is complicated and requires a considerable expenditure of time and resources.

**Methods:** The PD-Biosensor (PD-B) is based on the ionic conductivity (Cd). Since the Cd of a S is a function of electrolytes concentration and of viscosity, due the G concentration, it is possible to evaluate changes in the Cd of the PD S during a dwell with a 3.86% G concentration, during which there is a dilution of the electrolytes and G absorption present in PD S. This difference in Cd are measured by the PD-B and can be used to evaluate the functions of PM. We evaluate the functions of PM during a 3.86%-modified-PET by the PD-B and the classical PET parameters in 69 PD pts (38 M, 31 F).

**Results:** The values of Cd, in the D at 240' of dwell, was well correlated with transport of G ($D/D_0$) ($r^2$=-0.62), small solutes transport (D/PCr) ($r^2$=0.72) and $\Delta$Na ($r^2$=-0.63). Twelve pts (17%) had ultrafiltration failure (UFF). All the pts with UFF had a Cd, in the D at 240' of the dwell, more then 12.5 mS/cm. The ROC curve for UFF of Cd measured by PD-B at 240' had an area under curve (AUC) of 0.907 (chiSquare=10.20, p<0.002), the AUC of D/PCr was 0.879 (chiSquare=10.87, p=0.001) and the AUC of $D/D_0$ was 0.810 (chiSquare=8.50, p<0.01). The changes of Cd, measured by PD-B, during a 3.86%-modified-PET, are expression of changes in the peritoneal transport of G, small solutes (Cr) and Na: all these parameters can be measured together and with a single numeric parameter. The changes of Cd, measured by PD-B, are predictive of UFF.

**Conclusions:** The PD-B is a new, inexpensive and easy method to evaluate the functions of PM in real time without laboratory assay, calculation and interpretation of data. The PD-B can be used to evaluate the functions of PM more frequently, also at home, and may open new perspectives in PD.

## SA-OR127

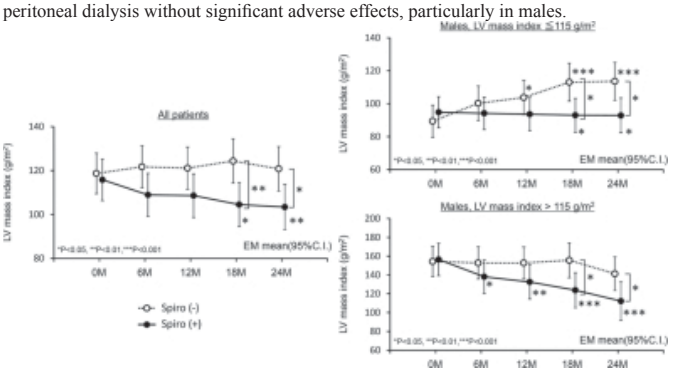
**Spironolactone Prevents Cardiac Hypertrophy in Peritoneal Dialysis Patients without Significant Adverse Effects** Yasuhiko Ito,[1] Masashi Mizuno,[1] Yasuhiro Suzuki,[1] Hirotake Kasuga,[2] Shoichi Maruyama,[1] Yukio Yuzawa,[2] Seiichi Matsuo.[1] *[1]Nephrology, Nagoya Univ, Nagoya, Japan; [2]Nagoya Spiro Study Group.*

**Background:** End-stage renal diseases treated by dialysis are associated with a high prevalence of increased left ventricular hypertrophy, which is associated with high mortality. Mineralocorticoid receptor antagonists are reported to improve the survival of patients with chronic heart failure (NEJM 1999, 2003, 2011); however, these effects remain uncertain in patients on dialysis.

**Methods:** We conducted a multicenter, open-label, prospective randomized trial in 158 patients under treatment with either angiotensin converting enzyme inhibitor or angiotensin type 1 receptor antagonist and on peritoneal dialysis with and without spironolactone (control group) for 2 years.

**Results:** Left ventricular mass index (LVMI) was significantly suppressed in patients taking spironolactone after 18 months. As normal values of LVMI differ between males and females, we separately analyzed the effects. LVMI for males with a normal LVMI of ≤115 g/m$^2$ at baseline did not change in the group given spironolactone, but significantly increased in the control group. The LVMI for males with a higher LVMI at baseline did not change in the control group but was significantly reduced in the spironolactone group. These effects were unclear in females. The effects of spironolactone were obvious in patients with reduced residual renal function. Effects on ejection fraction were also confirmed in patients with reduced residual renal function. Renal Kt/V and dialysate/plasma creatinine ratio did not significantly differ between the groups during the observation period. Serious adverse effects such as hyperkalemia were not observed.

**Conclusions:** Spironolactone may help to prevent cardiac hypertrophy in patients on peritoneal dialysis without significant adverse effects, particularly in males.



## SA-OR128

**Urgent-Start Peritoneal Dialysis versus Other Modalities of Dialysis: A Prospective Cohort Study** Arshia Ghaffari, Gbemisola Adeseun, Ushir V. Patel. *Div of Nephrology, Univ of Southern California, Los Angeles, CA.*

**Background:** Several reports have described the feasibility of urgent initiation of peritoneal dialysis (PD) in unplanned end-stage renal disease (ESRD) patients using low-volume recumbent PD soon after PD catheter placement. While short-term clinical outcomes are similar to other dialysis modalities, there is a lack of data about longer-term outcomes.

**Methods:** This is a single-center prospective cohort study comparing hospitalizations, central venous catheter (CVC) exposure and infectious complications amongst 111 incident ESRD patients (17 planned HD, 13 planned PD, 53 urgent HD, 28 urgent-start PD) at our dialysis center between Jan 1, 2010 and December 31, 2011 with a median followup of 365 days (range 90-365 days).

**Results:** The differences in hospitalization rates (planned PD 0.92 ± 1.16; urgent-start PD 0.89 ± 1.17; planned HD 1.2 ± 2.1; urgent HD 1.6 ± 1.8) and length of stay (planned PD 5.7 ± 8.17 days; urgent-start PD 4.39 ± 6.06; planned HD 9.4 ± 17.6; urgent HD 9.6 ± 11.5) were not significantly different amongst different dialysis modalities (p>0.05). As compared to the urgent HD group, the average duration of CVC use was significantly lower in all other groups (planned HD 33.4 ± 64.1 days; planned PD 31.9 ± 85.3; urgent-start PD 19.1 ± 44.13; urgent HD 248.3 ± 99.4, p<0.001). The bacteremia rate were significantly

higher in the urgent HD group as compared to all other groups (planned HD 0, planned PD 0, urgent HD 0.39 ±0.77, urgent PD 0.07± 0.26, (p=0.01). Peritonitis rates were comparable between the urgent-start PD and planned PD groups at 1 to 100.9 patient-months versus 1 to 25.4 patient-months respectively. There were 2 deaths in the urgent HD group while no deaths occurred in the other groups.

**Conclusions:** Our study demonstrates that patients urgently started on PD have significantly lower CVC exposure and bacteremia rates than patients urgently started on HD, while having comparable rates to planned PD and HD. Our study suggests that urgent-start PD is feasible in late presenting patients with outcomes that warrant more widespread adoption of this modality in clinical practice.

## SA-OR129

**Peritoneal Dialysis Start and Mortality** Arsh Jain,[1] Jessica M. Sontrop,[1] Jeffrey Perl,[2] Peter G. Blake,[1] William F. Clark,[1] Louise M. Moist.[1] *[1]Nephrology, London Health Sciences Centre, London, Canada; [2]Nephrology, St. Michael's Hospital, Toronto, Canada.*

**Background:** Several observational studies of hemodialysis patients show an association between early dialysis initiation and increased mortality. Few studies have examined this association among peritoneal dialysis patients.

**Methods:** We analyzed a cohort of 8,047 peritoneal dialysis patients and evaluated the association between timing of dialysis initiation and mortality (Canada, 2001-2009). We calculated estimated glomerular filtration rate (eGFR) at dialysis initiation and defined early, mid, and late starts as eGFR >10.5, 7.5–10.5, and <7.5 mL/min per 1.73 $m^2$, respectively. We used multivariable piece-wise Cox regression to evaluate mortality (overall and annually).

**Results:** Between 2001 and 2009, the proportion of patients starting peritoneal dialysis as early starts increased from 29% (95% CI: 26% to 32%) to 44% (95% CI: 41% to 47%). Compared with late starts, the overall mortality rate was not higher among early starts (adjusted HR 1.08; 95% CI: 0.96, 1.23) nor mid starts (adjusted HR 0.96; 95% CI: 0.86, 1.09). However, when examined annually, early starts were significantly more likely to die within the first year of starting dialysis compared with late starts (adjusted HR 1.38; 95% CI: 1.10, 1.73), but not in subsequent years.

**Conclusions:** In Canada, patients are initiating peritoneal dialysis at increasingly higher levels of eGFR. Contrary to most observational studies assessing hemodialysis, the early initiation of peritoneal dialysis, at an eGFR above 10.5 mL/min per 1.73 $m^2$, is not associated with increased mortality.

## SA-OR130

**Chondroitin Sulfate Attenuates Peritoneal Fibrosis Induced by Chlorhexidine Gluconate in Mice** Shinichi Abe,[1] Tomoya Nishino,[1] Kumiko Io,[1] Yoko Obata,[1] Takehiko Koji,[2] Shigeru Kohno.[1] *[1]Second Dept of Internal Medicine, Nagasaki Univ School of Medicine, Nagasaki City, Nagasaki Prefecture, Japan; [2]Dept of Histology and Cell Biology, Nagasaki Univ School of Medicine, Nagasaki City, Nagasaki Prefecture, Japan.*

**Background:** Long-term peritoneal dialysis causes peritoneal fibrosis in submesothelial areas. Previousreports suggest that the angiogenesis and inflammation play crucial roles in peritoneal fibrosis. Chondroitin sulfate (CS) is a typical glycosaminoglycan distributed in a wide variety of tissues, and recent studies suggest the effect to various inflammatory diseases by suppressing NF-kB activation. Therefore, we examined the effect of chondroitin sulfate on the progression of peritoneal fibrosis in mice.

**Methods:** 10 week-old male ICR mice were divided into three groups, chlorhexidine gluconate (CG), CG + CS, and control group. Peritoneal fibrosis was induced by the injection of CG into peritoneal cavity in mice every other day for 3 weeks. CS or vehicle was administered every day orally from the start of CG injection for 3 weeks. The mice were sacrificed 3 weeks after the first CG injection and peritoneal tissues were dissected out. Morphologic peritoneal changes were assessed by Masson's Trichrome staining. Inflammation and fibrosis associated factors were assessed by immunohistochemically.

**Results:** In CG-injected mice, the marked thickening of the submesothelial compact zone was shown. In contrast, the administration of CS suppressed the progression of submesothelial thickening and type III collagen accumulation in CG-injected mice. The numbers of a smooth muscle actin-positive cells and phosphorylated-Smad 2/3-positive cells were decreased to a significantly greater extent in CG + CS group than CG group. Also, the numbers of F4/80-positive cells and MCP-1-positive cells in CG + CS group were significantly fewer than that in CG group.

**Conclusions:** Our results indicate that CS can suppress peritoneal thickening and fibrosis in mice. These results suggest that CS may have therapeutic potential for peritoneal fibrosis.

## SA-OR131

**The Impact of Interaction of Advanced Glycation End-Products and Its Receptor for the Development of Peritoneal Fibrosis in Peritoneal Dialysis with Renal Failure** Akira Onishi,[1] Yoshiyuki Morishita,[1] Hiromichi Yoshizawa,[1] Ichiro Hirahara,[1] Shigeaki Muto,[1] Eiji Kusano.[2] *[1]Div of Nephrology, Dept of Medicine, Jichi Medical Univ, Shimotsuke, Tochigi, Japan; [2]Utsunomiya Social Insurance Hospital, Utsunomiya, Tochigi, Japan.*

**Background:** The interaction of advanced glycation end-products (AGEs) and its receptor; RAGE was suggested to contribute to the development of peritoneal fibrosis in peritoneal dialysis (PD); however, the impact of this interaction in renal failure (RF) that is the actual clinical condition of PD has not been fully elucidated. In this study, we investigated the impact of AGEs-RAGE interaction for the development of peritoneal fibrosis in PD with RF.

**Methods:** RF was induced by feeding 0.75% adenine-containing food for 2 weeks in Sprague-Dawley rats. Subsequently, 100 ml/kg of PD fluid containing 5 mM of methylglyoxal (MGO) was intraperitoneally injected every day for 3 weeks to induce peritoneal fibrosis. In some RF rats, PD fluid containing AGE inhibitors; 50 mg/kg of aminoguanidine (AG) or 1 mg/kg of pyridoxamine (PX) with MGO was injected. The rats with normal renal function (non-RF) that were injected with MGO-containing PD fluid served as control. Finally, the peritoneal tissue were obtained to investigate morphological changes by light microscopy, the expression of an epithelial marker; cytokeratin and a mesenchymal marker; α-smooth muscle actin (α-SMA), AGEs, and RAGE, and the signal transduction by immunofluorescence and/or qRT-PCR.

**Results:** Peritoneal fibrous thickening with decreased expression of cytokeratin and increased expression of α-SMA were more strongly observed in RF rats than those in non-RF rats. The increased expression of AGEs and RAGE was also more strongly detected in RF rats compared with those in non-RF rats. The increased expression of TGF-β1 and Snail was highly detected in RF rats compared with those in non-RF rats. These changes in RF rats were significantly inhibited by AG and PX.

**Conclusions:** The results of present study suggested that AGEs-RAGE interaction was enhanced and contribute to peritoneal fibrosis in PD with RF. The AGE inhibitors may be a potentially good therapeutic option for peritoneal fibrosis in PD with RF.

## SA-OR132

**Cell-Free Plasma DNA as Index of Apoptosis and Tissue Damage in Peritonitis** Grazia Maria Virzì, Sabrina Milan Manani, Alessandra Brocca, Sonya Day, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco. *Nephrology Dept-IRRIV, Vicenza, Italy.*

**Background:** Cell-free plasma DNA (cfDNA) is a circulating acellular DNA fragments and originates from necrotic and apoptotic cells reflecting inflammation. High levels of cfDNA have been reported in many clinical conditions as Chronic Kidney Disease. Its application has increased in diagnostic field. However, there is no data on cfDNA in peritoneal dialysis (PD) patients with peritonitis. The objective of this study was to evaluate the variation of cfDNA subsequent to peritonitis as index of apoptosis and tissue damage.

**Methods:** cfDNA was extracted from plasma in 54 PD patients: 33 without peritonitis, 29 with peritonitis recovered for more than 3 months (mo), and 8 with peritonitis during the last 3mo. cfDNA was quantified by Real-Time PCR for the β-globin gene, in triplicate. We compared patients with peritonitis in the last 3mo and without by Mann-Whitney test. We applied a linear transformation of cfDNA. Furthermore, we performed a univariate linear regression of log(cfDNA) on days from the start of last peritonitis. A p<.01 was considered statistically significant.

**Results:**

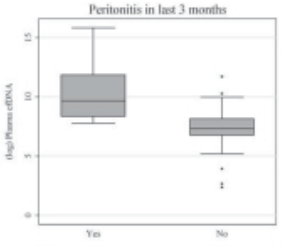


Figure1a:The median concentrations of plasma cfDNA of patients with and without peritonitis in the last 3 months

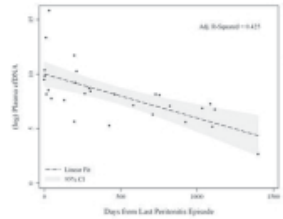

Figure1b: A significant negative correlation was observed between plasma cfDNA concentration and days from the start of last peritonitis (p<.01).

The median concentrations of patients cfDNA with and without peritonitis in the last 3mo were 16025 vs 1518.37 pg/µl, respectively (p<.01). A significant negative correlation was observed between cfDNA concentration and days from the start of last peritonitis (p<.01). Each one-unit increase in days from the start of peritonitis was associated with .402% decrease in cfDNA level.

**Conclusions:** Our data have demonstrated that cfDNA subsequent to peritonitis is increased in PD patients as index of tissue damage. Decreasing levels of cfDNA were observed in patients with a longer peritonitis-free period. cfDNA could be a marker of peritoneal membrane repair. Our results indicate the potential future role of cfDNA in the prognosis of tissue recovery from peritonitis.

**SA-OR133**

**The Development of *In Vivo* Small Interfering RNA Delivery System with Nanoparticles to Peritoneum for the Treatment of Peritoneal Fibrosis**
Hiromichi Yoshizawa,[1] Yoshiyuki Morishita,[1] Akira Onishi,[1] Shigeaki Muto,[1] Eiji Kusano.[2] *[1]Div of Nephrology, Dept of Medicine, Jichi Medical Univ, Shimotsuke, Tochigi, Japan; [2]Utsunomiya Social Insurance Hospital, Utsunomiya, Tochigi, Japan.*

**Background:** Peritoneal fibrosis is an intractable complication without any established therapies in peritoneal dialysis (PD). Gene therapies would be a potentially good strategy for treatment of peritoneal fibrosis; however, the delivery methods of treatment genes to peritoneum remain to be established. We attempted to develop in vivo small interfering RNA (siRNA) delivery system with non-viral nanoparticles (NPs) to peritoneum for treatment of peritoneal fibrosis.

**Methods:** Peritoneal fibrosis mice were produced by intraperitoneally injection of PD fluid containing 40mM of methylglyoxal to C57BL/6 mice every day for 2 weeks. For delivery of anti-fibrotic (TGFβ1) siRNA to peritoneum, 500nmol of lyophilized NPs composed with phospholipids were rehydrated by 100 μl of water containing TGF β1-siRNA (5nmol). Then, TGF β1-siRNA encapsulated with NPs (TGF β1-siRNA-NPs) were dissolved in 1000 μl of PD fluid and injected intraperitoneally to peritoneal fibrosis mice 3 times a week for 2 weeks. Peritoneal fibrosis mice those were injected with TGF β1-siRNA alone or non-targeted-siRNA encapsulated with NPs served as controls. Finally,the peritoneal tissues were obtained after peritoneal equilibrium test. to investigate the expression of TGF β1, epithelial cell markers (E-cadherin and occludin) and mesenchymal cell markers (α-SMA and vimentin) by qRT-PCR and/or immunohistocmestory, and morphological changes by light microscopy.

**Results:** TGFβ1-siRNA-NPs significantly knock downed TGF β1 expression in peritoneum compared with those of other groups. TGFβ1-siRNA-NPs also inhibited peritoneal fibrous thickening with decreases expression of epithelial cell markers and increases expression of mesenchymal cell markers in peritoneum compared with those of other groups. Furthermore, TGFβ1-siRNA-NPs maintained better peritoneal functions than those of other groups.

**Conclusions:** We developed in vivo anti-fibrotic siRNA delivery system with NPs to peritoneum in the therapeutic setting for peritoneal fibrosis in PD.

**SA-OR134**

**Mediators of Inflammation and Fibrosis in Peritoneal Dialysis**
Michael E. Ullian, Thomas Morinelli, Linda Walker, Megan Hicks. *Medical Univ of South Carolina.*

**Background:** Fibrosis of the peritoneal membrane limits the efficacy of peritoneal dialysis (PD), and angiotensin II (AngII) and glucose, the osmotic agent in PD fluid, appear to cause cycles of inflammation and fibrosis. We examined AngII-glucose interactions on the intracellular signals that mediate inflammation [cyclooxygenase 2 (Cox2)] and fibrosis [fibronectin (FN)] in cultured peritoneal mesothelial cells (PMC) and experimental PD.

**Methods:** Cells harvested from rat peritoneum were studied in culture passages 0 and 1, when characteristic cobblestone appearance was maintained. Cox2 and FN protein content (b-actin content for normalization) were quantitated by immunoblotting. Experimental PD was performed in 100 gm rats by intraperitoneal injection twice daily of 5 ml of saline or 4.25% glucose-containing PD fluid for 5 weeks, followed by parietal mesothelium fixation and Masson's Trichrome staining.

**Results:** In PMC, 10 nM AngII increased Cox2 expression 9.8-fold at 6 hr and 2.1-fold at 24 hr (n = 4); in contrast, FN expression occurred more slowly: 0.6-fold increase at 6 hr and 1.3-fold increase at 24 hr (n = 2). Glucose (2.5%) increased Cox2 expression 9.4-fold at 6 hr and 24.1-fold at 24 hr, and the addition of 10 nM AngII to the glucose increased Cox2 expression to 33.9-fold at 6 hrs but did not increase it at 24 hr. Exposure of PMC to maximal stimulation of glucose (4.25%, 24 hr), the osmotic control mannitol (4.25%, 24 hr), or AngII (100 nM, 6 hr) resulted in 17- to 26-fold increases in Cox2 expression that were 90% prevented by inclusion of 5 μM Ro-1069920, an inhibitor of NF-kB, which is a well-described mediator of inflammation (n = 2-4). Experimental PD in rats resulted in thickening of the mesothelium: [13 μm (saline) vs 24 μm (4.25% glucose-containing PD fluid), n = 8], which was completely prevented by inclusion of 10 μM losartan (AngII type 1 receptor antagonist), $p < 0.05$.

**Conclusions:** Glucose in PD fluid appears to cause cycles of inflammation and fibrosis of the peritoneal membrane, via mechanisms that include AngII and osmotic stress. The AngII type 1 receptor and NF-kB may be loci whose inhibitors could limit inflammation/fibrosis of the peritoneum and prolong PD as a renal replacement modality.

## TH-PO001

**RIFLE Classification in Geriatric Patients with Acute Kidney Injury in the Intensive Care Unit** Eun Young Seong,[1] Min Ji Shin,[1] Harin Rhee,[1] Il Young Kim,[2] Dong Won Lee,[2] Soo Bong Lee,[2] Byeong Yun Yang,[1] Ihm Soo Kwak.[1] *[1]Dept of Internal Medicine, Pusan National Univ School of Medicine; [2]Dept of Internal Medicine, Pusan National Univ Yangsan Hospital.*

**Background:** The RIFLE (risk, injury, failure, loss, and end-stage) classification is widely used to gauge the severity of acute kidney injury(AKI), but its efficacy has not been formally tested in geriatric patients. We studied 256 elderly patients who developed AKI in intensive care unit(ICU) in accordance with the RIFLE creatinine criteria.

**Methods:** Patients were eligible if they were ≥65 years and developed AKI in ICU between between January 2009 and April 2013. Exclusion criteria included patients on maintenance dialysis and stayed in ICU for <48 hours. We used the sRIFLE classification system in which only creatinine levels are used to classify patients.

**Results:** The mean age was 74.4±6.3 years. The cause of AKI was dehydration(11.7%), infection(47.7%), bleeding(4.3%), contrast(3.1%), drugs(5.1%), obstruction(2.3%), cardiogenic shock(17.2%), renal infarction(0.8%), rhabdomyolysis(3.9%). They were categorized into R (n=53,20.7%), I (n=102,39.8%), and F (n=101,39.5%) groups. Amon 256 patients, 97(37.9%) died during index hospitalization (19 days, interquartile range 10-34). Age was not significant factor discriminating between survivors and non-survivors. The in-hospital mortality rates for R, I, and F groups were 26.4%, 42.2%, and 39.6%,respectively. A logistic regression analysis was performed to identify the independent predictors for in-hospital mortality. There was no significant associations between RIFLE groups (for I vs. R: odds ratio (OR), 2.03; 95% confidence interval (CI), 0.98-4.19; p=0.56; for F vs. R: OR, 1.82; 95% CI, 0.88-3.78; p=0.11). After adjustment, hemoglobin and number of failing organs were significantly associated with higher in-hospital mortality rates, however, R,I, or F classifications were not significantly associated with increased hospital mortality.

**Conclusions:** RIFLE classification might not be associated with mortality rate in geriatric patients in ICU. In geriatric patients with acute kidney injury in ICU, various factors should be considered other than serum creatinine.

## TH-PO002

**The Effect of Minor Episodes of Acute Kidney Injury on Progressive Renal Dysfunction in Early Stage of Chronic Kidney Disease Patients** Eunjung Cho,[1] Myung-Gyu Kim,[1] So-Young Lee,[2] Won-Yong Cho,[1] Sang-Kyung Jo.[1] *[1]Korea Univ Anam Hospital, Republic of Korea; [2]Eulji Univ Hospital, Republic of Korea.*

**Background:** Several recent studies performed in in-hospital or ICU settings revealed that dialysis requiring severe acute kidney injury (AKI) episode is a well-known risk factor for progression of chronic kidney disease (CKD). However, the impact of minor episodes of AKI in ambulatory, outpatient setting in patients with early stages of CKD has not been well studied.

**Methods:** We retrospectively assembled a cohort of stable, 391 ambulatory patients with stage 2 or 3 CKD who had more than three values of serum creatinine and visited outpatient clinic longer than one year. Our primary outcome was a 15 ml/min/1.73m$^2$ decline of eGFR and we analyzed the risk of CKD progression as a function of AKI episodes. In addition, we also assessed the effect of eGFR variability defined as degree of deviation from the patient specific slope of eGFR on CKD progression.

**Results:** Over a mean follow-up of 905 days, 100 (25.6%) patients had AKI episodes. Only one patient needed renal replacement therapy and most patients (74%) showed less than two fold increase of eGFR. Patients with AKI episodes were older and more likely to have diabetes or hypertension and lower baseline GFR. More patients were taking diuretics or beta blocker than patients without AKI episodes. Mean follow up period was similar in both groups. We observed no mortality in our cohort during the follow-up period. Significantly more patients with AKI episodes reached primary outcome than patients without AKI episodes [19 (19.0%) vs. 18 (6.2%), p=0.001]. In multivariate Cox proportional hazard model, AKI episode and baseline eGFR were independent predictors of CKD progression (hazard ratio 5.515 for AKI vs. 1.039 for baseline GFR). However, eGFR variability was not found to be associated with faster progression of renal dysfunction.

**Conclusions:** Even minor AKI episodes in stage 2 or 3 CKD patients are thought to be still a powerful risk factor for progression of CKD and a multi-sided approach to develop tools for prevention, risk stratification or early detection, should be continued to improve ultimate prognosis.

## TH-PO003

**Effect of Acute Kidney Injury on Chronic Kidney Disease Progression and Proteinuria: Initial Results from a Pilot Study** Robert A.D. Scott,[1] Nitin V. Kolhe,[1] Chris W. McIntyre,[1,2] Richard J. Fluck,[1] Nicholas M. Selby.[1,2] *[1]Dept of Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]Div of Medical Sciences and Graduate Entry Medicine, Univ of Nottingham, United Kingdom.*

**Background:** The long term sequelae of AKI on renal function and mortality are well reported, but there remains the need for prospective studies to reinforce current evidence, allow determination of risk factors for poor outcome and to ensure that generalisable populations including all severities of AKI are studied.

**Methods:** We report the baseline results from a pilot study to test proposed methodology for a long-term, observational case-control study. Cases (AKI) and controls were identified from a hospital-wide electronic reporting system for AKI. Controls were matched to AKI patients on a 1:1 basis for CKD stage and age ± 5yrs. Renal function and proteinuria were measured at 3 months and will also be measured at 1 and 3 years. Survival data will be tracked to five years.

**Results:** 298 cases and controls were matched successfully with no differences in age (71 ± 11yrs versus 72 ± 12yrs, p=0.48) or baseline CKD stage. Baseline eGFR and serum creatinine were also similar between groups (p=0.22). At hospital discharge and at three months, serum creatinine was significantly higher in the AKI group. At three months, the mean delta eGFR was -4.5 ± 14ml/min in AKI group as compared with +3.4 ± 16ml/min in controls (p<0.001). A significantly greater proportion of patients in the AKI group demonstrated an increase of at least one CKD stage (29.7% versus 6.3%, p<0.001). Proteinuria was more common in the AKI group as compared to controls; in a significant proportion of cases this appeared non-glomerular in origin (as evidenced by a disproportionately low ACR:PCR ratio).

**Conclusions:** AKI is associated with a decline in renal function that persists to at least three months. Proteinuria in AKI patients may reflect renal parenchymal damage at the time of AKI or reflect pre-existing proteinuria that predisposed to AKI. These findings, along with longer term outcomes, will be further examined in a larger study following the successful pilot of this recruitment, consent and matching methodology.

## TH-PO004

**Community Acquired Acute Kidney Injury: Incidence and Outcomes** Robin G. Parry,[1] Aileen Coupe,[1] Anna L. Barton,[2] Angela Susan Mallard,[2] Paul Johnston.[1] *[1]Renal Unit, RCHT, Truro, Cornwall, United Kingdom; [2]Clinical Chemistry, RCHT, Truro, Cornwall, United Kingdom.*

**Background:** Acute Kidney Injury (AKI) is an important health issue. It is described in up to 20% of hospital admissions; however there are is a paucity of data concerning patients who develop AKI within the community (cAKI). We report an 8 month observational study of cAKI with respect to incidence and outcomes.

**Methods:** All General Practice (GP) serum creatinine results that exhibited a change of +/- 26 umol/L, or at least 50% change from previous results, were flagged by the pathology IT system for review to determine if AKI was present.

**Results:** A total of 606 samples were identified as having AKI between April-Nov 2012. 72 were removed as they were either repeat flags during the same AKI episode, did not meet the criteria or were not from GP locations. This left a total of 534 separate AKI episodes, identified on 528 patients. For the same period there were 159,280 samples received on 103,362 patients giving an incidence of 0.3% of samples in 0.5% of patients. AKI stage, age/sex split and follow up data are shown below.

| | AKI Total | Stage 1 | Stage 2 | Stage 3 |
|---|---|---|---|---|
| No of Patients (% of Total) | 534 | 313 (58.6%) | 165 (30.9%) | 56 (10.5%) |
| Female(%) | 51.7 | 52.7 | 49.1 | 53.6 |
| Median Age (years) (range) | 79 (19-102) | 79 (19-99) | 79 (47-102) | 80 (38-94) |
| Repeat creat within 14 days | 59.6% | 50.5% | 70.3% | 78.7% |
| Repeat creat within 28 days | 72.3% | 67.1% | 77.6% | 85.7% |

Of the repeat samples, 64.2% were taken in the community and 16.7% in acute hospital units. Worsening AKI was identified in 9.5% of patients. 28% did not have a repeat sample within 28 days (including 20% of patients who died).

**Conclusions:** The incidence of cAKI was low; however, these patients had a high mortality and high rate of hospital admission.The absence of repeat blood tests within 4 weeks in 28% of patients raises the possibility of under-recognition of the importance of AKI and a need for ongoing education.

## TH-PO005

**Effects of Renin-Angiotensin System Blockers on the Outcomes of AKI** Mark Dominic Uniacke,[1,2] Robert Lewis,[1] Scott Harris,[2] Paul J. Roderick.[2] *[1]Wessex Renal and Transplantation Service, Portsmouth, United Kingdom; [2]Univ of Southampton, United Kingdom.*

**Background:** We studied the effect of Renin-Angiotensin System Blockers (RASB) usage on the clinical features of AKI in hospitalized patients and the effect on outcomes 6 months later in those with and without pre-existing CKD.

**Methods:** A single-center prospective observational study of unselected hospital admissions between Nov. 2009 and Apr. 2011. Patients with AKI were recruited into two groups – Group 1: without pre-existing CKD and Group 2: with pre-existing CKD. Historic records of eGFR were used to identify baseline renal function. AKIN criteria were used to identify cases of AKI. 6 months later, mortality and residual functional loss (eGFR >25% fall from baseline) was assessed. Logistic Regression was used to assess the impact of RASB use on outcomes.

**Results:** 375 patients were recruited: 190 in Group 1 and 185 in Group 2. RASB use at baseline was 52%(n=99) in Group 1 and 74%(n=137) in Group 2. RASB was stopped in 90% and 92% of Groups 1 and 2 respectively at onset of AKI. There was no difference in AKIN staging between those taking and not taking RASB in either group.

In Group 1 those taking RASB at baseline were older, more likely male, and had more comorbidities. RASB had no influence on length of hospital stay (LOS), hospital or 6 month mortality, and no independent effect on recovery of function after adjustment for comorbidity.

In Group 2 there was no age, sex or comorbidity differences between those taking RASB at baseline compared to those who were not. LOS was longer in those not on RASB but there were no differences in hospital or 6 month mortality or recovery of function after adjustment for comorbidity.

After AKI, RASB were restarted in only 77% of Group 1 and 66% of Group 2. A clear clinical indication for continued used of RASB was identified in 33% and 65% of those who did not have them restarted.

**Conclusions:** Taking a RAS blocker prior to AKI does not appear to impact on the severity of AKI or its outcomes. The known clinical benefits of RASB, particularly in people with CKD, are denied to many patients following AKI.

*Funding:* Private Foundation Support

**TH-PO006**

**Community and Hospital Acquired Acute Kidney Injury in the General Hospital Population** Mark Dominic Uniacke,[1,2] Robert Lewis,[1] Scott Harris,[2] Paul J. Roderick.[2] *[1]Wessex Renal and Transplantation Service, Portsmouth, United Kingdom; [2]Univ of Southampton, United Kingdom.*

**Background:** Little is known about the natural history of AKI initiated in the community compared to AKI acquired in hospital. This is a study of hospitalized patients comparing the characteristics, natural history and outcomes of hospital and community acquired AKI.

**Methods:** A single-center prospective observational study of unselected hospital admissions between Nov. 2009 and Apr. 2011. The cohort consisted of two groups who sustained an AKI: Group 1 without pre-existing CKD and Group 2 with pre-existing CKD. Each group was further subdivided into those who had community acquired AKI evident on hospital admission and those who acquired an AKI in hospital. Historic records of eGFR were used to identify baseline renal function. AKIN criteria were used to identify cases of AKI. 6 months later, mortality and residual functional loss (eGFR >25% fall from baseline) was ascertained.

**Results:** 375 patients with AKI were recruited (Group 1 n =190, Group 2 n=185). AKI was community acquired in 62% of cases (n=118) in Group 1 and 39% of cases (n=72) in Group 2. In Group 1 community cases had a higher Charlson Comorbidity Score, were more likely to be medical admissions, to have underlying sepsis and to be of greater severity by AKIN staging. Hospital and 6 month mortality was higher in community cases while hospital acquired cases had a longer length of hospital stay. The odds of death within six months was increased in community AKI (OR 3.5, 95% C.I. 1.135 – 10.6, p=.03) but this was attenuated with adjustment for AKIN stage. No influence was found on recovery of renal function. In Group 2, community acquired AKI had higher AKIN stage and shorter hospital stay than hospital acquired AKI. There were no differences in AKI cause, mortality or in recovery of function.

**Conclusions:** Peak severity by AKIN staging was higher in community acquired AKI. In community cases without pre-existing CKD, sepsis was the most frequent cause of AKI and follow up mortality was higher. Sepsis in the community should be a target for preventive strategies.

*Funding:* Private Foundation Support

**TH-PO007**

**Angiotensin Converting Enzyme Inhibitors/Angiotensin Receptor Blockers and Risk of Contrast Induced Acute Kidney Injury: Systematic Review and Meta-Analysis** Jeffrey Ma,[1] Jesse Heyland,[1] Brenda Hemmelgarn,[1] Pietro Ravani,[1] Neesh I. Pannu,[2] Merril Knudtson,[3] Matthew T. James.[1] *[1]Div of Nephrology, Univ of Calgary, Calgary, Canada; [2]Div of Nephrology, Univ of Alberta, Edmonton, Canada; [3]Libin Cardiovascular Institute, Univ of Calgary, Calgary, Canada.*

**Background:** Contrast induced acute kidney injury (CI-AKI) is associated with adverse short and long-term outcomes. The effect of concurrent use of angiotensin-converting enzyme inhibitors (ACE-I) and angiotensin receptor blockers (ARB) on the risk of CI-AKI is uncertain. The purpose of this study is to determine the risk of CI-AKI associated with ACE-I/ARB use at the time of coronary angiography.

**Methods:** Electronic databases (MEDLINE and Embase from inception to September 2011) were searched for eligible studies. Two reviewers independently identified eligible articles and extracted data from randomized controlled trials (RCTs) and cohort studies. The random effects model of DerSimonian and Laird was used to obtain pooled estimates.

**Results:** A total of eight studies (5 RCTs and 3 cohort studies) including 1699 patients undergoing coronary angiography were identified. The mean age of participants ranged from 53.6 to 71.8 years, and mean baseline serum creatinine ranged from 80.0-141.6 umol/L. Among 5 RCTs identified, allocation concealment and blinding were reported in only one trial, and none reported an intention-to-treat analysis. All 3 cohort studies reported results following multivariable adjustment. Significant differences in the risk of CI-AKI associated with ACE-I/ARB use were identified based on study design (meta-regression p=0.04). Based on pooled results from cohort studies, ACE-I/ARB use was associated with an increased risk of CI-AKI (Relative Risk [RR] 2.84, 95% CI 1.71 – 4.69, $I^2$ 0%). Results from RCTs were heterogeneous, with no significant effect of ACE-I/ARB use on CI-AKI (Pooled RR 0.82, 95% CI 0.33 – 2.02, $I^2$ 48.9%).

**Conclusions:** Estimates of the risk of CI-AKI associated with concurrent use of ACE-I/ARB use differ significantly by study design, suggesting confounding effects among observational studies. The effects of ACE-I/ARB use on the risk of CI-AKI remain uncertain.

**TH-PO008**

**Albumin for Fluid Resuscitation Is Independently Associated with Acute Kidney Injury in Patients Undergoing Cardiac Surgery** Josee Bouchard,[1] Anne Julie Frenette,[2] Pascaline Bernier,[2] Annie Charbonneau,[2] Jean-Philippe Rioux,[1] David R. Williamson,[2] Stephan Troyanov.[1] *[1]Medicine, Hôpital du Sacré-Coeur de Montréal, Canada; [2]Pharmacy, Hôpital du Sacré-Coeur de Montréal, Canada.*

**Background:** The risk of acute kidney injury (AKI) with the use of albumin-containing fluids in the intensive care setting is not well characterized. We evaluated the risk of AKI associated with albumin (5 and/or 25%) following cardiac surgery.

**Methods:** We performed a retrospective cohort study including patients undergoing cardiac surgery in a tertiary care center from 2008 to 2010. AKI was defined by the RIFLE creatinine criterion. We performed a multivariate logistic regression (LR) to predict AKI and a propensity score predicting the likelihood to receive albumin. Our LR model included reduced left ventricular ejection fraction (LVEF), duration of extracorporeal circulation (ECC), hemodynamic instability, and use of pentastarch (HES 10%), red blood cells (RBC) or albumin.

**Results:** Our cohort included 984 patients, with a majority of Caucasian men, and a baseline eGFR of 72±19 mL/min. Twenty-three percent had a reduced LVEF and 23% underwent valvular surgery. Sixteen percent of patients received albumin, with a median dose of 1.4 g/kg (IQR 1.1-2.2). The incidence of AKI was 5.3% and was independently associated with a reduced LVEF, duration of ECC, hemodynamic instability, use of albumin and HES 10%, and transfusion of RBCs. In our model, albumin administration was associated with the highest odds ratio (OR), 2.43 (95% CI 1.28-4.61). We derived a propensity score, matching 141 cases to 141 controls. In this analysis, albumin was still associated with an increased AKI risk (OR 1.94 95% CI 1.21-3.11). The risk for AKI was higher as the albumin dose increased.

**Conclusions:** In our study, albumin administration was an independent risk factor of AKI after multivariable adjustment and remained significant in a propensity score model. We also identified a dose-relationship between albumin administration and the risk for AKI. Future studies should address the safety of albumin-containing fluids on kidney function in patients undergoing cardiac surgery.

**TH-PO009**

**Assessment of Nephrotoxic Medications in ICU Patients with Acute Kidney Injury** Kyle Gillis, Linda Awdishu, Ravindra L. Mehta. *Medicine, UCSD Medical Center, San Diego, CA.*

**Background:** AKI complicates up to 25% of ICU admissions and is associated with a high hospital and long-term mortality and adverse outcomes. Critically ill patients are exposed to multiple medications that can contribute to drug induced kidney injury. Improperly dosed medications may contribute to nephrotoxicity and further worsen underlying kidney function. We evaluated the prevalence of nephrotoxic agent exposure to test the hypothesis that nephrotoxic agent exposure would be present in greater than 25% of ICU patients who develop AKI.

**Methods:** We reviewed medical records of 94 patients enrolled in a prospective study of patients who developed AKI within the first 7 days of ICU admission. We examined exposure of nephrotoxic agents classified as antibiotics, NSAIDS, chemotherapy, ACE/ARB, immunosuppressive medications and contrast agents. Outcomes included AKI severity stage (AKIN criteria), duration, renal functional recovery and mortality.

**Results:** Nephrotoxic agent exposure was seen in > 65% of patients with over 25.27% of patients receiving multiple agents. Nephrotoxic antibiotics (58%), immunosuppressive agents (19%) and ACE/ARB agents (18%) were the commonest contributors. Patients with nephrotoxic exposure had a greater dialysis requirement, higher hospital mortality and were more likely to be dialysis dependent at hospital discharge. Patients with underlying CKD had similar hospital outcomes as those with de novo AKI. A multivariate regression model showed renal recovery was predicted by AKI severity stage and nephrotoxic exposure.

**Conclusions:** Nephrotoxic agents are important contributors to the development and resolution of AKI in critically ill patients. Additional studies are required to determine the susceptibility for drug induced kidney injury and establish the best techniques for medication dose adjustment.

*Funding:* NIDDK Support

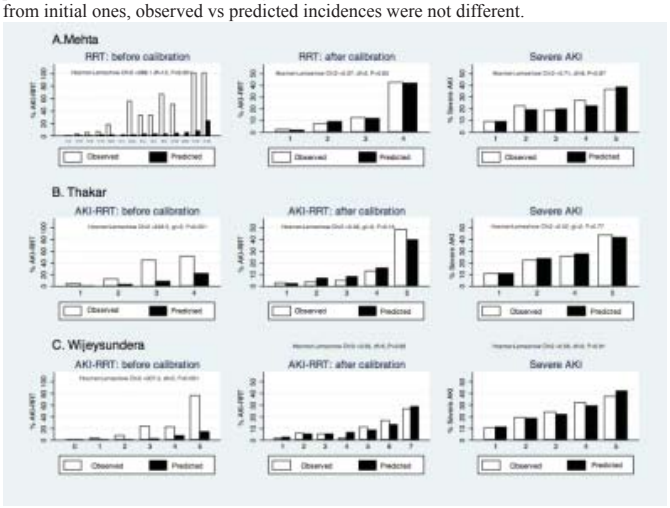
**TH-PO010**

**Validation of Three Clinical Scores to Predict Renal Replacement Therapy and Severe Acute Kidney after Cardiac Surgery** Cesar Flores-Gama, Maribel Merino, Armando Vazquez-Rangel. *Nephrology, Instituto Nacional de Cardiología Ignacio Chávez, Mexico City, Mexico.*

**Background:** Different scores to predict acute kidney injury requiring renal replacement therapy (AKI-RRT) after cardiac surgery (CS) have been developed, different criteria for starting RRT suggest that predicting severe AKI could be more useful. The aim of this study was to validate three clinical scores (Mehta, Thakar and Wijeysundera) to predict AKI-RRT and severe AKI.

**Methods:** Prospectively all patients over 17 years old undergoing CS with cardiopulmonary bypass at the Instituto Nacional de Cardiología Ignacio Chávez in Mexico City from March 2010 to June 2012 were included. RRT onset was not standardized. Severe AKI was defined as KDIGO stage ≥2 using urinary output and SCr criteria. Discrimination analysis was described using area under curve (AUC), and Hosmer-Lemeshow statistic. For calibration, logistic regression models were developed.

**Results:** A total of 752 patients (55 [42-65] years,eGFR 87±22 ml/min/1.73 m$^2$) were analyzed for Thakar and Wijeysundera scores, only 499 patients with valvular and/or coronary arterial bypass surgeries for Metha score. Forty five percent patients developed AKI, 16% severe AKI and 6.9% requiring RRT. AUCs for RRT for Mehta, Thakar and Wijeysundera scores were 0.85(0.78-0.92), 0.75(0.66-0.83) and 0.77(0.70-0.83) respectively. For severe AKI AUCs were 0.68, 0.64 and 0.66 respectively. Observed vs predicted incidences differ from original articles. After calibration, AUCs were not different from initial ones, observed vs predicted incidences were not different.



**Conclusions:** Clinical scores evaluated tend to underestimate the risk of RRT and severe AKI in our cohort. Result can be explained by a higher prevalence of RRT and severe AKI in our cohort, due to differences between cohorts. It is advisable to evaluate and calibrate scores in any population where they are meant to be used.

## TH-PO011

### Risk Factors for Acute Kidney Injury in Mechanically Ventilated Patients

Raul Lombardi,[1] Nicolas Nin,[2] Alejandro Ferreiro.[3] *[1]Dept of Critical Care Medicine, SMI, Montevideo, Uruguay; [2]CIBERES, Hospital Universitario de Torrejon, Madrid, Spain; [3]Dept of Nephrology, CASMU, Montevideo, Uruguay.*

**Background:** Few clinical studies have explored risk factors (RF) for AKI in patients under mechanical ventilation (MV). Therefore we carried out a study with the hypothesis that respiratory and ventilators variables, among others, are implicated in AKI in this setting.

**Methods:** The database of the 3th International Study of MV was used. Inclusion criteria: MV >24 hrs; two or more serum creatinine (SCr); a SCr ≤1.2 mg/dl at start of MV. AKI was diagnosed according to AKIN criteria. Variables known to be associated to AKI were included for the analysis. The study was divided in two periods: EARLY: first 48 hrs of MV; and LATE: day 5 to day 7. Accordingly, early AKI ($AKI_E$) and late AKI ($AKI_L$) were investigated. Demographic, reason for MV, physiological variables and ventilator parameters were recorded. Continuous variables are presented as mean (SD) or median IQR. Categorical variables as proportions. Comparison between groups was made by *U* Mann-Whitney or *t* test, or Fisher Exact test where appropriate. RF were assessed by a conditional logistic regression model. Variables with p<0.10 were retained in the model.

**Results:** 3520 pts were included. Mean age 58.4 (17.7). Male 58.5%. SAPS II 40 (30,52). GCS 10 (5,15). Main reasons for MV: coma and postoperative (PO). ICU mortality 21.8%. Total cases of AKI 699 (19.8%), $AKI_E$ 575 and $AKI_L$ 124. $AKI_E$ pts were older: 61.5 (17.2) vs. 58.7 (19.1); with more frequent PO reason for MV and less frequent pneumonia and coma; also higher proportion of cardiovascular (CV) SOFA ≥3; greater fluid balance; lower pH at admission. $AKI_E$ was independently associated to age, SAPS II, COPD, PO and cardiac arrest as reason for MV, CV SOFA, $Pa/FiO_2$, peak pressure, VT/kg, pH, SCr, platelet count at admission and 24 hrs fluid balance. $AKI_L$ to pneumonia pre-ICU, and CV SOFA, pH, Pa/FiO2, PEEP, plateau and platelet count all of them 24 hrs preAKI.

**Conclusions:** AKI is frequent in MV and the RF pattern is different according to the onset of AKI. $AKI_E$ was related to age, severity of illness, MODS at admission and injurious MV, while $AKI_L$ to MODS and injurious MV in ICU but not at admission.

## TH-PO012

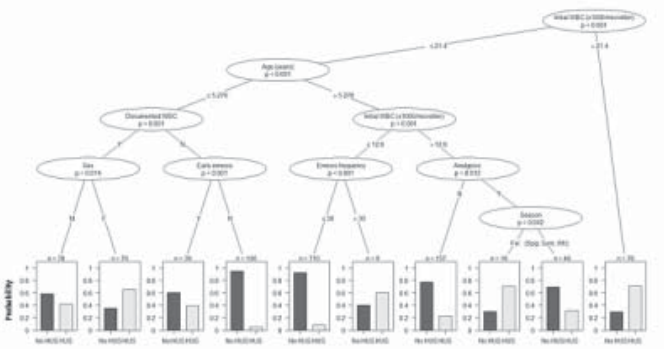
### Early Predictors of Hemolytic Uremic Syndrome (HUS) in Patients with Shiga Toxin Producing *Escherichia coli* (STEC) O157 Infection

Von Nguyen, Magdalena Kendall, Rajal K. Mody. *Centers for Disease Control and Prevention, Atlanta, GA.*

**Background:** Most studies examining risk factors for STEC-related HUS focus on children; information applicable to patients of all ages is limited.

**Methods:** We assessed 46 candidate predictors of HUS among a cohort of patients of all age groups with STEC O157 infection from 10 states during 2006–10. Confirmed HUS was defined as anemia, thrombocytopenia, serum creatinine ≥1.0 mg/dL if <13 years old ( ≥1.5 mg/dL if ≥13), and schistocytes. Probable HUS met the first 3 criteria. We built a classification tree for HUS using recursive partitioning; splitting criterion was the level of Bonferroni-adjusted significance of a permutation-based test.

**Results:** Among 1315 patients, 137 (10%) developed HUS (102 confirmed). The tree separated patients into 10 groups. Predictors identified were, in order, initial white blood cell count (WBC) (>21,400 cells/μL regardless of age and >12,800 cells/μL in patients >5.2 years old) and age ≤5.2 years. Among patients ≤5.2 years old, other predictors were any documented WBC, female sex, and emesis during the first 3 days of illness. Among patients >5.2 years old, other predictors were >30 emesis episodes in 24h, use of non-prescription analgesics, and illness during September–November. The probability of HUS varied from 6–71% across groups. The tree's sensitivity was 54%; specificity was 91%.



**Conclusions:** Distinct clinical profiles which varied by age, were associated with risk of HUS in STEC O157 infection. Profiles may help guide early clinical management of STEC O157 infection.

*Funding:* Other U.S. Government Support

## TH-PO013

### The Incidence and Risk Factors of Kidney Injury after Hepatobiliary Surgery

Won-Yong Cho,[1] So-Young Lee,[2] Eunjung Cho,[1] Myung-Gyu Kim,[1] Sang-Kyung Jo,[1] Hyoung-Kyu Kim.[1] *[1]Korea Univ Anam Hospital, Republic of Korea; [2]Eulji Univ Hospital, Republic of Korea.*

**Background:** Although intraperitoneal procedure is known to be one of major operations associated with postoperative acute kidney injury (AKI), the incidence, risk factors or its long-term renal outcome have not been well known. This study aimed to determine the risk factors and six month renal outcome after hepatobiliary surgery along with evaluating the role of urine neutrophil gelatinase-associated lipocalin (NGAL) in early detection of AKI.

**Methods:** Data were collected from 135 consecutive liver surgeries. Urine samples for NGAL determination were collected before, 6, 12, and 24 hr after surgery. AKI was defined according to the AKIN criteria. Outcome was defined as the decrease of eGFR at 6 month after surgery.

**Results:** AKI was developed in 9% after hepatobiliary surgery. Renal replacement therapy was required in only one patient. Urine NGAL at 12 hr post surgery was most predictive for the development of AKI (AUROC 0.769, p=0.003). Subclinical AKI (urine NGAL+, AKIN-) was diagnosed by the highest urine NGAL level (cutoff value, 92.85 ng/mL) during the first 24 hr after surgery, and additional 42 patients were included in AKI group. AKI group showed higher level of urine NGAL at all time points, SOFA score, prothrombin time (INR), lower albumin, and had longer operation time than those of non-AKI group. Older age and higher preoperative SOFA score were risk factors for the development of postoperative AKI. AKI group had longer hospital stay after surgery, but there was no difference in in-hospital mortality. AKI group showed significantly decreased eGFR at 6 month after surgery. Liver transplantation, baseline eGFR, maximum value of urine NGAL, and intraoperative fluid balance were associated with the decrease of 6 month eGFR.

**Conclusions:** In hepatobiliary surgery, urine NGAL was useful to diagnose AKI early and to predict 6 month renal outcome. To assess the impact of postop AKI or subclinical AKI on progressive decline of renal function, longer term follow up is needed.

## TH-PO014

### Acute Kidney Injury – What Happens after Discharge?

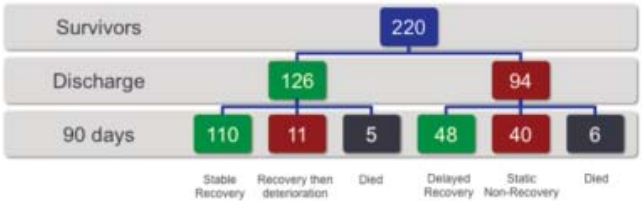
Simon Sawhney, Nick Fluck. *Renal Unit, Aberdeen Royal Infirmary, United Kingdom.*

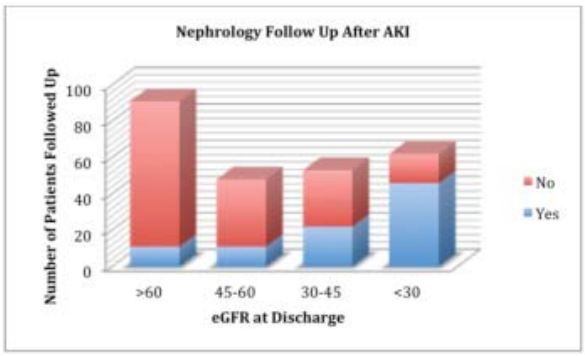
**Background:** Acute Kidney Injury (AKI) affects 1 in 5 hospital admissions. Mortality is high, but most survive to discharge although some recover incompletely. Severe AKI is linked with future CKD and mortality. KDIGO guidelines recommend outpatient surveillance. In practice, there is little data, but one study suggested as few as 10% receive outpatient renal review.

**Methods:** We audited outpatient referral in Northeast Scotland (population 500,000) over 6 months (July 2011-January 2012). Data collected included demographics, clinical context, renal function, dialysis, renal recovery (UK Renal Association criteria), mortality and follow-up.

**Results:** 333 referred patients had severe AKI with 26% hospital mortality. Of survivors, 58.1% recovered to within 20% baseline at discharge. Half of those with incomplete recovery improved over 90 days. Of hospital survivors, 36.8% received outpatient renal review. This was greater in young patients, those with incomplete recovery or renal impairment at discharge(all p 0.000). Follow up was not related to AKI severity, acute dialysis or ITU stay.

**Conclusions:** Only a minority of AKI is followed up. Nephrologists seem to prioritize by renal function but not AKI severity. Future studies should assess whether practice is consistent and supported by prognostic models.





| Follow Up | Yes | No | P-value |
|---|---|---|---|
| Baseline eGFR | 56.2 | 67.9 | 0.005$ |
| Discharge eGFR | 35.1 | 65.3 | 0.000$ |

## TH-PO015

**Hantavirus Infection – Acute Course of the Disease and Long-Term Outcome in 456 Patients from Southern Germany** Joerg Latus, Mark Dominik Alscher, Martin Kimmel, Niko Braun. *Nephrology, Robert- Bosch Hospital, Stuttgart, Germany.*

**Background:** Puumala virus (PUUV) is the most common Hantavirus species in Europe. Nephropathia Epidemica (NE), caused by PUUV, is characterized by acute renal failure (AKI) with thrombocytopenia. Data to predict a severe course of the disease, including acute course and and long-term outcome, are missing.

**Methods:** In cooperation with the local health authorities of the region, all patients with serologically confirmed NE between 2001 and 2012 were contacted (n = 1570). Between September 2012 and April 2013, altogether 456 patients were included in the study. Clinical and laboratory data were collected retrospectively from medical reports, a biobank, including blood samples, tissue and urine, was installed. During follow-up visit at our outpatient clinic, a careful PE, blood pressure measurement and lab investigations were done. During acute course, severe AKI was defined as RIFLE I and F.Long-term outcome focused on proteinuria and hypertension.

**Results:** Regarding renal dysfunction, serum levels of creatinine were elevated in 72%. 86% of the patients had AKI based on RIFLE classification. Abdominal pain, hematuria and proteinuria showed statistically significant ($p<0.01$) odds ratios (OR) (standardized OR=2.3 (95% CI, 1.4-3.7), OR=2.7 (95% CI,1.5-4.9) and OR=2.8 (95% CI,1.5-5.2) concerning severe AKI. Remarkably, neither platelets, hemorrhage, gender and age nor splenomegaly, hepatomegaly or pathological findings using x-ray were predictors for severity of AKI. None of the clinical symptoms or laboratory findings during acute course of the disease were predictors for hypertension at time of follow-up (median follow-up 17 (7-35 months). Hematuria and C-reactive protein levels during acute course were strong predictors for proteinuria within the long-term follow-up ($p<0.001$, OR=6.4 (95% CI, 3.5-12) and OR=1.3 (95% CI, 1.2-1.5).

**Conclusions:** Risk factors for a severe course of the disease were abdominal pain, proteinuria and hematuria. Regarding long-term outcome, development of hypertension seems to be independent of the severity of the acute disease whereas hematuria and the inflammatory response were strong predictors of proteinuria.

## TH-PO016

**Incidence, Risk Factors, and Outcomes of Pregnancy-Related Acute Kidney Injury Treated with Dialysis** Ainslie M. Hildebrand,[1] Kuan Liu,[2] Salimah Z. Shariff,[2] Joel G. Ray,[3] Michelle A. Hladunewich,[4] William F. Clark,[1] Amit X. Garg.[1,2] *[1]Div of Nephrology, Western Univ, London, Canada; [2]Institute for Clinical Evaluative Sciences at Western, London, Canada; [3]Dept of Medicine, Univ of Toronto, Toronto, Canada; [4]Div of Nephrology, Univ of Toronto, Toronto, Canada.*

**Background:** Acute kidney injury is a rare complication of pregnancy, but may be associated with significant morbidity and mortality in young and often otherwise healthy women. As renal dysfunction in pregnancy may be missed or misclassified using serum creatinine based definitions of acute kidney injury, we report the incidence of acute kidney injury treated with dialysis and describe the associated risk factors and maternal and fetal outcomes.

**Methods:** We used data from universal health care databases to study all consecutive pregnancies in Ontario over a 15-year period. Maternal outcomes included acute dialysis during the peripartum period, 90-day mortality, and dialysis dependence among women who survived beyond 90 days. Fetal outcomes included low birthweight, small for gestational age or intrauterine growth restriction, premature birth, stillbirth, neonatal death, and perinatal mortality.

**Results:** There were a total of 1,918,789 pregnancies in Ontario between 1997 and 2011. The cumulative incidence of acute dialysis during pregnancy was 1:10,000 over the study period. Among women who received acute dialysis, 4.3% died within the 90-day postpartum period and 3.9% of survivors were dialysis dependent. Adverse fetal outcomes associated with acute kidney injury treated with dialysis during pregnancy included low birthweight (unadjusted relative risk [RR] 4.7, 95% confidence interval [CI] 3.6 – 6.0), small for gestational age (RR 3.2, 95% CI 1.9 – 5.3), and premature birth (RR 2.5, 95% CI 2.0 – 3.1).

**Conclusions:** The incidence of acute kidney injury treated with dialysis is low, but adverse maternal and fetal outcomes exist. These results provide important prognostic information for patients and reinforce the role of the nephrologist in pre-conception counseling, risk factor reduction, and monitoring during pregnancy for women at risk.

## TH-PO017

**Iloprost: As an AKI Triggering Agent in Severe Atherosclerotic Patients** Mehtap Erkmen Uyar,[1] Piril Yucel,[2] Zeynep Bal,[1] Saliha Yildirim,[2] Emre Tutal,[1] Tankut Akay,[3] Siren Sezer.[1] *[1]Dept of Nephrology, Baskent Univ Medical School, Ankara, Turkey; [2]Dept of Internal Medicine, Baskent Univ Medical School, Ankara, Turkey; [3]Dept of Cardiovascular Surgery, Baskent Univ Medical School, Ankara, Turkey.*

**Background:** Iloprost, a stable prostacyclin analog, is used as a rescue therapy for severe peripheral arterial disease (PAD). Prostacyclin has important effects on microvascular blood flow, inhibition of platelet aggregation, leucocyte-vessel interaction and it is used frequently in the treatment of obstructive PAD. It has systemic vasodilatation and antiaggregant influence while severe vasodilatation might cause organ ischemia when severe atherosclerosis is the underlying cause. In this study we retrospectively analysed the renal outcome after iloprost infusion therapy in 87 patients.

**Methods:** 87 patients with PAD who received iloprost infusion with 1 ng/kg/min dosage for the last 6 months were retrospectively analyzed. All patients' clinical and biochemical parameters before (baseline, Cr1), during (third day, Cr2) and after (2 weeks after infusion, Cr3) the iloprost treatment were recorded. Acute kidney injury (AKI) was defined as ≥0.3 mg/dL increase in creatinine levels from baseline within 48 hours according to KDIGO guidelines.

**Results:** C2 (1.46±0.1 mg/dL) and C3 (1.53±0.12 mg/dL) levels were significantly higher from baseline Cr (1.15±0.6 mg/dL) values. AKI was observed in 36 patients (41.37%) on the third day of iloprost infusion. Binary logistic regression analysis revealed that smoking and no ASA use were the primary predictors (p: 0.02 and p:0.008 respectively) of acute kidney injury during iloprost treatment. In the third day of the infusion urinary output of patients was significantly increased from the initiation of therapy (1813.30±1123.46 cc vs. 1545.17±873.00 cc). 74.14±9.42 mm Hg vs. 70.07±15.50 mm Hg.

**Conclusions:** Even though the iloprost treatment is effective in peripheral arterial disease patients who are not suitable for surgery, severe systemic vasodilatation might cause renal ischemia ending up with non-oliguric acute kidney injury. Smoking, no ASA use and lower diastolic BP are the clinical risk factors for AKI during iloprost treatment.

## TH-PO018

**Low 25-Hydroxyvitamin D Level at Continuous Renal Replacement Therapy Initiation Predicts In-Hospital Mortality** Kyung Don Yoo, Hajeong Lee, Seung Seok Han, Jung Nam An, Yon Su Kim, Dong Ki Kim. *Internal Medicine, Seoul National Univ Hospital, Seoul, Jongno-gu, Korea.*

**Background:** The low 25-hydroxyvitamin D (25(OH)D) level has been known to be associated with the development and prognosis of acute kidney injury (AKI) in critically ill patients. However, the association between serum 25(OH)D level and outcome of AKI remains to be clarified in patients initiating continuous renal replacement therapy (CRRT).

**Methods:** This prospective observational cohort study included patients with severe AKI requiring CRRT, from Nov. 2011 to Nov. 2012. Patients with end-stage renal disease were excluded. Biochemical data including 25(OH)D were measured at the time of CRRT initiation. Patients with 25(OH)D level below the median were included in the Low group

and those with 25(OH)D level above the median were included in the High group. The primary outcome was in-hospital mortality, and the secondary outcome was duration of ventilator support and RRT.

**Results:** A total of 131 patients were analyzed. The mean age was 66.3 years and male patients were 73 (55.7 %). The mean APACHE II score was 29.18 ± 8.07. The median of serum 25(OH)D level was 6.90 ng/ml , and the mean serum 25(OH)D level were 3.97 ± 1.56 ng/mL and 12.47 ± 5.48 ng/mL in the Low group and the High group, respectively. There was no significant difference in baseline clinical characteristics including causes of AKI, Charlson comorbidity index between the groups. There was no significant difference in ventilator free days and RRT free days between two groups. However, the mortality rate was significantly higher in the Low group than in the High group (86.6 vs. 71.9 %, p=0.038). In survival analysis, low 25(OH)D level was proved to be an independent risk factor for in-hospital mortality after adjustment for by age, sex, mean arterial pressure, APACHE II ,SOFA score, c-reactive protein, hemoglobin, BUN and serum albumin (Hazard Ratio 1.63, 95% confidence interval 1.08–2.45;P=0.018).

**Conclusions:** In this study, we demonstrated that critically ill patients with AKI requiring CRRT showed severe 25(OH)D deficiency. Moreover, low 25(OH)D levelat the time of CRRT initiation might be associated with higher in-hospital mortality.

## TH-PO019

**Mean Platelet Volume Is a Prognostic Factor in Patients with Acute Kidney Injury Requiring Continuous Renal Replacement Therapy** Ji Suk Han,[1] Ji Sun Paeng,[2] Hye-Young Kang,[2] Sung Jin Moon,[3] Tae-Hyun Yoo,[1,2] Shin-Wook Kang,[1,2] Dae-Suk Han,[1] Hyung Jung Oh.[1] *[1]Dept of Internal Medicine, College of Medicine; [2]Brain Korea 21, Yonsei Univ, Seoul; [3]College of Medicine, Kwandong Univ, Gyeonggi-do, Korea.*

**Background:** Increased platelet size has been demonstrated to reflect platelet activity and to predict clinical outcome in patients with cardiovascular disease. However, the prognostic value of platelet size for mortality has never been explored in patients with acute kidney injury (AKI).

**Methods:** This study investigated the relationship between platelet size and mortality in 361 AKI patients who received continuous renal replacement therapy (CRRT) in an intensive care unit between August 2009 and October 2011. We retrospectively collected the data for mean platelet volume (MPV) representing platelet size, platelet count, and other biochemical parameters at the time of CRRT initiation. Kaplan-Meier (K-M) plots were constructed to determine and to compare 28-day mortality rates and multivariate Cox analyses were conducted to elucidate the independent prognostic value of MPV for mortality.

**Results:** The mean age was 61.1 years and 224 patients (62.0%) were male. The median MPV was 0.12 fL. At the start of CRRT, MPV was negatively correlated with platelet count ($r = -0.315$, $P < 0.001$), whereas it was positively associated with APACHE II score ($r = 0.135$, $P = 0.010$). During the study period, 239 deaths (66.2%) occurred. K-M curve revealed that all-cause mortality was significantly higher in patients with MPV ≥ 0.12 fL compared to those with MPV < 0.12 fL ($P < 0.001$). In addition, Cox regression analysis found that MPV was an independent predictor for mortality after adjustment of age, gender, platelet count, serum albumin, APACHE II score, and the cause of AKI (HR, 1.093; 95% CI, 1.023-1.167; $P = 0.008$).

**Conclusions:** MPV at the time of CRRT initiation might be a simple and useful predictor for mortality in AKI patients requiring CRRT.

## TH-PO020

**Minimal Changes in Postoperative Creatinine Values for Prediction of Mortality and Cardiovascular Events after CABG** Daniel Olsson, Marcus Liotta, Ulrik Sartipy, Martin Holzmann. *Karolinska Institutet, Stockholm, Sweden.*

**Background:** Acute kidney injury (AKI) is related to an increased risk of long-term mortality, end-stage renal disease and heart failure in patients with coronary heart disease. Coronary artery bypass grafting (CABG) is one of the most common surgeries and performed as often as 1.000.000 times annually world-wide. CABG is associated with a 5-30% risk of developing AKI The aim was to investigate the prognostic value of small, subclinical increases in postoperative serum creatinine (SCr), in patients undergoing CABG.

**Methods:** From the SWEDEHEART registry all 25.686 patients who underwent primary, isolated, non-emergent CABG in Sweden between 2000 and 2008 were included. Postoperative absolute SCr changes were categorized into 3 stages: stage 1, 0-0.3 mg/dL; stage 2, 0.3-0.5 mg/dL and stage 3, > 0.5 mg/dL. No AKI (reference group) was defined as no increase or decrease in postoperative SCr. Hazard ratios were calculated using logistic and Cox proportional hazard regression for 30-day mortality, long-term mortality and a composite of death, myocardial infarction, stroke and heart failure by AKI stage.

**Results:** During a mean follow-up of 4.5 years there were 4.350 (17%) deaths and 7.095 (28%) hospitalizations for MI, stroke, heart failure or death combined. The adjusted odds ratios with 95% confidence intervals (CI) in AKI stages 1, 2 and 3 for 30-day mortality were 1.37 (0.84-2.21), 3.64 (2.07-6.38) and 15.4 (9.98-23.9), respectively. The adjusted hazard ratios for long-term mortality in AKI stages 1, 2 and 3 were 1.07 (95% CI 1.00 to 1.15), 1.33 (95% CI 1.19 to 1.48) and 2.11 (95% CI 1.92 to 2.32), respectively. The corresponding results for the composite end-point were 1.09 (95% CI 1.03-1.15), 1.39 (95% CI 1.29-1.52) and 1.99 (95% CI 1.84-2.16), respectively.

**Conclusions:** Already subclinical increases in postoperative creatinine values are related to long-term mortality and cardiovascular events in patients undergoing CABG.

## TH-PO021

**Impact of Acute Kidney Injury Requiring Renal Replacement Therapy on Mortality and Renal Survival** Silvia Gonzalez S, Pedro J. Labrador, Jesús P. Marin, Clarencio Javier Cebrian Andrada, Maria C. Jimenez, Ines Castellano, Sandra Gallego, Vanesa Garcia-Bernalt, Juan R. Gómez-Martino. *Nephrology, San Pedro de Alcantara Hospital, Caceres, Spain.*

**Background:** The aim was to assess characteristics, renal survival and mortality of patients who developed acute kidney injury (AKI) stage 3, according to KDIGO guidelines, and needed renal replacement therapy (RRT).

**Methods:** All patients who required RRT due to AKI stage 3 along one year were included, excluding patients in intensive care unit. Demographic and personal history data, previous renal function, cause of AKI, renal function, renal survival, and mortality at one, three and six months after AKI were recorded.

**Results:** A total of 60 patients were enrolled (incidence 150 patients/$10^6$ population/year). Mean age 73.6±13.6 (range 25-91), 53.3% men. Patient's characteristics: 80% hypertensive, 32% diabetics, 42% dyslipemics, 43% obese, 23% smokers, and 58% with chronic renal failure (28.1% stage 3, 21.1% stage 4, and 8.8% stage 5). Cause of AKI: renal disease 60%, prerenal 32%, obstructive causes 8%.

Renal function (RF): Serum creatinine before AKI 1.78±1.2mg/dL; maximum serum creatinine during AKI hospitalization 7.48±4.04mg/dL; at discharge, 2.88±1.63mg/dL; one month later, 2.25±1.49mg/dL; three months later, 2.62±1.73mg/dL; and six months later, 2.53±2.09mg/dL.

During hospitalization, 20% died, 15% kept on RRT at discharge, and 65% recovered partial or completely RF. One month after AKI, 28.3% had die, 11.7% kept on RRT, and 60% preserved RF. Three months later, 41.7% died, 13.3% kept on RRT, and 45% preserved RF, 6.7% was missing. Six months later, 48.3% had died, 10% kept on RRT, 33.3% preserved RF, 8.3% were missing.

Previous RF according to KDOQI classification of patients who survived six months after AKI, was: stage 1 4.8%, 2 19%, 3 38.1%, 4 9.5% and 5 28.6%; at discharge, RF was: stage 1 2.5%, 2 7.5%, 3 17.5%, 4 45% and 5 27.5%.

**Conclusions:** In our health area AKI stage 3 requiring RRT has an incidence similar to other studies. Mortality in AKI patients increase in time, near to 50% six months after AKI episode, while renal survival decreases in this period. So nephrology follow-up must be established in these patients.

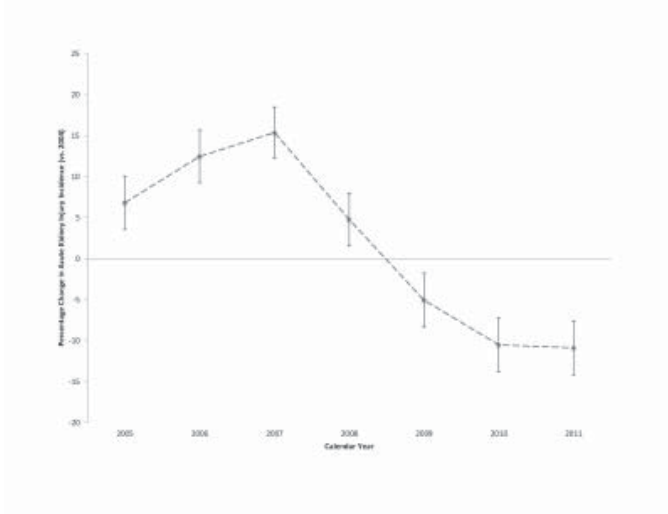
## TH-PO022

**Community-Based Trends in Hospitalized Acute Kidney Injury between 2004-2011: The Kaiser Permanente Experience** Alan S. Go,[1] Sijie Zheng,[2] Chi-Yuan Hsu,[3] Jingrong Yang,[1] Thida Tan,[1] Kathleen D. Liu,[3] Juan Daniel Ordonez.[2] *[1]Div of Research, Kaiser Permanente Northern California, Oakland, CA; [2]Div of Nephrology, Kaiser Oakland Medical Center, Oakland, CA; [3]Div of Nephrology, Univ of California, San Francisco, San Francisco, CA.*

**Background:** Administrative claims data suggest that the incidence of acute kidney injury (AKI) has increased over time, but few data exist about community-based temporal trends in AKI using changes in serum creatinine (SCr).

**Methods:** In Kaiser Permanente Northern California, a large integrated health care delivery system, we identified all hospitalized cases of AKI between 2004-2011 based on AKIN criteria (change in SCr of >=0.3 mg/dL or >50% relative change within 48 hours). We calculated the age-sex-race-adjusted incidence of AKI per year and examined the association of calendar year with AKI incidence using Poisson regression adjusting for age, sex, race, and other risk factors (diabetes, hypertension, GFR, and proteinuria) in the source population.

**Results:** Among 3,910,697 adults, mean age=48 yr; 52% were women, and 40% minorities. Adjusted incidence (per 100,000 person-years, p-y) of AKI increased from 352 in 2004 to 408 in 2007 but then decreased steadily to 322 in 2011, with similar trends in each AKI stage except for dialysis-treated AKI which increased over time (24 to 30 per 100,000 p-y). After adjustment for age, gender, race and other risk factors, compared with 2004, there was a 15% relative increase in 2007 and 11% relative decrease in 2011.



**Conclusions:** In a large, diverse community-based population, incidence of hospitalized AKI increased between 2004 and 2007 but decreased through 2011, which was not explained by population demographic and clinical factors. Studies are needed to evaluate how changes in targeted management practices may explain recent favorable trends in AKI.

## TH-PO023

**Urine Output Criteria for Defining Acute Kidney Injury: Association with Length of Stay and 5-Year Mortality in Critically Ill Children**

Rami Ali,[1,2] Jacques R. Lacroix,[2] Veronique Phan,[1] Philippe Jouvet,[1] Jean-Philippe Lafrance,[1] Ronald Gottesman,[2] Shari Ann Segal,[2] Ana Palijan,[2] Michael Pizzi,[2] Mariana Dumitrascu,[1] Nikki J. Rink,[2] Susan M. Samuel,[3] Michael Zappitelli.[2] *[1]U. Montreal, Montreal, Canada; [2]McGill U., Montreal, Canada; [3]U. Calgary, Calgary, Canada.*

**Background:** The relevance of acute kidney injury(AKI) urine output(UO) criteria in children is unclear. We determined impact of UO criteria on AKI incidence and outcome associations.

**Methods:** Retrospective cohort study (chart, administrative data) of children in to 2 intensive cares units(PICU) (excluded:no health number, serum creatinine(SCr), outcome data; dialysis, renal transplant). We compared AKI by Kidney Disease Improving Global Outcomes (KDIGO) SCr(AKI-SCr), UO(AKI-UO) and both(AKIfull) criteria for associations with outcomes: hospital[Hosp-LOS]; PICU length of stay[PICU-LOS] (multiple linear regression); 5-yr mortality(multiple logistic regression). We evaluated cardiac surgery(CS) subgroups (a priori).

**Results:** 850 children were included: (median[interquartile range,IQR]) 4.5[11.3] yrs, 54% male, 16% CS, 8% death, 31% AKI-SCr, 8% AKI-UO, 36% AKIfull. AKI-SCr and AKIfull were associated with Hosp-LOS(AKI-SCr: 14±22 *vs.*Non-AKI: 8 ±9d, p<0.0001) and PICU-LOS(AKI-SCr: 5±7 *vs.*Non-AKI: 2±2d,p<0.0001); in adjusted(adj) analyses, both with p<0.001. AKI-UO was associated with PICU-LOS(4±6d *vs.*3±4d, p<0.001), but less strongly with Hosp-LOS(11±19 *vs.* 9±12d, p<0.05); these remained significant after adjustment. The LOS associations were only significant in non-CS(not shown). All AKI methods predicted 5-yr mortality; this was strongest using AKI-UO in non-CS(Table).

| AKI Definition | All Patients 5-yr Mortality | | Non-CS 5-yr Mortality |
|---|---|---|---|
| | Unadjusted OR (95% CI) | Adjusted OR (95% CI) | Adjusted OR (95% CI) |
| AKI-SCr | 2.7 (1.6-4.4) | 1.7 (1.0-3.1) | 1.8 (1.0-3.3) |
| AKI-UO | 2.5 (1.2-4.9) | 2.5 (1.2-5.3) | 3.0 (1.3-6.7) |
| AKI-full | 2.8 (1.7-4.6) | 1.9 (1.1-3.3) | 2.0 (1.1-3.6) |

Adjustment for age, gender, PRISM score, trauma, neurologic disease, infection and vasopressors.

**Conclusions:** AKI-UO was more strongly associated with 5-yr mortality, but more weakly associated with LOS than AKI-SCr was. Studies should elucidate how this may impact on AKI definition in future research.

## TH-PO024

**Defining Renal Angina for the Prediction of Acute Kidney Injury in Patients with Septic Shock**

David D. Leedahl,[1] Erin N. Frazee,[1] Garrett E. Schramm,[1] Lakhmir S. Chawla,[2] Kianoush Banaei-Kashani.[3] *[1]Pharmacy Services, Mayo Clinic, Rochester, MN; [2]Renal Diseases and Hypertension, George Washington Univ Medical Center, Washington, DC; [3]Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

**Background:** The concept of renal angina (RA) has been recently proposed to enhance early identification of critically ill patients at high risk for acute kidney injury (AKI). The primary objective of this study was to define RA in a cohort of patients with septic shock.

**Methods:** This was a retrospective analysis of 390 adult patients admitted to the medical intensive care unit (ICU) of a tertiary, academic medical center with septic shock. We collected hourly urine output from septic shock recognition (hour 0) to the earlier of hour 96, urine catheter removal, or ICU discharge. Serum creatinine (SCr) measurements were collected until hour 96. The definition of RA was determined during the first 12 hours of resuscitation by evaluating the initial episode of oliguria, increase from baseline to peak SCr level, and Acute Physiology and Chronic Heath Evaluation (APACHE) III score in a multivariable receiver operator characteristic (ROC) analysis. The primary outcome was incidence of moderate to severe AKI according to Acute Kidney Injury Network (AKIN) criteria. Secondary outcomes included the need for renal replacement therapy and 28-day mortality.

**Results:** Ninety eight (25%) patients developed moderate to severe AKI after septic shock recognition. APACHE III score and SCr level increase in the first 12 hours were not statistically associated with moderate to severe AKI in multivariable ROC analysis. Consecutive oliguria for 3 hours had fair predictive ability for moderate to severe AKI (area under ROC curve = 0.73), and five hours of consecutive oliguria demonstrated optimal accuracy (82%, 95% CI 79%-86%).

**Conclusions:** The novel concept of RA, defined as 3 to 5 hours of consecutive oliguria in septic shock patients, may provide a valuable measure of AKI risk. Further validation to support this definition is needed.

## TH-PO025

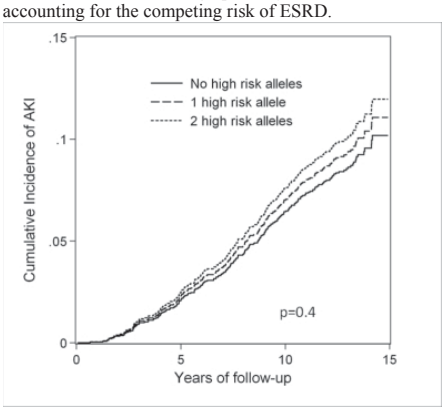
**Racial Disparity in Acute Kidney Injury: The Atherosclerosis Risk in Community Study**

M. Grams, Kunihiro Matsushita, Yingying Sang, Michelle M. Estrella, Adrienne Tin, Meredith C. Foster, Wen Hong Linda Kao, Josef Coresh. *Johns Hopkins Univ.*

**Background:** African-Americans face higher risk of acute kidney injury than Caucasians. The extent to which this increased risk is due to differences in clinical, socioeconomic, or genetic risk factors is not known.

**Methods:** We evaluated 10,589 African-American and Caucasian participants in the Atherosclerosis Risk in Community (ARIC) study, a community-based prospective cohort of middle-aged individuals. Participants were followed from baseline study visit (1996-1999) until first hospitalized AKI (defined by billing code), end-stage renal disease (ESRD), death, or December 31, 2010, whichever came first.

**Results:** African-American participants were slightly younger (61.8 years vs. 63.1 years, p<0.001), more often female (63.9% vs. 53.5%, p<0.001), and had higher baseline eGFR and prevalence of microalbuminuria. Annual family income, presence of health insurance, and education level were lower among African-Americans compared with Caucasians. The unadjusted incidence of hospitalized AKI was 8.1 cases per 1000 person-years among African-Americans and 6.2 cases per 1000 person-years among Caucasians. The elevated risk of AKI persisted after adjustment for demographics, cardiovascular risk factors, kidney markers, and time-varying number of hospitalizations (adjusted hazard ratio (HR) for African-American race: 1.27, 95% CI:1.07-1.50, p=0.007); however, after accounting for differences in income and/or insurance by race, the association was no longer significant. High risk variants of APOL1 were not significantly associated with AKI among African-Americans (demographic-adjusted HR 1.21, 95% CI: 0.80-1.82, p=0.4) even after accounting for the competing risk of ESRD.



**Conclusions:** African-Americans face higher risk of AKI than Caucasians, a difference which may be related to disparities in socioeconomic status.

*Funding:* NIDDK Support

## TH-PO026

**Renal Function Testing and Nephrology Follow-Up after Acute Kidney Injury: Update from a National Sample of Veterans**

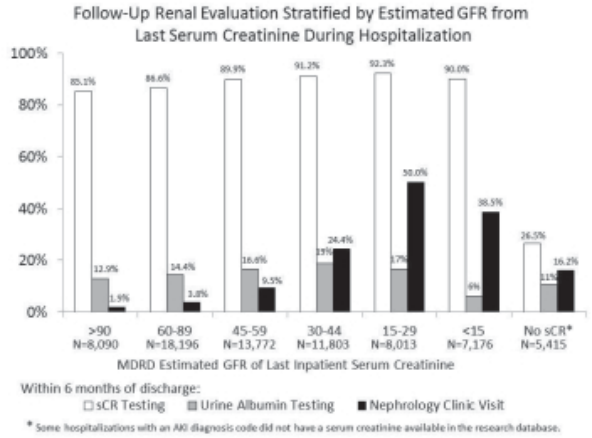
Diane Steffick,[1] Michael Heung,[1] Neil R. Powe,[2] Chi-Yuan Hsu,[2] Meda E. Pavkov,[3] Nilka Rios Burrows,[3] Rajiv Saran.[1] *[1]Univ of Michigan, Ann Arbor; [2]Univ of California San Francisco; [3]Centers for Disease Control and Prevention, Atlanta, GA.*

**Background:** Improving rates of follow-up renal evaluation after acute kidney injury (AKI) has been identified as an objective by the US Healthy People (HP) 2020 initiative. However, renal evaluation is not defined and optimal targets remain unclear. Using 3 different metrics, we look at renal evaluation from a health system perspective.

**Methods:** We examined all hospitalizations in the Veterans Affairs data in 2010 with AKI – either an ICD-9 code or a 0.3mg/dL increase in serum creatinine (sCr) from pre-admission baseline to peak. Hospitalizations where the patient died within 6 months of

discharge were excluded. Post-hospitalization renal evaluation was defined 3 ways: (1) sCr testing, (2) urine albumin testing, and (3) nephrology clinic visit. Post-AKI evaluation was assessed at 6 months and stratified by eGFR from the last inpatient sCr.

**Results:** The study found 72,465 hospitalizations with AKI where the patient was alive at 6 months after discharge. 84% of these hospitalizations had sCr, 14.5% had urine albumin and 17.5% had nephrology visits within 6 months of discharge. 15% of hospitalizations had no patient sCr or urine albumin testing and 82.5% had no nephrology follow-up. Follow-up evaluation increased with decreasing eGFR estimated by the last inpatient sCr (see Figure).



**Conclusions:** The vast majority of US VA patients underwent sCr testing during the 6 months after an AKI hospitalization. The proportion with nephrology follow-up visits was higher among those with poorer kidney function at discharge. Additional studies may determine the impact of renal follow-up on outcomes and cost-effectiveness.

## TH-PO027

**Evaluation of a Clinical Risk Assessment Scoring System for Acute Kidney Injury in Critically Ill Patients** Jane S. Kim, Ravindra L. Mehta. *School of Medicine, Univ of California, San Diego, San Diego, CA.*

**Background:** Acute kidney injury (AKI) is a major complication of hospitalization and is an independent risk factor for in-hospital mortality. Because clinical manifestations can vary widely, AKI is under-recognized. Several studies have evaluated risk scores for AKI in specific settings (e.g. cardiac surgery, contrast exposure). However, few studies identified the clinical risk factors for developing AKI in the intensive care unit (ICU). We evaluated the performance of a clinical risk score based on clinical and demographic factors to predict AKI in an ICU population.

**Methods:** Medical records of 327 patients who were admitted to the ICU at UCSD Hillcrest Medical Center and were screened for enrollment in a prospective registry for AKI were reviewed. Patient information within the first 48 hours of ICU admission was recorded, and AKI risk scores were calculated based on the presence of 5 co-morbidities (CKD, liver disease, CHF, hypertension, atherosclerotic CVD) and 5 acute clinical events (arterial pH, nephrotoxin exposure, sepsis, mechanical ventilation, and anemia). Point scores were applied to each variable, and univariate and multivariate analyses were performed to evaluate how well the risk factors in the model could predict AKI. Area under the curve (AUC) and Hosmer-Lemeshow were used to determine the model's discrimination and calibration.

**Results:** AKI developed in 153 (46.8%) of patients, and overall dialysis requirement was 7.3% with an in-hospital mortality of 9.8%. Development of AKI in the ICU was associated with higher scores for the variables included in the AKI risk score. Length of stay, dialysis requirements, and in-hospital mortality were also greater among patients with AKI. Higher scores predicted the development of AKI with an ROC curve with AUC of 0.778 ($p < 0.001$) and with Hosmer-Lemeshow test of $p = 0.334$.

**Conclusions:** A clinical risk score combining chronic co-morbidities and acute events within the first 48 hrs after ICU admission has a good performance in predicting development of AKi in critically ill patients. This score can allow physicians to identify patients at high risk for AKi at ICU admission and implement preventive strategies to improve outcomes.

## TH-PO028

**Association between Perioperative Blood Transfusions and Acute Kidney Injury in Patients Undergoing Joint Replacement Surgeries: A Retrospective Cohort Study** Ghanshyam Palamaner Subash Shantha, Ravi Gurusamy, Robert M. Corey, Himanshu Sharma, Jayakrishna Chintanaboina, John E. Prior. *Internal Medicine, The Wright Center For Graduate Medical Education, Scranton, PA.*

**Background:** Blood transfusions (BT) increase risk for perioperative acute kidney injury (AKI) in cardiac surgeries. This association has not been well studied in patients undergoing surgeries that involve minimal hemodynamic changes like joint replacement surgeries. In this retrospective cohort study, we assessed the association between BT and AKI among patients undergoing joint replacement surgeries.

**Methods:** Case records of 425 consecutive adult patients who underwent joint replacement surgeries, in 2 community hospitals in Scranton, Pennsylvania, from January - December 2011 were reviewed. Peri-operative (pre, during and post operative) red cell transfusions (BT) was considered exposure. Acute kidney injury (AKI) was defined by Acute Kidney Injury Network Criteria (AKIN). Cox proportional hazards regression was performed to assess the association between BT (coded as categorical variable) and AKI, after adjusting for age, gender, pre-operative hemoglobin (PH), eGFR, diabetes diagnosis, hypertension diagnosis, NSAIDS use, type of anesthesia, average intraoperative mean arterial pressure (MAP) and the type of joint replaced.

**Results:** The mean age was 68.7 years. The population was 58% male and 8% black. Baseline creatinine was $0.9 \pm 0.3$ mg/dl. Mean PH was $12.1 \pm 1.2$ g/dl. Three hundred and twelve (73%), 97 (23%) and 16 (4%) had knee, hip and shoulder replacements respectively. MAP was $93 \pm 6$ mmhg. Forty seven (11%) developed AKI. AKI developed $24 \pm 6$ hours post surgery. Of these, 39 (83%), 6 (13%) and 2 (4%) had stages 1, 2 and 3 AKI respectively. None of these AKI's were dialysis requiring. Sixty three (15%) received BT. BT was independently associated with AKI (Hazards ratio: 1.39, 95% C.I: 1.07 – 1.62, $P = 0.032$).

**Conclusions:** BT is associated with increased risk of AKI in patients undergoing joint replacement surgeries, independent of MAP and PH. AKI was predominantly stage I and non-dialysis requiring. Randomized trials are required to confirm our observational data.

## TH-PO029

**Association of Vitamin D and Acute Kidney Injury in Patients with Hematological Malignancies: A Retrospective Cohort Study** Ghanshyam Palamaner Subash Shantha,[1] Qasim Malik,[1] Manoj Das,[1] Pavan Kumar Irukulla,[1] Lawrence J. Cheskin.[2] *[1]Hematology/Oncology, The Wright Center For Graduate Medical Education, Scranton, PA; [2]Health Behavior and Society, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

**Background:** Association of vitamin D and acute kidney injury (AKI) in patients with hematological malignancies (HM) has not been well studied. In addition to inflammation, vitamin D deficiency has been associated with increased cell survival and poor outcomes in HM. In this retrospective cohort study, we assessed the association between vitamin D and AKI in HM.

**Methods:** Case records of 346 consecutive adult patients with HM from hematology/oncology divisions of 5 community hospitals in Scranton, Pennsylvania, from 2007 - 2012 were reviewed. Vitamin D levels (25-hydroxy cholecalciferol) at cancer diagnosis were considered exposure. AKI was defined by Acute Kidney Injury Network Criteria (AKIN). Cox proportional hazards regression was performed to assess the association between vitamin D levels and AKI, after adjusting for age, gender, eGFR, diabetes diagnosis, NSAIDS use, HsCRP, cancer stage, cancer type and type of chemotherapy.

**Results:** Mean age was 67.5 years. The population was 64% male and 27% black. Baseline creatinine was $1.0 \pm 0.2$ mg/dl. One hundred seven (31%), 57 (16%), 55 (16%), 43 (12%), 39 (11%), 38 (11%) and 7 (3%) had a diagnosis of chronic myeloid leukemia, acute myeloid leukemia, chronic lymphocytic leukemia, B cell lymphoma, T cell lymphoma, multiple myeloma and miscellaneous HM respectively. Mean follow-up period was $8 \pm 4$ months. Seventy six (22%) developed AKI [stage 1: 34 (45%), stage 2: 20 (26%), stage 3: 22 (29%)] within a mean of $4 \pm 2$ months. Six (8%) required dialysis. The unadjusted cumulative AKI incidence across quartiles 1-4 ($\leq 10$, $11 - 20$, $21 - 30$, $> 30$ mg/dl) of vitamin D concentration were 31, 30.5, 25.5, and 13% respectively. After adjustment, 1st vitamin D quartile had a 1.53 times the hazard of the fourth quartile (95% CI: 1.10, 1.72; P-trend = 0.022) for AKI.

**Conclusions:** Low vitamin D at cancer diagnosis is associated with incident AKI in patients with HM. Further studies are needed to elucidate the underlying mechanism.

## TH-PO030

**Severe AKI Increases Platelet Adhesion and Aggregation in Cancer Patients** James Hung,[1] Tania Rubia Flores Rocha,[2] Elbio Antonio D'amico,[2] Luis Yu.[1] *[1]Instituto do Cancer do Estado de Sao Paulo, Universidade de Sao Paulo, Brazil; [2]Hospital das Clinicas, Universidade de Sao Paulo.*

**Background:** The association between renal dysfunction (uremia) and bleeding due to impaired platelet function has been previously described in AKI patients. However, patients with cancer usually present hypercoagulable state. Thus, we sought to evaluate the effect of uremia on platelet function in cancer patients.

**Methods:** We prospectively analysed patients admitted to the Intensive Care Unit of a Cancer University Hospital with sepsis. Renal dysfunction was classified according to the AKIN criteria. DiaMed Impact R was used to evaluate platelet function under near physiological flow conditions using cone and plate technology. In this test, an image analyser quantifies the adhered platelets and results are expressed as percentage of well surface covered by aggregates (SC %) as an index of adhesion and average size of the aggregates (AS microm$^2$) as an index of aggregation.

**Results:** From August 2012 to February 2013, 103 patients were included: mean age 61±15 y, 57% male, 85% solid tumors, 15% hematological tumors, 67% on vasopressors, 68% developed AKI (AKIN 1 - 19 patients, AKIN 2 - 20 patients, AKIN 3 - 31 patients).

| | Without AKI[#] | AKIN 1 | AKIN 2 | AKIN 3 | p |
|---|---|---|---|---|---|
| Creatinine (mg/dl) | 0.80 (0.54-0.97) | 1.29 (0.96-1.84) | 1.40 (0.94-2.18) | 2.59 (1.98-3.78) | <0.05, # vs AKIN 1, # vs AKIN 2, # vs AKIN 3 |
| Urea (mg/dl) | 44 (33-60) | 66 (43-118) | 87 (65-140) | 142 (108-193) | <0.05, # vs AKIN 2, # vs AKIN 3 |
| Calcium (mg/dl) | 4.6 (4.0-4.8) | 4.7 (4.6-4.8) | 4.5 (4.4-4.8) | 4.6 (4.4-4.8) | 0.72 |
| Hemoglobin (g/dl) | 8.7 (8.2-11) | 9.8 (8.5-10.5) | 8.5 (7.8-9.2) | 9.7 (8.8-11.7) | <0.05, AKIN 2 vs AKIN 3 |
| Platelets ($x10^3$/mm3) | 184 (66-274) | 214 (118-296) | 236 (122-285) | 160 (68-284) | 0.56 |
| SC | 10.3±4.6 | 13.5±3.8 | 13.9±5.1 | 14.1±5.5 | <0.05, # vs AKIN 2, # vs AKIN 3 |
| AS | 44.9±13.9 | 51.3±13.5 | 52.6±13.7 | 54.9±14.2 | <0.05, # vs AKIN 3 |

**Conclusions:** Severe AKI (AKIN 3) increases platelet adhesion and aggregation in cancer patients.

*Funding:* Government Support - Non-U.S.

## TH-PO031

**Association between Pre-Operative Statin Use and Acute Kidney Injury Biomarkers in Cardiac Surgery** Amber O. Molnar,[1] Chirag R. Parikh,[2] Steven G. Coca,[2] Heather Thiessen Philbrook,[6] Jay L. Koyner,[3] Michael Shlipak,[4] Mary Lee Myers,[5] Amit X. Garg.[6] *[1]Div of Nephrology, Dept of Medicine, Univ of Ottawa, Ottawa, Canada; [2]Section of Nephrology, Yale Univ School of Medicine, VA CT Healthcare System, and the Program of Applied Translational Research, New Haven, CT; [3]Section of Nephrology, Dept of Medicine, Univ of Chicago, Pritzker School of Medicine, Chicago, IL; [4]Div of General Internal Medicine, San Francisco VA Medical Center, Univ of California, San Francisco, CA; [5]Div of Cardiac Surgery, Western Univ, London, Canada; [6]Div of Nephrology, Dept of Medicine, Western Univ, London, Canada.*

**Background:** Acute kidney injury (AKI) is a serious complication of cardiac surgery for which there remains no specific therapy. Animal data and several observational studies suggest that statins prevent AKI, but the results are not conclusive.

**Methods:** We conducted a multi-centre prospective cohort study of 625 adult patients undergoing elective cardiac surgery. All patients were on statins and were grouped on whether statins were continued or held in the 24 hours prior to surgery. The primary outcome was AKI defined by a doubling of serum creatinine or dialysis. The secondary outcome was the peak level of several kidney injury biomarkers. Results were adjusted for demographic and clinical factors.

**Results:** Continuing (vs. holding) a statin prior to surgery was not associated with a lower risk of AKI defined by a doubling of serum creatinine or dialysis, [adjusted relative risk (RR) 1.09 (95% confidence interval (CI) 0.44, 2.70)]. However, continuing a statin was associated with a lower risk of elevation of the following AKI biomarkers: urine interleukin-18, urine neutrophil gelatinase-associated lipocalin (NGAL), urine kidney injury molecule-1 (KIM-1), and plasma NGAL [adjusted RR 0.34 (95% CI 0.18, 0.62), adjusted RR 0.41 (95% CI 0.22, 0.76), adjusted RR 0.37 (95% CI 0.20, 0.76), adjusted RR 0.62 (95% CI 0.39, 0.98), respectively].

**Conclusions:** Statins may prevent kidney injury after cardiac surgery as evidenced by lower levels of kidney injury biomarkers.

*Funding:* Other NIH Support - The study was supported by the NIH grant RO1HL085757 (CRP) to fund the TRIBE-AKI Consortium to study novel biomarkers of acute kidney injury in cardiac surgery. SGC, AXG, and CRP are also members of the NIH-sponsored ASsess, Serial Evaluation, and Subsequent Sequelae in Acute Kidney Injury (ASSESS-AKI) Consortium (U01DK082185)., Pharmaceutical Company Support - Abbott Diagnostics and Sekisui Diagnostics Inc

## TH-PO032

**Risk Factors for Non-Steroidal Anti-Inflammatory Drugs Induced Acute Kidney Injury in Patients with Chronic Kidney Disease** Teruhiko Yoshida, Keita Hirano, Masahiko Nagahama, Yasuhiro Komatsu. *Div of Nephrology, Dept of Internal Medicine, St. Luke's International Hospital, Chuo-ku, Tokyo, Japan.*

**Background:** Acute Kidney Injury (AKI) is one of the major adverse effects of Non-Steroidal Anti-Inflammatory Drugs (NSAIDs), which restricts the prescription of NSAIDs for Chronic Kidney Disease (CKD) patients; however, clinical studies on the risk factors of NSAIDs-induced AKI are scarce. The aim of the present study is to clarify risk factors for NSAIDs-induced AKI to propose appropriate NSAIDs use in CKD patients.

**Methods:** In a retrospective cohort study, we identified 770 patients with CKD (eGFR (estimated glomerular filtration rate) <60ml/min/1.73m$^2$) who received Flurbiprofen axetil (Ropion®) between December 2006 and December 2011. We used the AKI criteria from KDIGO (Kidney Disease: Improving Global Outcomes) for defining AKI patients. Risk factors for AKI was evaluated by multivariate analysis.

**Results:** Mean (Standard Deviation) of age was 69.3(±13.1) years old, creatinine (Cr) and eGFR were 1.07(±0.59) mg/dl and 47.7(±11.7) ml/min/1.73m$^2$. Among all patients in the analysis (N= 325), 81 patients (25.0%) developed AKI. Diuretic use (Odds ratio(OR) 1.91, P=0.03), diabetes mellitus (OR 1.83, P=0.05), low eGFR (OR 1 (30<eGFR<60), OR 2.83, P=0.02 (eGFR<30)) were risk factors for AKI. We also found that AKI itself was a risk factor for CKD worsening (more than 50% of serum Cr increase in later than 3 months after NSAIDs prescription) (OR 3.02, P=0.04).

**Conclusions:** Our study suggests that NSAIDs should be used with caution in CKD patients with diuretic use, diabetes mellitus and low eGFR. NSAIDs-induced AKI might be irreversible disease resulting in CKD worsening.

## TH-PO033

**Risk Factors and Predictive Score of Acute Kidney Injury in Patients with Acute Myocardial Infarction** Tong Yue, Hong Cheng, Yi-Pu Chen. *Div of Nephrology, Beijing Anzhen Hospital, Capital Medical Univ, Beijing, China.*

**Background:** Although an acute kidney injury (AKI) commonly occurs among patients hospitalized for acute myocardial infarction (AMI), its risk factors is unknown. The article aims to develop a clinical predictive score in order to predict the AKI after AMI. The early identification of patients with risks of developing AKI can reduce its incidence.

**Methods:** We analyzed data on consecutive patients with AMI from January, 2010 to July, 2011 at Beijing Anzhen Hospital. All the patients were divided into two groups, AKI group and non-AKI group, with the definition of AKI by Acute Kidney Injury Network. The univariable analysis and logistic regression model were used to establish the predictive score.

**Results:** The total cohort consisted of 1429 patients. The derivation cohort consisted of 1033 patients and the validation cohort consisted of 396 patients.In the derivation cohort, the rate of AKI was 14.3%. Mortality was significantly higher in the AKI group (10.1% vs 0.6% in those without AKI, P=0.000). In the validation cohort, the rate of AKI was 15.7 %.A lot of in-patients occur AKI within a week, patients with AKI stay longer than without AKI.Univariate analysis disclosed age,hypertension, diabetes mellitus, chronic kidney disease(CKD), heart rate, lower estimated glomerular filtration rate (eGFR), anemia, severe Killip class, extensive anterior myocardial infarction, troponin I(TNI) ≥50ng/ml ,left ventricular ejection fraction (LVEF)<50%,shock, Ventricular Fibrillation,β-blocker non-use and longer time before admission to hospital as risk factors to develop AKI. After adjusting for other factors associated with AKI, reduced GFR at presentation, severe Killip class, extensive anterior myocardial infarction,hypertension, β-blocker non-use and longer time before admission to hospital were independently associated with AKI.

**Conclusions:** we developed a clinical predictive score for AKI after AMI. This predictive score presented good discrimination and calibration. It would help the clinicians to make decision for preventive intervention. Further studies on interventions to minimize AKI or to more aggressively treat patients developing AKI should be tested.

*Funding:* Government Support - Non-U.S.

## TH-PO034

**Cardiorenal Syndrome in Hospitalized Patients with Mild versus Moderate-to-Severe Concomitant Hyponatremia on Admission: A Retrospective Study** Rainer U. Pliquett, Katrin Schlump, Matthias Girndt. *Clinic of Internal Medicine, Nephrology, Martin-Luther-Universität Halle-Wittenberg, Halle, Germany.*

**Background:** Hyponatremia on admission has been related to a worse outcome among different co-morbidities including chronic heart failure. Regarding cardiorenal syndrome (CRS), a detrimental role for hyponatremia has been extrapolated from chronic heart failure studies (CJASN 2009;4:2013). Here, the degree of (acute) renal failure, (acute) cardiac failure on admission, duration of hospital stay, and 1-year mortality were determined for hospitalized CRS patients with mild or moderate-to-severe hyponatremia on admission.

**Methods:** Retrospective study of consecutive patients hospitalized for CRS in "University Hospital Halle" of Martin-Luther University Halle-Wittenberg from 01/01/2007 to 12/31/2011. Diagnosis was derived from diagnosis information using hospital documentation software. Among all CRS patients, patients with mild hyponatremia (<135 mmol/l; >=130 mmol/l) and moderate-severe hyponatremia patients (<130 mmol/l) were analyzed and entered this study. Information on plasma laboratory values including sodium, creatinine, brain-natriuretic peptide (BNP) on admission, duration of hospitalization and 1-year mortality (city-council inquiry) was gathered. Results were given as median with 95% confidence interval (CI). Significance was assumed for p<0.05 (one-tailed Mann-Whitney u test).

**Results:** Over a 5-year period, 386 CRS patients were admitted. In 262 patients, CRS diagnosis was confirmed. Hyponatremia occurred in 90 or 34.4% of CRS patients. Thereof, mild hyponatremia occurred in 59 (22.5%) patients, moderate-severe hyponatremia in 31 (11.8%). BNP was significantly higher in CRS patients with mild hyponatremia (754.5 pg/ml, CI: 799.5 - 2106) versus moderate-severe hyponatremia (491.5 pg/ml, CI: 300.2 - 1934; p<0.0001). Creatinine on admission was not different between groups (moderate-severe hyponatremia: Crea=226 µmol/l; mild hyponatremia: Crea=256 µmol/l; p ns). Likewise, duration of hospital stay (14.8 vs. 14.9 days) and 1-year mortality (25 of 56 patients or 44.6 % vs. 14 of 30 patients or 46.7 % in mild vs. moderate-severe hyponatremia) were not different. In a subgroup, 9 CRS patients with severe hyponatremia (Na ≤ 125 mmol/l) had a 1-year mortality of 66.7 %.

**Conclusions:** CRS patients with hyponatremia on admission had a considerably poor outcome (1-year mortality). Interestingly, irrespective of volume state, mild hyponatremia associates with worse cardiac function than moderate-severe hyponatremia on admission in CRS patients. The role of arginine vasopressin peptide (AVP) release as a compensatory mechanism and the role of renal failure for AVP action need to be further investigated.

### Incidence of Acute Kidney Injury following Left Ventricular Assist Device Placement: A Meta-Analysis of Prospective Cohort Studies

Reejis Stephen,[1] Chandrashekar Kashyap,[2] Sevag Demirjian,[2] Sankar D. Navaneethan.[2] *[1]Medicine, Bridgeport Hospital, Bridgeport, CT; [2]Nephrology, Cleveland Clinic, Cleveland, OH.*

**Background:** Left Ventricular Assist Device (LVAD) placement is an increasingly common therapy for bridge-to-transplant or destination therapy for patients with heart failure. Although some reports noted improvement in renal function following LVAD, it is associated with a high risk of acute kidney injury (AKI). We conducted a meta-analysis to determine the incidence of AKI with LVAD and whether this risk differs based on the type of the device.

**Methods:** We searched MEDLINE and Scopus (April 2013) for relevant prospective cohort studies and trials of LVAD therapy. Incidence rates for AKI reported in individual studies were pooled using an inverse of variance method. AKI was defined as rise in serum creatinine or requirement of dialysis as defined by individual studies. A random effects model was used, and subgroup analyses were performed to explore the influence of type of LVAD device (continuous vs. pulsatile) on the incidence of AKI.

**Results:** 15 prospective studies including 2586 patients were included in this meta-analysis. Mean follow-up of these studies varied from 28 days to 657 days. The incidence of AKI after LVAD was 21% (15 studies, 2586 patients, 95% CI 15%-30% p<0.001) with significant heterogeneity between the studies ($I^2$=92%) and the device type accounted for 40% of this heterogeneity. The incidence of AKI was higher in patients receiving pulsatile LVAD device placement at 25% (7 studies, 1217 patients, 95% CI 15%-38%, p<0.001) compared to 15.6% when continuous-flow devices were used (7 studies, 983 patients, 95% CI 10%-23%, p<0.001).

**Conclusions:** The incidence of AKI has varied widely in patients receiving LVAD therapy. Newer continuous-flow devices have reduced this risk which still remains substantial. Studies focused on renal function and potential risk factors are needed to better understand this phenomenon.

## TH-PO036

### Acute Kidney Injury and Mortality following Ventricular Assist Device Implantation

Jay L. Koyner, Abhijit S. Naik. *Nephrology, Univ of Chicago.*

**Background:** Ventricular assist devices (VADs) are increasingly common and their surgical implantation predispose patients to acute kidney injury (AKI). We sought to evaluate the incidence, risk factors and short and long term mortality of patients with AKI following VAD implantation.

**Methods:** We identified all patients who underwent VAD implantation at the University of Chicago from Jan. 2008 to Jan. 2012. Using demographic and lab data we evaluated the prevalence of AKI, defined as a ≥50% increase in serum creatinine over the first 7 post-op days (RIFLE Risk). Using a cox proportional hazards model (model: age, gender, race, preoperative eGFR, AKI, Diabetes Mellitus (DM), Body Mass Index (BMI), cardiopulmonary bypass time and intra-operative blood transfusion) we examined the factors that were associated with 30 and 365 day mortality.

**Results:** A total of 157 eligible patients had VADs, with 44 (28%) developing post-implantation AKI. There was no difference between baseline serum creatinine or eGFR for those with and without AKI (p= 0.57 and 0.87 respectively). In a multivariate analysis only DM (OR= 2.55(1.12-5.78), P=0.03) was identified as a significant predictor of postoperative AKI. Using a multivariate model (censoring for heart transplantation), DM [HR=2.98(1.02-8.68), P= 0.05], and AKI [HR= 3.02(1.13-8.03),P=0.03] were both independently associated with 30-day mortality. At 365 days, 21(48%) of those with AKI had died compared to 34(30%) without AKI (p= 0.037).

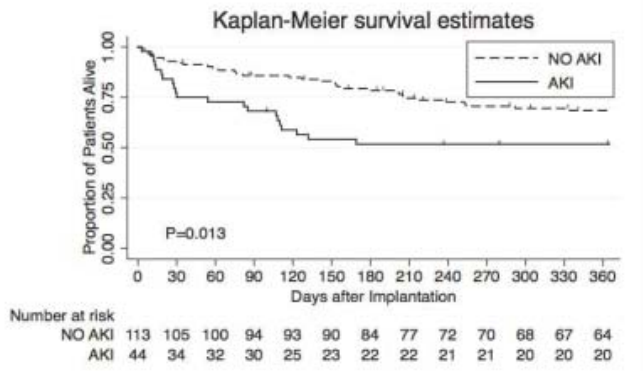

Figure 1: Patient Survival Following VAD Implantation

Pre-operative BMI (HR=0.93 (0.89-0.98)p=0.01), DM (HR= 2.01(1.13-3.60), P=0.02) and AKI (HR=1.85(1.03-3.30);P=0.04) were independently associated 365-day mortality. In survivors, there was no difference in serum creatinine or eGFR values at 365-days when comparing those with and without AKI(p=0.56 and 0.83).

**Conclusions:** AKI is common following VAD implantation. AKI and DM are independent predictors of 30 and 365 day mortality following VAD implantation.

### Independent Risk Factors in Common for Elderly Patients of Cardiorenal Sydrome Type I by Different Criteria

Lu Cai, Xinling Liang, Zhilian Li. *Div of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

**Background:** Cardiorenal sydrome type I reflects an abrupt worsening of cardiac function (eg. Acute heart failure) leading to acute kidney injury and is associated with substantial morbidity and mortality, especially in elderly patients. But there are no consensus diagnostic criteria for it. Thus, the objective of present study was to explore independent risk factors in common for elderly patients of cardiorenal sydrome type I by RIFLE, AKIN and KDIGO criteria of acute kidney injury.

**Methods:** Data was retrospectively collected from elderly patients (age ≥60 years old) with acute heart failure in Guangdong General Hospital between July 2002 and July 2012. The primary outcome was regarded as AKI defined as RIFLE, AKIN and KDIGO criteria, and baseline serum creatinine was defined as the lowest serum creatinine in the three months before admission.

**Results:** Among 808 elderly participants, more patients were diagnosed as AKI by KDIGO (46.2%) than RIFLE (37.9%) and AKIN (48.6%) . Logistic regression indicates that albumin<30g/L (OR 1.746), uric acid>436umol/L(OR 1.621), use of low-dose dopamine (2-3ug/kg/min) (OR 2.283) within 48 hours after admission were independent factors for cardiorenal sydrome type I by RIFLE and so were albumin<30g/L (AKIN:OR 1.798; KDIGO:OR 1.745), uric acid>436umol/L (AKIN:OR 2.658; KDIGO:OR 2.464), use of diuretics, angiotensin-converting-enzyme inhibitor/Angiotensin receptorinhibitor(ACEI/ARB) and low-dose dopamine(AKIN:OR 2.010; KDIGO: OR 2.173) within 48 hours after admission by AKIN and KDIGO.

**Conclusions:** Albumin<30g/L, uric acid>436umol/L and use of low-dose dopamine within 48 hours after admission were independent risk factors in common for elderly patient of cardiorenal sydrome type I by RIFLE, AKIN and KDIGO criteria.

### Relationship of the Time Interval between Coronary Angiography and Elective Off-Pump Coronary Artery Bypass Surgery with Postoperative Acute Kidney Injury

Yan Zhang, Nan Ye, Hong Cheng, Yi-Pu Chen. *Div of Nephrology, Beijing Anzhen Hospital, Capital Medical Univ, Beijing, China.*

**Background:** To investigate whether there are effects of time intervals between coronary angiography (CAG) and elective off-pump coronary artery bypass graft (OPCABG) on postoperative acute kidney injury (AKI).

**Methods:** Clinical data of patients undergoing CAG and OPCABG from June, 2010 to December, 2011 in Beijing Anzhen Hospital were retrospectively analyzed. All the patients were divided into AKI group and non-AKI group Univariate analysis was performed to find possible factors associated with AKI. Multivariate logistic regression analysis was used to identify whether the short time interval was one of the independent risk factors of AKI after adjusting for potential confounding variables.

**Results:** Of the 1513 patients, 436 patients (28.8%) developed AKI. The mortality rate in AKI group (5.7%) was 6 times higher then that in non-AKI group (0.9%). The incidence of AKI was highest (48.8%) in patients in whom OPCABG was performed ≤24h after CAG. Multivariate logistic regression analysis showed that the time interval less that 24h between CAG and OPCABG did increase the risk of AKI (OR=2.44, 95%CI为1.19, 4.99) after adjusting for the following confounding variables: male, advanced age, hypertension,

diabetes, NYHA heart function class III and IV, lower estimated glomerular filtration rate, numbers of coronary artery bypass grafts>3, intraoperative or postoperative intra aortic balloon pump, postoperative hypotension time ≥30min, dosage of furosemide ≥60mg/d.

**Conclusions:** It was one of the independent risk factors of postoperative AKI that the OPCABG was performed ≤24h after CAG.

*Funding:* Government Support - Non-U.S.

### TH-PO039

**Risk Factors and Clinical Predictive Score for Acute Kidney Injury after Off-Pump Coronary Artery Bypass Surguey** Yan Zhang, Nan Ye, Hong Cheng, Yi-Pu Chen. *Div of Nephrology, Beijing Anzhen Hospital, Capital Medical Univ, Beijing, China.*

**Background:** To investigate the risk factors of acute kidney injury (AKI) after off-pump coronary artery bypass graft (OPCAB), develop a clinical predictive score and validate its discrimination and calibration.

**Methods:** Clinical data 0f 1513 patients undergoing coronary angiography(CAG) and OPCAB from June, 2010 to December, 2011 at Beijing Anzhen Hospital were retrospectively analyzed. All the patients were divided into AKI group and non-AKI group. Univariable analysis and multivariate logistic regression analysis were used to establish the predictive score.

**Results:** 436 patients (28.8%) developed AKI. In a multivariable model about AKI included: increased age, male, hypertension, diabetes, New York Heart Association class III or IV, lower estimated glomerular filtration rate (eGFR), shorter time interval between CAG and elective OPCAB, much numbers of grafts, intraoperative or postoperative intra aortic balloon pump, longer postoperative hypotension time, larger dosage of loop diuretics. The predictive model was discriminated well (ROC=0.71) and had well calibrated according to the Hosmer-Lemeshow test (P=0.30).

**Conclusions:** We developed a clinical predictive score for AKI after CAG and OPCAB. This predictive score presented good discrimination and calibration.

*Funding:* Government Support - Non-U.S.

### TH-PO040

**Serum Hepcidin – A Protective and Inverse Biomarker of CI-AKI in Patients Undergoing Percutaneous Coronary Interventions-PCI** Jolanta Malyszko,[1] Jacek S. Malyszko,[1] Hanna Gajewska,[2] Ewa Koc-Zorawska,[1] Slawomir Dobrzycki.[2] *[1]Nephrol. Dept, Med Univ, Poland; [2]Invasive Cardiol., Med Univ, Bialystok, Poland.*

**Background:** Contrast-induced acute kidney injury (CI-AKI) is a common and potentially serious complication of percutaneous coronary interventions-PCI. Hepcidin, a peptide hormone that regulates iron homeostasis. Urinary hepcidin-25 has been shown to be elevated in patients who do not develop AKI.

In this study we tested the hypothesis whether serum hepcidin could represent an early protective biomarker of CI-AKI in 26 patients with normal serum creatinine undergoing PCI. In addition, we assessed serum and urinary NGAL, cystatin C, eGFR serum and urinary creatinine in these patients.

**Methods:** Hepcidin, serum and urinary NGAL, cystatin C, urinary L-FABP, KIM-1, and IL-18 were evaluated before, and after 2, 4, 8, 24 and 48 hours after PCI using commercially available kits. Serum creatinine was assessed before, 24 and 48 hours after PCI. ANOVA or Kruskall-Wallis ANOVA for repeated measurements were used in statistical analysis.

**Results:** We found a significant rise in serum hepcidin as early as after 4 hours when compared to the baseline values. It was also significantly higher 8 and 24 hours after PCI. Serum NGAL increased after 2, 4 and 8 hours, and in urinary NGAL after 4,8 and 24 hours after PCI. We found a significant rise in serum NGAL after 2, 4 and 8 hours, and in urinary NGAL and IL-18 after 4, 8&24 hours after PCI. Serum cystatin C increased significantly 8 hours, reaching peak 24 hours after PCI and then decreased after 48 hours. L-FABP and KIM-1 increase significantly after 24 and 48 hours after PCI. When contrast nephropathy was defined as an increase in serum creatinine by >25% of the baseline level 48 hours after PCI, the prevalence of CI-AKI was 4/26. Hepcidin were significantly lower 8 and 24 hours after PCI in patients with CI-AKI, while serum and urine NGALwere significantly higher in patients with CI-AKI . Hepcidin correlated negatively with NGAL ($r=-0.42$, $p<0.05$).

**Conclusions:** Our findings suggest that serum hepcidin might be an early predictive biomarker of ruling out CI-AKI after PCI, thereby contributing to early patient risk stratification.

### TH-PO041

**Risk Factors of Non-Early Recovery after an Episode of Acute Kidney Injury** Carlos Enrique Arias, Eva Rodriguez, Sheila Bermejo, Adriana Sierra, Julio Pascual. *Nephrology, Parc de Salut Mar-IMIN, Barcelona, Spain.*

**Background:** Acute kidney injury (AKI) might be a risk factor for the future development or accelerated progression of chronic kidney disease (CKD).

The aim is to determine risk factors are related to non-recovery after an AKI episode.

**Methods:** Retrospective observational cohort study during a follow-up period of 9 years. Potential subjects were identified and enrolled by systematic chart review using the hospital coding system (ICD-9). Patients were included after exclusion of pre-renal and obstructive etiologies or known CKD. We used the ADQI definition and classification.

**Results:** We included 228 patients, 64% men, age 64±19 years. Background revealed hypertension (53%), diabetes (28%), ischemic heart disease (17%) and peripheral vascular disease (23%). The most common etiology was ischemic AKI (42.5%), followed by septic (22.8%).Distribution of cases was: Risk 22.3%, Injury 25.9%, Failure 51.8%. Median duration of AKI episode was 32±44 days, and 30 (13.2%) patients needed renal replacement therapy during hospitalization. In our study, 185 patients (81.1%) recovered renal function during the first 4 weeks after diagnosis, compared with 43 (18.9%) patients who did not. In univariate analysis, the predictors of non-recovery of renal function after an episode of AKI were: age>64 years (OR 2.5, 95%CI 1.17-5.40), hypertension (OR 2.09, 1.04-4.22), AKI secondary to nephrotoxicity (OR 5.18, 1.68-16.0), and serum creatinine at admission >4mg/dl (OR 2.70, 1.37-5.3). In multivariate analysis, independent risk factors for lack of recovery of renal function in four weeks were: age>64 years (OR 2.54, 1.01-6.37), AKI secondary to nephrotoxicity (OR 3.58, 1.07-11.93) and serum creatinine during hospitalization >4mg/dl (OR 3.58, 1.07-11.93).

**Conclusions:** Age older than 64 years, serum creatinine >4mg/dl and that the AKI was related to nephrotoxicity were the independent risk factors for lack of recovery of renal function during the first 4 weeks after an episode of AKI.

### TH-PO042

**Retrospective Analysis of 30 Years' Data Base, over 68000 Patients Using IMIS (Integrated Medical Information System in Kochi University) to Search Risk Factor of Acute Kidney Injury** Taro Horino,[1] Kazunori Otomo,[2] Kazu Hamada,[1] Yoshiko Shimamura,[1] Koji Ogata,[1] Kosuke Inoue,[1] Yoshinori Taniguchi,[1] Yoshio Terada,[1] Yoshiyasu Okuhara.[2] *[1]Dept of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi Univ, Nankoku, Kochi, Japan; [2]Center of Medical information Science, Kochi Medical School, Kochi Univ, Nankoku, Kochi, Japan.*

**Background:** In Japan, the etiology of acute kidney injury (AKI) remains unclear. Therefore, we estimated risk factors of acute kidney injury by using large medical data base in Kochi University, or Integrated Medical Information System (IMIS) data base for 30 years.

**Methods:** 68504 patients who had hospitalized and were more 18 years old in Kochi Medical School from 1981 to 2010 were enrolled. AKI was diagnosed according to AKIN criteria. We investigated odds ratio for AKI of underlying diseases which developed within 30 days from AKI onset and continued during AKI course. All data were estimated by analysis software, Retrieval sYstem for Open Medical Analysis (RYOMA2).

**Results:** AKI patients were 8979 (13.1%); male 5541 (61.7%). In elderly patients especially over 70years, the risk of AKI up to 15.5%. The odds ratios of classical risk factors; septic shock, cardiogenic shock, liver failure, acute respiratory distress syndrome, pulmonary edema and acute lung injury were 16.45 (95%CI, 12.21-22.17), 9.96 (7.31-13.58), 9.36 (7.70-11.39), 9.12 (6.86-12.13), 7.97 (6.21-10.23), and 7.93 (5.94-10.58), respectively. Noteworthy, we detected also novel risk factors; the odds ratios of hemorrhagic gastric ulcer and hyperuricemia were 2.50 (2.15-2.90) and 1.76 (1.60-1.95), respectively. Furthermore, the incidence of AKI was elevated in patients, especially in female, with hyperuricemia (more 7.0 mg/dl in male and more 5.5 mg/dl in female) at dose-dependent manner. Interestingly, the risk of AKI is also increased hypouricemia (less than 3.0 mg/dl), so the curve of odds ratio for AKI risk shows "J-shaped" curve.

**Conclusions:** This is the first data investigated about the risk factors for AKI with using large scale medical data base in Japan. Our data revealed that hyperuricemia might be an important risk factor for AKI in addition to classical risk factors.

### TH-PO043

**Association between Mortality Risk and Severity of Acute Kidney Injury among Critical-Care Patients from Remote Islands: A Single Center Prospective Cohort Study** Junichi Ishigami,[1,2] Masato Tajima,[1] Ayako Motomura,[1] Tatemitsu Rai,[2] Shinichi Uchida,[2] Sei Sasaki.[2] *[1]Dept of Nephrology, Tokyo Metropolitan Hiroo Hospital, Tokyo, Japan; [2]Dept of Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan.*

**Background:** The prevalence of acute kidney injury (AKI) is high among critical-care patients in emergency department and their outcome remains poor. Tokyo Metropolitan Hiroo Hospital plays a major role to provide emergency medical care for people in the remote islands and patients are transferred to the hospital if immediate intensive care is required. We conducted a prospective observational cohort study to assess the prevalence of AKI and the outcome of the patients transferred from the islands.

**Methods:** 476 patients who were transferred from 10 remote islands to the hospital between December 1st 2010 and November 31st 2012 were included to the study. Patients were stratified according to the severity of AKI using AKIN (Acute Kidney Injury Network) definitions: Stage1, 2 and 3. Kaplan-Meire survival curve was used to assess the longitudinal risk of mortality. Logistic regression analysis was used to assess the multiple factors affecting the outcome.

**Results:** Among 476 patients, 54(11.3%), 17(3.6%) and 32(6.7%) developed AKIN 1, 2 and 3 respectively. 34 patients (7.1%) died within 30 days from ICU admission. Patients who developed AKI had longer length of ICU stay compared to patients who did not (6.4 versus 3.5 days; $p<0.001$). Patients developed either AKIN 2 or 3 had higher mortality risk compared to patients who did not develop AKI (HR 5.66, 95%CI 1.79 to 17.93; $p<0.0001$). In logistic regression model, development of AKI was not associated with age, sex, use of radiocontrast agents, history of diabetes mellitus, hypertension, dyslipidemia, cardiovascular disease, ischemic heart disease and congestive heart disease.

**Conclusions:** The patients developed AKI had longer length of ICU stay compared to those without AKI. Since AKIN 2 and 3 patients had highest mortality risk among the cohort, these patients should be transferred preferentially to a hospital with adequate emergency medical service.

**TH-PO044**

**Should We Consider Initial Insertion of Tunneled Hemodialysis Catheter in the Patients Who Need Renal Replacement Therapy in Intensive Care Unit?** Hoon Suk Park, Kyungyoon Chang, Hyung Wook Kim, Bum-Soon Choi, Cheol Whee Park, Chul Woo Yang, Dong Chan Jin. *Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, Seoul, Korea.*

**Background:** Non-tunneled hemodialysis (HD) catheter was known to be used safely without infectious complication up to 1 month, but recent trend is to recommend using tunneled catheter in the patients requiring renal replacement therapy (RRT) for more than one week. Nevertheless, there exist difficulties following such recommendation in ICU, because the patients in ICU have poor survival so that it is difficult to predict RRT duration, so we investigated the propriety of current recommendation for catheter choice in ICU.

**Methods:** Forty-five ICU patients receiving tunneled HD catheter insertion and 105 ESRD patients were respectively assigned to ICU and ordinary ESRD groups. Patient survival and tunneled catheter survival, in addition to duration of catheter use and immediate and long term complication rates were compared.

**Results:** Immediate complication rate including exit site bleeding, bruise and hematoma was rather higher in ordinary ESRD group (32.9 % vs. 8.1 %, p = 0.003). Long term complication rates including catheter dysfunction and catheter related infection were comparable (5.4 % in ICU group vs. 12.7% in ordinary ESRD group, p = 0.33). Duration of catheter use was significantly shorter in ICU group (39 ± 53 days vs. 73 ± 50 days, p < 0.001), although catheter survivals were comparable between 2 groups (p = 0.8). Patient survival in ICU group was significantly poor, compared with ordinary ESRD group (p = 0.002).

**Conclusions:** ICU patients receiving tunneled catheter insertion for RRT showed poor life survival rate with short span in catheter use, compared with ordinary ESRD group, although catheter survival was not inferior and its insertion was safely performed in ICU setting. Therefore, considering patient survival and span of catheter use besides infection risk, separate guideline for catheter choice in ICU setting is required.

**TH-PO045**

**Better Prediction Using Ratio of Contrast Volume to eGFR without BSA Normalization for Contrast Nephropathy** Hoon Suk Park, Kyungyoon Chang, Hyung Wook Kim, Bum-Soon Choi, Cheol Whee Park, Chul Woo Yang, Dong Chan Jin. *Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, Seoul, Korea.*

**Background:** Considering contrast is excreted through kidneys, use of estimated glomerular filtration rate (eGFR) without body surface area (BSA) normalization is expected to be appropriate for evaluating the risk of contrast-induced acute kidney injury (CI-AKI). No studies have thus far suggested use of eGFR without BSA normalization for predicting CI-AKI. We aimed to demonstrate eGFR without BSA normalization is more appropriate than eGFR with BSA normalization for predicting CI-AKI.

**Methods:** This study included 433 myocardial infarction patients treated with primary percutaneous coronary intervention. Demographic data and clinical findings were compared between groups with and without CI-AKI. Logistic regression analysis was performed to identify independent risk factors. We used receiver-operating characteristic curves to compare the prediction of CI-AKI between eGFRs with and without BSA normalization.

**Results:** The ratio of contrast volume to raw MDRD eGFR, which is the value of MDRD eGFR without BSA normalization (odds ratio [OR], 1.352; 95% confidence interval [CI], 1.140–1.604; p = 0.001) was an independent risk factor for CI-AKI in multivariate logistic regression analysis besides cardiogenic shock (OR, 4.509; 95% CI, 1.055–19.267; p = 0.042). Ratio of contrast volume to MDRD eGFR without BSA normalization exhibited 94.7% sensitivity and 64.1% specificity whereas ratio of contrast volume to MDRD eGFR with BSA normalization exhibited 88.9% sensitivity and 51.5% specificity. Difference between 2 area under curves was significant (0.0276; p = 0.004).

**Conclusions:** Ratio of contrast volume to eGFR without BSA normalization better predicts CI-AKI than does ratio of contrast volume to eGFR with BSA normalization.

**TH-PO046**

**Acute Kidney Injury in Emergency Hospital Admissions: Are We Missing the Middle?** Dhaneesha Senaratne,[1] Yvonne Chan,[1] Sanjay Kartikay Ojha,[2] Amir Bhanji.[2] *[1]School of Clinical Medicine, Univ of Cambridge, Cambridge, United Kingdom; [2]Dept of Renal Medicine, Addenbrooke's Hospital, Cambridge, United Kingdom.*

**Background:** Acute kidney injury (AKI) in acute admissions is common and associated with poor outcomes, independent of co-morbidities. The 2009 UK NCEPOD Report: Adding Insult to Injury showed that good assessment and management can improve outcomes but is only provided in half of patients. We aimed to assess the detection and management of AKI in our centre and whether this is influenced by AKI severity.

**Methods:** Acute admissions between 28/08/12 and 12/10/12 were retrospectively analysed. Patients with creatinine ≥150µmol/L and who fulfilled criteria for Stage 2 (2-3x baseline) or Stage 3 (>3x baseline) AKI were selected. These admissions were judged against standards established from The Renal Association guidance.

**Results: Patient characteristics**: 72 patients fulfilled inclusion criteria; 26 (36.1%) were Stage 2 and 46 (63.9%) were Stage 3. Stages were similar for age (p=0.397) and number of co-morbidities (p=0.442). **Assessment**: 2 patients (2.8%) fulfilled 6/6 assessment criteria; 1 (3.8%) was Stage 2 and 1 was (2.2%) Stage 3. **Management**: 43 patients (59.7%) fulfilled 3/3 management criteria; 14 (53.8%) were Stage 2 and 29 (63.0%) were Stage 3. 18 (25.0%) patients received renal team input during the admission; 2 (7.7%) were Stage 2 and 16 (34.8%) were Stage 3. **Outcome**: 16 patients (22.2%) died during the acute admission; 8 (30.8%) were Stage 2 and 8 (17.4%) were Stage 3 (p=0.190).

**Conclusions:** As both patient groups were balanced for age and number of co-morbidities one would expect better outcomes with lower severity of AKI. Although outcomes were not statistically significant, the trend suggests poorer assessment & management of less severe AKI at our centre. This has led to the local introduction of an AKI risk assessment tool and AKI care pathway.

**TH-PO047**

**Are Bicarbonate-Based Solutions Better in the Treatment of Patientes with Established Acute Kidney Injury?** Rolando Claure-Del Granado, Vania Prudencio. *School of Medicine, IIBISMED, Universidad Mayor de San Simon, Cochabamba, Bolivia.*

**Background:** Fluid administration constitutes an important part of the treatment of establish acute kidney injury (AKI). The optimal hydration strategy for AKI treatment remains unknown. AKI is often associated with metabolic acidosis, and acidosis has been linked to several adverse effects that are deleterious to kidney function. We hypothesized that the use of bicarbonate-based solutions will facilitate AKI recovery.

**Methods:** We analyzed data from 59 hospitalized non-ICU patients; who developed AKI. Patients with CKD K-DIGO 4 and 5 were excluded from the analysis. Twenty-nine patients received bicarbonate-based solutions for the management of AKI and 30 patients received different types of bicarbonate-free solutions. We assessed the effect of bicarbonate-based solutions on Δ serum creatinine (sCr), urine output (UO), days to achieve basal sCr, and the amount of fluids been administered on each group.

**Results:** Of the 59 patients included in the study, 29 patients received bicarbonate-based solutions and 30 patients received other types of IV fluids. Median baseline sCr was higher in the patients who received bicarbonate-based solutions (1.12 IQR[0.9 – 1.3] vs. 1.08 IQR[0.9 – 1.23] mg/dL; p<0.001). sCr reduction rate was higher in the group treated with bicarbonate-based solutions (mean Δ sCr -0.29±0.47 vs. -0.07±0.42 mg/dL; p=0.007). Patients treated with bicarbonate-based solutions; returned to their baseline sCr in fewer days (5.6±2.1 vs. 7.6±2.8 days; p<0.001). In patients where diuretics were not employed, no difference was found in 24 hour UO between patients who received bicarbonate-based solutions and those who received other types of solutions (1,592 IQR[1,409 – 1,905] vs. 1,647 IQR[1,296 – 2,192] ml; p=0.294). No difference also was found in the amount of fluids that each group received (bicarbonate-based 1,000 IQR[500 – 2,000] vs. bicarbonate-free 1,000 IQR[1,000 – 2,000] ml; p=0.903).

**Conclusions:** Bicarbonate-based solutions for the treatment of established AKI could improve renal function, accelerating renal recovery. An adequately powered randomized controlled trial is warranted to support the use of bicarbonate-based solution in patients with AKI.

**TH-PO048**

**Management of Acute Kidney Injury in Hospitalised Patients Remains a Challenge** Jennifer R. Joslin, Daniel Zubli, Hannah R. Wilson, Nathan Gauge, Mark Andrew Yates, Katherine E.S. Warren, Joanna Sutherby, Sabrina Rossi, Charlotte Masterton-Smith, Cornelia Junghans Minton, Tracy Ellimah, Anna Buckingham, Taryn Pile, Maria Ostermann. *Guy's & St. Thomas' NHS Hospital Trust, London, United Kingdom.*

**Background:** When managing patients with acute kidney injury (AKI), a multidisciplinary approach with good communication between medical teams and nursing staff is essential, especially when patients are transferred between wards and medical teams, and health care staff work shifts. In 2012, an AKI 'care bundle' was developed, in conjunction with the London AKI network. The aim of this audit was to evaluate whether there were differences in appreciation and management of AKI on the 1st day of AKI compared to the following days.

**Methods:** During a 7 day period in April 2013, electronic patient records of all level 1 medical and surgical patients in a London teaching hospital were screened. Medical notes of patients with AKI as defined by the KDIGO criteria were reviewed by doctors independent from the treating team to assess compliance with recommended management. Patients receiving palliative care were excluded.

**Results:** 64 patients presented with or developed AKI within the data collection. Data were available for the 1st day of AKI for all 64 patients and for 180 inpatient hospital days beyond the 1st day.

| | Management on 1st day of AKI | Management after 1st day of AKI | p-value |
|---|---|---|---|
| AKI recognised by managing team | 70% | 75% | NS |
| Documented AKI management plan | 87% | 83% | NS |
| Clinical assessment of fluid status | 63% | 67% | NS |
| Complete fluid balance chart | 33% | 43% | NS |
| IV fluids given if vulnerable to hypovolaemia | 74% | 76% | NS |
| Timely antibiotics given if septic | 71% | 68% | NS |
| Nephrotoxic drugs discontinued, if appropriate | 72% | 77% | NS |

**Conclusions:** Patients with AKI did not receive optimal care on a daily basis. However, care did not significantly deteriorate on subsequent days when compared to Day 1 of AKI. More work and education of all members of staff is necessary to achieve full compliance with the AKI bundle on a daily basis.

## TH-PO049

**Exertional Acute Kidney Injury in U.S. Military Personnel Is Not Always due to Rhabdomyolysis** John S. Hammes, Matthew J. Wauson, Joseph D. Hebreo, Daniel J. Dean. *Medicine, Naval Medical Center San Diego, San Diego, CA.*

**Background:** Exertion leading to acute kidney injury (AKI) is well described. It may be due to rhabdomyolysis (AKI-R) or patchy ischemia (AKI-ALPE) or exertional heat illness (AKI-EHI). We sought to determine why AKI-ALPE is appearing in U.S. military personnel (ADSM). The U.S. Marine Corps instituted a Combat Fitness Test (CFT) which involves intense bursts of exertion in 2008.

**Methods:** We reviewed inpatient and outpatient electronic health records of all ADSM's hospitalized with discharge diagnosis of AKI from 2008-2012. We evaluated demographic, clinical and laboratory parameters of patients (pts) for cases of AKI-R, AKI-ALPE, and AKI-EHI. AKI-ALPE was defined as AKI occurring after exertion, accompanied by loin or abdominal pain, and with a creatine kinase (CK) value less than 3000 IU/L which did not resolve with 24 hours of volume repletion.

**Results:** There were 15 cases of AKI-ALPE, 9 cases of AKI-R, and 11 cases of AKI-EHI. AKI-ALPE cases had similar peak SCr (3.7 vs 4.2 p=.7) to AKI-R. There was no difference in the need for dialysis between groups (7% vs 33%, p=.139). The mean number of days til recovery of kidney function (10.4 vs 13.4 p=.61) did not differ between AKI-ALPE and AKI-R. Of 15 AKI-ALPE cases, 9 had recently completed a Combat Fitness Test (CFT) compared with 0 of 20 non AKI-ALPE cases. Pts with AKI-EHI were quickly identified, cooled, and had lower severity of illness (mean peak SCr 1.6, 0 pts dialyzed). No patients died.

**Conclusions:** AKI-ALPE is an important cause of AKI in ADSM who have completed CFT. It may be severe enough to warrant dialysis and has a similar morbidity burden to that of AKI-R. Clinicians caring for AKI pts after exertion should consider ALPE when typical features of rhabdomyolysis are absent. Rapid recognition and cooling of patients with exertional heat illness has mitigated the morbidity of AKI-EHI in this population.

## TH-PO050

**Acute Kidney Injury due to Vitamin D Intoxication in Kashmiri Population** Muzafar Maqsood Wani, Imtiyaz Ahmad Wani. *Nephrology, SKIMS, Soura, Srinagar, J&K, India.*

**Background:** Vitamin D deficiency is highly prevalent in Kashmir. Most of the elderly get Vit D, given mostly as injections; at times dose prescribed is far above the permissible limit, resulting in many cases of Vit D toxicity with hypercalcemia and reversible acute kidney injury (AKI). We report 50 patients with malpractice-related Vit D intoxication with hypercalcemia and AKI.

**Methods:** 58 cases of Vit D toxicity were seen over 24 months (2011-2012). Detailed investigations and follow up was available in 50 cases. The diagnosis of Vit D intoxication was made on basis of history of multiple vitamin D injection intake (600,000 IU/injection), toxic blood levels of 25 OH Vit D and after ruling out common causes of hypercalcemia (malignancy and hyperparathyroidism). Their presentation was either de novo AKI (Group 1) or acute on top of chronic kidney disease (Group 2).

**Results:** Demographic and lab data is shown in table 1.

| Parameter | Group 1 - 39 (27;12) | Group 2- 11 ( 5;6) |
|---|---|---|
| Age (years) | 60.33±14.48 | 62.11±13.01 |
| Admission days | 7.05± 3.03 | 7.77± 3.86 |
| No of injections (million units) | 2-28 (1.2-16.8) | 3-24 (1.8-14.4) |
| Creat at presentation (mg/dl) | 3.25±.96 | 4.53±1.17 |
| Creat at follow up(mg/dl) | 1.41 ± .27 | 3.32 ± 1.06 |
| Calcium(mg/dl) | 13.76 ±1.47 | 13.68 ±2.02 |
| Calcium on follow up (mg/dl) | 10.76 ±1.23 | 11.11 ±1.08 |
| Vit D level (nmol/L) | 313.33 ± 54.84 | 303.73 ± 48.41 |
| PTH-(pg/ml) | 18.13 ± 9.62 | 42.31 ± 12.69 |

The average follow up was of 7.2± .6 months. The clinical presentation was weakness in 100%, constipation in 80%, abdominal pain in 60%, nausea/vomiting in 60%, anorexia in 50%, oliguria in 20% and altered sensorium in 20%. The treatment received was IV fluids in all, normal saline and steroids (short course) in 38 and bisphosphonates in 5.

**Conclusions:** This case series elucidates the alarming trend of AKI secondary to Vit D toxicity in Kashmiri population. It is a cause of reversible AKI which responds to conservative measures in most cases.

## TH-PO051

**Pre-Operative Fibroblast Growth Factor 23 (FGF23) Levels Predict Post-Operative Acute Kidney Injury in Pediatric Cardiac Surgery Patients: A Prospective Study** Mark Hanudel, Barbara Gales, Isidro B. Salusky, Katherine Wesseling-Perry. *Dept of Pediatrics, UCLA, Los Angeles, CA.*

**Background:** In CKD patients, FGF23 levels increase early in the CKD course, predict renal disease progression, and are associated with excess morbidity and mortality. Less is known about FGF23 in AKI; small, retrospective studies have shown higher FGF23 levels in AKI patients.

**Methods:** To prospectively assess the role of FGF23 in pediatric AKI, plasma FGF23 levels (2nd generation C-terminal, Immunotopics®) were measured pre-operatively and at 2, 6, 12, 24, 48, and 96 hours post-reperfusion in 20 patients without underlying CKD undergoing cardiopulmonary bypass (CPB). Serum creatinine was obtained at baseline and daily post-reperfusion. AKI was defined by the AKIN criteria; eGFR was calculated using the Schwartz formula; and cardiac surgery complexity was classified via RACHS-1 score.

**Results:** Of the 20 enrolled patients, 13 developed at least Stage 1 AKI post-operatively. The AKI group was younger than the non-AKI group; other baseline characteristics were similar between the two groups. Pre-operative FGF23 levels were inversely related to age ($r = -0.67$, $p=0.001$). Pre-operative FGF23 levels were higher in patients who developed AKI than in those who did not; this finding remained significant upon correcting for age. Post-operatively, FGF23 levels increased in all patients.

**Conclusions:** Pre-operative FGF23 levels predict the development of post-operative CPB-associated AKI. FGF23 levels increase in pediatric non-CKD patients undergoing CPB, even in patients without significant post-operative changes in serum creatinine, suggesting that FGF23 may be a more sensitive marker of AKI than serum creatinine.

| | AKI Patients | Non-AKI Patients | p-value |

## TH-PO052

**Small Molecule-Mediated Enhancement of Post Injury Repair Mechanisms after Acute Kidney Injury** Nataliya Skrypnyk,[1] Tatiana Novitskaya,[1] Takuto Chiba,[1] Lauren Brilli,[2] Lee McDermott,[2] Subramaniam Sanker,[2] Neil A. Hukriede,[2] Mark P. De Caestecker.[1] *[1]Div of Nephrology, Vanderbilt Univ, Nashville, TN; [2]Dept of Developmental Biology, Univ of Pittsburgh, PA.*

**Background:** Methyl-4-phenylthiobutanoate (m4PTB) is an HDAC inhibitor (HDACi) that promotes renal progenitor expansion in zebrafish embryos and accelerates recovery after ischemia reperfusion acute kidney injury (IR-AKI) in mice. In these studies we generated series of m4PTB analogues and compare efficacy with that of the HDACi SAHA in accelerating recovery and reducing post injury fibrosis after AKI.

**Methods:** m4PTB analogues substitute the zinc chelating carboxylic acid in m4PTB, with other HDACi warheads: 1) Carboxylic acid UPHD22 and 25 (m4PTB); 2) Hydroxamic acid (from TSA) UPHD29; and 3) Benzamide (Class 1 HDACi) UPHD186 and 36. We used zebrafish reporters to evaluate activity; mass spectrometry and quantitative analysis of renal histone H4 acetylation to assess pharmacokinetics (PK); IR-AKI and unilateral ureteral obstruction (UUO) mouse models. Compounds administered IP at 50mg/kg/day starting 1-day post injury for 7 days. Renal function assessed by serum creatinine, and post injury fibrosis with Sirius red and QRT-PCR for fibrotic markers.

**Results:** All 5 analogues show similar activity in zebrafish assays (ED50 600-1000nM). PK studies identified two patterns: long acting (SAHA, UPHD22 and 36) and short acting (UPHD25, 186 and 29). UPHD22, 25, 29 and SAHA reduce creatinine vs. vehicle in IR-AKI. UPHD186 further decreases creatinine vs. other analogues. UPHD25 and 186 reduce post injury fibrosis after IR-AKI. Treatment with UPHD186 3 days after injury

also reduces serum creatinine and post injury fibrosis after IR-AKI. In UUO, UPHD186, 22, 29 and 36 reduce fibrosis and expression of fibrosis markers. SAHA and UPHD25 are ineffective in this model.

**Conclusions:** The short acting PTBA analogue, UPHD186 with a Class 1 HDAC selective warhead, most effectively ameliorates AKI and reduces post injury fibrosis in IR-AKI and UUO models, and UPHD186 is still effective when administered 3 days after IR-AKI. UPHD186 has a broad range of applications that could be useful for delayed treatment of patients with AKI.

## TH-PO053

**Class I Histone Deacetylase Activity Is Required for Proliferation of Renal Epithelial Cells** Shougang Zhuang. *Dept of Medicine, Rhode Island Hospital, Alpert Medical School of Brown Univ, Providence, RI.*

**Background:** The process of renal regeneration after acute kidney injury is thought to recapitulate renal development, and proliferation of renal proximal tubular cells (RPTC) is a critical step in the regenerative response. Recent studies indicate that class I histone deacetylases (HDACs) are required for embryonic kidney gene expression, growth and differentiation. The role and underlying mechanisms of class I HDACs activation in RPTC proliferation, however, remains unclear.

**Methods:** In this study, we used cultured RPTC to examine this issue since four class I HDAC isoforms (1, 2, 3, and 8) are abundantly expressed in this cell type.

**Results:** Blocking class I HDAC activity with a highly selective inhibitor, MS-275, induced global histone H3 hyperacetylation, reduced RPTC proliferation, and diminished expression of cyclin D1 and proliferating cell nuclear antigen (PCNA). Silencing HDAC1, 3 or 8 with siRNA resulted in similar biological effects. Activation of epidermal growth factor receptor (EGFR) and signal transducers and activators of transcription 3 (STAT3) was required for RPTC proliferation, and STAT3 functioned downstream of EGFR. Treatment with MS-275 or knockdown of HDAC1, 3 or 8 suppressed EGFR expressionand phosphorylation, and silencing HDAC1 and 3 also reduced STAT3 phosphorylation. However, HDAC2 down-regulation did not affect RPTC proliferation, or phosphorylation of EGFR and STAT3.

**Conclusions:** Collectively, these data reveal a critical role of class I HDACs in mediating proliferation of renal epithelial cells through activation of the EGFR/STAT3 signaling pathway.

## TH-PO054

**Contribution of Thio Group in PTBA Analogues for Potency and Specificity of HDAC Activity Inhibition** Subramaniam Sanker,[1] Lee McDermott,[1] Mark P. De Caestecker,[2] Neil A. Hukriede.[1] *[1]Dept of Developmental Biology and Pharmaceutical Sciences, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Cell and Developmental Biology, Vanderbilt Univ Medical Center, Nashville, TN.*

**Background:** Acute Kidney injury (AKI) can result in irreversible kidney damage and fibrosis. Currently there are no established post AKI therapies to treat the resultant damage. Based on a zebrafish larval screen we identified that, histone deacetylase (HDAC) inhibitor phenylthiobutanoic acid (PTBA) and analogues initiate embryonic proliferation of renal progenitor cells (RPC) and expand larval kidney field. The methylated PTBA analogue UPHD-25 exhibits an EC-50 value of 800nM. UPHD-25 also activates proliferation of RPCs and enhances renal function following tubule injury in our zebrafish AKI model by inducing de-differentiation and proliferation of proximal tubule epithelial cells. In our mouse AKI models UPHD-25 reduces post-injury fibrosis and increases the regenerative capacity of renal tubular cells.

**Methods:** The Kidney field expansion is assayed by in situ hybridization using lhx1a antisense probes and RPC proliferation by quantification of GFP expression in Tg(lhx1a:eGFP)pt303 transgenic embryos.

**Results:** PTBA analogues target the zinc-dependent catalytic domains of class 1 and 2 HDACs. Bi-dentate $Zn^{++}$ chelators, N-(2-aminophenyl)-4(phenylsulfanyl)butanamide or N-(2 hydroxy phenyl)-4(phenylsulfanyl)butanamide do not significantly enhance the EC-50 values (EC-50 = 600nM). Class I HDACs have a similar binding pocket with small changes in the outer rim where the "thio" group possibly interacts. To understand the contribution of the "thio" group to the potency and specificity of inhibition, we synthesized and tested analogues where the "thio" moiety was shifted over the fatty acid chain in UPHD-188, UPHD-190 and UPHD-193. This "thio" moiety shift results in about 100-fold change in the EC-50 to low nM values.

**Conclusions:** Using this strategy we describe identification of the next generation of PTBA class HDAC inhibitors that enhance RPC proliferation and kidney field expansion at low nM values. This work was supported by NIDDK grants DK069403, DK090770, and DK079307.

## TH-PO055

**Lysophosphatidic Acid (LPA) Transactivates Epidermal Growth Factor Receptors (EGFR) via LPAR1/Gαi/o Signaling to Potentiate LPAR2/Gαq/αvβ6 Integrin Dependent TGFβ Signaling and Increase the Production of PDGF-B and CTGF by Proximal Tubule (PT) Cells** Hui Geng,[1] Rongpei Lan,[1] Prajjal Kanti Singha,[1] Pothana Saikumar,[1] Joel M. Weinberg,[2] Manjeri A. Venkatachalam.[1] *[1]U. Texas; [2]U. Michigan.*

**Background:** In cultured PT cells, LPA stimulates the production and secretion of fibrogenic peptides PDGF-B and CTGF via LPAR2-Gαq-αvβ6 integrin mediated TGFβ transactivation; *in vivo*, during fibrosis after ischemia-reperfusion injury (IRI), TGFβ dependent PDGF-B and CTGF production by PT is associated with LPAR2 and αvβ6 integrin overexpression (Am J Pathol. 181:1236, 2012).

**Methods:** We studied LPAR1 mediated PDGF-B and CTGF production by cultured PT cells and investigated the localization of LPA signaling molecules in kidneys after IRI.

**Results:** *In cultured PT cells*, LPA transactivated EGFR via LPAR1-Gαi/o signaling. This was inhibited by LPAR1 shRNA, LPAR1/3 inhibitor Ki16425 or Gαi/o inhibitor pertussis toxin (PTX). After LPAR1 mediated activation, EGFR and downstream MEK-ERK synergized with LPAR2 dependent TGFβ signaling to increase PDGF-B/CTGF production. Conversely, PTX, EGFR inhibitor AG1478 or Erk inhibitor U0126 synergized with TGFβ inhibitor SB431542 to optimally suppress net TGFβ signaling output and PDGF-B/CTGF production, and to promote PT differentiation. *In vivo after IRI*, PT expression of LPAR1, phospho-EGFR and phospho-ERK increased progressively and persisted in "atrophic" tubules associated with fibrosis. Expression of lysophospholipase D (autotaxin), the enzyme producing LPA from precursor lysophospholipids, also increased progressively in a similar time course, localizing in "atrophic" tubules associated with fibrosis.

**Conclusions:** LPAR2 mediated TGFβ transactivation and potentiation of TGFβ signaling through LPAR1 dependent EGFR activation may be a powerful mechanism to stimulate PDGF-B and CTGF fibrogenic peptide production by PT cells. Together with prior work (Am J Pathol.174:1291,2009 & 181:1236, 2012), the findings after IRI suggest that autotaxin mediated LPA production and signaling via LPAR2 and LPAR1 receptors is a candidate autocrine mechanism for sustained TGFβ signaling and PDGF-B and CTGF peptide production by PT in a context of IRI that causes fibrosis.

## TH-PO056

**HMGB1 Is a Novel Target of Sirt1 Deacetylation: Implications for Stress-Induced HMGB1 Translocation** May M. Rabadi, Sandhya Xavier, Michael S. Goligorsky, Brian B. Ratliff. *New York Medical College, Valhalla, NY.*

**Background:** During AKI, alarmins are released by stressed organs as part of the innate immune response to unleash a signaling cascade responsible for systemic inflammation causing potential multi-organ failure. During cellular stress, the alarmin high mobility group box 1 (HMGB1) undergoes nuclear-to-cytoplasmic translocation and release and this requires its acetylation. HMGB1 deacetylation is unclear, although, partially under the control of HDAC. We hypothesized that deacetylase activity of SIRT1 could participate in regulating nuclear retention of HMGB1, modulating the degree of damage signaling initiated by HMGB1 secretion during stress.

**Methods:** Acetylated HMGB1 was immunoprecipitated and incubated it with SIRT1. Proteomic analysis was used to show that SIRT1 deacetylates HMGB1, which in turn may affect its nuclear retention.

**Results:** We immunoprecipitated acetylated HMGB1 and incubated it with SIRT1, revealing that HMGB1 acetylation was decreased by 49% within 60 minutes. Proteomic analysis showed that SIRT1 deacetylates HMGB1 at four lysine residues positioned within the pro-inflammatory and NLS domain of HMGB1 (lysines 55, 88, 90 & 177). I*n vivo*, resveratrol in AKI led to decreased HMGB1 acetylation, nuclear retention, decreased systemic release and improved renal function. Conversely, genetic ablation and/or pharmacological inhibition of SIRT1 in endothelial cells stressed with LPS increased HMGB1 translocation, an effect significantly enhanced by inhibition of SIRT1 activity, as demonstrated using immunocytochemistry and real-time intravital imaging of HMGB1-GFP transfected cells. In contrast, deletion of SIRT1 or its inhibition both led to enhanced translocation and release of HMGB1. Results indicated SIRT1 regulates the acetylation of HMGB1 and its release during basal and pathophysiologic conditions.

**Conclusions:** In summary, our findings 1) establish HMGB1 as a target for SIRT1 deacetylation; 2) increased cytoplasmic translocation and circulating levels of HMGB1 after inhibition of SIRT1 activity; and 3) attenuation of cytoplasmic translocation and renal injury by pretreatment with an activator of SIRT1.

## TH-PO057

**a(E)-catenin Expression Regulates N-Cadherin and N-CAM Expression and Migration in NRK-52E Cells** Alan R. Parrish, LaNita A. Nichols, Elizabeth A. Borgmann, Xinhui WANG. *Medical Pharmacology and Physiology, Univ of Missouri School of Medicine, Columbia, MO.*

**Background:** The aging kidney is associated with a decreased ability to repair following acute kidney injury. We have shown a loss in expression of a-catenin and N-cadherin in the aging rat kidney and hypothesize that loss of a-catenin expression in tubular epithelial cells may elicit changes that result in the decreased repair capacity. In these studies, we demonstrate that a-catenin and N-cadherin are decreased in the aging kidney, with decreased protein expression detectable as early as 18 months in male Fischer 344 rats. Loss of the proteins is also observed in aged non-human primate kidneys, suggesting that this is not a species-specific response.

**Methods:** In an effort to elucidate alterations due to the loss of a-catenin, we generated NRK-52E cell lines with stable knockdown of a(E)-catenin (C2 cells).

**Results:** These cells exhibited decreased cell-cell adhesion, and increased monolayer permeability. Interestingly, C2 cells had decreased expression of N-cadherin. Increased proliferation in serum, and serum-free, was seen in C2 cells. Using a wound repair model, C2 cells had a deficits in wound repair, due to alterations in cell migration. Analysis of gene expression in the migrating control cells indicated that expression of N-cadherin and N-CAM, was increased during repair. Similar to N-cadherin, N-CAM expression was reduced in C2 cells, and the aging kidney.

**Conclusions:** Taken together, these data suggest that the loss of a-catenin, and subsequent down-regulation of N-cadherin and N-CAM expression, is a mechanism underlying the decreased migration of tubular epithelial cells that contributes to the inability of the aging kidney to repair following injury.

## TH-PO058

**Renal Denervation Prevents Epithelial Cell Cycle Arrest and Interstitial Fibrogenesis after Ischemia Reperfusion Injury**

Jinu Kim,[1] Babu J. Padanilam.[1,2] *[1]Cellular and Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE; [2]Medicine, Div of Nephrology, Univ of Nebraska Medical Center, Omaha, NE.*

**Background:** Cell cycle arrest and inflammation after renal ischemia reperfusion injury (IRI) contributes to development of tubulointerstitial fibrosis. We previously reported that renal nerves drive tubulointerstitial fibrogenesis in obstructive nephropathy. Here, we hypothesized that renal nerve-derived neuropeptide/neurotransmitter may promote tubular cell cycle arrest and tubulointerstitial fibrosis after IRI in mouse kidneys.

**Methods:** Unilateral ischemia was performed for 30 minutes followed by reperfusion for up to 14 days.

**Results:** IRI induced tubulointerstitial fibrosis demonstrated by collagen deposition and profibrotic protein expression from 4 days after the injury. Kidney inflammation demonstrated by leukocyte influx and proinflammatory protein expression was enhanced after IRI. Kidney denervation at the time of injury or up to 1 d post-injury, however, decreased the proinflammatory and profibrotic response. Furthermore, administration of norepinephrine and calcitonine gene-related peptide (CGRP) in denervated IRI kidneys restored inflammation and fibrosis. Norepinephrine or CGRP-administration increased the number of tubular cells at G2/M phase after IRI. Consistent with the in vivo study, treatment with norepinephrine or CGRP induced G2/M arrest in HK-2 human kidney proximal tubule cells, whereas antagonists against their respective receptors inhibited the induction of cell cycle arrest.

**Conclusions:** These data demonstrate that kidney denervation prevents tubular cell cycle arrest and inflammation to attenuate interstitial fibrogenesis after IRI.

## TH-PO059

**Cell-Specific Role of ERK in Kidney Repair following Kidney Ischemia/Reperfusion Injury**

Hee-Seong Jang,[1] Jee In Kim,[1] Joshua H. Lipschutz,[2] Kwon Moo Park.[1] *[1]Anatomy and Cardiovascular Research Institute, Kyungpook National Univ School of Medicine, Daegu, Korea; [2]Medicine, Univ of Pennsylvania and Philadelphia Veterans Affairs Medical Center, Philadelphia, PA.*

**Background:** Extracellular signal-regulated kinase (ERK) signals have shown to involve in kidney pathogenesis. However, the role of ERK in the repair process after kidney injury remains to be defined. Here, we investigated the role of ERK in proliferation and differentiation of tubular epithelial cells, and proliferation of interstitial cells following ischemia/reperfusion (I/R) injury in mouse kidney.

**Methods:** Mice were subjected to 30 minutes of renal ischemia. Some mice were administered with U0126, a specific inhibitor of ERK, daily during the recovery phase, beginning at 2 days after I/R until sacrifice.

**Results:** I/R caused severe tubular cell damage and functional loss in the kidney. Nine days after ischemia, the kidney was restored functionally even though the fibrotic lesion expanded. ERK was activated by I/R immediately and the activated ERK was sustained for 9 days. U0126 treatment inhibited the proliferation of tubular epithelial cells, basolateral relocalization of Na,K-ATPase and lengthening of primary cilia in tubular epithelial cells, whereas it enhanced the proliferation of interstitial cells, the accumulation of extracellular matrix, and the expansion of interstitial area. Furthermore, U0126 treatment elevated the expression of cell cycle arrest markers. U0126 treatment mitigated the post-I/R increase of Sec10, which is a crucial component of exocyst complex and an important factor in ciliogenesis and tubulogenesis. U0126 treatment also enhanced expression of fibrosis markers, TGF-β1 and phosphorylated NF-κB after ischemia.

**Conclusions:** The results demonstrate that activation of ERK is required for both the restoration of damaged tubular epithelial cells, and the inhibition of fibrosis progression following I/R injury.

*Funding:* Government Support - Non-U.S.

## TH-PO060

**Late Inhibition of Inhibitor of IkB Kinase Attenuates Acute Kidney Injury**

Nimesh Patel,[1] Florence Lilian Johnson,[1] Massimo Collino,[2] Mara Rogazzo,[2] Magdi Yaqoob,[1] Christoph Thiemermann.[1] *[1]The William Harvey Research Institute, Queen Mary Univ of London, London, United Kingdom; [2]Dept of Drug Science & Technology, Univ of Turin, Turin, Italy.*

**Background:** Acute kidney injury (AKI) caused by ischemia-reperfusion injury (IRI) is being increasingly regarded as a risk factor for chronic kidney disease (CKD). Activation of nuclear factor-κB (NF-κB) is known to play a key role in the production of various cytokines and chemokines, and seen to be a significant contributor to injury following IRI. NF-κB is a diverse family of transcription factors that can be activated by IκB kinase (IKK). We hypothesised that the specific inhibition of IKK with IKK16 will aid in the attenuation of renal, glomerular and tubular dysfunction.

**Methods:** Forty-three male Wistar rats underwent a right nephrectomy and unilateral renal ischemia by clamping the left renal artery with non-traumatic vascular clips for 30min. The rats were randomised into 5 groups; sham, control, 0.1mg/kg IKK16, 0.3mg/kg IKK16, 1mg/kg IKK16. IKK16 was administered i.v. 24h after the onset of reperfusion. Twenty-four hours prior to termination of the experiment, rats were placed into metabolic cages for the collection of urine at 48h. The experiment was terminated 48h after the commencement of reperfusion for the collection of serum and urine.

**Results:** When compared to rats subjected to sham-operation, rats subjected to unilateral renal IRI (control) demonstrated a significant increase in serum creatinine, creatinine clearance and fractional excretion of sodium indicating the development of renal, glomerular and tubular dysfunction, respectively. The administration of IKK16 demonstrated a dose dependant attenuation of dysfunction, which was seen to be significant in all 3 parameters when administered at a dose of 1mg/kg 24h into reperfusion.

**Conclusions:** We have shown here, for the first time that the late administration of an IKK inhibitor accelerates the rate of recovery of renal, glomerular and tubular dysfunction. The late inhibition of IKK may, therefore, have therapeutic potential in the recovery of AKI and the prevention of CKD. Further investigations are required to determine the exact role of IKK in the development of CKD.

**The Antidepressant Fluvoxamine Protects against Renal Ischemia/Reperfusion Injury**

Judit Hodrea,[1] Adam Hosszu,[1] Sandor Koszegi,[1] Zsuzsanna Antal,[3] Nora Fanni Banki,[3] Adam Vannay,[2] Laszlo J. Wagner,[4] Attila J. Szabo,[3] Tivadar Tulassay,[2,3] Andrea Fekete.[1,3] *[1]"Momentum" Diabetes Research Group, HAS-Semmelweis Univ, Budapest, Hungary; [2]Research Laboratory for Pediatrics and Nephrology, HAS-Semmelweis Univ, Budapest, Hungary; [3]1st Dept of Pediatrics, Semmelweis Univ, Budapest, Hungary; [4]Dept of Transplant Surgery, Semmelweis Univ, Budapest, Hungary.*

**Background:** The Sigma-1 receptor (S1R) agonist Fluvoxamine (FLU) diminishes heart ischemia/reperfusion (IR) injury through S1R – nitric-oxide synthase (NOS) system. Here we tested the effect of FLU pretreatment on IR survival, renal damage and expression of Sigma-Akt-NOS axis.

**Methods:** Male Wistar rats pretreated with FLU (20mg/bwkg); FLU+S1R antagonist NE-100 (1mg/bwkg; FN); FLU+ non-selective NOS blocker L-NAME (10mg/bwkg); FLU+eNOS blocker L-NIO (20mg/bwkg) or FLU+ nNOS blocker 7-NI (25mg/bwkg) had left renal pedicle clamped for 50 min. followed by 24h of reperfusion (T24) and were compared to vehicle-treated (VEH) rats and shams (n=8/group). We measured renal function, histology, and protein level of S1R, pAkt, peNOS and nNOS. Intrarenal capillary hemodynamics was determined by multiphoton microscopy. Additional groups were followed for 7 day survival.

**Results:** FLU pretreatment improved survival and resulted in less functional and histological kidney damage. IR induced renal vasoconstriction at T24 was ameliorated by FLU vs. VEH and FN respectively. This FLU effect was neutralized both by the S1R inhibitor and all NOS blockers. Protein levels of S1R, pAkt, peNOS and nNOS at T24 were more elevated in FLU vs. VEH and FN.

Moreover at 30 min after pretreatment, FLU produced intrarenal vasodilation in shams without IR. Parallel to this, protein levels of S1R, pAkt and peNOS were increased, while nNOS remained unchanged.

**Conclusions:** The antidepressant FLU improves survival and is protective against postischemic renal damage. This better outcome may be attributed to the S1R-NOS mediated intrarenal vasodilator effect of FLU in a time and NOS isoform specific manner. Fundings: LP2011-008; OTKAPD83431-NK84087/2010; TÁMOP4.2.2.B10/1.

## TH-PO062

**Nephroprotective Effects of TVP1022 in Experimental Model of Diabetic Renal Ischemic Injury**

Niroz Abu-Saleh,[1] Hoda Awad,[1] Mogher Khamaisi,[2] Ravit Cohen,[1] Samuel N. Heyman,[3] Zaher Armaly,[4] Zaid Abassi.[1] *[1]Technion, Haifa, Israel; [2]Joslin Diabetes Center, Boston; [3]Hadassah Hebrew Univ Hospital, Jerusalem, Israel; [4]Nazareth Hospital, Israel.*

**Background:** Ischemic acute kidney injury (iAKI) in diabetes mellitus is associated with a rapid kidney dysfunction. Both diabetes and iAKI are characterized by increased oxidative stress. TVP1022, non–MAO inhibitor S-isomer of rasagiline, has been shown

to possess anti-oxidative and anti-apoptotic proprieties in experimental models of cardiac and neuronal injuries. The current study examines the effects of TVP1022 and Tempol, on iAKI in diabetic rats.

**Methods:** Control and streptozotocin-injected rats were studied, with unilateral iAKI performed by clamping of the left renal artery for 30 min. Animals were also subjected to Tempol and TVP1022 (10 and 7.5 mg/kg/day, P.O. for 7 days, respectively), or to their vehicles. Urinary flow (V), sodium excretion (UNaV) and glomerular filtration rate (GFR) were determined 48h following iAKI. Renal morphology was assessed in H&E stained slides, and 4HNE immunofluorescent and nitrotyrosine mmunohistochemistry that were carried out in the various experimental groups.

**Results:** As compared with normoglycemic rats, kidney dysfunction was most prominent in the Lt. iAKI kidneys of diabetic vs. Control animals: V reductions (from 19.6±1.6 to 1.5± 0.4 vs. 7.2±1.2 to 5.5±1.5 µl/min, respectively) and GFR (from 1.17±0.056 to 0.026±0.01 vs. 1.16±0.04 to 0.43±0.1ml/min). iAKI induced outer and inner medullary damage (necrosis, congestion and cast formation), which was most prominent in diabetic animals, and provoked renal immunoreactive 4HNE and nitrotyrosin staining in both groups. Tempol and TVP1022 treatment increased GFR by two (0.044±0.003) and five (0.139±0.06) fold in diabetic ischemic kidneys, respectively. Tempol and TVP1022 treatment also decreased nitrotyrosin and 4HNE staining, whereas TVP1022 but not Tempol decreased necrosis and casts in the renal medulla.

**Conclusions:** TVP1022 treatment ameliorates renal dysfunction and histological changes in the iAKI diabetic model, suggesting a role for TVP1022 therapy in diabetic kidney protection under warm ischemic settings.

## TH-PO063

**Formoterol-Induced Mitochondrial Biogenesis Restores Renal Function Post Ischemic-AKI** Sean Robert Jesinkey,[1] Jason A. Funk,[1] Lauren P. Wills,[1] L. Jay Stallons,[1] Judit Megyesi,[2] Craig Cano Beeson,[1] Rick G. Schnellmann.[1,3] *[1]Center for Cell Death, Injury, and Regeneration, Dept of Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC; [2]Medicine, Univ of Arkansas for Medical Sciences, Little Rock, AR; [3]Ralph H. Johnson Veterans Affairs Medical Center, Charleston, SC.*

**Background:** At this time there are no drug therapies for acute kidney injury, resulting in high mortality. We hypothesized that stimulation of mitochondrial biogenesis 24 hours (h) after ischemia/reperfusion (I/R)-induced acute kidney injury (AKI) in mice would accelerate recovery of mitochondrial and renal function.

**Methods:** C57BL/6 mice were subjected to either sham or I/R-induced AKI followed by once daily injection (ip) with either vehicle or formoterol, a stimulator of mitochondrial biogenesis (Wills et al., 2012), 24 h after injury for 5 days. Renal function was measured by serum creatinine and renal injury was determined histologically and by measuring renal KIM-1. Mitochondrial injury and biogenesis was determined by measuring the abundance of nuclear- and mitochondrial-encoded mitochondrial proteins and by evaluating state 2 and 3 respiration in isolated mitochondria.

**Results:** On day 6, I/R alone resulted in increased serum creatinine and KIM-1 protein expression, and renal necrosis. Mitochondrial proteins NDUFB8 (nuclear-encoded) and COX1 (mitochondrial-encoded), and state 3 respiration were decreased. Formoterol treatment after I/R mice restored serum creatinine to control levels, and decreased renal necrosis and KIM-1 expression. Mitochondrial protein levels and state 3 respiration returned to control levels.

**Conclusions:** These results represent the first proof-of-principle study of a novel drug therapy to treat AKI by restoring mitochondrial function and accelerating the recovery of renal function after AKI has occurred.

## TH-PO064

**Disruption of Mitochondrial Homeostasis and Suppression of Mitochondrial Biogenesis in Folic Acid-Induced AKI** Ryan Whitaker, L. Jay Stallons, Rick G. Schnellmann. *Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.*

**Background:** Recent studies demonstrate that mitochondrial dysfunction is a mediator of AKI development and progression. We demonstrated persistent disruption of mitochondrial homeostasis and inhibition of mitochondrial biogenesis (MB) following I/R-induced AKI. These studies examine the mitochondrial dysfunction associated with folic acid (FA)-induced AKI.

**Methods:** Male CD1 mice were injected with a single IP dose of 250 mg/kg FA dissolved in 300 mM $NaHCO_3$. Sera and urine samples were collected and mice were euthanized at 0, 1, 2, 6, and 14 d. Serum and urine creatinine, and blood urea nitrogen (BUN) were measured using commercially available kits. Kidneys were removed and preserved for histology, qPCR and biochemical analyses.

**Results:** FA caused a rapid decrease in renal function in mice as serum creatinine and BUN levels increased 3-fold and 8-fold over controls at 2 d, respectively. Renal cortical NGAL expression was increased at 1-2 d after FA. All of these markers recovered to near control levels 6 d after FA. In contrast, renal morphology as assessed by PAS staining revealed continued injury through 14 d after FA. Mitochondrial electron transport chain expression and biogenesis remained disrupted 14 d after FA with decreased mRNA expression of PGC-1α, Tfam, NDUFβ8, COX1 and ATPSβ. Protein expression of components of the mitochondrial electron transport chain and transcriptional mediators of MB were decreased out to 6 d, but recovered to control levels by 14 d after FA. Mitophagy and mitochondrial dynamics were also disrupted with changes in PINK1 and mitochondrial fission/fusion proteins.

**Conclusions:** We conclude that mitochondrial dysfunction and disruption of mitochondrial homeostasis are key components of FA-induced AKI. Similar disturbances have been observed in other models of AKI and may represent a conserved mechanism of persistent renal dysfunction. The incomplete recovery of renal morphology after AKI may be linked to a persistent suppression of mitochondrial number and function and restoration of mitochondrial function following AKI may be key to the recovery of kidney function.

## TH-PO065

**Modulation of the Early Innate Immune Response by Heme Oxygenase-1 in Acute Kidney Injury** Ahmed I. Kamal,[1] Subhashini Bolisetty,[1] Ravindra Boddu,[1] James George,[2] Anupam Agarwal.[1] *[1]Medicine; [2]Cardiothoracic Surgery, Birmingham, AL.*

**Background:** Ischemia reperfusion injury (IRI) is a major cause of acute kidney injury. Heme oxygenase-1 (HO-1) is cytoprotective and anti-inflammatory by regulation of the innate immune response. We hypothesized that HO-1 regulates renal macrophage recruitment, infiltration and phenotype in renal IRI. We utilized HO-1 knockout (KO) mice and wild-type (WT) littermates to avoid nonspecific effects of pharmacologic modulators of HO activity.

**Methods:** Age and sex-matched HO-1 KO and WT mice were subjected to renal IRI by bilateral renal pedicle clamping for 10 minutes. This time was chosen due to increased sensitivity and mortality in HO-1 KO mice subjected to renal IRI at ischemic times of 15 or more minutes. Both kidneys were harvested at 1 or 7 days post IRI. Renal infiltrating cells were analyzed by flow cytometry and immunofluorescence staining.

**Results:** Even with 10 min IRI, 50% mortality was observed in HO-1 KO mice by 7 days. Renal function measured by serum creatinine at 24 hrs showed significantly increased levels in the HO-1 KO IRI group compared to all other groups (1.0±0.3 vs. 0.12±0.01,0.16±0.05 and 0.17±0.02 mg/dL for HO-1 KO IRI,WT sham,WT IRI and KO sham,respectively),(n=4-8,P= 0.025 Kruskal-Wallis test). Renal resident monocytes ($CD45^+CD11b^+MHCII^+Ly6C^-CD62L^-$) were significantly decreased in the HO-1 KO IRI kidneys compared to HO-1 WT IRI and sham groups (7.4±1.05 vs. 29±4.3,34.6±2.9 and 31.1±4.8 % of $CD45^+$ ,P<0.01). There was a significant increase in CDD11b cells (P<0.01), nonresident ($CD45^+CD11b^+MHCII^+Ly6C^+CD62L^+$) macrophages (P<0.01) and neutrophilic infiltration in the HO-1 KO IRI group (P<0.05). At 7 days, the HO-1 KO IRI mice exhibited increased serum creatinine (n=3,P=0.6).

**Conclusions:** Lack of HO-1 resulted in increased sensitivity to IRI and intra-renal infiltration by macrophages and neutrophils suggesting that the exaggerated inflammatory responses are a consequence of HO-1 deficiency. These results underscore an important role for HO-1 in modulating inflammatory responses in acute kidney injury and may represent a key target for therapeutic intervention.

## TH-PO066

**Interleukin-10 Deficiency Modifies Repair after Ischemic Acute Kidney Injury** Yu Chen,[1,3] Sanjeev Noel,[1] Samatha Bandapalle,[1] Maria Noel Martina Lingua,[2] Abdel Hamad,[2] Lorraine C. Racusen,[2] Hamid Rabb.[1] *[1]Dept of Medicine, Johns Hopkins Univ, Baltimore, MD; [2]Dept of Pathology, Johns Hopkins Univ, Baltimore, MD; [3]Dept of Medicine, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

**Background:** The role of inflammation in repair process following AKI is largely unknown. Previous studies in rats and cultured mouse cortical tubule cells have shown that interleukin-10 (IL-10) treatment protects from ischemic AKI (Deng, Star et al, *Kidney Int*, 2001). In this current study we hypothesized that IL-10 plays an important role in the repair following ischemic AKI.

**Methods:** C57BL/6 wild type (WT) and IL-10 deficient ($IL\text{-}10^{-/-}$) mice underwent unilateral renal pedicle ischemia for 45 minutes followed by reperfusion. Kidneys were harvested at 3 days or 10 days to examine histological, proliferative and inflammatory changes.

**Results:** Ischemic kidneys from $IL\text{-}10^{-/-}$ mice had significantly (p<0.05) less necrotic tubules than WT in the cortex at day 3 (31±4.7 vs 66.8±13.1) and day 10 (1±0 vs 7.3±3.8) as compared to WT mice. Outer medulla showed significantly (p<0.05) less necrosis in $IL\text{-}10^{-/-}$ mice at day 10 as compared to WT mice (12.5±5.9 vs 46.7±18.0). The epithelial cell proliferative marker, KI-67 staining, revealed significantly (p<0.05) less proliferating epithelial cells in $IL\text{-}10^{-/-}$ mice as compared to WT mice at day 3 (314.3±, 25.4 vs 667.1±32.5) and day 10 (84.5±6.5 vs 128.3±8.0). Higher number of kidney mononuclear cells (KMNCs) was found in $IL\text{-}10^{-/-}$ mice as compared to WT mice (15.8±2.0 vs 6.86±1.19), 10 days after ischemic injury. Percent of $CD25^+FoxP3^+$ (Treg) cells in $CD4^+TCR\beta^+$ cells was significantly (p<0.05) lower in $IL\text{-}10^{-/-}$ mice as compared to WT mice (14.3±1.6 vs 25±6.3) at day 10. There were no significant differences in CD4+, CD8+, NK1.1 cells between $IL\text{-}10^{-/-}$ and WT mice either at day 3 or 10.

**Conclusions:** These data demonstrates that IL-10 deficiency leads to abnormalities in kidney structure, epithelial cell proliferation, and leukocyte trafficking in the repair phase of ischemic AKI. While IL-10 has been previously shown to be protective in the initiation phase of AKI, it might have negative consequences during repair.

**Hydrogel Delivery of Co-Embedded EPC-MSC for Treatment of AKI and Modulation of Macrophage Proinflammatory Cyto-/Chemokine Release**
Ellen Nadel, Joseph Alexander Zullo, Matthew J. Baskind, Rishi Rajdev, May M. Rabadi, Cameron M. Demaree, Radovan Vasko, Michael S. Goligorsky, Brian B. Ratliff. *New York Medical College, Valhalla, NY.*

**Background:** We have shown that endothelial progenitor cells (EPC) embedded in hydrogels confers improvement in renal function during AKI and promotes angiogenesis. We attempted to improve EPC delivery by co-embedding with renal mesenchymal stem cells (MSC), while examining their paracrine mechanisms that affect proinflammatory macrophages.

**Methods:** A live/dead cell assay determined if EPC-MSC co-embedding improved viability during LPS treatment. EPC-MSC co-embedded in hydrogels were delivered to LPS-induced AKI mice and animals were assessed for effects on short-/long-term blood pressure (BP), renal blood flow (RBF), serum creatinine, proteinuria and angiogenesis (femoral ligation). The cyto-/chemokine release from embedded stem cells was examined including effects on modulating the release of proinflammatory molecules from RAW 264.7 macrophages.

**Results:** Hydrogel co-embedding improved stem cell viability during LPS exposure, an effect augmented by MSC hypoxic preconditioning. Delivery of co-embedded EPC-MSC to AKI mice demonstrated additive improvement (as compared to EPC delivery alone) only in short-term proteinuria, with no statistical differences observed for long-term proteinuria and short-/long-term serum creatinine, BP, RBF or angiogenesis. However, hypoxic preconditioning modestly enhanced the therapeutic efficacy of MSC, as compared to untreated MSC. Incubation of co-embedded EPC-MSC with macrophages significantly blunted the release of proinflammatory cyto-/chemokines (INFγ, TNFα, IL-1α, IL-1β, IL-6) from macrophages treated with 100 uM $H_2O_2$.

**Conclusions:** Hydrogel EPC-MSC co-embedding increased their viability during LPS exposure and improved proteinuria during AKI. However, co-embedding did not provide additive improvement in serum creatinine, BP, RBF and angiogenesis, presumably because EPC delivery alone normalized these parameters during AKI or femoral ligation. Paracrine molecules released from co-embedded EPC-MSC dramatically attenuated the release of proinflammatory cyto-/chemokines from macrophages during stress.

**TH-PO068**

**Directional Migration of CXCR4 Gene-Modified Bone Marrow-Derived Mesenchymal Stem Cells to the Kidney Area after Acute Kidney Injury**
Huiling Wang. *Div of Nephrology, Jiming Hospital, Shanghai, China.*

**Background:** Bone marrow-derived mesenchymal stem cells (BMSCs) can migrate to the injured kidney after acute kidney injury (AKI) but with limited efficiency. Here we investigated the effect of CXCR4 overexpression on BMSC migration to the AKI kidney and discussed the possible mechanisms.

**Methods:** CXCR4 gene-modified BMSCs (CXCR4-BMSCs, CXCR4-BMSCs/eGFP) and null-BMSCs (BMSCs/eGFP) were prepared by infecting BMSCs with lenti-CXCR4-eGFP or lenti-eGFP, mice AKI model were divided into 5 groups and sacrificed at 1-14 d after transplantation. Blood indicators,histology, expression of stromal cell-derived factor 1 (SDF-1) and BMSC migration were investigated. Hypoxia/re-oxygenation pretreated renal tubular epithelial cells (HR-RTECs) were prepared to generate AKI in vitro (to culture RTECs first in hypoxia condition for 12 hrs and then in re-oxygenation condition for 12hrs). SDF-1 levels in the HR-RTECs and in the supernatant of HR-RTECs were detected. The chemotaxis experiment was performed using the transwell chamber.he phosphorylation of AKT and MAPK in the BMSCs was also investigated.

**Results:** CXCR4-BMSC transplantation sharply increased the accumulation of BMSCs in the renal tissue, especially at day 3 and day 7. The AKI mice in the CXCR4-BMSCs group showed a greater improvement of renal function and the ATN scoring. HR pretreatment significantly enhanced the SDF-1 protein level in the RTECs and in the culture supernatant. The transwell chamber-based migration assay showed that migration of BMSCs to the HR-RTEC culturing chamber was CXCR4-dependent, and the number of migrating CXCR4-BMSCs was the highest. In addition, the migration could be fully inhibited by AMD3100, a CXCR4-specific antagonist. The migration could also be partly blocked by LY294002 (PI3K inhibitor) and PD98059 (MAPK inhibitor). Phosphorylated Akt and MAPK were increased in the BMSCs co-cultured with HR-RTECs and their expression was the highest in the CXCR4-BMSCs.

**Conclusions:** CXCR4 gene overexpression could enhance BMSC migration to the kidney area after AKI. The SDF-1/CXCR4 axis and the activation of PI3K/AKT and MAPK in BMSCs are the possible mechanisms underlying this function.

**TH-PO069**

**Deleterious Effects of Fibrate-Treated eEOCs in Acute Ischemic Kidney Injury**
Daniel Patschan, Susann Patschan, Gerhard A. Mueller. *Nephrology & Rheumatology, Univ Hospital of Göttingen, Göttingen, Niedersachsen, Germany.*

**Background:** Early Endothelial Outgrowth Cells (eEOCs), a major subpopulation of EPCs (Endothelial Progenitor Cells) have reliably been shown to protect mice from acute ischemic renal failure. In addition, different exogenous strategies have been established for improving renoprotective competence of eEOCs in AKI. PPAR-alpha can promote EPC differentiation. Since fibrates act as PPAR-alpha agonists we aimed to analyze consequences of fibrate treatment of eEOCs in murine AKI.

**Methods:** Male, 8-12 weeks old C57/Bl6N mice were subjected to bilateral renal ischemia followed by systemic injection with either untreated or clo-/fenofibrate (CF/FF) pretreated syngeneic murine eEOCs. Cellular consequences of fibrate treatment were evaluated by different in vitro assays (TGF-beta induced eEOC apoptosis/necrosis, eEOC migration, secretion of pro-/antiangiogenic mediators).

**Results:** Administration of CF treated eEOCs dramatically aggravated postischemic kidney dysfunction while FF treatment of the cells neither improved nor aggravated renal function after ischemia. Both substances significantly reduced cellular secretion of proangiogenic VEGF, such effect was more pronounced in the presence of CF. Migration analysis showed a complete CF induced disruption of cultured eEOCs. TGF-beta mediated eEOC apoptosis/necrosis was intesified by FF but not by CF.

**Conclusions:** Fibrates do not act as eEOC agonists in murine AKI. Contrasting to the literature on other cell types, fibrate induced PPAR-alpha activation decreases the functional competence of cultured eEOCs in vitro.

**TH-PO070**

**VEGF Transduced Amniotic Fluid-Derived Stem Cells in the Ischemic Acute Renal Injury in Rats**
Marina Gabriela M. Carvalho Mori Cunha,[1,3] Silvia Zia,[1] Fanny Oliveira Arcolino,[1] Marianne Carlon,[1] Diego Vilibaldo Beckmann,[2] Ney Luis Pippi,[2] Dominguita Luhers Graca,[2] Elena N. Levtchenko,[1] Jan A. Deprest,[1] Jaan Toelen.[1] *[1]KU Leuven, Leuven, Belgium; [2]Universidade Federal de Santa Maria, Brazil; [3]Universidade Estadual do Ceará, Fortaleza, Brazil.*

**Background:** We have shown that hAFSC (human amniotic fluid derived stem cell) has a nephroprotective effect when delivered in rats with renal ischemia and reperfusion (IR) injury, preventing extensive fibrosis as a late complication. The aim of the present study was to evaluate whether the overexpression of VEGF in the hAFSCs improves their nephroprotective effect in the IR models.

**Methods:** hAFSCs were isolated and characterized for immunophenotypic and differentiation properties. A cell line expressing CD24, c-kit and the renal progenitor markers Six2 and Lim1 was transduced with VEGF. IR injury was induced in 30 male 8w-old Wistar rats and treated 6h later via arterial injection. The control group received only vehicle, the naïve group received $1x10^6$ hAFSCs, VEGF+naïve group received $0,5x10^6$ VEGF and $0,5x10^6$ hAFSCs and VEGF group received $1x10^6$ VEGF cells. Serum creatinine and proteinuria levels were measured at 24h, 48h and 2 months after IR injury. Histological analysis was performed to quantify tubular necrosis and hyaline cast formation at 48h and interstitial fibrosis at 2 months. Additionally, the expression of Ki-67, ED-1 and α-SMA was assessed using immunohistochemistry at 48h.

**Results:** We observed improvement of nephroprotective effect only in the VEGF+naïve group. At 48h, we observed significantly less tubulointerstitial injury in the naïve and VEGF+naïve groups, which was characterized by a higher tubular proliferation, lower inflammatory response and inhibition of myofibroblast expression. The VEGF group aggravated the tubulointerstitial injury, renal function and the inflammatory response. The VEGF+naïve group showed less fibrosis at 2 months than the naïve group and the VEGF group showed more fibrosis than control.

**Conclusions:** VEGF-hAFSCs are more nephroprotective than naïve hAFSC when delivered in rats with renal ischemia and reperfusion injury, however it can have a dose dependent toxic effect and aggravate this injury.

**TH-PO071**

**Human Cord Blood-Derived Endothelial Colony Forming Cells Are Protective in Ischemic Acute Kidney Injury in Mice**
Dylan Burger, Shareef Akbari, David Allan, Rhian Touyz, Kevin D. Burns. *Div of Nephrology, Dept of Medicine, Kidney Research Centre- Ottawa Hospital Research Institute, Univ of Ottawa, Ottawa, Canada.*

**Background:** Endothelial colony forming cells (ECFCs) diminish injury in ischemia/reperfusion (I/R) models, through unknown mechanisms. The purpose of this study was to determine the direct effect of human ECFCs in acute kidney injury (AKI) in mice.

**Methods:** ECFCs were isolated from human umbilical cord blood and expanded in culture. Non-obese diabetic severe combined immunodeficient (NOD-SCID) mice underwent bilateral renal I/R and ECFCs ($10^6$/mouse) were injected via the jugular vein at reperfusion.

**Results:** Renal I/R caused significant increases in plasma creatinine, associated with tubular necrosis and apoptosis, interstitial macrophage infiltration, loss of proximal tubule brush border and renal production of reactive oxygen species (ROS) ($P<0.05$ for all vs sham, n=6-10). Administration of ECFCs decreased plasma creatinine and all indices of tubular injury ($P<0.01$ vs I/R alone). In ischemic kidneys, ECFC treatment increased expression of endothelial nitric oxide synthase (eNOS), suggesting endothelial protection (134% of I/R, $P<0.001$). ECFCs also significantly decreased renal macrophage infiltration (~5-fold vs I/R, $P<0.01$) and ROS production (~3-fold vs I/R, $P<0.05$). In ischemic kidneys after 72 hrs, endothelial cell proliferation was markedly increased, as determined by proliferating cell nuclear antigen (PCNA) staining. By contrast, ECFC treatment completely prevented the increase in endothelial cell proliferation ($P<0.001$). ECFCs were detectable in the blood, kidneys, and other organs 1 hr after infusion, but were absent after 24 hrs, suggesting that they act primarily through released factors.

**Conclusions:** These data indicate that human cord-blood derived ECFCs attenuate endothelial injury in a mouse model of I/R, associated with protection of renal function. The results suggest that human ECFCs may represent a therapeutic strategy for the treatment of ischemic AKI.

## TH-PO072

**Human Antigen-Expressing Rat and Human Marrow Stromal Cells or Human Adipose-Derived Stem Cells Induce an Antibody Response That Abolishes Their Robust Renoprotective Activity in Rats with Acute Kidney Injury** Anna Gooch,[1] Ping Zhang,[1] Zhuma Hu,[1] Florian Toegel,[3] Christof Westenfelder.[1,2] *[1]Medicine, U of Utah and VA Medical Centers, Salt Lake City, UT; [2]Physiology, U of Utah, Salt Lake City, UT; [3]Brigham and Women's Hospital, Boston, MA.*

**Background:** Our pre-clinical (AJP Renal 2005) and Phase I Clinical studies (Nat Rev Neph 2010) showed that allogeneic rat and human Marrow Stromal Cells (MSCs) effectively protect renal function post IRI Acute Kidney Injury (AKI) in rats and in on-pump cardiac surgery patients. Allogeneic cells do not elicit an antibody response, confirming MSCs' immune privileged properties. The present study tested whether the expression of human antigens such as Alkaline Phosphatase by Fischer344 rat (hPAP F344) rMSCs, by human MSCs (hMSC) or by human Adipose-derived Stem Cells (hASC) elicits an antibody response, and whether the presence of such antibodies affects the kidney-protective efficacy of cells in rats with AKI.

**Methods:** Bilateral IRI AKI was induced in F344s (n=6 /group). Post reflow, rats were infused with hPAP-ratMSC, hASCs, hMSC, or vehicle. At endpoint, renal ourcomes were examined, and sera were FACS analyzed for anti-hPAP and anti-human MSC-or ASC-specific IgG antibodies. Two groups of F344s (n=6 each) received hASC i.p., inducing an antibody response by d 14, at which time IRI AKI was induced, followed by a single infusion of hASCs or vehicle.

**Results:** Vs. controls, all 3 cell types significantly protected renal function and hastened recovery from AKI. Although robust renoprotective actions were observed by d 1-3, within 14 days, each treatment elicited a significant IgG antibody response (57-99%) directed at the infused cell type. Rats inoculated with hASCs and confirmed to have antibodies to hASCs were no longer renoprotected by hASCs when treated with them for AKI.

**Conclusions:** Xenogeneic hMSCs and hASCs are renoprotective in rats. However, the induction or presence of antibodies to xenogeneic antigens (e.g. Fetal Bovine Serum or bovine antigens) could render them unsafe and ineffective clinically, mandating the use of non-animal based culture media in clinical applications.

## TH-PO073

**Novel Prostacyclin Analog ONO-1301 (SR-ONO) Ameliorates AKI in a Rat Experimental Contrast-Induced Nephropathy Model** Haruyo Ujike,[1] Yohei Maeshima,[1] Norikazu Hinamoto,[1] Hiroyuki Watatani,[1] Kana Masuda,[1] Katsuyuki Tanabe,[1] Hitoshi Sugiyama,[1] Sakai Yoshiki,[2] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Okayama, Japan; [2]ONO Pharmaceutical Co., LTD., Osaka, Japan.*

**Background:** Contrast-induced nephropathy (CIN) is the third most common cause of acute kidney injury. Multiple factors including renal vasoconstriction, direct renal tubular toxicity, and oxidative stress contribute to tubular damage in CIN. ONO-1301(SR-ONO) is a novel sustained-release prostacyclin analog, possessing thromboxane $A_2$ ($TXA_2$), synthase inhibitory activity.We previously observed the inhibitory effects of SR-ONO on diabetic nephropathy as well as tubulointerstitial injuries in the unilateral ureteral obstruction (UUO) model. In the present study, we studied the therapeutic efficacies of intermittent administration of SR-ONO on renal alterations in the rat experimental CIN model, and examined therapeutic mechanisms.

**Methods:** Male SD rats were divided into four groups (n=10-14/group): sham, control CIN, and SR-ONO-treated CIN groups. CIN was induced by intravenous injection of indomethacin, N ω-nitro-L-arginine methyl ester after uninephrectomy. SR-ONO-treated CIN groups received a single subcutaneous injection of SR-ONO (1 or 3 mg/kg) following the administration of Oypalomin, and animals were sacrificed on Day 1.

**Results:** A single injection of SR-ONO was sufficient to maintain serum concentrations of ONO within the therapeutic range (Day 1). Treatment with SR-ONO resulted in significant improvement of CIN-induced renal dysfunction (BUN and Cr), albuminuria and elevation of urinary NAG. Urinary levels of prostaglandin $E_2$ ($PGE_2$), $PGI_2$ metabolite (2,3-dinor-6-OXO-$PGF_{1\alpha}$) and $TXA_2$ metabolite (11-dehydro-$TXB_2$) were not affected by SR-ONO treatment. SR-ONO treatment significantly suppressed CIN-induced tubulointerstitial injuries (histological score), interstitial ED-1+ monocyte/macrophage infiltration, the elevation of renal mRNA for TNF-a and CCL-2 (real-time PCR) and apoptosis (TUNNEL).

**Conclusions:** These results implicate the potential therapeutic efficacies of SR-ONO in ameliorating tubulointerstitial injuries in CIN.

## TH-PO074

**Protective Effects of Relaxin against Cisplatin-Induced Acute Nephrotoxicity and Subsequent Fibrosis in Rats** Takuya Yoshida,[1] Naoki Ikegaya,[2] Hiromichi Kumagai.[1] *[1]Dept of Clinical Nutrition, Univ of Shizuoka, Shizuoka, Japan; [2]Dept of Medicine, Yaizu Municipal Hospital, Yaizu, Japan.*

**Background:** Cisplatin (CDDP) induced acute kidney injury (AKI) involves pro-inflammatory responses, apoptosis of renal tubular epithelial cells and vascular damage. Furthermore, AKI can increase the risk of developing incident chronic kidney disease (CKD). Relaxin (RLX), a pregnancy hormone, has anti-apoptotic and anti-fibrosis properties. The aim of this study was to investigate the effects of RLX on nephrotoxicity by CDDP.

**Methods:** We investigated the mitigating effects of RLX on AKI induced by CDDP, and then also examined anti-fibrotic effect of RLX on renal fibrosisafter AKI. In the short-term experiments, rats were divided into three groups: 1) control group, 2) CDDP group, 3) CDDP+RLX group. In the third group, RLX was infused at 500ng/ hr via subcutaneous osmotic minipump for 5 or 14 days. CDDP wasadministered intraperitoneally (6mg/kg) after RLX or saline infusion. At 5, and 14 days after CDDP administration, renal function was assessed and kidneys were removed for analysis. In addition, the effect of RLX on renal fibrosis after AKI was evaluated at 6 weeks after CDDP administration as a long-term experiment.

**Results:** In the short-term experiments, CDDP transiently increased plasma levels of creatinine and urea nitrogen with the peak at the fifth day, and RLX provided protection against the increases of creatinine (-32%) and urea nitrogen (-28%). Semi-quantitative assessment of the histological lesions showed marked structural damage and apoptotic cells in CDDP group, those lesions being lessened by RLX treatment (TUNEL:-49%). Overexpression of interleukine-6 observed in the kidneys of CDDP group was reduced in the CDDP+RLX group. In the long-term experiment, the same treatment with RLX significantly reduced renal interstitial fibrosis when compared to CDDP group (-50%).

**Conclusions:** These results suggested that RLX provided protection against CDDP-induced acute kidney injury and the subsequent fibrosis by reducing apoptosis and inflammation.

## TH-PO075

**Activation of G-Protein-Coupled Receptor 40 Attenuates Cisplatin-Induced Apoptosis** Seong Kwon Ma,[1] Soo Yeon Joo,[1] Sang Heon Suh,[1] Chang Seong Kim,[1] Joon Seok Choi,[1] Eun Hui Bae,[1] Jongun Lee,[2] Soo Wan Kim.[1] *[1]Internal Medicine, Chonnam National Univ Medical School, Gwangju, Republic of Korea; [2]Physiology, Chonnam National Univ Medical School, Gwangju, Republic of Korea.*

**Background:** G-protein-coupled receptor 40 (GPR40) plays diverse physiological functions including cellular proliferation and inflammation. We investigated the role of GPR40 in the cisplatin-induced kidney injury.

**Methods:** We determined the protein expression of GPR40 and apoptotic markers in rats with cisplatin-induced kidney injury and cisplatin-treated human renal proximal tubule (HK-2) cells. HK-2 cells were cultured with cisplatin in the absence or presence of GW9508, a selective GPR40 agonist.

**Results:** After cisplatin treatment, the protein expression of GPR40 in the kidney was decreased in association with the increase of serum creatinine levels and the ratio of Bax/Bcl-2 expression. In HK-2 cells, cisplatin treatment increased the number of cells with condensed nuclei, which was ameliorated by GW9508 pretreatment. TUNEL stain showed that the pretreatment of GW9508 ameliorated cisplatin-induced apoptosis. Cisplatin treatment increased the ratio of Bax/Bcl-2 and cleaved caspase-3 expression, which were ameliorated by GW9508 pretreatment. Cisplatin-induced activation of reactive oxygen species/Src/caveolin/epidermal growth factor receptor was counteracted by the pretreatment of GW9508. The pretreatment of GW9508 also counteracted the cisplatin-induced phosphorylation of mitogen-activated protein kinases (MAPKs) and activation of nuclear NF-kB.

**Conclusions:** Activation of GPR40 attenuates cisplatin-induced apoptosis by the inhibition of pro-apoptotic factors, MAPKs and nuclear NF-kB.

## TH-PO076

**5-Aminolevulinic Acid (ALA) Protects against Cisplatin-Induced Acute Kidney Injury via Protection of Mitochondrial Viability and Prevention of Tubular Apoptosis without Compromising Its Anticancer Efficiency In Vitro and In Vivo** Yoshio Terada,[1] Masayuki Ishihara,[1] Kazu Hamada,[1] Tatsuki Matsumoto,[1] Yoshiko Shimamura,[1] Kosuke Inoue,[1] Yoshinori Taniguchi,[1] Taro Horino,[1] Keiji Inoue,[2] Taro Shuin,[2] Koji Ogata.[1] *[1]Dept of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Nankoku, Kochi, Japan; [2]Dept of Urology, Kochi Medical School, Nankoku, Kochi, Japan.*

**Background:** Nephrotoxicity is major limitation in cisplatin(CDDP)-based chemotherapy. 5-Aminolevulinic acid (ALA) is widely distributed, and it is a precursor of tetrapyrole compounds such as heme that is important in energy metabolism. The aim of this study is to evaluate protective role of ALA in CDDP-induced acute kidney injury (AKI). We also evaluated the effects of ALA on anticancer efficiency of CDDP in rats.

**Methods:** We used CDDP-induced AKI rats and cultured renal tubular cells (NRK-52E). We divided four groups of rats control, CDDP only, CDDP+ALA(post);(ALA 10mg/kg+Fe) after CDDP, CDDP+ALA(pre&post);ALA is started 5 days before CDDP.

**Results:** ALA treatments protect CDDP-induced AKI. CDDP increased Cr up to 6.5mg/dl, BUN up to 230mg/dl, ALA significantly reduced these changes (Cr2.1 and 1.8, BUN 55 and 50 in ALA pre and pre&post, respectively). ALA ameliorates CDDP-induced morphological renal damages, and reduced tubular apoptosis evaluated by TUNEL staining and cleaved caspase 3. Protein and mRNA levels of ATP5a, COX-IV, UCP2, PGC-1α in renal tissue were significantly decreased by CDDP, and ALA ameliorates these reduction. Heme Oxigenase (HO)-1 level is induced by CDDP, ALA treatment further up-regulates HO-1 both in vivo and in vitro. The CDDP-induced reduction of mitochondrial enzymes was significantly recovered by ALA+Fe than ALA only in vitro. We evaluated the size of transplantated renal carcinoma to the rat skin, ALA did not change the anti cancer effects of CDDP.

**Conclusions:** These data suggested that the protective mechanisms of ALA in CDDP-induced AKI are via protection of mitochondria and prevention of tubular apoptosis. Also there are no significant effects of ALA on anticancer efficiency of CDDP. Thus, ALA has the potential to prevent CDDP nephrotoxicity without compromising its efficacy.

**Inhibition of Poly (ADP-RIBOSE) Polymerase-1 (PERP-1) Activity Ameliorates Renal Proximal Tubular Epithelial Cells (PTEC) Injury Induced by Cisplatin** Hideaki Yamabe, Michiko Shimada, Reiichi Murakami, Takeshi Fujita, Ikuyo Narita, Yoshiko Shutto, Norio Nakamura. *Dept of Nephrology, Hirosaki Univ School of Medicine, Hirosaki, Aomori, Japan.*

**Background:** Cisplatin is a chemotherapy drug which is widely used to treat cancers. It is platinum-based and inhibits DNA production of cancer cells. However, it is well known cisplatin sometimes injures PTEC and induces acute kidney injury (AKI). PARP-1, which is nuclear protein, plays an important role in not only DNA repair but apoptosis or cell necrosis. This study investigated the effect of PARP-1 inhibitor on PTEC injury induced by cisplatin in vitro.

**Methods:** Human cultured PTEC of 4th passage were used. Cultured PTEC were incubated with cisplatin or cisplatin plus olaparib, which is PARP-1 inhibitor for 24 hours. The cytotoxicity by cisplatin or olaparib was evaluated by LDH release from PTEC. The amount of LDH in the cell supernatants and PTEC lysed by mellitin after removing the cell supernatants was measured. The cytotoxicity was expressed as ratio of the LDH amount in the cell supernatants to total LDH. PARP-1 expression was evaluated by immnofluorescent study using anti-PARP-1 antibody.

**Results:** Cisplatin (5.0-100 μM) injured PTEC for 24 hours incubation. Olaparib (0.1-10.0 nM) ameliorated cell injury induced by cisplatin (control: 37.6±3.04%, 5.0 μM cisplatin: 52.2 ±8.0%, $p<0.001$ vs control, 5.0 μM cisplatin plus 5.0 nM olaparib: 32.0±2.1%, $p<0.001$ vs 5.0 μM cisplatin, 5.0 nM olaparib: 29.1±0.8%). PARP-1 expression was enhanced by 5.0 μM cisplatin and the enhanced PARP-1 expression was inhibited by 5.0 nM olaparib.

**Conclusions:** We demonstrated that PARP-1 inhibitor ameliorated PTEC injury induced by cisplatin and enhanced PARP-1 expression by cisplatin was blocked by PARP-1 inhibitor. These data suggested that PARP-1 inhibitor might be useful for the prevention of AKI induced by cisplatin.

### TH-PO078

**Magnesium Deficiency Worsens and Magnesium Treatment Attenuates Cisplatin-Mediated Renal Cell Apoptosis and Acute Kidney Injury** Malvika H. Solanki, Prodyot K. Chatterjee, Madhu Gupta, Xiangying Xue, Andrei Plagov, Pravin C. Singhal, Christine N. Metz. *The Feinstein Institute for Medical Research, Manhasset, NY.*

**Background:** Cisplatin is an effective chemotherapeutic agent for treating ovarian, bladder and breast tumors. However, >25% of patients experience acute kidney injury (AKI), particularly the elderly with females>males. Magnesium (Mg) deficiency is common among the elderly and because renal Mg handling is impaired by cisplatin, we examined the effects of Mg deficiency and supplementation on cisplatin-AKI.

**Methods:** In vitro: The effect of Mg status on cisplatin-cell death was examined using LLC-$PK_1$ renal epithelial cells. In vivo: Older female C57BL/6 mice (10/group, 10mo old) were fed either normal (100%Mg) or 10%Mg-deficient diets for 2wks and then injected with saline or cisplatin (12mg/kg, i.p.). In addition, one group of Mg-deficient mice was supplemented with $MgCl_2$ in water and $MgSO_4$ s.c. prior to cisplatin. Kidney injury was assessed 48hrs post-cisplatin by blood urea nitrogen (BUN) levels, renal tubular damage (H&E staining), oxidative stress, apoptosis (TUNEL assay) and renal p53 expression (Western Blotting).

**Results:** Cisplatin-induced LLC-$PK_1$ cell death was significantly enhanced by Mg deficiency ($P<0.001$) and decreased by Mg replacement ($P<0.001$). In mice, Mg deficiency elevated BUN levels ($P< 0.05$), renal *Ncf1* and *Bak* mRNA expression ($P<0.05$) and renal cell apoptosis following cisplatin compared to 100%Mg controls ($P<0.05$). Mg deficient mice following cisplatin showed increased oxidative stress, renal damage ($P<0.01$) and enhanced renal p53 expression/phosphorylation compared to controls ($P<0.01$). Mg replacement significantly reversed the damaging effects of cisplatin ($P<0.01$).

**Conclusions:** Mg deficiency significantly exacerbates cisplatin-AKI and promotes renal oxidative stress and apoptosis in older female mice; Mg replacement reverses this effect. Mechanistic studies support the renoprotective role of Mg in regulating p53 expression and activation, a critical pathway involved in cisplatin-induced apoptosis. These findings warrant future studies examining Mg status and aggressive Mg replacement therapy in cisplatin-treated cancer patients.

**Remote Ischemic Precondition Provide Renal Protection against AKI** Pu Duann,[1] Ling-Mei Chiang.[2] *[1]DHLRI, Ohio State Univ Medical Center, Columbus, OH; [2]Paediatrics, Chang-Gung Memorial Medical Center, Keelung, Taiwan.*

**Background:** TRIM72 (tripartite motif 72), primarily expressed in muscles, was newly identified in nephron. TRIM72 is capable to form a membrane patch in maintaining the the integrity of plasma lemma. Primary culture of proximal tubule epithelium cells transfected with GFP-TRIM72 showed fluorescence storage in microvessicle and tether to cytoplasma inner plasma membrane. It implied TRIM72 excute its cyto-regenerating role and physiological function in a form of microvesicles traffickling manner. We therefore explore the cell biology of TRIM72 in form of microvessicle and exosome.

**Methods:** Ischemia-reperfusion induced AKI was conducted on Sprague Dawley rats using non-occlusive clamping on renal arteries for 35 minutes followed with reperfusion. Microvessicles (100-650 nm) or exosomes (30-70 nm) were isolated from plasma/urine of rats by differential centrifugation. Remote ischemia preconditioning (RIP) was conducted via alternate femoral arterial non-occlusive clamping. TRIM72-containg microvessicles / exosomes were isolated from kidney or muscle by sucrose gradient fractionation.

**Results:** Western blot analysis revealed both TRIM72-containg microvessicles and exosomes increased after RIP in plasma. The TRIM72 containing microvessicles and exosomes prior to acute kidney injury were recruited to injured nephron and reduced proteinuria. AKI induced prior RIP failed to obtain any beneficial effects. The TRIM72(+)-microvessicles and exosomes released from RIP induced after AKI were not reabsorbed by the injured kidney thereby excreted to urine. Renal brush border isolated by ultracentrifuge-based fractionation showed an abundance of TRIM72 and was further upregulated after AKI. TRIM72(+)-microvessicles isolated from a multitude of RIP-pretreated donor rats were isolated for adoptive transfer. These microvessicles were shown to successfully protect recipients from AKI as seen by reduced proteinuria. Microvessicles from sham-treated donors failed to show any salutary effects.

**Conclusions:** RIP release circulating TRIM(+)-microvesicles and exosomes. It protect host from Ischemia reperfusion mediated AKI. The injury nephron recruited RIP-released TRIM(+)-microvesicles.

### TH-PO080

**Meclizine Preconditioning Protects against Ischemic Kidney Injury** Seiji Kishi,[1] Gabriela Campanholle,[2] Mohit Jain,[3] Craig R. Brooks,[1] Vishal M. Gohil,[4] Takaharu Ichimura,[1] Joseph V. Bonventre.[1] *[1]Renal Div, Brigham and Women's Hospital, Boston, MA; [2]Dept of Nephrology, Univ of Washington, Seattle, WA; [3]Dept of System Biology, Harvard Medical School, Boston, MA; [4]Biochemistry & Biophysics, Texas A&M Univ, TX.*

**Background:** Meclizine, a commonly used anti-histamine, has been identified in a nutrient-sensitized screen for drugs that shift energy metabolism from mitochondrial respiration to glycolysis. Meclizine has cardioprotective and neuroprotective effects in cellular and animal models.

**Methods:** C57BL/6 mice were pretreated with meclizine or vehicle, and subjected to bilateral renal ischemia (30 min) followed by reperfusion (I/R injury). Serum, urine and kidney tissue samples were collected at 24 hours after injury. Experiments in vitro involved cell viability and intracellular metabolite analyses on meclizine-treated kidneys and renal tubular epithelial cells (RPTEC) subjected to chemical hypoxia.

**Results:** Meclizine pretreatment 17hr, but not 3 or 8hr, prior to ischemia protected mice from I/R injury in a dose dependent manner as reflected by reduced BUN, serum creatainine, tubular necrosis, neutrophil and macrophage infiltration. Inflammatory cytokines, IL-1b, IL-6, TNFa, MCP-1, were also decreased. Oxygen consumption of isolated kidney mitochondria pre-treated with meclizine was decreased without increasing energy metabolism pathways and glycolytic enzymes. Meclizine preconditioning of RPTEC decreased LDH release after chemical hypoxia in a dose-dependent manner. NaCN-induced cytochrome C release from mitochondria was inhibited by meclizine pretreatment. Furthremore, meclizine administration increased intracellular phosphoethanolamine. Ethanolamine pretreatment protected against chemical hypoxia-induced cell death.

**Conclusions:** Meclizine pretreatment protects against mouse I/R injury and chemical hypoxia in vitro. Meclizine induces intracellular phosphoethanolamine accumulation which inhibits mitochondrial respiration, downregulates cytochrome c release and promotes cell protection. Meclizine, a drug which has been used extensively clinically without major side effects, may be an important candidate as a pharmacological renal preconditioning agent.

### TH-PO081

**Remote Ischemic Pre-Conditioning Mobilizes Mesenchymal Stem Cells and Endothelial Progenitor Cells and Has Therapeutic Potential for Acute Kidney Injury** Jon D. Ahlstrom,[1] Zhuma Hu,[1] Ping Zhang,[1] Christof Westenfelder.[1,2] *[1]Depts of Medicine, Univ of Utah and VA Medical Centers, Salt Lake City, UT; [2]Depts of Physiology, Univ of Utah and VA Medical Centers, Salt Lake City, UT.*

**Background:** Acute kidney injury (AKI) is a common and serious syndrome for which there is currently no effective and approved treatment. One novel therapy for AKI that has shown potential both in animal models and in clinical trials is the use of Remote Ischemic Pre-Conditioning (RIPC). RIPC therapy consists of several brief episodes of ischemia/reperfusion at a remote location such as a limb, where short periods of ischemia are generated with a simple non-invasive procedure. Our laboratory has previously shown in animal models and in a Phase I Clinical Trial that Mesenchymal Stem Cells (MSCs) are a safe and effective therapy for AKI. This study examined the hypothesis that RIPC mobilizes therapeutically beneficial progenitor cells into the circulation.

**Methods:** To evaluate whether or not RIPC increases the numbers of MSCs mobilized into the circulation, male Sprague Dawley rats weighing 200-300 g were randomized into either RIPC or sham procedure groups (n=6 per group). RIPC was performed on both hind limbs with 3 cycles of 4 min ischemia/4 min reperfusion. One day following RIPC,

whole blood was sampled and evaluated by flow cytometry for the relative abundance of MSCs, endothelial progenitor cells (EPCs), and hematopoietic stem cells (HSCs). MSCs were defined as CD45-/CD271+, EPCs as CD45-/CD34+ and HSCs as CD45+/CD34+.

**Results:** At 24 hours following the RIPC procedure, the numbers of circulating MSCs were increased 3.7 fold (from 195±57 to 732±112 MSCs per mL of whole blood, p<0.001), and the numbers of EPCs in circulation were increased 3.8 fold (from 29.5±1.1 to 114.6±14 EPCs per mL of whole blood, p<0.001). RIPC did not significantly change the numbers of circulating HSCs.

**Conclusions:** RIPC significantly increases the numbers of circulating MSCs and EPCs. Since both are known to afford renoprotection post AKI, our data identify an important mediator mechanism that explains, at least in part, whereby RIPC promotes renal repair following AKI.

## TH-PO082

**The Water Soluble Triptolide Derivative PG490-88 Protects against Cisplatin-Induced Acute Kidney Injury** Hyun-Jung Kim,[1] Kameswaran Ravichandran,[1] Zhibin He,[1] Danica Ljubanovic,[2] Charles L. Edelstein.[1] *[1]UC Denver; [2]Univ Hospital Croatia.*

**Background:** Triptolide, a traditional Chinese medicine, has anti-inflammatory, anti-proliferative and pro-apoptotic activities in pre clinical studies. As interstitial inflammation and tubular apoptosis are features of cisplatin-induced AKI and Triptolide has anti-inflammatory and pro-apoptotic actions, we determined the effect of the water soluble Triptolide derivative PG490-88 (PG) in a mouse model of cisplatin-induced AKI.

**Methods:** Mice injected with Cisplatin (C), (20mg/kg) develop apoptosis on day 1, ATN on day 2 and renal failure on day 3. Mice were injected with PG (0.5 mg/kg) prior to C.

**Results:** PG protected against renal failure and ATN despite having no effect on tubular apoptosis. SCr (mg/dL) was 0.25 in vehicle (V), 0.23in PG, 1.53 in C (P<0.001 vs. V), 0.77in PG+C (P<0.01 vs. C). BUN (mg/dL) was 30 in V, 26 in PG, 206 in C (P<0.001 vs. V), 136 in PG+C (P<0.05 vs. C). ATN score was 0 in V and PG, 4.3 in C (P<0.001 vs. V), 2.4in PG+C (P<0.01 vs. C). Apoptotic tubular cells (/10 HPF) was 0 in V and PG, 10.3 in C (P<0.001 vs. V), 15.3 in PG+C (P<0.01 vs. V, NS vs. C). Triptolide is known to inhibit pro-inflammatory cytokines and chemokines. IL-1α, IL-1β, IL-6, IL-8, IL-33 and TNFα were significantly increased in C, but unaffected by PG. MAPKpathways are activated in cisplatin-induced AKI and known to be inhibited by PG. On immunoblot and densitometry analysis p-p38was not increased by C norinhibited by PG (P=NS vs. V), p-JNK was 1.6 fold increased by C (P=NS vs. V) and 1.2 fold inhibited by PG (P=NS vs. V) and p-ERK was 3.6 fold increased by C (P<0.0001 vs. V) and 2.0 fold inhibited by PG (P<0.05 vs. V). On densitometry analysis, the p-NFκB/t-NFκB ratio was 10.5 fold increased in the nuclear extracts in AKI (P<0.001 vs. V) and the increase in nuclear extracts was completely inhibited by PG.

**Conclusions:** The protection of PG against cisplatin-induced AKI was associated with a decrease in ERK and NFkB pathways. Inhibition of NFkB in cisplatin induced AKI merits further study.

*Funding:* Other NIH Support - 5R01DK074835-04

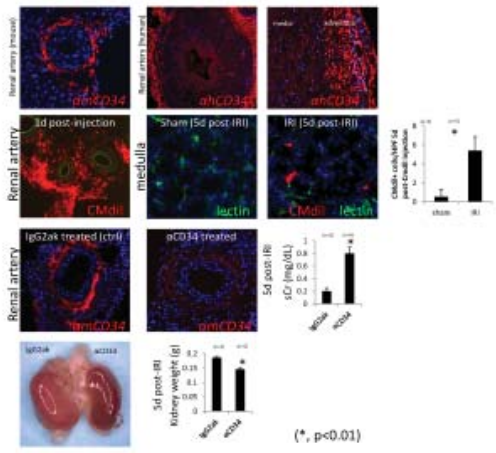
## TH-PO083

**Endothelial Progenitor Cells Exist in the Adventitia of the Renal Artery and Migrate to Repair Kidney Microvasculature** Paul Pang, Padsawan Khamlue, Vanesa Bijol, Andrew M. Siedlecki. *Medicine, Brigham and Women's Hospital, Boston, MA.*

**Background:** Endothelial progenitor cells resident in arterial vessels are defined by the expression of CD34 in the adventitial layer; distinct from mature endothelial cells present in the intima. Presence and function of endothelial progenitor cells in adventitial layer of renal arteries has not been described.

**Methods:** Renal artery tissue was digested and sorted for CD34+ cells. Animals underwent ischemia/reperfusion injury followed by isolation of CD34+ cells from renal arteries 5 days after injury.

**Results:** The adventitia of renal arteries from adult mice and humans contained CD34+ cells.



Mouse renal arteries were digested and cells were sorted (CD34+, CD105-, CD45.2-). Isolated cells formed tube-like structures, and expressed CD34, CD133 but not CD144 or CD31. Cmdil cytotracker was locally injected to the adventitia of the renal artery with care to avoid intra-arterial injection . 5d post-IRI, Cmdil+ cells were present in peritubular capillaries in the outer medulla. Cmdil+ cells were not identified in tubular epithelial cells and were not present in the parenchyma 5 days after sham injury. αCD34 antibody was injected to the same region as above. Compared to IgG2ak control injection, kidneys with αCD34 were decreased in size 5 days after IRI. Serum creatinine was increased on day 5, 0.8mg/dL±0.05 vs 0.2±0.03 ( p<0.01), compared to IgG2ak control injection. By microarray 5d post-IRI, CD34+, CD45.2-, CD105- cells upregulated mir-125, mir-214, and mir-145, mir-532 >2.5-fold (p<0.01) compared to shams and downregulated mir-152 3.9-fold(p<0.01); each of which are associated with tissue repair or cell differentiation.

**Conclusions:** We show that EPCs are present in the adventitia of the renal artery and migrate to the kidney after injury. Further, their deletion delays recovery from IRI.

*Funding:* NIDDK Support

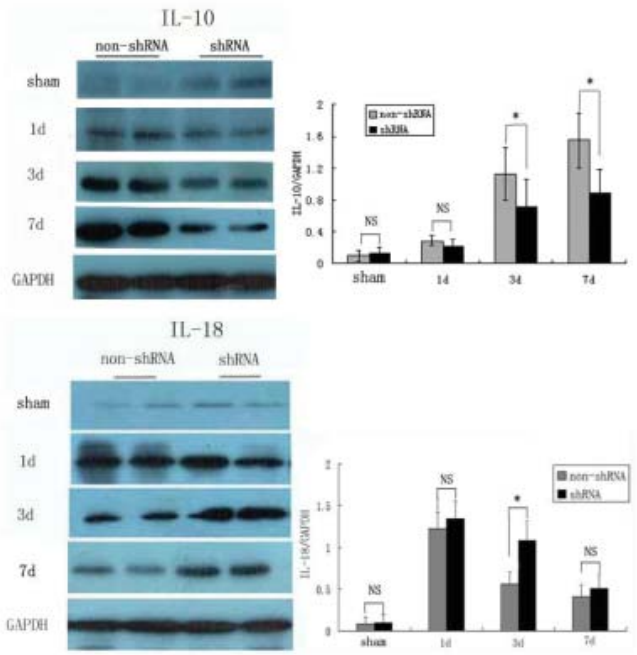
## TH-PO084

**IKKα-Dependent NF-kB p52/RelB Alternative Pathway Enhances Inflammation Resolution in Renal Ischemia-Reperfusion Injury** Qian Zhang, Changchun Cao, Xin Du, Binbin Pan, Qian Zhang. *Nanjing Hospital Affiliated to Nanjing Medical Univ.*

**Background:** Renal ischemia-reperfusion(IR) injury is a major cause of acute kidney injury(AKI). Recent evidence suggests inflammation play an important role in pathophysiology of AKI, which is thought to be regulated by nuclear factor-κB (NF-κB). Activation of NF-κB is dependent on the activation the inhibitor of NF-κB kinase(IKK) β and IKKα . Our previous study indicated targeted silencing of IKKβ prevents renal ischemia injury and inflammation induced by ischemia-reperfusion(IR). While the effect of IKKα and its potential targets are not well understood.

**Methods:** We have examined the role of IKKα in IR injury by shRNA. Mice were divided into four groups: sham-operated**,** IR injury , shRNA-treated and shRNA-treated scrambled. All were subjected to IR injury by bilateral pedicle clamping for 25 min after pentobarbital anesthesia. Application of shRNA or saline started 2 weeks before IR. All mice were sacrificed 24h, 72h and 7d. Serum and kidney tissue samples were collected for further evaluation.

**Results:** Higher blood urea nitrogen, serum creatinine levels and severe renal function were noted in IR injury mice as compared with sham-operated mice. After induction of IR injury, IKKα was increased from 24h to day 7, with a peak on day 3 compared with sham-operated mice. IKKα activation was paralleled by an increase in p52, RelB and IL-10,IL-18. shRNA-tre.ated mice significantly decreased IKKα activity, inhibited p52, RelB, IL-10 and promoted IL-18 at all time points (Figure 1).



**Conclusions:** IKKα-Dependence NF-κB p52/RelB alternative pathway could be activated after IR injury, low-expression of IKKα may block inflammation resolution via down-regulated NFκB alternative pathway family members of both p52 and RelB.

## TH-PO085

**A Mouse Model of Nephrectomy-Induced Renal Repair: An Elegant Tool to Study Renal Regeneration** Benjamin Arthur Vervaet, Nathalie Le Clef, Patrick C. D'Haese. *Biomedicine, Univ Antwerp, Belgium.*

**Background:** Enhanced renal repair is defined as the remarkable repair of an acutely injured kidney upon removal of the healthy contralateral kidney. If the latter kidney is left in place, repair is only marginal and the injured kidney turns fibrotic. The molecular mechanism of this phenomenon is unknown. As most original observations were done in species less accessible to genetic manipulation for mechanistic studies, i.e. dogs and rats, we aimed at optimizing an "enhanced renal repair" model in C57BL/6J mice.

**Methods:** Acute kidney injury was induced by left ischemia/reperfusion (I/R) after which either right nephrectomy (Nx) or mock-Nx was performed 3 days later. Two critical ischemic parameters (i.e. duration of and body temperature during ischemia) were varied. Wild type mice (25g, n=4-6 per group) underwent either 30 min of ischemia at 35, 36 or 37°C or, alternatively, 21, 23, 25 or 30 min of ischemia at 36°C. Control mice underwent mock-I/R and mock-Nx surgery. Mice were euthanized 6 weeks after I/R. Kidneys were weighed and qPCR analysis of the profibrotic genes Col1, Col4, TGFbeta and CCN2 was performed.

**Results:** In the groups undergoing I/R in combination with mock-Nx, no mortality was noted. Of the groups undergoing I/R in combination with Nx, only the mice undergoing 21 min. of ischemia at 36°C survived. Others perished within 48 hours after Nx. In the I/R (21min) without Nx group the median left kidney-to-body weight ratio (mg/g) was 2.8 (range 2.1-3.1), whereas that of its right healthy kidney was 6.7 (range 6.4-7.0). In the Nx group, left kidney-to-body ratio was 6.9 (range 6.0-7.3) and that of its right kidney at the time of Nx 6.5 (range 5.9-7.5). When no Nx was performed, Col1, Col4, TGFbeta and CCN2 were upregulated 18-, 5-, 7- and 3-fold compared to controls, respectively. In case of Nx, this decreased to 5-, 2-, 2-, and 0-fold upregulation, respectively.

**Conclusions:** We clearly demonstrated in C57BL/6J mice that Nx performed 3 days after I/R (21 min, 36°C) is able to strongly attenuate development of renal atrophy and fibrosis. This is indicative of enhanced renal repair and provides a useful tool to study the cell biological mechanisms driving renal regeneration.

*Funding:* Government Support - Non-U.S.

## TH-PO086

**Delayed Administration of a Single Dose of Lithium Promotes Recovery from Cisplatin-Induced Acute Kidney Injury** Hui Bao,[1] Yan Ge,[1] Lance D. Dworkin,[1] Ai Peng,[2] Rujun Gong.[1] *[1]Nephrology, Brown Univ, Providence, RI; [2]Nephrology, Shanghai Tenth People's Hospital, Shanghai, China.*

**Background:** Evidence suggests that glycogen synthase kinase (GSK)3β is a key regulator of tissue injury, repair and regeneration. Lithium, a selective inhibitor of GSK3β and FDA approved first-line mood stabilizer, has been well known for its pro-reparative activities in multiple organ systems. However, its effect on renal repair following acute kidney injury (AKI) remains uncertain.

**Methods:** The role of GSK3β in post-AKI kidney repair was examined in a murine model of cisplatin-induced nephrotoxicity and in cultured renal proximal tubular cells *in vitro*.

**Results:** In a murine model of cisplatin-induced AKI, delayed treatment with a single low dose of lithium accelerated recovery of kidney function, promoted repopulation of renal tubular epithelia and improved kidney repair. This was associated with reduced GSK3β activities and elevated expressions in renal tubular epithelia of pro-proliferative molecules, including Cyclin D1, c-Myc and HIF-1α. In cultured renal tubular cells, GSK3β activity was transiently repressed by cisplatin followed by a prolonged upregulation. Rescue treatment with lithium reduced GSK3β activity, enhanced nuclear expression of Cyclin D1, c-Myc and HIF-1α, and boosted cellular proliferation. Moreover, ectopic expression of a kinase dead mutant of GSK3β enhanced the expression of Cyclin D1, c-Myc and HIF-1α and amplified cellular proliferation following cisplatin injury, reminiscent of the effect of lithium; whereas forced expression of a constitutively active mutant of GSK3β abrogated the lithium's effect, suggesting that GSK3β inhibition is sufficient and indispensable for lithium's pro-reparative effect. Mechanistically, GSK3β colocalized and physically interacted with Cyclin D1, c-Myc and HIF-1α in renal tubular cells. *In silico* analysis revealed that Cyclin D1, c-Myc and HIF-1α all harbor putative GSK3β consensus phosphorylation motifs, inferring a GSK3β directed phosphorylation and subsequent degradation of these molecules.

**Conclusions:** Pharmacological targeting of GSK3β by lithium might represent a novel therapeutic strategy to improve renal salvage after AKI.

## TH-PO087

**Resolution of Neutrophilic Inflammation during the Recovery Phase in Ischemia/Reperfusion Injury** Sang-Kyung Jo, Won-Yong Cho, Myung-Gyu Kim, Hyoung-Kyu Kim. *Internal Medicine, Korea Univ Medical Center, Seoul, Republic of Korea.*

**Background:** Although effective clearance of leukocytes seems to be prerequisite for restoration of normal function and structure, mechanisms underlying resolution in IRI are not known. To examine the possible mechanisms of resolution, we hypothesized that infiltrated neutrophils might be removed by processes of 1) apoptosis, 2) reverse transendothelial migration (rTEM) and 3)urinary expulsion via leukocytes-epithelial interaction.

**Methods:** The role of neutrophil apoptosis in resolution and recovery was determined in Bax KO bone marrow chimera in which only bone marrow derived cells are resistant to apoptosis. To examine the role of rTEM, number of circulating ICAM-$1^+$ reverse transmigrated neutrophils, as well as the effect of in vivo blockade of junctional adhesion molecule-C (JAM-C), a negative regulator of rTEM on functional, histologic kidney recovery were determined. Urinary expulsion of neutrophils was examined by flow cytometric detection of Gr-$1^+$ neutrophils in urine and also the effect of MMP-9 inhibitor, that suppress leukocytes-epithelial interaction was tested.

**Results: apoptosis** While initial Scr and neutrophil influx were not different, clearance of neutrophils was significantly delayed in Bax $KO^{BM}$ chimera and it was also associated with delayed functional, histologic recovery, higher tissue cytokines, impaired regeneration and accelerated fibrosis. **rTEM** Number of ICAM-$1^+$ reverse migrated neutrophils increased on day 2 and in vivo blockade of JAM-C resulted in not only increase in circulating ICAM-$1^+$ neutrophils, but also faster resolution of neutrophilic inflammation and functional, histologic recovery. Presence of Tomm-Horsfall protein in circulating neutrophils confirmed that these neutrophils are derived from injured kidneys. **Urinary expulsion** Gr-$1^+$ neutrophils were identified in urines and treatment with minocycline or MMP-9 inhibitor was associated with decrease in urinary MPO, as well as delayed resolution of inflammation, impaired recovery.

**Conclusions:** We suggest that apoptosis, rTEM and urinary expulsion are critically involved in natural resolution mechanisms of neutrophilic inflammation and also in recovery following IRI.

## TH-PO088

**Activation of the miR-17/106 Family and miR-21 during Murine Kidney Ischemia-Reperfusion Injury** Peter Hamar, Mária Godó Godó, Csaba Revesz, Tamás Kaucsár. *Institute of Pathophysiology, Semmelweis Univ, Budapest, Hungary.*

**Background:** Ischemia induced acute tubular necrosis (ATN) is a main cause of acute kidney injury. MicroRNAs (miRNAs) are posttranscriptional regulators of gene-expression. Our aim was to investigate the miRNA profile and time course of selected miRNAs to characterize the miRNA network activated during recovery from AKI.

**Methods:** At 1, 3, 6, 15, 24 and 48 hours after sublethal (20 min) or lethal (30 min) renal ischemia (I/R) of C57BL/6 mice, renal function (urea, NGAL) and morphology (PAS stain) were assessed. MiRNA profile was evaluated at 24 hours post-ischemia (Luminex multiplex assay) and was further analyzed during reperfusion (real-time PCR). Renal cell proliferation was evaluated by CyclinD1 immunohisto on tissue microarray.

**Results:** Three miRNAs (miR-21, miR-17-5p, miR-106a) were significantly elevated 24 h after I/R (3.0, 1.5 and 1.4 fold, respectively, $p<0.05$). Real-time PCR demonstrated, that these miRNAs started to elevate after 24 hours of reperfusion further increasing at 48 hours (miR-21: 2.3 fold, $p<0.01$; miR-17: 2.2 fold, $p<0.01$; miR-106a, 1.9 fold, $p<0.01$). After sublethal I/R, renal miR-17-5p increased until the 3. day of reperfusion, while the miR-21 increase started later and lasted longer. Interestingly miR-17-5p and miR-21 correlated with each other over the course of recovery from I/R. This correlation was dependent on the severity of ischemia. Histology was pathologic already at 1, blood urea started to elevate at 3, renal NGAL mRNA at 6 and plasma NGAL at 15 hours. CyclinD1 nuclear staining decreased significantly after 1 hour (0.51 fold, $p<0.01$), but returned to control at 48 hours.

**Conclusions:** Our results demonstrated that besides miR-21, the miR-17/106 family is additionally activated during the maintenance and recovery phases of renal I/R. A correlation between these miRNAs warrant further investigations. Cyclin-D1 staining revealed recovery of renal tubular epitehlium. Thus, our results suggest that these miRNAs may be involved in the regeneration processes and could represent possible therapeutic tools in the treatment of I/R. Support: OTKA:K81972.

## TH-PO089

**Activation of Tim-3/Gal-9 Pathway Promotes the Proliferation of Foxp3$^+$ Treg in Mice with Renal Ischemia Reperfusion Injury** Yamei Wang, Yuhong Tao. *Dept of Pediatrics, West China Second Univ Hospital, Sichuan Univ, Chengdu, Sichuan Province, China.*

**Background:** Foxp3$^+$regulatory T cells (Treg) participate in the repair of renal ischemia reperfusion injury(IRI). Other studies have shown that galectin-9 (Gal-9), a beta galactoside binding mammalian lectin, binds to the regulatory molecule T cell immunoglobulin mucin-3 (Tim-3) on T cells and regulates immune responses by increasing Foxp3$^+$ Treg . This study is to investigate whether Tim-3/Gal-9 pathway promotes the proliferation of Foxp3$^+$Treg in mice with renal IRI for the first time.

**Methods:** The left renal pedicle was clamped in C57BL6 male mice for 45 min, followed by reperfusion. Expression of Gal-9 was detected by qRT-PCR, immunohistochemistry staining and Western blot. Tim-3 in kidney mononuclear cells (KMNCs) was determined using qRT-PCR and flow cytometry. The percentage of Foxp3$^+$Treg in CD4$^+$T cells and expression of Foxp3 mRNA were measured with flow cytometry and qRT-PCR, respectively. To explore the influence of Tim-3/Gal-9 pathway on the proliferation of Foxp3$^+$Treg and the protection from renal IRI, recombinant adeno-associated virus(RAAV) carrying Gal-9 was injected into mice two days before kidney IRI surgery in order to overexpress Gal-9 and activate Tim-3/Gal-9 pathway. Then, the percentage of Foxp3$^+$ Tregs, the expression of Foxp3 mRNA and cytokines were evaluated at day 3,10 and 21.

**Results:** The expression of Gal-9 and Tim-3 in the injured kidney at day3,10 and 21 increased significantly compared with that in injured kidney at day 1 or baseline. The percentage of Foxp3$^+$Treg in CD4$^+$T cells and Foxp3 mRNA was upregulated with time. Mice treated with RAAV carrying Gal-9 were significantly protected from renal IRI. Overexpression of Gal-9 decreased the levels of inflammatory cytokines (TNF-alpha and IFN-gamma) and increased the levels of cytokines (IL-10 and TGF-beta) in injured kidney . Furthermore, the proportion of Foxp3$^+$Treg cells and the level of Foxp3 mRNA in injured kidney were significantly higher than those in uninjured kidney or adenovirus group.

**Conclusions:** Tim-3/Gal-9 pathway involves the proliferation of Foxp3$^+$Treg in mice with renal IRI. Gal-9 becomes a potential novel immunotherapeutic target in renal IRI.

*Funding:* Government Support - Non-U.S.

## TH-PO090

**Thrombospondin-1 Mediates ECFC Recruitment after Renal Ischemia-Reperfusion Injury In Vivo** Simon Paul Parmentier,[1] Jan Sradnick,[1] Vladimir T. Todorov,[1] Bernd Hohenstein,[1] Christian Hugo.[1] *[1]Dept of Internal Medicine III, Div of Nephrology, Dresden, Germany; [2]Dept of Internal Medicine III, Div of Nephrology, Dresden, Germany; [3]Dept of Internal Medicine III, Div of Nephrology, Dresden, Germany; [4]Dept of Internal Medicine III, Div of Nephrology, Dresden, Germany; [5]Dept of Internal Medicine III, Div of Nephrology, Dresden, Germany.*

**Background:** Thrombospondin-1 (TSP-1) is an important mediator of renal I/R injury. Induced early on TSP-1 as an anti-angiogenic molecule might not only relate to tubular injury, but could also mediate indirect -progenitor cell driven- effects. Various studies suggest a role of mainly circulating EPC following I/R injury. The present survey investigated the role of TSP-1 in the recruitment of EPCs after I/R in the mouse kidney.

**Methods:** Unilateral I/R (25min) was induced in left kidneys (after right kidney nephrektomy) of 25 C57/Bl6 and 12 TSP-1 deficient mice. Five mice served as healthy controls. Tissues were harvested 4, 24 and 72 hours after I/R and processed for histology. CD34+/Flk-1+/CD133-/CD45-ECFC and CFU were measured using FACS analysis.

**Results:** I/R injury led to profound changes in renal morphology after 72h in TSP-1 deficient and Wt mice. PAS staining showed less tubular damage in TSP-1 deficient mice (by scoring, $p<0.01$). Compared to WT kidneys, ECFCs were significantly decreased in TSP-1 deficient mice after 24 and 72h (24h=$p<0.01$;72h=$p<0.01$), matching histological differences. Surprisingly, differences in renal ECFC numbers could be detected after 4 hours of I/R, which is before the occurrence of major histological changes (TSP-1 -/- vs wt $p<0.05$).

**Conclusions:** TSP-1 deficiency protects from I/R injury. Less This ECFC were recruited, either as consequence or cause of histological differences in TSP-1 -/- vs. WT mice. The early (4h) difference supports a direct link between TSP-1 and progenitor cell activation. Further studies should reveal the concise biochemical interactions.

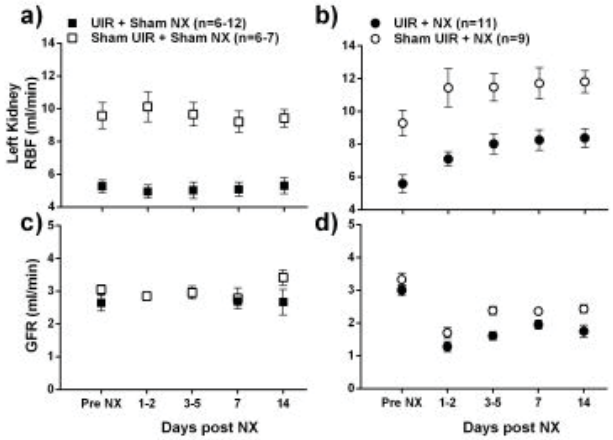
## TH-PO091

**The Hemodynamic Correlates of "Renal Counterbalance" Phenomenon in Conscious Rats** Aaron J. Polichnowski,[1] Hector Licea-Vargas,[2] Rongpei Lan,[3] Maria M. Picken,[2] Jianrui Long,[4] Geoffrey A. Williamson,[4] Karen A. Griffin,[1] Manjeri A. Venkatachalam,[3] Anil K. Bidani.[1] *[1]Medicine, Edward Hines Jr. VA Hospital and Loyola Univ Chicago, Hines, IL; [2]Medicine/Pathology, Loyola Univ Chicago, Maywood, IL; [3]Pathology, Univ of Texas Health Scie Ctr, San Antonio, TX; [4]Electrical and Computer Engineering, Illinois Institute of Technology, Chicago, IL.*

**Background:** In contrast to bilateral ischemia reperfusion (IR) injury, unilateral IR (UIR) results in progressive kidney fibrosis and atrophy. However, contralateral nephrectomy (NX) even 2 wks after UIR results in striking structural and functional recovery (*Circ Res*, 1980, 46:440) through poorly understood mechanisms.

**Methods:** Chronically instrumented male Sprague-Dawley rats (BP radiotransmitters, Transonic renal flow probes) underwent left RBF and 24 hr GFR measurements (FITC inulin, osmotic minipumps) at 2 weeks after 40 min of left UIR or Sham UIR. Both UIR and control rats underwent NX or sham NX at 15 days after UIR. After multiple RBF and GFR measurements, rats were sacrificed at 4 wks after UIR (2 wks after NX).

**Results:** Mean±SE. UIR was associated with a persistent reduction ($P<0.05$) in RBF (Fig 1a). NX increased RBF within 1-2 days in a pattern qualitatively similar to that in sham IR rats (Fig 1b). Although differences in total GFR were not seen in the absence of NX (Fig 1c), the pattern of recovery after NX was similar to RBF (Fig 1d).



Striking beneficial effects ($P<0.05$) of NX were also seen on left kidney weights after UIR (10.4±0.9 vs 4.7±0.3 g/kg without NX). Compensatory hypertrophy was also seen in sham UIR rats (5.7±0.2 vs 4.2±0.2 g/kg), but of lesser magnitude.

**Conclusions:** These data indicate that NX associated hemodynamic improvements occur early and likely play a role in subsequent structural recovery after UIR (*Am J Phys Renal*, 2012, 302:1210).

## TH-PO092

**Tissue Engineering of Microvessels to Perfuse Isolated Glomeruli In Vivo** William Gee Chang,[1] Alessia Fornoni,[2] Jordan S. Pober.[3] *[1]Medicine, Yale Univ, New Haven, CT; [2]Medicine, Univ of Miami, Miami, FL; [3]Immunobiology, Yale Univ, New Haven, CT.*

**Background:** More than 400,000 patients receive treatment for end stage renal disease in the United States. Kidney transplantation is the most effective therapy, but there are not enough donor organs to meet the rising demand. Tissue engineering of a kidney is a potential solution to this organ shortage. However, kidneys are more anatomically complicated than other tissues that have been produced by bioengineering because they contain structures such as glomeruli and tubules that are composed of distinct cell types with distinctive relationships within the vascular system.

**Methods:** Our laboratory has previously reported that human umbilical vein endothelial cells transduced with the anti-apoptotic protein Bcl-2 (designated Bcl-2-EC) can spontaneously organize into perfused microvessels within type I collagen/fibronectin gels when implanted in immunodeficient mice. As a first step in tissue engineering of renal microvasculature, we combined Bcl-2-ECs with microdissected intact whole rat glomeruli in type I collagen gels and implanted them within immunodeficient mice.

**Results:** We observed that rat glomeruli remained viable for up to two weeks, and maintained podocyte specific nephrin staining. Using GFP-expressing rat glomeruli and intravital rhodamine dextran injection, we saw that ~30% of glomeruli were perfused by microvessels derived from Bcl-2-ECs. However, in the absence of Bowman's capsule and tubular outflow, several glomeruli lost their glomerular capillary tuft morphology and became perfused capillary plexi. Transmission electron microscopy revealed endothelial swelling, loss of endothelial fenestrae, and podocyte foot process effacement after two weeks *in vivo*.

**Conclusions:** Anastomosis of capillaries derived from Bcl-2-ECs with isolated glomeruli provides proof of concept that self-assembled microvessels can perfuse specialized organ structures. We hypothesize that addition of tubular outflow would

ameliorate some of the morphological changes observed, and that the tissue engineered constructs described here could be further modified to engineer functional kidney tissue in the future.

## TH-PO093

**Development of the Kidney Peritubular Microvascular Niche *Ex Vivo***

Giovanni Ligresti,[1] Takahide Aburatani,[1] Sijie Sun,[2] Kimberly A. Muczynski,[1] Susan K. Anderson,[1] Jonathan Himmelfarb,[1] Jeremy Stuart Duffield,[1] Ying Zheng.[1] *[1]Dept of Medicine, Univ of Washington, Seattle; [2]Dept of Bioengineering, Univ of Washington, Seattle.*

**Background:** Dysfunction or loss of peritubular capillaries (PTCs) features chronic kidney disease and fibrosis where pericytes (PCs) dissociate from the endothelium and become scar-forming myofibroblasts, which promote the formation of scar tissue. Much remains unknown about the interactions between endothelial cells (ECs) and pericytes in normal and injured kidney, partially because kidney vasculature has complex architecture, flow dynamics and pleiotropic functional properties. Studies are also limited due to the lack of ex vivo models that recapitulate such a biological complexity, particularly in human kidney. In this study we overcome these challenges by engineering a microphysiological system (MPS) for the kidney peritubular microvascular niche ex vivo to study the interactions between Ecs and PCs under varying flow conditions.

**Methods:** We isolated kidney microvascular endothelial cells (KMECs) and pericytes from both mouse and human kidneys by flow cytometry, and seeded them in the engineered MPS.

**Results:** KMECs self-organize into a vascular network resembling kidney blood microvessels. Confocal microscopy shows a continuous endothelial monolayer with CD31 and VE-cadherin staining at cell contacts. Scanning EM reveals that KMECs have a flat cell shape with perforating fenestrations suggesting they preserve their normal function ex vivo. When kidney pericytes are added into the system they migrate to the microvasculature and participate in basement membrane matrix deposition on the abluminal side of the endothelium, whereas KMECs seeded alone into the MPS are unable to secrete basement membrane components. We also showed that the engineered kidney vascular bed is very sensitive to shear with highly aligned ECs and pericytes.

**Conclusions:** We have developed a microphysiological system that recapitulates the kidney perivascular niche ex vivo and allows for the study pericyte interaction wit kidney endothelium. The system should allow identification of key molecular mechanisms that can be exploited for therapeutic purposes in kidney fibrosis.

## TH-PO094

**A Bioinformatics Approach Identifies an Intricate Transcriptional Network Regulating the Uromodulin Gene**

Rajneesh Srivastava,[1] Radmila Micanovic,[2] Sarath Chandra Janga,[1] Tarek M. El-Achkar.[2] *[1]School of Informatics, IUPUI, Indianapolis; [2]School of Medicine, Indiana Univ and Indianapolis VA, Indianapolis.*

**Background:** Uromodulin is a glycoprotein uniquely produced by the kidney. Although its expression is thought to modulate renal homeostasis, the set of sequence specific transcription factors (TFs) which regulate the Uromodulin gene (UMOD) and their upstream binding locations are not well characterized. Our study aims to build a high resolution map of the transcriptional regulation of UMOD.

**Methods:** Phylogenetic foot-printing on the upstream regulatory regions of a diverse set of human UMOD orthologs was performed using MEME-SUITE. This allowed the identification of 10 high confidence conserved binding motifs (BMo) and the corresponding position specific weight matrices. We further analyzed the predicted BMo by TOMTOM, which identified TFs likely to bind these discovered motifs. Predicted TFs were then integrated with existing protein-protein interaction databases like Biogrid and tissue-specific protein expression resources to delineate the important regulators controlling the expression of UMOD.

**Results:** Based on the reliable set of BMo in the upstream regulatory regions of UMOD (Fig. 1a) , we build a high confidence list of transcription factors that could potentially bind to these discovered motifs such as GATA3, HNF 1, SP1, SMAD3, RUNX2 and KLF4. Construction of a manually curated protein interaction network between the predicted TFs controlling UMOD regulatory region in human revealed several highly connected TFs such as SP1 and SMAD3 and the likely protein complexes formed between them (Fig. 1b). The significant expression of these in Kidney cells compared to other tissues suggests a central role in controlling UMOD expression (Fig. 1c).

**Conclusions:** Our findings will form a roadmap for understanding the regulation of Uromodulin expression in health and disease.

## TH-PO095

**The Shape of the Curve of Protein Concentration as a Function of Distance across the Glomerular Basement Membrane: Analysis and Implications for Fundamental Mechanisms**

Douglas L. Somers.[1,2] *[1]Univ of Iowa, Iowa City, IA; [2]Iowa City VA, Iowa City, IA.*

**Background:** Fujigake et al (KI 1993) measured protein distribution across the Glomerular Basement Membrane (GBM) using immuno-gold labeling of in-situ fixed glomeruli. Transferrin concentration declines steeply from endothelial to epithelial interfaces, whereas albumin concentration increases to a peak (albumin peak anomaly) partway through the GBM, then declines steeply to low concentrations at the epithelial interface. These results also demonstrate the podocyte paradox -podocytes are important to prevent proteinuria, but proteins never get to the podocyte. No model of GBM protein transport has yet explained the variation between different proteins, the steepness of protein concentration decline, the podocyte paradox, nor the albumin peak anomaly.

**Methods:** Protein concentrations are calculated from probability distribution functions. Assumptions include: i. Endothelial glycocalyx (EG) is the initial barrier to protein translocation, providing an energy trap for some proteins (i.e. albumin), but not others (i.e. transferrin), ii. Proteins escape from EG to GBM with a thermal energy distribution, but those proteins with binding to EG are emitted with less energy, and iii, proteins emitted from the EG travel a certain distance (depending on emission energy) into GBM under constant epithelial-towards-endothelial acceleration, so turning around and returning to the EG.

**Results:** This model reproduces the variation between different proteins, the albumin peak anomaly, and the sharp decline in concentration toward the epithelial interface. Protein deceleration in the GBM represents a decrease in protein momentum. There are few realistic physical mechanisms available to change protein momentum; momentum transfer from a different molecular species emitted from the podocyte provides a force and resolves the podocyte paradox.

**Conclusions:** The results of Fujigake et al suggest: i. Endothelial glycocalyx is the initial protein barrier in the glomerular capillary wall for some, though not all, proteins, ii. The glomerulus appears to be a diffusion pump.

## TH-PO096

**Clearance and Hemocompatibility Assessment of a Parallel Plate Mini-Scale Dialyzer Based on Silicon Nanopore Membranes**

Steven Kim,[1,2] Zohora Iqbal,[2] James A. Heller,[2] Eun Jung Kim,[2] Rishi Kant,[2] William Fissell,[3] Shuvo Roy.[2] *[1]Nephrology, UCSF; [2]Bioengineering, UCSF; [3]Nephrology, Vanderbilt Univ.*

**Background:** Silicon nanopore membranes (SNM) have previously shown a remarkable capacity for hemofiltration. Their compact geometry and uniform pore size distribution offer potential advantages over polymer hollow fiber membranes. To assess these advantages for hemodialysis, we designed a prototype parallel plate mini-scale dialyzer and evaluated its clearance and hemocompatibility.

**Methods:** Computational fluid dynamics was used to refine a parallel-plate design (4.2*w* x 7.6*l* x 1*h cm*) for enhanced blood flow and minimal pressure drop, and subsequently machined from titanium. Polyethylene glycol (PEG)-coated SNM with 4.4 nm pores and effective surface area of 3.46cm$^2$ were assembled in a parallel-plate arrangement. Artificial serum (PBS with Cr: 9mg/dL, BUN: 88mg/dL, alb: 3g/dL) or heparinzed porcine blood was

recirculated (40ml), while dialysate (140mEq NaCl) was recirculated in a counter-current fashion (40ml). Dialysis was performed with zero transmembrane pressure at $Q_d \sim Q_b \sim 30$ml/min. Solute clearance (K) was calculated by fitting concentrations measured hourly for 4hr (n=3) to an exponential decay function: $C(t)=C_i e^{-Kt/V}$. C(t): concentration at time $t$ ,$C_i$: initial concentration, t: time, V: volume. Platelet adhesion and activation on SNM were evaluated by immunohistochemistry (IHC) after flowing heparinized porcine blood (<1hr post-collection) for 4 hours at 5ml/min.

**Results:** The mini-dialyzer was tested without complications for a total of ~24 hours and exhibited ~4 mmHg pressure drop. Creatinine and urea clearances were calculated to be 49.4±1.9, 73.0±2.2 ml/min/m$^2$ (artificial serum) and 38.6±0.7, 67.2±1.5 ml/min/m$^2$ (blood), respectively. There was no significant change in albumin. Diffusion of solutes into dialysate was confirmed. Single-pass changes were below the level of detection. IHC showed a qualitative reduction in platelet activation on PEG-coated SNM and no thrombi were visualized after 4 hours.

**Conclusions:** These preliminary results confirm that SNM exhibit clearance consistent with mathematical models, while PEG coatings offer a hemocompatible interface for blood flow.

## TH-PO097

**Multi-Detector Computed Tomography to Identify Device Defects and Failure Modes in an Implantable Silicon Hemofilter** Steven Kim,[1,2] Olufoladare G. Olorunsola,[3] Charvi Shetty,[3] James A. Heller,[2] Zohora Iqbal,[2] Rishi Kant,[2] Steven Hetts,[3] Maythem Saeed,[3] William Fissell,[4] Youngho Seo,[3] Mark Wilson,[3] Shuvo Roy.[2] *[1]Nephrology, UCSF; [2]Bioengineering, UCSF; [3]Radiology, UCSF; [4]Nephrology, Vanderbilt.*

**Background:** New innovations in membrane technology using microelectromechanical systems techniques have led to the development of a silicon nanopore membrane (SNM) based hemofilter for use in an implantable bioartificial kidney. Such a device will require non-invasive imaging methods to monitor device functionality, identify potential problems, and detect failure modes. This study aims to address these challenges by developing imaging techniques to non-invasively visualize a hemofilter prototype.

**Methods:** The hemofilter was constructed with a parallel plate design (3.8*w* x 1.8*h* x 8*l* cm). A titanium plate measuring 3.8*w* x 0.3*h* x 6.5*l* with a blood path height of 2.4mm was mounted with SNM. A bottom plate without SNM served as an internal control. The non-blood-contacting plates were constructed from aluminum. A peristaltic pump infused iodinated contrast through the blood paths (1-20ml/min) and deionized water through the filtrate path (h=0.2mm). Serial imaging was performed using multi-detector computed tomography (MDCT) before and during contrast infusion. Images (140kVP & 250mA) were acquired in a plane parallel to the direction of flow and reformatted in orthogonal planes.

**Results:** Several potential device-related malfunctions were correctly identified using MDCT. Qualitative assessment of contrast in the blood path showed areas of inhomogeneous flow. Trapped loculated gas was easily visible and allowed for localization and tracking without disassembly. Microscopic leaks were detectable, manifesting as active extravasation of contrast from the device. Finally, membrane fracture leading to device failure was also confirmed using MDCT.

**Conclusions:** Despite the challenges of imaging a predominately metallic object, we were able to non-invasively image flow and identify device defects within a hemofilter prototype. The imaging method allows for internal evaluation of the device without requiring disassembly, which will be invaluable in future studies for the development of the bioartificial kidney.

## TH-PO098

**Therapeutic Plasma Exchange Using High Cut-Off Membrane Plasma Separator** Atsushi Ohkubo,[1] Naoki Kurashima,[1] Ayako Nakamura,[1] Satoko Miyamoto,[1] Hiroshi Seshima,[1] Soichiro Iimori,[2] Naofumi Yui,[2] Tatemitsu Rai.[2] *[1]Dept of Clinical Engineering, Tokyo Medical and Dental Univ, Japan; [2]Dept of Nephrology, Tokyo Medical and Dental Univ, Japan.*

**Background:** Therapeutic plasma exchange (PE) using albumin solution as replacement fluid is a treatment of choice for acute exacerbation of inflammatory demyelinating disorders of the central nervous system (CNS-IDDs). Though it is important to remove IgG for treatment, coagulation factors are also potentially removed by this modality. Recently, a newly designed high cut-off membrane plasma separator with smaller pore size have become available. The purpose of this study is to evaluate the efficacy of high cut-off membrane plasma separator by investigating the removal rate of IgG and coagulation factors during treatment by PE with albumin solution replacement.

**Methods:** A retrospective analysis of patients treated with PE with albumin solution replacement between May 2011 and April 2013 in our hospital was performed. They were either treated with the high cut-off membrane plasma separator (high cut-off group) or the conventional type of membrane separator (control group). Seven and nineteen patients were assigned to the high cut-off and control groups, respectively. The removal rates of IgG and coagulation factors were compared during the PE procedures. Data were expressed as group means ± standard deviations and a *p* value under 0.05 was considered statistically significant.

**Results:** The amount of plasma replaced was significantly larger in the high cut-off group compared with that in the control group (1.21 ± 0.01 vs 0.87 ± 0.09 plasma volume, respectively). The removal rates of IgG showed no significant differences between the two groups (high cut-off group 55.9 ± 5.6 % vs control group 65.0 ± 4.7 %). The removal rate of Fib was significantly lower in the high cut-off group (high cut-off group 19.2 ± 8.0 % vs control group 62.8 ± 10.9 %).

**Conclusions:** High cut-off membrane plasma separator with smaller pore size is equally effective in removal of IgG while retaining coagulation factors compared to the conventional type of membrane separator in the treatment of CNS-IDDs by PE with albumin solution replacement.

## TH-PO099

**Protein Bound Toxin Removal by Increased Ionic Strength Hemodiafiltration** Eric Devine,[1] Horst-Dieter Lemke,[1] Joachim Jankowski,[2] Christoph Wanner,[3] Detlef H. Krieter.[3] *[1]eXcorLab GmbH, Obernburg; [2]Dep. of Medicine IV (CBF), Charité-Universitätsmedizin, Berlin; [3]Nephrology, Univ Hospital, Würzburg, Germany.*

**Background:** Protein bound uremic toxins (PBT) are poorly removed by dialysis. Aim was to develop a strategy based on ionic strength modification in plasma to enhance PBT removal.

**Methods:** In *ex vivo* pre-dilution hemodiafiltration (pre-HDF) using freshly donated human blood and substitution fluid differing in NaCl content, the hemocompatibility of 0.15, 0.36, and 0.50 M NaCl concentration in blood ($[NaCl]_{blood}$) was assessed during 120 min. Two different setups of two serial dialyzers (PUREMA®) in pre-HDF also were tested: i) standard infusion and increased [NaCl] in dialysate of the 1st filter (pre-SDial); ii) transmembrane infusion through the 1st dialyzer of substitution fluid increased in [NaCl] (TM-SDial). The removal rate (*RR*) of indoxyl sulfate (IS) was assessed with the same setups over 30 min in conditioned (100 µM IS) human plasma (n=3) at 0.15 and 0.50 M [NaCl]. Animal hemocompatibility experiments were performed in 4 sheep applying pre-HDF (0.36 and 0.45 M $[NaCl]_{blood}$) and TM-Sdial (0.36 and 0.60 M $[NaCl]_{blood}$) randomized and crossover during 90 min after a 30 min baseline period at physiologic $[NaCl]_{blood}$.

**Results:** Not till $[NaCl]_{blood}$ was 0.50 M, significant hemolysis (free Hb 17.6±7.2 and 2.1±1.6 %; P<0.05) and a decrease of the white blood cell count (WBC; 57.7±20.4 and 52.3±12.8 %; P<0.05) were noted at 120 min with both pre-HDF and pre-SDial, resp. Less cell damage was seen with TM-SDial. Red blood cell (RBC) and platelet (PLT) counts, complement C5a and thrombin-antithrombin III concentrations were always unchanged. Independently of the setup, the *RR* of IS was significantly higher at 0.50 M vs. 0.15 M [NaCl] (18±1 vs. 13±1 %/run; P<0.001). In sheep, free Hb and LDH concentrations at 120 min were increased only with pre-HDF at 0.36 M and TM-SDial at 0.60 M $[NaCl]_{blood}$ compared to baseline (range 0.12-0.14 vs. 0.18-0.22 % and 449-462 vs. 490-506 U/L, resp.; P<0.05). RBC, WBC, PLT and blood pressure were constant. No adverse events were observed.

**Conclusions:** Ionic strength HDF enhances the removal of PBT and can be safely applied at the conditions studied.

## TH-PO100

**Toxicity of Bisphenol A in Hemodialysis: *In Vitro* Study** Mauro Neri, Jeong Chul Kim, Grazia Maria Virzì, Alessandra Brocca, Francesco Garzotto, Claudio Ronco. *Nephrology Dep-IRRIV, Vicenza, Italy.*

**Background:** Bisphenol A (BPA) is an environmental hormones or endocrine disrupting molecular compound. It is used in the production of polycarbonate (PC) housing (hous.) and polysulfone (PS) membranes of many hollow-fiber hemodialyzers.

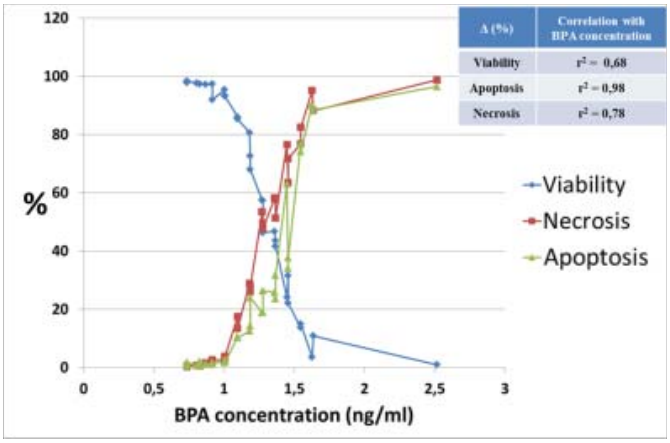
In our *in vitro* study we compared the BPA elution from 3 hemodialyzers and the BPA cytotoxic effect on a monocyte cell line.

**Methods:** We considered these dialyzers: Nipro Elisio 17H (Polypropylene hous., Polynephron membranes), B-Braun Diacap (PC hous., PS membranes), Nipro Elisio 170H (PC hous., Polynephron membranes). We circulated 600ml of cell culture media for 4 hours through dialysis circuit. For each dialyzer, we measured the eluted BPA mass through ELISA kit. By cytometer we evaluated the effect of BPA between viability, necrosis and apoptosis of monocytes incubated for 24 hours in samples taken before and after the treatment. We measured the correlation between BPA concentration and its toxicity on cells.

**Results:** The results are summarized as follow (Median (IQR))

| Dialyzer | BPA eluted (ng/treatment) | Δ% Viability | Δ% Necrosis | Δ% Apoptosis |
|---|---|---|---|---|
| Elisio 17H | 83.2 (42.9,123.4) | -0.93 (-0.95,-0.90) | 0.72 (0.33,1.11) | 0.61 (0.53,0.69) |
| Diacap | 255.4 (255.3,255.5) | -12.83 (-13.30,-12.36) | 2.52 (2.49,2.56) | 2.34 (2.27,2.41) |
| Elisio 170H | 230.1 (228.3,232.0) | -12.37 (-13.2,-11.56) | 2.33 (2.26,2.40) | 2.45 (2.43,2.48) |

Elisio 17H released less BPA than the other dialyzers: the viability of the monocytes is higher, necrosis and apoptosis are lower. The BPA citotoxicity is evident in the correlation curve with viability, necrosis and apoptosis:



**Conclusions:** Viability, necrosis and apoptosis of monocytes are influenced by BPA concentration. Use of alternative polymers for dialyzer's components may reduce BPA elution during dialysis. However, more experiments are needed to confirm these results.

### Monitoring Intravascular (Vb), Interstitial (Vi), and Intracellular (Vc) Volume Changes during Hemodialysis (HD) in Patients (pts) with End-Stage Renal Disease (ESRD) in Chronic Out-Patient (CU) and Acute In-Patient (AU) Unit Settings

Susie Q. Lew,[1] Manuel T. Velasquez,[1] Julian M. Stewart,[2] Leslie Montgomery,[3] Wayne A. Gerth,[3] Richard W. Montgomery.[3] *[1]Medicine, George Washington Univ, Washington, DC; [2]Medicine, New York Medical College, Valhalla, NY; [3]LDM Associates, San Jose, CA.*

**Background:** A multi-frequency electrical impedance spectroscopic (EIS) technique was developed that enables non-invasive measurement of compartmental volume (CV) changes. The aims: 1) to evaluate the feasibility & precision of EIS to quantify acute changes in Vb, Vi, & Vc during HD, & 2) to assess differences in CV changes in relation to the total amount of fluid removed (Vt) in CU & AU.

**Methods:** Using EIS, we evaluated changes in Vb, Vi, & Vc in ESRD pts in CU & AU. Each HD was completed according to the nephrologist's prescription. Volume changes were obtained by analysis of electrical impedance spectra taken on the left calf of each pt at approximate 1-min intervals throughout each HD by a quadrapolar EIS device as previously described. (Montgomery, et al:, *Med. Biol. Eng. Comput* 3 April 2013).

**Results:** Table 1 shows the mean volumes of fluid removed during HD from Vb, Vi, Vc, & Vt in CU & AU. Table 2 shows the mean pre & post HD CVs & the associated % distributions in CU & AU. A negative value indicates a gain in volume.

| Table 1 | | | | | | | |
|---|---|---|---|---|---|---|---|
| Vb (%) | Vc (%) | Vi (%) | Vt (%) | Vb (mL) | Vc (mL) | Vi (mL) | Vt (mL) |
| CU (n=53) | | | | | | | |
| 12 +/-8 | -11 +/-12 | 30 +/-13 | 9 +/-5 | 96 +/-65 | -44 +/-52 | 81 +/-44 | 133 +/-70 |
| AU (n=22) | | | | | | | |
| -21 +/-73 | -6 +/-13 | 15 +/-20 | 1 +/-4 | -4 +/-58 | -51 +/-81 | 72 +/-81 | 16 +/-46 |
| Table 2 | CU | | | AU | | | |
| | Vb | Vc | Vi | Vb | Vc | Vi | |
| mL pre | 717 | 407 | 270 | 379 | 654 | 425 | |
| | 51% | 29% | 19% | 26% | 45% | 29% | |
| mL post | 621 | 451 | 189 | 383 | 705 | 353 | |
| | 49% | 36% | 15% | 27% | 49% | 25% | |

**Conclusions:** Summary: 1-The patterns of CV changes differed between CU & AU. 2-AU pts retained a larger % of total fluid in the Vi & Vc compartments. 3-Vc increased during HD in pts at both centers. The EIS technique was able to track acute fluid volume changes in the 3 principal fluid compartments of ESRD pts' calves during HD. Results indicate that Vc in the monitored calves tended to increase during HD at both centers as overall calf volumes were being reduced.

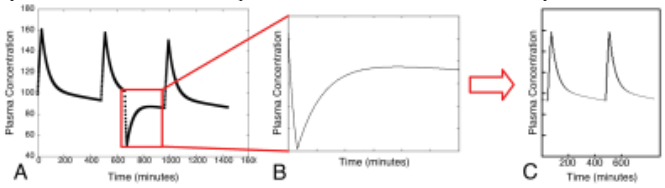
### Use of the Hemodialysis Procedure to Measure Individual Pharmacokinetics

Rueben Banalagay,[1] Don Mitchell Wilkes,[1] William Fissell.[2] *[1]Electrical Engineering, Vanderbilt Univ, Nashville, TN; [2]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN.*

**Background:** Hemodialysis is an underappreciated opportunity to assess individual pharmacokinetics. As dialysis is started and stopped, drug clearance suddenly changes, disturbing drug equilibration between pharmacokinetic compartments. Individual response to this perturbation reveals individual pharmacokinetics. Here, we utilize linear systems theory to create individualized pharmacokinetic models from intradialytic data.

**Methods:** A simple two compartment pharmacokinetic model was simulated, incorporating a patient receiving regular drug doses and one dialysis session. Equally timed samples of the plasma concentration and dialysate during the transient response of the dialysis perturbation were extracted from the dataset. The samples were used to estimate a linear systems model of the patient. The model was then excited with a signal representing the original dosing schedule of the patient. The resulting output signal was compared with the original dataset to assess prediction accuracy. In addition, the effect of decreasing the sample size and adding varying levels of white Gaussian noise were studied to evaluate the robustness of our approach.

**Results:** In ideal cases of large sample sizes with little noise, the produced linear systems model was shown to reproduce the simulated data almost exactly.



In simulations of more real-world scenarios, robust estimates in the presence of noise were still achievable with as few as 10 samples.

**Conclusions:** Our simulations suggest that the dialysis procedure can be used to create individualized pharmacokinetic models of the patient. By reformulating the effect of dialysis in the language of linear systems, one could easily characterize a particular patient's pharmacokinetics and make reasonable predictions of the patient's drug levels over time.

## TH-PO103

### Ion Exchange Resin and Conductivity Measure Approach for Sodium Concentration Measurement during Dialysis (HD): In Vitro Experiments

Emanuele Mambelli,[1] Andrea Tura,[2] Stefano Sbrignadello,[2] Giovanni Pacini,[2] Antonio Santoro.[1] *[1]Nephrology Dialysis and Hypertension Unit, Policlinico S. Orsola-Malpighi, Italy; [2]Institute of Biomedical Engineering, National Research Council, Padova, Italy.*

**Background:** The measurement of sodium concentration is important to preserve the HD patient from possible events of hypo- or hyper-natremia during the dialysis session. Usually, the sodium measurement is performed by direct or indirect potentiometry, or by flame photometry, through laboratory equipment which is typically expensive, and also requires intervention of the clinical personnel to perform the measurement. Thus, continuous and automatic sodium measurement during dialysis is not possible with that approach. We propose a new method, where the conductivity measurement occurs after treatment of the ultrafiltrate through a ion-exchange resin.

**Methods:** We performed some in vitro experiments. We prepared 40 ml sodium chloride (NaCl) samples at 280, 140, 70, 35, 17.5 mEq/l, and some "mixed samples", i.e., with added potassium chloride (KCl) at different concentrations (4.375-17.5 mEq/l), to simulate the confounding factors in a conductivity-based sodium measurement. We measured the conductivity of all samples. Afterwards, each sample was treated for 1 min with 1g of DOWEX G-26 cation exchange resin, and conductivity was measured again (figure1).

| NaCl → KCl ↓ | 280 | 140 | 70 | 35 | 17.5 |
|---|---|---|---|---|---|
| | | | Pre-treatment | | |
| 17.5 | $\varepsilon_{pre}$ = 17.28 | - | - | - | - |
| 8.75 | $\varepsilon_{pre}$ = 15.27 | $\varepsilon_{pre}$ = 19.93 | $\varepsilon_{pre}$ = 31.53 | - | - |
| 4.375 | $\varepsilon_{pre}$ = 12.78 | $\varepsilon_{pre}$ = 13.09 | $\varepsilon_{pre}$ = 20.54 | $\varepsilon_{pre}$ = 24.09 | $\varepsilon_{pre}$ = 33.13 |
| | | | Post-treatment | | |
| 17.5 | $\varepsilon_{pre-post}$ = 6.35 | - | - | - | - |
| 8.75 | $\varepsilon_{pre-post}$ = 7.45 | $\varepsilon_{pre-post}$ = 7.07 | $\varepsilon_{pre-post}$ = 12.83 | - | - |
| 4.375 | $\varepsilon_{pre-post}$ = 2.94 | $\varepsilon_{pre-post}$ = 0.41 | $\varepsilon_{pre-post}$ = 17.13 | $\varepsilon_{pre-post}$ = 23.07 | $\varepsilon_{pre-post}$ = 11.71 |

**Table 1**. Concentration (mEq/l) of mixed samples (NaCl+KCl), and corresponding difference ε in the conductivity (%) compared to the samples with NaCl alone at the same concentration, without resin treatment, and with resin treatment (pre-post resin conductivity difference).

**Results:** On average, the difference in the conductivity between mixed samples, and corresponding pure NaCl samples (at the same NaCl concentration) was 20.9%. After treatment with the exchange resin, when considering the pre-post resin variation in conductivity, the difference between mixed samples, and corresponding pure NaCl samples was 9.9% only.

**Conclusions:** Ion-exchange resin treatment coupled with conductivity measures can be a possible simple approach for continuous and automatic measures of sodium during dialysis session.

## TH-PO104

### A Machine-Based Method to Anticipate Intradialytic Morbid Events

Camille Linick Stewart,[1,3] Jane Mulligan,[2] Greg Grudic,[2] Michael Bronsert,[1] Mark Talley,[1] Steven L. Moulton.[1,2,3] *[1]Surgery, Univ of Colorado School of Medicine, Aurora, CO; [2]Flashback Technologies, Boulder, CO; [3]Surgery, Children's Hospital Colorado, Aurora, CO.*

**Background:** Intradialytic morbid events (IME) due to ultrafiltration-induced hypovolemia are commonplace during hemodialysis (HD). The compensatory reserve index (CRI) is a novel mathematical algorithm originally developed for noninvasive monitoring of blood loss on the battlefield. CRI continuously monitors pulse oximetry waveform features and in real-time interprets how these features change with central volume loss,

from normovolemia (CRI=1) to decompensation (CRI=0). We hypothesized that changes in CRI would anticipate future IME in chronic end-stage renal disease (ESRD) patients undergoing HD.

**Methods:** Demographic, clinical information and continuous measurements of CRI, blood pressure (BP) and heart rate (HR) were collected from chronic ESRD patients during HD. IME were defined as a decrease in systolic BP or symptom (e.g. cramps, dizziness) triggering intervention. Univariate and multivariate logistic regression generalized estimating equation models were designed to evaluate correlation with future IME.

**Results:** 85 ESRD patients had CRI and HR recorded during HD; 56 also had continuous BP recorded. There were 44 IME among 33/85 (38%) patients. There were no differences in age, gender, race, weight gain, duration of treatment, volume of ultrafiltrate removed, heart disease or diabetes status among patients who sustained an IME versus those who were event-free ($p>0.05$). In multivariate analysis, a 0.15 decrease in CRI over a 15-minute interval was independently associated with an IME in the upcoming 15 minutes (4.076, 95% CI 1.748-9.508, $p=0.003$), whereas 10-point changes in HR and BP were not ($p>0.05$). Patients with this type of change in CRI were 4 times more likely to experience an IME.

**Conclusions:** Decreasing CRI is associated with future IME. Demographic, clinical and traditional vital sign parameters did not correlate with IME. CRI is a novel, noninvasive parameter that is able to anticipate and may help to prevent intradialytic morbid events in chronic ESRD patients who undergo HD.

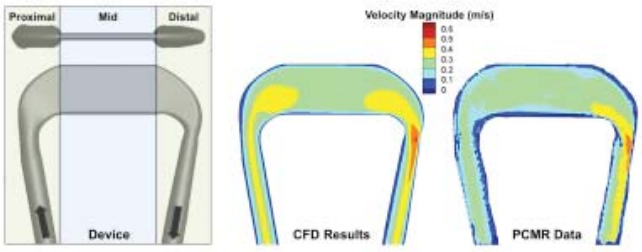
## TH-PO105

**Simulation and Validation of Flow in a Hemofilter Device** Amanda Buck,[1] Daniel Colvin,[1] Mark S. Goodin,[2] Joseph J. Groszek,[1] Shuvo Roy,[3] William Fissell.[1] *[1]Vanderbilt Univ; [2]SimuTech Group; [3]Univ of California, San Francisco.*

**Background:** When designing biomedical devices for use in vasculature, it is vital that flow through the device not initiate or exacerbate blood clotting, which may lead to device failure. Computational fluid dynamics (CFD) simulations can predict pathophysiologically relevant variables; however, they require assumptions related to flow conditions. *In vitro* studies require fewer assumptions and can be used to validate CFD results. The purpose of this study was to compare MR-measured and CFD-simulated flow fields in a hemofilter device.

**Methods:** Steady flow in the device was measured using phase contrast MR (PCMR). The PCMR data were acquired using a 9.4 T Varian scanner. Citrated bovine blood was circulated through the device at 100 ml/min using a peristaltic pump (Cole Parmer) with offset pump heads to mitigate pulsatility. CFD simulations were conducted using CFX (Ansys, Inc.) at conditions matching the *in vitro* flow experiment.

**Results:** Velocity maps demonstrate excellent agreement between measured and simulated flow fields in the mid and distal portions of the device.



The CFD- (0.51 m/s) and PCMR-determined (0.56 m/s) peak velocities in the distal constriction differed by 9%; however, calculated velocities were higher in the proximal region. At the inlet, the CFD results show fully developed flow while PCMR data show a flatter velocity profile. This may reflect slight variations in flow due to the pulsatile nature of the pump. The similarity of the distal flow fields suggests the channel region in the middle of the device may mitigate the effect of inlet flow profile on the distal portion of the hemofilter.

**Conclusions:** These results demonstrate good agreement between measured and simulated velocity fields and suggest that these complementary approaches can yield information valuable for device design.

## TH-PO106

**A Longitudinal Study on the Hemodynamic and Lumen Changes in Human Arteriovenous Fistulas** Christi M. Terry,[1] Michelle Fitts,[1] Daniel B. Pike,[1] Yan-Ting E. Shiu,[1] Yong He,[2] Scott A. Berceli,[2] Alfred K. Cheung.[3,1] *[1]UofU, SLC, UT; [2]U of FL, Gainesville, FL; [3]VASLHCS, SLC, UT.*

**Background:** Arteriovenous fistulas (AVF) often fail to mature, likely partly due to aberrant wall shear stress (WSS). We have developed and begun to use an MRI-to-computational fluid dynamics (CFD) pipeline for in-depth serial assessment of AVF hemodynamics and lumen geometry in an on-going NIDDK-sponsored multicenter study.

**Methods:** At 1-3 days, 6 wks, and 6 mos post-AVF creation, non-contrast black-blood and cine phase-contrast MR images were acquired and used for reconstructing AVF lumen geometry and measuring artery inlet and vein outlet blood flow, in 3 patients. Using these data, WSS throughout a long segment of the AVF was simulated by CFD in 1 patient. Early WSS was co-registered with later vein lumen cross-sectional areas at 1-mm intervals using the anastomosis as an anatomical landmark.

**Results:** Table 1 shows the longitudinal changes in lumen area and flow for the inflow artery and outflow vein are shown. Venous blood flow rapidly increased after AVF creation, but decreased by 6 mos (§$p<0.05$), whereas arterial inflow rapidly increased and remained increased (*$p<0.05$). Inflow artery lumen areas decreased at 6 wks and 6 mos compared to 1-3 d (†$p<0.05$), whereas outflow vein lumen areas increased over time (‡$p<0.05$). WSS was assessed in 1 patient: Vein lumen area at 6 wks correlated with 1-3 d vein WSS ($r=-0.49$, $p<0.05$), with higher WSS (>30dyn/cm$^2$) correlating with decreased lumen areas.

| Table 1. | Flow (ml/min) | | | | Avg total vessel area (mm$^2$) | | |
|---|---|---|---|---|---|---|---|
| | baseline | 1-3 d | 6 wks | 6 mos | 1-3 d | 6 wks | 6 mos |
| inflow artery | ~75 | 724 ± 385.7 | 933.0 ± 274.9* | 1001.8 ± 194.3* | 25.1 ± 5.4 | 23.6 ± 8.0† | 19.5 ± 5.0† |
| outflow vein | ~5 | 425.5 ± 67.0 | 392.4 ± 201.0 | 341.1 ± 122.6§ | 22.7 ± 13.0 | 44.0 ± 17.1 | 59.2 ± 40.7‡ |

**Conclusions:** The pipeline is a robust tool and provides a means to evaluate the impact of WSS on AVF maturation. Correlational analyses of WSS and other hemodynamic profiles with lumen area changes, in a large number of patients from our multi-center study, should provide novel insight into factors that contribute to AVF failure and success.

*Funding:* Other NIH Support - NIDDK

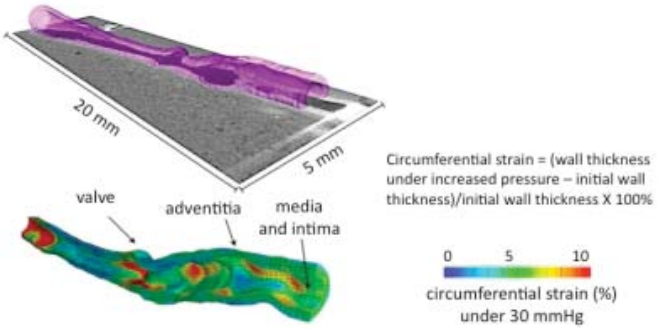
## TH-PO107

**A Novel Method for High-Resolution Characterization of Vein Deformation under Arterial Blood Pressure** Yan-Ting E. Shiu,[1] Arnold David Gomez,[1] Huan Li,[1] Ilya S. Zhuplatov,[1] Alfred K. Cheung,[1,2] Edward Hsu.[1] *[1]U of Utah, SLC, UT; [2]VASLCHCS, SLC, UT.*

**Background:** Hemodialysis arteriovenous grafts often fail due to neointimal hyperplasia (NH) at the venous anastomosis (VA). Analogous to the known association between abnormal wall deformation and NH in artery, aberrant venous wall deformation at the VA induced by increased hydrostatic blood pressure may play a role in the focal nature of NH formation, but a clear correlation has not yet been demonstrated. We have developed a new method to characterize venous wall deformation, laying the foundation to investigate this correlation.

**Methods:** Techniques for characterizing arterial wall deformation are seldom useful to measure changes in the thickness of thin venous wall, which are often ≤ 100 μm - below the resolution of conventional MRI or ultrasound. Our method uses micro-computed tomography (μCT) and deformable image registration to measure strain. A μCT-compatible device was built to image a freshly explanted porcine vein under hydrostatic pressure (0-160 mmHg). An iodine-based staining protocol was optimized to provide soft-tissue contrast for visualization while preserving the tissue's morphological structure. μCT images (17 μm resolution) were segmented to reconstruct the vein (**Fig. 1**, top), which was used to calculate the strain.

**Results:** Best contrast and negligible tissue shrinkage of the vein was obtained using 10% Lugol solution and a 3-hour soaking. The strain map (**Fig. 1**, bottom) shows highly heterogeneous strain values in the vein, in addition to complex anatomical features such as non-uniform wall thickness and a valve.



**Conclusions:** We have developed a robust method to assess the strain of thin vein under hydrostatic pressure. Serial analyses using this method should illuminate the relationship between early wall deformation and subsequent focal NH formation and have implications in the design of anti-NH strategies for vascular accesses.

*Funding:* NIDDK Support

## TH-PO108

**Correlation between Wall Shear Stress and Subsequent Lumen Area Change at Venous Anastomosis Is Different from That at Arterial Anastomosis** Yan-Ting E. Shiu,[1] Daniel B. Pike,[1] Christi M. Terry,[1] Yong He,[2] Huan Li,[1] Ilya S. Zhuplatov,[1] Alfred K. Cheung.[3,1] *[1]UofU, SLC, UT; [2]U of FL, Gainesville, FL; [3]VASLHCS, SLC, UT.*

**Background:** Neointimal hyperplasia (NH) occurs much more commonly at the venous anastomosis (VA) than at the arterial anastomosis (AA) of arteriovenous grafts (AVG). Aberrant wall shear stress (WSS) may play a role in increased susceptibility of the vein to NH formation. We examined this hypothesis by comparing the WSS and subsequent lumen area between the venous and arterial anastomoses in a swine model of AVG stenosis.

**Methods:** AVG were implanted between the common carotid artery and external jugular vein in swine. At 1, 2, 3, or 6 wk (n=5 at each wk) after graft implantation, contrast-free black-blood and cine phase-contrast magnetic resonance images were acquired and used

to assess the lumen geometry and blood inflow and outflow rates. These parameters were then used for computational fluid dynamics simulations. WSS magnitudes and lumen area changes were calculated for 4 cm lengths of arterial and venous segments, upstream and downstream from their respective anastomoses.

**Results:** Although WSS at wk 3 was higher in the artery than in the vein (116 ± 57 vs. 36 ± 21 dyne/cm$^2$; p<0.05), subsequent lumen area changes from wk 3 to wk 6 were larger in the vein than in the artery (44 ± 35 vs. 12 ± 4 mm$^2$; p<0.05). No linear correlation was found in the artery between WSS at wk 3 and lumen area changes from wk 3 to wk 6 (r=0.12; p=0.50). In contrast, a biphasic correlation was found in the vein: when WSS was low (<20 dyne/cm$^2$) at wk 3, lumen area increased from wk 3 to wk 6 (r=0.98; p<0.05); when WSS was high (>40 dyne/cm$^2$) at wk 3, lumen area decreased from wk 3 to wk 6 (r=-0.93; p<0.05); no correlation was found where WSS was in the 20-40 dyne/cm$^2$ range (r=0.47; p=0.69).

**Conclusions:** The observation of differential WSS-lumen area correlations between the vein and the artery is novel. The finding of a biphasic relationship between early WSS and later lumen area change in AVGs is also novel. These differential hemodynamics relationships enhance our understanding of the pathogenesis of NH in AVG and have implications in the design of anti-NH strategies.

## TH-PO109

**Antimicrobial Peptide Coating Prevents Bacteria Survival and Protein Fouling on Catheter Materials** Jennifer A. Neff, Danir F. Bayramov, Fatima Alim, Burke Chan, Esha A. Patel. *Allvivo Vascular, Inc., Lake Forest, CA.*

**Background:** Catheter related bacteremia associated with dialysis access is a major cause of morbidity and mortality. Technologies to combat infection that will not select for resistant bacteria are needed. A catheter coating containing a cationic antimicrobial peptide (CAP) was tested for its effect on bacteria attachment and survival, fibrinogen (Fb) deposition, and CAP release profile.

**Methods:** Polyurethane (PU) discs coated with a CAP/polymer formulation were tested for bacteria attachment and survival. Samples were challenged with 5x10$^7$ cfu/mL *Staphylococcus Epidermidis* following incubation in heat inactivated 50% serum (HIS) for 96 hrs with HIS being replaced daily. Discs were sampled every 24 hr for live, attached bacteria by plating after washing and sonicating in a CAP neutralizing agent. Resistance to Fb adsorption was evaluated by incubating samples in PBS containing 2 mg/mL of Fb, followed by ELISA. Peptide content and release were quantified by RP-HPLC.

**Results:** Within 2 hrs, the CAP/polymer coating resulted in a 3 log reduction in bacteria attachment relative to uncoated PU followed by nearly complete sterilization of samples after 96 hrs in HIS (Figure 1). Placebo coated (polymer only) samples showed nearly 2 log reduction in bacteria attachment at early incubation times in HIS (Figure 1), and a 70% reduction in Fb adsorption by 1 week. Sustained release of CAP at therapeutically effective levels was confirmed by RP-HPLC over a period exceeding 1 week.

**Conclusions:** The formulated polymer coating displayed improved non-fouling properties and reduced Fb deposition. Incorporating CAP and tailoring its release profile further led to a significant reduction in bacteria attachment and survival. Antimicrobial coatings often facilitate protein deposition, making it difficult to achieve a nonfouling surface. This CAP/polymer formulation provides a promising approach to reduce both infection and occlusion of catheters without contributing to development of drug resistant bacteria.

## TH-PO110

**Proteomic Analysis of Nephron Segments of Formalin-Fixed Paraffin-Embedded Human Kidney Tissues** Tadashi Yamamoto,[1] Shigeru Miyazaki,[2] Hidehiko Fujinaka.[1] *[1]Dept of Structural Pathology, Institute of Nephrology, Niigata Univ, Niigata, Japan; [2]Shinrakuen Hospital, Japan.*

**Background:** Nephrons are the functional units of the kidneys and consist of several parts (glomerulus, proximal tubule, descending and ascending loop of Henle and distal tubule) connected to collecting ducts. Knowing of proteome profile of each nephron segment will contribute to complete understanding of kidney functions.

**Methods:** We separated nephron segments (glomeruli, proximal tubules, descending and ascending loops of Henle and distal tubules) and collecting ducts by laser microdissection of FFPE-human kidney sections after immune-labeling of each part with antibodies against unique proteins in each part. Tissue sections of total area of ~1 mm$^2$ each were digested with trypsin after autoclave treatment (On-site direct digestion, OSDD method). Peptides were collected from the sections and purified by C-18 Stage-Tip and analyzed by LC-MS/MS (Thermo Orbitrap LTQ) and proteins were identified by Mascot with FDR less than 5%.

**Results:** More than 1000 proteins were identified by a single MS analysis of each sample and proteins uniquely expressed in each nephron segment were selected: glomerulus; 153, proximal tubule; 306, distal tubule; 58, and collecting duct; 40. Gene Ontology annotation analysis showed that the most enriched cellular components were cytoskeleton proteins in the glomerulus, cytoplasm proteins in the proximal tubule, mitochondrion proteins in the distal tubule, and cytoplasmic part proteins in the collecting duct. The protein quantity was compared by label-free normalized spectral index. Among the uniquely expressed proteins the highest were proteins translated from S100A6 gene in the glomerulus, MPDZ in the proximal tubule, HIST1H2B in the distal tubule, and MAST4 in the collecting duct.

**Conclusions:** The proteome analysis of nephron segments demonstrated their significant features and provided useful knowledge of their functions.

## TH-PO111

**MRI Characterization of UUO Kidney Injury Using CEST and MTR Techniques** Feng Wang,[1,2] Keiko Takahashi,[2] Zhongliang Zu,[1] Raymond C. Harris,[2] Christopher Chad Quarles,[1,2] Takamune Takahashi.[2] *[1]Vanderbilt Univ Institute of Imaging Science; [2]Vanderbilt O'Brien Kidney Disease Center, Nashville, TN.*

**Background:** Chemical exchange saturation transfer (CEST) and magnetization transfer (MT) MR imaging enables the assessments of metabolites with exchangeable protons and macromolecules in tissues, respectively. Since these techniques are poorly applied to kidney disease, we evaluated its ability in sensing kidney injury/progression using mice with unilateral ureteral obstruction (UUO).

**Methods:** MRI protocols were optimized on Agilent 7T MRI. MT ratio (MTR) was measured based on a 2D RF-spoiled gradient echo sequence. Off-resonant RF irradiation was accomplished using Gaussian RF pulses (6000 Hz, 12ms), and a control scan was performed without MT pulses. CEST was performed using a continuous wave CEST sequence (a 8.0 s irradiation pulse followed by a multishot SE-EPI readout). A control scan was performed by setting the RF offset to 20000 Hz. $MTR_{asym}$ was acquired using asymmetric analysis. The CEST and MTR maps were generated for UUO and sham-operated mice at day 1, 3, and 6 after surgery.

**Results:** 1. MTR was significantly reduced in inner medulla (IM) and papilla (P) in UUO day 3 kidneys, while the changes in cortex (C) and outer medulla (OM) were minimum. At day 6, the IM and P of UUO kidneys showed remarkably reduced MTR, perhaps due to severe cell injury or death. At this stage, MTR was also slightly decreased in C and OM in UUO kidneys. 2. CEST: The z-spectrum of IM and P in day 3 and 6 UUO kidneys was highly asymmetric and the CEST contrasts were broadly and largely increased from ~1.2 to 3.5 ppm in $MTR_{asym}$ curve. The CEST contrasts at 2 and 3.5 ppm offsets in the OM of UUO kidneys and at 1.2 ppm in contralateral kidneys increased from day 3 to day 6. The MTR and $MTR_{asym}$ maps in UUO kidneys showed focal variations on the disease progression.

**Conclusions:** The CEST and MTR techniques can be used for the assessment of UUO injury and progression. The MTR may be used for assessing severe renal cell injury that decreases tissue macromolecular components, while CEST may provide the changes in metabolites including glucose, amine and amide.

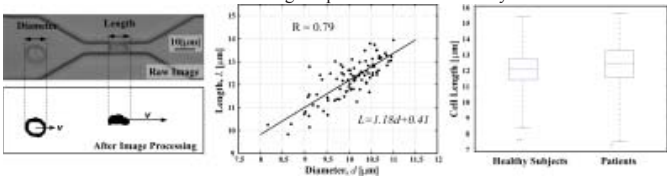
**Image-Based Screening for Erythrocyte Characteristics of Patients Receiving Dialysis Service** Chia-Hung Dylan Tsai,[1] Shuhei Yoshikawa,[1] Shinya Sakuma,[1] Fumihito Arai,[2] Makoto Kaneko.[1] *[1]Osaka Univ, Suita, Osaka; [2]Nagoya Univ.*

**Background:** Dialysis process includes massive blood exchange between a patient and a dialysis device. It is known that erythrocytes of a patient receiving dialysis tend to have shorter life cycles. This work is aimed to understand how the dialysis process changes cell characteristics in terms of cell size and cell deformability.

**Methods:** An image-based screening for erythrocyte condition is introduced. The system is constructed of three parts: a high-speed camera, a PDMS microchannel and an image-processing algorithm. The frame rate of the camera can be up to 10,000 fps, which provides the capability of high-throughput screening. The microchannel with width of 4.5μm forces erythrocytes through the channel one after another. Image-based algorithm is implemented for processing the images captured from the camera, and erythrocyte conditions, such as size and deformability, are evaluated.

**Results:** Erythrocytes from 4 patients receiving dialysis service and 4 healthy subjects were tested. The cell length inside a microchannel is found highly correlated with cell diameter, which shows that the cell length is a valid index for cell size. The results indicate that the patients have greater variation in the size of their erythrocytes and, furthermore, distribution of cell size is wider among the patients than the healthy ones.



**Conclusions:** The greatest advantage of the proposed system is that erythrocyte can be evaluated one-by-one, and we can visually check the cell from the captured frames, if necessary. We confirmed that the patients receiving dialysis services tend to have bigger erythrocytes and wider distribution. This could be a reason causing shorter life cycle of patients' erythrocytes. For the future work, cell motion inside the channel will be analyzed for evaluating cell deformability.

## TH-PO113

**Regional Renal Perfusion Assessment with Contrast Enhanced Ultrasound in Ischemia-Reperfusion Injury** Krisztina Fischer,[1,2] Can Meral,[1] Ferenc A. Jolesz,[1] Takaharu Ichimura,[2] Joseph V. Bonventre.[2] *[1]Radiology, Brigham and Women's Hospital; [2]Renal Div, Brigham and Women's Hospital, Boston, MA.*

**Background:** Alterations in renal microperfusion play an important role in the development of acute kidney injury. Currently, however, there is no reliable technique that provides assessment of the renal perfusion at the bedside. Contrast enhanced ultrasound (CEUS) is an ultrasound imaging technique which uses gas microbubbles administered into the bloodstream.

**Methods:** We developed a renal perfusion estimation method, using Vevo 2100 ultrasound equipment and MicroMarker contrast agent (VisualSonics) with our own analysis software. CEUS with destruction-refilling sequences was performed in a 28-min bilateral ischemia-reperfusion (IR) model in mice (n=6) at pre-IR, 15, 30, 45, 60 min and 24 hr post-I. Plateau image intensity was used to estimate renal perfusion. High resolution, pixel-by-pixel, analysis was performed on each imaging clip, resulting in parametric maps of the kidney, representing relative blood volume in each pixel.

**Results:** Region analysis showed that the perfusion decreased the most in the outer medulla (OM) by 63% (p=0.004) 60 min post-I and remained 38% (p=0.002) less than pre-IR at 24 hr post-I.

| Average Plateau Image Intensity N=6 | Pre-IR | 15 min post-I | 30 min post-I | 45 min post-I | 60 min post-I | 24 hr post-I |
|---|---|---|---|---|---|---|
| C (SD) | 39(7) | 36(12) | 31(13) | 25(14) | 18(14) | 34(7) |
| OM (SD) | 36(7) | 30(12) | 27(11) | 20(11) | 13(8) | 22(2) |
| IM (SD) | 37(7) | 38(12) | 35(12) | 27(10) | 16(8) | 30(8) |

Parametric perfusion maps confirmed that the outer medullary perfusion decreased disproportionately to the reduction in the cortical © and inner medullary (IM) perfusion.

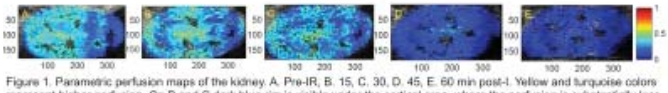

Figure 1. Parametric perfusion maps of the kidney. A. Pre-IR, B. 15, C. 30, D. 45, E. 60 min post-I. Yellow and turquoise colors represent higher perfusion. On B and C dark blue rim is visible under the cortical area, where the perfusion is substantially less than the other parts of the kidney.

**Conclusions:** CEUS can detect and monitor renal microvascular perfusion changes in space and time in IR injury in mice and represents a technique that can be translated to use in man.

## TH-PO114

**Immunomodulation with a Selective Cytopheretic Device (SCD) Reduces Myocardial Infarct Size in a Canine Model of Ischemia-Reperfusion Injury (IRI)** H.D. Humes,[1,2,3] D. Buffington,[1] A. Westover,[1] P. Smith,[1] Hani N. Sabbah.[4] *[1]Innovative BioTherapies; [2]Univ of MI; [3]CytoPherx; [4]Henry Ford HS.*

**Background:** IRI, characterized by a vigorous inflammatory response immediately post reperfusion via molecular signals generated by injured endothelium and cardiomyocytes, results in increased injury from leukocyte (LE) infiltration into the peri-infarct zone. This response becomes important in healing necessary to reestablish cardiac performance, but is excessive and maladaptive. The SCD, a novel biomimetic device, has shown efficacy in preclinical models of acute/chronic diseases for which inflammation is an exacerbating factor. When placed in an extracorporeal blood circuit (EBC) with regional citrate anticoagulation (RCA), the low ionized calcium environment provides a synchronized effect to both sequester and alter the activity of the transiently bound LE. The safety/efficacy of the SCD was demonstrated in clinical studies of ICU ARF/MOF patients and is currently being evaluated in a US multicenter, randomized pivotal IDE trial. Pilot studies were initiated to determine SCD effects on the acute inflammatory cascade indicative to IRI.

**Methods:** SCD was evaluated in a canine model of IRI, based on left circumflex coronary artery occlusion. Myocardial Infarct (MI) was induced for 3h and SCD therapy established using an EBC with RCA, 30min prior to reperfusion and continued for up to an additional 3h post. Systemic inflammation was monitored by CD11b expression of LE populations using flow cytometry and LE infiltration was evaluated by histology. Systemic cytokine and cardiac injury marker troponin-I (cTn-I) levels were assayed. Left ventricular (LV) function, MI size and edema were evaluated in treated (n=3) and compared to control (n=4) animals.

**Results:** SCD therapy resulted in 50% reduction of MI size (19.2±2.7 vs. 10.2±4.5% of LV volume respectively, p<0.05), less edema (LV wall thickening) and 10x lower cTn-I levels. LE infiltration was prominent in the peri-infarct zone of controls but negligible in the SCD group.

**Conclusions:** Pilot studies demonstrate that immunomodulation with the SCD represents a novel therapy with the potential to improve outcomes associated with myocardial IRI.

*Funding:* Other U.S. Government Support

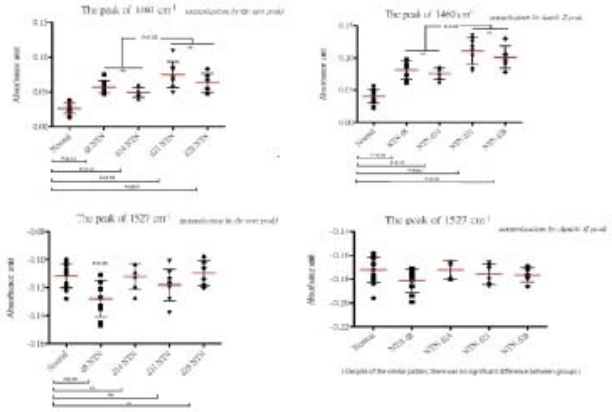
## TH-PO115

**Application of Fourier Transform Infrared Spectroscopy to Plasma Biomarker Detection in Experimental Glomerulonephritis** Mei-Ching Yu,[1] Frederick W.K. Tam,[1] Robert J. Unwin,[2] Peter R. Rich,[3] Liberty Foreman.[3] *[1]Kidney & Transplant Institute, Imperial College London; [2]UCL Centre for Nephrology, Univ College London Medical School, Royal Free Hospital; [3]Structural and Molecular Biology, UCL, United Kingdom.*

**Background:** FTIR has been used in medicines for studying molecular composition and structures in cells and tissues. However, the application to biofluids, particularly blood is limited. Our previous work showed specific characteristic bands of urine spectra in the experimental glomerulonephrits (GN),and the changes were accordance with the progression of renal injury (ASN 2012). Although plasma creatinine ($P_{Cr}$) is a common clinical test to assess renal impairment, it is insensitive at the early stage of renal disease. The aim of this work is to employ FTIR to analyse plasma from nephrotoxic nephritis (NTN) for exploring potentially biomarkers of early renal injury.

**Methods:** Plasma from NTN Wistar Kyoto rats on day 8 (9), day 14 (6), day 21 (8) and day 28 (6) were compared to normal (15). 5µl plasma was required and dried for FTIR. Sample spectrum intensity normalized by the intensity of the 1640 $cm^{-1}$ peak of urea was compared to by the 1542 $cm^{-1}$ peak of Amide II. The subsequent analytic procedures were the same as our previous work (ASN 2012).

**Results:** The change in the band at 1460 $cm^{-1}$ showed the same pattern after normalization either with urea or Amide II peaks, of the progression of the experimental GN. Additionally,significant differences were validated.



In this model, $P_{Cr}$ remains normal until at least day 14. To detect this novel marker is more sensitive than measuring $P_{Cr}$.

**Conclusions:** Several renal biomarkers relevant to progression of experimental GN have been identified from IR spectra of plasma and urine samples. Conclusively, FTIR is becoming an emerging non-invasive diagnostics of rapidly screening patients at risk of progressive kidney disease.

## TH-PO116

**Sensitive and Specific Measurement of Urine Neutrophil Gelatinase-Associated Lipocalin by Localized Surface Plasmon Resonance Using Artificial Antibodies on Gold Nanocages** Jeremiah J. Morrissey,[1,3] Limei Tian,[2] Keng-Ku Liu,[2] Naveen Gandra,[2] Evan D. Kharasch,[1,3,4] Srikanth Singamaneni.[2,3] *[1]Anesthesiology, Washington Univ in St. Louis; [2]Mechanical Engineering and Materials Science, Washington Univ in St. Louis; [3]Siteman Cancer Center, Washington Univ in St. Louis; [4]Biochemistry and Molecular Biophysics, Washington Univ in St. Louis, St. Louis, MO.*

**Background:** Biosensing platforms based on localized surface plasmon resonance (LSPR) provide highly sensitive, cost-effective, and point-of-care diagnostic tools. Similar to ELISAs, current plasmonic biosensors use expensive and labile natural antibodies. Macromolecular imprinting aims to overcome storage, stability and variability problems of natural antibodies by synthesizing specific artificial antibodies with high stability, reusability and cost-efficiency.

**Methods:** We used organo-siloxane monomers to provide amine, hydroxyl and methyl functional groups mimicking a natural antibody and when polymerized around absorbed recombinant human neutrophil gelatinase-associated lipocalin (NGAL), a biomarker of acute and chronic kidney injury, molded reversible recognition cavities specific for NGAL detected as a shift in LSPR wavelength.

**Results:** The artificial antibodies, cast on cuboidal gold nanocages (about 60nm/side) reliably detected 25 ng/ml of NGAL and each sensor pad, after stripping, may be recycled at least 5 times. The LSPR signal from NGAL was stable over a pH range from 5.0 to 8.5 and specific gravity from 1.005 to 1.030. Other human urinary proteins with lipocalin-like domains such as FABP1, FABP3 or orosomucoid; and myoglobin or hemopexin (1-10 ug/ml); and hemoglobin or serum albumin (up to 500 ug/ml) interfered less than 20% with the LSPR signal of NGAL.

**Conclusions:** Molecular imprinting of nanocages with surface synthetic antibodies opens up a novel class of plasmonic nanostructures with sensitive and specific biorecognition capability. These technical and conceptual developments open up new possibilities in biomedical applications of plasmonic nanostructures particularly in label-free and antibody-free diagnostic tools relevant to disease diagnosis, toxicology testing, and biotechnology.

## TH-PO117

**Development of a Microphysiological Organ-on-a-Chip Incorporating Primary Human Renal Epithelial Cell Cultures** Edward J. Kelly,[1] Zhican Wang,[1] Jenna L. Voellinger,[1] Jeremy Stuart Duffield,[2] Thomas Neumann,[3] Anna Tourovskaia,[3] Gregory Kramer,[3] Jonathan Himmelfarb.[2] *[1]Pharmaceutics, Univ WA, Seattle, WA; [2]Medicine, Univ WA, Seattle, WA; [3]Nortis Inc., Seattle, WA.*

**Background:** Kidney disease is a public health problem that affects more than 20 million in the USA, yet little is understood about the impact of kidney disease on drug disposition. Consequently there is a critical need to model the human kidney to improve our understanding of drug efficacy, safety, and toxicity, especially during drug development. The proximal tubule (PT) plays a central role in the elimination of endogenous toxins and xenobiotics, but cultured PT cells bear little resemblance to their in vivo counterparts. In addition, the role of peri-tubular capillaries in tubule secretion is poorly understood. Finally, rodent modeling of xenobiotic handling in vivo has proven a poor predictor of human handling. To study human PT functions we have developed a microphysiological system (MPS) to recapitulate the PT.

**Methods:** We have developed and optimized methods for purifying, expanding, storing human Kidney PT cells. We developed single lumen 3D microphysiological devices with flow in which a kidney PT can be recapitulated.

**Results:** In optimized culture conditions in 2D human PT cells uniformly express E-cadherin, aquaporin-2, KIM-1 and form tight junctions as demonstrated by ZO-1 localization. PT cells proliferate with a doubling time of ~ 30hrs and remain viable following freeze/thaw cycles. When seeded into the MPS, they are able to form a confluent and patent tubule under conditions of continuous flow. PT cells cultured under these conditions retain expression of the epithelial marker E-cadherin and form tight junctions, exhibiting >90% cell viability for >21 days ex vivo. These tubules are currently being evaluated functionally, the results of which will be presented.

**Conclusions:** It is possible to recapitulate a functioning PT ex vivo in a MPS for several weeks. This system more accurately reflects human physiology, being able to predict renal handling of xenobiotics and potentially assess mechanisms and biological response relating to kidney injury.

## TH-PO118

**RNA-Seq of Microdissected Renal Tubules Identifies Segment-Specific Transcription Factors** Jae Wook Lee, Chung-Lin Chou, Fahad Saeed, Mark A. Knepper. *NIH.*

**Background:** We carried out RNA-seq in microdissected rat renal tubule segments to identify the transcriptomes of the 12 major renal tubule segments and to identify transcription factors that could be involved in cell type-specific gene expression.

**Methods:** Renal tubules were manually microdissected using a high resolution microscopy system capable of discriminating cell types. After reverse transcription and amplification, cDNA libraries were sequenced using an Illumina HiSeq 2000 sequencer. Sequences were aligned to the rat reference genome (rn4) and expression levels were calculated in 'reads per kilobase exons per million mapped reads' (RPKM). The accuracy of tubule identification was successfully confirmed by plotting distributions of well established markers for each tubule segment. Expression of a gene was considered region- or tubule-specific if the RPKM in a region or tubule was larger than 90% of the sum of RPKMs across all tubule segments. Multiple samples were analyzed for each renal tubule segment.

**Results:** Individual tubule segments had between 6888 and 9300 transcripts with RPKM > 0. Several homeobox family transcription factors were found to be segment-specific, such as *Pbx4* in proximal tubule segments; *Irx1* and *Irx2* in the cortical thick ascending limb; *Hmx2* and *Pbx3* in the cortical collecting duct; and *Hoxb5* and *Pbx1* in the inner medullary collecting duct. Interestingly, *Hoxb7* (thought to be collecting duct-specific) was found not only in collecting ducts but also thick ascending limbs. Transcription-factor mediators of TGF and Wnt signaling such as *Smad2*, *Tcf4,* and *Tcf12* were found only in collecting duct segments. Other examples of region-specific transcription factors include: *Hnf4a* (proximal segments); *Rarg* (thick ascending limbs); *Mafb* (cortical collecting duct); and *Pparg* and *Elf5* (inner medullary collecting duct).

**Conclusions:** These data provide baseline information needed to model cell type-specific gene expression along the nephron and collecting duct.

## TH-PO119

**PPARα Promotes $Na^+/H^+$ Exchanger NHE1 Expression to Inhibit Renal Tubule Cells Apoptosis through Recruiting Ezrin/Radixin/Moesin Proteins and Phosphoinositide 3-Kinase** Yung-Ho Hsu,[1] Tso Hsiao Chen,[2] Cheng-Hsien Chen.[1,2] *[1]Div of Nephrology, Dept of Internal Medicine, Shuang Ho Hospital, Taipei Medical Univ, Taipei, Taiwan; [2]Div of Nephrology, Dept of Internal Medicine, Wan Fang Hospital, Taipei Medical Univ, Taipei, Taiwan.*

**Background:** Peroxisome proliferator-activated receptor-alpha (PPARα) is a transcription factor and has been reported to inhibit gentamicin-mediated proximal tubule cell apoptosis. However, the antiapoptotic mechanism of PPAR-α is still unknown.

**Methods:** In this study, we investigated the mechanism of antiapoptotic effect of PPARα by overexpressing PPARα in NRK-52E cells.

**Results:** We found that PPAR-α overexpression induced the expression of $Na^+/H^+$ exchanger NHE1 in NRK-52E cells. Three potential PPAR response elements in NHE1 promoter region were identified by chromatin immunoprecipitation. The $Na^+/H^+$ exchanger activity was also increased in PPARα-transfected cells. Flow cytometry showed that PPARα overexpression augmented the resistance to apoptosis-induced shrinkage in NRK-52E cells. A potent $Na^+/H^+$ exchanger inhibitor, 5-(N-Ethyl-N-Isopropyl) Amiloride (EIPA), inhibited the antiapoptotic effect of PPARα in gentamicin-treated cells. NHE1 siRNA transfection also inhibited PPARα-induced $Na^+/H^+$ exchanger activity and the antiapoptotic effect. In immunoprecipitation, NHE1 physically associated with phosphorylated ezrin/radixin/moesin (ERM) and phosphoinositide 3-kinase (PI3K) in PPARα-transfected cells. We also found that PPARα induced activation of the pro-survival kinase, Akt. PPARα-induced Akt activity was inhibited by EIPA and NHE1 siRNA transfection. Wortmannin, a phosphoinositide 3-kinase (PI3K) inhibitor, inhibited PPARα-induced Akt activity and the antiapoptotic effect of PPARα. But wortmannin did not influence the association between NHE1 and phospho-ERM.

**Conclusions:** We conclude that PPARα promotes NHE1 expression, and then recruits ERM proteins and PI3K to mediate Akt-dependent cell survival.

## TH-PO120

**Elucidating the Mechanism of Tenofovir-Induced Kidney Injury** Laura Chappell-Campbell, Jeremy S. Leventhal, Pengfei Gong, Michael J. Ross. *Icahn Sch of Med at Mt Sinai.*

**Background:** Tenofovir (TFV) is the most commonly-used antiretroviral drug for treatment of HIV-1 infection. 2% of patients treated with TFV develop AKI and 30% have subclinical signs of proximal tubular epithelial cell (PTEC) dysfunction. Though studies suggest mitochondrial injury is an important component of TFV nephrotoxicity, little is known about the mechanism by which TFV injures mitochondria.

**Methods:** We created an novel *in vitro* model of TFV toxicity using human PTEC. To increase PTEC susceptibility to TFV toxicity, studies were performed using PTEC stably transfected with *OAT1*, which mediates basolateral TFV uptake. Protein expression was analyzed for markers of mitochondrial fission and fusion, autophagy-associated protein LC3, and the cellular energy sensor AMPK. Subcellular localization of mitochondria and LC3 was visualized via confocal microscopy. Electron microscopy (EM) was used to analyze mitochondrial morphology and to identify autophagosomes.

**Results:** *OAT1* transfection markedly increased the toxicity of TFV. TFV treatment increased expression and activation of AMPK in *OAT1*-overexpressing PTEC. Since AMPK activation can reflect cellular energy deprivation, we studied whether TFV also increased autophagy in PTEC. TFV incubation markedly increased LC3-I levels, with more modest effects on LC3-II. Confocal imaging of TFV-treated PTEC demonstrated colocalization of mitochondria with LC3, suggesting autophagosomal localization of mitochondria (mitophagy). EM studies corroborated these findings, showing increased autophagosome accumulation and mitophagy in TFV-treated cells. No significant effect of TFV on mitochondrial fission and fusion was observed.

**Conclusions:** These data demonstrate that TFV induces activation of AMPK, an important regulator of autophagy. Mitophagy was also induced by TFV and our finding that TFV increased LC3-I levels without changes in LC3-II suggests either a defect in autophagosome formation or increased autophagosome turnover. In conclusion, TFV induces activation of cellular energy deprivation response pathways. Future studies are needed to determine whether this response is due to aberrant mitophagy leading to loss of mitochondria or to direct mitochondrial injury.

## TH-PO121

**HIV-Induced Downregulation of Deptor Contributes to the Activation of mTOR Pathway in HIV-Associated Nephropathy** Partab Rai,[1] Kavithalakshmi Sataranatarajan,[2] Viki Kumar,[1] Rivka Lederman,[1] Ashwani Malhotra,[1] Balakuntalam S. Kasinath,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Univ of Texas Health Science Center, San Antonio, NY.*

**Background:** mTOR pathway has been shown to play a pathogenic role in the development of HIV-associated nephropathy (HIVAN). However, the role of deptor, a negative regulator of mTOR has not been studied to date. We hypothesized that HIV may be activating mTOR pathway in HIVAN via down regulation of kidney cell deptor expression.

**Methods:** Kidneys were harvested from age and sex matched control and Tg26 mice (n=6).Renal cortical sections were immunolabeled for deptor, phospho-mTOR, and total mTOR. Protein blots from renal tissues of control and Tg26 mice were probed for deptor,

phospho-mTOR, phospho-p70S6K, phospho-Akt, total mTOR, and actin. To determine the effect of HIV on tubular cell deptor expression and mTOR activation, mouse proximal tubular cell (MTC) were transduced with either empty vector (EV/MTC) or NL4-3 (HIV/MTC). Protein blots of EV/MTCs and HIV/MTCs were probed for deptor and phospho-p70S6K expression. To establish a causal relationship between deptor down regulation and HIV-induced tubular cell protein synthesis, MTC were transfected with deptor plasmid and then evaluated for the effect of HIV milieu (deptor/HIV/MTC) on mTOR activation and tubular cell protein synthesis.

**Results:** Renal cortical sections in Tg26 mice displayed attenuated kidney cell expression of deptor but enhanced expression of phospho-mTOR. Renal tissue lysates of Tg26 mice also exhibited attenuated expression of deptor and enhanced expression of phsopho-p70S6K, an effector molecule of mTOR activation. In *in vitro* studies, deptor/HIV/MTC displayed enhanced expression of deptor but attenuated expression of phospho-mTOR and phospho-p70S6K. Additionally deptor/HIV/MTC displayed attenuated tubular cell protein synthesis when compared to HIV/MTC.

**Conclusions:** These findings indicate that HIV-induced down regulation in renal cell deptor expression contributed to the activation of the mTOR pathway in HIVAN.

*Funding:* NIDDK Support

## TH-PO122

**Quality Control of Mitochondria by Autophagy in the Kidney Has an Essential Role for the Adaptation to Metabolic Acidosis**

Tomoko Namba,[1] Tomonori Kimura,[1] Yoshitsugu Takabatake,[1] Atsushi Takahashi,[1] Takeshi Yamamoto,[1] Jun Matsuda,[1] Fumio Niimura,[2] Taiji Matsusaka,[3] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Pediatrics, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan; [3]Internal Medicine, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.*

**Background:** It has been shown that autophagy plays a protective role in kidney. Metabolic acidosis (MA), a common acid-base disorder, causes various cellular adaptations including ammoniagenesis. We aimed to prove a hypothesis that autophagy promotes cellular adaptation of kidney proximal tubular cells under MA through mitochondrial homeostasis.

**Methods:** MA was induced in proximal tubule-specific autophagy-deficient mice and GFP-LC3 transgenic mice by treating with NH4Cl in drinking water for 4 weeks. We also used autophagy-deficient proximal tubular cells and examined the role of autophagy in adaptations for MA with pH conditioned medium.

**Results:** We demonstrated that autophagy is induced in proximal tubules by acid *in vivo* and *in vitro* as assessed by the GFP-positive dot formation in the kidney of acid-loaded GFP-LC3 transgenic mice and degradation of p62 using kidney proximal tubular cells when cultured in an acidic medium. Next, acid-loaded autophagy-deficient mice demonstrated severe MA with significantly reduced ammonium production in kidney compared with those of wild type mice, which was confirmed by *in vitro* analysis. To prove our hypothesis, we analyzed the mitochondrial function of autophagy deficient condition under MA. COX and SDH stains of kidney indicated the reduced activity of mitochondrial respiratory chain in acid-loaded autophagy-deficient mice. Mitochondrial membrane potential was significantly reduced in Atg5-deficient kidney proximal tubular cells compared with that of the control when cultured in both normal and acidic medium, respectively.

**Conclusions:** Our results indicate that MA evokes mitochondrial dysfunction and quality control of mitochondria by autophagy has an essential role for the adaptation to MA.

## TH-PO123

**Klotho Protects against Mouse Renal Fibrosis by Regulation of Autophagy**

Hye Eun Yoon, Sung Jun Kim, Su Jin Choi, Sungjin Chung, Seok Joon Shin. *Internal Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

**Background:** Autophagy is a cellular process of degradation of damaged components in the cytoplasm and regulates cell death. Klotho is known to have a renoprotective effect. In this study, we investigated whether Klotho protein protects against renal fibrosis by regulating autophagy in an obstructive kidney model.

**Methods:** Mice received unilateral ureteral obstruction (UUO) surgery with or without intraperitoneal administration of secreted Klotho protein. We evaluated renal fibrosis and apoptosis and expressions of superoxide dismutase (SOD), heat-shock protein 70 (Hsp70), beclin-1, LC3-II/LC3-I, Akt, FoxO3a, Bax, Bcl-2, Bim, cleaved PARP, and alpha-smooth muscle actin (αSMA), in the obstructed kidneys on days 1, 3 and 7.

**Results:** Secreted Klotho protein significantly decreased collagen deposition and fibrotic areas in obstructed kidneys compared with those of controls. Secreted Klotho protein significantly increased the expressions of antioxidant enzymes, SOD (SOD1 and SOD2) and Hsp70. Administration of secreted Klotho protein significantly induced beclin-1, an autophagy gene, and increased the LC3-II/LC3-I ratio in obstructed kidneys compared with controls. The numbers of apoptotic cells and the expression of Bax/Bcl-2, Bim and cleaved PARP were significantly decreased in obstructed kidneys of Klotho-treated mice compared with controls. Secreted Klotho protein significantly attenuated expression of α-SMA, a marker of epithelial mesenchymal transition, in obstructed kidneys compared with controls. In Klotho protein-treated mice, the expression of phosphorylated Akt did not show significant changes in obstructed kidneys, but the expression of phosphorylated FoxO3a was significantly decreased compared with controls.

**Conclusions:** We speculate that Klotho protects against renal fibrosis in an obstructed kidney model via direct modulation of FoxO3a signaling, without regulation of Akt, and subsequent attenuation of oxidative stress and induction of autophagy.

## TH-PO124

**The Crosstalk between NF-kB and c-mip Regulates Podocyte Survival**

André Pawlak, Virginie Ory, Melanie Mangier, Mario Ollero, Djillali Sahali. *INSERM, U 955, Equipe 21, Univ Paris-Est Creteil Val-de-Marne, Créteil, France.*

**Background:** We have shown upregulated c-mip expression in nephrotic proteinuria patients concomitantly with downregulation of the antiapoptotic factor Rel-A, a master member of NF-kB. In contrast, in inflammatory glomerular diseases such us proliferative lupus nephritis, RelA is upregulated in podocytes while c-mip is decreased at transcript and protein levels. In light of the divergent expression of these two proteins, we hypothesized that c-mip is transcriptionally repressed by NF-kB.

**Methods:** We identified within the human c-mip promoter a palindromic sequence corresponding to a consensus NF-kB response element (kB-RE). To assess whether NF-kB binds to this sequence in vivo, we performed chromatin immunoprecipitation in mouse podocytes and electrophoretic mobility shift assay (EMSA) using nuclear extracts from HEK cells overexpressing RelA and a radiolabeled c-mip kB-RE oligonucleotide. The full-length sequence containing the entire c-mip proximal promoter was ligated upstream of luciferase gene and cotransfected to HEK cells with NF-kB p50, p65/RelA or both, as well as with the empty vector. C-mip expression was analyzed in wild-type and RelA-deficient mouse embryonic fibroblasts (MEF).

**Results:** The short region flanking the kB-RE was precipitated by the anti-RelA antibody, but not by the rabbit IgG control. Incubation of nuclear extracts from HEK cells overexpressing RelA with the radiolabeled c-mip kB-RE produced only one band shift in EMSA. This shift appeared to be specific as it was abolished by co-incubation with a mutated probe and shifted upwards in the presence of an anti-RelA antibody. In transfected HEK, luciferase activity driven by c-mip promoter was strongly reduced in the presence of RelA, but not by NF-kBp50. Moreover, in RelA-deficient MEF, c-mip was dramatically increased, while it was barely detected in wild-type.

**Conclusions:** These results suggest that RelA binds to the c-mip promoter and exerts a powerful inhibitory effect on c-mip transcription. Conversely, c-mip promotes RelA downregulation.Thus, a tightly regulated crosstalk between these two proteins seems to play a key role in the regulation of podocyte survival.

## TH-PO125

**DNA Damage Response with Cell Cycle Restriction Has Implications for Tissue Repair in Cisplatinum-Induced Nephrotoxicity**

Samriti Dogra,[1] Preeti Viswanathan,[2] Sriram Bandi,[3] Sanjeev Gupta.[3] *[1]Pediatric Nephrology, Montefiore Medical Center, Bronx, NY; [2]Pediatric Gastroenterology, Montefiore Medical Center, Bronx, NY; [3]Medicine, Albert Einstein College of Medicine, Bronx, NY.*

**Background:** Molecular mechanisms of chemotherapy-induced nephrotoxicity will help improve clinical outcomes. We defined whether cisplatinum (CP)-induced nephrotoxicity involved DNA Damage Response (DDR) and recruitment of master switches activated by ATM and related pathways.

**Methods:** We used HK-2 and MCT proximal tubular epithelial cells and HuH-7 hepatocytes. After exposing cells to CP, we performed MTT assays for cell viability, qRT-PCR arrays including 84 relevant genes for DDR, Comet assays for double-stranded DNA breaks, cytostaining or western for expression of ATM-related genes, ATM promoter expression assays with TdT reporter after lentiviral transduction, and FACS for cell cycling.

**Results:** In response to CP in IC50 doses, HuH-7, HK-2 and MCT cells showed losses of viability. In CP-treated HuH-7 cells, typical evidences of DDR were obvious, including differences in expression of multiple genes at the mRNA level, γH2AX expression, Comet formation, induction of ATM promoter activity with TdT reporter, along with rapid loss of cells in S or G2/M, more cells in G0/G1, and greater p53 expression. After CP, MCT cells showed similar evidences of DDR, although cell cycle restriction was less pronounced, and p53 expression was unchanged, possibly due to underlying transformation with SV40 antigen. In HK-2 cells, which were transformed by HPV E6/7 oncogenes, p53 expression conversely declined, Comets were absent, ATM promoter was not regulated, and cell cycling was only minimally affected after CP.

**Conclusions:** Renal tubular cells were susceptible to CP toxicity and MCT cells exhibited characteristic ATM-dependent DDR. In HK-2 cells, ATM-dependent DDR and cell cycle arrest were altered via p53 counter-regulation. Therefore, CP-induced DDR in MCT cells offers suitable systems to dissect molecular mechanisms driving DDR and restricting cell cycle progression, and also to develop exciting new ways for either preventing renal damage or promoting tissue repair in drug-induced nephrotoxicity.

**Localization of Bcl-xL and Bax Interactions in Kidney Cells**

Nang San Hti Lar Seng,[1] Judit Megyesi,[1,2] Adel Tarcsafalvi,[1] Peter M. Price.[1,2] *[1]Univ AR Med Sci; [2]VA Med Ctr.*

**Background:** Cisplatin is a widely-used chemotherapeutic agent in various solid tumors. However, in addition to its cytotoxic effect on cancer cells, cisplatin also causes kidney cell death especially in the S3 segment of proximal tubules, which is associated with acute kidney injury (AKI). This side effect compromises the usefulness of cisplatin as an anti-cancer agent. The molecular mechanisms of how cisplatin kills kidney cells is still unknown. We reported that Cdk2, a cell cycle protein, is involved in cisplatin-induced kidney cell death and y inhibiting Cdk2, we protected kidney cells from apoptosis. Here we report Bcl-xL, an anti-apoptotic protein belonging to the Bcl-2 family, is a novel substrate of Cdk2.

**Methods:** Using MS/MS, we identified the localization of Cdk2 phosphorylation sites on Bcl-xL and generated phosphomimetic Bcl-xL and phosphodefective Bcl-xL. We performed apoptosis assays to investigate the downstream effects of these Bcl-xL modifications. Bcl-xL was shown to elicit its pro-survival function by interacting with pro-death proteins, such as Bax. When Bcl-xL is prevented from interacting with Bax, Bax oligomerizes, and permeabilizes mitochondria to induce apoptosis. A GFP fragment reassembly system was utilized in kidney cell lines to determine Bcl-xL/Bax interaction and localization. GFP was divided into N-terminal and C-terminal fragments, and Bcl-xL and Bax were fused with different fragments of GFP individually. If Bcl-xL and Bax interact, the two GFP fragments are brought close enough together to allow reassembly and emit fluorescence. Here we report the interaction and the localization of wild type and modified Bcl-xL's with Bax in kidney cells.

**Results:** We found that in normal kidney cells, Bcl-xL and Bax interact at the mitochondrial membrane, which supports the "embedded together" and "retrotranslocation" models for Bcl-xL/Bax interaction. These models propose that Bcl-xL and Bax interact at the mitochondrial membrane and that Bcl-xL retrotranslocates Bax into the cytoplasm, preventing its conformational activation.

**Conclusions:** We hypothesize that Cdk2 serves as a catalyst to disrupt Bax and Bcl-xL interaction and/or localization, resulting in cell death after cisplatin exposure.

## TH-PO127

**Aldosterone Promotes Autophagy in Podocytes** Junming Fan,[1,2] Nan Mao,[1] Ji Wen,[1] Zi Li.[1] *[1]Dept of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China; [2]Div of Nephrology, Dept of Internal Chinese Medicine, Luzhou Medical College, Luzhou, Sichuan, China.*

**Background:** The concentration of aldosterone was inappropriately higher in many disease, such as hypertension and chronic kidney disease. Previous reports have showed that aldosterone could induce podocyte injury by reactive oxygen species (ROS). When podocytes were induced with cytokines, some oxidized proteins and damaged organelles may be accumulated, then autophagy may be triggered.Our study is toinvestigate that effection of aldosterone on the autophagy and the ROSsignaling pathway in podocyte.

**Methods:** Podocytes were incubated with aldosterone ($10^{-8}$ M), Nacetylcysteine (NAC, 50 mM), 3-Methyladenine (3-MA, 4 mM) and rapamycin (1ng/ml), respectively. Morphological changes were observed by transmission electron microscopy and fluorescence microscope. Examination of autophagic vacuoles with monodansylcadaverine or acidine orange was under confocal microscope. Flow cytometry was performed to detect the generation of intracellular ROS and cell apoptosis. The expression of the LC3B, Beclin-1, Nephrin, $SOD_2$ or Catalase was detected by western blot.

**Results:** Aldosterone promotes autophagy in podocytes. It was observed that the number of autophagosomes was increased in aldosterone and rapamycin treatment groups, whereas rapamycin further enhanced aldosterone-induced autophagosome formation by transmission electron microscopy, immunofluorescence, MDC and AO staining examinations. The expressions of LC3-II, beclin-1, $SOD_2$ and catalase were increased in aldosterone and $H_2O_2$ treatment groups. Flow cytometry showed that the generation of intracellular ROS was increased in aldosterone and $H_2O_2$ treatment groups. But all these results were reversed by NAC pretreatment. The inhibition of autophagy by 3-MA promoted aldosterone-induced podocyte apoptosis and decreased the expression of nephrin in podocytes.

**Conclusions:** Aldosterone promotes the podocyte autophagy which was inhibited by antioxidants. These results suggested that aldosterone promoted podocyte autophagy through the ROS pathway.

## TH-PO128

**DNases Mediate Pyknosis in Kidney Tubular Epithelial Cells** Tariq Fahmi,[1] Kanika Topiwala,[1] Anna G. Stewart,[1] Sudhir V. Shah,[1,2] Alexei G. Basnakian.[1,2] *[1]Pharmacology and Toxicology, Univ of Arkansas for Medical Sciences, Little Rock, AR; [2]Central Arkansas Veterans Healthcare System, John L. McClellan Memorial Veterans Hospital, Little Rock, AR.*

**Background:** Apoptosis in kidney cells is commonly associated with pyknosis, an irreversible nucleus/chromatin condensation. The mechanism of pyknosis, which could be used as a target for kidney protection against injury, is unknown. The aim of this study was to determine the role of apoptotic endonucleases as possible mechanisms of pyknosis in rat kidney tubular epithelial NRK-52E cells in response to serum deprivation.

**Methods:** We utilized a new near infrared (NIRF) florescent probe to measure DNase activity in live cells. DNA fragmentation in fixed cells was measured by TUNEL assay. Expression of apoptotic endonucleases, chaperones and markers of cellular compartments was assessed by immunocytochemistry.

**Results:** We demonstrated that during pyknosis, DNase activity asymmetrically concentrates on one side of the nucleus (near Golgi) and it is strongly colocalized with DNase 2α, caspase-activated DNase (CAD) and DNase I while EndoG and DNase I like2 showed very low colocalization with the activity. Confocal 3D microscopy showed that nuclear membrane stained for lamin B was not broken. siRNA silencing of DNase 2α, CAD, DNase I and EndoG showed suppression of pyknosis and TUNEL staining by all endonucleases except EndoG. Overexpression of all the endonucleases except EndoG showed induction of pyknosis and TUNEL. Among studied chaperones, which included HSP60, HSP70 and HSP90, only HSP60 was highly colocalized with DNase activity. siRNA knockdown of HSP60 resulted in the inhibition of both pyknosis and TUNEL.

**Conclusions:** These data identify endonucleases DNase 2α, CAD and DNase I and chaperone HSP60 as mediators of pyknosis in the kidney cells.

## TH-PO129

**GLCCI1 Executes Glucocorticoid Action in Thymocyte Apoptosis** Zentaro Kiuchi, Yukino Nishibori, Yugo Ito, Kunimasa Yan. *Pediatrics, Kyorin Univ School of Medicine, Tokyo, Japan.*

**Background:** Glucocorticoid (GC)-induced apoptosis contributes to a variety of cellular phenomena including programmed-death of thymocytes and cell-death of lymphoid malignancy; however, what molecules are the actual executioners remains largely obscure. GC induced transcript 1 (GLCCI1) is known as an upregulated gene by synthetic GC; therefore, we aimed to study the protein function of GLCCI1 possibly involved in apoptotic pathway.

**Methods:** Full-length human GLCCI1 cDNA was cloned and used for the generation of recombinant protein, anti-GLCCI1 specific antibody, and stably expressing cell-line (HEK-GLC). Thymocyte cell line (WEHI) was treated with dexamethasone (DEX) in the absence or presence of glucocorticoid receptor (GR) antagonist, subjected to RT-PCR and Western blot study. Immunofluorescence was studied to determine the cellular localization of GLCCI1 in HEK-GLC, WEHI. Mice were injected by DEX and their thymi were subjected to RT-PCR and Western blot study. Mass spectrometry was studied to identify phosphorylation sites in HEK-GLC. Yeast-two hybrid screen followed by co-immunoprecipitaion and in vitro phosphorylation assay was studied to identify functional ligand of GLCCI1.

**Results:** GLCCI1 was a tubulin-associated and highly phosphorylated-protein, possessing serine/threonine phosphorylation sites more than 50. GLCCI1 was bound to both dynein light chain LC8-type 1 (LC8) and its functional kinase p21-protein activated kinase 1 (PAK1), thereby inhibiting kinase activity of PAK1 on LC8 phosphorylation. Synthetic GC upregulated GLCCI1 in the presence of GR, associated with the activation of caspase-3 and -9 and Bim. $CD4^+CD8^+$ double-positive thymocytes endogenously expressed far higher amount of GLCCI1 compared with non-double positive thymocytes and splenic T cells, which was further upregulated by synthetic GC, associated with upregulation of caspase-3 and -9 and Bim.

**Conclusions:** These findings uncover a novel intrinsic pathway that controls thymocyte apoptosis and further suggests that GLCCI1 may function as a direct executioner of synthetic GC's action against many immunological disorders and lymphoid malignancy through interacting with a number of kinases including PAK1.

## TH-PO130

**Angiogenin Is Secreted by the Stressed Renal Epithelium and Induces the Production of tiRNA** Nicolas Bouvier,[1] Alexandre Karras,[2] Eric Thervet,[2] Nicolas Pallet,[1,2] Iadh Mami.[1] *[1]INSERM U775, Paris, France; [2]Nephrology, HEGP, Paris, France.*

**Background:** Angiogenin (ANG) is a stress-activated ribonuclease that cleaves tRNA, producing stress-induced tRNA fragments (tiRNA) can directly inhibit protein synthesis by a novel mechanism of RNA interference**.**

The objective of our study is to test whether ER stress induces ANG production, and to delineate the mechanisms and biological functions of ANG synthesis and secretion by kidney epithelial cells during ER stress.

**Results:** ER stress induces the production and secretion of ANG by human renal epithelial cells in culture. Using siRNA, we have demonstrated that the UPR transducers IRE1 and ATF6, but not PERK, regulate ANG production at the transcripts and protein levels. ANG expression is also increased in rat kidneys challenged with tunicamycin, cyclosporine, and ischemic stress. Recombinant human ANG reduces UPR-induced apoptotic cell death, UPR-induced autophagy, and the intensity of ER stress. During ER stress, ANG is translocated from the nucleus to the cytoplasm, where it colocalizes within stress granules. ANG promotes the formation of tiRNA during ER stress which interfere with the initiation of translation. Therefore, ANG-mediated translation inhibition may involve tiRNA production, to decrease protein load, thereby promoting ER stress relief. Our results also indicate that inhibition of ANG expression by RNA interference reduces the intensity of UPR-induced N-kB signaling, as well as proinflammatory cytokines secretion, suggesting that ANG promotes tubular inflammation. Finally, we measured the concentration of ANG in urines of 100 patients with kidney disease by ELISA. Urinary ANG/creatinine ratio were positively correlated with estimated glomerular filtration rate. By immunohistochemistry analysis of human kidney biopsies we show that ANG is expressed in ischemic kidney and during cyclosporine nephrotoxicity, but not in normal kidneys.

**Conclusions:** ANG is directly and specifically be secreted by the stressed kidney epithelium during the UPR, promotes tiRNA production and protects against UPR-induced apoptosis. ANG is a potential non invasive diagnostic biomarker of tissue injury.

## TH-PO131

**Tubular DNA Damage Response and Cell Cycle Arrest Mediate Progression of Diabetic Nephropathy** Jae-Hyung Chang, Takaharu Ichimura, Joseph V. Bonventre. *Renal Div, Brigham and Women's Hospital, Boston, MA.*

**Background:** Diabetic nephropathy (DN) has been traditionally considered as a primary glomerular disease. Increasing evidence, however, suggests that the kidney tubule plays a central role, and that tubulointerstitial injury may contribute to glomerular changes in diabetes. Recently, our laboratory has shown that in ischemic, toxic and obstructive mouse models, injured proximal tubular epithelial cells (PTEC) undergo cell cycle arrest in G2/M and assume a pro-fibrotic secretory phenotype as a consequence of maladaptive repair. This process involves activation of DNA damage response (DDR) proteins and results in interstitial fibrosis and glomerulosclerosis.

**Methods:** Using a mouse model of type 1 diabetes and porcine tubular cell lines, we determined if the diabetic environment facilitates DNA damage in PTEC, activates DDR signaling and promotes senescent cell cycle arrest, ultimately leading to tubulointerstitial fibrosis and glomerulosclerosis.

**Results:** Hyperglycemic treatment of KIM-1-PK1 cells, a porcine tubular cell line which stably expresses human kidney injury molecule-1 (KIM-1), results in enhanced expression of markers of nuclear DNA damage and DDR activation (pATM and pH2AX), as well as induction of p16, a marker of senescent cell cycle arrest. Also, expression of TGF-β was up-regulated in these cells. In streptozotocin (STZ)-induced diabetic mice, 15 weeks after induction of diabetes, kidneys had interstitial fibrosis, tubular atrophy and glomerulosclerosis, together with significantly enhanced expression of nuclear pH2AX and apical KIM-1 in PTEC when compared to control non-diabetic animals. At this timepoint, there were significantly fewer Ki67-positive proliferating PTEC in diabetic kidneys compared to the control kidney. Also, cortical tubular expression of p16 and the number of phosphohistone H3 positive tubular cells were increased in diabetic mice, indicating an increase in the proportion of PTEC in cell cycle arrest in diabetes.

**Conclusions:** These data suggest that tubular DDR signaling and premature senescent cell cycle arrest may lead to accelerated fibrosis and may represent novel pharmacological targets for the treatment of DN.

## TH-PO132

**URAT 1 Inhibition Protects Humans Proximal Tubule Cells from Apoptotic Damage Induced by Uric Acid** Emanuele L. Parodi, Daniela Verzola, Francesca Viazzi, Debora Garneri, Annalisa Gonnella, Roberto Pontremoli, Giacomo Garibotto. *Dept ofInternal Medicine and Cardionephrology, Univ of Genoa, Genoa, Italy.*

**Background:** Serum uric acid (UA) has been shown to predict the development of chronic kidney disease (CKD) and has been associated with signs of renal damage such as albuminuria, intrarenal vascular stiffness and tubular atrophy in several conditions. The mechanisms underlying the effects of UA on renal proximal tubular epithelial cells (PTCs) have not been elucidated. In CKD, increased apoptosis contributes to cell loss and structural damage. We investigated the effect of UA on apoptosis in human PTCs line (HK-2) and the underlying mechanisms.

**Methods:** Apoptotic damage was induced by serum deprivation and adding UA at different concentrations (7,5 -12 mg/dl) for 48 hours. Cell viability was evaluated by MTT test and apoptosis by positivity for cleaved caspase-3 (p17 fragment). Pro- and anti-apoptotic proteins were studied by Western Blot. The pathways involved in UA apoptosis were investigated by Caspase inhibitors, NADPH Oxidase inhibitor (DPI), urate transporter antagonists (losartan and probenecid).

**Results:** Highest UA concentration decreased tubule cell viability (-30%, p=0.015) and increased significantly apoptotic cells (14%±0,35 vs 2%±0,87 untreated cells p=0.0001). UA up-regulated Bax ( +60% p<0.05) and down regulated X-linked inhibitor of apoptosis protein (XIAP) (-30% p<0.05).Caspase-9 inhibitor blunted apoptosis, while caspase-8 inhibitor had no effects. UA induced changes in the mitochondrial membrane as shown by mitocapture apoptosis assay. DPI had inhibitory effects on apoptosis (-70%, p=0.0001). Incubation with probenecid 20 μM and losartan 10 μM inhibited apoptosis induced by 12 mg/dl UA exposition (p<0.01 and <0.0001, respectively).

**Conclusions:** These results indicate that mildly elevated UA levels promote apoptosis in PTCs by triggering intrinsic caspase activation, thus contributing to mechanisms of cell loss which have been already shown to be activated in CKD. This mitochondrial pathway seems to be attenuated by losartan and probenecid, probably through their binding to URAT-1. These findings support a role for UA in promoting renal injury in humans.

## TH-PO133

**Effect of the F11R Receptor Antagonist P4D on Human Renal Mesangial Cells (HRMCs)** Anna Babinska, Albert Sohn, Sabeen Khan, Isabelle Ayoub, Moro O. Salifu. *Div of Nephrology, SUNY Downstate Medical Center, Brooklyn, NY.*

**Background:** We recently tested and demonstrated the expression of F11R (a receptor involved in atherosclerosis), on mesangial cells. The presence of F11R on mesangial cells and other cells of mesenchymal origin (endothelial and smooth muscle cells) raises the question as to whether F11R may be involved in mesangial sclerosis associated with TGF beta such as seen in diabetic nephropathy. In this study, we tested the hypothesis as to whether the administration of specific F11R inhibitor peptide 4D (P4D) could inhibit glucose induced mesangial cell proliferation (formazan production) and TGF beta secretion.

**Methods:** Cultured HRMCs were treated with 500μM of Peptide 4D in the present of 10mM of glucose for 24h and 48 h and mitochondrial activity (Formazan production) using MTT Assay (Sigma) was measured, as a marker of proliferation. TGF beta secretion was measured using ELISA method. HRMCs with 10mM glucose plus P4D was Group A while HRMCs with 10mM glucose alone was Group B.

**Results:** There was a dose a dose dependent (100, 250 and 500 μM) inhibitory effect of P4D on proliferation of HRMCs. At 24 hours, there was a 12.7% inhibition of proliferation (formazan production) in HRMCs in Group A compared to Group B (100% vs. 87.3 ±1.3%, p=0.04). At 48 hours, there was 16.7% inhibition of proliferation in Group A compared to Group B (100% vs. 83.3±2.9%, p=0.01). The P4D induced inhibition of proliferation increased at 48 hours. With respect to TGF beta release, at 24 hours, there was no significant inhibition of TGF beta release in Group A (normalized at 10,000 cells) compared to Group B (12.1± 5.3 vs. 18.5± 8.8 pg/ml, p=ns). However at 48 hours, there was significant inhibition of TGF beta release in Group A compared to Group B (47.8±10.5 vs. 76.9±9.1 pg/ml, p=0.02). The P4D induced inhibition of TGF beta release increased at 48 hours.

**Conclusions:** We observed a dose dependent inhibitory effect of P4D on proliferation of HRMCs. Inhibitory effect of P4D on mesangial cell proliferation and TGF beta secretion in the present of glucose was also observed. Further studies are needed to determine the role of P4D in diabetic nephropathy.

## TH-PO134

**Senescent Renal Tubular Epithelial Cells Promote an Epithelial-Mesenchymal Transition State through the Paracrine Secretion of TGF-β1** Guangyan Cai, Jingchao Wang, Xiang-Mei Chen. *Dept of Nephrology, State Key Laboratory of Kidney Disease, Chinese PLA General Hospital, Beijing, Beijing, China.*

**Background:** Kidney aging is often associated with renal fibrosis, which leads to renal function decline. The relationship between senescence and fibrosis in the aging kidney was still unknown.This study is to investigate whether epithelial-mesenchymal-transition (EMT) develops in senescent renal tubular epithelial cells and the potential mechanisms.

**Methods:** We detected both senescent and EMT markers in aged kidney tissue from 24-month-old F344 rats, and in high glucose induced premature senescent primary proximal tubular cells (PTC). The conditional medium from senescent PTC was collected to co-culture with primary PTC for 48h to investigate its role in mediating EMT. p53 siRNA was introduced to inhibit PTC senescence. TGF-β1 protein level in the supernatant of senescent PTCs were evaluated by ELISA. TGF-β1 receptor I inhibitor was used to investigate the role of TGF-β1 signaling in mediating EMT during PTC senescence.

**Results:** In the aged kidney,SA-β-gal positive staining, decreased expression of E-cadherin and increased expression of α-SMA were observed in renal tubulo-interstitial fibrosis region. SA-β-gal positive staining,p53 and p21 expressions were significantly increased in PTC induced by high glucose for 24h.While decreased expression of E-cadherin and increased expression of vimentin and α-SMA,were found in PTC after high glucose treatment for 48h, which suggested that senescence developed earlier than EMT in PTC.Conditional medium from senescent PTC down-regulated E-cadherin but up-regulated vimentin and α-SMA expressions of primary PTC. Silenced p53 inhibited the PTC senescence and further inhibited EMT state through paracrine effect.Conditioned medium from senescent PTC contained high level of TGF-β1 by ELISA. TGF-β1 receptor I inhibitor inhibited activation of Smad3 and Smad4, and blocked pro-EMT effect of the conditioned medium from senescent PTC.

**Conclusions:** Senescent PTCs promote an EMT state through the paracrine secretion of TGF-β1, which might play an import role in renal fibrosis during kidney aging.

## TH-PO135

**Uremia Triggers Differentiation of Proatherogenic $CD14^{++}CD16^{+}$ Monocytes** Adam M. Zawada, Jenny Sarah Schneider, Kyrill S. Rogacev, Danilo Fliser, Gunnar H. Heine. *Internal Medicine IV - Nephrology and Hypertension, Saarland Univ Medical Center, Homburg, Saarland, Germany.*

**Background:** Monocytes, the central drivers of vascular inflammation, are a heterogenous cell population. Three monocyte subsets are characterized flow-cytometrically: classical CD14++CD16-, intermediate CD14++CD16+ and non-classical CD14+CD16++ monocytes. Recently we provided evidence that CD14++CD16+ monocytes are independent predictors of cardiovascular outcome in patients with chronic kidney disease (CKD). However, until now it remains enigmatic which mechanisms are responsible for the increase of CD14++CD16+ monocytes in CKD.

**Methods:** In order to analyze whether uremia *per se* induces shifts in monocyte subsets we developed a method for *in vitro* monocyte subset differentiation. Hematopoetic stem cells were isolated (CD34 Microbead Kit, Miltenyi) and cultivated in the presence of TPO, SCF, Flt-3L and IL-3 to generate monocyte subsets. In addition, media were supplemented with 10 % uremic or control sera. Expression of signature markers of CD14++CD16+ monocytes (CCR5, ACE, TLR2, TLR4, CD74, HLADR, Tie2 and ENG) as well as their functional characteristics (ROS production and phagocytosis) were also determined by flow-cytometry.

**Results:** Uremia induced differentiation of CD14++CD16+ monocytes (percentages of CD14++CD16+ monocytes at day 6 of differentiation; control: 9.8 ± 1.4 %, uremia: 14.5 ± 2.5 %; $p < 0.05$). Moreover, expression of TLR2 on CD14++CD16+ monocytes was significantly increased under uremic conditions, whereas expression of other surface markers was not altered. Finally, CD14++CD16+ monocytes differentiated in presence of uremia produced significantly more reactive oxygen species ($p < 0.05$) and showed higher phagocytosis capacity ($p < 0.05$).

**Conclusions:** We show for the first time that uremia *per se* induces differentiation of CD14++CD16+ monocytes. These results may contribute to a better understanding of monocyte dysregulation in CKD patients. Further studies will have to analyze which uremic factors are responsible for the increase in CD14++CD16+ monocytes in CKD.

## TH-PO136

**Transfection of sirt-1 Gene Decreases the Apoptosis of Podocyte under the Diabetic Condition** Eun Kyoung Lee,[1] Kyung Sun Park,[2] Jai Won Chang,[3] Hyun woo Kim.[4] *[1]Internal Medicine, Dankook Univ Hospital, Cheonan, Republic of Korea; [2]Internal Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea; [3]Internal Medicine, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea; [4]Internal Medicine, Jeju National Univ Hospital, Jeju, Republic of Korea.*

**Background:** Podocyte injury plays a role in the pathogenesis of diabetic nephropathy, leading cause of end-stage renal disease. The human sirt-1 gene, the mammalian ortholog of yeast Sir2, is associated with prolonged life span.

**Methods:** We performed this study as the first step to investigate whether the prevention of apoptosis of podocyte under the diabetic condition can ameliorate decline of renal function. The human nephrin promoter was inserted into the plasmid including human sirt-1 gene. We used lipofectamin for the transfection of final plasmid into the mouse podocytes. We compared the degrees of apoptosis between transfected and non-transfected podocytes under the mixture of 30 mM of glucose, 200 μM of linoleic acid and 1 μM of angiotensin II.

**Results:** Human sirt-1 gene tranfected podocytes decreased the degree of apoptosis of them in dose-dependent manner, confirmed by reduction of caspase-3 via western blot ($p < 0.05$). The plasmid containing only nephrin promoter did not show the anti-apoptotic effect on podocytes under the same condition (p = NS). These results were determined by the protein produced by sirt-1 gene which was confirmed by polyclonal antibody to sirt-1 derived protein ($p < 0.05$). The addition of 2 μM of resveratrol, sirt-1 activator, potentiated anti-apoptotic effect of sirt-1 gene in the podocyte confirmed by further decreasing the concentration of caspase-3 ($p < 0.05$). In contrast, podocyte culture with 10 mM of nicotinamide, sirt-1 antagonist, completely reverse previously mentioned anti-apoptotic effect of sirt-1 confirmed by further increasing caspase-3 ($p < 0.05$).

**Conclusions:** Current findings suggest that the activation of human sirt-1 gene in the podocyte reduce the apoptosis of them under the diabetic milieu.

## TH-PO137

**The Basal Expression of Key Autophagy Genes Is Reduced in the Hearts of Uremic Rats** William Edward White, Julius Edward Kieswich, Andrew Duncan Stewart Findlay, Steven Michael Harwood, Magdi Yaqoob. *William Harvey Research Institute, Barts & The London, Queen Mary School of Medicine & Dentistry, London, United Kingdom.*

**Background:** End stage renal disease (ESRD) is characterised by an accelerated aging phenotype. Normal and pathological aging is associated with a decrease in autophagy, the process by which worn out and dysfunctional cellular components are delivered to lysosomes for degradation. A reduction in basal autophagy may thus be implicated in accelerated aging seen in ESRD. We have analysed the expression of autophagy genes in cardiac tissues in a rat model of uremia to determine whether this differs from that in healthy animals.

**Methods:** Rats were rendered uremic using an adenine diet. RNA was purified from cardiac tissues from these and age and sex matched controls and reverse transcribed. Real-time PCR was performed using a Qiagen autophagy-dedicated microarray. Fold change in gene expression between the control and uremic group was calculated using 2 (-Δ Δ Ct) method using the manufacturer's data analysis software.

**Results:** The expression of 21 of 84 autophagy-related genes tested was ≥ 2-fold down-regulated in the uremic compared to the control group (n=3). Key genes involved in autophagosome formation *Ambra1*, *Atg4b*, *Atg7*, *Atg9a*, *Atg101* and *ULK1*, autophagy regulating genes *Arsa*, *Bak1*, *Bid*, *Cxcr4*, *Dapk1*, *Dram2*, *Mapk14*, *Nfkb1*, *Pink1*, *Park2*, *Rgs19*, *Tgfb1*, *and Tm9sf*, and lysosome-related genes *Cln3* and *Ctsd* were all down-regulated. The genes encoding traditionally investigated autophagy-related proteins LC3 and Atg5 were also down-regulated, but less than 2-fold.

**Conclusions:** Although limited, these preliminary investigations suggest a reduced expression of several key autophagy genes in the hearts of uremic rats. Whilst this needs to be corroborated with translational evidence of impaired autophagy, previous studies have demonstrated corresponding changes in mRNA levels of autophagy genes associated with changes in autophagy activity, thus these results suggest that basal autophagy is impaired. Given that impaired autophagy is associated with ageing, it may have a role in pathological aging in ESRD, and may be a target for pharmacological interventions to correct this.

## TH-PO138

**Identification of Small Molecule Inhibitors of Kidney Podocyte Injury Using High Content Imaging** Kenneth Young,[1] Insa Winzenborg,[2] Uwe Andag.[3] *[1]In Vitro Pharmacology, Evotec AG; [2]Screening Operations, Evotec AG, Hamburg, Germany; [3]Diabetic Complications, Evotec AG, Goettingen, Germany.*

**Background:** Podocytes are essential constituents of the glomerular filtration barrier. Diabetic nephropathy, the leading diagnosis in end-stage renal disease, is recognized to involve injury or loss of podocytes with the resultant onset of proteinuria. High content imaging using cellular screening assays with predictive relevance to human disease states provides a mechanism for identifying novel drug targets. As part of a greater CureNephron initiative, Evotec has screened for small molecule inhibitors of kidney podocyte injury using treatment with palmitate combined with high glucose to mimic diabetic conditions. The primary screen measured apoptosis in human conditionally immortalized podocytes, while secondary assays measured changes in the podocyte actin cytoskeleton.

**Methods:** In total, 50,000 maximally diverse compounds were screened from Evotec's drug discovery library. Apoptosis was quatified using a caspase 3/7 detection reagent (Essen BioSciences) measured on an Opera automated confocal imaging platform. In conjunction, a small number compounds from a commercially available annotated library were also screened. Amongst these, compounds with known podocyte protective qualities were identified thereby providing proof of concept for the assay set-up.

**Results:** With the set threshold the screen identified 48 novel hits capable of reducing palmitate/high glucose-induced podocyte apoptosis. Of these, 7 compounds were also able to reduce podocyte apoptosis in response to addition of puromycin aminonucleoside. Further characterization of selected hits indicated that all compounds were able to reduce palmitate/high glucose-induced changes in the podocyte actin cytoskeleton. Key compounds (demonstrating 40–80% protection, and 0.4–1.8 μM potency) were then selected for hit expansion.

**Conclusions:** Evotec have identified novel compounds suitable for small molecule derived target deconvolution. These compounds may enable the identifation of novel druggable targets capable of reducing podocyte injury and hence having therapeutic potential against diabetic nephropathy.

## TH-PO139

**Role of Adapter Protein Nck in Actin Polymerization Mediated by Dynamin** Valentina A. Shchedrina, Sanja Sever. *Dept of Medicine, Nephrology Div, Massachusetts General Hospital, Charlestown, MA.*

**Background:** Nck is an adaptor protein that links receptor and receptor-associated tyrosine kinases with proteins that directly or indirectly regulate reorganization of actin cytoskeleton. For example, Nck binds to plasma membrane protein, nephrin, a key structural and signaling component of the slit diaphragm in podocytes, and to downstream effectors that regulate actin cytoskeleton. Based on our hypothesis SH3 domains of Nck1 interact with proline-rich domain of dynamin (dyn) and facilitate dynamin oligomerization that causes actin polymerization at membrane vicinity.

Thus, we investigated whether SH3 domains of Nck1 can regulate dynamin oligomerization state and subsequent actin remodeling in podocytes.

**Methods:** To study a possibility of the Nck-driven dynamin oligomerization *in vitro*, two methods were applied. First, the GTPase activity of human dyn isoform 1 (dyn1) was measured in the presence of SH3 domains of human Nck1. Second, dynamin oligomerization state was detected using fluorescence-lifetime imaging microscopy (FLIM) of ECFP/EYFP-tagged dyn1 in the presence of SH3 domains of Nck1. To study a possibility of Nck-driven actin reorganization *in vivo*, podocytes overexpressing SH3 domains of Nck1 were stained with actin antibodies and changes in actin cytoskeleton were detected by confocal microscopy.

**Results:** Binding SH3 domains of Nck1 to dyn1 to promotes dynamin oligomerization and increases the rate of GTP hydrolysis. Nck1-SH3 domains increase the rate of GTP hydrolysis in concentration-dependent manner that reflects specificity of this interaction. In addition, FLIM analysis detected dynamin oligomerization upon interaction with SH3 domains of Nck1.

**Conclusions:** Our data suggest that Nck-driven dynamin oligomerization could contribute in actin cytoskeleton regulation and that in this case dynamin is one of the downstream effector of the nephrin-Nck signaling pathway.

**miR-34c Ameliorates Renal Fibrosis via Down-Regulation of Jagged1** Ryuji Morizane, Toshiaki Monkawa, Shizuka Fujii, Hiroshi Itoh. *Internal Medicine, Keio Univ School of Medicine, Tokyo, Japan.*

**Background:** micro RNAs (miRNAs) are small non-coding RNAs that act as posttranscriptional repressors by binding to the target mRNAs. On the other hand, mesenchymal-epithelial transition (EMT) and renal fibrosis are pathological process of chronic kidney disease (CKD), and the relationship to miRNAs is becoming recognized as a potential target for CKD therapies.

**Methods:** We examined miRNA expression in three experimental models; unilateral ureteral obstruction (UUO) of mice, TGF-β on a mouse renal tubular cell line (MCT) as EMT models, and Activin induced renal epithelialization of mouse embryonic stem cells as an epithelialization model. We performed microarray of miRNA using these three experimental models. We found three miRNAs involved in these three models, and analyzed functions of one of three miRNAs using TGF-β and UUO.

**Results:** We identified three miRNAs presumably involved in EMT using microarray analysis, and focused on one of three miRNAs, miR-34c. Over-expression of miR-34c under TGF-β stimulation in MCT significantly attenuated up-regulation a mesenchymal gene, Snail1, and retained a epithelial gene, KSP-cadherin. To confirm these effects of miR-34c, we performed over-expression of miR-34c in mice with UUO. Mice were injected with miR-34c precursor from the tail vein, and the unilateral ureter was subsequently ligated. On day 7 of UUO, we harvested kidneys, and analyzed EMT and renal fibrosis using real-time PCR and α-SMA staining. miR-34c injected mice showed significantly less fibrosis than sham injected mice, and Snail1 and Vimentin were significantly suppressed by miR-34c. To find the target mRNA of miR-34c, we have examined the expression of genes that were known to involve in TGF-β pathway and have a complementary sequence to miR-34c. PCR and Western blot showed miR-34c significantly suppressed Jag1 while TGF-β up-regulated Jag1.

**Conclusions:** We have identified a new miRNA involved in EMT and renal fibrosis. miR-34c attenuated EMT and renal fibrosis in UUO mice via down-regulation of Jag1, and our study suggested a new therapeutic approach for renal fibrosis.

## TH-PO141

**Collagen I Downregulates the Inner Medulla Tubular Cells AQP2 Expression and Traffic through Integrin Linked Kinase (ILK)** Jose Luis Cano-Peñalver,[1] Mercedes Griera,[1] Alicia Luengo,[1] Andrea Garcia-Jerez,[1] Nuria Troyano,[1] Diego Rodriguez-Puyol,[2] Sergio De Frutos Garcia,[1] Manuel Rodriguez-Puyol.[1] *[1]Biología de Sistemas, Unidad Fisiología, Universidad de Alcala, Alcala de Henares, Madrid, Spain; [2]Fundacion de Investigacion Biomedica, Hospital Universitario Principe de Asturias, Alcala de Henares, Madrid, Spain.*

**Background:** Progressive interstitial fibrosis produces structural changes in the kidney, where abnormal extracellular matrix (ECM) may lead to functional changes.

The collecting tubule AQP2 modifies the tubular water reabsorption through transcriptional and postraslational regulations of its content as well as its quick cytoplasm-to-apical membrane trafficking. ECM messenger ILK (integrin linked kinase) modulates different transcription factors as well as cytoskeleton function.

**Methods:** We studied the ILK implication in the AQP2-dependent tubular absorption by using an in vitro model of cultured inner medulla collecting duct cells line (mIMCD3) over collagen I (COL I) or inactive gelatine as control. We depleted ILK expression in mIMCD3 by transfection with specific siRNAs.

**Results:** We previously shown (ASN kidney week 2012) that in vivo model of conditional ILK-deletion in adult mice, basal poliuria and decreased urine osmolality was due to cortical and medullar AQP2 expression and cytoplasm-to-apical traffic downregulation. LK-depleted mIMCD3 have decreased expression and cytoplasm-to-membrane traffic of AQP2, both in basal conditions or under activation with desmopressin. ILK-depleted cells, where AQP2 activity was diminished, got a lower decrease in intracellular osmolality under hypotonic stress. Confirming that changes in ECM components may modify AQP2, COL I-cultured cells have diminished ILK expression, AQP2 expression and traffic, as the intracellular osmolality change under hypotonic stress compared with gelatine-cultured control cells.

**Conclusions:** ILK levels decreased by ECM component COL I or by siRNA transfection in mIMCD3, reducing the water reabsorption capability, due to impaired ILK-dependent AQP2 expression and traffic.

## TH-PO142

**Cellular Inhibitor of Apoptosis Protein 1 (cIAP1) Represses Albumin-Induced Chemokines and Adhesion Molecules Synthesis by Kidney Tubular Epithelial Cells** Joseph C.K. Leung,[1] Ai Ing Lim,[1] Loretta Y.Y. Chan,[1] Wai Han Yiu,[1] Kar Neng Lai,[2] Sydney C.W. Tang.[1] *[1]Dept of Medicine, The Univ of Hong Kong, Hong Kong; [2]Dept of Health Assessment, Hong Kong Sanatorium and Hospital, Hong Kong.*

**Background:** Protein overload activates proximal tubule epithelial cells (PTEC) to release chemokines and stimulates inflammatory response in the interstitium. Bone morphogenic protein-7 (BMP-7) has been shown to reduce infiltrating cells and kidney damage in acute and chronic renal failure. The present study examines the inhibitory effects and the relevant molecular mechanism of BMP-7 on chemokines and adhesion molecules synthesis by PTEC activated with human serum albumin (HSA).

**Methods:** PCR array was used to screen the expression profiles of chemokines and adhesion molecules in cultured human PTEC. The molecules that were upregulated by HSA and can be significantly reduced by BMP-7 were identified. The kinetic of their expression in PTEC was determined by RT-PCR and ELISA. The activation of NF-κB and the relevant molecules of the signaling pathways were examined by RT-PCR, western blotting, immunofluorescence microscopy and transcriptional factors ELISA.

**Results:** Expression of CXCL1, CXCL2 and VCAM-1 by PTEC was upregulated by HSA, and the expression was significantly reduced by BMP-7. Further experiments confirm that BMP-7 reduced the HSA up-regulated gene and protein expression of CXCL1, CXCL2 and VCAM-1 dose and time dependently. HSA activated both the canonical and noncanonical NF-κB pathways in PTEC, as shown by the reduced expression of IκB, the nuclear translocation of p50 and p52, and data from the transcriptional factor ELISA. The NF-κB activation was repressed by BMP-7. Interestingly, the HSA-upregulated expression of cIAP1 and TRAF3 by PTEC, was further increased by BMP-7. To the contrary, the expression of NIK in PTEC was increased by HSA but down-regulated by BMP-7.

**Conclusions:** Our data suggest that HSA up-regulates CXCL1, CXCL2 and VCAM-1 *via* both the canonical and noncanonical NF-κB pathways in PTEC. BMP-7 suppresses these events through increased production of cIAP-1 and TRAF3, which inhibits the accumulation of NIK and the subsequent activation of NF-κB pathways.

## TH-PO143

**The Protective Effect of Adrenomedullin on Liver Injury Induced by Bilateral Nephrectomy or Renal Ischemia-Reperfusion in Mice** Tatsuhiko Tabata,[1] Saki Takahashi,[1] Hiroko Sonoda,[1] Yu Miyahara,[1] Mari Isomi,[1] Johji Kato,[2] Kazuo Kitamura,[3] Masahiro Ikeda.[1] *[1]Veterinary Pharmacology, Univ of Miyazaki, Miyazaki, Japan; [2]Frontier Science Research Center, Univ of Miyazaki, Miyazaki, Japan; [3]Internal Medicine, Univ of Miyazaki, Miyazaki, Japan.*

**Background:** Experimental studies have shown that acute kidney injury (AKI) induces distant organ failure including hepatic dysfunction. However the mechanism of AKI-induced hepatic dysfunction remains unclear. Recent studies have suggested that uremic toxin causes tissue injury, which is mediated by a mechanism related to hypoxia.

**Methods:** In this study, therefore we examined whether hypoxia-related mechanisms are involved in AKI-induced hepatic injury using two mice models of bilateral nephrectomy (BNx) and renal ischemia-reperfusion (I/R).

**Results:** Plasma urea nitrogen, creatinine, aspartate transaminase, and alanine transaminase were significantly increased 6 and 24 h after induction of either BNx or I/R, compared with those of sham-operated animals. PCR array analyses showed that BNx and I/R up-regulated 20 genes associated with hypoxia, including adrenomedullin (AM), and down-regulated 6 genes. As AM has been reported to have protective effect against tissue injury, we then analyzed the expression level of AM-related genes, including AM binding protein-1 and AM receptor components such as calcitonin receptor-like receptor (CRLR) and receptor activity-modifying protein (RAMP) 2 and 3. Real-time PCR analyses showed that BNx and I/R up-regulated RAMP2 and RAMP3 within 32 h after either operation. Finally, we examined the effect of AM on BNx- or I/R-induced liver injury in vivo. AM (10 mg/kg) was intraperitoneally administered to mice 30 min before and just after each operation. AM significantly lessened the severity of liver injury 24 h after each AKI-operation, without improving renal function, in comparison with controls.

**Conclusions:** These results suggest that the hypoxia-related mechanism is involved in AKI-induced hepatic injury, and that AM may have the potential to protect against AKI-induced liver injury.

## TH-PO144

**Study of NOV/CCN3 Expression and Effects in Different In Vivo Models of Chronic Kidney Disease** Pierre-Olivier Marchal,[1] Chantal Kazazian,[1] C. Chatziantoniou,[2] Christos E. Chadjichristos,[2] Cécile Martinerie.[1] *[1]INSERM UMRS_938/UPMC, Paris, France; [2]INSERM UMR_702/UPMC, Paris, France.*

**Background:** Independently of its origin chronic kidney disease (CKD) results in high inflammation and fibrosis. Current treatments are partially effective and consequently new therapeutic targets are required. NOV/CCN3 was reported to be antifibrotic with pro-angiogenic and anti-mesangioproliferative effects in anti-Thy1.1 model and to inhibit profibrotic CTGF/CCN2 in mesangial cells. NOV is a secreted multifunctional protein belonging to the CCN family involved in different physiological and pathological processes (angiogenesis, inflammation, cancers). To further explore NOV involvement in CKD we analyzed its expression in other *in vivo* models and tested its ability to modulate expression of profibrotic and inflammatory molecules.

**Methods:** NOV expression was analyzed at various times in the following models: renin transgenic mice (RenTg) at early stages (9-12-21w) and late stages (53w), Angiotensin II (AngII) perfused mice (1-2-4w) and unilateral ureteral obstruction (UUO, 3-7-15d). In these models expression of NOV, profibrotic and inflammatory molecules were assessed in cortex by RT-qPCR and Western blot. NOV *in vitro* effects were studied on rat aortic vascular smooth muscle cells (VSMC).

**Results:** In RenTg mice we observed two phases: one early in which NOV expression was increased by AngII (3.5 folds, 12w), especially in VSMC, then returned at basal level (21w) and one late in which NOV was correlated with the increase of TNFα (53w). In VSMC NOV downregulated profibrotic AT1R (90%) and CTGF (40%) whereas it stimulated *MCP-1 (23 folds) and was increased by TNFα (3.5 folds). In AngII-perfused mice and UUO we also observed a correlation between* NOV, TNFα and MCP-1. Moreover, NOV injection stimulated MCP-1 in kidney of healthy mice.

**Conclusions:** Our results suggests that NOV could have a dual role: protective at early stage but participates to inflammation at late stage of CKD. Ongoing experiments on NOV KO mice should bring us more evidences to this hypothesis.

## TH-PO145

**$P2Y_{12}$ Receptor Protein Is Co-Localized with AQP2 in the Collecting Duct Principal Cells of Rat and Mouse** Bellamkonda K. Kishore,[1] Janos Peti-Peterdi,[2] Karie G. Villanueva,[2] David L. Strasburg,[1] Noel G. Carlson,[1] Donald E. Kohan,[1] Yue Zhang.[1] *[1]VA Medical Center & Univ of Utah, Salt Lake City, UT; [2]Univ of Southern California, Los Angeles, CA.*

**Background:** $P2Y_{12}$ receptor (R) is an ADP-activated G protein-coupled receptor that inhibits adenylyl cyclase activity, thus potentially reducing cellular cAMP levels. We observed that administration of clopidogrel (Plavix®), which irreversibly blocks $P2Y_{12}$-R, significantly increased urinary concentration and protein abundance of AQP2 in the medulla, and ameliorated lithium-induced polyuria in rats. Immunoblots using a commercial antibody confirmed the expression of $P2Y_{12}$-R protein in the kidney, however, the precise cellular localization of it in the kidney has not yet been established.

**Methods:** We generated and characterized a peptide-derived rabbit polyclonal antibody specific for a 16-amino acid C-terminal sequence of mouse $P2Y_{12}$-R, which differs from rat sequence by only one amino acid residue. This peptide has no sequence identity with $P2Y_{13}$, $P2Y_{14}$, GPR34, GPR82, GPR87, or GPR171. The affinity purified antibody was used in immunoperoxidase and confocal immunofluorescence microscopy to localize $P2Y_{12}$-R protein expression in normal healthy rat and mouse kidneys and to compare its distribution to that of AQP2.

**Results:** In both rat and mouse renal cortex, strong labeling for $P2Y_{12}$-R was seen on the brush border of the proximal tubules (PT). Moderate labeling was seen in the vascular smooth muscle cells (VSMC) of large and small arterioles. Weaker labeling was found at the apical membrane of the collecting ducts (CD) in the cortex and medulla, co-localizing with AQP2. $P2Y_{12}$-R labeling in CD was present exclusively in AQP2-positive cells suggesting expression in principal, but not intercalated cells.

**Conclusions:** The observed expression pattern of $P2Y_{12}$-R and AQP2 in vasopressin-responsive CD principal cells is consistent with the in vivo effects of pharmacological blockade of $P2Y_{12}$-R in normal and lithium-treated animals. The functional significance of the expression of $P2Y_{12}$-R on the brush border of PT cells and in the cortical arterioles needs to be elucidated.

## TH-PO146

### Elevated Soluble Tumor Necrosis Factor Alpha Receptor 1 and 2 Concentrations in Hemodialysis Patients Are Not Reflected by Alterations in Membrane Expression

Nathalie Neirynck, Griet Lrl Glorieux, Eva Schepers, Annemieke Dhondt, Raymond C. Vanholder. *Nephrology Div, Ghent Univ Hospital, Belgium.*

**Background:** Elevated serum concentration of soluble TNFα receptor 1 (sTNFR1) and 2 (sTNFR2) and TNFα in hemodialysis (HD) patients are at least in part attributed to decreased renal clearance. It is not known whether the membrane expression of these receptors is altered in HD and as a consequence also contributes to the differences in serum concentration and possibly to the altered leukocyte function in HD patients, since membrane expression of TNFR1 and 2 is important for TNFα signal transduction. In this study, the soluble and membrane expression of TNFR1, 2 and TNFα were determined in parallel in order to unravel the link between both.

**Methods:** Whole blood samples of healthy controls (C) and predialysis samples of HD patients were labelled with fluorescent anti-membrane (m)TNFR1, anti-mTNFR2 and anti-mTNFα and analyzed by flow cytometry (n= 8). The mean fluorescence intensity (MFI) was measured when all leukocytes were gated together (tMFI), as well as the MFI of the monocytes, granulocytes and lymphocytes when gated separately. Soluble concentrations were measured by ELISA.

**Results:** The soluble concentrations were markedly higher in HD for sTNFR1 (C: 993 vs HD: 9558 pg/ml, $p < 0.001$), sTNFR2 (C:2245 vs HD: 16344 pg/ml, $p < 0.001$) and TNFα (C: 2.2 vs 9.9 pg/ml, $p < 0.001$), while the total leukocyte membrane expression did not differ for mTNFR1 (tMFI: C: 682 vs HD: 693, p = NS), mTNFR2 (tMFI: C: 762 vs HD: 852, p = NS) and mTNFα (tMFI: C: 616 vs HD 670, p = NS). Furthermore, evaluating the different leukocyte subtypes separately, there was also no difference in receptor expression on monocytes, granulocytes and lymphocytes, except for the expression of mTNFR2, which was decreased on lymphocytes in HD compared to C (C: 648 vs HD: 521, $p < 0.05$).

**Conclusions:** This study suggests that the elevated concentrations sTNFR1 and sTNFR2 in hemodialysis patients compared to healthy controls were rather due to a decreased renal clearance than an altered cellular expression.

## TH-PO147

### Blockage of IL-8 Receptor Signaling Inhibits Cyst Development in ADPKD

Jong Hoon Park, Eunji Lee, Je Yeong Ko. *Biological Science, Sookmyung Women's Univ, Seoul, Korea.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is one of the most highly prevalent inherited disorders and results in the progressive development of thousands of cysts in both kidneys. There are several signaling pathways, which are already known or continuously identifying as well, to initiate and lead to the progression of ADPKD. Some cytokines and growth factors secreted by the cyst-lining epithelia were defined to initiate and promote cyst growth. In our previous study, interleukin (IL)-8 increased significantly in cells following knockdown of Mxi1, an antagonist for c-myc, which is overexpressed in ADPKD.

**Methods:** We used WT9-7 and WT9-12 as human PKD cell lines and the HRCE cell line as the control. Interlukin-8 was measured by enzyme-linked immunosorbent assay and the expression of IL-8 receptor or other signaling molecules were checked by western blot. IL-8 signaling was inhibited either by IL-8 receptor antagonist treatment or gene siliencing of receptor. Inhibiting effect on IL-8 signaling and cell proliferation was tested by western blot and XTT assay, respectively. Finally, 3D culture of MDCK cells under antagonist treatment or knockdown of IL-8 receptor was performed to identify the effect on kidney cystogenesis *in vitro.*

**Results:** In this study, we focused on whether IL-8 signaling is associated with renal cyst formation, and tested the possibility of IL-8 as a new therapeutic target for PKD. First, IL-8 secretion and expression of its receptor increased remarkably in human PKD cells. Furthermore, receptors specific for IL-8 was easily detected particularly at the cyst-lining epithelial cells of the kidney in human patients with PKD. IL-8 secretion decreased under treatment with an IL-8 receptor antagonist, and activation of the signaling molecules diminished as well. A three-dimensional culture was performed to understand how IL-8 affected cyst formation, and resulted in alleviation of cystogenesis after blocking the IL-8 receptor signals.

**Conclusions:** These results suggest that IL-8 and its mediating signals might be a factor stimulating cystogenesis in ADPKD and have potential as a new biomarker and therapeutic target for the disease.

## TH-PO148

### Prostaglandin E2 Inhibits Growth and Stimulates Sodium Transporters through EP4, but Increases Fibronectin and ROS Production through EP1 in Mouse Proximal Tubule Cells

Rania Nasrallah, Andrew J. Karam, Richard L. Hebert. *Kidney Research Centre, Cellular and Molecular Medicine, Univ of Ottawa, Ottawa, Canada.*

**Background:** Proximal tubule (PT) growth promotes PT hyper-reabsorption in chronic kidney disease, which in turn contributes to hyperfiltration. Prostaglandin (PG) $E_2$ is a key regulator of renal growth and tubular transport, but its role in the PT is unknown.

**Methods:** Transforming growth factor β (TGFβ) is a main regulator of PT in kidney disease, thus we compared the effects of $PGE_2$ to TGFβ. Mouse PT cells (MCT) were stimulated for 24 hours with $PGE_2$, in the presence or absence of TGFβ.

**Results:** By Realtime PCR we showed that $PGE_2$ $EP_1$ receptors are increased 2-3 fold by $PGE_2$ and TGFβ, but $EP_4$ is unchanged. $EP_1$ was inhibited with the $EP_1$ receptor antagonist ONO-8711. Both TGFβ and $PGE_2$ attenuated DNA and protein synthesis, with 50-80 % reductions in $H^3$-thymidine and $H^3$-leucine incorporation, the inhibition was additive upon co-stimulation. In MCT lysates assayed by Western blotting, the cyclin-dependent kinase inhibitor p27 is increased 2-fold by $PGE_2$; TGFβ attenuated the $PGE_2$ response upon co-stimulation but ONO-8711 had no effect. In contrast TGFβ but not $PGE_2$ increased p21 by 4-fold. While TGFβ increases cyclin D1 up to 3-fold, $PGE_2$ alone had no effect, but it attenuated TGFβ-mediated cyclin D1. Na-K-ATPase α1 (NaK) was increased 2.5-fold by $PGE_2$. TGFβ had no effect on NaK, but attenuated $PGE_2$-stimulated NaK to 0.6-fold of control. Consistently, TGFβ also reduced $PGE_2$-stimulated sodium hydrogen exchanger NHE1 by 50% and NHE3 by 70%, but neither was affected by ONO-8711. $PGE_2$ and TGFβ also increased fibronectin levels in MCT, by 2-fold and 6-fold respectively. Finally, $PGE_2$ increased ROS generation (lucigenin activity) by 2-fold. ONO-8711 blocked $PGE_2$-mediated fibronectin and ROS.

**Conclusions:** In summary, $PGE_2$ and TGFβ are acting via different mechanisms to inhibit the cell cycle, and have opposite effects on sodium transporters. Accordingly, $PGE_2$ stimulates fibronectin and ROS generation via $EP_1$ receptors, but affects growth and sodium transporters via $EP_4$ pathways in the proximal tubule.

*Funding:* Government Support - Non-U.S.

## TH-PO149

### Autophagy Is Impaired in Unilateral Ureteral Obstruction (UUO) Model of Renal Fibrosis

Yang Ou,[1] Djamali Muhoza,[1] Christian Herzog,[1] Randy S. Haun,[2,3] Gur P. Kaushal.[1,3] *[1]Internal Medicine, Univ of Arkansas for Medical Sciences; [2]Pharmaceutical Sciences, Univ of Arkansas for Medical Sciences; [3]Central Arkansas Veterans Healthcare System, Little Rock, AR.*

**Background:** Autophagy is a highly conserved protein degradation system in eukaryotes. Very little is known about the role of autophagy during progressive renal fibrosis. We examined whether renal fibrosis results from defective autophagy using UUO as a model of renal fibrosis.

**Methods:** Renal fibrosis was induced in mice using the UUO model. Autophagy was inhibited by autophagy flux inhibitor chloroquine and upregulated by autophagy enhancing drug Torin-1. We used Beclin-1 transgenic (Beclin-1 Tg) mice under the control of the androgen-inducible KAP2 (kidney androgen-regulated protein) promoter and obtained overexpression of Beclin-1 in the proximal tubules.

**Results:** The autophagy-related proteins Beclin-1, Atg5, Atg7, and Atg12, and the conversion of LC3-I to LC3-II, were increased at 1d, 3d, 5d, and 9d after UUO. Production of matrix proteins including α-SMA, fibronectin, and collagen-I was elevated following UUO. Accumulation of autophagy-specific substrate p62, Keap1, ubiquitinated proteins and LC3-I/LC3-II conversion were observed in obstructed kidneys. The level of p62 and LC3-I/LC3-II conversion were not further increased in UUO mice administrated with chloroquine, indicating that autophagy is impaired during the progression of renal fibrosis. Concomitant accumulation of p62, Keap1, ubiquitinated proteins supports the notion that autophagy is defective in the UUO model since Keap1 is degraded in a p62-dependent manner and p62 plays a central role for targeting ubiquitinated proteins to autophagosomes. Accumulation of p62 and collagen-I was slightly reduced in Beclin-1 Tg mice and in mice receiving Torin-1, suggesting that impaired autophagy status following UUO injury could not be efficiently recovered by upregulation of autophagy.

**Conclusions:** Accumulation of renal fibrosis is accompanied by defects in autophagy in the UUO model. Overexpression of Beclin-1 in transgenic mice and administration of Torin-1 were unable to completely overcome the autophagy deficiency.

## TH-PO150

**Endostatin – A Contributor to Fibrosis of Aging Kidney** Chi Hua Sarah Lin, Jun Chen, Michael S. Goligorsky. *New York Medical College, Valhalla, NY.*

**Background:** Aging is associated with progressive organ fibrosis. Microvascular rarefaction is a permanent companion of fibrotic process occurring with a relative synchrony in all organs, kidney included, partly due to impaired angiogenesis in the elderly. Therefore, we hypothesize that a common denominator - an anti-antigenic substance - might exist to explain it.

**Methods:** Endostatin, a key anti-angiogenic factor, is a 20-22 kDa c-terminal fragment of collagen XVIII, a ubiquitous component of sub-endothelial membranes especially in vessels with fenestrated endothelium, like those in renal glomeruli and peritubular capillaries. Therefore, we sought to investigate the level of endostatin in kidney and plasma of aging mice by immunoblotting and ELISA as well as cellular effect of endostatin.

**Results:** In aged mice (22 mo-old) kidney, the expression of p16 gene and the ratio of short/long (S/L) endoglin, markers of senescence, were increased as examined by RT-PCR. Examination of aged kidney showed decreased microvascular density. The protein level of endostatin in the plasma and kidney samples from aged mice was 2 and 3 fold increased. To understand cellular effects of Endostatin, we isolated primary endothelial cells (ECs) from kidney of control mice by enzymatic digestion followed by double selection on CD31-coated magnetic beads. The isolated ECs (CD31+, VE-cadherin+ and Endoglin+) were treated with mouse Endostatin at concentrations 25 μg/ml for 5.5 days. Cells showed signs of impaired angiogenesis, as evidenced by decreased formation of cord-like structures. Endostatin treatment also decreased VE-cadherin expression with a concomitant increase in the expression of α-smooth muscle actin in primary EC, indicative of a phenotypic switch toward endothelial-mesenchymal transition.

**Conclusions:** These data document that 1) Endostatin levels are increased in the aged kidney and plasma and 2) Endostatin causes primary ECs transdifferentiation into mesenchymal-like cells. This mechanism of endostatin action may account for microvascular rarefaction of kidney aging.

## TH-PO151

**RNA-Seq Mapping of G Protein-Coupled Receptor Expression along the Nephron and Collecting Duct** Jae Wook Lee, Fahad Saeed, Chung-Lin Chou, Mark A. Knepper. *NIH.*

**Background:** G protein-coupled receptors (GPCRs) are important regulators of physiological function in renal tubule epithelia. Here we describe the expression profile of all known GPCRs along the renal tubule using RNA-seq.

**Methods:** We manually microdissected each renal tubule segment from collagenase-treated rat kidneys, using a high resolution microscopy system capable of discriminating cell types. After reverse transcription and amplification, cDNA libraries were sequenced using an Illumina HiSeq 2000 sequencer. Sequences were mapped to the rat reference genome (rn4) and expression levels were calculated in 'reads per kilobase exons per million mapped reads' (RPKM). GPCRs were identified from the list of all expressed genes (PANTHER search term "G protein-coupled receptor").

**Results:** Of 853 annotated rat GPCRs, 60 GPCRs had RPKM > 1.0 in at least one renal tubule segment. Expression patterns of vasopressin receptors (*Avpr1a* and *Avpr2*), calcium-sensing receptor (*Casr*), and other receptors (*Pth1r*, *Gcgr*, *Calcr*, and *Ptger3*) were consistent with the literature. Based on rule-based clustering algorithm, we identified segment-specific expression patterns for additional GPCRs. These include: growth hormone-releasing hormone receptor (*Ghrhr*) in the thin descending and ascending limbs (median RPKM 647.0 and 17.5); taste receptor type 1, member 1 (*Tas1r1*) in the medullary and cortical thick ascending limbs (6.1 and 3.1); frizzled proteins in the connecting tubule, cortical collecting duct, and outer medullary collecting duct (*Fzd1*, 8.9, 31.8, 11.5 and *Fzd4*, 44.1, 27.4, 14.7); soluble frizzled-related protein 2 (*Sfrp2*) in the cortical collecting duct and distal convoluted tubule (50.5 and 60.8); and purinergic receptors in the collecting duct (*P2ry2* in the cortical collecting duct, 6.6; *P2ry14* in the outer medullary collecting duct, 166.7). Eleven orphan GPCRs were found: *Gpr56* and *Gprc5c* showed widespread expression along the renal tubule.

**Conclusions:** Further studies are needed to assign physiological functions to the GPCRs not previously known to be expressed in the kidney. Additional analysis of these RNA-seq data (in addition to GPCR genes) will provide further information on segment-specific signaling pathways.

## TH-PO152

**APOL1 Risk Variants Cause a Greater Increase in Autophagy, Apoptosis and Necrosis in Podocytes, Accompanied by Decreased Podocyte Viability Compared to Wild-Type APOL1** Xiqian Lan, Kang Cheng, Partab Rai, Tejinder Singh, Nirupama Chandel, Rivka Lederman, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical Center, Great Neck, NY.*

**Background:** Compared with European Americans, African Americans develop much higher rates of nephropathy including hypertension-associated end-stage renal disease (ESRD), focal segmental glomerulosclerosis (FSGS), and HIV-associated nephropathy (HIVAN). Recently, emerging reports show that this major health disparity is strongly associated with two coding sequence variants in the *APOL1* gene encoding Apolipoprotein L1 (ApoL1). However, the cellular function of Apol1 and the role of these variants in the risk for nephropathy are still unknown.

**Methods:** Lentiviruses for over expression of ApoL1 wild type and variant proteins were constructed, using constructs kindly provided by the laboratory of Karl Skorecki at the Technion in Haifa. Human podocytes were infected with these lentiviruses. Western blots, MTT assay, and staining assays with acridine orange, Annexin V, or 7-AAD were performed to compare the effects of wild type and variant Apol1 on human podocytes.

**Results:** Western blots results showed that ApoL1 wild type and variant proteins were successfully over expressed in human podocytes. Staining assays revealed that over expression of wild type ApoL1 increased autophagy, apoptosis, and necrosis; while all of these effects were further increased by overexpression of the Apol1 risk variants. MTT assay indicated that cell viability was dramatically decreased by Apol1 risk variants.

**Conclusions:** Apol1 risk variants displayed cytotoxicity to podocytes through enhancing autophagy, apoptosis, and necrosis. Since loss of podocytes is an initiating step in the development of FSGS, the present study supports a pathogenic role for podocyte expression of APOL1 risk variants in the development of kidney lesions in in susceptible subjects.

## TH-PO153

**Effect of Uremic Toxins on Leukocytes: The Enigma of Organic Solute Transport Finally Unraveled** Eva Schepers,[1] Henricus A.M. Mutsaers,[2] Annemieke Dhondt,[1] Nathalie Neirynck,[1] Rosalinde Masereeuw,[2] Raymond C. Vanholder,[1] Griet Lrl Glorieux.[1] *[1]Internal Medicine, Nephrology Divsion, Ghent Univ Hospital, Ghent, Belgium; [2]Pharmacology and Toxicology, Radboud Univ Nijmegen Medical Centre, Nijmegen, Netherlands.*

**Background:** Several uremic toxins (UT), both protein bound and not, have been shown to cause leukocyte dysfunction. As a consequence of the increased levels of UT in the circulation in chronic kidney disease, induction of cytotoxicity must be linked to increased cytoplasmic levels. However, until now, the expression of organic uptake transporters, as abundantly expressed on e.g. proximal tubular cells, has never been demonstrated on leukocytes.

**Methods:** Monocytes were isolated by a positive selection using MACS after Ficoll density gradient centrifugation from healthy controls (C) and hemodialysis patients (HD). Gene expression of the uptake transporters organic anion transporter 1 (OAT1), OAT3, organic cation transporter 2 (OCT2), OATpolypeptide4C1 (OATP4C1) was evaluated using RT-pPCR. In addition, expression at protein level of OATP4C1 [mean fluorescence intensity (MFI)] was evaluated by flow cytometry.

**Results:** Only the uptake transporter, OATP4C1, was expressed in monocytes. No difference in OATP4C1mRNA levels could be observed in monocytes from HD (n=9) versus C (n=10) (ΔCt: 7.9±0.4 vs. 8.1±0.6,NS). Protein expression of OATP4C1 on monocytes was confirmed by flow cytometry also revealing expression on lymphocytes and granulocytes. However, no significant difference in the protein expression level in HD (n=8) versus C (n=4) was observed (470±139 vs. 479±155; 282±102 vs. 272±120; 532±146 vs.692±181, respectively, NS). OATP4C1 was significantly more expressed on monocytes and granulocytes compared to lymphocytes ($P<0.05$).

**Conclusions:** These data show for the first time the expression of an organic uptake transporter protein, OATP4C1, on leukocytes. This transporter has been suggested to play a role in the uptake of the known UT. Thus, diffferent UT could enter leukocytes via OATP4C1 contributing to many of the known cytotoxic effects. The functionality of the transporter in HD remains to be evaluated but this protein could be a target for preventing cytotoxicity in CKD.

## TH-PO154

**Nanoscale Protein Architecture of the Mouse and Human Kidney Glomerular Basement Membrane** Hani Suleiman,[1] Lei Zhang,[1] Jeffrey H. Miner,[2] Andrey S. Shaw,[1] Adish Dani.[1] *[1]Pathology & Immunology, Washington Univ, Saint Louis, MO; [2]Renal Div, Washington Univ, Saint Louis, MO.*

**Background:** In multicellular organisms, proteins of the extracellular matrix play structural and functional roles in a variety of organs, so understanding ECM protein organization is an important goal. The kidney glomerular basement membrane (GBM) is a unique, thick BM that is an integral part of the glomerular filtration barrier and participates in filtering large volumes of plasma to form the ultrafiltrate. The GBM is thought to result from fusion of two distinct basement membranes secreted by two different cells, podocytes and endothelial cells.

**Methods:** We used well characterized epitope-specific antibodies to carry out sub-diffraction resolution stochastic optical reconstruction microscopy (STORM) and deep-etch electron microscopy correlation to resolve the in situ molecular organization of proteins within the mouse and human GBM.

**Results:** We constructed a molecular reference frame that revealed a laminar organization of ECM proteins within the GBM. Agrin, a large heparan sulfate proteoglycan, was localized in two parallel leaflets with a peak distance between each other of 138 nm. With agrin as a reference, we mapped the position of a panel of molecules in the GBM, including the integrin b1 ectodomain. The laminin α5 C-terminus co-localized with podocyte and endothelial cell integrin b1, whereas the more N-terminal LM-521 epitopes were found near the center of the GBM, revealing a definitive orientation. The human GBM possesses a dense layer of collagen α3α4α5(IV) covering more than 50% of the GBM's thickness, but it is excluded from the GBM's edges where integrin b1 penetrated.

**Conclusions:** Separate analyses of domains near the N- and C-termini of agrin, laminin, and collagen IV in mouse and human revealed a highly organized arrangement within the GBM, visualized *in situ*. The results are consistent with separate basement membrane layers contributed by podocytes and endothelium. Integrin b1's major ligands are likely the laminin a5 C-terminus and agrin.

**Indoxyl Sulfate Signals for Rapid mRNA Stabilization of Cbp/p300-Interacting Transactivator with Glu/Asp-Rich Carboxy-Terminal Domain 2 (CITED2) and Suppresses the Expression of Hypoxia-Inducible Genes in Experimental CKD and Uremia**

Tetsuhiro Tanaka, Junna Yamaguchi, Yoshiki Higashijima, Masaomi Nangaku. *Div of Nephrology and Endocrinology, Univ of Tokyo School of Medicine, Tokyo, Japan.*

**Background:** Tubulointerstitial hypoxia serves as a final common pathway in progressive renal disease. Circumstantial evidence suggests that the function of hypoxia-inducible factor (HIF)-1 may be suppressed in a CKD milieu. In this study, we investigated the effect of indoxyl sulfate (IS) on the expression of hypoxia-inducible genes in vitro and in vivo.

**Methods:** In vitro, the expression of HIF-1α, CITED2 and HIF-1 target genes was quantified by immunoblotting and real-time PCR. Binding of HIF-1 to the target gene promoters was evaluated by chromatin immunoprecipitation (ChIP). mRNA stability of CITED2 was measured by actinomycin D treatment. The role of MAP kinase pathways was evaluated by using specific inhibitors. In vivo, the effect of IS on HIF-1 target genes was investigated in the rat remnant kidney, with or without the oral adsorbent, AST-120. Additionally, angiogenic, HIF-1 target genes was quantified in the isoproterenol-induced heart failure (HF) model in rats treated with or without Indole.

**Results:** In vitro, IS reduced the hypoxic induction of HIF-1-target genes, which was not associated with quantitative changes in HIF-1α, but with the functional impairment of the HIF-1α C-terminal transactivator domain (CTAD). Among candidate suppressors of the HIF-1αCTAD, CITED2 was significantly upregulated by IS. The induction of CITED2 was mediated by posttranscriptional mRNA stabilization through the ERK1/2 signaling. In a CKD model in vivo, tubular expression of several HIF-1-target genes, such as vascular endothelial growth factor (VEGF) and heme oxygenase-1 (HO-1) was markedly restored by treatment with AST-120. Furthermore, Indole significantly suppressed the induction of hypoxia-inducible, angiogenic genes in rats with heart failure.

**Conclusions:** Results of these studies reveal a novel role of IS in modulating the transcriptional response of HIF-1 and provide insight into the molecular mechanisms underlying progressive nephropathies as well as cardiorenal anemia syndrome.

## TH-PO156

**Pharmacological Blockade of ADP-Activated $P2Y_{12}$ Receptor in Rat IMCD Potentiates dDAVP-Induced AQP2, AQP3 and V2 Receptor Expression**

Yue Zhang,[1] Younis Baqi,[2] Noel G. Carlson,[1] Donald E. Kohan,[1] Christa E. Müller,[2] Bellamkonda K. Kishore.[1] *[1]VA Medical Center & Univ of Utah, Salt Lake City; [2]Univ of Bonn, Bonn, Germany.*

**Background:** $P2Y_{12}$ receptor (R) is an ADP-activated G protein-coupled receptor that inhibits adenylyl cyclase activity. We found that $P2Y_{12}$-R protein is expressed in rat renal medullary collecting ducts (IMCD), and its irreversible blockade by the administration of clopidogrel (Plavix®) significantly increased urinary concentration and protein abundance of AQP2 in the medulla. These effects were not seen in Brattleboro rats, which genetically lack arginine vasopressin (AVP). So, in order to understand the exact relationship between AVP and $P2Y_{12}$-R here we used PSB-0739, a potent non-nucleotide antagonist of $P2Y_{12}$-R in primary cultures of rat IMCD cells, and examined the interaction between the $P2Y_{12}$-R and AVP, in relation to AQP2 expression.

**Methods:** PSB-0739 was synthesized and characterized by the methods established in our laboratory. Primary cultures of rat IMCD cells grown in Transwell® inserts were incubated with no agents (control) or dDAVP (50 nM) or PSB-0739 (100 nM) or a combination of these agents for 24 h (n = 6 inserts/condition). Cells were harvested, mRNA extracted, reverse transcribed and real-time RT-PCR was performed for AQP2, AQP3 and V2-R. Expression levels of target genes were normalized to that of β-actin.

**Results:** PSB-0739 alone did not affect AQP2 expression, but dDAVP alone increased AQP2 expression by 9.5-fold. Combination of PSB-0739 and dDAVP further increased AQP2 expression by 3.4-fold (i.e., 32-fold vs. controls). PSB-0739 also enhanced dDAVP-induced modest expression of AQP3 and V2-R, making them significantly higher than the control group ($P < 0.05$).

**Conclusions:** These data suggest that blockade of $P2Y_{12}$-R in IMCD in the absence of dDAVP has little or no effect, but it markedly potentiates the effect of dDAVP on AQP2, AQP3 and V2-R expression. This is the first example showing that pharmacological blockade of a purinergic receptor in IMCD can markedly potentiate the effect of AVP on AQP2, AQP3 or V2-R expression, thus emphasizing the significance of autocrine/paracrine regulation by extracellular nucleotides.

## TH-PO157

**Targeting PHD2 with Antisense ASOs Can Increase Erythropoietin Production for the Treatment of Anemia Associated with Chronic Kidney Disease**

Sue Murray, Raechel Peralta, Melanie Katz, Andy Watt, Shuling Guo, Gene Hung. *Antisense Drug Discover, ISIS Pharmaceuticals, Carlsbad, CA.*

**Background:** Anemia is a prevalent and premature comorbidity in chronic kidney disease (CKD). It is associated with multiple adverse clinical consequences including increased mortality. Today Erythropoiesis-stimulating agents (ESAs), together with iron supplementation, are the cornerstones of therapy for correcting anemia in CKD patients. Prolyl hydroxylase domain protein 2 (PHD2) is an oxygen/redox-sensitive enzyme that induces cellular adaptations to stress conditions. Inactivation of Phd2 enhances a hypoxia-inducible transcription factor (HIF)-mediated detoxification program in healthy organs, which prevents oxidative damage, organ failure, and tissue demise. In the present study, we examined the effects of reducing PHD2 mRNA expression in liver and kidney in balb/c mice, using an optimized antisense oligonucleotide (ASO) designed specifically for PHD2.

**Methods:** ASO was administered subcutaneously at a dose of 25mg/kg, twice a week for 3 weeks.

**Results:** ASO treatment caused ~80% and 65% reduction in PHD2 mRNA expression in liver and kidney respectively. A 7-fold increase in spleen weight was observed as compared to saline treated group, similar to what was observed in PHD2 conditional knockout mice (BLOOD, 15 March 2008, Vol 11 (6) 3229-3235). In addition, PHD2 ASO treated kidney EPO mRNA levels were increased 600 fold compared to the saline treated group. Further analysis of the kidney by in-situ EPO RNA staining confirmed the increase and showed it to be localized to the cells in the interstitial space. As a result, serum EPO levels were also elevated after PHD2 ASO treatment, ~5000 ± 128 (pg/ml) in PHD2 treatment group compared to saline control group, which is ~60 ± 13 (pg/ml).

**Conclusions:** In conclusion, specific reduction of PHD2 with ASO treatment in mice increased EPO production and this approach may have therapeutic implications for treatment of anemia associated CKD.

## TH-PO158

**Four-Week Safety, Efficacy and Pharmacodynamic Study of Prolyl Hydroxylase Inhibitor GSK1278863 in Anemic Non-Dialysis Subjects Not Receiving Recombinant Human Erythropoietin**

Louis Holdstock, Amy M. Meadowcroft, Rayma Maier, Delyth Jones, Brendan Johnson, Alexander Ralph Cobitz, John J. Lepore. *GlaxoSmithKline.*

**Background:** Prolyl hydroxylase inhibitors (PHIs), such as GSK1278863, are an emerging therapeutic class of oral agents for the treatment of anemia. PHIs inhibit hypoxia inducible factor (HIF)-prolyl hydroxylases, resulting in accumulation of stable HIFα transcription factors, thus stimulating pathways activated during hypoxia, including erythropoiesis and iron mobilization. PHIs raise hemoglobin (Hgb) concentrations with lower circulating erythropoietin (EPO) levels than recombinant human erythropoietins (rhEPOs; Provenzano, 2011), therefore potentially reducing the increased cardiovascular risk that has been associated with rhEPO therapy (Pfeffer, 2009).

**Methods:** This randomized, placebo-controlled, double-blind study explored the relationship between GSK1278863 dose and Hgb response in 73 subjects with anemia secondary to chronic kidney disease (CKD; stage 3-5) who were naïve to rhEPO and non dialysis dependent (NDD). The study also explored the effects of GSK1278863 on circulating EPO, hepcidin and vascular endothelial growth factor (VEGF) levels. Subjects with a stable baseline Hgb of 8.5-11.0g/dL were randomized to receive 0.5, 2 or 5mg GSK1278863 or placebo for 4 weeks.

**Results:** GSK1278863 produced a dose-dependent change in mean Hgb from baseline at Week 4 (placebo: -0.26g/dL; 0.5mg: 0.12g/dL; 2mg: 0.32g/dL; 5mg: 0.95g/dL). Hepcidin levels also decreased in a dose-dependent manner. The increases in Hgb occurred with small, dose-dependent increases in EPO within or close to the normal physiologic range and no changes in VEGF. GSK1278863 was generally safe and well tolerated.

**Conclusions:** These data inform the dose-response relationship of GSK1278863 for Hgb elevation in anemic NDD CKD subjects not receiving rhEPO, and they suggest that GSK1278863 can raise Hgb within a clinically relevant range with small elevations in EPO and without increasing VEGF.

## TH-PO159

**Hepcidin in Chronic Kidney Disease after Iron Infusion and Its Relationship to Haemoglobin Increment**

Sourabh Chand,[1] Douglas G. Ward,[2] Zhi-Yan Valerie Ng,[1] Mark Trehane Drayson,[2] Richard Borrows.[1] *[1]Queen Elizabeth Hospital Birmingham, United Kingdom; [2]Univ of Birmingham.*

**Background:** There is a drive to use less EPO and more iron infusions for CKD anaemia management but this still comes at a financial and potentially toxic cost. Hepcidin is an iron regulator which promotes iron retention in the reticulo-endothelial system. We investigated hepcidin and traditional clinical iron markers to their predictive utility to haemoglobin (Hb) increment post iron infusion and what influences hepcidin levels in CKD.

**Methods:** Over a 6 month period, 129 consecutive non-dialysis CKD patients attended our bolus Ferinject® service as part of their anaemia management. Hepcidin levels as determined by mass spectrometry, transferrin saturation (TSAT), ferritin, eGFR, liver function tests, Hb and high sensitive CRP levels (hsCRP) were measured pre iron infusion and 6 weeks later.

**Results:** Ferinject® mean dose was 12.6mg/Kg. Ferritin and TSAT were highly correlated. In a multivariate model (adjusted for ferritin, hsCRP, eGFR, age, iron dose/weight, gender, functioning renal transplant, access, use of:ESA, anti-proliferative, ACE I/ARB, low B12 and a low folate) only ferritin was significantly associated with hepcidin levels (CI 0.594 (0.473-0.715) p<0.001). eGFR was the only predictor of pre-infusion Hb level in a multivariate model adjusted for the same variables (CI 1.42 (0.23-2.61) p=0.02). In the multivariate model with the addition of pre-infusion Hb adjustment, hepcidin was an independent predictor of Hb increment post Ferinject® infusion (CI -0.84 (-1.38 to -0.31) p=0.002). Ferritin, TSAT and hepcidin had similar predictive utility for a 1g/dL Hb increase post Ferinject® infusion (c-statistics: 0.68, 0.70, 0.69). Alkaline phosphotase was significantly increased post Ferinject® infusion (p<0.001).

**Conclusions:** Hepcidin is an iron storage marker which is moderately predictive for Hb increment following iv Ferinject® infusion. Although displaying similar predictive performance to ferritin and TSAT, hepcidin may also play a mechanistic role. This data suggests hepcidin antagonists may be of use for patients with higher hepcidin levels to increase iron utilisation following intravenous infusion.

## TH-PO160

### Atherosclerotic Plaque Characterization and Heme Oxygenase-1 Expression in Chronic Kidney Disease: The 'Vulnerable Plaque Phenotype'

Kristien El Daenen,[1] Inge Fourneau,[2] Eric Verbeken,[3] Bert Bammens.[1] *[1]Laboratory of Nephrology, KU Leuven, Belgium; [2]Vascular Surgery, KU Leuven, Belgium; [3]Dept of Imaging and Pathology, KU Leuven, Belgium.*

**Background:** CKD is characterized by accelerated atherosclerosis as compared to the general population. Heme Oxygenase-1 (HO-1), an inducible heme degrading enzyme, is protective against atherosclerosis and has a major role in plaque stabilization a.o. through inhibition of monocyte migration and differentiation.

**Methods:** Patients planned for peripheral artery or abdominal aorta aneurysm surgery were included to retrieve an arterial biopsy during surgery (n=82). For the purpose of this study, the biopsies of 23 patients with CKD stages 3-5D were compared with those of 36 patients without CKD. Atherosclerotic plaques were scored blindly for lesion type [intimal thickening or xanthoma (IT or IX), (thin) fibrous cap atheroma ((T)FCA) or fibrocalcific plaque (FCP), according to an adapted scoring system based on the AHA classification by Virmani et al], presence of inflammation and/or plaque complications (erosion, rupture, hemorrhage, not specified). HO-1 expression was judged semi-quantatively by immunostaining of the paraffin sections.

**Results:** CKD and non-CKD patients were well-matched for Framingham risk factors, cardiovascular event history and lipidlowering therapy. There was an equal distribution of lesion types in the two groups. Plaques of CKD patients showed higher inflammatory activity by higher number of foam cells, independent of statin use (p 0.035). There were more complicated plaques in the CKD group (p0.03). There was clear HO-1 expression in (T)FCA and FCP, but the semi-quantitative scoring system didn't reveal any significant differences between the CKD and non-CKD patients.

**Conclusions:** Atherosclerotic plaques of CKD patients have higher inflammatory activity and higher rates of complications as compared to non-CKD patients. These findings are supportive for a 'vulnerable plaque phenotype' of atherosclerosis in CKD. Expression of HO-1, although known to play a role in plaque stabilisation, is not different between the two groups. Whether this finding represents a relative lack of HO-1 effectivity in CKD needs further investigation.

## TH-PO161

### LDL Receptor Deficient Mice Are a Suitable Model of Aggravated Atherosclerosis in Renal Impairment and the Impact of Bone Marrow Derived Cytokines

Sibylle Von Vietinghoff, Shuwang Ge, Barbara Hertel, Inga Soerensen, Hermann G. Haller. *Internal Medicine, Hannover Medical School, Germany.*

**Background:** Chronic kidney disease significantly elevates the risk of atherosclerosis. Inflammatory leukocyte infiltration of the vascular wall is mediated by specific cytokines in normal kidney function. To date, the experimental study of atherosclerosis in renal failure has used the Apolipoprotein E deficient mouse that is limited by (a) excessive hyperlipidemia and (b) the fact that ApoE is expressed in diverse cell types including bone marrow cells. This study evaluated LDL receptor deficient (LDLr-/-) mice regarding renal function and the suitability of bone marrow transplantation for ablation of a specific cytokine.

**Methods:** LDLr-/- mice underwent unilateral nephrectomy or sham surgery and were maintained on high-fat diet for six weeks. Glomerular filtration rate was assessed by FITC-inulin clearance. Bone marrow transplantation was conducted after lethal irradiation two weeks before renal surgery, efficacy was assessed by PCR and flow cytometry. Aortic lesion size was quantified histologically and leukocyte infiltration determined by confocal microscopy and flow cytometry.

**Results:** Unilateral nephrectomy did not significantly alter serum creatinine but reduced measured glomerular filtration rate by 30% six weeks after surgery. This significantly increased aortic root lesion size. Similar effects were observed in male and female mice. Circulating leukocyte, erythrocyte and thrombocyte counts, total cholesterol and triglycerides were not significantly altered, however, in renal impairment there was a trend towards increased LDL and vLDL assessed by lipid chromatography. Renal impairment enhanced aortic leukocyte accumulation and proliferation. Bone marrow transplantation depleted specific T cell cytokine expression and decreased the effect of renal impairment on atherosclerotic lesion size.

**Conclusions:** Unilateral nephrectomy significantly decreases GFR and increases atherosclerotic lesion size in LDLr-/- mice. Reconstitution with specific cytokine deficient bone marrow in this model is a new approach for the study of the impact of kidney function on inflammation in atherosclerosis.

*Funding:* Government Support - Non-U.S.

## TH-PO162

### Possible Involvement of microRNAs in Vascular Damage in Experimental CKD

Fatiha Taibi,[1] Valérie Metzinger-Le Meuth,[2] Eleonore Ourouda Mbaya,[1] Laurent Metzinger,[1] Ziad Massy.[3] *[1]Univ Picardie Jules Verne, Amiens, France; [2]Univ Paris 13 Nord, Paris, France; [3]Chief, Div of Nephrology, Paris-Ile-de-France-Ouest Univ (UVSQ), Paris, France.*

**Background:** Chronic kidney disease (CKD) is associated with vascular calcifications and atherosclerosis. There is a need to discover novel biomarkers in order to achieve earlier diagnosis of these disorders, predict illness progression and response to adjuvant therapy. We focused on microRNAs since they are implicated in a variety of cellular functions in cardiovascularphysiopathology.

**Methods:** We examined changes over time in microRNAs in aortas of CKD and non-CKD wild type mice and of CKD and non-CKD apolipoprotein E knock-out mice. We evaluated the expression of miRNAs known to be implicated in vascular biology (miR-126, -143, -145, -221, -222 and -223), in order to assess their prognostic significance.

**Results:** The vascular smooth muscle-specific miR-143 and miR-145 were lowered in the pathological states and the level of protein target Myocardin was accordingly increased. The inflammatory miR-223 was increased at the later stages of CKD, and specific protein targets NFI-A and GLUT-4 were dramatically decreased. Expression of miR-126 was severely increased and expression of protein targets VCAM-1 and SDF-1 was altered during the course of CKD. Finally, we detected marginal changes in miR-221 and miR-222 expression. The phosphate binding drug sevelamer alleviates miRNA deregulations suggesting a direct link between the miRNA alterations we found and vascular disorders.

**Conclusions:** In conclusion, miR-126, -143, -145 and -223 are deregulated during the course of aortic vascular calcification and atherosclerosis in our CKD and atherosclerotic models, and are thus potential biomarkers of these diseases.

*Funding:* Government Support - Non-U.S.

## TH-PO163

### Apolipoprotein B/A1 Ratio, as a Risk Predictor of Cardiovascular Disease in Patients with Chronic Kidney Disease

Soo Bong Lee, Il Young Kim, Dong Won Lee, Min Ji Shin, Byeong Yun Yang, Harin Rhee, Eun Young Seong, Ihm Soo Kwak. *Dept of Internal Medicine, Pusan National Univ School of Medicine, Republic of Korea.*

**Background:** The apolipoprotein B/A1 ratio (apoB/A1) was known to be risk predictor of cardiovascular disease (CVD). CVD is the leading cause of death in chronic kidney disease (CKD) patients. Measuring carotid artery intimal-medial thickness (CIMT) is non-invasive modality used to evaluate subclinical atherosclerosis and to predict future CVD. In this study, we hypothesized that apo B/A1 could be associated with CVD in CKD patients and investigated the association between apo B/A1 and CIMT.

**Methods:** We retrospectively reviewed the 293 patients who had visited the health screening and promotion center in our university hospital in Korea. The patients were divided into 2 group which are CKD group (n=99, estimated glomerular filtration rate (eGFR): 15-59 mL/min and non-CKD group (n=194, eGFR $\geq$ 60 mL/min). Information on demographics and clinical data were obtained in each patient at the time of measuring CIMT. CIMT was measured by high-resolution B-mode ultrasonography. To investigate which factors are associated with CIMT in each 2 groups, simple and multiple linear regression analysis between variables in baseline characteristics and CIMT were performed.

**Results:** In simple linear regression analysis, non-CKD group showed age, presence of diabetes and presence of hypertension correlated with CIMT. However, in CKD group, not only age, presence of diabetes and presence of hypertension but also apo B/A1(r=0.521, P<0.001) correlated with CIMT. In multiple linear regression analysis, non-CKD group showed age, presence of diabetes, and presence of hypertension were independently associated with CIMT. In CKD group, apo B/A1 in addition to age , presence of diabetes, and presence of hypertension was independently associated with CIMT.

**Conclusions:** This study showed serum apo B/A1 was independently associated with CIMT only in CKD group, not in non-CKD group. Because CIMT is a strong predictor of CVD, the result of this study demonstrates serum apo B/A1 could be included in cardiovascular risk stratification in CKD patients.

## TH-PO164

### Increased Inducibility of Ventricular Arrhythmia in a Rat Model of Chronic Kidney Disease

Chia-Hsiang Hsueh,[1] Neal X. Chen,[2] Peng-Sheng Chen,[1] Shien F. Lin,[1] Sharon M. Moe.[2] *[1]Div of Cardiology, Indiana Univ, Indpls, IN; [2]Div of Cardiology, Indiana Univ, Indpls, IN.*

**Background:** Patients with chronic kidney disease (CKD) suffer from higher incidence of cardiovascular mortality than those without CKD and over 25% of patients on dialysis die of sudden cardiac death (SCD). The mechanisms remain unclear. We used a rat model to study mechanisms of sudden cardiac death in CKD.

**Methods:** We studied 7 normal rats (NL) and 9 Cy/+ Han:SPRD rat with CKD (CKD) at 35-45 weeks old, which we have observed to have unexpected sudden death with progressive CKD. Hearts were removed for Langendorff perfusion and optical mapping.

We determined ventricular fibrillation (VF) inducibility, action potential duration (APD), calcium transient duration (CaT), dominant frequency during VF and used real time PCR to gauge gene expression.

**Results:** CKD rats had higher blood urea nitrogen (BUN) than control (52.4±6.9 vs. 23.8±1.5 mg/dL, p<0.01). Echocardiography and histology documented hypertrophic myocardium in CKD rats, but the LV ejection fraction of CKD rats was comparable to that of normal rat (69±3 vs. 72±4 %). CKD rats had longer RR interval (237±11 ms) than normal (206±9 ms, p<0.05). APD at the 80% of repolarization (APD80) in CKD rats (78±5) was longer than normal (61±4 ms, p<0.05), but CaT80 was unchanged (98±4 vs. 91±4 ms). VF was induced in 7 of 9 CKD rats compared to 1 of 7 normal rats (p<0.05). Dominant frequency during VF was higher in CKD rats (26.5±1.2 Hz) than in NL rats (19.8±2.0 Hz, p<0.05). There was up-regulation of calcium transporters (TRCP6 and NCX1), angiotensin 1 receptor, and TGFβ1 mRNA (p<0.05) suggesting altered micro-environment in CKD rats that are known to predispose to arrhythmias.

**Conclusions:** CKD rats with advanced CKD, compared to age matched normal rats, had bradycardia, hypertrophic myocardium and longer APD than control. The hearts exhibited increased VF inducibility with slower activation rate (lower dominant frequency). These data demonstrate that structural and/or cellular level changes in CKD predispose to ventricular arrhythmias and are a likely etiology of the increased risk of ventricular arrhythmias and sudden cardiac death in CKD.

## TH-PO165

**Glyoxalase I Prevents Age-Related Endothelial Dysfunction through Modulation of eNOS Phosphorylation** Airi Jo,[1] Takamoto Ohse,[1] Hiroaki Nishimatsu,[2] Masao Takahashi,[3] Satoshi Unuma,[1] Takehiko Wada,[1] Yoichiro Ikeda,[1] Toshio Miyata,[4] Yasunobu Hirata,[3] Reiko Inagi,[1] Masaomi Nangaku.[1] *[1]Div of Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; [2]Dept of Surgical Sciences / Urology, The Univ of Tokyo, Tokyo, Japan; [3]Dept of Cardiovascular Medicine, The Univ of Tokyo, Tokyo, Japan; [4]United Centers for Advanced Research and Translational Medicine, Tohoku Univ, Sendai, Japan.*

**Background:** Development of chronic kidney disease (CKD) is closely related to aging. Both glycative stress and endothelial dysfunction are linked to aging-associated changes including CKD. To elucidate the mechanisms for CKD progression in elderly patients, we investigated how glycative stress alters endothelial function with aging, using experimental anti-glycation model rats with systemic overexpression of glyoxalase I (GLO1), which detoxifies a representative glycation precursor methylglyoxal (MG).

**Methods:** Four groups of rats were examined, namely young (13-week-old) and mid-age (53-week-old) wild type (WT) and GLO1 transgenic (Tg) rats. Endothelial glycation level was evaluated by immunohistochemistry for MG-modified proteins. Age-related changes of endothelium-dependent and -independent vasorelaxation were assessed by vascular functional studies. To investigate the mechanism on the change of endothelial function, we studied nitrotyrosine formation, protein expression and post-translational modification of endothelial nitric oxide synthase (eNOS).

**Results:** Accelerated MG-modification of proteins by aging was significantly attenuated in Tg endothelium. Age-related impairment of endothelium-dependent vasorelaxation was attenuated in Tg rats, whereas vasorelaxation independent of endothelium was identical between WT and Tg rats. While total and dimeric form of eNOS did not differ between WT and Tg rats, inhibitory eNOS phosphorylation on Thr495, was increased with aging and was decreased in mid-age Tg rats compared with WT rats.

**Conclusions:** GLO1 attenuated age-related glycative stress and endothelial dysfunction in endothelium, with decreased eNOS phosphorylation on Thr495. Our study strongly suggests that regulation of glycative stress present a promising strategy for the prevention of aging and CKD.

## TH-PO166

**Impact of Vascular Calcifications Assessed by Simple Radiography in the Prognosis of Non-Dialysis Chronic Kidney Disease Patients: Results of the 3-Year Observational OSERCE-II Study** Jose L. Gorriz, Pablo Molina, Jordi Bover, Javier Nieto, Alberto M. Martinez-Castelao, Angel Luis M. De Francisco, Guillermina Barril, Maria angeles Guerrero-Riscos, Luis Miguel Molinero. *OSERCE-II Study Investigators, Spain.*

**Background:** Whereas the poor prognosis effect of the presence of vascular calcifications (VC) has been clearly defined in dialysis patients, their impact in the earlier stages of chronic kidney disease (CKD) is not well established. The present study evaluated the prevalence of the VC in non-dialysis CKD patients, its correlation with other cardiovascular risk factors, and its value for the prediction of death, hospitalizations and renal and cardiovascular events.

**Methods:** OSERCE-II is a multicenter, observational, prospective, study which enrolled 722 non-dialysis CKD subjects (3-stage: 40%; 4-stage: 46%; 5-stage:14%; mean age:66±13 years; women:35%; diabetes mellitus:37%) attending 39 hospitals in Spain from 2009 to 2012. At baseline, VC were assessed by the Adragao score (AS;X-ray pelvis and hands) and the Kauppila score (KS;X-ray lateral lumbar spine). Ankle-brachial index, blood pressure and biochemical parameters were measured. Cardiovascular and renal events and hospitalization episodes were assessed.

**Results:** VC were present in 79% of the patients, being prominent in 47% (AS ≥3:30%; KS>6:31%). During an observational period of 3 years there were 74 deaths(10%), 174 patients(24%) needed hospitalizations and 154 patients(21%) started dialysis treatment. Cardiovascular was the most common cause of death (42%). By multivariate analysis, the factors independently associated with mortality were age [OR:1.067(1.033-1.101); p<0.001], diabetes [OR:1.738(1.003-3.012); p=0.049] and AS ≥3 [OR:2.130(1.222-3.712); p=0.008]. Diabetes [OR:1.880(1.319-2.681);p<0.001], low albumin levels [OR:0.661(0.434-0.861); p=0.005] and KS>6 [OR:1.524 (1.056-2.199); p=0.024] were independent predictors of hospitalization. Patients with VC didn't showed higher risk for need to start dialysis.

**Conclusions:** VC detected by plain radiography is highly prevalent in CKD patient. AS and KS represent a reliable and inexpensive tool for the assessment of death and hospitalization risks in these patients.

## TH-PO167

**Histopathology of Peripheral Arterial Disease in Chronic Kidney Disease** W. Charles O'Neill,[1] Randolph A. Hennigar.[2] *[1]Renal Div, Emory Univ, Atlanta, GA; [2]Dept of Pathology, Emory Univ, Atlanta, GA.*

**Background:** Peripheral arterial disease is a serious problem in patients with end-stage renal disease (ESRD) and chronic kidney disease (CKD) but the underlying pathology, its relationship to vascular calcification, and whether it differs from that in patients without kidney disease is unclear.

**Methods:** A total of 175 arteries (45 above the knee and 130 below the knee) in lower limb amputations performed for critical limb ischemia in 60 patients were examined retrospectively by reviewing sections stained with hematoxylin and eosin.

**Results:** ESRD was present in 21 patients, CKD in 21, and no CKD (defined as a serum creatinine < 1.0) in 18. Mean age was 65.0 +/- 1.9 years and 58% had diabetes, which did not differ between groups. The serum creatinine was 1.6 +/- 0.1 and 0.80 +/- 0.03 in patients with and without CKD. Of the 15 patients using warfarin, 7 had ESRD and 6 had CKD. Intimal thickening was present in 92% of arteries but lipid accumulation and inflammation were each apparent in only a third of these. This did not differ between patients with ESRD, CKD, or no CKD. The prevalence of medial calcification was similar in CKD and non-CKD arteries (63%) but increased to 86% in ESRD arteries (p <0.01). The prevalence of intimal calcification increased from 29% to 43% to 52% in non-CKD, CKD, and ESRD respectively, but this was not significant. Both medial and intimal calcification were present in 35% of arteries and 46% of calcified arteries but the intimal calcification was almost always less extensive than the medial calcification. Arterial pathology was similar in diabetic vs. non-diabetic arteries, and warfarin use did not alter the prevalence or severity of either medial or intimal calcification.

**Conclusions:** The principal arterial lesions in ESRD and CKD patients with critical limb ischemia are non-atherosclerotic intimal thickening and medial calcification. Except for a greater prevalence of medial calcification in ESRD arteries, the histopathology did not differ from that in patients without CKD and was unaffected by diabetes or warfarin use. Most of the vascular calcification in lower extremities is medial rather than atherosclerotic.

## TH-PO168

**High Ankle Brachial Index Is Associated with Vascular Calcification in Chronic Kidney Disease** Jing Chen,[1] Matthew Jay Budoff,[2] Jiang He,[1] Faheemuddin A. Ahmed,[1] Yanxi Liu,[1] Chung-Shiuan Chen,[1] Heather LaGuardia,[1] Damodar R. Kumbala,[1] Arnold B. Alper,[1] Vecihi Batuman,[1] L. Lee Hamm.[1] *[1]Tulane Univ; [2]Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center in Torrance.*

**Background:** The ankle brachial index (ABI) is a noninvasive measure of subclinical CVD and atherosclerosis of the lower extremities. Recently, data suggested that high ABI was associated with cardiovascular mortality and vascular calcification in dialysis patients. However, the association of the spectrum of vascular calcification and high ABI is not well studied in pre-dialysis patients.

**Methods:** We investigated the association of vascular calcification with risk of high ABI (>1.4) in 243 patients with chronic kidney disease (CKD). Vascular calcification was assessed using electron-beam computed tomography (EBCT) and coronary artery calcification (CAC) Agatston score was calculated.

**Results:** CAC was classified as none (0), moderate (>0-100) or severe (>100) according to Agatston scores. Compared to those without CAC, the patients with moderate and severe CAC had increased risk of having high ABI. For example, the odds ratio (95% confidence interval) associated with moderate and severe CAC was 7.5 (1.0, 58.3) and 18.3 (2.6, 128.4) for ABI ≥ 1.4, respectively, after adjustment for age, gender, race, high-school education, physical activity, current cigarette smoking, weekly alcohol drinking, body mass index, LDL-cholesterol, plasma glucose, mean arterial pressure, estimated glomerular filtration rate, and history of cardiovascular disease.

**Conclusions:** These data indicate that CAC may be associated with risk of high ABI in patients with CKD independent of the risk factors for arthrosclerosis.

## TH-PO169

**Calcification Is a Risk Factor for Intraplaque Hemorrhage in Coronary Atherosclerosis of Patients with Chronic Kidney Disease: The Hisayama Study** Toshiaki Nakano,[1,2] Toshiharu Ninomiya,[1] Kazuhiko Tsuruya,[1] Yutaka Kiyohara,[3] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [2]Pathophysiological and Experimental Pathology, Kyushu Univ, Fukuka, Japan; [3]Dept of Environmental Medicine, Kyushu Univ, Fukuoka, Japan.*

**Background:** People with chronic kidney disease (CKD) are at the increased risk of coronary heart disease. We previously reported that CKD was associated significantly with severity of atherosclerosis and frequencies of intraplaque hemorrhages in coronary arteries(Am J Kidney Dis 2010:55:21-30, Kidney Int 2013:doi:10.1038/ki.2013.111). The aim of this study is to investigate the risk factors for intraplaque hemorrhage in coronary atherosclerosis among patients with CKD.

**Methods:** We randomly selected 126 subjects from 844 consecutive autopsy samples of residents of the town of Hisayama, Japan, and examined the frequencies of calcified lesions and intraplaque hemorrhages in coronary arteies. The three main coronary arteries were evaluated in each subject. The subjects were classified into four categories based on estimated glomerular filtration rate (eGFR): ≥ 60, 45-59, 30-44, and <30 ml/min/1.73 $m^2$.

**Results:** The frequencies of intraplaque hemorrhages increased gradually with lower eGFR levels (p for trend =0.01), and were higher in subjects with coronary calcification than those without it for each eGFR level (with calcification: 7.7%, 12.5%, 12.8%, 18.8%, without calcification: 1.47%, 0%, 1.69%, 9.5% for eGFR ≥ 60, 45-59, 30-44, and <30 ml/min/1.73 $m^2$, P=0.037, $\chi^2$ test). The likelihood of intraplaque hemorrhages increased with lower eGFR (OR 1.29 [95% CI, 1.03-1.62]), lower HDL cholesterol (OR 1.45 [1.09-1.92]), and the presence of coronary calcification (OR 7.68[2.57-22.95])) in univariate analysis. In multivariate analysis, coronary calcification was significantly associated with a greater risk of the presence of intaplaque hemorrhages (OR 8.78 [2.71-28.44]).

**Conclusions:** Our findings suggest that coronarycalcification is a risk factor for the presence of intraplaque hemorrhages in coronary atherosclerosis. Patients with CKD have frequent coronary calcification, which possibly lead to vulnerable plaques.

## TH-PO170

**"Middle Molecules" Are Key Mediators of Uremia Associated Osteoblastic Transformation of Mesenchymal Stromal Cells** Bjoern Hegner,[1] Theres Schaub,[1] Daniel Zickler,[1] Claudia Lange,[2] Joachim Jankowski,[1] Ralf Schindler,[1] Duska Dragun.[1] *[1]Charité Universitätsmedizin Berlin, Germany; [2]Univ Medical Center Hamburg, Germany.*

**Background:** Severe vascular calcification resembling heterotopic osteogoenesis remains unsolved problem in uremic patients. Cells of mesenchymal origin including endothelial and vascular smooth muscle cells are prime targets of uremic solutes. Mesenchymal stromal cells (MSCs) as common progenitors of both are suitable model to identify mechanisms by which uremic milieu may disturb vascular health. We studied effects of 64 individual uremic retention solutes (URS) on osteoblastic transformation of MSCs in order to identify therapeutic strategies feasible for targeting of vascular calcification.

**Methods:** Bone marrow derived MSCs were separately treated with 64 individual URS at uremic concentrations in osteoblastic induction medium. Osteoblastic differentiation was measured by alkaline phosphatase activity, western blot, immunocytochemistry, and calcium deposition. Co-incubation with specific blockers of peptidic URS in uremic serum exposed MSCs served to determine their relative importance for calcification. In an additional translational approach, osteoblastic potential of serum obtained upon high cut-off (HCO) dialyzer treatment was compared to that obtained upon conventional dialysis.

**Results:** Pro-inflammatory cytokines (IL-1β, TNF-α) followed by 3 other "middle molecules": FGF-2, FGF-23, and PTH were the strongest inducers of a calcifying osteoblastic MSC phenotype among 64 URS in a dose dependent manner. Blocking IL-1β, TNF-α, and FGFs alone, or in combination effectively obviated osteoblastic properties of uremic serum. Moreover, substance removal with HCO dialyzers had similar favorable effects attenuating osteoblastic differentiation and calcium deposition by MSCs.

**Conclusions:** Our findings emphasize importance of "middle molecules" as key mediators of uremic calcifying MSC phenotype. Since conventional dialysis strategies fail to effectively remove this group of URS, either targeted dialysis modalities or specific pharmacologic interventions may be instrumental for reduction of unsolved problem of vascular calcification in chronic kidney diseases.

## TH-PO171

**Parathyroid Hormone-Mediated Chondrocyte Transition of Endothelial Eells Promotes Media Calcification in Experimental Secondary Hyperparathyroidism** Min Wu, Rining Tang, Hong Liu, Dan Liu, Bi-Cheng Liu. *Institute of Nephrology, Southeast Univ, Nanjing, China.*

**Background:** Secondary hyperparathyroidism (SHPT) is closely associated with development of media calcification in patients with chronic kidney disease. Studies have demonstrated that heterotopic chondrogenesis contributes to AMC. And recent investigations suggest the potential of endothelial cells to transdifferentiate into chondrocytes. Thus, the purpose of this study is to investigate whether elevated PTH could induce transition of endothelial cells into chondrocyte-like cells in experimental SHPT.

**Methods:** Uremia-related SHPT was induced by feeding rats an adenine diet (0.75%) for 4 weeks followed by high phosphorus diet (1.03%) until they were euthanized. Cultured human aortic endothelial cells (HAECs) were treated with PTH. Endothelial, mesenchymal and chondrocyte markers were examined by immunohistochemistry, immunofluorescent staining, real-time PCR and western blot.

**Results:** After 4 weeks of an adenine diet, serum creatine , BUN and PTH concentrations significantly increased compared with control rats ($p$<0.05), reflecting the installation of uremia-related SHPT. At 8 weeks after the establishment of uremia, von Kossa staining showed severe media calcification in the aortas. Western blot analysis showed that downregulation of endothelial marker CD31 and the upregulation of mesenchymal markers (a-SMA and FSP1) and chondrocyte markers (SOX9 and COL2A1). Confocal microscopy further revealed the co-localization of CD31 and SOX9 in the aortic media of SHPT group. Besides, exposure of cultured HAECs to PTH upregulated the expressions of FSP1 and α-SMA and downregulated the levels of CD31 in concentration-dependent and time-dependent manners ($P$<0.05). And a western blot analysis indicated that expressions of SOX9were significantly increased in PTH-treated cells compared with the control.

**Conclusions:** Elevated PTH could induce the transition of HAECs into chondrocyte-like cells via EndMT, which might be involved in media calcification in uremia-related SHPT.

## TH-PO172

**Plasma Hydrogen Sulfide ($H_2S$) Levels in CKD Patients** Stephen G. John,[1] Michael J. Garle,[2] Paul J. Owen,[1] Vera Ralevic,[2] Saoirse O'Sullivan,[2] Chris W. McIntyre.[1,2] *[1]Royal Derby Hospital, United Kingdom; [2]Univ of Nottingham, United Kingdom.*

**Background:** Animal models of chronic kidney disease (CKD) and CKD patients have reduced plasma hydrogen sulfide ($H_2S$) concentrations. $H_2S$ inhibits phosphate-induced calcification and osteoblastic differentiation of vascular smooth muscle cells, which suggests a role in arterial calcification. We aimed to investigate the role of $H_2S$ in vascular calcification and arterial stiffness in CKD.

**Methods:** We recruited 54 hypertensive non-diabetic patients ( ≥70 yrs) (CKD 3/4 (n=29), non-CKD controls (n=25)). Pulse wave velocity (PWV) and analysis were assessed by applanation tonometry, central hemodynamics by continuous digital pulse wave analysis, vascular calcification (VC) by superficial femoral artery CT and routine bloods were collected. Plasma $H_2S$ was assayed following conversion to methylene blue using the zinc-dimethyl phenylenediamine trapping method. Patients were assessed at baseline (after antihypertensive (AHT) withdrawal), after AHT reintroduction to BP 130/80mmHg, and after 12 months follow-up. Data are presented as median±IQR or Spearman correlations.

**Results:** Baseline $H_2S$ level (2.25±2.42μM) was independent of CKD status, gender and age but lower in smokers (1.77±1.64, 2.43±3.07μM, p=0.037). In those with significant VC (50%), $H_2S$ inversely correlated with VC score (r=-0.427, p=0.026) and arterial stiffness (AIx r=-0.463, p=0.015). Protein-corrected $H_2S$ inversely correlated with carotid-femoral PWV (r=-0.408, p=0.039). $H_2S$ inversely correlated with PTH (r=-0.297, p=0.038) and, in CKD, with serum calcium (r=0.470, p=0.010). No correlations were seen with vitamin D, phosphate or central hemodynamics.

AHT reintroduction was associated with a significant rise in $H_2S$ (2.25±2.42, 4.82±6.15μM, p<0.001), with a trend to a blunted improvement with beta-blockade (1.15±4.49, 4.14±6.03μM, p=0.089).

Over 12 months $H_2S$ fell (4.82±6.15, 3.74±1.92μM, p=0.005) and VC change inversely correlated with $H_2S$ change (r=-0.343, p=0.023).

**Conclusions:** These data support a central role for $H_2S$ in both cardiovascular risk and the progression of VC. $H_2S$ modulation by AHT therapy suggests a further non-traditional role for both AHT therapy and potentially the choice of agents used.

## TH-PO173

**Chronic Kidney Disease Is an Independent Factor for Atheromatosis Disease** Angels Betriu,[1,4] Montserrat Martinez-Alonso,[2,4] M. Vittoria Arcidiacono,[3,4] Merce Borras,[1,4] Jose M. Valdivielso,[3,4] Elvira Fernandez.[1,3,4] *[1]Nephrology, Univ Hospital Arnau de Vilanova, Lleida, Spain; [2]Biostatistics Unit, IRBLleida, Lleida, Spain; [3]Experimental Nephrology, IRBLleida, Lleida, Spain; [4]NEFRONA Group.*

**Background:** Although cardiovascular (CV) mortality in patients with chronic kidney disease (CKD) is well known, it is still questioned if CKD per se is a promoting factor of the atheromatosis process. Therefore, the aim of the study was to study the impact of CKD on atheromatosis from early to late stages: 3 (E3); 4-5 (E4-5) and 5D (E5D) in comparison with a control population not affected by CKD (C) taking into account age, gender and diabetes, three well known atherogenic factors.

**Methods:** We analyzed 2445 CKD patients (CKD3: 937; CKD4-5: 820; CKD5D: 688) and 559 controls, 18 to 75 years old without previous cardiovascular events (NEFRONA study). CV risk was measured by SCORE charts. Carotid (common, bulb, internal and external) and femoral (common and superficial) arteries were explored with B-mode ultrasound to detect atheromatous plaques. The estimation of atheromatous plaques presence was calculated by a multivariate logistic regression model by gender, age and diabetes; plaque prevalence was stratified by the same variables.

**Results:** CKD patients were 61.7% men, 57.9 years old, and 25.7% of them were diabetic. While control subjects were 53.3% men, 54.6 years old and 10.7% of them were diabetic. CKD patients presented a higher prevalence of plaque compared to that observed in control subjects (70% vs 51%; p<0.001). Moreover, plaque presence was higher as the age of patients increased, in men and diabetic subjects. Importantly, plaque prevalence increased in parallel with CKD severity with the highest value at 5D stage. This trend was

observed in both genders, for all the age ranges and presence or absence of diabetes. In contrast, SCORE values were higher in E3 and decreased with CKD severity and plaque presence (C:1.4, E3:2.6; E4-5:2.2; E5D:1.3).

**Conclusions:** CKD per se is a cause of atheromatosis and the process is exacerbated by the severity of the disease, age and diabetes. Importantly, B-mode ultrasound of the carotid and femoral arteries is a better predictor of CV disease than SCORE charts.

## TH-PO174

**Chronic Kidney Disease Promotes Carotid Adventitial Neovascularization**

M. Vittoria Arcidiacono,[1] Merce Borras,[2] Ana Vilar,[2] M. Luisa Martin-Conde,[2] Belart Montserrat,[3] Lourdes Craver,[2] Angels Betriu,[2] Elvira Fernandez.[1,2] *[1]Experimental Nephrology, IRBLleida; [2]Nephrology, Univ Hospital Arnau de Vilanova; [3]Sistemes Renals, Lleida, Spain.*

**Background:** Plaque vulnerability is strongly associated with the presence of Vasa Vasorum (VV) coming from the adventitial layer. Detection of the increases of carotid adventitial VV could be a good tool for early detection of the atheromatosis. Knowing that chronic kidney disease (CKD) patients are prone to develop atheromatosis, we studied the adventitial VV in CKD and healthy patients, and its association with causes of neoangiogenesis. Moreover, the right common carotid artery is less subject to hemodynamic factors, therefore we studied separately the left and right carotid arteries.

**Methods:** Forty-two healthy patients with none of the classical atheromatous risk factors were compared with 89 CKD patients (3-4: 44, 5D:45), age<75 years and without previous cardiovascular events. Anthropometric, blood pressure, and analytical data (at fasting: lipid profile, C-reactive protein, glucose, calcium, phosphorous, PTH and Vascular Endothelial Growth Factor (VEGF)) were collected. Contrast-enhanced ultrasound (CEUS) was performed to evaluate adventitial VV in plaque-free common arteries, and B-mode ultrasound was performed to evaluate the intima-media thickness (IMT) and plaque presence.

**Results:** Control and CKD patients did not differ in age and gender. CKD patients showed a higher right adventitial VV and a higher right IMT than those observed in control patients (p=0.01; p=0.006), while the left carotid did not differ. Moreover, the right adventitial VV only correlates with the relative IMT (p=0.04) and with total cholesterol (p=0.03). Besides higher levels in CKD patients than in control patients (p=0.005), there was no correlation between VEGF levels and adventitial VV.

**Conclusions:** The differences between the left and right carotid arteries in VV increases, suggest that is mandatory to study separately the two arteries. Moreover, the correlation with IMT and cholesterol levels, a well know cardiovascular risk factor, suggest that CEUS imaging is a good tools in exploring the etiopatogenesis of atheromatosis in CKD patients.

## TH-PO175

**ADAM17 Inhibition by the Calcimimetic R568 and Its Combination with Vitamin D Attenuates Systemic Inflammation, Renal Damage and Motor-Neuron Dysfunction in Experimental Kidney Disease**

M. Vittoria Arcidiacono,[1] Sabrina Degaspari,[1] Petya Valcheva,[1] Sandra De la Fuente,[1] Elvira Fernandez,[1,2] Adriana S. Dusso.[1] *[1]Experimental Nephrology, IRBLleida; [2]Nephrology, HUAV, Lleida, Spain.*

**Background:** ADAM17 causes systemic inflammation, renal and cardiovascular damage through the cleavage and release to the circulation of the inflammatory cytokines TNFα, ICAM-1 and VCAM-1, and impairs motor-neuron function through the cleavage of pentraxin, essential for neuronal synapsis. Vitamin D inhibition of ADAM17 and induction of klotho contribute to renal and cardiovascular protection. Because high dietary calcium prevents the parathyroid hyperplasia caused by enhanced ADAM17-TGFα/EGFR signals, this study examined the efficacy of the calcimimetic R568 and its synergy with vitamin D in attenuating renal, cardiovascular and motor-neuron dysfunction in mouse kidney disease.

**Methods:** Two months after 75% nephron reduction, mice were treated with either R568 (s.c. 60 μg/g body weight), 25-hydroxyvitamin D (i.p. 80 ng weekly) + paricalcitol (i.p. 16 ng thrice weekly) or the combination for 6 weeks.

**Results:** Treatment with R568, at doses ineffective to suppress PTH, prevented the progression of renal damage (ΔBUN=0; p<0.01 ), while the R568-Vitamin D combination improved renal function (ΔBUN<0; p<0.05). The reversal of renal damage could be partially accounted for by vitamin D prevention of reductions in renal klotho, the longevity gene also cleaved by ADAM17. R568 alone or its combination with vitamin D elicited similar efficacy in preventing the loss of motor-neuron function assessed in Ladder rung walking and Rota-Rod tests, an effect associated to parallel reductions in monocyte ADAM17 expression (p<0.05), a marker of systemic inflammation. Despite the absence of vascular calcification in these uremic mice, serum VCAM-1, a marker of vascular damage, correlated directly with the degree of renal damage.

**Conclusions:** Thus, the efficacy of R568 or its combination with vitamin D to prevent the impairment of motor-neuron function in CKD parallels their ability to inhibit monocyte and/or renal ADAM17 and to attenuate renal klotho loss in the course of CKD.

## TH-PO176

**Evaluation of Cardiac Troponin I in Patients with Chronic Kidney Disease**

Om Parkash Kalra, Nithyananthan Peramanathan, Sunil Agarwal, Ashok K. Tripathi, Anil Kumar Yadav. *Univ College of Medical Sciences and Guru Teg Bahadur Hospital, Delhi, India.*

**Background:** Elevated levels of cardiac troponin I (cTnI) have been reported in patients with chronic kidney disease (CKD) even in the absence of acute coronary syndrome (ACS). Elevated levels of cTnI may predict future development of cardiovascular events. In this study, we assessed the cTnI levels in patients with CKD and correlated them with the structural and functional abnormalities of left ventricle (LV).

**Methods:** This cross-sectional study involved 90 subjects in the age group 31 to 60 years, divided into three groups (30 in each). Group I: Healthy controls (HC), Group II: Patients with CKD stages 3 – 5 not on hemodialysis, Group III: Patients with acute myocardial infarction (AMI) without CKD. cTnI was measured using a highly sensitive ELISA test in all groups and 2D echocardiography was done in patients with CKD to assess the following parameters: LV mass (LVM), LV mass index (LVMI) and LV systolic as well as diastolic functions.

**Results:** The mean cTnI levels in patients with CKD (142.83 pg/mL) were significantly higher (p<0.001) than healthy controls (75.22 pg/mL) and significantly lower (p<0.001) when compared with patients having AMI (456.16 pg/mL). The prevalence of elevated cTnI levels (>122. 21 pg/mL i.e., >99$^{th}$ percentile value of cTnI in healthy controls) in patients with CKD was found to be 43.3%. In patients with CKD, there was significant positive correlation (p<0.01) between cTnI and various parameters, such as LVM, LVMI and E/E' (r=0.470, 0.500 and 0.461 respectively); however, correlation between cTnI and LV ejection fraction was not significant (r= -0.276, p=0.141).

**Conclusions:** In patients with CKD, cTnI levels were elevated even in the absence of AMI. The prevalence of elevated cTnI levels in patients with CKD stages 3-5 not on hemodialysis was found to be 43.3%. The elevated levels of cTnI were associated with the presence of LV hypertrophy and diastolic dysfunction in patients with CKD. Elevated cTnI levels may help in identifying patients with CKD at increased risk for future cardiovascular events, so that these patients may be subjected to more aggressive and targeted intervention.

## TH-PO177

**Renalase Is Removed by Kidneys and during Dialysis – Excess Related to CKD Complications?**

Jolanta Malyszko, Ewa Koc-Zorawska, Jacek S. Malyszko. *Nephrol. Dept, Med Univ, Bialystok, Poland.*

**Background:** Hypertension and cardiovascular complications are very common in CKD. Renalase could be synthesized not only by the kidney but also by cardiomyocytes, liver, and adipose tissue. Renalase deficiency was claimed to be present and reponsible for hypertension and cardiovascular complication in CKD. Data on renalase levels in serum were conflicting with low activity and high levels reported in patients with hypertension and CKD. We aimed to assess the renalase levels in patients after unilateral (CKD) and bilateral nephrectomy (HD), in HDF as well as in urine, ultrafiltrate in HD patients. We also assessed the effect on HD session on renalase levels.

**Methods:** Renalase (plasma, ultrafiltrate, urine) in 100 HD patients were studied using commercially available assays. Renalase was also assessed in 17 HDF patients and 24 healthy controls. We also studied renalase presence using Western Blot analysis.

**Results:** Renalase was found in ultrafiltrate in HD patients and was not affected by type of dialysers (high-flux vs low-flux). Urine renalase in HD patients (n=60) was lower than in healthy volunteers (n=24). Patients with residual renal function had lower renalase relative to anuric patients (p<0.001). In univariate analysis, plasma renalase correlated with urinary renalase (r=-0.28, p<0.05) and renalase in the ultrafiltrate (r=0.31, p<0.05) in HD patients and with urinary renalase in healthy volunteers (r=0.61, p<0.01). Urinary renalase correlated with residual renal function. HD session lower slightly renalase and type of heparin has no effect. HDF patients has significantly lower renalase than HD patients. In Western blot we found that patients after bilateral nephrectomy had the highest renalase, followed by unilateral nephrectomy.

1-control, 2- renalase commercial, 3, 4 HD, 5-7 after bilateral nephrectomy, 8, 9- after unilateral nephrectomy

**Conclusions:** Renalase is cleared by kidneys and it seems that renalase excess not deficiency might contribute to the observed cardiovascular complications in CKD.

*Funding:* Government Support - Non-U.S.

## TH-PO178

**In Chronic Kidney Disease Signal Regulatory Protein-a Not Only Impairs Insulin Signaling in Skeletal Muscle but also Contributes to Fibrosis**
Sandhya S. Thomas,[1] Liping Zhang,[1] William E. Mitch.[1] *[1]Medicine, Baylor College of Medicine, Houston, TX; [2]Medicine, Baylor College of Medicine, Houston, TX; [3]Medicine, Baylor College of Medicine, Houston, TX.*

**Background:** Insulin resistance in chronic kidney disease (CKD) begins as early as a serum creatinine 1.0 mg/dL impairing insulin signaling with loss of muscle mass. We have demonstrated for the first time that signal regulatory protein alpha (SIRPα) is upregulated in CKD and adversely influences insulin signaling by forming an immunocomplex with the insulin receptor and insulin receptor substrate-1. This results in tyrosine dephosphorylation of the insulin receptor and IRS-1 downregulating p-Akt causing muscle protein loss.

**Methods:** Western blots analysis was performed based on C2C12 cell lysates and CKD vs. control human skeletal muscles. C2C12 myoblasts were treated to overexpress SIRP-a or GFP, with silencing RNA (SiRNA) SIRP-α or scrambled SiRNA (control) and finally infected with adenovirus dominant negative AKT (Ad-AKT-AAA) vs. GFP control.

**Results:** There is a 3.8-fold increase of SIRPα in skeletal muscle samples of patients with advanced CKD vs. aged matched controls. Overexpression of SIRPα in muscle cells stimulates expression of p-Smad3, a transcription factor initiating activin and TGFβ signaling, and expression of the fibrosis marker alpha smooth muscle actin (α-SMA). Silencing SIRPα in muscle cells treated with a cytokine mixture similar to that which is found in CKD patients, caused a decrease in expression of p-Smad3 reducing expression of α-SMA. To determine if SIRPα influences p-Smad3 via a PI3/Akt dependent pathway, we silenced SIRPα in skeletal muscle cells that were infected with Ad-AKT-AAA. In SIRPα-silenced muscle cells that had been infected with Ad-AKT-AAA, p-Akt was upregulated and p-Smad3 was downregulated when compared to results in control muscle cells transfected with a scrambled SiRNA (and infected with Ad-AKT-AAA), which revealed a decrease in p-Akt and upregulation of p-Smad3.

**Conclusions:** These results imply that SIRPα increases p-Smad3 by a mechanism that is dependent on the PI3/Akt pathway, suggesting that SIRPα influences muscle fibrosis via a new pathway in chronic kidney disease.

## TH-PO179

**Circulating dp-ucMGP: Modifiable Risk Marker in Chronic Kidney Disease**
Elke Theuwissen,[1] Elke Magdeleyns,[1] Heather Pham,[2] Cees Vermeer.[1] *[1]Cardiovascular Research Institute, Maastricht Univ, VitaK, Maastricht, Limburg, Netherlands; [2]Immunodiagnostic Systems, Boldon, United Kingdom.*

**Background:** Vascular calcification is a major burden in chronic kidney disease (CKD), associated with increased morbidity and mortality. Matrix Gla-protein (MGP) is primarily synthesized by vascular smooth muscle cells and acts as an inhibitor of vascular calcification; its activity depends on vitamin K-dependent γ-glutamate carboxylation. Vascular vitamin K insufficiency leads to the formation of inactive undercarboxylated MGP. Circulating inactive desphospho-uncarboxylated MGP (dp-ucMGP) is a recognized marker for vascular vitamin K status.

**Methods:** Circulating dp-ucMGP was measured with our lab-developed sandwich dual-antibody ELISA. The capture antibody was directed against the non-phosphorylated MGP sequence [3–15] and the detecting antibody directed against the uncarboxylated MGP sequence [35–49].

**Results:** Circulating dp-ucMGP levels varied between 1000 and 8000 pmol/L in CKD patients (normal range: 100 and 600 pmol/L), which is consistent with a strongly increased vascular calcification risk and which demonstrates the pronounced vascular vitamin K insufficiency in these patients. Circulating dp-ucMGP was shown to augment progressively with CKD stage. In CKD patients, increased dp-ucMGP levels were associated with aortic calcification and overall mortality. As for healthy subjects, increased vitamin K intake resulted in a dose-dependent decrease of circulating dp-ucMGP in CKD patients.

**Conclusions:** Our data suggest that in all stages of kidney disease/failure, vitamin K insufficiency is a strong risk factor for the progression of the disease and overall mortality. Further, these data form a strong argument to investigate potential clinical benefits of extra vitamin K intake for kidney disease patients.

## TH-PO180

**Normalization of AMPK Activity Corrects Renal Insulin Resistance in Non-Diabetic CKD**
Aihua Deng, Roland C. Blantz. *Medicine, UCSD&VASDHS, San Diego, CA.*

**Background:** Our last study observed that the ablation infarction (A/I) kidney, a typical non-diabetic CKD model, develops renal insulin resistance, defined as reduced effects of insulin on renal metabolism & function, and that such insulin resistance is associated with an early alteration of AMPK pathway. This study is to further test renal insulin functional resistance and to test treatments that can correct such insulin resistance.

**Methods:** A/I was created by removing right kidney and ligating two branches of left renal artery. Treatments by metformin or ANG II blockade with captopril and losartan (C&L) began on day 1. GFR and RBF were measured before and after acute arginine or insulin administrations; expressions of AMPK and its target ACC detected by Western blot; blood glucose measured after over night fasting.

**Results:** A/I kidney lost responses to arginine and insulin along with reductions in phosphorylations of AMPK and its target ACC. Both treatments which increased AMPK activity recovered kidney functional response to arginine or insulin.

| | Normal | 1wk A/I | 1wk A/I + Metformin | 1wk A/I + C&L |
|---|---|---|---|---|
| | Basal/Arginine | Basal/Arginine | Basal/Arginine | Basal/Arginine |
| GFR(ml/min) | 1.19±0.08/1.64±0.07* | 0.65±0.02/0.64±0.06 | 0.94±0.01/1.03±0.01* | 1.18±0.08/1.39±0.13* |
| RBF(ml/min) | 7.80±0.66/9.75±0.65* | 3.93±0.19/3.73±0.19 | 6.05±0.31/7.25±0.31* | 7.29±0.4/8.46±0.7* |
| | Basal/Insulin | Basal/Insulin | Basal/Insulin | Basal/Insulin |
| GFR(ml/min) | 1.16±0.07/1.40±0.09* | 0.71±0.08/0.61±0.11 | 0.98±0.06/1.26±0.05* | 1.09±0.14/1.36±0.07* |
| RBF(ml/min) | 7.90±0.12/9.43±0.36* | 4.44±0.7/4.36±0.7 | 6.05±0.31/7.25±0.31* | 6.88±0.6/8.33±0.6 |
| | | Normal/1wkAI | Normal/1wkAI+ Metformin | Normal/1wkAI+C&L |
| Fasting Blood Glucose(mg%) | | 78±4/101±6* | 89±7/86±2 | 70±3/53±5 |

**Conclusions:** A reduction of AMPK activity in the early stage of non-diabetic CKD is associated with the development of renal insulin resistance and normalization of renal AMPK activity can correct such insulin resistance.

## TH-PO181

**Blockade of KCa3.1 Attenuates Renal Inflammation in Diabetic Mice**
Chunling Huang, Xinming Chen, Carol A. Pollock. *Renal Lab, Kolling Institute of Medical Research, Univ of Sydney, Sydney, NSW, Australia.*

**Background:** Inflammation plays a key role in the development and progression of diabetic nephropathy. KCa3.1, a potassium channel protein, is associated with vascular inflammation, atherogenesis, and proliferation of endothelial cells, macrophages, and fibroblasts. We previously demonstrated that blockade of KCa3.1 ameliorated renal fibrosis in diabetic nephropathy through inhibition of TGF-β1 pathway. The present study aimed to identify the role of KCa3.1 in the inflammatory responses of diabetic nephropathy.

**Methods:** Two animal models of diabetes induced with streptozotocin were used in this study: (1) wild type verse KCa3.1-/- mice, and (2) diabetic eNOS-/- mice treated with or without a selective inhibitor of KCa3.1 (TRAM34). After mice were sacrificed, the expression of proinflammatory cytokines Chemokine (C-C motif) ligand 20 (CCl20), IL-6 and TNF-α were examined by real time PCR and immunohistochemistry staining. The activity of NF-kB and markers of inflammation (CD68 and CD45) were measured by immunohistochemistry staining.

**Results:** Both mRNA and protein levels of CCL20, IL-6 and TNF-α significantly decreased in kidneys of diabetic KCa3.1-/- mice compared to diabetic wild type mice. Similarly, TRAM34 reduced the expression of inflammatory markers described above in diabetic eNOS-/- mice compared to diabetic vehicle groups. Furthermore, blocking the KCa3.1 channel in both animal models led to the reduction of phosphorylation of NF-kB.

**Conclusions:** KCa3.1 mediated renal inflammation under diabetic condition through the NF-kB pathway.

*Funding:* Government Support - Non-U.S.

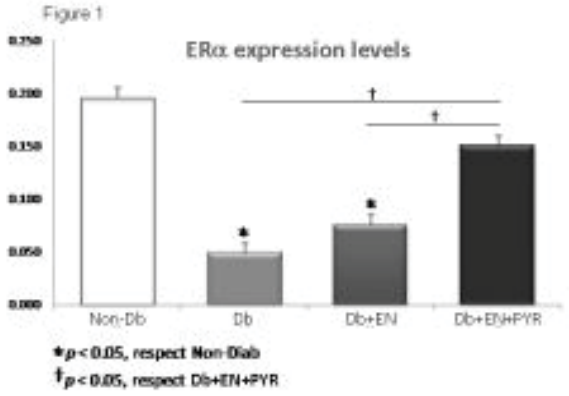
## TH-PO182

**Restoration of Repressed Estrogen Receptor α in Post-Menopausal Women and Female Mice with Diabetic Kidney Disease**
Elena M. Yubero-Serrano,[1] Shobha M. Swamy,[1] Jaime Uribarri,[1] Mark Woodward,[2] Helen Vlassara,[1] Gary E. Striker.[1] *[1]Mount Sinai School of Medicine, New York; [2]George Institute for Global Health, Sidney, Australia.*

**Background:** ERα expression is reduced in diabetic kidney disease (DKD) and post-menopausal (PMP) females by high oxidative stress (OS). Since advanced glycation endproducts (AGEs) increase OS in DKD and sevelamer carbonate (SevCarb) blocks absorption of food AGEs, reduces OS and restores cellular anti-OS defenses in DKD, we asked if SevCarb restores ERα expression in peripheral monocytes in T2DM/DKD PMP women. The mechanism was explored using pyridoxamine (PYR), a B6 vitamer that inhibits intracellular AGE formation, decreases OS and reduces DKD in mice. Thus, we asked if PYR increases ERα expression in the kidneys of female sclerosis-prone (ROP/Os) diabetic mice.

**Methods:** PMP women (n=125)/T2DM (HbA1c>6.5)/DKD (eGFR 25-80ml/min/1.73 $m^2$, AER>300mg/day) were randomly assigned to either SevCarb (4800mg/day) or calcium carbonate ($CaCO_3$,1950mg/day) for 3 months in an intention-to-treat, semi-blinded trial. Female ROP Os/+ diabetic mice (Db) (8-12 weeks old) were randomized to received enalapril (EN) and EN+PYR for 5 months.

**Results:** SevCarb treated T2DM/DKD women showed a robust increase in ERα levels after 3 months (baseline:0.96; 3 months:2.91; p=0.012). ERα levels also increased in men (strong trend). SevCarb reduced HbA1c, AGEs, Nrf2 and total cholesterol. These changes were absent after $CaCO_3$ treatment. PYR+EN treatment increased ERα levels compared to Db or Db+EN mice.



**Conclusions:** Sevelamer carbonate, but not $CaCO_3$, reduced AGE levels in PMP women with DKD and restored ERα levels, improved anti-oxidant defenses and decreased selected CVD risk factors. A longer and larger clinical trial is necessary to determine if these changes affect clinical endpoints. Pyridoxamine restored ERα levels in sclerosis-prone mice with DKD.

## TH-PO183

**Atrasentan Does Not Significantly Impact Thoracic Bioimpedance in Patients with Type 2 Diabetes and Nephropathy**

Dick de Zeeuw,[1] Blai Coll,[2] Hans-Henrik Parving,[3] The Radar Steering Committee.[4] *[1]Univ of Groningen, Groningen, Netherlands; [2]AbbVie, N. Chicago; [3]Univ Hospital of Copenhagen, Copenhagen, Denmark; [4]Multiple Affiliations.*

**Background:** Atrasentan, a selective endothelin receptor A antagonist, has been shown to reduce residual albuminuria in patients with type 2 diabetes and proteinuria. The potential long term renoprotective properties could be hampered by fluid retention, a common side effect of endothelin antagonists. Fluid retention was assessed by measuring thoracic bioimpedance following atrasentan treatment in subjects who are receiving maximum tolerated labeled doses of RASi.

**Methods:** 48 subjects with type 2 diabetes, macroalbuminuria (UACR ≥300 and ≤3500 mg/g) and eGFR between 30-75 ml/min/1.73 $m^2$, were enrolled in this multicenter, double-blind, placebo-controlled study. Subjects (n=16 per group) were randomized to atrasentan 0.5 mg/day, 1.25 mg/day, or placebo once daily for 8 wks. Thoracic bioimpedance was measured using the ZOE® Fluid Status Monitor. The changes from baseline to each postbaseline visit up to wk 8 were tested for significance by repeated measures analysis of variance.

**Results:** Mean baseline thoracic bioimpedance was 23±4, 22±4, and 24±5 Ohms for the placebo, 0.5 mg, and 1.25 mg dose groups. Thoracic bioimpedance did not change significantly over 8 wks for the 0.5 mg (-0.4 Ohms, p=0.718) and 1.25 mg (0.2 Ohms, p=0.836) groups, compared to placebo. No significant differences were observed in peripheral edema (44%, 31% and 50%, respectively), and there was only one case of congestive heart failure in the 1.25 mg group. Body weight increased by 1.5 kg in the 0.5 mg (p=0.053) and 1.2 kg in the 1.25 mg (p=0.125) groups, compared to placebo. Forty subjects completed the study at wk 8: placebo (n=15), 0.5 mg dose (n=14), and 0.75 mg dose (n=11). After stopping atrasentan for 30 days, bioimpedance measurements (placebo, n=14; 0.5 mg dose, n=11; and 1.25 mg dose, n=11) and body weight (placebo, n=14; 0.5 mg dose, n=12; and 1.25 mg dose, n=11) remained stable.

**Conclusions:** Administration of atrasentan in doses of 0.5 mg or 1.25 mg once daily for 8 weeks does not show any significant changes on thoracic bioimpedance.

*Funding:* Pharmaceutical Company Support - AbbVie

## TH-PO184

**Blockade of Angiotensin II Type I Receptor (AT1) and CC Chemokine Receptor 2 (CCR2) Heteromers in 5/6 Renal Ablation Model**

Yuan Zhang,[1] Robyn S. Kelly,[1] Alison Joy Cox,[1] James H. Williams,[2] Elizabeth Ann McCall,[2] Kevin Pfleger,[3] Darren J. Kelly.[1] *[1]The Univ of Melbourne; [2]Dimerix Bioscience; [3]The Univ of Western Australia.*

**Background:** Progressive chronic kidney disease (CKD) is associated with pathological fibrosis and podocyte loss, characteristic features that correlate closely with declining renal function and development of proteinuria. Both AT1 and CCR2 receptors have been consistently implicated in this disease progression. The combination of AT1/CCR2 blockade has been shown to inhibit the heteromer of these receptors and potentially increase the therapeutic effects in CKD. This study sought to test the hypothesis that blockade of the AT1-CCR2 heteromer with a combination of Irbesartan and Propagermanium (CCR2 pathway inhibitor) would have an additive benefit on progressive renal injury in 5/6 renal ablated rats.

**Methods:** 5/6 renal ablated rats (n=12) were randomly assigned to receive daily either Irbesartan (Irb; 10mg/kg) or a combination of Irb (10mg/kg) and Propagermanium (PPG; 30mg/kg) or vehicle (V) for 12 weeks. In addition to renal function and histopathology examination, podocyte loss and the concentration of urinary MCP-1 were also measured.

**Results:** Without affecting body weight and blood pressure, the combination of Irb and PPG therapy in 5/6 renal ablated rats was associated with significantly less proteinuria (V: 372±52, Irb: 287±32, Irb+PPG: 136±16 mg/day), urinary MCP-1 (V: 4048±587, Irb: 2533±409, Irb+PPG: 2105±538 pg/ml) and podocyte loss (V: 9±0.8, Irb: 10±0.6, Irb+PPG: 13±0.7 podocytes/glomerulus) when compared to vehicle or Irbesartan treatment. Both mono and combination therapy attenuated tubulointerstitial fibrosis (V: 5.69±0.8, Irb: 3.72±0.41, Irb+PPG: 4.10±0.7 %/area) and glomerulosclerosis (V: 1.37±0.13, Irb: 0.52±0.08, Irb+PPG: 0.66±0.13), along with improved glomerular infiltration rate (V: 0.43±0.13, Irb: 0.91±0.12, Irb+PPG: 0.90±0.16 ml/min/kg) when compared with vehicle treated in 5/6 renal ablated rats.

**Conclusions:** Blockade of the AT1-CCR2 heteromer with Irbesartan and Propagermanium was superior to Irbesartan alone in reducing proteinuria and podocyte loss in the 5/6 renal ablation rat model of CKD.

*Funding:* Pharmaceutical Company Support - Dimerix Bioscience, Perth, Australia

## TH-PO185

**Chronic Nicotine (Ch-NIC) Induced Exacerbation of Subpressor Angiotensin-II (SP-AngII) Induced Renal Dysfunction and Chronic Kidney Disease (CKD) Is Partially Mediated through the Endothelin-A (ET-A) Receptor**

Kiran B. Chandrashekar,[1] Istvan Arany,[3] Arnaldo F. Lopez-Ruiz,[1] Andrea P. Soljancic,[1] Ruisheng Liu,[1,2] Luis A. Juncos.[1,2] *[1]Nephrology, Univ of Miss Medical Center; [2]Physiology & Biophysics, Univ of Miss Medical Center; [3]Pediatrics, Univ of Miss Medical Center.*

**Background:** Previously we reported that Ch-NIC worsens SP-AngII induced renal dysfunction despite insubstantial blood pressure (BP) changes and also that it incites renal vascular remodeling which partly contributes to SP-AngII induced CKD. Smoking (Ch-NIC) increases plasma endothelins which damage microcirculation by regulating vascular growth–promoting factors and inducing microvascular remodeling.We hypothesized that ET-A receptor blockade protects against Ch-NIC induced renal dysfunction in SP-AngII induced CKD.

**Methods:** SD rats received saccharine or nicotine with or without SP-AngII. Separate groups were pretreated with ABT-627 (selective ET-A antagonist).

**Results:**

| | Systolic BP(mmHg) | RVR(ml/min/mmHg) | CRVR(TPU/mmHg) | MRVR(TPU/mmHg) | NGAL(UI/mg creat) | TGF(ng/µg protein) |
|---|---|---|---|---|---|---|
| **Control** | 110±3 | 16±3 | 3±0.3 | 4±0.4 | 0.3±0.1 | 14±2 |
| **Ch-NIC** | 114±6 | 15±1 | 3±0.1 | 4±0.1 | 0.7±0.1* | 20±1* |
| **Ch-NIC+ABT-627** | 107±4 | 16±1 | 3±0.2 | 4±0.1 | 0.7±0.1 | 10±1# |
| **SP-AngII** | 164±6 *#† | 24±2 #† | 4±0.4 #† | 6±0.4 #† | 6±0.5 #† | 28±1 #† |
| **SP-AngII+ Ch-NIC** | 171±3 | 39±2 ψ | 4±0.1 ψ | 10±1 ψ | 8±0.1 ψ | 40±2 ψ |
| **SP-AngII+ Ch-NIC+ABT-627** | 142±3 ψπ | 20±1 ψπ | 3±0.1 ψπ | 5±0.2 ψπ | 4±0.6 ψπ | 24±2 ψπ |

Data:Mean ± SEM;P< 0.05;*vs. CT;# vs. SP-AngII;† vs. Ch-NIC+ABT-627;Ψ vs. SP-AngII;π vs. SP-AngII+Ch-NIC.

**Conclusions:** ET-A blockade prevents Ch-NIC-induced worsening of SP-AngII induced changes in renal hemodynamics, injury, fibrosis and vascular remodeling, albeit attenuating SP-AngII-induced hypertension. This protective effect was independent of heme oxygenase system (data not shown). Our data suggests that Ch-NIC induced exacerbation of SP-AngII induced renal dysfunction and CKD is partially mediated through activation of the ET-A receptor.

*Funding:* Other NIH Support - NIH DK073401

## TH-PO186

**Protective Effects of Enalapril, Atrasentan, and Paricalcitol on Glomerulosclerosis, Proteinuria, and Cardiac Oxidative Stress in Uremic Rats**

Eduardo Slatopolsky,[1] Cynthia S. Ritter,[1] Jane L. Finch,[1] Helen Liapis,[1] Edu Suarez,[2] Leon Ferder,[2] James A. Delmez,[1] Sarah Zhang.[1] *[1]Washington Univ School of Medicine, St. Louis; [2]Ponce School of Medicine.*

**Background:** The cardio-renal involvement in CKD patients accelerates the progression of renal insufficiency. Activation of RAAS, the endothelin A receptor (ETaR), and oxidative stress play a critical role in the deterioration of renal function.

**Methods:** We compared the action of enalapril, atrasentan (an ETaR antagonist) and paricalcitol in the kidney using the 5/6$^{th}$ nephrectomized rat model, in the following groups: Normal control (NC), Uremic (U), U+enalapril (UE), U+atrasentan (UA), U+paricalcitol (UP), and a combination of the 3 drugs together (UEAP). The rats were treated for 3 month.

**Results:** The combination treatment had the greatest protective effect on all parameters examined. Uremia resulted in a marked rise in 24hrs protein excretion, 4.4±1.8 (NC) *vs* 360.6±45.4 mg/24 hrs (U); the UEAP group had a marked reduction to 134.7±24.1 mg/24 hrs ($p<0.001$). Serum creatinine increased from 0.48±0.02 (NC) to 1.22±0.11 in the U group, and decreased to 0.87±0.05 mg/dl in the UEAP group. The systolic BP increased to 169±7mmHg in the U group and remained normal in the UEAP group. The U rats showed significant glomerulosclerosis, interstitial sclerosis and inflammation; this was decreased significantly in the UEAP group. The monocyte chemotactic protein MCP-1 significantly increased 12-fold in the U group, but only 3.5-fold in the UEAP group (ns *vs* control). Similarly, ED-1, a marker of macrophage infiltration in the kidney, significantly increased 18-fold in the U group, but only increased 3-fold in the UEAP group (ns *vs* control). The mortality in the U group was 33.3% and zero in UEAP group. Hypertrophy of the left ventricle (LV) was prevented in the UEAP group; this group had the lowest level of lipid peroxidation, and the anti-oxidant enzyme glutathione peroxidase was significantly increased.

**Conclusions:** In conclusion, the combination of these 3 drugs greatly improved renal function and histology, proteinuria, LV hypertrophy and cardiac oxidative stress in the uremic rat.

*Funding:* Pharmaceutical Company Support - Abbott Pharmaceutical

## TH-PO187

**Inverse Correlation of Epidermal Growth Factor and Lipocalin-2 in Patients with Chronic Kidney Disease** Shahaan Smith,[1] Viji Nair,[1] Felix H. Eichinger,[1] Ivan Formentini,[2] Maria Bobadilla,[2] Maria Chiara Magnone,[2] Keith A. Bellovich,[3] Susan P. Steigerwalt,[3] Matthias Kretzler,[1] Wenjun Ju.[1] *[1]Univ of Michigan; [2]Hoffmann-La Roche; [3]Renaissance Renal Research Institute, for the Michigan O'Brien Renal Center (P30) & ERCB Consortium.*

**Background:** Epidermal growth factor (EGF) and neutrophil gelatinase-associated lipocalin (LCN2) are potential urinary biomarkers for CKD. Therefore, it is important to understand the mechanism linking these two tubular markers to CKD. A study using LCN2 deficient mice demonstrated a critical role of LCN2 in renal failure, and their *in vitro* data suggested that EGF might activate LCN2 expression. However, if LCN2 is a down-stream target that links EGF to CKD progression in humans remains unknown. This prompted us to study the relationship between EGF and LCN2 in patients with CKD in cohort studies from Europe (European Renal cDNA Bank, ERCB) and North-America (Michigan O'Brien Renal Center P30, CPROBE).

**Methods:** Renal RNA levels were derived from gene expression profiling performed on tubulointerstitial compartment of micro-dissected renal biopsy tissue from two independent cohorts: 164 ERCB subjects and 42 CPROBE subjects. Pearson correlation was used to correlate marker levels with kidney function, assessed by estimated glomerular filtration rate (eGFR) using the MDRD equation. Urinary EGF and LCN2 were measured by ELISA.

**Results:** Our study shows that intra-renal RNA levels of EGF and LCN2 in tubulointerstitial compartment are significantly correlated with eGFR-MDRD in ERCB (r=0.66, and r=-0.48, respectively), and in CPROBE (r=0.42, and r=-0.63, respectively). A significant inverse correlation was observed between EGF and LCN2 RNA level in both study cohorts (r=-0.54, and r= -0.61, respectively). The inverse correlation is retained at the urine marker protein level in CPROBE patients (r=-0.46, p=0.007).

**Conclusions:** The consistent association between reduced EGF level and increased LCN2 expression in CKD patients supports that LCN2 may be one of the paths that mediate the role of EGF in CKD progression. Future studies will focus on determining the signaling mediators between EGF and LCN2 in human tubular cells.

*Funding:* NIDDK Support, Pharmaceutical Company Support - Hoffmann-La Roche

## TH-PO188

**Uric Acid and Risk of Chronic Kidney Disease Progression in a United Kingdom Cohort** Matthew Denker, Jason Roy, Harold I. Feldman. *Medicine, Univ of Pennsylvania, Philadelphia, PA.*

**Background:** Uric acid (UA) is a potential risk factor for CKD progression, supported by some but not all observational studies. We aimed to identify patients with CKD with varying degrees of kidney dysfunction in order to test whether the association between UA and CKD progression differs by baseline CKD severity.

**Methods:** We conducted a retrospective cohort study using UK's The Health Improvement Network (THIN) database to identify adult patients with CKD who had a UA recorded after meeting CKD criteria, a corresponding serum creatinine (Cr), and at least 1 Cr subsequent to both UA and latter Cr. Those with ESRD prior to UA or with <1 year follow-up were excluded. Linear mixed effects models were fit to model slope of ΔeGFR over time, adjusted for baseline covariates including age, sex, BMI, BP, eGFR, hemoglobin, albuminuria, RAAS-blockers, diuretics, and hypouricemic agents. Censoring occurred at the earliest of dialysis initiation, kidney transplant, death, or January 2012.

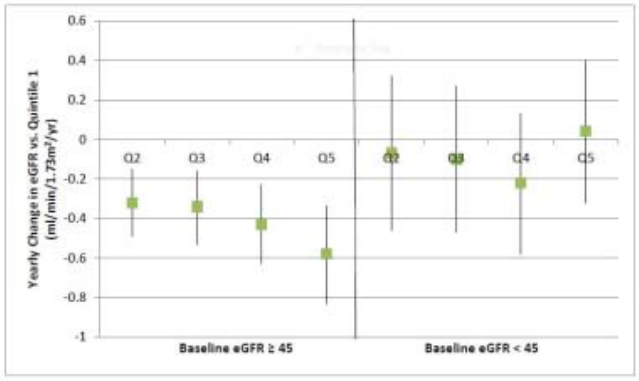
**Results:** We identified 21,478 patients: 47% men, median age 73.9 yrs, mean baseline eGFR (beGFR) 53 ml/min/1.73m². Median follow-up was 3.7 yrs.

Table 1. Baseline characteristics by uric acid quintile.

| Baseline characteristic | Q1 | Q2 | Q3 | Q4 | Q5 |
|---|---|---|---|---|---|
| Number of patients | 4410 | 4294 | 4142 | 4488 | 4144 |
| Median uric acid (mg/dl) | 4.4 | 5.7 | 6.8 | 8.0 | 9.7 |
| Mean SBP (mmHg) | 139.0 | 140.7 | 140.3 | 139.6 | 136.8 |
| Gout (%) | 15.4 | 16.4 | 23.5 | 37.6 | 46.3 |
| Mean eGFR (ml/min/1.73m²) | 61.3 | 56.5 | 53.4 | 49.7 | 43.1 |

The association between UA and CKD progression differed by beGFR (test for interaction p<0.001). In patients with more preserved kidney function, higher UA was associated with faster loss of eGFR (p<0.001). UA was not associated with progression in those with beGFR<45.

Figure 1. Adjusted yearly change in eGFR associated with each quintile of uric acid when compared to quintile 1.



**Conclusions:** UA was associated with more rapid loss of eGFR in those with mild-moderate CKD. Since the UK population is 3% black, generalizability of findings may be limited to white patients in US.

*Funding:* NIDDK Support

## TH-PO189

**Effects of Febuxostat versus Allopurinol in Reducing Serum Urate in Subjects with Hyperuricemia and CKD Stage 3-5: One Year, Randomized Trial** Nobuhito Hirawa,[1] Keisuke Yatsu,[2] Mari Katsumata,[1] Akira Fujiwara,[2] Sanae Saka,[1] Yoshiyuki Toya,[2] Gen Yasuda,[1] Satoshi Umemura.[2] *[1]Dept of Nephrology and Hypertension, Yokohama City Univ Medical Center, Yokohama, Kanagawa, Japan; [2]Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Kanagawa, Japan.*

**Background:** Febuxostat (Feb), an orally administered non-purine selective inhibitor of xanthine oxidase, was developed recently. Compared to allopurinol (Allo), Feb directly inhibits xanthine oxidase and is metabolized by liver, partly. Thus, Feb may be easy to use in patients with renal impairment. In this study, to clarify the urate-lowering efficacy and safety of Feb, we compare the effectiveness of Feb and Allo in subjects with hyperuricemia and CKD stage 3-5 for one year.

**Methods:** Forty patients with CKD stage 3-5 and hyperuricemia (serum urate levels > 8mg/dl) were randomized to receive once-daily Feb (10mg) or Allo (50mg) for four weeks. After that, Feb and Allo were permitted to increase the dose until 40mg/day (Feb) in all participants, and 100 mg (Allo) in CKD stage 3. The 1st endpoint was the UA values at one year. Furthermore, we examined the effects on renal function and investigated the safety of Feb and Allo treatments in CKD stage 3-5 patients.

**Results:** The average age and eGFR of the participants were 63 years old and 22 ml/min/1.73m2. There were no differences in BP, Cr, UA values between Feb group and Allo group in the control period. Feb and Allo significantly decreased the serum UA levels at 2 weeks after treatments. The UA level of Feb group was significantly lower than Allo group in 12 weeks, 24 weeks and one-year of treatments (p<0.01). There was no difference in serum creatinine and eGFR by two treatments. The changes of the slope of 1/Cr were negatively correlated with the alterations of the serum UA (P<0.05). Using the multivariate analysis, the UA values of one-year treatment were associated with Feb use, baseline UA value, but not with baseline eGFR. Obvious side effects were not recognized in Feb treatments.

**Conclusions:** Febuxostat is effective and safe in patients with hyperuricemia and CKD stage 3-5 for one-year treatment.

## TH-PO190

**Interaction between Hyperuricemia and Smoking on Renal Arteriolopathy in Chronic Kidney Disease Patients** Kentaro Kohagura,[1] Tsuyoshi Miyagi,[1] Masako Kochi,[1] Yusuke Ohya,[1] Kunitoshi Iseki.[2] *[1]Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus, Nishihara-Cho, Okinawa, Japan; [2]Dialysis Unit, Univ of the Ryukyus, Nishihara-Cho, Okinawa, Japan.*

**Background:** We have recently reported that hyperuricemia (HU) was associated with renal arteriolopathy in chronic kidney disease (CKD) patients. Smoking (SMK) is also potential risk factor for renal arteriolopathy. However, the effect of combination SMK and HU on renal arteriopathy is unknown.

**Methods:** We examined the cross-sectional association between HU and renal arteriolopathy with or without SMK (current or past) using renal biopsy specimen. Arteriolar hyalinosis and wall thickening were assessed by semi quantitative grading for arterioles among 167 patients with CKD (mean age, 43.4 yrs; 88 men and 81 women).

**Results:** Subgroup analysis showed that HU+/SMK+ group had highest grade of arteriolopathy followed by HU+/SMK-, HU-/SMK+. Interaction between HU and SMK on index of renal arteriolopathy was significant (p=0.003). That is, effect of HU on renal arteriolopathy was significantly augmented by coexistence of SMK. Multiple logistic analysis adjusted for age hypertension and diabetes mellitus showed that HU+/ SMK+ was significantly associated with higher risk for the presence of higher-grade renal arteriolar

hyalinosis and wall thickening compared with HU-/SMK- as a reference, but HU+/SMK- was not. The adjusted odds ratios (95% CI) of hyalinosis and wall thickening were 4.2 (1.1 to 15.4) and 3.6 (1.0-12.7), respectively.

**Conclusions:** In conclusion, significant interaction between HU and SMK on renal arteriolopathy was observed in CKD patients. Further prospective study is needed to determine whether CKD patients in hyperuricemia who have smoking habit show rapid decline in eGFR.

## TH-PO191

**Effect of Cholecalciferol on Proteinuria in Patients with Chronic Kidney Disease** Subir K. Paul, Shejuti Paul, Rajesh Boorgu, Narasimha R. Boorgu, Jamie N. Cockrell. *Shoals Kidney and Hypertension Center, Florence, AL.*

**Background:** Proteinuria is well-known to be associated with adverse cardiovascular outcome. When angiotensin converting enzyme inhibitor (ACEI) and angiotensin receptor blocker (ARB) are contraindicated, poorly tolerated, or have inadequate effects, the therapeutic choice for proteinuria in chronic kidney disease (CKD) patients becomes mostly limited to optimum blood pressure control. Recently, Vitamin D receptor activation has shown to reduce proteinuria in diabetic nephropathy. The effect of nutritional Vitamin D on proteinuria in CKD is unknown. This study examines the effects of cholecalciferol (CHO) on proteinuria in patients with CKD.

**Methods:** 61 patients with stage 3 and early stage 4 CKD with urine protein creatinine ratio (UPCR) of 0.5 or more and 25 OH Vitamin D (25OHD) level of less than 32 ng/ml were studied. 31 patients were treated with an average dose of 2050 mg of CHO daily for 3 to 9 months. 30 patients did not receive CHO treatment. Patient characteristics including age, race, gender, estimated GFR, presence of diabetes, hypertension, glomerulopathy, number of patients on ACEI or ARB, control of hypertension and diabetes were similar in both groups. Comprehensive metabolic profile, UPCR, and 25OHD levels were measured at baseline and during 4 to 9 months.

**Results:** Baseline 25OHD level for treated and untreated patients was 20.03 ng/mL and 21.73 ng/mL respectively (P=0.32). 25OHD level increased to 36.4 ng/mL (P<0.0001) following therapy in treated group and remained similar at 21.8 ng/mL (P=0.96) in untreated group. Baseline UPCR in treated and untreated group was 3.91 and 3.55 (P= 0.74) respectively. While in treated group, UPCR decreased from 3.91 to 1.64 (P=0.003), UPCR mildly increased from 3.55 to 4.07 (P=0.69) in untreated group. Baseline serum albumin was 3.71 g/dL and 3.71 g/dL (P= 0.98) in treated and untreated patients respectively. Serum albumin increased from 3.71 g/dL to 3.97 g/dL (P=0.01) in treated group but was unchanged from 3.71 g/dL to 3.72 g/dL (P=0.91) in untreated group.

**Conclusions:** We conclude that CHO therapy may ameliorate proteinuria in patients with CKD. Large randomized trials are warranted.

## TH-PO192

**Endothelial Glycocalyx Perturbation Accompanies Renal Failure** Martijn Dane,[1,3] Meriem Khairoun,[1] Bernard Van Den Berg,[1] Dae Hyun Lee,[1] Margien G.S. Boels,[1] Angelique Rops,[2] Johan Van der Vlag,[2] Hans Vink,[3] Anton Jan Van Zonneveld,[1] Marlies Reinders,[1] Ton J. Rabelink.[1] *[1]Nephrology, LUMC, Leiden, Netherlands; [2]Nephrology, RUNMC, Nijmegen, Netherlands; [3]Physiology, MUMC, Maastricht, Netherlands.*

**Background:** End-stage renal disease (ESRD) is accompanied by endothelial dysfunction. Since the endothelial glycocalyx (endothelial surface layer, ESL) governs interactions between flowing blood and the vessel wall, perturbation could influence disease progression. In this study we used non-invasive sidestream darkfield (SDF) imaging to investigate whether renal failure is associated with perturbation of the ESL. To this end we measured the accessibility of red blood cells to the endothelial surface in the microcirculation (perfusion boundary region, PBR).

**Methods:** The PBR was measured in patients with ESRD (n=23), after a successful living donor kidney transplantation (n=12),in patients who developed interstitial fibrosis / tubular atrophy after kidney transplantation (IFTA, n=10) and healthy controls (HC) (n=10). In addition, the endothelial activation marker Angiopoietin-2 (Ang2) and the shed ESL components syndecan-1 and soluble thrombomodulin (sTM) were measured using ELISA. All differences shown have a P-value of <0.05.

**Results:** ESRD patients showed an increased PBR compared to controls (2.05 ± 0.25 vs. 1.82 ± 0.16 µm), which was accompanied by increased circulating levels of sTM (19.9 ± 8.2 ng/mL vs. HC 7.1 ± 1.2 ng/mL) and syndecan-1 (107.5 ± 51.1 ng/mL vs. HC 49.8 ± 17.4 ng/mL). Patients with IFTA also revealed an increased PBR (2.18 ± 0.20 µm), which coincided with elevated sTM levels (41.9 ± 24.7 ng/ml, vs. HC) which were even higher than in ESRD. Interestingly, after successful transplantation, patients had a PBR of 1.84 ± 0.2 µm, indistinguishable from healthy controls, without elevated plasma levels of sTM (13.0 ± 3.0 ng/mL) or syndecan-1 (54.8 ± 32.6 ng/mL). In addition, a significant correlation between PBR, Ang2 and eGFR, (Spearman's rho = 0.306 and -0.342 resp.) was observed.

**Conclusions:** Loss of renal function is strongly associated with perturbation of the endothelial glycocalyx. Successful kidney transplantation, however, results in recovery of the endothelial glycocalyx.

## TH-PO193

**Activation of Coagulation during Chronic Kidney Disease Is Counterbalanced by Defective Platelets Adhesion: An Intravital Videomicroscopy Analysis** Stephane Burtey, Stéphane Poitevin, Roxane Darbousset, Bertrand Gondouin, Christophe Dubois. *UMR_S 1076, Aix-Marseille Univ, Marseille, France.*

**Background:** Patients with chronic kidney disease (CKD) have an increased risk of thrombosis and an increased risk of hemorrhage. The physiopathology of this counterintuitive association is unknown. We identified indolic solutes as critical in the induction of tissue factor (TF) expression and procoagulant activity. We hypothesize that TF could play an important role in vivo to promote clot formation.

**Methods:** To confirm it we used a well described in vivo live imaging of thrombi formation dependant of TF. Endothelial cells of the cremaster arterioles in anesthetized mouse were activated by laser pulse. Platelets aggregation and fibrin formation at the lesion site were imaging by intravital videomicroscopy. The fibrin and the platelets were revealed by labels antibodies. The kinetics of thrombi was analyzed in more than 30 thrombi in five C57/bl6 mice with renal failure induced by 5/6 nephrectomy (Nx) and four control mice. The integrative fluorescence activity is expressed in median of arbitrary units (AU).

**Results:** In mice with 5/6 Nx the fibrin formation began earlier. The same mean fluorescence intensity (5AU, 10 AU and 20 AU) was observed 50+/-10 seconds earlier in mice with renal failure than in control mice. At time 300s, the fibrin formation at the lesion site is more important in 5/6 Nx mice (30 AU) than in control mice (20 AU) (p<0.0001). In contrast, we observed less fluorescence for platelets staining at all the time in 5/6 Nx mice compared to control mice. We confirmed this defect in platelets aggregation by performing bleeding time experiment. The median bleeding time of 5/6 Nx mice was significantly increased compared to control.

**Conclusions:** We confirmed in vivo the association of activated coagulation and defective platelets adhesion in a mouse model of renal failure. The coagulation activation is dependant of TF. This association could explain the increased risk of thrombosis observed in human combined with increased bleeding risk. The intravital videomicroscopy give us the opportunity to identify the mechanisms leading to the paradoxal hemostatic state observed in CKD.

## TH-PO194

**Vascular Injury Promotes Glomerulotubular Junction Abnormalities (GTJA) which May Progress Chronic Kidney Disease (CKD): Three-Dimensional (3D) Inspection of Vasculo-Glomerular Alterations** Noriko Uesugi,[1] Yoshihito Shimazu,[2] Takaaki Aoba,[2] Michio Nagata.[1] *[1]Pathol., Tsukuba Univ, Tsukuba, Japan; [2]Pathol., Nippon Dental Univ, Tokyo, Japan.*

**Background:** GTJA including atubular glomeruli (AG) has been identified as a cause of nephron loss in number of glomerular diseases. GTJA is 3D event and was likely underappreciated because of difficulties of morphologic recognition.To verify the hypothesis that vascular injury by hypertension(HT) concern occurrence of GTJA promoting nephron loss in CKD, we investigated three-dimensional vasculo-glomerular architectures of GTJA in human kidney with CKD stage 1-3.

**Methods:** Kidney tissue was obtained from 23 samples of surgically removed non-tumor parts of renal carcinoma in Japanease (Male 18, Female 5; age: 45-86.; without proteinuria, 13 with HT). The prevalence of GTJA in CKD was first surveyed on 500 serial sections in 3mm$^2$ size with double staining by PAS and Elastica. On that basis, we selected 7 cases for 3D reconstruction, in which 120 serial sections were double or triple-stained in combination with CD10 (anti-proximal tubular marker), CD34 (anti-endothelial marker), and smooth muscle actin (SMA; anti-vascular medial marker). Individual immunostained images of a whole histological section were acquired with virtual slide system and 3D reconstruction were conducted using Image-J software.

**Results:** High resolution 3D reconstruction images from interlobular arteries to glomeruli with proximal tubular image was successfully obtained. GTJA was noticed in 4.3±5.2% in HT cases and 0.7±0.3% in non–HT cases (p=0.09). Severe GTJA including AG showed complete disconnection of vascular pole and afferent arterioles (AA) associated with severe interstitial fibrosis. Occlusion of near interlobular arteries (AA) was found in some cases. Other GTJA showed marked narrowing of AA by intimal fibrosis and long distance convoluted running of AA with opened lumina. Loss of CD10 expression was often noticed in atrophic tubules.

**Conclusions:** In the pathogenesis of CKD, arteriolosclerosis caused by HT likely promote development of GTJA , resulting in nephron loss. Anomalous vasculo-glomerular architecture in CKD kidney can be monitored in 3D reconstruction.

*Funding:* Government Support - Non-U.S.

## TH-PO195

**Chronic Kidney Disease and Fracture Risk in the Action to Control Cardiovascular Risk in Diabetes Trial** Tamara Isakova,[1] Timothy Craven,[2] Julia J. Scialla,[1] Huiliang Xie,[1] Thomas L. Nickolas,[3] Adrian Schnall,[4] Joshua Barzilay,[5] Ann Schwartz.[6] *[1]Univ of Miami Miller School of Medicine; [2]Wake Forest School of Medicine; [3]Columbia Univ Medical Center; [4]CWRU School of Medicine; [5]Emory Univ School of Medicine; [6]UCSF School of Medicine.*

**Background:** Large epidemiological studies demonstrate that type 2 diabetes independently increases fracture risk. One mechanism that could explain this increased risk is the higher prevalence and incidence of chronic kidney disease (CKD) that is associated with type 2 diabetes.

**Methods:** In secondary analysis of 6661 participants included in an ancillary study of fractures in the Action to Control Cardiovascular Risk in Diabetes (ACCORD) trial, we used logistic regression to examine relationships between different definitions of CKD and centrally adjudicated non-vertebral fracture rates over a median follow up time of 4.9 years.

**Results:** We found that definitions relying on baseline estimated glomerular filtration rate (eGFR) and/or albuminuria were not associated with fracture risk.

| CKD Definition | Incidence Densities† (95% CI) | Adjusted‡ Odds Ratio (95% CI) |
|---|---|---|
| Reference | 1.53 (1.39 – 1.68) | 1 |
| Baseline eGFR < 60 ml/min/1.73 m² | 1.87 (1.55 – 2.27) | 1.13 (0.81 – 1.60) |
| Reference | 1.59 (1.43 – 1.76) | 1 |
| Baseline UACR ≥ 30 mg albumin/g creatinine | 1.58 (1.35 – 1.85) | 1.03 (0.82 – 1.28) |
| Reference | 1.54 (1.38 – 1.73) | 1 |
| Baseline eGFR <60 ml/min/1.73 m² and baseline UACR >30 mg albumin/g creatinine | 1.93 (1.43 – 2.61) | 1.38 (0.82 – 2.33) |
| Reference | 1.42 (1.23 – 1.62) | 1 |
| Incident CKD* | 1.97 (1.65 – 2.34) | 1.47 (1.14 – 1.89) |

*Incident CKD defined as last eGFR <60 ml/min/1.73 m² and 20% drop during follow up, or UACR ≥ 30 mg albumin/g creatinine during follow up
†Per 100 person-years at risk
‡Adjusted for age, gender, socioeconomic status, living situation, smoking, glycemic control intervention arm, BP, HbA1C, baseline eGFR and albuminuria, and use of hormone replacement therapy, steroids, diuretics, statins and anti-psychotic medications.

However, incident CKD, defined as last eGFR <60 ml/min/1.73 m² and 20% drop in eGFR during follow-up or development of urinary albumin to creatinine ratio ≥30 mg albumin/g creatinine during follow-up, was significantly associated with more fractures. Compared to participants who did not develop incident CKD, those who did had significantly increased odds of non-vertebral fracture, independent of other covariates (odd ratio, 1.47; 95% confidence intervals, 1.14 – 1.89).

**Conclusions:** These data suggest that longitudinal measures of kidney function are more sensitive predictors of fracture risk than baseline CKD status. The findings also justify further investigation of abnormalities in mineral metabolism that develop early in the course of CKD as potential mediators of bone fragility in this population.

*Funding:* NIDDK Support, Other NIH Support - NHLBI

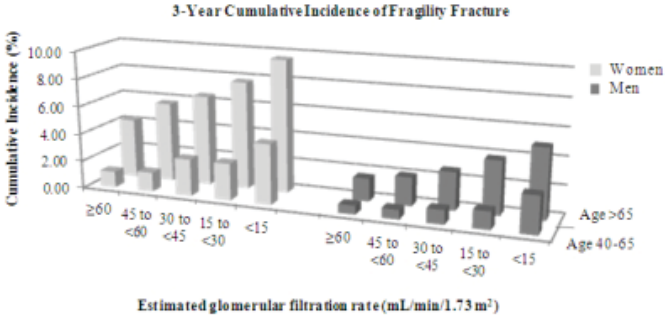
## TH-PO196

**3-Year Incidence of Fragility Fracture in Chronic Kidney Disease** Kyla Lynn Naylor,[1,2] Eric McArthur,[3] Amit X. Garg.[1,2,3] *[1]Nephrology, Western Univ, London, Canada; [2]Epidemiology and Biostatistics, Western Univ, London, Canada; [3]Institute for Clinical Evaluative Sciences, London, Canada.*

**Background:** There is much clinical value in simply knowing how likely a person is to fracture according to their level of kidney function, sex and age.

**Methods:** Using large healthcare databases from Ontario, Canada we conducted a retrospective cohort study of adults aged ≥ 40 years (n = 679,114, mean age 62 years) stratified at cohort entry by their estimated glomerular filtration rate (eGFR ≥60 mL/min/1.73 m², 45 to <60, 30 to <45, 15 to <30, <15 or chronic dialysis), sex and age (40-65 versus >65 years). The primary outcome was the 3-year cumulative incidence of fragility fracture (proportion of adults who fractured at least once within 3-years of follow-up). Fractures of the hip, forearm, pelvis or humerus were counted in the primary outcome. In additional analyses the following were examined: fracture incidence per 1000 person-years; hip fracture alone; stratification by prior history of fracture (yes *vs* no); and stratification by both baseline eGFR and proteinuria.

**Results:** The 3-year cumulative incidence of fracture increased in a graded manner in groups of adults with a lower level of eGFR for both men and women for both age groups. For example, the 3-year cumulative incidence of fracture in women aged > 65 years across the five eGFR groups were 4.3%, 5.8%, 6.5%, 7.8% and 9.6%. The corresponding estimates for men aged > 65 were 1.6%, 2.0%, 2.7%, 3.8% and 5.0%. Similar graded relationships were observed in all additional analyses.



**Conclusions:** Many men and women with chronic kidney disease will fracture. These results can be used for simple bedside prognostication and to guide sample size requirements for future fracture prevention trials.

*Funding:* Government Support - Non-U.S.

## TH-PO197

**Toll Like Receptor 2 / 4, MYD88, TNF-α and IL-6 Expression in Leukocytes of Hemodialysis and Pre-Dialysis Patients** Caren Cristina Grabulosa,[1] Edgar Ferreira Cruz,[1] Jose Tarcisio Carvalho,[1] Aline Trevisan Peres,[1] Beata Marie Redublo Quinto,[1] Lilian Cuppari,[1] Maria Dalboni.[1] *[1]Universidade Federal de Sao Paulo; [2]Tufts-New England Medical Center.*

**Background:** Toll-like receptors (TLR) are involved in mechanisms of immunity response. There are few studies that describe TLRs expression in leukocytes from chronic kidney disease patients. However, to evaluate TLR-2, TLR-4, MyD88, TNF-α and IL-6 expression in neutrophils (PMN), monocytes (MN) and lymphocytes (LYM) from HD and PD patients.

**Methods:** Blood samples from 38 hemodialysis (HD) patients, 33 pre-dialysis (PD) and 43 age-and gender-matched healthy volunteers (CONT) were analyzed for TLR2, TLR4, MYD88, TNF-α and IL-6 expression on PMN, MN and LYM. Besides, we studied PMN and MN from PD patients unstimulated and stimulated by lipopolysaccharide (LPS) and peptidoglycan (PG), by flow cytometry.

**Results:** PMN from PD patients without stimulus exhibited significant upregulation of TLR2 (4446±2426 vs 285±79; p=<0.001), TLR4 (4479±2189 vs 317±293; p=<0.001) and MYD88 (1018±670 vs 374±44; p= <0.001) expression compared to CONT and HD groups. HD patients showed upregulation only for PMN TLR2+MyD88+ expression compared to CONT and PD groups. We observed in PMN TLR2+ and PMN TLR4+ a positive correlation with TNF-α, IL-6 and MyD88 expression stimulated by LPS and PG in all groups ( r = 0.40; p < 0.05 and r = 0.37; p < 0.05, respectively). PD neutrophils stimulated by LPS and PG showed a higher expression of TLR2 and TLR4 compared to unstimulated PD neutrophils: TLR2 (unstimulated: 4446±2426; LPS: 5751±1445 and PG: 5706±1419; p <0.01) and TLR4 (unstimulated: 4786±2558; LPS: 6934±3141 and PG: 5779±2402; p <0.01). In contrast, PD stimulated by LPS and PG were significantly lower than unstimulated monocytes (unstimulated: 170±161; LPS: 111±35 and PG: 109±30; p < 0.05).

**Conclusions:** It is possible that the activation of PMN from PD patients (more TLR2 and TLR4 expression) probably reflected the effect of high serum levels concentration of uremic toxins. Moreover, the positive correlations between TLR2/4 and MyD88 with cytokines from leukocytes unstimulated and stimulated confirm the role of this mechanism in CKD inflammatory response.

*Funding:* Government Support - Non-U.S.

## TH-PO198

**Kidney-Brain Crosstalk during Sepsis** Misako Asada, Motoko Yanagita. *Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.*

**Background:** Patients with chronic kidney disease (CKD) have a higher prevalence, severity, and mortality of sepsis. However, the mechanism that CKD influences the outcome of sepsis remains unclear. The main cause of death in septic patients is multi-organ failure, and increasing evidences support the presence of crosstalk between kidney and other distant organs via soluble and cellular inflammatory mediators. Here we investigated the influences of CKD on kidney-brain crosstalk in the context of systemic inflammation.

**Methods:** We divided C57BL/6J male mice (8~9week) into 4 groups: sham-operated mice injected with vehicle (sham/vehicle mice), sham mice injected with lipopolysaccharides (LPS, 2.5mg/kg BW)(sham/LPS mice), mice operated with unilateral ureter obstruction (UUO)(UUO mice), and mice operated with UUO and injected with LPS (UUO/LPS mice). Mice were sacrificed 5 days after the operation, and organs were subjected to histological analysis and quantitative reverse transcription polymerase chain reaction (qPCR).

**Results:** The expression of IL-6, TNF-a and MCP1 was significantly up-regulated in both kidneys of UUO/LPS mice compared to that of UUO and sham/LPS mice. The expression of kidney tubular damage markers increased in both kidneys in UUO/LPS mice compared to UUO mice. We evaluated the damages in the brain and demonstrated that the expression of IL-6, IL-6R and GFAP, a marker for activated glial cells during brain inflammation, as well as cleaved caspase 3, a marker for apoptosis, was significantly up-regulated in UUO/LPS mice compared to other 3 groups. Induction of GFAP was further confirmed by immunostaining. To analyze the molecular mechanism for kidney-brain crosstalk, we evaluated the expression of neuroprotective factors and found that EGF was significantly decreased in both kidneys in UUO/LPS mice compared to other 3 groups. Furthermore, we confirmed the EGFR phosphorylation in the brain of UUO/LPS mice was decreased significantly.

**Conclusions:** Existence of fibrotic kidneys during sepsis aggravates brain injury, possibly due to the reduced expression of EGF in the kidneys. EGFR mediated signaling in brain may be important to maintain the brain condition.

## TH-PO199

**Race and Severity of Kidney Disease Modify the Associations between Hyponatremia and Death** Sankar D. Navaneethan,[1] Jesse D. Schold,[2] Jonathan J. Taliercio,[1] Susana Arrigain,[2] Stacey Jolly,[3] James F. Simon,[1] Joseph V. Nally.[1] *[1]Nephrology; [2]Quantitative Health Sciences; [3]Medicine, Cleveland Clinic.*

**Background:** Hyponatremia is associated with falls and higher risk for death in elderly population. We studied the associations between hyponatremia and death among chronic kidney disease (CKD) patients.

**Methods:** The risk for development of hyponatremia and association with death was examined using logistic regression and Cox-proportional hazard models. We tested 2-way interactions between serum sodium and the following covariates in the adjusted model: age, gender, race, diabetes, heart failure and eGFR.

**Results:** Out of 45,021 CKD patients, 3.6% (n=1645) had hyponatremia (sodium <135 mg/dl in men and <132 mg/dl in women). Male gender, presence of diabetes and malignancy were associated with higher risk for hyponatremia while higher age, eGFR and BMI were associated with lower risk for hyponatremia. After covariate adjustment that included heart failure, kidney and liver function, hyponatremia was associated with a 47% increased risk (95% CI 1.36, 1.60) for death. Caucasians but not blacks had higher risk for death with hyponatremia. The association between hyponatremia and death was pronounced among those with stage 3 CKD and younger patients.

| Variable | Hazard ratio | 95% CI |
|---|---|---|
| Age | | |
| 18-64.3 years | 1.47 | 1.26, 1.72 |
| 64.3-73.0 years | 1.87 | 1.57, 2.22 |
| 73.0-80.6 years | 1.65 | 1.39, 1.96 |
| >80.6 years | 1.17 | 1.01, 1.36 |
| Race | | |
| Caucasians | 1.52 | 1.39, 1.66 |
| African Americans | 1.20 | 0.97, 1.48 |
| Stage of CKD | | |
| Stage 3a (eGFR 45-59) | 1.54 | 1.37, 1.73 |
| Stage 3b (eGFR 30-44) | 1.49 | 1.30, 1.71 |
| Stage 4 (eGFR 15-29) | 1.27 | 1.05, 1.53 |

Similar results were noted in a subset of patients (n=8,205) when adjusted for LVEF (instead of clinical diagnosis of heart failure).

**Conclusions:** Hyponatremia is associated with death among those with CKD. Caucasians and those with stage 3 CKD sustain higher risks for death than African Americans and those with advanced kidney disease. Future studies should explore the reasons for the modified effects noted in our study.

## TH-PO200

**Association of Anemia and Mineral and Bone Disorders with Health-Related Quality of Life in Predialysis Patients** Priscilla P. How,[1] Jun Jie Benjamin Seng,[1] Jia Jia Lee,[1] Hwee-Lin Wee,[1] Pallavi Tyagi,[2] Vathsala Anantharaman.[2] *[1]Pharmacy, National Univ of Singapore, Singapore, Singapore; [2]Medicine (Div of Nephrology), National Univ Hospital, Singapore, Singapore.*

**Background:** Chronic kidney disease (CKD) patients have poor health-related quality of life (HRQoL), which has been associated with increased morbidity and mortality. Compared with dialysis patients, the impact of CKD-related complications such as anemia and, mineral and bone disorders (MBD), on HRQoL in predialysis patients is less well-studied. This study aimed to examine the association of anemia and MBD with HRQoL in predialysis patients.

**Methods:** A cross-sectional study involving predialysis patients from the National University Hospital, Singapore, outpatient renal clinic was conducted. Patients' HRQoL were assessed using the Kidney Disease Quality of Life Short Form (KDQOL-SF™) and EuroQol 5 Dimensions–3 levels (EQ5D-3L). Psychosocial variables were evaluated using the Medical Outcomes Family Functioning Measure questionnaire. Separate hierarchical multiple linear regressions were performed using HRQoL scales as dependent variables, with adjustment for socio-demographic, clinical and psychosocial variables, to determine associations.

**Results:** Among 246 patients who completed the study, 227 and 225 patients possessed the relevant data for the anemia and MBD analyses, respectively. Eighty-four (37.0%) patients had anemia while 96 (42.7%) patients had MBD. After adjusting for potential confounders, anemia was associated with poorer physical component summary (β=-3.95, p=0.006) and mental component summary scores (β=-4.50, p=0.003), but better EQ5D-3L visual analogue scale scores (β=6.64, p=0.021). Anemia was not associated with EQ5D-3L utility scores. Although no association was found between MBD and the four summary HRQoL scales, it was associated with poorer scores in other disease-specific HRQoL domains such as symptoms (β=-22.30, p<0.001).

**Conclusions:** Anemia and MBD were associated with poorer HRQoL in predialysis patients. Future research should explore the impact of optimal anemia and MBD treatment on improving patients' HRQOL.

## TH-PO201

**Daily Patient Reported Outcome Reporting Is Practical and Demonstrates Differential Patient Experience** Zoe C.L. Pittman,[1] Stephen G. John,[1] Chris W. McIntyre.[1,2] *[1]Royal Derby Hospital, United Kingdom; [2]Univ of Nottingham, United Kingdom.*

**Background:** Patient reported outcomes (PRO) are increasingly recognised as a critical metric in chronic disease. Whilst a variety of generic and disease specific PRO measures (PROMs) have been used in CKD, studies are mainly cross-sectional with limited longitudinal data. None of the available PROMs are designed for iterative application. We designed and implemented a CKD specific online dynamic PROM for daily use.

**Methods:** PRO selection was informed by published data on symptom burden and a patient survey. 6 separate domains (general well being (GWB), pain, sleep, breathing, energy and appetite) were included. A custom website was built to capture PROs daily utilising visual analogue scales (free selection of status from 0(worst) to 100(best)). Additional clinical information was collected from the patient record.

**Results:** 43 patients submitted at least one set of data via the website with a median follow up at analysis of 247 days (range 10 – 312 days), 64% male, mean age 62±12 yrs. 80% (17 Dialysis and 17 CKD) submitted data for > 30 days. 65% continued to submit data at 90 days. Dialysis patients had significantly lower median [IQR] scores for sleep (51[32–83], 96[71–98], p=0.001), appetite (69[52–95], 96[78–99], p=0.014), energy (50[40–81], 83[67–95], p=0.013) and GWB (60[47–84], 87[71–97] p=0.010). There was no statistical difference in scores for pain or breathing. Individual patients demonstrate a variety of mainly stable bandwidths of response. Analysis of individual patient response patterns revealed detectable score changes associated with specific events (admission, fistula formation, dialysis start). In individual dialysis patients there were changes related to fluid status, admissions and differing scores dependent on dialysis or non-dialysis day.

**Conclusions:** We have successfully introduced a web based PROM for frequent use which is acceptable to patients and has the ability to discriminate symptom burden cross-sectionally and longitudinally. Further work will look to prospectively examine the predictive power of changes in PRO and make formal comparison with current measures of health related quality of life and symptom scores.

## TH-PO202

**Depression in the Chronic Kidney Disease in Children (CKiD) Cohort Study** Amy Kogon, Matthew Matheson, Joseph T. Flynn, Bradley A. Warady, Susan L. Furth, Stephen R. Hooper. *CKiD Study Group.*

**Background:** No large studies exist regarding the prevalence of depression in pediatric chronic kidney disease (CKD). Using CKiD data, we assessed the factors associated with depression.

**Methods:** Depression was defined as a score ≥ one standard deviation above the mean on the Children's Depression Inventory (CDI) or a history of depression concurrent with active treatment. Associated factors were determined by multivariate linear and logistic regression analyses. Separate models assessed clinical/demographic factors and cognitive/psychosocial factors.

**Results:** 344 children (median age 13 years [IQR 10, 15]) completed the CDI; 18 had elevated depression scores and 7 had normal scores and were undergoing treatment for depression. Higher maternal education and higher height z-score were protective for depression. There was a trend towards more depression in patients with congenital CKD. Depressed subjects had lower academic achievement scores (WIAT-II) (p=0.06) and lower quality of life scores (PedsQL) (p<.0001).

| Factor | OR for depression [95% CI] |
|---|---|
| Age | 1.08 [0.89,1.30] |

| Duration of CKD | 0.95 [0.83,1.08] |
| Etiology of CKD | |
| Glomerular | 3.37 [0.31,36.64] |
| Non-glomerular, congenital | 8.07 [0.94,69.33] |
| Non-glomerular other | 1.00 |
| GFR (per 10 ml/min/1.73m$^2$) | 1.12 [0.79,1.60] |
| Height z-score | 0.58 [0.35,0.96] |
| BMI z-score | 0.87 [0.55,1.36] |

**Conclusions:** The prevalence of depression in this pediatric CKD cohort was lower than in other reports. Few clinical factors predicted depression. The association with congenital CKD without an association with duration of disease suggests that there may be a common pathway linking congenital CKD to the occurrence of depression. Depression may be a modifiable factor contributing to academic achievement and quality of life in these patients.

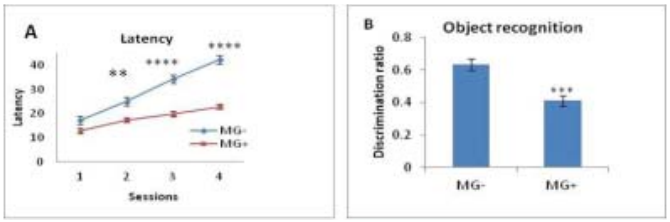
## TH-PO203

**Advanced Glycation End Products (AGEs) Increase the Risk for Cognitive Decline in Aging Mice with Chronic Kidney Disease (CKD)** Shobha M. Swamy, Elena M. Yubero-Serrano, Jaime Uribarri, Helen Vlassara, Gary E. Striker. *Mount Sinai School of Medicine, New York, NY.*

**Background:** Cognitive decline in CKD has been associated with elevated inflammation and reactive oxygen species (ROS) and decreased SIRT1. Accumulation of glycotoxins (AGEs) has been implicated in the increased inflammation/ROS, leading to the complications of aging, including cognition and CKD.We recently reported that high levels of circulating MG-derivatives (very reactive AGEs) were associated with higher brain and cerebrospinal fluid (CSF) AGE levels and a significantly faster rate of cognitive decline in T2D and in non-diabetic elderly subjects. Here we asked if there was an effect of methylglyoxal on motor co-ordination, learning and memory in aged mice with CKD fed with an AGE-enriched diet, compared to isocaloric pair-fed controls.

**Methods:** C57BL6 mice (18-19 month old) fed a Low AGEs diet supplemented with MG (MG+) diet for 10 generations developed insulin resistance and CKD, whereas mice pair-fed a Low AGEs (MG-) were unaffected. AGE-induced cognitive changes were assessed by Rotorod and object recognition tests.

**Results:** Despite repeated learning sessions MG+ mice showed a significant decrease in the latency (time to fall from the Rotorod) (Fig. A) at lower speed and shorter distance, compared to MG- mice. MG+ mice showed poor recognition ability with significantly lower discriminatory capacity between novel and a familiar object, compared to MG- mice (Fig. B).



**Conclusions:** As in aging humans, the motor and memory dysfunction in the current study of C57Bl6 mice with CKD appear to be due to increased ROS and inflammation secondary to the accumulation of AGEs in the brain. Littermates pair-fed a low AGE diet did not show these changes. Clinical studies will need to be conducted to determine if reduction of dietary AGEs may protect against cognitive decline in CKD patients.

## TH-PO204

**Effect of Ferumoxytol and Iron Sucrose on Serum Phosphorus Levels** Naomi V. Dahl, Gloria Lau, Zhu Li, Pallabi De, William Strauss. *AMAG Pharmaceuticals.*

**Background:** Administration of certain IV iron preparations (ferric carboxymaltose [FCM], saccharated ferric oxide, and iron polymaltose) has been associated with hypophosphatemia (Wolf et al., Bone Min Res, 2013; Schouten, J Clin Endoc Metab, 2010), with an incidence of serum phosphate reductions to <2 mg/dL occurring in up to 70% of patients with abnormal uterine bleeding (AUB) around 14 days after treatment with FCM (Van Wyck, Transplant 2009). Recent studies have demonstrated an acute, FGF23-mediated phosphate wasting in response to FCM but not iron dextran, suggesting that the specific carbohydrate moiety might be involved in the FGF23 response to IV iron. Ferumoxytol (FER) is an IV iron approved for the treatment of iron deficiency anemia (IDA) in adult patients with chronic kidney disease (CKD). It is also being evaluated as a treatment for IDA patients without CKD who have a history of unsatisfactory oral iron therapy or in whom oral iron cannot be used.

**Methods:** To explore the effect of FER on serum phosphate (P) levels in women with AUB, we pooled data from 2 phase-3, randomized controlled studies in 1413 patients with IDA and eGFR ≥30mL/min/1.73m$^2$. In these studies, patients were randomized to FER (2 doses, 510mg, 3-8 days apart) or comparator: placebo (0.9% saline) or iron sucrose (IS), 1g (5 doses, 200mg, over 14 days).

**Results:** This subgroup analysis includes the 605 women with AUB (65% white, 22% African American) and available baseline and follow-up P values (432 FER, 91 IS, 82 placebo), mean age 40.2±8.5. Mean baseline P for all 3 groups was 3.4±0.5mg/dL. There was no decrease in mean P at any week, except for IS at week 3 (-0.3 ±0.7 mg/dL). No FER or placebo patients experienced any P reduction below 2 mg/dL during the 5-week study period. The decreases in the IS group mainly occurred at weeks 2 and 3.

| Patients Experiencing Post-baseline Decrease in Phosphorus from ≥2.5 mg/dL, n(%) | Ferumoxytol (N=432) | Iron Sucrose (N=91) | Placebo (N=82) |
|---|---|---|---|
| to <2.5 – 2.0 mg/dL | 8 (1.9) | 10 (11.0) | 5 (6.1) |
| to <2.0 – 1.0 mg/dL | 0 | 3 (3.3) | 0 |
| to <1.0 mg/dL | 0 | 0 | 0 |

**Conclusions:** In this study, ferumoxytol did not appear to decrease serum P levels in an at-risk population.

## TH-PO205

**Predictor for Bleeding-Related Upper Gastrointestinal Lesions in Anemic Patients with Chronic Kidney Disease** Youn Mi Song,[1] Sangju Lee,[2] Hye Eun Yoon,[2] Yoon-Kyung Chang,[2] Chul Woo Yang,[2] Suk Young Kim,[2] Hyeon Seok Hwang.[2] *[1]Div of Gastroenterology, Depts of Internal Medicine College of Medicine, The Catholic Univ of Korea, Daejeon, Korea; [2]Div of Nephrology, Depts of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Daejeon, Korea.*

**Background:** Anemia and iron deficiency are common complication in patients with chronic kidney disease (CKD). However, information about the diagnostic indicators for bleeding-related upper gastrointestinal (GI) lesions is scarce and few studies have investigated anemic upper GI lesions.

**Methods:** We included 165 anemic patients with nondialysis-dependent CKD stages 3–5 (44 patients at stage 3, 52 patients at stage 4, and 69 patients at stage 5). Transferrin saturation (TSAT), serum ferritin, mean corpuscular volume (MCV), and corrected reticulocyte count data were collected to evaluate diagnostic utility for bleeding-related upper GI lesions, which were identified by esophagogastroduodenoscopy.

**Results:** Bleeding-related GI lesions were found in 57 (34.5%) patients. The areas under the receiver operating characteristic curves used to predict bleeding-related lesions was 0.63 for TSAT ($p = 0.007$) and the best cutoff value was 19.7% (sensitivity, 0.53, specificity, 0.76). The combination of cutoff values of TSAT < 20% or serum ferritin level < 100 ng/mL provided the 17% increment of sensitivity, compared to TSAT <20% alone. The corrected reticulocyte levels and MCV had no significant diagnostic utility. In patients with CKD stage 5, the sensitivity for TSAT or its combination with serum ferritin was significantly lower than in patients with CKD stage 3 (all $p < 0.05$).

**Conclusions:** TSAT is a significant predictor of anemic lesions in the upper-GI tract and serum ferritin can increase the sensitivity of TSAT. However, these indicators should be used with caution in patients with CKD stage 5 because their sensitivity is poor in this context.

## TH-PO206

**Glycosuria under Normoglycemia May Be an Unrecognized Characteristic of Chronic Kidney Disease** Takahito Ito, Yoko Shima, Naoko Morikage, Ryuta Fujimura, Chisako Nakano, Akira Wada, Masafumi Yamato. *Div of Nephrology, Osaka National Hospital, Osaka, Japan.*

**Background:** Normal nephrons do not lose glucose in the urine under normoglycemia. We studied the relation between chronic kidney disease and glycosuria.

**Methods:** From April/1/2010 to October/31/2011, we had 3786 datasets in each of which urine dipstick glucose level, serum glucose concentration, serum creatinine concentration, and HbA1c were measured at the same time. If a subject was tested repeatedly during the period, the oldest data set was adopted. Finally, we used 1629 datasets of the different subjects (64.1±13.5 y, 1049 males) in the following analysis. None took phenazopyridine, timiperone or procaine which might result in a false-positive glycosuria.

**Results:** Glucose concentration and HbA1c were 113.0 mg/dL [IQR: 97.0-155.0] and HbA1c 5.70% [IQR: 5.00-6.60], respectively. When the presence of glucose in the urine (1-plus or more) was defined as glycosuria, the numbers of subjects with and without glycosuria were 523 (Group G) and 1106 (Group N), respectively. There was no statistical difference of age or estimated glomerular filtration rate (eGFR) between Groups G and N. Using 596 subjects whose serum glucose and HbA1c were lower than their median values (glucose ≤112 and HbA1c≤5.6, respectively), we performed two sub-analyses. (1) Subjects with and without glucosuria were re-classified into Group GG and NN, respectively. eGFR of Group GG (N=29) was significantly lower than that of Group NN (N=567)(50.9±35.7 vs. 68.9±27.4, P=0.0061). Age was not significant. (2) We defined the subjects with eGFR lower than 60 as "CKD" (N=199) and compared them with "non-CKD" (N=397). The non-adjusted and age-adjusted odd ratios for glycosuria in "CKD" were 2.230 [95% CI: 1.050-4.767] and 2.256 [1.013-5.075], respectively. Even when a trace level of glucose in the urine was included in the definition of glycosuria, we obtained similar results.

**Conclusions:** Glycosuria under normoglycemia is more often in CKD. This phenomenon may come from abnormal glucose transport, saturated glucose transport in the reduced number of nephrons, and/or delayed tubular fluid flow leading to the dissociation between blood and urinary glucose levels.

**Modeled eGFR, eGFR Slope, and Mortality Risk among Adults with Moderate and Advanced CKD** Xiaoqin Tang,[1] Robert M. Perkins,[2] Ion D. Bucaloiu,[1] H. Lester Kirchner.[1] *[1]Geisinger Medical Center, Danville, PA; [2]Bassett Medical Center, Cooperstown, NY.*

**Background:** Single time-point GFR estimates are used for risk prognostication among those with CKD. Various applications of longitudinal eGFR using linear models—to include time-independent slope and variability—have been shown to be independent predictors of mortality. We wished to extend these applications by modeling both longitudinal eGFR history--forming estimates of current value of eGFR and time-dependent slopes at any time point--and then test the independent association of these variables with mortality risk in an adjusted, joint survival model.

**Methods:** We retrospectively assembled a cohort of Geisinger primary care patients with stage G3 or G4 CKD (1/1/2001 to 6/30/2012) who had a minimum of 4 outpatient eGFR results and 6-months follow-up. Patients were excluded for prior history of dialysis or renal transplantation. Patients were followed through 12/31/2012 for death. EGFR was modeled using a random intercept and slope model with a flexible spline transformation of time to capture patient-specific, non-linear patterns. Time to death was modeled with Cox Proportional Hazard regression.

**Results:** A total of 16,737 patients met cohort entry criteria. The sample had mean age 69.4 years, 28% had diabetes, and mean baseline eGFR was 51 mL/min. During 98,075 person-years of follow up, 3709 (22%) patients died. In fully adjusted models, each 5 mL/min/1.73m$^2$ decrease in current eGFR value was associated with a mortality hazard ratio(HR) of 1.05 (95% CI 1.03, 1.09). For the time-dependent slope of the eGFR trend, each 2 mL/min/1.73m$^2$/year decrement was associated with a HR of 1.09 (95% CI 1.05, 1.12). Both diabetes and gender modified these associations, such that the mortality risk was significantly greater among non-diabetics and females.

**Conclusions:** Modeled longitudinal eGFR and time-dependent eGFR slope each independently associates with mortality risk among patients with moderate and advanced CKD. Comparing results to baseline eGFR (HR=1.07 (95% CI: 1.05, 1.07)), the joint model may provide more prognostic value to predicting mortality.

## TH-PO208

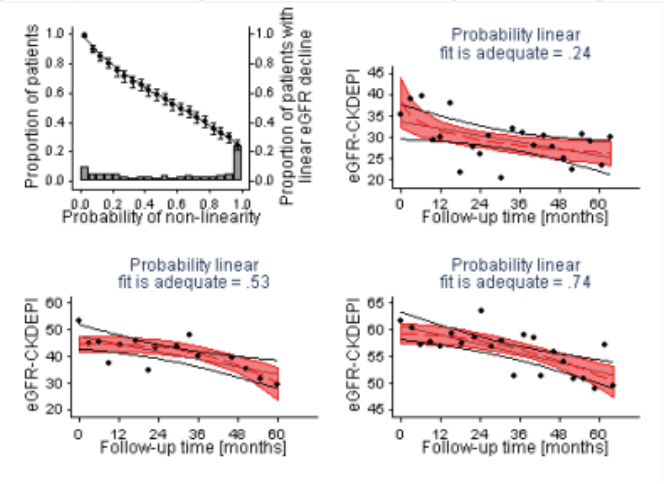
**Mathematical Models for the Evaluation of eGFR Decline in CKD Patients: Linear versus Non-Linear** Jan A.J.G. van den Brand,[1] Tjeerd Maarten-Hein Dijkstra,[3] Arjan D. Van Zuilen,[2] Peter J. Blankestijn,[2] Jack F. Wetzels,[1] Tom Heskes.[3] *[1]Nephrology, Radboud Univ Medical Centre, Nijmegen, Netherlands; [2]Nephrology, Univ Medical Centre Utrecht, Netherlands; [3]Institute for Computing and Information Sciences, Radboud Univ, Nijmegen, Netherlands.*

**Background:** Li et al. recently questioned the concept that eGFR decline is linear in CKD patients (Li et al. AJKD 2012). We aimed to evaluate what proportion of CKD patients showed possible non-linear eGFR decline with a simpler technique.

**Methods:** We analysed data of patient that participated in MASTERPLAN (Van Zuilen et al. Kidney Int. 2012). Kidney transplant patients were excluded. GFR was estimated using the eGFR-CKDEPI equation for serum creatinine. Ordinary least squares regression was used to obtain a linear model of eGFR over time. An optimal first order model was

selected from possible powers $x^{-3}$, $x^{-2}$, $x^{-1}$, $x^{-1/2}$, ln(x), □x, $x^2$ and $x^3$ using STATA's fractional polynomials (Statacorp, TX). The fit for both models was compared using Akaike's Information Criterion (AIC). The probability that a linear fit was acceptable was calculated as probability = exp[ ($AIC_{fp}$-$AIC_{lin}$) / 2].

**Results:** In total, 640 patients were included, 69% were male and mean age was 60 ± 12.6 years, baseline eGFR was 37 ± 15 ml/min per 1.73m$^2$. The mean number of serum creatinine values per patient was 14.6 ± 5.2 over the course of 4.2 ± 1.2 years. The histogram shows the proportion of patients by the probability of linearity (top left panel); the line plot shows the total proportion of patients with a linear eGFR decline by acceptance threshold probability for linearity (top left) and eGFR course for three patients as an example.



**Conclusions:** In most CKD patients eGFR decline is linear. However, even when accepting a low threshold (5%), eGFR decline is non-linear in 10% of patients. Our findings confirm previous work by Li et al. using a simpler technique.

## TH-PO209

### Predictors of Progression in European CKD Patients: The Tangri Model and Beyond

Mieke J. Peeters,[1] Arjan D. Van Zuilen,[2] Jan A.J.G. van den Brand,[1] Michiel Bots,[2] Peter J. Blankestijn,[2] Jack F. Wetzels.[1] *[1]Radboud Univ Nijmegen Medical Centre, Nijmegen; [2]Univ Medical Center Utrecht, Utrecht, Netherlands.*

**Background:** Patients with CKD may progress to ESRD and benefit from early referral to nephrological care. However, treatment adds costs and may also have adverse effects. Therefore, adequate prediction of CKD progression is important. We validated the predictive models developed by Tangri *et al* [Peeters *et al* NDT 2013]. We performed analyses to identify additional predictors of CKD progression.

**Methods:** MASTERPLAN is a controlled trial in patients with CKD. CKD progression was defined as ESRD (initiation of chronic dialysis or kidney transplantation) or a 50% increase in serum creatinine concentration. Patients who died before reaching an endpoint were censored. Clinical parameters and laboratory data at MASTERPLAN baseline were assessed as predicting factors for CKD progression, using univariate and multivariate Cox regression.

**Results:** We evaluated all 788 patients (67% male, mean age 59 years, mean eGFR 36 ml/min), 330 patients showed CKD progression. In univariate analysis treatment center, cause of kidney disease, diabetes mellitus, age, BMI, systolic blood pressure, current smoking, activity score, eGFR, protein creatinine ratio, and serum levels of hemoglobin, PTH, calcium, phosphate, albumin, bicarbonate, potassium, and uric acid were associated with CKD progression. Predictors of CKD progression in multivariate analysis are shown in the table.

| | HR (95% CI) |
|---|---|
| Congenital kidney disease (mainly ADPKD) | 3.04 (2.16-4.27) |
| Systolic blood pressure (per 10 mmHg) | 1.13 (1.06-1.21) |
| Current smoking | 1.48 (1.10-1.99) |
| eGFR (per 5 ml/min/1.73m$^2$) | 0.86 (0.80-0.92) |
| Protein creatinine ratio (per 10 mg/g) | 1.003 (1.002-1.004) |
| Hemoglobin (per 1 g/dl) | 0.88 (0.81-0.97) |
| Calcium (per 1 mg/dl) | 0.67 (0.52-0.87) |
| Uric acid (per 1 mg/dl) | 1.05 (1.02-1.08) |

**Conclusions:** We identified independent predictors of CKD progression in our MASTERPLAN cohort. We confirmed variables that were included in models by Tangri *et al*. The cause of kidney disease, blood pressure, current smoking, hemoglobin, and uric acid provided added value.

## TH-PO210

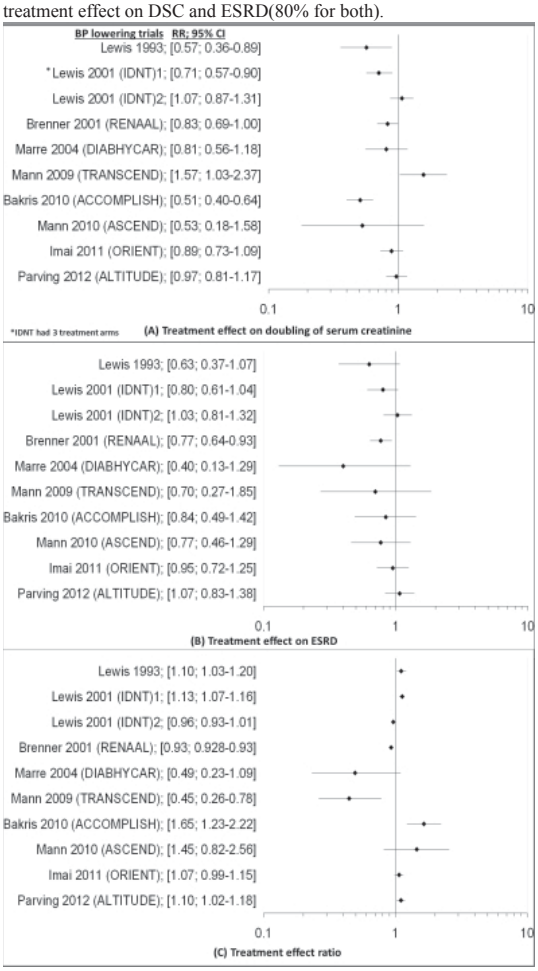
### The Validity of Doubling of Serum Creatinine as a Surrogate Marker for ESRD: A Systematic Review of Randomized Trials

Min Jun,[1,2] Tanvir Chowdhury Turin,[1] Hiddo Jan Lambers Heerspink,[3] Mark Woodward,[2] Braden J. Manns,[1] Marcello Tonelli,[4] Vlado Perkovic,[2] Brenda Hemmelgarn.[1] *[1]U/Calgary, Canada; [2]George Institute for Global Health, Australia; [3]U/Groningen, Netherlands; [4]U/Alberta, Canada.*

**Background:** This systematic review assessed the validity of doubling of serum creatinine(DSC) as a surrogate for endstage renal disease (ESRD) in trials assessing the effects of blood pressure(BP) lowering in high-risk adults with diabetes, CKD stages 1-4 and/or renal transplantation.

**Methods:** MEDLINE, EMBASE and the Cochrane Library were searched (1946-Jun 2012) for randomized trials reporting the effects of BP lowering on ESRD and DSC. Abstract review and data extraction was done independently by 2 reviewers. The association between treatment effects on DSC and ESRD was expressed as the "treatment effect ratio(TER)" (effect on ESRD/effect on DSC; ideal surrogate would have a TER close to 1). This test is a key element of Prentice's operational criteria for validating surrogate markers(treatment has a significant impact on surrogate and the true outcome[TO];surrogate has a significant impact on the TO; the full effect of treatment on the TO is captured by the surrogate).

**Results:** The systematic review yielded 7531 abstracts of which 9 BP lowering trials in 36500 patients with diabetes, hypertension and/or CKD 1-4 met the inclusion criteria. 1 trial had 3 arms and was treated as 2 trials. Majority of the trials showed a beneficial treatment effect on DSC and ESRD(80% for both).



TERs varied(0.45-1.65) although 6 studies were within ±13% of the null.

**Conclusions:** These results show that in trials assessing the effects of BP lowering drugs in high-risk patients, DSC is a relatively good surrogate for ESRD. We assessed the validity of DSC according to only 1 of 3 elements of Prentice's criteria for validation of a surrogate marker. Future studies will need to consider for the remaining criteria where possible.

**TH-PO211**

**Validity and Statistical Power of Alternative eGFR-Based Endpoints: A Report from an NKF FDA Workshop** Tom Greene,[1] Chia-Chen Teng,[1] Jian Ying,[1] Andrew M. Redd,[1] Mark Woodward,[2] Lesley Inker,[3] Josef Coresh,[2] Andrew S. Levey.[3] *[1]Univ of Utah; [2]Johns Hopkins Univ; [3]Tufts Univ.*

**Background:** Because the follow-up period required to observe the FDA approved doubling of serum creatinine (SCR) endpoint can be prohibitive, we investigated the performance of alternative endpoints defined by ESRD or confirmed reductions in eGFR of either 57% (approximate doubling of SCR), 40% or 30% on the validity and efficiency of CKD RCTs.

**Methods:** We used statistical simulation to determine the efficiency (defined as the required sample size [N] to achieve 90% power) and validity (defined as the Type 1 error for the eGFR-based endpoint when there is no treatment effect on time to ESRD) of alternative eGFR-based endpoints under different scenarios. Simulations were calibrated with data from 11,982 patients in 41 CKD RCTs.

**Results:** We simulated 800 repetitions for each endpoint over more than 800 scenarios. In the base case scenario, use of a 30% eGFR decline endpoint reduced the required Ns for 3 year RCTs by 19% to 54% compared to the required Ns for a 57% eGFR decline endpoint in trials with a moderate to high baseline eGFR for treatments with no acute effect. However, use of a 30% eGFR decline endpoint increased the required N and led to inflated Type 1 error for treatments with an acute effect of -1.5 ml/min/1.73m$^2$ in the opposite direction of the long term effect.

| % Differences in Required N for 30% and 40% eGFR Decline vs. Required N for 57% eGFR Decline | | | | |
|---|---|---|---|---|
| Alternative Outcome, ESRD or: | Acute Effect (ml/min/1.73m$^2$) | Median Baseline eGFR (ml/min/1.73m$^2$) | | |
| | | 67.5 | 42.5 | 27.5 |
| 30% eGFR Decline | 0 | -54% | -19% | +13% |
| | -1.5 | +18%* | +46%* | +48% |
| 40% eGFR Decline | 0 | -45% | -17% | -7% |
| | -1.5 | -14% | -1% | +12% |
| * Actual type 1 error exceeded 10% when the targeted type 1 error was 5% | | | | |

**Conclusions:** A moderate acute effect in the opposite direction from the long term treatment effect can lead to increased Type 1 error and/or increased required N when using smaller eGFR event thresholds. However, the endpoint of ESRD with 30% or 40% decline in eGFR may reduce the required sample size and thereby increase the efficiency of trials with moderate to high baseline eGFR when an acute effect is not expected.

**TH-PO212**

**Longitudinal eGFR, eGFR Slope, and Incident Cardiovascular Events among Adults with CKD** H. Lester Kirchner,[1] Robert M. Perkins,[2] Ion D. Bucaloiu,[1] Xiaoqin Tang.[1] *[1]Geisinger Medical Center, Danville, PA; [2]Basset Medical Center, Cooperstown, NY.*

**Background:** Single time-point GFR estimates are used for risk prognostication among those with CKD. Various applications of longitudinal eGFR using linear models—to include time-independent slope and variability—have been shown to independently predict cardiovascular events. We wished to extend these applications by modeling both longitudinal eGFR—forming estimates of current eGFR value and time-dependent eGFR slope at any time point—and then test the independent association with incident cardiovascular event risk in an adjusted, joint model.

**Methods:** We retrospectively assembled a cohort of Geisinger primary care patients with stage G3-G4 CKD(1/1/2001 to 6/30/2012) who had a minimum of 4 outpatient eGFR results and 6-months follow-up. Exclusion criteria included a history of dialysis, renal transplantation, myocardial infarction (MI), heart failure(HF), or TIA/stroke. Patients were followed through 12/31/2012 for the first occurrence of MI, HF, or stroke (incident CVD), or were censored at ESRD, death or end of study. EGFR was modeled using a random intercept and slope model with a flexible spline transformation of time to capture non-linear trends. Time to incident CVD was modeled using Cox Proportional Hazard regression.

**Results:** 16,304 patients met cohort entry criteria (mean age 68.4 y, 37% male, 23% with diabetes, mean baseline eGFR 51 mL/min) and contributed 89,682 person-years of follow up. 1997 (12%) patients developed incident CVD. In fully adjusted models, each 5 mL/min/1.73m$^2$ decrease in current eGFR was associated with a hazard ratio(HR) of 1.07 (95% CI 1.04, 1.09). For the time-dependent slope of eGFR trend, each 2 mL/min/1.73m$^2$/year decrement was associated with a HR of 1.22 (95% CI 1.15, 1.30). Both diabetes and gender modified the eGFR slope associations, such that the associations were significantly greater among non-diabetics and females.

**Conclusions:** Longitudinally modeled eGFR and time-dependent eGFR slope each independently associates with incident CVD risk among patients with moderate and advanced CKD. The relative prognostic value of static, single time point eGFR vs. joint modeling of eGFR warrants investigation.

**TH-PO213**

**Impact of the Number of Albuminuria Measurements on Sample Size Requirements for Clinical Drug Trials** Tobias Felix Kröpelin,[1] Hiddo Jan Lambers Heerspink,[1] Dennis L. Andress,[2] Dick de Zeeuw.[1] *[1]Univ Medical Center Groningen; [2]AbbVie Laboratories.*

**Background:** Change in albuminuria is used as a surrogate endpoint in clinical trials of CKD progression. Yet, the number of urine samples (albumin measurements) needed to precisely quantify an anti-albuminuric drug effect is unknown. We assessed the impact of the number of urine samples on the precision of anti-albuminuric drug effects and sample size requirements for clinical trials.

**Methods:** Data from the Selective vitamin D receptor activation for albuminuria lowering (VITAL) trial were used. Urinary albumin:creatinine ratio (UACR) was measured at randomization and every 4 weeks during 24-weeks of treatment. At each visit three consecutive first morning void (FMV) urines were collected. The effect of paricalcitol 2 µg/day versus placebo, in subjects that submitted at each visit three first morning voids (N=137), was assessed as the geometric mean UACR change from baseline to week 24 and secondly as the geometric mean change considering all follow up visits. In both analyses, UACR change was calculated based on 1, 2, or 3 consecutive FMV UACR measurements.

**Results:** The mean UACR reduction slightly varied according to the number of UACR measurements and was somewhat smaller when all UACR data over time were considered (Table 1). However, the precision of the treatment effect increased (decreased standard error) with increasing number of UACR measurements. Thus, a post-hoc power calculation showed that the number of patients required to obtain a significant treatment effect decreased with more UACR measurements and markedly decreased when all UACR measurements over time were considered.

| | FMV UACR measurements | | | FMV UACR | | |
|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 1 | 2 | 3 |
| | Albuminuria change % (SE) | | | Sample size | | |
| Δ UACR Baseline to week 24 | -17% (11.6) | -15% (10.4) | -17% (10.2) | 268 | 244 | 188 |
| Δ UACR over time (including all visits) | -13% (5.0) | -14% (4.8) | -16% (4.6) | 109 | 85 | 61 |

**Conclusions:** Clinical trials can be more efficiently designed if they take into account all albuminuria measurements collected over time rather than considering a change in albuminuria between two pre-determined time-points.

**TH-PO214**

**Variation in GFR Estimates and Prevalence of CKD among the Veterans with Use of Two Creatinine Values** Nilang G. Patel,[3] Neha Nainani,[2] Rajiv Ranjan,[1,2] Nida Arabi,[2] James W. Lohr,[1,2] Pradeep Arora.[1,2] *[1]Medicine, VAMC, Buffalo, NY; [2]Medicine, Univ at Buffalo, Buffalo, NY; [3]Medicine, VAMC and VCU, Richmond, VA.*

**Background:** A GFR of less than 60ml/min/1.73 m$^2$ for at least 3 months duration is considered to be CKD. Most of the epidemiological studies used only one serum creatinine value to estimate GFR. However, this would likely overestimate the true prevalence of CKD. The purpose of this study was to assess the prevalence of CKD in the veteran population using 2 creatinine values.

**Methods:** A retrospective cohort study of 97,451 veterans seen in primary care clinic in the VISN 2 network over 7 years. GFR estimation and CKD prevalence were determined using the MDRD study equation and the CKD-EPI study equation based on one (MDRD-1, CKD-EPI-1) and two serum creatinine values (MDRD-2, CKD-EPI-2) at least 3 months apart.

**Results:** Out of 97451 patients, 95% were male, 91% were white and 56% were above the age of 60 years. For any given age,the average eGFR was higher when estimated by CKD-EPI equation than by MDRD equation except in very elderly patients (> 80 yrs of age) where eGFR was lower by CKD-EPI than MDRD equation. With increase in age, the prevalence of CKD also increased after 60 years of age. Prevalence of CKD by the different equations is shown in table.

| | MDRD-1 | MDRD-2 | CKD-EPI-1 | CKD-EPI-2 |
|---|---|---|---|---|
| CKD Prevalence | 51.6% | 31.9% | 47.2% | 29.7% |
| Net decrease in Prevalence | 38% | | 37% | |

By using 2 values of serum creatinine and the MDRD equation the prevalence of CKD decreased from 51.6% to 31.9%, a net decrease in the prevalence by 38%. The decrease in prevalence was seen primarily in stage 3a CKD. Similarly using 2 values of serum creatinine and CKD-EPI equation the prevalence of CKD decreased from 47.2% to 29.7% a net decrease in the prevalence by 37%, mostly due to overestimation of CKD stage 3a. The use of 2 serum creatinine values did not add any additional value for those who had an index GFR of less than 45 ml/min/1.73 m$^2$.

**Conclusions:** Veterans have a higher prevalence of CKD than the general population. CKD prevalence is more accurately classified using 2 serum creatinine values.

**TH-PO215**

**Effect of Renin Angiotensin System Inhibitor Therapy on Renal and Cardiovascular Outcomes in Patients with Chronic Kidney Disease: A Systematic Review and Meta-Analysis** Xinfang Xie,[1] Youxia Liu,[1] Jicheng Lv,[1] Xiangling Li,[2] Wanyin Hou,[1] Hong Zhang.[1] *[1]Renal Div, Peking Univ First Hospital, Beijing, China; [2]Hospital of Weifang Medical College.*

**Background:** We undertook a systematic review and meta-analysis to evaluate the effect of ACE inhibitors or angiotensin receptor blockers (ARBs) on the cardiovascular and renal outcomes in people with CKD.

**Methods:** We systematically searched MEDLINE Embase and Cochrane library for trials published between 1970 and November 2012. We included prospective randomised controlled trials assessing the effects of ACE inhibitors or ARBs on renal or cardiovascular outcomes in people with CKD. Summary estimates of relative risk(RR) used a random effects model.

**Results:** Overall 109 trials were included, providing data for 50,740 patients with CKD. As compared to placebo, ACE inhibitors reduced kidney failure (defined as doubling serum creatinine or end-stage kidney disease) by 38% (RR 0.62, 95% CI 0.53-0.72) and ARBs by 11% (0.89, 0.82-0.97). There's significant difference on the kidney protection between ACE inhibitors and ARBs (p<0.001). Compared to other blood pressure lowering agents, both ACE inhibitors (0.78, 0.67-0.91) and ARBs (0.77, 0.61-0.97) produced more kidney protection without difference (p =0.88). ACE inhibitors and ARBs reduced the risk of major cardiovascular events in patients with CKD as compared to either placebo (RR 0.86, 95% CI 0.80-0.93) or antihypertensive agents (0.88, 0.79-0.97) without heterogeneity (p=0.22). ACE inhibitors also reduced cardiovascular death (0.87, 0.77-0.99) or all death (0.89, 0.79-0.99) while ARB didn't. Adverse events were significantly increased by ACE inhibitors or ARBs, including hyperkalemia and cough compared to placebo. ARBs therapy was associated with greater risk of hyperkalemia than ACE inhibitors (p for heterogeneity =0.004).

**Conclusions:** ACE inhibitors or ARBs reduce the risk of kidney failure or cardiovascular events in the patients with CKD as compared to placebo or other blood pressure agents. ACE inhibitors showed more kidney protection ascompared to ARBs and also reduced the death thus could be of the first choice in this population.

## TH-PO216

**Effects of Spironolactone in Combination with ACE Inhibitor or Angiotensin Receptor Blockers in Aldosterone Escape and Non-Escape Group of Patients with Proteinuria** Ha Yeon Kim, Yong Un Kang, Chang Seong Kim, Joon Seok Choi, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea.*

**Background:** The present study was aimed to investigate whether add-on aldosterone blockade therapy has beneficial antiproteinuric effects in aldosterone escape and non-escape group, and to compare changes in proteinuria in patients according to estimated GFR (eGFR) in association with changes of vitamin D level.

**Methods:** In this prospective intervention trial, we studied the effects of spironolactone (25mg/day) in 219 patients who showed persistent proteinuria after ACE inhibitor or ARB medications for more than 3 months. Plasma aldosterone, potassium, eGFR and urine protein to creatinine ratio (UPCR) were determined at baseline and 6 months after spironolactone add-on treatment. Patients were divided according to their aldoterone level during ACE inhibitor or ARB treatment in an escape group (plasma aldosterone > 80 pg/ml, n=69, 31.5%) and a non-escape group (n=150, 68.5%).

**Results:** There was not a decrease in UPCR in both groups (p=0.763 in aldosterone escape group, p= 0.528 in non-escape group). UPCR was significantly decreased with treatment of spironolactone in patients with eGFR ≥ 60mL/min/1.73 $m^2$ (1.36±1.269 to 1.19±1.333 g/g Cr, p=0.042), not in eGFR < 60mL/min/1.73 $m^2$ (1.54±1.250 to 1.59±1.581 g/g Cr, p=0.712). Hyperkalemia (K ≥5.5mEq/L) was developed in 30 of the 103 patients with eGFR < 60 mL/min/1.73 $m^2$ (29.8 %) and in 8 of the 120 patients with eGFR ≥ 60 mL/min/1.73 $m^2$ (7.1 %). In all patients, 25-OH vitamin D was increased after adding spironolactone (p=0.004 in aldosterone escape group, p <0.001 in non-escape group, p=0.003 in patients with eGFR ≥ 60mL/min/1.73 $m^2$, p <0.001 in patients with eGFR < 60 mL/min/1.73 $m^2$). UPCR was correlated with 25-OH Vitamin D negatively (R=-0.222 P = 0.008).

**Conclusions:** Change of proteinuria was not different between aldosteron escape and non-escape group after add-on spironolactone treatment. Proteinuria was significantly decreased by add-on spironolactone treatment in patients with eGFR ≥ 60mL/min/1.73 $m^2$but not in patients with eGFR < 60mL/min/1.73 $m^2$.

## TH-PO217

**Renal Protctive Effects by Rosvastatin through the Amelioration of Intra-Renal Vascular Resistance** Keiko Fujimura, Shu Wakino, Koichi Hayashi, Hiroshi Itoh. *Dept of Internal Medicine, School of Medicine, Keio Univ, Tokyo, Japan.*

**Background:** Nephrosclerosis has been one of the common causes of renal insufficiency. One of the major clinical characteristics of nephrosclerosis is the increased intra-renal vessel resistance and the decreased renal blood flow. The effects of these renal anatomical changes were not clinically fully evaluated. A recent trial has shown that statin have renal protective effects in patients with CKD. By using Ultrasound pulse-doppler analysis (Doppler), we aimed to assess the effects of rosuvastatin treatment on the progression of CKD with nephrosclerosis.

**Methods:** We used our CKD cohort composed of the patients with nephrosclerosis with CKD whose eGFR levels were less than 60 ml/min/1.73$m^2$. The patients with diabetes and biopsy-proven nephritis were excluded. The relationship between various parameters of Doppler and biochemical parameters were examined. Among these subjects, we recruited 33 patients, treated them with rosuvastatin (Ros) at the dose of 2.5-5mg until the LDL-cholesterol (LDL-C) levels reached under 100mg/dl and observed for a year. We compared the changes of various parameters including those of Doppler before and after Ros treatment.

**Results:** In regression analysis, resistance index (RI) and maximum velocity of renal blood flow(Vmax) were corrlated with eGFR.Ros significantly lowered LDL-C (before vs. after; -5.5±4.5% vs. -17.7±6.7%,p<0.05). Although Ros did not supressed the increase in proteinurea, albuminuria,and the excreation of renal tubular marker, it blunted the decline of eGFR (before vs. after; -4.2±2.0% vs. 4.2±2.4%,p<0.05).In Doppler analysis, Ros significantly supressed the increase of RI (before vs. after;4.2±3.7% vs. -4.6±2.1%,p<0.05), although it had no effects on the increasing rate in Vmax andVmin, that are supposed to reflect the stenotic changes of main renal artery.The changes in RI and eGFR by Ros were not associated with those in LDL-C levels.

**Conclusions:** Ros had renal protective effects with the improvement of renal vessel resistance and that effects were independent of LDL-C lowering effects.

## TH-PO218

**Metformin Is Safe and Effective in Stage 3 and 4 Diabetic Chronic Kidney Disease Patients – A Randomized Trial** Sanjib Kumar Sharma, Denis Piyyush, Anup Ghimire, Bhawesh Koirala, Madhab Lamsal. *B P Koirala Institute of Health Sciences, Dharan, Nepal.*

**Background:** In absence of evidence against use of metformin in CKD 3-4, we conducted clinical trial to study the use of metformin in diabetic CKD in stage 3 and 4. The aim of the study was to evaluate the efficacy of metformin in terms of glycemic control, incidence of lactic acidosis, episodes of hypoglycemia in patient with diabetic stage 3 and 4 CKD.

**Methods:** In a randomized open labeled clinical trial, a total of 218 patients were randomized by computer-generated table of random number in two groups - Insulin group (109) and Metformin group (109). Baseline characteristics of the patients in both groups were similar. During initial wash out period all the existing anti-diabetic medication were stopped. After the wash out phase, the patients were allocated to one of the two groups as per their randomization number. The OHA and Insulin were initiated and increased stepwise as per protocol. Patients were followed at 1 week, 2 weeks, 1 month and then monthly for six month. Blood analysis for acidosis and bicarbonate, serum creatinine, electrolyte, glucose profile, was measured in each visit. HbA1c was measured at 3 and 6 month. When targeted blood sugar was not achieved in metformin group sulfonylureas was added.

**Results:** Four patients from Metformin group and 5 patients from Insulin did not complete the study. Two patients on metformin were switched over to insulin due to intolerance to metformin.

The glycosylated hemoglobin decreased by 1.2% and 1.4% percent at 6 month in metformin and Insulin group respectively. There was no case of lactic acidosis in either group. One patient in metformin group showed increase serum creatinine that return to baseline on switching over to Insulin. There was no case of sevre hypoglycemia in either group, though minor episodes hypoglycemia therapy was recorded in 3 and 7 patients in Metformin and Insulin group respectively.

**Conclusions:** Metformin is a safe and effective oral hypoglycemic agent in diabetic stage 3 and 4 CKD. Its use in this group of patients is not associated with lactic acidosis.

## TH-PO219

**Renoprotective Effect of Combining Pentoxiphylline with Angiotensin Converting Enzyme Inhibitor or Angiotensin II Receptor Blocker in Moderate to Severe Kidney Disease** Ping-Min Chen,[1] Ping Yu Chen,[1] Tai-Shuan Lai,[2] Wen-Chih Chiang,[1] Shuei-Liong Lin.[1] *[1]Dept of Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan; [2]Dept of Internal Medicine, National Taiwan Univ Hospital, Bei-Hu Branch, Taipei, Taiwan.*

**Background:** Several studies showed that pentoxifylline (PTX), a phosphodiesterase inhibitor, had beneficial effect on proteinuria and chronic kidney disease (CKD). This study was to examine whether there was an add-on effect of combining PTX with angiotensin converting enzyme inhibitor (ACEI) or angiotensin II receptor blocker (ARB).

**Methods:** A single-center retrospective study was conducted, enrolling total of 697 patients with CKD stage of 3B-5 (age 18-80). All patients were documented long-term use of ACEI or ARB. Patients were stratified into combination treatment group (combined PTX with ether ACEI or ARB) and single medication group (ACEI or ARB use only). The primary outcome was long-term renal replacement therapy (RRT). Survival analysis was compared between the two groups. Multivariate cox regression analysis was used to evaluate the effect of individual risk factor. Subgroup analysis was also performed by dividing the patients into lower and higher proteinuria groups (baseline urine protein/creatinine ratio < 1 g/g or ≥ 1 g/g).

**Results:** Addition of PTX with either ACEI or ARB showed a better renal outcome (p = 0.044). There were no between group differences regarding all-cause mortality or cardiovascular events. Subgroup analysis revealed that the protective effect of add-on PTX was demonstrated in the higher proteinuria group (p = 0.009), but not in the lower proteinuria group. Multivariate cox regression model confirmed combination therapy had less chance of RRT again (HR 0.705, 95% CI 0.505 – 0.985, $P$ = 0.040), especially in higher proteinuria group (HR 0.606, 95% CI 0.420 – 0.873, $P$ = 0.007).

**Conclusions:** Combination treatment of PTX with ACEI or ARB showed a better renal outcome than single use of ACEI or ARB, especially in higher proteinuria patients. Large randomized control trials are needed to provide more evidence of the add-on effect of PTX in CKD patients.

**TH-PO220**

**NT-proBNP, Troponin T, and Risk of Incident Heart Failure in Chronic Kidney Disease: The CRIC Study** Nisha Bansal,[1] Amanda Hyre Anderson,[2] Wei Yang,[2] Myles S. Wolf,[3] John W. Kusek,[3] Christopher deFilippi,[3] Alan S. Go,[3] Robert Christenson,[3] Rajat Deo,[2] James P. Lash,[3] Dominic S. Raj,[3] Sylvia E. Rosas,[2] Michael Shlipak,[1] Harold I. Feldman.[2] *[1]UCSF; [2]UPenn; [3]CRIC Study.*

**Background:** Heart failure (HF) is a major complication of chronic kidney disease (CKD). NT-proBNP and high sensitivity troponin T are associated with HF in the general population, but these associations remain unclear in the setting of CKD.

**Methods:** We studied 3,483 participants of the Chronic Renal Insufficiency Cohort (CRIC) Study (mean age: 58 yrs; 48% diabetic; 42% black; mean eGFR: 45 mL/min) who did not report HF at baseline. Incident HF hospitalizations were adjudicated using standard criteria. Associations of each biomarker with incident HF were assessed using Cox models after multivariable adjustment, and then additionally adjusted for both biomarkers.

**Results:** Median (IQR) NT-proBNP and troponin T was 135.3 (58.6-335.6) and 11.19 (5.4-21.8) pg/mL, respectively. Over a median of 4.7 years, 284 incident HF events occurred. Those in the highest (versus lowest) quintile of NT-proBNP had an 11-fold higher adjusted rate of incident HF (Table). Compared to those with undetectable troponin T, those in the highest quartile of detectable troponin T had a 4-fold higher adjusted rate of incident HF. Results did not change after adjustment for the alternative biomarker.

| | | HR* (95% CI) | P-value |
|---|---|---|---|
| NTproBNP (ng/mL) | Ref: ≤47.6 | | |
| | >47.6-95.8 | 3.3 (1.4-8.1) | <0.001 |
| | >95.8-188.8 | 3.9 (1.6-9.5) | |
| | >188.8-433 | 6.3 (2.6-15.0) | |
| | >433 | 11.4 (4.7-27.5) | |
| Troponin T (ng/mL) | Ref: undetectable | | |
| | >3-7.8 | 1.4 (0.6-3.4) | <0.001 |
| | >7.8-13.6 | 2.3 (1.0-5.3) | |
| | >13.6-24.4 | 2.6 (1.2-6.0) | |
| | >24.4 | 4.1 (1.8-9.4) | |

* Adjusted for demographics, clinical center, diabetes, Hx of CVD, smoking, alcohol, log(24-hr urine protein), eGFR, SBP, BMI, LDL, hemoglobin, medications, serum phosphorus, log(PTH), and log(FGF23)

**Conclusions:** Troponin T and NT-proBNP, possibly reflecting subclinical myocardial stress and dysfunction, were significantly and independently associated with incident HF among a diverse cohort of CKD patients.

*Funding:* NIDDK Support

**TH-PO221**

**Risk of Nephropathy Associated with Choice of Add-On Therapy for Diabetes Treatment after Metformin** Adriana Hung,[1,2] Christianne Roumie,[1,2] Robert Greevy,[1,2] Xulei Liu,[1,2] Carlos Grijalva,[1,2] Harvey J. Murff,[1,2] T. Alp Ikizler,[1,2] Marie Griffin.[1,2] *[1]Veterans Affairs, Nashville, TN; [2]Vanderbilt Univ, Nashville, TN.*

**Background:** Glycemic control reduces the risk of chronic kidney disease (CKD). The addition of a second agent is often needed when diabetes is sub-optimally controlled with metformin monotherapy. We compared the effectiveness of adding either insulin or sulfonylurea to metformin in preventing kidney function decline or death.

**Methods:** We assembled a national retrospective cohort of veterans who initiated diabetes treatment with metformin monotherapy between October 2001 and September 2008 and added either insulin or a sulfonylurea after at least 3 months of monotherapy through September 2010.The primary renal composite outcome was a GFR event, defined by both a decline in GFR of 25% and reaching a GFR<60 ml/min or dialysis. The secondary outcome was a composite of a GFR event, dialysis or death. Marginal structural Cox proportional hazard models compared the hazard of the outcomes between exposure groups, after adjusting for baseline and time-varying covariates. Sensitivity analyses and subgroup analysis by HbA1c at the time of add-on therapy were also performed.

**Results:** There were 29505 patients (15%) that added a second drug to metformin during the specified time frame and were included in this analysis; 1,310 (4%) insulin and 28195 (96%) sulfonylurea. Patients who added insulin were younger (59 vs. 61 years), more often African Americans (21% vs. 12%) and had higher HbA1c median (8.5% vs. 7.7%). There was no difference in the rates of the primary composite outcome of eGFR events or dialysis between those who added insulin versus sulfonylureas, (31 versus 23 per 1000 person-years, respectively ([aHR] 0.91, 95% Confidence Intervals [CI] 0.62, 1.31)). The rates for the secondary outcome of eGFR event, dialysis or death were 58 and 37 per 1000 person-years, respectively (aHR 1.11, 95% CI 0.85, 1.45). The risk for the primary outcome did not differ by HbA1c subgroups at the time of add-on therapy.

**Conclusions:** The risk of renal events or death was similar among patients who added insulin to metformin monotherapy and patients who added a sulfonylurea.

**TH-PO222**

**Comparative Effectiveness of Insulin versus Combination Insulin and Sulfonylurea in Preventing Renal Outcomes** Adriana Hung,[1,2] Christianne Roumie,[1,2] Robert Greevy,[1,2] Xulei Liu,[1,2] Carlos Grijalva,[1,2] Harvey J. Murff,[1,2] Marie Griffin,[1,2] T. Alp Ikizler.[1,2] *[1]Dept of Veterans Affairs, Nashville, TN; [2]Vanderbilt Univ, Nashville, TN.*

**Background:** Evidence based recommendations for the choice of diabetic regimen for prevention of renal outcomes among those with low GFR are lacking. We compared renal outcomes among diabetes patients who intensified their sulfonylurea monotherapy regimen by adding insulin versus those who switched to insulin monotherapy.

**Methods:** This retrospective cohort included veterans who initiated treatment with a sulfonylurea between 2001 and 2008 and then added or switched to insulin therapy through 12/2010. The primary outcome was a renal composite of a sustained decline of GFR of 35% or ESRD; the secondary outcome was a composite of an GFR event, ESRD or death. Follow-up started at the time of addition or switching to insulin regimen and continued until an outcome, loss to follow-up, death or end of the study. The risk for the outcomes was compared between regimens using marginal structural Cox models. Time-varying covariates were: HbA1c, blood pressure, BMI, co-morbidities and medications. Stratified analyses included subgroups: by GFR ( ≥ or <60 ml/min) and by HbA1c (<7, 7-9 and >9%).

**Results:** Among sulfonylurea monotherapy initiators, we identified 1857 patients that added insulin to sulfonylurea and 1581 that switched to insulin monotherapy. Patients' characteristics were similar between groups, median age was 64 years and 98% were men. There were 4.9 versus 5.2 renal composite events per 100 person-years among sulfonylurea + insulin versus insulin monotherapy users respectively ( [*aRH*] 0.91 95% CI 0.73, 1.13). For the secondary outcome of an eGFR event, ESRD or death, the respective rates were 11.1 versus 13.1 renal composite events per 100 person-years ( [*aRH*] 1.07 95% CI 0.93, 1.24). Results were similar by eGFR and HbA1c subgroups, and in analyses that required persistence on the intensifying regimen.

**Conclusions:** There were no differences in the risk of a sustained decline in eGFR, ESRD or death between patients who intensified their sulfonylurea regimens by adding insulin versus those that switched to insulin monotherapy.

**TH-PO223**

**Low Dose Aspirin for Prevention of Cardiovascular Events in Patients with Chronic Kidney Disease: A Propensity-Matched Study** Ji Yong Jung,[1] Han Ro,[1] Chungsik Lee,[2] Sun Moon Kim,[3] Ae Jin Kim,[1] Hyung Soo Kim,[1] Jae Hyun Chang,[1] Hyun Hee Lee,[1] Wookyung Chung.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Gachon Univ of Gil Medical Center, Incheon, Korea; [2]Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Korea; [3]Div of Nephrology, Dept of Internal Medicine, Chungbuk National Univ Hospital, Cheongju, Korea.*

**Background:** Chronic kidney disease (CKD) is a powerful risk factor for development of cardiovascular disease (CVD). Previous trials have investigated the effect of low dose aspirin on prevention of CVD in patients with diabetes but not in CKD patients. In addition, the role of aspirin in diabetics is controversial and the available literature is contradictory. Therefore, we studied whether low dose aspirin would be beneficial in patients with chronic kidney disease (CKD) as high risk group for CVD.

**Methods:** Using propensity score matching, 191 low dose aspirin (100mg/day) recipients and 382 non-recipients were 1:2 paired for analysis from 2,624 patients with CKD. The primary endpoint was atherosclerotic CVD including coronary arterial disease, stroke, and peripheral arterial disease. Secondary endpoints included death from any cause, bleeding events, and time to serum creatinine doubling and renal death.

**Results:** Low dose aspirin was prescribed for 8.9% of patients with CKD. The incidence of primary endpoint of any atherosclerotic CVD was not significantly different in the aspirin users than in the non-aspirin users after PS matching (hazard ratio = 1.025; 95% confidence interval = 0.642 – 1.637; P = 0.917). Secondary endpoints including all-cause mortality, time to serum creatinine doubling and renal death, hemorrhagic stroke and significant gastrointestinal bleeding events were not significantly different between the aspirin and non-aspirin users.

**Conclusions:** These results suggest that use of low dose aspirin did not reduce the risk of atherosclerotic CVD in CKD patients. Further randomized clinical trials are warranted to confirm the effect of low dose aspirin therapy on the development of CVD in these patients.

**TH-PO224**

**Warfarin Treatment Associates with Better Outcomes in Myocardial Infarction Patients with Atrial Fibrillation Regardless of the Severity of Concurrent Renal Disease** Juan Jesus Carrero,[1] Marie Evans,[1] Karolina Szummer,[3] Jonas Spaak,[2] Robert Edfors,[3] Lars Lindhagen,[3] Stefan H. Jacobson,[2] Peter Stenvinkel,[1] Tomas Jernberg.[3] *[1]Div of Renal Medicine, Karolinska Institutet, Stockholm, Sweden; [2]Clinical Sciences, Danderyd Univ Hospital, Stockholm, Sweden; [3]Div of Cardiology, Karolinska Institutet, Stockholm, Sweden.*

**Background:** Recent cohort studies show that warfarin treatment in patients with advanced chronic kidney disease (CKD) and atrial fibrillation (AFib) is associated with increased mortality and increased incidence of ischemic stroke. We assessed outcomes associated to warfarin treatment in patients with established cardiovascular disease and AFib in relation to kidney function.

**Methods:** Prospective cohort study from the 2003-2010 SWEDEHEART registry including consecutive survivors of a MI with AFib and known serum creatinine (n=24317). Patients were classified into CKD stages based on their eGFR. Primary outcome was a composite of death, readmission due to MI, ischemic stroke and major bleeding within 1 year from discharge. Secondary outcome was the composite of death, MI and ischemic stroke. Multivariate adjustment included age, sex, comorbidities, presentation at admission, hospital course and discharge medication.

**Results:** A total of 5292 (21.7%) patients were treated with warfarin at discharge, and as many as 53.5% of included patients had manifest CKD (eGFR<60 ml/min/1.73 $m^2$). As compared with those who did not receive warfarin treatment, warfarin was associated with a lower risk of the primary outcome in each CKD strata: eGFR>60, Hazard ratio (HR) 0.77, 95% confidence interval (CI) 0.69-0.85; eGFR 60-30, 0.75 (0.68-0.82); eGFR 29-15, 0.83 (0.69-0.99); and eGFR<15 ml/min/1.73 $m^2$, 0.58 (0.39-0.58). The same was observed for the secondary outcome. Major bleeding events were neither increased nor reached statistical significance in warfarin-treated versus non-treated patients across dysfunctional CKD stages.

**Conclusions:** Warfarin treatment was associated with a decreased 1-year risk of death, readmission for MI, stroke and bleeding in consecutive MI patients with AFib. This association was not influenced by the severity of concurrent renal disease.

*Funding:* Government Support - Non-U.S.

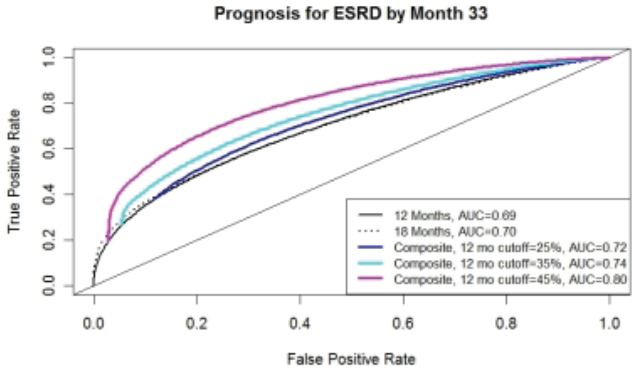
## TH-PO225

**Diabetic Kidney Disease: Results from the Irbesartan Diabetic Nephropathy Trial (IDNT)** Jamie P. Dwyer,[1] Julia Lewis,[1] Tom Greene,[2] Nan Hu,[2] Edmund J. Lewis,[3] The Collaborative Study Group.[3] *[1]Vanderbilt Univ; [2]Univ of Utah; [3]Rush Univ.*

**Background:** The composite endpoint of time to of SCR (dSCr) or ESRD is accepted by the FDA and traditionally used to determine treatment effects on progression of chronic kidney disease (CKD) in contemporary clinical trials. However, the follow-up time required for these events can be substantial.

**Methods:** We assessed the accuracy of endpoints defined by smaller confirmed increases in SCR at either 12 months or 18 months for prediction of subsequent occurrences of ESRD using analyses of time dependent receiver operating characteristic (ROC) curves in the Irbesartan Diabetic Nephropathy Trial (IDNT) data base.

**Results:** Shown are time-dependent ROC curves with associated areas under the curve (AUC) for alternative early SCR endpoints relative to occurrence of ESRD by 33 months. We considered the following early SCR endpoints: a) Confirmed increases in SCR at 12 months; b) Confirmed increases in SCR at 18 months, and c) Three additional composite endpoints defined by confirmed increases in SCR by varying levels at 18 months OR a confirmed increase in SCR at 12 months by either 25%, 35% or 45%.



Sensitivities at thresholds defining 90% specificity were 34.9% for a 27.7% confirmed increase in SCR at 12 months, 36.4% for a confirmed increase of 36.3% at 18 months, and 51.1% for a composite defined by a 45% confirmed increase at 12 months OR a 29.3% confirmed increase at 18 months.

**Conclusions:** Endpoints defined by confirmed increases in SCR during the first 12 to 18 months of follow-up are predictive of occurrence of ESRD. Composite endpoints incorporating designated increases at either 12 or 18 months may further improve prognostic accuracy compared to SCR endpoints defined at a single follow-up time.

## TH-PO226

**Urinary Albumin:Creatinine and Protein:Creatinine Are Prognostically Equivalent for CKD Progression: Results from CANPREDDICT** Claudio Rigatto,[1] Adeera Levin,[2] Catherine M. Clase,[3] Brendan J. Barrett,[5] Francois Madore,[4] Norman Muirhead,[6] Navdeep Tangri,[1] Mila Tang,[7] Ognjenka Djurdjev.[8] *[1]Univ of Manitoba; [2]Univ of British Columbia; [3]McMaster Univ; [4]Univ de Montréal; [5]Memorial Univ of Newfoundland; [6]London Health Science Center; [7]St. Paul's Hospital; [8]British Columbia Renal Provincial Agency.*

**Background:** Proteinuria is an important prognostic variable in patients with chronic kidney disease (CKD). Both albumin-to-creatinine ratio (ACR) and protein-to-creatinine ratio (PCR) are widely used to estimate proteinuria. No study has directly compared the ability of these measures to predict progression to end-stage renal disease (ESRD).

**Methods:** We examined the ability of baseline measures of ACR and PCR to predict progression to ESRD over one year in 2544 patients participating in CanPREDDICT, a prospective cohort study of adult patients with advanced CKD from multiple causes. ACR and PCR were log transformed for analysis. We created a base Cox multivariable model (BCM) for prediction of RRT using standard clinical variables, and then compared differences in the performance (discrimination [c statistic, IDI] and reclassification [NRI]) of enriched Cox models (ECM) created by addition of either logACR or logPCR.

**Results:** Both ACR and PCR independently predicted need for RRT at one year, and each remained highly significant after adjustment for the BCM variables. Both log ACR and log PCR improved BCM performance significantly and to the same degree.

**Table 1:** Multivariate performance PCR vs. ACR in predicting kidney failure in patients with stage 3-4 CKD

| Variable | BCM + logPCR | BCM + logACR | P value (ACR vs PCR) |
|---|---|---|---|
| C-statistic | 0.87 [0.83,0.89] | 0.87 [0.83,0.89] | NS |
| Δ C-statistic (vs. BCM alone) | 0.02 [0.01,0.04] | 0.03 [0.01, 0.04] | NS |
| NRI | 0.57 [0.38, 0.72] | 0.59 [0.36, 0.69] | NS |
| IDI | 0.04 [0.02, 0.06] | 0.04 [0.02,0.06] | NS |

Sensitivity analyses using alternate choices for BCM variables did not change these results.

**Conclusions:** ACR and PCR are equally and interchangeably valid predictors of progression to RRT at 1 year. Clinicians can choose whichever test is most appropriate for the specific renal diagnosis, without loss of general prognostic information applicable to CKD.

## TH-PO227

**Microalbuminuria and CKD Modify the Association of Arterial Stiffness with Death** Javier A. Neyra,[1] Ian McCoy,[1] Nishank Jain,[1] Robert D. Toto,[1] Susan Hedayati.[1,2] *[1]Univ of Texas Southwestern, Dallas; [2]Veterans Affairs North Texas.*

**Background:** Pulse pressure (PP), a marker of arterial stiffness, is associated with mortality and is increased in advanced CKD. Few studies investigated the effect modification of CKD on this association of PP with death. We hypothesized that the independent association between higher PP and death would be greater among patients with CKD and microalbuminuria compared to those without.

**Methods:** Logistic regression was used to explore the association of PP with mortality among 2,859 participants of the probability-sampled, population-based, multi-ethnic Dallas Heart Study followed for a median of 8 years. Odds ratios were expressed for each 5-unit increase in PP. Models were adjusted for age, race, gender, eGFR and urinary albumin-to-creatinine ratio (ACR). Interactions between PP X eGFR and PP X ACR were tested. Analyses were stratified by CKD presence, defined as an eGFR of <60 mL/min/1.73 $m^2$ or presence of microalbuminuria ( ≥ 17 mg/g creatinine in men and ≥25 in women).

**Results:** Mean (SD) age was 45 (10) years, eGFR 100 (24), and ACR 19 (138). 50% were African American, 31% Caucasian, 17% Hispanic, and 2% of other races. Eight percent (242/2,859) had CKD. Those with CKD had a higher PP at 55.0 mmHg, 95% CI (53.0, 57.0) vs. those without, 48.0 (47.6, 48.4) mmHg, p<.0001. There were 155 total deaths with a higher number in the CKD group (48 deaths or 20% vs. 107 deaths or 4% in non-CKD), p<.0001. Every 5 unit increase in PP was associated with a 23% increase in death, OR 1.23, 95% CI (1.18, 1.32), which remained significant after adjustment, OR 1.08 (1.01, 1.16). There was a significant interaction between PP and both eGFR and ACR, p = 0.02 and 0.04. In stratified adjusted models, PP was associated with death in CKD, OR 1.11 (1.003, 1.23) but not in non-CKD participants, OR 1.04 (0.96, 1.13). This difference was highly significant, p<.0001.

**Conclusions:** Among a multi-ethnic community-dwelling sample, arterial stiffness, estimated by PP, was independently associated with death more so in CKD compared to non-CKD participants. This data suggests that arterial stiffness as estimated by increased PP may be a way to risk-stratify patients with early CKD.

**TH-PO228**

**Chronic Kidney Injury and Hypertension Associate with Increased Urinary Succinate Levels** Peter M.T. Deen,[1] Joris Hubertus Robben,[1] Juliette Hadchouel,[5] Gerjan Navis,[3] Ewout J. Hoorn,[4] Jack F. Wetzels.[2] *[1]Physiology, Radboud Univ Nijmegen Med. Centre, Nijmegen, Netherlands; [2]Nephrology, Radboud Univ Nijmegen Med. Centre, Nijmegen, Netherlands; [3]Nephrology, Univ Med. Centre Groningen, Groningen, Netherlands; [4]Nephrology, Erasmus Univ Rotterdam, Rotterdam, Netherlands; [5]INSERM U970, Paris Cardiovascular Research Center, Paris, France.*

**Background:** The renal succinate receptor SUCNR1 senses the krebs cycle intermediate succinate, which is secreted from cells in response to (pseudo)oxidative stress. As it recently emerged as an activator of RAAS and pro-fibrotic events in DM1 and hypertension, we measured urinary succinate excretion in renal diseases to identify disorders in which SUCNR1 may play a role.

**Methods:** Urinary succinate was measured with an optimized low-volume enzymatic assay. Measured succinate concentrations were corrected for urinary creatinine levels. P-values <0.05 were considered significant.

**Results:** Urinary succinate levels were: 2.7 fold higher in CKD stage 2-4 patients than of healthy controls; 4.2 fold higher in hypertensive CKD patients versus controls; 1.4 fold higher in primary aldosteronism patients versus controls; 1.7 fold higher in a mouse model of Familial Hyperkalemic Hypertension (FHHt) with *WNK1* mutations vs. wild-type littermates. In hypertensive CKD patients treated with ACE inhibitors, urinary succinate decreased 3.1 fold following use of Angiotensin receptor blockers (ARBs) and 2.7 fold when subjected to a low-sodium diet. In contrast, subjecting healthy individuals to a high/low sodium diet, or 1-5 days aldosterone infusion in adrenalectomized rats did not change urinary succinate levels.

**Conclusions:** Renal succinate release is increased in all animal models and patients with affected renal function associated with chronic oxidative stress. With hypertensive CKD patients, urinary succinate levels correlated with the extent of sodium intake, hypertension and proteinuria. As urinary succinate activates SUCNR1, these data indicate to a role for SUCNR1 in activation of the intrarenal RAAS system and/or renal fibrosis as are commonly observed in these chronic renal disorders.

**Microalbuminuria and Risk of Cancer** Ali Abbasi,[1,2] Ron T. Gansevoort,[2] Rudolf A. De Boer,[3] Eva Corpeleijn,[1] Rijk O.B. Gans,[2] Hans L. Hillege,[1] Pim Van der Harst,[3] Ronald P. Stolk,[1] Gerjan Navis,[2] Stephan J.L. Bakker.[2] *[1]Epidemiology, Univ Medical Center Groningen, Univ of Groningen, Groningen, Netherlands; [2]Internal Medicine, Univ Medical Center Groningen, Univ of Groningen, Groningen, Netherlands; [3]Cardiology, Univ Medical Center Groningen, Univ of Groningen, Groningen, Netherlands.*

**Background:** Information on the potential association of microalbuminuria (MA) with cancer risk is sparse. We aimed to investigate whether MA is associated with overall and specific cancer risk in the general population.

**Methods:** We acquired data of 40,584 participants (aged 28-75 years) from the PREVEND study, an observational cohort study (Groningen, the Netherlands), that started in 1996-97. All incident cancers requiring hospitalisation were ascertained via the Dutch national hospital registry up to 2009.

**Results:** During a median follow-up of 12.7 years, 4156 (10.2%) subjects developed cancer. The most common cancer sites were respiratory (4.0%), oropharynx (2.4%), genitourinary (2.3%) and digestive system (2.2%). In an age-and sex-adjusted Cox regression model, the HR (95%CI) for all cancer was 1.26 (1.14-1.40) in subjects with MA (urine albumin concentration (UAC)>20mg/L) as compared to normoalbuminuria (UAC<10mg/L) (P=0.001). In a multivariable model adjusted for age, sex, smoking and diabetes, the significant association of MA remained, corresponding with a 23% increased risk of cancer. HRs for MA versus normoalbuminuria for specific cancers were for respiratory 0.93 (0.78-1.12), oropharynx 1.29 (1.04-1.61), genitourinary 1.66 (1.36-2.02) digestive system 1.18 (0.94-1.49), breast 1.17 (0.88 -1.56) and prostate 1.29 (0.93-1.80). In a subcohort of 8,592 subjects, who were screened in detail at baseline, the association of MA (>30mg/24hr) with cancer was corroborated adjusted for the aforementioned variables, even when additionally adjusted for history of cancer, hsCRP, leukocyturia and erythrocyturia (HR 1.29 (1.05-1.53)). No significant independent association was found with eGFR (or impaired eGFR).

**Conclusions:** MA is independently associated with an increased risk of incident cancer in the general population, particularly genitourinary cancers.

**TH-PO230**

**Overall Prevalence of Proteinuria Is Low but the Relative Prevalence of Non-Albumin Proteinuria Is High in a Community Cohort of Patients with Chronic Kidney Disease: Results from the Triple A Kidney Project** Shona Methven,[1] Alan G. Jardine,[2] Mark S. MacGregor.[3] *[1]School of Clinical Sciences, Univ of Bristol, United Kingdom; [2]Institute of Cardiovascular and Medical Sciences, Univ of Glasgow, United Kingdom; [3]Renal Unit, Univ Hospital, Crosshouse, Kilmarnock, United Kingdom.*

**Background:** Measurement of proteinuria with albumin: creatinine ratio (ACR) alone does not take account of non-albumin proteinuria (NAP). We describe the prevalence of NAP in a community cohort of patients with chronic kidney disease (CKD).

**Methods:** Participants with a diagnosis of CKD Stage 3 were recruited from 7 primary care facilities across Ayrshire, Scotland in the Triple A Kidney Project. Detailed baseline clinical and laboratory assessment was undertaken, including measurement of early morning ACR and protein:creatinine ratio (PCR) in all participants. Albumin:protein ratio (APR) was calculated and compared with that of a nephrology clinic population (n=1874).

**Results:** Four hundred and eleven participants were recruited, mean age 70.6±9.6 years, 59% female, 99.5% white, 20% diabetic and median eGFR 54 (IQR 44 – 61)mL/min/1.73m$^2$. Only 2.7% of the cohort had documented glomerular disease and 69% were taking renin-angiotensin blocking drugs. Twenty six per cent (n=107) had detectable proteinuria measured by PCR ( ≥15mg/mmol, [ ≥133mg/g equivalent]), 17% by ACR ( ≥3mg/mmol, [ ≥2.65mg/g equivalent]) and 14% had elevated PCR and ACR. Of those with PCR 15-50mg/mmol (133-442mg/g) (n=91), only 50% had detectable albuminuria and 70% had an APR<0.4 (ie predominantly NAP). Of those with PCR>50mg/mmol (>442mg/g), 44% had APR<0.4. In the nephrology clinic population, 55% of those with PCR 15-50mg/mmol had an APR <0.4 and 23% of those with PCR>50mg/mmol had an APR <0.4.

**Conclusions:** Overall prevalence of proteinuria was low in this community cohort but the relative prevalence of NAP was high, and notably higher than a nephrology clinic population, especially in those with <0.5g/day equivalent total proteinuria. This would not have been detected using ACR alone. The presence of albuminuria and NAP may reflect different underlying disease processes and the outcomes of this discordant group will be assessed.

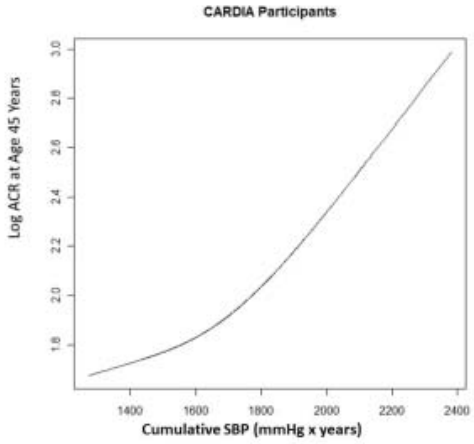
**Urine Albumin/Creatinine Ratio (ACR) and Cumulative Systolic Blood Pressure (CumSBP) in the Coronary Artery Disease in Young Adults (CARDIA) Study** Holly J. Kramer,[1] David R. Jacobs,[2] Cora E. Lewis,[5] Kirsten Bibbins-Domingo,[3] Alex Chang,[4] Carmen A. Peralta,[3] Paul Muntner,[5] David Siscovick,[6] Mark J. Pletcher,[3] Kiang Liu.[7] *[1]Loyola Univ Chicago; [2]Univ of Minnesota; [3]Univ of California San Francisco; [4]Johns Hopkins Univ; [5]Univ of Alabama; [6]Univ of Washington; [7]Northwestern Feinberg School of Medicine.*

**Background:** We hypothesized that an association exists between CumSBP exposure from age 30 through 45 years and ACR at age 45 among black and white adults without diabetes at age 30 (n=1895).

**Methods:** SBP values were averaged between consective visits (years 0, 2 5, 7, 10, 15, 20 and 25) and then multiplied by number of years between visits and summed to determine CumSBP (mmHg x years) during ages 30-45 years. Log ACR at age 45 vs. cumulative SBP was plotted using an additive model after adjustment for race, sex, smoking, waist circumference, education, incident diabetes and blood pressure medication use. Multinomial logistic regression models were used to examine the association between cumSBP exposure and presence of high normal ACR (sex and race adjusted ACR 13-24.9 mg/g) at age 45 or albuminuria (sex and race adjusted ACR => 25 mg/g) at age 45 vs. normal ACR (sex and race adjusted ACR < 13 mg/g) at age 45 after adjustment for covariates.

**Results:** After adjustment for covariates including use of anti-hypertensive medications during age 30-45 years, each 75 mmHg x year increase (5 mmHg per year from age 30-45 years) in CumSBP was associated with a 11% (95% CI 1.02, 1.21) higher odds of high normal ACR at age 45 and a 24% higher odds of albuminuria at age 45 vs. normal ACR at age 45 (95% CI 1.13, 1.36). Figure:



log ACR at age 45 vs. CumSBP after adjustment for covariates.

**Conclusions:** Cumulative SBP during young adulthood is associated with increased ACR at age 45 years.

## TH-PO232

**Obesity, Chronic Kidney Disease (CKD) and End-Stage Renal Disease (ESRD) among Individuals in the REGARDS Study** Holly J. Kramer,[1] Suzanne E. Judd,[2] David A. Shoham,[1] Paul Muntner,[2] David G. Warnock,[2] Orlando M. Gutierrez,[2] Rikki M. Tanner,[2] William M. McClellan.[3] *[1]Loyola Univ Chicago; [2]Univ of Alabama; [3]Emory Univ.*

**Background:** The association between obesity and chronic kidney disease (CKD) is poorly understood. This study examines the independent associations between BMI and waist circumference (WC) with prevalent albuminuria, reduced estimated glomerular filtration rate (eGFR) and incident end stage renal disease (ESRD).

**Methods:** Participants in the REasons for Geographic and Racial Differences in Stroke (REGARDS) study (n=27, 085) with BMI, WC, spot urine albumin-to-creatinine ratio (ACR), and estimated glomerular filtration rate (eGFR) measured at baseline were linked to the United States Renal Data System to identify incident cases of ESRD.

**Results:** Prevalence of albuminuria (ACR ≥30 mg/g) and CKD (eGFR < 60 ml/min/1.73m$^2$), increased across World Health Organization defined obesity categories for BMI and gender-specific WC. After multivariable adjustment there was a significant trend toward lower prevalence for albuminuria and CKD in the BMI groups ≥ 25 kg/m$^2$ vs. BMI < 25 kg/m$^2$ but higher prevalence in the WC groups ≥ 80 and ≥ 94 cm compared to WC referent group (< 80 and < 94 cm in women and men, respectively). A total of 160 individuals developed ESRD (0.6%); increased BMI was associated with a reduced risk of incident ESRD after adjustment for WC and all covariates while higher WC was associated with heightened risk of ESRD. Individuals in the highest WC category ( ≥ 108 and ≥ 122 cm in women and men respectively) had a 5.05-fold (95% CI 2.23, 11.2 ) higher hazard ratio for ESRD compared to WC referent group after adjustment for BMI but this association was no longer significant after adjustment for all covariates (HR 2.03; 95% CI 0.90, 4.55).

**Conclusions:** Higher WC is associated with an increased risk of ESRD after adjustment for BMI while higher BMI is associated with decreased ESRD risk after adjustment for WC. The association between higher WC and ESRD risk support the possibility that increased abdominal adiposity may influence kidney disease progression.

## TH-PO233

**A Cross Sectional Study on the Relationship of Retinal Vascular Diameter, Hypertension and Albuminuia** Wen Huang,[1] Ning Ding,[1] Liping Jiang,[1] Guojuan Zhang,[1] Ningli Wang,[2] Yuan Bo Liang.[2] *[1]Nephrology, TongRen Hospital, Beijing, China; [2]Eye Center, TongRen Hospital, Beijing, China.*

**Background:** Microvascular abnormalities are common findings in patients with chronic kidney disease.Recent studies have reported an association between retinal vessel diameter and chronic kidney disease.But there are still some controversies and researches based on Chinese population are scarce.Hence we did a cross-sectional study to test the hypothesis that the retinal vessel diameter may correlated with renal microvascular abnormalities.

**Methods:** This was a population-based cross-sectional study based on the data of Handan eye study(HES).HES recruited 7577 participants,of whom 5541 had complete information on retinal vessel diameter,albuminuria and blood pressure.Retinal arteriolar and venular diameters were measured and summarized as central retinal arterial equivalent(CRAE) and central venular equivalent(CRVE).The presence of microalbuminuria was defined as urinary albumin:creatinine ratios ≥17 mg/g for men and ≥25 mg/g for women. Hypertension was defined as either systolic blood pressure ≥140mmHg or diastolic blood pressure ≥90mmHg or use of antihypertensive medication.

**Results:** Among the 5541 patients,male45.9%,age(51.83±11.63),hypertension (48.2%),DM(6.1%).After adjustment for age,gender and other confounders,the narrowest retinal arterial diameter correlated with an increased risk of albuminuria (multivariable OR: 1.24, 95%CI 1.02-1.51) compared with the widest. Retinal venular diameter had no correlation with albuminuria.Hypertension correlated with an increased risk of albuminuria (multivariable OR: 1.41, 95%CI 1.21-1.64) compared with absence of hypertension. Exposure to both hypertension and retinal arterial narrowing obviously increased the risk of albuminuria (multivariable OR: 1.69, 95% CI 1.31-2.19).

**Conclusions:** We concluded that retinal arterial diameter was independently correlated with albuminuria,while no such association was found in retinal venular diameter.In hypertensive patients,retinal arterial narrowing was significantly correlated with albuminmuia.

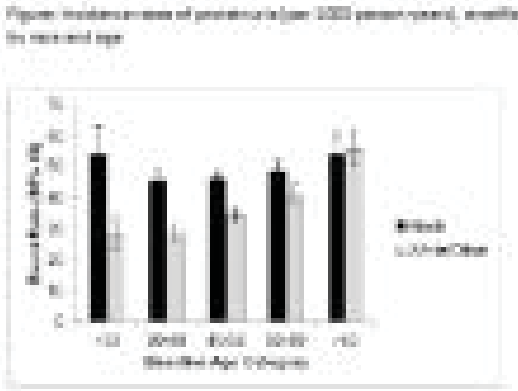
## TH-PO234

**Risk Factors for Proteinuria in a National Cohort of HIV-Infected Veterans** Tanushree Banerjee,[1] Rebecca Scherzer,[1] Neil R. Powe,[1] Diane Steffick,[2] Vahakn B. Shahinian,[2] Meda E. Pavkov,[3] Sharon Saydah,[3] Michael Shlipak.[1] *[1]UCSF; [2]UM; [3]CDC.*

**Background:** As patients with HIV disease live longer, kidney disease has become more common, manifested by proteinuria and rapid progression to ESRD. Few studies have evaluated risk factors associated with proteinuria in HIV-infected individuals. We examined non-HIV and HIV-related factors associated with incident proteinuria in a national registry of HIV-infected veterans.

**Methods:** HIV-infected veterans without pre-existing kidney disease receiving health care in the Veterans' Health Administration medical system between 1996 and 2011 were included. Race (black versus non-black) was self-reported. Proteinuria was defined by consecutive dipstick measures of 1+ or higher. We computed incidence rates stratified by age and race. A Fine-Gray competing risk model (accounting for death) adjusted for HTN, DM, CVD, CD4 lymphocyte count, viral load (>100k copies/mL), hepatitis C virus (HCV) co-infection, and eGFR was used to estimate independent associations with incident proteinuria.

**Results:** During follow-up (median=5.2 years; range 0.1-14.1 years), of the 21,346 participants, 7,362 developed proteinuria. Compared with non-blacks, blacks had 1.48-fold higher risk of proteinuria (95% CI 1.41-1.55), but the association varied by age.



Both HIV and non-HIV related factors were associated with new proteinuria: elevated viral load (HR=1.14, 95% CI 1.05-1.25), CD4 lymphocyte count ≤200 cells/mm$^3$ (HR=1.12, 95% CI 1.06-1.19), HCV infection (HR=1.21, 95% CI 1.15-1.27]); HTN (HR=1.26, 95% CI 1.19-1.33), and DM (HR=1.64, 95% CI 1.53-1.75) were also independently associated with incident proteinuria.

**Conclusions:** Risk of proteinuria was overall higher in blacks compared with non-blacks and the association of age with proteinuria differed by race. Several HIV and kidney related risk factors were associated with higher proteinuria risk.

*Funding:* Other U.S. Government Support

## TH-PO235

**High Dietary Acid Load Is Associated with ESRD in a Longitudinal Cohort of U.S. CKD Adults** Tanushree Banerjee,[1] Deidra C. Crews,[2] Donald E. Wesson,[3] Anca Tilea,[4] Rajiv Saran,[4] Desmond Williams,[5] Nilka Rios Burrows,[5] Neil R. Powe.[1] *[1]UCSF; [2]JHU; [3]Texas A&M College of Medicine; [4]UM; [5]CDC.*

**Background:** Previous research in adults with CKD has shown an improvement in kidney injury and slowed GFR decline due to the reduction in dietary acid. We sought to examine the association between high dietary acid load, quantified by dietary net acid excretion (NAE), and progression to ESRD, in a nationally representative sample of US adults.

**Methods:** Among 1,486 CKD (15<eGFR<60) adults aged ≥20 years who participated in the National Health and Nutrition Examination Survey III between 1988 till 1994, NAE was determined by the dietary recall questionnaire (24 hrs) using a model by Remer and Manz. The development of ESRD was ascertained over an average of 13.2 years of follow-up via linkage with the Medicare ESRD Registry. We used the Fine-Gray competing risks model (accounting for competing risk of mortality) to estimate the hazard ratio [HR] for ESRD associated with high versus low dietary acid load after adjusting for demographics, socio-economic position, diabetes and hypertension, eGFR and urinary albumin:creatinine, and daily caloric intake.

**Results:** The median value of NAE was 47.24 mEq/d. Persons with higher NAE were younger (p<0.0001). Persons with higher dietary acid load were more likely to be males (58.9%), non-Hispanic black (31.6%), have diabetes (36.9%), or lower eGFR (30.2%) compared to their counterparts (all p<0.05). Poverty, level of education, and hypertension, did not differ across tertiles of NAE. Adults in the highest and middle versus lowest tertile of dietary acid were more likely to develop ESRD (HR [95% CI]: 6.16 [6.12-6.20] and 3.48 [3.46–3.50], respectively] after adjustment even when the competing risk of death before developing ESRD was accounted for. On studying the association of early ESRD events (within 6 years) with dietary acid, the HRs [95% CI] of the highest and middle tertile were 9.93 [9.35-10.54] and 3.79 [3.66-3.92] respectively, compared with the lowest tertile.

**Conclusions:** Dietary acid load in persons with CKD is independently and strongly associated with increased risk of ESRD over time in a graded fashion.

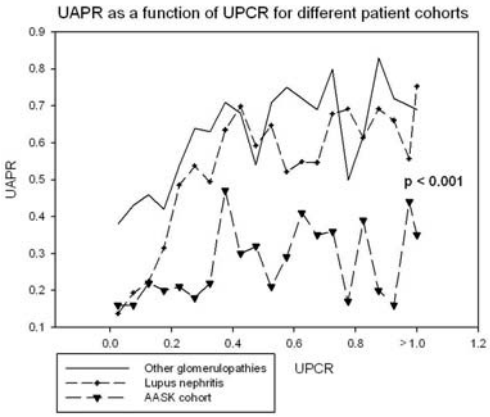
**TH-PO236**

**The Nephropathy of the Patients in the African American Study of Kidney Disease and Hypertension Manifests Low Albumin/Protein Ratios Typical of a Tubulo-Interstitial Nephropathy: Clinical and Pathophysiologic Implications** Udayan Y. Bhatt,[1] Robert D. Toto,[2] Shona Methven,[3] Stephan J.L. Bakker,[4] Ron T. Gansevoort,[4] Mahboob Rahman,[5] Daniel J. Birmingham,[1] Cynthia A. Kendrick,[6] Jennifer J. Gassman,[6] Christopher J. Deighan,[7] Tom Greene,[8] Brad H. Rovin,[1] Lee A. Hebert.[1] *[1]Internal Medicine, Ohio State Univ Wexner Med Ctr, Columbus, OH; [2]Univ of Texas Southwestern; [3]Univ of Bristol, United Kingdom; [4]Univ Medical Center Groningen, Netherlands; [5]Case Western Univ; [6]Cleveland Clinic; [7]Western Infirmary Glasgow, United Kingdom; [8]Univ of Utah.*

**Background:** The pathogenesis of the nephropathy (N) studied in African American Study of Kidney Disease and Hypertension (AASK) is unclear. AASK-N is believed to be from hypertension, but in the AASK trial better BP control did not slow GFR decline. Also, biopsy in AASK-N shows pervasive global glomerulosclerosis, suggesting a glomerulopathy, but AASK-N progresses at proteinuria levels far below that of traditional glomerulopathies. Another paradox is that AASK-N albumin/protein ratios (APR) are low, typical of tubulo-interstitial (T-I)-N not glomerulopathy. The present work addresses this paradox.

**Methods:** We analyzed APR and PCR (protein/creatinine ratio) from published works (# of pts): AASK cohort (691), Glasgow glomerular disease and T-I-N (5,586), Groningen Univ transplant-N (606), Ohio SLE Study lupus N (127).

**Results:**



At any given PCR, APR of AASK-N is below that of glomerulopathies ($p < 0.001$ by ANOVA repeated measures) but not T-I-N or transplant-N (data not shown). Neither preservation artifact or African ancestry explain these differences (data not shown).

**Conclusions:** AASK-N manifests as a tubulopathy. So, in AASK-N non-albumin proteinuria may predict progression better than albuminuria.

**TH-PO237**

**The Effect of Normalizing Spot Albumin to Creatinine Ratio Normalized for Creatinine Excretion Rate on Accuracy of Albuminuria Estimation: The Prevention of REnal and Vascular ENd-Stage Disease (PREVEND) Study** Joseph A. Abdelmalek,[1] Ron T. Gansevoort,[2] Hiddo Jan Lambers Heerspink,[2] Joachim H. Ix,[1,3] Dena E. Rifkin.[1,3] *[1]Div of Nephrology, UCSD, San Diego, CA; [2]Univ Medical Centre Groningen, Groningen, Netherlands; [3]Dept of Med, VA San Diego, San Diego, CA.*

**Background:** The urine albumin-to-creatinine ratio (ACR) is recommended instead of 24-hour urine collections for estimation of albuminuria. In those with extremes of muscle mass, however, variations in the spot urine creatinine value may lead to false under- or over-estimation of albuminuria. Correcting this value for estimated 24-hour creatinine excretion rate (CER), as a proxy of muscle mass, may improve the accuracy of the ACR for estimating albuminuria.

**Methods:** We evaluated 2711 community-living individuals with spot ACR and two 24 hour urine collections for albuminuria. We created a normalized ACR (ACR*eCER) by multiplying the ACR and estimated 24-hour CER using a previously validated equation. The average of the two 24-hour urine albumin excretion (UAE) measurements served as the gold standard for comparison. We compared the accuracy of the ACR and ACR*eCER by comparing the percentage of participants falling within 20% (1-P20) and 30% (1-P30) of the gold standard among all participants, and subgroups stratified by weight, age, and gender. We hypothesized that the biggest improvements in accuracy might be in those at extremes of body weight.

**Results:** The mean age was 49 years, 46% were male, mean eGFR was 84 ± 15 ml/min/1.73m$^2$ and the median 24 hour UAE was 7.2 mg/day (interquartile range 5.4-11). In the full cohort, ACR*eCER improved accuracy (1-P20: 40.3 vs 59.5, 1-P30: 62 vs 76.5, $p<0.001$). In subgroup analysis, the greatest improvement was noted among subgroups with higher rates of creatinine excretion. Improvement was seen in the middle and highest weight tertiles, in all tertiles of age (particularly the lowest and middle tertiles), and in both genders (particularly males).

**Conclusions:** In a large community-dwelling cohort, adjusting ACR for estimated CER modestly improved the accuracy of the ACR for estimation of 24 hour UAE, particularly among individuals with higher rates of creatinine excretion.

*Funding:* NIDDK Support

**TH-PO238**

**Exercise Ameliorates Incidence of Proteinuria in a Large Japanese General Population Sample** Yasuyuki Nagasawa,[1,2] Ryohei Yamamoto,[2] Maki Shinzawa,[2] Yukiko Hasuike,[1] Takahiro Kuragano,[1] Hiromi Rakugi,[2] Yoshitaka Isaka,[2] Takeshi Nakanishi,[1] Kunitoshi Iseki,[3] Kunihiro Yamagata,[3] Kazuhiko Tsuruya,[3] Hideaki Yoshida,[3] Shouichi Fujimoto,[3] Koichi Asahi,[3] Tsuyoshi Watanabe,[3] Toshiki Moriyama.[2,3] *[1]Dept of Internal Medicine, Div of Kidney and Dialysis, Hyogo Medical College, Nishinomiya, Hyogo, Japan; [2]Div of Nephrology and Geriatric Medicine, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [3]Steering Committee for the "Research on the Positioning of Chronic Kidney Disease in Specific Health Check and Guidance in Japan", Tokyo, Japan.*

**Background:** Exercise habitant is well known to have favorable effect upon metabolic syndrome. And metabolic syndrome might cause proteinuria and CKD. But it remains unknown that exercise habitant have favorable effect upon proteinuria. Aim of this study is to reveal the effect of exercise habitant upon proteinuria.

**Methods:** This study is cross-sectional cohort study. Subjects were 290213 persons who received the Specific Health Check and Guidance in Japan in Okinawa, Ibaraki, Miyagi, Niigata, Tokyo, Osaka, Fukushima, Fukuoka prefectures, without missing-data.The exercise score (ES) was defined as total of three exercise habitats; more than once a week half hour or over exercise with slight sweat, more than one hour daily walk or physical activity, faster walking than average of same generation. Outcome was defined as proteinuria. Explanatory variables included sex, age, BMI, mean BP, HbA1c, TG, HDL-C, UA, eGFR, smoking, previous cardiac or stroke or kidney diseases.

**Results:** In whole subjects, ES significantly ameliorated the incidence of proteinuria (ES1 0.9 [ 0.86 - 0.94 ],P<0.001; ES2 0.85 [ 0.81 - 0.9 ] ,P<0.001; ES3 0.77 [ 0.73 - 0.81 ] HR0.9, P<0.001 ). There was significant interaction between ES and BMI in male. After the male subjects were divided into quintile as following BMI, in more than third groups (22.9<BMI<24.1), there was no significant ES effect upon incidence of proteinuria. In female, ES improves incidence of proteinuria, regardless of BMI. Reporting bias might cause this phenomenon in male.

**Conclusions:** Exercise habitant might ameliorate the incidence of proteinuria.

*Funding:* Government Support - Non-U.S.

**Hyperuricemia Is Associated with Cardiovascular Mortality in Chronic Kidney Disease** Diana Chiu, James Ritchie, Darren Green, Smeeta Sinha, Philip A. Kalra. *Salford Vascular Research Group, Univ of Manchester, MAHSC, Manchester, United Kingdom.*

**Background:** Hyperuricemia is a common finding in patients with Chronic Kidney Disease (CKD). There are few long-term outcomes studies examining the association of hyperuricemia with cardiovascular deaths in CKD.

**Methods:** Baseline bloods were analyzed from the Chronic Renal Insufficiency Standards Implementation Study (CRISIS), a prospective observational study of outcome in patients with all-cause CKD stages 3-5, managed in secondary care. Hyperuricemia was defined as serum uric acid >0.43mmol/l. Predictors of cardiovascular deaths, data from Office for National Statistics, were selected using forward stepwise cox regression (included variables with p<0.05 on univariate analysis). As Allopurinol affects uric acid levels, only patients not on this medication were included in this particular analysis.

**Results:** From 883 patients, with available baseline uric acid results and not taking allopurinol, mean eGFR was 35±16.2 ml/min/1.73m$^2$, 542 (61.4%) were males, 293 (33.2%) were diabetics, 171 (19.4%) had history of ischemic heart disease (IHD) and 596 (67.5%) were current/ex-smokers. Median follow-up was 41 months (interquartile range 25-57months), and there were 225 (25.5%) deaths with 60 (6.8%) cardiovascular deaths. In the final cox regression model hyperuricemia was an independent predictor of cardiovascular death.

| Cox Regression Model | | | |
|---|---|---|---|
| Variable | Hazard Ratio | 95% CI | P |
| Hyperuricemia | 2.22 | 1.10-4.47 | 0.03 |
| Age | 1.05 | 1.02-1.08 | <0.01 |
| Diabetes Mellitus | 2.40 | 1.37-4.19 | <0.01 |
| History of IHD | 2.76 | 1.59-4.79 | <0.01 |
| Albumin | 0.90 | 0.84-0.97 | <0.01 |
| eGFR | 0.96 | 0.93-0.98 | <0.01 |
| Predictors included: Age, gender, smoker, diabetes mellitus, history of ischemic heart disease, diuretic use, ACE inhibitor use, albumin, hemoglobin, C-reactive protein, eGFR | | | |

There was no association between hyperuricemia with all-cause mortality in a cox regression model with the same predictors (p=0.325).

**Conclusions:** Hyperuricemia is an independent predictor of cardiovascular deaths in this non-dialysis CKD cohort. Further studies are required to explore causality in this relationship.

**TH-PO240**

**The Association between Serum Uric Acid and Change of Renal Function in a Community-Based Population: A Longitudinal Survey of a Nationwide Cohort in Japan** Keita Kamei,[1] Kazuko Suzuki,[1] Kazunobu Ichikawa,[1] Tsuneo Konta,[1] Shouichi Fujimoto,[2] Kunitoshi Iseki,[2] Toshiki Moriyama,[2] Kunihiro Yamagata,[2] Kazuhiko Tsuruya,[2] Kenjiro Kimura,[2] Ichiei Narita,[2] Koichi Asahi,[2] Tsuyoshi Watanabe.[2] *[1]Dept of Cardiology, Pulmonology and Nephrology, Yamagata Univ School of Medicine, Yamagata, Japan; [2]Steering Committee of Research on Design of the Comprehensive Health Care System for Chronic Kidney Disease (CKD) Based on the Individual Risk Assessment by Specific Health Checkup.*

**Background:** Hyperuricemia is a risk for adverse renal outcomes in chronic kidney disease. This study investigated the effect of uric acid on renal function in a large community-based population.

**Methods:** We used a nationwide database of 110,616 subjects (aged 29-74, male 39%), participated in an annual health check, "The Specific Health Check and Guidance in Japan" between 2008-2010, and examined the relationship between serum uric acid level at baseline and 2-year change of estimated GFR obtained by the Japanese equation.

**Results:** The analysis of variance (ANOVA) showed the decline of eGFR was faster in subjects with low uric acid. However, after the adjustment with gender, age, baseline eGFR, and other possible confounders, the eGFR change was inversely correlated with uric acid and the mean value of the 2-year change of eGFR (mL/min/1.73m$^2$) was +0.43, +0.24, +0.09, -0.20 and -0.72 in subjects with baseline uric acid <4.0, 4.0-4.9, 5.0-5.9, 6.0-6.9 and >7.0 mg/dL, respectively (P <0.001). Multiple linear regression analysis showed that baseline uric acid was independently associated with eGFR change and the regression coefficient of per 1 mg/dL increase of uric acid was -0.24 (95% confidence interval [-0.30, -0.18], P <0.001) in total population. In sensitivity analysis, the effect of serum uric acid on eGFR change was significant especially in elderly, female, and subjects without obesity, hypertension, diabetes, and alcohol consumption.

**Conclusions:** This study showed that an increase of serum uric acid is independently associated with faster renal decline in the Japanese general population, especially elderly, female and subjects without comorbidities.

**TH-PO241**

**Association of Serum Uric Acid Genetic Risk Score with Chronic Kidney Disease in Mexican American, American Indian and Alaska Native Populations** V. Saroja Voruganti,[1] Sandra L. Laston,[1] Karin Haack,[1] Shelley A. Cole,[1] Jack W. Kent,[1] Sven O.E. Ebbesson,[2] Jean W. Maccluer,[1] John Blangero,[1] P. Zager,[3] Jason G. Umans,[4] Anthony Comuzzie.[1] *[1]Genetics, Texas Biomedical Research Institute, San Antonio, TX; [2]Norton Sound Health Corporation, Nome, AK; [3]Univ of New Mexico, Albuquerque, NM; [4]Medstar Health Research Institute, Hyattsville, MD.*

**Background:** Serum uric acid (SUA) has been associated with prevalent and incident CKD. We previously reported that SUA independently predicted incident CKD stage 3 in American Indians of the Strong Heart Family Study (SHFS). Additionally, we have identified genetic linkages and associations of polymorphisms (SNPs) in renal urate transporters in SHFS, Mexican Americans of the San Antonio Family Heart (SAFHS), Zuni Indians of the Genetics of Kidney Disease in Zuni Indians (GKDZI) and Western Alaska Natives from Genetics of Coronary Artery Disease in Alaska Natives (GOCADAN) studies.

**Methods:** We applied the principle of Mendelian randomization to elucidate causality between SUA and CKD using a genetic risk score by summing six risk alleles of *SLC2A9* SNPs (rs10805346, rs16890979, rs6832439, rs737267, rs13131257, and rs6449213), each weighted by its association with SUA.

**Results:** The risk score was associated with eGFR ($p < 4 \times 10^{-3}$) in SHFS and with urinary albumin/creatinine ratio (UACR) ($p < 7 \times 10^{-4}$) in SAFHS. These associations were attenuated by adjustment for SUA to $p > 0.54$ and $p > 0.35$, respectively. The risk score was not associated with CKD in the GKDZI or GOCADAN populations.

**Conclusions:** Genetic approaches in two distinct populations support epidemiologic evidence for a causal role of SUA in CKD.

**TH-PO242**

**Genetic Variants of SLC22A12 Are Associated in a Population-Specific Manner with Serum Uric Acid and CKD Phenotypes** V. Saroja Voruganti,[1] Benjamin Umans,[1] Karin Haack,[1] Sandra L. Laston,[1] Sven O.E. Ebbesson,[2] Jean W. Maccluer,[1] Jason G. Umans,[3] Anthony Comuzzie,[1] Shelley A. Cole.[1] *[1]Texas Biomedical Research Institute, San Antonio, TX; [2]Norton Sound Health Corporation, Nome, AK; [3]Medstar Health Research Institute, Hyattsville, MD.*

**Background:** Renal transporters play a key role in the regulation of serum uric acid (SUA) levels. The solute carrier family 22, member 12 (SLC22A12) gene encodes a urate/anion exchanger localized primarily to the apical membrane of renal proximal tubular epithelial cells. In a previous genome-wide linkage scan of SUA in American Indian participants of the Strong Heart Family Study, we identified a locus on chromosome 11 whose confidence interval contains the candidate gene SLC22A12.

**Methods:** We conducted a follow-up fine mapping by genotyping 20 single nucleotide polymorphisms (SNPs) in SLC22A12 to identify potential functional variants that might affect SUA. We used measured genotype analysis, implemented in SOLAR, to investigate the association between SLC22A12 and SUA and CKD phenotypes.

**Results:** We found significant association of rs17146104 (p = 0.0006) and nominal association with rs12221796 (p = 0.005) with lower SUA levels (minor allele frequency (MAF)= 1- 41%). As a replication step we genotyped these same SNPs in Western Alaska Natives from the Genetics of Coronary Artery Disease in Alaska Natives study. While these two SNPs were not associated with SUA; seven other SNPs (rs2360872, rs538737, rs552307, rs11602903, rs12802649, rs10897518 and rs12786214) from SLC22A12 (MAF =1- 42%) were significantly ($p < 0.004$) associated with lower SUA, possibly reflecting differences in linkage disequilibrium patterns and/or functional alleles between these populations. Interestingly, these seven SNPs were associated with increased estimated glomerular filtration rate ($p < 0.002$) in American Indians but not in Western Alaska Natives. In contrast, albumin-creatinine ratio was not associated with this gene in either population.

**Conclusions:** Our results highlight the value of studies in unique non-European populations to define physiologically-relevant variants contributing to renal phenotypes and outcomes.

*Funding:* Other NIH Support - C06 RR013556 and C06 RR017515- Research Facilities Improvment Program; MH59490-NIMH; U01 HL082490- NHLBI; U01-HL65520, U01-HL41642, U01-HL41652, U01-HL41654 and U01-HL65521 -NHLBI

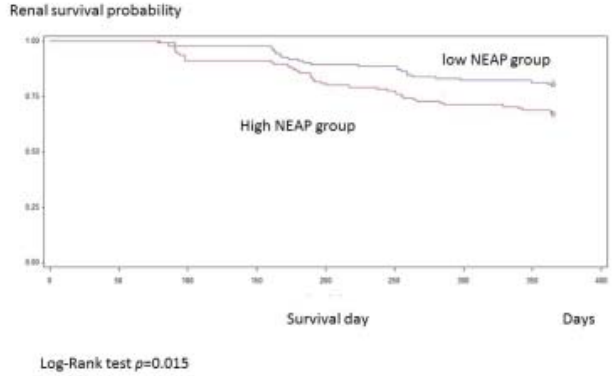
**TH-PO243**

**Dietary Acid Load Is Associated with Chronic Kidney Disease Progression in Elderly Patients** Eiichiro Kanda,[1] Masumi Ai,[2] Renjiro Kuriyama,[3] Masayuki Yoshida,[2] Tatsuo Shiigai.[4] *[1]Tokyo Kyosai Hospital; [2]Tokyo Medical and Dental Univ; [3]Kokubunji Minamiguchi Clinic; [4]Shiigai Clinic.*

**Background:** Nonvolatile acid is produced from the metabolism of organic sulfur in dietary protein. The acid load loeads to increased acid excretion, and promotes kidney damage. However, the evidence for this is not sufficient. In this retrospective cohort study, we investigated the role of dietary acid load in chronic kidney disease (CKD) progression.

**Methods:** 249 CKD patients (male 76.3%) were enrolled in this retrospective cohort study in Japan. The primary endpoint was renal death;a 25% decline in estimated glomerular filtration rate (eGFR) or starting dialysis. Their net endogenous acid production (NEAP) was measured as an alternative marker of dietary acid load using protein intake and potassium excretion per day calculated from 24 hour urine samples. We used time-dependent Cox proportional hazard models adjusted for demographics to examine the association between NEAP level and the outcome.

**Results:** Average age (SD) was 70.6 (7.0) years; eGFR, 22.2 (14.1) ml/min/1.73 m$^2$; NEAP level, 81.4 (41.5) mEq/day. Patients with NEAP levels in the upper half of the range [109.7 (41.1) mEq/day] showed a high risk of CKD progression compared with patients with NEAP levels in the lower half of the range [52.9(12.0) mEq/day]: hazard ratio (HR), 2.013 (95% CI, 1.214, 3.338); adjusted HR, 1.928 (95% CI, 1.143, 3.251).



A longitudinal relationship between the increase in NEAP level and GFR decline was shown by adjusted generalized estimating equation [beta=-0.1076 (0.0080), p=0.029].

**Conclusions:** In elderly CKD patients, our findings suggest that a high NEAP level is independently associated with CKD progression and that an increase in NEAP level is associated with eGFR decline. Monitoring and control of dietary acid load are necessary for the prevention of CKD progression.

**TH-PO244**

**Higher Intake of Vegetable Protein Is Associated with Lower All-Cause Mortality in Chronic Kidney Disease** Xiaorui Chen, G. Wei, R. Filipowicz, Tom Greene, A. N. Habib, T. S. Bjordahl, Srinivasan Beddhu. *Dept of Med, U of Utah, SLC, UT.*

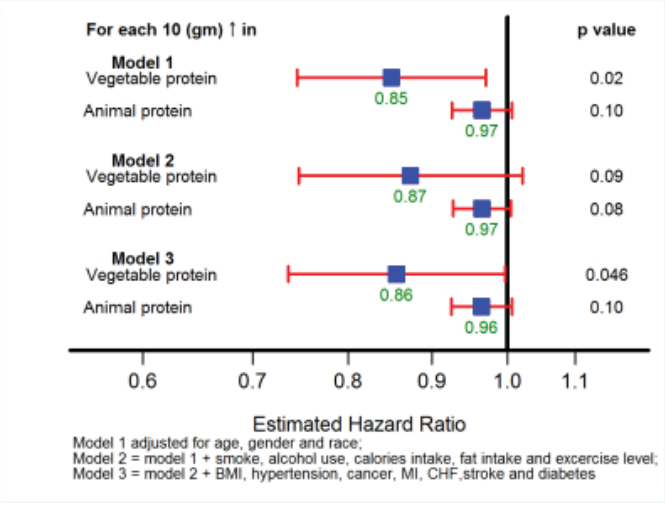
**Background:** Compared to animal protein (AP), vegetable protein (VP) intake is associated with lower production of uremic toxins and lower serum phosphorus levels. It is unclear whether VP has a mortality benefit in CKD.

**Methods:** The study population consisted of 1,104 National Health and Nutrition Examination Survey (NHANES) III participants aged 20 yrs or older with eGFR<60 ml/min/1.73 $m^2$ and non-missing data for VP, AP and mortality. VP and AP intake was estimated from 24h dietary recalls. Mortality was based upon the results from a probabilistic linkage with vital statistic records through 12/31/2006. Cox regression models were used to relate each 10g in VP or AP with all-cause mortality (ACM).

**Results:** The clinical characteristics of the study population by VP groups (defined by median VP intake) are summarized in Table1.

| | VP≤17.8 g/d | VP>17.8 g/d |
|---|---|---|
| VP(g/d) | 12.4 ± 4.2 | 27.3 ± 9.4 |
| Age(yr) | 69 ± 15 | 69 ± 13 |
| Male(%)* | 24 | 48 |
| AA Race(%)* | 10 | 4 |
| MI(%) | 14 | 16 |
| CHF(%) | 13 | 12 |
| Stroke(%) | 8 | 10 |
| Diabetes(%) | 21 | 21 |
| Cancer(%) | 11 | 11 |
| Smoking(%) | 14 | 12 |
| Alcohol use(%) | 25 | 33 |
| Calories intake* | 1245 ± 523 | 1983 ± 758 |
| Fat intake* | 47.0 ± 27.2 | 74.0 ± 40.6 |
| AP(g/d)* | 37.8 ± 26.2 | 48.3 ± 32.0 |
| eGFR(ml/min/1.73$m^2$) | 48.8 ± 10.5 | 49.7 ± 9.6 |
| BMI | 27.6 ± 6.0 | 27.7 ± 5.7 |
| Cancer(%) | 11 | 11 |
| * P value≤0.001 | | |

During the follow-up period, 591 deaths (43.0%) occurred. The association of VP and AP with ACM is displayed in Figure 1.



**Conclusions:** We conclude that VP intake might be associated with lower ACM in CKD population. Interventional trials are needed to establish whether increasing VP will decrease mortality in CKD population.

## TH-PO245

**Prevalence and Correlates of Sleep Disorders in Hispanics with Chronic Kidney Disease in the Hispanic Community Health Study/Study of Latinos (HCHS/SOL)** Ana C. Ricardo, Michael F. Flessner, Gerardo N.M.N. Heiss, Leopoldo Raij, Alberto R. Ramos, Susan Redline, Sylvia E. Rosas, Phyllis C. Zee, Daniela Sotres-Alvarez, Martha L. Daviglus, James P. Lash. *On behalf of the HCHS/SOL Investigators.*

**Background:** Hispanics/Latinos are disproportionally affected by chronic kidney disease (CKD). In non-Hispanics, sleep disorders are more common in individuals with CKD than in those without CKD. However, few data exist on measures of sleep in Hispanics with CKD.

**Methods:** HCHS/SOL, a population based study, enrolled 16,415 adults in 4 US communities. We estimated prevalence and associations of sleep disorders with albuminuria (urine albumin-to-creatinine ratio ≥30mg/g) and low estimated glomerular filtration rate (CKD-EPI eGFR <60ml/min/1.73$m^2$) in 11,873 participants with complete data. Sleep apnea was defined as apnea-hypopnea index (AHI, 3% desaturation) ≥15. Sleep symptoms were based on questionnaires.

**Results:** Mean age (SD) was 41 (0.3) yrs and 52% were women. Prevalence of albuminuria and low eGFR were 8.7% (95% CI: 8.0,9.5), and 2.7 % (95% CI: 2.2,3.1), respectively. Prevalence of sleep disorders are shown in Table.

| Prevalence | Albuminuria, % (95% CI) | | p | Low eGFR, % (95% CI) | | p |
|---|---|---|---|---|---|---|
| | Yes | No | | Yes | No | |
| AHI ≥15 | 21.1 (17.5,24.8) | 8.7 (7.9,9.5) | <0.001 | 26.3 (19.3,33.2) | 9.3 (8.5,10.2) | <0.001 |
| ESS>11 | 12.2 (9.5,14.9) | 11.6 (10.7,12.5) | 0.682 | 13.3 (7.9,18.7) | 11.6 (10.8,12.5) | 0.529 |
| Insomnia | 9.9 (7.6,12.2) | 7.1 (6.4,7.9) | 0.006 | 16.1 (7.4,24.8) | 7.1 (6.4,7.8) | 0.004 |
| Restless legs | 1.8 (0.8,2.8) | 1.3 (0.9,1.7) | 0.219 | 8.0 (0.0,16.7) | 1.2 (0.9,1.5) | <0.001 |

In multivariable analyses, albuminuria was associated with a 47% increased odds of AHI ≥15 (odds ratio 1.5, 95% CI: 1.1,2.0), but not independently associated with Epworth Sleepiness Scale (ESS) >11. No association was seen between low eGFR and sleep disorders. In participants with albuminuria, risk factors significantly associated with AHI ≥15 included older age, male, and higher body mass index.

**Conclusions:** In a large cohort of Hispanic/Latinos, prevalence of sleep apnea and self-reported sleep disorders was higher in persons with CKD compared with those without CKD. In addition, albuminuria was independently associated with a higher risk of sleep apnea.

*Funding:* NIDDK Support, Other NIH Support - National Heart, Lung, and Blood Institute (NHLBI)

## TH-PO246

**The Sleep and Nephrology Outcomes Research (SNORE) Study: Design and Preliminary Findings** Muna T. Canales,[1,2] Nicole Kay,[1] Areef Ishani,[3] I. David Weiner,[1,2] Richard Berry,[1,2] Rebecca Beyth.[1,2] *[1]Malcom-Randall VAMC; [2]Univ of Florida, Gainesville, FL; [3]Minneapolis VAMC, Minneapolis, MN.*

**Background:** Sleep apnea (SA) is common and deleterious to the cardiovascular system. Through similar mechanisms SA may cause renal injury in patients with moderate to severe CKD. We report the design and preliminary findings of an ongoing 3-year prospective study of 250 veterans with CKD to: 1) determine the impact of SA on CKD progression, QOL and 2) validate and refine a SA risk assessment tool, the Berlin Questionnaire (BQ), for CKD.

**Methods:** We identified veterans age 18-99 in NF/SGVHS with ≥2 MDRD egfr 15-44, ≥3 months apart. We excluded those with dialysis or kidney transplant, PAP or $O_2$ therapy, inability to consent, active cancer, or solid organ transplant. Veterans were randomly invited in batches of 30-100 letter mailings every 1-2 weeks to participate with follow up phone call for non-response. At baseline, participants undergo full sleep study, KDQOL-SF, Epworth Sleepiness Scale (ESS) and BQ and renal function measurement. Renal function and KDQOL-SF will be assessed annually for 3y. Assuming prevalence of SA (apnea-hyponea index or AHI>5) 54%, ESRD rate 5%/y, 10% doubling SCr over 3y, 2y accrual period with 3y follow-up, 10% lost to follow-up, we can detect HR 1.5 for the composite outcome (doubling SCr or ESRD) with n=250 (80% power, $\alpha$=0.05).

**Results:** 34 baseline visits have occurred through 6/4/13. Mean age of enrollees is 76±9.5y; 100% male, 88% white, 35% DM, 85% HTN. Mean BMI 30±4; mean MDRD eGFR 33±7; median UACR 44 mg/gCr (IQR 12-190). Median ESS score 7.5 (IQR 4-10), 25% had ESS>10. 44% were high risk for SA by BQ score ≥2; preliminary sleep study scoring found 65% with AHI ≥5 and 30% with AHI ≥15. 38% reported excellent/very good health. From the KDQOL-SF, mean physical component summary score was 61±25 and mental component summary score was 74±23. Burden of kidney disease and sleep (pre-specified key kidney-specific QOL domains) were 82±22 & 67±17, respectively.

**Conclusions:** The SNORE Study will provide valuable insight into the impact of SA on CKD progression and QOL. Validation and refinement of a SA risk assessment tool could improve risk assessment in CKD.

*Funding:* Veterans Affairs Support

## TH-PO247

**Low Serum Magnesium Is Associated with the Development of End-Stage Renal Disease (ESRD) in the Atherosclerosis Risk in Communities (ARIC) Study** Adrienne Tin,[1] M. Grams,[1] Nisa M. Maruthur,[1] Brad C. Astor,[2] David J. Couper,[4] Tom Mosley,[3] Josef Coresh,[1] Wen Hong Linda Kao.[1] *[1]Johns Hopkins Univ; [2]Univ of Wisconsin; [3]Univ of Mississippi Medical Center; [4]Univ of North Carolina.*

**Background:** Magnesium (Mg) is important in many enzymatic reactions and the regulation of mitochondrial function and vascular tone. Low serum Mg levels have been associated with incident hypertension and diabetes; both are important risk factors of ESRD. Whether serum Mg might independently associate with incident ESRD is unknown.

**Methods:** ARIC participants (10986 EA, 3697 AA) with baseline eGFR >15 were followed from 1987-2010. We analyzed the association between ESRD and serum Mg levels by quartiles using Cox regression adjusted for self-reported race, age, gender, baseline eGFR, diabetes, systolic blood pressure, smoking status, prevalent coronary heart disease, HDL-C, triglycerides, hypertension medication, BMI, serum albumin, and LDL-C. We further tested for this association excluded diuretics users.

**Results:** AA had significantly lower Mg than EA (mean of 0.79 mmol/L in AA vs 0.83 mmol/L in EA, p=1.1x$10^{-140}$). We observed a total of 276 ESRD events (141 in AA and 135 in EA). Individuals in lower quartiles of Mg levels were more likely to develop ESRD compared with individuals in the higher quartiles (Table 1). The association of quartile 1 vs. quartile 4 remain significant after excluded diuretics users (event/n=183/12048). Table 1. Hazard ratio (HR) and 95% confidence interval (CI) for ESRD by quartiles of serum Mg.

| | Quartile 1 | Quartile 2 | Quartile 3 | Quartile 4 | P Trend |
|---|---|---|---|---|---|
| Range (mmol/L) | 0.25-0.7 | 0.75 | 0.8 | 0.85-1.15 | |
| HR (CI) adjusted for self-reported race only | 4.4 (3.2, 6.1) | 1.8 (1.3, 2.6) | 1.3 (0.9, 1.8) | 1.0 | <0.0001 |
| HR (CI) adjusted for all covariates | 2.4 (1.7, 3.3) | 1.6 (1.1, 2.2) | 1.2 (0.9, 1.7) | 1.0 | <0.0001 |
| HR (CI) adjusted for all covariates, excluded diuretics users | 2.4 (1.5, 3.7) | 1.5 (1.0, 2.3) | 1.4 (0.9, 2.1) | 1.0 | 0.0002 |

**Conclusions:** In a large sample of middle-aged adults, low serum Mg conferred an increased risk of ESRD. This finding raises the possibility of whether alteration of Mg may be a novel therapeutic target in chronic kidney disease.

*Funding:* NIDDK Support

## TH-PO248

**Serum Phosphorus and Outcomes in an African-American CKD Population**
Shailesh Basani,[1] Praveen Kandula,[2] Ranjani N. Moorthi,[1] Deming Mi,[1] He Xia,[1] Marc Rosenman,[1] Sharon M. Moe,[1] Jonathan W. Bazeley.[1] *[1]Indiana Univ, Indpolis, IN; [2]Massachusetts General Hospital, Boston, MA.*

**Background:** Serum phosphorus ($PO_4$) levels, even within the normal range, have been positively associated with adverse outcomes in chronic kidney disease (CKD) populations. However, subjects in the previous studies were mainly white and racial differences have not been previously examined despite differences in vitamin D and PTH homeostasis in African-Americans (AA). We tested the hypothesis that race alters the relationship between $PO_4$ level and mortality and/or time to dialysis initiation.

**Methods:** A retrospective cohort of adult patients with CKD (eGFR < 60ml/min at baseline) visiting the nephrology clinic at a large urban county hospital from 2007-10 was studied. Excluding subjects with no $PO_4$ measurement at index date (first clinic visit in 2007-2010a total of 996 subjects were identified and were followed until death or May 2012. A Cox proportional hazard model adjusted for baseline demographics, comorbidities, medications, and laboratory values was used to study the association of $PO_4$ and race on the composite end point of time to death or dialysis initiation (days to event from index date).

**Results:** Of 996 patients, 53% were female, 60% were AA and 56% had diabetes mellitus. The mean age was 58.5 ± 13.8 years (mean ± SD), mean eGFR was 33.4 ± 13.3 ml/min/1.73m$^2$. The median $PO_4$ level was (3.8mg/dl; interquartile range 3.3-4.4). During a median follow up of 1125 days, 331 (33.2 %) participants either died or initiated on dialysis. In univariate analysis higher $PO_4$ was associated with increased mortality, time to dialysis or both in the whole cohort and in AA only. However, in the multivariable model $PO_4$ was not a significant factor in predicting time to death or dialysis initiation. The adjusted hazard ratio was 1.13 (CI 0.98, 1.29) for every 1mg/dl increase in serum phosphorus in the whole cohort and it was similar 1.07 ( CI 0.89, 1.3) in the AA cohort.

**Conclusions:** Phosphorus was not associated with mortality or dialysis initiation in an urban population of CKD patients that was predominantly AA, raising questions on the generalizability of previous research studies to the clinic setting.

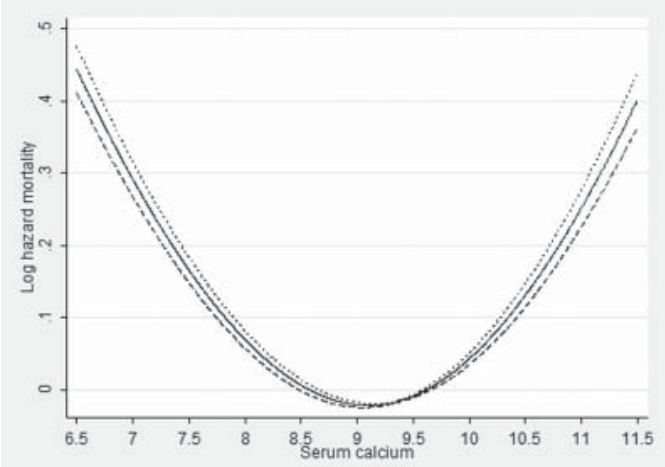
## TH-PO249

**Association of Serum Calcium Concentration with Mortality in a Nationally Representative Cohort of U.S. Veterans with Non-Dialysis Dependent Chronic Kidney Disease**
Barry M. Wall,[1,2] Kamyar Kalantar-Zadeh,[3] Leigh Darryl Quarles,[1] Jun Ling Lu,[1] Csaba P. Kovesdy.[1,2] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]VA Medical Center, Memphis, TN; [3]Univ of California, Irvine, CA.*

**Background:** Epidemiologic studies have shown an association between higher serum calcium concentration and increased mortality in both dialysis dependent and non- dialysis dependent CKD patients. Data concerning the association of lower calcium with mortality have been conflicting.

**Methods:** We evaluated the association of serum calcium concentration with all-cause mortality in a national cohort of 528,388 US veterans with stable non-dialysis dependent CKD stages 1-5. The association of calcium concentration with all-cause mortality was examined in time-dependent Cox models. The analyses were adjusted for age, gender, race, comorbidities (DM, CVD, CHF and Charlson index), estimated GFR, serum albumin and bicarbonate concentration, and administration of antihypertensive medications. Uncorrected calcium concentration was used for all analyses.

**Results:** The mean age of the cohort was 74 ± 9 yr and 98% were male. Over a median follow-up of 4.6 years, 177,502 patients died (mortality rate: 78.3/1000 patient-years (95% confidence interval [CI] 77.9 - 78.7). Compared to patients with serum calcium 8.4 to<10.2 mg/dL, those with serum calcium <8.4 and > 10.2 mg/dL had adjusted mortality hazard ratios (95% CI) of 1.34 (1.34-1.37) and 1.47 (1.43-1.52), respectively. Calcium concentration displayed a U-shaped association with mortality.



**Conclusions:** We conclude that both low and high calcium concentrations are associated with increased mortality in patients with non-dialysis dependent CKD. Calcium concentrations of 9.0 - 9.2 mg/dL were associated with the lowest mortality in this population.

*Funding:* NIDDK Support, Veterans Affairs Support

## TH-PO250

**Serum Calcium and Renal Outcomes in Patients with Chronic Kidney Disease**
Lee-Moay Lim,[1] Hung-Chun Chen.[1,2] *[1]Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; [2]Faculty of Renal Care, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

**Background:** Mineral disorders especially hyperphosphatemia are associated with adverse renal outcome in chronic kidney disease (CKD) patients. Hypercalcemia and hypocalcemia have been associated with mortality in some studies but the association with renal outcome is not well characterized. Whether adding calcium besides phosphorus or in the form of calcium x phosphorus into the predictive model could improve discrimination of renal outcome is not known.

**Methods:** We examined whether serum calcium is associated with renal outcomes in a prospective cohort study of 3303 CKD stage 3-5 outpatients. Cox proportional hazard models and logistic regression were performed by quartiles of calcium.

**Results:** The mean age of our cohort was 63.5 ± 13.5 years, mean eGFR 24.7 ± 15.1 ml/min per 1.73m$^2$ and mean calcium level 9.1 ± 0.8 mg/dL. In the baseline data, cardiovascular disease, hyperphosphatemia, high PTH and hypoalbuminemia were associated with hypocalcemia but eGFR did not show the association. Low serum calcium (<8.7 mg/dL) was associated with increased risk for renal replacement therapy (RRT) [adjusted hazard ratio (HR) 1.34(1.11-1.61), P<0.01] and rapid renal function progression (eGFR slope < -4ml/min/1.73m2/yr) [adjusted odd ratio (OR) 1.28(1.01-1.63), P<0.01] compare those with normal serum calcium (9.1-9.6mg/dL). The result remained significant after stratification for serum phosphors and iPTH. When combination of serum calcium and phosphorus were modeled, high serum phosphorus (>4.2 mg/dL) in conjunction with low serum calcium (<9.1 mg/dL) had highest risk for RRT and rapid renal function progression [HR 1.69 (1.32-2.18), P<0.01].

**Conclusions:** In advanced CKD patients, low serum calcium was associated with increased risk of RRT and rapid renal function progression. Integration of serum calcium besides phosphorus should be considered in predicting renal outcomes.

## TH-PO251

**Multivariate Risk Factors for Progression of CKD from Stage 4 to Stage 5**
Mark D. Faber, Hassan Fehmi, Naima Ogletree, Denise White Perkins. *Div of Nephrology, Depts of Int Med, Fam Med & Public Health Sciences, Henry Ford Hospital, Detroit, MI.*

**Background:** The incidence of ESRD in African-Americans (AA) far exceeds that of non-AA patients. There is much less data or agreement about the effect of race and other variables on rates of progression from stage 4 CKD (CKD-4, the likely "last chance" to prevent or delay ESRD) to stage 5 (CKD-5).

**Methods:** Administrative databases within Henry Ford Health System identified persons with CKD-4 (6 variable MDRD eGFR 15-29 ml/min/1.73 m$^2$) during 2010. The first eGFR defined the index date. Subsequent eGFRs and health care services were assessed for a 2 year follow-up period. Patients dying within 30 days or not returning for eGFR were excluded. Progression to CKD-5 was defined as 2 or more eGFRs <15 ml/min/1.73 m$^2$ at least 30 days apart. Analyses were conducted using SPSS v19.0.

**Results:** Of 5,780 patients with CKD-4, 868 had no follow-up eGFR and 56 died within 30 days. The remaining population of 4,586 was 39% male and 30% AA with mean age 72.8 yrs. 23.7% had a subsequent eGFR< 15, confirmed in 512 (10.5%) with a second eGFR <15. 2-year mortality was 4.1%. 40.7% had a nephrology visit during follow-up but only 7.9% had it in CKD-4. Further analysis was limited to the 512 with confirmed CKD-5. Progression was associated with male gender (12.9% v 9.0%, p <.001), AA race (12.3% v 9.8%, p <.01), younger age (66.6 v 73.5 years, p <.001) and diabetes (DM, 13.8% v 8.8%, p <.001). In a multivariable logistic regression model, DM, male gender and younger age were still risk factors for progression but the effect of race disappeared. During follow-up, patients with CKD-5 utilized more hospital stays (mean 1.3 v .89, p <.001), inpatient days (mean 8.7 v 5.8, p <.001) and ER visits (mean .73 v .49, p <.001).

**Conclusions:** The risk of progression from CKD-4 to CKD-5 over two-years was significant. Progression was associated with greater health care utilization. The infrequency of early nephrology evaluation, which may reduce risk of progression to ESRD, is alarming. There is a need to further clarify the relationship between CKD progression, which did not appear to be affected by race, and the widely disparate rates of incident and prevalent ESRD.

## TH-PO252

**Impact of Febuxostat on Renal Function in Gout Subjects with Moderate-to-Severe Renal Impairment** K. Saag,[1] A. Whelton,[2] M. Becker,[3] P. MacDonald,[4] Y. Zhou,[4] L. Gunawardhana.[4] *[1]Birmingham VA Medical Center, AL; [2]UCRC Inc and Johns Hopkins Univ, MD; [3]Univ of Chicago Pritzker School of Medicine, IL; [4]Takeda, IL.*

**Background:** Up to 20% of patients with hyperuricemia (serum urate [sUA] >6.8 mg/dL) and gout have moderate-to-severe renal impairment. Higher sUA (>8.5 mg/dL) further increases this risk. This 12-m pilot study evaluated the efficacy of urate-lowering with febuxostat (FEB) on the progression of renal impairment in gout subjects.

**Methods:** In this randomized controlled trial, subjects received 1:1:1 FEB 30mg BID, FEB 40/80mg QD (40 to 80mg to achieve sUA <6.0 mg/dL) or placebo (PLB) daily. Eligible subjects fulfilled ARA criteria for gout, were without tophi, had an sUA >7.0 mg/dL and estimated glomerular filtration rate (eGFR; MDRD) ≥15 to ≤50 mL/min (severe, 15 to <30 mL/min; moderate, 30 to ≤50 mL/min). Assessments included change from baseline (CFB) in serum creatinine (sCr) and eGFR, and percentage of subjects with sUA <6.0 mg/dL.

**Results:** Of 96 subjects enrolled, 80% were men with baseline mean (SD) sUA 10.5 (1.70) mg/dL; 95 qualified for the primary efficacy analysis. Titration from FEB 40mg QD to 80mg QD occurred for 20/32 subjects. CFB in sCR and eGFR was small (**Table**). At m 12, 69%, 45% and 0% of subjects in the FEB 30mg BID, 40/80mg QD and PLB groups, respectively, achieved target sUA <6.0 mg/dL ($p$<0.001). Overall, ≥1 adverse event was reported by 78%, 88% and 78% of subjects in the FEB 30mg BID, FEB 40/80mg QD and PLB groups, respectively. One PLB subject had treatment-related renal impairment.

**Conclusions:** Our data show a small favorable trend in renal function in subjects receiving FEB compared to PLB. Differences in sCr and eGFR were not statistically different. In this prospective study, reduction of sUA to target level was safe and effective in this selected study population with renal impairment.

## TH-PO253

**Short-Term Aerobic Training Reduces Endothelin-1 but Not Arterial Stiffness in Stage 3 CKD** Sam A. Headley, Michael J. Germain, Richard J. Wood, Anthony E. Poindexter, Jyovani W. Joubert, Charles M. Milch, Elizabeth E. Evans, Allen Cornelius, Britton W. Brewer, Beth Parker. *ESSS, Springfield College, Springfield, MA.*

**Background:** Short-term aerobic training has been shown to lead to a reduction in arterial stiffness. The current study was designed to examine the effect of 16 weeks of moderate intensity aerobic training (MIT) on the stiffness of central arteries, as assessed by pulse wave velocity (PWV) and the augmentation index (Aix), in a sample of stage 3 CKD patients. Also examined was the effect of MIT on some key biomarkers of vascular function.

**Methods:** Forty-six CKD patients (mean age = 57 ± 8.2 yrs) were randomly assigned to either the treatment group (T, n= 25) or to the control group (C, n= 21). A graded exercise test was performed at baseline (BL) and resting Aix and PWV were measured prior to an acute bout of 40 mins of aerobic exercise or a seated non-exercise control session. Fasting blood samples were also taken. Subjects in T then performed 16 weeks of supervised aerobic training 3x /week at 50-60% of their measured aerobic capacity ($VO_{2peak}$). Individuals randomized to C were told to follow their doctor's recommendations but not to start an exercise program. Identical measures as described above were repeated after 16 weeks. Blood samples were analyzed for endothelin-1, FGF23, and HsCRP. Data were analyzed by ANCOVA with BL and age as covariates.

**Results:** All data are presented as means ± SD.The 16 week intervention was associated with a significant increase in $VO_{2peak}$ and a decrease in endothelin-1 in T compared to C. There were no significant changes in any other variables.

| Variable | Pre | Post | p-value |
|---|---|---|---|
| $VO_2$ peak (ml/kg/min) | 19.6 ± 6.7 (T)<br>18.0 ± 6.0 (C) | 21.2 ±7.7(T)<br>17.5 ± 5.7(C) | p<0.05 |
| PWV (m/s) | 10.7 ± 2.9 (T)<br>11.0 ± 2.2 (C) | 10.8 ± 2.9(T)<br>10.9 ± 2.4 (C) | p=0.75 |
| Endothelin-1 (fmol/ml) | 1.60 ± 1.0 (T)<br>1.68 ± 1.3 (C) | 1.27 ± 0.7 (T)<br>2.19 ± 2.2 (C) | p =0.027 |

**Conclusions:** Short-term aerobic training that is associated with an increase in aerobic capacity does not change central arterial stiffness in stage 3 CKD but seems to reduce endothelin-1 levels.

## TH-PO254

**The Association between Change in Weight and Change in GFR: Does Body Surface Area Adjustment Matter?** Alex Chang,[1] Xuelei Wang,[4] Cynthia A. Kendrick,[7] Lawrence J. Appel,[6] Holly J. Kramer,[3] Jackson T. Wright,[4] Brad C. Astor,[5] Tom Greene.[2] *[1]Nephrology, Johns Hopkins Univ; [2]Epidemiology, Univ of Utah; [3]Nephrology, Loyola Univ Medical Center; [4]Nephrology, Case Western Reserve Univ; [5]Nephrology, Univ of Wisconsin; [6]Welch Center for Prevention, Epidemiology, and Clinical Research, Johns Hopkins Univ; [7]Cleveland Clinic; [8]Statistical Sciences Core, Case Western Reserve Univ.*

**Background:** Controversy exists over whether glomerular filtration rate (GFR) should be indexed to body surface area (BSA). Higher body mass index is associated with higher absolute GFR but not GFR indexed to BSA in cross-sectional studies. Previous longitudinal studies have indexed GFR to baseline rather than concurrently measured BSA. Little is known about whether longitudinal changes in weight track with changes in GFR, and whether this relationship exists after adjusting for concurrently-measured BSA.

**Methods:** Participants in the African-American Study of Kidney Disease and Hypertension underwent measurements of weight and GFR at baseline, 3, 6, and every 6 months during the trial. Using linear mixed effects models adjusted for treatment assignment, we examined the association between change in weight from baseline and change in iothalamate-measured GFR indexed to baseline BSA and then indexed to concurrently-measured BSA.

**Results:** Every 5kg increase in weight was associated with a 1.04ml/min/1.73m$^2$ (95% CI: 0.82 to 1.27; p<0.001) increase in GFR indexed to baseline BSA, but not when adjusted for current BSA (0.14ml/min1.73m$^2$; 95% CI: -0.08 to 0.37; p=0.2).

**Relationship between Weight Change Categories and GFR**

| Weight Change Category (kg) | iGFR/baseline BSA (ml/min/1.73m$^2$) Estimate (95%CI) | iGFR/current BSA (ml/min/1.73m$^2$) Estimate (95%CI) |
|---|---|---|
| ≤ -13.43 | -4.21 (-5.99 to -2.43) | -1.56 (-3.54 to 0.43) |
| -13.42 to -8.95 | -4.53 (-6.87 to -2.19) | -1.05 (-3.53 to 1.42) |
| -8.94 to -4.48 | -5.36 (-7.74 to -2.97) | -2.40 (-4.85 to 0.06) |
| -4.47 to 4.48 | Ref | Ref |
| 4.49 to 8.95 | 4.20 (1.41 to 6.99) | -0.38 (-3.14 to 2.38) |
| 8.96 to 13.43 | 10.88 (5.67 to 16.10) | 0.95 (-4.10 to 6.00) |
| ≥13.44 | 20.26 (11.69 to 28.83) | 2.07 (-6.23 to 10.36) |

**Conclusions:** Weight change is directly associated with changes in measured GFR; this association essentially disappeared after adjusting for concurrently-measured BSA. Future studies need to be done to understand how weight-related changes in GFR may affect long-term kidney outcomes.

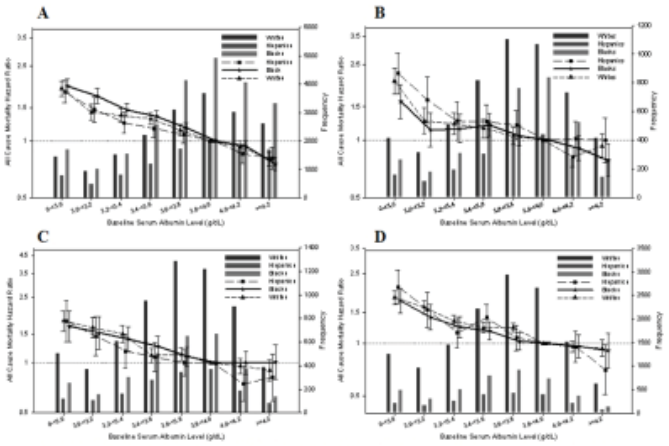
## TH-PO255

**Combined Effect of Age and Race on Mortality Predictability of Serum Albumin Level in Hemodialysis Patients** Alla Victoroff,[1] Vanessa A. Ravel,[1] Elani Streja,[1] Jongha Park,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, UCI, Orange, CA; [2]Univ of Ulsan College of Medicine, Ulsan, Korea; [3]Memphis VA Medical Center, Memphis, VA.*

**Background:** Serum albumin level is a well-known marker for morbidity and mortality in end stage renal disease patients and is one of several markers of nutritional status. Although serum albumin is positively associated with better survival overall, the association could be modified by race/ethnicity as well as age.

**Methods:** Over a 5-year period (7/2001-6/2006), we identified 105,523 maintenance hemodialysis (MHD) patients who had a baseline serium albumin. We used Cox proportional hazard model to compare the mortality among non-Hispanic Whites, Hispanics, and African Americans in 4 different age groups.

**Results:** After full adjustment, Whites and Hispanics in the younger age group (<65 y) maintained a slight survival advantage over Black MHD patients across the lowest albumin levels (<3.0-3.4 g/dL). In patients aged 65 – <70 years, Whites and Hispanics with serum albumin <3.6 g/dL reported increased mortality, but Blacks with serum albumin as low as 3.0-3.4 g/dL failed to show significant mortality increase. In patients aged over 75 years, associations between lower serum albumin levels (<3.6 g/dL) and increased mortality are seen similarly across racial/ethnic groups. However, higher serum albumin levels ( ≥4.0 g/dL) were less frequently observed in this age group compared to patients <65 years old, and did not demonstrate a significant association with greater survival.



(A) <65 y. (B) 65-<70 y. (C) 70-<75 y. (D) ≥75 y. Reference group: hemodialysis patients with serum albumin level 3.8 – <4.0 g/dL.

**Conclusions:** Although baseline serum albumin levels were associated with survival over all, the association could be modified by race/ethnicity as well as age. Younger Black MHD patients may be more tolerant of lower serum albumin levels compared to their counterparts. However, elderly MHD patients seemed to be more vulnerable to protein-energy wasting.

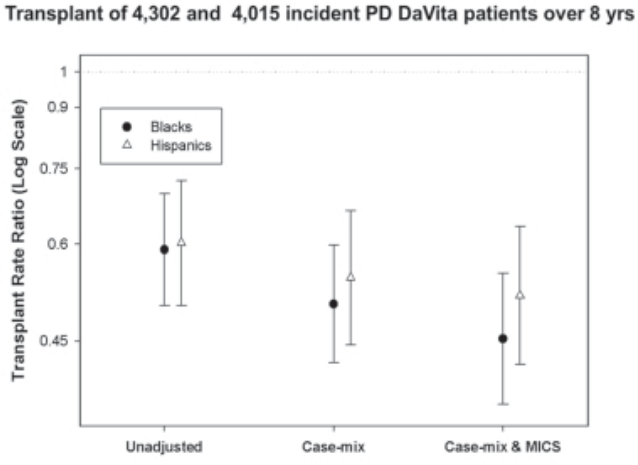
## TH-PO256

**Association of Race-Ethnicity with Transplant Rates in Incident Peritoneal Dialysis Patients** Elani Streja,[1] Chunyang Li,[1] Miklos Zsolt Molnar,[1] Wei Ling Lau,[1] Connie Rhee,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[1] Rajnish Mehrotra.[3] *[1]Harold Simmons Center, UCI, Orange, CA; [2]Harborview Medical Center, Univ of Washington, Seattle, WA; [3]Memphis Veterans Affairs Medical Center, Memphis, VA.*

**Background:** Racial disparities in dialysis patients receiving kidney transplants have been previously reported, particularly for African Americans receiving hemodialysis. However, racial disparities for receipt of kidney transplant among peritoneal dialysis patients is less well known.

**Methods:** We examined 8-year (7/2001-6/2009) rates of transplant in a cohort of 5,067 DaVita incident (< 90 days dialysis vintage days at the time of entry into cohort) PD patients including 1,052 African-Americans, 765 Hispanic, and 3,250 Whites using Cox proportional hazard regression models with adjustment for case mix and surrogates of the malnutrition-inflammation complex syndrome (MICS) and censoring for death.

**Results:** Among African-Americans, Hispanics, and Whites the mean age (mean + SD) was 52+14, 53+16, and 59+15 yrs old and included 55%, 48% and 42% women; and 46%, 57% and 48% diabetics, respectively. Over 8 years, 22% of Whites, 17% of African-Americans and 18% of Hispanics had a kidney transplant. Compared to Whites, African-Americans and Hispanics had a decreased likelihood of transplant: HRs (95%CI) 0.45 (0.37-0.55) and 0.52 (0.42- 0.63), respectively. Compared to African-Americans, Hispanics had a slightly higher likelihood of transplantation.



**Conclusions:** We corroborate previous findings that African-American and Hispanic PD patients are less likely to undergo kidney transplantation in comparison to white PD patients.

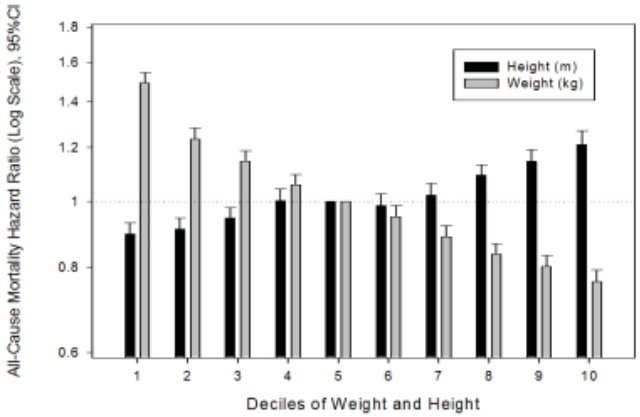
## TH-PO257

**Major Contribution of Height to Altered Effect of Body Mass Index on Mortality Risk in ESRD Patients** Elani Streja,[1] Vanessa A. Ravel,[1] Bryan B. Shapiro,[1] Kamyar Kalantar-Zadeh,[1] Joel D. Kopple.[2] *[1]Harold Simmons Cntr, UCI, Orange, CA; [2]Harbor-UCLA Med Cntr, UCLA, Torrance, CA.*

**Background:** It is well established that in maintenance dialysis (MD) patients, the hazard ratio for mortality (HrM) is related to body mass index (BMI) in a pattern that is essentially opposite of that of the general population. This phenomenon is thought to reflect the effect of body weight on mortality. However, BMI values are also determined by the square of body height. We therefore examined the contribution of height to the BMI relation to HrM.

**Methods:** We compared all-cause mortality of deciles of weight and height in 117,644 MD patients who were followed for up to 6 years (2001 through 2007), using the fifth decile as reference. Mortality risks were estimated with Cox proportional hazards models adjusted for case-mix and MICS markers. Weight analyses were adjusted for height and vice-versa.

**Results:** Patients were 62 ± SD15 years old and included 45% women and 57% diabetics. For a given weight decile, there was an inverse relationship between height and HrM, which is the reverse of what has been reported in the general population (A Kemkes-Grottenthaler Am J Phys Anthropol 2005;128:340). Whereas both weight and height exhibited incremental and strictly linear associations with death risk, weight deciles showed a wider range of HrMs (0.76 to 1.49), whereas the height decile HrM range was 0.90 to 1.21, suggesting a stronger association of weight than height with mortality in these patients.



**Conclusions:** In contrast to the general population, body height is inversely related to HrM in MD patients and contributes importantly to the inverse relation between HrM and BMI in these individuals. Nonetheless, the dramatically altered HrM vs. BMI in MD patients vs. normals is driven more by body weight than height. The cause of the altered relationship between HrM and height in ESRD needs investigation.

*Funding:* NIDDK Support

## TH-PO258

**A Target Organ Damage Based Scoring System (ABCK) Combined with a Cardiovascular Risk Score Improves Prediction of Overall Mortality and Events in a Low Risk Population Cohort** Branko Braam,[1] Lutgarde Thijs,[2] Tatiana Kouznetsova,[2] Jasjeet K. Minhas Sandhu,[3] Dean Eurich,[3] Jan A. Staessen,[2] Carlo A. Gaillard.[4] *[1]Medicine/Nephrology, Univ of Alberta, Edmonton, Canada; [2]Studies Coordinating Centre, Div of Hypertension and Cardiovascular Rehabilitation, Dept of Cardiovascular Diseases, Univ of Leuven, Belgium; [3]Public Health Sciences, Univ of Alberta, Edmonton, Canada; [4]Medicine/Nephrology, Univ Groningen, Netherlands.*

**Background:** Current cardiovascular (CV) prediction models rely on risk factors, but not on target organ damage (TOD) in an individual. The current study tested whether a newly developed multi-organ TOD classification improved prediction of death and CV events.

**Methods:** A population-based prospective cohort (n=1970) was evaluated for traditional CV risk factors. In addition, TOD was staged in arteries, brain, cardiac and kidneys (ABCK classification). Using baseline SCORE, Framingham and ABCK scores, cox proportional hazard models were developed to asses independent effects of each system in predicting 10 year mortality and CV events.

**Results:** Over 10 years, 163 subjects died, 49 (2%) had an AMI, 45 (2%) had a stroke, 46 (2%) developed end-stage renal disease and 14 (0.7%) developed severe peripheral artery disease. Using patients with a very low TOD burden as reference, increasing ABCK scores were associated with increased 10 year risk of overall mortality and CV events: low TOD group hazard ratio (HR) 2.10 (95%CI 0.15-2.88); medium TOD group risk HR 5.97 (95%CI 4.15-8.58), high TOD group risk HR 27.7 (95%CI 14.7-52.6). When related to the SCORE and Framingham scores, the ABCK score was still independently associated with death and CV events in medium and high-risk individuals. Moreover, when combined with Framingham or SCORE, ABCK substantially increased the HR for mortality (HR ranged from 2 in low risk and TOD groups to 60 in highest risk and TOD groups).

**Conclusions:** Addition of a relatively simple-to-use TOD score can improve the prediction of CV events in a population cohort.

## TH-PO259

**Arterial Stiffness Is Associated with Vascular Calcification in Chronic Kidney Disease** Jing Chen,[1] Raymond R. Townsend,[2] Matthew Jay Budoff,[3] Faheemuddin A. Ahmed,[1] Chung-Shiuan Chen,[1] Yanxi Liu,[1] Maria Waight,[1] Heather LaGuardia,[1] Damodar R. Kumbala,[1] Fred E. Husserl,[4] Eric E. Simon,[1] L. Lee Hamm,[1] Jiang He.[1] *[1]Tulane Univ, New Orleans, LA; [2]Univ of Pennsylvania School of Medicine, Philadelphia, PA; [3]Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center in Torrance, Los Angeles, CA; [4]Ochsner Health System, New Orleans, LA.*

**Background:** Arterial stiffness is very common and associated with increased risk of cardiovascular disease in patients with chronic kidney disease (CKD). The underlying etiology for increased arterial stiffness is not fully understood.

**Methods:** We investigated the association of vascular calcification with risk of arterial stiffness in 235 patients with chronic kidney disease (CKD). Arterial stiffness was measured by aortic pulse wave velocity (PWV) and defined as PWV greater or equal to 12 m/sec. Vascular calcification was assessed using electron-beam computed tomography (EBCT) and coronary artery calcification (CAC) Agatston score was calculated.

**Results:** The prevalence of arterial stiffness was 37% in this study population. In the linear regression model, log-transformed coronary arterial calcification (CAC) was significantly and positively associated with log-transformed pulse wave velocity. For example, one standard deviation higher log-transformed CAC Agatston score (2.8) was associated with a 0.03 m/sec (95% confidence interval: 0.02, 0.05, p<0.0001) higher log-transformed pulse wave velocity after adjustment for age, gender, race, high-school education, physical activity, current cigarette smoking, weekly alcohol drinking, body mass index, LDL-cholesterol, plasma glucose, mean arterial pressure, estimated glomerular filtration rate (eGFR), and history of cardiovascular disease.

**Conclusions:** These data indicate that CAC may be associated with increased arterial stiffness in patients with CKD independent of the risk factors for arthrosclerosis.

## TH-PO260

**Varied Relationships between Urinary Symptoms and CKD in the U.S. Population** Paul L. Kimmel,[1] Chyng-Wen Fwu,[2] Kevin C. Abbott,[3] Ziya Kirkali,[1] Tamara G. Bavendam,[1] Paul W. Eggers.[1] *[1]Div of Kidney, Urologic and Hematologic Diseases, NIDDK, NIH, Bethesda, MD; [2]Social & Scientific Systems, Inc., Silver Spring, MD; [3]Walter Reed National Military Medical Center, Bethesda, MD.*

**Background:** The relationship between urinary symptoms, genitourinary disease and CKD has been unclear. Conventional wisdom suggests nocturia is an early sign of CKD, without supporting evidence.

**Methods:** We used the US National Health and Nutrition Examination Survey (NHANES) 2005-2010 to assess the subjective report of nocturia ≥ 2 times per night and NHANES 2001-2010 to identify self-reported cases of urinary incontinence (UI) with markers of CKD (defined as urinary albumin-creatinine ratio ≥ 30 mg/g or eGFR < 60, by CKD-EPI equation). We limited our study sample to participants ≥ 40 years old because CKD, nocturia, and UI are not prevalent among younger populations. Logistic regression odds ratios (OR) were calculated for nocturia and UI associated with CKD after adjusting for age, race or ethnicity, diabetes mellitus, hypertension, BMI, parity (for models in women), diuretics and renin-angiotensin inhibitors. Because of gender differences in occurrence of nocturia and UI, separate analyses were conducted in men and women.

**Results:** 8,960 participants were included in nocturia analyses and 14,187 participants were included in UI analyses.The multivariate-adjusted OR of nocturia in CKD compared to non-CKD was 1.44 (95% confidence interval, 1.19-1.74), significant, among men, and 1.26 (1.07-1.47), significant, among women. The adjusted OR of UI was 1.19 (0.98-1.44) and 1.14 (0.97-1.33) among men and women, respectively.

**Conclusions:** Although the association of CKD and UI could not be detected after adjustment for known risk factors, a robust relationship between nocturia and CKD was found. We conclude possible relationships between UI and CKD are mediated by other factors, but nocturia is a potential diagnostic symptom independently associated with CKD. Absence of nocturia makes a diagnosis of CKD less likely.

## TH-PO261

**Persistent Asthma Increases the Risk of Chronic Kidney Disease: A Retrospective Cohort Study in China** Zhangsuo Liu.[1,2] *[1]Nephrology, The First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China; [2]Key-Disciplines Laboratory Clinical-Medicine Henan, Zhengzhou, Henan, China.*

**Background:** Chronic kidney disease (CKD) is a growing public health problem with well-established risk factors. Other contributing factors, however, remain to be identified. Systemic inflammation in asthma plays a significant role in the development of other diseases. We therefore initiated a study to assess whether the growing prevalence of asthma is associated with an increase in the risk of CKD.

**Methods:** This retrospective study used data from 3015 patients with asthma at the Department of Respiratory Medicine from 2005 to 2011. History, asthma control test (ACT), and asthma stage were used to assess the traits of asthma. CKD was defined as estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73 $m^2$ in twoconsecutive follow-up surveys. Odds ratios (OR) were obtained by logistic regression.

**Results:** A total of 2354 subjects with complete data were recruited for this study. After 6 years of follow-up, 72 (3.1%) participants developed CKD. Persistent asthma was associated with a significantly increased risk for CKD (OR, 2.87; 95% CI, 1.41-5.03) in unadjusted analyses. After adjustment for demographic factors and additional adjustment for hypertension, diabetes, BMI, and personal smoking habits, the increased risk for CKD (OR, 2.07; 95% CI, 1.34-4.42) remained significant. Compared to patients with no asthma traits, there was a significant risk for those who met all three criteria (OR, 3.39; 95% CI, 1.36-8.73) after adjusting for potential confounding factors.

**Conclusions:** We found that persistent asthma was associated with an increased risk of CKD in a study group from China.

**Oral Disease in People with Chronic Kidney Disease: A Systematic Review and Meta-Analysis of Cohort Studies** Giovanni F.M. Strippoli,[1,2,3,4] Suetonia Palmer,[5] Marinella Ruospo,[1,2] Jonathan C. Craig,[4] Giorgio Gentile,[6] David W. Johnson,[7] Pauline J. Ford,[7] Marcello Tonelli,[8] Michele De Benedittis,[3] Massimo Petruzzi.[3] *[1]Diaverum; [2]Mario Negri Sud Consortium; [3]Univ of Bari; [4]Univ of Sydney; [5]Univ of Otago; [6]Univ of Perugia; [7]Univ of Queensland; [8]Univ of Alberta.*

**Background:** Oral disease includes a wide spectrum of clinical abnormalities affecting the mouth including mucosa, teeth, periodontal tissue and salivary function. While observational data for these diseases are available in people with chronic kidney disease (CKD), existing published information has not yet been systematically evaluated. We aimed to summarize the overall prevalence of oral diseases in people with CKD and explore associations between oral disease and mortality.

**Methods:** We conducted a systematic review and meta-analysis of observational studies reporting prevalence or clinical outcomes of oral disease in people with CKD. English-language studies were identified from systematic searching MEDLINE through April 2010. Multiple reviewers extracted participant characteristics. Estimates of prevalence, mean score, or risk of mortality were summarized using random-effects meta-analysis and expressed as rates or means and 95% confidence intervals (CI). Effects of severity of CKD on estimates were analyzed using subgroup analysis.

**Results:** 112 studies (150 cohorts) including 18 339 people with CKD and 16 310 controls were analyzed. 103 cohorts were in people on dialysis, 22 cohorts were in earlier stages of CKD and 25 cohorts were in kidney transplant recipients (15.6%). The mean decay/missing/filled teeth (DMFT) index in people with CKD was 13.7 and number of teeth was 19.4. Nearly 40% of people with CKD had enamel hypoplasia and over half had periodontitis. Overall, the mean plaque index was 1.62 and periodontal pocket depth (PPD) was 2.30 mm. Approximately 25% of people with CKD reported never brushing.

**Conclusions:** Data evaluating the prevalence and severity of oral disease in people with CKD are sparse and incomplete. Large longitudinal studies of the prevalence and clinical associations with oral disease in CKD are now needed.

## TH-PO263

**Reasons Patients Might Not Pursue Kidney Transplant: A Survey of Nephrologists' Perceptions** Jeffrey P. Yourshaw, Ankita Tandon, Kevin C. Roe, Nasrollah Ghahramani. *Internal Medicine, Penn State College of Medicine, Hershey, PA.*

**Background:** Unfavorable views about kidney transplant (KT) have been cited as potential reasons for reluctance by some patients to actively pursue KT. We examined nephrologists' perceptions of their patients' reasons for not choosing KT and analyzed the association between these perceptions and respondent demographics, practice characteristics, and previous training.

**Methods:** Invitations were sent to 3180 nephrologists in the eastern US. 822 expressed interest, and 250 were randomly invited to complete a questionnaire about demographics, practice characteristics, and their perceptions of reasons why patients might not choose KT. A total of 216 surveys with complete responses were analyzed. Chi-square and stepwise logistic regression were performed.

**Results:** The 3 most common factors perceived by nephrologists as important reasons their patients might not choose KT included "inadequate understanding of the process" (84% of respondents), "inadequate financial resources" (76%), and "cumbersome pre-transplant testing" (70%). In multivariate analysis, nephrologists whose fellowship training had a transplant program were more likely to consider inadequate understanding (OR: 4.0; p=0.01) and inadequate financial resources (OR: 5.01; p=0.002) as important reasons patients might not pursue KT. Nephrologists who attended at least one transplant-related CME per year considered inadequate financial resources as an important reason patients might not pursue KT (OR 2.61; p=0.01). In practices where less than half of the respondent's patients completed high school, cumbersome testing was considered an important reason patients would not pursue KT (OR:2.75; p=0.01).

**Conclusions:** Nephrologists believe that inadequate understanding, insufficient financial resources and cumbersome testing are regarded by patients as the most important reasons they might not pursue KT. Nephrologists' perceptions are influenced by their training and ongoing medical education, as well as the characteristics of their patient population. It is possible that nephrologists' perceptions of the reasons for patient reluctance might, in turn, impact their encouragement of pursuing KT.

## TH-PO264

**MDRD versus CKD-EPI Equation to Estimate Glomerular Filtration Rate in Obese Patients** Pierre Delanaye,[1] Emmanuelle Vidal-Petiot,[2] Antoine Bouquegneau,[1] Francois Vrtovsnik,[2] Etienne Cavalier,[3] Jean-Marie H. Krzesinski,[1] Martin Flamant.[2] *[1]Nephrology-Dialysis-Transplantation, Univ of Liege, CHU Sart Tilman, Liege, Belgium; [2]Dept of Renal Physiology and Nephrology, AP-HP and Denis Diderot Univ, Paris, France; [3]Clinical Chemistry, Univ of Liege, CHU Sart Tilman, Liege, Belgium.*

**Background:** Obesity is a recognized risk factor both for the development and progression of chronic kidney disease (CKD). Accurate estimation of glomerular filtration rate (GFR) is thus important in these patients. We tested the performances of two creatinine-based GFR estimates, the MDRD and CKD-EPI equations, in an obese population.

**Methods:** Patients with body mass index (BMI) higher than 30 kg/m² were included. The reference method for measured GFR (mGFR) was $^{51}$Cr-EDTA (single injection method, two blood samples at 120 and 240 minutes). Both indexed and non-indexed results were considered. Serum creatinine was measured using the IDMS-traceable compensated Jaffe method. Mean bias (eGFR-mGFR), precision (SD around the bias) and accuracy within 30% (percentage of estimations within 30% of mGFR) were calculated for both equations.

**Results:** The population included 366 patients (185 women) from two different areas. Mean age was 55 ± 14 years and mean BMI was 36 ± 7 kg/m². Mean mGFR was 56 ± 26 mL/min/1.73 m² (71 ± 35 mL/min without indexation). In the total population, mean bias was +1.9 ± 14.3 and +4.6 ± 14.7 mL/min/1.73 m² ($p<0.05$), and accuracy 30% was 80 and 76% for the MDRD and CKD-EPI equations ($p<0.05$), respectively. In patients with mGFR>60 mL/min/1.73 m², mean bias was +4.6 ± 18.4 and +9.3 ± 17.2 mL/min/1.73 m² ($p<0.05$), and accuracy 30% was 81 and 79% (NS) for the MDRD and CKD-EPI equations, respectively.

**Conclusions:** The CKD-EPI equation did not outperform the MDRD study equation in this population of obese patients. The unexpected positive bias of the MDRD study equation in patients with a mGFR above 60 mL/min/1.73 m² questions the physiological relevance of BSA indexation which may lead to underestimating renal function in obese patients.

## TH-PO265

**Determinants of the Creatinine Clearance to Glomerular Filtration Rate Ratio in Patients with Chronic Kidney Disease** Yen Chung Lin,[1,2] Nisha Bansal,[2] Eric Vittinghoff,[3] Alan S. Go,[4] Chi-Yuan Hsu.[2] *[1]Div of Nephrology, Dept of Internal Medicine, Taipei Medical Univ Hospital; Dept of Internal Medicine, School of Medicine, College of Medicine, Taipei Medical Univ, Taipei, Taiwan; [2]Div of Nephrology, School of Medicine, Univ of California-San Francisco, San Francisco, CA; [3]Dept of Epidemiology and Biostatistics, School of Medicine, Univ of California-San Francisco, CA; [4]Div of Research, Kaiser Permanente Northern California, Oakland, CA.*

**Background:** Creatinine secretion, as quantified by the ratio of creatinine clearance (CrCl) to glomerular filtration rate (GFR), may introduce another source of error when using serum creatinine concentration to estimate GFR. We studied in a large modern cohort of patients with chronic kidney disease (CKD) factors which influence CrCl/iGFR ratio. We specifically wanted to examine whether higher levels of albuminuria would be associated with higher, and black race with lower CrCl/GFR ratio, as suggested by prior literature.

**Methods:** We included 1342 Chronic Renal Insufficiency Cohort (CRIC) participants who had baseline measure of iothalamate GFR (iGFR) and 24-hour urine collections. We cross-sectionally analyzed the relationship between albuminuria (categorized as: <30, 30-299, 300-2999 and ≥3000 mg), and race/ethnicity (non-Hispanic white, non-Hispanic black, Hispanic) and CrCl/iGFR ratio by multivariate-adjusted regression model.

**Results:** Mean iGFR was 48.0 ± 19.9 ml/min/1.73m², median albuminuria was 84 mg per day, and 36.8% of the study participants were black. Mean CrCl/iGFR ratio was 1.19 ± 0.48. There was no association between the CrCl/iGFR ratio and urine albuminuria (coefficient 0.11 [95% CI -0.01 - 0.22] for higest verus lowest levels of albuminuria, p= 0.07). There was also no association between race and CrCl/iGFR ratio (coefficient for blacks was -0.03 [95% CI-0.09 - 0.03] compared with whites, p=0.38).

**Conclusions:** Contrary to what had been suggested by prior smaller studies, CrCl/GFR ratio does not vary with degree of proteinuria or race/ethnicity. The ratio is also closer to 1.0 than reported by several frequently cited reports in the literature.

*Funding:* NIDDK Support, Other NIH Support - Supported by the National Institutes of Health DK88865 (Dr. Bansal), DK60902 (Dr. Go and Dr. Hsu) and DK92291 (Dr. Hsu), Government Support - Non-U.S.

## TH-PO266

**Assessment of Cystatin C Glomerular Filtration Rate in Patients with Liver Cirrhosis** Kriengsak Vareesangthip,[1] Sukit Raksasuk,[1] Supot Nimanong,[1] Wimolphan Artsom,[1] Sunanta Chiewvit,[2] Kanit Reesukumal.[3] *[1]Dept of Medicine, Siriraj Hosp., Mahidol U.; [2]Dept of Radiology, Siriraj Hosp., Mahidol U.; [3]Dept of Clinical Pathology, Siriraj Hosp., Mahidol U., Bangkok, Thailand.*

**Background:** In cirrhotic patients have lower serum creatinine (SCr) due to a decrease production of SCr in liver and due to an increase in the volume distribution cause by retention of water. Moreover, in cirrhosis patients have hypoalbuminemia from malnutrition making a decrease in muscle mass. Thus, the cirrhotic patients have a lower baseline of SCr level less than the general population and have found that SCr have been slowly to change. Therefore, SCr in cirrhotic patients were not correlated with actual glomerular filtration rate (GFR). There is evidence that GFR assessed by cystatin C might be showed positive correlation with actual GFR. This study aimed to assessment of GFR between to SCr-GFR (c-GFR), DTPA-scan GFR and cystatin C GFR methods in cirrhotic patients.

**Methods:** Twenty-two cirrhotic patients were recruited and were monitored for GFR in all three methods (c-GFR, DTPA-scan GFR and cystatin C GFR). Clinical and laboratory parameters were prospectively collected.

**Results:** Among 22 cirrhotic patients (male = 14, female = 8) were enrolled to study (mean age 58.64 years). The causes of cirrhosis were chronic hepatitis B (32%), chronic hepatitis C (36%), alcohol (14%), autoimmune hepatitis (14%) and miscellaneous (4%). The Child Pugh classification A was 86% and B 14%. Three patients (13.6%) were known case of diabetes. Eight patients (36.4%) were diagnosed of hypertension. Two patients (9%) were used spironolactone. The agreement analysis between Tc99-DTPA scan and c-GFR and between Tc99-DTPA scan and cystatin C were calculated according to Altman-Bland plot. The results demonstrated no significant correlation between Tc99-DTPA scan and SCr and between Tc99-DTPA scan and cystatin C estimating to GFR in subgroup analysis including, gender, Child Pugh classification, HbA1C levels and diuretic used.

**Conclusions:** In this study using the GFR assessment by Tc99-DTPA scan as a gold standard, cystatin C GFR has no advantage over c-GFR in order to estimate GFR in patients with liver cirrhosis.

*Funding:* Government Support - Non-U.S.

## TH-PO267

**Comparing Cystatin C and Creatinine for Estimating Measured GFR and CKD Prevalence in a Community-Based Sample of the Elderly** Lesley Inker,[1] Li Fan,[1] Aghogho A. Okparavero,[1] Vilmundur Gudnason,[2] Gudny Eiriksdottir,[2] Margret B. Andresdottir,[3] Hrefna Gudmundsdottir,[3] Olafur S. Indridason,[3] Runolfur Palsson,[3] Lenore J. Launer,[4] Tamara Harris,[4] Gary F. Mitchell,[5] Andrew S. Levey.[1] *[1]Tufts MC; [2]Icelandic Heart Association; [3]National Univ Hospital Iceland; [4]NIA; [5]CV Engineering.*

**Background:** There is controversy about the accuracy of GFR estimating equations compared to measured GFR (mGFR) in the elderly.

**Methods:** We measured GFR using plasma clearance of iohexol in 805 older adults enrolled in the community-based Age, Gene/Environment Susceptibility (AGES)-Reykjavik Study. We estimated GFR using the CKD-EPI equations based on creatinine (eGFRcr), cystatin C (eGFRcys) and both (eGFRcr-cys), and determined prevalence of CKD Stage 3-5 (GFR<60 ml/min/1.73m²). Creatinine and cystatin C assays are traceable to reference materials.

**Results:** Mean age was 79.4±3.8 years. The table compares level of mGFR and eGFR, equation performance and CKD prevalence.

**Table Comparison the performance of eGFRcr, eGFRcys and eGFRcr-cys**

| | Median GFR ($25^{th}$,$75^{th}$) | Bias Median Difference (95%CI) | Precison IQR(95%CI) | Accuracy P30(95%CI) | CKD Stages 3-5(%) (95%CI) |
|---|---|---|---|---|---|
| mGFR | 64(52,73) | NA | NA | NA | 39.0(35.8,42.5) |
| eGFRcr | 68(54,80) | -2.7(-3.5,-2.2) | 12.1(11.2,13.5) | 91.4(89.3,93.4) | 34.8(31.4,38.0) |
| eGFRcys | 61(48,74) | 1.9(1.2,2.6) | 11.5(10.7,12.5) | 93.5(91.8,95.2) | 48.0(44.5,51.4) |
| eGFRcr-cys | 65(51,76) | -0.6(-1.2,0.0) | 10.0(9.0,11.0) | 95.9(94.5,97.1) | 38.3(35.5,42.2) |

Bias=mGFR-eGFR. $P_{30=\%}$ eGFR within 30% of mGFR. Units for GFR, bias and IQR= ml/min/1.73 m².

eGFRcys had a higher rate of false positive diagnosis of CKD Stage 3-5 [29%(24-33)] compared to eGFRcr [14%(10-19)] and eGFRcr-cys [18%(14-22)].

**Conclusions:** eGFRcr and eGFRcys have similar accuracy but opposite direction of bias. In contrast, eGFRcr-cys is unbiased in estimating GFR, leading to a closer approximation of mGFR and CKD prevalence than either eGFRcr or eGFRcys. We suggest using eGFRcr-cys when accurate estimates of mGFR or CKD prevalence in the elderly are required.

## TH-PO268

**Estimation of Glomerular Filtration Rate in Persons Aged 70 Years or Older** Yanni Wang,[1] Chenggang Shi,[1] Xilian Qiu,[2] Jianhua Huang,[3] Cailian Cheng,[1] Xun Liu.[1] *[1]Div of Nephrology, Dept of Internal Medicine, The 3rd Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China; [2]Dept of Laboratory Medicine, The First Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China; [3]Dept of Laboratory Medicine, The 3rd Affiliated Hospital of Sun Yat-sen Univ, Guanghzou, China.*

**Background:** GFR estimating equations need proper validation in the elderly population because of the age related change in renal function and the progressive loss of muscle mass with age.

**Methods:** A total of 345 Chinese participants aged 70 years or older who had undergone technetium-99m diethylenetriaminepentaacetic acid($^{99m}$Tc-DTPA) renal dynamic imaging were enrolled. The two-level race CKD-EPI equation, the four-level race CKD-EPI equation and the BIS1 equation were compared.

**Results:** Although bias was similar among the two-level race CKD-EPI equation and the BIS equation (median difference, -0.2 ml/min/1.73m²for the two-level race CKD-EPI equation vs.0.3 ml/min/1.73m²for the BIS equation[P = 0.6]), precision was improved with the BIS equation (IQR for the difference, 14.1 ml/min/1.73m²), as compared with the two-level race CKD-EPI equation and with the four-level race CKD-EPI equation (IQR for the difference, 19.3 and 20.4 ml/min/1.73m²[P < 0.001 for bothcomparisons]), leading to an improvement in accuracy (15% accuracy, 40.3 vs. 29.9 and 28.4 %; 30% accuracy, 66.1 vs.

53.0 and 51.0 %; 50% accuracy, 85.8 vs. 75.1 and 74.8 %; P < 0.001 for allcomparisons]), as was GFR category classification (GFR category misclassification rate, 38.8 vs. 44.9 and 47.5 %, respectively[P = 0.007 and P = 0.001].

**Conclusions:** The BIS1 equation may be the optimal one for elderly Chinese persons aged 70 years or older.

*Funding:* Government Support - Non-U.S.

## TH-PO269

**Extended Iohexol Clearance Protocol in Older Adults with Reduced Kidney Function** Natalie Ebert,[1] Amina Loesment,[1] Peter Martus,[2] Markus van der Giet,[3] Elke Schaeffner.[1] *[1]Charité Campus Virchow, Nephrology, Berlin, Germany; [2]Biostatistics and Clin Epidemiology, Eberhard Karls Univ, Tübingen, Germany; [3]Charité Campus Benjamin Franklin, Nehrology, Berlin, Germany.*

**Background:** Performing iohexol clearance in people with considerably reduced kidney function is a logistic challenge as it requires a 24h measurement. As an additional project of the Berlin Initiative Study (BIS) we measured iohexol clearance including a 24h-measurement in 61 individuals with chronic kidney disease and compared measured GFR (mGFR) including the 24h measurement to mGFR results without the 24h measurement.

**Methods:** In a sample of 61 subjects mGFR was determined by using iohexol measurements at 120 min, 180 min, 240 min, 300 min (=5h), and 1440 min (= 24h). mGFR was determined using measurements until 300 min ($mGFR_{300}$) and measurements until 1440min ($mGFR_{1440}$). For both approaches the slow component according to the method of Schwartz was determined and the bodysurface area was adjusted for by the Dubois formula. Absolute and percentage differences were calculated.

**Results:** Patients were 79.4 years old (mean, range 70 to 94 yrs), 23% were female. $mGFR_{300}$ and $mGFR_{1400}$ were highly correlated ($R^2 = 0.90$) but $mGFR_{1400}$ (25.0 ± 7.44 ml/min/$m^2$) was significantly smaller than $mGFR_{300}$ (31.0 ± 8.26 ml/min/$m^2$). The raw difference $mGFR_{300}$ - $mGFR_{1400}$ was 6.0 ± 2.65 ml/min/$m^2$ and the percentage difference was 19.8 ± 8.2%. Moreover, in 60 of 61 subjects (98%) $mGFR_{1400}$ was smaller than $mGFR_{300}$ (p < 0.001). Applying the correction formula $mGFR_{1400}$ = -1.486 + 0.854*$mGFR_{300}$ led to an error of ±4.76 ml/min/$m^2$ (two-fold standard error of estimate). Inclusion of a quadratic term did not improve the prediction of $mGFR_{1400}$.

**Conclusions:** The reason for the decline of $mGFR_{1400}$ compared to $mGFR_{300}$ was the fact that the actual iohexol measurement values at 24h were considerably larger as predicted by extrapolation of the slow component from measurements at 5 h. We conclude that the exponential decay does not fit the longterm filtration of iohexol. A linear correction formula for $mGFR_{300}$ leads to an $R^2$ of 0.90 which should be sufficient for applications.

*Funding:* Private Foundation Support

## TH-PO270

**GFR Estimating Equations in HIV-Infected Patients: One Patient, One GFR Estimating Equation** Amandine Gagneux-Brunon,[1] Pierre Delanaye,[2] Christopher R. Mariat,[1] Olivier Moranne.[3] *[1]Universitary Hospital of Saint-Etienne, Saint-Etienne, France; [2]CHU de Liege, Belgium; [3]CHU de Nice, France.*

**Background:** An accurate Glomerular Filtration Rate estimation is needed in HIV-infected (HIV+) patients. CKD-EPI equations based on serum creatinine only or with serum cystatin C were described as accurate in this population. Yet, they are biased; Our aim was to validate GFR estimating Cockcroft and Gault (CG), MDRD, CKD-EPI equations, and to identify factors affecting performance of eGFR in European HIV+ patients with measured GFR greater than 60 mL/min/1.73$m^2$.

**Methods:** GFR was measured by iohexol plasma clearance, serum creatinine (Scr) and cystatin C (Scys) were measured by traceable and standardized methods. We evaluated CG, MDRD, and CKD-EPI equations based on Scr and/or Scys.

**Results:** One hundred eighty five (93% of whites, 33 women, 152 men,) HIV+ patients have been included from februar 2011 to june 2012. Ninety three percent were receiving highly active antiretroviral therapy. Mean (±SD) age was 49 years (±10). Mean mGFR was 99 (±20) ml/min/1.73$m^2$. Mean absolute bias (± SD) were respectively for CG, MDRD, CKD-EPI Scr, CKD-EPI Scys, CKD-EPI combined 1.1 (± 24.6), -3.3 (± 23.5), 0.8 (±19.6), 0 (±21), 0 (±20) mL/min/1.73$m^2$. Accuracy-30 % for CG, MDRD, CKD-EPI Scr, CKD-EPI Scys, CKD-EPI combined were respectively 77, 79, 88, 83, 87. CKD-EPI Scr and combined were significantly more accurate than CG and MDRD. Absolute bias of CG was in multivariate analysis significantly associated with age, body mass index and measured GFR while bias of CKD-EPI Scys was associated with diabetes mellitus, HIV-Viral load, ethnicity and measured GFR. HIV-viral load was not associated with bias of CKD-EPI combined equation. Bias of MDRD was associated with mGFR and CKD-EPI with mGFR level and age.

**Conclusions:** In European HIV+ patients, CKD-EPI Scr was the one of the most accurate GFR equations. mGFR level was significantly associated with the bias of all GFR estimating equations. Clinicians should be aware that factors as GFR level diabetes mellitus, HIV-Viral load, age, ethnicity and body mass index may influence the performance of GFR estimating equations in HIV+patients.

## TH-PO271

**Demographic and Biochemical Determinants of Glomerular Filtration Rate in Chinese Children with Chronic Kidney Disease** Mengchun Gong, Yan Qin, Xuemei Li. *Nephrology, Peing Union Medical College Hospital, Beijing, China.*

**Background:** There is no research on Chinese children's renal function evaluation using the plasma clearance of an exogenous substance, the golden standard method of GFR measurement, and thus no GFR-estimating tools based on data from this vast population. The objectives of this study include measurement of the GFR, analysis of the determinants of measured GFR and selection of the best parameters in estimating GFR, which can be used to develop a GFR-estimating equation for the Chinese children.

**Methods:** Plasma clearance of $^{99m}$Tc-DTPA was measured using the radioactive counts of the plasma sampled at two different time spots (2 hours and 4 hours) after the peripheral bolus injection of measured dose of $^{99m}$Tc-DTPA and calculated as measured GFR (mGFR) . mGFR was normalized by body surface area (BSA), calculated by the Haycock equation. Univariate linear regression was used to determine the capacity of demographic markers, including gender, age, body weight, height and BSA, and the biochemical markers, including Jaffe-Creatinine (JCr), enzymatic creatinine (ECr), urea and cystatin C (CysC), in explaining the inter-individual variance of mGFR and nGFR.

**Results:** Eighty-nine children were included with 49% male. The average level of mGFR and normalized GFR (nGFR) was 67.5±2.8mL/min and 93.4±23.2mL/min×1.73$m^2$, respectively. Univariate analysis showed that the inter-individual variance of mGFR can be explained mainly by demographic markers and the $R^2$ value for height, body weight, age and BSA were 0.313, 0.365, 0.296 and 0.367 (all with p<0.01). However, the inter-individual variance of nGFR can be mainly explained by renal function-related biochemical markers, with $R^2$ value for H/ECr 0.620, H/JCr 0.472, 1/Ecr 0.582, 1/JCr 0.506, 1/CysC 0.588 and 1/BUN 0.372 (all with p<0.001), and can not be explained by demographic markers, with all the $R^2$ value for height, body weight, age and BSA lower than 0.005 and p value >0.05.

**Conclusions:** The inter-individual variance of the BSA-normalized GFR can be mainly explained by the renal function-related biochemical markers. Height/ECr and 1/CysC are two parameters selected for developing the GFR-estimating equations for the Chinese children.

## TH-PO272

**Comparison of Creatinine-Based and Cystatin C-Based Glomerular Filtration Rate-Estimating Equations in Children with Lupus Nephritis** Mengchun Gong, Yan Qin, Xuemei Li. *Nephrology, Peking Union Medical College Hospital, Beijing, China.*

**Background:** There is no data about glomerular filtration rate (GFR), measured through plasma clearance of the exogenous markers, and its estimation tools in children with lupus nephritis (LN).

**Methods:** We determined GFR with plasma clearance of $^{99m}$Tc-DTPA in 21 hospitalized children with clinically (N=10) or pathologically (N=11) proved LN and compared the performance of ten different equations, biochemically based on serum Creatinine (4), serum Cystatin C (3) or their combination (3), in estimating GFR, with parameters of correlation, precision and accuracy.

**Results:** The Schwartz1976, Schwartz2009 and CKiD equations, the most widely accepted tools for GFR estimation in children, significantly overestimate GFR in LN children (bias 38.6, 43.6, 11.5 mL/min×1.73$m^2$, respectively, all p<0.01 in the paired t-test). Compared with the other nine equations, the Filler (eGFR=91.62×(1/sCysC)^1.123)and the Zappitelli-CysC equation (eGFR=75.94×(1/sCysC)^1.17×[1.384]^Tx) produced eGFR with better correlation with nGFR, stronger explanation capacity of variance in nGFR, smaller and non-significant bias, higher intra-class correlation coefficients, higher ratio of eGFR within nGFR±10% and ±30%.

| Equations | BiasΦ | γ¶ | R²†(%) | ICC‡ | nGFR±10% (%) | nGFR±30% (%) |
|---|---|---|---|---|---|---|
| Filler | 7.5 | 0.85 | 72 | 0.87 | 29 | 86 |
| Zappitelli-CysC | -8.4 | 0.85 | 72 | 0.87 | 43 | 86 |
| Grubb | 16.5* | 0.83 | 69 | 0.68 | 27 | 57 |
| Schwartz1976 | 38.6* | 0.73 | 53 | 0.45 | 19 | 38 |
| Schwartz2009 | 43.6* | 0.86 | 74 | 0.57 | 19 | 38 |
| Counahan | 8.5 | 0.77 | 60 | 0.68 | 24 | 81 |
| Leger | 8.3 | 0.64 | 41 | 0.59 | 14 | 57 |
| CKiD | 11.5* | 0.88 | 77 | 0.81 | 33 | 75 |
| Bouvet | -7.6 | 0.70 | 49 | 0.71 | 38 | 62 |
| Zappitelli-Combi | 37.6* | 0.90 | 80 | 0.65 | 0 | 29 |

Φ mL/min×1.73$m^2$; * p<0.01;¶ linear correlation factor; † linear regression; ‡ ICC: intraclass correlation factor.

**Conclusions:** Equations biochemically based on serum creatinine significantly overestimate GFR in children with LN while those based on serum Cystatin C provide eGFR with satisfactory precision and accuracy.

*Funding:* Government Support - Non-U.S.

## TH-PO273

**Development of a Bedside Glomerular Filtration Rate-Estimating Equation for Chinese Children with Chronic Kidney Disease** Mengchun Gong, Xuemei Li, Yan Qin. *Nephrology, Peking Union Medical College Hospital, Beijing, China.*

**Background:** It has been proved that American and European equations to calculate estimated glomerular filtration rate (eGFR) significantly overestimate the value in Chinese children and adults. No equation had been developed, based on the measurement of GFR

with the exogenous-marker clearance method and the enzymatic creatinine, for the Chinese children with Chronic Kidney Disease (CKD).

**Methods:** Plasma clearance of $^{99m}$Tc-DTPA was measured using the radioactive counts of the plasma sampled at two different time spots (2 hours and 4 hours) after the peripheral bolus injection of measured dose of 99mTc-DTPA and calculated as measured GFR (mGFR) . mGFR was normalized by body surface area (BSA), calculated by the Haycock equation. which was calculated using the Haycock equation, and nGFR was used for further analysis. Height to Creatinine ratio (H/Cr) was used as the base for coefficient adjustment according to linear regression study and literature. To assess the properties of the estimating equations, we calculated the root mean square error (RMSE) and $R^2$ in linear regression, the correlation coefficient and the percentage of eGFR within 30 and 15% of nGFR.

**Results:** 89 children were included with 49 percent male. The average level of nGFR was 93.4±23.2mL/min×1.73m$^2$. Univariate analysis showed that the inter-individual variance of nGFR can be mainly explained by H/Cr, with the $R^2$ of 0.620 (p<0.001). For its bedside use, the exponent of H/Cr as set to be 1 and the equation becomes eGFR=27.6×Height (cm)/Cr (mmol/L), named as the PUMCH Equation. In the training dataset, the average eGFR was 96.3±38.2mL/min×1.73m$^2$ and the bias is 2.9mL/min×1.73m$^2$ (P=0.27). The correlation coefficient between eGFR and GFR is 0.84 (P<0.001). Linear regression showed $R^2$ of 0.711 and root mean square error as 0.090. Accuracy analysis showed 38% and 77% of eGFR were within the range of GFR±15% and ±30%, respectively.

**Conclusions:** The newly-developed PUMCH equation for GFR-estimation produced satisfactory precision and accuracy in Chinese children with CKD with its simple structure for bedside use. Further internal and external validation study is necessary to approve its wide-spread application.

## TH-PO274

### Can Estimation of GFR Be Improved by Using Bioimpedance Techniques?

Fansan Zhu,[1] Mathew Hotta,[2] Christina M. Wyatt,[2] Lesley Inker,[3] Li Liu,[1] Nathan W. Levin.[1] *[1]Renal Research Institute, New York, NY; [2]Mount Sinai Medical School, New York, NY; [3]Tufts Univ School of Medicine, Boston, MA.*

**Background:** The current method to estimate glomerular filtration rate (GFR) from creatinine (GFR CKD-EPI) uses serum creatinine (Scr) or cystatin (CysC) and surrogates for muscle mass, particularly race and gender. The aim of this study was to investigate whether estimation of GFR can be improved by adding bioimpedance parameters which incorporates assessment of extracellular fluid (ECV), muscle mass (MM) and calf normalized resistivity (CNR) to models with Scr or CysC or both together to compare with the gold standard GFR (mGFR).

**Methods:** 39 HIV patients (13 females) were studied. Plasma clearance of iohexol was used as mGFR, CysC and sCr were measured. Bioimpedance techniques (BI) were performed to provide ECV, MM and CNR (Zhu et al., ASN abstract 2009). A linear mixed regression model (LMRM) using parameter of sex, race, age, height and weight in the basic model with sCr or CysC or both, and combining ECV, MM and CNR as other models were established according to mGFR.

**Results:** Using correlation with mGFR the basic LMRM with CysC ($R^2$=0.72) is better than with Scr ($R^2$=0.69) but the best result was when were included both CysC and Scr ($R^2$=0.76) (Table 1). Correlation and standard error of estimation (SEE) with mGFR was better in females than in males in all models. Correlations and SEE with mGFR were improved for model with Scr ($R^2$=0.73-0.77), CysC ($R^2$=0.74-0.79) or Scr and CysC ($R^2$=0.79-0.83) when the model included BI parameters.

**Conclusions:** The accuracy of GFR estimation can be improved by use of a BI model which considers muscular mass, fluid volume and degree of hydration, regardless of filtration marker used and the models using both markers is better than using either alone. This model could be helpful to improve GFR estimation.

Table1

## TH-PO275

### Association of Traumatic Amputation with Concentrations of Serum Creatinine and Cystatin C in Male Soldiers: A Case Control Study

John Stephen Thurlow, Kevin C. Abbott, Dustin J. Little, Stephen W. Olson. *Nephrology, Walter Reed National Military Medical Center, Bethesda, MD.*

**Background:** Whether concentrations of serum creatinine, or Cystatin C, are significantly altered after traumatic amputation has not been systematically studied.

**Methods:** Healthy male soldiers who (n=33) were identified in the Armed Forces Amputee Care Program Data Base as having undergone traumatic amputations. Matched controls selected for age, duration of pre and post sample intervals, and comparable health screening were also selected (n=12). **Predictors:** Presence or absence of traumatic amputation, further categorized as small, medium, and large subgroups by Osterkamp estimations using DEXA scan measurements. **Outcomes:** serum creatinine and Cystatin C concentrations. **Measurements:** The Department of Defense Serum Repository was used to compare pre and post traumatic amputation levels (minimum interval of 3 months after amputation) of mean serum creatinine (mg/dl), Cystatin C (mg/L), serum albumin, and white blood cell count. Paired Student's t-test was used for comparisons.

**Results:** Mean serum creatinine was significantly lower after amputation overall (1.05±0.18 pre vs. 0.84±0.14 post; p<0.001), in the medium amputation subgroup (1.10±0.17 vs. 0.84±0.12; p<0.001), and in the large amputation subgroup (0.97±0.17 vs. 0.76±0.11; p<0.001). The difference was not statistically significant in the small amputation subgroup (1.08±0.23 vs. 0.94±0.13; p=0.15). Cystatin C remained unchanged overall (0.80±0.10 vs. 0.79±0.08, p=0.55), as well as in the small amputation (0.75±0.10 vs. 0.79±0.09; p=0.60), medium amputation (0.81±0.09 vs. 0.80±0.07; p=0.92), and large amputation (0.84±0.08 vs. 0.79±0.11; p=0.21) subgroups. In the control group, interval serum creatinine and Cystatin C were not significantly different.

**Conclusions:** Concentrations of mean serum creatinine, but not Cystatin C, are significantly lower after traumatic amputation, changes not observed in matched controls. Reliance on current creatinine based estimates of renal function in patients after amputation could limit identification and management of kidney disease.

*Funding:* Other U.S. Government Support

## TH-PO276

### Plasma Cystatin C Is a Valid Marker of Glomerular Filtration Rate in Mice

Marie Buleon,[1,2] Acil Jaafar,[1] Nicolas Mayeur,[1,2] Marion Vallet,[1] Francoise Praddaude,[1,2] Ivan A. Tack.[1,2] *[1]Service Explorations Fonctionnelles Physiologiques, Laboratoire Physiologie, CHU Toulouse, Toulouse, France; [2]INSERM U1048, I2MC, Univ P Sabatier, Toulouse, France.*

**Background:** Determination of the glomerular filtration rate (GFR) is ideally performed by measuring the renal clearance of exogenous markers such as inulin and $^{Cr51}$EDTA. In mice, this technic present numerous shortcomings. Thus, for years, the follow up of renal function has been based on the dosage of blood markers, such as creatinine and urea. However, various works have underlined the limitations of these markers and a reliable and easy to use endogenous marker to estimate GFR is still lacking in mice. Cystatin C is a valid marker of GFR in human but its relevance, in mice, is unknown.

**Methods:** We prospectively compared cystatin C (human PETIA and mouse ELISA), creatinine (Jaffé and enzymatic assays) and urea to GFR (inulin clearance: mGFR) in male or female C67Bl6 mice, aged between 16 and 40 weeks, healthy or subjected to chronic renal failure (partial nephrectomy or following acute kidney injury).

**Results:** In a first group (n=80), urea, enzymatic creatinine and ELISA cystatin C were significantly correlated to mGFR. Neither PETIA Cystatin C, nor Jaffe creatininemia were correlated with mGFR. We therefore focused on ELISA cystatin C, enzymatic creatinine and urea using complementary groups. Urea was significantly but weakly correlated to mGFR (r Spearman -0.28, p<0.05). ELISA Cystatin C and creatinine were significantly correlated although cystatin C correlation was tighter (r Spearman -0.76 and -0.62, respectively). When applied to a population splitted by mGFR level (<120, 120 to 240, >240 µL/min, n=15 in each group), ELISA cystatin C was the only marker able to significantly distinguish groups from each other (Kruskall-Wallis test, p<0.001). Finally, a Cystatin C-based equation to estimate GFR in mice was developed and validated using Bland & Altman procedure.

**Conclusions:** Our results indicate that mELISA cystatin C, but not hPETIA, is better correlated to GFR in mice than enzymatic creatininemia and could be an interesting and highly discriminative GFR marker. Conversely, the use of Jaffé creatinine and urea to estimate GFR is not relevant.

## TH-PO277

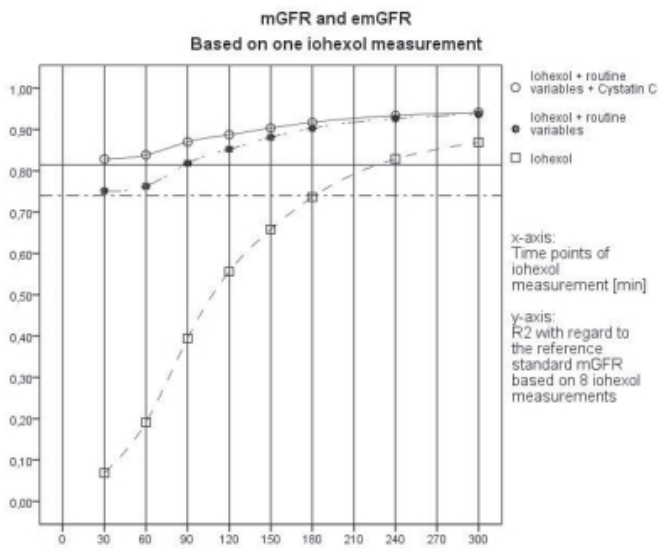
### Efficient Approaches for GFR Assessment in Older Adults

Peter Martus,[1] Natalie Ebert,[2] Markus van der Giet,[2] Olga Jakob,[3] Elke Schaeffner.[2] *[1]Inst Clinical Epidemiology and Med. Biostatistics, Eberhard Karls Univ, Tübingen, Germany; [2]Dept. of Nephrology, Charité, Berlin, Germany; [3]Inst of Biostatistics and Clin Epidemiology, Charité, Berlin, Germany.*

**Background:** Assessment of glomerular filtration rate (GFR) is crucial as the GFR value determines the stage of chronic kidney disease (CKD) and is associated with mortality and cardiovascular morbidities. Equations to estimate GFR have limitations.

**Methods:** We combined variables for the estimation of GFR (eGFR) with a reduced set of measurements of the marker iohexol (mGFR). In a population based sample of 570 subjects (70 ys +) from the Berlin Initiative Study (BIS) we investigated 3 types of GFR equations: (1) the BIS1 and BIS2 equations based on age, gender, serum creatinine, and serum cystatin C, (2) equations based on one or two iohexol measurements, and (3) equations based on the combination of BIS1 or BIS2 with additional iohexol measurements. Thus, our approaches combine estimation and (reduced) measurement of GFR (labeled "em GFR"). We investigated strategies in which only a subset undergoes iohexol measurements. Reference standard was based on eight iohexol measurements. The cut off of 60 mL/min per 1.73 m$^2$ was chosen to assess accuracy. Equations were constructed in a learning sample (n = 285) and validated in an independent sample (n = 285).

**Results:** Misclassification rates were 17.2% (BIS1), 11.6% (BIS2), 12.6% (iohexol$_{240}$, iohexol measurement 240 min), 10.5% (iohexol$_{300}$), 4.9% (iohexol$_{300}$ combined with BIS1), and 5.3% (iohexol$_{300}$ combined with BIS2). Using iohexol only in subjects with eGFR$_{BIS1}$ between 50 and 70 mL/min per 1.73 m$^2$ (52%) led to a misclassification rate of 5.6%.



**Conclusions:** Existing eGFR equations may benefit from the addition of a single iohexol measurement. Strategies for the determination of GFR lead to a relevant increase of diagnostic validity.

## TH-PO278

**Assessment of Estimated Glomerular Filtration Rate Using Creatinine and Cystatin C in Patients with Rheumatoid Arthritis**

Mitsuhiro Kawano,[1] Ryo Inoue,[2] Yukiko Tani,[2] Yasushi Kakuchi,[2] Hiroshi Fujii,[1] Kazunori Yamada.[1] *[1]Div of Rheumatology, Kanazawa Univ Hospital, Kanazawa, Japan; [2]Div of Internal Medicine and Rheumatology, Ishikawa Prefectural Saiseikai Kanazawa Hospital, Kanazawa, Japan.*

**Background:** The estimated glomerular filtration rate (eGFR) using creatinine (Cr) may be overestimated in patients with rheumatoid arthritis (RA) due to their loss of muscle mass. Recently, Cystatin C (CysC) has been focused on as a useful marker of renal function. This prompted us to clarify the factors causing discrepancies between eGFR using Cr (eGFRcr) and that using CysC (eGFRcys).

**Methods:** 245 RA patients were enrolled in this study. We calculated eGFRcr/eGFRcys as a marker of the discrepancy of measurement of renal function. We divided patients into two groups: group A with a ratio<0.8, n=39, and group B with a ratio ≥0.8, n=206. We searched for associated factors, such as age, body weight, disease duration, and serum albumin.

**Results:** In no patients was a significant difference noted between eGFRcr and eGFRcys. The average age (years), body weight (kg), disease duration (month), serum albumin (mg/dl), and SDAI of the patients in group A were 70.6, 51.3, 190.3, 3.9, and 10.7 respectively, while those in group B were 61.0, 57.0, 110.0, 4.1, and 6.1, respectively, showing significant differences between the two groups.

**Conclusions:** The renal function of the patients with high age, low body weight, long disease duration, malnutrition and high disease activity was overestimated by eGFRcr. This should be kept in mind when assessing renal function in RA patients.

## TH-PO279

**Comparison of CKD-EPI Creatinine and Cystatin C-Based Formula and Simple Cystatin C Formula in Patients with Moderate Decreased GFR**

Nina Hojs,[1] Sebastjan Bevc,[1] Radovan Hojs,[1] Robert Ekart,[2] Maksimiljan Gorenjak,[3] Ludvik Puklavec.[4] *[1]Dept of Nephrology, Univ Clinical Centre, Maribor, Slovenia; [2]Dept of Dialysis, Univ Clinical Centre, Maribor, Slovenia; [3]Dept of Clinical Chemistry, Univ Clinical Centre, Maribor, Slovenia; [4]Dept of Nuclear Medicine, Univ Clinical Centre, Maribor, Slovenia.*

**Background:** New KDIGO guidelines suggest subdividing of stage 3 CKD (GFR=30-59 ml/min/1.73m$^2$) into stages 3A and 3B because a marked increase of all-cause and cardiovascular mortality is seen at GFR <45 ml/min/1.73m$^2$. Recently, serum cystatin C ($S_{cys}$)-based formulas and the creatinine & cystatin C-based formula (CKD-EPI creatinine & cystatin formula) were proposed. The aim of our study was to compare CKD-EPI creatinine & cystatin formula and simple $S_{cys}$ formula (100/$S_{cys}$) against 51CrEDTA clearance in patients with stage 3 CKD.

**Methods:** 151 adult Caucasians (75 women, 76 men; mean age 60.6 years) were included. In each patient 51CrEDTA clearance, serum creatinine ($S_{crea}$; IDMS traceable method) and $S_{cys}$ (immunonephelometric method) were determined. GFR was calculated using the CKD-EPI creatinine & cystatin formula and simple $S_{cys}$ formula.

**Results:** Mean 51CrEDTA clearance was 42.7±8.7 ml/min/1.73m$^2$, mean $S_{crea}$ 1.9±0.7 mg/dl, mean $S_{cys}$ 2.1±0.7 mg/l. Correlations between 51CrEDTA clearance and both formulas were found (P<0.0001). In ROC analysis (cut-off for GFR 45 ml/min/1.73m$^2$) no significant difference of diagnostic accuracy between CKD-EPI creatinine & cystatin formula and simple $S_{cys}$ formula was found (P=0.453). Bland and Altman analysis for the same cut-off showed that CKD-EPI creatinine & cystatin formula underestimated (bias: -10.1 ml/min/1.73m$^2$) and simple $S_{cys}$ formula (bias: 11.8 ml/min/1.73m$^2$) overestimated measured GFR. Both equations lacked precision. Analysis of ability to correctly predict patient's GFR below or above 45 ml/min/1.73m$^2$ showed similar ability for simple $S_{cys}$ formula (66.2%) and CKD-EPI creatinine & cystatin formula (66.9%).

**Conclusions:** Our results indicate that simple $S_{cys}$ formula is a reliable marker of GFR in stage 3 CKD patients and is comparable to CKD-EPI creatinine & cystatin formula.

## TH-PO280

**The Correlation and Comparison among Three Methods for GFR Measurement: Renal Inulin Clearance, Systemic Inulin Clearance, and 51Cr-EDTA Plasma Clearance**

Ran-Hui Cha,[1] Hajeong Lee,[2] Dong Ki Kim,[2] Yon Su Kim.[2] *[1]National Medical Center, Seoul, Korea; [2]Seoul National Univ Hospital, Seoul, Korea.*

**Background:** Renal inulin clearance with continuous infusion method has been recognized as the gold standard for the measurement of glomerular filtration rate (GFR). However, inconvenience and complications associated with the method led to the development of alternative methods. We aimed to explore the relationships among three different methods for GFR measurement.

**Methods:** Three different tests including renal inulin clearance with continuous infusion method (gold standard), systemic inulin clearance with a single injection method (standard protocol over 4 hours and extended protocol over 24 hours), and plasma $^{51}$Cr-EDTA clearance over 5 hours were performed in each subject to measure GFR. Total of 114 participants had all of three tests.

**Results:** There was a strong correlation between systemic inulin clearance and renal inulin clearance with a single injection method ($\gamma$=0.89, P<0.001), but renal inulin clearance overestimated systemic inulin clearance in overall. There was a very strong correlation between systemic inulin clearance measured by standard protocol and extended protocol ($\gamma$=0.99, P<0.001), and the difference between them was very small. The strong correlation between gold standard method and systemic inulin clearance with single injection method (standard protocol) was observed ($\gamma$=0.89, P<0.001). The systemic inulin clearance (standard protocol) underestimated renal inulin clearance, in general (correlation coefficient:0.89; slope:0.64). Plasma $^{51}$Cr-EDTA clearance also had a very strong correlation with gold standard method ($\gamma$=0.92, P<0.001), and overestimated the renal inulin clearance on the whole (correlation coefficient:0.92; slope:0.81).

**Conclusions:** Renal inulin clearance overestimated systemic inulin clearance using a single injection method in overall. Alternative methods for GFR measurement such as systemic inulin clearance with a single injection method and plasma $^{51}$Cr-EDTA clearance correlated well with gold standard, even though those alternatives somewhat underestimated and overestimated gold standard, respectively.

## TH-PO281

**Correlation between MDRD-4 and CKD-EPI Formulas to Estimate Glomerular Filtration Rate in Hypertensive and Type 2 Diabetic Patients**

Victor Omar Frías-Navarro, Laura Cortes-Sanabria, Alfonso M. Cueto-Manzano, Héctor R. Martínez Ramírez, Erika Fabiola Gómez-García, Blanca Liliana Maldonado-Ruiz, Roberto A. Atilano Maciel. *Medical Research Unit in Kidney Diseases, Mexican Institute of Social Security, Guadalajara, Jalisco, Mexico.*

**Background:** The simplified equation of the MDRD-4 is one of the most used formula to estimate GFR. More recently, CKD-EPI has been developed suggesting a better performance especially in the case of normal kidney function. Notwithstanding, few data are available regarding the correlation of such formulas in diabetic and hypertensive hispanic populations.

**Methods:** Cross sectional study performed in 3 out of 24 randomly selected primary healt-care units. From these units, patients with DM2 and/or hypertension (diagnosed and treated by family physicians) were randomly selected and invited to participate. Serum creatinine was measured by Jaffe method, and GFR was estimated with the simplified MDRD and CKD-EPI formulas.

**Results:** 1480 patients, mean age 60±11 years, were included. There were 936 (63%) women, and 519 (35%) patients with DM2, 615 (42%) with DM2+H, and 346 (23%) hypertensives only. The prevalence of CKD by the MDRD-4 formula was 13.6% and 13.9% with the CKD-EPI formula. Correlation between MDRD-4 and CKD-EPI in the whole sample was r= 0.886 (CI95% 0.72-0.92), whereas it was r=0.94.8 (CI95% 0.92-0.97) in DM2; r=0.912 (CI95% 0.85-0.94) in DM2+hypertension, and r=0.939 (CI 95% 0.93-0.99) in hypertensives only.

| Characteristics | DM2 (n=519) | DM2/H (n=615) | Hypertension (n=346) |
|---|---|---|---|
| Age, years | 57 ± 12 | 63 ± 10* | 60 ± 11* † |
| Female, % | 57 ± 12 | 411 (67)* | 248 (72) † |
| Evolution, years | | | |
| DM2 | 8 (3-13) | 10 (4-15) | - |
| Hypertension | - | 7 (3-13) | 8 (3-13) |
| SBP, mmHg | 124 ± 18 | 137 ± 20* | 135 ± 19* |
| DBP, mmHg | 74 ± 10 | 80 ± 11* | 80 ± 10* |
| BMI, kg/m$^2$ | 28 ± 4 | 31 ± 6* | 31 ± 5* |

**Conclusions:** The prevalence of CKD was similar when calculated by the MDRD-4 or the CKD-EPI formulas. There is a strong correlation between these two formulas in hypertensives patients without DM2, and in diabetic patients with or without hypertension. Any of these formulas could be used interchangeably to estimate GFR in hispanic populations with these diseases.

## TH-PO282

**Performance of Japanese and CKD-EPI GFR Equations in Japanese Subjects** Yoshinari Yasuda, Imai Junko, Shoichi Maruyama, Seiichi Matsuo. *Nephrol & CKD Initiatives, Nagoya Univ, Nagoya, Japan.*

**Background:** Japanese GFR equations based on serum creatinine (Scr) (Eqcr), serum cystatin C (Scys) (Eqcys) and average value of eGFRcr and eGFRcys (Eqave) were developed in 413 Japanese and validated in 350 Japanese participants, however they have not well evaluated in another validation set. Thus, their performances were analyzed in comparison with CKD-EPI equations based on Scr (CKD-EPIcr), Scys (CKD-EPIcys) and Scys in combination with Scr (CKD-EPIcr-cys) in this study.

**Methods:** Study subjects were 291 consecutive Japanese patients examined GFR by inulin renal clearance in Nagoya University Hospital. Standardized Scr was measured by enzymatic method. Standardized Scys was measured by colloidal gold immunoassay. Performance of Japanese equations (Eqcr, Eqcys and Eqave) were compared with CKD-EPI equations (CKD-EPIcr, CKD-EPIcys and CKD-EPIcr-cys), respectively.

**Results:** Age (mean +- SD, years old) and gender distributions (male %) were 59.7 +- 13.5, 67% in 183 CKD, 64.0 +- 13.5, 80% in 86 malignancy before uni-nephrectomy and 61.0 +- 7.9, 40% in 22 renal transplant donor. GFR (mean +- SD, ml/min/1.73 m2) were 47.6 +- 24.7 in CKD, 61.3 +- 25.1 in malignancy and 74.2 +- 18.1 in donor. 15% and 30% accuracy, correlation and root mean square error (RMSE) were shown in Table.

| | 15% accuracy | 30% accuracy | correlation | RMSE |
|---|---|---|---|---|
| Eqcr | 50.1 | 74.6 | 0.862 | 13.82 |
| Eqcys | 48.1 | 75.6 | 0.876 | 13.43 |
| Eqave | 55.0 | 77.0 | 0.892 | 12.32 |
| CKD-EPIcr | 19.9 | 47.1 | 0.881 | 22.31 |
| CKD-EPIcys | 47.4 | 74.9 | 0.882 | 14.44 |
| CKD-EPIcr-cys | 29.6 | 46.0 | 0.902 | 22.57 |

15% and 30% accuracy were better in Eqave compared to other equations. And CKD-EPIcr and CKD-EPIcr-cys equations overestimated GFR.

**Conclusions:** Japanese and CKD-EPIcys GFR equations performed well among Japanese patients.

*Funding:* Government Support - Non-U.S.

## TH-PO283

**Regional Differences in Chronic Kidney Disease Prevalence in Japan: A Japanese Nationwide Health-Check Study** Yoshinari Yasuda,[1] Kiyoshi Shibata,[1] Kunitoshi Iseki,[2] Toshiki Moriyama,[2] Kunihiro Yamagata,[2] Kazuhiko Tsuruya,[2] Hideaki Yoshida,[2] Shouichi Fujimoto,[2] Koichi Asahi,[2] Tsuyoshi Watanabe,[2] Seiichi Matsuo.[1] *[1]Nephrology/CKD Initiatives, Nagoya Univ, Nagoya, Japan; [2]Research on the Positioning of CKD in Specific Health, MHWL, Japan.*

**Background:** Regional variations in the increasing rate of End Stage Kidney Diseases (ESKD) was reported in Japan, however, factors associating these regional differences have not been fully elucidated. In this study, prevalence of Chronic Kidney Disease (CKD) and its risk factors were analyzed in a Japanese nationwide database with a focus on the regional differences.

**Methods:** Study subjects were 386,517 (163,454 male) participants in a Japanese nationwide health-check including 13 prefectures. Prevalence of CKD and risk factors, including hypertension (HTN), diabetes mellitus (DM), dyslipidemia (DL) and obesity (OB), were analyzed in 4 regions divided by the increasing rate of ESKD as follows; the highest (H), 2 middle (M1 and M2) and the lowest (L) areas. CKD was defined as an estimated glomerular filtration rate less than 60 mL/min/1.73 m$^2$ and/or proteinuria greater than 1+ by a dipstick method. Odds ratios for CKD were analyzed in 4 areas. Regional differences in optimal treatment rate in HTN, DM and DL were assessed according to each guideline.

**Results:** CKD prevalence in H, M1, M2 and L areas were 21.4%, 25.5%, 20.9% and 18.5% in male and 18.6%, 15.7%, 16.4% and 11.4% in female, in good agreement with the increasing rate of ESKD. Odds ratios for CKD were significantly high in HTN, DM and OB in all 4 regions. Prevalence of HTN was significantly high in L area, however, the rate of under treatment in HTN and good blood pressure control rate were significantly high in L area. In H area, the rate of no treatment was the highest among 4 areas in HTN, DM and DL.

**Conclusions:** Association between regional variations in CKD prevalence and those in the increasing rate of ESKD was demonstrated. Although HTN, DM and OB were risk factors for CKD in all 4 areas, the rate of under treatment and good control rate in HTN and DM may affect regional differences.

*Funding:* Government Support - Non-U.S.

## TH-PO284

**Validation of Korean Coefficient for GFR Estimation by the Modification of IDMS MDRD Equations** Yun Jung Oh,[1] Ran-Hui Cha,[2] Chungsik Lee,[1] Hajeong Lee,[3] Dong Ki Kim,[3] Yon Su Kim.[3] *[1]Internal Medicine, Cheju Halla General Hospital, Jeju, Korea; [2]Internal Medicine, National Medical Center, Seoul, Korea; [3]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea.*

**Background:** Race and ethnicity are important determinants of estimating glomerular filtration rate(GFR). Korean coefficients for the isotope dilution mass spectrometry(IDMS) Modification of Diet in Renal Disease(MDRD) equations were developed in 2010, however, those coefficients have not been validated thoroughly yet. We validated performance of Korean coefficients for IDMS MDRD equations from previous study, and derived new Korean coefficients using both development and validation study data.

**Methods:** Equation development and validation were performed in separate groups(development group; N=147 from 2008 to 2009, validation group; N=125 from 2010 to 2012). We compared the performance of IDMS MDRD equations and modified equations with Korean coefficients. And the performance was assessed by correlation coefficient, bias, and accuracy between estimated GFR(eGFR) and reference GFR(rGFR; systemic inulin clearance with a single injection method).

**Results:** We found strong correlation between eGFR calculated by modified equations with Korean coefficients and rGFR($\gamma$=0.89 and 0.89 for modified 4 and 6 variable IDMS MDRD equation, P<0.001, P<0.001, respectively), but it was not different from the correlation coefficients between eGFR calculated by IDMS MDRD equations and rGFR. Despite the modified equations performed with less bias than original IDMS MDRD equations, overall performance was not significantly different from each other showing a similar accuracy. New Korean coefficients for 4 and 6 variable IDMS MDRD equations were 1.020 and 0.973, respectively. The overall performance of new Korean IDMS MDRD equations was not different from original IDMS MDRD equations, either.

**Conclusions:** Korean coefficients for IDMS MDRD equations developed before showed good performance in the validation study group. However, there was no significant difference between original and modified IMDS MDRD equation with new Korean coefficient in terms of performance of GFR estimation after all.

## TH-PO285

**Prevalence of Chronic Kidney Disease in Europe** Katharina Brueck,[1] Vianda S. Stel,[1] Christoph Wanner,[2] Wim Van Biesen,[3] Charles Tomson,[4] Giovanni Tripepi,[5] Carmine Zoccali,[5] Kitty J. Jager.[1] *[1]ERA-EDTA Registry, Netherlands; [2]Univ Hospital Würzburg, Germany; [3]Ghent Univ Hospital, Belgium; [4]Southmead Hospital, United Kingdom; [5]CNR-IBIM, Italy; [6]On behalf of the European CKD Burden Consortium.*

**Background:** The wide variation in definitions for prevalence of chronic kidney disease (CKD) complicates attempts to compare the burden of CKD between countries. The aim of our study was to examine the prevalence of CKD in all stages in subjects not on renal replacement therapy across European countries, using standardized definitions.

**Methods:** A literature review was performed to identify all European studies that could provide data on CKD prevalence. The representatives of eligible studies received a questionnaire on the availability of data and health care system characteristics. Based on available data and the new KDIGO practice guideline, standardized definitions for CKD prevalence were defined as presence of albuminuria >= 30mg/g and/or eGFR by CKD-EPI formula <60 ml/min/1.73m² without the chronicity criterion (as only 4 studies had these data). These definitions were used to extract the prevalence of CKD for various subgroups (e.g. age group, gender and diabetic status). All prevalence data were age and sex standardized to the EU27 population.

**Results:** Out of 71 studies, we so far received data on prevalence from 16 studies from 11 countries. The age and sex standardized prevalence of CKD stage 3-5 in the age group 20-74 years ranged from 1% in central Italy to 5.4% in Portugal. In this age group, the CKD stage 3-5 prevalence ranged from 1.3-6.4% in females and 0.8-4.2% in males. In the age group 65-74 years, this prevalence was 4.8% in central Italy, 11.4% in Finland, 13.3% in Poland, 19.7-21.5% in Germany, 22.3% in the Netherlands and 24.3% in Portugal.

**Conclusions:** This is the first study on international differences in the prevalence of CKD using standardized definitions. The prevalence of CKD varied hugely across European countries. Data on co-morbidities and health care system characteristics will be used to explain the international differences in CKD prevalence. Together they will provide a complete overview of the burden of CKD in Europe.

## TH-PO286

**Estimated Glomerular Filtration Rate and Urine Albumin Creatinine Ratio Category-Specific Prevalence and Descriptions of People with Type 2 Diabetes in the U.S.** Robert A. Bailey,[1] Yiting Wang,[2] Vivienne J. Zhu,[2] Marcia Rupnow.[1] *[1]Janssen Scientific Affairs, LLC, Raritan, NJ; [2]Janssen Research and Development, LLC, Titusville, NJ.*

**Background:** Kidney Disease: Improving Global Outcomes (KDIGO) updated classification of chronic kidney disease (CKD) in 2013, using both estimated glomerular filtration rate (eGFR) and urine albumin creatinine ratio (ACR). However, little is known about eGFR and/or ACR category-specific prevalence among people with type 2 diabetes (T2D) using this new classification.

**Methods:** We used the continuous National Health and Nutrition Examination Surveys (NHANES), 1999-2010, and identified participants with T2D using a definition similar to previous studies. eGFR was calculated using the CKD Epidemiology Collaboration (CKD-EPI) equation. eGFR and ACR categories were defined according to KDIGO, and prevalence was age-adjusted to the 2010 diabetes population according to the National Health Interview Survey (NHIS). We used SAS®(v9.2) survey procedures to account for the stratified, clustered sampling with unequal sampling weights in NHANES.

**Results:** The final analysis included 2,413 participants with T2D; mean age was 61.4;diabetes duration was 9.8 years. Mean (standard error) of eGFR (ml/min/1.73m$^2$) and ACR(mg/g) were 79.6 (0.7) and 107.8(1.9), respectively. The weighted eGFR and ACR category-specific prevalence is shown in Table 1.

| Weighted %(unweighted N) | ACR (mg/g) Categories | | | Row |
|---|---|---|---|---|
| eGFR (ml/min/1.73 m$^2$) Categories | A1 (<30) | A2 (30-300) | A3 (>300) | |
| G1 (≥ 90) | 27.8% (582) | 9.5% (230) | 1.5% (48) | 38.8% (860) |
| G2 (60-89) | 27.8% (637) | 8.8% (239) | 2.6% (81) | 39.2% (957) |
| G3a (45-59) | 7.7% (197) | 3.6% (104) | 1.5% (44) | 12.8% (345) |
| G3b (44-30) | 2.9% (72) | 2.1% (59) | 0.9% (29) | 5.9% (160) |
| G4 (15-29) | 0.7% (19) | 1.2% (27) | 0.8% (28) | 2.7% (74) |
| G5 (<15) | 0.05% (2) | 0.0% (1) | 0.33% (14) | 0.4% (17) |
| Column | 66.9% (1,509) | 25.2% (660) | 7.9% (244) | 100% (2413) |

**Conclusions:** Our study is the first to provide estimates of eGFR and ACR category-specific prevalence for T2D based on the KDIGO classification in a nationally representative sample.

## TH-PO287

### Detection of Subclinical Chronic Kidney Disease (CKD), in Relatives of Dialysis Patients and Cardiovascular Disease Patients in Chile

Alvaro A. Castillo,[1,2] Mauricio J. Castillo,[2] Domingo Lancelloti,[2] Alejandra Lagos.[2] *[1]Dialysis Unit, Hosp. La Serena, La Serena, Chile; [2]Salud Publica, Faculty Medicine, U. Catolica Norte, Coquimbo, Chile.*

**Background:** CKD is a serious public health problem. It can be prevented with early detection and treatment. Our objective is to determine the prevalence of sub-clinical CKD in different risk groups in Chile.

**Methods:** Performed in 3 regions of Chile (Coquimbo, Santiago, Valdivia). Groups analyzed: 1) Primary Health Care (PHC) consultants without cardiovascular risk factors (CON), 2) Patients from Cardiovascular (CV) program of PHC (PHC-CV) 3) Family ≥ 18 y. (parent-brother-children) of dialysis patients (non genetic etiology) (FAM). Aproved by Ethical Committee. 1,143 subjects signed informed consent, from 12 health centers. Survey applied based on: Chilean CKD Guideline Questionnaire, blood pressure measurement, weight, height, lab tests: Creatinine, MicroAlbuminuria/Creatininuria Ratio (ACR), Urine dipstick. eGFR using MDRD-4 equation. Classification of CKD and ACR according to NKF-KDOQI.

**Results:**

| RESULTS | CON n | CON% | PHC-CV n | PHC-CV% | FAM n | FAM% | p value |
|---|---|---|---|---|---|---|---|
| Number | 324 | | 356 | | 463 | | |
| Female | 198 | 61 | 249 | 70 | 311 | 67 | |
| Mean Age (SD) | 40.2(13) | | 58.8(14.1) | | 41.2(14.6) | | <0.0001 |
| Declared Diabetes | 1 | 0.3 | 115 | 32.3 | 45 | 9.7 | <0.001 |
| Declared Hypertension | 4 | 1.2 | 298 | 83.7 | 120 | 25.9 | <0.001 |
| Measured Hypertension | 17 | 5.3 | 93 | 26.1 | 103 | 22.2 | <0.001 |
| CKD stage 3 | 4 | 1.4 | 23 | 7.1 | 8 | 1.8 | |
| CKD stage 4 | 0 | | 4 | 1.2 | 1 | 0.2 | |
| CKD stage 5 | 0 | | 0 | | 0 | | |
| ACR 30 - 300 | 10 | 3.3 | 41 | 12.9 | 42 | 9.3 | |
| ACR > 300 | 3 | 1 | 14 | 4.4 | 9 | 2 | |

**Conclusions:** PHC-CV and FAM showed high prevalence of CKD and abnormal ACR, significantly higher than CON. Early detection of CKD should focus on these groups. FAM is easy to access through the relative on dialysis. In Chile 18,000 patients are on dialysis, data allows estimating that 8,000 FAM would suffer CKD, currently undetected. FAM presents high prevalence of hypertension, ACR and CKD, despite being significantly younger than PHC-CV.

## TH-PO288

### Prevalence of Chronic Kidney Disease and Metabolic Syndrome in an Adult Korean: Result from the Korean National Health Screening

Yong Un Kang, Joon Seok Choi, Chang Seong Kim, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea.*

**Background:** Chronic kidney disease (CKD) and metabolic syndrome (MS) are increasing public health problems. However, there has been limited data on CKD and MS prevalence, and its relationship in large based-population. This study was aimed to examine the prevalence of CKD and MS, and the association between MS and its components with CKD in Korea.

**Methods:** We performed a cross-sectional study in non-institutionalized civilians using the general health screening data of 10,549,230 (47.2±13.9 years, men 56.3%) participants aged more than 20 years from the Korean National Health Screening 2011. CKD was defined as dipstick proteinuria or an estimated GFR (eGFR) of <60 ml/min per 1.73 m$^2$.

**Results:** The prevalence of CKD (n=688,182) was 6.52% (5.75% in men, 7.52 in women). The prevalence estimates of CKD stage, respectively, were 0.86% for stage 1; 0.95% for stage 2; 3.74% for stage 3; 0.1% for stage 4; 0.86% for stage 5. 23.5% of the study population (n=2,477,247) had MS (12.1% for central obesity; 12.5% for high triglyceride; 5.9% for low HDL cholesterol; 15.5% for high blood pressure; 5.9% for high fasting glucose). 41.1% of the study population with CKD (n=282,551) had MS (11.4% for central obesity; 8.2% for high triglyceride; 5.1% for low HDL cholesterol; 17.3% for high blood pressure; 4.4% for high fasting glucose). In multivariate-adjusted analysis, presence of MS was associated with an increased risk for CKD (odds ratio=1.458, 95% confidence interval 1.450–1.467, $P < 0.0001$). Also, the individual components were associated with increased risk for CKD.

**Conclusions:** MS and the individual components predict the risk of prevalent CKD.

## TH-PO289

### The Relationship between eGFR and Fasting Blood Sugar in a Multiethnic Adolescent Population: National Health and Nutrition Examination Survey Data 2001-2003

Gangadarshni Chandramohan,[1] Kamyar Kalantar-Zadeh,[3] Magda Shaheen.[2] *[1]Pediatrics, Horbor-UCLA Medical Center, Torrance, CA; [2]Internal Medicine, Charles Drew Univ Research Center, Los Angeles, CA; [3]Internal Medican & Pediatrics, Univ of California: Irvine, Irvine, CA.*

**Background:** Prevalence of type II diabetes (DM), is high among minority children. In type II DM, the early sigh of renal injury is increase in eGFR due to hyperfiltation.

**Methods:** A retrospective cross-sectional analysis of children between the ages of 13-17 years from the National Health and Nutrition Survey (NHANES) obtained from 2004-2005, was performed. Abnormal fasting blood sugar (FBS) was defined using the standard guidelines. HIgh eGFR was defined as the 4th quartile sGFR of the study population. Statistical analysis were done using SUDAAN and SAS software program.

**Results:** There were 1149 children, high FBS 10%. Among Whites, AA and Hispanics, high eGFR noted in 25%, 18% and 13% (p=0.009), respectively. High FBS found in 10, 11, 10% in White, AA and Hispanics respectively. The mean eGFR differed significantly between the ethnic groups. Odds ratio to have high eGFR was high among Whites and Blacks with high FBS. Table 1: The odds ratio for having 4th quartile eGFR Based on FBS among the Total population and by Ethnicity.

| Variables | Odds Ratio (95% CI) | p-Value |
|---|---|---|
| Total population with Abnl. FBS vs. nl FBS | 3.1 (2.2 - 4.3) | |
| Whites with abnl FBS vs. nl FBS | 3.5 (2.2 - 5.7) | 0.0001 |
| AA with abnl FBS vs. nl FBS | 2.9 (1.5 - 5.5) | 0.001 |
| Hispanic with abnl FBS vs. nl FBS | 2.1 (1.0 - 4.5) | 0.05 |

**Conclusions:** Prevalaence of high eGFR was significantly high among Hispanic than other ethnic groups. Mean eGFR was significantly higher among Hispanic than AA and Whites. Analyzing FBS independently in each ethnic groups revealed an interesting finding among adolescent children, excibiting an association with high eGFR. Therefore, in determing eGFR in children with abnoraml FBS may shed light on future management in regards to the aggressiveness of the intervention, with a potential role for ACE inhibition, even before the development of microalbuminuria.

### Epidemiology of Autosomal Dominant Polycystic Kidney Disease in the United States

Cynthia J. Willey,[1] Frank S. Czerwiec,[2] Holly Krasa,[2] Robert D. McQuade,[2] Robert W. Schrier,[3] Vicente E. Torres.[4] *[1]Pharmacy Practice, Univ of RI, Kingston, RI; [2]Otsuka Pharmaceutical, Rockville, MD; [3]Univ of Colorado, Aurora, CO; [4]Mayo Clinic, Rochester, MN.*

**Background:** Most studies of PKD in the U.S. focus upon small cohorts of patients and have limited generalizability. Only one population-based study examined US incidence of ADPKD using data from Olmsted County, Minnesota from 1935 to 1980. Our study reviewed current literature and analyzed national data to estimate total and diagnosed prevalence of APDKD in the U.S.

**Methods:** Diagnosed and total prevalence were derived using incidence rates from Iglesias et al based on symptomatic or screened cases compared with the addition of cases diagnosed at autopsy. Diagnosis rates were then increased by 25% to reflect recent improvements in diagnostic imaging technology. Data from the U.S. Renal Data System (USRDS) were used to estimate average survival time. Validation analyses were performed using the National Ambulatory Medical Care Survey (NAMCS) to examine consistency between expected patients in the U.S. with ADPKD and the annual number of ambulatory visits for patients with ADPKD.

**Results:** USRDS data suggest an average duration of disease of approximately 61.8 years for adult patients with ADPKD. Taken with incidence rates from the Rochester Epidemiology Project, a total prevalence rate of 0.46 per 1,000 was calculated with an estimate that 95% of those are currently diagnosed. Validation analysis using data from the NAMCS focused on probable ADPKD and included patients with autosomal dominant or unspecified polycystic kidney disease (ICD9 CM: 753.12-753.13). Results were consistent with 97,667 diagnosed cases estimated from the NAMCS and 116,228 estimated using data from the Rochester Epidemiology project.

**Conclusions:** Although total prevalence (including undiagnosed cases) will be slightly higher, these data support a diagnosed prevalence of approximately 1/2000 and yield an estimate of less than 200,000 diagnosed ADPKD cases in the U.S.

*Funding:* Pharmaceutical Company Support - Otsuka Pharmaceutical

## TH-PO291

### Switching from Modification of Diet in Renal Disease to Chronic Kidney Disease Epidemiology Collaboration Formula Has Negligible Impact on Staging in an Established Chronic Kidney Disease Population

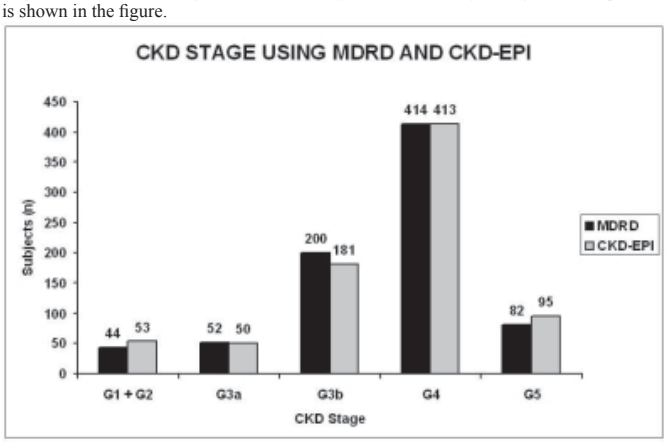
Eduard A. Iliescu,[1,2] Sandra Belanger,[2] M. Khaled Shamseddin,[1,2] Sarah Aloudat,[1,2] Christine A. White.[1,2] *[1]Queen's Univ; [2]Kingston General Hospital, Kingston, Canada.*

**Background:** The 2012 Kidney Disease Improving Global Outcomes (KDIGO) Guidelines recommend the CKD-EPI formula to calculate eGFR from serum creatinine (1B). The aim of this study is to examine the practical impact of switching from MDRD

to CKD-EPI formula on the staging of chronic kidney disease (CKD) in the region of South-Eastern Ontario (pop. 485,000).

**Methods:** This is a cross-sectional study of prevalent CKD patients followed at Kingston General Hospital. This is the only CKD clinic in the region and manages all referred cases of CKD with few exceptions. The primary variables were serum creatinine, and eGFR calculated using the CKD-EPI and MDRD formulae (ml/min/1.73m$^2$). The number of patients in each KDIGO CKD stage with the two equations was compared (G1 > 90, G2 = 60 – 89, G3a = 45 - 59, G3b = 30 - 44, G4 = 15 – 29, and G5 < 15 ml/min).

**Results:** There were 792 subjects, 42 % female, 0 % African Canadian, mean age 71 years. Looking at individual subject classification, compared to MDRD, CKD-EPI classified subjects to the same stage in 91 %, a less severe stage in 4 %, and a more severe stage in 5 %. The resulting distribution of subjects by CKD stage using the two equations is shown in the figure.



**Conclusions:** The results of this study suggest that, in an established CKD population, the impact of the CKD-EPI vs. MDRD formula in the staging of CKD is negligible. As expected there was a net increase in the number of subjects classified to G1 + G2, but there was also a net increase subjects in Stage G5 which could impact CKD clinic resource planning. The strength of this study is the regional perspective reducing selection bias. Generalizability is limited by lack of racial diversity.

## TH-PO292

**Prevalence of CKD and Associated Risk Factors in Italy: The CARHES Study** Luca De Nicola,[1] Chiara Donfrancesco,[2] Roberto Minutolo,[1] Cinzia Lo Noce,[2] Luigi Palmieri,[2] Amalia De Curtis,[3] Licia Iacoviello,[3] Giuseppe Conte,[1] Diego Vanuzzo,[4] Simona Giampaoli.[2] *[1]Italian Society Nephrology; [2]National Institute Health; [3]Catholic Univ Campobasso; [4]National Association of Cardiogists-ANMCO, Italy.*

**Background:** Identification of CKD and associated cardiovascular (CV) comorbidities is a key priority for public health worldwide. No study however has addressed this issue in a nationally representative survey in Europe.

**Methods:** The CArdiovascular risk in Renal patients of the 2008-12 national Health Examination Survey (CARHES) examined random samples of Italian general population aged 35-79 years, stratified by age and gender, in all regions (220 persons/1,5 million of residents; response rate 56%). CKD was defined as urinary albumin:creatinine ratio ≥30 mg/g (stage 1-2) or estimated GFR (CKD-EPI equation-enzymatic assay of serum creatinine) <60 mL/min/1.73m$^2$ (stage 3-5). Biochemical tests were centralized.

**Results:** 3848 men and 3704 women were examined. Table shows CKD prevalence overall and by stage, % (95%CI).

| | Total | Men | Women |
|---|---|---|---|
| **CKD all** | 7.1(6.5-7.7) | 7.5(6.7-8.4) | 6.5(5.8-7.4) |
| **1** | 2.6(2.3-3.0) | 2.7(2.2-3.2) | 2.6(2.1-3.2) |
| **2** | 1.5(1.3-1.8) | 2.1(1.7-2.6) | 0.9(0.6-1.3) |
| **3a** | 2.1(1.8-2.5) | 2.0(1.5-2.4) | 2.3(1.8-2.8) |
| **3b** | 0.5(0.4-0.7) | 0.5(0.3-0.7) | 0.5(0.3-0.8) |
| **4** | 0.2(0.1-0.3) | 0.2(0.1-0.4) | 0.1(0.0-0.3) |
| **5** | 0.1(0.0-0.2) | 0.1(0.0-0.3) | 0.1(0.0-0.3) |
| **Estimated CKD population (N)** | 2,194,572 | 1,090,124 | 1,104,448 |

Stage 1-2 constituted 58% of CKD cohort. CKD prevalence increased with ageing (age 35-49: 2.7%; 50-59: 3.4%; 60-69: 8.7%; 70-79: 17.0%). As compared to No CKD, CKD subjects were older (66±11 vs 56±12 y), had higher albuminuria, fasting glucose, triglycerides, systolic BP, BMI and waist circumference while total and HDL cholesterol were lower. CKD was also associated with higher prevalence of hypertension (75 vs 48%), diabetes (29 vs 10%), obesity (39 vs 25%) and CV disease (7.1 vs 1.8%).

**Conclusions:** In Italy CKD is characterized by lower prevalence as compared to other countries, predominance of early stages and higher CV risk profile vs No CKD due, at least in part, to the older age.

## TH-PO293

**Thyroid Function and Chronic Kidney Disease in a Large Canadian Survey** Alexis Payette, Jacobien Verhave, Josee Bouchard, Barbara Duda, Francois Madore, Stephan Troyanov. *Div of Nephrology and Endocrinology, Hôpital du Sacré-Cœur, Montreal, Canada.*

**Background:** Hypothyroidism is common in patients with CKD and TSH levels are negatively correlated with eGFR in the general population. However, the effect of levothyroxine (LT) treatment on this association is uncertain.

**Methods:** We analyzed biological and clinical data from a random cohort of 20,004 participants aged 40 to 69 years from the general population. This cross-sectional study is part of the CARTaGENE data bank, a research infrastructure contributing to diagnosis, treatment and prevention of chronic diseases.

**Results:** Among 19,212 subjects with measured serum TSH and creatinine, we observed a negative correlation between TSH and eGFR in both LT treated and untreated individuals. In addition, at equal TSH, the eGFR was on average 4 mL/min/1.73 m$^2$ lower in subjects under LT:

| | Normal TSH no LT (n=16884) | Elevated TSH no LT (n=380) | Normal TSH under LT (n=1232) | Elevated TSH under LT (n=146) | Low TSH no LT (n=324) | P |
|---|---|---|---|---|---|---|
| eGFR | 88 ± 14 | 86 ± 15 | 84 ± 15 | 82 ± 15 | 91 ± 14 | <0.01 |
| eGFR<60(%) | 3.4 | 5.5 | 7.1 | 8.2 | 2.8 | <0.01 |
| Women(%) | 49 | 49 | 76 | 68 | 49 | <0.01 |
| Age | 54 ± 8 | 54 ± 8 | 57 ± 8 | 55 ± 8 | 53 ± 8 | <0.01 |
| BMI | 27 ± 5 | 28 ± 5 | 29 ± 6 | 29 ± 6 | 27 ± 5 | <0.01 |
| Diabetes(%) | 7 | 4 | 11 | 14 | 5 | <0.01 |
| Dyslipidemia(%) | 28 | 25 | 35 | 32 | 25 | <0.01 |

In reference to a normal TSH without LT, the odds ratio (95% CI) for CKD (eGFR<60 mL/min/1.73m<sup style="text-indent: 36pt;">>2[/sup]) was 1.96 (1.24-3.11) for an elevated TSH without LT, 2.2 (1.8-2.8) for a normal TSH under LT and 2.23 (1.20-4.14) for an elevated TSH under LT, after adjustment for gender, age, BMI, diabetes and dyslipidemia.

**Conclusions:** In conclusion, the negative correlation between eGFR and TSH exists in both treated and untreated subjects. In addition, at equal TSH, patients under LT therapy have a lower eGFR than untreated subjects, even after adjusting for confounders. These results suggest an association between thyroid disease and CKD regardless of current thyroid function status and therapy.

## TH-PO294

**Prevalence of Chronic Kidney Disease in the SardiNIA Study Cohort and Its Relationship to eGFR-Related Genetic Loci and Clinical Risk Factors** Antonello Pani,[1] Jennifer Bragg-Gresham,[2] Marco Masala,[3] Doloretta Piras,[1] Alice Atzeni,[1] Maria G. Pilia,[3] Liana Ferreli,[3] Lenuta Balaci,[3] Nicolò Curreli,[3] Alessandro Delitala,[3] Francesco Loi,[3] David Schlessinger,[4] Francesco Cucca.[3] *[1]Nefrologia e Dialisi, Ospedale Brotzu, Cagliari, Italy; [2]Center for Statistical Genetics, Univ of Michigan, Ann Arbor, MI; [3]IRGB, CNR, Monserrato e Lanusei, Italy; [4]Laboratory of Genetics, NIA, Baltimore, MD.*

**Background:** An increase in leading CKD risk factors explains only part of the differential prevalence seen worldwide. We aimed to measure CKD prevalence, eGFR, and their relationship with traditional and additional risk factors in a Sardinian founder population.

**Methods:** Calibration of creatinine was done to correctly estimate eGFR, that was calculated by CKD-Epi and MDRD 175 equations. A new genetic score based on 13 previously reported eGFR- and CKD-related loci was used. We performed: a cross sectional analysis to establish CKD prevalence among 4,842 individuals, and a longitudinal analysis of renal function in 4,074 of these individuals who underwent 3 visits along 10 years. Uni- and multivariable analyses were done to establish the correlation between clinical, ultrasound, and genetic variables with changes in eGFR (linear mixed models), CKD and fast vs slow eGFR decline (logistic regression analysis).

**Results:** CKD prevalence was 14.5%. Micro- and macroalbuminuria prevalence was 9.5% and 3.4%, respectively. The average decline in eGFR during the follow-up was 1 ml/min/year. Genetic risk score, old age, female gender, and hyperuricemia were independently correlated with all the outcomes. Diabetes and abnormal kidney length were associated with CKD; hypertension was correlated to fast eGFR decline. Diabetes, hypertension, and high baseline eGFR were significantly predictive of future decline of eGFR.

**Conclusions:** CKD prevalence was similar to observations in China, higher than in Norway, and lower than in the USA. Genetic risk score contributes independently of traditional CKD risk factors. Along with differences in health practice and in traditional risk factors, it may provide an entrée to further explication of differential CKD prevalence worldwide.

**TH-PO295**

**Prevalence of Renal Impairment (RI) among Cancer Patients with Bone Metastases in the United States** Vahakn B. Shahinian,[1] Kristina Chen,[2] Rohini Hernandez,[2] Jane Quigley,[3] Melissa Pirolli,[3] David Quach,[3] Alexander Liede,[2] Jorge Arellano.[2] *[1]Univ of Michigan Medical School, Ann Arbor, MI; [2]Amgen, Inc, Thousand Oaks, CA; [3]IMS Health, Plymouth Meeting, PA.*

**Background:** Pts diagnosed with cancer and bone mets are at risk of serious bone complications. Intravenous bisphosphonates (IVBPs) are approved for prevention of skeletal-related events, but are known to be nephrotoxic and may require dose adjustment or discontinuation in pts with RI which can result in higher rates of complications (Hatoum et al 2008). This study aimed to measure the extent of RI in cancer pts with bone mets in a real-world setting.

**Methods:** The study identified pts treated in oncology clinics across the US using the Oncology Services Comprehensive Electronic Records (OSCER), a large electronic medical record database. Pts (age ≥18) with solid tumors and bone mets diagnosed in 2008–2012 were identified, excluding pts with an ICD-9 diagnosis(dx) code for AKI, ESRD, or multiple myeloma. RI was defined by a single value of eGFR <60 mL/min/1.73m$^2$ (CKD-EPI); CKD was defined by ≥2 eGFR values <60, at least 90 days apart. Percent of pts treated with an IV BP was also examined by eGFR category.

**Results:** The cohort included 15,623 pts (mean age 67.1 ± 12 years, weight 76.5 ± 18 kg; female 56%; breast, prostate or lung cancer 83%), of whom, 49.2% had RI during a mean 23.7 months of follow-up after bone mets dx (9.7% with eGFR <30).

| Lowest eGFR | All | < 15 | < 30 | < 60 | < 90 |
|---|---|---|---|---|---|
| N (%) | 15623 | 216 (1.4) | 1516 (9.7) | 7686 (49.2) | 13779 (88.2) |
| Mean eGFR | 61.1 | 10.1 | 22.1 | 41.7 | 55.8 |
| Pt Receiving IV BP within 12 months | 65% | 35% | 51% | 62% | 65% |

Among pts with RI and at least one eGFR after 90 days, 80.7% (4,686/5,810) had CKD and 62% received an IVBP within 12 months from eGFR<60. Similarly, among pts with evidence of severe RI (eGFR <30), 51% received IVBP therapy.

**Conclusions:** These data from pts treated in community oncology clinics across the US demonstrate that nearly half of pts with bone mets had evidence of RI during the course of their disease. Despite RI, a large proportion of pts were treated with an IVBP. Careful consideration of treatment options and close monitoring of renal function in this population is imperative to achieve optimal therapeutic outcomes.

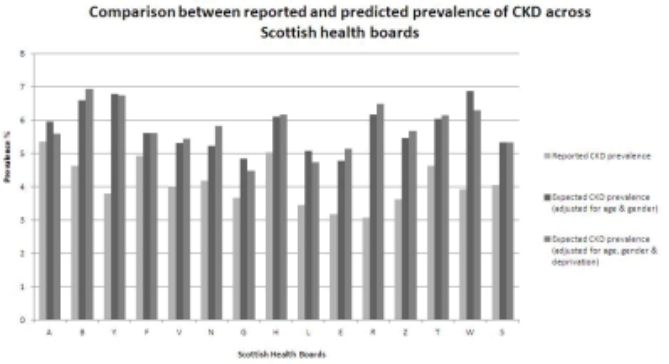
**Understanding Variation in CKD Prevalence amongst Scottish Health Boards** Beng Hock So,[1,2] Mario D. Hair,[1] Shona Methven,[3] Alan G. Jardine,[2] Mark S. MacGregor.[1] *[1]Univ Hospital Crosshouse, Scotland; [2]Univ of Glasgow, Scotland; [3]Univ of Bristol, England.*

**Background:** Almost all people in Scotland are registered with primary care practices, which maintain registers of chronic kidney disease (CKD) stages 3-5. Registry CKD prevalence is 4.1% nationally. However, there is marked variation between the 14 Health Boards (HB) from 3.1 to 5.4%. We explored the reasons for this variation.

**Methods:** CKD prevalence, age and gender distribution for each HB was obtained from NHS Scotland. We derived age and gender standardised CKD (AGCKD) rates: all CKD stages 3-5 were identified from NHS Ayrshire & Arran's (A&A) laboratory database ( ≥18 population 313,503) with two or more eGFRs <60 mL/min/1.73m$^2$ ≥90 days apart. We applied AGCKD to the population structures of the other HBs to derive expected rates. Based on A&A data we derived a regression co-efficient to adjust CKD rates for deprivation.

**Results:** In A&A, 18,291 adults had CKD (5.83% total, 7.34% women, 4.24% men). The reported prevalence is 5.4%; the gap represents failure of ascertainment. Applying AGCKD to the population structure of each HB reduced variation. The gap between observed and expected prevalence varied from 0.6% to 3.1% and was significant (t(13)=7.53, p<0.001). At primary care practice level, AGCKD was associated with deprivation (r=0.66, p<0.001). After adjusting HB prevalence for deprivation the gap between observed and expected rates varied from 0.2% to 3.4%.



**Conclusions:** There is considerable unexplained variation in CKD rates amongst HBs. By deriving age and gender specific rates of CKD relevant to our population then adjusting for deprivation, we derived expected CKD rates for each HB, allowing benchmarking. The gap between observed and expected CKD rates may represent failure of ascertainment, or true prevalence differences due to unexplained factors in those populations and requires further exploration.

**TH-PO297**

**Chronic Kidney Disease in Pakistani Population: A Community Based Cross-Sectional Study** Saleem Jessani,[1] Muhammad Islam,[1] Rasool Bux,[1] Tazeen H. Jafar.[1,2] *[1]Aga Khan Univ, Karachi, Pakistan; [2]Duke-NUS Graduate Medical School, Singapore.*

**Background:** Chronic Kidney Dsease (CKD) is increasing being recognized as a global public health problem. However, there is dearth of information on the prevalence and determinants of CKD from low and middle income countries. The objectives of the study were to determine the prevalence and determinants of CKD and to explore the existing management of such patients with regards to blood pressure (BP) control and use of anti-hypertensive medications.

**Methods:** Glomerular filtration rate was estimated (eGFR) using the CKD-EPI equation with a correction factor (0.686 × eGFR CKD-EPI$^{1.059}$) for South Asians. CKD was defined as eGFR < 60 ml/min per 1.73m$^2$ (reduced eGFR) or urinary albumin to creatinine ratio (UACR) ≥30 mg/g (albuminuria) based on spot urine sample. Multivariable models were built for the primary outcome of CKD using logistic regression analysis. The candidate socio-demographic predictors were age, sex, education, tobacco use, physical activity, and clinical predictors were BMI, hypertension, diabetes, systolic and diastolic BP, fasting plasma glucose, serum triglycerides, low density lipoproteins, high density lipoproteins, total cholesterol, history of coronary artery disease and history of stroke.

**Results:** A total of 2873 adults (48% men) were screened from 12 randomly selected communities in Karachi. The prevalence (95%CI) of reduced eGFR, albuminuria and CKD was 5.3% (4.5 – 6.2), 9.4% (8.4 – 10.5) and 12.5% (11.3 – 13.8) respectively. The factors independently associated with CKD were older age, hypertension, diabetes, history of stroke, raised systolic BP, raised fasting glucose and raised triglycerides. About 51% CKD patients with hypertension were on anti-hypertensive medications and only 6.7% had their BP controlled to <130/80 mm Hg.

**Conclusions:** CKD is common among adults in Pakistan, especially among older individuals with co-morbidities. Blood Pressure control and use of anti-hypertensive medications among CKD patients is sub-optimal. Efforts to prevent to CKD in Pakistan must target high risk population and be integrated with major non-communicable diseases care in Pakistan and neighboring South Asian countries.

**TH-PO298**

**Short Term Risk versus Lifetime Risk in Stage 3 Chronic Kidney Disease** Candace D. Grant, Shayan Shirazian, Pardeep Kumar, Milind K. Bhagat, Joseph Mattana. *Dept of Medicine, Winthrop Univ Hospital, Mineola, NY.*

**Background:** While there are proven therapies that slow CKD progression, these therapies can at times be harmful and costly. The ability to accurately predict the risk of CKD progression and overall lifetime risk would be extremely valuable. The short term versus lifetime risk of CKD progression should be taken into account when making clinical decisions based on risk assessments. In a representative CKD practice, we compared the short term and lifetime risk assessment in our stage 3 CKD patients to determine whether decisions based on a short term risk assessment would underestimate the lifetime risk of CKD progression.

**Methods:** The electronic charts of 120 CKD stage 3 patients seen in our nephrology practice were reviewed. Eligible patients had at least one documented eGFR within the past year. Additional variables collected for risk assessment were urine albumin to creatinine ratio, urine protein to creatinine ratio, calcium, phosphorus, albumin, and bicarbonate. Patients were risk stratified using a validated 2 year ESRD risk calculator and a lifetime ESRD risk estimator. Patients were considered to be at a low risk for progression to ESRD if their 2 year calculated risk was <5%.

**Results:** Of the 120 patient charts reviewed, 44 patients met the study criteria and had complete data sets. The average age was 61.4±13.2, 58% were men, 77% were white, and the mean GFR was 40 ml/min/1.73m$^2$. The average 2 year calculated ESRD risk was 3.5% and the average lifetime risk was 13.5%. When stratified by age, there was no significant discrepancy in the 2 year risk and lifetime risk for patients 70 years and older (2.3% and 4.9% respectively). Comparison of the 2 year ESRD risk (4.2%) to the lifetime risk (18.5%) resulted in an underestimation of risk in 22 out of 27 (82%) patients below 70 years of age.

**Conclusions:** For younger patients, short term risk calculators should be used in conjunction with lifetime risk calculators to get a more accurate sense of the patients overall prognosis. This will ensure that despite the low short term risk, the high long term risk of progression would necessitate aggressive risk attenuation therapy.

**TH-PO299**

**Renoprotective Effect of Pentoxifylline in Childhood Chronic Kidney Disease** Yo Han Ahn, Jiwon M. Lee, Hee Gyung Kang, Hae Il Cheong, IL-Soo Ha. *Dept of Pediatrics, Seoul National Univ Children's Hospital.*

**Background:** Pentoxifylline (PTX) attenuated renal fibrosis in animal studies. It was also reported to offer beneficial effects on renal function and proteinuria in diabetic kidney disease and membranous nephropathy in adults. Previously our group presented a preliminary data of PTX in pediatric CKD patients, and here we report our follow-up result.

**Methods:** From 2004 to 2013, 52 children with stage 2 to 4 CKD (estimated glomerular filtration rates (eGFR) 15~90 mL/min/1.73m$^2$) were treated with PTX of 700 mg/m$^2$/day

for 25±28 months. All of them were also on either angiotensin-converting enzyme inhibitor or angiotensin receptor blocker to attenuate progression of CKD. Among them, 29 patients (M:F 21:8, age 14.0±4.4 years) had taken PTX for more than 12 months, so their eGFR before and after PTX administration were analyzed to assess renoprotective effect of PTX.

**Results:** During the 12-month period before administration of PTX, eGFR of those patients decreased significantly, from 43.1±17.4 at 12 months before PTX treatment (-12mo) to 38.2±14.6 mL/m/1.73m$^2$ at the beginning of PTX (0mo, *P*=0.009). However after administration of PTX, there was no significant decline of eGFR during the next 12 months (38.0±17.2 mL/m/1.73m$^2$ at 12 months after PTX treatment (+12mo, P=0.863). When analyzed the change of eGFR (DGFR) before and after PTX treatment, PTX showed reno-protective effect in patients with lower grade CKD, stage 2&3a, -4.2±11.1 before vs. 1.5±0.5 after treatment, P=0.019) while those with CKD stage 3b&4 showed no significance (0.4±4.2 vs. 1.5±0.5, P=0.710). Compare to patients with underlying glomerulopathy (GN) against those with non-GN, PTX was more beneficial for those with non-GN (P = 0.037). On the other hand, significant number of patients (n=23, 44.2%) experienced side effects of PTX, such as nausea or vomiting and drug fever, and had to discontinue PTX.

**Conclusions:** PTX showed renoprotective effect in childhood CKD, especially in early stage CKD and in those with non-GN cause of CKD. However, significant side effect was observed at the same time, thus randomized controlled trial is necessary to validate the benefit of this anti-fibrotic medication.

## TH-PO300

### Is Glomerular Filtration Rate Related to Vascular Lesions in HIV Patients?

Corinne Isnard-Bagnis,[1] Philippe Rouvier,[2] Sophie Tezenas du Montcel,[3] Paulo Francisco Fernandes,[6] Macroui Sonikian,[5] Jerome Tourret,[1] Rachid Agher,[4] Gilbert Deray,[1] Marc Antoine Valantin,[4] Roland Tubiana,[4] Christine Katlama.[4] *[1]Nephrology, Assistance Publique Hôpitaux de Paris, Paris, France; [2]Pathology Dept, Assistance Publique Hôpitaux de Paris, Paris, France; [3]Clinical Research Unit, Assistance Publique Hôpitaux de Paris, Paris, France; [4]Infectious Disease Dept, Assistance Publique Hôpitaux de Paris, Paris, France; [5]Nephrology, A Fleming General Hospital, Athens, Greece; [6]Nephrology, Hopital Santa Maria, Lisboa, Portugal.*

**Background:** Renal diseases in HIV patients are secondary to the viruses (HIV or HIV/HCV co-infection), their treatments or to metabolic complications. As the causes of chronic kidney disease evolve in HIV population, it is critical to describe what histopathological lesions correlate with glomerular filtration rate (GFR).

**Methods:** 196 biopsies performed in a single center over 10 years in HIV patients were retrospectively analyzed. For 82 biopsies, corresponding clinical and biological data were available both at the time of biopsy. GFR was estimated as sMDRD.

**Results:** Among the 196 biopsies, the main renal histopathological diagnosis included: Acute tubular necrosis (n=34, 17.4%), HIVAN (n=29, 14.8%), nephroangiosclerosis (NAS) (n=28, 14.3%), FSGS (n=25, 12.8%), interstitial fibrosis, tubular atrophy (IFTA) (n=11, 5.61%) and diabetic glomerulosclerosis (n=10, 5.1%). IFTA was present in 25% of HIV-related diagnosis (FSGS+HIVAN) and 36% in non HIV-related (all others) diagnosis (p=0.11). NAS was present in 25% of HIV-related diagnosis (FSGS+HIVAN) and 44% in non HIV-related (all others) diagnosis (p=0.058). IFTA did not influence GFR in any diagnosis. When NAS lesions were present in HIV-related diagnosis, GFR was significantly lower (p=0.032).

**Conclusions:** Nephroangiosclerosis lesions are more frequent in non HIV-related histopathological diagnosis (patients with metabolic complications) and significantly influence glomerular filtration rate in HIV patients. Accelerated ageing and endothelial vascular lesions secondary to HIV infection and HAART may explain this correlation.

## TH-PO301

### Chronic Kidney Disease in Patients with Sickle Cell Anemia

Elvira Gosmanova,[1] Sahar Zaidi,[1] Jim Y. Wan,[2] Patricia Adams-Graves.[1] *[1]Medicine, UTHSC, Memphis, TN; [2]Preventive Medicine, UTHSC, Memphis, TN.*

**Background:** Little is known about the prevalence of different stages of chronic kidney disease (CKD) in patients with sickle cell anemia (SCA). We evaluated the prevalence and the changes of CKD stages during a 5-year period in a cohort of SCA patients aged >18 years who were followed at the Diggs-Kraus Sickle Cell Clinic, Memphis, TN.

**Methods:** We studied 98 patients with SCA [mean age 31.6 years, 43% males, 56% with Hemoglobin SS disease, mean serum creatinine (SCr) 0.79 mg/dL, mean blood pressure (BP) 120.2/74.0 mmHg]. CKD stages 1 through 5 were defined using estimated glomerular filtration rate (eGFR), and albuminuria grades were defined based on spot urine protein to creatinine ratio (UPCR) (normal or A1- UPCR<0.15mg/g, A2 or microalbuminuria-UPCR 0.15-0.5mg/g, A3 or macroalbuminuria- UPCR>0.5mg/g) according to the latest KDIGO recommendations. In patients with eGFR>60ml/min/1.73m$^2$, CKD diagnosis was made if grade A2 or A3 albuminuria was present. CKD progression was defined as an increase in CKD stage with an additional >25% eGFR reduction from baseline.

**Results:** At baseline, 28.6% of patients had CKD. After a mean follow up of 5.0+0.9 years, 17 patients developed new CKD (mainly stage 1 based on A2 or A3 albuminuria) and the overall CKD prevalence increased to 41.8%. In addition, 8 patients had worsening of preexisting CKD stage. In univariate analysis, older age (p=0.02) and higher baseline systolic BP (SBP) (p=0.03) were associated with the development of new CKD; whereas, lower baseline eGFR (p=0.001), A3 albuminuira (p=0.005), and lower serum hemoglobin (p=0.04) predicted CKD progression. In multivariate analysis, each 1mmHg increase in SBP was associated with increased risk of new CKD (adjusted OR 1.06, p=0.005), and baseline A3 albuminuria strongly predicted the progression of CKD (adjusted OR 17.0, p=0.006).

**Conclusions:** CKD is common in patients with SCA, and its prevalence increases with increasing age. Several baseline modifiable and non-modifiable factors were associated with the development and progression of CKD in SCA patients. Strategies targeting control of blood pressure and proteinuria may be beneficial for individuals with SCA.

## TH-PO302

### Renal Pathology in West Side of Chicago

Esho Georges, Harsha C. Gondi, Rafath Ullah, Mana Dissadee, Andres Serrano. *Nephrology Div, Mount Sinai Hospital Medical Center, Chicago, IL.*

**Background:** The purpose of our study is to review all renal pathologies done at our institution between 2008-2012, trying to identify the renal diseases that affect our population which composed mainly of Hispanics and African-Americans.

**Methods:** We reviewed medical records of our (100) cases retrospectively looking for renal pathology, gender, ethnicity, age group, labs and other data done at time of diagnosis.

**Results:** The mean age of the group was 45.7 yr with 55% females and 45% males. Hispanics account for 52% and African-Americans for 44%. At the time of the biopsy, 67% of patients have hypertension and 34% have diabetes mellitus. The mean serum creatinine is 2.8 mg/dl and mean urine protein/creatinine is 5.1 gm/gm.

Diabetic nephropathy (DN) and focal segmental glomerulosclerosis (FSGS) are the most common pathology (each accounts for 19%), followed by advanced global glomerulosclerosis (AGGS) (17%), IgA nephropathy (IgAN) (12%) and membranous nephropathy (MN) (12%). Interestingly, almost close to one fifth of the patients have end-stage renal disease, which likely indicates lack of medical evaluation in this group of patients!

Among Hispanics, FSGS was the most common diagnosis (23%), followed by IgAN (21.1%), DN (19.2%), AGGS (19.2%) and MN (9.6%). Among African-Americans, the most common diagnosis was DN (20.4%), followed by MN (15.9%), AGGS (13.6%), and FSGS (11.3%). It is interesting that MN was more frequent among African-Americans than FSGS, which traditionally has been described to be more prevalent in this population, and that FSGS was the most common diagnosis among the Hispanics.

Among diabetics, DN was the most common diagnosis (55.8%). However, (44.2%) of the diabetic patients have a different diagnosis.

**Conclusions:** In conclusion, DN and FSGS are the most common cause of renal disease at our institute. However, almost close to one fifth of cases have AGGS, which likely indicates lack of medical evaluation and unawareness of their renal disease. Among African-Americans, DM and MN were more frequent than FSGS. Finally, more than 40% of patient with diabetes mellitus, have a diagnosis that was not DN.

## TH-PO303

### A Panel of Novel Biomarkers of Kidney Injury Improves Prediction of Glomerular Filtration Rate Declines in Chronic Kidney Disease

Boon Wee Teo,[1] Peh Joo Ho,[2] Qi Chun Toh,[1] Hwee Min Loh,[3] Martin B. Lee,[1] Evan J.C. Lee.[1] *[1]Medicine, Yong Loo Lin School of Medicine, National Univ of Singapore, Singapore; [2]Statistics and Applied Probability, Faculty of Science, National Univ of Singapore, Singapore; [3]Medicine, National Univ Hospital, Singapore.*

**Background:** The association of a panel of novel kidney injury or disease biomarkers in spot urine (KIM1, kidney injury molecule 1; LFABP, liver-type fatty acid-binding protein; NGAL, neutrophil gelatinase-associated lipocalin; αGST and πGST, gluthathione s-transferase; collagen IV) with progression of chronic kidney disease (CKD) in stable patients is unknown. We hypothesize that a panel of these biomarkers can provide additional predictive value in estimated glomerular filtration rate (eGFR) decline beyond traditional predictors including proteinuria. We assess a panel of biomarkers with eGFR decline in a multi-ethnic Asian population of CKD.

**Methods:** We retrieved stored urine samples from the Asian Kidney Disease Study patients with CKD (n=81, 49.4% male). We examined traditional and novel biomarkers against eGFR decline using univariate and multivariate analysis. Variables of interest were natural log-transformed where appropriate. We used exhaustive stepwise selection of variables in multiple linear modeling to determine the best predictive models and Akaike Information Criterion (AIC) to select the best. We used cross-validation to validate and rank the models by prediction error.

**Results:** Population means: age 58.7±12.4 years, 53.1% diabetes history, serum creatinine 2.03±1.17 mg/dL , serum total protein 70.67±5.78 g/L, urine creatinine 6.9±4.6 mmol/L baseline eGFR 45.2±28.6 mL/min/1.73m$^2$, Kim-1 0.7±0.6 ug/L, LFABP 42.2±50.0 ug/L, NGAL 29.8±52.1 ug/L, αGST 6.5±23.8 ug/L, πGST 6.9±11.1 ug/L, Collagen IV 5.7±6.0 ug/L. Urine albumin to creatinine ratio (UACR) is rendered insignificant in a model including diabetes history, serum protein, αGST, NGAL and L-FABP but is the best model with the smallest AIC value (202.6) and smallest prediction error.

**Conclusions:** A panel of novel biomarkers of kidney injury offers additional prediction of CKD progression in a model including albuminuria.

*Funding:* Government Support - Non-U.S.

**TH-PO304**

**Uric Acid Transporter ATP-Binding Cassette Transporter G2 (ABCG2) Is Increased in the Intestine of the Rat 5/6 Nephrectomy Model of Chronic Kidney Disease** Hirofumi Yano, Yoshifuru Tamura, Kana Kobayashi, Shunya Uchida. *Nephrology, Teikyo Univ School of Medicine, Tokyo, Japan.*

**Background:** Uric acid (UA) remains to be a risk factor of chronic kidney disease (CKD). Therefore, it is important to clarify the mechanism of UA excretion in CKD. The specific mechanisms of intestinal excretion in extrarenal excretion are unknown. We evaluated the expression of UA transporter, intestinal tract of the ATP-binding cassette transporter G2 (ABCG2), in a rat 5/6 nephrectomy model of CKD.

**Methods:** Male Wistar rats (6 week old) were randomly assigned to the 5/6 nephrectomized (Nx) group or the sham-operated control group. Urine and blood samples were collected every 4 weeks. All the rats were sacrificed at 8 weeks to obtain liver, duodenum, jejunum, ileum, and transverse colon tissues. Uricase activity was measured in the liver. Expression of ABCG2 in intestinal mucosa was measured with a real time PCR.

**Results:** Nx group showed significantly decreased urine UA excretion/body weight and UA clearance compared to the control group at 4 and 8 weeks after nephrectomy. In contrast, serum UA and uricase activity were not significant. In Nx group, the expression of ABCG2 in the ileum showed significant increase upregulation. While other intestines revealed no changes.

**Conclusions:** Nx rats exhibited lower excretion of urine UA and over-expression of ABCG2 in the ileum. The fact that serum UA did not increase despite the decrease in UA excretion suggests that other excretory pathway, probably intestine, beside kidney may operate as a complementary role that corroborates the increase in ABCG2 expression in the ileum.

**TH-PO305**

**Visceral Fat Area (VFA) Assessed by Bioelectric Impedance Analysis (BIA) Is Associated with Renal Function in Healthy Subjects** Soo Bong Lee, Il Young Kim, Dong Won Lee, Min Ji Shin, Harin Rhee, Byeong Yun Yang, Eun Young Seong, Ihm Soo Kwak. *Dept of Internal Medicine, Pusan National Univ School of Medicine, Yangsan, Republic of Korea.*

**Background:** The bioelectric impedance analysis (BIA) can be used in many clinical settings and easily give us information about body composition of each person including muscle mass, percentage of total body fat and visceral fat area (VFA).Though some studies have been reported regarding the adverse effect of abdominal obesity on residual renal function in chronic kidney disease (CKD) patients, that effect in healthy population is less well known. Therefore, we evaluated the effects of VFA on glomerular filtration rate (GFR) in healthy subjects.

**Methods:** We searched healthy subjects over 18 years old who underwent BIA and routine laboratory tests through health screening and promotion center in our university hospital in 2012. All of them have no underlying illness and subjects with proteinuria or hematuria were excluded. GFR was estimated by the Modification of Diet in Renal Disease (MDRD) and Chronic Kidney Disease EPIdemiology (CKD-EPI) equations. Multiple linear regression analysis between eGFR and body composition measured by BIA was done. Because the eGFR was affected by body mass, subjects were divided two groups according to BMI and compared their eGFR.

**Results:** Total 500 healthy subjects were included. Percentage of total body fat, obesity index and waist hip ratio did not show meaningful relationship with eGFR. Age, body weight, skeletal muscle, VFA were statistically significant predicting factors of eGFR by multiple linear regression analysis ($p<0.001$). Interestingly, the association of increased VFA with decreased renal function is more prominent in non obese group with low BMI below 25 than others ($p=0.001$ vs. $p=0.295$, respectively).

**Conclusions:** VFA is a significant determinant of eGFR in company with Age, body weight, skeletal muscle especially in non obese group in healthy subjects. Although many studies focused on association of general obesity and renal function, visceral fat reflecting abdominal obesity seems to have important role on renal function and should not be ignored even in healthy subjects.

**TH-PO306**

**Lower Serum Albumin Level Is Associated with Higher Fractional Excretion of Creatinine** Masaru Horio,[1] Enyu Imai,[2] Yoshinari Yasuda,[3] Tsuyoshi Watanabe,[4] Seiichi Matsuo.[3] *[1]Functional Diagnostic Science, Osaka Univ Graduate School of Medicine, Osaka, Japan; [2]Nakayamadera Imai Clinic, Takarazuka, Japan; [3]Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [4]Third Dept of Medicine, Fukushima Medical Univ, Fukushima, Japan.*

**Background:** Creatinine clearance (Ccr) overestimates glomerular filtration rate (GFR) due to the tubular secretion of creatinine. Fractional excretion of creatinine (FE-Cr, ratio of Ccr to GFR ) increases with decreasing GFR. Association of serum albumin level with the tubular secretion of creatinine was also reported previously. Alteration of FE-Cr may affect the performance of GFR estimating equations based on serum creatinine. We analyzed the factors influencing FE-Cr and compared the performance of GFR equations in subjects stratified by serum albumin levels.

**Methods:** 757 Japanese subjects were included. GFR was measured by inulin renal clearance. GFR and Ccr were measured simultaneously. Multivariate analysis was used to evaluate the factors influencing FE-Cr. Age, gender, GFR, body mass index (BMI), body weight, height and serum albumin level were analyzed. Estimated GFR was calculated by Japanese GFR equations based on serum creatinine (Eq-cr), serum cystatin C (Eq-cys) and 5 variables including serum albumin (Eq-5var).

**Results:** FE-Cr in subjects with serum albumin <3.0, 3.0-3.9 and >4.0g/dl were 1.63±0.48, 1.53±0.55, and 1.40±0.36, respectively. Multivariate analysis showed that GFR ($p<0.0001$) and serum albumin level ($p=0.004$) were independent parameters affecting FE-Cr. Biases of Eq-cr, Eq-cys and Eq-5var in subjects with serum albumin <3.0 g/dl were -9.5±17.5, -0.7±17.1 and -0.6±14.8 ml/min/1.73m$^2$, respectively. Eq-cr significantly overestimated GFR compared with Eq-cys or Eq-5var. Biases in subjects with serum albumin >4.0 g/dl were 6.4±18.8, 2.0±18.1 and 3.0±18.3 ml/min/1.73m$^2$, respectively. Eq-cr significantly underestimated GFR compared with Eq-cys or Eq-5var.

**Conclusions:** GFR and serum albumin level were independent parameters affecting FE-Cr. Alteration of FE-Cr according to the serum albumin levels may be one of the reasons of the bias of GFR equation based on serum creatinine.

*Funding:* Government Support - Non-U.S.

**TH-PO307**

**Effects of C-Reactive Protein (CRP) on the Risk of Developing Chronic Kidney Disease in Rheumatoid Arthritis** Masako Kochi,[1] Kentaro Kohagura,[1] Kunitoshi Iseki,[2] Yusuke Ohya.[1] *[1]Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus, Nishihara-Cho, Japan; [2]Dialysis Unit, Univ of the Ryukyus, Nishihara-Cho, Japan.*

**Background:** Chronic inflammation is common in Rheumatoid arthritis (RA) and related to the risk of cardiovascular, liver and pulmonary disease in RA patients. However, the effects of inflammation on chronic kidney disease (CKD) progression are unknown in RA.

**Methods:** We retrospectively investigated the effects of baseline C-reactive protein (CRP) on the incidence of CKD defined as positive dipstick testing for proteinuria and/or an eGFR (estimated glomerular filtration rate) of ≤60 ml/minute/1.73 m$^2$. We studied 361 outpatients, 61 men and 300 women, and the mean age and eGFR were 56.9 years and 89.2 ml/minute/1.73 m$^2$, respectively.

**Results:** Over a median follow-up of 6.5 years, 42 (12%) patients developed CKD. Elevated CRP were independently associated with the development of CKD. After adjustment for age, gender, traditional risk factors, anti-RA drug use, and the baseline eGFR, the adjusted hazard ratio of CRP was 1.37 (95% confidence interval: 1.19–1.55; $p < 0.0001$).

**Conclusions:** CRP had an independent association with the development of CKD in RA. The impact of anti-inflammation therapy on CKD remains to be studied further.

**TH-PO308**

**Markers of Inflammation and Oxidative Stress in Patients with Predialyis Chronic Kidney Disease** Luis H.B.C. Sette,[1] Edmundo Pessoa Lopes,[1] João Geraldo Carvalho Fernandes,[1] André Martins Galvão.[2] *[1]Universidade Federal de Pernambuco, Recife, Pernambuco, Brazil; [2]Laboratório de Imunobiologia Keizo Asami LIKA, Recife, Pernambuco, Brazil.*

**Background:** Nontraditional cardiovascular risk factors such as inflammation, malnutrition and oxidative stress (OS) promote and accelerate atherosclerosis in CKD patients and can be acessed by measuring the inflammation markers: serum ferritin, C-reactive protein (CRP) and albumin and the OS markers: gamma glutamyl transferase(GGT), TBARS, thiol, carbonyl and catalase.

**Methods:** Between September 2011 and December 2012 were evaluated patients in the clinic of Nephrology at the Hospital of Clinics of the Federal University of Pernambuco (HC-UFPE). Glomerular filtration rate (GFR) was estimated by the Cockroft-Gault formula and the patients were classified into five stages of CKD. Were measured in serum: markers of inflammation: ferritin, CRP, albumin, GGT, and markers of EO: TBARS, thiol, carbonyl and catalase.

**Results:** Were included 140 patients with a mean age of 64.4 years and 51.4% male. Mean GFR was 28.8 mL/min/1,73m2 and patients showed the following distribution according to the stages of CKD: 16 (11.4%) stage 5 patients, 69 (49.2%) stage 4, 55 stage 3 patients (39.2%). Among the markers of inflammation assessed it was observed an increase in serum ferritin and reduction of albumin in accordance to the GFR and the progression of CKD. There was no association between serum GGT, CRP and markers of EO with the GFR or the stages of CKD.

| **Biomarkers*** | **GLOMERULAR FILTRATION RATE** | |
|---|---|---|
| | Coeficient | p-value |
| GGT | 0.063 | 0.460 |
| **Ferritin** | **-0.236** | **0.005** |
| RCP | 0.041 | 0.620 |
| TBARS | -0.060 | 0.468 |
| Catalase | 0.046 | 0.576 |
| Carbonyl | -0.012 | 0.885 |
| Thiol | -0.146 | 0.076 |
| **Albumin** | **0.265** | **0.001** |
| * Spearman correlation | | |

**Conclusions:** Among the markers of inflammation and oxidative stress evaluated, there was an increase in serum ferritin and reduction of albumin as the fall in GFR and progression of CKD.

**TH-PO309**

**The Time Is Now to Implement Novel Urinary Biomarkers to Identify Cardiorenal Syndrome in Children with Dilated Cardiomyopathy**
Ahmad Kaddourah, Stuart Goldstein, John L. Jefferies, Michael R. Bennett. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

**Background:** Type II cardio-renal syndrome (CRS) describes renal dysfunction in the presence of chronic heart disease. Traditionally, elevated serum creatinine (Cr) and proteinuria have been used as markers for renal dysfunction. The role of the novel urinary biomarkers (NUB) has not been investigated in children with dilated cardiomyopathy (DCM). We aim to evaluate the changes in traditional kidney function markers in DCM children, and determine the diagnostic value of NUB in DCM children.

**Methods:** This is a cross-sectional study in children with DCM and left ventricular dysfunction defined as ejection fraction < 55%. Urine and blood samples were collected to run mesure serum Cr, urinary protein / Cr ratio, and four NUB: KIM-1, NGAL, IL-18, and L-FABP. eGFR was calculated using modified Schwartz formula. The NUB concentrations were adjusted for each mg of urinary Cr. NUB concentrations were compared to 22 control urine samples taken from 22 healthy children.

**Results:** 40 subjects between 2 and 21 year-old have been enrolled. The mean (SD) eGFR was 116 (62.1) ml/min/m$^2$. The median urinary protein / Cr ratios was 0.15 (0.09-0.24) mg/mg (normal is < 0.2). Both NGAL and IL-18 concentrations were significantly higher in DCM children than controls. Similarly, FABP concentration was higher in DCM children but the difference was not statistically significant. KIM-1 concentration showed no difference between the two groups.

| NUB/Cr | DCM children Median (IQR) | Controls Median (IQR) | P |
|---|---|---|---|
| NGAL/Cr | 13 (6-49) | 8(3-21) | 0.03 |
| IL-18 / Cr | 58 (30-116) | 26 (16-41) | 0.01 |
| FABP /Cr | 6 (3-15) | 3 (2-5) | 0.05 |
| KIM/Cr | 412 (270-672) | 379 (277–553) | 0.50 |

**Conclusions:** Our data suggests that the majority of children with DCM have normal eGFR and urinary Protein/Cr ratio; however, both NGAL and IL-18 were significantly higher in DCM children than in controls indicating subclinical ongoing kidney injury that cannot be detected by currently available renal function markers. Our data demonstrates the importance of using more sensitive markers to diagnose CRS in children with DCM.

**TH-PO310**

**Estimated GFR Differs from Measured GFR in Its Associations with Retinal Vasculopathy in the General Population**
Bjorn Odvar Eriksen,[1,3] Geir Bertelsen,[1,3] Therese Von Hanno,[1,2] Ulla Dorte Mathisen,[3] Toralf Melsom,[3] Ellisiv B. Mathiesen.[1,3] *[1]Univ of Tromsø, Tromsø, Norway; [2]Nordland Hospital, Bodø, Norway; [3]Univ Hospital of North Norway, Tromsø, Norway.*

**Background:** Estimated GFR (eGFR) from creatinine and/or cystatin C is used extensively in epidemiological research. Validation of eGFR against measured GFR (mGFR) has demonstrated reasonably good performance. However, both creatinine and cystatin C depend on non-GFR factors which can confound associations with pathological conditions compared to mGFR. Few studies have investigated the extent of this problem in epidemiological research. We compared the associations between eGFR and mGFR and retinal vasculopathy, a marker of systemic microvasculopathy.

**Methods:** In the Renal Iohexol Clearance Survey in Tromsø 6 (RENIS-T6), we measured GFR as iohexol clearance and performed retinal photography in a representative sample of middle-aged persons from the general population without cardiovascular disease. A total of 1521 persons without chronic kidney disease, diabetes, or micro- or macroalbuminuria were examined. Three eGFR equations based on creatinine and/or cystatin C from the CKD-EPI-Collaboration were used. Cystatin C was calibrated to the international reference ERM-DA471/IFCC.

**Results:** mGFR in the lowest quartile was associated with an increased multivariable-adjusted odds ratio of having retinopathy (odds ratio 1.8, 95% CI 1.1-2.6) in logistic regression analyzes, but the associations with all three eGFR were weaker and not statistically significant. Retinal venular diameter had statistically significant but opposite multivariable-adjusted associations with eGFRcrea (-1.5µm per 10 mL/min/1.73 m$^2$ reduction, 95% CI -2.8 to -0.2) compared to eGFRcys (+1.3µm per 10 mL/min/1.73 m$^2$ reduction, 95% CI 0.3 to 2.3), but not with eGFRcyscrea or mGFR in multiple linear regression anlyzes. The results for arteriolar diameters were similar, but the association with eGFRcys was not statistically significant (P=0.09).

**Conclusions:** eGFR based on creatinine and/or cystatin C differ from mGFR in their associations with retinal vasculopathy. This is a potential source of bias in epidemiological studies.

**TH-PO311**

**Late Dialysis Initiation Is Associated with Elevated Mortality among Patient Subgroups in the United States**
Austin G. Stack,[1,2] Ailish Hannigan,[2] Liam F. Casserly,[1,2] Hoang Thanh Nguyen.[2] *[1]Nephrology and Internal Medicine, Univ Hospital Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick, Ireland.*

**Background:** Recent studies have demonstrated an inverse relationship between the timing of dialysis initiation, based on estimated glomerular filtration rate (eGFR) and mortality. The extent to which this association is influenced other markers of kidney function (urea nitrogen and creatinine concentrations) is not clearly understood. We explored relationships of GFR with mortality at dialysis initiation in the context of varying concentrations of urea and creatinine.

**Methods:** Mortality risks were compared among 'early start' (eGFR: 10-15, and > 15ml/min/1.73 m$^2$) and 'late start' patients (eGFR: < 5 and 5-10) in 1, 220, 000 incident US patients who started dialysis between 1995-2008 and stratified by quintiles of urea (Q1 < 61.1, Q2 61.1-77.0, Q3 77.0-93.0, Q4 93.0-114.0 and Q5> 114.0 mg/dL) and serum creatinine. The association of eGFR with 2-year mortality was explored using Cox regression with adjustment for demographic, clinical and laboratory characteristics with eGFR 5-10 ml/min as the referent and adjusted Hazard ratios (HR) were determined. The Interaction terms (GFR*urea and GFR*creatinine) were significant in the full model.

**Results:** The association of GFR with mortality varied significantly by concentrations of urea nitrogen. For levels > 93 mg/dL, the association of GFR with mortality was u-shaped, while for levels > 93 mg/dL, the pattern was more direct. A similar mortality risk pattern emerged when stratification was made by serum creatinine concentrations.

| | Hazard Ratio for Death by eGFR at Dialysis Initiation (ml/min/1.73m$^2$) | | | |
|---|---|---|---|---|
| Urea Nitrogen (mg/dL) | < 5 | 5 to <10 | 10 to <15 | > 15 |
| < 61.1 | 1.26** | 1.00 | 1.03** | 1.08** |
| 61.1 to <77.0 | 1.16** | 1.00 | 1.07** | 1.12** |
| 77.0 to < 93.0 | 1.03** | 1.00 | 1.08** | 1.14** |
| 93.0 to < 114.0 | 0.94** | 1.00 | 1.10** | 1.14** |
| > 114.0 | 0.84** | 1.00 | 1.09** | 1.14** |

**P<0.001

**Conclusions:** The association of GFR estimated at dialysis initiation with mortality varies significantly and substantially according to measured concentrations of urea and creatinine. Late dialysis initiation is associated with elevated mortality risks in selected patient subgroups.

**Clinical Value of Pathologic Examination of Non-Neoplastic Kidney in Patients with Upper Urinary Tract Malignancies**
Hyunjin Noh,[1] Jee wan Wee,[1] Soon Hyo Kwon,[1] Jin Seok Jeon,[1] Dong-Cheol Han,[1] So-Young Jin.[2] *[1]Internal Medicine, Soon Chun Hyang Univ College of Medicine, Seoul, Republic of Korea; [2]Pathology, Soon Chun Hyang Univ College of Medicine, Seoul, Republic of Korea.*

**Background:** Despite surgical resection remains the standard of care in the treatment of upper urinary tract malignancies, nephrectomy is a recognized a risk factor for developing chronic kidney disease (CKD). Since a solitary kidney has been considered an absolute contraindication to percutaneous biopsy, histologic diagnoses in the patients received nephrectomy would be an obstacle. In this study, we investigated the clinical value of pathologic examination of non-neoplastic tissue from the resected kidney to determine unrecognized kidney disease.

**Methods:** Between January 2010 and July 2012, 32 patients with renal cell carcinoma and 2 patients with transitional cell carcinoma received uninephrectomy or uninephroureterectomy. The routine pathologic evaluation of non-neoplastic tissues was performed.

**Results:** Out of 31 patients, only 9 patients (29%) had normal kidney. Thirty-four cases of pathologic diagnoses were obtained because 3 patients had dual diagnoses. Of the 34 cases, 10 (29.4%) showed vascular diseases (7 hypertensive nephrosclerosis, 3 ischemic nephropathy), 8 (23.5%) showed diabetic nephropathy, 6 (17.6%) showed glomerulonephritis (2 IgA nephropathy, 4 C1q nephropathy). and 1 case (3%) showed reflux nephropathy. During the median follow-up period of 9 months, 14 patients (46.7%) experienced post-operative acute kidney injury (AKI) and 10 patients (32.3%) progressed to CKD. Patients who experienced AKI had higher rates of developing CKD (p = 0.002, odds ratio 16.3). None of the clinical variables was associated with the pathologic abnormality.

**Conclusions:** Our study indicates that a routine pathologic examination of nephrectomized, non-neoplastic tissue will provide valuable information on the remnant kidney. Further studies based on a larger patient population will be needed to determine the influence of pathologic diagnoses on the long-term renal outcome.

**Early Detection of Kidney Disease in Children and Adolescents in Mexico: A Pilot Study**
Mara Medeiros,[1] Nadia Olvera,[2] Rebeca Reyes,[2] Luis Velasquez-Jones,[1] Georgina Toussaint,[1] Gregorio T. Obrador.[2] *[1]Hospital Infantil de Mexico Federico Gomez, Mexico, DF, Mexico; [2]Fundacion Mexicana del Riñon, Mexico, DF, Mexico.*

**Background:** Early detection of chronic kidney disease (CKD) is important to treat patients and prevent the progression to end stage kidney disease. The etiology of CKD is different in children and adolescents than in adult population, congenital anomalies (A/Hypo/dysplastic kidney, obstructive uropathy and reflux uropathy) and glomerulonephritis are the leading cause in pediatric patients, in contrast to adults where diabetes and hypertension are the main causes.

**Methods:** A pilot study was performed in Mexico City. Children and adolescents with any of the following risk factors were invited to participate: history of prematurity, history of urinary tract infection, history of acute renal injury, hypertension, obesity, weight or

height below 10th percentile for age and gender, ≥ 5 years with diabetes, familiar history of CKD (first grade). Patients with previous diagnosis of chronic kidney disease were excluded. Informed consent was obtained in all cases. A questionnaire was applied. Blood pressure, weight, height, abdominal circumference were measured. A urine sample was obtained for urinalysis and microalbumin/creatinine ratio. Blood sample was obtained for serum creatinine, blood gasometry, glucose, sodium, potassium, chloride, calcium, BUN, hemoglobin, hematocrit. Glomerular filtration rate was estimated with Schwartz formula.

**Results:** Eighty-eight participants were included, median age 10 years (range 1 month-18 years), 45 (52%) were female. The most common risk factors were family history of CKD in 33 (37.5%), prematurity in 18 (20.4%), obesity 14 (15.9%). Twenty-nine participants (33%) had an abnormal renal evaluation including one or more of the following: 12 (13.6%) had microalbuminuria, 8 had anemia (9%), 7 had hematuria (7.9%), 10 had hypertension (11.3%), 3 leukocyturia (3.4%), 1 renal glycosuria (1.1%), only two patients (2.2%) had eGFR<60ml/min/1.73m$^2$ (CKD stage 3). None had metabolic acidosis.

**Conclusions:** The prevalence of kidney disease was 33% in children with known risk factors. Early detection programs are useful to diagnose and prevent CKD progression in this population.

## TH-PO314

**Implementing Surveillance/Education Programs to Facilitate Timely Renal Referral in Chronic Kidney Disease** Nicole Piero,[1] Loretta Simbartl,[1] Charuhas V. Thakar.[2] *[1]Nephrology, VA Medical Center, Cincinnati, OH; [2]Nephrology, Univ of Cincinnati, Cincinnati, OH.*

**Background:** Referral to a renal subspecialty in patients with Stage IV chronic kidney disease (CKD)[glomerular filtration rate (GFR) < 30 ml/min/1.73m2] allows optimal management of its complications including end stage renal disease (ESRD) planning. We examined the impact of development and implementation of a surveillance/education program to facilitate timely renal referral followed by a shared care approach to manage CKD complications.

**Methods:** Within our Veterans Affairs healthcare system, starting Nov 2012, a customized informatics program compiles a monthly report of patients who have had 1 outpatient lab revealing a GFR < 30; we also identify demographics, comorbidities [e.g. hypertension, including home blood pressure (BP) monitoring], and renal evaluation in the prior 24 months. Concurrently, an educational program, led by nephrology and pharmacy is offered to primary care providers to raise awareness of CKD evaluation, and management of its complications. We compared (Chi-square) a historical cohort (2006 – 2010) with the 6-month implementation period (11/2012-04/2013) to evaluate improvement in renal referral in those with Stage IV CKD.

**Results:** In the historical cohort (42,942 veterans within our system) 79% patients were without CKD 19% with CKD Stage III, and 2% had CKD Stage IV/V. Compared to those without CKD, proportion of patients with renal referral in Stage III and Stage IV/V CKD was 35.7% and 47.6% respectively ($p < 0.0001$). Since the beginning of the surveillance program in Nov 2012 there were 348 patients with Stage IV CKD seeking care in our system, with 63% completing renal referrals. 97.4% of them had a diagnosis of hypertension, and 8% were enrolled in the program for home BP monitoring. After accounting for differences in demographics and comorbid conditions, renal referral during the implementation period was higher than historical period (63% vs 47.6%, $p < 0.0001$).

**Conclusions:** A combination of system-wide surveillance and education facilitates timely renal referral in patients with Stage IV CKD. This allows for increased opportunities for co-morbidity management and proper ESRD planning.

## TH-PO315

**The Cost Effectiveness of Primary Screening for Chronic Kidney Disease: A Systematic Review** Thomas W. Ferguson,[1] Paul Komenda,[2] Kerry Macdonald,[4] Claudio Rigatto,[2] Manish M. Sood,[3] Navdeep Tangri.[2] *[1]Community Health Sciences, Univ of Manitoba, Winnipeg, Canada; [2]Nephrology, Seven Oaks General Hospital, Winnipeg, Canada; [3]St. Boniface General Hospital, Winnipeg, Canada; [4]Library Services, Univ of Manitoba, Winnipeg, Canada.*

**Background:** Chronic Kidney Disease (CKD) is a major health problem with a rising incidence and prevalence worldwide. Data on the cost-effectiveness of CKD screening in the general population have been conflicting. Our objective was to evaluate key factors influencing the cost-effectiveness of screening for CKD by proteinuria or eGFR.

**Methods:** To achieve our objective we conducted a systematic review of studies from PubMed, Scopus, EMBASE, and Cochrane Database of Systematic Reviews from the date of their establishment until June 2012. Studies reporting incremental cost-effectiveness ratios (ICER) of screening for CKD by either protenuria or estimated glomerular filtration rate (eGFR) in comparison with no screening or usual care were selected. Articles were assessed for quality of reporting and risk of bias based on validated criteria.

**Results:** We screened 1,462 abstracts of which 161 were selected for a full-text review. Nine studies met criteria for inclusion. Eight studies evaluated the cost-effectiveness of proteinuria screening and two evaluated screening with eGFR. For proteinuria based screening, the reported cost per quality-adjusted life year (QALY) ranged from $14,063.18 to $160,018.03 in the general population, $5,297.59 to $54,943.12 in the diabetic population, and from $23,028.37 to $73,939.36 in the hypertensive population. For eGFR screening, one study reported a cost per QALY of $23,679.71 in the diabetic population and the range across the two studies was $100,252.88 to $109,911.56 in the general population. The incidence of CKD, rate of progression, and the effectiveness of drug therapy were major drivers of cost-effectiveness.

**Conclusions:** Screening for CKD is suggested to be cost-effective in patients with diabetes and hypertension. CKD screening may be cost-effective in populations with higher incidence of CKD, rapid rates of progression, and more effective drug therapy.

## TH-PO316

**Exploration of Candidate Biomarkers for the Rapid Screening of Glomerular Disease and Its Application Research** Ye Tao, Jin Qiaoling. *Dept of Nephrology, West China Hospital, Chengdu, Sichuan, China.*

**Background:** So far, GD is the leading cause of CKD in China .The national CKD survey was completed recently in china, it shows that the prevalence rate of CKD was10.8% for adults above the age of 18, which has become a serious public health problem. The early screening of GD will help clinicians to take corresponding treatment scheme, to delay the development of renal disease, improve the prognosis of the patients. Estimation of renal lesion severity is an important part of clinical treatment, Besides the clinical manifestation, pathological diagnosis of renal biopsy is the most commonly used and effective means, but it is not suitable for repeated examination because of trauma. So, researchers have been working to find strong evidence in blood and urine of patients, in order to reflect the injury and severity of renal.Therefore, search for a quick, accurate and non-invasive examination method for early diagnosis of glomerular disease is very necessary.

**Methods:** A protein array which can screen 274 cytokines simultaneously was used to screen urine specimen collected from the GD patients and healthy subjects. Enzyme linked immunosorbent (ELISA) was used to quantify those potentially useful cytokines. ROC curve (relative operating characteristic curve) assess the values for clinical application.

**Results:** We obtained four cytokines through the protein array, monocyte chemotactic factor -1(MCP-1), angiogenin, adiponectin ( Acrp30), dipeptide peptidase IV (DPPIV/CD26). Researchers have reported the clinicalsignificance of MCP-1 in glomerular disease, and there is no urinary Acrp30 detection kit for sale. Therefore, only the cytokine CD26 was quantified by ELISA and analyzed by ROC curve. The area under the curve of CD26 was 0.898±0.022, the sensitivity was 86.3% and the specificity was 81.9%.

**Conclusions:** In this study we found that the CD26 can be used for clinical screening of GD, but can't be used in the identification of glomerular disease. Otherwise, the study found CD26 was related to urinary protein, which suggested that CD26 can be used to noninvasive monitoring treatment response of GD.

*Funding:* Clinical Revenue Support

## TH-PO317

**Decrease of Glomerular Filtration Rate at 30-Day Readmission after Percutaneous Coronary Intervention** Claudine T. Jurkovitz, Paul Kolm, Daniel Elliott, James R. Bowen, William S. Weintraub. *Value Institute, Christiana Care Health System, Newark, DE.*

**Background:** Chronic kidney disease (CKD) is a risk factor for 30-day readmission in patients who undergo Percutaneous Coronary intervention (PCI). Whether patients with CKD have a decline in kidney function between the first and the repeat admissions is unknown.

**Methods:** We conducted a retrospective analysis of all patients admitted in our hospital for PCI in 2010-2012. Glomerular filtration rate (GFR) was estimated using CKD-Epi. CKD was defined as GFR<60 ml/min/1.72m$^2$. A significant decrease in kidney function was defined as a decline in GFR ≥30% between the first (index visit) and 30-day admissions. We used Paired T-test and McNemar's test to compare results between index visit and readmission and logistic regression to calculate the probability of significant decline at each CKD stage, adjusted for demographics, diabetes, hypertension, congestive heart failure (CHF), angiotensin converting enzyme inhibitor (ACEI) or receptor blocker (ARB) at index visit.

**Results:** A total of 4,432 patients had PCI of whom 616 (14%) were readmitted within 30 days. Of those, 69% were male, 49% were 65 or older, 83% were white, 15% black, 13% had diabetes, 80% hypertension, 26% CHF, 25% CKD and 63% were taking ACEI/ARB at index visit. Average GFR was 75.6±26.9 at index visit and 72.6±28.5 at readmission ($p<0.001$); Of those without CKD at index visit, 6% had a significant decline in GFR between index visit and readmission, whereas it raised to 11% among those with CKD ($p=0.02$). CHF was the only significant predictor of GFR decline (Odds ratio (OR)= 3.1; 95%CI=1.5-6.2). Although index visit GFR was not an independent predictor (OR=1.1/10 ml decrease, 95%CI=1.0-1.3, $p=0.09$) there was an apparent trend in the probability of kidney function decline. Probability was 0.05 for those without CKD at index visit, 0.11, 0.14, 0.16 for those with GFR 30-59, 15-29 and <15 respectively.

**Conclusions:** The decline in kidney function between the 2 hospital admissions is mostly seen in patients with CKD and seems to be related essentially to CHF. Monitoring these patients at discharge is key to prevent further decline of kidney function and end stage renal disease.

*Funding:* Other U.S. Government Support

## TH-PO318

**Impact of Reimbusement Change of ESAs on Management of Anemia in Patients with Non-Dialytic Chronic Kidney Disease** Sun Moon Kim, Hye-Young Kim. *Internal Medicine, Chungbuk National Univ Hospital.*

**Background:** Anemia is common in patients with chronic kidney disease (CKD). The correction of anemia with erythropoiesis-stimulating agents (ESAs) is of particular financial interest. Recently, use of ESAs in non-dialytic patients was reimbursed by Korean

National Health Insurance System and it enabled physicians to use ESAs in non-dialytic CKD patients at half the previous cost. In this study, we investigated the prescription rate of ESAs and the status of anemia control before and after reimbursement.

**Methods:** Medical records of patients with non-dialytic CKD stage 4, 5 (eGFR <30ml/min/1.73m$^2$) were reviewed in one tertiary medical center. The prescription of ESAs, Hb, estimated GFR, history of transfusion, and iron supplementation at 6 months before, 6 months and 12 months after the change of reimbursement criteria.

**Results:** A total of 607 medical records were analyzed. The mean age of patients was 59.2 ± 14.5, and mean eGFR was 19.10 ± 6.80 ml/min/1.73m$^2$. The proportion of patients received ESAs was 20.6% before reimbursement while the proportion was increased to 37.5% at 6 months and 40.4% at 12 months after reimbursement (p <0.001). Especially, 36.9% of patients with Hb <10g/dl were prescribed ESAs before reimbursement, whereas 57.7%, and 64.0% of those patients at 6 months and 12 months after reimbursement (p <0.001). However, neither mean Hb nor the proportion of patients with Hb < 10g/dl was changed. Mean Hb was 9.60 ± 1.97 g/dl before reimbursement, 9.34 ± 1.83 g/dl, and 9.71 ± 1.78 g/dl and at 6 months and 12 months after reimbursement (p=0.195). The proportion of patients with Hb <10 g/dl was 51.0% before reimbursement, 59.9%, and 56.8% at 6 months and 12 months after reimbursement (p=0.458). The requirement of red blood cell transfusion was 0.46 pint/person-year before reimbursement, 0.32 pint/person-year, and 0.15 pint/person-year at 6 months and at 12 months after reimbursement (p=0.001).

**Conclusions:** With reimbursement of ESAs in patients with nondialytic CKD, the prescription rate of ESAs in the population was increased. Although mean hemoglobin levels did not change in the population, the requirement of red blood cell transfusion was significantly decreased.

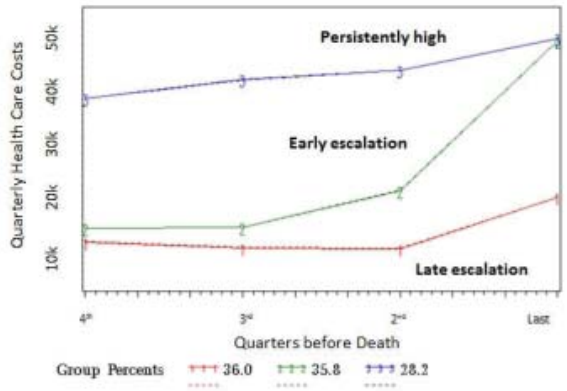
## TH-PO319

**End-of-Life Cost Trajectories among Medicare Beneficiaries with End-Stage Renal Disease** Ann M. O'Hare,[1] William Kreuter,[2] Paul Louis Hebert,[3] Kenn B. Daratha.[4] *[1]Depts of Medicine and Health Services, VAPSHCS and Univ of Washington, Seattle, WA; [2]School of Nursing, Washington State Univ, Spokane, WA.*

**Background:** Little is known about trajectories of healthcare intensity before death among patients with ESRD.

**Methods:** We used group based trajectory modeling to describe cost trajectories during the year before death among adults who entered the USRDS registry between January 1, 1995 and December 31, 2007, had Medicare as primary payer for ESRD during the year before death and died before January 1, 2009 (n=199,120).

**Results:** We identified three groups of patients with distinct cost trajectories: those with late cost escalation, those with early cost escalation and and those with persistently high costs (Figure).



Across these respective groups, median costs during the last year of life ranged from $57,513 to $157,476, median hospital days ranged from 7 to 44, median ICU days ranged from 0 to 7, and the percentage of patients that died in the hospital ranged from 33.8 to 52.6%. Compared with the group with late cost escalation, those with early cost escalation and persistently high costs were younger, had a shorter duration of ESRD, and included a higher proportion of women and black patients, a higher proportion with Medicaid eligibility, and a higher proportion with diabetes as the cause of ESRD. As compared with patients who died between 1995 and 2000, those who died from 2005-2008 were 41% (95% confidence interval (CI) 36-47%) more likely to have early cost escalation and 63% (95% CI 56-69%) more likely to have persistently high costs during the last year of life after adjustment for other patient characteristics.

**Conclusions:** Patients who died in more recent years, younger patients, black patients, women, and those with diabetes as a cause of ESRD were more likely to have experienced a prolonged period of intensive healthcare utilization before death.

*Funding:* Private Foundation Support

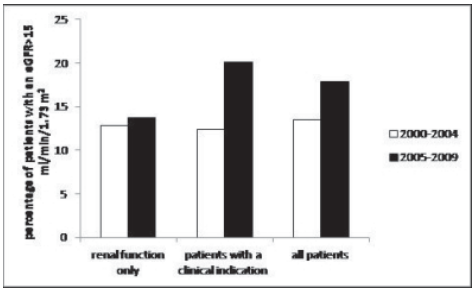
## TH-PO320

**Trends in Timing and Indications for Chronic Dialysis within a Large U.S. Health System (2000-2009)** Ann M. O'Hare,[1,2,4] Bruce Wynar,[1] Mark Perkins,[1] Chuan-fen Liu,[1,3] Jaclyn Lemon,[1] Paul Louis Hebert.[1,3] *[1]Dept of Veterans Affairs, VA Health Services Research & Development Center of Excellence, Seattle, WA; [2]Dept of Medicine, Univ of Washington, Seattle, WA; [3]Dept of Health Services, Univ of Washington, Seattle, WA; [4]Group Health Research Institute, Seattle, WA.*

**Background:** Reasons for an upward trend in estimated glomerular filtration rate (eGFR) at the time of dialysis initiation are not known. Prior studies have been limited by an absence of information on clinical indications for dialysis.

**Methods:** To evaluate whether trends in eGFR at dialysis initiation reflect changes in indications for dialysis and/or timing of initiation, we reviewed the electronic medical records of a national random sample of patients who initiated chronic dialysis in the Department of Veterans Affairs (VA) in fiscal years (FY) 2000-09 (n=1,735).

**Results:** Between FY2000-04 and 2005-09, the percentage of patients with an eGFR>15ml/min/1.73 m$^2$ at initiation increased from 13.5 to 17.9% (P=0.012).



In both time periods, types of clinical indications were similar, as was the proportion of patients in whom the decision to initiate dialysis was based only on level of renal function (27.6% vs. 29.1%, P=0.48). The adjusted odds ratio for initiation at an eGFR>15ml/min/1.73$^2$ in FY2005-09 vs. 2000-04 was 1.31 (95% confidence interval (CI) 0.99, 1.71) for the overall cohort, 0.84 (95% CI 0.48, 1.47) for those in whom the decision to initiate dialysis was based only on level of renal function, and 1.49 (95% CI 1.09, 2.05) for those with one or more clinical indications.

**Conclusions:** Recent trends in eGFR at initiation within the VA were driven by a selective tendency toward earlier initiation of dialysis among patients with clinical signs and symptoms, and did not reflect changing indications for dialysis or earlier initiation in asymptomatic patients.

## TH-PO321

**Variability in Management of Hemodialysis Patients and Associated Healthcare Utilization** Bjoerg Thorsteinsdottir,[1] Priya Ramar,[2] Megan Reinalda,[2] Robert C. Albright,[1] Amy W. Williams,[1] Nilay D. Shah.[2] *[1]Medicine, Mayo Clinic, Rochester, MN; [2]Health Care Policy and Research, Mayo Clinic, Rochester, MN.*

**Background:** With new efforts to define care models, it is essential to understand the impact of different providers on quality and resource utilization. We studied the role of nephrologists (Neph) and primary care physicians (PCP) in the care of hemodialysis(HD) patients in a health system serving a population of 395.000. Nephrologist presence varies between units, offering a natural experiment in the management of HD patients between PCP and Neph.

**Methods:** Patients initiating HD from 2001-2010 were linked to United States Renal Database System Medicare claims. Patients with <90 days follow up were excluded as were services after a transplant. Outpatient (OP) visits were identified using CPT-4 codes and specialty. Mid-Level providers were grouped with Neph as most worked in HD. The proportion of PCP visits per person-year (ppy) was grouped into quartiles. We estimated the association between the quartile of PCP visits with hospitalizations, emergency department (ED) and other specialty visits.

**Results:**

| | Groups* | | |
|---|---|---|---|
| | <25$^{th}$ percentile(N=939) | 25$^{th}$-75$^{th}$ percentile (N=1961) | >75$^{th}$ percentile (N=926) |
| Follow-up(py) | 2877.2 | 7767.0 | 2987.9 |
| Mean age(years) | 56.0 | 61.0** | 63.2** |
| Males(%) | 64.1 | 58.6** | 57.0** |
| Died(%) | 28.0 | 40.6** | 57.6** |
| Transplant(%) | 45.7 | 34.0** | 8.3** |
| Median survival (years) | 4.7 | 4.2 | 3.6** |
| Charlson score first year of HD | 1.9 | 3.2** | 3.6** |
| PCP visits ppy | 2 | 3.5** | 7.3** |
| Nephrology visits ppy | 5.6 | 6.3** | 1.5** |
| Other specialty ppy | 4.1 | 7.8** | 8.2** |
| Hospitalizations ppy | 1.0 | 1.6** | 2.2** |
| ED visits ppy | 0.7 | 1.3** | 1.6** |

*Groups based on proportion of primary care E&M visits out of total E&M visits to primary care, mid-level/nephrology providers. **Denotes p-value < 0.05 when compared to <25$^{th}$ percentile group.

**Conclusions:** Patients who get most of their care from primary care providers are older, sicker, utilize more resources, and have worse outcomes than those managed primarily by nephrologists. Further studies are needed to better understand the differences in these patient groups.

## TH-PO322

**Role of Meditation in Reducing Sympathetic Hyperactivity and Quality of Life in Lupus Nephritis Patients with Chronic Kidney Disease**
Sirawit Bantornwan, Nuttasith Larpparisuth, Tanyarat Teerapornlertratt, Kriengsak Vareesangthip. *Dept of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkoknoi, Bangkok, Thailand.*

**Background:** Lupus nephritis is an important leading cause of chronic kidney disease (CKD) among the young population. Some physiological studies reveal that meditation may reduce sympathetic hyperactivity which is commonly found in SLE. We hypothesized that meditation could be beneficial in correcting autonomic dysfunction and improving quality of life in lupus nephritis patients with CKD.

**Methods:** We prospectively enrolled thirty lupus nephritis patients and categorized into meditation group and control group. Method of meditation was instructed by an expert in Buddhist studies every month. Participants in the intervention group were advised to meditate every day for 24 weeks. To evaluate change in sympathetic activity, normetanephrine level was measured at beginning and the end of study compared between both groups. Quality of life was determined by SF-36. Heart rate variability was also measured in meditation group at baseline and after practice.

**Results:** After meditation for 6 months, serum normetanephrine level decreased in both groups, but without statistically significant ($p$=0.28). In aspect of quality of life, score of physical and mental components improved significantly. In meditation group, physical score increased from 21.4 (5.0-50.2) to 62.2 (51.8-88.4) points ($p$<0.01) and mental score increased from 16.9 (4.4-46.0) to 72.4 (45.1-81.6) points ($p$<0.01). Although, physical and mental score in control group also increased, from 19.4 (10.4-49.2) to 55.4 (36.4-83.4) points ($p$<0.01) and 13.9 (7.7-44.2) to 45.0 (29.8-77.6) points ($p$<0.01), respectively, but quality of life score in meditation group increased more significantly (p<0.01). The parameter of heart rate variability in time and frequency domain also improved in meditation group.

**Conclusions:** In lupus nephritis patients with CKD, meditation reduced normetanephrine, improved quality of life and heart rate variability. Our results support the important role of meditation as a valuable adjunctive treatment of CKD from lupus nephritis.

## TH-PO323

**Patient Awareness of Chronic Kidney Disease Is Associated with Blood Pressure Control**
Jillian Molli Berkman,[1] H. Omer Ikizler,[1] Julie A. Wright Nunes,[2] T. Alp Ikizler,[1] Kerri L. Cavanaugh.[1] *[1]Vanderbilt Univ; [2]Univ of Michigan.*

**Background:** Patient awareness of kidney disease is limited and variably relates to clinical outcomes. Different methods to characterize awareness may contribute these inconsistent findings. Furthermore, little is known about the impact of a patient's understanding of the severity of their chronic kidney disease (CKD).

**Methods:** In a cross-sectional study from May 2012 to July 2013, adults with CKD (eGFR<60 ml/min) seen in nephrology clinic were asked questions regarding their CKD diagnosis and its severity. Blood pressure (BP) readings were abstracted from the medical record.

**Results:** Among 252 patients the mean age was 57.9 (12) years, 42% were male, 17.3 % were Black, and 13.2% had limited health literacy. Patients answered three awareness questions: "Do you have a problem with your kidneys?" (96% correct), "Do you have chronic kidney disease?" (80 % correct), and "Do you have decreased kidney function?" (84% correct). Thirty-six percent (n=91) correctly identified their CKD stage; 12% (n=30) reported no CKD. Compared to those aware of the CKD stage, those unaware were more likely to be older (59 vs. 55 yrs; p=0.01), African American (22% vs. 9%; p=0.01), of lower income (38% vs. 24%; p=0.02), and were less likely to have participated in a CKD education class (25% vs. 38%; p=0.03). Unaware patients also had significantly lower kidney knowledge (63% vs. 71%; p=0.01), and less self-care participation (26.0 vs 27.9; p=0.03). Aware patients were more likely to have a controlled blood pressure (<130/80 mmhg) (52% vs. 34%; p=0.007), and lower systolic blood pressure (132 vs 139; p=0.02). These findings persisted in regression analyses adjusted for age, gender, race, income, education, diabetes, and previous CKD-education [OR 2.49 (95% CI 1.31-4.76); p=0.006], and [B (95%CI): -5.8 (-12.2 - 0.57)); p=0.07] respectively.

**Conclusions:** Awareness of CKD remains poor. Those aware are more likely to attain recommend blood pressure goals. Assessing patient awareness of CKD severity may identify those at risk for poor outcomes including less optimal BP control.

*Funding:* NIDDK Support, Private Foundation Support

## TH-PO324

**The Optimal Time to Measure Blood Pressure as a Representative Value of 24-Hour Mean Blood Pressure**
Jiwon Ryu,[1] Ran-Hui Cha,[2] Sunae Yoon,[3] Dong-Ryeol Ryu,[4] Jieun Oh,[5] Sejoong Kim,[1] Sang Youb Han,[6] Eun-Young Lee,[7] Yon Su Kim.[8,9] *[1]Internal Medicine, Seoul National Univ Bundang Hospital, Republic of Korea; [2]Internal Medicine, National Medical Center; [3]Internal Medicine, Catholic Univ College of Medicine; [4]Internal Medicine, Ewha Womans Univ College of Medicine; [5]Internal Medicine, Hanlym Univ College of Medicine; [6]Internal Medicine, Inje Univ College of Medicine; [7]Internal Medicine, Soon Chun Hyang Univ College of Medicine; [8]Internal Medicine, Seoul National Univ College of Medicine; [9]Kidney Research Institute, Seoul National Univ Medical Research Center.*

**Background:** Hypertension is important treatment target in chronic kidney disease(CKD). 24 hours blood pressure(BP) is gold standard to measure high BP, but, which is quite discomfortable. However representative time for BP as a 24-hrs BP in CKD patients is still unknown.

**Methods:** We evaluated whether there may be proper time to measure BP for predicting the average of 24 hrs BP in CKD patients(stage 2-4) from the multicenter, cross-sectional study (n, 1317; mean age, 57 years; men, 62.9%).

**Results:** Regression analysis showed that systolic BP(SBP) at the 7AM and 9:30PM are best agreed with the 24-hr mean SBP(mSBP)(r=0.677, r=0.656, respectively). The proportion of patients within 30% of 24-hr mSBP was the most at 7AM(95.6%) and then 9:30PM(95.3%). Among corresponding values of BP to 135mmHg by calculation with regression, 7AM was the closest(136.74mmHg), 9:30PM was the next(138.78mmHg), office mSBP was the last(142.61mmHg). The agreement between hypertensive groups classified by 135mmHg of 24-hrs mSBP and calculated values mentioned above showed the group of 7AM was most agreed with 24-hr mSBP(70.8%). The 9:30PM was lesser agreed(68.1%) and the office mSBP was least agreed(60.7%). By ROC curve, in evaluation of diagnostic values for hypertension, its standard is 135mmHg, 7am had the best(AUC: 0.843) and office mSBP had least(AUC: 0.774).

**Conclusions:** These datas suggest that optimal time to measure BP in CKD patients may be 7AM in the morning, and 9:30PM in the evening. This shows that office mean SBP is less useful than our time to measure BP.

## TH-PO325

**Seroconversion Rates following Intradermal and Intramuscular Hepatitis B Vaccine in Hemodialysis Patients Not Responding to Primary Vaccination Protocol – A Review of Prospective Trials**
Aliya Saeed, Farhanah Yousaf, Haroon Rashid, Josephine E. Kulogowski, Marilyn Galler, Bruce S. Spinowitz, Chaim Charytan. *New York Hospital Queens, Flushing, NY.*

**Background:** The response to Hepatitis B vaccine in dialysis population is reduced. Alternative route of vaccine administration may elicit a response via a distinct immunologic pathway that may help achieve seroconversion.

**Methods:** We performed a literature search using Medline with Mesh terms including "hepatitis B," "hepatitis B vaccines," and "injections, intradermal." The inclusion criteria was any prospective trial comparing seroconversion rates defined as antibody titer of > 10 IU/L immediately (1-3 months), 6 months, or at 12 months after the completion of intradermal (ID) and intramuscular (IM) administration of a fixed hepatitis B vaccination protocol in previously non-responding dialysis patients.

**Results:** Four of 158 studies met inclusion criteria. A total of 204 patients were studied, 120 of whom received ID hepatitis B vaccine while 84 received IM. At 1-3 months, 6 months, and 12 months, the mean seroconversion rate in ID group was 85%, 70%, and 61% versus mean seroconversion rates of 64%, 61%, and 28% in IM group, respectively.

| Author (Year of Publication) | Sample Size (ID:IM) | Vaccine | Vaccine Dose Protocol ID IM | Seroconversion [1-3 months after completion] (ID%:IM%) | Seroconversion [6 months after completion] (ID%:IM%) | Seroconversion [12 months after completion] (ID%:IM%) |
|---|---|---|---|---|---|---|
| Barraclough et al (2009) | 59(29:30) | Engerix B (GlaxoSmith Kline Pharmaceuticals) | 5 mcg 2 x/wk x 8 wks 40 mcg at wk 1 and 8 | 79:40 | 28:50 | 38:0 |
| Radziszewski et al (2007) | 62(49:13) | Engerix B (Smith Kline Beecham) | 10 mcg qwk x 12 10 mcg qwk x 12 | 82:85 | 88:100 | 88:69 |
| Micozkadioglu et al (2007) | 33(17:16) | Genhevac B, Pasteur | 10 mcg qwk x 8 40 mcg at 0, 1, 2, 6 months | - | 94:50 | - |
| Fabrizi et al (1997) | 50(25:25) | Engerix B (Smith Kline & Beecham) | 5 mcg qwk x 16 40 mcg at 0 and 1 month | 94:67 | 69:43 | 57:14 |

**Conclusions:** ID vaccination may achieve higher seroconversion rate and the effect may be maintained longer versus IM vaccination. Additional trials are needed to elaborate the role of ID vaccination in previous non-responding hemodialysis patients.

## TH-PO326

**Volume-Outcome Relationship in Percutaneous Native Renal Biopsy** Hiroyuki Yamamoto, Hideki Hashimoto, Mitsuhiro Nakamura, Hideo Yasunaga. *Univ of Tokyo School of Public Health, Tokyo, Japan.*

**Background:** Hemorrhagic complication remains the major complication of percutaneous renal biopsy. Our aims in this study are to identify individual-level risk factors relating to hemorrhagic complications of the procedure, and to investigate a volume-outcome relationship after adjusting for these risk factors.

**Methods:** Using a large claim-based data called Diagnosis Procedure Combination (DPC) database in Japan, we identified inpatients with renal disorders who underwent percutaneous biopsy within four days after admission during July to December in years of 2007 to 2010 (total 24 months). Patients were classified by age, sex, clinical syndromes (chronic nephritic syndrome, nephrotic syndrome, rapidly progressive nephritic syndrome, recurrent or persistent hematuria, acute nephritic syndrome and other disorders), and quintiles of hospital volume of the biopsy. Generalized estimation equation was used to account for clustering of patients at institutional levels.

**Results:** A total of 15191 patients from 942 hospitals were enrolled to this study. Overall hemorrhagic complication incidence was 2.1%, including hemorrhagic events on ICD codes (1.6%); red blood cell transfusion (0.5%); required angiography or endovascular procedure (0.1%); surgical interventions (0%). In-hospital deaths with hemorrhagic complications were observed in 0.06% of the patients. Significantly high complication incidence was observed in patients group younger than 30 (adjusted OR 1.97, 95% CI 1.39-2.80), and those aged 60 and over (adjusted OR 1.64, 95% CI 1.15-2.36) with reference to middle-aged patients group. Patients who had rapidly progressive nephritic syndrome (adjusted OR 3.41, 95% CI 2.22-5.25) had significantly higher hemorrhagic complication incidence with reference to patients who had chronic nephritic syndrome. No significant difference was observed across the hospital volume groups after adjustment of patient-level variables.

**Conclusions:** This study finds no significant volume-outcome relationships in hemorrhagic complication.

*Funding:* Government Support - Non-U.S.

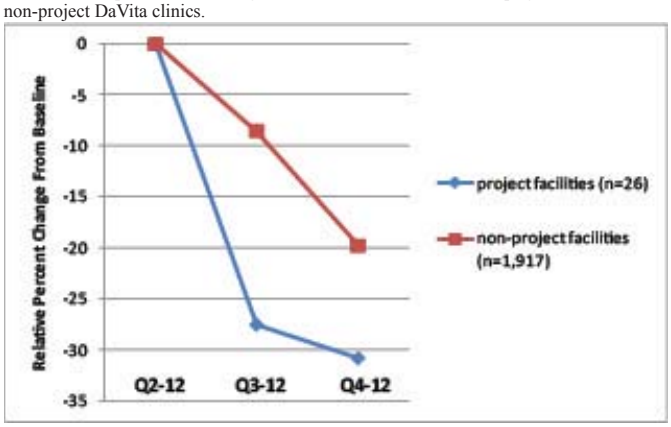
## TH-PO327

**A Pilot Quality Improvement Program to Minimize Catheter-Related Bloodstream Infection in an Outpatient Hemodialysis Setting** David B. Van Wyck,[1] Nancy Culkin,[1] Peter J. Pronovost,[2] Christine A. Goeschel,[2] Mahesh Krishnan,[3] Allen R. Nissenson.[1] *[1]DaVita Healthcare Partners, Denver, CO; [2]Johns Hopkins Univ Armstrong Institute for Patient Safety and Quality, Baltimore, MD; [3]DaVita Clinical Research, Minneapolis, MN.*

**Background:** Technical and adaptive approaches from the Johns Hopkins University Armstrong Institute have reduced catheter-related bloodstream infection (CRBSI) in hospitals.

**Methods:** To evaluate whether similar approaches could prevent CRBSI in chronic dialysis patients, we conducted a collaborative, multifaceted, quality improvement program in 26 Maryland-area DaVita hemodialysis facilities. We used the Armstrong Comprehensive Unit-based Safety Program (CUSP) to survey elements of culture and practice in patient safety, adapted tools and interventions for the dialysis setting, and monitored CRBSI rates.

**Results:** The survey was completed by 431/497 teammates (TMs; employees). We found areas for systematic improvement in pre-, intra-, and post-dialysis central venous catheter (CVC) care from the medical literature. We created a procedural kit with checklist, antimicrobial swabs for skin prep, triple-antibiotic ointment for exit site application, alcohol swabs to facilitate hub scrub, and exit site dressing. Another kit/procedural checklist was created for CVC dialysis initiation and termination. To enhance TM engagement, clinics implemented daily team briefings to collectively identify and plan for high-risk patients. TMs charted each new CRBSI episode utilizing a calendar to monitor progress. During the evaluation period, we saw a greater decline in CRBSI rates in project clinics than in non-project DaVita clinics.



**Conclusions:** Safety assessment tools and interventional approaches that reduce CRBSI in hospitals can be successfully applied to reduce CRBSI in chronic dialysis facilities.

## TH-PO328

**Reduction in Catheter-Related Bacteraemia in a Renal Network Using Quality Improvement Methodology** Sajeda Youssouf, Azri Nache, Janet Hegarty. *Salford Royal NHS Foundation Trust, United Kingdom.*

**Background:** Haemodialysis catheter related bacteraemia remains a significant safety issue in HD care. Despite initiatives to increase definitive access, 30% of patients in the UK still use catheters for haemodialysis. In two of our dialysis units we had 36 catheter-related bacteraemias in 12 months at baseline, resulting in 24 admissions, 296 bed days and 3 transfers to level 3 care, despite evidence-based interventions such as antimicrobial line locks to reduce infections.

**Methods:** We sought to improve our catheter-related bacteraemia rate using multifaceted interventions learned from best available evidence and learning from best performing units as part of a quality improvement collaborative over a two year period. We used plan-do-study-act (PDSA) cycles to rapidly introduce small scale changes and implement them fully if successful. This method allowed frontline staff to learn from each other and share their experience of improvement. Successful changes were compiled into a change package for use elsewhere in our network. Data was collected prospectively for a formal evaluation of our work.

**Results:** Our units tested and implemented mutliple changes including: dressing care, exit site and bacteraemia database, traffic light system and an algorithm for high-risk HD catheters, nurse-led anticoagulation protocols and patient information leaflets.

The total number of catheter-related bacteraemias decreased by 83% (36 to 5). There was a significant reduction in admissions (24 to 5) and bed days (296 to 108). No patient required level 3 care. Our bacteraemia rate decreased by 78% from 1.8 to 0.4 per 1000 catheter days ($p<0.01$) over the 2-year cycle. This has been sustained for 7 months since the end of the project, at 0.57 per 1000 catheter days.

**Conclusions:** We have demonstrated a significant improvement in our catheter-related bacteraemia rate. This was achieved by staff being given the responsibility and power to change practice within an improvement framework. Critically, we have also begun to achieve a change in our culture and attitude to preventable harm from bacteraemia. Results obtained with this method are comparable to those achieved in randomised controlled trials of antimicrobial interventions.

## TH-PO329

**Preparation for Renal Replacement Therapy (RRT): Perspectives of Nephrology and Primary Care Providers** Raquel Greer,[1] Jessica M. Ameling,[1] Carrie E. Andrews,[1] Patti Ephraim,[1] Bernard G. Jaar,[1] Kerri L. Cavanaugh,[2] Vanessa Grubbs,[3] L. Ebony Boulware.[1] *[1]Johns Hopkins Univ; [2]Vanderbilt; [3]UCSF.*

**Background:** Early shared decision-making (SDM) and preparation for RRT is recommended for patients with advanced chronic kidney disease (CKD), but many patients continue to initiate RRT urgently with temporary vascular access.

**Methods:** We conducted directed telephone interviews of nephrology providers (n=10, nephrologists, physician assistants, and nurses) and primary care physicians (PCPs, n=4) to identify modifiable challenges to optimal RRT preparation for future interventions. Providers were affiliated with nephrology practices in San Francisco, CA and Baltimore, MD. Using open-ended questions, we assessed providers' perceived: 1) challenges to patients' RRT preparation and 2) role of PCPs and nephrologist-PCP collaboration in patients' RRT preparation. Two independent abstractors coded transcribed audio-recorded interviews and identified major themes.

**Results:** Nephrology providers' most commonly identified challenges focused on patients' difficulty "fully appreciating" the health impact of CKD and the need to prepare for RRT, including patients': 1) denial of CKD severity, 2) fear of dialysis, 3) lack of CKD knowledge, 4) preference for alternative CKD treatment approaches, and 5) low perceived urgency for RRT preparation. Many nephrology providers also cited late referrals from PCPs limited adequate time to build trusting relationships with patients to improve their preparation. PCPs' desired more involvement in preparation to ensure RRT transitions could be as "smooth as possible", but cited several challenges including their: 1) uncertainty of optimal time of nephrology referral and 2) limited RRT knowledge. PCPs desired role was to provide patients with emotional support, help patients weigh RRT options, and affirm nephrologist recommendations. Nephrologists and PCPs desired improved collaboration, including better information exchange and delineation of roles during RRT preparation.

**Conclusions:** Interventions facilitating patients' acceptance of CKD diagnoses and engagement in SDM, as well as nephrology-PCP collaboration may improve patients' RRT initiation outcomes.

*Funding:* NIDDK Support

## TH-PO330

**Development and Evaluation of a Preventive Program for Contrast-Induced Nephropathy: A Quality Improvement Report** Keita Hirano,[1] Kumiko Shimasaki,[1] Kenichiro Koitabashi,[2] Fumika Taki,[1] Masahiko Nagahama,[1] Yasuhiro Komatsu.[1] *[1]Div of Nephrology, Dept of Internal Medicine, St. Luke's International Hospital, Japan; [2]Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Japan.*

**Background:** A prophylactic program for contrast-induced nephropathy (CIN) can prevent acute kidney injury while providing appropriate imaging studies that involve radio-contrast media. We report the effectiveness of a hospital-wide electronic medical record-based CIN prevention program.

**Methods:** We conducted a prospective cohort study including a total of 720 consecutive chronic kidney disease patients being seen on an outpatient basis at the St. Luke's International Hospital (Tokyo, Japan) between April 2012 and March 2013. Admitted patients receiving a CT or those undergoing hemodialysis or emergency CT were excluded (n=507). Our CIN prevention program consists of (1) an automatic alerting system when a physician orders enhanced CT for patients with GFR less than 45 mL/min/1.73m$^2$, (2) an automatic nephrologist referral to order prophylactic hydration and follow-up, and (3) monthly quality indicator (QI) measurements and feedback to physicians. The percentage of patients with eGFR≤45mL/min/1.73m$^2$ who received appropriate prophylactic saline hydration before and after CT and nephrologists' follow-up were selected as quality indicators and were reported monthly.

**Results:** The mean age of the study participants was 73.8±9.6 years and comprised of 65.3% males and an average eGFR of 35.6±10.4 ml/min/1.73m$^2$. Implementation rates of the protocol improved from 0.0% to 40.7%, and the hydration performed rates improved from 20.0% on April 2012 to 74.1% on March 2013. Two patients developed CIN (1.8%). The rate was relatively lower than that of previous studies.

**Conclusions:** To close the evidence-practice gap of contrast-induced nephropathy, hospital-wide prevention programs and monthly QI measurements and reporting can enhance evidence-based practice, reduce the incidence of CIN, and increase the appropriate use of enhanced CT.

## TH-PO331

**Chronic Kidney Disease in Primary Care: Assessing the Role for Sub-Specialty Co-Management** John Andrew Updike, George P. Bayliss. *Medicine, Rhode Island Hospital, Providence, RI.*

**Background:** This study sought to determine whether nephrology sub-specialty co-management of chronic kidney disease (CKD) positively affects adherence to the Kidney Disease Outcomes and Quality Initiative practice guidelines and whether co-management affects screening and treatment independent of CKD severity or identification of disease by the primary care provider as evidenced by a designated ICD-9 code.

**Methods:** A retroactive cohort study of 160 patients with at least one provider visit at the Rhode Island Hospital Medical Primary Care Unit resident trainee clinic between Feb. 1, 2012, and Feb. 1, 2013, with an eGFR<60 ml/min/1.73m$^2$ on two lab draws 3 months apart. Independent variables included age; gender; severity of renal impairment; nephrology sub-specialty referral; co-management correspondence; ICD-9 coding; KDOQI recommended annual assessment of anemia, nutrition, bone health, electrolytes, kidney disease progression; treatment with Angiotensin coverting enzyme inhibitor or receptor blocker.

**Results:** 90% of patients had stage III CKD. 26% were co-managed with nephrology sub-specialists. Documented correspondence was present in only 53% of these patients. Only 54% of patients had ICD-9 codes documenting CKD. Serum creatinine level and the presence of Stage IV CKD demonstrated significant logistic fit between nephrology referrals ($p<0.0001$, $p<0.0001$), co-management ($p<0.0001$, $p<0.0015$) and ICD-9 documentation ($p<0.0003$, $p<0.0018$). There were significant one-way comparisons between ICD-9 documentation and nephrology referrals ($p<0.0001$) and co-management ($p<0.0001$). Multivariate analysis showed nephrology co-management to be an independent predictor of screening for bone health (serum phosphorus, $p<0.037$; serum PTH, $p<0.0088$) and anemia (hemoglobin, $p<0.012$).

**Conclusions:** There are significant correlations between adherence to screening recommendations and identification, documentation and sub-specialist CKD co-management in the primary care setting. Nephrology co-management independently affects bone health and anemia screening. Further work should be directed at assisting medical residents identify patients with stage III CKD and increase the percentage of successful nephrology referrals.

*Funding:* Clinical Revenue Support

## TH-PO332

**Multidisciplinary Intervention Model Is Better Than Conventional Health-Care and Nurse-Coordinated Models in the Management of Early CKD in Type 2 Diabetes Mellitus** Héctor R. Martínez Ramírez, Laura Cortes-Sanabria, Erika Fabiola Gómez-García, Alfonso M. Cueto-Manzano. *Unidad de Investigacion Medica en Enfermedades Renales, Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.*

**Background:** Multidisciplinary approach could optimize care in early CKD. ***Aim:*** to compare the effect of a multiple intervention model (MIM); conventional health-care model (CHCM);nurse-coordinated model (NCM) on lifestyle and renal function of DM2 patients and early CKD.

**Methods:** MIM was carried out in a Family Medicine Unit with patients receiving an educational intervention, by multidisciplinary team: social worker, dietitian, physical trainer and family physician (FP) for 4 wks, and supported by self-help groups; in other unit, NCM were seen by a nurse, focused on individuals' needs; CHCM were managed by FP. Patients had lifestyle, clinical, biochemical evaluations and follow up by 12 months. Max. score of lifestyle questionnaire is 100. All FP had course in early CKD.

**Results:** Comparison of delta results

| Lifestyle Questionnaire | MIM | NCM | CHCM |
|---|---|---|---|
| Knowledge of disease | 2.05 ± 3.5*†£ | 0.17 ± 3.5 | 0.84 ± 3.4 |

| Albuminuria (mg/day) | - 28.1 ± 98.5* | 21.2 ± 139 | 31.9 ± 132 |

*$p$ <0.05 *vs* baseline same group; †$p$<0.05 *vs* same evaluation CHCM; ≤ $p$<0.05 *vs* same evaluation NCM.

**Conclusions:** MIM could improve the lifestyle habits of patients with DM2 and early CKD and preserver better renal function than NCM and CHCM.

## TH-PO333

**PRIMED for Patient Care: Multi-Disciplinary Simulation-Based Team Training Develops Staff Confidence and Skills in Managing Dialysis Emergencies** Laura E.A. Harrison, Katie Fielding, Richard J. Fluck, Lindsay J. Chesterton. *Renal Medicine, Royal Derby Hospital, Derby, United Kingdom.*

**Background:** Emergency situations can occur frequently during haemodialysis (HD) treatments and present a number of specific challenges to ensuring best patient outcomes. Realistic relevant simulation training can improve clinical knowledge and technical skills and strengthen communication and team behaviour, with a resulting improvement in patient safety.

**Methods:** We designed a simulation-based team education programme, PRactical Interdisciplinary Management of Emergencies on Dialysis (PRIMED) training, which has been delivered to over 100 renal staff (53% nurses, 16% doctors, 31% HD support workers). Clinical emergency scenarios take place in the dialysis unit with a Laerdal SimMan® 3G, standard HD machine and a dummy HD treatment. Session format includes facilitated debrief and feedback, with the opportunity for further guided, hands-on practice. Impact on staff confidence and skills was assessed using Likert-based evaluation forms, coupled with audit of weekly emergency buzzer calls.

**Results:** More staff felt confident in their management of emergencies during HD after PRIMED training (70% pre, 89% post). 95% of staff felt the training had a beneficial effect on their clinical practice. Composite confidence score was 44/55 pre-session, 48/55 post-session and 50/55 at follow-up, p=0.04. Staff confidence increased collectively in 2-3 specific areas after individual sessions, dependent on clinical and human factors highlighted in the session, including information handover, management of the HD machine, leadership and decision-making. There was a significant decrease in emergency buzzer use from ≥5/day to 0-3/week.

**Conclusions:** PRIMED is an innovative workplace based simulation programme that aims to equip all renal team members with a structured approach to the recognition, assessment and management of the acutely unwell patient on HD. Implementation has improved confidence across the spectrum of staff involved in dialysis. Frequency of emergency calls has fallen, potentially related to earlier recognition and treatment of unwell patients. Further work is ongoing to assess the impact on patient care and clinical practice.

## TH-PO334

**Podocalyxin Regulates Pronephric Glomerular Development in Zebrafish** Tomoko Obara. *Cell Biology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.*

**Background:** Vertebrate glomerular podocytes possess a highly sialylated transmembrane glycoprotein, Podocalyxin. In mammals, the sialic acid of Podocalyxin plays a crucial role in the formation of the characteristic podocyte architecture required for glomerular filtration.

**Methods:** To explore the possibility, we examined the function of Podocalyxin in the developing zebrafish pronephros by disrupting the expression of *podocalyxin* through the use of morpholino antisense oligonucleotides.

**Results:** Podocalyxin was localized at the apical membrane of podocytes throughout pronephric glomerular development in zebrafish. Translational blocking of *podocalyxin* expression resulted in pericardial edema and a hypoplastic glomerulus. Whereas regular foot processes with a slit diaphragm covered 66.7 ± 7.8% of the urinary surface of glomerular basement membrane, only 14.4 ± 7.5% of this area was covered with regular foot processes in the translationally blocked morphants. Splice blocking of *podocalyxin* exon 2, which partially encodes the bulky mucin domain with extensive sialic acid-containing sugar chains, resulted in the deletion of 53% of mucin domain-coding sequence from *podocalyxin* mRNA. Approximately 40% of these splice-blocked morphants had mild pericardial edema. Although the pronephric glomerulus in the splice-blocked morphants exhibited almost normal appearance with developed glomerular capillaries and mesangium, they had only 36.3 ± 6.9% of the area covered with regular foot processes.

**Conclusions:** Podocalyxin is predominantly expressed in the podocytes and plays a distinct role in the formation of the podocyte foot processes with a slit diaphragm during zebrafish pronephric development.

## TH-PO335

**Zebrafish Pronephros Tubulogenesis Is Reliant on the Polarity Proteins Prkc Iota and Zeta** Gary F. Gerlach, Rebecca A. Wingert. *Dept of Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

**Background:** The zebrafish pronephros provides an excellent in vivo renal system to study the mechanisms of vertebrate nephrogenesis. When and how renal progenitors undergo tubulogenesis to form nephrons is poorly understood, but is known to involve a mesenchymal to epithelial transition (MET) and the acquisition of polarity.

**Methods:** Here, we determined the precise timing of these critical events during pronephros tubulogenesis, and document that lumen formation is preceded by the apical and basolateral segregation of proteins. As the ternary polarity complex is an essential regulator of epithelial cell polarity across tissues, we performed gene knockdown studies to assess the roles of the related factors protein kinase C iota and zeta (prkci, prkcz), which exhibited tight localization to the nephron epithelium apical surface prior to lumen formation and maintained this localization within the fully developed nephron.

**Results:** Nephron epithelial cells in prkci/z morphants had disrupted polarity, with aberrant localization of phospho-ERM and $Na^+/K^+$ ATPase to their respective apical and basolateral domains, and the actin cytoskeleton displayed a disordered arrangement. In addition, prkci/z morphants had dramatic defects in nephron tubule morphogenesis, with the proximal tubule failing to undergo normal convolutions. prkci/z morphants showed several deficiencies in nephron functionality, including abrogated renal clearance and proximal tubule dextran uptake, a measure of endocytosis. Surprisingly, tubule cells in prkci/z morphants displayed ectopic expression of podocyte-specific genes, including wt1a, wt1b, and podx1-like.

**Conclusions:** These data suggest a model in which the redundant activities of prkci and prkcz are essential to establish polarity and also maintain proper epithelial cell-type identity in the nephron tubule. Our studies provide a useful foundation for further analysis of MET during nephrogenesis, and have implications for understanding the pathways that affect nephron epithelial cells during kidney disease and regeneration.

## TH-PO336

**mecom Is Essential for Proximodistal Segmentation and Epithelial Cell Fate Choice in the Zebrafish Pronephros** Yue Li, Christina N. Cheng, Valerie Verdun, Rebecca A. Wingert. *Dept of Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

**Background:** The zebrafish pronephros provides a conserved developmental model to study nephrogenesis, in particular to delineate the poorly understood processes of how nephron segment pattern and cell type choice are established. Zebrafish nephrons are segmented into distinct epithelial regions that include a series of proximal and distal tubules, comprised of intercalated transporting epithelial cells and multiciliated cells (MCC).

**Methods:** The transcription factor MDS1 and EVI1 complex locus (mecom) is broadly expressed in renal progenitors and later restricted to the distal tubule. Here, we show that mecom is necessary to form the distal tubule, and to restrict both proximal tubule formation and MCC fate choice.

**Results:** Previous studies have shown that RA regionalizes the renal progenitor field into proximal and distal domains and that Notch signaling later represses MCC differentiation. We found that mecom and RA have opposing roles in patterning discrete proximal and distal segments. Further, we discovered that RA is required for MCC formation, and that one mechanism by which RA promotes MCC fate choice is to inhibit mecom. Next we determined the epistatic relationship between mecom and Notch signaling, which works by lateral inhibition to limit MCC fate choice. Inhibition of Notch signaling with the γ-secretase inhibitor DAPT revealed that Notch and mecom do not have additive effects in blocking MCC formation, suggesting they function in the same pathway. Ectopic expression of the Notch signaling effector, Notch Intracellular Domain (NICD) rescued the expansion of MCCs in mecom morphants, indicating that mecom activity promotes Notch signaling.

**Conclusions:** Our findings suggest a model in which mecom and RA arbitrate proximo-distal segment patterning, and that MCC fate choice is modulated by a complex interplay in which RA inhibition of mecom, and mecom promotion of Notch, titrates MCC number. Taken together, our studies have revealed several essential and novel roles for mecom during nephrogenesis.

## TH-PO337

**Single-Minded Homologue 1a (sim1a) Mediates Renal Progenitor Patterning during Zebrafish Nephrogenesis** Christina N. Cheng, Rebecca A. Wingert. *Dept of Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

**Background:** During zebrafish development, a functional embryonic kidney known as the pronephros arises from renal progenitors in the intermediate mesoderm. Initial patterning of the renal progenitor field is characterized by the formation of rostral and caudal domains. Once the pronephros is established, it consists of two nephron tubules that have proximal and distal segments mostly similar to mammals like humans—including the proximal convoluted tubule (PCT), proximal straight tubule (PST), distal early (DE), Corpuscle of Stannius (CS), distal late (DL), and a duct. Thus, the zebrafish is a simplified yet conserved model for the study of vertebrate nephrogenesis.

**Methods:** To date, the mechanisms that establish nephron segmentation pattern remain poorly understood. Using whole mount *in situ* hybridization (WISH) to profile renal progenitor gene expression in zebrafish, we discovered that the transcription factor, *single-minded homologue 1a* (*sim1a*), is the initial marker of the renal progenitor caudal domain. *sim1a* expression is dynamic during nephrogenesis and ultimately maintained in both the proximal tubule segments (PCT, PST) along with the cluster of CS progenitors.

**Results:** These findings suggested that sim1a might have roles in nephron segment patterning and CS formation. We performed functional analysis of sim1a using morpholino knockdowns. sim1a deficiency caused an expansion of the PCT and an abrogation of the PST and CS populations. However, the domains of both the DE and DL segments were unchanged. Our results suggest that sim1a activity is necessary to pattern the PST and CS, andmay negotiate the PCT/PST boundary, possibly by inhibiting PCT fate choice.

**Conclusions:** Taken together, our study has revealed novel roles for sim1a during nephrogenesis. These findings provide useful insights into the genetic pathways that direct nephron development, and may have implications for understanding the causes of renal birth defects in humans.

## TH-PO338

**Development of Intercalated Cells Requires Transcription Factor CP2L1** Max Werth,[1] Kai M. Schmidt-Ott,[2] Andong Qiu,[3] Jonathan M. Barasch.[1] *[1]Medicine, Columbia Univ, New York, NY; [2]Max-Delbrueck Center for Molecular Medicine, Berlin, Germany; [3]Tongji Univ, Shanghai, China.*

**Background:** Kidney epithelia derive from metanephric mesenchyme by a process that includes epithelial conversion followed by specification of different epithelial cell types. Little is known about how multiple cell types come to occupy the collecting ducts. Here we investigated a transcription factor that was induced during tubulogenesis.

**Methods:** To identify genes that regulate specific cell types, we created an *in vitro* model of nephrogenesis. We incubated rat metanephric mesenchyme with growth factors (LIF and FGF), and observed the time course of epithelial induction using microscopy and gene expression profiling. We identified 70 transcription factors that were regulated during epithelial conversion. We next over-expressed each of these factors in the metanephric mesenchyme using adeno-viral mediated gene transfer and found that only one transcription factor induced conversion, the Grainyhead family member, Cp2l1. We then generated kidney specific knockout of Cp2l1.

**Results:** During development Cp2l1 was expressed in distal parts of s-shaped bodies and in the ureteric bud. In the adult Cp2l1 was observed in the loop of henle, distal convoluted tubule and collecting ducts. In the conditional knockout we observed the complete absence of alpha- and beta-Intercalated Cells and their markers and instead we observed a monotonous pattern of principal cell-like epithelia. To further investigate Cp2l1 function we compared ChIP-seq with gene expression data from Cp2l1 knockouts. The comparison yielded 82 genes that were significantly downregulated in the knockouts and contained Cp2l1 binding sites within 10KB of the transcriptional start site. Many of these genes were components of mature intercalated cells, confirming a direct role for Cp2l1 in the regulating intercalated cells differentiation. Moreover, both gene expression and ChIP-seq data suggested that Cp2l1 regulates the patterning of Notch signaling throughout the collecting duct.

**Conclusions:** Taking together, this data implicate that Cp2l1 plays a continuing role in the establishment and maintenance of the kidney intercalated cells.

## TH-PO339

**Ureteropelvic Junction Obstructions in Mice with Conditional Inactivation of Exocyst Sec10 in Kidney and Upper Urinary Tract Epithelium** Noemi Polgar,[1] Vanessa H. Lui,[1] Amanda J. Lee,[1] Xiaofeng Zuo,[2] Joshua H. Lipschutz,[2] Ben Fogelgren.[1] *[1]Anatomy, Biochemistry, and Physiology, Univ of Hawaii; [2]Medicine, Univ of Pennsylvania.*

**Background:** Congenital obstructive nephropathy, the most common cause of pediatric chronic kidney disease and ESRD, is caused by obstruction of the urinary tract during fetal development. The most common cause of congenital obstructive nephropathy is ureteropelvic junction obstruction (UPJ obstruction), when the stenosis is localized to the upper urinary tract where the renal pelvis transitions into the ureter. Despite the high prevalence and medical burden of UPJ obstructions, we have a poor understanding of its molecular and genetic basis, with a scarcity of non-surgical genetic animal models.

**Methods:** In previous studies using cell culture models, we have shown the eight-protein exocyst trafficking complex to be critical in maintaining aspects of polarized epithelial cells. To further *in vivo* studies of polarized exocytosis in renal development and disease, we have generated a novel transgenic mouse to conditionally knockout Sec10, a central component of the exocyst. This is the first conditional mouse strain for any exocyst subunit, and should be valuable in studying the exocyst's role in various tissues and diseases.

**Results:** We crossed this floxed-Sec10 strain with the Ksp-Cre mouse strain to induce a knockout in Sec10 specifically in ureteric bud-derived epithelial cells during development. Surprisingly, 90% of the $Sec10^{FL/FL}$;Ksp-Cre conditional knockout mice died quickly after birth, displaying severe bilateral hydronephrosis due to congenital obstructions of the upper urinary tract. From histological analysis, these blockages were due to an overgrowth of the surrounding smooth muscle cells at the UPJ, with complete disappearance of the ureter lumen.

**Conclusions:** This novel transgenic mouse model of UPJ obstruction may be valuable for further studies of the causes and consequences of human congenital obstructive nephropathy.

**TH-PO340**

**Bmp7 Maintains Undifferentiated Kidney Progenitor Population and Determines Nephron Numbers at Birth** Motoko Yanagita,[1] Mayumi Tomita,[1] Misako Asada,[1] Nariaki Asada,[1] Jin Nakamura,[1] Akiko Oguchi,[1] Atsuko Y. Higashi,[1] Shuichiro Endo,[1] Aris N. Economides.[2] *[1]Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [2]Regeneron Pharmaceuticals, Inc., NY.*

**Background:** The number of nephrons, the functional units of the kidney, varies among individuals. A low nephron number at birth is associated with a risk of hypertension and the progression of renal insufficiency. The molecular mechanisms determining nephron number during embryogenesis have not yet been clarified. Germline knockout of bone morphogenetic protein 7 (Bmp7) results in massive apoptosis of the kidney progenitor cells and defects in early stages of nephrogenesis. This phenotype has precluded analysis of Bmp7 function in the later stage of nephrogenesis.

**Methods:** We utilized conditional-null allele of Bmp7 in combination with systemic inducible Cre deleter mice in order to analyze Bmp7 function at desired time points during kidney development. We also employed kidney explants culture system and colony-forming assays to investigate the inhibitory effect of Bmp7 on epithelialization of the kidney progenitor cells.

**Results:** Systemic knockout of Bmp7 in vivo after the initiation of kidney development resulted in the precocious differentiation of the kidney progenitor cells to nephron (glomeruli and tubules), in addition to the prominent apoptosis and the reduction of progenitor cells. Quantitative assessment also confirmed that knocking out of Bmp7 in kidney explants culture resulted in accelerated differentiation of progenitor population, and the same effect could be imparted by inhibiting Smad signaling in wild-type kidney explants. Finally colony-forming assays demonstrated that Bmp7 inhibited epithelialization of the progenitor cells.

**Conclusions:** During embryonic development, Bmp7 acts on progenitor cells as an anti-apoptosis and anti-differentiation factor, and thereby coordinately maintains the renal progenitor pool in an undifferentiated status, and determines the nephron number at birth.

**Preterm Birth: Kidney Size and Function in Early Adulthood** Megan R. Sutherland, Catherine Fallaha, Anne-Laure Lapeyraque, Fanny Huyard, Mariane Bertagnolli, Anik Cloutier, Thuy Mai Luu, Anne Monique Nuyt. *Dept of Pediatrics, Sainte-Justine Univ Hospital and Research Center and the Faculty of Medicine, Univ of Montreal, Montreal, Canada.*

**Background:** Infants born preterm at <29 weeks gestation (term=37 completed weeks) are delivered at a time of active nephrogenesis; postnatally, ongoing renal development is likely impaired. The aim of this study was to determine the long-term impact of preterm birth on renal size and function in early adulthood.

**Methods:** Young adults born preterm at <29 weeks gestation (n=9 male, 11 female), between 1987-1993 (Montreal, Quebec), were compared to age-matched controls born at term (n=7 male, 13 female). Morning blood and urine samples were assessed for creatinine levels and microalbuminuria; GFR was estimated using the MDRD equation. Ultrasonography was performed to measure kidney size, and to determine the resistivity index (RI) of the renal arteries.

**Results:** Subjects born preterm had a significantly greater GFR compared to the term-born controls, particularly the females (males: control 93.8 ± 8.4, preterm 104.8 ± 5.3 ml/min/1.73m$^2$; females: control 107.5 ± 4.8, preterm 140.3 ± 12.2 ml/min/1.73m$^2$). There was no significant difference in the albumin:creatinine ratio between groups (control: 0.70 ± 0.07 mg/mmol; preterm: 0.67 ± 0.09 mg/mmol). Significant reductions in both absolute right (males: control 172.8 ± 18.1, preterm 140.3 ± 5.0 ml; females: control 145.7 ± 9.5, preterm 115.0 ± 8.3 ml) and left kidney volumes were observed in the preterm group. There was also a trend (p=0.08) for decreased relative volume of the right kidney in the preterm group compared to the controls, but no difference in the relative volume of the left kidney. There was no difference between groups in the RI of the renal arteries.

**Conclusions:** In early adulthood, both renal size (significantly reduced) and function (possible hyperfiltration) were affected by preterm birth. In the long-term, these changes have the potential to predispose to renal disease.

*Funding:* Government Support - Non-U.S.

**TH-PO342**

**The Super Kidney: Putting the Foundation for the Future** Ashraf El-Meanawy, Sterling E. Udom, Adil Jadoon. *Medical College of Wisconsin.*

**Background: Nephron loss** is the quintessence of progressive renal disease. Subjects **born** with **low nephron number** are at a disadvantage and have higher risk for kidney disease and hypertension. Prematurity and low birth weight (LBW) are the leading causes for low nephron endowment. The mechanism of low nephron number associate with LBW and prematurity is not known and no interventions exist to increase nephron number. In this work, we show that we identified potential molecular target and we can increase the number of nephrons in mice.

**Methods:** 1)Cells expressing HHIP were exposed to Dimethyloxallyl Glycine (DMOG) or vivo-morpholino and subjected to western blots to evaluate HHIP expression. 2)e12.5 mouse embryonic kidney cultures were exposed to DMOG, room air oxygen, or at 6,9, or 12% oxygen concentration. Cultured kidneys were then stained for ureteric bud (UB) marker calbindin D28K. UB branches were examined using confocal microscopy. 3) Time-pregnant CD1 mice were injected with a vivo-mopholino oligonucleotide against HHIP mRNA or DMOG 1 day before expected delivery. The pops also received the same treatment daily for 2 days after birth. Control mice received saline injections. Mice were sacrificed at 28-32 days of age and nephrons were counted.

**Results:** DMOG and vivo-morpholino knocked down HHIP protein level in cell cultures. Kidney cultures showed increase in ureteric bud branching when cultured under lower oxygen tension or in presence of DMOG. Mice treated with vivo-morpholino oligo specific to HHIP or DMOG showed statistically significant increase in nephron number compared to control animals.

**Conclusions:** Mice are born before termination of nephrogenesis and thus similar to extreme premature humans with regard to kidney development. Extreme premature infants present a future health care challenge as well as therapeutic opportunity. Prematurity causes early termination of nephrogenesis which lead to reduction and nephron number. We provide experimental evidence for potential target and ability to increase number of nephrons in live animals. The kidney with more nephrons might maintain function for longer time against nephron loss stressors and could represent the SUPERKINEY.

*Funding:* Clinical Revenue Support

**TH-PO343**

**Modulation of Maternal Light Exposure Affects Circadian Gene Expression in Fetal Kidneys** Krisztina Meszaros,[1] Linda Pruess,[1] Matthias Gondan,[2] Eberhard Ritz,[3] Franz S. Schaefer.[1] *[1]Center for Pediatrics and Adolescent Medicine, Heidelberg Univ; [2]Institute of Medical Biometry and Informatics; [3]Ruperto Carola Univ of Heidelberg, Germany.*

**Background:** Homeostatic kidney functions oscillate in a circadian manner, based on the oscillatory expression of a 'clock' gene network that controls numerous kidney specific genes regulating key kidney functions such as electrolyte and water excretion *(e.g. αENaC, NHE3, BSC1, AVPR2 and SGK1)*. Whereas alterations of circadian light exposure are known to cause a variety of adverse effects on body functions in adults, little is known about a potential impact on fetal organ development and function. We sought to explore the effect of altered maternal circadian light exposure on the development of oscillatory clock- and clock-controlled gene expression in the fetal kidney.

**Methods:** Pregnant SD rats were randomly allocated to different light patterns (12h:12h (LD), constant light (LL) and constant darkness (DD)) with free access to food and water at constant temperature. Mothers (6-10 per group) with their offspring were sacrificed at 4-h intervals one day before the expected delivery. Intrarenal circadian gene expression patterns were profiled by RT-PCR for the canonical clock genes Clock, Per1, Cry1, Cry2 and the clock-controlled genes αENaC, NHE3, BSC1, AVPR2 and SGK1.

**Results:** Pups from mothers kept at LD displayed circadian expression of the core clock gene ***Clock*** *(p<0.01)* and the clock-controlled genes ***αENaC*** *(p<0.001)* and ***NHE3*** *(p<0.001)*. Kidneys of fetuses from mothers exposed to LL exhibited circadian expression of ***Clock*** *(p<0.01)*, ***Per1*** *(p<0.05)*, ***Cry2*** *(p<0.05)*, ***aENaC*** *(p<0.001)*, ***SGK1*** *(p<0.001)*, ***NHE3*** *(p<0.001)*, ***BSC1*** *(p<0.01)* and ***AVPR2*** *(p<0.05)*. In contrast, fetal kidneys with maternal DD exposure completely lacked circadian fluctuations of intrarenal gene expression.

**Conclusions:** Circadian expression of clock and clock controlled genes is present even before birth in the developing kidney and differentially affected by modulation of light exposure. Maternal exposure to constant light enhances, whereas constant darkness suppresses the development of circadian gene expression in the fetal kidney.

**TH-PO344**

**Abstract Withdrawn**

**TH-PO345**

**The Histone H3K79 Methyltransferase, Dot1l, Regulates the Fate of Ureteric Bud Tip Cells** Fenglin Wang, Xiao Yao, Zubaida R. Saifudeen, Samir S. El-Dahr. *Pediatrics, Tulane Univ School of Medicine, New Orleans, LA.*

**Background:** Ureteric bud tip cells (UB-TC) act as progenitors during branching morphogenesis by generating daughter tip and trunk cells. Current models suggest that UB epithelial progenitors give rise to plastic principal cells, which have the potential to give rise to intercalated cells. This process is restrained epigenetically by the histone H3K79 methlytransferase, Dot1l. The role of Dot1l in UB-TC fate is unknown.

**Methods:** 1. Developmental expression of Dot1l and H3K79me2 was determined by QPCR, immunofluorescence and Western blots; 2. The role of Dot1l in the UB lineage was examined by crossing Hoxb7-Cre:GFP and Dot1$^{(f/f)}$ mice and progeny was examined at E12.5-P1; 3. The renal phenotype was analyzed by section IF and ISH.

**Results:** 1. p63, a master regulator of epithelial cell differentiation in skin and prostate, marks a subset of Ret$^+$ UB-TC. p63$^+$ cells display two distinctive features: transient expression from E17.5-P5 and lack of phospho-H3, a marker of mitosis. P63$^+$ cells are not normally seen in the UB trunk and may represent a progenitor UB-TC population.

2. *Dot1l* and H3K79me2 are developmentally up-regulated and are highly enriched in chromatin of differentiated epithelial cells of the distal nephron.

3. Loss of H3K79me2 in UB lineage increases the number of p63$^+$ UB-TCs; this effect is preceded by premature onset of p63 expression at E12.5, expansion of the *Ret$^+$/Wnt11$^+$* domain, and increased number of dividing (pH3$^+$) cells in terminal ampulla. UB branch number and overall kidney size are not affected by *Dot1l* deletion.

4. At P1, elongating collecting ducts lacking H3K79me2 exhibit ectopic presence of p63$^+$ cells, a lower intercalated cell/collecting duct ratio, and decreased expression of the intercalated cell master regulator, Foxi1.

**Conclusions:** 1. Chromatin-based mechanisms mediated via Dot1l/H3K79 methylation control the terminal differentiation fate of UB-TC; 2. In the absence of Dot1l, $p63^+$ UB-TC proliferate and later populate elongating collecting ducts; 3. Dot1l deletion disrupts the balance between p63 vs Foxi1, which may determine the fate of collecting duct precursor cell types.

## TH-PO346

**Ureteric Bud Branching Is Suppressed by the Loss of Trps1 due to the Activation of TGF-β Signaling** Ting Gui,[1] Yasuteru Muragaki,[2] Gengyin Zhou.[1] *[1]Pathology Dept, The Medical School of Shandong Univ, Jinan, Shandong, China; [2]The First Dept of Pathology, Wakayama Medical Univ, Wakayama, Japan.*

**Background:** We previously found that ureteric bud branching is suppressed in the embryonic kidneys of Trps1-deficient (KO) mice (published in JASN, 2011). However, how Trps1 is involved in UB branching remains unknown.

**Methods:** E11.5 ureteric bud and E12.5 whole kidney culturing exposure with smad3 inhibitor and TGF-b; Trps1 KO mice; DNA array.

**Results:** In the present study, we unveil the molecular mechanisms by which the loss of Trps1 suppresses UB branching. When we compared gene expression patterns via DNA microarray analysis using cultured ureteric buds isolated from E11.5 kidneys of WT and KO embryos, we found aberrant expression of genes associated with the transforming growth factor (TGF)-b/Smad3 signaling pathway in the KO UBs. Western blot and immunohistochemistry analyses showed increased levels of Rb1cc1, Arkadia1, and phosphorylated Smad3 and decreased levels of Smurf2, Smad7, and c-Ski in the KO embryonic kidneys. In addition, TUNEL staining and immunohistochemical detection of PCNA revealed that the apoptosis of UB cells was upregulated and, conversely, that cell proliferation was suppressed. Finally, we demonstrated that the suppression of UB branching in the KO UBs was restored by the exogenous addition of the Smad3 inhibitor SIS3, whereas the addition of TGF-b1 accelerated the suppression of UB branching in organ cultures of both isolated UBs and whole embryonic kidneys.

**Conclusions:** Considering these results, we conclude that UB branching is suppressed through increased activation of the TGF-b/Smad3 signaling pathway when Trps1 is lost.

## TH-PO347

**Unraveling the Molecular Mechanisms Regulating Principal Cell Differentiation** Kameswaran Surendran,[1,2] Justin J. Grassmeyer,[1] Malini Mukherjee.[1] *[1]Children's Health Research Center, Sanford Research/USD, Sioux Falls, SD; [2]Dept of Pediatrics, Sanford School of Medicine, Sioux Falls, SD.*

**Background:** The mammalian collecting ducts are composed of principal and intercalated cell types that arise from a common precursor. Studies in mice identified *Mind bomb-1* (*Mib1*), a mediator of Notch and Wnt signaling, to be critical for principal cell differentiation. Mice with *Mib1* deficient collecting ducts develop symptoms similar to patients with mutations in *Aquaporin-2* (*Aqp2*) and *arginine-vasopressin receptor 2* (*Avpr2*) who suffer from nephrogenic diabetes insipidus (NDI). Considering defective principal cell differentiation can result in NDI, our goal is to identify genes regulating principal cell differentiation. For this purpose we analyzed mice in which *RBPJ* and hence Notch signaling is inactivated in developing collecting ducts.

**Methods:** We compared the following between wild-type littermates and mice with RBPJ-deficient collecting ducts: number of principal and intercalated cells by immunohistochemistry and quantitative(q) RT-PCR, urine concentrating capacity,gene expression profiles using Illumina mouse bead chips, and expression pattern of Elf5 using $Elf5^{+/LacZ}$ mice. We ectopically activated Notch1 in the developing collecting ducts of mice and measured *Elf5* mRNA levels by qRT-PCR.

**Results:** Collecting duct inactivation of *RBPJ* increased intercalated and, diminished principal cell number, and reduced urine-concentrating capacity. Comparison of gene expression profiles of wild-type developing kidneys and those with Notch signaling deficient collecting ducts revealed a total of 180 differentially expressed genes by at least 1.25-fold in wild type versus mutant kidneys with $p<0.05$. One of the down-regulated genes is Elf5, which we observe is expressed in principal cell lineage prior to Aqp2. Ectopic Notch activation in developing collecting ducts results in precocious Elf5 expression.

**Conclusions:** Notch/RBPJ signaling regulates principal cell fate selection to ensure proper water homeostasis.Elf5 is an early principal cell lineage marker activated in a Notch signaling dependent manner and is a candidate regulator of principal cell differentiation.

## TH-PO348

**Dicer Ureteric Bud Mutant Analysis: New Insights in Mammalian Kidney Development** Vidya Nagalakshmi Kusma Harinathan, Jing Yu. *Dept of Cell Biology, Univ of Virginia, Charlottesville, VA.*

**Background:** In order to understand the ureteric bud (UB)-derived microRNAs (miRNAs) in mammalian kidney development, we have generated a conditional *Dicer* UB mutant with a *HoxB7Cre* driver line. Our earlier mutant phenotype analyses imply a critical role for miRNAs in UB branching and tubule size control. The present study aims at identifying the target genes up-regulated in *Dicer* UB mutants and analyzing the UB- expression pattern of up-regulated transcripts during various stages of embryonic kidney development.

**Methods:** Our combined approach involved, transcriptional profiling, *in situ* hybridization, and bioinformatics analyses on some of the potential miRNA target genes up-regulated in *Dicer* UB mutants.

**Results:** We have observed that some of the potential miRNA target genes up-regulated in *Dicer* mutants are spatially and temporally restricted during kidney development. We identified, for the first time, temporally regulated genes in the wild-type UB epithelium whose expression is present in the UB epithelia during early stages and absent in later stages of kidney development. Moreover, this temporal regulation is subjected to miRNA regulation, as in *Dicer* mutants expression of these genes persists into later stages. Further analysis on mechanistic roles of these temporal genes in kidney development is underway and this will help us to understand the intricate developmental processes occurring at cellular level in UB epithelial morphogenesis and the importance of miRNAs in their regulation during kidney development.

**Conclusions:** In summary, our study demonstrated the requirement of UB-derived, *Dicer*-dependent miRNAs in mammalian kidney development and revealed a previously unrecognized developmental phenomenon which implicates miRNAs in temporal control of mammalian UB development.

## TH-PO349

**A Grainyhead-Like 2/Ovo-Like 2 Pathway Regulates a Transcriptional Network That Controls Collecting Duct Lumen Size** Janett Ruffert,[1,2] Annekatrin Aue,[1,2] Christian Hinze,[1,2] Katharina Walentin,[1,2] Max Werth,[1,2] Jonathan M. Barasch,[3] Andong Qiu,[3] Kai M. Schmidt-Ott.[1,2] *[1]Max Delbrück Center for Molecular Medicine, Berlin, Germany; [2]Dept of Nephrology, Charité-Universitätsmedizin Berlin; [3]Dept of Medicine, Columbia Univ College of Physicians and Surgeons, New York.*

**Background:** The molecular and cellular mechanisms that govern tubular lumen size regulation may provide critical insights into the pathogenesis of kidney diseases. The transcription factor grainyhead-like 2 (Grhl2) is expressed in epithelial cells of the ureteric bud and the distal nephron.

**Methods:** To investigate the role of Grhl2 in the renal collecting duct (CD) we bred Hoxb7/Cre; $Grhl2^{flox/-}$ mice, which exhibit a deletion of functional Grhl2 protein in most cells of the CD. For further analysis of Grhl2 function in CD epithelia, we generated inner medullary collecting duct (IMCD3) cells with a lentiviral knockdown of Grhl2.

**Results:** A closer examination of the CD in Grhl2-deficient mice revealed that the papillary CD lumen area was markedly reduced at 4 weeks of age. In three-dimensional culture, IMCD3 cells formed cysts of polarized epithelial cells enclosing a central lumen. However, in Grhl2 knockdown cells lumen formation was perturbed resulting in cysts with a markedly reduced lumen area. Genome-wide screening for Grhl2 targets by microarray analyses of Grhl2-deficient IMCD3 cells and chromatin immunoprecipitation with next generation sequencing in IMCD3 cells and kidneys revealed that Grhl2 regulates multiple genes involved in epithelial junction formation and polarity, as well as other transcription factors including the gene encoding the zinc-finger transcription factor ovo-like 2 (Ovol2). Ovol2 expression was markedly reduced in IMCD3 cells following Grhl2 knockdown and in Hoxb7/Cre; $Grhl2^{flox/-}$ kidneys. Overexpression of Ovol2 in Grhl2 knockdown cells rescued cystic lumen formation. Microarray analyses of Grhl2 knockdown cells overexpressing Ovol2 showed reconstitution of the transcription levels for the majority of Grhl2-dependent genes.

**Conclusions:** Our data thus indicate a novel Grhl2/Ovol2 pathway that controls a transcriptional network governing collecting duct lumen size regulation.

## TH-PO350

**Tissue Specific Knockout of Dragon in Collecting Duct Leads to Urinary Concentrating Defect** Wenjie Chen,[1] Richard Bouley,[1] Dennis Brown,[1] Yin Xia,[2] Herbert Y. Lin.[1] *[1]Program in Membrane Biology, Div of Nephrology, Center for Systems Biology, Massachusetts General Hospital, Harvard Medical School, Boston, MA; [2]Program in Reproduction, Development and Endocrinology, The Chinese Univ of Hong Kong, Hong Kong, China.*

**Background:** Dragon, encoded by the *RGMB* gene, acts as a bone morphogenetic protein (BMP) coreceptor that enhances BMP signaling. The Dragon global knockout mouse dies 2-3 weeks after birth (Ma et al. 2011). In a previous study, we showed that Dragon localized predominantly to the apical surfaces of tubular epithelial cells in the thick ascending limbs, distal convoluted tubules, and collecting ducts of mice, and may play a role in maintaining tight junction integrity in these cells (Xia et al. 2010).

**Methods:** To further investigate the role of Dragon in kidney function, we generated the Dragon-Floxed mouse and crossed this line with the HoxB7-Cre mice, to generate the collecting duct conditional knockout mice Dragon (cd/cd) with a C57BL6/CD-1 mixed genetic background.

**Results:** The 6-week old Dragon (cd/cd) mice had increased volume of urine by 54 percent and water intake by 18 percent, and had decreased urine osmolarity by 28 percent compared to control mice. Interestingly, real-time PCR analysis showed that AQP2 mRNA levels were decreased by 20 percent in Dragon (cd/cd) mice. In addition, in some Dragon (cd/cd) mice the papilla was grossly hypomorphic.

**Conclusions:** We hypothesize that Dragon regulates the development of the collecting duct and the expression of AQP2 and urine concentration in the kidney.

## TH-PO351

**The Ureteric Bud Epithelium-Derived Cdc42 Regulates Fzd4/8 Expression and Ureteric Bud Branching Morphogenesis during Mammalian Kidney Development** Qun Ren, Jing Yu. *Cell Biology, Univ of Virginia, Charlottesville, VA.*

**Background:** Cdc42 is a ubiquitously expressed small GTPase belonging to the Rho family. Active Cdc42 regulates a wide variety of cellular function and affect multiple cellular processes such as establishing and maintain cell polarity and regulate epithelial morphogenesis. However, its role in the ureteric bud epithelium during kidney development has not been examined.

**Methods:** To address this issue, we specifically ablated Cdc42 function from the ureteric bud epithelium with Hoxb7cre (referred to as Cdc42 mutants).

**Results:** This genetic manipulation led to neonatal lethality within 48 hours post-partum. The mutant kidneys were hypoplastic and exhibited cystic dilatation, and were defective in principal and intercalated cell differentiation. Ureteric bud branching morphogenesis was compromised as early as E12.5, and expression of Fzd4 and Fzd8 in the ureteric bud epithelium was greatly reduced. Interestingly, apico-basal polarity of the ureteric bud epithelium was unaffected, nor was the apical localization or phosphorylation of aPKC , indicating that Cdc42 does not regulate apico-basal polarity of the ureteric bud epithelium and does not employ aPKC as its effector in the ureteric bud epithelium. Instead, PAK1 phosphorylation was reduced significantly in the ureteric bud epithelium. Consistent with a role of PAK in mediating Cdc42 function in the ureteric bud epithelium, inhibition of the PAK activity disrupted ureteric bud branching morphogenesis.

**Conclusions:** Our work demonstrates that Cdc42 regulates the expression of Fzd4/8 in the ureteric bud epithelium and is required for kidney branching morphogenisis,most likely through its effector PAK1.

## TH-PO352

**Ureteric Bud (UB) Prorenin Receptor (PRR) Is Essential for Normal Collecting Duct (CD) Development and Function** Renfang Song, Graeme James Preston, Ihor V. Yosypiv. *Pediatrics, Tulane Univ School of Medicine, New Orleans, LA.*

**Background:** We tested the hypothesis that targeted inactivation of the *PRR in the UB epithelia using Hoxb7$^{Cre}$ (PRR$^{UB-/-}$) is essential for normal CD development and function.*

**Methods:** UB-specific knockout of PRR was confirmed by qRT-PCR analysis which revealed an 80% decrease in PRR mRNA levels in E11.5 intact UBs (iUBs) isolated from PRR$^{UB-/-}$ compared with PRR$^{UB+/+}$ mice (0.19±0.03 vs. 1.0±0, p<0.001).

**Results:** In situ hybridization and immunohistochemistry demonstrated reduced expression of Aqp2, Foxi1, $H^+$-ATPase α4 and AE1 in mutant CDs on E18.5. On P1, kidney weight (15.6±0.45 vs. 24.5±0.43 mg, p<0.001) and kidney-to-body weight ratio (3.77±0.09 vs. 5.90±0.26 mg/g, p<0.01) was lower in mutants than in controls. Histological examination demonstrated the presence of cysts in collecting ducts, dilation of proximal tubules and decreased glomerular number in mutants. On P30, kidney weight (130±5.8 vs. 280±20 mg, p<0.001) and kidney-to-body weight ratio (7.9±0.23 vs. 16.2±0.6 mg/g, p<0.01) was lower in mutants than in controls. On P30, dilated CDs with thin epithelial layer were observed in PRR$^{UB-/-}$ kidneys. To test the functional consequences of the deficiency of the collecting duct PRR, we examined renal function, urinary volume, osmolality and pH on P30. Mutant mice had increased levels of serum creatinine (237±0.13 vs. 59±14 μmol/l, p<0.001). Despite similar water intake (2.5±0.37 vs. 2.2±0.36 ml, p=0.52), 24-hour urine volumes were higher (3.2±0.32 vs. 2.2±0.24 ml, p<0.05) and urine osmolalities were lower (830±39 vs. 1645±160 mg, p<0.001) in mutants compared with controls. Baseline urine pH did not differ between PRR$^{UB-/-}$ and PRR$^{UB+/+}$ mice (6.40±0.05 vs. 6.52±0.17, p=0.51). Acidic loading with $NH_4Cl$ resulted in a decrease in urine pH in control (6.40±0.05 vs. 6.02±0.12, p<0.05) and no change in urine pH in mutant (6.52±0.17 vs. 6.50±0.13, p=0.91) mice.

**Conclusions:** We conclude that UB/collecting duct PRR is essential for kidney morphogenesis, differentiation and acquisition of function by collecting duct cells involved in water and acid-base homeostasis.

## TH-PO353

**Mutations in Renin-Angiotensin System (RAS) Genes Are Associated with Isolated Multicystic Dysplastic Kidney (MCDK) in Children** Renfang Song, Graeme James Preston, Ihor V. Yosypiv. *Pediatrics, Tulane Univ, New Orleans, LA.*

**Background:** To determine whether MCDK is linked to mutations in RAS genes, we amplified the coding exons and the adjacent intronic sequences of the RAS genes by PCR: renin (9 exons), angiotensinogen (AGT, 5 exons), ACE (26 exons) and angiotensin 1 receptor (AT1R) (1 exon).

**Methods:** DNA was extracted from peripheral blood of 10 unrelated patients with MCDK diagnosed by renal ultrasonography (US) (mean age 8.5±1.1 years) and pooled healthy race-, age- and sex-matched controls according to standard procedures. 6 patients with MCDK were females and 4- males. Left kidney was affected in 6 cases. Renal function in all affected individuals was normal. Absence of MCDK or other renal anomalies in controls was confirmed by US. Both strands of PCR products were sequenced using dideoxy chain termination method on a 373A DNA sequencer (Applied Biosystems). The effect of mutation on protein function was predicted with PolyPhen-2 software.

**Results:** 9 novel mutations in *RAS* genes were found in 6 patients with MCDK. 3 novel and known heterozygous *AGT* mutations were found. 1 variation was probably damaging, 1 was possibly damaging and one was benign. 7 heterozygous *renin* mutations were found. 3 were probably damaging and 4 were benign. 6 heterozygous ACE mutations were found. 3 mutations were probably damaging and 3-benign. 3 heterozygous *AT1R* mutations were found. 2 variations were possibly damaging and one was benign.

**Conclusions:** In summary, we report novel associations of mutations in the genes encoding renin, AGT, ACE or AT1R with isolated MCDK in children in the United States. These findings highlight the crucial role of the RAS in the pathogenesis of MCDK in children.

## TH-PO354

**Dual Loss of Par-1a/b Proteins Leads to Altered Proximal Tubular Epithelial Cells Polarity in Murine Kidneys** Oleh M. Akchurin,[1] Nadira Ramkellawan,[1] Zhongfang Du,[1] James M. Pullman,[1] Anne Muesch,[1] Katalin Susztak,[2] Kimberly J. Reidy.[1] *[1]Albert Einstein College of Medicine; [2]Univ of Pennsylvania.*

**Background:** Par-1 is a member of the "partitioning defective" family of proteins, which are required to establish columnar epithelial cell polarity in vitro, but their role in kidney epithelial polarity in vivo has not been described. Par-1 has four mammalian homologues (Par-1a, -1b, -1c, and -1d), and complete loss of both Par-1a and -1b is early embryonic lethal. We have previously shown that all 4 homologues of Par-1 are expressed in the developing kidney, and block of Par-1 signaling inhibited growth of metanephric mesenchymes in vitro. We **hypothesized** that Par-1a/b are required for establishing renal epithelial polarity and normal kidney development in vivo.

**Methods:** Double-heterozygous Par-1a/b mutant mice were bred and offspring were sacrificed on day 1 of life. Par-1a-/-Par-1b+/- (Par1a/b KH) and Par-1a+/-Par-1b-/- (Par1a/b HK) genotypes were compared to the wild type (WT).

**Results:** Par-1a/b HK kidneys appear hypoplastic with a reduced kidney weight to body weight ratio (3.3±0.5 mg/g HK vs. 5.9±0.3 mg/g WT; p<0.002). A dilated renal pelvis was observed in 20% of the Par-1a/b KH mice, suggestive of ureteric bud branching defects. Grossly visible cysts were identified in a subset of Par-1a/b KH mice. On light microscopy, Par-1a/b KH mouse kidneys had dilated cystic tubules. Immunofluorescence (IF) labeling demonstrated that dilated tubular structures were LTL-positive and DBA-negative, suggesting that they originate from the proximal tubule. We also observed a decreased megalin expression in Par-1a/b KH proximal tubules and drastically reduced surface expression of E-cadherin. Preliminary results of IF labeling with acetylated tubulin suggest absence of the primary cilia in cysts and shorter primary cilia in Par-1a/b KH mice compared with a WT.

**Conclusions:** Par-1a/b are required for proper apical-basal polarity in vivo and contribute to normal kidney development. Par-1a/b gene deletion leads to renal hypoplasia and cystic dilatation of the proximal tubules. Ongoing studies are examining the mechanisms by which Par-1a/b contribute to cystogenesis and kidney development.

## TH-PO355

**Hypoxia Inducible Factor-1a Regulates Branching Morphogenesis in Kidney Development without Ureteric Bud Cell Proliferation** Kenji Tsuji, Shinji Kitamura, Hitoshi Sugiyama, Hirofumi Makino. *Medicine and Clinical Science, Okayama Univ Graduate School of Medicine, Okayama, Japan.*

**Background:** Embryos are exposed under hypoxia ($O_2$ 2-9%) in developing stage. During kidney development, GDNF signaling from metanephric mesenchyme through Ret and GFR-a1 is the common pathway involved in ureteric bud (UB) branching which is related to GFR associated nephron numbers. It has been reported that hypoxia-inducible factor (HIF)-1a makes an important role for development. However there are few reports about the relationship between HIF-1a and UB branching. Here we examined whether HIF-1a regulates the UB branching on renal development or not.

**Methods:** We harvested embryonic 13 days kidneys (E13Ks) from pregnant rats and cultured under normoxia (20% $O_2$ / 5% $CO_2$) or hypoxia (5% $O_2$ / 5% $CO_2$). We evaluated the kidneys on the point of morphology and gene expression. We also examined UB cell proliferation under normoxia or hypoxia using electric cell-substrate impedance sensing (ECIS) method.

**Results:** The number of ureteric end buds of cultured E13Ks under hypoxia significantly increased compared to under normoxia (the numbers of end buds under hypoxia v.s. normoxia; 57.7±12.5 v.s. 40.6±6.6/ kidney, p<0.01). Quantitative RT-PCR revealed increased GDNF, GFR-a1, RET and FGF10 mRNA level in cultured E13Ks under hypoxia compared to under normoxia. When we cultured E13Ks under hypoxia with HIF-1a inhibitor (digoxin), we could not observe increased UB branching (the numbers of end buds under hypoxia v.s. hypoxia with digoxin; 57.7±12.5 v.s. 41.5±7.5/ kidney, p<0.01). Direct inhibition of HIF-1a using siRNA decreased UB branching during E13Ks culture under hypoxia (the numbers of end buds under hypoxia v.s. hypoxia with HIF-1a siRNA; 57.7±12.5 v.s. 39.0±4.76/ kidney, p<0.01) and GDNF, GFR-a1 mRNA level significantly. In addition, UB cells under hypoxia proliferated significantly less than under normoxia in vitro.

**Conclusions:** HIF-1a regulates branching morphogenesis via GDNF/RET and/or FGF10 signal pathway without UB cell proliferation.

## TH-PO356

**Whole Exome Profiling Identifies Biological Processes Modified by Ebf1 during Podocyte Maturation** Jackie A. Fretz. *Orthopaedics and Rehabilition, Yale School of Medicine, New Haven, CT.*

**Background:** We previously identified Early B Cell Factor 1 (Ebf1) as a gene up-regulated in podocytes during the final stages of postnatal murine nephrogenesis. Deficiency of this transcription factor results in a unique phenotype of abrogated glomerular development that disproportionately effects peripheral glomerular development. Although this coincides with the late expression profile of Ebf1 in podocytes, it raised intriguing questions regarding the function of Ebf1 in the development of peripheral vs. juxtamedullary glomeruli.

**Methods:** To address these questions we performed RNA-seq to compare expression profiles of Ebf1-replete and Ebf1-deficient podocytes at three separate postnatal times: P2, 14, and 21. Samples were compared between genotypes and across time for multivariate analysis.

**Results:** Several podocyte-related markers including Pod1/Tcf21 and Lmx1b, were identified showing the specificity for the selected cells. The most similar populations were P0 podocytes from Ebf1-replete and –deficient cells. P14 and P21 Ebf1-replete podocytes were the next most closely related populations, and also more like the P0 podocytes than deficient cells at P14 or P21.

**Conclusions:** Analysis of the biological processes affected by Ebf1-deficiency identified modification in extracellular matrix formation, cell adhesion and locomotion, Wnt signaling, and neuronal development. Many of these processes have been shown previously to be essential for proper podocyte differentiation. Additionally, enrichment of processes involved in skeletal development and lipid metabolism were identified. These correlate to other known functions of Ebf1 in disparate cell lineages, and may identify conserved functions of this transcription factor in multiple cell types.

*Funding:* NIDDK Support, Other NIH Support - NIAMS

## TH-PO357

**The Role of miR-222 in Glomerular Development by Targeting NPM1** Shiying Cui,[1] Yanfang Ding,[1] Jinyao Zhao,[1] Xian Wu,[1] Guang Wang,[1] Mingyi Cui,[2] Tianbai Li.[1] *[1]Dalian Medical Univ, Dalian, China; [2]The Fourth People's Hospital, Liaoyang, China.*

**Background:** MicroRNA (miRNA) has been implicated in the regulation of organic development processes through repression of specific mRNAs at the posttranscriptional stage. The purpose of this study is to define a miRNA expression signature in glomerular development, and verify the function of miRNA-target in developing and developed glomeruli.

**Methods:** To reach this goal, mouse kidneys at the developed (P28) and developing (E18.5) stages, and podocytes (MPC-5) at undifferentiated (33'C) and differentiated (37'C) status were used in the study. Total RNA and protein were purified from glomeruli that were isolated from the kidneys at both developing and developed stages. MicroRNA microarray, Western Blotting, quantitative Real-Time Polymerase Chain Reaction (qRT-PCR), and immunohistochemistry were further performed.

**Results:** Of the 224 mouse miRNAs analyzed in the microarray, 62 were significantly expressed, and 39 with at least 2-fold difference in the glomerulus at P28 compared to E18.5. Target prediction from three bioinformatics softwares showed that the 803 targets of all key miRNAs had functions being relevant to cellular development. Of which, the reciprocal expression of miR-222- NPM1 (Nucleophosmin 1) , a pair of miRNA-target predicted, was validated by qRT_PCR, immunohistochemistry and western blotting in vivo, and further confirmed by miR-222 overexpression and luciferase reporter assays in vitro. The function of miR-222 by targeting NPM1 in podocyte proliferation and migration was finally verified in MPC-5 cells.

**Conclusions:** This study may advance the current level of understanding of miRNAs in glomerular development.

*Funding:* Government Support - Non-U.S.

## TH-PO358

**MicroRNAs Are Critical Regulators of FOXD1 Progenitors and Kidney Stroma during Nephrogenesis** Naoki Nakagawa,[1] Allie M. Roach,[1] Ivan G. Gomez,[1] Akio Kobayashi,[2] Jeremy Stuart Duffield.[1] *[1]Renal Div, Kidney Research Institute, Univ of Washington, Seattle, WA; [2]Harvard Stem Cell Institute, Boston, MA.*

**Background:** Recent studies have identified important roles for post-transcriptional regulators including microRNA in nephron development and in adult kidney diseases but the importance of microRNA in regulating stromal cell functions has not been explored and stromal functions in nephrogenesis remain ill-defined.

**Methods:** In order to study the function of kidney stromal cells, and the importance of post-transcriptional gene regulation in kidney stroma, during nephrogenesis, we mutated the microRNA activating enzyme *Dicer-1*, specifically in stromal cells that derive from *Foxd1* expressing kidney progenitors of the nephrogenic interstitium.

**Results:** *Dicer-1* mutants were born at less than expected Mendelian ratios, and surviving pups died shortly after birth. There was a striking reduction in kidney volume and absence of urine production. Histological examination revealed highly disorganized tubular and microvascular compartments as well as glomerular abnormalities. Elongation and differentiation of the loop of Henle was attenuated resulting in absence of inner medulla and papilla, and polarization of proximal tubules was impaired with loss of brush border. Peritubular capillary formation was disorganized with large highly branched capillaries, indicating that mesenchymal cells are necessary for correct blood vessel formation. These phenotypic changes were associated with evidence of reduced activation of stromal cells and lack of segmentation of the stroma. In addition Foxd1 is activated after nephrogenesis in podocyte progenitor epithelium, where Foxd1 and dicer activity in podocyte progenitors are necessary for differentiation into mature podocytes.

**Conclusions:** We conclude that microRNA post-transcriptional gene regulation is critical in *Foxd1* progenitor derived kidney stroma functions in nephrogenesis. These studies highlight the strategic importance of kidney stroma in organogenesis.

## TH-PO359

**Soluble Form of Angiotensin-Converting Enzyme (ACE) Is Enough for Kidney Development, but Not to Maintain Blood Pressure** Michifumi Yamashita,[1,2,3] Saurabh Chattopadhyay,[3] Ganes C. Sen.[2,3] *[1]Pathology, Univ Hospitals Case Medical Center, Cleveland, OH; [2]Pathology, Case Western Reserve Univ, Cleveland, OH; [3]Molecular Genetics, Lerner Research Institute, Cleveland Clinic, Cleveland, OH.*

**Background:** ACE, a central component of Renin-Angiotensin System (RAS), is essential for kidney development and blood pressure (BP) regulation. ACE-/- mice show glomerular and tubular hypoplasia, and low BP. There are two forms of ACE: membrane-bound form and soluble form. ACE is expressed on the cell surface as type I ectoprotein, with enzymatically active ectodomain, transmembraine domain, and short cytoplasmic domain. The ectodomain can be cleaved to generate the soluble form. These two forms are equally enzymatically active. We reported (Kessler SP, et al. JBC 2003) membrane-bound ACE in the vascular endothelial cells is enough for kidney development as well as normal blood pressure. Here we investigate the roles of the soluble ACE in kidney development and renal functions.

**Methods:** We generated transgenic (TG) mice with Tie-1 promoter-driven expression of the soluble ACE in the background of ACE-/- mice, and analyzed the mice morphologically and physiologically, as well as at molecular level.

**Results:** The expressed ACE protein lacked the transmembrane and the cytoplasmic domains, and was constitutively secreted into the blood stream. The TG mice showed normal kidney structure grossly and microscopically. The urine output, water intake, and urine osmolarity were normal. However, TG mice showed still low BP compared to Ace+/+ wild type (WT) mice. The local RAS activity in kidney from TG mice was similar to WT mice: Renin and Angiotensin II in the kidney tissue from TG mice were comparable to WT mice, although TG mice did not show any ACE expression in kidney tissue. The systemic RAS activity was also similar between two groups: plasma renin activity, serum ACE activity, and plasma Angiotensin II level did not show significant difference between the two groups.

**Conclusions:** Soluble ACE is enough for kidney development, but not to maintain BP. The cytoplasmic domain of ACE in vascular endothelial cells, and its signaling might be important for BP regulation.

*Funding:* Other NIH Support - National Heart, Lung, and Blood Institute, R01HL048258

## TH-PO360

**The bHLH Transcription Factor Tcf21 Is Required for Differentiation and Maintenance of Podocytes in Development, Health and Disease** Yoshiro Maezawa,[1] Tuncer Onay,[1,5] Rizaldy P. Scott,[1] Lindsay S. Keir,[2] Henrik Dimke,[1] Chengjin Li,[1,5] Vera Eremina,[1] Asish Ghosh,[5] Jeffrey H. Miner,[3] Seppo Vainio,[4] Susan E. Quaggin.[1,5] *[1]SLRI, Toronto, Canada; [2]Uniersity of Bristol, United Kingdom; [3]Washington Uniersity, St. Louis; [4]Biocenter Oulu, Finland; [5]Feinberg Cardiovascular Research Institute and Div of Nephrology, Northwestern Univ, Chicago.*

**Background:** Tcf21 is a bHLH transcription factor essential for embryonic development. Global Tcf21 knockout (gl-KO) mice die minutes after birth with hypoplastic lungs and tetralogy of Fallot. In kidneys of glo-KO mice, mesenchyme-to-epithelial transformation, branching morphogenesis and nephrogenesis are arrested.

**Methods:** In addition to mesenchymal expression, Tcf21 is expressed in embryonic and adult podocytes. To examine the role of Tcf21 in podocytes, we created a conditional allele for Tcf21 and crossed them to PodocinCre (pod-KO) and Wnt4-Cre mice resulting in deletion of Tcf21 from differentiated and progenitor podocyte populations, respectively.

**Results:** Pod-KO mice don't exhibit overt defects in podocyte differentiation, but the glomerular structure is greatly simplified with decreased endothelial and mesangial cells. By 4 weeks of age, 30-40% of Pod-KO mice develop FSGS-like lesions and massive proteinuria, while 60% of mice never develop proteinuria. Microarray analysis of glomeruli from Pod-KO mice revealed candidate downstream targets, including Vegf, Pgf and Wif1. ShRNA knockdown of Tcf21 in human podocytes results in altered cell shape and migration. Earlier deletion of Tcf21 from podocyte precursors (Wnt4-Cre) leads to columnar shaped podocytes, aberrant distribution of Podocin and defects of mesangial migration, suggesting more profound defect of podocyte differentiation. Strikingly, induction of diabetes in the non-proteinuric Pod-KO mice results in increased proteinuria, suggesting a protective role for Tcf21.

**Conclusions:** Our results demonstrate a critical role for Tcf21 in the differentiation and maintenance of podocytes in both developing and mature kidneys. Identification of direct targets of this transcription factor may provide new therapeutic targets for proteinuric renal disease including diabetic nephropathy.

*Funding:* Government Support - Non-U.S.

## TH-PO361

**Maternal Diabetes Impairs Nephrogenesis via Augmented Hedgehog Interacting Protein (Hhip) Gene Expression** Xin-Ping Zhao,[1] Min-Chun Liao,[1] Shiao-Ying Chang,[1] Shaaban Abdo,[1] Yessoufou Aliou,[1] Isabelle Chenier,[1] Julie R. Ingelfinger,[2] Shao-Ling Zhang.[1] *[1]CRCHUM-Hotel Dieu, Univ of Montreal, Montreal, Canada; [2]Pediatric Nephrology Unit, Massachusetts General Hospital, Boston, MA.*

**Background:** We hypothesized that maternal diabetes impairs nephrogenesis via augmented hedgehog interacting protein (Hhip) gene expression, given screening gene arrays (Affymetrix GeneChip Mouse Gene 1.0ST array platform) we had performed had indicated that Hhip was significantly modulated by maternal diabetes.

**Methods:** We created an in vivo murine model using kidneys from the suckling pups of non-diabetic, diabetic, and insulin-treated diabetic dams. MK4 (an embryonic late metanephric mesenchymal (MM) cell line) and ureteric bud (UB) cell lines, were used for *in vitro* studies.

**Results:** Kidneys of the offspring of diabetic dams as compared to the control offspring displayed features suggesting retarded nephrogenesis, such as small kidneys and less UB branching morphogenesis. Augmented Hhip expression was observed on the offspring of diabetic dams, initially localized to the differentiated MM and UB epithelium, and then in maturing glomerular and tubulointerstitial cells. We also observed heightened Hhip active transforming growth factor beta 1 (TGFβ1) signaling, associated with dysmorphogenesis in these offspring. The *in vitro* studies demonstrated that Hhip overexpression decreased sonic hedgehog (Shh) and paired box gene 2 (Pax2) expression and increased transcriptional nuclear factor-kappa B (NF-kB, p50/p65), phosphorylation of p53 and TGFβ1 gene expression. In contrast, Pax2 gene overexpression inhibited Hhip and NF-kB and activated Shh, N-myc and $p27^{Kip1}$ gene expression. Moreover, high glucose stimulated Hhip gene expression, and then targeted TGFβ1 signaling. Thus, Pax2 via a negative autocrine feedback mechanism attenuated the stimulatory effect of high glucose on Hhip gene expression.

**Conclusions:** We conclude that impaired nephrogenesis induced by maternal diabetes is mediated, at least in part, via augmented Hhip gene expression.

*Funding:* Government Support - Non-U.S.

## TH-PO362

**Wilms' Tumor 1 Initiates the Differentiation Cascade by Suppressing Enhancer of Zeste Homolog 2-Mediated Silencing of Key Genes** Murielle M. Akpa,[1] Lee Lee Chu,[2] Diana Iglesias,[2] Paul R. Goodyer.[1,2] *[1]Human Genetics, McGill Univ, Montreal, Canada; [2]Pediatrics, McGill Univ Health Center Research Institute, Montreal, Canada.*

**Background:** During nephrogenesis, stem cells from the metanephric mesenchyme are induced to form nephrons upon receipt of an inductive signal from the ureteric bud. Wilms tumor 1 (WT1) is believed to play a key role in triggering the differentiation cascade. Stem cell state is maintained by repressive epigenetic marks in key differentiation genes catalyzed by EZH2, a member of Polycomb Repressor Complex 2 (PRC2).

We hypothesize that WT1 is crucial to the derepression of differentiation genes through modulation of EZH2 expression.

**Methods:** We studied the effect of WT1 on EZH2 expression in human amniotic fluid-derived mesenchymal stem cells (amMSCs) and its mechanism of action. We transfected and used immunoblots, luciferase-reporter gene assay and quantitative PCR as analysis tools. The active WT1 binding site on the EZH2 promoter was defined by EMSA. The effect of WT1 on DNA and histone methylation was determine by bisulfite analysis and ChIP-qPCR.

**Results:** An ontogeny of EZH2 in the developing mouse kidney showed high levels of EZH2 during early kidney development, decreasing drastically after birth and disappearing by adulthood. We showed a downregulation of the endogenous expression of EZH2 in amMSCs due to WT1. *in silico* analysis of the EZH2 promoter sequence identified three putative WT1 binding sites. We show WT1 exerting a repressive effect on EZH2 through site S1. We observed increase in CTNNB1 expression and amMSCs showed increased responsiveness to WNT9B in the presence of WT1. Expression of nephron differentiation genes, such as *PAX8*, *WNT4* and *RAR-alpha*, was also enhanced. DNA and histone methylation patterns of the CTNNB1 promoter showed that the derepression of CTNNB1 was mediated by epigenetic modifications at the histone level.

**Conclusions:** We show that WT1 plays a key role in the differentiation process, achieved in part through direct transcriptional repression of EZH2. This repression leads to de-repression of key differentiation genes through epigenetic modifications at the histone level.

## TH-PO363

**COUP-TFII Heterozygous Mutant Mice as an Animal Model for Nephron Insufficiency and Chronic Kdney Disease** Chengtai Yu,[1] Seymour Rosen,[2] Akio Kobayashi,[3] Sophia Y. Tsai,[1] Ming-Jer Tsai.[1] *[1]Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX; [2]Dept of Pathology, Harvard Medical School, Boston, MA; [3]Dept of Medicine, Harvard Medical School, Boston, MA.*

**Background:** The nephron is the basic structural and functional unit of the kidney. Nephron formation is regulated by the cross talk between the ureteric bud and the metanephric mesenchyme, but in humans this initial nephron population is highly variable. It has been suggested that more limited nephronogenesis is related to chronic renal injury. Currently, there is no good animal model available to address this hypothesis.

**Results:** Herein, we demonstrate that the orphan nuclear receptor, chicken ovalbumin upstream promoter transcription factor II (COUP-TFII), is required for kidney progenitor cell renewal and nephrogenesis. Using $Six2^{Cre/+}$ to delete one copy of *COUP-TFII* in kidney progenitor cells, we observed hypoplastic kidneys at the postnatal day (P0). The mutant kidney showed a decreased subcapsular nephrogenic zone, reduced nephron mass and proximal tubular hypertrophy. These mutant mice survived into adulthood and had hypoplastic kidneys with marked tubular hypertrophic changes and glomerulosclerosis. There was renal failure and high grade proteinuria in these COUP-TFII heterozygous mice. Mechanistically, COUP-TFII directly regulates Six2 expression to maintain the size of progenitor cell pool, which subsequently determines the number of nephrons in the kidney. Our data suggest losing one copy of *COUP-TFII* reduces the kidney progenitor cell pool, impairs nephrogenesis, and eventually leads to nephron deficiency. Moreover, COUP-TFII conditional heterozygotes exhibit reduced expression of WT1 and its downstream targets podocalyxin and nephrin in the podocyte, causing development of glomerulosclerosis, which may have a component of hypertrophic injury as well. In summary, we present COUP-TFII heterozygous mice as a genetic animal model of nephron insufficiency and it can serve as a platform to develop future therapeutic interventions.

## TH-PO364

**New Epigenetic Marker, H4K20ac Related to Transcriptional Suppression Is Induced in Postneonatal Kidney Maturation and Organ Hypertrophy** Jun-Ya Kaimori,[1] Kazumitsu Maehara,[2] Yasuyuki Ohkawa,[2] Hiroshi Kimura,[3] Yoshitsugu Obi,[4] Masaki Hatanaka,[4] Hidetoshi Tsuda,[1] Shiro Takahara,[1] Hiromi Rakugi,[4] Yoshitaka Isaka.[4] *[1]Advanced Technology of Transplantation, Osaka Univ, Suita, Osaka, Japan; [2]Dept of Advanced Initiative Medicine, Kyushu Univ, Fukuoka, Kita-Kyushu, Japan; [3]Graduate School of Frontier Biosciences, Osaka Univ, Suita, Osaka, Japan; [4]Dept of Geriatrics & Nephrology, Osaka Univ, Suita, Osaka, Japan.*

**Background:** Post-neonatal kidney maturation was characterized by brake in cell proreferation, drastic gene expression changes and also change in suseptibility to genetic dease after gene deleation in mouse model. In order to elucidate this developmental change from epigenetic point of view, we set the complehensive epigenetic screen by using multiple antibodies angainst different kinds histone modifications. We discovered that new histone modification H4K20ac was induced in this period and also induced by various stimuli related to organ hypertrophy.

**Methods:** We made chip-seq analyses by H4K20ac antibody and next generation sequencer. And we conducted MACS analysis for peak localization and motief search analysis for transcription factors binding to H4K20ac.

**Results:** In peak localizatin analysis, H4K20ac was precipitated in the promoter regions of silent genes, which was totally opposite to the conventional views of histone acetylations. And we also found this modification did not localise on Lamina Associated Domain in which lots of permanent silent genes are located, suggesting that H4K20ac is related to regulated silent genes expressions. In the motif search, we found that lots of transcriptional activators, AP-2, STAT3, and Myc could not bind to H4K20ac precipitating promoters, whereas only transcriptional suppressor, NRSF coud bind to this region. In the comparison with ENCODE data base, H4K20ac also was localised on the future open chromatin regions, suggestiong that H4K20ac can predict the future chromatin changes.

**Conclusions:** H4K20ac is totally different and new kind of histone acetylation and may be related to organ hypertrophy by suppressing regulated genes by repulsing transcriptional activators form promoter resion.

## TH-PO365

**Hypoxia-Inducible Factor-1α Is a Negative Regulator of Nephrogenesis** Bjoern Buchholz,[1] Gunnar Schley,[1] Carsten Willam,[1] Nicolai Burzlaff,[2] Holger Scholz,[3] Kai-Uwe Eckardt.[1] *[1]Dept of Nephrology and Hypertension, Univ of Erlangen-Nuremberg, Erlangen, Germany; [2]Dept of Chemistry and Pharmacy, Univ of Erlangen-Nuremberg, Erlangen, Germany; [3]Dept of Physiology, Charité - Universitaetsmedizin Berlin, Berlin, Germany.*

**Background:** Outgrowth and branching of the ureteric bud is essential to generate the renal collecting system which concurrently induces nephrogenesis, thereby determining the definitive number of nephrons. Limited nephron number due to intrauterine growth restriction (UGR) predisposes to arterial hypertension and chronic kidney disease. IUGR is associated with increased renal expression of the Hypoxia-Inducible Factor-1α (HIF-1α). The functional relevance of HIF-1α within this context remains elusive. Therefore, we analysed the effects of HIF-1α on nephrogenesis.

**Methods:** Metanephric mouse kidneys at E12.0-12.5 and E13.0-E13.5 were dissected and cultured ex vivo. One kidney served as control whereas the contralateral kidney was cultured either in the presence of 1% $O_2$, 5% $O_2$, the HIF-stabilizers dimethyloxalylglycine (DMOG; 1mM) or 2-(1-chloro-4-hydroxyisoquinoline-3-carboxamido) acetate (ICA; 10 and 100μM) or the HIF-1α inhibitor chetomin (100nM). In addition, metanephric kidneys with a tubule-specific overexpression of HIF-1α (THP-Cre; $VHL^{lox;lox}$) were compared with corresponding controls. After 72h, kidneys were photographed and z-stacks were generated providing omnifcoal photos of the kidneys. Then, kidney sizes (optical area in $mm^2$), number of branches (Dolichos biflorus Agglutinin positive tubules) and number of glomeruli (WT1 positive structures) were analysed.

**Results:** 1% $O_2$, 5% $O_2$,DMOG, ICA (100μM) as well as tubule-specific overexpression of HIF-1α signficantly inhibited kidney growth at both time-points which was accompanied

by reduced branching and reduced number of glomeruli. In contrast, chetomin increased kidney sizes and the number of branches in preliminary experiments.

**Conclusions:** HIF-1α is a negative regulator of nephrogenesis. Therefore, HIF-1α could be a mediator of IUGR-dependent reduction in nephron number.

### TH-PO366

**Planar Cell Polarity Effectors, Daam1 and WGEF, Are Required for Cilia Formation and Nephric Tubulogenesis** Rachel Katherine Miller,[1] Malgorzata Kloc,[2] Le Huang,[3,4] Qianghua Hu,[3] Sharada Mokkapati,[3] Vicki Huff,[3,4] Pierre D. McCrea.[3,4] *[1]Biochemistry and Molecular Biology, The Univ of Texas MD Anderson Cancer Center, Houston, TX; [2]Immuno-Biology Laboratory, The Methodist Hospital Research Institute, Houston, TX; [3]Genetics, The Univ of Texas MD Anderson Cancer Center, Houston, TX; [4]Program in Genes & Development, The Univ of Texas Graduate School of Biomedical Sciences, Houston, TX.*

**Background:** Recent studies from our group and others indicate that canonical (beta-catenin-mediated) Wnt signaling is essential for induction of nephron development. Additionally, studies suggest that primary cilia are required for a switch from canonical to non-canonical Wnt signaling, and that defects in primary cilia formation or signaling lead to cystogenesis. Deficiencies in non-canonical Wnt signaling, which contributes to planar cell polarity (PCP), underlie a number of developmental or later defects, such as polycystic kidney disease and nephronophthisis.

**Methods:** Using *Xenopus laevis* (frog) embryos, supplemented with *Danio rerio* (zebrafish) and more recently the mouse Wilms tumor model, we assess the roles of PCP components in kidney tubule morphogenesis utilizeing RT-PCR, in situ hybridization, knockdown, immunostaining, electron microscopic and biochemical techniques.

**Results:** We find that Daam1 and WGEF are expressed in the *Xenopus* embryonic kidney. Daam1 knockdown reduces the expression of pronephric differentiation/ development markers, while having little impact upon determination and patterning. Additionally, knockdown of Daam1 and WGEF result in reduced tubulogenesis. Daam1 and WGEF are important for forming cilia in both the skin of embryos and in the kidney, which have functional associations with morphogenesis. We are beginning investigate renal tumors to determine if cilia or PCP are altered in these tissues. Thus far, we have preliminary data indicating that ciliogenesis may be increased in a mouse model of Wilms tumor.

**Conclusions:** Our data together suggest that the Daam1/ WGEF/ Rho PCP trajectory is necessary for tubulogenesis and possibly ciliogenesis within the developing kidney and may be relevant to human pediatric kidney diseases.

### TH-PO367

**Role of the Primary Cilium in Early Steps of Nephrogenesis** Evelyne Fischer,[1] Filippo Massa,[2] Armelle Jm Christophorou,[1] Cecile Madaras,[1] Serge Garbay,[1] Marco Pontoglio.[1] *[1]Cochin Institute, INSERM/CNRS/Paris Descartes Univ, Paris, France; [2]Institute of Biology Valrose, Nice, France.*

**Background:** Renal morphogenesis is a highly coordinated process that requires reciprocal inductive interactions between the ureteric bud and the metanephric blastema. Nephron formation starts with the condensation of mesenchymal cells around a ureteric bud tip that ultimately give rise to a mature nephron formed by a glomerulus and a long tubular structure connected to the collecting system. Several studies have highlighted the important role of a subcellular organelle, the primary cilium, in the maintenance of tubular diameter. During nephrogenesis, disruption of this organelle in already formed, but still elongating, tubules leads to tubular cysts formation.

**Methods:** However, the role of the primary cilium during the initial steps of nephrogenesis is still elusive. To identify this potential role, we have inactivated Kif3a, a kinesin gene necessary for ciliary assembly, specifically in the metanephric mesenchyme and not in the ureteric bud (Six2-GFP::Cre).

**Results:** Mutant pups were born with a normal mendelian ratio but died within a few days after birth. At birth, mutant kidneys were enlarged and filled with cysts. Histological analyses showed that mesenchymal to epithelial transition was not affected by the lack of primary cilium. Nephron progenitors were formed but they were abnormally shaped and gave rise to cystic tubules and glomerular cysts. In addition, the total number of nephrons was significantly reduced.

**Conclusions:** Our results suggest that, in addition to its known roles, the primay cilium plays an important role in nephron morphogenesis and is involved in the regulation of nephron number.

*Funding:* Government Support - Non-U.S.

### TH-PO368

**p53 Promotes Adhesion of Six2+ Cells within the Nephron Progenitor Niche** Yuwen Li,[1] Jiao Liu,[1,2] Marilyn Li,[3] Samir S. El-Dahr,[1,2] Zubaida R. Saifudeen.[1,2] *[1]Pediatrics, Tulane Univ, New Orleans, LA; [2]Hypertension and Renal Centers of Excellence, Tulane Univ; [3]Molecular and Human Genetics, Baylor College of Medicine, Houston, TX.*

**Background:** Retention of nephron progenitors cells (NPC) within the niche is necessary to allow NPC-niche interactions and timely activation of transcriptional programs that drive differentiation. Six2+ cap mesenchyme (CM) devoid of transcription factor p53 ($Six2^{p53-/-}$) is disorganized, with a greatly diminished Cited1+ self-renewing population. We hypothesize that p53 regulates transcriptional programs to retain progenitor cells within a structured niche.

**Methods:** To test our hypothesis we compared transcription profiles by PolyA-selected paired-end RNA-Seq of $Six2^{p53+/+}$ and $Six2^{p53-/-}$ FACS-isolated cells from E15.5 kidneys. Cell aggregation assessment of isolated mutant cap cells was done.

**Results:** Differential expression of ~3400 genes (Audic Claverie p-value<0.05, FC 1.5) include 283 lincRNA and 21 premiRNAs. Purity of isolated CM was confirmed by high read density of CM genes (Six2, GDNF, Crym, Cited1), but not RV (Cdh1, Fgf8) or UB (Wnt9b, cRet) genes.Expression of floxed-p53 gene exons 2-10 was nearly abolished in $Six2^{p53-/-}$ cells. Accordingly p53 target genes p21, PUMA and NOXA are downregulated. Cited1 expression was decreased, but not Six2. Highest enrichment of differentially expressed genes was observed for genes in cell adhesion (>5-fold, Itga6, Netrin, Col1A1), migration (regulatory proteins for Rho/Rac/Cdc42 - ARHGAP9, 24, 30 and Cdc42ep5), development/morphogenesis (>1.8-fold, PDGFRA/B, Hnf1b, Wnt5a, HNF4, Gas6) and calcium signaling - S100A4 (-8.5 fold) and S100A6 (-3.8 fold). IF staining showed decreased NCAM and Ncad in caps of $Six2^{p53-/-}$ kidneys. $Six2^{p53-/-}$ cells showed decreased aggregation at isolated ureteric tips in hanging drop assays, compared to $Six2^{p53+/+}$ cells.

**Conclusions:** p53 loss from the Six2+ cells resulted in loss of niche architecture and a smaller CM with diminished Cited1+ population. In support, RNA-Seq identified deregulated expression of genes involved in cell adhesion, migration, development and signaling. Our data support a role for p53 as a regulator of transcriptional programs that maintain niche integrity.

### TH-PO369

**Podocyte-Specific Autophagy Deficiency Exacerbates High-Fat Diet-Induced Glomerular Injury** Kosuke Yamahara,[1] Mako Yasuda,[1] Atsuko Tagawa,[1] Shinji Kume,[1] Yuki Tanaka,[1] Shin-ichi Araki,[1] Daisuke Koya,[2] Masakazu Haneda,[3] Takashi Uzu,[1] Hiroshi Maegawa.[1] *[1]Dept of Medicine, Shiga Univ of Medical Science, Otsu, Shiga, Japan; [2]Div of Diabetology & Endocrinology, Kanazawa Medical Univ, Kahoku, Ishikawa, Japan; [3]Dept of Medicine, Asahikawa Medical Univ, Asahikawa, Japan.*

**Background:** Diabetic nephropathy is a leading cause of end-stage renal disease worldwide. Methods for reducing proteinuria in diabetic nephropathy patients are still required. Podocytes are terminally differentiated and are unable to proliferate. Disruption of cell homeostasis in podocytes therefore results in impairment to glomerular filtration barrier function, leading to proteinuria in diabetic nephropathy. Intracellular degradation systems are essential for maintaining cell homeostasis. One of these systems, autophagy, is evolutionary conserved machinery for bulk degradation of cytoplasmic components. Alterations in autophagy have recently been found to be the pathogenesis for some metabolic diseases. This study examined the role of podocyte autophagy in diabetic nephropathy.

**Methods:** We generated podocyte-specific autophagy-deficient (Podo-$Atg5^{-/-}$) mice by podocyte-specific *Atg5* gene deletion. Eight-week-old control ($Atg5^{f/f}$) and Podo-$Atg5^{-/-}$ mice were fed with either a standard diet or a high-fat diet for 32 weeks.

**Results:** At the end of the experimental period, both $Atg5^{f/f}$ and Podo-$Atg5^{-/-}$ mice developed obesity and hyperinsulinemic hyperglycemia resembling type 2 diabetes mellitus. In Podo-$Atg5^{-/-}$ mice, high-fat diet-induced increases in urinary albumin excretion were significantly higher compared with those of $Atg5^{-/-}$, although high-fat diet-induced glomerular histological changes were almost the same in both groups. Fibrosis and infiltration of inflammatory cells in tubulointerstitial lesions and proximal tubular cell apoptosis were significantly exacerbated in Podo-$Atg5^{-/-}$ mice fed a high-fat diet.

**Conclusions:** The results suggest that autophagy is essential to protect podocytes from diabetes-related cellular toxicity. Although further study is required, autophagy appears to be a possible new therapeutic target for reducing proteinuria in diabetic nephropathy.

*Funding:* Government Support - Non-U.S.

### TH-PO370

**Enhanced Glomerular Toll-Like Receptor 4 Expression and Signalling in Patients with Type 2 Diabetic Nephropathy and Microalbuminuria** Giacomo Garibotto,[1] Laura Cappuccino,[1] Barbara Villaggio,[1] Fabio Enzo Gianiorio,[1] Mariano Mij,[2] Francesca Viazzi,[1] Gennaro Salvidio,[1] Daniela Verzola.[1] *[1]Div of Nephrology, Dialysis and Transplantation, Genoa Univ and AOU San Martino-IST, Genoa, Italy; [2]Div of Nephrology and Dialysis, General Hospital, Imperia, Italy.*

**Background:** Toll-like receptors 4 (TLR4) can be activated by endogenous ligands in diabetes and promote inflammation in the kidney tubulointerstitial compartment at a clinical stage of diabetic nephropathy . However, there is no information on molecular events taking place in diabetic microalbuminuria, when renal damage is most likely to be reversible.

**Methods:** We studied TLR4 gene and protein expression and TLR4 downward signaling in kidney biopsies of type 2 diabetic patients with microalbuminuria(n=12, age 60±12 yr, 6M/6F, eGFR= 99± 4, AER 158±15 mg/min), in patients with overt nephropathy (n=11,age 63±3 yr, 5M/6F, eGFR 32±3, proteinuria 3.7±1.0 g/day) and in control kidney (5M/4F, age 60±4 yrs,eGFR= 102± 3). As a second step, to identify specific transcriptional pathways that underlie the pathogenesis of disease we studied selected TLR-4 downward gene expression profiles from laser-capture microdissected glomeruli and tubulointerstitium.

**Results:** In microalbuminuric patients TLR4 mRNA was markedly overexpressed in the glomeruli and in tubulointerstitium. Within the glomerular tuft, TLR4 was localized in podocytes. NF-kB signalling was ~ 4 fold higher in the glomeruli as compared to normal kidney. TNF-α, IL6, CCL-5 and CCR-5 -mRNAs were markedly (about 3-5 fold, p<0.01)

upregulated in microdissected glomeruli, while TNFα and TNFR1 were upregulated both in glomeruli and in the tubulointerstitial compartment ($p<0.02$). Surprisingly, both CCL2-mRNA and CD68 were not expressed in microalbuminuria, while they were both upregulated in the tubulointerstitial compartment of clinical diabetic nephropathy.

**Conclusions:** Our data demonstrate the activation of innate immunity in the glomeruli of patients with type 2 diabetes and early nephropathy and suggest that enhanced TLR4 signaling contribute to the progression that occurs after the microalbuminuric form of nephropathy evolves to overt disease.

*Funding:* Government Support - Non-U.S.

## TH-PO371

**RTN1 Is a Novel Risk Gene for Kidney Disease** Ying Fan,[1,2] Jason A. Bonomo,[3] Peter Y. Chuang,[1] Wenzhen Xiao,[1,2] Sandeep K. Mallipattu,[1] Nicholette D. Palmer,[3] Donald W. Bowden,[3] Barry I. Freedman,[3] Niansong Wang,[2] John C. He.[1] *[1]Medicine, Mount Sinai School of Medicine, NY; [2]Nephrology, Shanghai Six Municipal Hospital, Shanghai Jiaotong Univ, Shanghai, China; [3]Section on Nephrology and Center for Genomics and Personalized Medicine Research, Wake Forest School of Medicine, NC.*

**Background:** Factors contributing to the progression of kidney disease remain unclear.

**Methods:** We profiled gene expression in kidneys from a murine model of HIV-associated nephropathy (HIVAN) and identified an association between the expression of reticulon-1 (Rtn1), which encodes for an endoplasmic reticulum (ER)-associated protein, and the severity of kidney disease. We validated RTN1 expression in both mouse and human diseased kidneys by real-time PCR, western blot, and immunostaining. We determined the role of RTN1 in ER stress.We performed genetic association studies of RTN1 SNPs and ESRD.

**Results:** Upregulation of protein and mRNA expressions of Rtn1 was confirmed in diseased kidneys of murine models for HIVAN, diabetic kidney disease (DKD), and unilateral ureteral obstruction. Renal RTN1 mRNA level was higher in patients with DKD and correlated with estimated glomerular filtration rate (eGFR). Of the three known RTN1 isoforms, only RTN1-A's protein expression was elevated in kidneys of mice and human with HIVAN and DKD. Protein expression of RTN1-A in the human kidneys, as shown by immunostaining, correlated inversely with eGFR in patients with DKD. In HK2 cells, RTN1 overexpression induced ER stress and apoptosis whereas RTN1 knockdown attenuated tunicamycin-, hyperglycemia-, and albumin-induced ER stress and apoptosis, indicating that RTN1 is a key molecule mediating ER stress in kidney cells. We identified three single nucleotide polymorphisms of RTN1 (rs1952034, rs12434215, and rs12431381) in African Americans that significantly associated with type 2 diabetes (T2D)-associated ESRD, non-diabetic ESRD, and all-cause ESRD, but not T2D without nephropathy, with and without adjustment for age, gender, APOL1 G1/G2 allele status, and ancestry.

**Conclusions:** Our data suggest that RTN1 is a novel risk gene for kidney disease and may contribute to kidney injury through ER stress.

## TH-PO372

**Establishment of a Novel Inflamed Animal Model of Diabetic Nephropathy** Kun Ling Ma, Yang Zhang, Jing Liu, Wu Yu, Jie Ni, Bi-Cheng Liu. *Institute of Nephrology, Southeast Univ School of Medicine, Nanjing, China.*

**Background:** It has been demonstrated that diabetic nephrology (DN) is a chronic inflammatory disease. Inflammatory stress plays crucial roles in the progression of DN. Therefore, an inflamed model of DN would be helpful to clarify the pathogenesis of DN. However, an adequate reliable inflamed model of DN is currently lacking. This study aimed to establish a novel inflamed animal model of DN and evaluate its significance in DN.

**Methods:** Twenty male db/db mice were randomly divided into two groups for eight weeks (n=10, each group): mice with daily distilled water injection (Control) or mice with every one day 10% casein injection (inflamed group). Body weight and 24-hour urinary protein were measured every week. The plasma levels of serum amyloid A (SAA) and tumor necrotic factor-a (TNF-a) were checked by enzyme-linked immunosorbent assay. The morphological changes of renal pathology and ultra-microstructures were checked by pathological staining and electron microscope. Immunofluorescent staining and Western blotting were used to check the protein expression of podocyte specific molecules and inflammatory cytokines in kidneys.

**Results:** The 24-hour urinary protein, plasma levels of SAA and TNF-α, as well as the protein expression of inflammatory cytokines in kidneys were significantly increased in inflamed group compared to the control. Moreover, there were more significant mesangial expansion, collagen accumulation, and foot process effacement in inflamed group compared to the control. Further analysis showed that inflammation markedly decreased the expression of wilims tumor-1 and nephrin, which were specific biomarkers of podocyte, suggesting accelerating injuries of podocyte induced by inflammation.

**Conclusions:** An inflamed animal model of DN was successfully established.This inflamed model may provide a useful tool for investigating the pathogenesis of DN under inflammatory stress.

## TH-PO373

**Semaphorin3a Role in Diabetic Nephropathy** Alda Tufro,[1] Pardeep Kumar Aggarwal,[1] David B. Thomas.[2] *[1]Pediatrics/ Nephrology, Yale Univ, New Haven, CT; [2]Pathology, Univ of Miami, Miami, FL.*

**Background:** Accumulating evidence supports crucial pathogenic roles of vascular endothelial growth factor–a, nitric oxide and semaphorin3a (sema3a) disregulation in diabetic nephropathy (DN). Sema3a is a guidance protein secreted by podocytes and essential for normal kidney development. We recently showed that excess podocyte sema3a causes renal disease via direct plexin$A_1$-nephrin interaction and integrin disregulation, and identified increased sema3a expression in Db/Db and STZ-induced diabetic kidneys.

**Methods:** Renal biopsies from T1D and T2D patients were examined by IHC. Sema3a was measured by ELISA and immunoblotting. Proteinuria was assessed by SDS-PAGE-Coomassie staining and albumin ELISA. Diabetes was induced with streptozotocin using the ADMCC protocol. Mouse renal phenotype was examined by LM, IF and EM.

**Results:** Here we report that podocyte sema3a is increased in human diabetic nephropathy, as detected by immunohistochemistry in renal biopsies (DN Class III–IV), whereas sema3a was barely expressed in non-diabetic control biopsies. Moreover, podocyte sema3a was increased in T1D diabetic mice, as assessed by immunoblotting and IHC. Using a sema3a ELISA assay we find that sema3a plasma level and urine excretion are significantly higher in diabetic mice than in non-diabetic controls, and urine sema3a excretion is higher in diabetic mice with advanced DN than in those with mild DN. Next, we examined the role of sema3a in DN using a doxycycline inducible, podocyte-specific Sema3a overexpression mouse model (podocin-rtTA:tet-O-Sema3a, herein called Sema3a$^+$). Sema3a$^+$ mice were made diabetic with streptozotocin (DM-Sema3a$^+$). Induced diabetic Sema3a$^+$ overexpressing mice (DM-Sema3a$^+$ + dox) developed massive proteinuria, decreased renal function and extensive nodular glomerulosclerosis consistent with advanced DN, while uninduced diabetic mice (DM-Sema3a$^+$ – dox) with identical genotype had a mild DN phenotype.

**Conclusions:** Collectively, our data indicate that excess sema3a plays a pathogenic role in DN and worsens the progression of the disease.

*Funding:* NIDDK Support

## TH-PO374

**Renal Failure but Hypercalciuria in Mice with Deletion of the Gene Encoding the Transient Receptor Potential Canonical 1 (TRPC1) Channel: Model of Metabolic Syndrome with Chronic Kidney Disease (CKD)** Bonnie Eby,[1] Alexander Lau,[1] Chris Skaggs,[1] Lindsay J. Barron,[1] Leonidas Tsiokas,[2] Kai Lau.[1] *[1]Renal, Univ of Oklahoma, Oklahoma City, OK; [2]Cell Biology, Univ of Oklahoma, Oklahoma City, OK.*

**Background:** TRPC1 gene on chromosome 3q22–24 is in the linkage region for diabetic nephropathy. TRPC1 expression was reduced in diabetic rodents & patients, but a causal relationship was unclear. Since null mice display features of metabolic syndrome, we tested the hypothesis of renal phenotypes induced by TRPC1 deficiency. In parathyroid cells, TRPC1 protein complexes with STIM1 to mediate store-operated Ca entry. Activating STIM1 mutations produce hypoparathyoidism. So we asked if TRPC1 deficiency produces hyperparthyroidism.

**Methods:** From 1st to 20th months (mon), standard metabolic, ultrasonic (US) & clearance (Cl) studies were done in male littermates of TRPC1 +/+, +/- & -/- born to heterozygotic parents. Creatinine (Cr) was measured by HPLC.

**Results:** Through the 1st year, null mice were uniformly ~10% heavier than +/- & +/+. At 2 mon, their livers were heavier & density from 7-20 mon increased, indicative of hepatosteatosis. At 1 year, they had hypertriglyceridemia, confirming metabolic syndrome. In null mice, serum creatinine (Cr) (0.132 vs. 0.087 mg%) was elevated & Cr clearance (Cl) (1.6 vs. 3.1 ml/miin) reduced. CrCl remained ~50% lower even factored for body (48 vs. 90 µl/min/g) & kidney weight (3.2 vs. 6.4 ml/min/g). Urine albumin (12 vs.7 µg/d; 23 vs.14 µg/mg Cr) was elevated & hematocrit reduced in null mice. Renal US from 7-20 mon uniformly showed >20% reduced volume. There was no difference in serum Ca [9.6 vs. 9.1 mg%], urine Ca (1 vs. 0.99 mg/d), or Ca Cl (12.3 vs. 12.9 µl/min), but fractional Ca excretion was elevated in null mice (0.9 vs. 0.5%). +/- mice had similar renal phenotypes.

**Conclusions:** 1. TRPC1 null mice have 50% □ in GFR, reduced kidney volume & increased proteinuria, offering an excellent model to study obesity- & metabolic syndrome-related CKD. 2. They show no signs of hyperparathyroidism but display hypercalciuria, suggesting a role of TRPC1 channels in renal Ca homeostasis. 3. Haploid deficiency seems sufficient to induce the renal phenotypes.

## TH-PO375

**Reducing Leukocyte Infiltration with a Novel Integrin Agonist Prevents Diabetic Nephropathy** Saravana Kumar Kanagavelu, Mohd Hafeez Faridi, Tristan Hays, Vineet Gupta. *Dept of Internal Medicine, Rush Medical Univ, Chicago, IL.*

**Background:** Diabetic nephropathy(DN) is a major complication of chronic kidney disease and the leading cause of end stage renal disease in humans. DN leads to a number of complex pathologic changes in human kidneys, including basement membrane thickening, glomerular mesangial expansion, glomerulosclerosis and a significant loss of podocytes. Additionally, inflammation plays a significant role in the development and progression of DN and a high influx of leukocytes in the tissue biopsies. This suggests that reducing leukocyte activation, recruitment and influx may be a beneficial strategy for developing therapeutics

against DN. We recently identified novel compounds (leukadherins) for reducing the influx of inflammatory leukocytes in the tissue. This abstract describes our results with our novel compounds in a murine model of DN.

**Methods:** We used a newly established murine model(BTBR ob/ob) of DN, where the disease closely resembles human DN. Starting at the onset of DN in 4 wks old animals, the animals were administered our novel compound(LA1) daily for eight weeks. Animals were monitored for blood glucose level, body weight, renal function and for glomerular defects using histopathology at different time points.Daily administration of LA1 significantly reduced the number of infiltrating leukocytes and preserved kidney function in fully diabetic animals. We saw no effect of LA1 interventions on glycemia, as expected. Histo analyses showed a significant reduction in glomerular mesangial sclerosis in treated animals.

**Results:** Daily administration of LA1 significantly reduced the number of infiltrating leukocytes in the kidney and preserved kidney function in fully diabetic animals. We saw no effect of our interventions on glycemia, as expected. Histopathological analyses showed a significant reduction in glomerular mesangial sclerosis in treated animals.

**Conclusions:** Our research suggests that LA1 significantly protects the kidney function in DNand provides a novel approach to the treatment of DN. It validates CD11b/CD18 as a novel therapeutic target for DN and integrin CD11b/CD18 activation as a mechanistic strategy for developing novel therapeutics.

**Cathepsin L Is Essential for the Development of Proteinuria in Diabetic Mice**

Marjolein Garsen,[1] Angelique Rops,[1] Toin Van Kuppevelt,[2] Henry Dijkman,[3] Thomas Reinheckel,[4] Jo H.M. Berden,[1] Johan Van der Vlag.[1] *[1]Nephrology, Radboud Univ Medical Center; [2]Biochemistry, Radboud Univ Medical Center; [3]Pathology, Radboud Univ Medical Center, Nijmegen, Netherlands; [4]Molecular Medicine, Albert-Ludwigs-Univ Freiburg, Freiburg, Germany.*

**Background:** Proteinuria in diabetic nephropathy (DN) is caused by damage to the glomerular filtration barrier (GFB). Heparan sulfate (HS) is a negatively charged polysaccharide and abundantly expressed in the GFB. HS expression is reduced in proteinuric patients, which is associated with an increased expression of the HS-degrading enzyme heparanase (HPSE). HPSE is essential for the development of proteinuria in DN. Cathepsin L (CTSL) is a lysosomal cysteine protease that cleaves pro-HPSE, thereby giving HPSE its biologic activity. In addition, CTSL degrades the actin-associated protein synaptopodin in podocytes. Both mechanisms may contribute to the development of proteinuria.

**Methods:** To precise the exact role of CTSL in the development of proteinuria, we induced type 1 diabetes mellitus by streptozotocin in wildtype (wt) and CTSL knockout (ko) mice. Mice were sacrificed after 4 weeks and urine, blood and kidneys were collected.

**Results:** Diabetic wt mice developed proteinuria, whereas diabetic CTSL ko mice failed to develop proteinuria. Serum creatinine was increased in diabetic wt mice. HPSE mRNA expression was increased in both diabetic wt and CTSL ko mice. CTSL mRNA expression remained unaltered by induction of diabetes in wt mice. HPSE protein expression and activity were increased in diabetic wt mice, whereas the glomerular HS expression was decreased. HPSE protein expression and activity were low in both non-diabetic and diabetic CTSL ko mice, which was associated with an preserved glomerular HS expression. The protein expression of synaptopodin was comparable between all mice. Furthermore, no differences in glomerular ultrastructure were observed by transmission electron microscopy in these mice.

**Conclusions:** Our data show that CTSL is causally involved in the pathogenesis of proteinuria in DN. Most likely CTSL-deficiency caused loss of HPSE activity, which prevents the loss of glomerular HS expression.

## TH-PO377

**microRNA-214 (miR-214) Regulates Mesangial Cell (MC) Hypertrophy and Matrix Expansion through PTEN**

Amit Bera,[1] Falguni Das,[1] Meenalakshmi M. Mariappan,[1] Nandini Ghosh-Choudhury,[2] Balakuntalam S. Kasinath,[1] Goutam Ghosh-Choudhury.[1] *[1]Medicine, UTHSCSA, San Antonio, TX; [2]Pathology, UTHSCSA.*

**Background:** Our recent report demonstrates that decreased expression of the tumor suppressor protein PTEN contributes to mesangial cell (MC) hypertrophy and matrix protein expression in response to high glucose (HG). The mechanism of PTEN repression by HG is not clear. MicroRNAs strategically silence mRNA translation.

**Methods:** Analysis of 3'UTR of PTEN mRNA revealed the presence of miRNA recognition element (MRE) for miR-214.

**Results:** HG significantly enhanced the expression of miR-214 in MC. To determine the link between miR-214 and PTEN, in vitro we used a sensor plasmid containing the PTEN 3'UTR fused to luciferase cDNA. Cotransfection of this reporter plasmid with miR-214 expression vector significantly inhibited the luciferase activity similar to HG in MCs. Expression of miR-214 in MCs markedly inhibited PTEN protein level analogous to its downregulation by HG, resulting in increased phosphorylation of Akt and its endogenous substrate GSK3beta. Furthermore, miR-214 significantly increased fibronectin expression similar to HG. Conversely, anti-miR-214 markedly inhibited HG-induced fibronectin expression. Moreover, expression of miR-214 increased inactivating phosphorylation of PRAS40, resulting in activation of mTOR and MC hypertrophy analogous to HG treatment. Anti-miR-214 significantly attenuated HG-stimulated mTOR and hypertrophy of MC. Finally, in the diabetic renal cortices of type 1 OVE26 transgenic mice, we found increased expression of miR-214, which correlated with renal hypertrophy, decreased PTEN and, increased activation of Akt, mTOR and fibronectin expression.

**Conclusions:** Together, our results for the first time demonstrate a significant functional role of miR-214 in targeting PTEN to regulate MC hypertrophy and fibronectin expression, two features of diabetic renal complications.

**Urinary Microvesicles Detect Podocyte Injury in Diabetic Nephropathy**

Ladan Zand, Muthuvel Jayachandran, Stephen T. Turner, M. Regina Castro, Joseph P. Grande, Vesna D. Garovic. *Mayo Clinic, Rochester, MN.*

**Background:** Podocyte injury plays a major role in the pathogenesis of diabetic nephropathy. Previous studies have suggested that this injury may occur in the early phases of glomerular disease prior to development of proteinuria. We hypothesized that podocyte injury in diabetic nephropathy could be identified by urinary microvesicles (MVs) containing podocyte-specific markers & is present prior to proteinuria. MVs are small membrane-enclosed sacs that are shed from injured cells & contribute to a variety of pathophysiological processes.

**Methods:** Digital flow cytometry was used to identify urinary MVs derived from podocytes. Forty one patients (male=24, female=17) were recruited, 31 had type 2 diabetes mellitus (DM) & 10 were healthy controls (median age 42 years). DM patients were divided into 3 groups: Group I (<30 mg/L of albumin, n=13, median age 61 yrs), Group II (albumin 30-300 mg/L, n=10, median age 61 yrs), and Group III (albumin >300 mg/L, n = 8, median age 64.5 yrs). Data were analyzed by non-parametric Kruskal-Wallis test. Results are shown as median. Units for urinary MVs are expressed as MVs/μL of urine.

**Results:** There was no difference in GFR between healthy controls and Group I (88 vs. 82ml/min/1.73m$^2$), but GFR was significantly lower in patients with proteinuria (62ml/min/1.73m$^2$). Group I patients compared to the healthy controls had significantly higher number of urinary MVs expressing podocyte markers such as synaptopodin (1074 vs. 33, P<0.0001), nephrin (567 vs. 22, P=0.0002), podocin (1454 vs. 37, P=0.0007), and podocalyxin (838 vs. 11, P<0.0001). There were also significantly greater number of parietal cell specific markers, claudin-1 plus CK-8 positive MVs (479 vs. 3, P=0.0007). There was a trend towards fewer MVs expressing podocyte markers in patients with proteinuria compared to those without proteinuria in DM groups (data not shown).

**Conclusions:** Podocyte injury is present in type 2 diabetic nephropathy & predates proteinuria. Characterization of podocyte-derived MVs in the urine could be used as a novel biomarker for podocyte injury in type 2 DM patients.

## TH-PO379

**SREBP Inhibition Modulates Diabetic Nephropathy in db/db Mice with Type 2 Diabetes**

Xiaoxin Wang, Moshe Levi. *Medicine, Univ of Colorado, Aurora, CO.*

**Background:** Sterol Regulatory Element Binding Proteins (SREBPs) are master transcriptional regulators of fatty acid and cholesterol synthesis. In view of the importance of SREBPs in a diverse number of target organ complications in obesity and diabetes, including atherosclerosis and nonalcoholic fatty liver disease, there has been a concentrated effort to develop inhibitors of SREBP activation. Recently, Betulin [lup-20(29)-ene-3β, 28-diol] has been shown to specifically inhibit the activation of SREBP.

**Methods:** In this study we examined the effects of Betulin induced SREBP inhibition on diabetic nephropathy in db/db mice with type 2 diabetes. We treated db/db mice on C57 BKS background with 30mg/kg body weight/day of Betulin mixed with chow for 12 weeks.

**Results:** We have found increased renal lipid accumulation in the kidneys of db/db mice mediated by increased expression of nuclear SREBP-1 and SREBP-2 protein. Treatment with Betulin prevented the upregulation of SREBPs in the kidney resulting in a correspondent reduction of kidney triglyceride and cholesterol accumulation. SREBP inhibition prevented the increases in urine albumin excretion (db/db: 59±13 μg/24hr; db/db-betulin: 21±3 μg/24hr; p<0.05) and mesangial matrix expansion as shown by PAS staining of the kidneys of db/db mice (mesangial matrix index: db/db, 2.25±0.08; db/db-betulin, 1.60±0.11; p<0.05). The treatment also prevented podocyte loss determined by staining with p57 and WT-1. Furthermore, improvement in oxidative stress and inflammation was also observed in the treatment groups (urinary TBARS: db/db, 181±27 mmol/day vs. db/db-betulin, 103±24 mmol/day, p<0.05; urinary MCP-1: db/db, 146±22 mmol/day vs. db/db-betulin, 83±15 mmol/day, p<0.05). To determine if Betulin has direct effects in kidney podocytes, we cultured human podocytes in high glucose conditions. Betulin prevented the high glucose induced increased the expression of SREBP-1 and SREBP-2 and lipid accumulation in human podocytes.

**Conclusions:** Our study therefore indicates a renoprotective role for SREBP inhibition in diabetic nephropathy by preventing lipid accumulation and modulating oxidative stress and inflammation.

## TH-PO380

**SGLT2 Inhibition Modulates Renal Lipid Metabolism and Inflammation and Prevents the Development of Nephropathy in Diabetic Mice**

Xiaoxin Wang, Moshe Levi. *Medicine, Univ of Colorado, Aurora, CO.*

**Background:** Inhibition of the renal sodium gradient dependent glucose transporter SGLT2 results in lowering of blood glucose in diabetic humans and rodent models but the effects on progression of diabetic renal disease has not been fully established.

**Methods:** We determined the effects of the inhibition of SGLT2 via a selective SGLT2 inhibitor on diabetic nephropathy in db/db mice.

**Results:** After 12 weeks treatment, we found that SGLT2 inhibition caused marked decreases in urinary albumin (745±36 mg/g in db/db vs. 207±5 mg/g in treated db/db, $p<0.001$) and urinary TBARS (thiobarbituric acid-reacting substances), (1.09±0.13 mmol/g in db/db vs. 0.48±0.10 mmol/g in treated db/db, $p<0.01$) an indicator of oxidative stress. SGLT2 inhibition prevented renal lipid accumulation via inhibition of LPK, SCD-1 and DGAT1, key enzymes that mediate fatty acid and triglyceride synthesis. SGLT2 inhibition also prevented inflammation via inhibition of CD68 macrophage accumulation, and expression of p65, TLR4, MCP-1 and OPN. These effects were associated with prevention of mesangial expansion, accumulation of extracellular matrix proteins as determined by fibronectin and type IV collagen quantitative immunofluorescence microscopy, and podocyte loss as determined by WT1 and synaptopodin quantitative immunofluorescence microscopy (all $p<0.05$).

**Conclusions:** In summary, our study showed that SGLT2 inhibition modulates renal lipid metabolism and inflammation and prevents the development of nephropathy in db/db mice.

## TH-PO381

**Effects of Bile Acid Sequestrants on Kidney Disease in Mice with Diet Induced Obesity, Insulin and Leptin Resistance** Xiaoxin Wang, Moshe Levi. *Medicine, Univ of Colorado, Aurora, CO.*

**Background:** Bile acid sequestrants (BAS) including colesevelam are orally administered nonabsorbable polymers that decrease serum cholesterol and serum glucose in patients and animal models with type 2 diabetes mellitus. The effects of BAS on renal dysfunction in obesity and insulin resistance or type 2 diabetes mellitus have not been studied. Sevelamer, an effective phosphate binder for treating ESRD, has been shown to bind bile acids, advanced glycation end products and uremic toxics, which would be of benefit to treating diabetic patients with chronic kidney disease. Our goal was to evaluate the effect of sevelamer on metabolic and renal parameters in an obese animal model with insulin and leptin resistance and to determine underlying mechanisms.

**Methods:** Our studies were performed in C57BL/6J male mice fed a control low fat (LF) diet (10 kcal% fat) or high fat (HF) diet (60 kcal% fat). The diets were supplemented with a) no addition or b) 2% sevelamer.

**Results:** BAS prevented the increase in urine albumin excretion (HF: 47.7±6.66 mg/g; HF/sevelamer: 24.8±3.17 mg/g, $p<0.05$) and decreased the PAS staining in the kidney of HF mice. Treatment with BAS decreased the renal lipid accumulation as shown by oil red O staining. HF diet induced upregulation of profibrotic genes (TGF-β, CTGF, and PAI-1) and proinflammatory genes (MCP-1, TLR2, and TLR4) in the kidney which were decreased by treatment with BAS. In addition BAS induced downregulation of extracellular matrix protein fibronectin and macrophage marker CD68 expression in the kidney. The beneficial effects of BAS were also associated with decreases in renal gluconeogenic gene expression (PEPCK and G6Pase) and renal glucose transporter (SGLT2). Treatment with BAS also and most notably increased renal expression of Nrf1, SIRT1, PGC-1a,SIRT3, ERRa, that mediate mitochondrial biogenesis, MCAD and LCAD, that mediate fatty acid oxidation, and Nrf2, HO-1, and SOD, that mediate anti-oxidative stress.

**Conclusions:** In summary, our study showed a novel renoprotective role for bile acid sequestrant treatment in mice with diet induced obesity, insulin and leptin resistance.

## TH-PO382

**Loss of IFT Complex A Protein, THM1, Causes Hyperphagia-Induced Obesity with Fatty Liver Disease, Prediabetes, and Hypertension** Damon T. Jacobs,[1] Michael P. Schonfeld,[1] Luciane M. Silva,[1] Anindita Chatterjee,[1] George Talbott,[2] David Beier,[2,3] Pamela Vivian Tran.[1] *[1]Anatomy and Cell Biology, Univ of Kansas Medical Center, Kansas City, KS; [2]Genetics Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [3]Center for Developmental Biology and Regenerative Medicine, Seattle Children's Research Institute, Seattle, WA.*

**Background:** Primary cilia are antenna-like structures present on most vertebrate cells that mediate signaling pathways. Cilia defects cause ciliopathies, which manifest common clinical features, such as obesity. Obesity is a costly, worldwide epidemic and treatments are invasive and largely ineffective. The IFT complex A gene, *Thm1*, negatively regulates Hedgehog (Hh) signaling and is the most commonly mutated gene in ciliopathies.

**Methods:** We examined a role for murine *Thm1* in obesity using a *Thm1* conditional knock-out (cko) allele together with a ubiquitous, tamoxifen-inducible Cre recombinase.

**Results:** While *Thm1* deletion during early embryogenesis resulted in cystic kidney disease, *Thm1* deletion during adulthood caused a two-fold weight gain relative to wild-type mice over a 13-week period. In adult *Thm1* cko mice, adipose depots were significantly larger than in wild-type, and *Thm1 cko* livers had numerous lipid droplets, indicative of fatty liver disease. *Thm1* cko serum glucose, leptin and insulin levels were elevated, suggesting a prediabetic state. Further, *Thm1* cko mice showed higher blood pressure. To determine if the 15% increase in food intake observed in *Thm1* cko mice caused obesity, *Thm1* cko mice were pair-fed for 13 weeks following *Thm1* deletion. Indeed, body weights and fat depots of pair-fed *Thm1* cko mice were similar to wild-type, suggesting hyperphagia is a primary cause of the obese phenotype. In the hypothalamus, *Thm1* cko primary cilia appear stunted. We are examining signaling pathways that are differentially regulated in the *Thm1* cko hypothalamus and may play a role in hyperphagia.

**Conclusions:** The *Thm1* cko mouse is a novel model of obesity. Since THM1 negatively regulates Hh signaling, increased Hh activity may contribute to cilia-mediated hyperphagia and may reveal a novel therapeutic target for obesity.

## TH-PO383

**SGLT2 Inhibitor Empagliflozin Attenuates Hyperglycemia, Kidney Growth, and Albuminuria and Prevents Glomerular Hyperfiltration in Diabetic Akita Mice** Volker Vallon,[1] Maria Gerasimova,[1] Michael A. Rose,[1] Takahiro Masuda,[1] Eric Mayoux,[3] Hermann Koepsell,[2] Scott C. Thomson,[1] Timo M. Rieg.[1] *[1]Div of Nephrology, UC San Diego & VA San Diego Healthcare System, La Jolla, CA; [2]Univ of Wurzburg, Germany; [3]Boehringer-Ingelheim, Biberach, Germany.*

**Background:** Inhibitors of the sodium-glucose cotransporter SGLT2 are new antidiabetic drugs that enhance urinary glucose excretion. We determined whether the SGLT2 inhibitor empagliflozin (EMPA) alters blood glucose levels (BGL) and early kidney changes in Akita mice ($Ins2^{+/C96Y}$), a non-obese insulin-dependent model of type 1 diabetes.

**Methods:** Akita were compared with littermate $Ins2^{+/+}$ controls (WT). At 4 weeks of age, mice received a diet containing EMPA (300mg/kg diet) or repelleted control diet (veh) for 15 weeks (n=10-13/group). GFR was measured after 14 weeks in conscious mice by plasma kinetics of FITC-Sinistrin. * $P<0.05$ vs veh.

**Results:** EMPA, Akita, and EMPA/Akita increased SGLT2 expression in renal membrane fraction vs veh-treated WT (+47±11*, +38±10* and +56±9*%, respectively). EMPA lowered BGL in non-fasted Akita vs veh (means of 187-261* vs 517-535mg/dl (100-140mg/dl in WT). In WT, EMPA modestly reduced GFR vs veh (250±12* vs 306±23µl/min) and tended to increase kidney weight (KW:312±5 vs 299±5mg). EMPA prevented the diabetes-induced GFR increase in Akita (255±14* vs 397±34µl/min) and attenuated the rise in KW (340±7* vs 410±9mg) and urinary albumin/creatinine ratio (151±18* vs 315±73µg/mg). EMPA increased urinary glucose/creatinine ratios in WT (2110±153* vs 7±1µmol/mg) but not in Akita (7099±430 vs 6909±1165µmol/mg); i.e., in Akita, EMPA-induced inhibition of glucose reabsorption was counterbalanced by reduced filtered glucose. EMPA attenuated/prevented the modest upregulation of systolic blood pressure and markers of kidney injury/inflammation in Akita (incl. mRNA for NFkB, CCL2, CD14, TIMP2).

**Conclusions:** Inhibition of SGLT2 with empagliflozin in diabetic Akita mice lowers hyperglycemia and attenuates kidney growth and albuminuria in proportion. Prevention of diabetes-induced rise in GFR by EMPA is consistent with a role of SGLT2 in proximal hyperreabsorption and the tubulocentric concept of hyperfiltration.

## TH-PO384

**Reduction of Renal Mitochondria in Type 1 Diabetes Is Associated with Increased Mitophagy** Joseph Satriano, Kumar Sharma. *Nephrology, UC San Diego & VASDHS, San Diego, CA.*

**Background:** Autophagy has been implicated in diabetic kidney disease however, the role of specific types of autophagy have not been identified and its functional role remain unclear.

**Methods:** Autophagy was evaluated in type 1 diabetic F1 Akita mice. Renal histology, albumin/creatinine ratio and mitochondrial protein and complex activity was measured. Autophagy protein expressions were evaluated by immunoblotting. All values are relative densitometry units±SEM normalized against alpha-Tubulin.

**Results:** In F1 Akita mice the kidneys underwent hypertrophy, mesangial matrix expansion and albuminuria. There were also a significant decreases in kidney mitochondrial density and Complex I and IV activities. As expected mTORC1 activity markedly increased (via p-p70S6K Wt 10549±1202, Ak 16008±608) and AMPK activity markedly decreased (p-AMPK T172 Wt 3968±1049, Ak 1047±487). In accord with these changes we observed a pronounced decrease in autophagy (LC3-II/LC3-I ratio; Wt 0.237±0.027, Ak 0.101±0.024), and this was verified by the accumulation of the autophagy adapter or linker protein, p62/Sequestosome-1 (p62; Wt 6998±724, Ak 15945±7734). A number of specific AuTophaGy (Atg) genes and proteins are induced in response to autophagic stimulation. There are 2 conjugation pathways involved in the developing autophagosomal membrane. Atg3, utilized only in the pathway specific to LC3 lipidation, was decreased in accord with LC3-II levels (Atg3 Wt 11493±1380, Ak 6703±1157). However, Atg5 and Atg7, required for the Atg12-conjugation pathway, and Beclin-1, required for initiation of phagophore nucleation, were not changed (Atg5 13650±2110, Ak 14551±1340; Atg7 Wt 12565±2078, Ak 12101±1232; Beclin-1 Wt 8008±579, Ak 6610±505) Mitophagy selective adapter proteins, PINK1 (Wt 1975±463, Ak 4580±1744) and Bnip3 (Wt 2446±811, Ak 10430±2464), were increased in Akita mice kidneys. Studies are ongoing with AMPK activation and in AMPK KO mice.

**Conclusions:** A shift from general autophagy to selective mitophagy may lead to a progressive reduction of mitochondria and homeostatic function in diabetic mice.

*Funding:* NIDDK Support, Veterans Affairs Support

## TH-PO385

**The Lin28-Let7 Pathway Modulates TGF-β-Induced Collagen Expression in Glomerular Mesangial Cells under Diabetic Conditions** Jung Tak Park, Mitsuo Kato, Nancy E. Castro, Rama Natarajan. *Beckman Research Institute, City of Hope, Duarte, CA.*

**Background:** Accumulation of mesangial extracellular matrix (ECM) proteins such as collagen type 1-α2 (col1a2) and type 4-α1 (col4a1) is a key feature of diabetic nephropathy (DN). Although transforming growth factor-β1 (TGF-β) plays an important role in ECM regulation, the mechanisms are not fully understood. Here we examined the role of microRNAs (miRNAs).

**Methods:** miRNAs, mRNA and protein levels were examined by RT-qPCR or Western blotting in TGF-β-treated mouse mesangial cells (MMC) with or without let7-b mimic or inhibitor oligonucleotide transfection. Promoter and 3'-UTR constructs were cloned for reporter assays.

**Results:** RNA deep sequencing showed down-regulation of the miRNA let-7 family members (let-7b/c/d/g/i) in TGF-β-treated MMC. qPCR confirmed this down-regulation along with the up-regulation of col1a2 and col4a1. Ectopic expression of let-7b in TGF-β-treated MMCs attenuated the col1a2 and col4a1 up-regulation. Interestingly, let7-b inhibitors increased col1a2 and col4a1 levels, suggesting let7-b mediates TGF-β induced col1a2 and col4a1. Co-transfection of MMCs with mouse col1a2 or col4a1 3'-UTR luciferase constructs and let-7b inhibitors increased luciferase activity. TGF-β induced col 3'UTR luciferase activity was attenuated by Let-7b mimic, suggesting col1a2 and col4a1 are direct targets of let-7b. In addition, Lin28b, a negative regulator of let-7, was up-regulated in TGF-β-treated MMCs. To test if TGF-β induces Lin28b through Smad-response elements, the promoter region of Lin28b was cloned into the pGL4P vector. Luciferase assays showed that promoter constructs with potential Smad sites responded to TGF-β, which was abolished in constructs without the Smad binding site, suggesting that Lin28b is transcriptionally increased through the Smad site. Furthermore, let-7b levels were decreased, while Lin28b, col1a2 and col4a1 levels were increased in glomeruli of diabetic mice compared to nondiabetic controls, demonstrating in vivo relevance of this Lin28/let-7/collagen axis.

**Conclusions:** These results demonstrate a novel new role for the Lin28/let-7 pathway in controlling TGF-β-induced collagen accumulation in DN.

*Funding:* Other NIH Support - DK081705 and DK058191

## TH-PO386

**Neutralization of TGF-Alpha Attenuates Progression of Experimental Kidney Disease** Josef G. Heuer, Catherine Beidler, Elaine Conner, Jeffrey Boyles, Dianna L. Jaqua, Derek D. Yang, Derrick R. Witcher, Matthew D. Breyer. *Biotherapeutic Discovery Research, Eli Lilly and Company, Indianapolis, IN.*

**Background:** Previous studies have demonstrated a role for transforming growth factor-alpha (TGFa) in the progression of chronic kidney disease in subtotal nephrectomized FVB/N mice (Laouari et al., (2012) EMBO Mol Med 4, 1–15). To determine if TGFa plays a role in the progression of renal disease in other experimental models of progressive renal injury, a TGFa neutralizing monoclonal antibody (Mab41) was generated and used in models of subtotal nephrectomized 129S6 mice and uninephrectomized (uniNx) db/db mice.

**Methods:** Mab41 or a control IgG was dosed once weekly subcutaneously for 4 months to subtotal nephrectomized male 129/S6 mice beginning at 2 weeks post surgery or uninephrectomized (UniNx) female db/db mice beginning at 8 and 16 weeks of age. Animals were assessed for serum clinical chemistry markers, cytokines, albuminuria, urine TGFa, renal pathology and urine NGAL (UniNx db/db only).

**Results:** Albuminuria, serum creatinine, inflammatory markers and renal fibrosis were all significantly elevated in subtotal nephrectomized 129/S6 mice compared to sham animals and 16 weeks of treatment with Mab41 significantly improved all these parameters. Similarly, diabetic UniNx db/db mice exhibited significant increases in albuminuria, mesangial matrix expansion, inflammatory markers, urine TGFa and urine NGAL relative to lean db/m mice. Neutralization of TGFa with Mab41 for 16 weeks significantly reduced all these parameters relative to a control antibody.

**Conclusions:** We conclude that TGFa plays an important role in progression of chronic kidney disease in diverse experimental models of renal injury.

*Funding:* Pharmaceutical Company Support - Eli Lilly and Company

## TH-PO387

**The NMDA Antagonist Memantine Reduces Albuminuria and Podocyte Foot Process Effacement in the Akita Mouse Model of Type 1 Diabetes Mellitus** Stuart E. Dryer,[1,2] Hila Roshanravan.[1] *[1]Biology and Biochemistry, Univ of Houston, Houston, TX; [2]Div of Nephrology, Baylor College of Medicine, Houston, TX.*

**Background:** We have previously characterized NMDA receptors in primary rat podocytes and in mouse and human podocyte cell lines. These receptors are activated by L-homocysteic acid (HCA), the primary oxidation product of L-homocysteine. NMDA receptors are ligand-gated ion channels (ionotropic receptors) that are highly permeable to $Ca^{2+}$ ions. Activation of podocyte NMDA receptors evokes $Ca^{2+}$ influx, and increased generation of reactive oxygen species via activation of NADPH oxidases. Hyperhomocysteinemia is common in diabetes, and there is evidence that genes regulating homocysteine metabolism comprise susceptibility loci for diabetic nephropathy. Therefore we hypothesized that hyperactivation of NMDA receptors drives a portion of the progression of diabetic nephropathy.

**Methods:** We implanted 7-week old male Akita mice (B2.B6-Ins2$^{Akita/Mathj}$) with subcutaneous Alzet minipumps filled with either memantine or saline. Memantine is a weak non-competitive NMDA antagonist used for treatment of Alzheimer's dementia, and the daily dose delivered in this study was similar to those used clinically. Similar minipumps were implanted into control DBA/2J mice. Renal function was estimated after 28 days.

**Results:** Akita mice had substantial albuminuria by 11 weeks of age. However we observed that 28 days of memantine treatment markedly reduced 24-hr albumin excretion in Akita mice compared to saline-treated controls. Memantine had no effect on albumin excretion in DBA/2J mice. The effects of genotype, the interaction between memantine and genotype are both significant by two-way ANOVA ($P < 0.05$). Using transmission EM we saw a reduction in podocyte foot process effacement in memantine-treated Akita mice. Memantine had no effect on foot process morphology in DBA/2J mice.

**Conclusions:** These data suggest that sustained hyperactivation of NMDA receptors in vivo may contribute to development of diabetic nephropathy, and suggests a therapeutic strategy based on a drug already approved by FDA for pharmacotherapy of dementias.

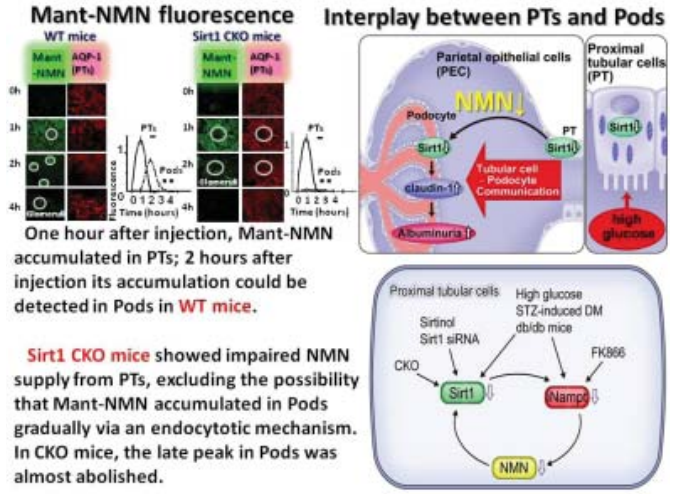
## TH-PO388

**Interaction of Proximal Tubular Cells and Podocytes through a Mediator of Nicotinamide Mononucleotide in Diabetic Nephropathy** Kazuhiro Hasegawa, Shu Wakino, Koichi Hayashi, Hiroshi Itoh. *Dept of Nephrology, Keio Univ, Tokyo, Japan.*

**Background:** We previously showed that a decrease in Sirt1 expression in proximal tubules (PT) reduces Sirt1 levels and increases claudin-1 levels in podocytes (Pods), leading to the initiation of albuminuria (Alb) in diabetic nephropathy (DN) mice (STZ and db/db). PT-specific Sirt1 transgenic (**TG**) and conditional knockout (**CKO**) mice showed prevention and aggravation of Alb, respectively (oral sessions at ASN 2011, 12). We also showed a role for nicotinamide mononucleotide (**NMN**) as a candidate mediator of the interplay between PTs and Pods using conditioned medium from PTs. In this study, we investigated the retrograde interplay from PTs to Pods in an *in vivo*.

**Methods:** We synthesized **Mant (N-methylanthraniloyl)-NMN** as a fluorescence-labeled nucleotide. Saline (Sal) or Mant-NMN was administered by arterial injection and kidneys were examined by multiphoton microscopy.

**Results:** We observed a PT–Pods flow of NMN.



NMN in **WT+Sal** mice was detected mainly in PTs because of the high expression levels of the NMN-producing enzyme iNampt there. **NMN** and iNampt levels were decreased in **WT+DN**, but these decreases were prevented in **TG+DN**. Similarly, **NMN** and iNampt levels were decreased in **CKO+Sal**, and were further reduced in **CKO+DN**. These results suggested that iNampt levels are affected, at least in part, by glucose and/or the Sirt1-determined **NMN** levels around PTs, which regulate Sirt1 and claudin-1 expression levels in Pods. To confirm a role for **NMN** in the progression of DN, we examined the effects of FK866, an inhibitor of iNampt. FK866 (30 mg/kg) decreased **NMN** levels leading to increased claudin-1 expression and Alb, which were rescued in **TG+FK866** and the **NMN injection+FK866** condition, and worsened in **CKO+FK866**.

**Conclusions:** Sirt1 in PTs protects against Alb in DN by maintaining **NMN** levels around Pods and controlling Pods function.

## TH-PO389

**In-Vivo Effect of Podocyte DNA Methyltransferase 1 on Suppressing Diabetic Albuminuria through Epigenetic CpG Methylation of Claudin-1** Kazuhiro Hasegawa, Shu Wakino, Koichi Hayashi, Hiroshi Itoh. *Dept of Nephrology, Keio Univ, Tokyo, Japan.*

**Background:** We previously created kidney-specific **Sirt1** transgenic (**TG**) and conditional knockout (**CKO**) mice (oral sessions at ASN 2011, 12).
