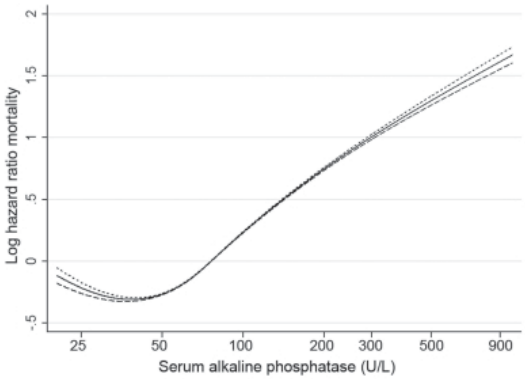
**Background:** Bone and mineral disorders are common and are associated with mortality in ESRD. The association of serum total alkaline phosphatase (ALP) with kidney function and with mortality in non-dialysis dependent (NDD) CKD has not been studied extensively.

**Methods:** We evaluated the association of ALP with estimated GFR (eGFR) and with all-cause mortality in a national cohort of 578,293 US veterans with stable NDD-CKD stages 1-5. Associations were examined in regression models, and in time-dependent Cox models, with adjustments for age, gender, race, comorbidities (including liver disease), eGFR, serum levels of liver enzymes and bilirubin, and medication use.

**Results:** The adjusted odds ratio (95%confidence interval [CI]) of ALP>120 U/L associated with a 10 ml/min/1.73m$^2$ lower eGFR was 1.25 (1.23-1.26, p<0.001). Over a median follow-up of 6.2 years 214,374 patients died (mortality rate: 70.0/1000 patient-years (95%CI: 69.7-70.3)). Compared to ALP levels of 50-119, ALP levels of <50, 120-199 and >=200 U/L were associated with adjusted mortality hazard ratios (95%CI) of 0.74 (0.73-0.75), 1.66 (1.64-1.68) and 2.56 (2.50-2.63), p<0.001 for all. The adjusted mortality hazard ratio (95%CI) was 2.02 (2.00-2.04, p<0.001, Figure 1) for one unit higher natural log-transformed ALP. Associations with mortality were similar in patients with all stages of NDD-CKD.



**Conclusions:** Hyperphosphatasemia is more common with decreasing kidney function, and is associated with increased mortality in patients with NDD-CKD. The effect of therapeutic interventions lowering ALP level will need to be examined in clinical trials.

## SA-PO570

**Early Detection of Vascular Calcification in Retinal Vessels and Skin of Dialysis Patients**
Ramya Bhargava,[1] Faisal R. Ali,[1] Katie A. Law,[2] Jane Gray,[1] John Lear,[1] Nicholas D. Bryan,[2] David B. Henson,[2] Paul E. Brenchley,[1] Alastair J. Hutchison.[1] *[1]MRI, UK, United Kingdom; [2]Manchester Univ.*

**Background:** Vascular calcification is common in dialysis(HD) patients but early detection is difficult. We hypothesised that 1) retinal imaging by fundus photography & OCT scan may detect early calcification in retinal vessels and 2) that skin biopsies from calcified dialysis patients may have higher phosphorus(P31) & calcium(Ca43) content than normal.

**Methods:** HD patients with Xray evidence of vascular calcification in hands & pelvis with Adragao score ≥4 were invited to takepart in the study. 10 had fundus photography & OCT scans. 20 patients & 10 normal controls underwent skin biopsies. Biopsy samples were incinerated & acid digested; P31 & Ca43 were measured by spectroscopy. Skin content of P31 & Ca43 were compared in patients & controls. P31 was correlated with Serum PTH, Serum P & with Ca43.

**Results:** 1. No retinal vascular calcification was evident in any HD patients with vascular calcification in hands/pelvis; 2. No significant difference was seen in P31 & Ca43 between calcified patients & normal controls; 3. Positive correlation seen between P31 & Ca43 in patients & controls; 4. No correlation between P31 & serum PTH or serum P in patients & controls.

| | Calcified HD patients | Normal controls | P-value |
|---|---|---|---|
| N | 20 | 10 | |
| Age(mean±SEM) | 53.4±4 | 44.5±4.1 | NS |
| Gender(M:F) | 3:1 | 2:3 | |
| Serum Cr(mmol/L) | 875.2±56.4 | 70.2±4.5 | 0.0001 |
| Serum P(mmol/L) | 1.6±0.1 | 1.1±0.1 | 0.0017 |
| Sample Wt(mg) | 37.5±3 | 33.2±2.7 | NS |
| Skin P31(mcg/g) | 412.4±38.5 | 381.0±24.1 | NS |
| Skin Ca43(mcg/g) | 8.9±1 | 7.7±0.9 | NS |
| **Correlation of skin P31 with other parameters** r-Pearson's coefficient (95%CI), P-value | | | |
| vs Ca43 | 0.8 (0.5 to 0.9), 0.0001 | 0.9 (0.6 to 0.9), 0.0004 | |
| vs Serum PTH | 0.2 (-0.3 to 0.6), NS | | |
| vs Serum P | 0.1 (-0.3 to 0.5), NS | 0.2 (-0.5 to 0.7), NS | |

**Conclusions:** 1. Retinal vasculature is possibly protected from calcification that occurs elsewhere in HD patients; 2. Skin content of Phosphorus & Calcium is not a marker of vascular calcification.

## SA-PO571

**Clinical Significance of Breast Arterial Calcification in End-Stage Renal Disease**
Ekamol Tantisattamo, Na'Da Abouhassan, W. Charles O'Neill. *Renal Div, Emory Univ, Atlanta, GA.*

**Background:** The clinical significance of medial arterial calcification in end-stage renal disease (ESRD) is unclear because it often coexists with atherosclerotic calcification. As opposed to other sites, breast arterial calcification (BAC) is exclusively medial and is a convenient marker to address this question.

**Methods:** Mammograms were identified in 162 women with ESRD and those closest to the date of ESRD were reviewed. Coronary artery disease (CAD) was defined as a history of myocardial infarction or coronary stenosis of >50% by angiography. Peripheral artery disease (PAD) was defined as a history of bypass or amputation.

**Results:** Age at baseline mammography was 60.0 +/- 1.0 (SEM) y, ESRD duration was 4.7 +/- 0.4 y, 55% had diabetes, and 61% had BAC; follow-up was 2.9 +/- 1.7 y. Patients with BAC were older (62.6 +/- 1.2 vs. 53.2 +/- 1.6; p <0.0001) and more likely to be diabetic (65% vs. 40%; p=0.002). Serum calcium, phosphate, and parathyroid hormone did not differ significantly between patients with and without BAC and use of Ca-based and Ca-free phosphate binders, vitamin D compounds, and calcimimetics was similar. Patients with BAC had a higher prevalence of PAD (20% vs. 4.8%; p=0.006) but not CAD (27% vs. 22%) at follow-up. Follow-up duration was similar in the 2 groups. In a logistic regression

model, BAC (4.2; 1.1-16) and diabetes (10; 2.2-47) were independent determinants of PAD (odds ratios; 95% confidence intervals). After exclusion of patients with pre-existing disease at baseline, the incidence of PAD was greater in patients with BAC (10 % vs. 3.2%) but was not significant due to small numbers. The incidence of CAD was not increased.

**Conclusions:** Breast arterial calcification is independently associated with peripheral arterial disease in ESRD, suggesting that medial arterial calcification contributes to the pathophysiology of this disorder. Coronary artery disease is not associated with BAC in ESRD. In addition to being a marker, BAC may also predict PAD. Mammography may be a convenient and useful tool to identify patients at risk for peripheral arterial disease.

## SA-PO572

### Prevalence and Determinants of Bone in Vascular Calcification

W. Charles O'Neill,[1] Randolph A. Hennigar.[2] *[1]Renal Div, Emory Univ, Atlanta, GA; [2]Dept of Pathology, Emory Univ, Atlanta, GA.*

**Background:** The occurrence of bone in calcified arteries has led to the hypothesis that vascular calcification is an osteogenic process. However, the prevalence and distribution of bone in calcified arteries and its relationship to the calcification and other factors are not known.

**Methods:** A total of 175 arteries in specimens of lower limb amputations from 60 patients were examined retrospectively by reviewing sections stained with hematoxylin and eosin. ESRD was present in 21 patients, CKD in 21, and no CKD (defined as a serum creatinine < 1.0) in 18. Mean age was 65.0 +/- 1.9 years and 58% had diabetes. Warfarin was prescribed in 15 patients.

**Results:** Calcification was present in 136 arteries from 52 patients, which was medial in 62, intimal in 11, and both in 63. Bone was observed in 16 arteries (medial in 14, intimal in 2) from 13 patients. There was no association with age, gender, diabetes, renal failure, or warfarin use, but bone was present in more than one artery in 3 patients, suggestive of patient-specific factors. Bone was present in 5% and 14% of arteries above and below the knee, with the highest prevalence in the posterior tibial artery (28%). The presence of bone did not correlate with the severity of calcification and was absent in over 80% of sections with severe calcification (>50% of arterial circumference). Medial cells staining for osteocalcin were noted in only 2 of 10 sections from heavily calcified arteries. Osteoclasts were noted in 9 sections from 7 patients and bone was present in all but one of these sections.

**Conclusions:** Bone formation is uncommon in arterial calcification, even when severe, indicating that not all calcification eventuates in bone formation. Although larger numbers are needed, the data suggest that patient-specific factors and arterial distribution, rather than severity of calcification are determinants of bone formation. Bone appears to be required for recruitment of osteoclasts to calcified arteries. These results question the notion that bone formation is an integral component of vascular calcification.

## SA-PO573

### Statins and Vitamin D in U.S. Veterans with Chronic Kidney Disease (CKD)

Maryam Sharif- Hassanabadi, Andy Cheng, Seyed-ali Sadjadi, Navin Jaipaul. *Nephrology, Jerry L Pettis VA Medical Center, Loma Linda, CA.*

**Background:** Low(insufficient or deficient) Vitamin D and hyperlipidemia are common in CKD patients and associated with increased mortality. Prior studies have suggested variable effects of statins on 25-hydroxy-vitamin D [25(OH)D] levels. We conducted a single center retrospective cohort study of 632 patients with CKD stage 3 or 4 to determine whether vitamin D status is associated with statin use.

**Methods:** Computerized extraction was used to identify patients with at least one 25(OH)D level between January 2010 to October 2012. Data on patient demographics, laboratory variables, comorbidities, season of 25(OH)D level, and Statin use was collected by chart review. All statistical analyses were performed using SPSS version 20.

**Results:** Briefly, 592 (93%) patients were male with mean age of 71(+/-10.7). 477 (75%) had CKD stage 3. The prevalence of low 25(OH)D in our study population was 76.3%. The most commonly used Statin was Simvastatin (70.4%), followed by Rosuvastatin (15.3%), Pravastatin (7.5%), Atorvastatin (4.6%) and Lovastatin (2.2%). Unadjusted associations of additional study variables are summarized in table 1. Table 1.

| Characteristic | Statin Non-User (N=220) | Statin User (N=412) | p-value |
|---|---|---|---|
| Vitamin D, N(%) | | | <0.05 |
| *Normal≥30 ng/ml* | 62(28.2) | 89(21.6) | |
| *Insufficient 21-29 ng/ml* | 61(27.7) | 155(37.6) | |
| *Deficient≤20 ng/ml* | 97(44.1) | 169(41.0) | |
| Serum Calcium, mg/dL | 9.2+/-0.7 | 9.2+/-0.7 | <0.05 |
| Serum Phosphorus, mg/dL | 3.7+/-0.9 | 3.9+/-0.8 | <0.05 |
| Serum PTH, pg/mL | 141.0+/-146.8 | 140.4+/-134.7 | 0.45 |
| Body Mass Index (BMI), kg/m$^2$ | 28.2+/-6.0 | 31.2+/-6.9 | <0.05 |

In adjusted analysis, the odds of vitamin D insufficiency or deficiency increased by 6% or 7%, respectively, for each 1 kg/m$^2$ increase in BMI, and decreased by 33% or 27%, respectively for non-winter season. Statin usage was significantly associated with a higher prevalence of hypertension, coronary disease, higher BMI and phosphorus levels.

**Conclusions:** After adjusting for covariates, Statin use was not significantly associated with vitamin D status in our CKD study population.

## SA-PO574

### Results of a 12-Week Dose Titration Study Evaluating the Safety and Efficacy of Velcalcetide, a Novel Peptide Agonist of the Calcium-Sensing Receptor (CaSR), for the Treatment of Secondary Hyperparathyroidism (SHPT) in Hemodialysis (HD) Subjects

Geoffrey A. Block,[1] Kevin J. Martin,[2] David A. Bushinsky,[3] Gregory Bell,[4] Karen Pickthorn,[4] Saling Huang,[4] Yan Sun,[4] Reshma Kewalramani,[4] Christian Mix.[4] *[1]Denver Neph; [2]St. Louis Univ; [3]Univ of Rochester; [4]Amgen.*

**Background:** Velcalcetide (AMG 416/KAI-4169), a novel peptide agonist of the CaSR given intravenously thrice-weekly at the end of HD, is being evaluated as a treatment for SHPT.

**Methods:** A single arm, 12-week, dose titration study. Major inclusion criteria: serum iPTH ≥350 pg/mL (≥12 subjects with iPTH >700 pg/mL), corrected Ca (cCa) ≥8.5 mg/dL, and stable doses of vitamin D. Subjects receiving cinacalcet entered a ≥2-week washout period. Velcalcetide was initiated at 5 mg and titrated every 4 weeks (max dose 20 mg) to achieve iPTH ≤300 pg/mL. Serum iPTH, corrected Ca (cCa), P, and FGF23 were measured pre-HD weekly. The primary endpoint was % change from baseline in iPTH during the efficacy period (14 days before and 3 days after the last dose of velcalcetide).

**Results:** 37 subjects were enrolled and received at least one dose of velcalcetide. 32 subjects(87%) completed the 12-week treatment period; 5 subjects discontinued: adverse event(2), withdrawal of consent(1), "other" reasons(2); no subject discontinued for GI adverse event or symptomatic hypocalcemia. Mean(SD) baseline iPTH was 853(644) pg/mL. Mean reductions from baseline during the efficacy period included iPTH 53.6% (95% confidence interval:46.4%,60.8%), cCa 15%(13%,17%), P 10%(4%,17%) and FGF23 52%(34%,70%); 89% had ≥30% reduction in iPTH and 56% had iPTH ≤300 pg/mL.

The most common individual treatment-emergent adverse events (TEAEs) were blood calcium decreased (9 subjects,24%), diarrhea (5 subjects,14%), and symptomatic hypocalcemia (4 subjects,11%). Serious TEAEs were reported in 3(8%) subjects and none deemed related to drug. 2 subjects (5%) had cCa <7.5 mg/dL and 2(5%) experienced nausea; no vomiting events were recorded.

**Conclusions:** Velcalcetide was well-tolerated, resulted in substantial reductions in serum iPTH and FGF23 without discontinuation of therapy due to hypocalcemia or GI adverse events, and may address some limitations of oral daily medications.

## SA-PO575

### Long Term Safety and Efficacy of Velcalcetide (AMG 416), a Calcium-Sensing Receptor (CaSR) Agonist, for the Treatment of Secondary Hyperparathyroidism (SHPT) in Hemodialysis (HD) Patients

Geoffrey A. Block,[1] Kevin J. Martin,[2] David A. Bushinsky,[3] Yan Sun,[4] David M. Spiegel,[4] Reshma Kewalramani,[4] Christian Mix.[4] *[1]Denver Neph; [2]St. Louis Univ; [3]U of Rochester; [4]Amgen.*

**Background:** Velcalcetide (AMG 416/KAI-4169), a novel peptide agonist of the CaSR given intravenously (IV) thrice-weekly at the end of HD, is being evaluated as a treatment for SHPT.

**Methods:** Among subjects who completed a 12-week dose escalation study (parent study), data are reported from the subsequent 40 weeks of treatment in a single arm, open-label extension (OLE) study. The OLE study is currently ongoing. Major inclusion criteria for the parent study included iPTH ≥350 pg/mL, corrected Ca (cCa) ≥8.5 mg/dL and stable doses of active vitamin D. Following entry into the OLE study, doses of velcalcetide were adjusted to achieve and maintain iPTH ≤300 pg/mL. The primary objective for this observation period was assessment of long-term safety and tolerability. Change over time in iPTH, cCa and P from baseline in the parent study was also assessed.

**Results:** 30/37 subjects from the parent study enrolled in the OLE study. During the 40-week follow-up, 4(13%) subjects reported the adverse event of symptomatic hypocalcemia and 3 additional subjects(10%) developed at least 1 episode of asymptomatic serum cCa <7.5 mg/dL. No subjects experienced 2 consecutive cCa <7.5 mg/dL. The adverse events of nausea and vomiting were each reported by 2 subjects(7%). Mean(SD) baseline iPTH on entry to the parent study was 862(672) pg/mL. Velcalcetide decreased iPTH at week 13 (OLE study start) to 444(676) pg/mL, at week 26 to 305(550) pg/mL (n=25), and at week 52 to 252(131) pg/mL (n=20). At week 52, 17/20(85%) achieved at least a 30% reduction in iPTH, 16/20(80%) achieved a iPTH ≤300 pg/mL, and mean(SD) serum cCa and P were 8.9(0.5) mg/dL and 5.5(1.5) mg/dL, respectively (similar to week 13 values of 8.6(0.7) and 5.1(1.6) mg/dL, respectively).

**Conclusions:** This is the first report of long-term use of velcalcetide, an IV CaSR agonist given with thrice-weekly HD. Velcalcetide was well-tolerated with no subjects withdrawing from study drug due to hypocalcemia, nausea or vomiting; reductions in serum iPTH during this time were maintained.

*Funding:* Pharmaceutical Company Support - Amgen

## SA-PO576

**The Long Acting Calcimimetic R-641 Significantly Lowers Serum FGF23 in Experimental Chronic Kidney Disease** Thilo Krueger,[1] Chun Ouyang,[2] Peter Boor,[1] Nadine Kaesler,[1] Vincent Brandenburg,[3] Georg Schlieper,[1] Willi Jahnen-dechent,[4] Markus Ketteler,[5] Xiaodong Li,[6] William G. Richards,[6] Jürgen Floege.[1] *[1]Nephrology and Clinical Immunology, RWTH Univ Clinic Aachen, Aachen, Germany; [2]Nephrology, The First Affiliated Hospital of Nanjing Medical Univ, Nanjing, China; [3]Cardiology, RWTH Univ Clinic Aachen, Aachen, Germany; [4]Biomedical Engineering, RWTH Univ Aachen, Aachen, Germany; [5]Nephrology, Hospital Coburg, Coburg, Germany; [6]Amgen Inc., Thousand Oaks, CA.*

**Background:** Secondary hyperparathyroidism contributes to vascular calcification in chronic kidney disease (CKD). Calcimimetics lower parathyroid hormone (PTH) secretion by activating the calcium sensing receptor in the parathyroid gland. Here we investigated whether administration of a calcimimetic and PTH injection influences vascular calcification and serum levels of FGF23 in a rat CKD model.

**Methods:** CKD was induced in rats by adenine diet for 4 weeks. Four treatment protocols then continued for further 4 weeks: vehicle, PTH-(1-34), R-641+vehicle, R-641+PTH-(1-34). R-641 or vehicle were administered every third day. In the R-641+PTH group each R-641 dose was followed 48 hrs later by 80 µg/kg PTH s.c. Blood samples were collected; vascular calcification was assessed by measurement of calcium content in aortic walls. PTH-(1-84) and FGF23 serum levels were measured by ELISA.

**Results:** Compared to healthy controls, adenine significantly increased aortic calcium content. R-641 administration significantly reduced aortic calcium content (65 vs. 9 µg/g). Serum PTH was significantly lower in R-641 treatment groups compared to CKD rats (939 vs. 3212 pg/ml). Adenine diet induced a significant increase in FGF23 serum levels (1.4 vs. 198.4 ng/ml); R-641 treatment resulted in significantly lower values (71.4 ng/ml). PTH administration did neither change vascular calcium content in CKD nor FGF23 serum levels in CKD alone or with R-641 co-administration.

**Conclusions:** After 4 weeks treatment, administration of R-641 significantly reduced vascular calcification and lowered serum FGF23 levels in experimental CKD. PTH injection had no influence on vascular calcification or FGF23 serum levels.

*Funding:* Pharmaceutical Company Support - AMGEN Inc.

## SA-PO577

**The Long Acting Calcimimetic R-641 Does Not Induce Adynamic Bone Disease in Chronic Kidney Disease** Thilo Krueger,[1] Peter Boor,[1] Vincent Brandenburg,[2] Georg Schlieper,[1] Willi Jahnen-dechent,[3] Markus Ketteler,[4] Xiaodong Li,[5] William G. Richards,[5] Jürgen Floege.[1] *[1]Nephrology and Clinical Immunology, RWTH Univ Clinic Aachen, Aachen, Germany; [2]Cardiology, RWTH Univ Clinic Aachen, Aachen, Germany; [3]Biomedical Engineering, RWTH Univ Aachen, Aachen, Germany; [4]Nephrology, Hospital Coburg, Coburg, Germany; [5]Amgen Inc., Thousand Oaks, CA.*

**Background:** Secondary hyperparathyroidism is a frequent complication of CKD and contributes to renal osteodystrophy. Calcimimetics lower parathyroid hormone (PTH) secretion by activating the calcium sensing receptor. Constant suppression of PTH secretion, however, may lead to low bone turnover adynamic bone disease. Here we investigated whether repeated administration of a long acting calcimimetic leads to adynamic bone disease in a rat CKD model.

**Methods:** In a dose finding experiment we tested 5, 10 and 20 mg/kg of the long acting calcimimetic R-641 in rats. CKD was induced by adenine diet for 4 weeks. After 3 weeks 10 mg/kg R-641 was administered every third day for further 4 weeks. Bones were labelled with calcein (10 mg/kg) by injection at 10d and 3d prior to sacrifice. Femoral bones were subjected to histomorphometry and blood samples were collected weekly. Vascular calcification was assessed by calcium content determination from thoracic aortas. PTH-(1-84) was measured by ELISA.

**Results:** A single dose of R-641 lowered serum calcium for over 48 hours dose dependently while suppressing PTH levels for 12 hours. Compared to healthy controls, adenine treatment increased osteoid area, osteoblast and osteoclast numbers. Adenine reduced bone area compared to controls. Treatment with R-641 reduced osteoblast numbers and significantly decreased osteoid area without reaching criteria of adynamic bone disease. R-641 reduced vascular calcium content (9 vs. 65 µg/g). Serum PTH was lower in R-641 treatment groups compared to CKD rats (939 vs. 3212 pg/ml).

**Conclusions:** After 4 weeks treatment, a long acting calcimimetic reduced vascular calcification, improved secondary hyperparathyreoidism but did not lead to adynamic bone disease.

## SA-PO578

**Does Decrease of Plasma Fibroblast Growth Factor 23 Concentration during Cinacalcet Treatment Depends on the Decrease of Serum Phosphate Concentration?** Marcin Adamczak, Piotr Kuczera, Andrzej Wiecek. *Dept of Nephrology, Endocrinology and Metabolic Diseases, Medical Univ of Silesia, Katowice, Poland.*

**Background:** Fibroblast growth factor 23 (FGF23) is an important factor involved in the pathogenesis of calcium-phosphate abnormalities in patients with chronic kidney disease and increased plasma FGF23 concentration is a cardiovascular risk factor in these patients. The aim of this prospective, single-arm, open-label clinical study was to assess the influence of six-month cinacalcet treatment on plasma FGF23 concentration and its relationship to the serum phosphate changes in hemodialysed patients (HDP) with secondary hyperparathyroidism (sHPT).

**Methods:** In 58 HDP with sHPT (PTH>300pg/ml) serum PTH, FGF23, calcium and phosphate concentrations were assessed before the first dose of cinacalcet and after 3 and 6 months of treatment. The results are shown as means and 95% confidence index.

**Results:** Serum PTH concentration decreased significantly after 3 and 6 month of treatment. Plasma FGF23 concentration decreased after 3 and 6 months of treatment from 593 (457-730)pg/ml to 513 (380-645)pg/ml; p=0.099 and to 433 (304-561)pg/ml; p=0.015, respectively. FGF23 concentration decreased in 52% of patients. In patients with FGF23 decrease a significant ($p<0.05$) decrease in serum phosphate concentration after 3 and 6 months of treatment [1.92 (1.69-2.14); 1.74 (1.53-1.95) and 1.68 (1.47-1.88)mmol/l, respectively] but not in patients with stable plasma FGF23 concentration [2.13 (1.91-1.35); 2.21 (1.97-2.44); 2.13 (1.92-2.33)mmol/l were observed. There was a significant positive correlation between changes of plasma FGF23 and serum phosphate concentration (0-3 month of treatment) ($R=0.30$, $p=0.03$). In the multivariate analysis changes of plasma FGF23 concentration (0-6 month of treatment) was explained by the serum phosphate concentration changes ($\beta=0.29$; $p=0.04$), but not by the serum PTH and calcium concentration changes, nor by the dose of cinacalcet.

**Conclusions:** Decrease of plasma FGF23 concentration in HDP treated with cinacalcet seems to be related mostly to the decrease of serum phosphate concentration.

*Funding:* Government Support - Non-U.S.

## SA-PO579

**Use of Sevelamer Carbonate to Examine the Role of Intraluminal Phosphate in Secondary Hyperparathyroidism** Kenneth R. Phelps,[1] Darius Mason.[2] *[1]Stratton VAMC, Albany, NY; [2]Albany College of Pharmacy, Albany, NY.*

**Background:** In CKD, [PTH] rises with influx of phosphate (P), and filtrate [P] ($[P]_f$) rises in the cortical distal nephron (CDN). We surmised that increased $[P]_f$ promotes sequestration of Ca in complexes and thus creates a need for high [PTH] to maintain Ca reabsorption. Since $[P]_f$ in the CDN is roughly proportional to $E_P/GFR$ (P excreted/volume of filtrate), we hypothesized that [PTH] would correlate with $E_P/C_{cr}$ in CKD, and would fall with $E_P/C_{cr}$ as sevelamer (SC) reduced influx of P.

**Methods:** Patients with CKD (mean eGFR 28.7 ± 1.7) were randomized in double-blind fashion to SC (2.4 g with meals) or placebo (PL) for 4 wks. $E_P/C_{cr}$ was calculated as $[P]_u[cr]_s/[cr]_u$. [PTH]1-84 was measured by IRMA (Scantibodies), $[1,25(OH)_2D]$ by RIA (Labcorp), and intact [FGF23] by ELISA (Immutopics). Data are post-treatment means (SEM). Δ is change with treatment. Differences were analyzed by unpaired t-test, and regressions by least squares.

**Results:** In SC, $E_P/C_{cr}$ was lower and decrements in $E_P/C_{cr}$ were greater than in PL. [PTH] was not different between groups, but Δ[PTH] and % Δ[PTH] were different.

| Group | SC (n = 14) | PL (n = 15) | P |
|---|---|---|---|
| $E_P/C_{cr}$, mg/dL | 0.9 (0.1) | 1.4 (0.1) | 0.02 |
| $\Delta E_P/C_{cr}$, mg/dL | -0.5 (0.1) | 0.02 (0.11) | 0.01 |
| % $\Delta E_P/C_{cr}$ | -36.4 (7.2) | -0.06 (6.7) | 0.004 |
| [PTH], pg/mL | 66.4 (13.7) | 95.9 (13.4) | 0.14 |
| Δ[PTH], pg/mL | -12.3 (6.3) | 10.5 (8.6) | 0.04 |
| % Δ[PTH] | -11.7 (5.8) | 16.4 (10.0) | 0.02 |

[PTH] correlated with $E_P/C_{cr}$ in SC ($R^2 = 0.53$; $P = 0.003$) and PL ($R^2 = 0.35$; $P = 0.02$). Δ[PTH] correlated with $\Delta E_P/C_{cr}$ in SC ($R^2 = 0.56$; $P = 0.002$) and PL ($R^2 = 0.36$; $P = 0.02$). [PTH] was unrelated to $[P]_s$ and $[1,25(OH)_2D]$. In SC, [PTH] varied directly (not inversely) with [FGF23] ($R^2 = 0.37$; $P = 0.02$).

**Conclusions:** SC reduced $E_P/C_{cr}$ in CKD, and decrements in [PTH] were greater with SC. In both groups, [PTH] correlated with $E_P/C_{cr}$, a surrogate for $[P]_f$ in the CDN, and Δ[PTH] correlated with $\Delta E_P/C_{cr}$. Confounders did not explain the correlations. The results support the hypothesis that in CKD, high $[P]_f$ creates an impediment to Ca reabsorption in the CDN.

## SA-PO580

**Evidence for an Impediment to Tubular Calcium Reabsorption in Chronic Kidney Disease** Kenneth R. Phelps,[1] Kim Stote.[2] *[1]Stratton VAMC, Albany, NY; [2]SUNY Empire State College, Saratoga Springs, NY.*

**Background:** [PTH] is elevated in primary hyperparathyroidism (PHPT) and in hyperparathyroidism due to CKD. Plasma ionized Ca ($[Ca]_i$) and tubular Ca reabsorption/volume of filtrate ($TR_{Ca}/C_{cr}$) are increased in PHPT. Because $[Ca]_i$ is usually normal in CKD, we hypothesized that $TR_{Ca}/C_{cr}$ is also normal despite high [PTH].

**Methods:** We studied 29 patients with CKD (eGFR < 60), 7 patients with PHPT, and 28 control subjects (C). We obtained fasting serum/plasma creatinine ($[cr]_s$), ionized calcium ($[Ca]_i$), ultrafilterable calcium ($[Ca]_{uf}$), and [PTH] 1-84 (IRMA, Scantibodies), and urine cr and Ca ($[cr]_u$, $[Ca]_u$). $[Ca]_i$ was measured with an ion-selective electrode. $[Ca]_{uf}$ was measured by spectrophotometry after centrifugation in an Amicon Centrifree filter. Since the filtration rate of calcium ($C_{cr}[Ca]_{uf}$) is the sum of rates of excretion and reabsorption ($E_{Ca}$ and $TR_{Ca}$), $[Ca]_{uf}$ equals $E_{Ca}/C_{cr} + TR_{Ca}/C_{cr}$. $E_{Ca}/C_{cr}$ was calculated as $[Ca]_u[cr]_s/[cr]_u$, and $TR_{Ca}/C_{cr}$ as $[Ca]_{uf} - E_{Ca}/C_{cr}$. Means were compared with ANOVA.

**Results:** $E_{Ca}/C_{cr}$ was comparable in all groups. $[Ca]_i$, $[Ca]_{uf}$, and $TR_{Ca}/C_{cr}$ were similar in CKD and C even though [PTH] was higher in CKD. In PHPT, $[Ca]_i$, $[Ca]_{uf}$, and $TR_{Ca}/C_{cr}$ were higher than in CKD and C; [PTH] was intermediate between but not significantly different from concentrations in CKD and C.

| Group | CKD (n = 29) | PHPT (n = 7) | C (n = 28) |
|---|---|---|---|
| eGFR, mL/min/1.73m$^2$ | 28.7 (1.7)[a] | 83.3 (9.8) | 85.4 (2.0) |
| [PTH], pg/mL | 82.2 (9.8)[b] | 49.6 (8.0)[c] | 28.8 (2.3) |
| $E_{Ca}/C_{cr}$, mg/dL | 0.06 (0.01) | 0.07 (0.01) | 0.06 (0.01) |
| $[Ca]_i$, mg/dL | 5.0 (0.04) | 5.7 (0.1)[a] | 5.0 (0.02) |
| $[Ca]_{uf}$, mg/dL | 5.4 (0.05) | 6.1 (0.2)[a] | 5.4 (0.05) |
| $TR_{Ca}/C_{cr}$, mg/dL | 5.3 (0.04) | 6.0 (0.2)[a] | 5.3 (0.04) |

Values are mean (SEM). [a]P < 0.001 v other groups. [b]P < 0.001 v C. [c]P = 0.10 v CKD and 0.39 v C. All other differences NS.

**Conclusions:** $TR_{Ca}/C_{cr}$, $[Ca]_i$, and $[Ca]_{uf}$ were similar in CKD and C and higher in PHPT. The combination of normal $TR_{Ca}/C_{cr}$ and high [PTH] suggested the presence of an impediment to Ca reabsorption in CKD. It appears that [PTH] rose as necessary to compensate for the impediment and maintain normocalcemia.

**Effect of PA21, a New Iron-Based Phosphate Binder on FGF23 and Vascular Calcifications Compared with Lanthanum Carbonate and Sevelamer Carbonate in Uremic Rats** Olivier Phan,[1] Marc P. Maillard,[1] Felix W. Funk,[2] Olivier Bonny,[1] Michel Burnier.[1] *[1]CHUV; [2]Vifor (Internationnal) Inc.*

**Background:** Elevated serum phosphate and FGF23 levels are associated with cardiovascular disease in patients with chronic renal disease. Whether FGF23 can act on vascular calcification is still on debate. Few studies have analysed how to suppress FGF23 up-regulation using phosphate binders.

The aim of this study was to evaluate the effects of PA21 compared with lanthanum carbonate (La) and sevelamer carbonate (Se) on serum FGF23, phosphorus, calcium, iPTH concentrations and to investigate a potential effect on the development of vascular calcifications in an adenine-induced rat model of CRF.

**Methods:** After induction of CRF through a 4 week adenine-diet, renal function was significantly impaired in all groups. All uremic rats developed severe hyperphosphatemia and serum PTH increased significantly. Phosphate binders were then given for 4 weeks to all uremic rats, except for the uremic control rats. The concentration of each binder (% of binder added to the diet) was chosen to deliver approximately the same amount of active pharmaceutical moiety to each rat: PA21 5% (corresponding to 1% iron), La 2% (1% lanthanum), Se 1.5% (1% sevelamer). A computer-assisted automated quantitative measurement was used to assess the degree of calcification from von Kossa stained vessel sections.

**Results:** Hyperphosphatemia and increased serum PTH levels were controlled in the phosphate binder treated groups to the same extent. PA21 was the only phosphate binder that was associated with a decrease of FGF23. In uremic control rats, vascular calcifications were more prominently present in the thoracic aorta compared to the carotids and the abdominal aorta. Vascular calcifications of thoracic aorta were significantly decreased by the three phosphate binders to a similar extent. PA21 was more efficient than lanthanum carbonate to prevent calcifications in the upper part of the thoracic aorta.

**Conclusions:** PA21 was as effective in the control of hyperphosphatemia, secondary hyperparathyroidism and vascular calcifications as La and Se. The role of FGF23 as a potential factor of calcification needs to be confirmed.

## SA-PO582

**Maxacalcitol Ameliorates Pathological Left Ventricular Hypertrophy by Inhibiting the Calcineurin-NFAT Pathway** Kazunori Inoue,[1] Isao Matsui,[1] Takayuki Hamano,[2] Akihiro Shimomura,[1] Yasuo Kusunoki,[1] Chikako Nakano,[1] Yoshitsugu Obi,[1] Yoshiharu Tsubakihara,[2] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

**Background:** Cardiovascular disease, such as heart failure accompanied by pathological left ventricular hypertrophy (LVH), is the leading cause of death in CKD. Studies on vitamin D receptor knockout mice have revealed that active vitamin D (aVD) is one of the promising agents that ameliorate LVH. Both maxacalcitol (22-oxacalcitriol (OCT)) and paricalcitol are clinically available less calcemic analogue of aVD, however, their actions differ from each other in some points. Therefore, we examined (1) the potential of OCT as a therapeutic agent for LVH and (2) the underlying mechanisms especially focusing on the difference between OCT and paricalcitol.

**Methods:** Six-week-old male Wister rats were subjected to heminephrectomy and then divided into four groups; normal saline + vehicle (N+V), normal saline + OCT (N+O), angiotensin II (Ang II) + vehicle (A+V), or Ang II + OCT (A+O). Vehicle or OCT at a dose of 0.15 μg/kg BW was administered subcutaneously twice a day. Using neonatal rat ventricular myocytes (NRVM), we examined the difference between OCT and paricalcitol in view of the calcineurin-NFAT pathway, which plays a pivotal role in the pathogenesis of LVH.

**Results:** Compared with group A+V, heart weight, wall thickness, and mRNA expression levels of the hypertrophic markers were decreased in group A+O. We found that OCT inhibited Ang II-induced activation of calcineurin A, and that OCT recovered mRNA levels for atrogin-1 in AngII infused rats. In vitro analyses also demonstrated that OCT inhibited Ang II-induced hypertrophy by inhibiting the calcineurin-NFAT pathway. In comparison with the same concentrations of paricalcitol, OCT more effectively inhibited the hypertrophy by inducing atrogin-1-dependent ubiquitination of calcineurin A in calcinurin-overexpressed NRVM.

**Conclusions:** Our findings provide a novel approach to inhibit calcineurin-NFAT pathway in pathological cardiac hypertrophy.

## SA-PO583

**Response of Hyperplastic Parathyroid Gland to Withdrawal of a Calcimimetic Compound** Masahide Mizobuchi,[1] Hiroaki Ogata,[2] Ai Yamazaki,[1] Noriko Nunota Arai,[1] Naoto Kobayashi,[1] Fumihiko Koiwa,[3] Eriko Kinugasa,[2] Takanori Shibata,[1] Tadao Akizawa.[1] *[1]Dept of Medicine, Div of Nephrology, Showa Univ School of Medicine; [2]Dept of Internal Medicine, Showa Univ Northern Yokohama Hospital; [3]Dept of Medicine, Div of Nephrology, Showa Univ Fujigaoka Hospital.*

**Background:** Calcimimetics have been shown to have suppressive effects on PTH secretion and parathyroid cell proliferation. However, little is known about the mechanistic change in parathyroid cells when calcimimetics are withdrawn. We studied the response of parathyroid glands to the withdrawal of cinacalcet in 5/6$^{th}$ nephrectomized uremic rats.

**Methods:** Uremic rats (Nx) were fed a 1.2% high phosphate diet for 2 weeks to develop secondary hyperparathyroidism and then divided by 3 treatment groups: 1) with vehicle (Veh), 2) with cinacalcet (15 mg/kg/day, gavage) (Cina), and 3) with cinacalcet and a VDRA 22-oxacalcitriol (OCT: 0.15μg/kg, 3 times a week, intraperitoneally) (Cina+Maxa). After 2 weeks treatment, vehicle and cinacalcet were withdrawn while maxacalcitol treatment was continued. Immediately (day 0) and 7 days (day 7) after the withdrawal, blood and parathyroid tissues were obtained. Normal rats with vehicle at day 0 and 7 were utilized as normal controls (NC).

**Results:** Cina and Cina+OCT showed equally and significantly lower PTH than Veh at day 0 whereas PTH in the Cina and Cina+OCT was increased up to indistinguishable levels in the Veh at day 7. Serum P was comparable among Veh, Cina, and Cina+OCT in both day 0 and 7. Cinacalcet treatment significantly decreased ionized Ca compared with Veh at day 0, and this decrease was restored by day 7. At day 0, PCNAmRNA was significantly increased in Veh compared with that in NC and this increase was significantly suppressed in Cina and Cina+OCT. At day 7, however, Cina, but not Cina+OCT showed significant increase in PCNAmRNA compared with Veh.

**Conclusions:** These results suggest that, although PTH rebound is not present, simultaneous use of VDRA is preferred regarding parathyroid cell proliferation when cinacalcet is withdrawn.

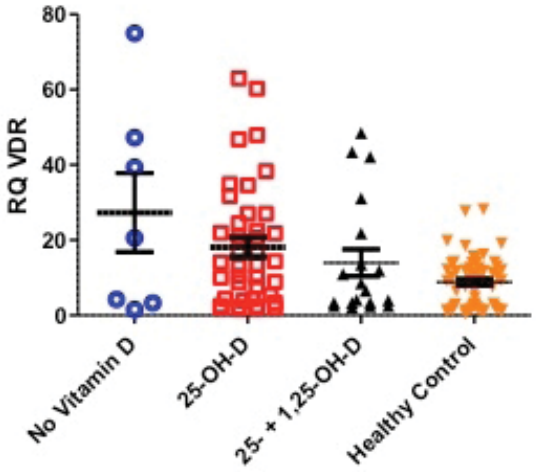
## SA-PO584

**Frequencies of Proinflammatory Monocyte Subsets Correlate with Vitamin D Receptor Expression** Eric Seibert, Christof Ulrich, Felix Kohler, Bogusz Trojanowicz, Roman Fiedler, Matthias Girndt. *Internal Medicine II, Martin-Luther-Univ Halle-Wittenberg, Halle (Saale), Germany.*

**Background:** Proinflammatory monocyte subsets are associated with cardiovascular mortality in HD patients. It is also known that mortality of dialysis patients is associated with vitamin D status and supplementation. We therefore examined the correlation between frequency of proinflammatory monocyte subsets and total leukocyte Vitamin D receptor (VDR) expression and their dependency on different vitamin D medications.

**Methods:** In 74 hemodialysis patients and 60 healthy controls, relative quantity (RQ) of total leukocyte VDR mRNA expression (qRT-PCR, normalized on beta-actin) and frequency of monocyte subsets (flow cytometry, MACS Quant, Miltenyi) were determined. Monocytes were subdivided into CD14++CD16-(Mo1), CD14++CD16+(Mo2) and CD14+CD16++(Mo3) cells. Vitamin D medication was classified by use of cholecalciferol, active vitamin D or none of them.

**Results:** RQ of VDR was significantly higher in HD patients than in healthy controls (19.0±18.9 vs. 8.9±6.6, $p<0.01$). Likewise, Mo2 were higher in HD patients than in controls (8.5±0.3 vs. 3.2±0.2%, $p<0.0001$). Mo2 frequencies and VDR RQ were dependent on vitamin D medication, being highest in patients without vitamin D and lowest in healthy controls. Use of active vitamin D compounds in addition to cholecalciferol was beneficial (fig.1). Frequencies of Mo2 were significantly correlated with VDR RQ ($R^2=0.11$, $p<0.001$).



**Conclusions:** Frequencies of proinflammatory monocyte subsets are correlated with VDR expression. Additionally, VDR expression and Mo2 frequencies vary between groups with different vitamin D compound medication. This may constitute a mechanistic link between beneficial effects of vitamin D supplementation and the prognostic value of proinflammatory monocyte subsets.

## SA-PO585

**Local Synthesis of Calcitriol by 1αhydroxylase Is Involved in Vascular Calcification Induced by Uremia** Noelia Torremade,[1] M. Vittoria Arcidiacono,[1] Petya Valcheva,[1] Milica Bozic,[1] Sara Panizo,[2] Elvira Fernandez,[1] Jose M. Valdivielso.[1] *[1]IRBLleida; [2]Hospital Universitario Central de Asturias.*

**Background:** Vascular calcification is a complication of chronic kidney disease. We have previously demonstrated that uremia increases the expression of 1αhydroxylase in vascular smooth muscle cells (VSMC). The objective of this study is to determine the role of the local synthesis of calcitriol on uremia-induced vascular calcification.

**Methods:** Wild type and 1alpha hydroxylase KO mice (1αOHase KO) underwent 75% of renal mass reduction, and were treated with calcitriol (400 ng/kg/day) for two weeks. At the end of the experiment, serum samples were collected and Ca, P and BUN were quantified. The artery was used to evaluate vascular calcification by calcium quantification and alizarin red staining. In vitro WT and 1αOHase KO VSMC were treated with healthy and uremic rat serum to evaluate its effect on calcification. Normal rat VSMC overexpressing 1αOHasewere incubated under high P media.

**Results:** WT mice (n=7) show increased mortality when treated with calcitriol. However, 1αOHase KO mice (n=10) did not. Serum calcium levels (WT: 16.38 ± 0.48, KO: 15.18 ± 0.46 mg/dl), phosphorus (WT: 8.15 ± 0.42, KO: 8.43 ± 0.46 mg/dl), BUN (WT: 44.99±2.19, KO: 46.13±4.02 mg/dl), and 1,25D levels (WT: 150,21±0,89; KO: 123,28±14,171 pg/ml) increased and were similar in both calcitriol-treated groups. PTH levels decreased in both groups (WT: 29,25±0,84, KO: 30,48±0.70 pg/ml). Vascular calcium content significantly increased in the WT mice compared to 1αOHase KO mice (WT: 895,70±172,26; KO: 556.74±77.71 µgCa/mg protein p<0.05). Similar results were observed with alizarin red staining and immunohistochemical detection of Runx2, which increased only in WT mice. In vitro, WT VSMC treated with uremic serum showed a significant increase in calcification that was not observed in 1αOHase KO cells (WT: 3452.50 ± 498.07; KO: 510.72 ± 94.82 µgCa/mg protein. n=6 to 8, P <0.05). Normal VSMC overexpressing 1αOHaseshowed an increas of calcification when incubated in high P media.

**Conclusions:** These results suggest that local production of calcitriol in the artery may mediate vascular calcification observed in uremia.

*Funding:* Government Support - Non-U.S.

## SA-PO586

**Thyroid Hormones Decrease Plasma 1α,25-Dihydroxyvitamin D Levels through Transcriptional Repression of the Renal 25-Hydroxyvitamin $D_3$ 1α-Hydroxylase Gene (CYP27B1)** Hironori Yamamoto,[2] Mina Kozai,[1] Tomohiro Kagawa,[1] Otoki Nakahashi,[1] Shoko Ikeda,[1] Rina Onishi,[1] Yutaka Taketani,[1] Eiji Takeda.[1] *[1]Clinical Nutrition, Health Biosciences, Univ of Tokushima, Tokushima, Japan; [2]Health and Nutrition, Human Life, Jin-ai Univ, Echizen, Fukui, Japan.*

**Background:** Hyperthyroid patients have been reported to have low levels of plasma 1α,25-dihydroxyvitamin D ($1,25(OH)_2D$), however, its detailed mechanism is still poorly understood. The present study determined whether renal 25-hydroxyvitamin D-1α-hydroxylase (CYP27B1) gene expression was negatively regulated by thyroid hormones.

**Methods:** For hyperthyroid mice, C57BL/6 mice were given 3,3',5-tri-iodothyronine ($T_3$) at 20 or 200 µg/100 g of body weight by intraperitoneal injection for 24 hr. Real-time PCR were performed using kidney total RNA and gene specific primers. The transcriptional activity of CYP27B1 gene were measured by CYP27B1 luciferase reporter vector and renal proximal tubular opossum kidney (OK-P) cells.

**Results:** $T_3$-induced hyperthyroid mice showed marked decreases in plasma $1,25(OH)_32$[/sub]D levels and in renal expression of CYP27B1 mRNA. In addition, we observed that $T_33$[/sub] administration significantly decreased plasma $1,25(OH)_32$[/sub]D and renal CYP27B1 mRNA levels that were increased by low calcium diet, and induced hypocalcemia in mice fed a low calcium diet. $T_33$[/sub] decreases the basal transcriptional activity of the CYP27B1 gene through thyroid hormone receptors (TRα, TRβ1) and the retinoid X receptor α (RXRα) in OK-P cells. Interestingly, we identified an everted repeat negative thyroid hormone response element (1α-nTRE) overlapping the sterol response element (SRE) and the TATA-box in the human CYP27B1 gene. Finally, we established that CYP27B1 gene transcription is positively and negatively regulated by SRE-binding proteins (SREBPs) and $T_33$[/sub]-bound TRβ1/RXRα via the 1α-nTRE.

**Conclusions:** These results suggest that transcriptional repression of the CYP27B1 gene by $T_3$-bound TRs/RXRα, acting through the 1α-nTRE, results in decreased renal CYP27B1 expression and plasma $1,25(OH)_2D$) levels.

*Funding:* Government Support - Non-U.S.

## SA-PO587

**Vitamin D Is Cardioprotective but Not Essential for Fibroblast Growth Factor-23 Production** Carlos Cuervo, Gaston E. Zilleruelo, Michael Freundlich. *Pediatric Nephrology, Univ of Miami Miller School of Medicine, Miami, FL.*

**Background:** The mechanisms regulating FGF23 are unclear. $1,25(OH)_2D_3$ (D) and PTH both increase FGF23 levels. However, undetectable FGF23 levels in 1-α hydroxylase ablated mice and the regulatory transcription by a D response element in the FGF23 promoter, suggest D-indispensability for bone FGF23 secretion challenging the notion that PTH in the absence of D is sufficient for FGF23 production. Absent D also results in renin-angiotensin system (RAS) upregulation and may cause hypertension and cardiac hypertrophy (CH), as in CKD. These relationships were studied in vitamin D dependent rickets type I (VDDR-I), where abolished 1-α OH activity results in↓or undetected circulating D and ↑PTH levels.

**Methods:** After diagnosing VDDR-I at age 8 months, oral calcitriol and supplemental Ca were maintained for the subsequent 12 years, and measurements obtained while under Rx (on-Rx) or following periods of non-adherence (off-Rx).

**Results:** Hypocalcemia and rickets healed on-Rx but reappeared off-Rx. Final height and blood pressure were normal, the echocardiogram displayed normal ventricular dimensions and cardiac function. Comparing off-Rx vs. on-Rx, 1,25D levels were lower (15±4.5 vs.40±12.8 pg/ml, p=0.01), Alk-P higher (1,986±986 vs.1,532±184 U/L, p<0.05), PTH higher (931±228 vs. 43±24 pg/ml, p<0.005), FGF23 lower (70±3.5 vs. 270±0.3 RU/ml, p<0.0005), and renin higher (5.4±1.5 vs. 3.8±0.92 ng/ml/hour, p<0.02). 1,25D correlated with renin (r= -0.61, p<0.05) and PTH (r= -0.87, p<0.005). Plasma aldosterone and Ang II, and urine tetrahydroaldosterone were↑off-Rx and normalized on-Rx. During off-Rx at nadir 1,25D levels <8pg/ml, FGF23 levels were normal (70 RU/ml) while PTH was↑(751 pg/ml) and FEPO4↑(65%).

**Conclusions:** VDDR-I replicates data in animals deficient in D biosynthesis with RAS stimulation, and shows D acting as a negative regulator of renin production. Long-term D therapy in VDDR-I effectively prevented hypertension and CH strengthening the notion that D displays cardioprotective properties. Furthermore, maintenance of normal FGF23 concentrations with prevailing undetectable 1,25D levels, suggests D-independent PTH-mediated FGF23 secretion by the bone.

## SA-PO588

**$24,25(OH)_2$ D Concentration during Treatment of Vitamin D Deficiency** Hala M. Alshayeb,[3] Arif Showkat,[1] Leigh Darryl Quarles,[1] Geeta G. Gyamlani,[1,2] Valentin David,[1] Barry M. Wall.[1,2] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]VA Medical Center, Memphis, TN; [3]Marshall Univ, Huntington, WV.*

**Background:** Although FGF23 upregulates Cyp24 in CKD, $24,25(OH)_2D$ levels have been shown to be directly related to eGFR in human subjects, possibly related to decreased total enzymatic activity in CKD (Kidney Int, 2012). Low 25(OH)D is a predictor of reduced $24,25(OH)_2D$, suggesting that production may be substrate dependent. To further assess these interactions, $24,25(OH)_2D$ levels were measured before and after treatment of vitamin D deficiency with cholecalciferol in patients with normal eGFR, CKD, and ESRD.

**Methods:** Patients with 25OHD level < 20 ng/ml received 10,000 IU/week of cholecalciferol for 8 weeks: CKD patients(n=14) matched with non-CKD (n=14) for age, sex, race, and diabetes and unmatched ESRD hemodialysis patients (n=14).

**Results:** There were no significant differences between CKD and non-CKD groups in basal levels of 25(OH)D and $24,25(OH)_2D$. Baseline iPTH and FGF-23 were higher in CKD patients. Cholecalciferol treatment resulted in increments in serum 25(OH)D (18.6 ± 8 ng/ml vs 12.2 ± 9, p=0.03) and in $24,25(OH)_2D$ (1.14 ± 0.89 ng/ml vs 1.02 ± 0.74, p=0.7) in non-CKD and CKD, respectively. $24,25(OH)_2D$ were not higher in CKD ( before or after cholecalciferol). Cholecalciferol resulted in an increase in FGF23 (44 ± 57 pg/ml, P=0.01) in non-CKD, but not in CKD or ESRD. In a multivariable analysis, low post-treatment serum $24,25(OH)_2D$ level was predicted by low post-treatment 25(OH)D (p<0.03), low eGFR( P=0.05) and high baseline PTH (p<0.01). The change in 25 (OH)D level in ESRD cohort was 16.5 ± 0.7 ng/ml, while 24,25OH2D were extremely low and did not change with cholecalciferol.

**Conclusions:** $24,25(OH)_2D$ increases with cholecalciferol therapy in CKD and non-CKD subjects, consistent with substrate dependent production. Despite decreased nephron mass in CKD, there was a similar increment in $24,25(OH)_2D$ following cholecalciferol suggesting Cyp24a1 up-regulation. Pesisistent markedly reduced $24,25(OH)_2D$ in ESRD is likely related to more severely reduced functioning nephron mass.

## SA-PO589

**Associations of Serum 25-Hydroxyvitamin D and 1,25-Dihydroxyviatmin D Levels with All-Cause Mortality and Cardiac Death in the Hemodialysis (HEMO) Study** Jessica B. Kendrick,[1] Alfred K. Cheung,[2,3] Tom Greene,[3] Michel Chonchol.[1] *[1]Univ of Colorado; [2]VASLCHCS; [3]Univ of Utah.*

**Background:** Determine whether serum vitamin D levels are related to all-cause mortality (ACM) and a composite of first cardiac hospitalization or cardiac death in patients requiring hemodialysis.

**Methods:** The HEMO Study was a randomized multicenter study evaluating the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. 25-hydroxyvitamin D (25(OH)D) and 1,25-dihydroxyvitamin D ($1,25(OH)_2D$) levels were measured in stored serum samples obtained at baseline and annually in 1,340 patients in this cohort. Quartiles of serum 25(OH)D and $1,25(OH)_2D$ concentrations were chosen as the primary predictor variable, with the lowest quartile serving as the reference category. Time-dependent Cox proportional-hazards models were used to examine the association between vitamin D levels with ACM and a composite of first cardiac hospitalization or cardiac death.

**Results:** Participants had a mean age of 57±14 years, 55% were females and 46% were white. During a median follow-up of 3.0 years, 582 (43%) died from any cause, and 514 (41%) had a cardiac event. Median (IQR) serum 25(OH)D and $1,25(OH)_2D$ levels were 19.1 [14.2, 26.6] ng/mL and 6.3 [2.9, 14.5] pg/mL, respectively. After adjustment for potential confounders available in the database including inflammatory markers and usage of calcitriol, the highest quartile of 25(OH)D was associated with a decrease risk of ACM (HR;0.55, 95% CI 0.40-0.75) and cardiac events (HR; 0.70, 95% CI 0.52-0.0.94), when compared to the lowest quartile. Similarly, when 25(OH)D was evaluated as a continuous variable, higher levels of 25(OH)D were associated with a decreased risk of ACM and cardiac outcomes (HR; 0.77, 95% CI 0.66-0.90 and HR; 0.79; 95% CI 0.68-0.92, respectively per doubling of 25(OH)D level). There was no association between $1,25(OH)_2D$ levels with ACM or cardiac events.

**Conclusions:** Low serum 25(OH)D level, but not $1,25(OH)_2D$ level, is independently associated with ACM, cardiac hospitalizations and death in patients requiring hemodialysis.

*Funding:* NIDDK Support

## SA-PO590

**Human Cathelicidin and Vitamin D: Baseline Associates and Effects of Ergocalciferol** Ishir Bhan, Ravi I. Thadhani. *Nephrology Div, Massachusetts General Hospital, Boston, MA.*

**Background:** Cathelicidin is an antimicrobial peptide produced by the innate immune system that is regulated at a genetic level by vitamin D. Low plasma levels of cathelicidin have been to increased risk of infection in dialysis. We sought to determine baseline associates of plasma cathelicidin in a healthy population and to determine the effects of ergocalciferol ($D_2$) treatment.

**Methods:** We enrolled 100 healthy subjects free of chronic kidney disease or active infection at a university clinical research center. Baseline levels of 25-OH vitamin D were assessed. Subjects with levels ≤ 32 ng/ml were treated with 50,000 IU ergocalciferol x 5 doses (250,000 IU total) and returned for follow up laboratory studies (n=35). Levels of cathelicidin, 25-OH $D_2$, 25-OH $D_3$ and $1,25(OH)_2$ D, vitamin D binding protein, albumin, white blood count (WBC) with differential, and total and regulatory T-cells were assessed before and after treatment.

**Results:** Baseline plasma cathelicidin (total hCAP18) was associated with 25-OH D levels (R=0.25, p=0.015), which was largely driven by levels of 25-OH $D_3$ among individuals with total 25-OH D levels ≤ 32 ng/ml. This association remained significant and stable despite adjustment for demographic and laboratory factors. No association with 25-OH $D_2$ levels was observed. Additional predictors of cathelicidin included total WBC (R=0.32, p=0.002), absolute lymphocyte count (R=0.33, p=0.001), absolute neutrophil count (R=0.25, p=0.0.18), total T cell count (R=0.31, p=0.004), and regulatory T cell count (R=-0.25, p=0.23). Ergocalciferol treatment increased 25-OH $D_2$ (by 30 ng/ml, p<0.0001) and $1,25(OH)_2$ D (by 12 pg/ml, p<0.001) decreased 25-OH $D_3$ levels. No change in calcium, phosphorus, PTH, T-cells or plasma cathelcidin was observed with treatment.

**Conclusions:** Despite robust baseline associations with 25-OH $D_3$ levels, treatment with high-dose $D_2$ failed to augment plasma cathelicidin in a healthy population. The form of vitamin D ($D_2$ vs $D_3$) may be relevant to studies of its immunologic effects.

## SA-PO591

**Loop Diuretics Are Associated with Higher PTH in Patients with Normal GFR** Kristin M. Corapi,[1] Gearoid M. McMahon,[2] Julia Beth Wenger,[1] Julian L. Seifter,[2] Ishir Bhan.[1] *[1]Renal, Massachusetts General Hospital, Boston, MA; [2]Renal, Brigham and Women's Hospital, Boston, MA.*

**Background:** Loop diuretics are known to increase urinary calcium excretion and are associated with elevated PTH in patients with chronic kidney disease. We assessed whether loop diuretics are linked to higher PTH levels in patients with normal renal function.

**Methods:** We studied adult participants (≥18 years) from NHANES 2003-2004 and 2005-2006. Subjects with an eGFR<60ml/min were excluded. The primary outcome, PTH, was log-transformed due to non-normality. Univariate analysis was done using a chi square test or simple linear regression to identify significant predictors of PTH. The association between the use of loop diuretics and PTH was tested using a multi-variable linear regression model adjusted for known covariates after application of appropriate weights.

**Results:** 8,875 participants were eligible for inclusion, 157 of whom were using loop diuretics. Loop users and non-users did not differ in season of exam, serum calcium, or serum phosphorus. Loop users were more likely to be older, African American, female, and have a higher BMI. Loop users also had a lower mean 25-(OH) vitamin D and albumin, but higher alkaline phosphatase and uric acid. Median PTH was significantly higher in loop users than in non-users, 51.1 vs 37.3 pg/mL (p<0.001). In the multivariable-adjusted model, the use of loop diuretics was associated with significantly higher log PTH levels (p=0.002). After adjusting for other predictors, use of a loop diuretic was associated with a 12% higher median PTH value compared to non-loop users.

| Model | β | *p* value |
|---|---|---|
| **Univariate Model** | | |
| Loop diuretic | 0.036 | <0.001 |
| **Multivariable Model*** | | |
| Loop diuretic | 0.115 | 0.002 |
| * = adjusted for age, gender, race, BMI, uric acid, phosphorus, calcium, 25(OH) vitamin D, albumin, alkaline phosphatase | | |

**Conclusions:** In patients with normal renal function, loop diuretics are independently associated with higher PTH levels. Given the known adverse consequences of elevated PTH, it is important that providers be aware of this relationship.

## SA-PO592

**Bone Mineral Metabolism Parameters and Microalbuminuria in the National Health and Nutrition Examination Surveys 1999-2010** Timothy Ellam, Sheila E. Francis, Timothy Ja Chico. *Dept of Cardiovascular Science, Univ of Sheffield, United Kingdom.*

**Background:** Greater levels of serum phosphorus, parathyroid hormone (PTH) and alkaline phosphatase (ALP) are independent predictors of adverse cardiovascular outcomes in the presence or absence of kidney disease. Endothelial dysfunction has been implicated as a causal mechanism. We hypothesized that these factors are associated with higher-normal albuminuria and the likelihood of microalbuminuria, a cardiovascular risk marker considered to reflect endothelial dysfunction.

**Methods:** We examined associations of the above bone metabolic parameters with urine albumin:creatinine ratio (ACR), urine albumin concentration and likelihood of microalbuminuria (ACR>17mg/g in men and >25mg/g in women). Linear and logistic regression analyses were performed in the NHANES 1999-2010 cohorts (N=23,036 adults with eGFR≥60 and without macroalbuminuria) with adjustment for covariates including age, gender, BMI, race, blood pressure, diabetes, poverty:income ratio, eGFR, serum lipids, hemoglobin, and CRP. Bone-specific ALP and PTH measurements were available in NHANES 1999-2004 (N=10,341) and 2001-2006 (N=6,923) respectively.

**Results:** Greater serum phosphorus or estimated dietary phosphorus intake (whether absolute, indexed to body weight, calorie intake or calcium intake) did not predict higher log ACR or likelihood of microalbuminuria. Serum total ALP, bone-specific ALP and PTH were independent predictors of higher log ACR and log urine albumin (p<0.001 for all), though increased likelihoods of microalbuminuria with increasing levels of these parameters were non-significant following full covariate adjustment.

| | Fuly adjusted coefficients for prediction of LnACR | | |
|---|---|---|---|
| | β quintile 5 vs 1 | Corresponding fold-change in ACR | p |
| ALP | 0.07 | 1.08 | 0.002 |
| Bone-ALP | 0.18 | 1.20 | <0.001 |
| PTH | 0.16 | 1.18 | <0.001 |

**Conclusions:** Higher levels of ALP, Bone-ALP and PTH are independently associated with greater urinary albumin excretion in a representative sample of the general population. Whether targeting these parameters improves cardiovascular health remains to be determined.

## SA-PO593

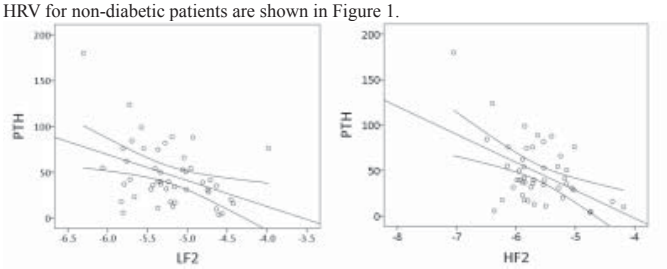
**Parathyroid Hormone and Heart Rate Variability in Hemodialysis Patients** Dimitrios J. Poulikakos,[1,2] Debasish Banerjee,[1,2] Marek Malik.[1] *[1]Cardiovascular Sciences Research Centre, St. George's Univ of London, London, United Kingdom; [2]Renal and Transplantation, St. George's Hospital NHS Trust, London, United Kingdom.*

**Background:** Depressed Heart Rate Variability (HRV) reflects abnormal cardiac autonomic regulation and has been linked with increased cardiovascular risk and sudden cardiac death. High parathyroid hormone levels have been associated with sudden cardiac death. We aimed to investigate the association between HRV indices and parathyroid hormone (PTH) in hemodialysis (HD) patients.

**Methods:** Continuous Holter electrocardiograms were obtained during HD and repeated 5 times at 2-weeks intervals in 80 stable HD patients. The high- (HF) and low-frequency (LF) components of HRV in absolute values were calculated every 5 minutes and averaged during the first and last hour of the recordings denoted with (1) and (2) respectively. Logarithmic transformation was applied to normalize the distribution of data. Pre-HD intact PTH, corrected calcium (Ca) and phosphate (P) levels were measured before the first recording.

**Results:** Data were available for 75 subjects (Age 60±15,32% females, 37% diabetics, intact PTH=44±32 pmol/L, Ca=2.3±0.2mmol/l, P=1.6±0.4mmol/l). All HRV indices showed

intrasubject stability. Diabetics had lower LF2 (-5.5±0.5 vs. -5.2±0.5 p=0.012). In non-diabetics PTH correlated negatively with all HRV indices (LF1 r= -0.348, p =0.016, LF2 r= -0.398 p = 0.006, HF1 r= -0.428 p 0.003, HF2 r= -0.491, p=0.000) and P correlated positively with LF1 (r=-0.415, p=0.005), HF1 (r=-0.437, p=0.003) and HF2 -0.319, p=0.033). There was no association between PTH and HRV indices in diabetics. Scatterplots for PTH and HRV for non-diabetic patients are shown in Figure 1.



**Conclusions:** High PTH and phosphate were associated with depressed HRV in non-diabetic HD patients. Prospective studies are necessary to further evaluate the role of mineral abnormalities in autonomic imbalance in HD patients.

## SA-PO594

**mTOR Is Central to Parathyroid Cell Proliferation in Experimental Secondary Hyperparathyroidism** Oded Volovelsky, Gili Cohen, Gilad Wasserman, Tomer Meir, Oded Meyuhas, Justin Silver, Tally Naveh-Many. *Hadassah Hebrew Univ, Jerusalem, Israel.*

**Background:** Parathyroid (PT) cell proliferation is central to secondary hyperparathyroidism (SHP). The signal transduction pathways for parathyroid cell proliferation are not defined. We demonstrate the role of mTOR in parathyroid cell proliferation of SHP.

**Methods:** We induced SHP by a low calcium diet or adenine high Pi CKD. PT cell proliferation was measured by BrdU and Ki67 staining of PT sections. Western blots of mTOR pathway activated PT proteins were performed. The mTOR inhibitor rapamycin was injected ip or added to PT glands in culture. Knock-in mice, whose ribosomal protein S6 (rpS6) is unphosphorylatable due to substitution of all five phosphorylatable serines to alanines ($rpS6^{P-/-}$) and wild type ($rpS6^{P+/+}$) mice were fed a calcium deficient diet.

**Results:** PT cell proliferation was increased in both models of SHP. Significantly, the mTOR pathway was activated in the PTs of the SHP rats, as measured by increased phosphorylation of components along this pathway. To examine the role of mTOR in SHP we injected the mTOR inhibitor rapamycin to the SHP rats. Rapamycin decreased PT mTOR activation and prevented PT cell proliferation in both models of SHP. Rapamycin decreased PT cell proliferation in CKD rats when injected at the start of the adenine diet (prophylactic effect) or later, to correct established PT cell proliferation. To verify whether the effect of mTOR inhibition is direct, PT glands from CKD rats were maintained in organ culture with and without rapamycin. Remarkably, proliferation continued in culture as measured by BrdU incorporation, and was inhibited by rapamycin, as observed in vivo, indicating a direct effect of the inhibitor on PT cell proliferation. rpS6 kinase is a downstream target of the mTOR pathway. Knock-in $rpS6^{P-/-}$ and wild type mice were fed a calcium deficient diet. Hypocalcemia led to the expected increase in serum PTH in $rpS6^{P+/+}$ wild type mice but less so in the $rpS6^{P-/-}$ mice, emphasizing the role of mTOR in SHP.

**Conclusions:** This is the first demonstration that mTOR is a significant regulator of PT cell proliferation and it exerts this effect, at least partially, through rpS6 phosphorylation.

## SA-PO595

**Elevated Sclerostin Levels Decrease Markedly after Successful Renal Transplantation and Correlate with Renal Function and Improvement of Persistent Hyperparathyroidism** Marco Bonani,[1] Daniel Rodríguez Gutiérrez,[1] Nilufar Mohebbi,[1] Thomas Fehr,[1] Jens G. Brockmann,[2] Rudolf P. Wuthrich.[1] *[1]Div of Nephrology, Univ Hospital Zurich, Zurich, Switzerland; [2]Div of Visceral and Transplantation Surgery, Univ Hospital Zurich, Zurich, Switzerland.*

**Background:** Sclerostin is a soluble inhibitor of Wnt signaling which inhibits bone formation. Secreted by osteocytes in response to mechanical unloading it acts as an important regulator of bone formation and localized bone remodeling. Sclerostin levels increase along CKD progression and are particularly elevated in patients on dialysis. The dynamic changes of sclerostin before and after renal transplantation have not been investigated.

**Methods:** We analyzed serum sclerostin levels in 42 patients (mean age 49±14years, 64%male, BMI 25.7±6.0kg/m$^2$) before, and 0.5, 3, 6 and 12 months after kidney transplantation. We also explored the correlation of sclerostin with relevant parameters of CKD-MBD.

**Results:** Sclerostin levels were significantly higher in patients with CKD stage 5 before transplantation (n=42) compared to control patients with normal renal function (n=96) (61.8±32.3 vs 28.4±10.9pmol/l;p<0.001). Within 14 days after transplantation and in parallel with the improvement of renal function, sclerostin values decreased markedly to levels slightly below the normal range (21.0±14.7). Sclerostin levels amounted to 21.0±12.5 and 23.8±14.9 after 3 and 6 months, and increased to 28.0±16.8pmol/l after 12 months. Sclerostin levels were similar in male and female, and in diabetic and non-diabetic patients at all timepoints. After transplantation, sclerostin levels correlated negatively with PTH (r=-0.170,p=0.033) and positively with age (r=0.311,p=0.045), but there was no significant correlation between sclerostin and BMI, eGFR, serum calcium, phosphate, magnesium, 25OH- and 1,25$(OH)_2$-vitamin D. Furthermore, sclerostin levels did not correlate with pre- and post-transplant bone mineral density at the hip and lumbar spine.

**Conclusions:** The marked reduction of elevated serum sclerostin levels shortly after kidney transplantation reflects the improvement of renal function and may contribute to the normalization of bone health after renal transplantation.

## SA-PO596

**Phosphaturic Hormones Predict the Progression of Anemia in Patients with CKD** Takayuki Hamano,[1] Chikako Nakano,[2] Naohiko Fujii,[3] Yoshitsugu Obi,[2] Isao Matsui,[2] Yoshitaka Isaka,[2] Yoshiharu Tsubakihara.[1] *[1]Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [3]Center for Clinical Epidemiology and Biostatistics, Univ of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

**Background:** It was reported that 25-hydroxyvtiamin D (25D) and 1,25-dihydroxyvitamin D (1,25D) levels are associated with severity of anemia in patients with CKD. However, it remains elucidated which MBD markers predict the progression of anemia in this population.

**Methods:** In the OVIDS-CKD study, we prospectively followed temporal change of hemoglobin (hgb) levels. At baseline, we measured 6 MBD markers including intact FGF23, 1-84 PTH, 25D, 1,25D, serum calcium, and phosphate. Outcome of interest is the slope of hgb. We followed the patients until the start of ESA therapy or the end of observation period. We employed a linear mixed effects model with hgb as a time-dependent outcome variable. The interaction term time*each MBD marker was entered into the model to examine if these markers modify the relationship between time and hgb (hgb slope). Since, we have already reported that FGF23 and 25D predict renal outcome (CJASN 2012), eGFR was adjusted as a time-dependent covariate in this model. Only for patients with hgb>10.5 and not receiving ESA at baseline, secondary outcome was defined as time to hgb<10.5 or the start of ESA therapy.

**Results:** We enrolled 738 Japanese predialysis outpatients. Cox models revealed that out of 6 makers only 25D and FGF23 levels predicted the time to the secondary outcome, in addition to prior CVD, proteinuria, baseline hgb, and eGFR. (adjusted HR per unit change of log FGF23 and 10 ng/mL of 25D: 1.65 [1.15-2.36] and 0.66 [0.46-0.96], respectively). However, this result was confounded by time-dependent eGFR. Mixed effects model adjusting for time-dependent eGFR revealed that FGF23 and PTH levels were associated with faster decline of hgb (-0.053 [-0.091~-0.016]g/dL/year and -0.044 [-0.079~-0.008] g/dL/year per SD increase, respectively).

**Conclusions:** Two phosphatonins predict the progression of anemia.

## SA-PO597

**The Association between Handgrip Strength and Vitamin D Status in Maintenance Hemodialysis Patient** Keita Kimura,[1] Akio Nakashima,[2] Yasuo Kimura,[1] Keitaro Yokoyama,[2] Takashi Yokoo,[2] Mitsuyoshi Urashima.[3] *[1]Shikashiwa Clinic, Chiba, Japan; [2]Div of Nephrology and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan; [3]Div of Molecular Epidemiology, The Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** Sarcopenia is highly prevalent in patient undergoing hemodialysis. Assessment and prevention of this disorder are important, because it relates to impairment of activity of daily life, falling, and even to poor prognosis. Hand grip strength (HGS) is simple and reliable method for evaluating muscle function. In hemodialysis patient, HGS correlates with lean body mass and nutritional status. Vitamin D is thought to play a role in sarcopenia. In elderly people, 25-hydroxy vitamin D [25(OH)D] positively associates with muscle strength. However, in hemodialysis patient, the association between muscle function and vitamin D is not fully explored.

**Methods:** HGS was measured in 129 patients on maintenance hemodialysis. Laboratory data including serum 25(OH) D, 1,25-dihydroxyvitamin D [1,25$(OH)_2$D], calcium, phosphorus, alkaline phosphatase, intact-PTH, albumin, and hemoglobin were measured. Clinical characteristics of the patients were also obtained. The association of HGS with these factors was analyzed.

**Results:** Average serum 25(OH)D concentration was 19.4 ng/ml. Higher HGS was associated with younger age, male gender, higher hemoglobin, lower alkaline phosphatase and higher 25(OH) D. Neither 1,25$(OH)_2$D nor use of vitamin D were not associated. After adjusting by the potential confounding factors, the association between HGS and 25(OH) D was still evident.

| | Regression Coefficinet | Standard Error | P-value | 95% Confidence Interval |
|---|---|---|---|---|
| 25(OH)D | 0.30 | 0.09 | 0.001 | 0.13 to 0.44 |
| Age | -0.162 | 0.07 | 0.018 | -0.30 to -0.28 |
| alkaline phosphatase | -0.09 | 0.004 | 0.07 | -0.02 to 0.001 |
| Hemoglobin | 1.42 | 0.61 | 0.021 | 0.21 to 2.62 |

**Conclusions:** Our results clearly showed the association between 25(OH)D and HGS in hemodialysis patient. Considering high prevalence of Vitamin D deficiency and sarcopenia in this population, our results will provide the rationale for planning the controlled study using vitamin D for improving sarcopenia.

**SA-PO598**

**25-Hydroxy Vitamin D Deficiency Is Common in Patients with Chronic Kidney Disease in a Scottish Community Cohort: Results from the Triple A Kidney Project** Shona Methven,[1] Alan G. Jardine,[2] Mark S. MacGregor.[3] *[1]School of Clinical Sciences, Univ of Bristol, United Kingdom; [2]Institute of Cardiovascular and Medical Sciences, Univ of Glasgow, United Kingdom; [3]Renal Unit, Univ Hospital, Crosshouse, Kilmarnock, United Kingdom.*

**Background:** There is increasing awareness of the importance of chronic kidney disease-mineral bone disorders (CKD-MBD), but little is known about primary vitamin D deficiency in patients with CKD. We describe the prevalence of 25-hydroxy vitamin D (25-OHVitD) deficiency in patients with CKD in a geographical area with low levels of sunshine.

**Methods:** Participants with a diagnosis of CKD stage 3 were recruited from 7 primary care facilities across Ayrshire, Scotland in the Triple A Kidney Project. Detailed baseline clinical and laboratory assessment was undertaken, including measurement of 25-OHVitD and parathyroid hormone (PTH) using an immunoassay in all participants (Abbott Architect).

**Results:** Four hundred and eleven participants were recruited, mean age 70.6±9.6 years, 59% female, 99.5% white, 20% diabetic and median eGFR 54 (IQR 44–61) ml/min/1.73m$^2$. Serum adjusted calcium, phosphate and alkaline phosphatase levels were normal (2.2(±0.1) mmol/L; 0.9(±0.2)mmol/L and 78(±29)µg/L respectively). However, mean 25-OHVitD was 38 (±22)nmol/L, with 40.3% having insufficient 25-OHVitD levels (25-49nmol/L), 20.2 being deficient (14-24nmol/L) and 13.7% having undetectable 25-OHVitD (<14nmol/L). Mean PTH was 8.7 (±4.9)pmol/L (upper limit of normal [ULN] 7.5pmol/L) and 47.2% of the total cohort had elevated PTH, rising to 67.1% in those with CKD Stage 3B. Mild hyperparathyroidism was not related to severity of kidney disease (p=0.332), but PTH >3 times ULN was more common in Stage 3B (p<0.001).

**Conclusions:** Primary 25-OHVitD deficiency and mild secondary hyperparathyroidism are very common in those with CKD stage 3 in Scotland, presumably related to low levels of sunshine and diet. The degree of 25-OHVitD deficiency did not vary with renal function, whereas secondary hyperparathyroidism was more severe with poorer renal function. Vitamin D deficiency may predispose to more severe CKD-MBD in the future. Intervention studies are required to assess vitamin D replacement in this group.

**SA-PO599**

**Dialysis Patients with Severe Secondary Hyperparathyroidism: A Homogeneous Population?** Emmanuelle Laurain,[1,2] Michele Kessler,[1] Luc Frimat.[1] *[1]Nephrology, Nancy Universitary Hospital, Vandoeuvre les Nancy, France; [2]Epidémiology, Nancy Universitary Hospital, Vandoeuvre les Nancy, France.*

**Background:** Diagnosis of Secondary hyperparathyroidism (SHPT) remains complex, and its management is not yet well standardized. One hypothesis that could explain these difficulties is that dialysis population with SHPT would not be homogeneous due to various pathophysiological types. The aim of this study was to identify subgroups in CKD patients with incident SHPT on the basis of clinical, biological and therapeutic data routinely available to the clinician.

**Methods:** EPHEYL is a prospective, multicenter, pharmacoepidemiological study including chronic dialysis patients (≥ 3 months) recently diagnosed with SHPT [serum parathyroid hormone (PTH) level ≥ 500 pg/mL or cinacalcet prescription or parathyroidectomy]. Multivariate analyses using multiple correspondence analysis and ascendant hierarchical clustering on clinico-biological (symptoms, PTH, phosphorus, calcemia and alkaline phosphatase levels) and therapeutic characteristics of SHPT (cinacalcet, vitamin D, calcium, or non-calcic phosphate binder) were performed to identify subgroups.

**Results:** 305 patients (261 patients with incident PTH ≥ 500 pg/mL, 44 patients with cinacalcet initiation) were included from December 1st, 2009 and May 30th, 2012. Their mean age was 67+15 years, and 60% were men. They had been on maintenance dialysis for a mean period of 28+35 months (92% on hemodialysis, 8% on peritoneal dialysis). Four subgroups of SHPT patients were identified: 1/ "intermediate patients" with hyperphosphatemia without hypocalcemia (n=113); 2/ younger patients with severe cardiovascular co-morbidities, hyperphosphatemia and hypocalcemia despite SHPT polymedication (n=73); 3/ elderly patients with few cardiovascular co-morbidities, controlled phospho-calcium balance, and few pharmacological treatments (n=75); 4/ patients who initiated cinacalcet despite a lower PTH (n=43). The quality criterion of the model had a threshold of 14 (> 2) suggesting a good classification.

**Conclusions:** Among dialysis patients, SHPT affects a very heterogeneous population at the time of SHPT diagnosis. The therapeutic management and issues seem to vary according to each subgroup.

*Funding:* Government Support - Non-U.S.

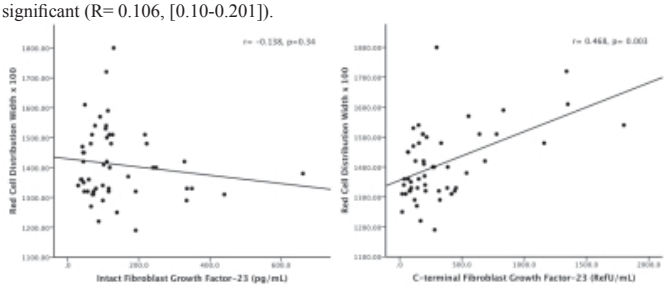
**SA-PO600**

**RDW Is Associated with cFGF23 and Not with iFGF23** Carlo A. Gaillard,[1] Fenna Breda, Van,[1] Mireille E. Emans,[2] Karien Van der Putten,[3] Branko Braam,[4] Frans J. van Ittersum,[1] Marc G. Vervloet.[1] *[1]Nephrology, UMCG/ VUMC, Netherlands; [2]Cardiology, UMCU, Netherlands; [3]Internal Medicine, TerGooiziekenhuis, Netherlands; [4]Medicine, Univ of Alberta, Canada.*

**Background:** Fibroblast growth factor-23 (FGF23) and red cell distribution width (RDW) are associated with poor clinical outcomes. RDW is associated with iron deficiency. Recent studies suggest a mechanistic link between iron deficiency and FGF23. In this post-hoc analysis we hypothesized that in CKD patients with heart and renal failure, iron metabolism links FGF23 and RDW.

**Methods:** Associations between levels of iFGF23 (intact), cFGF23 (c-terminal) and RDW were analyzed in 54 participants of the EPOCARES study (PMID 20383871). Two assays detecting FGF23 were used: one detected only iFGF23, the other detected free c-terminal FGF23 fragments and iFGF23.

**Results:** cFGF23 and RDW (correlation coefficient (r)= 0.468, p= 0.003) were associated, iFGF23 and RDW were not (r= -0.069, p= 0.627). Yet, iFGF23 and cFGF23 were both associated with cystatin C (r= 0.632, p < 0.001 and r= 0.414, p=0.02). Multivariable linear regression analysis, that included PTH, phosphate, BMI, smoking and cystatin C did not alter the strength of the association between cFGF23 and RDW (regression coefficient (R)= 0.163, [0.081-0.246]). After adjusting for markers of iron metabolism, this association was attenuated (R= 0.147, [0.061-0.232]). In the full adjusted model correcting for both markers of inflammation and iron metabolism the association remained statistically significant (R= 0.106, [0.10-0.201]).



**Conclusions:** cFGF23 and not iFGF23 levels were associated with RDW levels in CKD and CHF patients. This suggests a connection between c-terminal fragments and RDW, possibly independently of iron status and inflammation. Studies are needed that unravel what mechanisms are responsible for this association and whether this explains the link of RDW with outcome.

**SA-PO601**

**Klotho, Proteinuria and Acidosis in CKD Patients** Solenne Pelletier,[1] Laurence Dubourg,[2] Jocelyne Drai,[3] Sandrine Lemoine,[4] Aoumeur Hadj-aissa,[2] Denis Fouque.[1] *[1]Nephrology, Centre Hospitalier Lyon Sud, Pierre-Benite, France; [2]Explorations Fonctionnelles Renales, Hopital Edouard Herriot, Lyon, France; [3]Biology, Centre Hospitalier Lyon Sud, Pierre-Benite, France; [4]Nephrology, Hopital Edouard Herriot, Lyon, France.*

**Background:** a-Klotho(Kl) is a recently discovered FGF23 cofactor involved in phosphorus metabolism. Kl overexpression is associated with extended longevity, whereas Kl-KO animals die prematurely. We included 60 chronic kidney disease (CKD) stage 1-5 patients and studied relationships between renal function, proteinuria, bone biomarkers, acid-base status and serum a-Kl concentration.

**Methods:** Blood was drawn after overnight fast for PTH, FGF-23, calcium, phosphorus, 25OH vitamin D, bone specific alkaline phosphatase (bSAP). Serum a-Kl was measured by Elisa (IBL, Japan, normal values 239-1266 pg/mL); proteinuria was obtained from 24hr urine. Renal function was assessed by urinary inulin clearance.

**Results:** We found positive relationships between a-Kl and FGF23 (p<0.005, r=0.36), serum bicarbonate (p=0.05, r=0.26), and an inverse relationship with proteinuria (p=0.03, r=-0.32). No relationship was found between a-Kl and renal function, serum PTH, vitamin D, bSAP, calcium and phosphorus. Multivariate analysis including proteinuria, FGF23 and bicarbonate showed that FGF23 and bicarbonate were significantly associated with serum a-Kl (p<0.01).

**Conclusions:** The present findings show for the first time a potential link between 2 important amenable conditions occurring during CKD: proteinuria and acidosis. We suggest including these parameters during future Klotho studies in CKD patients. Whether correcting acidosis may improve serum a-Kl deserves further research.

**SA-PO602**

**Plasma Exchange Induces Vitamin D Deficiency** Thomas F. Hiemstra,[1] Alina L. Casian,[2] David R.W. Jayne.[2] *[1]Dept of Medicine, Univ of Cambridge; [2]Vasculitis and Lupus Clinic, Addenbrooke's Hospital.*

**Background:** Plasma exchange (PEX) is a widely used immune-modulating therapy for diseases mediated by antibodies or pathogenic proteins, or for transplant desensitisation. Vitamin D (25OHD) deficiency is associated with skeletal and extra-skeletal pathology, is

permissive to activity of a number of autoimmune diseases, and may be associated with poorer renal allograft survival. We asked whether PEX would induce vitamin D deficiency through removal of its carrier, vitamin D binding protein (DBP).

**Methods:** We performed a prospective cohort study of patients receiving plasma exchange at Addenbrooke's Hospital, Cambridge. Vitamin D metabolites, DBP and biochemical parameters were measured before the start and after every plasma exchange treatment, as well as 7 and 28 days after completion of PEX.

**Results:** 11 Caucasian patients (7 males) aged 59 ± 13 years received 5.5 ± 0.9 PEX treatments, for ANCA-associated vasculitis (n=5), myasthenia gravis (n=3), paraneoplastic neuropathy (n=2) and voltage-gated potassium channel antibody-mediated encephalopathy (n=1). Baseline estimated glomerular filtration rate was 56.9 ± 39.5 ml/min/1.73m$^2$, and 5 patients had chronic kidney disease stage 3 or worse.Baseline 25(OH)D levels were 50.6 ± 30.1 nmol/L. PEX significantly reduced 25OHD levels after 5 treatments to 22 ± 9.4nmol/L (p = 0.0017), and vitamin D remained low 7 days (26.4 ± 9.8nmol/L, p=0.02) and 28 days (30.8 ± 15.5, p=0.048) after cessation of PEX. $1_\alpha25(OH)_2D$ levels reduced from 103 ± 52pmol/L to 42 ± 4pmol/L (p = 0.003) with PEX, but had returned to baseline levels after 7 days. PEX also significantly reduced DBP levels from 206.5 ± 64.7µg/mL to 98.5 ± 34µg/mL (p = 0.0001), but levels had returned to baseline after 7 days. PEX significantly reduced corrected Calcium from 2.23 ± 0.12 mmol/L to 1.98 ± 0.08 mmol/L (p = 0.0007), but did not alter phosphate. Analyses of plasma effluent confirmed removal of DBP, vitamin D and PTH by PEX.

**Conclusions:** We identified sustained reduction in 25OHD and acute reversible reduction in $1_\alpha25(OH)_2D$ by a typical course of PEX, likely through its removal with DBP in plasma effluent. PEX-treated patients should receive vitamin D supplementation.

## SA-PO603

### Serum Phosphorus and Fibroblast Growth Factor 23 Do Not Modify the Association of Angiotensin II Inhibition with Outcomes in Subjects with Advanced Chronic Kidney Disease

,[1] Kristen L. Jablonski,[1] Jessica B. Kendrick,[1] Alfred K. Cheung,[2,3] Gerard John Smits,[1] Michel Chonchol.[1] *[1]Div of Renal Diseases and Hypertension, Univ of Colorado Denver, Aurora, CO; [2]VA Salt Lake City Healthcare System, Salt Lake City, UT; [3]Univ of Utah, Salt Lake City, UT.*

**Background:** In chronic kidney disease (CKD), there is a fibroblast growth factor 23 (FGF23) -mediated increase in fractional excretion of phosphorus to compensate for decreased kidney function. Higher levels of phosphorus and FGF23 are associated with kidney disease progression and mortality in advanced chronic kidney disease. However, it is unknown whether these associations differ by degree of hyperphosphatemia or FGF23 level.

**Methods:** We studied the effects of ACE/ARB use in 1753 subjects with advanced CKD (1099 CKD, eGFR=18±6 ml/min/1.73m$^2$; and 654 ESRD) who participated in the Homocysteine in Kidney and End Stage Renal Disease study. Outcome measures were dialysis initiation for those with CKD and death among the whole cohort. Cox regression models adjusted for important confounding variables and propensity score analysis was used to assess the association of ACE/ARB use with dialysis initiation and death. Analyses were stratified by serum levels of phosphorus and FGF23.

**Results:** Average age was 66±12 years, 36% were black, and 870 (50%) were taking ACE/ARB. Over a mean follow-up of 3 years, there were 714 (41%) deaths and 615 patients (56%) initiated chronic dialysis. In adjusted analyses, all subjects treated with ACE/ARB had a significantly lower risk of death [HR 0.81 (95% CI, 0.70-0.95; p=0.007)] and those with CKD had a lower risk of dialysis initiation [HR 0.86 (95% CI, 0.73-0.97; p=0.03)]. Neither serum phosphorus nor FGF23 levels significantly modified the association of ACE/ARB use with each outcome (p interaction 0.4 for death and p interaction 0.7 for dialysis initiation).

**Conclusions:** ACE/ARB use is associated with a reduced risk of kidney disease progression and death even when simultaneously accompanied by higher serum phosphorus and FGF23.

## SA-PO604

### Signaling of FGF-23-Klotho under Normal and Hyperglycemic Conditions

Sudha P. Chennasamudram, Ruchi Singh, Tetyana L. Vasylyeva. *Pediatrics, Texas Tech Univ Health Sciences Center, Amarillo, TX.*

**Background:** Fibroblast growth factor 23 (FGF23) is a protein produced by osteocytes and is involved in reabsorption of phosphorus in kidney. FGF23 binds to FGF receptors in the presence of a co-receptor called klotho to form a ternary complex in the distal tubule. This ternary complex acts on the proximal tubules to down-regulate tubular reabsorption of phosphate. In chronic kidney disease (CKD) patients, elevated levels of FGF23 have been observed leading to higher mortality rates. Diabetes is one of the leading causes of progression of CKD. The signaling pathways of FGF23-klotho under hyperglycemic conditions are poorly understood. Mechanisms involved in FGF23 pathways under hyperglycemic conditions could further provide information on the role played by FGF23 in the progression of CKD. The study objective is to investigate the effects of FGF-23-klotho signaling under hyperglycemic conditions.

**Methods:** Human proximal epithelial cells (HK2) and glomerular endothelial cells (GEC) were cultured and maintained at 37° C in a 5% CO2 incubator. Cells were treated with different concentrations (10, 25, 50 and 100 ng/mL) of FGF23 in the presence and absence of Klotho under normal (5mM) and hyperglycemic (25 mM) conditions. Formation of reactive oxygen species (ROS) in HK2 cells was investigated by flow cytometry. Effects of FGF23 on apoptosis in glomerular endothelial cells were also studied.

**Results:** Treatment of HK2 cells with 100 ng/mL of FGF23 under hyperglycemic conditions increased the percentage of ROS significantly compared to the cells under normal glucose. When klotho was added, there was a decrease in the percentage of ROS induced by FGF23 under hyperglycemic conditions. There was no change in the percentage of apoptotic cells before and after treatment of FGF-23 under hyperglycemic conditions in HK2 cells. But the percentage of apoptotic cells in GEC after 24 hours of FGF23 treatment under hyperglycemic conditions was higher compared to the cells under normal glucose.

**Conclusions:** High concentrations of FGF23 under hyperglycemic conditions are toxic to glomerular endothelial cells. The stress induced by FGF23 under hyperglycemic conditions is ameliorated by klotho in HK2 cells.

### Klotho and Human Coronary Heart Disease

Juan F. Navarro-Gonzalez,[1,2] Javier Donate,[2] Mercedes Muros,[3] Horacio Perez Hernandez,[4] Violeta Cazaña,[2] Javier Garcia Perez,[1] Carmen Mora.[2] *[1]Nephrology Service, Univ Hospital Ntra. Sra. de Candelaria, Tenerife, Spain; [2]Research Unit, Univ Hospital Ntra. Sra. de Candelaria, Tenerife, Spain; [3]Clinical Analysis Service, Univ Hospital Ntra. Sra. de Candelaria, Tenerife, Spain; [4]Cardiology Service, Univ Hospital Ntra. Sra. de Candelaria, Tenerife, Spain.*

**Background:** Klotho is involved in maintenance of vascular health. We aimed to analyze the relationship between Klotho and human coronary artery disease (CAD).

**Methods:** Soluble klotho were measured in 371 patients underwent coronary angiography. Klotho gene expression was analyzed in thoracic aorta specimens from 70 patients underwent cardiac surgery.

**Results:** Soluble Klotho concentration was lower ($P < 0.001$) in patients with significant CAD (n = 233). The coronary stenosis severity index was significantly lower in patients with the higher soluble Klotho levels ($P < 0.001$). Multiple regression analysis showed that serum Klotho concentrations were inverse and significantly associated with CAD (adjusted $R^2 = 0.67$, $P < 0.001$). Multivariate logistic regression showed that risk factors for significant CAD included age, diabetes, smoking and inflammation, whereas serum Klotho levels were associated with a lower risk for CAD. Lower mRNA expression level of Klotho was observed in 46 patients with significant CAD, as compared with subjects without significant CAD ($P < 0.01$). Logistic regression analysis showed that *Klotho* expression was independently associated with lower risk for CAD.

**Conclusions:** Patients with significant CAD present lower concentrations of soluble Klotho, as well as reduced levels of *Klotho* gene expression in the vascular wall. Reduced serum Klotho concentrations and decreased vascular Klotho gene expression were significantly associated with the presence and severity of CAD, independently of established cardiovascular risk factors.

## SA-PO606

### Bone FGF23 Expression Is Increased after Solid Organ Transplantation

R.C. Pereira,[1] Helena Liisa Valta,[2] Hannu J. Jalanko,[2] Isidro B. Salusky,[1] Navdeep Kaur Tumber,[1] Outi Makitie,[2] Katherine Wesseling-Perry.[1] *[1]Pediatrics, UCLA, Los Angeles, CA; [2]Univ of Helsinki, Helsinki, Finland.*

**Background:** Expression of FGF23 in bone cells is increased in patients with all stages of CKD and bone immunoreactive FGF23 correlates with skeletal mineralization in both pre-dialysis CKD and dialysis pts. Immunosuppressive agents, particularly glucocorticoids, have been associated with higher circulating FGF23 concentrations; however, the effect of organ transplantation of bone FGF23 values remains unknown.

**Methods:** Bone histomorphometry was performed in 12 pediatric pre-dialysis CKD pts and in 22 pediatric solid organ transplant (tx) pts. All tx pts were treated with a calcineurin inhibitor, prednisone, an antimetabolite and vitamin D3 (400 or 800 IU/d). No pts received calcitriol or other active vitamin D sterols. Five micron sections of non-decalcified bone were incubated with antihuman FGF-23 (225-244) followed by biotinylated 2o antibody, then developed with ABC complex/HRP and AEC kit (Vector). Number of FGF-23 expressing osteocytes was normalized by tissue area.

**Results:** GFR was lower in kidney transplant recipients than in recipients of other solid organs; however, bone FGF23 expression did not differ based on the type of organ received. Bone FGF23 expression was higher in patients with transplanted organs than in non-transplanted pre-dialysis CKD patients, despite higher GFRs in liver and heart allograft recipients. Considering all patients together, bone FGF23 immunoreactivity (FGF23/T.Ar) was inversely correlated with osteoid thickness ($r = -0.46$, $p<0.01$).

| | Liver or Heart Transplant (n=14) | Kidney transplant (n= 8) | Pre-dialysis CKD (n=12) | Normal range |
|---|---|---|---|---|
| Age (y) | 14.8 ± 0.8 | 16.9 ± 2.0 | 13 ± 1 | |
| Gender | 6M/8F | 4M/4F | 9M/3F | |
| Time since transplantation (y) | 4.8 ± 1.2 | 8.9 ± 2.2 | | |
| GFR (ml/min/1.73m$^2$) | 72.8 ± 4.4 * | 42.5 ± 3.8 | 54.7 ± 5.9 | |
| Calcium (mg/dl) | 10.0 ± 0.1 | 10.3 ± 0.1 ** | 9.4 ± 0.1 | 8.4-10.2 |

| **Bone Immunoreactivity** | | | | |
| Bone FGF23/T.Ar (#/mm$^2$) | 2.0 ± 0.4<br>1.5 (1.1, 2.2) | 2.2 ± 0.7 **<br>1.5 (1.1, 2.8) | 0.8 ± 0.1<br>0.8 (0.4, 1.2) | 0.35 ± 0.1 |

* Indicates a difference between kidney transplant recipients and liver or heart transplant recipients (p<0.05)
**Indicates a difference between kidney transplant recipients and pre-dialysis CKD patients (p<0.05)

**Conclusions:** Therapy with immunosuppressive agents is associated with a marked increase in bone FGF23 immunoreactivity, regardless of the type of allograft received and despite, in the case of liver and heart allograft, higher GFR. The implications of these findings for bone biology and systemic complications remain to be evaluated.

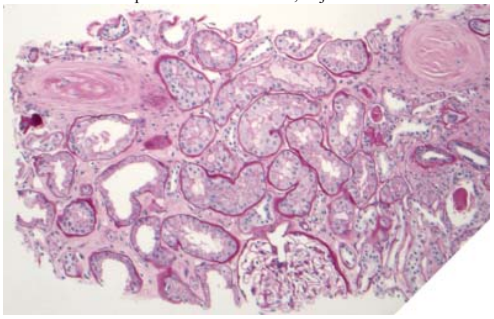
## SA-PO607

**Renal Sclerosing Peritubular Nodule – How Rare Is It?** Sajan Thomas. *Nephrology, Goldcoast Hospital, Goldcoast, Queensland, Australia.*

**Background:** Neurofibromatosis type 2 (NF2) is a rare autosomal dominant disorder. It affects about 1 in 25,000 people. Kidney involvement in NF2 has not been studied extensively. A relatively rare lesion, the renal sclerosing peritubular nodule (RSPN), was first described in a mother and 2 sons with NF2 who died and underwent autopsy in 1981.

**Methods:** A 53-year-old man with neurofibromatosis type II was referred for investigation and management of his deteriorating renal function. Physical examination revealed cutaneous manifestations of NF2. Serial blood tests showed declining renal function. Urine showed microscopic hematuria with no proteinuria. An ultrasound showed normal size kidneys and renal tract.A renal biopsy was performed.

**Results:** Light microscopy showed 3 out of 9 glomeruli globally sclerosed. Within the interstitium were paucicellular nodules, adjacent to tubules.



The nodules were lightly eosinophilic on H&E, PAS negative and argyrophilic on PASM.The nodules stained blue with Masson trichrome, resembling collagen. In the context of the clinical history, the morphology of the collagenous nodules was consistent with RSPN.

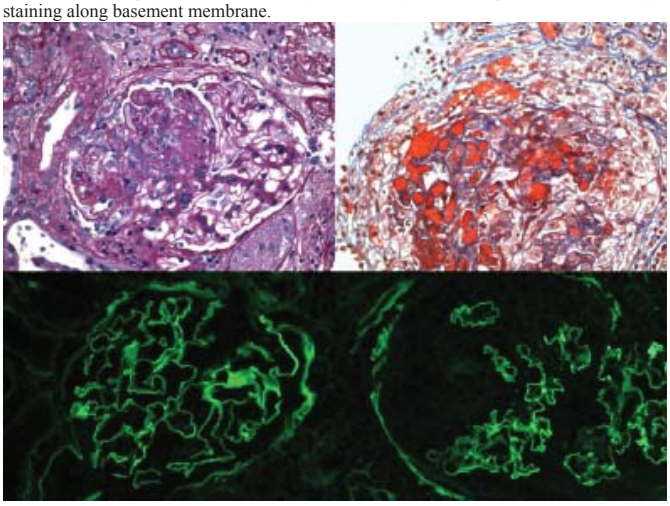
**Conclusions:** Our case represents a rare form of a hereditary renal abnormality in NF2. There are only two previous case reports. It has been thought that these nodules do not alter normal kidney function, even when they are extensive, however none of the previous patients survived into their fifth decade. With increasing frequency of NF2 patients surviving with advanced medical care, RSPN like lesions are more likely to be seen on their renal biopsy. Since these histologic lesions appear morphologically progressive early recognition , careful monitoring of the renal function and avoidance of potentially nephrotoxic agents is prudent.

## SA-PO608

**Necrotizing Crescentic Glomerulonephritis with Linear Anti-IgG Deposits in a Patient with History of Granulomatosis with Polyangiitis** Ninad D. Parekh, Elie El-Charabaty, Suzanne E. El Sayegh. *Dept of Medicine, Div of Nephrology, Staten Island Univ Hospital, Staten Island, NY.*

**Background:** Granulometosis with polyangiitis (GPA) typically shows no or minimal immune deposits on immunofluorescence staining of renal biopsy and presence of large amount of immune deposits should prompt possibility of other etiologic process. It is essential to establish diagnosis to guide appropriate management therapy.

**Methods:** A 47-year-old Hispanic male presents with fatigue and lethargy. He has history of GPA, diabetes mellitus, hypertension, and hyperlipidemia. His medications include Zocor, lisinopril, azathioprine, and insulin. On exam, he is afebrile, vital signs stable. Remainder of physical exam is unremarkable. Laboratory data revealed creatinine 5.2 mg/dl (baseline 1.5 mg/dl) otherwise normal electrolytes. Urinalysis showed numerous dysmorphic red cells with red cell casts, and urine protien/creatinine ratio of 2.03 mg/mg. His serologies are all negative except anti-proteinase-3 (anti-pr3) antibody at very low titers. Kidney biopsy showed necrotizing crescentic glomerulonephritis with linear IgG staining along basement membrane.



The patient was treated with intravenous methyl prednisolone 1 gm/day for 3 days followed by oral prednisone at 1 mg/kg/day, and monthly intravenous cyclophosphamide 15mg/kg. Patient had with partial renal recovery at 2 months.

**Conclusions:** The presence of anti-pr3 antibody supports recurrence of GPA. However, linear IgG staining favours anti-GBM disease. Anti-GBM disease and GPA both are treated with prednisone and cyclophosphamide. However, anti-GBM disease is also treated with plamapheresis. In case of GPA, plasmapheresis is beneficial only in severe renal disease or pulmonary hemorrhage. Since our patient did not have detectable circulating anti-GBM antibody, decision was made not to proceed with plasmpheresis.

## SA-PO609

**ANCA Negative Renal Vasculitis in a Patient with Scleroderma: A Case Report** Sarah Khan, Bhupinder Sangha, Karina Sulaiman, Neville R. Dossabhoy, Zulqarnain Abro. *Nephrology, LSUHSC, Shreveport, LA.*

**Background:** There is no convincing evidence in the literature that a true vasculitis occurs in scleroderma. We describe a rare case of polyarteritis nodosa (PAN) vasculitis causing renal failure in a patient with localized scleroderma.

**Methods:** A 51 year old African American female with history of hypertension and syphilis presented with fatigue, severe dyspnea and significant swelling of hands and feet. She reported 6-8 months of polyarthralgia affecting the hands, feet and knees. She also reported a rash that developed on her trunk, back and legs 2 weeks prior. Physical exam was remarkable for lower extremity pitting edema and moderate sized, hypopigmented maculo-papular rash on her thorax and legs. Labs revealed Creatinine 8 mg/dL, BUN 68 mg/dL, Troponin 5.44, WBC 17,000, Hgb 8.7, CRP 3.6, ESR 32, Scl-70 Antibody +, ANA +, Hep B, C and HIV negative (neg), normal C3 & C4, ANCA neg, lupus anticoagulant neg. UA showed protein 500, RBC 50-75/hpf, WBC 20-30/hpf; urine drug screen neg. Echocardiogram showed large pericardial effusion with early tamponade, severe global hypokinesis and LVEF 20-25%. Patient was admitted to ICU and required emergent dialysis. A kidney biopsy showed inflammatory vasculitis associated with vascular thrombosis and focal renal parenchymal infarcts, suggestive of PAN. Renal angiogram showed moderate sized aneurysms consistent with PAN. A skin biopsy revealed increased hyalinized and thickened dermal collagen in superficial and deep dermis with diminished skin appendages, consistent with scleroderma. Patient was started on pulse steroids and IV Cytoxan. She was discharged on intermittent hemodialysis and prednisone 60mg PO daily, with no sign of renal recovery yet.

**Conclusions:** Systemic sclerosis patients can present with a vasculopathy called intimal fibro-proliferation. There is no convincing evidence in the literature that true vasculitis occurs in systemic sclerosis or localized scleroderma. Our patient, who did not meet the criteria for systemic sclerosis but had documented localized scleroderma on skin biopsy, with PAN seen on kidney biopsy and renal angiogram, could be the first reported case of ANCA negative vasculitis occurring in scleroderma.

## SA-PO610

**ANCA Vasculitis Associated with Influenza Vaccination** Megha Shah,[1] Tanu Duggal,[2] Paul E. Segal,[1] Naima Carter-Monroe,[3] Duvuru Geetha.[1] *[1]Dept of Medicine, Johns Hopkins Univ, Baltimore, MD; [2]Dept of Medicine, Sinai Hospital of Baltimore, MD; [3]Dept of Pathology, Johns Hopkins Univ, Baltimore, MD.*

**Background:** Administration of influenza vaccine has been associated with development of auto antibodies and autoimmune rheumatic disease.

**Methods:** Two patients were diagnosed with AAV at our institution 2 and 4 weeks after influenza immunization. Both patients had renal involvement, with one requiring

dialysis. Both patients were treated with cyclophosphamide(CYC) and prednisone(P) and in the patient with dialysis dependent renal failure plasmapheresis(PE) was added to the immunosuppressive regimen. Both patients achieved disease remission. The patient with initial dialysis dependent renal failure reached end stage renal disease. The characteristics and clinical outcomes of our 2 patients and 6 previously reported cases of AAV associated with influenza vaccine are reported in Table 1.

| Age | Sex | Time from immunization to disease onset | New diagnosis/ Relapse | Disease type | ANCA type | Treatment | Outcome |
|---|---|---|---|---|---|---|---|
| 83 | F | 2 wks | New | MPA | MPO | CYC/P | Remission |
| 28 | F | 2 wks | New | GPA | C/PR3 | CYC/P | Remission |
| 55 | F | 3 wks | New | MPA | P/MPO | CYC/P/PE | Remission, Dialysis Independent |
| 70 | M | 3 wks | New | GPA | P/MPO | CYC/P | ESRD, Death |
| 67 | F | 12 days | Relapse | GPA | C/PR3 | CYC/P | Remission |
| 20 | M | NK | Relapse | GPA | C | MMP/P/PE | Death |
| 50 | M | 2 wks | New | GPA | C/PR3 | CYC/P | Remission |
| 75 | F | 4 wks | New | GPA | P/MPO | CYC/P/PE | ESRD, Remission |

**Conclusions:** Renal involvement is common in AAV associated with influenza vaccine and treatment with conventional immunosuppression is successful in remission induction. While a causal role of vaccine in ANCA associated vasculitis cannot be confirmed with these case reports, the temporality suggests that influenza vaccine may be a triggering factor for induction of vasculitis in predisposed individuals.

## SA-PO611

**ANCA Associated Vasculitis Associated with Subacute Bacterial Endocarditis – A Match to Watch Out for** Asif A.K. Ansari, Diana L. Deitzer, Andres G. Chiesa-vottero. *Cleveland Clinic Foundation.*

**Background:** Infections such as sub-acute bacterial endocarditis (SBE) are seldom associated with elevated Antineutrophil cytoplasmic antibody (ANCA) titers and in some cases triggering features consistent with ANCA associated vasculitis (AAV). The presence of SBE and AAV in combination poses a clinical dilemma as therapeutic strategies are different and no complementary. We report a challenging case of AAV associated with SBE of mitral valve due to streptococcus mutans presenting with acute kidney injury (AKI).

**Methods:** 68 year old man presented with nonspecific symptoms of weight loss and weakness spanning 2 months. He was noted to have petechial rash on legs and a systolic murmur in mitral area on clinical examination. Laboratory studies showed hemoglobin of 7.6 mg/dl, platelets 70,000 cells/microliter, LDH 384 U/L, with undetected haptoglobins, low Complement C3 levels and c- ANCA positive. Serum creatinine was 3.6 mg/dl on admission and progressively worsened peaking at 6.88 mg/dl. Renal biopsy performed showed pauci-immune crescentric glomerulonephritis with fibrinoid necrosis. Blood cultures were positive for streptococcus mutans, with echocardiography revealing mobile mitral valve (MV) vegetation. Patient was treated surgically with MV repair and excision of vegetation, intravenous ceftriaxone and corticosteroids. Patient briefly required renal replacement therapy, and eventually had good clinical recovery.

**Conclusions:** Although rare, bacterial infections are being reported as triggers for AAV. This entity may be missed if appropriate investigations are not performed, resulting in inadequate therapy. Both SBE and AAV can result in AKI, and have an overlapping presentation and is often difficult to determine the underlying etiology. Optimal therapy in the presence of both conditions is not known, and immunosuppressive medications must be used judicially as can potentially worsen sepsis. Elevated ANCA with low complement levels should raise the suspicion of AAV associated with SBE. Our case supports the use of corticosteroids for life-threatening AAV complicating SBE.

## SA-PO612

**Anti-Glomerular Basement Membrane Disease after Nephrectomy for Xanthogranulomatous Pyelonephritis in a Child Expressing HLA DR15 Major Histocompatibility Antigens** Emma O'Hagan, Tamara Mallett, Karl McKeever, Mairead Convery. *Paediatric Nephrology, Royal Belfast Hospital for Sick Children, Belfast, Co. Antrim, United Kingdom.*

**Background:** The estimated incidence of Antiglomerular basement membrane (anti-GBM) antibody disease is 0.5 per million in adults but much rarer in children. We present the case of a 7 year old boy who developed anti-GBM antibody disease following nephrectomy for diffuse unilateral Xanthogranulomatous Pyelonephritis (XGP).

**Methods:** A previously well 7 year old boy was treated with anti-microbials and nephrectomy for diffuse, unilateral XGP, diagnosed on CT scan and confirmed on histopathology . Post-operative ultrasound scan of the contralateral kidney was normal as was estimated glomerular filtration rate (eGFR 128mls/min/1.73$^2$). Three months later the child represented with gross haematuria and acute kidney injury requiring haemodialysis (eGFR 9.9 mls/min/1.73$^2$ ). Renal biopsy showed severe crescentic glomerulonephritis with 95% of glomeruli demonstrating circumferential cellular crescents and strong linear IgG staining of the glomerular basement membranes. Anti-GBM antibodies were positive and anti-neutrophil cytoplasmic antibodies were negative. Treatment with plasma exchange, methylprednisolone and cyclophosphamide led to normalisation of anti-GBM titres. Frequency of haemodialysis has reduced as renal function gradually improves (eGFR 21.8 mls/min/1.73m$^2$).

**Conclusions:** Case studies in the adult literature have reported the development of a rapidly progressive anti-GBM induced glomerulonephritis following lithotripsy where patients expressed HLA DR2/HLA DRB15 major histocompatibility (MHC) antigens. Our patient expresses the HLA DRB15 MHC antigen which is positively associated with anti-GBM disease. We postulate that disruption of the GBM during nephrectomy exposed the target antigen to trigger anti-GBM disease in this patient. Anti-GBM disease is a rare but potentially treatable cause of acute kidney injury, which should be considered in patients who have a rapidly progressive form of glomerulonephritis and a history of recent renal surgery. We believe this to be the first reported case of a child with anti-GBM antibody disease following renal surgery.

## SA-PO613

**Goodpasture's Disease and Severe Thrombocytopenia: Thrombotic Thrombocytopenic Purpura or Not?** Howon Lee,[1] Jill Adamski,[2] Huma Fatima,[2] Eric L. Wallace.[1] *[1]Div of Nephrology, UAB; [2]Dept of Pathology, UAB.*

**Background:** Goodpasture's syndrome is a rare autoimmune disease caused by antibodies against cryptic epitopes in Type IV collagen and presents with rapidly progressive glomerulonephritis and pulmonary hemorrhage. The association of Goodpasture's syndrome with microangiopathic hemolytic anemia (MAHA) was made in 1984 prior to ADAMTS-13 testing. Subsequently, 2 case reports have associated thrombotic thrombocytopenic purpura (TTP) with Goodpasture's syndrome. Only one reported an ADAMTS-13 level, 17%, which is higher activity than usually reported in TTP. We report a case of Goodpasture's associated with MAHA and severe thrombocytopenia with a normal ADAMTS-13 level.

**Methods:** A 50 year old woman presented to the hospital with dyspnea, discolored urine, and lower extremity edema. Laboratory evaluation showed a creatinine 12 mg/dl, hemoglobin 6.2 g/L, and platelet count 459 x103 /cm$^2$ . Urinalysis showed a nephritic urine sediment. Serology test including ANCA was negative. Anti-GBM levels were 240 AI. She was given pulse dose steroids and initiated on dialysis. Renal biopsy, consistent with Goodpasture's, revealed linear IgG staining along the glomerular basement membrane, 100% crescents, but no evidence for thrombotic microangiopathy . Platelet count decreased to 131,000/μL. Plasmapheresis (TPE) was initiated, and IV cyclophosphamide given. Platelet count continued to decrease requiring 3 platelet transfusions. Laboratory evaluation revealed evidence of MAHA with schistocytes, decreased haptoglobin, increased LDH and indirect bilirubin. ADAMTS-13 activity was normal (55%). Heparin platelet factor 4 antibody was positive with a negative serotonin release assay, and a strong non-drug IgG antiplatelet antibody with unknown specificity was found. Despite 7 consecutive TPE, the platelet count decreased to 21,700/μL, and diffuse alveolar hemorrhage (DAH) developed. 3 weeks after initiation of therapy, platelet count improved and DAH resolved. The patient remained on dialysis.

**Conclusions:** This case illustrates that although there can be an association between Goodpasture's and MAHA, true TTP is unlikely on the basis of ADAMTS-13 levels in both our case and previous report.

## SA-PO614

**Plasmapheresis in Anti-Glomerular Basement Membrane Disease, How Much Is Enough?** Nitin Relia, Aleksandra Gmurczyk, Jennifer A. Tuazon, James J. Paparello. *Nephrology Div, Northwestern Univ, Chicago, IL.*

**Background:** Anti GBM disease is caused by pathogenic circulating antibodies and manifests as fulminant renal failure with crescent formation and pulmonary hemorrhage, although it can present as renal disease alone. The current standard of care for treating Anti-GBM disease is immunosuppression to reduce new antibody production and plasmapheresis to remove existing antibodies in circulation. Although plasmapheresis is central to the management of Anti-GBM disease, the duration of plasmapheresis that should be undertaken is unclear. KDIGO practice guidelines published June 2012 recommend Plasmapheresis for 14 days or until anti-GBM antibody titers are undetectable. These guidelines can be interpreted that a two week course of plasmapheresis is an adequate regimen for all anti – GBM disease.

**Methods:** The clinical course and data on 3 patients with anti-GBM disease without pulmonary involvement is presented. Two of the 3 patients required dialysis. All 3 patients were plasmapheresed until antibody titers became undetectable.

**Results:** The average number of exchanges required to achieve an undetectable anti-GBM antibody was 34. All 3 patients had improved renal outcome in follow up.

| Patient characteristics | Patient 1 | Patient 2 | Patient 3 |
|---|---|---|---|
| Age/Sex | 25 yr/Male | 19 yr/Female | 43 yr/Female |
| Creatinine at presentation (mg/dl) | 3.0 | 4.2 | 3.4 |
| Peak creatinine (mg/dl) | 9.5 | 7.6 | 13.0 |
| % of Crescents on Renal Biopsy | 60% | 75% | 100% |
| Dialysis (Y/N) | N | Y | Y |
| Number of Plasmapheresis sessions | 40 | 25 | 39 |
| Immunosuppression | Steroids, 3 monthly doses of Cytoxan, 2 doses of Rituximab | Steroids, 4 monthly doses of Cytoxan | Steroids, 6 monthly doses of Cytoxan |
| Follow up (months) | 36 | 36 | 12 |
| S.Cr (mg/dl) at most recent f/u | 1.8 | 1.6 | 2.5 |

The two dialysis dependent patients became dialysis independent.

**Conclusions:** The positive outcomes (in patients with poor prognosticators) of this small case series suggests that the course of plasmapheresis in patients with anti- GBM disease should be dictated by the anti-GBM antibody titer, and not simply a pre-specified number of treatments.

## SA-PO615

**IgA Vasculitis (Henoch-Schönlein Purpura Nephritis) Associated with Cystic Fibrosis** Sampath Kumar Thiruveedi, Robert L. Benz. *Dept of Nephrology, Lankenau Hospital, Wynnewood, PA.*

**Background:** IgA Vasculitis (HSP) is a systemic vasculitis characterized by tetrad of Palpable purpura, Arthralgia/arthritis, abdominal pain & renal disease. IgA Vasculitis is characterized by the tissue deposition of IgA-containing immune complexes. It is less

common in adults but represents a more severe clinical syndrome, with higher frequency of renal involvement. It is very rarely seen in association with cystic fibrosis with only 2 case reports on our literature search. Here we present one such rare association and discuss limitations in treatment.

**Methods:** 50 year old white male with history of cystic fibrosis, recurrent pulmonary infections, diabetes mellitus, Hypertension & CHF. He presented in October 2010 with abdominal pain & was found to have Jejunal inflammation on CT scan, ulceration on enteroscopy and Vasculitis on biopsy. Diagonisis of HSP was made but his kidney function was normal. In August 2011 he had microscopic hematuria. In April 2012 he had macroscopic hematuria, 1.3 gram proteinuria & increase in creatinine from 0.8 to 1.7. Serologic work up for proteinuria was negative and ultrasound showed normal size kidneys. In August 2012 He had nephrotic syndrome with 4.4 gm proteinuria & creatinine of 2.2. He was presumptively treated as IgA vasculitis with prednisone 1mg/kg & lisinopril. Despite 6 months of steroids his proteinuria increased to 6.6 grams & creatinine to 2.8. Kidney biopsy confirmed acute & chronic focal IgA glomerulonephritis. Cellcept was started cautiously as steroid sparing agent but discontinued a week later due to lobar pneumonia. He continues to be maintained on lower dose of prednisone.

**Conclusions:** Renal biopsy in Cystic fibrosis is technically difficult with inability to lie prone from poor respiratory reserve & coughing but can disclose a heterogeneous spectrum of nephropathies. Presented here is a case with typical demographics of Caucasian race and male sex for IgA vasculitis. Witnessed is the severity of illness with declining GFR and poor response to steroid therapy. Life threatening sepsis or infections limit the use of more aggressive immunosuppressive therapy in a group of patients particularly prone to resistant bacteria and recurrent infections.

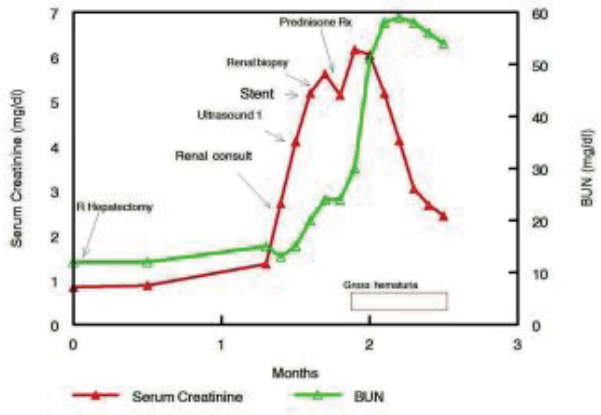
## SA-PO616

### IgA Nephropathy Precipitated after Hemi-Hepatectomy for Colorectal Metastasis

Siddiq Anwar, Derek Larson, Muhammad A. Ashraf, Helen Liapis, Aubrey R. Morrison. *Washington Univ School of Medicine, St. Louis, MO.*

**Background:** Mesangial IgA deposition in the renal glomerulus is a recognized complication of end stage liver disease (ESLD). We report a patient, who developed visible hematuria, acute kidney injury (AKI) and a lower legs rash suggestive of Henoch–Schönlein purpura(HSP) 8 weeks after a right hemi-hepectectomy. This was subsequently diagnosed as IgA nephropathy (IGAN).

**Methods:** A 50-year White male with a history of colorectal cancer developed AKI following his hemi-hepatectomy. This was initially attributed to a urinary tract infection and acute tubular necrosis, however he subsequently developed a 'rash' and proteinuria which raised the suspicion for a glomerular entity. Patient was readmitted with AKI 4 weeks later and an initial ultrasound revealed mild hydronephrosis. Urology was consulted for stenting, however, even after stenting, the patient continued to have an increase in his serum creatinine (SC) which eventually peaked at 6.2mg/dl. A renal biopsy showed mesangial hypercellularity with IgA dominant deposition consistent with IgA nephropathy. Three of ten glomeruli were globally sclerosed and one displayed crescent formation. The patient was subsequently placed on prednisone 80 mg daily with gradual improvement in SC. He did not require renal replacement therapy during his hospitalization.



**Conclusions:** In ESLD, it has been suggested that impaired clearance of immune complexes by hepatic kupper cells may allow them access to the systemic circulation leading to deposition of these complexes in kidney. This is the first reported case where IGAN and likely HSP has been associated acutely post liver resection. In this instance the clinical abnormalities resolved with a prolonged course of prednisone.

## SA-PO617

### Concurrent and Sequential Analysis of Glomerular Albumin Permeability, Soluble Urokinase Receptor, and Angiotensin 1 Receptor Antibody in a Renal Transplant Recipient with Recurrent Focal Segmental Glomerular Sclerosis

Siddiq Anwar, Nima Naimi, Muhammad A. Ashraf, George Jarad, Helen Liapis, Daniel C. Brennan. *Washington Univ School of Medicine, St. Louis, MO.*

**Background:** Recurrent focal segmental sclerosis (rFSGS) in kidney transplant (KT) is difficult to predict and causes graft loss. Early rFSGS is hypothesized to be secondary to one or more circulating factors: glomerular albumin permeability factor ($P_{alb}$ ), soluble urokinase receptor (suPAR), and angiotension-1 receptor antibody (AT1Rab).

**Methods:** We analyzed stored samples 1 yr pre-transplant, at transplant and on recurrence for $P_{alb}$, suPAR, and AT1Rab in a 23 yr. white male. He presented 8 months after 1 haplotype match KT with rFSGS and acute renal injury (AKI) requiring dialysis (HD). All 3 biomarkers were elevated 1 yr pre-transplant when he was not on HD. At transplant, Palb and AT1Rab were elevated, but suPAR level was not. 4 months later he developed CMV viremia and antimetabolite was stopped with resolution of viremia. Subsequently maintained on prednisone and tacrolimus. 8 months after KT, develops AKI and biopsy showed rFSGS with no rejection. C4d and anti-HLA antibodies were negative. At recurrence, all 3 biomarkers were elevated. 7 days after therapy with aborted plasma exchange (secondary to side effects) plus high dose steroids, Palb and suPAR remained significantly positive but AT1Rab was borderline positive. 12 weeks into treatment with high-dose steroids, rituximab and galactose, patient remains on HD.

| | 1 year pre-transplant | At transplant | 1 month Post-transplant | 3 months | 4 months | 8 months On admission | Post pulse steroids and failed PE and PP-1 week after admission |
|---|---|---|---|---|---|---|---|
| Creatinine mg/dl | 4.09 | HD | 1.3 | 1.2 | 1.2 | HD | HD |
| FK trough ng/ml | - | - | 6.4 | 6 | 5.8 | - | |
| CMV PCR copies/ml | - | - | - | 4533 | < 200 | < 200 | - |
| BK virus PCR | - | - | - | ND | - | ND | - |
| P/C ratio | - | - | 0.09 | - | - | 17.7 | - |
| DSA | - | ND | - | ND | - | - | - |
| $P_{alb}$ | 0.77 | 0.51 | - | - | - | 0.61 | 0.58 |
| SuPAR pg/ml | 3573 | 2898 | - | - | - | 4691 | 4428 |
| AT1R Antibody level U/ml | 20.4 | 23.2 | - | - | - | 16.8 | 13.5 |

HD: Hemodialysis, CMV: cytomegalovirus. Ig G: immunoglobulin G. PCR: polymerase chain reaction. ND: not detected. FK: tacrolimus. P/C: protein to creatinine. DSA: donor specific antibodies. suPAR: Soluble urokinase receptor-Suspicious: > 3000 pg/ml, >3500 pg/ml are suggestive of suPAR-mediated FSGS (Reiser lab, Rush University, USA). Glomerular albumin permeability: Palb. $P_{alb}$ -Normal: 0, Nonspecific: 0.2 to 0.5, Increased risk: Values greater than 0.5(Renal Research, KC VA Medical Center, Kansas City, USA). AT1Rab: Angiotension-1 receptor antibody: Neg :< 10, Borderline: 10 to 17, Positive: > 17 (Immunogenetics Laboratory, The Johns Hopkins University, Baltimore, USA)

**Conclusions:** Previous reports suggest elevated suPAR and high $P_{alb}$ at transplant confers risk of rFSGS. Although an N=1 study, this highlights uncertainties and difficulties in monitoring and interpretation of Palb, suPAR and AT1Rab pre and post transplantation. Further studies are needed to validate published reports and establish better surveillance protocols.

## SA-PO618

### IgA Nephropathy with Renal Atypical Mycobacterium Infection

Zaheer Amin Virani, Anup Chaudhari, Hemant J. Mehta, Mohd. Majid Mohd. Ayyub Momin. *Nephrology, Lilavati Hospital, Mumbai, Maharashtra, India.*

**Background:** IgA Nephropathy due to mycobacterium tuberculosis elsewhere in the body has been described. However, presence of IgA nephropathy and mycobacterium infection in the kidney as a cause of IgA nephropathy is rare.

**Methods:** FK, F/18, was admitted with fever of 5 days duration associated with dry cough and coryza. There was no history of oedema, urinary complaints, rash or joint pains. On evaluation, BP 170/90 mm of Hg, bilateral pitting oedema feet. Her investigations showed microcytic hypochromic anaemia, Urine showed 4+ proteins, 80 to 100 rbc/hpf with hyaline and granular casts. Spot urine protein creatinine ratio was 6.15. Metabolic acidosis, hyperphosphatemia, Vit D deficiency and dyslipidemia were seen. Sr. Creatinine was 3.15mg%. (eGFR by MDRD 20.42 ml/min). She was negative for HBV, HCV, HIV, ANA, dsDNA, ASO-Titres, Anti-GBM and ANCA, C3 level was 120mg/dl. USG-KUB showed normal size kidneys with increased echogenicity. Histopathological diagnosis on kidney biopsy: MPGN with early cellular crescent formation with non caseating granuloma and chronic tubulointerstitial nephrites thought to represent mycobacterial infection associated IgA nephropathy. Search was made for evidence of mycobacterium infection. HRCT chest showed bilateral basal pleural thickening. Mantoux skin test and Gamma interferon detection for mycobacterium were positive. Bactec TB culture of urine showed occasional AFB on smear, and mycobacterium spps other than tuberculosis (MOTT) on culture. Serum IgA level was 378.3 mg/dl (upper limit of normal 348 mg/dl) She was started on Inj.

Methylprednisone 1gm daily for 3 days followed by oral prednisolone at 60 mg/day.Four drug anti tuberculosis treatment (H, R, E, Z) was started. Despite steroids and AKT patient continued to have worsening azotemia and was initiated on haemodialysis after 7 months.

**Conclusions:** There is evidence to suggest that tuberculosis, in addition to other conditions associated with mucosal exposure to antigens producing an IgA immune response can result in IgA nephropathy. This glomerulopathy is reported as a potential renal complication of concurrent mycobacterial infection. IgA nephropathy due to MOTT in kidney is rare.

## SA-PO619

**A Unique Case of IgA Heavy Chain Deposition Disease** Pradeep Dhakarwal, Anshul Kumar, Kathryn E. Ussai. *Nephrology Div, Lehigh Valley Hospital/ USF, Allentown, PA.*

**Background:** To our knowledge only 5 cases of IgA heavy chain deposition disease(HCDD) have been reported and 2 were female. We present a case of IgA HCDD and compare the clinicopathological features with earlier cases.

**Methods:** 65 year old white female was referred for edema, proteinuria and microscopic hematuria. She had history of hypertension and pulmonary embolism. Creatinine (Cr) at presentation was 0.81mg/dL, Hb, calcium were normal and urineP/Cr was 1.2 Urine microscopy had dysmorphic RBCs and RBC cast. ANA, anti dsDNA, ANCA, anti GBM, and complements were negative. SPEP, UPEP was negative but serum and urine kappa/ lambda was elevated. Renal biopsy light microscopy showed nodular scleroses with mesangial nodules. IF had 3+ staining of mesangial nodules and 2+ linear staining of GBM, TBM, vessel walls for IgA with negativity for IgG, IgM, kappa, lambda. On EM abundant powdery deposits within mesangial nodules were seen. Findings diagnostic of IgA HCDD. Bone marrow biopsy had hypercellular marrow involved by kappa light chain IgA plasma cells. She was started on cyc, bortezomib, and dexamethasone. Cr increased to 1.97 within one week of the first cycle and urineP/Cr increased to 9.3. She underwent 6 plasma-exchange (PLEX) and Cr decreased to 1.05. The decision was based on possible removal of heavy chains by PLEX, and for the possibility of developing light chain disease in addition HCDD. Second cycle of chemotherapy is ongoing, plan is for stem cell transplantation after induction.

**Conclusions:** All reported cases of IgA HCDD presented with hypertension, elevated Cr, microscopic hematuria, anemia and positive SPEP. 4 of 5 patients had nephrotic range proteinuria at presentation. In all cases kidney biopsy had crescentic features with nodular glomerulosclerosis; considered characteristic pattern in this subset of HCDD. Plasma cell dyscrasia was present in all patients. Our patient presented with normal Cr, 1.2g proteinuria, normal hemoglobin and negative SPEP. Renal biopsy had no crescents. This patient received PLEX with decrease in Cr. In summary, we report the sixth case of IgA HCDD, with multiple findings different from earlier cases, including an apparent response to PLEX.

## SA-PO620

**ACTH a Novel Treatment in IgA Nephropathy** Vinh Q. Nguyen,[1] Ashraf El-Meanawy.[2] *[1]Nephrology, Medical College of Wisconsin, Milwaukee, WI; [2]Nephrology, Medical College of Wisconsin, Milwaukee, WI.*

**Background:** IgA nephropathy is the most non-infectious glomerulonephritis worldwide. Despite this, treatment options remains limited as current data on immunosuppressive therapy of MMF and cyclosporine have been inconclusive. This leaves supportive therapy and corticosteroids to be the cornerstone of current therapy for aggressive disease.

We report a case of IgA nephropathy treated with ACTH with improvement in proteinuria.

**Methods:** JB is a 38 y/o white male who was diagnosed with IgA nephropathy biopsy proven in his early 20's when he presented with hematuria. He now presented to the clinic with worsening creatinine with proteinuria. On PE his BP was 129/85, HR: 68 and well built. The remainder of his exam was unremarkable other than trace bilateral edema. His creatinine at the time was 2.04 ml/min with 0.9 g/g on spot P/C ratio. Patient was offered steroids and cellcept which he declined. He opted to have a second opinion at Mayo Clinic where a biopsy was performed showing positivity for IgA, IgM and moderate C3. He was treated with steroids. He returned to our clinic with worsening proteinuria of 3.3 g/g and a creatinine of 3.0 ml/min and was started on cellcept. Subsequently his renal function and proteinuria did not improve and ACTH was initiated. His serum creatinine stablize at 2.6-3.0 ml/min with improvement of proteinuria down to 1.7 grams/gram.

**Conclusions:** ACTH is a therapy that has been considered in primary membranous nephropathy. However its role in IgA nephropathy has yet of be described. Besides the glucocorticoid effects, it has been thought that ACTH has anti-inflammatory and immune modulating properties. We believe that in selective patients who failed corticosteroids and MMF, ACTH is a viable option.

## SA-PO621

**Successful Treatment of Rapidly Progressive Immunoglobulin A Nephropathy with Human Immunodeficiency Virus Infection by Steroid Pulse Therapy and Tonsillectomy** Daisuke Fujimoto,[1] Yoshikazu Miyasato,[2] Taku Miyoshi,[2] Masataka Adachi,[2] Kenichiro Kitamura.[2] *[1]Dept of Nephrology, Kumamoto General Hospital, Yatsushiro, Japan; [2]Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.*

**Background:** Several renal syndromes including Immunoglobulin A (IgA) nephropathy have been described in patients with human immunodeficiency virus (HIV) infection. Hotta et al. reported that steroid pulse therapy combined with tonsillectomy was effective for clinical remission in patients with IgA nephropathy (Am J Kidney Dis, 2001). Here, we report a case of rapidly progressive IgA nephropathy with HIV infection treated successfully with steroid pulse therapy and tonsillectomy.

**Methods:** A 43-year-old man was referred to our department for rapidly progressive renal impairment, proteinuria, and hematuria. He was under treatment of acquired immunodeficiency syndrome (AIDS) with Highly Active Anti-Retroviral therapy (CD4 count: >200/μL, HIV RNA: undetectable). Kidney biopsy revealed IgA nephropathy with cellular crescents. Firstly steroid pulse therapy (methylprednisolone 0.5-1g/day for 3 consecutive days, 3 courses) was initiated and prednisolone (30mg/day) and mizoribine (initially 50mg/day, loaded up to 150mg/day) were orally administered as aftertreatment. Two months later, he underwent tonsillectomy. One course of methylprednisolone pulse therapy was added after tonsillectomy. During steroid pulse therapy, CD4 count dropped below 200/μL, but no serious complication occurred. Serum creatinine (Cr) level increased up to 4.15mg/dL and gradually decreased to 1.1mg/dL. Although hematuria still exists, urinary protein declined from 3g/gCr to 0.3g/gCr during the 10 months treatment period.

**Conclusions:** Steroid pulse therapy combined with tonsillectomy dramatically ameliorated the rapid progression of IgA nephropathy in our current case and no serious complication occurred in such a highly immunocompromised host. This combined therapy could be considered in the treatment of rapidly progressive IgA nephropathy in patients with HIV infection.

## SA-PO622

**Resolution of C1q Deposition but Not of the Clinical Nephrotic Syndrome after Immuno-Modulating Therapy in Focal Sclerosis** Michelle L. Blake,[1] Eva Csongradi,[1,2] Tibor Fulop.[1] *[1]Internal Medicine, Univ of Mississippi Medical Center; [2]Medicine, Univ of Debrecen Medical and Health Science Center, Hungary.*

**Methods:** A 30 year-old Caucasian female referred for further management of biopsy-proven C1q nephropathy (C1qNP) and nephrosis. She was normotensive but had severe, bilateral pitting edema, serum albumin of 1.4 gm/dL and urine protein/creatinine (UPC) concentrations of 4800/133 mg/dL. Serologic work-up was negative, including complement C3 and C4 levels and antinuclear antibodies. A renal biopsy revealed minimal change nephropathy vs. focal sclerosis and C1qNP on immunopathology. She had failed a trial of high-dose oral prednisone. At follow-up she failed a regimen of mycophenolate mofetil 1,500 mg twice a day and prednisone 40 mg daily for 14 months and then monthly IV cyclophosphamide 750 mg x 9 cycles. She received the maximum tolerated ACE inhibitor and spironolactone therapy. Her random UPC ratio ranged 5-35 gm/day, serum creatinine (sCr) progressively rose from 1.0 mg/dL to 1.4 mg/dL. Two years after her initial visit we faced the dilemma of ongoing nephrotic-range proteinuria failing maximized therapy. The decision was made to repeat renal biopsy to reassess the underlying histology. The biopsy revealed focal sclerosis but no C1q deposition. Combined diuretic and ACE inhibitor therapy was continued for symptomatic control; restarting immune-modulating therapy was felt likely to be of little benefit. She was lost to follow-up up till 16 months post biopsy, when sCr rose to 2.8 mg/dL and she remained severely nephrotic with a UPC ratio of 23.

**Conclusions:** How an underlying glomerulonephritis changes with treatment remains a relatively little explored subject. While clinical nephrosis did not change with immunosuppressive therapy, C1q deposition ceased, making the latter entity likely an immunologically mediated process. Our case illustrates at least two points: first, an established pathologic diagnosis does not obviate the need for repeated renal biopsy later on, should diagnostic uncertainty persist. Second, histological diagnoses may evolve over time, especially in a patient receiving active and powerful immune-modulating treatment.

## SA-PO623

**Late Recurrence of Light Chain Deposition Disease after Kidney Transplantation Treated with Bortezomib: A Case Report** Tariq Javed, Abdul Moiz, Jorge C. Garces, Catherine G. Staffeld-Coit. *Ochsner Multi-Organ Transplant Institute, Ohsner Clinic Foundation, New Orleans, LA.*

**Background:** Herein, we present a case of a patient who developed recurrence of LCDD, several years after kidney transplantation, leading to allograft dysfunction requiring renal replacement therapy. The patient had a significant improvement in her renal function after receiving bortezomib and was able to come off dialysis.

**Methods:** A 55 YO Caucasian female with history of Type 2 DM and HTN, ESRD secondary to LCCD underwent living-unrelated kidney transplantation. Her induction consisted of IV solumedrol and rabbit thymoglobulin (4.5mg/kg in 3 divided dosages). She had immediate allograft function without the need of renal replacement therapy. Her creatinine stabilized between 0.8-1.0mg/dl. After 6 years of transplantation routine labs showed a Cr of 1.8mg/dl and nephrotic range proteinuria (9.5g/g) on spot protein to creatinine ratio. She subsequently underwent a kidney biopsy. A diagnosis of recurrent

light-chain deposition disease was made based on the biopsy findings. Oncology was consulted and a bone marrow biopsy was performed which was consistent with a plasma cell dyscrasia and she met criteria for multiple myeloma. Patient initially received five cycles of plasmapharesis without any improvement. She eventually required renal replacement therapy three times a week. She then received one cycle of Bortezomib (Velcade 1.3mg/m2 intravenously) along with IV dexamethasone. She received 4 doses of Bortezomib on day 1, 4, 8 and 11. There was no immediate clinical response to the treatment and she remained dialysis dependent. She was discharged to a rehabilitation center due to significant debility and deconditioning. Her renal function was closely monitored while she remained on dialysis. She gradually exhibited signs of renal recovery after staying on dialysis for 2 months. Dialysis was held when her urine output improved (> 1L/day), and her creatinine eventually settled between 1.5-1.7 mg/dl.

**Conclusions:** Bortezomib may provide an alternative to currently available treatment options in patient with LCDD recurrence after transplantation.

## SA-PO624

**Heavy Chain Deposition Disease: A Case Report** Sassan Ghazan-Shahi, Iain D. Young, Ralph M. Meyer, Christine A. White. *Internal Medicine - Nephrology, Queen's Univ, Kingston, Canada.*

**Background:** Heavy Chain Deposition Disease (HCDD) is a rare condition with few case reports in the literature. It is one of the three subtypes of monoclonal immunoglobulin deposition disease (MIDD) in the kidney. The most common clinical features are hypertension, microscopic hematuria, nephrotic range proteinuria, and variable degrees of renal insufficiency. The characteristic histopathological finding of HCDD is nodular glomerulosclerosis.

**Methods: Case Presentation**: An 82 yo female with proteinuria and microscopic hematuria. She reported increased bilateral leg edema, shortness of breath on exertion and generalized fatigue. There was no gross hematuria. She denied any other constitutional symptoms including fever, night sweats, weight loss or loss of appetite. There were no symptoms suggestive of a vasculitic or connective tissue disorder. **Past Medical History:** COPD and peripheral vascular disease. Her medications were perindopril/indapamide, metoprolol, ASA. **Physical examination:** BP=170/80 mmHg, clear lungs, broad and displaced PMI, S3 gallop and III/VI systolic ejection murmur over the aortic area, bilateral leg edema to knees. No ascites or organomegaly. **Table 1** shows categorized list of the investigations. **Image 1** and **Image 2** show light microscopy and immunofluorescence microscopy of the kidney biopsy.

**Table 1: Categorized list of investigational studies performed**

| | |
|---|---|
| **Hematologic/Chemistry** | |

| **Other investigations** | |
| Echocardiogram | LVEF=30%<br>Dilated cardiomyopathy |
| Skeletal survey | Osteoporosis |
| MRI | No lytic lesions |

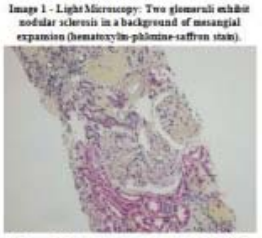

**Image 1 - Light Microscopy: Two glomeruli exhibit nodular sclerosis in a background of mesangial expansion (hematoxylin-phloxine-saffron stain).**

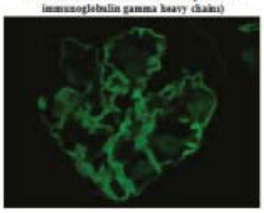

**Image 2 - Intense continuous staining of GBM. A similar pattern of linear staining of the basement membrane of one tubule is also apparent. (direct immunofluorescence with antisera specific for immunoglobulin gamma heavy chains)**

**Outcome:** She was started on Chlorambucil and Prednisone cycles The response to therapy over 9 months f/u period was favourable indicated by improvement of symptoms, lowered proteinuria and serum M-Protein.

**Conclusions:** Almost all reported cases of HCDD are in pateints with advanced renal insufficiency. Despite the severity of biopsy findings, the renal function in this case was reasonably well preserved on presentation and throughout the follow up period. Given the echocardiographic findings of possible cardiomyopathy, we are proposing possibility of cardiac deposition disease.

## SA-PO625

**A Case of Membranoproliferative Glomerulonephritis (MPGN) with Type I Cryoglobulinemia Associated with Monoclonal Gammopathy of Undetermined Significance (MGUS)** Shoko Hasegawa,[1] Toshiaki Nakano,[1] Akihiro Tsuchimoto,[1] Kazuhiko Tsuruya,[1,2] Takanari Kitazono.[1] *[1]Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

**Background:** The association of cryoglobulinemia and renal involvement is well known. Renal involvement usually is reported in mixed (type II or III) cryoglobulinemia, mostly associated with chronic hepatitis C infection. Renal involvement in monoclonal, type I cryoglobulinemia is unusual.

We report the a rare case of a patient exhibiting pathological characteristics of MPGN, which was induced by type I cryoglobulinemia associated with MGUS.

**Methods:** A 36-year-old Japanese woman was admitted because of proteinuria, hematuria and skin ulcers on the both legs. Urinary protein to creatinine ratio was 3.0 g/gCr and urinary sediment analysis revealed red blood cell of 60-70 /high power field and other various casts. The histopathology of skin biopsy showed an obstruction of superficial blood vessels with eosinophilic amorphous materials. Immunoelectrophoresis revealed a monoclonal immunoglobulin (Ig) G-K, type I cryoglobulin. Serum IgG was 1.3 g/dL (< 3 g/dl), and a bone marrow biopsy demonstrated 4% of plasma cells. The cryocrit was 35%. A renal biopsy showed mesangial hypercellularity, endocapillary proliferation, and double-contour formation of the glomerular basement membrane. Electron microscopic examination revealed a deposition of annular or curved cylinder tubular material in the glomerular basement membrane. The final diagnosis was MPGN caused by type I cryoglobulinemia associated MGUS. Within 2 months after initiation of Oral prednisolone therapy (50mg/day), proteinuria and hematuria had disappeared.

**Conclusions:** Renal histopathology of type I cryoglobulinemia shows generally noninflammatory glomerulopathies, including thrombotic and hypocellular lesions, without evidence of vasculitis (Karras A et al. Am J Kidney Dis 2002). We described a rare case of MPGN and skin ulcers with type I cryoglobulinemia associated with MGUS. The hematuria and proteinuria improved after therapeutic dose of prednisolone.

## SA-PO626

**Mixed Cryoglobulinemia and Membranoproliferative Glomerulonephritis Associated with Ehrlichiosis** Dawn J. Caster,[1] James T. Summersgill,[1] Paisit Paueksakon,[3] Rob Massung,[4] Wun-ju Shieh,[5] Kenneth R. McLeish.[1,2] *[1]Medicine, Univ of Louisville, Louisville, KY; [2]VAMC, Louisville, KY; [3]Pathology, Vanderbilt, Nashville, TN; [4]Rickettsial Zoonoses Branch, Centers for Disease Control and Prevention, Atlanta, GA; [5]Infectious Diseases Pathology Branch, Centers for Disease Control and Prevention.*

**Background:** Ehrlichiosis is a tick-borne disease with diverse clinical presentations, ranging in severity from a flu-like illness with fever and myalgias to a serious systemic disease with multisystem organ failure. Nephrotic syndrome has previously been reported in two cases of human ehrlichiosis. A kidney biopsy was performed in only one of those cases, and it demonstrated minimal change disease. This case describes a patient with ehrlichiosis who developed nephrotic syndrome, cryoglobulinemia, and membranoproliferative glomerulonephritis (MPGN).

**Methods:** A 40-year- old white male presented to the emergency department in late June complaining of shortness of breath, diffuse myalgias, headache, and lower extremity edema. Initial labs demonstrated pancytopenia, creatinine of 0.9 mg/dL, and albumin of 2.9 g/dL. The urinalysis showed protein concentration greater than 600 mg/dL and 15-29 red blood cells. A 24-hour urine collection contained 18 g of protein. He subsequently developed acute kidney injury and underwent kidney biopsy which showed MPGN and acute tubular injury. A tick-borne disease panel was positive for IgM and IgG to *Ehrlichia chaffeensis*. Serum testing revealed type 3 mixed cryoglobulinemia with no evidence of hepatitis C infection. Cryoprecipitate contained IgM and IgG to *E. chaffeensis*.

**Conclusions:** Mixed cryoglobulinemia is frequently associated with infections, particularly hepatitis C. Additional etiologies of mixed cryoglobulinemia include autoimmune disorders and hematologic malignancies. Our case is the first to describe ehrlichiosis associated with cryoglobulinemia and MPGN.

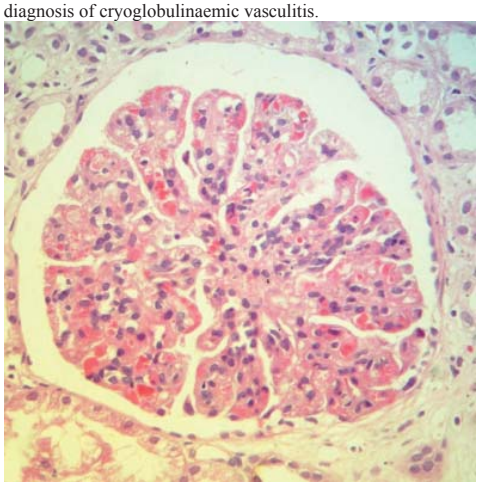
## SA-PO627

**Hepatitis C Negative Cryoglobulinaemic Vasculitis in a Young Woman** Talita Mourao Chaves Corrica, Tatiana Santos, Guilherme Fonseca Mendes, Talita Cardoso Proenca, Cláudia Fagundes, Luiz Fernando Christiani, Maria izabel Neves de Holanda Barbosa. *Nephrology, Hospital Federal de Bonsucesso, Rio de Janeiro, Brazil.*

**Background:** Cryoglobulinaemic vasculitis is caused by deposits of monoclonal or polyclonal imunoglobulins and complements compounds in small vessel walls in cold temperature, which promotes acute inflammation. This diseased is most often due to chronic HCV infection nevertheless, cryoglobulinemia is considered essential, in which no causal agent can be determined.

**Methods:** We report a case of a 39 year old woman presented with weakness, fever, arthralgia of small and large joints induced by cold temperatures. Upon examination the patient showed diffuse palpable purpura and nose and distal limbs ulcers. There was progressive worsening of skin lesions and anuria. Antibiotic therapy was started aimed to treat infectious vasculitis and hemodialysis was initiated. Sorology to HBV, HCV and

HIV, ANA, anti-DNA and ANCA were all negative, fraction of the complement C3 was normal and C4 reduced. Renal findings included renal failure with proteinuria and hematuria Ultrasound demonstrated normal kidney size and cortical-medullary relationship preserved. Cryoglobulinemia was suspected and subsequent serum cryoglobulin levels were positive. The peripheral blood smear showed characteristic findings and renal biopsy confirmed the diagnosis of cryoglobulinaemic vasculitis.



The patient was treated with steroids and monthly pulse of cyclophosphamide, with recovery of renal function after the second month of treatment and disappearance of the skin lesions.

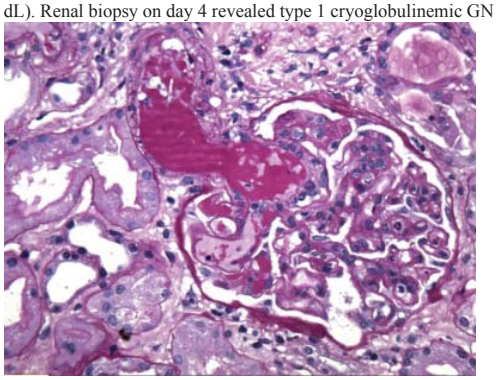
**Conclusions:** This case demonstrates that in patients with suspected vasculitis, even with negative sorology for hepatitis C, essential cryoglobulinemia should be considered, as early diagnosis and therapy promotes a higher chance of better outcome.

## SA-PO628

**The Cool Side of Acute Kidney Injury: Type 1 Cryoglobulinemic Glomerulonephritis in a Patient with Waldenstrom's Macroglobulinemia** Mamta Shah,[1] Rahul Mutneja,[1] Sparsha Kukunoor,[1] Dhwanil Vyas,[1] Andre A. Kaplan.[2] *[1]Internal Medicine, Univ of Conecticut, Farmington, CT; [2]Nephrology, Univ of Connecticut, Farmington, CT.*

**Background:** Renal manifestations of Waldenstrom's Macroglobulinemia (WM) include amyloidosis, glomerular/interstitial IgM deposition, cast nephropathy, intracapillary IgM deposition and cryoglobulinemic glomerulonephritis (GN). Type 1 cryoglobulinemic GN has been infrequently described.

**Methods:** 64 year old female with WM, not on treatment, presented with vomiting and blurry vision. She was found to be hypertensive with acute renal failure (Creatinine-5.2 mg/dl). Random urine protein was >600mg/dL. Labs 2 weeks prior showed a creatinine (Cr) of 0.6 mg/dL, cryoglobulins of 29% and IgM of 1330 mg/dL. She underwent immediate therapeutic plasma exchange (TPE) and hemodialysis (HD) for presumed hyperviscosity and renal failure. Serum viscosity drawn prior to TPE returned normal (1.5 U). Following HD and TPE Cr fell to 3.4mg/dL. 4 days later she received only TPE following which Cr was 2.5 mg/dL with concomitant decline of cryoglobulins (6%) and IgM (301 mg/dL). Renal biopsy on day 4 revealed type 1 cryoglobulinemic GN (courtesy Dr Herlitz).



She was started on bortezomib, rituximab and steroids and was sent home with follow up. Cr at discharge was 0.6 mg/dL.

**Conclusions:** Cryoglobulinemia (cryo) is present in 8-18% of WM patients. Cryo associated Raynaud's, palpable purpura or GN is seen in less than 5% of these patients. Symptoms related to hyperviscosity and cryo are indications for WM treatment. Bortezomib, rituximab and dexamethasone have been most studied. The rapid improvement in renal function post TPE, before immunosuppressive/steroid therapy is suggestive of rapid re-cannulation of cryoglobulin-clogged glomerular arterioles as is commonly seen with TPE treatment of cryo associated coalescing purpura of the skin.

## SA-PO629

**Sustained Remission of Refractory Membranoproliferative GN (MPGN) Associated with Monoclonal Gammopathy (MGUS) following Bortezomib/Dexamethasone Therapy** Marvin Aiko Schwarz,[1] Yonn-dschun Ko,[4] Thorsten Wiech,[3] Jürgen Floege,[1] Karl August Brensing.[2] *[1]Cardiology and Nephrology, RWTH Univ Hospital Aachen, Aachen, NRW, Germany; [2]Nierenzentrum Bonn, Bonn, NRW, Germany; [3]Dept of Pathology, Univ Hospital Hamburg Eppendorf, Hamburg, Germany; [4]Center of Oncology, Johanniter Krankenhaus Bonn, Aachen, NRW, Germany.*

**Background:** MPGN type 1 is known to be associated with monoclonal gammopathy of undetermined significance (MGUS). However, the causal relationship between the two entities is not well established.

**Results:** A 63-year-old man presented in 2005 with arterial hypertension, microscopic hematuria, proteinuria of 7.4 g/day and a GFR of 99 ml/min. Renal biopsy disclosed MPGN type I. An extensive screen for conditions associated with MPGN type I only revealed an MGUS IgG kappa in serum and Bence-Jones-proteinuria. From 2005 to 2012 the patient was treated with cyclosporine and low-dose steroids. While he initially responded with a partial remission of proteinuria, in 2011 and 2012 proteinuria relapse to full nephrotic syndrome (proteinuria 10-13 g/day, weight gain 10 kg). GFR decreased to about 55-60 ml/min. In view of the MGUS, no therapy with MMF was attempted. In 2012 his MGUS had remained stable with a maximal proportion of plasma cells of 10-12% in a bone marrow biopsy. Given this situation and the lack of alternative treatment recommendations in the 2012 KDIGO guidelines, in June 2012 we decided to switch the therapy to a plasma cell targeting therapy with bortezomib and dexamethasone (Bor/Dex). Proteinuria decreased from 10.5 g/day to 1.9 g/day within 5 months and to 1.1 g/day at 12 months after chemotherapy. GFR increased to 105 ml/min and the patient had full clinical remission. Chemotherapy was well tolerated. The maximal proportion of plasma cells decreased to 2-4% in 2013. A repeated kidney biopsy 3 months after 4 Bor/Dex courses therapy revealed almost complete regression of immunoactivity markers.

**Conclusions:** Our case suggests that the MGUS was indeed the cause of MPGN type 1 here. However, we can not fully exclude that Bor/Dex might have also acted directly on the kidney disease. Bor/Dex therapy warrant further investigation in similar situations.

## SA-PO630

**Hepatitis C Negative Cryoglobulinemic MPGN after Two Decades of Rheumatoid Factor Positivity** Ingrid Calliste, Liliana E. Rios Rojas, Joseph Mattana, Nobuyuki (Bill) Miyawaki. *Internal Medicine, Div Nephrology, Winthrop Univ Hospital, Mineola, NY.*

**Background:** Membranoproliferative glomerulonephritis (MPGN) is is a lesion often associated with cryoglobulinemic (CG) glomerulonephritis in hepatitis C (HCV) infection yet rare cases of HCV negative CG MPGN have been documented. We present a case of an elderly female without clinical features of rheumatoid arthritis (RA) or HCV who had a positive rheumatoid factor (RF) titer as a surrogate for CG for 20 years and eventually developed CG MPGN with monoclonal IgM kappa deposits.

**Methods:** A 67 year old female with hypertension, intermittent microhematuria and gradually worsening proteinuria over eight years from 500mg/day to 3000mg/day despite angiotension receptor blockade and acceptable blood control was initially observed conservatively with serologies and biochemical testing given her preserved creatinine of less than 0.9mg/dL. She had a persistently positive RF since an arthritis assessment done nearly 20 years ago without any clinical features of RA. Her serologies were otherwise negative, including complement levels and HCV by PCR and antibody. Only one of numerous monoclonal assessments ordered through the years was transiently and faintly positive for IgM kappa. Quantitative immunoglobulin levels were unremarkable. Once her urine protein reached 3000mg/day a kidney biopsy was done and revealed MPGN with positive IgM and kappa deposits. Testing for cryoglobulins was positive.

**Conclusions:** Many cases of MPGN remain idiopathic but associated cases are often linked to HCV CG and the immune complex deposits, complement dysregulation, and thrombotic microangiopathies. Lymphoproliferative disorders, in the presence of paraproteinemias, have also been described in MPGN both with and without CG. Monoclonal IgM anti-IgG autoantibodies, commonly referred to as RF, are often considered a surrogate marker for CG. We speculate that this patient's slowly progressive course was likely due to years of low-grade production of IgM kappa. This case illustrates the possibility that isolated RF positivity in the setting of microscopic hematuria and proteinuria may signal the presence of an underlying paraproteinemic process.

## SA-PO631

**Membranoproliferative Glomerulonephritis (MPGN) and Central Venous Catheter (CVC) Infections** John Sy,[1] Cynthia C. Nast,[3] P.T.T. Pham,[2] P.C. Pham.[1] *[1]Nephrology, Olive View MC, Sylmar, CA; [2]Nephrology, UCLA MC, LA, CA; [3]Pathology, Cedars Sinai MC, LA, CA.*

**Background:** Chronic indwelling infected CVCs have been reported to be associated with MPGN *via* activation of the classical complement pathway.

**Methods:** We report a case of recurrent MPGN in association with recurrent CVC infections and review the literature for common clinical manifestations that may aid clinicians in early identification of both conditions. A 23 year-old male with prior small bowel resection due to trauma and chronic total parenteral nutritional support (TPN) *via* a CVC since the age of 17 presented with anasarca and low grade fevers. Evaluation: Urinalysis: 2+ blood, no casts, 2.0 g proteinuria, creatinine (Cr) 1.9 (baseline 1.4 mg/dL),

albumin 2 gm/dL. HIV, RPR, ANA, hepatitis B, C screen were negative. Complements: low C3 68, low-normal C4 19, low CH50 <28 mg/dL; Echocardiogram: no vegetations. Blood cultures: *Staphylococcus epidermidis*. Kidney biopsy: MPGN type I. Fourteen years later, he had a similar presentation with recurrent MPGN.

**Conclusions:** Literature review identified 3 similar cases; in all, the CVC was used for TPN for short bowel syndrome. All cases had multiple CVC infectious episodes prior to the diagnosis of kidney injury. Renal presentations ranged from incidental microscopic hematuria, non-nephrotic proteinuria, +/- cellular/granular casts, to relatively rapid to insidious rise in Cr, ranging from 0.5-2 months, in association with active urinary sediments. Extra-renal manifestations included edema/anasarca, fevers, and/or palpable purpura (leukocytoclastic vasculitis). Complement levels were depressed in all but one case. Blood cultures in 3 out of 4 cases revealed *Staph. Epidermidis*. Following CVC replacement and antibiotic therapy, Cr, proteinuria, and hematuria improved in all patients. Proteinuria improved within days and Cr within 2 weeks. Complete kidney function occurred within 3-10 months. Recurrent CVC infection in association with recurrent MPGN supports a causal relationship by the former. MPGN is associated with repeated episodes of CVC infections and may be predicted with surveillance urinalysis, Cr, +/- complements. Kidney injury may herald or coincide with CVC infections.

## SA-PO632

### Membranoproliferative Glomerulonephritis with Background Non-Collapsing Focal and Segmental Glomerulosclerosis in Untreated HIV Infection

Zaid Brifkani,[1] Raafat Farag Makary,[2] Leighton R. James.[3] *[1]Dept of Medicine/Nephrology and Hypertension, Univ of Florida, Jacksonville, Jacksonville, FL; [2]Dept of Pathology and Laboratory Medicine, Univ of Florida, Jacksonville, Jacksonville, FL; [3]Dept of Medicine/Nephrology and Hypertension, Univ of Florida, Jacksonville, Jacksonville, FL.*

**Background:** Membranoproliferative Glomerulonephritis (MPGN) is uncommon in patients with HIV-associated Nephropathy (HIVAN). The most common feature in HIVAN is a picture of collapsing Focal Segmental Glomerulosclerosis (FSGS).

**Methods:** We report the case of a young African American man with a history of cocaine use, who presented to the hospital with worsening 1-month lower extremity edema , two years after being diagnosed with HIV. Apparently, he never started recommended therapy and was not on any medications at the time of admission. He was found to have reduced $CD4^+$ cells (81 cells/mL) and elevated creatinine (4.4 mg/dL). Urinalysis revealed blood (small) and protein (600 mg/dL). Urine microscopy showed white blood cells (9 cells/high power field [hpf]), red blood cells (2/hpf) and hyaline casts (12/hpf). He had nephrotic range proteinuria (24 gm/24 hours), but negative workup for SLE and Hepatitis. Accordingly, a kidney biopsy was performed. Light microscopy demonstrated mesangial sclerosis, thickened glomerular capillary basement membrane (GBM), marked tubular atrophy and marked tubular dilatation. Immunohistochemistry showed no specific immunoglobulins or complement deposits. Electron microscopy revealed mesangial expansion, increased cellularity, thickened endothelial GBM, with subendothelial electron dense deposits along with tubuloreticular inclusions in the endothelium of interstitial blood vessels, all consistent with MPGN and non-collapsing FSGS. The patient was started on combined antiretroviral therapy (cART) and has maintained stable renal function without need for renal replacement therapy or immunosuppression.

**Conclusions:** This case demonstrates a rare presentation of MPGN in the setting of HIVAN with background non-collapsing FSGS, and highlights the importance of early initiation of cART therapy.

## SA-PO633

### Successful Antiviral Tripel Therapy in a Longstanding Refractory Hepatitis C Virus (HCV) Infection with an Acute Exacerbation (MPGN I with Acute Kidney Injury and Cryoglobulinemic Vasculitis)

David Callau, Joerg Latus, Niko Braun, Mark Dominik Alscher, Martin Kimmel. *Dept of Internal Medicine, Div of Nephrology, Robert Bosch Hospital, Stuttgart, Germany.*

**Background:** The HCV infection is a very common disease with about 170 million chronically infected patients worldwide. In almost 80% of cases the acute infection passes into a chronic form with possible hepatic and extrahepatic manifestations. Before 2011 the standard therapy of a chronic HCV infection consisted of interferon alfa as a single therapy or in combination with ribavirin. After approval of the two protease-inhibitors boceprevir and teloprevir in 2011 the standard therapy for patients with a genotype 1 changed. In patients with chronic kidney disease (CKD) these therapies are not approved due to side effects of ribavirin and have so far not been evaluated in studies.

**Methods:** In april 2012 a 58 y/o female was admitted to the hospital with severe complications of a known chronic HCV infection. In the past the HCV infection has been treated ineffectively (partial non-response) with pegylated interferon alfa and ribavirin. Currently she presents with a cryoglobulinemic vasculitis and a membranoproliferative glomerulonephritis with an acute kidney injury. We decided to treat our patient with a boceprevir based tripel therapy which was continued for a total of 48 weeks due to a beginning liver cirrhosis. After 10 weeks the viral load was negative for the first time and renal function improved significantly during the therapy.

**Conclusions:** Limited data suggests that a therapy with ribavirin in patients with CKD seems to be save under close monitoring. Our patient with severe renal and extrarenal manifestations was treated successfully with a protease-inhibitor based tripel therapy. Nevertheless, it is necessary to plan an interventional study to evaluate the exact risk-benefit-profile of a tripel therapy regimen in patients with CKD and hepatitis C.

## SA-PO634

### Clinical and Histopathologic Maintenance of Disease Remission off Eculizumab in Two Patients with Recurrent C3 Glomerulopathy

Jonathan J. Hogan, Andrew S. Bomback, Leal C. Herlitz, Pietro A. Canetta, Jai Radhakrishnan, Michael B. Stokes, Glen S. Markowitz, Vivette D. D'Agati, Gerald B. Appel. *Columbia Univ Medical Center, NY, NY.*

**Background:** Eculizumab, a monoclonal Ab against C5, has emerged as a potential treatment for C3 glomerulopathies (C3G). Duration of therapy with this agent, however, remains an unresolved issue.

**Methods:** In 2012, we reported the 1st trial of eculizumab in C3G. Six subjects received the drug for 1 year:2 failed treatment,2 were re-started on eculizumab due to relapse, and 2 subjects remained off the drug with no evidence of relapse.We reviewed their clinical course and protocol biopsies performed before,upon completion, and one year after completion of eculizumab therapy.

**Results:** Both patients were white males, aged 20 and 42, with recurrent C3G in the allograft diagnosed within 2 months prior to initiating eculizumab therapy. Maintenance immunosuppression of MMF and FK506 was unchanged while on and off eculizumab. Genetic and autoAb testing revealed a mutation in MCP and a C3NeF in patient 1; patient 2 had no detectable mutation or autoAb. Patient 1's Cr fell from 2.0 to 1.4 mg/dl by completion of therapy. One year later, Cr remained 1.2-1.4 mg/dl with no proteinuria. Biopsies done at completion of therapy and 1 year later showed mild mesangial proliferation with no evidence of endocapillary proliferation or exudative features. Patient 2's proteinuria fell from 10.6 g/g by UPCR to 1.8 g/g by completion of therapy with stable creatinine. One year later, UPCR remained 1.4 g/g. Biopsy done at completion of therapy showed decreased mesangial proliferation and resorption of electron dense deposits on EM compared to pre-treatment. Biopsy performed 1 year later showed similarly mild mesangial proliferation and further resorption of deposits. Notably, in both patients, the de novo IF staining for kappa-restricted $IgG_2$ and $IgG_4$ (binding of eculizumab to C5 in renal tissue), present in biopsies performed at completion of therapy, was no longer seen one year off therapy.

**Conclusions:** In 2 patients with recurrent C3G,1 year of treatment with eculizumab was associated with clinical and histopathologic remission that persisted after discontinuation of therapy.

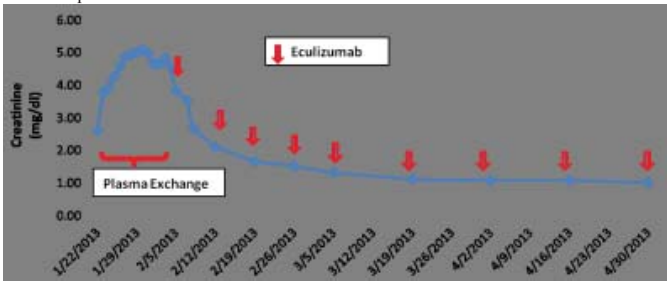
## SA-PO635

### Atypical Hemolytic Uremic Syndrome Treated with Eculizumab

Hilda E. Fernandez, Dan Negoianu. *Nephrology, Univ of Pennyslvania, Philadelphia, PA.*

**Background:** This case report of aHUS illustrates the efficacy of plasma exchange and Eculizumab in the treatment of thrombotic microangiopathy resulting from a mutation of MCP/CD46.

**Methods:** 23 yo male presented with non-bloody diarrhea and "wine-colored" urine with a rise in creatinine (Cr) to 1.9mg/dl. No prior history of renal dysfunction nor family history of renal failure. On exam, he was hypertensive with a blood pressure of 160/90, with 1+ non-pitting edema of legs. Laboratory findings included anemia (Hgb 8.6g/dL), thrombocytopenia (platelets 28/μL), and LDH 1800 U/L. C3 level was low (81mg/dL), and C4 was normal. Peripheral smear demonstrated schistocytes, shiga toxin was negative, and stool culture was negative for EColi O157:H7. ADAMST13 activity was normal. Genetic testing was performed as a send out lab. Patient was started on plasma exchange on hospital day #3 for concern for TTP/aHUS. Throughout hospitalization, the patient remained non-oliguric and did not require dialysis. Following daily plasma exchange for 2 weeks, LDH and platelet counts improved, though Cr remained elevated. He was started on Eculizumab weekly for 4 weeks, then every 2 weeks. Cr normalized to 1.01mg/dl, and LDH and platelet levels remained normal.



Genetic testing returned and demonstrated a CD46 (MCP) gene mutation of unknown significance at c.586G>A, p.Gly196Arg. The FH HUS Mutation Database lists this as a missense variant that indicates undetected C4b cofactor activity.

**Conclusions:** The use of Eculizumab was initiated as his creatinine had not improved to the same degree as his platelets and LDH following two weeks of plasma exchange. Prompt treatment with plasma exchange appeared to attenuate the disease, however initiation of Eculizumab allowed discontinuation of plasma exchange and was associated with further improvement of renal function and persistent remission of aHUS.

## SA-PO636

**Dermatomyositis-Induced Minimal Change Disease: A High Interferon State** Shailaja Chidella,[1] Hitesh H. Shah,[1] James M. Pullman,[2] Kenar D. Jhaveri.[1] *[1]Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY; [2]Pathology, Montefiore Medical Center/ Albert Einstein School of Medicine, Bronx, NY.*

**Background:** Dermatomyositis (DMS) is an autoimmune disease that characterized by involvement of proximal musculature and skin. Renal involvement is uncommon in dermatomyositis compared to other autoimmune disorders such as SLE. We report a patient who developed proteinuria in the setting of active DMS.

**Methods:** A 40-year-old Hispanic female was referred by rheumatology for evaluation of proteinuria. Three weeks prior to presentation, she had been diagnosed with DMS based on skin biopsy findings and systemic complaints. On presentation, she was normotensive and had trace lower extremity edema. She had normal lupus and other connective tissue serologies. A 24-hour urine collection revealed 2gm of proteinuria. Both serum albumin (3.7g/dl ) and serum creatinine were normal. Viral panels including hepatitis B and C, HIV, parvo virus B19 were negative. She has no history of diabetes mellitus or HTN. She denied any NSAID use. A kidney biopsy revealed normal light microscopy, normal IF but EM showed minimal change disease (MCD) with diffuse food process effacement. In addition, significant number of tubuloreticular inclusions (TRI) were noted. She had never received any interferon (IFN) therapy. Of all the connective tissue diseases, DMS has the highest IFN production. Given the podocyte effacement with presence of TRI, a secondary cause of MCD was considered. Given her recent diagnosis of DMS and new onset proteinuria, an association with DMS and MCD was made. At that point, she was started on oral steroids for treatment of DMS and MCD and her proteinuria is currently improving.

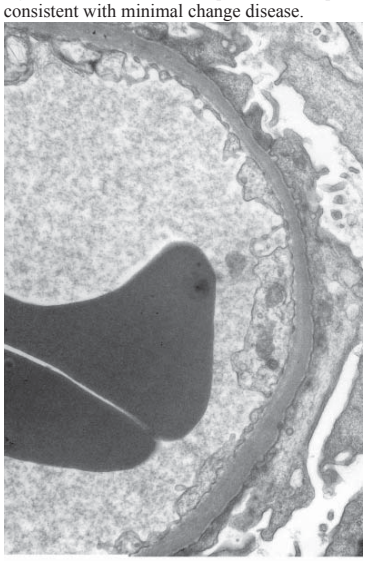
**Conclusions:** DMS is an autoimmune disease with varied systemic manifestations. Typically, it is not known to cause renal disease. We report a case of MCD secondary to DMS along with TRIs on kidney biopsy suggesting that active DMS is a high IFN signature state that can lead to the glomerular disease in these patients.

## SA-PO637

**Minimal Change Disease Associated with Waldenstrom's Macroglobulinemia** Olga Kuchmak[1] William L. Clapp,[2] A. Ahsan Ejaz.[3] *[1]Div of Nephrology, Hypertension and Transplantation, Univ of Florida, Gainesville, FL; [2]Dept of Pathology, Univ of Florida, Gainesville, FL; [3]Div of Nephrology, Hypertension and Transplantation, Univ of Florida, Gainesville, FL.*

**Background:** Waldenstrom's macroglobulinemia (WM) is a cancer of the B-lymphocytes, whereas minimal change disease (MCD) has been postulated to be associated with a Th2 immune response. MCD is common in children and WM is rare even in the adult predilection group. Occurrence of MCD associated with WM is rare, as described in this case report.

**Methods:** 73 year-old WM with history of diastolic dysfunction presented with generalized anasarca and recent 50 lbs weight gain. Labs were significant for the following: BUN 52mg/dL, Creat 2.58mg/dL, Total Prot 5.7g/dL, Alb 0.7g/dL, normal C3, C4, negative serology for hepatitis, HIV, ANCA and ANA. UA showed protein 3+, WBC 11/hpf, RBCs 2/hpf; random UPCr 12; UPEP and SPEP were positive for M (monoclonal) spike. Immunofixation electrophoresis revealed an IgM kappa monoclonal antibody and serum IgM level was 2,952 mg/dL. Subsequent bone marrow biopsy revealed mildly increased kappa predominant plasma cells present. Flow cytometry identified a small, kappa-predominant CD20(+) B-cell population. Overall findings were compatible with Waldenstrom's macroglobulinemia. A renal biopsy was performed. Light microscopy showed mild mesangial expansion. On immunofluorescence, kappa and lambda stains were approximately equal in intensity and distribution. Electron microscopy findings were significant for extensive foot process fusion presence with microvillous formation, features consistent with minimal change disease.



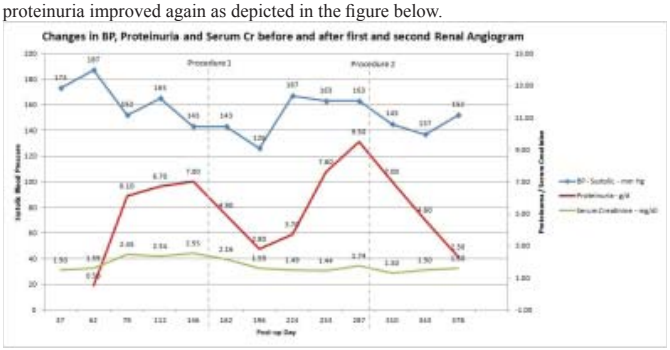
**Conclusions:** We report a rare case of MCD associated with WM. Although there was no evidence of complement activation by IgM or of Th2 response, the concurrence of MCD and WM points to the emerging role of immune response and immunoglobulins in renal diseases.

## SA-PO638

**Focal Segmental Glomerulosclerosis due to Transplant Renal Artery Stenosis** Salima Sadruddin, Anne L. King, Gaurav Gupta. *Nephrology, Virginia Commonwealth Univ, Richmond, VA.*

**Background:** Unilateral renal artery stenosis can result in Focal Segmental Glomerulosclerosis (FSGS) in the contra-lateral kidney due to hyperfiltration. Rarely FSGS has been diagnosed in an allograft with multiple arteries and a significant stenosis in a branch of the transplant renal artery.

**Methods:** A 45 year old white male with stage 5 chronic kidney disease due to diabetes underwent a pre-emptive deceased donor kidney transplant (KTx). Day 0 donor biopsy did not show any evidence of FSGS. The patient's serum creatinine plateaud at 1.5mg/dL within one month post-KTx and hypertension was controlled without medication. His blood pressure started rising after 6 weeks post-KTx and he developed nephrotic proteinuria of 7g/d. Allograft biopsy demonstrated FSGS with negative immunofluorescence and segmental podocyte effacement on electron microscopy. Due to absence of prior history of FSGS and presence of an accessory transplant renal artery a diagnosis of transplant renal artery stenosis (TRAS) was considered. A renal angiogram demonstrated upper pole TRAS which was successfully treated with angioplasty and drug-eluting stent placement. This was followed by a rapid improvement in proteinuria, renal function and blood pressure. Two months after the procedure, the patient's blood pressure and proteinuria again started to rise. A second renal angiogram showed in-stent restenosis as well as stenosis of another previously angioplastied lesion. It was once again successfully treated. The patient was switched to prasugrel from clopidogrel. He was continued on aspirin. Hypertension and proteinuria improved again as depicted in the figure below.



**Conclusions:** We report a case of FSGS due to the stenosis of a branch of the transplant renal artery. TRAS should be considered in the differential diagnosis of de-novo FSGS in patients with multiple transplant renal arteries.

## SA-PO639

**Focal Segmental Glomerulosclerosis Complicated by Hepatitis B Infection and Rheumatoid Arthritis** Kristin Mercado Luzentales, Beatrice P. Concepcion. *Section of Nephrology, Philippine General Hospital, Manila, Philippines.*

**Background:** Hepatitis B virus-associated nephropathy usually presents as membranous nephropathy (MN). Studies have reported a strong association between hepatitis B and MN. It is rarely associated with focal segmental glomerulosclerosis (FSGS). Rheumatoid arthritis (RA) has been associated with MN, amyloidosis, mesangioproliferative GN and diffuse proliferative GN but not with FSGS.

**Methods:** A 48-year old female consulted due to joint pains, tea-colored urine, edema and hypertension. Laboratory tests revealed anemia, azotemia, proteinuria and hematuria. Initial impression was systemic lupus erythematosus but antinuclear antibody test was negative. Other work-up revealed nephrotic-range proteinuria, hepatitis B surface antigenemia and high rheumatoid factor levels. HBV DNA was undetectable. Liver function tests and ultrasound were normal. She was diagnosed with RA and was given low-dose Prednisone. She was referred to a gastroenterologist for clearance prior to starting Methotrexate. She was given Lamivudine while on Methotrexate. Kidney biopsy revealed collapsing FSGS. Screening for HIV was negative. She was initially treated for idiopathic FSGS with high-dose steroids, with no response. Three months later, she had elevated levels of HBV DNA, hence Adefovir was added. On review of the biopsy, there was segmental foot process effacement, which is more consistent with secondary FSGS. Steroids were tapered off. Methotrexate was shifted to Hydroxycholoroquine. There was decreasing proteinuria, azotemia and HBV DNA levels six months later.

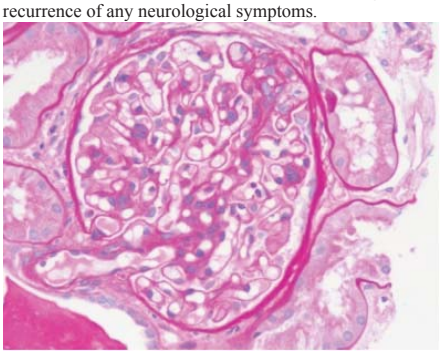
**Conclusions:** In the 8 cases reported before where FSGS was complicated by hepatitis B infection, HBV antigen was demonstrated in the glomeruli or tubules by immunostaining. In our case, this cannot be done due to its inavailablility in our country. It is well-known that drugs used in the treatment of RA can cause FSGS but there is only one reported case of RA associated with FSGS. This is the first reported case of FSGS complicated by hepatitis B infection and RA. Improvement was seen with treatment of both hepatitis B and RA. Treatment is challenging because the drugs used for RA could worsen hepatitis B infection.

**SA-PO640**

**Tip Variant Focal Segmental Glomerulosclerosis (FSGS) Associated with Interferon-β Treatment of Multiple Sclerosis (MS)**
Rhys David Russell Evans, Pandora Rudd, Andrew Rennie Hall, Mark Harber. *Whittington Hospital and UCL Centre for Nephrology, London, United Kingdom.*

**Background:** The nephrotic syndrome is a rare complication of treatment with Interferon. Minimal change disease and collapsing FSGS have been reported to occur in association with Interferon-b. We report a case of the nephrotic syndrome caused by tip variant FSGS in the setting of Interferon-b treatment of MS.

**Methods:** A 43 year old woman presented to the emergency department with swelling of her hands and feet. She had MS and had been treated with Interferon-b for the last 15 months without significant side effect. Other medical problems included migraine, oesophagitis, obesity and depression. She had been well until one week prior to presentation when she developed swelling of her hands and feet. She was hypertensive (199/110) with pitting oedema to the knee. Urine dipstick was positive for blood (3+) and protein (4+). Her creatinine was 64umol/L with an albumin of 27g/L, cholesterol 8.8mmol/L, and urinary protein:creatinine (PCR) 1284mg/mmol consistent with the nephrotic syndrome. ESR was 62mm/hour (CRP 8mg/L) with an otherwise unremarkable renal screen. A renal biopsy demonstrated tip variant FSGS. Her Interferon was held and she was treated with an ACE inhibitor, diuretics and tacrolimus. Her proteinuria and albumin have improved with latest urinary PCR 100mg/mmol and albumin 30g/L. Her creatinine has risen to 119umol/L in association with the above. Her oedema is resolving and she remains well in herself without recurrence of any neurological symptoms.



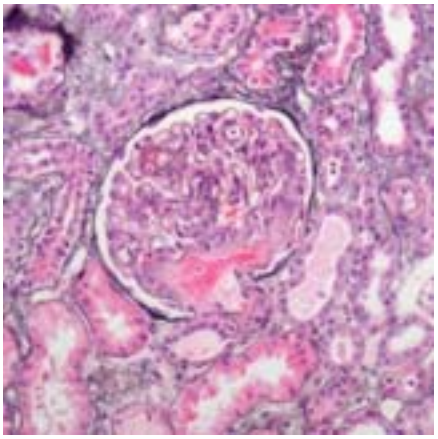
**Conclusions:** Minimal change disease and collapsing FSGS are rare complications of Interferon-b treatment of MS. This is the first report of the nephrotic syndrome caused by the tip variant of FSGS in this setting.

**SA-PO641**

**Thrombotic Microangiopathy in a Patient Treated with a Protease Inhibitor Based Regimen for Hepatitis C**
Rhys David Russell Evans, Mathena Pavan, Deepak Suri, Mark Harber. *Whittington Hospital, London, United Kingdom.*

**Background:** Current evidence advocates the use of triple therapy (pegylated interferon, ribavarin and a protease inhibitor) for the management of Hepatitis C genotype 1. We report a case of thrombotic microangiopathy in the setting of triple therapy with full recovery of renal function in response to cessation of antivirals and plasma exchange.

**Methods:** A 53 year old woman presented to the emergency department having collapsed in the hepatology outpatients. She had been started on peginterferon alpha, ribavirin and telaprevir for treatment of Hepatitis C 12 weeks prior to admission. The treatment had been complicated by a rash but had been otherwise well tolerated with undetectable Hepatitis C RNA at 4 weeks. She described a one-week history of fatigue, nausea and vomiting. She had a diffuse maculopapular rash extending from her trunk to her limbs but examination was otherwise unremarkable. Her creatinine had risen from a normal baseline to 444umol/L, with low haemoglobin (6.4g/dL) and platelets (88 x$10^9$/L). Her urinalysis was positive for blood (1+) and protein (3+). She had an elevated LDH (1147 iU/L), undetectable haptoglobins and red cell fragments on blood film. Renal biopsy demonstrated microthrombi and fragments in the glomeruli and small vessels and a diagnosis of thrombotic microangiopathy (TMA), thought to be a complication of her hepatitis C treatment, was made. She had a negative screen for other causes of TMA.



Her antivirals were discontinued and she was treated with 7 sessions of plasma exchange. This resulted in complete resolution of her acute kidney injury and improvement in her thrombocytopaenia.

**Conclusions:** Whilst TMA complicating interferon treatment of Hepatitis C has been documented, this is the first description of TMA complicating triple therapy. Protease inhibitors may exacerbate the side effects of interferon.

**SA-PO642**

**Diabetic Nephropathy without Diabetes: A Case Report**
Sara A. Combs, J. Pedro Teixeira, M. Scott Lucia, Richard J. Johnson. *Univ of Colorado, Aurora, CO.*

**Background:** Diabetic nephropathy (DN) is the most common cause of end-stage renal disease (ESRD) in the US. We present a case of a 45 year-old Hispanic man with no known history of diabetes who presented with renal failure and nephrotic syndrome and had advanced DN on biopsy.

**Methods:** The patient presented to the ED with progressive dyspnea, chest pain, and lower extremity swelling over 3-4 weeks. Exam revealed a blood pressure of 220/100 mm Hg and generalized edema. His BMI was 29.9 kg/m2, though he reported a 50- to 100-pound weight loss in the past few years. Serum creatinine was 7.5 mg/dL (eGFR by MDRD of 8 mL/min), potassium 5.8 mEq/L, bicarbonate 15 mEq/L, serum albumin 2.0 g/dL, BUN 101 mg/dL, phosphorus 6.1 mg/dL, calcium 6.8 mg/dL, and hemoglobin 9.3 g/dL. Urine microscopy revealed 10 to 20 RBCs per hpf with few granular casts. Urinary protein was measured at 11 g by 24 hour collection. Fasting glucose was in the normal to impaired range (average 94, range 80-110 mg/dL) with normal random glucose levels. Hemoglobin A1c was 5.9%. SPEP and UPEP, serum lambda/kappa ratio, HIV and HCV antibodies, HBV surface antigen, and ANA were all negative. Renal ultrasound revealed normal kidney size and echogenicity. Hemodialysis was initiated with improvement in the patient's symptoms. Renal biopsy demonstrated marked nodular glomerulosclerosis, felt to be consistent with advanced DN. Dilated fundoscopic exam revealed severe bilateral diabetic retinopathy.

**Conclusions:** Advanced diabetic glomerulosclerosis in a subject without a known history of diabetes is rare. Some conditions such as light chain nephropathy may have a histologic lesion similar to diabetes. In this case, the presence of diabetic retinopathy makes true diabetic glomerulosclerosis likely. We suspect that he had diabetes but that it reversed with his weight loss, which may have been precipitated by his progressive renal failure. Decreased insulin clearance from the loss of GFR could have also contributed to the normalization of glucose levels. Clinicians should be aware that undiagnosed diabetes may remit leaving advanced retinal and diabetic disease that may be the first manifestations of the prior diabetic condition.

**SA-PO643**

**Membranous Nephropathy as a Manifestation of Chronic Graft versus Host Disease after Allogeneic Hematopoietic Stem Cell Transplantation**
Yul Hee Cho, Ji Hee Lim, Min Young Kim, Myung Hyun Lee, Ji Hyun Yu, Keun Suk Yang, Seun Deuk Hwang, Chul Woo Yang, Yong-Soo Kim, Cheol Whee Park. *Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, College of Medicine, Seoul, Republic of Korea.*

**Background:** Membranous nephropathy (MN) is the most common glomerular disease after allogeneic hematopoietic stem cell transplantation (HSCT). The pathogenesis of MN after allogeneic HSCT is not well understood. We described the clinical and histopathological characteristics and outcomes of 12 patients with post HSCT MN.

**Methods:** We investigated the renal pathologic and clinical findings of 12 patients who developed MN after HSCT at Seoul St. Mary's Hospital. We also measured the anti-PLA2R (M-type phospholipase A2 receptor) antibodies using commercial antigen specific ELISA kit in the serum samples from the seven patients at the time of renal biopsy.

**Results:** Of the 12 patients, all had chronic Graft Versus Host Disease (cGVHD) and indication of biopsy was proteinuria (>1g/day) without microscopic hematuria, in 58% (7/12) of patients with nephrotic syndrome. Overall response rate, including complete remission (urinary protein level < 0.3g/day)and partial remission (urinary protein level

0.31-3.4g/day), was 83%. Two patients did not respond to treatment. The median follow-up period was 26 months and none of them developed end stage renal disease. All of the seven patients with MN after HSCT had negative for anti-PLA2R ELISA assay.

**Conclusions:** MN after HSCT is the most common of manifestation of cGVHD of renal disease. Eight-three percent of patients responded either partially or completely to immunosuppressive treatment. Anti PLA2R antibodies were all negative in these patients. These results suggest that MN after HSCT is one of characteristics of cGVHD and has a different pathogenesis from idiopathic MN.

## SA-PO644

**Membranous Nephropathy Post Allogeneic Haematopoietic Stem Cell Transplant – A Case Series** Karen Lok Yee Keung,[2] Subramanian K. Kumar.[1] *[1]Nephrology, Gosford Hospital, Gosford, NSW, Australia; [2]Nephrology, Westmead Hospital, Westmead, NSW, Australia.*

**Background:** Membranous nephropathy is a rare complication following allogeneic haematopoietic stem cell transplantation, and clinical observations to date suggest an association between chronic graft versus host disease (cGVHD) and membranous nephropathy in this setting. Whether this is a secondary process and perhaps a manifestation of graft versus host disease in the kidney is difficult to verify. Primary membranous nephropathy is a possibility, but there have been no published case reports of serum PLA2R antibody testing in these patients.

**Methods:** Here, we describe 5 cases of membranous nephropathy following allogeneic haematopoietic stem cell transplantation; serum anti-PLA2R antibody testing was available at the time of diagnosis for two of these patients.

**Results:** A history of cGVHD involving variable sites was identified in all five patients. All patients were treated with prednisolone with or without other agents after biopsy proven membranous nephropathy. At the time of last follow up, two patients had developed end stage renal failure and were dialysis dependent; two achieved complete remission with one remaining on low dose prednisolone alone, whilst the other was on a tapering immunosuppression regime. The fifth patient was in remission but required multiple agents to maintain this. In both patients who underwent testing for serum anti-PLA2R antibody, the result was negative.

**Conclusions:** The presence of a cGVHD history in all five of our patients with membranous nephropathy supports the findings in other cases series that there is likely an association between the two, but the exact nature of this relationship is difficult to establish. The absence of serum anti-PLA2R antibody in both patients in which the test was performed, suggests an alternative antigen to PLA2R is the target in patients with membranous nephropathy post allogeneic haematopoetic stem cell transplant. Furthermore, since the presence of the anti-PLA2R antibody supports the diagnosis of primary membranous nephropathy, the negative result in both cases would support the diagnosis of membranous nephropathy in this clinical context as a secondary process.

## SA-PO645

**Response to Oral Corticosteroids in Relapsing Membranous Nephropathy with Acute Kidney Injury following Influenza Vaccine** Chinmay P. Patel, Hitesh H. Shah. *Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.*

**Background:** Membranous nephropathy (MN) is one of the most common forms of nephrotic syndrome in adults. Here, we describe a unique case of relapsing MN with acute kidney injury (AKI) following 2009 H1N1 influenza vaccine with management and long term follow-up.

**Methods:** A 60-year-old female presented with 1 week history of acute onset lower extremity edema 5 days after receiving 2009-10 influenza vaccine. Patient had refused influenza vaccination in the past as her father had died from Guillain-Barre syndrome after receiving influenza vaccine. She denied NSAID use. Physical exam was significant for hypertension and lower extremity edema. Laboratory data revealed AKI with serum creatinine (Scr) of 10.2. Her spot urine total protein to creatinine ratio (TP/CR) was 23. Serological workup and age appropriate cancer screening was negative. Kidney biopsy showed stage 1 MN with acute interstitial nephritis (AIN). She was started on daily oral prednisone (0.75mg/kg) with tapering doses over the next 2 months. 5 weeks after initiation of oral prednisone, her Scr had normalized (0.9) and spot urine TP/CR decreased to 1.3. However 1 week after completion of prednisone therapy, patient was found to have elevated Scr of 2.3. Her spot urine TP/CR increased to 28. At this point, patient underwent repeat kidney biopsy which showed MN with resolution of AIN. Daily oral prednisone was restarted at 0.75 mg/kg and tapered over the next 4 months. One month after initiation of steroids, her Scr decreased to 0.9 and spot urine TP/CR decreased to 0.2. Since then, she has refused further influenza vaccinations. At 3 year follow-up, our patient continues to remain in complete clinical remission with stable renal function and spot urine TP/CR of 0.1. Therefore, we strongly believe that abrupt onset MN in our patient was secondary to the activation of immune response triggered by the influenza vaccine.

**Conclusions:** To the best of our knowledge, this is the first described case of relapsing MN with AKI following influenza vaccination. Based on our experience, one can consider a course of oral corticosteroids in patients who develop MN and AKI after influenza vaccine.

## SA-PO646

**Syphilis-Associated Membranous Nephropathy Mimicking Class V Lupus Nephritis** Chinmay P. Patel,[1] Aditya Kadiyala,[1] James M. Pullman,[2] Hitesh H. Shah,[1] Kenar D. Jhaveri.[1] *[1]Hofstra North Shore-LIJ School of Medicine, Great Neck, NY; [2]Montefiore Medical Center, Bronx, NY.*

**Background:** Syphilis is a well known cause of secondary membranous nephropathy (MN), but is not commonly diagnosed in the US. We present a case of secondary syphilis presenting with acute onset nephrotic syndrome with unusual kidney biopsy findings.

**Methods:** A 21-year old Caucasian male was admitted with a 3 day history of worsening anasarca, facial edema & 10 lbs weight gain. He was recently diagnosed with a rectal fissure and was started on mesalamine for a presumed diagnosis of inflammatory bowel disease. He was homosexual. On physical exam, he was thin built, normotensive & had periorbital puffiness. Groin area showed bilateral erythematous macular rash. There was no adenopathy & the rest of the physical examination was unremarkable. Pertinent admission laboratory data showed normal CBC, liver enzymes & lipid panel. Serum creatinine was 1.1mg/dl & serum albumin was 2.1g/dl. A 24 hour urine revealed 15 gms of protein. Serological workup was negative for hepatitis B, C, HIV, ANA, & Anti-dsDNA antibodies. C3, C4 were in normal range. Patient had a positive RPR and FTA-Ab. In his kidney biopsy, LM showed thickening of glomerular basement membranes with no other changes. IF showed a "full-house " pattern with granular staining in the capillary walls & mesangium for IgG, IgA, IgM, C3 and C1q. EM showed extensive foot process effacement & many small subepithelial electron dense deposits diagnostic of MN. Clinical criteria for SLE were otherwise absent. The final diagnosis was syphilis-related MN with similarities to class V lupus nephritis. The patient's nephrotic syndrome went into remission within 2 weeks of treatment with 3 doses of benzathine penicillin, supporting syphilis as a primary cause. Six months after treatment, the patient remains in remission.

**Conclusions:** The presence of a "full-house" IF pattern on renal biopsy, usually characteristic of lupus nephritis, did not preclude the diagnosis of syphilis-associated MN. Despite its rare occurrence, syphilis associated renal diseases should be considered in the differential diagnosis of "lupus-like nephritis" especially in high-risk patient groups.

## SA-PO647

**Hypereosinophilic Syndrome Associated with Membranous Nephropathy– Third Case in the Literature** Shiba Khorsandi,[1] Salvatore Chillemi,[1] Arshia Abbasi,[1] Nitin Behl,[1] Deepthi Karanam,[1] Reza Amerinasab,[1] Tatyana Gavrilova,[1] Michael Yudd,[1] Joshua Kaplan.[1] *[1]Nephrology, UMDNJ; [2]Nephrology, UMDNJ; [3]Nephrology, UMDNJ; [4]Nephrology, UMDNJ; [5]Nephrology, UMDNJ; [6]Nephrology, UMDNJ; [7]Nephrology, UMDNJ; [8]Nephrology, UMDNJ; [9]Nephrology, UMDNJ.*

**Background:** The Hypereosinophilic Syndrome (HES) is a group of disorders characterized by persistent eosinophilia without an identifiable cause, and usually with eosinophil-mediated end organ damage. Skin, gastrointestinal, heart, and lung involvement are common, renal manifestations are rare. We report a case of HES with Membranous Glomerulopathy.

**Methods:** A 63 year old white man presented with pruiritc diffuse erythematous dermatitis and eosinophilia with no identifiable cause. He had mild eosinophilia during the previous 10 years. Skin biopsy suggested psoriasiform dermatitis. Four months later he had explosive new-onset nephrotic range proteinuria (9 g/day) with serum creatinine 1.3mg/dl. Absolute eosinophils were 1400/ mm3 and peaked at 4300/mm3 over one year. Serum IgE was > 50,000 IU/ml. Studies including, ANA, anti-DNA, ANCA, serum/urine protein electrophoresis, complement, hepatitis B/C serologies, and HIV were negative or normal. Studies for parasites and malignancy were negative, and he was on no medications. Bone marrow showed increased eosinophils (30%) without abnormal myeloid maturation, increased blast population or a lymphoproliferative disorder (absence of FIP1L1-PDGFRA, JAK2-V617F, BCR-ABL and 4q12 mutations). Renal biopsy showed classic Membranous Nephropathy (MN). Tubulointerstitial nephritis with eosinophils was not present. Cyclosporine and steroids induced a full remission of nephrotic syndrome and resolution of erythema and eosinophilia.

**Conclusions:** This is the third case in the medical literature describing the association of membranous nephropathy with HES, in this case HES lymphocytic variant. The close temporal onset of both HES and MN, and their resolution with treatment suggest a close relation, not merely a coincidental association. Both HES and the nephrotic syndrome responded to cyclosporine and steroids. The etiologic link of the 2 syndromes is unknown.

*Funding:* Private Foundation Support

## SA-PO648

**IgG4-Related Tubulointerstitial Nephritis with Minimal Change Disease** Shiba Khorsandi,[1] Joshua Kaplan,[1] Michael Yudd,[1] Nitin Behl,[1] Arshia Abbasi,[1] Deepthi Karanam,[1] Salvatore Chillemi,[1] Reza Amerinasab.[1] *[1]Nephrology, UMDNJ; [2]Nephrology, UMDNJ; [3]Nephrology, UMDNJ; [4]Nephrology, UMDNJ.*

**Background:** Immunoglobulin G4 (IgG4)-related tubulointerstitial nephritis (TIN) is a newly recognized clinicopathologic entity. We report a rare case of IgG4-related TIN with minimal change disease in a patient who has Sjogren's disease.

**Methods:** A 44 year-old Indian woman presented with bilateral leg swelling. Past medical history included autoimmune hepatitis, in remission on prednisone 5 mg daily. Her blood pressure was 140/77 mm Hg, and the physical examination was unremarkable other than 2+ pitting edema in her lower extremities. She was found to have proteinuria (17.9 g/24h). Serum Cr was 2.7 mg/dl with baseline Cr level 0.8 mg/dL. Antinuclear

antibodies titer was > 1:640. Anti-SSA and SSB antibody were elevated, confirming the diagnosis of Sjogren's disease. Complement studies showed normal C4 and decreased C3. Anti-dsDNA,HIV, hepatitis B/C were undetectable. Serum IgG level was high. Urinalysis revealed 3+protein with no red or white blood cells. Renal biopsy showed extensive foot process effacement and dense interstitial plasma cell infiltrates. No immune complex mediated glomerular lesions are identified. Staining for IgG4 was positive in plasma cells. She received pulse methylprednisolone 1 gram for 3 days, then prednisone 60 mg daily, which was slowly tapered down to 10 mg daily over one year. Cr decreased to 0.9 mg/dL and proteinuria to 1.3 g/24h after 3 months. Serum IgG level dropped and clinical symptoms improved.

**Conclusions:** A less commonly cause of TIN is within the IgG4 related systemic diseases that have been observed in many organ systems. More recently, it has been described in the kidney and typically presents with a gradual decrease in kidney and minimal or no proteinuria. We describe a rare case presenting with significant proteinuria and decreased GFR, with a kidney biopsy showing IgG4-related TIN superimposed on minimal change disease. One hypothesis is that the proliferating plasma cells produce IgG4 that is auto reactive against podocyte antigens. The mainstay of treatment is glucocorticoids, and nephrologists need to be aware of this entity that responds well to steroid therapy.

## SA-PO649

**Kaposi's Sarcoma in a 78-Year-Old Female with Membranous Glomerulonephritis** Hanna Bartosik,[1] Magdalena Krajewska,[1] Agnieszka Halon,[2] Krzysztof Letachowicz,[1] Katarzyna Jakuszko,[1] Katarzyna Madziarska,[1] Waclaw Weyde,[1,3] Marian Klinger.[1] *[1]Dept of Nephrology and Transplanatation Medicine, Wroclaw Medical Univ, Poland; [2]Dept of Pathomorphology and Oncological Cytology, Wroclaw Medical Univ, Poland; [3]Faculty of Dentistry, Wroclaw Medical Univ, Poland.*

**Background:** Nephrotic syndrome occurs in elderly patients, mainly as a secondary manifestation of vasculitis or neoplasm. In nephrology Kaposi's sarcoma is usually connected with immunosuppressive treatment in transplant recipients.

**Methods:** A 78-year-old Caucasian HIV-negative female with the history of diabetes mellitus and atheromatosis was admitted to Nephrology Department due to severe nephrotic syndrome (total protein level 41 g/l, albumin level 14 g/l) which had occurred 2 months earlier. The patient was treated with ACE inhibitors and diuretics. ANA, ANCA vaculities were excluded. Anti PLA2R antibodies were negative twice. All performed diagnostic tests did not reveal possible cause of nephrotic syndrome. Kidney biopsy was performed showing membranous nephritis of mild expression (the first stage in histological classification). Due to severe course of the disease and acute kidney injury (creatinine level 4.1 mg/dl) intravenous steroids, diuretics together with albumin were introduced. ACE inhibitors were stopped and cyclosporine treatment was started. Due to deterioration of kidney function and no remission of nephrotic syndrome cyclosporine was substituted with a low-dose of tacrolimus (2 mg per day with blood level 4 ng/ml). After 2 weeks of treatment improvement was noticed. After next 2 weeks skin changes were found, mainly on the left lower limb. Biopsy was taken. The diagnosis was Kaposi's sarcoma. A dose of tacrolimus was reduced to 1.5 mg per day and everolimus treatment was started 10 days later (0.75 mg per day). After 3 weeks of the regimen regression of sarcoma is observed. Remission of nephrotic syndrome and mild renal function impairment (creatinine level 1.7 mg/dl) is still maintained.

**Conclusions:** There is still a question whether Kaposi's sarcoma is connected with immunosuppressive treatment or membranous glomerulopathy is the first sign of the disease?

## SA-PO650

**Lupus Nephritis with a False Positive Antiglomerular Basement Membrane Antibody** Ekamol Tantisattamo,[1] Satyanarayana Chekuri.[2] *[1]Renal Div, Emory Univ School of Medicine, Atlanta, GA; [2]Dept of Medicine, Univ of Hawaii John A. Burns School of Medicine, Honolulu, HI.*

**Background:** Antiglomerular basement membrane (anti-GBM) disease is a rare cause of rapidly progressive glomerulonephritis (RPGN). It can be diagnosed by renal pathology or positive serum anti-GBM antibody (Ab). However, false positive anti-GBM Ab may occur and lead to delay in diagnosis and treatment of other medical conditions. We report a case with acute kidney injury (AKI) and positive serum anti-GBM Ab, but renal biopsy showing lupus nephritis (LN) class V.

**Methods: Case Description:** A 33 year-old man with history of nephrotic range proteinuria of 5.7 g/day lost to follow up for 5 years. He presented with progressive painless scrotal swelling for 3 weeks. Physical exam showed marked inflamed scrotum consistent with cellulitis. His BP was 123/75 mmHg. He was found to have AKI with a serum creatinine (SCr) of 6.8 mg/dL. Baseline SCr was 2.1 mg/dL 7 months earlier. He refused renal biopsy. Laboratory workup revealed positive ANA and anticardiolipin antibodies. C3 was low at 66 mg/dL and C4 was normal. Anti-dsDNA and ANCA were negative. RPR was reactive and FTA-ABS confirmed syphilis. He was treated for presumed late latent syphilis. Urine exam showed hematuria and 24-hour urine protein was 31 g. Anti-GBM Ab returned positive; as a result, plasmapheresis and pulse methylprednisone were started. Renal function had not improved after 1 week of treatment, and intermittent hemodialysis was initiated due to hyperkalemia. He finally underwent a renal biopsy which confirmed LN class V. Plasmapheresis was discontinued, and he was treated for lupus nephritis with intravenous cyclophosphamide and oral prednisone. SCr improved to 2.5 mg/dL.

**Conclusions:** Being a useful diagnostic tool for anti-GBM disease, serum anti-GBM Ab could be false positive. This leads to therapeutic management with highly potential complications, and delays definite diagnosis if renal biopsy is not performed. Renal biopsy in patients with a positive serum anti-GBM Ab especially whose clinical presentations are not typical for anti-GBM disease is warranted to confirm the definite diagnosis and prompt an appropriate treatment.

## SA-PO651

**How to Interpret Repeat Renal Biopsies in Lupus Nephritis? Lessons from the Transplantation of a Donor Kidney with Lupus Nephritis** Michael McRae, Mathieu Rousseau-Gagnon, Isabelle Houde, Julie Riopel, David Philibert, Sacha A. De Serres. *CHUQ - Hotel-Dieu de Quebec, Univ Laval.*

**Background:** The relevance of repeat biopsy in patients with lupus nephritis (LN) is controversial. Recent recommendations from EULAR/ERA-EDTA state that it provides useful information, suggesting a 6-month biopsy as an important adjunct to treatment. From a pathological standpoint, little is known about the time needed to clear immune deposits and proliferation within the kidney after successful treatment.

**Methods:** We describe the histological evolution of a kidney from a donor with proliferative mesangial LN at the pre-implantation biopsy, transplanted to a recipient with ESRD due to vesico-ureteral reflux. This case provides an opportunity to assess the clearance of immune lesions over time in a kidney explanted from its lupus environment.

**Results:** The donor was a 50-year old male, with past medical history limited to high blood pressure. Urine sediment showed mild proteinuria, but no hematuria. At pre-implant biopsy (Bx) there was 4% glomerulosclerosis, moderate mesangial enlargement, and mild hypercellularity, tubular atrophy and interstitial fibrosis. Immunofluorescence (IF) revealed moderate to strong mesangial IgG, IgA, IgM, C1q and C3. Electron microscopy (EM) showed numerous mesangial immune complex deposits and a single tubuloreticular inclusion. The recipient was a 26-year old man who received induction with daclizumab and maintenance therapy with prednisone, mycophenolate mofetil and tacrolimus. A for-cause Bx at 1 month posttransplant showed light microscopy findings similar to pre-implant Bx, and a slight attenuation of all IF stainings. A protocol Bx at 8 months showed stable mesangial expansion, but persistent IgM, C3 and C1q staining. A for-cause Bx at 33 months displayed normal mesangium and completely negative IF. Nine years post transplant, the patient maintains a stable renal function.

**Conclusions:** This case suggests that the resolution of histological LN lesions is a slow process. Persistent lesions after 6 months of treatment may be seen without ongoing systemic immune injury. Caution is advised in the interpretation of early biopsies following initial therapy for LN.

## SA-PO652

**Risks of Steroid Therapy in Lupus Nephritis – 3 Cases of Central Serous Retinopathy** Raquel Vaz,[1] Maria Francisca Barros,[1] Ana Teresa Nunes,[1] Inês Castro Ferreira,[1] Ricardo Neto,[1] Edite M. Pereira,[2] Eva Borka Mariz,[3] Isabel Tavares.[1] *[1]Nephrology, CHSJ, Porto, Portugal; [2]Internal Medicine, CHSJ, Porto, Portugal; [3]Rheumatology, CHSJ, Porto, Portugal.*

**Background:** Steroids are highly effective but associated with important morbidity. Central serous retinopathy (CSR), resulting from fluid accumulation behind neurosensory retina, is a rare but reversible condition described during treatment with steroids. We report 3 cases.

**Methods:** Case1:A 27-year-old female presented in May 2012 with lupus nephritis(LN) class IV and thrombotic microangiopathy(TMA), treated with 3 pulses of methylprednisolone(MP) followed by oral prednisolone(PDN) 1mg/Kg/day, intravenous(IV) cyclophosphamide(CYC) and plasma exchange(PE). As no improvement was observed she was given rituximab.TMA eventually remitted but she developed bilateral CSR. PDN was tapered to 7.5mg/day and mycophenolate mofetil(MMF) added. Eye lesions resolved and she mantains renal and haematological remission. Case2:A 32-year-old female developed LN class IV+V in 2010 treated with IV CYC and PDN 1mg/Kg/day. CYC was later switched to MMF, by then on PDN 20mg/day. 7 months later CSR was diagnosed. PDN was reduced to 2.5mg/day. Her eye symptoms improved but lupus disease exacerbated. Tacrolimus was added to MMF and PDN withdrawn. 1year later she is in renal and extrarenal remission, without new eye lesions. Case3: A 46-year-old female was admitted in 2001 with LN class IV. She was treated with 3 pulses of MP followed by oral PDN(1mg/Kg/day) and IV CYC. In 2005 PDN dose was increased and azathioprine(AZA) initiated due to renal flare. In 2007 she had a new flare PDN was increased and AZA switched to MMF. She was kept on low-dose PDN and stopped MMF in 2012. In January 2013 she presented with a new flare. MMF was restarted and PDN dose increased(0.5mg/Kg/day). She developed CSR and PDN was reduced to 10mg/day. Eye lesions improved and she maintains renal remission.

**Conclusions:** Discontinuation or reduction of steroid dose is essential in approach CSR and differential diagnosis with inflammatory disorders or toxicity from other drugs is mandatory. CSR highlights the need for new and less toxic therapies for lupus, including steroid sparing strategies.

## SA-PO653

**Catastrophic Antiphospholipid Syndrome in a Small Child** Marissa J. Defreitas, Alcia D. Edwards- Richards, Vimal Master Sankar Raj, Jayanthi Chandar, Wacharee Seeherunvong, Asumthia S. Jeyapalan, Gaston E. Zilleruelo, Carolyn L. Abitbol, Chryso P. Katsoufis. *Pediatric Nephrology, Univ of Miami/Holtz Children's Hospital, Miami, FL.*

**Background:** Catastrophic antiphospholipid syndrome (CAPS) is rare but associated with high mortality. We report a child with CAPS and multi-organ system failure with hepatic thrombotic microangiopathy (TMA) and markedly elevated antiphospholipid antibodies (aPL). Multimodal therapy including plasma exchange and Rituximab led to a full recovery.

**Methods:** A healthy 5 year old female presented with fever and gastrointestinal symptoms. Acute kidney injury, liver failure, and hemolytic anemia were revealed. Acute respiratory distress syndrome necessitated mechanical ventilation. Continuous renal replacement therapy was initiated for oliguric renal failure. Serratia marcescens bacteremia and metapneumovirus pneumonia were noted. Therapeutic plasma exchange was initiated for thrombocytopenia associated multi-organ failure. After 3 sessions, her clinical status improved. Liver biopsy noted microthrombi in the portal vein. aPL were markedly elevated. A diagnosis of CAPS prompted methylprednisolone pulse therapy. Proteinuria and an elevated Cystatin C led to a renal biopsy which showed acute tubular necrosis without TMA. She was started on enoxaparin prophylaxis and angiotensin receptor blockade for hypertension and renoprotection. A cumulative dose of Rituximab 1.5g/m2 was given and aPL subsequently decreased.

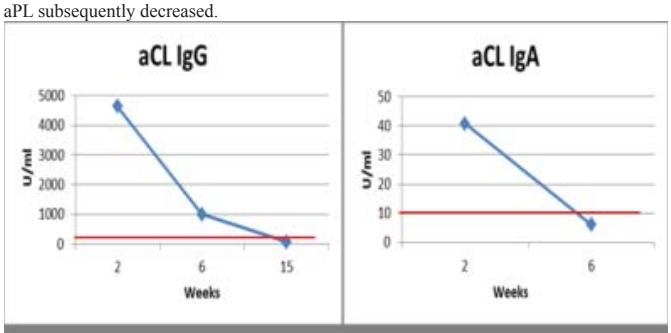


Figure1. Normal: Anticardiolipin (aCL) IgM , beta 2 glycoprotein (β2GP1) IgM, Lupus anticoagulant. Abnormal: β2GP1 IgG 150 to 127 SGU (normal <20). Red lines = normal values.

**Conclusions:** The patient showed complete recovery from CAPS with early initiation of multimodal therapy with plasma exchange, corticosteroids, Rituximab, and anticoagulation. The kidney biopsy did not show evidence of TMA despite the acute renal failure. This may reflect recovery of kidney injury after treatment or sampling error. Pediatric CAPS is uncommon, but a high index of suspicion allows for prompt diagnosis and treatment.

## SA-PO654

**A Case of a 62-Year-Old Male with IgG4-Related Disease Complicated by Systemic Lupus Erythematosus** Xiao-hu Shi, Xuemei Li, Mingxi Lee, Xuewang Lee. *Dept of Nephrology, Peking Union Medical College Hospital, Beijing, China.*

**Background:** IgG4 related Disease(IgG4-RD) was considered as an autoimmune disease which complicated by Autoimmune Pancreatitisa, Mikulicz's Disease. But it rarely involved SLE. We report a case of IgG4-RD complicated by SLE in a patient with chronic glomerulonephritis and progressive renal failure.

**Methods:** 62 y/o Asian male with a history of intermittent fever, hyperglobulinemia and increased Scr(0.78 to 4.24mg/dL) for 2yrs without any effect by kinds of antibiotics. On admission, Scr kept increasing(3.88 to 5.52mg/dL) in 2ws. PE revealed mild edema and Generalized Lymphadenopathy. Lab work revealed: globulin 70g/L while albumin 38g/L, and moderate proteinuria(1.9 to 2.98g/24h,UV 2 to 2.5L). Serumproteinelectrophoresis showedγ-globulin 43.4%. IgG subtype was fond extraordinary abnormal that: $IgG_1$ 20600mg/L(<11400),$IgG_2$ 5020mg/L(<6400),$IgG_3$ 2330mg/L(<1100), $IgG_4$ 39400mg/L(<1400). Immunologic test showed: $C_3$ 0.034g/L. ANA: 1:1280(homogeneous type), dsDNA: 1:40(ELISA),445IU/mL(IgG). Coombs' test was positive. But anti-GBM, ANCA, aSSA , aSSB, ACL, $\beta_2$GP1 and lupus anticoagulant were negative. USG & CT showed largish kidneys(12.8 and 13.1cm) and lymphadenectasis in mediastinum and peritoneal cavity without ureteralobstruction. BMB analysis showed no abnormal cell population. Renal biopsy showed: Glomerular proliferation in mesangial cells & matrix, severe plasma cell-rich interstitial inflammation(improved by immunohistochemistry test) and severe tubulointerstitial fibrosis which showed typically "storm form". IF was negative. Diagnosis of IgG4 related TIN and SLE(ACR 2009) were both confirmed. With a initial dose of 50mg/d prednisone and 100mg CTX. SCr was improved to 1.6mg/dL, IgG4 to 1224 mg/L, C3 to 1.2g/L, dsDNA to negative. In 7Ms follow-up, Prednisone gradually reduced to 15mg and CTX was stopped when accumulation reached to 12g.

**Conclusions:** IgG4-RD was more and more valued by clinician and was reported to associate with AIP, MD and WG, but rare case on IgG4-RD with SLE. Our patient developed IgG4-RD complicated by SLE suggesting that the pathogenesis and progress of this disease deserved further research.

## SA-PO655

**Diffuse Infiltrative Leukocytosis Syndrome, Immunotactoid Glomerulopathy, and HIV-Associated Nephropathy, in a Patient with Acute Kidney Injury: Case Report and Review of the Literature** Dinesh Kannabhiran, Saif A. Muhsin, Jeffrey I. Silberzweig, Surya V. Seshan. *NewYork-Presbyterian Hospital/Weill Cornell Medical Center, New York, NY.*

**Background:** Patients with HIV infection may suffer from a variety of renal diseases: functional disorders, HIV-associated nephropathy (HIVAN), lesions secondary to other infections, immune mediated diseases and drug-related disorders. We describe a case of acute kidney injury (AKI) with nephrotic range proteinuria in a patient with HIV infection, whose biopsy showed diffuse infiltrative lymphocytosis syndrome (DILS) and immunotactoid glomerulopathy (ITG) in addition to HIVAN.

**Methods:** A 51-year-old HIV infected woman presented with a 1 week history of lower limb swelling and Sicca symptoms. She stopped highly active anti-retroviral therapy (HAART) a year prior. Examination showed cervical lymphadenopathy, tonsillar enlargement, and lower limb pitting edema. Investigations revealed an elevated creatinine (2.0 mg/dL), and low albumin (1.1 mg/dL). Urinalysis showed 11 white and 41 red blood cells per high power field, a protein-creatinine ratio of 8.5 and no casts. The CD4 count was low ($287 \times 10^6$ cells/L) and the CD8 count was high ($1834 \times 10^6$ cells/L). C3 was markedly reduced. Testing was negative for Hepatitis C & B viruses, cryoglobulins, antinuclear antibodies, and rheumatoid factor. Protein electrophoresis was normal. Ultrasonography showed large kidneys. A kidney biopsy revealed findings suggestive of HIVAN in addition to ITG. There was diffuse CD8 lymphocyte interstitial inflammation suggestive of DILS. HAART was restarted. Serum creatinine was 1.38 before discharge. She received outpatient pulse steroids.

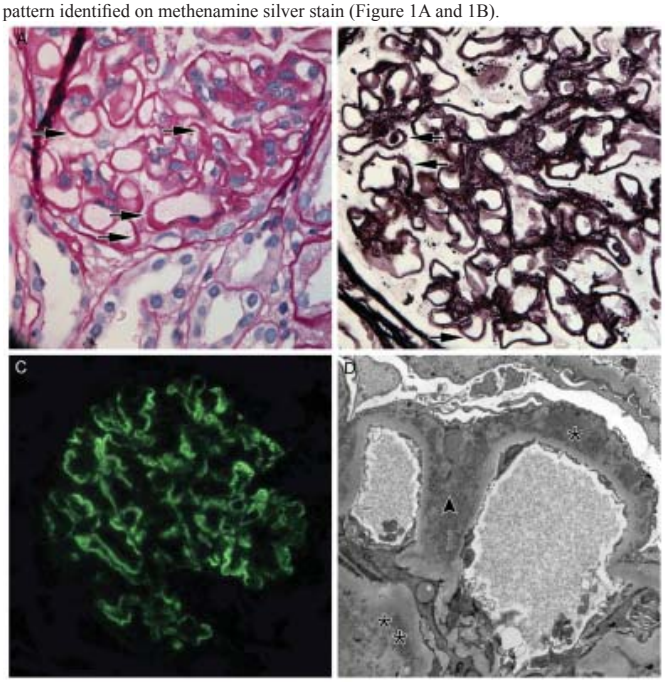
**Conclusions:** There have been few cases described in the literature of HIVAN in association with ITG, half of which were associated with viral hepatitis. We report the 4th case of HIVAN and ITG with negative viral serology leading us to question whether ITG could be triggered by factors related to HIV. To our knowledge, this is the first case describing the clinical presentation and kidney biopsy evidence of HIVAN, DILS, and ITG. Our case demonstrates the importance of renal biopsy for HIV infected individuals presenting with AKI.

## SA-PO656

**Atypical IgA Nephropathy with Membranous Features in a Patient with HIV** Sarah E. Panzer,[1] Shalini Tayal,[2] Jessica B. Kendrick.[1,2] *[1]Univ of Colorado Denver; [2]Denver Health Medical Center.*

**Background:** IgA nephropathy can exhibit a broad degree of plasticity in the clinical presentation, pathologic manifestations, and disease progression. The defining histologic lesion in IgA nephropathy is mesangial deposition of IgA; however, the findings on light microscopy can be quite variable. In this case report we describe an unusual histologic finding of a severe form of IgA nephropathy with membranous features in a patient with HIV.

**Methods:** A 63 year-old Caucasian male with HIV and new-onset hypertension was referred to the renal clinic for evaluation of nephrotic range proteinuria and intermittent gross hematuria. Renal biopsy demonstrated mesangial hypercellularity and expansion with diffuse global thickening of the glomerular basement membrane and a 'spike and dome' pattern identified on methenamine silver stain (Figure 1A and 1B).



Immunofluorescent staining showed strong IgA deposition in the glomerular basement membrane and mesangium (Figure 1C). Electron microscopy demonstrated numerous mesangial, intramembranous, and subepithelial electron dense immune-complex deposits with intervening membrane spikes between subepithelial deposits (Figure 1D). The patient was initially managed with angiotensin converting enzyme inhibitor therapy. However, renal insufficiency developed and the degree of proteinuria remained in the nephrotic range. Thus, the patient was treated with a six month course of alternating cyclophosphamide and prednisone and had a partial response to treatment.

**Conclusions:** Our case represents an atypical form of IgA nephropathy presenting with a membranous pattern histologically. Data regarding this form of IgA nephropathy is scarce and it is unclear whether the presence of histologic features of membranous incurs a worse prognosis. To our knowledge this is the first reported case of this constellation of histologic findings in a patient with HIV.

## SA-PO657

**Idiopathic Hypocomplementemic Immune Complex-Mediated Tubulointerstitial Nephritis: An Unattended Differential Diagnosis for Sub-Acute Renal Insufficiency in Elderly Patients** Fahima Nasreen,[1] Ana Paula Rossi,[1] Douglas M. Dressel,[2] James C. Wasserman.[1] *[1]Nephrology, Maine Medical Center, Portland, ME; [2]Pathology, Maine Medical Center, Portland, ME.*

**Background:** Immune complex (IC) deposits in renal tubular basement membrane (TBM) are commonly encountered with glomerular diseases. In Sjögren's syndrome, however, tubulointerstitial (TI) IC deposit occurs without significant glomerular involvement. We describe a case of idiopathic IC TI nephritis with distinct serologic, light microscopic (LM) and immunofluorescence (IF) findings, and response to steroid therapy.

**Methods:** A 74-year-old male with no prior history of kidney disease presented with fatigue, anorexia, weight loss of 40 lb over 9 months, and chronic sinus congestion for years. Physical examination was unremarkable and renal ultrasound was normal. Serum creatinine (SCr) level was 2.1 mg/dl, increase from a baseline of 1.0 mg/dl 6 months prior. The patient had mild proteinuria with no cellular or granular casts. Spot urine protein to creatinine ratio (UPCR) was 0.4 g/g. Immunological tests showed low complement (C3 77mg/dl, C4 < 3mg/dl), normal IgG, normal serum protein electrophoresis, negative ANA and ANCA. LM showed 49% globally sclerosed glomeruli with extensive tubular atrophy, diffuse interstitial infiltrate with reactive lymphoid cells and interstitial fibrosis. IF exposed granular deposits of IgG, C3, C1Q, and kappa and lambda light chains in the interstitium and TBM. The patient was started on prednisone 1mg/kg/d with excellent response. Clinical improvement was associated with improved renal function, which has been stable at 2 years post-diagnosis (SCr 1.1 mg/dl; spot UPCR 0.1g/g).

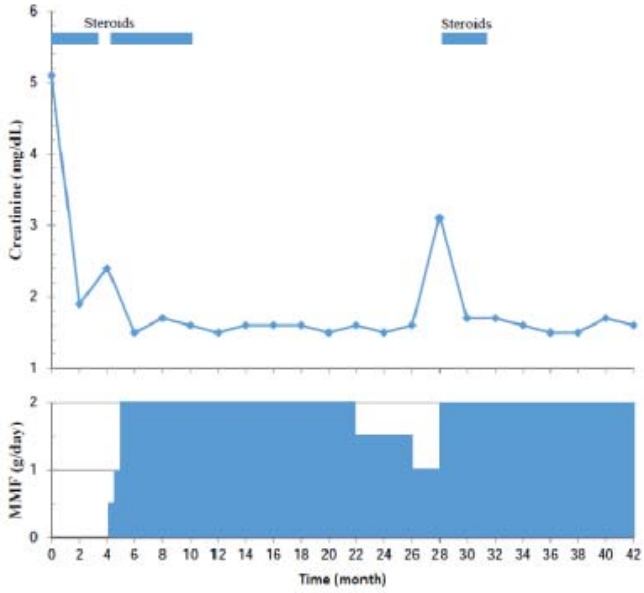
**Conclusions:** IC- mediated TI nephritis is a relatively new and rare entity with clinical features that may include sinusitis, anorexia, weight loss, and renal insufficiency. TI IC deposition and interstitial plasma cell infiltrates appear to be involved in local IC formation. Idiopathic IC mediated TI nephritis may occur in elderly patients presenting with acute or sub- acute kidney injury and, therefore, should be considered in the differential diagnosis of elderly patients presenting with renal insufficiency.

## SA-PO658

**Idiopathic Granulomatous Interstitial Nephritis Responding to Mycophenolate Mofetil Therapy** Napat Leeaphorn, Patompong Ungprasert, William W. LeCates. *Internal Medicine, Bassett Medical Center, Cooperstown, NY.*

**Background:** Granulomatous interstitial nephritis (GIN) is a rare histologic disease. Many etiologies have been reported such as sarcoidosis, drugs, and infections. Idiopathic GIN is diagnosed by exclusion. GIN generally responds well to steroids, but there is limited data with therapy other than corticosteroids.

**Methods:** A 68-year-old Caucasian man presented with fever. He was found to have acute renal failure (SCr of 3.7mg/dl, normal 4 months earlier) with bland urine sediment. Renal biopsy showed granulomas consistent with GIN. Oral methylprednisolone was initiated with good response, SCr~1.9 mg/dL. However, he developed hyperglycemia from steroids, and had a relapse after discontinuation of steroids. Therefore, MMF was chosen as a maintenance agent. We followed the patient for 3.5 years, and the patient has been in remission with MMF monotherapy with only one episode of relapse after an attempt to taper the dose of MMF.



**Conclusions:** The possible causes of GIN in this patient included drug-induced, sarcoidosis, tuberculosis and idiopathic. The patient was taking several medications that could potentially cause GIN. However, the need for long term MMF treatment with an inability to discontinue MMF after a long period of follow-up makes drug-induced GIN unlikely. The patient had never had any findings indicative of systemic sarcoidosis. Calcium, 1,25(OH)2 D, and ACE levels were normal. Tuberculosis was excluded by negative histologic stain and negative QuantiFERON-TB Gold. Since no obvious cause could be identified in our case, the diagnosis of idiopathic GIN was made. To the best of our knowledge, this is the first report of successful treatment with MMF of an adult patient with idiopathic GIN. This case supports the use of MMF as a potential alternative therapy for GIN.

## SA-PO659

**Leiomyosarcoma Associated with Nephrotic Syndrome** Ibrahim Qaqish,[1] Maxwell L. Smith,[2] Leslie F. Thomas.[3] *[1]Nephrology Fellowship, Mayo Clinic Arizona, Phoenix, AZ; [2]Div of Laboratory Medicine & Pathology, Mayo Clinic Arizona, Phoenix, AZ; [3]Div of Nephrology & Hypertension, Mayo Clinic Arizona, Phoenix, AZ.*

**Background:** The association of solid tumors with minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS) is uncommon. Renal cell carcinoma, colorectal carcinoma, lung and bronchus carcinoma, and thymoma account for the majority of reported cancers associated with MCD. Solid tumors associated with FSGS are rare with renal cell carcinoma and thymoma being the most commonly reported. Here we present the first reported case of leiomyosarcoma associated with MCD.

**Methods:** A previously healthy 46 year-old woman developed the nephrotic syndrome. The initial urine protein:creatinine (UPC) was 4.92. Renal biopsy demonstrated normal glomeruli by light microscopy and diffuse podocyte foot process effacement on electron microscopy. No secondary cause was identified. A retroperitonal ultrasound was normal, and additional imaging was not performed. After two months of prednisone therapy, the patient's proteinuria was significantly reduced (UPC 0.62). However, after three months of prednisone therapy, the patient's proteinuria began to worsen (UPC 1.64). Cyclosporine and mycophenolate mofetil were added, and triple immunosuppressive therapy was continued for an additional three months with improvement in proteinuria (UPC 0.15). Six months after her diagnosis of nephrotic syndrome, the patient developed lower back pain. Computed tomography revealed large masses located in her liver, skeleton, and lung. Biopsy showed a high-grade pleomorphic sarcoma consistent with metastatic leiomyosarcoma. Immunosuppressives were held, and chemotherapy with gemcitabine and docetaxel was initiated. A decrease and stabilization of tumor burden was observed. Nine months after the initiation of chemotherapy, the patient continues to demonstrate stable tumor burden and a complete remission of the nephrotic syndrome.

**Conclusions:** Leiomyosarcoma may lead to MCD and the nephrotic syndrome. Reduction in tumor burden achieved via targeted chemotherapeutic agents may result in a complete and sustained remission of MCD associated with leiomyosarcoma.

## SA-PO660

**Granulomatous Interstitial Nephritis: A Potential Precursor to Pauci-Immune Small Vessel Vasculitis** Liliana E. Rios Rojas,[2] Vladimir Liberman,[1] Ingrid Calliste,[2] James Drakakis,[2] Joseph Mattana,[2] Nobuyuki (Bill) Miyawaki.[2] *[1]Internal Medicine, Winthrop Univ Hospital, Mineola, NY; [2]Internal Medicine, Div of Nephrology, Winthrop Univ Hospital, Mineola, NY.*

**Background:** Granulomatous interstitial nephritis (GIN) is a rare entity with a poor outcome. Little is known about the etiology, nor whether it may be a precursor to other renal pathologies. We present a case of GIN in which a repeat kidney biopsy revealed a substantially different diagnosis with important therapeutic implications.

**Methods:** A 57 year old woman with malaise and fever, without infection, was admitted with acute kidney failure with a serum creatinine (SCr) of 4.4mg/dL, hematuria and proteinuria. Pulse steroid and plasmapheresis were initiated for suspected rapidly progressive glomerulonephritis. Kidney biopsy revealed GIN. Mycobacterium, fungi, paraproteinemias, and ANCA tested negative. No evidence of tenosynovitis-interstitial nephritis-uveitis syndrome or sarcoidosis existed. Her GIN was attributed to ciprofloxacin or esomeprazole and maintained on prednisone. SCr improved to 3.2mg/dL at the time of hospital discharge and reached a nadir of 2.3mg/dL three months later. Prednisone was tapered off but in the next two months her SCr rose to 3.7mg/dL. Prednisone was resumed but the SCr increased further to 4.8mg/dL in a month. A repeat kidney biopsy was performed and instead of GIN, this biopsy revealed a pauci-immune small vessel vasculitis (ANCA testing was again negative). She received methylprednisolone and rituximab, then was maintained on prednisone and azathioprine. Her renal function steadily improved with a decline in creatinine to 3.0mg/dL within three months.

**Conclusions:** GIN is a poorly understood, rare entity associated with a poor outcome despite steroid treatment. This case suggests the possibility that some instances GIN may be a precursor to the development of pauci-immune small vessel vasculitis; hence treatment failure or a rising SCr after an initial favorable response to steroids might be an indication for re-biopsy. The possibility of missed or developing pauci-immune small vessel vasculitis may explain, in part, the poor overall outcome of GIN with steroid treatment.

## SA-PO661

**Minimization** Claire T. Kassakian, George P. Bayliss. *Dept of Medicine, Rhode Island Hospital, Providence, RI.*

**Background:** We present the case of a 48 yr old man with HIV and Kaposi's sarcoma who developed steroid responsive Minimal Change Disease, but who suffered a relapse of Kaposi's prompting an accelerated steroid taper regimen.

**Methods:** The patient is a 48 yr old man with a history of HIV for 10 yrs compliant with anti-retroviral therapy on Atripla and Kaposi's Sarcoma initially referred to renal clinic for a rising creatinine, proteinuria, and weight gain. In clinic, he was found to be hypertensive and 40 pounds above his baseline weight with periorbital edema and anasarca. Lab data was notable for a Creatinine of 1.97mg/dl from a normal baseline, 10.2g of protein on 24 hour urine collection, Albumin of 2.0, CD4 count 321 and viral load of 55. Urine sediment showed lipid laden renal tubular epithelial cells and occasional lipid droplets in casts. He was admitted to the hospital for emergent renal biopsy illustrating ischemic ATN in addition to a podocytopathy most consistent with Minimal Change Disease with subclinical IgA deposition. Tenofovir was held. His Creatinine continued to rise, peaking at 7.2 at which time he received IV pulse dose steroids before continuing oral Prednisone 80mg daily. Over three weeks, his Creatinine and proteinuria fell to 1.8 and 918mg respectively. While his proteinuria continued to decline with the lowest microalbumin to creatinine ratio of 151 mg/mg, he noted cutaneous lesions consistent with prior relapses of Kaposi's in addition to hyperlipidemia and glucose intolerance. Therapy with liposomal Daunorubicin was initiated with good initial response. After 6 weeks, his Prednisone dose was tapered over four weeks to 10mg daily. Despite the rapid taper, weekly microalbumin to creatinine ratios remained relatively between 151 to 361.

**Conclusions:** Treatment of Minimal Change Disease is not infrequently complicated by adverse complications of high dose steroid therapy including hyperlipidemia and glucose intolerance. We present a case of a patient with a history of HIV on antiretroviral therapy and Kaposi's sarcoma in remission whose treatment was complicated by recurrence of Kaposi's sarcoma prompting a rapid taper of his oral Prednisone in addition to chemotherapy with liposomal Daunorubicin.

## SA-PO662

**Primary Sjogren Syndrome with Minimal Change Disease** Xiaoxiao Shi,[1] Zhou Zhang,[1,2] Yubing Wen,[1] Hang Li,[1] Xuemei Li,[1] Xuewang Lee,[1] Limeng Chen.[1] *[1]Nephrology, Chinese Academy of Medical Sciences & Peking Union Medical College Hospital, Beijing, China; [2]No.4 Dept of Internal Medicine, Guizhou Hospital, Foshan City, China.*

**Background:** Glomerular involvement in primary Sjogren Syndrome (pSS), especially minimal change disease (MCD), has rarely been reported. We report four cases of pSS with MCD.

**Methods:** Four cases of MCD confirmed by renal biopsy in pSS patients were enrolled as pSS-MCD group. Ten pSS patients with membranous nephropathy (MN) of the same period were enrolled as control group (pSS-MN group). Medical records were summarized and compared.

**Results:** The four pSS-MCD patients were mainly middle-aged females (37-61y; female: male= 3:1). They were diagnosed as pSS by dry mouth, dry eyes, positive anti-SSA, anti-SSB antibodies, and labial gland biopsy. They all clinically presented as nephrotic syndrome, with severe proteinuria (3.70-19.02g/d) and remarkable hypoalbuminemia (12-19g/L). They also showed mild microscopic hematuria and leukocyturia but normal blood pressure. Only one female, who had the most severe proteinuria (19.02g/24h), showed renal function impairment (Scr 200μmol/L). None of them showed renal tubular acidosis. Compared with pSS-MN group, pSS-MCD patients had more severe hypoalbuminemia (15.0g/L vs. 26.5g/L, P=0.009), but no significant differences were shown in other clinical characteristics. In renal biopsy, they all showed typical glomerular lesions of MCD and focal distribution of tubulo-interstitial injury, which presented as thickened TBM, tubular atrophy, mild interstitial fibrosis and interstitial infiltration of mononuclear inflammatory cells. Besides the injuries of kidney and exocrine glands, the two cases with hypokalemia (3.0 and 3.2mmol/L) also showed hematologically involvement with decreased white blood cell count of $3.32 \times 10^9$/L and $3.36 \times 10^9$/L. Steroid (1mg/kg/d) was given to all patients and great improvement of proteinuria was observed.

**Conclusions:** We report the 4 cases of pSS with MCD with typical nephrotic syndrome, severe hypoalbuminemia and good response to steroid.

## SA-PO663

**Periodic Fever, Aphthous Stomatitis, Pharyngitis, and Adenitis (PFAPA) Syndrome and IgA Nephropathy** Keisuke Sugimoto, Hitomi Nishi, Tomoki Miyazawa, Mitsuru Okada, Tsukasa Takemura. *Pediatrics, Kinki Univ School of Medicine, Osakasayama, Osaka, Japan.*

**Background:** Periodic fever, aphthous stomatitis, pharyngitis, and adenitis syndrome (PFAPA) is a auto-inflammatory disease. Periodic abnormalities involving the mechanism regulating cytokine secretion have been suggested, the levels of IL-6, IFN-γ, and IL-1β increase markedly during episodes of fever. A recent study has demonstrated an involvement of the CX3CR1-fractalkine axis in the exacerbation of gross hematuria in IgAN. Fractalkine is enhanced by exposure to IL-1 and IFN-γ in mesangial cells. Immune complexes deposition in the glomeruli could promote both systemic and local secretion of various inflammatory cytokines and cell-proliferative hormones. Here, we present a child case with PFAPA and concurrent IgAN, not reported previously. This patient is of interest in terms of the pathogenic mechanisms underlying the two diseases, since a disoriented immune response and fractalkine has been suspected in both diseases.

**Methods:** A 10-year-old boy presented with periodic fever, exudative tonsillitis, oral aphthous ulcer, and cervical lymph node inflammation. These conditions had occurred at intervals of about 2-6 weeks since the age of 3 years. Microscopic hematuria, first detected at age 8 years, worsened during episodes of PFAPA-related fever; since 10 years of age, the hematuria was accompanied by sustained proteinuria. Histological evaluation of a renal biopsy specimen was IgAN. In the kidney specimen, fractalkine immunoreactivity and heavy macrophage infiltration were prominent. Multi-drug cocktail therapy improved the urinalysis findings, and subsequent tonsillectomy succeeded in controlling recurrences of PFAPA and IgAN. In a post-treatment, mesangial proliferation was decreased, and fractalkine immunoreactivity was absent.

**Conclusions:** Immunologic reactions against certain antigens in local mucosa, including tonsils, may be impaired in PFAPA and IgAN, as evidenced by the suppression of both diseases in our patient by tonsillectomy. Accordingly, the concurrence of PFAPA and IgAN in our patient appeared to be a consequence of shared autoimmune mechanisms and systemic and local increases in cytokine concentrations.

## SA-PO664

**ANCA Vasculitis and Renal Failure Associated with Cocaine Abuse – A Case Report** Wonngarm Kittanamongkolchai,[1] Robert M. Perkins.[2] *[1]Internal Medicine, Bassett Medical Center, Cooperstown, NY; [2]Div of Nephrology, Bassett Medical Center, Cooperstown, NY.*

**Background:** ANCA vasculitis is usually idiopathic. We report a rare case of possible levamisole induced ANCA vasculitis presenting with pulmonary hemorrhage and renal failure.

**Methods:** A 46 year-old female presented with fever, a 40-pound weight loss, and hemoptysis. She required mechanical ventilation for diffuse alveolar hemorrhage. Physical exam revealed palpable purpura and digital ischemic lesions. Blood evaluation showed neutropenia, serum creatinine of 4.1 mg/dL, negative ANA, anti-dsDNA > 45 IU/mL, anti-MPO > 8 U/mL, anti-PR3 >8 U/mL, and hypocomplementemia. Urine microscopy demonstrated dysmorphic red blood cells. Urine PCR was 3.68 g/g. A drug screen was positive for cocaine. Skin biopsy demonstrated leukocytoclastic vasculitis. Kidney biopsy showed focal segmental necrotizing and crescentic glomerulonephritis, pauci-immune type, with background segmental membranous glomerulopathy. She was treated with plasmapheresis, pulse steroids, and IV cyclophosphamide. She achieved remission and was transitioned to maintenance immunosuppression. Her subsequent course has been marked by persistent, downtrending, low-level anti-MPO and PR3 titers and no clinical relapse over a two-year period.

**Conclusions:** This case illustrates many features of drug-induced ANCA-vasculitis, including multiple autoantibody positivity and the histologic combination of membranous and necrotizing crescentic glomerrulonephritis. Levamisole, a common cocaine adulterant, has been reported as a cause of ANCA-associated vasculitis. Pathognomonic manifestations are dermatologic infarction, neutropenia, and dual MPO- and PR3-positivity, as in this patient. Pulmonary hemorrhage and renal involvement is rare in levamisole-induced vasculitis and would be challenging to distinguish from idiopathic ANCA vasculitis. Nephrologists should be aware of the consequences of the growing use of cocaine adulterated with levamisole in order to recognize characteristics of this reversible cause of glomerulonephritis.

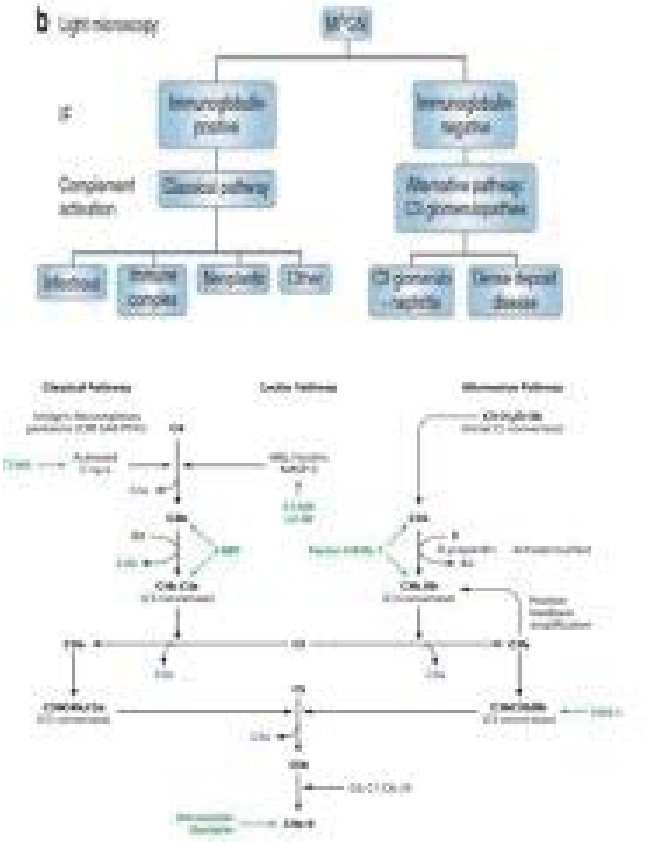
## SA-PO665

**C3 Glomerulopathy in a Young African American Adult** Julio C. Chirinos, Devasmita Choudhury. *Nephrology, UT Southwestern Medical Center, Dallas, TX.*

**Background:** Membranoprolipherative Glomerulonephritis (MPGN) is a pattern of glomerular injury recognized easily by light microscopy. Electron microscopy allows sub grouping in MPGN types I, II and III by localizing the area in which the electron dense deposits, and immunofluorescence detects immunoglobulin in MPGN type I and III, but not in type II. All 3 forms stain positive for C3. This sub grouping led to confusion, because of the presence of immunoglobulin negative MPGN I and III. This entities along with Type II MPGN are now under the subgroup of C3 glomerulopathy (C3G).

**Methods:** 35 year old man with PMHx of HTN diagnosed 3 years ago, on amlodipine only, referred referred by PCP for hyperkalemia and worsening renal function. Patient had no complaints at all, just that the last 1-2 months has been feeling more tiered than normal but was because has been exercising more for intentional weight loss. Reports he makes normal amounts of urine, but foamy for the last few months. **PE:** BP: 180/91 HR: 81; No distress. S1S2 normal. Lungs Clear, No LE edema. Labs: BMP: K 6 ; CO2: 19 scr: 59/4.42 (last Scr 1.4 in 2011); Hb 10. UA: No RBCs, no WBCs, P/C: 5 grams. Renal US: Bilateral echogenic kidneys (11 and 12 cm). Serology: Negative. SPEP, UPEP: negative. **Renal Biopsy:** Mesangiocapillary proliferation, consistent with MP type I. Diffuse interstitial fibrosis. **IF: C3 ++ no Ig. EM:** Effacement of visceral epithelial cell foot processes. Multiple mesangial proliferation.

**Conclusions:** This case give us the example of why a new classification for MPGN was needed.



This classification allows differences in therapy, since pathophysiology is also different. In types I and III therapy is focused in underlying disease triggering and driving the chronic antigenemia. The focus in C3G in contrast should focus on the dysrregulation of the alternative pathway.

**SA-PO666**

**Membranoproliferative Glomerulonephritis Type II with C3b-Autoantibodies – Potential Value of Immunoadsorption** Christina Taylan,[1] Peter F. Zipfel,[2] Rasmus J.C. Ehren,[1] Gesa Schalk,[1] Lutz Thorsten Weber.[1] *[1]Pediatric Nephrology, Univ Hospital of Cologne, Cologne, Germany; [2]Leibniz Institute for Natural Product Research and Infection Biology, Jena, Germany.*

**Background:** In Membranoproliferative Glomerulonephritis Type II (MPGN II) 50% - 80% of patients have autoantibodies (AAB) as complement activating agent.

**Methods:** We report a 7-year-old caucasian girl who was treated in January 2013 for the first episode of acute renal failure after viral upper airway infection. Renal biopsy revealed MPGN II. Additional findings like ANA, ANCA, GBM antibodies and ds-DNA-antibodies remained normal. Genetic analysis showed no mutation. Factor H (FH) Protein and the CFHR1 Protein with its two isoforms were unsuspectable. Functional complement showed low levels of C3 (0,08g/l min-0,8gl max) and an increase of SC5b-9 of 936 (<320) ng/ml. No autoantibodies to FH or C3Nef were found. Plasmapheresis was started after biopsy. Due to recurrent plasma intolerance and a high SC5b-9 therapy with eculizumab was indicated. Consistent with dysregulation of C3 convertase an autoantibody against this protein was found. Eculizumab was stopped after 10 doses. 3 months after diagnosis the child was set on Immunoabsorption (IA). To prevent new AAB development we started a medication with Mycophenolat mofetil 1200 mg/qm BSA/d. Under plasmapheresis renal function remained impaired though plasma C3 levels increased. With the beginning of Eculizumab plasma creatinine levels decreased and diuresis recured, but the child remained dialysis dependent. With the beginning of IA once a week proteinuria (from 6,4g/l to 0,35g/l) and plasma creatinine levels (from 7,26mg/dl to 1,80mg/dl) markedly decreased and diuresis normalized. Dialysis was stopped.

**Conclusions:** In AAB mediated cases of MPGN II IA may be the therapy of choice. However, it might be challenging to identify the individual dose and frequency of IA to preserve renal function and to control proteinuria. So far it remains open, if monitoring of antibody levels could be a helpful tool. In our patient antibody levels dropped from 870 AU to 303 AU after 4 weeks of treatment.

**SA-PO667**

**Retinal Cotton Wool Spots and Renal Impairment Associated with Interferon Beta 1 Alpha Therapy for Multiple Sclerosis** Eleni Chelioti,[1] Evangelia Gkalitsiou,[1] Evdokia Efthimiou,[1] Maria Sotiraki,[1] Spyridon Fradelos,[2] Alexia Papalexandrou,[1] Maria Tsilivigou,[1] Gabriel Papadakis.[1] *[1]Dept of Nephrologr, General Hospital of Piraeus, Greece; [2]Dept of Ophthalmology, General Hospital of Piraeous, Greece.*

**Background:** Interferon is now the mainstay of maintenance therapy for multiple sclerosis (MS). Retinopathy is a well-known adverse effect of interferon-alpha in patients treated for hepatitis C. On the other hand, retinal lesions are rarely related with subcutaneous interferon beta 1 alpha (IFNβ1α) in MS.IFNβ1α nephrotoxicity is also an extremely rare side effect. We report a case of IFN-associated retinopathy and nephropathy in a patient with MS receiving subcutaneous INFβ1α.

**Methods:** A 42-years old female with a history of MS was on treatment with IFNβ1α(44μg/3times a week)for 10 years. She presented with anemia, thrombocytopenia, albuminouria, mild elevation of liver enzymes and renal impairment. She displayed sudden hypertension without visual disorders. Ocular fundus exam showed several retinal cotton wool spots indicating IFN-retinopathy and interferon was discontinued. Subsequent imaging exploration revealed normal sized kidneys. Further biochemical and immunological analyses were negative for autoimmune renal diseases. The retinopathy disappeared without specific therapy 2 months after discontinuing IFNβ1α and kidney function reached normal levels. IFNβ1α resumed 16 weeks after stopping treatment due to MS relapse. On an iterative fundus exam 3 months after resumption of IFNβ1α, no further cotton wool spots have recurred.

**Conclusions:** Our case supports that both complications resolved after drug cessation and the diagnosis of IFNβ1α retinopathy and nephropathy was retained due to the lack of any other etiology. There are only eight reports on MS related interferon-β retinopathy. Likewise there is only one case of IFNβ1α associated retinopathy and nephropathy. To our knowledge this represents the second case of IFNβ1α associated cotton wool spots and renal impairment and the first in the English-language ophthalmic literature. Given this limited number of cases no safe conclusions regarding causality, screening, dose related issues, severityand treatment options can be made.

**SA-PO668**

**The Transplant Triumphs – Rapid Reversal of Nephrotic Range Proteinuria of Native Kidney Origin after Live Donor Kidney Transplant** Dhananjay P. Kulkarni, Ismail M. Qattash. *Internal Medicine/ Nephrology, The Univ of Illinois at Urbana- Champaign, Urbana, IL.*

**Background:** Proteinuria after renal transplantation increases both risk for graft failure and risk for death. In this case report we describe a finding of reversal of nephrotic range proteinuria after renal transplantation.

**Methods:** A 62 y/o Caucasian female with uncontrolled diabetes mellitus type 2, severe hypertension, coronary artery disease status post bypass grafting was referred to our clinic for abnormal renal function and proteinuria. Chronic kidney disease stage IV (GFR 16 ML/MIN/1.73 M^2) with nephrotic range proteinuria and high urinary protein-creatinine ratio was noted. Patient had findings consistent with diabetic process including ophthalmopathy and neuropathy. She continued to have heavy proteinuria and had a hospital visit for severe nausea and vomiting. Creatinine peaked at 3.4 and urea was 66. She was started on hemodialysis and her symptoms resolved. After 3 months patient underwent a living donor kidney donated by her son, with native kidneys in situ. Patient was on immunosuppressant therapy with mycophenolic acid and tacrolimus. TMP/SMX and valganciclovir were also continued for prophylaxis as per transplant nephrology service. Subsequent labs showed her creatinine return to normal and a complete resolution of proteinuria in 3.5 weeks from transplant. On follow-up at 2 years, patient remained free of any proteinuria and had normal renal function parameters.

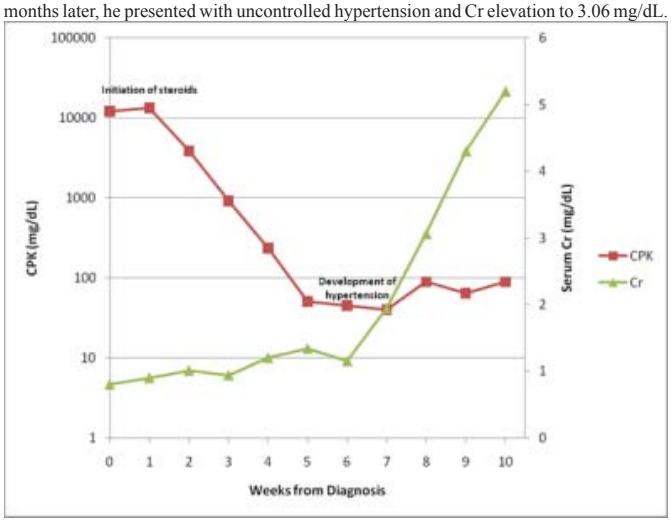
**Conclusions:** Proteinuria after transplantation carries poor prognosis, thus complete resolution of proteinuria post-transplant although rare is striking. A small proportion of live donor transplant recipients with immediate graft function have been known to have a complete resolution of proteinuria after average 4.5 weeks (range 1-10 wks). As our patient had findings suggestive of diabetic process including ophthalmopathy and neuropathy, a kidney biopsy was not performed. Thus a possibility of an alternate renal pathology responding to immunosuppression cannot be completely excluded. Although mechanisms explaining resolution of proteinuria of native kidney origin post-transplant remain unclear, they need to be studied in greater detail.

**SA-PO669**

**Scleroderma Renal Crisis as an Initial Presentation of Systemic Sclerosis in a Patient with Underlying Polymyositis** Yusra R. Cheema, Cybele Ghossein. *Nephrology, Northwestern Univ, Feinberg School of Medicine, Chicago, IL.*

**Background:** Systemic sclerosis (SSc) is a relatively rare connective tissue disease affecting 200 per 1 million adults. About 20% of patients with systemic sclerosis also have clinical or serologic evidence of another connective tissue disease. Of those with an overlap syndrome, 40% have evidence of both SSc and inflammatory myositis. Typically, patients with SSc/polymyositis overlap syndrome present first with signs of SSc and are diagnosed with polymyositis later in the course. Here we present the case of a patient initially diagnosed with polymyositis, started on treatment with corticosteroids and subsequently presenting with scleroderma renal crisis as the only manifestation of systemic sclerosis.

**Methods:** A 54 year-old man initially presented with complaints of fatigue and myalgias. On admission, a CPK level was elevated at 13,127 mg/dL. A rheumatologic work-up was unremarkable including negative anti-Jo1, anti-Scl 70, and anti-RNP antibodies. Serum creatinine (Cr) was 0.8 mg/dL. Patient underwent a muscle biopsy consistent with polymyositis and was started on high dose steroids with improvement in CPK levels. Two months later, he presented with uncontrolled hypertension and Cr elevation to 3.06 mg/dL.



Renal biopsy demonstrated vascular changes and focal thrombotic microangiopathy consistent with scleroderma renal crisis. Patient was started on escalating doses of captopril, amlodipine and aliskiren for BP control. Cr initially stabilized at 4.5mg/dL but renal function continued to worsen over ensuing 4 months, ultimately requiring initiation of hemodialysis.

**Conclusions:** In patients with an underlying connective tissue disease, the development of renal dysfunction particularly following initiation of corticosteroid therapy should raise suspicion for possible overlap syndrome and scleroderma renal crisis.

## SA-PO670

**Unusual Systemic Manifestations of Levamisole Induced Cocaine Vasculitis: Rapidly Progressive Glomerulonephritis** Rona S. Smith,[1] Ryan Jessee,[2] Aneel Kumar,[1] Laura D. Carbone,[1] Lekha K. George.[1] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Duke Univ, Durham, NC.*

**Background:** Levamisole exposure with tainted cocaine causes cutaneous vasculitis that has distinct lab and clinical features distinguishing it from classical ANCA associated vasculitis. We report an unusual sequelae of this syndrome –Rapidly Progressive Glomerulonephritis (RPGN) and discuss the potential role of Rituximab in its management in a patient with history of chronic cocaine abuse that developed vasculitis manifestations of midline facial lesions, neutropenia, skin lesions, and pulmonary and renal manifestations.

**Methods:** A 30 year old female, with long history of intranasal cocaine use, presented with worsening skin ulcerations. Physical examination showed violaceous, eschar-like skin lesions in various stages of healing on her hands, knees, and thighs along with upper airway midline lesions. Lab findings on admission showed an increase in serum creatinine from 0.8 (baseline) to 5.4 mg/dl, leukopenia (WBC count 2,200/mm$^3$), positive C-ANCA (13.4U/ml), and positive P-ANCA (15.9U/ml). Urinalysis showed gross hematuria, and proteinuria (150mg/dl). Antineutrophil elastase, specific for levamizole associated cocaine vasculitis, was also positive.

**Results:** CT scan showed paranasal sinus disease, septal defects, and a noncalcified nodule of the lung. Renal biopsy showed focal necrotizing and crescentic glomerulonephritis consistent with pauci-immune ANCA vasculitis. The patient was treated with total of 3gm (1mg/kg/day) of methylprednisolone. Due to fertility concerns, cytopenia, relapsing nature of disease with systemic manifestation, rituximab 375 mg/m$^2$ was also given. This resulted in disappearance of skin lesions, lung nodule, and improvement in serum creatinine to 1.6 mg/dl and WBC count to 4,200/mm$^3$.

**Conclusions:** This case of levamisole-induced vasculitis with palpable purpura, leucopenia, and positive ANCA and antineutrophil elastase along with RPGN, responded well with a regimen of high dose steroids and Rituximab. This response suggests a potential role of Rituximab in the management of such vasculitis with renal involvement.

## SA-PO671

**Renal Amyloidosis in Skin Poppers – Revisited** Vasil Peev,[1] Ruchir R. Chokshi,[1] Mario Carlos Ponce,[2] David B. Thomas,[3] Jair Munoz Mendoza.[1] *[1]Div of Nephrology and Hypertension, Univ of Miami; [2]Dept of Medicine, Univ of Miami; [3]Div of Pathology, Univ of Miami, Miami, FL.*

**Background:** Renal amyloidosis secondary to long-term subcutaneous (SC) drug use ("skin popping") originally described in African American population in New York in the 1980s, is nowadays rarely diagnosed despite the growing number of intravenous drug abusers.

**Methods:** A 47 year-old Caucasian male with history of hepatitis C, recurrent skin abscesses due to five year history of heroin and cocaine SC and intra venous drug use (IVDU), presented to our hospital with a right arm skin abscess. Physical exam revealed multiple skin needle marks, cachexia, hepatomegaly, 2+ pitting lower extremity edema and a diastolic 3/6 murmur in the aortic area. Initial laboratory data showed elevated serum creatinine (3.8 mg/dL), low albumin (2.1 g/dL), high LDL cholesterol (179 mg/dL) and nephrotic-range proteinuria (5.8 grams in 24 hours). Urine analysis showed no blood or pyuria. He tested positive for hepatitis C, and negative for hepatitis B and HIV. Culture from the skin abscess grew streptococcus hemolyticus and blood cultures were negative. A transesophageal echocardiogram showed vegetations in aortic and mitral valves. Further investigation revealed normal C3 (24 mg/dL) and C4 (47 mg/dL), negative rheumatoid factor and cryoglobulins, and absence of Bence Jones protein or monoclonal gammopathy. A kidney biopsy revealed AA amyloidosis involving multiple glomeruli, interstitium and vessels as well as foci of severe acute tubular necrosis with kappa and lambda immunofluorescence negativity for light chain monoclonality.

**Conclusions:** This case illustrates a rapidly progressive renal failure resulting from AA amyloid deposition secondary to sustained inflammatory response in a patient with SC and IVDU. Although this condition has mainly been reported in blacks, with more than 10-year history of IVDU, we now describe a case in a Caucasian man with a shorter period of IVDU. We also want to call attention to this nearly forgotten condition in an era of FSGS being the most commonly diagnosed cause of nephrotic syndrome in the African American population.

## SA-PO672

**Resolution of Syphilis Induced Rapidly Progressive Crescentic Glomerulonephritis (RPGN) with Penicillin Therapy** Deepak K. Nandikanti,[1] Rona S. Smith,[1] Aneel Kumar,[1] Barry M. Wall,[1,2] Lekha K. George.[1] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]VAMC, Memphis, TN.*

**Background:** Renal manifestations of Syphilis are variable, with membranous nephropathy being the most commonly described lesion. We describe a patient with RPGN secondary to latent Syphilis, which resolved after Penicillin (PCN) treatment in the absence of immunosuppressive therapy.

**Methods:** A 28-year old black male with a history of HIV never on HAART therapy presented with one week of nausea, vomiting and abdominal pain. He was treated for STDs in past but never diagnosed or treated for Syphilis. He was afebrile and normotensive. Physical examination was normal. Serum Creatinine (SCr) was 7.2 mg/dl (1.1mg/dl one mg prior). Urinalysis: 3+ protein, WBC 15-20/HPF, many RBCs, and RBC casts. Spot urine protein to creatinine ratio (UPC) was 4.0. CD4 count was 412 with undetectable HIV viral load. Serologies for ANA, ANCA, anti-ASO, hepatitis B and C, anti GBM, C3, C4 were negative or normal. RPR was positive with titer of 1:32. Treponema pallidum particle agglutination assay was reactive, confirming Syphilis diagnosis. CSF was negative for neurosyphilis. Ultrasound showed normal sized kidneys. Kidney biopsy LM showed focal and segmental necrotizing lesions and crescents. IF showed mesangial granular staining for C3 (3+) and IgM (1+). EM showed effacement of foot process without deposits. He received weekly Benzathine PCN for 3 wk. RPR titers decreased to 1:4. SCr rapidly improved with the first dose of PCN. UPC improved to 2.0 after 3 weekly doses of PCN . His SCr was 1.1 mg/dl and RPR titres 1: 4 at three months follow up. These dramatic improvements in renal function occurred in the absence of any immunosuppressive therapy.

**Conclusions:** RPGN with crescents typically leads to ESRD in the absence of effective treatment, which usually includes immunosuppressive therapy. Our patient had dramatic renal recovery with PCN treatment, a finding which to our knowledge has not been previously reported. We strongly recommend that Syphilis be considered in the differential diagnosis of all patients with proteinuria or suspected glomerulonephritis, particularly in high risk populations.

## SA-PO673

**A Case of Fibronectin Glomerulopathy with Rapidly Progressive, Severe Nephrotic Syndrome Leading to End-Stage Renal Disease** Ikue Ishimoto,[1] Eisei Sohara,[1] Eisaku Ito,[2] Motoko Chiga,[1] Soichiro Iimori,[1] Tomokazu Okado,[1] Tatemitsu Rai,[1] Shinichi Uchida,[1] Sei Sasaki.[1] *[1]Dept of Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan; [2]Dept of Pathology, Tokyo Medical and Dental Univ, Tokyo, Japan.*

**Background:** Fibronectin glomerulopathy occurs between the second and fifth decades of life in most patients, and it is known to be slowly progressive with mild proteinuria leading to kidney failure. The case of a 78-year-old woman with a rapid course of nephrotic syndrome due to fibronectin glomerulopathy is reported.

**Methods:** She had proteinuria that rapidly increased to 6.8 g/day in a month and microscopic hematuria. A renal biopsy specimen showed lobular glomerulopathy and membranoproliferative glomerulonephritis-like lesions on light microscopy. There was scanty staining for immunoglobulins and complement. Electron microscopy revealed granular deposits with fibril formation, which is 12-16 nm in diameter and typically arranged in an irregular fashion, indicating fibronectin glomerulopathy. Immunohistochemistry of the fibronectin showed intense staining in the mesangium and peripheral loop. Therefore, this case was diagnosed as fibronectin glomerulopathy. The kidney function was rapidly decreased, necessitating hemodialysis two months after renal biopsy.

**Conclusions:** To the best of our knowledge, such a rapid clinical course of nephrotic syndrome has not been previously reported in fibronectin glomerulopathy. In addition, this case is interesting because proteinuria occurred at 78 years of age, the oldest onset of fibronectin glomerulopathy reported to date. Taken together, it is important to consider fibronectin glomerulopathy in the differential diagnosis of nephrotic syndrome in older people.

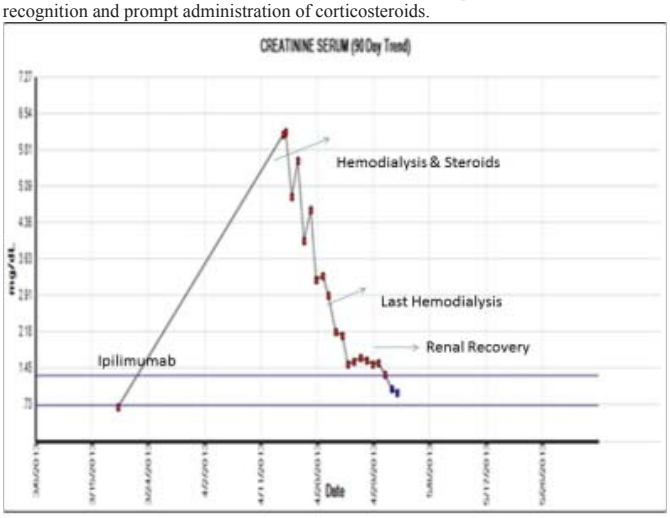
**SA-PO674**

**Ipilimumab-Induced Immune-Related Nephritis** Thuy-Trang T. Ngo,[1] Charles K. Minn,[1] Maen Abdelrahim,[2] Ala Abudayyeh.[3] *[1]Nephrology, The Univ of Texas Medical School-Houston; [2]Nephrology, The Univ of Texas Medical School-Houston; [3]Internal Medicine, Baylor College of Medicine; [4]General Internal Medicine, Section of Nephrology, Univ of Texas-MD Anderson Cancer Center, Houston, TX.*

**Background:** Ipilimumab, a fully human monoclonal IgG1 antibody against cytotoxic T-lymphocyte antigen-4(CTLA-4) expressed on the surface of activated T cells and monocytes, offers a new therapeutic option in the treatment of metastatic melanoma. By inhibiting CTLA-4, ipilimumab increases anti-tumor immune response. Since CTLA-4 plays a major role in regulating immune tolerance to self-antigens, its blockade can result in autoimmune destruction of tissues by enhancing T-cell response in peripheral organs. Common immune related side effects such as dermatitis, enterocolitis, hepatitis, and endocrinopathies are widely documented. However, renal involvement has rarely been described with only one case of ipilimumab-induced acute renal failure reported in the literature to date.

**Methods:** A 62 year old male presented with a history of uveal melanoma which progressed to metastatic disease was treated with ipilimumab (10mg/kg) which resulted in immune mediated nephritis in the presence of peripheral eosinophilia, enlarged kidneys, rash, colitis, autoimmune transverse myelitis, and uveitis.

**Conclusions:** Immune-related adverse effects from ipilimumab are generally dose dependent and typically occur between 3 to 12 weeks after drug administration. At the current approved ipilimumab regimen of 3 mg/kg every 3 weeks for four doses, immune-related adverse events occur in approximately 60% of patients. High-dose steroid therapy has been shown to effectively control side effects associated with ipilimumab immune stimulation. Greater awareness of this rare autoimmune nephritis may facilitate early recognition and prompt administration of corticosteroids.

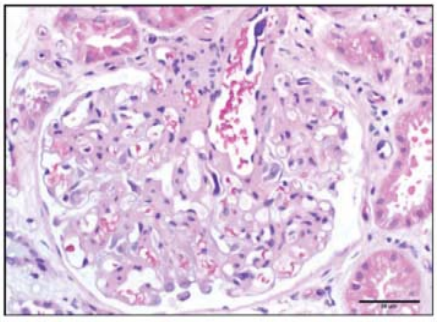


**SA-PO675**

**Primary Myelofibrosis Causes Glomerulopathy** Thuy-Trang T. Ngo,[1] Manjunath Kottalgi,[1] William F. Glass,[1] Ala Abudayyeh.[2] *[1]Nephrology, The Univ of Texas Medical School at Houston; [2]Nephrology, The Univ of Texas Medical School at Houston; [3]Pathology, The Univ of Texas Medical School at Houston; [4]Section of Nephrology, The Univ of Texas- MD Anderson Cancer Center.*

**Background:** Myeloproliferative neoplasms (MPNs) are clonal hematopoietic stem cell disorders in which proliferation of one or more of the myeloid lineages occur resulting in fibrosis of the bone marrow. Renal involvement by MPN is infrequent. Glomerular abnormalities in primary myelofibrosis (PMF) patients have rarely been described.

**Methods:** A 66 year-old Caucasian male recently diagnosed with primary myelofibrosis (PMF) (on JAK-2 inhibitor) presented with increased leg swelling, poorly controlled hypertension,23 grams of proteinuria, and worsening serum creatinine. Renal pathology revealed diffuse mesangial matrix expansion and mild mesangial hypercellularity, effaced podocyte foot processes, and glomerular intracapillary megakaryocytes without immune deposits on immunofluorescence. These findings are consistent with myeloproliferative neoplasm-related glomerulopathy.



H&E: mesangial matrix expansion and intra-arteriolar and intracapillary megakaryocytes.

**Conclusions:** MPN-related glomerulopathy is thought to be a late complication of MPN. Previous study reported a mean time from diagnosis of MPN to renal biopsy was 7.2 years. Our patient underwent a renal biopsy in less than 3 months from diagnosis of PMF, suggesting glomerulopathy can develop sooner than previously thought. Renal biopsy is diagnostic, usually demonstrates variable degrees of mesangial hypercellularity and sclerosis, segmental sclerosis, features of chronic thrombotic microangiopathy (TMA), and intracapillary megakaryocytes cell infiltration on light microscopy. Steroids and renin-angiotensin system blockade appear to be ineffective in treating MPN-related glomerulopathy. Prompt recognition of disease entity is essential for diagnosis and proper management of this renal disorder.

**SA-PO676**

**Pauci-Immune Crescentic Glomerulonephritis Associated with Oropharyngeal Cancer** Amaka Edeani, Derek M. Fine. *Div of Nephrology, Johns Hopkins School of Medicine, Baltimore, MD.*

**Background:** Glomerulopathies of many forms have been described in association with solid and hematological neoplasms, most common is the association of membranous glomerulopathy with solid tumors. We report a case of ANCA-negative crescentic glomerulonephritis (GN) in a patient with oropharyngeal cancer.

**Methods:** A 52 year old male with tonsillar squamous cell carcinoma, diagnosed in 2011, treated to remission with tonsillectomy, radiation therapy and cisplatin. In June of 2012, he was diagnosed with a likely new squamous cell carcinoma of the right lateral tongue. He underwent resection and restarted a course of cisplatin and radiation therapy, completed in November 2012. He was admitted in December 2012 with gross hematuria and a serum creatinine of 1.7mg/dL, attributed at the time to cisplatin-induced nephrotoxicity. Hematuria spontaneously resolved and he was discharged with a creatinine of 1.9mg/dL. Three weeks later, he presented with recurrent hematuria, with creatinine now 4.5mg/dL and 24hr proteinuria of 5.24 gram. Serologic workup revealed negative anti-GBM, p-ANCA, c-ANCA, anti-streptolysin O, anti-myeloperoxidase antibodies and Hepatitis serologies. Urine and serum electrophoreses were negative. Renal biopsy revealed necrotizing crescentic glomerulonephritis with cellular crescents and acute tubular necrosis, with no immune complex deposits. Diagnosed with an ANCA-negative pauci-immune GN, he received pulsed steroids; however, renal failure worsened (creatinine up to 5mg/dL) and in addition to ongoing oral steroids, cyclophosphamide 75mg once daily was initiated with rapid improvement in renal function, with creatinine down to 3.3mg/dL by day of discharge 3 days later and 1.56mg/dL 4 weeks later.

**Conclusions:** Biava et al in 1984 described a case series of patients suggesting an increased incidence of solid tumors in those with pauci-immune crescentic glomerulonephritis. Subsequent observations have demonstrated these to be ANCA-associated. Associated tumors include prostate, lung, gastric and bladder cancer, and some hematologic malignancies. We describe here an unusual case of ANCA negative disease which has responded well to cyclophosphamide based therapy.

**SA-PO677**

**Single Center Experience with ACTH for the Treatment of Resistant Nephrotic Syndrome** Arafat Y. Melhem, Paul G. Schmitz. *St. Louis Univ, St. Louis, MO.*

**Background:** ACTH injection was approved by the FDA in 1952 for the treatment of the nephrotic syndrome (NS). Its use was largely abandoned with the development of oral corticosteroids. However, 2 recent case series in patients with NS revealed that ACTH induced a remission in >50%. In this report we examined our experience with ACTH for resistant NS.

**Methods:** We retrospectively examined 5 cases of resistant NS between 2011-2013 that received salvage therapy with ACTH. The age ranged between 23-59 years and the histology revealed: MCD (n=1), iMN (n=1), or FSGS (n=3). The subjects had been receiving multiple immunosuppressive agents (IS) at the time of initiation (mean = 3.3 IS). The duration of NS in our subjects was 4-16 years. The duration of ACTH administration was 7.4 ± 3 months. Complete remission (CR) was defined as stabilization of the serum Cr. coupled with a protein excretion of <0.5 g/24h. A partial remission (PR) was defined as a protein excretion between 0.5-3.5 g/24h. ACEi/ARBs and diuretics were employed in all patients.

**Results:** 2 of the 5 patients achieved CR and one exhibited a PR (but met the definition of a CR 2 months after stopping ACTH). The average follow-up was 11.8 months with a range of 7-16 months. Importantly, 2 patients with CR were disease free 6 months after

discontinuing ACTH treatment. Proteinuria decreased from an average of 6.2gm/24h to 3.4gm/24h. In addition, the eGFR increased from a mean of 63.8 mL/min to 71.4 mL/min. One patient experienced skin pigmentation, weight gain, worsening diabetes and cushinoid features. This patient remained on therapy, since she had failed 6 IS. While on therapy her Cr. decreased from 6.3 to 3.5 mg/dl and proteinuria declined from 6.7gm/24h to 3.5gm/24. Another patient experienced gastroesophageal reflux, which was controllable with conservative medical therapy. No other adverse events were reported.

**Conclusions:** In our center, we observed remarkable improvement in several patients that were highly resistant to IS. Our remission rate was comparable to previously published studies (60%). Moreover, the remissions persisted for up to 6 months after discontinuing the therapy. Subcutaneous ACTH is a unique and promising alternative to standard IS in patients with resistant NS.

## SA-PO678

### Proteinuria Relapse before Recovery of B Cells and Responsiveness to Rituximab in a Patient with Idiopathic Focal Segmental Glomerulosclerosis

Ilse M. Rood,[1] Job Huussen,[2] Jeroen Deegens,[1] Jack F. Wetzels.[1] *[1]Nephrology, Radboud Univ Nijmegen Medical Center, Nijmegen, Netherlands; [2]Nephrology, Slingeland Hospital, Doetinchem, Netherlands.*

**Background:** Focal segmental glomerulosclerosis (FSGS) is one of the most common causes of nephrotic syndrome (NS) in adults. FSGS is a heterogeneous disease with many underlying causes. A potential cause is the production of permeability factors by lymphocytes. This has been the rationale for targeted B-cell-therapy using rituximab (RTX). Several case reports showed remission of proteinuria in patients with idiopathic FSGS (iFSGS). We present a patient with a relapse before recovery of peripheral B cells, who achieved remission after renewed RTX therapy.

**Methods:** A 65-year old woman presented with proteinuria of 3.0 g/24h and a serum albumin of 24 g/l. Renal function was normal (serum creatinine 51 µmol/l). A renal biopsy showed lesions consistent with FSGS. After ruling out secondary causes, iFSGS was diagnosed. Treatment with prednisone was effective in inducing a partial remission. However, over the years there were multiple relapses necessitating repeated courses of prednisone. Treatment with cyclophoshamide or ciclosporin did not result in a lasting remission. Because of side effects of the therapies, RTX treatment was given at the time of new relapse (1000mg on day 1 and 15). A renewed partial remission occurred. Seven months later she had a new relapse (proteinuria 4.2 g/24h, serum albumin 24 g/L, serum creatinine 144 µmol/l). At that time B-cell CD19+ count was $0.01 \times 10^9$/L. Although B-cells were not recovered, a new dose of RTX was given, resulting in a new partial remission (proteinuria 1 g/24h, serum albumin 32 g/l).

**Conclusions:** This is the first reported case of a relapse of the NS after treatment with RTX when there was no evidence of B-cell recovery. Interestingly, a new dose of RTX resulted again in a partial remission. This case illustrates either that B-cells in secondary lymphoid tissues can still activate T-cells or that B-cell independent mechanisms of RTX are involved in the relapse (by directly affecting podocyte function).

## SA-PO679

### Successful Treatment with Dexamethasone and Bortezomib for Proliferative Glomerulonephritis with Monoclonal IgG Deposits in Multiple Myeloma

Rio Noto,[1] Nozomu Kamiura,[1] Yuichiro Ono,[2] Sumie Tabata,[2] Shigeo Hara,[3] Akihiro Yoshimoto.[1] *[1]Dept of Clinical Nephrology, Kobe City Medical Center General Hospital, Kobe, Hyogo, Japan; [2]Dept of Clinical Hematology, Kobe City Medical Center General Hospital, Kobe, Hyogo, Japan; [3]Dept of Diagnostic Pathology, Kobe Univ Hospital.*

**Background:** The pathophysiology of proliferative glomerulonephritis with monoclonal IgG deposits (PGN-MID) remains unknown. In 30% of PGN-MID cases, there was a monoclonal component detectable in the serum, but only two cases of myeloma were reported previously. Now we present the first case of PGN-MID leading to the diagnosis of multiple myeloma and subsequent successful treatment.

**Methods:** A 75 year old male with hypertension presented with progressive leg edema and fatigue. He was found to have nephrotic range proteinuria (13 grams on a spot protein-creatinine ratio) and hypoalbuminemia of 2.8 g/dL. His serum creatinine was 1.39 mg/dL. His urine showed 30–49 RBC/hpf, but no dysmorphic cells or cellular casts. On serum and urine protein electrophoresis, he had monoclonal spikes in both the serum and urine. Cryoglobulin test for serum resulted negative. Renal histopathology demonstrated lobular mesangial proliferation with moderate tubular atrophy and negative Congo red staining. Glomeruli showed granular capillary staining for IgG, C1q and C3 with light chain isotype restriction limited to kappa by immunofluorescence, although tubular deposits were absent. Analysis for IgG subclass confirmed restriction to IgG1 subtype. Granular electron dense deposits were present in subendothelial and mesangial locations. Bone marrow examination revealed 17% of IgG kappa positive monoclonal plasma cells. A diagnosis of PGN-MID in multiple myeloma was made and we started on bortezomib and dexamethasone. Patient has had significant positive response within 3 months with improvement of proteinuria to 0.66 grams/day and serum albumin to 3.4 mg/dL.

**Conclusions:** Redondo-Pachon *et al*. reported a case of PGN-MID and multiple myeloma refractory to treatment. However, we first demonstrated in this case that treatment for myeloma is effective for PGN-MID when plasma cell dyscrasia is involved in the pathogenesis.

## SA-PO680

### Seronegative Immune Complex Mediated Glomerulonephritis: Renal Limited Anti-Nuclear Antibody Negative Lupus?

Smitha Thomas-Mathew, Meenu Gaba, Mark Birkenbach, Iris J. Lee. *Dept of Nephrology and Pathology, Temple Univ School of Medicine, Philadelphia, PA.*

**Background:** Positive ANA is required for renal disease to be a stand alone clinical criterion sufficient for diagnosing systemic lupus erythematosus (SLE). Pathologic features of lupus nephritis are quite specific, yet cases of ANA negative lupus like renal disease exist. Whether such cases represent development of serologic SLE over time or a distinct disease entity that portend different prognoses remains unclear.

**Methods:** A 25-year old African-American female presented with lower extremity swelling. Her past medical and family histories were unremarkable. Her physical exam was notable only for trace to +1 pitting edema in the lower extremities. Complete blood count, basic metabolic panel, (BUN-15, creatinine-0.89 mg/dl), liver enzymes, were normal. Urinalysis was negative for blood, with 3+ protein and bland sediment. A 24 hour urine protein was 2926 mg. Serum C3, C4, ANA, dsDNA, anti Ro, anti La, antiphospholipid, hepatitis panel, RPR were negative. Our patient had no signs or symptoms of SLE. HIV1/2 antibody was initially positive, but the western blot was indeterminate and HIV viral load was not detected. Repeat HIV was negative. Renal biopsy demonstrated mild mesangial expansion and hypercellularity with immune deposits in a mesangial and capillary wall location observed by immunofluorescence and electron microscopy. Immune deposits demonstrated strong staining for IgG with weaker staining observed for IgM and IgA. Moderately intense staining for C3, C4, and C1q was observed. The patient was treated with prednisone and mycophenolate mofetil 1500mg twice daily.

**Conclusions:** The concept of ANA negative lupus as a distinct diagnostic entity remains problematic. Evidence from the literature, as well as utilization of Hep-2 cell lines for higher sensitivity ANA testing has decreased the incidence of ANA-negative lupus to < 2%. There is limited data available on treatment and prognosis of such cases. We report a rare entity; "seronegative lupus like nephritis" which needs further study to determine mechanisms and evolution of disease, and management to prevent rapid progression.

## SA-PO681

### A Case of Recurrent Uveitis and Tubulointerstitial Nephritis – An Elusive Oculorenal Syndrome

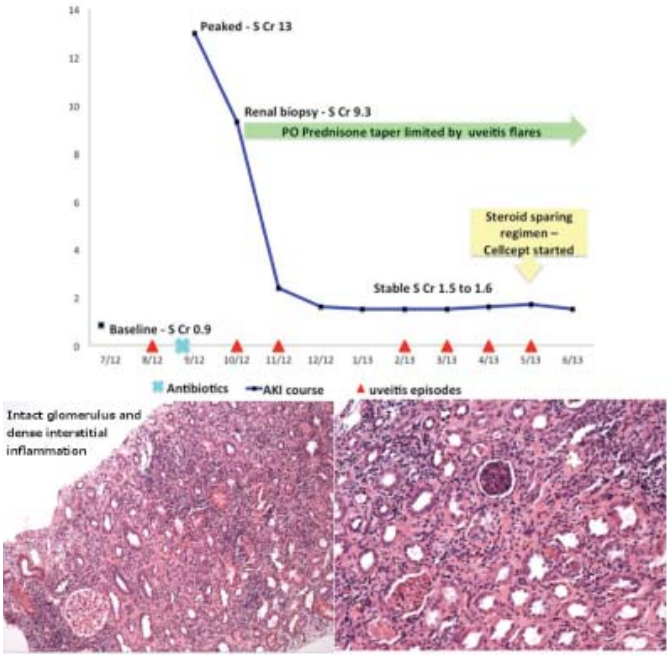
Nisha N. Patel,[1] Menaka Sarav.[2] *[1]Dept of Nephrology, Univ of Chicago, Chicago, IL; [2]Dept of Nephrology and Hypertension, NorthShore Univ HealthSystem, Evanston, IL.*

**Background:** We present a patient with acute tubulointerstitial nephritis and recurrent uveitis (TINU). This case demonstrates the complicated clinical course typical of oculorenal syndromes and the difficulty in distinguishing between these diseases.

**Methods:** A 49 year old African American female with history of pulmonary nodules (not biopsied), cerebral aneurysm, primary uveitis (2 months ago) and recent use of antibiotics for cough (2-3 weeks ago) presented with nausea, vomiting, malaise. Physical exam demonstrated volume depletion and labs showed AKI with a serum creatinine of 13. CXR showed no hilar lymphadenopathy. Working hypothesis was ATN from volume depletion, AIN from antibiotics and Oculorenal syndromes.

| Differential diagnosis for Oculorenal Syndrome |
|---|
| TINU |
| Sarcoidosis |
| Sjogren's syndrome |
| Infectious diseases such as tuberculosis, brucellosis, toxoplasmosis, histoplasmosis |
| SLE |
| Rheumatoid Arthritis |
| Behcet's disease |
| Drugs (NSAIDS, Antibiotics) |
| Wegener's Granulomatosis |

Renal biopsy demonstrated acute tubulointerstitial nephritis with absence of granulomas. ACE levels normal and Quantiferon gold test is negative to date. Prednisone was started with plans for taper over the next 2-3 months. Renal function improved, however steroid taper was limited by recurrent uveitis. She was recently started on mycophenolate mofetil as part of a steroid sparing regimen.



**Conclusions:** The diagnosis of TINU is suggested by the combination of uveitis and acute interstitial nephritis. The distinction of TINU from sarcoidosis and other granulomatous diseases is particularly difficult when there is an absence of a specific organ involvement. Case reports have shown the benefit of mycophenolate mofetil for recurrent uveitis and in a case of TINU.

## SA-PO682

**Urinary Levels and Renal Deposition of Bb Are Associated with the Severity of ANCA-Associated Glomerulonephritis** Shen-Ju Gou, Jun Yuan, Chen Wang, Min Chen, Ming-hui Zhao. *Renal Div, Peking Univ first Hospital, Beijing, China.*

**Background:** Our previous study revealed that complement activation products of the alternative pathway could be detected in renal specimens of human ANCA-associated vasculitis (AAV). The current study aimed to investigate the clinical and pathological significance of complement activation products in the urine and kidneys of patients with AAV.

**Methods:** Renal biopsy specimens from 29 patients with AAV were collected. Urine samples from 27 out of the 29 patients in active stage and 22 patients in remission stage were also collected. The renal deposition of Bb, C3d and C5b-9 were detected by immunohistochemistry. The urinary levels of Bb, C3a, C5a and soluble C5b-9 were determined by enzyme-linked immunosorbent assay.

**Results:** The deposition, measured by the mean optical density, of Bb in glomeruli correlated with the proportion of total crescents, the extent of interstitial infiltrate, interstitial fibrosis and tubular atrophy (r=0.50, P=0.006; r=0.59, P=0.001; r=0.45, P=0.01; r=0.55, P=0.002, respectively), while correlated inversely with the proportion of normal glomeruli (r=-0.49, P=0.008). The urinary levels of Bb, C3a, C5a and soluble C5b-9 were all significantly higher in active stage comparing with those in remission stage. The urinary levels of Bb in patients with active AAV correlated with the serum creatinine and correlated inversely with the proportion of normal glomeruli in renal specimens (r=0.56, P=0.002; r=-0.49, P=0.009, respectively).

**Conclusions:** The present study provided further evidence that complement activation via the alternative pathway occurred in the development of AAV. The renal deposition of Bb and urinary Bb levels were associated with the severity of renal injury.

*Funding:* Government Support - Non-U.S.

## SA-PO683

**Characteristics and Outcomes of ANCA-Associated Vasculitides** Vladimir Tesar, Zdenka Hruskova, Eva Jancova. *Dept of Nephrology, 1st Faculty of Medicine, Charles Univ, Prague, Czech Republic.*

**Background:** To present basic characteristics and long-term outcomes of ANCA-associated vasculitides (AAV) patients included in a nation-wide Registry.

**Methods:** Sixteen vasculitis centres (9x Nephrology, 4x Rheumatology, 2x Immunology, 1x Pediatrics) have participated in web-based data collection since 2009. Data consist of retrospective questionnaire completed once at entry, and of prospective follow-up with a visit recorded every 3-6 months. Statistical analysis included the Kaplan-Meier method and log-rank test for survival analysis.

**Results:** A total of 652 patients (M/F 311/341, median age at diagnosis 58, range 11-89 years) were included, 359 (55%) PR3(or c)-ANCA positive, 261 MPO(p) ANCA positive (40%) and 19 (3%) ANCA negative. Double positivity for ANCA and anti-GBM was found in 25 (4%). The mean time of follow-up was 66±57 months. Granulomatosis with polyangiitis was the most common diagnosis with 58%, and 34% suffered from microscopic polyangiitis (including renal-limited form). Cumulative organ involvement involved kidney in 89%, lungs in 61% and ENT in 38%. Mean S-creatinine at diagnosis was 211 ± 161 μmol/L, 161 patients required dialysis.Cyclophosphamide was used in 89% of the patients, plasma exchange in 232 (36%) and biological therapy in 34 (5%). The estimated 5-year survival was 81.5% (95% CI = 78.1% - 84.9%) and was higher in patients aged ≤65 years than in the older ones (85% vs. 67%, p<0.001) and in patients with better renal function at diagnosis compared to those with S-creatinine ≥ 200 and ≥ 500 μmol/L (91%, 80 % and 67%; p<0.05 and p<0.001, respectively). During follow-up, 41% of the patients relapsed. Last available VDI (Vasculitis Damage Index) ranged between 0 and 16 (median 4).

**Conclusions:** In the studied population, GPA was the most common AAV, reflecting the northern European type. Older age and severe renal involvement were associated with higher mortality. Long-term survival was similar to previous studies, often associated with a significant morbidity.

## SA-PO684

**Infection, Relapse and Mortality in Antineutrophil Cytoplasmic Antibody Associated Vasculitis** JulieAnne G. McGregor,[1] Roberto Negrete-Lopez,[2] Caroline J. Poulton,[1] Jason M. Kidd,[1] Suzanne L. Katsanos,[1] Lindsey R. Goetz,[1] Yichun Hu,[1] Patrick H. Nachman,[1] Ronald J. Falk,[1] Susan L. Hogan.[1] *[1]UNC Kidney Center, Chapel Hill, NC; [2]Hospital Universitario-UANL, Monterrey, Nuevo Leon, Mexico.*

**Background:** Study goal was to evaluate risk factors for infections, relapse and death within 2 years (yrs) of diagnosis in a cohort with biopsy-proven antineutrophil cytoplasmic antibody associated vasculitis (AAV) (1992-2011).

**Methods:** All recieved immunosuppression. Infection (inf), relapse and death within 12 & 24 months (mos) were assessed. Severe inf (intravenous antibiotics, intensive care unit, or cause of death) and prophylactic therapy was recorded. Inf number was grouped as no inf, 1-2 or >3 inf. Fisher exact or Kruska-Wallis tests were used with Cox regression to estimate hazards ratios (HR) and 95% confidence intervals.

**Results:** 490 patients (median age 59 yrs; 47% male, 55% MPO-ANCA) were followed for a median of 2.8 yrs. Within 12 mos, 55% had inf, 19% relapsed and 8% died. Within 24 mos, 66% had inf, 36% relapsed and 12% died.

More inf in 12 mos were associated with age (median age 57yrs with no inf, 60yrs with 1-2 inf and 66yrs with ≥3 inf; p= 0.02) and steroid-induced diabetes mellitus (DM) (19% in those with no inf, 27% in those with 1-2 inf, and 44% in those with ≥3 inf, p= 0.002). Female sex was the sole risk for more inf in 12-24 mos (39% female with no inf; 52% with1-2 inf, 57% with ≥3 inf, p=0.02), with urinary tract infections (UTI) most frequent (31% vs men 10%; p= <0.0001). Prophylactics did not reduce inf.

Relapse in 12 mos was more common in females (60% vs males 40%, p=0.014) and less likely with renal limited AAV (8% vs. GPA 33% and MPA 58%, p=0.019). Only PR3-ANCA was associated with relapse in 12-24 mos (p=0.005 vs. MPO).

Death was associated with more inf in 12 mos (0 3%; 1-2 11%; ≥3 13% p=0.002). A severe inf within 24 mos was a risk for death from any cause in this timeframe (HR 5.6, 95% CI 1.2, 27.2).

**Conclusions:** Elderly patients and those with steroid induced DM must receive less aggressive immunosuppression. UTI in females needs to prompt prophylaxis. This information on inf, relapse and death in the first 1-2 years following AAV diagnosis can guide immunosuppressive strategies.

## SA-PO685

**Use of Cyclophosphamide in ANCA Associated Nephritis: Experience of a Tertiary Care Center** Philippe Lachance, David Philibert. *Nephrology, CHUQ, Québec, Canada.*

**Background:** Cyclophosphamide (CYC) at 2mg/kg is the cornerstone of induction therapy in ANCA associated nephritis (AAN) with a 50 to 90 % remission rate but with infection and leucopenia in up to 50 % of cases. The aim of this study is (1) to describe retrospectively the safety and efficacy of reduced CYC regimen in our center and (2) to examine potential predictors of irreversible kidney injury (IKI).

**Methods:** Single arm retrospective study which included all incident AAN patients from January 2009 to July 2012 at Hotel-Dieu de Québec, a tertiary nephrology center. CYC dose, rate of remission, infection (from the medical file) and leucopenia (WBC<4) were reported and compared to those in the literature. Complete remission was defined as stable or normalizing creatinine with bland urinary sediment while it was considered partial if erythrocytes were presents. IKI was defined by need for chronic dialysis. All renal biopsies were reviewed. A damage score including tubular atrophy, glomerulosclerosis and interstitial fibrosis (0 to 3 pts each) was created. Patients with IKI were compared to the others to determine which features predict dialysis dependence.

**Results:** Twenty-six (26) patients (median age 59 (51, 70) years) were included with a median creatinine of 604 (263,880) μmol/L. Seven (27%) also had pulmonary manifestation. The median CYC induction and total doses were 1.13 (0.83, 1.38) mg/kg and 12 (7.7, 27) g respectively. Fourteen (54%) patients received plasmapheresis. After a median follow-up of 9 (4, 21) months, eighteen patients (70%) were in partial or complete remission. Infections and leucopenia occurred in six (23%) and nine (35%) patients respectively. IKI best correlated with peak serum creatinine (r=0.67). The histopathologic score correlated with IKI (r=0.52). AUC for this score was 0.85. A score > 5 yielded a 86% sensitivity and 74 % specificity.

**Conclusions:** Lower doses of CYC yielded remission rate similar to the literature with probably less infection and leucopenia. Peak serum creatinine seems to correlate well with IKI as well as histopathologic findings. However, combination of these two features is probably needed to accurately predict patients with IKI. More data are needed to draw firm conclusion.

## SA-PO686

**Crescentic and Focal Necrotizing Glomerulonephritis in Patients with Normal Serum Creatinine** Stephen Paul McAdoo, Anisha Tanna, Olga Randone, Jeremy B. Levy, Megan Griffith, Frederick W.K. Tam, H. Terence Cook, Tom Cairns, Charles D. Pusey. *Imperial College Renal & Transplant Centre.*

**Background:** Focal necrotizing and crescentic glomerulonephritis (FN/CGN) usually present as RPGN and have a poor prognosis if untreated. These pathological findings, however, are not always accompanied by abnormal renal function at presentation. We aimed to establish the frequency and outcomes of patients presenting with FN/CGN and normal serum creatinine (sCr) at our centre.

**Methods:** We conducted a retrospective review (1995-2011) of all adult patients who presented with native renal biopsy proven FN/CGN and normal sCr (<120micromol/l).

**Results:** 38 patients were identified, median age 57 years (range 17-78), 29% male. Biopsies showed median 14 glomeruli (4-33), with 32% (4-100%) of glomeruli affected by necrosis/crescents. All patients received immunosuppression in accordance with local protocols. Median duration of follow-up was 45 months (2-184). Clinical features and outcomes are summarised in the Table below. The majority of patients had good outcomes at one year and at last follow-up. Only 18% of patients had pre-existing diagnoses of autoimmune disease associated with GN. 2 patients progressed to ESRF (both due to lupus nephritis, at 21 & 29 months) and 4 patients died during follow-up (2, 12, 96 & 122 months).

| **Diagnosis** | **Number of Cases (%)** | **% Crescents/Necrosis (range)** | |
|---|---|---|---|
| Pauci-immune GN | 28 (74%) | 32% (4-100%) | |
| Lupus Nephritis | 7 (18%) | 17% (4-50%) | |
| Anti-GBM disease | 2 (5%) | 36% (26-47%) | |
| IgA Nephropathy | 1 (3%) | 50% | |
| **Biochemistry** | **At Biopsy** | **At 1 Year*** | **At last Follow-Up*** |
| sCr (umol/l) | 84 (52-115) | 82 (58-145) | 77 (57-107) |
| Albumin (g/dl) | 29 (10-40) | 38 (30-46) | 37 (22-45) |
| uPCR (mg/mmol) | 71.2 (0-681) | 23 (0-272) | 15 (0-238) |

* censored for death/dialysis

**Conclusions:** This is the first reported series of severe renal pathology in patients presenting with normal creatinine. Low threshold of suspicion for FN/CGN, prompt renal biopsy and early initiation of treatment may prevent irreversible kidney damage and improve long-term outcomes in these patients.

## SA-PO687

**Analysis of 70 Patients with Severe ANCA Vasculitis Requiring Plasma Exchange at MGH: 2005-2013** William Franklin Pendergraft,[1-3] Charles T. Owens,[1-3] Andrew P. Murphy,[3] Colin M. Berry,[3] Karen A. Laliberte,[3] Robert Makar,[4] John Niles.[2,3] *[1]Joint Nephrology Fellowship Program, Massachusetts General Hospital (MGH) and Brigham and Women's Hospital, Boston, MA; [2]Div of Nephrology, MGH, Boston, MA; [3]Vasculitis and Glomerulonephritis Clinic, MGH, Boston, MA; [4]Blood Transfusion Service, Dept of Pathology, MGH, Boston, MA.*

**Background:** Anti-neutrophil cytoplasmic autoantibody (ANCA) vasculitis can cause necrotizing and crescentic glomerulonephritis and pulmonary capillaritis resulting in kidney and lung failure, respectively. When the disease process becomes severe, plasma exchange is often instituted to remove pathogenic autoantibodies.

**Methods:** We performed a retrospective analysis of clinical data related to all ANCA vasculitis patients in our center who required plasma exchange since 2004. Initially, those with acute organ-threatening disease had plasma exchange added to their treatment. For most, this happened within 24 hours of diagnosis or transfer to our institution. Standard exchange dose was typically 4 L/1.73 m2, and a total of seven exchanges were planned to occur over a 10-14 day period. On rare occasion, one to three extra exchanges were added for those with very active disease and exchanges were eliminated for several patients with rapid responses. Serologic and clinical parameters were measured and analyzed.

**Results:** 70 patients [41 women (59%)] with ANCA vasculitis required plasma exchange. There were 52 MPO-ANCA patients and 18 PR3-ANCA patients. In addition to plasma exchange, most patients also received cyclophosphamide, corticosteroids and rituximab induction therapy. Disease severity improved in the majority of patients. 41 patients developed acute kidney injury, but escaped the need for renal replacement therapy while 29 patients required dialysis during initial hospitalization of which 13 recovered renal function.

**Conclusions:** This study describes one of the largest single-center reports of its kind. Plasma exchange appears to contribute to the overall positive outcome of this group. Future work will revolve around identifying differences between these patients and others who did not require plasma exchange in order to determine its utility.

## SA-PO688

**Late-Onset Neutropenia (LON) in ANCA Vasculitis: An Under Recognized Complication of Rituximab** William Franklin Pendergraft,[1-3] Andrew P. Murphy,[3] Karen A. Laliberte,[3] John Niles.[2,3] *[1]Joint Nephrology Fellowship Program, Massachusetts General Hospital (MGH) and Brigham and Women's Hospital, Boston, MA; [2]Div of Nephrology, MGH, Boston, MA; [3]Vasculitis and Glomerulonephritis Clinic, MGH, Boston, MA.*

**Background:** Rituximab (RTX) is an FDA-approved agent that depletes CD20-positive B cells for induction of remission in anti-neutrophil cytoplasmic autoantibody (ANCA) vasculitis patients. Our group manages the largest active cohort of ANCA vasculitis patients in the world, the majority of which are receiving RTX for durable maintenance of remission. LON has been reported to be a complication of chronic RTX exposure; however, these reports are limited in ANCA vasculitis patients.

**Methods:** We conducted a systematic retrospective analysis of ANCA vasculitis patients from 2006-2013 who were treated with RTX maintenance of remission therapy and developed LON. Continuous B cell depletion was performed in all patients by scheduled RTX infusion every four months. Complete blood counts with differentials (CBC) were checked every two months. Patients who developed neutropenia from cocaine use as well as patients with both MPO- and PR3-ANCA were excluded from this analysis.

**Results:** 215 patients treated by our group from April 2006 through June 2013 underwent continuous CD20-positive B cell depletion with RTX. 17 patients developed LON (defined as absolute neutrophil count (ANC) < 1000 cells/mm$^3$). Median ANC nadir was 350 cells/mm$^3$. Four episodes resolved without intervention by the time of repeat blood work; however, thirteen episodes were treated with granulocyte colony-stimulating factor (GCSF). Four patients had associated fever and were hospitalized for intravenous antibiotics. In all patients, neutropenia resolved in less than one week and in no patient was RTX discontinued due to this effect.

**Conclusions:** A serious and under recognized adverse feature associated with RTX use appears to be LON and concomitant risk of infection. Fortunately, LON resolves with GCSF use and typically does not recur with continued RTX use. A CBC with differential should be checked in every RTX-treated ANCA vasculitis patient every two months and immediately upon onset of fever.

*Funding:* Clinical Revenue Support

## SA-PO689

**Hypogammaglobulinemia in ANCA Vasculitis Patients Undergoing Continuous B Cell Depletion Using Rituximab** William Franklin Pendergraft,[1-3] Andrew P. Murphy,[3] Karen A. Laliberte,[3] John Niles.[2,3] *[1]Joint Nephrology Fellowship Program, Massachusetts General Hospital (MGH) and Brigham and Women's Hospital, Boston, MA; [2]Div of Nephrology, MGH, Boston, MA; [3]Vasculitis and Glomerulonephritis Clinic, MGH, Boston, MA.*

**Background:** Anti-neutrophil cytoplasmic autoantibody (ANCA) vasculitis is a systemic autoimmune disease characterized by small vessel inflammation caused by pathogenic autoantibodies primarily directed against proteinase 3 (PR3) and/or myeloperoxidase (MPO). Rituximab is an FDA-approved humanized monoclonal antibody that depletes CD20-positive B cells. There is increasing evidence that chronic B cell depletion can lead to hypogammaglobulinemia. Our group currently manages over 400 patients with ANCA vasculitis, the majority of which receive rituximab every four to six months to maintain durable remission; thus, we sought to investigate the effect of prolonged rituximab exposure on immunoglobulin concentrations.

**Methods:** We conducted a systematic retrospective analysis of ANCA vasculitis patients from 2006-2013 who were treated with rituximab maintenance of remission therapy and who developed hypogammaglobulinemia.

**Results:** 215 patients treated by our group from April 2006 through June 2013 underwent continuous CD20-positive B cell depletion with rituximab. Hypogammaglobulinemia, defined as an IgG level of < 400 mg/dL, developed in only 17 patients. Rituximab was discontinued in nine of these patients; however, none of these patients relapsed. As expected, the other eight patients, where rituximab was continued, also remained in remission. Six were hospitalized for infection or fever; however, three of these were associated with fever in the setting of late-onset neutropenia. Two patients received intravenous immunoglobulin (IVIg) for recurrent bronchitis.

**Conclusions:** Hypogammaglobulinemia was a rare, late and modest complication that improved with rituximab cessation and/or IVIg administration. There does not appear to be any apparent predictor or association for patients who develop hypogammaglobulinemia; however, as the size of this cohort grows, the power to identify an association may increase.

## SA-PO690

**Clinical Characteristics and Renal Outcome in ANCA Associated Vasculitis with Renal Involvement: A 6-Year Retrospective Cohort Analysis** Ping Fu.[1] *[1]Dept of Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China; [2]Dept of Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China; [3]Dept of Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.*

**Background:** Renal vasculitis is common manifestation in antineutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis (AAV), and is an important cause ESRD. This study aimed to analyze clinical characteristics and renal outcome of patients with renal involvement of AAV.

**Methods:** Patients who presented to the West China Hospital with renal involvement of AVV were retrospectively recruited. All patients were followed up from 3 to 60 months. Diagnostic subgroups were granulomatosis with polyangiitis (GPA); microscopic polyangiitis (MPA); eosinophilic granulomatosis with polyangitis (EGPA) or renal-limited vasculitis (RLD). We recorded patient demographics, laboratory tests, complications, treatments.The primary end-point outcome was the combination of doubling of base line of serum creatinine, end stage renal disease (ESRD), or death.

**Results:** 147 patients were analyzed. There were 69 men and 78 women with age of 56.02 ±15.33. The duration was 4.88 ±6.63 months. 8.8%patients were categorized as having GPA, 85.0% as MPA, 5.4% as PICGN. ANCA serology identified cANCA in 10.2% patients and pANCA in 87.1% patients. The mean serum creatinine at initial of disease was 363.97 umol/L. 15.6% patients required hemodialysis at the beginning of the disease. 11(7.4%) patients who presented with a doubling of creatinine level, ESRD occurred in 30 patients (20.4%), of whom 2 (1.4%) died. Relapse occurred in 29 patients (19.7 %). Renal survival at 1 and 5 years were 85.0% and 72.8% respectively. Old age more than 60 years, initial high serum creatinine level, high CRP level and infectious complication were predictors of poor renal outcome.

**Conclusions:** Age, serum creatinine level were the independent predictor of patients' survival of AAV. Old age and serious infection affect mortality and renal outcome of ANCA-associated systemic vasculitis. To improve renal outcome, earlier diagnosis, controlling infectiou complication should be established.

## SA-PO691

**Validation Study of the New Histopathologic Classification of ANCA-Associated Glomerulonephritis** Taewoo Lee, A. Gasim, JulieAnne G. McGregor, Caroline J. Poulton, Susan L. Hogan, Ronald J. Falk, Patrick H. Nachman, J. Charles Jennette. *UNC Kidney Center, The Univ of North Carolina at Chapel Hill.*

**Background:** A new histopathologic classification consisting of four classes (focal, crescentic, mixed and sclerotic) was recently introduced to predict prognosis of ANCA-associated glomerulonephritis (ANCA-GN) (Berden et al, J Am Soc Nephrol 2010).We aimed to ascertain the prognostic value of the classification in a large inception cohort.

**Methods:** ANCA-GN patients with >1 year of follow-up were included and categorized according to the new classification. Long-term patient and renal survival was assessed using competing risk regression analysis and adjusting for clinical characteristics (demographics, ANCA type, ANCA phenotype, estimated GFR (eGFR), and treatment) and additional histopathologic variables including chronicity score (0-16 points, sum of interstitial fibrosis, tubular atrophy, glomerular and crescent sclerosis) and arteriosclerosis (0-4 points).

**Results:** 207 patients were included: median age 65 years (IQR 49-73), 45% female, median eGFR 8.2 ml/min/1.73m2 (5.6-13.8), 42% MPO-, 58% PR3-ANCA. Patients and renal outcomes per histopathological classification are summarized in the table.

| | Focal (n=22) | Crescentic (n=77) | Mixed (n=71) | Sclerotic (n=39) |
|---|---|---|---|---|
| Renal death | 4% | 21% | 21% | 49% |
| Patient death | 30% | 33% | 25% | 15% |

The new classification was not associated with the composite outcome of patient or renal survival (P= 0.098 in Log-rank test and P=0.921 in trend test). In multivariate analysis, eGFR <15 ml/min [Subdivision hazard ratio (SHR) 1.85 (95% CI 1.43-1.96)] and severe chronicity [SHR per unit increase 1.10 (1.01-1.19)] were risk factors for renal death. Use of cyclophosphamide [SHR 0.3 (0.13-0.69)] and eGFR ≥ 15 ml/min [SHR 0.38 (0.15-0.97)] were significantly associated with patient survival after adjustment for age, ANCA type, and the new classification.

**Conclusions:** The new histopathologic classification alone is insufficient in assessing prognosis in ANCA-GN. A classification scheme that incorporates measures of tubulo-interstitial damage may be of improved prognostic value.

## SA-PO692

**MPO-Positive Cells and Extracellular MPO Are Associated with Capillary Injury in Glomeruli in Lupus Nephritis** Soko Kawashima, Shinya Kaname, Yoshinori Komagata, Yoshihiro Arimura, Akira Yamada. *First Dept of Internal Medicine, Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan.*

**Background:** We have recently reported that in human MPO-ANCA-associated glomerulonephritis (GN), MPO exists along the glomerular capillary walls near infiltrated MPO-positive cells, suggesting that MPO release from neutrophils directly causes capillary injury (Clin Nephrol 2013). Here we investigated a possible role of MPO in the pathogenesis of glomerular capillary injury in patients with lupus nephritis, in which neutrophil infiltration and vascular necrosis are also frequently observed.

**Methods:** We analyzed 589 renal specimens obtained from 27 patients with lupus nephritis class IV. Glomerular infiltration of MPO-positive cells, deposition of extracellular MPO and endothelial cell injury were analyzed. Colocalization of MPO and CD34 deposition was also examined by immunofluorescence staining.

**Results:** The infiltration of MPO-positive cells and MPO deposition were observed in some glomeruli, especially in the glomeruli at an active injury phase with severe inflammatory cell infiltration, whereas MPO was rarely stained in sclerotic/fibrotic glomeruli with high chronicity. MPO deposition was mainly located in the glomerular capillary walls near the infiltrated MPO-positive cells. Interestingly, there were various degrees of MPO deposition along the capillary walls, and necrotic lesions were strongly associated with diffuse-type MPO deposition that covered more than 50% of the capillary loops, but was rarely associated with limited-type MPO deposition where only a small part of capillary walls was involved. Moreover, in some parts of necrotic lesions with MPO deposition phenomenon of neutrophil extracellular traps (NETs) was suggested to occur.

**Conclusions:** These results indicate that MPO deposition released from infiltrated MPO-positive cells, particularly diffusely distributed deposition along the glomerular capillary wall, may play important roles in the pathogenesis of lupus nephritis.

## SA-PO693

**Outcomes of Elderly Patients with ANCA-Associated Vasculitis Treated with Immunosuppressive Therapy** Parminder K. Judge, Richard Haynes, Edward J. Sharples. *Oxford Kidney Unit.*

**Background:** ANCA-associated vasculitis (AAV) is a common cause of acute kidney injury (AKI) in the elderly. Treatment requires immunosuppression (IS), which can have significant toxic effects. The aim of this study was to assess morbidity and mortality associated with immunosuppression in elderly patients with AAV.

**Methods:** A retrospective review of all patients presenting with AAV to a tertiary renal unit between 1990 and 2011 was conducted using the units' information database. 264 patients were reviewed and 32 who did not receive standard IS were excluded. 232 patients given induction therapy with prednisolone and cyclophosphamide (P&C) were studied.

**Results:** There were 146 (63%) males and 86 females (37%). 122 patients were PR3 positive and 110 were MPO positive. Mean creatinine at presentation was 528 µmol/L. Median duration of follow-up was 59 months. 76 patients had pulmonary involvement (18 severe). Older patients (aged >65) were significantly more likely to require dialysis at presentation (RR 1.66 [1.13-2.5]) and longer-term and were treated with lower total cyclophosphamide dose (mean 6.5g) than those <55 years (mean 10.5 g). Older patients were more likely to develop leukopaenia (RR 2.3 [1.7-3.3]) and infections in the first year (RR 2.4 [1.5-3.9]). After multivariable adjustment, age and dialysis at presentation were significant predictors of death (HR 1.07 [1.03-1.11, p=<0.001] and HR 2.2 [1.10-4.38, p=0.03] respectively).

**Conclusions:** Among patients treated with P&C, older age and dialysis-dependency were associated with worse survival. Older patients were also more likely to develop treatment-related complications despite lower cumulative doses. Morbidity and mortality associated with treatment must therefore be carefully balanced against that associated with the disease process itself.

## SA-PO694

**Laser Microdissection and Mass Spectrometry of ANCA-Negative Pauci-Immune Crescentic Glomerulonephritis Shows Accumulation of Components of the Alternative and Terminal Pathway of Complement** Sanjeev Sethi, Julie A. Vrana, Ladan Zand, Jason David Theis, Samih H. Nasr, Fernando C. Fervenza. *Mayo Clinic.*

**Background:** Pauci-immune crescentic glomerulonephritis (CRGN) is associated with positive-anti neutrophil cytoplasmic antibody (ANCA) titers in 80-90% of patients. The remaining patients are ANCA-negative CRGN. Recent studies have suggested a role for the alternative pathway of complement in the pathogenesis of ANCA-negative pauci-immune CRGN.

**Methods:** We identified 8 patients with ANCA-negative pauci-immune CRGN. Using laser microdissection, we dissected 2-4 non-scarred glomeruli/sample. Three samples were dissected for each case. For comparison, we identified 3 patients with ANCA-positive pauci-immune CRGN, one was proteinase 3 and two were myeloperoxidase positive. Peptides extracted from the microdissected tissue were subjected to liquid chromatography and mass spectrometry (MS). MS raw data files were queried using 3 different algorithms (Sequest, Mascot and X!Tandem), the results were combined and assigned peptide and protein probability scores in Scaffold. For each sample, a list of proteins with spectra numbers based on peptides identified by MS was generated.

**Results:** MS data showed high spectra numbers for C3 (14.75 ± 1.7) and moderate spectra numbers for C9 (6.3± 1.3) in glomeruli dissected from patients with ANCA-negative pauci-immune CRGN. On the other hand, MS showed low spectra numbers for C3 (4± 2) and no spectra numbers for C9 in ANCA positive pauci-immune CRGN. Importantly, C4B was absent in all cases of ANCA-negative pauci-immune CRGN. Spectra numbers of Ig- gamma-1 chain C region was detected in both ANCA positive (9 ± 5.2) and ANCA-negative (6.3 ± 1.3) pauci-immune CRGN. Both ANCA-negative and ANCA positive pauci-immune CRGN showed high spectra numbers for fibrinogen alpha chain, collagen alpha-2 and -1 (IV) chain.

**Conclusions:** Laser microdissection and MS studies indicate a role for the alternative and terminal pathway of complement in ANCA-negative pauci-immune CRGN. This is evidenced by the presence of large spectra numbers of C3 and moderate spectra numbers of C9 in glomeruli of ANCA-negative pauci-immune CRGN compared to ANCA-positive pauci-immune CRGN.

## SA-PO695

**Phase 2 Clinical Trial of CCX168, an Orally Administered C5aR Antagonist, in Patients with ANCA-Associated Renal Vasculitis (CLEAR)**
Annette Bruchfeld,[1] Matthias Schaier,[2] Lorraine Harper,[3] Michel Y. Jadoul,[4] Marten Segelmark,[5] Istvan Szombati,[6] Michael Venning,[7] Patrick Hamilton,[7] Christian Hugo,[8] Paul L.A. Van daele,[9] Ondrej Viklicky,[10] David R.W. Jayne,[11] Antonia Potarca,[12] Juan C. Jaen,[12] Thomas J. Schall,[12] Pirow Bekker.[12] *[1]Karolinska Institute, Sweden; [2]Univ Hosp Heidelberg, Germany; [3]Univ of Birmingham, United Kingdom; [4]Cliniques Saint-Luc, Belgium; [5]Linköping Univ, Sweden; [6]Budaclinic, Hungary; [7]Manchester Univ, United Kingdom; [8]Dresden Univ, Dresden, Germany; [9]Erasmus MC Center, Netherlands; [10]Instit of Clin and Exp Med, Czech Republic; [11]Univ of Cambridge, United Kingdom; [12]ChemoCentryx, Inc., Mountain View, CA.*

**Background:** CCX168 blocked C5a-induced neutrophil chemotaxis and CD11b expression in blood samples in Ph1. It markedly reduced glomerular crescent formation and necrosis, and proteinuria and hematuria in transgenic hC5aR mice with anti-MPO-induced GN.

**Methods:** This Ph2 trial tested whether CCX168 could substitute, at least partially, for CS. In Step 1, 12 pts were randomized 2:1 to 30 mg CCX168 BID + a reduced dose of prednisone (20mg/d) or placebo BID + a full dose of prednisone (60mg/d) for 12 wks. All patients received CYC 15 mg/kg IV up to 1.2g q2-3wk. If Step 1 were successful, in Step 2, 12 patients received the same treatments as Step 1, except the CCX168 group received no CS. Eligible patients had GPA, MPA, or renal limited vasculitis, were anti-PR3 or MPO+ and had active renal vasculitis. Primary objective: safety and tolerability. Secondary objectives: feasibility of reducing CS and effect of CCX168 on renal disease.

**Results:** Baseline characteristics are shown below.

| Baseline characteristic | Step 1 N=12 | Step 2 N=14 |
|---|---|---|
| Age | 59±14 | 54±15 |
| M/F | 6/6 | 9/5 |
| Newly diagnosed/Relapsed | 9/3 | 11/3 |
| Anti-MPO+/PR3+ | 7/6 | 7/7 |
| s-creat, µmol/L | 120±41 | 114±40 |

No SAEs related to CCX168 occurred in Steps 1 or 2. No rescue CS was required in Step 1 in the treatment period and two rescue events in Step 2 (treatment still blinded).

**Conclusions:** CCX168 shows promise in the treatment of ANCA-associated renal vasculitis.

## SA-PO696

**Endothelial Cell Injury Contributes to the Formation and Development of Extracapillary Lesions in Crescentic Glomerulonephritis**
Emiko Fujita,[1] Akira Shimizu,[2] Akiko Mii,[1] Megumi Fukui,[1] Shuichi Tsuruoka.[1] *[1]Dept of Nephrology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan; [2]Dept of Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

**Background:** Glomerulonephritis (GN) with extracapillary lesions is known to have a poor prognosis. However, the endothelial injury has not been elucidated. In the present study, we clarified the association of endothelial cell injury with the formation of extracapillary lesions and the development of crescentic GN.

**Methods:** Renal biopsy samples of crescentic GN including ANCA-related GN (n=30), lupus GN (n=30), and purpura GN (n=30) were diagnosed by pathologic studies. Endothelial cell injury was assessed electron microscopy and by immunostaining against CD34 that is expressed on all endothelial cells, and was characterized by the formation of extracapillary lesions and development of crescentic GN.

**Results:** In ANCA-related GN, lupus GN, and purpura GN, almost all active necrotizing glomerular lesions (n=36) began as focal and segmental leukocyte infiltration with loss of individual CD34+ endothelial cells. Subsequently, necrotizing lesions developed and were characterized by expansive loss of CD34+ cells together with exudation of fibrinoid materials (n=36), rupture of basement membrane (n=10), and crescent formation (n=83). By electron microscopy, capillary destruction was evident with fibrin exudation. In the chronic stage of crescentic GN (n=12), glomerular sclerosis developed without the appearance of glomerular capillaries. Furthermore, the remaining glomerular lobes without crescents had marked collapsing tufts with loss of endothelial cells and the development of glomerular sclerosis.

**Conclusions:** In crescentic GN, loss of glomerular capillaries with endothelial cell injury is strongly associated with the formation of necrotizing and extracapillary lesions. Furthermore, impaired capillary regeneration and collapse of remaining capillaries with loss of endothelial cells contribute to the development of glomerular sclerosis. The endothelial cell injury then induces the formation and development of extracapillary lesions in crescentic GN.

## SA-PO697

**Duration of Hematuria in ANCA Associated Glomerulonephritis (ANCA-GN): Does It Matter?**
Teresa K. Chen, Pradeep Manoharan, Duvuru Geetha. *Medicine, Johns Hopkins Univ.*

**Background:** Hematuria is considered a marker of active renal disease in ANCA-GN, both in activity tools for clinical trials and in routine clinical practice. Induction immunosuppression is often continued until hematuria has resolved. This study aims to describe predictors of hematuria resolution in ANCA-GN and whether hematuria duration is associated with estimated GFR (eGFR) at 1 year.

**Methods:** We conducted a retrospective study of 55 patients with biopsy-proven ANCA-GN. Proteinuria was defined as ≥1+ on dipstick and hematuria as >5 rbc/hpf. GFR was estimated using MDRD. The primary exposure was duration of hematuria, defined as <90 vs. ≥ 90 days post renal biopsy. The primary outcome was eGFR at 1 year. We used both linear and logistic regression, adjusting for age, gender, ANCA type, baseline eGFR, and proteinuria. Additional analyses were conducted to identify clinical and laboratory predictors of hematuria resolution.

**Results:** Mean age at diagnosis was 57 yrs (53% male, 80% Caucasian, 38% c-ANCA, 45% p-ANCA). At entry, all patients had hematuria, 94% had proteinuria, and mean (SD) serum creatinine was 3.1 (2.3) mg/dL. The majority (93%) were treated with cyclophosphamide or rituximab and steroids. Mean time to hematuria resolution was 91 (77) days, and 34 (62%) patients had hematuria resolution prior to 90 days. Older age and lower baseline eGFR were associated with lower eGFR at 1 year (p=0.03 and p<0.001, respectively). Hematuria resolution (<90 vs. ≥90 days) was not predictive of eGFR at 1 year (p=0.89). In sensitivity analyses, age, gender, baseline eGFR, proteinuria, and ANCA type were not associated with timing of hematuria resolution.

Table 1: Predictors of eGFR at 1 year.

| Baseline variables | Change in eGFR at 1 year | 95% CI | p-value |
|---|---|---|---|
| Hematuria ≥90 days versus <90 days | -0.87 | (-13.93, 12.19) | 0.89 |
| Age, per 10 years older | -4.78 | (-8.99, -0.58) | 0.03 |
| Female | -8.56 | (-21.44, 4.32) | 0.19 |
| ANCA type | | | |
| Negative | REF | REF | REF |
| p-ANCA | 2.08 | (-18.53, 22.68) | 0.84 |
| c-ANCA | -1.54 | (-19.00, 15.91) | 0.86 |
| Baseline eGFR, per 10 ml/min/1.73 $m^2$ lower | -7.55 | (-10.78, -4.31) | <0.001 |
| Proteinuria ≥1+ versus <1+ on dipstick | 10.08 | (-15.90, 36.05) | 0.44 |

**Conclusions:** Duration of hematuria does not predict eGFR at 1 year in ANCA-GN. We propose that among patients otherwise in clinical remission, the persistence of hematuria should not delay transition from induction to maintenance immunosuppression.

## SA-PO698

**Increased Risk for Antineutrophil Cytoplasmic Antibodies Associated Renal Vasculitis (AAV), Specifically Antimyeloperoxidase (P-ANCA) for Hispanic Patients (HISP)**
Salwa Rhazouani,[1] George N. Coritsidis,[1] Aleef M. Rahman.[2] *[1]Medicine/Nephrology, Elmhurst Hospital Center, Elmhurst, NY; [2]Stony Brook Univ Medical Center, Stony Brook, NY.*

**Background:** AAV is an uncommon diagnosis with most clinical observations arising from Europe, Japan and the United States. Recent data has suggested an increase in antiproteinase 3 associated (C-ANCA) vasculitis in Mexicans. Since data from Central & South America is limited, a retrospective analysis of biopsies from our institution that serves a large immigrant Hispanic population was conducted.

**Methods:** All renal biopsies (1999-2012) were analyzed for: age, gender, proteinuria(g/d), MDRD glomerular filtration rate (eGFR,ml/min/1.73 m2), renal outcomes and histology at presentation. Data presented as average ± standard error of mean. Multivariate logistic regression models were used to determine odds.

**Results:** Of 281 biopsies reviewed: AAV represented 12% (34/281) of the total; 21.9% of all HISP biopsies (25/114) and 5.4% of all non-Hispanic biopsies (9/167). AAV was the second most common glomerulonephritis after SLE (21.9 % vs. 23.7%) in HISP. HISP presented at 53.1± 3.4 years old, with proteinuria and eGFR of 3.4 ± 0.5 and 16.5 ± 3.2, respectively. 28% of HISP (7/25) had hemoptysis. Among 25 HISP with AAV, 56% (n=14/25) had P-ANCA and 40% (10/25) C-ANCA. Of all HISP AAV, 61% were South American and only 15% Mexican. 70% of South Americans had P-ANCA. 44% of HISP-AAV are dialysis dependent.

*P-Value<0.05, **P-Value<0.005

| Non-Adjusted Model | Characteristic | AAV OR, 95% CI | C-ANCA OR, 95%CI | P-ANCA OR, 95% CI |
|---|---|---|---|---|
| | Hispanic | 4.80 [2.14, 10.75]** | 5.12 [1.37, 19.07]* | 7.46 [2.093, 26.63]** |
| Adjusted Model | Characteristic | AAV OR, 95% CI | C-ANCA OR, 95% CI | P-ANCA OR, 95% CI |
| | Hispanic (ref: non-Hispanic) | 5.61 [2.37, 13.25]** | 5.38 [1.41, 20.49]* | 8.521 [2.266, 32.04]** |
| | Age | 1.06 [1.035, 1.098]** | 1.04 [0.999, 1.086] | 1.081 [1.038, 1.125]* |
| | Gender ( ref:females) | 2.017 [0.907, 4.48] | 3.36[ 0.975, 11.58] | 0.992 [0.334, 2.94] |

**Conclusions:** AAV was the second most common glomerulonephritis in HISP. The odds of having AAV is 5.6 times higher for HISP than non-Hispanics when adjusted for age and gender.The odds of having P-ANCA is 8.5 times higher for HISP than non-Hispanics.

## SA-PO699

**Rituximab for Remission Induction of Recurrent ANCA Associated Glomerulonephritis Post Kidney Transplant**
Duvuru Geetha, Christine Adefuin Murakami, Pradeep Manoharan, Naima Carter-Monroe. *Johns Hopkins Univ, Baltimore, MD.*

**Background:** Kidney transplantation (KTX) is the treatment of choice for patients with end stage renal disease (ESRD) due ANCA associated vasculitis (AAV). Relapses of AAV occur after KTX and may adversely affect allograft survival. Combined therapy with cyclophosphamide (CYC) and glucocorticoids has been the cornerstone of treatment for these relapses. B cells are implicated in the pathogenesis of AAV. Rituximab (RTX),

a B cell depleting monoclonal antibody is approved for remission induction in AAV. We report the clinical presentation and outcomes of 5 KTX recipients who were treated for recurrent glomerulonephritis (GN) with RTX.

**Methods:** We identified 37 patients who underwent KTX for ESRD due to AAV between 1999 and 2012. Seven patients experienced recurrent GN and 5 were treated with RTX. We collected demographics, details of immunosuppression, clinical features at relapse and outcomes following RTX use in these patients.

**Results:** The median age at the time of KTX was 26 years (4 Caucasians, 3 females). The disease phenotype was microscopic polyangiitis in 3 and granulomatosis with polyangiitis in 2 patients (p-ANCA=3, c-ANCA=2). All patients were in remission with 4 being ANCA positive at time of KTX, 3 received indcution therapy and all were maintained on steroids, mycophenolate mofetil and tacrolimus. Biopsy proven recurrent GN occurred at a median of 26 months. All patients had rise in serum creatinine and hematuria and were ANCA positive at relapse. RTX was used with steroids in all 5 patients. Four patients achieved disease remission after RTX, the fifth patient was refractory to RTX and CYC. All patients showed evidence of B cell depletion and 2 patients were ANCA negative post RTX. Follow up biopsies in 3 patients showed resolution of active GN in 2 patients and persistent active GN in 1 patient. At the time of last follow up, 2 patients had reached ESRD, one to refractory vasculitis and one to rejection and recurrent GN due to medication noncompliance.

**Conclusions:** RTX is an alternative to CYC for remission induction in recurrent AAV associated GN in KTX patients.

## SA-PO700

**ANCA-Associated Renal Vasculitis: Insights from an Observational Cohort Study** Mark N. Canney, Eoin O Sullivan, Philip Hugh Bredin, Michael Clarkson. *Dept of Renal Medicine, Cork Univ Hospital and Univ College Cork, Ireland.*

**Background:** ANCA-associated vasculitis (AAV) is a life threatening illness requiring robust immunosuppression that carries attendant risks of leucopenia and sepsis. Our unit is the sole tertiary referral centre for AAV in Southwest Ireland (population 650,000). Here we report the incidence and outcomes of renal AAV in an Irish population. Furthermore we explore the role of renal biopsy and IV vs oral cyclophosphamide (CYC) in the management of this condition.

**Methods:** The Cork Renal Vasculitis Registry captures all incident AAV patients in Southwest Ireland with clinical evidence of renal involvement. The period of interest was 2005-2012. Data was obtained from laboratory results and patient records, and analysed using SPSS v16.0.

**Results:** 73 patients met the inclusion criteria giving an incidence of 15.4 cases per million patient years. The majority were male (59%), anti-MPO ANCA positive (64%) and received CYC as induction therapy (68%). One year patient survival was 88%. Patients who received oral CYC tended to develop more severe leucopenia than those who received IV CYC (p=0.08). Patients who did not undergo renal biopsy had a higher creatinine at baseline than those biopsied (387 vs 279µmol/L, p=0.065). They received more plasma exchange (47% vs 10%, p<0.001) and pulse methylprednisolone (72% vs 40%, p=0.007) as induction therapy. Not having a renal biopsy associated with a higher risk of death and ESKD even after adjusting for confounding variables such as age, creatinine at presentation and initial BVAS (p=0.03). Intriguingly not having a biopsy associated with higher grade leucopenia (p<0.001) suggesting the potential of relative over-immunosuppression in more critically ill patients at presentation.

**Conclusions:** Induction with oral CYC may result in more severe leucopenia than IV CYC, in keeping with suggestions from clinical trial data. In severe renal AAV, not undergoing a renal biopsy associated strongly with more intense induction immunosuppression, higher grade leucopenia and higher risk of death/ESKD. Inability to perform a renal biopsy at presentation may be an important signal identifying patients at highest risk of adverse outcomes.

## SA-PO701

**In Sweden, ANCA Associated Nephritis Is a More Common and a More Severe Disease as Compared to Lupus Nephritis** Marten Segelmark,[1] Maria Weiner,[1] Christopher Sjöwall,[2] Ola Nived,[3] Per Eriksson,[2] Aladdin Mohammad.[3] *[1]Nephrology, Linköping Univ, Linköping, Sweden; [2]Rheumatology, Linköping Univ, Linköping, Sweden; [3]Rheumatology, Lund Univ, Lund, Sweden.*

**Background:** The aim of this study was to compare incidence rates and outcome between lupus nephritis (LN) and anti-neutrophil cytoplasm antibody (ANCA) associated nephritis (AAN) during a 12 year-period in two geographically defined populations in south Sweden.

**Methods:** In health care districts surrounding the University Hospital of Lund (population 237 000) and in districts surrounding the University Hospital of Linköping (population 417 000) all patients with biopsy proven LN and AAN during the period 1997 to 2008 were included in the study if they: (i) resided within the study areas at the time of onset of nephritis, (ii) had a clinical diagnosis of either SLE or AAV and (iii) experienced a first flare of biopsy-proven nephritis during the study period.

**Results:** During the study period 83 patients (Lund 44+ Linköping 39) with biopsy proven AAN were identified as compared to 27 patients with LN (13+14).

| Disease | n | Sex (M/F) | Age at diagnosis median (range) | p-creatinine (mg/dL) | Deaths | ESRD |
|---|---|---|---|---|---|---|
| AAN | 83 | 36/47 | 68 (15-88) | 2.82 | 36 | 19 |
| LN | 27 | 22/5 | 36 (18-72) | 0.88 | 2 | 1 |

The combined annual incidence rate per million inhabitants was estimated to be 10.5 (95% CI 8.2-12.7) for AAN and 3.4 (95% CI 2.1-4.7) for LN. Patients were followed until January, 2013. During the follow-up time 38 patients died (AAN 36, LN 2; p=0.033), and 20 patients developed end-stage renal disease (AAN 19, LN 1; p=0.021).

**Conclusions:** In Sweden AAN outnumber LN almost three to one, and outcome is considerably worse. In our country SLE is often diagnosed and treated early which in many cases prevent the development of severe nephritis, while AAN is often diagnosed at later stages leading to severe consequences.

*Funding:* Private Foundation Support, Government Support - Non-U.S.

## SA-PO702

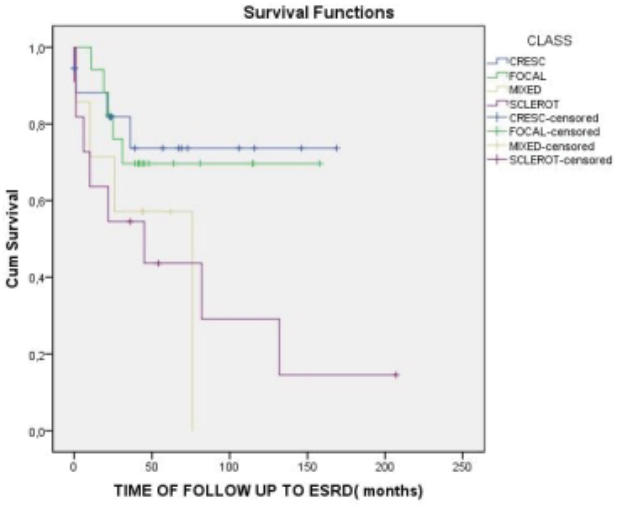
**Reclassification of ANCA-Associated Vasculitis (AAV) from a Nephrology Department According to a New Histopathologic Classification** Jesús P. Marin, Juan R. Gomez-Martino, Ines Castellano, Clarencio Javier Cebrian Andrada, Silvia Gonzalez S, Maria C. Jimenez, Sandra Gallego, Vanesa Garcia-Bernalt, Pedro J. Labrador. *Nephrology Div, Hospital San Pedro de Alcantara, Caceres, Spain.*

**Background:** AAV are the main cause of rapidly progressive glomerulonephritis. The aim of our study is to classify our patients with AAV diagnosed by renal biopsy according to histopathologic classification published by Berden et al in the JASN in 2010.

**Methods:** This is a retrospective descriptive study. From renal biopsies made during the last 20 years we analized AAV, describing: age, sex and histological category. Patients were classified in four classes:"focal" (≥ 50 % normal glomeruli),"crescentic"(≥ 50% glomeruli with cellular crescents)," mixed" (< 50 % normal, < 50 % crescentic, < 50 % globally sclerotic glomeruli), and "sclerotic" (≥ 50 % globally sclerotic glomeruli), following clinical evolution.

**Results:** From 629 biopsies, 67 (10,6%) corresponded to AAV. Patients had a mean age of 62,5 ± 12,6 years. Men/women 34:33. Histopathologic classification and evolution are represented in Table 1 and renal survival in Figure 1.

| CATEGORY | % | RRT (%) *p<0,05 | NO RRT (%) | EXITUS |
|---|---|---|---|---|
| **FOCAL(21)** | 31,3 % | 6(28,6%)* | 15(71,4 %) | 5(23,8%) |
| **CRESCENTIC(23)** | 34,4 % | 8(34,8%)* | 15(65,2%) | 5(21,74%) |
| **MIXED(8)** | 11,9 % | 5(62,5%)* | 3(37,5%) | 2(25%) |
| **SCLEROTIC(15)** | 22,4 % | 11(73,3%)* | 4(26,7%) | 1(6,67%) |



**Conclusions:** Following this classification, most of patients belong to crescentic class, followed by focal, sclerotic and mixed class. Patients of sclerotic class had the highest percentage of starting RRT, and focal class the least percentage. Highest mortality corresponded to mixed class. The severity of initial damage can predict evolution and renal survival.

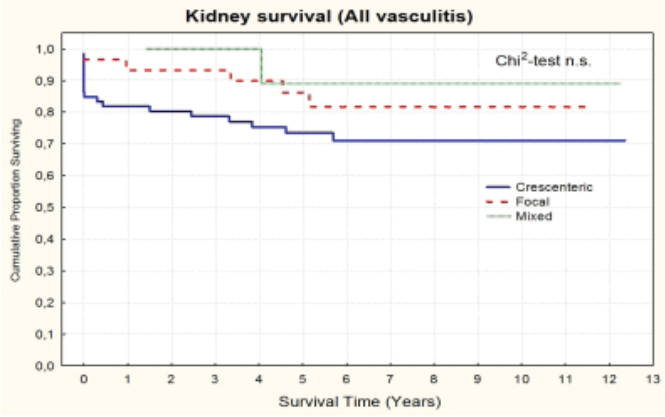
## SA-PO703

**Impact of Renal Histological Classification on Long Term Renal Outcome in ANCA Associated Vasculitis** Wladimir M. Szpirt,[1] Elizabeth Krarup,[2] Martin Egfjord.[1] *[1]Nephrology, Rigshospitalet; [2]Nephrology, Herlev, Copenhagen, Denmark.*

**Background:** The four histological subclasses in renal biopses of patients with ANCA associated vasculitis (AAV) have been proposed and shown to have an impact on renal outcome.

**Methods:** A prospective cohort study of all AAV pts. referred to our centre between 2000-2010 was performed. All pts. had AAV based on positive ANCA and a compatible clinical syndrome. 132 pts. were admitted and 118 followed for a mean of 5.7 years (range 0.2-12.3; 676 patient years) and 116 were kidney biopsed. 57% were male, 47% were MPO-ANC A positive. 36% had high creatinine >500. 40% were aged >65. 105 pts. were Plasma Exchange(PLEX)-d (mean 7 (5-11)). and the use was decided on severity of renal biopsy and ANCA titres. Immunsuppression consisted of prednisolone 1 mg/kg/day and a low dose of daily oral Cyclophosphamide (100 mg/day in pts. <65 years and 50 mg/day in pts. >65). AZA/MMF was given for maintenance of remission.

**Results:** The renal histological subclasses were classified into focal(≥50% normal glomeruli, n=30), mixed(<50% crescents and < 50% sclerotic, n=12), crescentic (>50% crescents, n=66) and sclerotic(>50% sclerosis, n=5 - not shown). 6 biopsies were inconclusive due to few glomeruli. Furthermore interstitial fibrosis was scored and 75 biopses were fibrosis free whether 41 had fibrotic changes. No significant differences were found between the classes, however at 5 years the best survival was found for mixed (89%), followed by focal (87%) and crescentic (73%) subclass, whether 3 out of 5 sclerotic kidneys were still functioning. Comparison of plus/minus fibrosis showed 5 years renal survival of 81% for non fibrotic kidneys compared to 72% with fibrosis (n.s.).



**Conclusions:** Only few renal biopses showed chronic sclerotic picture and the biopsy findings including interstital fibrosis were correlated to long term renal outcome, however the differences were not significant.

## SA-PO704

**Evaluating Lupus Nephritis with Serial Kidney Biopsies** Anthony Alvarado,[1] Ana Malvar,[2] Valeria Gabriela Alberton,[3] Bruno Jorge Lococo,[2] Maria Fernanda Toniolo,[3] Brad H. Rovin.[1] *[1]Ohio State Univ Wexner Medical Center, Columbus, OH; [2]Hospital Fernandez, Buenos Aires, Argentina; [3]C.D. Pathologico, Buenos Aires, Argentina.*

**Background:** The effectiveness of lupus nephritis (LN) therapy is determined mainly by improvement in proteinuria and renal function. The histologic response to therapy is generally not evaluated because serial kidney biopsies are not usually obtained in patients who have improved. Also, stopping therapy in responders is a clinical decision, and renal pathology is not taken into account. In this study serial renal biopsies were correlated with clinical response to determine the concordance of clinical and histologic findings.

**Methods:** Biopsies were done in 25 Hispanic LN patients at LN diagnosis (BX1), after 6 months of induction therapy with either MMF (2.4g/d) or cyclophosphamide (1g/mo X6) (BX2), and during maintenance therapy with either MMF or azathioprine, after at least 42 months of total treatment, and 24 months of clinical inactivity (BX3). Biopsies were read by a single renal pathologist (VA) and NIH activity (AI) and chronicity (CI) indices were calculated. Serum creatinine (SCr) and proteinuria (PR) were measured serially.

**Results:** Between BX1 and BX3, SCr and PR improved significantly (1.0±0.4 vs 0.8±0.3 mg/dl and 3.3±2.1 vs 0.3±0.2 g/d respectively, P<0.001). From BX1 to BX3 AI declined (9±4 vs 1.9±1.7, P<0.001) and CI increased (2.8±1.4 vs 4.3±1.6, P<0.01). However in individual patients who were complete responders (n=16, SCr normal; PR<0.5g/d) only 6 had an AI of 0-1 at BX3, while 8 had an AI≥3 at BX3 (range 3-5). Multivariate modeling showed that improvement in AI at BX3 correlated with cyclophosphamide induction plus the decline in SCr between BX1 and BX2, or cyclophosphamide induction plus the increase in complement component C4 between BX1 and BX3.

**Conclusions:** These data demonstrate discordance between clinical and histologic responses in LN patients on immunosuppressive therapy for more than 3 years, with 50% of complete responders still having active histologic lesions. The implications of this continued low-level activity for discontinuation of therapy remains to be determined.

*Funding:* Other NIH Support - National Center for Advancing Translational Sciences

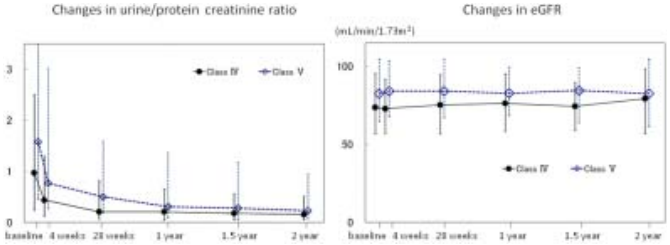
## SA-PO705

**Two-Year Maintenance Therapy with Tacrolimus for Class IV and V Lupus Nephritis Patients, Sub-Analysis of Post-Marketing Surveillance in Japan (TRUST Study)** Hirofumi Makino,[1] Naoko Wakasugi,[2] Tsutomu Takeuchi.[3] *[1]Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan; [2]Astellas Pharma Inc., Japan; [3]Keio Univ School of Madicine, Japan.*

**Background:** Tacrolimus (TAC) is an immunosuppressive macrolide that blocks T cell activation, and it is widely administered following organ transplantation. Recently some small randomized controlled trials have shown that TAC is an effective maintenance treatment for lupus nephritis (LN), and a small open-label trial showed that TAC is effective in class V LN. However, in any trials, the sample sizes were small and the follow-up period was not sufficiently long, and the safety and efficacy with class IV LN has not been clear enough.

**Methods:** Post-marketing Surveillance has been conducted in Japan. The design was an open-label, non-comparative, non-interventional observational study. Patients were registered centrally between 2007 and 2010, and we have conducted an interim analysis included all the registered 1375 patients. To clarify the safety and efficacy of TAC for class IV and V LN, the sub-analysis was performed.

**Results:** Of 1375 patients, we studied the 214 patients with biopsy-proven Class IV and 159 patients with Class V. There was no difference in the safety by class. The patients with Class V had higher urine protein/creatinine ratio(P/C ratio) with higher e-GFR at baseline, but the improvement of P/C ratio two years after TAC treatment were almost equivalent, and the eGFR was maintained in both classes.



**Conclusions:** Sub-analysis of data from TRUST showed that 2 years TAC treatment was a safe and effective treatment in both Class IV and V LN. It seemed to take a longer time to complete remission in Class V compared to Class IV, we found that 2 years TAC treatment achieved the maintenance of remission in both classes, and the renal functions were maintained similarly in both classes.

*Funding:* Pharmaceutical Company Support - Astellas Pharma Inc.

## SA-PO706

**The Achilles Heel of Lupus Nephritis Treatment – Identifying Non Adherence Using Hydroxychloroquine Blood Levels** Suceena Alexander, Gary Chusney, Vivienne D. Chusney, Janet Lee, Tom Cairns, Liz Lightstone. *Dept of Renal Medicine and Leslie Brent Laboratory, Imperial College Kidney and Transplant Institute, London, United Kingdom.*

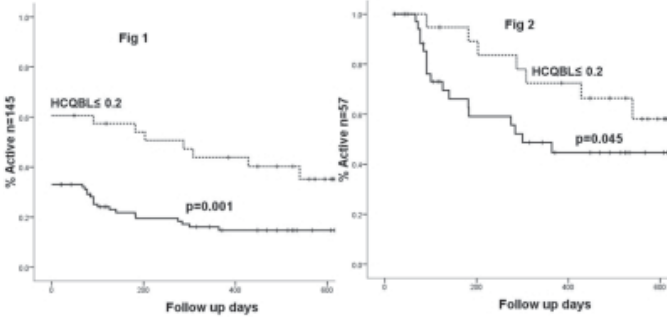
**Background:** Non adherence (NA) to lupus nephritis (LN) treatment (Rx) is the most important factor for non remission (NR) or renal relapses (RR). Hydroxychloroquine (HCQ) has very long half life, so low levels represent NA. In this first report in LN, we examined NA as defined by HCQ blood levels (HCQBL) ≤0.2ng/L and its correlation with clinical outcomes.

**Methods:** 145 patients (pts) with WHO class III, IV or V LN had HCQBLs measured during Rx. Complete remission (CR) was defined as protein creatinine ratio (PCR) <50mg/mmol and normal serum creatinine (SCr) or ±15% of baseline. RR was defined as >30% increase in PCR or SCr requiring renal biopsy or change in Rx.

**Results:** Comparison of NA and adherent pts at HCQBL testing (table).

| | HCQ≤0.2(N=33) | HCQ>0.2(N=112) |
|---|---|---|
| Gender M:F | 4:29 | 19:93 |
| Age(yrs) | 39.2±13.1 | 39.9±13.7 |
| Indian & SE Asians% | 54.5 | 41.1 |
| Blacks% | 24.2 | 28.6 |
| Class V% | 30.3 | 29.5 |
| Duration of LN(yrs) | 6.1±5.1 | 7.6±8.8 |
| Duration of HCQ Rx(yrs) | 3.1±3.1 | 4.1±4.4 |

All variables were comparable. Mean HCQ dose was 5.4±1.8 mg/kg/day. NA was present in 33 pts (22.8%). NA pts had significantly lower CR (39.4% vs. 66.1%, p=0.006) at testing and after median follow up of 16 mts (60.6% vs. 82.1%, p=0.012)(Fig1).



Time to CR was significantly longer in NA pts with disease activity at testing (p=0.045) (Fig2). Proportion of pts with RR was 11.1% at 12 mts and did not differ between groups.

**Conclusions:** These data demonstrate that >20% of pts are NA for HCQ and this is associated with poorer outcomes. Key questions are whether NA with HCQ reflects more generalized NA and whether HCQ levels can be used prospectively to improve adherence and outcomes.

## SA-PO707

**Soluble Forms of Urine Intercellular Adhesion Molecule 1 (ICAM-1) and Vascular Cell Adhesion Molecule 1 (VCAM-1) Are High-Sensitivity Biomarkers for Lupus Nephritis Flare** Daniel J. Birmingham,[1] George Sigal,[2] Nicole Marie Reyes,[1] Pankaj Oberoi,[2] Brad H. Rovin,[1] Lee A. Hebert.[1] *[1]The Ohio State Univ Medical Center, Columbus, OH; [2]Meso Scale Discovery, Rockville, MD.*

**Background:** Identifying biomarkers of lupus nephritis (LN) flare would help elucidate LN flare pathogenesis, and could lead to forecasters of impending flare to allow earlier treatment. Cross-sectional studies of urine samples have identified a number of candidates. However, little has been done to rigorously test how these candidate biomarkers temporally change relative to LN flare onset.

**Methods:** The present study sought to fill this gap by testing 18 different candidate biomarkers of LN or acute kidney injury in serial bimonthly urine samples leading up to flare. The samples were from the Ohio SLE Study (OSS), a prospective longitudinal study of recurrently active lupus patients. Soluble biomarker levels, normalized to urine creatinine levels, were determined from 24-hour OSS urine samples collected at 10, 8, 6, 4, and 2 months prior to, and at, LN flare (n=16).

**Results:** Using a mixed-effects stepwise regression model, incorporating repeated measures ANOVA, and accounting for other covariates such as WHO classification, flare severity, age, race, C3, and use of medications, 9 of the 18 biomarkers were found to be significantly increased at the time of LN flare. The most sensitive of these were sICAM-1 and sVCAM-1 (both $P < 0.0001$), which increased by at least 25% at LN flare in 15/16 and 14/16 LN flares respectively. Both sICAM-1 and sVCAM-1 were also significantly increased at 2 months prior to LN flare. The next most sensitive biomarker was complement C5a ($P = 0.0002$), which increased by at least 25% at LN flare in 9/16 LN flares. Notable biomarker candidates that did not change relative to LN flare included neutrophil gelatinase-associated lipocalin, beta-2-microglobulin, vascular endothelial growth factor, osteopontin, and cystatin C.

**Conclusions:** Increases in urine levels of sICAM-1 and sVCAM-1 occur prior to LN flare and identify LN flare with high sensitivity, suggesting that enhanced leukocyte adhesion is a key factor in the pathogenesis of LN flare.

*Funding:* NIDDK Support, Other NIH Support - PO1 DK55546, UL1 RR025755

## SA-PO708

**Short Term Outcome of Induction Therapy in Pediatric Patients with Proliferative Lupus Nephritis** Murty Adabala,[1] Rudolph P. Valentini,[1] Rossana Baracco,[1] Tej K. Mattoo.[1] *[1]Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI; [2]Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI; [3]Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI; [4]Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI.*

**Background:** Lupus Nephritis (LN) & its treatment are associated with morbidity & mortality.The objective of this study was to evaluate the clinical outcome at 6 months following induction therapy in pediatric patients with proliferative LN.

**Methods:** Retrospective chart review (23 patints) of LN patients with WHO class IV & severe class III followed at vasculitis clinic (2004-2011). All patients received the induction treatment with pulse Methylprednisolone followed by daily prednisone & monthly cyclophosphamide for 6 moths. We reviewed the clinical presentation, laboratory parameters, renal histology & correlated these variables with the clinical outcome at six months.

**Results:** African Americans 10 (44%) & females 14 (61%). The mean age at diagnosis of LN was 13.8 y. At presentation 19 (82%) had WHO class IV LN, 15 (65%) had nephrotic syndrome, 19 (82%) had azotemia, 17 (74%) had hypertension. At six months 13 (57%) patients had complete remission, 3 (13%) progressed to end stage renal disease (ESRD) & 7 (30%) had partial remission. Rapidly progressive glomerulonephritis (RPGN) & severe activity (activity score of 15/24 and >) on renal biopsy at presentation were associated with progression to ESRD ($p<0.05$).

| Outcome<br>Variables at presentation | Complete remission ( n=13) | Partial remission (n=7) | End stage renal disease (n=3) |
|---|---|---|---|
| RPGN | 0 | 4 | 3 |
| Mean eGFR ( ml/min/1.73m$^2$) | 71 | 39 | 25 |
| Mean Serum albumin (gm/dl) | 2.5 | 1.9 | 2.1 |
| Activity Index (> 15/24) | 0 | 0 | 3 |

Logistics regression analysis identified serum albumin < 2 gm/dl and estimated glomerular filtration rate (eGFR) < 30 ml/min/1.73m$^2$ at presentations as predictors of poorer outcome with partial response or progression to ESRD.

**Conclusions:** Patients with proliferative LN with hypoalbuminemia (serum albumin <2 gm/dl) and eGFR (< 30ml/min/1.73m$^2$)at presentation have a lower probability of attaining complete remission at 6 months with current induction treatment.

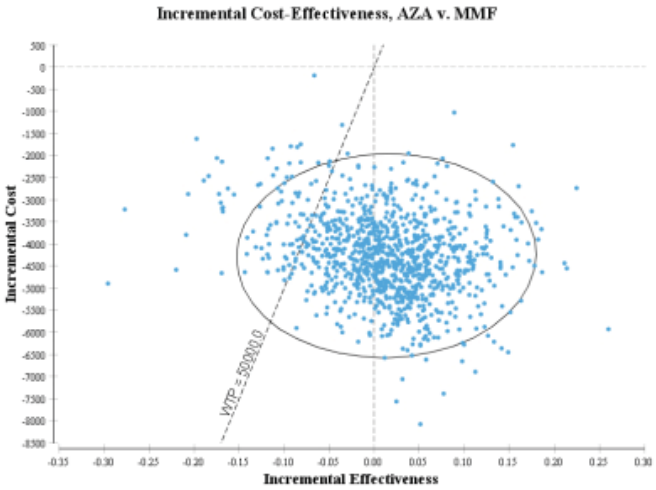
## SA-PO709

**The Cost-Effectiveness of Azathioprine versus Mycophenolate Mofetil as Maintenance Therapy for Proliferative Lupus Nephritis** Robert Nee, Ian Matthew Rivera, Christina M. Yuan, Dustin J. Little, Kevin C. Abbott. *Nephrology, Walter Reed National Military Medical Center, Bethesda, MD.*

**Background:** Clinical practice guidelines recommend that after induction therapy, patients with Class III and Class IV lupus nephritis (LN) receive maintenance therapy with azathioprine (AZA) or mycophenolate mofetil (MMF). However, the cost-effectiveness of these two treatment strategies has not been reported.

**Methods:** Using a third-party payer perspective, we constructed a Markov model with a 3-year time horizon to compare the cost-utility of generic formulations of AZA and MMF as maintenance therapy. We used individual-level simulations to account for patient age variability and probabilistic sensitivity analysis (PSA) to account for parameter uncertainty. We factored in drug adverse events and rescue therapy for LN relapse on either AZA or MMF. Probabilities, utility and disutility weights were based upon published studies, while costs of medications and health services were drawn from public sources. Model outcomes were costs, quality-adjusted life-years (QALY), incremental cost-effectiveness ratios (ICER) and net monetary benefit.

**Results:** Compared with AZA strategy, the ICER for MMF was $214,856/QALY gained. One-way sensitivity analysis showed that MMF is the favored strategy only if its yearly cost was less than $886, at a willingness-to-pay (WTP) $50,000/QALY. Results of PSA demonstrated that the probability that AZA was cost-effective compared to MMF was 90.9% at WTP $50,000/QALY.



**Conclusions:** Our state-transition model suggests that an AZA-based strategy is more cost-effective than MMF as maintenance therapy over a 3-year timeframe for proliferative LN. "*The views expressed in this abstract are those of the authors and do not necessarily reflect the official policy of the Department of the Army, the Department of the Navy, the Department of Defense, or the US government.*"

## SA-PO710

**Podocyte Lesions Involved in Lupus Nephritis Based on the 2003 ISN/RPS System** Yan Wang, Di Song, Feng Yu, Suxia Wang, Minghui Zhao, Youkang Zhang. *Renal Div, Dept of Medicine, Peking Univ First Hospital; Institute of Nephrology, Peking Univ.*

**Background:** The podocyte lesions in lupus nephritis is still an intriguing controversy in ISN/RPS system. We assess the associations between podocyte lesions and clinico-pathological features in a large cohort of lupus nephritis patients.

**Methods:** Clinico-pathological data of 202 patients with renal biopsy proven lupus nephritis were reviewed. Morphometric analysis of podocyte foot process width(FPW) was performed to access the degree of podocyte injury, its correlations with clinical and pathological parameters were further analyzed.

**Results:** The podocyte foot processes in patients with lupus nephritis effaced variously, reflected by the FPW ranged from 626.16nm to 8253.78nm(median: 1397.39nm). 13 patients with lupus podocytopathy, including 9 with minimal change glomerulopathy and 4 with focal and segmental glomerulosclerosis pattern, met the histological criteria of lupus podocytopathy with a FPW of 2026nm±1793nm. The degree of foot process effacement was positively correlated with proteinuria($r=0.509$, $P<0.001$). The FPW of 1240nm can distinguish the nephrotic syndrome with sensitivity(81.5%) and specificity(62.7%). The degree of foot process effacement aggravated significantly from class I to class V, and patients with combined lupus nephritis presented with the severest podocyte lesions. The complete remission rate was significantly higher and the long-term renal outcome was better in group with calcineurin inhibitors than that with other regimens in patients with FPW higher than 1240 nm.

**Conclusions:** Podocyte damage was common in lupus nephritis. Lupus podocytopathy acted as an extreme form of lupus podocyte lesions. Podocyte injury mediated by immune complex deposits existed in different types of lupus nephritis, notably in class V and combined types. Hence, whether a subclass of lupus podocyte injury should be added to the ISN/RPS histopathological classification system for guiding therapy and judging prognosis, need further investigation.

## SA-PO711

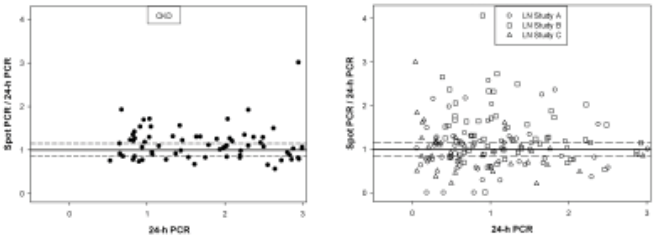
**Spot Urine Protein/Creatinine Ratio Is More Unreliable in Estimating 24-h Proteinuria in Lupus Nephritis Than in Other Forms of Chronic Glomerular Diseases**

Lee A. Hebert,[1] Daniel J. Birmingham,[1] Ganesh B. Shidham,[1] Derek M. Fine,[2] Roger A. Rodby,[3] Giuseppe Remuzzi,[4] Paul Louis Hebert,[5] Brad H. Rovin.[1] *[1]Internal Medicine, Ohio State Univ Wexner Med Ctr, Columbus, OH; [2]Johns Hopkins Univ, Baltimore, MD; [3]Rush Univ Medical Center, Chicago, IL; [4]IRCCS-Istituto di Richerche Farmacologiche Mario Negri, Bergamo, Italy; [5]Univ of Washington, Seattle, WA.*

**Background:** Spot urine protein/creatinine ratio (PCR) is often used clinically to estimate 24-h P. However, spot PCR shows considerable hour-to-hour variability. Spot collections (Cl) reveal this variability. Longer Cl conceal it. Spot PCR is useful in cohort studies where its variability is mitigated by averaging. However, clinical decisions often are based on a single spot PCR. Here, spot PCR variability is a liability. Here we compare spot PCR variability in lupus nephritis (LN) and chronic kidney disease (CKD).

**Methods:** For LN, we use the published works (N=3, 165 pts) that documented C content of the 24-h Cl (studies A, B, C); for CKD, the REIN cohort (98 pts). Almost all spot were morning Cl.

**Results:** Calibration plots show that most [spot PCR/24-hr PCR] values fall well outside the limits of agreement with 24-h PCR.



Coefficient of variation (CV) of [spot PCR/24-h PCR] is greater in LN than CKD (mean CV (95% CI) LN versus CKD is 0.538 (0.459, 0.621) versus 0.335 (0.185, 0.456), $p < 0.001$). KDIGO and ACR recommend spot PCR but its variability is confounding, especially in LN. For example, 0.6 PCR increase is a BILAG-A renal flare. Spot PCR would not be reliably detect this change (see Figure). Also, spot PCR is not reliable for screening. It over and under estimates about equally.

**Conclusions:** Spot PCR testing is substantially inaccurate, particularly in LN. Its impact on clinical decision making, compared to 24-h PCR, needs further study.

## SA-PO712

**Lower Renal miR-150 Expression Levels Are Associated with Better Response to Treatment in Lupus Nephritis Patients**

Hua Zhou,[1,4] Sarfaraz Hasni,[2] Howard A. Austin,[3] James E. Balow,[3] Ilias Alevizos,[1] Gabor Illei.[1] *[1]NIDCR; [2]NIAMS; [3]NIDDK/NIH; [4]Dept of Nephrology, The 1st Hospital, China Medical Univ, Shenyang, China.*

**Background:** We recently reported that renal miR-150 expression correlated significantly with chronicity index (CI) in lupus nephritis (LN) patients and showed a causative role of miR-150 in promoting renal fibrogenesis. In this study, we examined the association of pre-treatment renal miR-150 levels and response to treatment (cyclophosphamide and corticosteroids) in LN patients.

**Methods:** 28 renal biopsies (formalin fixed paraffin embedded tissue blocks) obtained from patients with active proliferative LN before starting treatment with cyclophosphamide and corticosteroids. Based on their response to treatment at 24 months patients were classified as treatment effective (n=16) and ineffective group (n=12). Total RNAs were extracted from the biopsies and renal miR-150 expression was measured by TaqMan RT-PCR. The renal miR-150 level was expressed in relation to the expression of U48 (ΔCt: U48Ct – miR-150Ct). Statistical analysis was done by Prism 5 software package.

**Results:** Consistent with our previous report in a different cohort of LN patients, renal miR-150 level positively correlated with CI ($r=0.63$, $p<0.05$) but not with activity index ($r=0.12$, $p=0.49$). Pre-treatment renal miR-150 level was significant lower in treatment effective group compared to ineffective group (ΔCt: $1.62 \pm 0.22$ vs. $2.72 \pm 0.38$, $p=0.015$, respectively). In a receiving operating characteristic analysis, renal miR-150 was an accurate predictor of treatment effectiveness in an area under the curve (AUC: 0.73, $p<0.05$).

**Conclusions:** Increased renal miR-150 levels are associated with an increased CI and poor response to immunosuppressive therapy in active proliferative LN patients. Pre-treatment levels of renal miR-150 have a good potential as biomarkers to predict the effectiveness of immunosuppressive treatment in LN, but its practical application needs further validation in larger cohort of patients. The potential use of miR-150 as a predictor of treatment response in proliferative lupus nephritis should be further assessed in noninvasive clinical samples such as urine and blood.

## SA-PO713

**An Open Label Randomized Controlled Trial to Compare the Efficacy and Complication between Low Dose and High Dose Intravenous Cyclophosphamide for Induction of Remission in Thai Patients with Proliferative Lupus Nephritis**

Ratana Chawanasuntorapoj,[1] Boonyarit Cheunsuchon,[2] Pisal Parichatikanond,[2] Kriengsak Vareesangthip,[1] Chairat Shayakul.[1] *[1]Medicine, Siriraj Hosp.; [2]Pathology, Siriraj Hosp., Mahidol U.*

**Background:** Proliferative lupus nephritis (pLN) is a major organ involvement affecting the worse prognosis in SLE patient. The pathogenesis consists of genetic, environment and immunology. The high incidence and poor prognosis are found in Asian, Afro-American ]and Hispanic. The cost and effective standard induction treatment, intravenous cyclophosphamide (IVCY) 0.75-1g/BSA (high dose, HDCYC) monthly for 6 doses provides the good response. The adverse effects are concerned: infection, gonadal toxicity and malignancy. The low dose intravenous cyclophosphamide (LDCYC) is effective in Caucasian with less complication. This study was to investigate the efficacy and complication of LDCYC comparison with HDCYC in Asian.

**Methods:** We randomly assigned 149 pLN patients to a HDCYC**,** 0.75-1 g/BSA IVCY monthly adjusted according to nadir WBC for 6 doses, and a LDCYC, 500 mg IVCY every 2 week for 6 doses. After induction therapy, both were followed by azathioprine.

**Results:** 76 and 73 patients were enrolled to HDCYC(G1) and LDCYC(G2) from Mar 2005 to Nov 2012. Median time to follow up was 40 months. Overall demographic data; age, blood pressure, onset, albumin, proteinuria, RPGN, activity and chronicity index were comparable. Median creatinine was 1.1 and 0.9 in G1 and G2, *p=0.04.* Induction treatment failure at 6 months was lower in G1, 24.7% compared to 34.3% in G2. The complete response at 12 months was significantly higher in G1, 76.5% compared to G2, 52.3. Renal flare was insignificantly low in G1, 35.5% and 45.2% in G2. 5 years renal and patient survival were comparable in G1 (90 and 83.2%) and G2 (89 and 86%). Regarding the complication including avascular necrosis, DM and infection were not different. There are 9 cases dead in each group and infection was a common cause. The gonadal toxicity was higher in G1 and malignancy was found 2 cases in G1.

**Conclusions:** The low dose CYC could be the effective to induce response in pLN. However, the complte response at 12 months was significantly high in high dose CYC.

*Funding:* Government Support - Non-U.S.

## SA-PO714

**Latin American Lupus Nephritis Cohort: Maintenance Therapy with Mycophenolate Sodium**

Vanina Vazquez,[1] Juan Jose Lopez,[2] Bruno Jorge Lococo,[3] Alicia Isabel Fayad,[4] Marcelo Alejandro De Rosa,[5] Vicente Altobelli.[6] *[1]Nefrologia, Hospital Simplemente Evita, Gonzalez Catan, Buenos Aires, Argentina; [2]Nefrologia, Hospital Gobernador Centeno, La Pampa, Argentina; [3]Nefrologia, Hospital Fernandez, Ciudad Autonoma de Buenos Aires, Buenos Aires, Argentina; [4]Nefrologia, Hospital de Niños A. Gutierrez, Ciudad Autonoma de Buenos Aires, Buenos Aires, Argentina; [5]Nefrologia, CyMSA, Ciudad Autonoma de Buenos Aires, Buenos Aires, Argentina; [6]Nefrologia, Centro Nefrologico Salta, Salta, Argentina.*

**Background:** Mycophenolate has emerged as promising alternative in Lupus Nephritis(LN) treatment but its effects on Latin American(LA) population to maintain response induced by cyclophosphamide (CYC) has been not well defined.

**Methods:** 46 pts,prospective study.Treatment:CYC iv induction followed by enteric-coated mycophenolate sodium (EC-MPS) 30 months maintenance.Analysis:EC-MPS efficiency to maintain complete response(CR)and to improve partial response(PR) achieved with CYC,persistent partial response(PPR), safety by adverse events(AE) listing.

**Results:** Induction:26% achieved CR,73.9% PR. Maintenance:all CR was sustained,50% PR switched to CR.End-study:63% achieved CR,36.9% showed PPR. PPR group showed > hypertension rate,sCr≥1.2, moderate interstitial fibrosis(IF) and tubular atrophy(TA) vs CR group.Risk predictor variables of association to RRP:elevated baseline sCr,moderate IF and TA.Most frequent AE:minor infections 36.6%,gastrointestinal intolerance 15.2%.

| | Total CTR | PPR | | Association and RR (95%IC) | |
|---|---|---|---|---|---|
| n 46 | n/% | n/% | p | | p |
| n pts | 29/63.04 | 17/36.9 | | | |
| WHO class | | | | | |
| IV % | 19/65.5 | 12/70.5 | 0.132 | | |
| Baseline sCr ≥ 1.2 mg/dl,% | 50 | 82.35 | 0.05 | 1.59(1.05-2.41) | 0.03 |
| Proteinuria >3.5 g/d,% | 53.33 | 76.47 | 0.19 | 1.48(0.95-2.29) | NS |
| HTN:BP≥140/90,% | 43.33 | 58.8 | 0.0001 | 1.59(0.98-2.58) | NS |
| Interstitial Fibrosis | | | | | |
| moderate,% | 0 | 23.52 | 0.0001 | 6.82(0.83-56.17) | 0.05 |
| Tubular Atrophy | | | | | |
| moderate,% | 3.33 | 29.41 | 0.015 | 8.53(1.09-67.05) | 0.04 |

**Conclusions:** Severe LN LA population can be safely and effectively treated with CYC and maintenance EC-MPS included those with risk factors for worse treatment response.

## SA-PO715

**Effects of an Intensified Treatment of Linphocyte Depletion without Immunosuppressive Maintenance Therapy in Severe SLE over a Four Year Follow-Up** Dario Roccatello, Daniela Rossi, Carla Naretto, Simone Baldovino, Mirella Alpa, Savino Sciascia, Ilaria Salussola, Vittorio Modena. *Giovanni Bosco Hospital and Univ of Turin, Italy.*

**Background:** B-lymphocytes (BL) play a critical role in Systemic Lupus Erythematosus (SLE). BL depletion therapy still remains an attractive option, despite the disappointing results of RCTs.

**Methods:** Twelve SLE patients [2 males, mean age 43.8 yrs (29-54)] with polyarthralgia and multiorgan involvement including class IV or V (ISN/RPS) glomerulonephritis (9 cases), skin lesions (9cases, with necrotizing ulcers in3), polyneuropathy (7cases, with CNS involvement in 2), lymphoadenopathy (6) e polysierositis (5) have been treated with an intensive BL depletion protocol for intolerance to conventional immunosuppressive therapy (6 cases) or as a front line therapy (6 cases). Protocol: Rituximab 375 $mg^2$ on days 1,8,15,22, and2more doses after one and two months, associated with 2 IV administrations of 10 mg/kg of cyclofosfamide and 3 infusions of methylprednisolone (15 mg/kg) followed by oral prednisone (0.8 mg/die, rapidly tapered to 5 mg/day in 10 weeks), without further immunosuppressive maintenance therapy.

**Results:** This protocol obtained a complete depletion of CD20+ BL for 12-18 months. Patients had been followed-up for 48.9 (25-93) months. ESR (baseline mean value: 54.2; 3 months: 33; end of follow-up: 14.9), anti-dsDNA antibodies (baseline: 192; 3 months:112; end of follow-up: 17) and proteinuria (baseline: 4.9 g/24 hours; 3 months:0.97; end of follow-up: 0.22) significantly declined ($p<0.05$), while C4 values (baseline 11 mg/dl) significantly increased ($p<0.05$) after 3 months (22 mg/dl) and at the end of the follow-up (20 mg/dl).3patients relapsed after 36,41 and72months respectively. They showed again a complete remission after retreatment over 13-48 months of observation.

**Conclusions:** These data confirm the opportunity to reconsider the regimens of BL depletion in the treatment of the most severe forms of SLE despite the disappointing results of RCTs. A promising role of Rituximab in protocols of "intensified induction therapy" in selected patients for whom avoiding immunosuppressive maintenance therapy could be particularly appealing.

## SA-PO716

**Oral Sirolimus Was More Effective Than Intravenous Cyclophosphamide in Patients with Proliferative Lupus Nephritis** Jian Hui Yang. *Renal Div, Zhejiang Provincial People's Hospital.*

**Background:** To evaluate the efficacy and safety of sirolimus on refractory lupus nephritis.

**Methods:** Forty-eight patients with proliferative lupus nephritis who failed to response refractory to regular dose of prednisone were randomized to sirolimus group (SRL) or intravenous pulse cyclophosphamide (CTX). The patients ages, gender, hematuria, proteinuria and other clinco-pathological features were of no marked differences between two groups. The former group were administrated with 0.3~0.5mg/d.kg-1 oral prednisone and 2 mg/d sirolimus (NCPC GENETECH BIOTECHNOLOGY CO. LTD) for 6 to 12 months. Sirolimus doses were adjusted so that the serum sirolimus concentration could be maintained between 4 to 10 ng/ml. The later group were given same dose of oral prednisone and intravenous CTX (0.6g)bimonthly. Patients who could not withstand the administration were excluded. No angiotensin-converting enzyme inhibitors or angiotensin receptor blockers were taken in these patients. The clinical manifestations, laboratory parameters and adverse reactions were observed.

**Results:** Three months after initiation of these therapy, the patients' SLEDAI, DNA antibody titer, urine protein decreased more markedly in SRL group compared with CTX group. Hypoalbuminemia and hypocomplementemia was alleviated more rapidly in the former group. Complete remission were induced in 19 patients treated with SRL while it was seen only 10 patients treated with CTX . Serum creatinine level was significantly reduced in SRL group than CTX group. Although hyperlipidemia and hypercholesterolemia were commoner in SRL group, no other serious adverse reactions such as leucocytopenia, bleeding cystitis and alopecia were found apart from acnes and upper tract infections.

**Conclusions:** Low dose of oral SRL was more effective and safer than CTX in patients with lupus nephritis. Hyperlipidemia or hypercholesterolemia in lupus nephritis was not the contradictions of sirolimus.

## SA-PO717

**Diffusion Weighted Imaging and Blood Oxygen Level-Dependent MR Imaging of Kidneys in Patients with Lupus Nephritis** Xiao Li, Nan Chen. *Dept of Nephrology, Ruijin Hospital, Shanghai Jiao Tong Univ School of Medicine, Shanghai, China.*

**Background:** To investigate the role of diffusion weighted imaging (DWI) and blood oxygen level-dependent (BOLD) magnetic resonance (MR) imaging in the assessment of renal involvement and pathological changes in patients with lupus nephritis (LN).

**Methods:** Thirty-eight patients with LN (34 biopsied) and 16 healthy controls underwent coronal echo-planar DWI and BOLD MR imaging of the kidneys with a single breath-hold time of 16s. The apparent diffusion coefficient (ADC) and R2* value of the kidneys was calculated with high b values (b=500 $s/mm^2$). Image analysis was performed on a GE workstation (Sun Microsystems, ADW4.2) with Functool 2 image analysis software. The relation between the renal injury variables and the ADCs or R2* values were evaluated.

**Results:** The mean ADC values of kidneys in patients with LN were $2.41\pm0.25 \times 10^{-3}$ $mm^2/s$, the mean R2* values of the renal cortex and medulla were 10.73/sec±1.74 and 13.48/sec±3.16 respectively, which were all significantly lower than those in volunteers ($p=0.048$, $p=0.048$ and $p=0.008$, respectively). In the patients with LN, the mean ADC values were correlated with eGFR ($r=0.558$, $p<0.05$). There was a negative correlation between the ADC values of the right kidneys and pathological chronic indexes ($r=-0.493$, $p<0.05$). Moreover, the R2* values of the renal medulla were negatively correlated with 24 hours proteinuria ($r=-0.344$, $P<0.05$), the degree of tubulointerstitial lesions($r=-0.342$, $P<0.05$). Among 10 patients who repeated MR scan after treatment for 9 to 12 months, 7 patients got complete remission (CR) and 3 had no response (NR). The ADC and R2* values of kidneys were significantly higher than before in CR patients (all $P<0.05$), while the ADC and R2* values being lower than before in NR patients with no statistical significance ($P>0.05$).

**Conclusions:** The functional MR imaging showed lower ADC values and R2* values of renal cortex and medulla in patients with LN than normal controls, which were associated with renal function, proteinuria and pathological changes. DWI and BOLD MR imaging may be used to non-invasively monitor disease activity, evaluate therapeutics efficacy in lupus nephritis.

*Funding:* Government Support - Non-U.S.

## SA-PO718

**Severely Low 25-Hydroxyvitamin D Levels Are Associated with Worse Renal Outcomes in Proliferative Lupus Nephritis** Alcino Pires Gama, Luciana Loureiro Nardotto, Lectícia Jorge, Cristiane Bitencourt Dias, Rui Toledo Barros, Viktoria Woronik. *Nephrology, Univ of Sao Paulo, Sao Paulo, Brazil.*

**Background:** The associations between 25-hydroxyvitamin D(25OHD) levels and lupus nephritis(LN) are not clearly known. The aim of this study was to evaluate if very low serum levels of 25OHD in proliferative LN patients are associated with worse renal outcome.

**Methods:** Medical records from 2009 to 2012 of 72 subjects with biopsy-proven proliferative LN were retrospectively analyzed. Severe 25OHD deficiency was defined as <10ng/ml. The study's endpoints were either progression of chronic kidney disease(CKD) - defined as a clearance reduction greater than 5ml/min/y - or progression to end-stage renal disease(ESRD).

**Results:** Median levels of 25OHD were low at baseline(16,5±7,9ng/ml). Clinical features, follow-up times, biopsy features and renal outcomes are shown on table 1.

| | 25OHD<10 n=17 | 25OHD>10 n=55 |
|---|---|---|
| CLINICAL | | |
| Age/y | 32,8±3,3 | 32±1,4 |
| Female(%) | 17(100%) | 10(82%) |
| Hb g/dl | 9±0,5 | 9,8±0,2 |
| C3 mg/dl | 61,5±7,5 | 65,4±4,5 |
| eGFR ml/min | 36±6,7 | 47±4,5 |
| Albumin g/dl* | 2,1±0,2 | 2,6±0,1 |
| Proteinuria g/24h | 4,9±0,8 | 4,4±0,5 |
| BIOPSY | | |
| Class IV(%) | 12(71%) | 47(85%) |
| Activity | 5,5±0,9 | 5,5±0,4 |
| Chronicity* | 2,5±0,6 | 3,8±0,3 |
| OUTCOMES | | |
| Follow-up/y | 1,7±0,2 | 2,3±0,1 |
| CKD progression(%)* | 9(53%) | 14(25%) |
| ESRD(%)* | 7(41%) | 8(14%) |

*p<0,05

Table 1. Clinical, biopsy features and outcomes. Results shown as median±SD or n(%)

After a median follow up 1,7±0,2 years, the 25OHD<10ng/ml group had worse renal outcomes: (1) progression of CKD 53% vs 14%, p<0,05; (2) ESRD 41% vs 14%, p<0,05. These outcomes were observed despite better biopsy features on the low-25OHD group at baseline (chronicity index 2,5±0,57 vs 3,8±0,32, p<0,05).

**Conclusions:** Severely low 25OHD levels at baseline were associated with worse renal outcomes (either progression of CKD or progression to ESRD) in biopsy-proven proliferative LN patients, even though this group presented better biopsy features at baseline.

## SA-PO719

**Persistent Proteinuria as a Major Predictor of Renal Outcome in Lupus Nephritis Class V (LNV)** Alcino Pires Gama, Luciana Loureiro Nardotto, Lectícia Jorge, Cristiane Bitencourt Dias, Rui Toledo Barros, Viktoria Woronik. *Nephrology, Univ of Sao Paulo, Brazil.*

**Background:** Natural history studies of LNV suggest a relatively low rate of progression to ESRD. The aim of this study was to review the prognosis and the predictors of renal outcome in LNV.

**Methods:** The medical records of patients (n=97) with biopsy-proven LN, WHO class V without any past history of proliferative lupus nephritis were reviewed retrospectively. The study endpoint was ESRD.

**Results:** Clinical and histological features are showed in table 1.

| Baseline and Histologic Features | ESRD (n=11) | No ESRD (n=86) |
|---|---|---|
| AGE(y) | 30±11 | 35±11 |
| Female | 10(90%) | 79(92%) |
| eGFR(ml/min)* | 40±29 | 93±41 |
| Proteinuria(g/day) | 6.4±4.7 | 4.2±4 |
| Serum Albumine(g/dl)* | 2±0.4 | 2.8±1 |
| C3 Level* | 58.7±32 | 93±38 |
| Hemoglobin(g/dl)* | 10.2±2.3 | 12±1.7 |
| Hematuria | 4(37%) | 34(40%) |
| Crescents* | 5(46%) | 8(10%) |
| Interstitial Fibrosis | 6(54%) | 29(34%) |
| At one year Features | | |
| eGFR(ml/min)* | 45±47 | 97±37 |
| Proteinuria(g/day)* | 5.3±5.5 | 1.3±1.1 |
| Serum Albumine(g/dl) | 3.8±0.7 | 3.8±0.6 |
| C3 Level | 94±36 | 109±34 |
| Hemoglobin(g/dl)* | 10.8±2.5 | 12.4±1.6 |
| Follow up(y) | 6.6±4.7 | 7.2±3.5 |

Results are shown as median±SD or n(%). *p<0,05

On a mean follow-up of 7.1 years, 11.3% of the patients reached ESRD. Logistic regression analysis showed that persistent proteinuria at one year and decreased serum C3 levels(hypoC3) on baseline was associated with the endpoint after adjustments for initial eGFR (OR 2.2 IC 1.1-4.2, p=0.020;OR 0.93 IC 0.87-0.99, p=0.024 respectively). The best cutoff of PP to identify patients who presented ESRD was a PP>6 with a positive predictive value of 100% and a negative predictive value of 91% defined by ROC curve (AUC 0,83 p=0.02).

**Conclusions:** Persistent proteinuria at one year and HypoC3 on baseline were a independent risk factors for ESRD in LNV in our study, these clinical features are helpful to identifying patients at high risk for poor outcome.

*Funding:* Government Support - Non-U.S.

## SA-PO720

**Could Proteinuria Less Than 500 mg/day Be an Actual Indicator of Lupus Nephritis Biopsy?** Marcelo Alejandro De Rosa, Jorge E. Toblli, Graciela Elena De Rosa, Alicia Marini. *Nephrology Div, Hospital de Clinicas. Univ of Buenos Aires, Buenos Aires, Argentina.*

**Background:** Renal biopsy is required to confirm the diagnosis of lupus nephritis (LN) according to the current ACR guidelines (Arthritis Care & Research 2012; 64: 797–808), in case of unexplained increasing serum creatinine level, proteinuria >1.0 g/day , or combinations of the following: a) proteinuria 0 .5 g/day plus hematuria, b) proteinuria >0.5 g/day plus cellular casts.

The goal of this pilot study was to determine the value of renal biopsy in lupus patients presenting with glomerular hematuria and proteinuria below 500 mg/day with normal renal function.

**Methods:** Renal biopsies from 38 lupus patients with glomerular hematuria and proteinuria below 500 mg/day were evaluated by LM and immunofluorescence microscopy and classified according to the ISN-RPS 2003. No patients with renal failure or previous renal biopsy were included. Glomerular hematuria was considered at the presence of 3 or more dysmorphic RBCs per high-power field plus acanthocytes more than 5% and RBC casts. The urinary sediment corresponding to every patient was observed by neprologists.

**Results:** The mean patient age was 35.5 years old (range 19 to 65) years. Male/female= 8/30. The 24hr proteinuria was negative in 2 pts. (5%), proteinuria trace in 16 pts. (42%), and between trace and 500 mg/day in 20 pts. (52%). From the total of 38 biopsies, 2 were class II (5%), 15 class III (39%), 18 class IV (47%) and 3 class V (8%).

**Conclusions:** The present results show that Class III, IV, or V are present in a substantial proportion of lupus patients with mild clinical manifestations of renal disease and it may suggest a new potential indication for renal biopsy. In addition, since these histological classes of LN are associated with poor prognosis and require an early diagnostic and appropriate treatment, we think the data presented in this pilot study acquire importance.

*Funding:* Government Support - Non-U.S.

## SA-PO721

**Treatment of Lupus Nephritis with Mycophenolate Mofetil (MMF). Long Term Outcomes** Beatriz Rodriguez Cubillo, Stelios A. Panagoutsos, Javier Juega Marino, Megan Griffith, Tom Cairns, Liz Lightstone. *[1]Renal, Imperial College Kidney and Transplant Institute, London, United Kingdom; [2]Hammersmith Hospital, London, United Kingdom.*

**Background:** Very little is known on long term outcomes of patients treated with lupus nephritis with MMF as compared to induction with CyP. We have used MMF for induction and maintenance treatment from 1999. We report the outcomes of patients treated for >5yrs.

**Methods:** Retrospective analysis of all adult patients with biopsy proven LN between January 1999 and March 2013 and on MMF either for induction and/or maintenance therapy for >5yrs. A 64/348 patients were identified from our lupus biopsy d/base. Renal remission – normal serum creatinine or no worse than 20% above baseline, and urine PCR <50mg/mmol.

**Results:** Median follow-up 80.87mths (72.01-102.90). 32(50.8%) patients received CyP induction. The rest received rituximab+ MMF(10) or MMF alone(11) as first induction therapy. Most frequent additional maintenance drugs were prednisolone & hydroxychloroquine. **Outcomes at latest f/up:**Maintenance prednisone treatment was stopped in 38 patients(67.9%); No patients died;5(7.9%) required RRT(0 of those whose urine PCR was<100 at 6mths), 4(6.5%) had sustained doubling of serum creatinine(SDSC); remission was achieved in 82% and 58% had a relapse. Serum creatinine improved from 90µmol/L [70.75-123.25] in yr 1 to 73.5/L [65.6-113.25]) by yr 5. There were no significant differences in long term outcomes whether induced with CyP or MMF; patients considered able to withdraw steroids had fewer relapses – 35% vs 67% in the steroid dependent group. Adverse events: Infections were documented in 33(52.2%); neutropenia in 11(17.2 %) & GI symptoms in 20.6%. There were 7 pregnancies in the 46 women(15.27%).

**Conclusions:** Our data, from a single centre retrospective study, suggest that treatment with MMF both for induction and maintenance is as efficacious in the long term as induction with CyP.

## SA-PO722

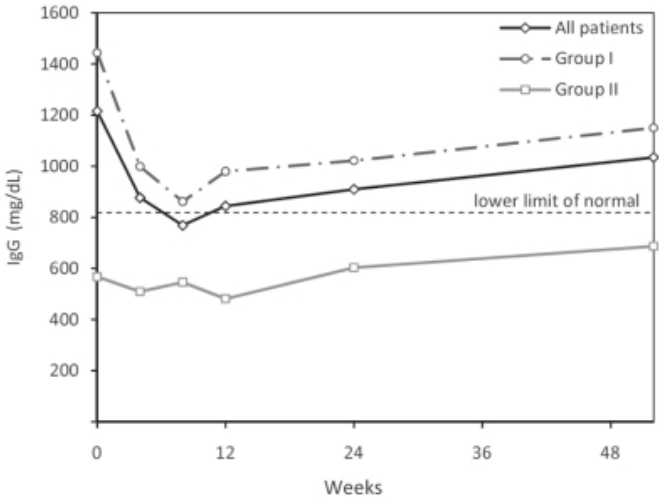
**The Effect of Corticosteroids and Mycophenolate Mofetil Treatment on Serum Immunoglobulin G Levels in Lupus Nephritis Patients** Desmond Y.H. Yap, Susan Yung, Gary Chan, Daniel Tak Mao Chan. *Medicine, The Univ of Hong Kong, Hong Kong, Hong Kong.*

**Background:** Depressed serum immunoglobulin G (IgG) is associated with heightened infective risk. The effect of corticosteroids and mycophenolate mofetil (MMF) on circulating IgG levels in lupus nephritis (LN) patients remains unclear.

**Methods:** Active class III/IV±V LN patients who received prednisolone (0.8mg/kg/d) and MMF (1g bd) as induction treatment were included and their longitudinal IgG profiles analyzed.

**Results:** 46 patients were included. Prior to treatment, 34 (73.9%) patients (Group I) had normal or elevated IgG (1444.0±600.5 mg/dL) while 12 (26.1%) (Group II) had IgG below the lower limit of normal (567.8±160.9 mg/dL). The mean IgG at baseline, 6- and 12-month after treatment were 1215.4±649.7 mg/dL, 914.5±362.4 mg/dL and 1034.6±452.5 mg/dL respectively. After initiation of prednisolone and MMF, IgG declined significantly after 2 weeks, reaching a nadir at 8-week, then followed by gradual normalization.

**Figure 1.**



Similar longitudinal IgG profile was observed in Group I patients while Group II patients showed insignificant IgG changes within the first 6 months. By 6-month, 18 (39.1%) patients had low IgG but only one had IgG <300mg/dL. IgG level was negatively correlated with proteinuria at 6-month (r=-0.657; p<0.001) but had no association with serum creatinine, serological markers, lymphocyte counts and MMF dose. 5 of 18 patients with low IgG had infections within the first year, but IgG level below the lower limit of normal was not associated with excessive infection (RR 1.863; 95% CI 0.466 to 6.818, p=0.280).

**Conclusions:** Proteinuria significantly affects serum IgG levels in LN patients. Treatment with prednisolone and MMF does not lead to clinically important IgG depression and excessive infection.

## SA-PO723

**Maintenance Therapy with Mycophenolate versus Azathioprine in Lupus Nephritis** Pavan Kumar Rao Navva.[1] *[1]Nephrology, Andhra Medical College, Vishakhapatnam, Andhra Pradesh, India; [2]Nephrology, Andhra Medical College, Vishakhapatnam, Andhra Pradesh, India.*

**Background:** Lupus nephritis is one of the commonest renal lesions affecting young women contributing to considerable morbidity and mortality. It requires long term treatment to preserve renal function. We tried to compare Mycophenolate mofetil, Azathioprine and Cylophophamide in Maintenance therapy of Lupus nephritis.

**Methods:** All biopsy proven Class 3 & 4 Lupus Nephritis patients in a Tertiary care centre in South East India were followed from May 2011 to May 2013. After initial induction with Cyclophosphamide for 6 months, maintenance therapy was started with either Mycophenolate(MMF) or Azathioprine(AZA) or quarterly Cyclophosphamide pulses(CYP). The decision to opt for any of the treatment modalities was given to the patient/attender with prior counseling regarding fertility and malignancy risk. We had 52 patients during the period, 4 patients were lost to follow up. Of the 48 remaining, 19 received MMF, 22 AZA and 7 CYP.

**Results:** Among 48 patients,the mean age in MMF group was 22.4±2.5yrs, AZA group 24.5±3.4 yrs and in CYP group 22.9±3.1 yrs. There was one male in each of the treatment

groups. At the start of the Maintenance therapy all the patients had attained either complete or partial remission. At the end of the study period 13 patients in the MMF group, 18 in AZA group and 5 in CYP group continued to be in remission. Four(21.1%) in the MMF group, 2(9.1%) in the AZA group and 1(14.3%) in the CYP group had died during the study period. 2 each in the MMF and AZA group and 1 in the CYP group had progressed to ESRD during the study period. The commonest cause of death was infection due to pneumonia in 4 and cellulitis leg in 2, leading in septicaemia. The incidence of flare either nephritic or nephrotic was 4 (21.1%) in the MMF group, 4(18.8%) in the AZA group and none in the CYP group, all of which responded to treatment.

**Conclusions:** We found that in our population the remission was equally maintained in all treatment groups. The mortality rates were higher in MMF group compared to AZA and CYP groups. The incidence of flares was similar in all the groups. Although all modalities were efficient we need larger studies to ascertain higher infection rates in MMF group in our area.

*Funding:* Government Support - Non-U.S.

## SA-PO724

### Lupus Podocytopathy: Clinical Characteristics, Pathology, and Therapy

Jason Cobb, Jose E. Navarrete. *Nephrology, Emory Univ School of Medicine, Atlanta, GA.*

**Background:** Minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) in systemic lupus erythematosus (SLE) patients has been described as the lupus podocytopathy. Lupus podocytopathy pathology is characterized by diffuse foot process effacement with a lack of significant immune complexes.

**Methods:** We are presenting nine cases in our clinical practice with varying clinical characteristics at presentation, renal pathology, and response to therapy.

**Results:** At the time of kidney biopsy four patients were new diagnosis, and in five patients the average duration of known lupus was 7.1 years. At time of presentation the average creatinine was 3.26 mg/dL, 7.8 grams of urine protein per day, and serum albumin of 1.5 g/dL. All patients presented with hematuria. Renal pathology showed significant diffuse foot process effacement in all cases. Two patients with FSGS only, one patient with MCD only, one patient with minimal mesangial lupus nephritis with MCD, three patients with mild mesangioproliferative lupus nephritis with MCD, and two patients with mild mesangioproliferative lupus nephritis with FSGS. Seven of nine patients were treated primarily with corticosteroids and other therapies included calcineurin inhibitors, cyclophosphamide, and plasmapharesis. The patients were followed for an average of 3.4 years, with three patients requiring dialysis and only one required dialysis indefinitely.

**Conclusions:** We analyzed nine cases with varying presentations of the same disorder in our clinical practice. There were no correlation between severity of renal dysfunction and laboratory findings such as double stranded DNA elevation, decrease levels of C3/C4, and degree of proteinuria. No correlation for pathological changes such as presence of tubular reticular inclusion bodies or degree of interstitial fibrosis and atrophy, and amount of mesangial proliferation. The most severe renal dysfunction at time of presentation (creatinine > 5 mg/dL) was seen in the two patients with collapsing FSGS features. Our goal is to a complete analysis of all the cases of lupus podocytopathy in our large academic hospital system.

## SA-PO725

### Risk Factors to Not Achieve Complete Remission in Mexican Patients with Lupus Nephritis

Arreola Guerra Jose Manuel, Juan M. Mejia-Vilet, Rodrigo J. Rosado, Norma O. Uribe-uribe, Luis E. Morales-Buenrostro. *Nephrology & Pathology, National Institute of Medical Sciences and Nutrition SZ, Mexico City, DF, Mexico.*

**Background:** The induction therapy in Lupus Nephritis (LN) has been changed. The aim of this study is to compare the efficacy (complete remission) of different options of induction therapy in incipient patients with LN.

**Methods:** Retrospective cohort study of all patients with biopsy proven LN in the period between mar/08 and Feb/13. We included 185 patients with at least 3 months of follow-up. We evaluate the remission status in the month 3, 6 and 12. Time to complete remission (CR) was evaluated with the univariate and multivariate Cox regression analysis.

**Results:** Seventy-six patients received cyclophosphamide (CFM), Mycophenolate Mofetil (MMF) and 43 Azathioprine (AZA). Univariate and multivariate analysis is shown in table1. In the univariate analysis, the induction therapy with CFM was singnificantly less effective than MMF or AZA to achieve CR (p<0.029). In the multivariable analysis only SLEDAI index was statistically significant.

| Variable | CR (n=68) | w/o response or partial remission (n=117) | HRUnivariate (IC95%) | HR Multivariate (CI95%) | p value |
|---|---|---|---|---|---|
| Creatinine | 1.06(0.7-1.9) | 0.94(0.69-1.27) | 0.63(0.44-0.89) | 0.78 (0.55-1.11) | 0.179 |
| Pr/Cr index | 2.82(1.86-4.4) | 4.01(2.27-6.48) | 0.90(0.82-0.98) | 0.92(0.85-1.01) | 0.106 |
| dsDNA Ab | 95.6(34.1-394) | 132(24.9-489) | 0.99(0.99-1.00) | 0.99(0.99-1.0) | 0.860 |
| Chronicity grade | 3(2-5) | 3(2-6) | 0.67(0.51-0.88) | 0.80(0.58-1.10) | 0.175 |
| Class IV LN | 34(50%) | 78(66%) | 0.55(0.34-0.89) | 0.76(0.43-1.33) | 0.341 |
| **SLEDAI** | 12(8-12) | 12(8-12) | 1.07(0.96-1.19) | **1.12(1.003-1.25)** | **0.043** |
| CFM | 21(31%) | 55(47%) | 0.57(0.35-0.92) | 0.63(0.34-1.15) | 0.138 |
| AZA | 19(27%) | 24(20%) | 1.38(0.82-2.32) | 0.95(0.51-1.75) | 0.213 |
| MMF | 28(41%) | 38(32%) | 1.36(0.84-2.21) | 1.04(0.56-1.92) | 0.883 |

**Conclusions:** In Mexican patients with LN we don't find diferences in the outcomes of the diferents groups of induction. Only the SLEDAI index was significant related with CR. This represent the clinical practice of our center, were the most agresive cases were biased to receive CFM.

## SA-PO726

### Lupus Nephritis as the Main Histopathological Diagnosis in a Renal Biopsy Registry: Analysis of a Local Renal Biopsy Registry in Mexico

Juan M. Mejia-Vilet, Arreola Guerra Jose Manuel, Rodrigo J. Rosado, Norma O. Uribe-uribe, Luis E. Morales-Buenrostro. *Nephrology and Pathology Depts, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubiran, Mexico City, Mexico.*

**Background:** Renal biopsy (RBx) registries have been advocated worldwide to define the patterns of distribution of renal diseases.

**Methods:** Retrospective study of our institutional RBx registry, including 710 consecutive RBx analyzed by the same pathologist, from 04/2008-04/2013.

**Results:** 710 native RBx were performed in 689 adult patients. Secondary glomerulopathies (SGN) comprise 416 (58.6%), being lupus nephritis (LN) responsible for 319 out of 416 cases (76.6% of SGN), followed by diabetic nephropathy (9.8%), amyloidosis (3.8%), hereditary nephropathies (2.9%). Primary glomerulopathies (PGN) comprise 181 cases (25.5%), with focal and segmental glomerulosclerosis (FSGS) in 34.8%, followed by membranous nephropathy (27.1%), IgAN (16.6%), minimal change disease (11.0%), mesangioproliferative non-IgA (4.4%), membranoproliferative GN (3.9%). Vascular pathologies comprised 9.3% (pauciimmune GN 90.9%) and tubulointerstitial pathologies 3.9% of the total.

| | NEPHROTIC | NEPHRITIC | AUA | CKD | RPGMN |
|---|---|---|---|---|---|
| **FSGS (n=63)** | 57.1% | 1.6% | 36.5% | 4.8% | 7.9% |
| **MN (n=49)** | 91.8% | 0% | 8.2% | 0% | 0% |
| **IgAN (n=30)** | 23.3% | 0% | 70.0% | 3.3% | 3.3% |
| **MCD (n=20)** | 80.0% | 0% | 20.0% | 0% | 0% |
| **LN (n=319)** | 34.2% | 18.8% | 27.9% | 7.5% | 11.6% |
| **Vasculitis (n=41)** | 3.3% | 3.3% | 23.3% | 8.3% | 61.7% |

In LN, a 6.4:1 female predominance was observed, with 86.9% of cases diagnosed before age 40 (mean 30.4y) and 30.1% within 6 months of lupus diagnosis (mean 58.9). According to the ISN/RPS classification, the most common pattern was class IV+V (48.2%), followed by class IV (17.8%), class III+V (14.9%), class V (7.1%), class III (5.8%), class II (2.6%), class VI (2.6%) and lupus podocytopathy (1.0%).

**Conclusions:** In our center, LN surpasses all other glomerulopathies in frequency, being nephrotic syndrome it's most common presentation. Among PGN, FSGS is the most frequent, ressembling previously described changes in GN epidemiology. This highlights the importance of local RBx registries around the world.

## SA-PO727

### Clinicopathologic Features of Lupus Nephritis in African Americans and Hispanics in an Inner-City Safety Net Hospital

Albert M. Osei,[1,2] Richard A. Nunez Lopez,[1] Matilda Malm,[1,2] Mark A. Kraus,[1,2] Peter D. Hart.[1,2] *[1]John H. Stroger Jr. Hospital of Cook County; [2]Rush Univ Medical Center, Chicago.*

**Background:** Systemic Lupus erythematosus disproportionately afflicts women and ethnic minorities in the United States with renal involvement in nearly one half. To better understand lupus nephritis among African Americans and Hispanics, we reviewed the clinical and histopathologic features at the time of renal biopsy.

**Methods:** We retrospectively reviewed all renal biopsies from 2003 to 2012 at our institution to define patients with lupus nephritis. Cases were divided based on both the ISN/RPS classification and ethnicity. Tubulointerstitial involvement was classified as mild, moderate or severe if the corresponding percentages were less than 25, 25 to 50 or more than 50 respectively.

**Results:** Of 162 biopsies with lupus nephritis, 65% were performed in African Americans and 35% in Hispanics. Overall, and in each ethnicity the majority of patients were females (77% vs. males 23%). Mean age at the time of the biopsy was higher in African Americans compared to Hispanics (36±11 vs.33±10years, P≤0.05). Initial serum creatinine was also higher in African Americans than Hispanics (2.2±1.8 vs. 1.52±1.50mg/dL, P≤0.05). Degree of proteinuria, hypocomplementemia, and ANA panel did not differ. In African Americans, ISN/RSP class V was the most frequent lesion (26%), then class IV (20%), IV +V (14%) and III (11%). In Hispanics class V was also the most frequent (25%), followed by class IV (23%), III (18%) and III+V (18%). The serum creatinine did differ between class V and class IV (1.4± 1.3 vs.2.8±2.1mg/dl p≤ 0.05) and among tertials of tubulointerstitial fibrosis (severe 3.3±1.6; moderate 2.3±1.7; and mild 1.4±1.6mg/dl;p≤0.001). No such differences was noted for the degree of proteinuria. Also, lower levels of bicarbonate predicted severity of tubulointerstitial fibrosis (mild 24.6±2.9; severe 22.5±3.3mEq/L;p≤ 0.05) and the same was true for hemoglobin (mild 10.6±1.6; severe 9.8±1.5g/dl p≤0.05).

**Conclusions:** African Americans with lupus nephritis compared to Hispanics were older, had higher initial serum creatinine and more class IV +V disease. Further studies are needed to understand the impact of these differences.

## SA-PO728

### African Americans with Mixed Lupus Nephritis Have Better Prognosis Than Pure Proliferative Glomerulonephritis at a Safety Net Hospital

Jane Vernik,[1,2] Richard A. Nunez Lopez,[1] Mark A. Kraus,[1,2] Peter D. Hart.[1,2] *[1]Div of Nephrology, John Stroger Hospital of Cook County, Chicago, IL; [2]Internal Medicine, Rush Univ, Chicago, IL.*

**Background:** It has been described that adults with mixed Lupus Nephritis (combined membranous with focal or diffuse proliferative GN; MLN) have a worse clinical course than those with either segmental of diffuse proliferative lupus nephritis (PLN). Little information

is available regarding the outcome of African Americans with MLN. By reviewing our biopsy registry, we sought to evaluate if African Americans presenting with MLN had a different clinical outcome than patients with PLN.

**Methods:** We retrospectively examined medical records of the patients biopsied at our institution between January 01,2001 and May 30, 2012 and diagnosed with MLN or PLN based on either WHO or ISN/RPS classification. In patients who underwent multiple biopsies, only data related to the initial biopsy were included.

**Results:** Of the 769 biopsies performed, 141 had LN. 84 of these were identified as initial biopsies with MLN or PLN. 51( 60%) were of African American patients with 22 classified as MLN and 29 as PLN.

The incidence of crescents did not differ significantly between the MLN (41%; n=9) and PLN (45%; n=13) groups (p=0.12).There was no significant difference among serum creatinine, degree of interstitial fibrosis and tubular atrophy,C3, C4 and proteinuria at the time of biopsy.

All patients were induced with combination of high dose steroids and cytotoxic medications, with majority receiving cyclophosphamide and prednisone. Most of the patients were maintained on low dose prednisone and either Mycophenolate mofetil or Azathioprine.

A significant reduction in serum creatinine was noted in the MLN group at 1 year follow up (1.3+/- 0.6 mg/dL, N=13) compared to the time of biopsy (2.4+/-2.4 mg/dL, N=22) (p=0.05). Creatinine remained stable in the PLN group (2.8+/- 2.8 mg/dL to 2.8+/- 0.7 mg/dL; n=20; p=0.9). Serum creatinine was significantly lower in MLN vs PLN at 1 year follow up (p<0.05).

**Conclusions:** African American patients presenting with mixed lupus nephritis (MLN) have a better serum creatinine at one year follow up than those with proliferative lupus nephritis (PLN).

## SA-PO729

### Diagnostic Significance Determining the Level of Urinary Neutrophil Gelatinasa Associated Lipocalin in Patients with Lupus Nephritis

Violeta Rabrenovic,[1] Dragan Jovanovic,[1] Milica Petrovic,[1] Milan M. Radovic.[2] *[1]Dept of Nephrology, Military Medical Academy, Belgrade, Serbia; [2]Clinical Center of Serbia, Belgrade, Serbia.*

**Background:** The aim of the study was to monitor and compare the parameters of activity of lupus nephritis, between the examined and control groups of 20 pts each, at baseline, and 2 and 4 months after the start of treatment.

**Methods:** The prospective study included a group of 40 patients who were homogeneous in terms of demographic data (gender, age, body weight, type of lupus nephritis and therapeutic modality) in which 20 were associated with lupus nephritis in remission and 20 patients with active disease. We monitored and compared the parameters of the two groups in 3 visits over 2 months. : Proteinuria, the ratio of urinary protein and creatinine Upr/Cr, SLEDAI / r score, complement C3, C4, ANA, dsDNA antibodies, Urinary neutrophil gelatinasa associated lipocalin -uNGAL. All patients had creatinine clearance -Cockcroft-Gault ≥ 60 m / min. U NGAL was determined by CMIA immunochemical test (commercial kits of Abbott Diagnostic on ARCHITECT ® i2000 SR).

**Results:** A statistically significant difference (p <0.001) was observed for the comparison of anti dsDNA antibodies, proteinuria, U pr/ cre, SLEDAI index / r scores, uNGAL between these two groups of rounds. The uNGAL was significantly correlated with parameters of active disease p <0.001, the values of the area under the ROC curve (AUC) the maximum sensitivity of 95% sensitivity and 100% specificity expressed in u NGAL The coordinates of the ROC curve for the u NGAL, limit. "cut off" was 52.95 ng / ml. With that value, all patients with uNGAL more than 52.95 ng / ml, should be in the group with active disease, and none in the group with lupus nephritis in remission.

**Conclusions:** The results show the importance in the diagnosis of disease activity, and in confirmation of remission of lupus nephritis, which can result in application of more appropriate therapeutic modality and individual approach to treatment. This study suggests that the determination of uNGAL in patients with lupus nephritis in daily clinical practice can contribute to the optimal effect of treatment.

## SA-PO730

### Vitamin D Is Negatively Correlated to Urinary MCP1 in Lupus Nephritis Patients

Aline Lázara Resende, Cristiane Bitencourt Dias, Fabiana Graciolli, Luciene dos Reis, Vanda Jorgetti, Viktoria Woronik. *Sao Paulo Univ, Sao Paulo, Brazil.*

**Background:** The association between vitamin D levels and SLE disease activity remains controversial. Urinary levels of Monocyte chemoattractant protein-1 (uMCP-1) are recognized as a specific biomarker of Lupus Nephritis (LN) activity. The aim of this study was to characterize the vitamin D status of newly diagnosed LN patients and its relationship to uMCP1 levels.

**Methods:** We included pre-menopausal female patients with ≤ 2 months of diagnosed LN attended from 2010 to 2012. The levels of uMCP1 were determined by specific ELISA (R&D Systems) and standardized to urine creatinine (Cr). 25-hydroxyvitamin $D_3$ [25(OH) D] were measured by chemoimmunoassay. Age-matched healthy female control's samples were collected at the end of winter. Statistical analysis were performed by Mann–Whitney test, Spearman correlation coefficient and linear regression models.

**Results:** LN patients presented a mean age of 29.5±10 years and were on glucocorticoid use for 34±12 days. Proliferative LN was observed in 86.6% of cases, with a mean proteinuria of 4.7±2.9 g/day and an estimated GFR of 37 (31-87) ml/min/1.73m². All SLE patients presented vitamin D insufficiency (9.9±4.4 ng/ml, range 4-20). Clinical and biochemical features of LN patients and controls are summarized below.

| | LN patients (n=15) | Controls (n=15) | p |
|---|---|---|---|
| Age (years) | 29.5±10 | 31.7±6.4 | 0.25 |
| Body Mass Index (BMI) (Kg/m²) | 24±3 | 24±4 | 0.74 |
| Estimated GFR (ml/min/1.73m²) | 37 (31-87) | 90 (73-100) | 0.009 |
| 25(OH)D (ng/ml) | 9.9±4.4 | 24.3±6.2 | <0.001 |
| Urinary MCP1 (pg/mg Cr) | 1594 (595-2447) | 177 (113-267) | <0.001 |

The levels of 25(OH)D correlated negatively with uMCP1 (r= -0.63, p<0.001). The correlation between uMCP1 and 25(OH)D remained unchanged even after adjusted for age, BMI and estimated GFR (beta coeff. -0.56, 95% CI -0.008 to -0.002, p=0.002).

**Conclusions:** 25(OH)D levels were negatively correlated to uMCP1, independently of age, BMI and estimated GFR. The negative correlation between vitamin D and markers of disease activity in SLE support the presumed immunomodulatory effects of vitamin D and should be further evaluated.

*Funding:* Government Support - Non-U.S.

## SA-PO731

### Proliferative Lupus Nephritis-NIH Regimen versus Tacrolimus and Mycophenolate Combination

Krishna Patil, Mahesh Bennikal, Arpita Roychowdhury, Rajendra Pandey, Jayaprada Jadhav, Rajesh Waikhom, Dipankar Sirkar, Sanjay Dasgupta. *Nephrology, IPGMER, Kolkata, WB, India.*

**Background:** Is multitarget therapy superior to NIH regimen?Future lies in individualizing therapy.

**Methods:** Open label prospective randomized trial.Arm I:NIH(CYC based) regimen(n[thinsp]=[thinsp]14).Arm II:Tacrolimus plus Mycophenolate and Prednisolo ne(n[thinsp]=[thinsp]14).Primary endpoints:complete or partial remission(CR/PR),non response and mortality.Secondary outcomes:Change in SLEDAI,creatinine,eGFR,proteinu ria,hematuria,C3,anti dsDNA,LNDAI & histologic activity & chronicity indices.Episodes of infection & steroid toxicity over 6 months therapy.

**Results:** Primary outcomes:CR&PR(p=0.21 and 0.33 respectively),non response(p=0.33) and mortality(p=1.00)were similar.Secondary outcomes:Arm I faired better over arm II with respect to mean change in serum creatinine(p=0.017),eGFR(p=0.042),C3 (p=0.014), and histological activity index-HAI(p=0.036).The episodes of LRTI & UTI were higher in the arm I(p=0.019 & p=0.028 respectively).Steroid toxicity was higher in arm I(p= 0.001 ).GI intolerance was higher in arm II(p= 0.046). Subgroup analysis: In arm I: HAI of >/=15 predicted poor outcome(p=0.03) & In arm II a LNDAI of >/=9 predicted poor outcome(p= 0.055).12 out of 14 patients in the arm I had a LNDAI of >/=9.Dialysis dependence beyond 1 month of adequate immunosuppression predicted non responsiveness to therapy in both arms.3 of the 4 deaths in the arm II were amongst non dialysis requiring patients and 1 of them died after attaining PR,where as all 4 deaths in the arm I were among dialysis dependent patients.

**Conclusions:** Multitarget regimen should be reserved for patients with stable renal function, LNDAI <9 and having contraindication to CYC.CYC arm had greater improvement in the C3 levels and HAI. HAI of >/=15 predicts poor outcome with CYC. Dialysis dependence after 1 month of either regimen should prompt one to withdraw/switch immunosuppression.Infection episodes & steroid toxicity were more in NIH arm but early fatal infection episodes in arm II raises concern over its safety.Larger trials are needed to validate the utility of LNDAI or HAI in individualizing therapy,predicting outcomes & guiding when to choose alternatives at the outset.

## SA-PO732

### Managing Lupus Nephritis with Cyclophosphamide or Mycophenolate Mofetil in a Large Nephrology Centre

Hannah M.M. Burton, Tracey M.E. Salter, Rebecca Suckling, David Makanjuola, Fiona E. Harris. *St. Helier Hospital, United Kingdom.*

**Background:** Since the NIH trials of the 1980s cyclophosphamide has been the mainstay of induction therapy for lupus nephritis (LN). The Euro-Lupus Nephritis Trial (ELNT) then demonstrated the benefits of a low-dose cyclophosphamide regime. In 2012 a Cochrane review concluded that mycophenolate mofetil (MMF) was as effective as cyclophosphamide in inducing remission. We appraised our management of LN over two decades to ascertain if our protocol could be optimised.

**Methods:** We present our single centre observational data. We retrospectively analysed the records of patients presenting with LN from 1992-2012. Response to induction therapy was assessed at 1 year, with complete remission defined as serum creatinine (sCr) ≤124μmol/L and urine protein:creatinine ratio (UPCR) ≤33g/mol, and partial remission defined as ≤25% increase in sCr from baseline and 50% reduction in UPCR to ≤150g/mol.

**Results:** Sixty four patients (89% female, mean age 39) had biopsy-proven LN and were followed up for an average of 2351 days. The ethnic mix was Black (23%), Asian (32%), White (43%) and Other (2%). 23 patients received cyclophosphamide induction therapy; 25 received MMF. Of the remainder, 2 received rituximab, 5 received prednisolone/ azathioprine and 9 received prednisolone.

| | Cyclophosphamide | MMF | Other |
|---|---|---|---|
| No. of patients | 23 | 25 | 16 |
| WHO Class: | | | |
| I | 1 | 0 | 0 |
| II | 0 | 1 | 3 |
| III | 1 | 0 | 1 |
| IV | 15 | 9 | 5 |
| IV/V | 2 | 4 | 1 |
| V | 2 | 11 | 6 |
| Other | 2 | 0 | 0 |
| Deaths | 0 | 2 | 3 |
| No. of patients requiring renal replacement therapy | 1 (at 720 days) | 2 (at 1898 & 2388 days) | 2 (at 1819 & 3903 days) |
| Adverse events (mean no./ patient) | 2.8 | 2.3 | 1.9 |

**Conclusions:** In the cyclophosphamide group, 46% achieved remission at 1 year, compared with 71% and 54% at 6 months (low dose and high dose group respectively) in the ELNT. This discrepancy in results may be at least partially explained by the different demographics. The remission rate was 52% in our MMF group compared with 46% in our cyclophosphamide group. This suggests that MMF is not inferior to cyclophosphamide with respect to outcome, in keeping with the Cochrane findings. We acknowledge that indication bias may have influenced the results in our cohort.

## SA-PO733

**Renal Involvement in Sjögren Syndrome** Maryam Khosravi,[1] Chris Laing,[2] Stephen B. Walsh.[3] *[1]Royal Free & Univ College London Centre for Nephrology; [2]Royal Free & Univ College London Centre for Nephrology; [3]Royal Free & Univ College London Centre for Nephrology.*

**Background:** Sjögren syndrome (SS) is an autoimmune disorder that has been estimated to affect as much as 1-2% of the adult female population. Epithelial cells are targets for a cell-mediated autoimmune response, in the lacrimal and salivary glands, as well as the renal tubulointerstitial compartment.

The prevalence of renal involvement in SS has been estimated at approximately 30%. The renal manifestation of SS is classically of distal renal tubular acidosis (dRTA), decreased renal excretory function.

**Methods:** We characterised 13 patients with renal SS who presented to the UCL Centre for Nephrology.

**Results:** Of the 13 patients, all were female, the mean age was (55.6 ± 12.6 years). Immunologically, All were positive for extractable nuclear antigens: 12 were Ro (SSA) positive, 9 were La (SSB) positive, 5 had hypocomplementemia (low C4), 1 had ANA, 7 had hypergammaglobulinemia (mean IgG 20.4± 8). All had urinary acidification (UA) tests with both furosemide and fludrocortisone and then oral ammonium chloride. The mean nadir urinary pH was 5.58 ± 0.47; all individual UA tests confirmed the presence of dRTA. The mean serum creatinine was 112.6± 38.9, and isotopic GFR measurements confirmed impaired renal excretory function in all patients with a mean GFR of 42.5 ± 9.02 ml/min). No patients had evidence of Fanconi syndrome, no patients had glycosuria or evidence of tubular proteinuria, the mean protein creatinine ratio was 46.3± 62.5 mg/mmol. Renal biopsies were obtained in 9 patients; all showed a diffuse diffuse lymphoplasmocellular infiltrate of mononuclear cells with variable tubular atrophy. 8 patients were started on immunosuppressive treatment with reducing course corticosteroids and mycophenolate mofetil (mean dose 937.5 mg daily). 8 patients also required supportive treatment with sodium bicarbonate (mean dose 562.5 g daily) and potassium (mean dose 57.6 mmol/daily).

**Conclusions:** dRTA in renal SS is common, and this is usually due to a pronounced and diffuse interstitial nephritis which adversely affects the GFR, often significantly. This is often underappreciated and may respond to immunosuppression.

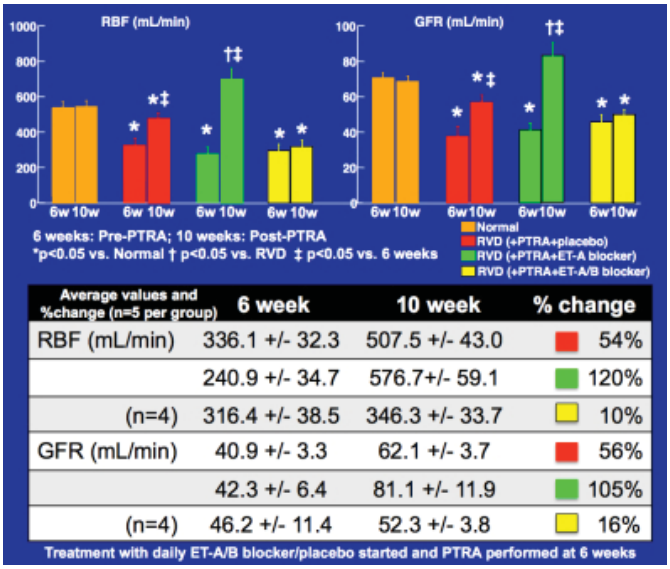
## SA-PO734

**Renal Angioplasty, Endothelin Receptor Blockers, and Recovery of Renal Function: A, Not B** Alejandro Chade, Nicholas Stewart. *[1]Physiology and Biophysics, [2]Medicine, [3]Radiology, Univ of Mississippi Medical Center.*

**Background:** Renal angioplasty and stenting (PTRAS) improves renal function in only 30% of patients with renovascular disease (RVD), underscoring the need for more effective therapeutic strategies. Because endothelin (ET)-A receptor blockade attenuates renal dysfunction and cardiovascular risk in chronic renal disease, we hypothesized that PTRAS followed by ET-A receptor blocker therapy would improve the renal outcomes in RVD. In addition, since little is known about the role of ET-B receptors in RVD, we determined whether PTRAS followed by dual ET-A and –B receptor blockade would synergize to provide greater renoprotection than ET-A antagonism alone.

**Methods:** Unilateral RVD was induced in 12 pigs by renal artery stenosis. After 6 weeks, single-kidney blood flow (RBF) and filtration (GFR) was quantified *in vivo* in the stenotic kidney using multi-detector computed tomography (MDCT). Then, all pigs underwent PTRAS and blindly randomized in: controls (RVD+PTRAS), and treated with ET-A blockers (Atrasentan, RVD+A) or with ET-A and ET-B blockers (RVD+PTRAS+AB, n=4 each). ET blockers/placebo were administered daily for 4 weeks and then in vivo MDCT studies repeated at 10 weeks.

**Results:** PTRAS resolved renal artery stenosis in all pigs and improved RBF and GFR. However, improvements were greater in RVD+PTRAS+A at 10 weeks, leading to almost a full recovery of renal function. In contrast, combined ET-A/B blocker therapy abolished the beneficial effects of both PTRAS and PTRAS+A.



| Average values and %change (n=5 per group) | 6 week | 10 week | % change |
|---|---|---|---|
| RBF (mL/min) | 336.1 +/- 32.3 | 507.5 +/- 43.0 | 54% |
| | 240.9 +/- 34.7 | 576.7+/- 59.1 | 120% |
| (n=4) | 316.4 +/- 38.5 | 346.3 +/- 33.7 | 10% |
| GFR (mL/min) | 40.9 +/- 3.3 | 62.1 +/- 3.7 | 56% |
| | 42.3 +/- 6.4 | 81.1 +/- 11.9 | 105% |
| (n=4) | 46.2 +/- 11.4 | 52.3 +/- 3.8 | 16% |

**Conclusions:** These results show that blockade of the ET-B receptors diminished the therapeutic effects of both PTRAS and ET-A blockade on RBF and GFR, implying an important role for a functional ET-1/ET-B pathway in the recovery of renal function in RVD. Furthermore, our study supports the potential therapeutic use of ET-A blockers to significantly improve the outcomes of PTRAS in RVD.

## SA-PO735

**Oxidative Stress: The Role in the Pathogenesis of Cardiorenal Syndrome Type 1** Grazia Maria Virzì, Alessandra Brocca, Massimo de Cal, Giacomo Mason, Sonya Day, Claudio Ronco. *Nephrology Dep-IRRIV, Vicenza, Italy.*

**Background:** Cardiorenal Syndrome Type 1 (CRS1) is characterized by acute cardiac events leading to acute kidney injury. Loss of redox homeostasis in reactive oxygen species (ROS) and reactive nitrogen species (RNS) results in a proinflammatory and profibrotic milieu via distinct mechanisms which promotes cardiovascular and renal structural and functional abnormalities. This pilot study examined the putative role of ROS/RNS-linked oxidative stress as a pathogenic mechanism of CRS1.

**Methods:** Subjects were selected from a prospective community-based cohort study with HF (58%male, mean age 80±8yrs, medianCrea 0.98mg/dl, IQR 0.87-1.15), CRS1 (54%male, mean age 76±10yrs, median Crea 1.34mg/dl, IQR 1.12-1.83). Quantitative determinations for IL6, Myeloperoxidase (MPO), Nitric Oxide (NO), Copper/Zinc Superoxide Dismutase (Cu/ZnSOD), and Endogenous Peroxidase Activity (EPA) were performed in HF (n=12), and CRS1 (n=11) patients. The Mann-Whitney U test was performed for cohort comparison (p<.05 was statistically significant) by STATA.

**Results:**

| | HF | CRS1 |
|---|---|---|
| MPO pg/ml | 505.6 (421.7-547.8 | 746.9 /665.2-940.0) |
| NO µM | 205.6 (95.0-277.5) | 507.3 (404.7-557.3) |
| Cu/ZnSOD pg/ml | 184.5 (160.5-192.0) | 274.5 (191.8-326.8) |
| EPA U/l | 274.5 (191.8-326.8) | 2978.4 (2071.8-4069.9) |
| IL6 pg/ml | 22.19 (16.6-24-6) | 90.68 (59.9-105.3) |

CRS1 patients displayed significant augmentation in circulating ROS and RNS, as well as expression of inflammatory cytokines, as IL6. Quantitative analysis of all oxidative stress markers showed significantly lower oxidative stress levels in HF compared to CRS1 patients (p<.05).

**Conclusions:** This pilot study demonstrates the significantly heightened presence of dual redox disequilibrium in CRS1 compared to HF patients: ROS/RNS production involving NADPH oxidase and MPO; superoxide production of hydrogen peroxide and NO; upregulation of proinflammatory mediators via peroxynitrite. Our findings indicate that oxidative stress is a potential therapeutic target, as it promotes inflammation by ROS/RNS-linked pathogenesis. For the first time we demonstrate evidence for the delineation of 2 distinct oxidative roles in CRS1 pathogenesis.

## SA-PO736

**In Vitro Study of Cell Responses at Radiocontrast Medium** Grazia Maria Virzì,[1] Alessandra Brocca,[1] Massimo de Cal,[1] Dinna N. Cruz,[2] Claudio Ronco.[1] *[1]Nephrology Dep-IRRIV San Bortolo Hosp, Vicenza; [2]Univ of California.*

**Background:** Radioontrast-induced nephropathy (RCIN) accounts for >10% of all causes of hospital-acquired renal failure, causes a prolonged inhospital stay and represents a powerful predictor of poor outcome. Mechanisms of RCIN are not completely understood. In this study, we investigated the in vitro effects of Contrast Media (CM) on renal tubular cells (RTCs) in terms of cell viability, and cell damage.Moreover, we evaluated the relationship between NGAL and RCIN in these patients.

**Methods:** In this study, we included 4 groups: 5RCIN patients with AKI(RCIN), 14 patients with AKI but no-exposition to CM(AKI_no CM), 5patients with exposition to CM but no AKI(CM_noAKI) and 16 healthy controls(CTR). Plasma from different cohorts were incubated with RTCs in standard condition for 24h and, subsequently, viability, apoptosis and necrosis was evaluated by cytofluorometric assay. Quantitative analysis of NGAL was performed in plasma. The Kruskal–Wallis test for multiple comparisons was applied to compare the groups. Pearson's Rank Order Correlation Coefficient ® was used to test the correlation between variables. A p-value of <.01 was considered statistically significant.

**Results:** RCIN groups is characterized by lower viability and higher apoptosis rates compared with other groups (p<.01).AKI_noCM and CM_noAKI groups have decreased viability and increased apoptosis compared with CTR. AKI_noCM group showed a stronger cell damage and apoptosis compared with CM_noAKI (p<.01). CM-noAKI group showed a significantly decreased viability rate and a significantly increased level of apoptosis compared with CTR (p<.01). There is a positive correlation between NGAL levels and Apoptosis (0.87) and Necrosis (0.75) and an inverse correlation between NGAL and cell viability (-0.84).

**Conclusions:** This study clearly demonstrates that CM-induced epithelial tubular renal cells apoptosis represents a key mechanisms of RCIN-AKI. In our results, the toxic effect of CM was evident and causes renal tubular cells death by apoptosis. These results suggest that AKI and CM may add their effects in RCIN patients and could induce in vivo a strong damage on kidney structures and functions.

## SA-PO737

**Ribonuclease 6: A Novel Antimicrobial Peptide in the Human and Murine Urinary Tract** Brian Becknell, Kirk M. McHugh, David S. Hains, John David Spencer. *Nationwide Children's Hospital.*

**Background:** Recent studies stress the importance of antimicrobial peptides (AMPs) in preventing urinary tract infections (UTIs). Members of the Ribonuclease A superfamily are potent AMPs that contribute to sterility in other organ systems. The goal of this study was to determine the expression and antimicrobial activity of Ribonuclease 6 (Rnase6) in the urinary tract.

**Methods:** Cystitis in mice was achieved via transurethral inoculation of $10^8$ colony forming units of uropathogenic E.coli (UPEC) into 8-12 week old C57BL/6 females. Organs were harvested for isolation of RNA/protein or fixed in 4% PFA. RNA/protein were also isolated from non-infected human bladder/kidney tissue and tissue with pyelonephritis. Human RNASE6 and mouse Rnase6 mRNA levels were measured by qRT-PCR. Immunohistochemistry localized Rnase6 expression. Immunoblot quantitated protein levels. Antimicrobial kill assays were performed using recombinant human RNase6 against $10^6$ CFU/mL UPEC.

**Results:** Human RNASE6 and mouse Rnase6 mRNAs are detectable at low levels throughout the uninfected urinary tract, but their encoded peptides are undetectable by immunoblotting. UPEC infection induces murine Rnase6 bladder mRNA 3-fold by 48 hours (p = 0.001). At this time point, murine Rnase6 protein localizes to myeloid cells infiltrating the bladder urothelium. Similarly, IHC demonstrates that leukocytes express Rnase 6 in kidney tissue with pyelonephritis. Human RNASE6 and mouse Rnase6 proteins are detectable by immunoblotting in kidneys with acute pyelonephritis as well as infected urinary sediment. Recombinant human RNASE6 protein binds to the bacterial cell wall and demonstrates dose-dependent bactericidal activity toward UPEC. Recombinant Rnase 6 demonstrates minimal cytotoxicity toward host tissues.

**Conclusions:** This study demonstrates that human RNASE6 and mouse Rnase6 proteins are expressed in the urinary tract and implicates human RNASE6 as a novel AMP toward UPEC. Our results suggest that RNase6 is a leukocyte-derived AMP that may play an important role in innate immunity of the urinary tract. RNase6 may represent a novel therapeutic target for children with complex UTI.

## SA-PO738

**Single Photon Emission Computed Tomography Imaging of Kidney Aminopeptidase N Expression in a Transgenic Mouse Model of Urothelial Transitional Cell Carcinoma** Hariprasad Gali,[1] Gopal Pathuri,[1] Andria F. Hedrick,[1] Venkateshwar Madka,[2] Vibhudutta Awasthi,[1] Chinthalapally V. Rao,[2] Benjamin D. Cowley.[3] *[1]Dept of Pharmaceutical Sciences, College of Pharmacy; [2]Hematology/Oncology Section; [3]Nephrology Section, Dept of Internal Medicine, College of Medicine, The Univ of Oklahoma Health Sciences Center.*

**Background:** Aminopeptidase N (APN; CD13; EC 3.4.11.2) is a zinc-dependent membrane-bound exopeptidase that catalyzes the removal of N-terminal amino acids from peptides. APN is well known to be highly expressed on renal proximal tubules. APN expression has been demonstrated to be significantly decreased in renal cancer tissues compared to adjacent normal tissues. Thus, molecular imaging of APN expression noninvasively could provide useful information regarding tumor extent in the kidney.

**Methods:** Tc-99m labeling of a probestin conjugate containing a $PEG_2$ linker and a $N_3S$ tripeptide chelator sequence, Asp-DAP-Cys, was achieved using our reported procedure (Bioorg Med Chem Lett. 2012, 22:4567-70). Whole body SPECT imaging was conducted at 2 hr post-injection of $^{99m}$Tc-probestin in a transgenic UPII-SV40T mouse and a wild-type mouse. UPII-SV40T mice spontaneously develop urothelial carcinoma *in situ* and invasive transitional cell carcinoma that invade into renal tissues. Histopathology and immunohistochemistry analysis were used to evaluate APN expression in the kidney.

**Results:** Radioactivity uptake was not observed in the tumor region of the transgenic mouse kidney whereas the entire renal parenchyma was visible in the wild-type mouse. Histopathological studies confirmed that both the pelvis and parenchyma regions were normal in the wild type mouse kidney and the presence of transitional cell cancer in the renal pelvis of the transgenic mouse kidney. Proliferating cell nuclear antigen staining of the transgenic mouse kidney confirmed the presence of tumor. An immunohistochemical study confirmed that the APN expression in tumor tissue was much lower than that in the adjacent normal tissue.

**Conclusions:** Results reported here provide preliminary support for the use of $^{99m}$Tc-probestin SPECT for imaging kidney APN expression noninvasively in animal models of urothelial tumors.

*Funding:* Other NIH Support - NIH grant S10RR025652 funded the NanoSPECT system and NIH NCI-N01CN 53300

## SA-PO739

**Evaluation of Positron Emission Tomography Renography in a Rat Model of Autosomal Dominant Polycystic Kidney Disease** Hariprasad Gali,[1] Gopal Pathuri,[1] Andria F. Hedrick,[1] Vibhudutta Awasthi,[1] Benjamin D. Cowley.[2] *[1]Dept of Pharmaceutical Sciences, College of Pharmacy; [2]Nephrology Section, Dept of Internal Medicine, College of Medicine, The Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.*

**Background:** We have identified *p*-$^{18}$F-fluorohippurate (F-18 PFH) as a potential radiopharmaceutical for PET renography. The objective of this study was to obtain an initial F-18 PFH PET renogram and kidney PET images of a male and a female Han:SPRD rat in order to assess the potential application of this novel technique to monitor progression of ADPKD.

**Methods:** F-18 PFH (~26 µCi) was IV injected into a 35 week-old male and a 38 week-old female Han:SPRD rat. Han:SPRD rats develop ADPKD, which is more severe in males. Dynamic PET imaging data in list-mode were acquired over a period of 30 min after injection followed by CT imaging data for 1 min. The PET scan time was divided into 30-sec time frames and the data was reconstructed using 2D filtered backprojection algorithm. Regions of interest (ROIs) were drawn over kidneys guided by CT images. Radioactivity within the ROIs of each frame was calculated, decay-corrected, and the renogram was plotted from the ROI activities.

**Results:** The renograms revealed a time-to-peak ($T_{max}$) of about 6 min and a time to half-maximal activity ($T_{1/2max}$) of >30 min for both kidneys for both rats. For comparison, our previously reported $T_{max}$ and $T_{1/2max}$ values for 10 week-old female healthy Sprague Dawley rats were 2.9 ± 0.4 min and 7.1 ± 1.3 min respectively (Nucl Med Biol. 2012, 39:1195-201). At the renogram peak, about 8 % injected dose (%ID) was observed in each kidney for male rat whereas about 14 and 12 %ID was observed in left and right kidney respectively for female rat. Kidney PET images of female rat at the renogram peak display higher activity compared to male rat indicating more functional tubular mass in female rat kidneys than male.

**Conclusions:** This preliminary study indicates that F-18 PFH PET renography may be a suitable technique to monitor progression of ADPKD in animal models. However, further research is required to validate the results and correlate the PET renogram parameters with the disease status.

## SA-PO740

**Enalapril Treatment Prevents and Reverses Renal Damage in the ZSF1 Obese Rat Model of Diabetic Nephropathy** Paul Harrison, Kathleen A. Lincoln, Hongxing Chen, Holly Clifford, Kristina Gueneva-Boucheva, Hu Sheng Qian, Glenn A. Reinhart, Carine Boustany. *Cardiometabolic Disease Research, Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT.*

**Background:** The prevalence of diabetic nephropathy is on a rise despite medical advancements. Novel therapies to slow the decline in renal function are urgently needed. Accordingly, preclinical models of diabetic nephropathy (DN) are warranted to support the advancement of novel compounds into the clinic. Recent reports suggest that the obese diabetic ZSF1 rat model closely approximates the pathophysiological conditions of human DN, including: hypertension, proteinuria and hyperglycemia. Angiotensinogen Converting Enzyme Inhibitors (ACEi) have been shown to slow the decline in renal function in patients with DN.

**Methods:** A 15 week time course study was conducted to assess the effect of enalapril initiated at different times on blood pressure, proteinuria and fibrosis. Male ZSF1 obese rats (n=9/group), telemetry instrumented for blood pressure recording, were randomly assigned to six treatment groups. Enalapril administration (3 mg/kg in the drinking water; achieving clinically relevant concentration) was initiated on study weeks 1, 3, 5, 8 and 10 for a treatment duration of 15, 12, 10, 8 and 5 weeks, respectively. Vehicle treated ZSF1 obese animals were used as comparators. Weekly urine collections, body weight, water and food consumption recordings, and clinical observations were performed. Blood pressure was continuously recorded. Blood collections for creatinine and pharmacokinetic determinations were performed on select weeks. At termination, renal tissue was assessed for incidence of glomerulosclerosis and interstitial fibrosis.

**Results:** Enalapril administered in a prophylactic (duration of 15 and 12 weeks) and therapeutic (duration of 10, 8 and 5 weeks) manner significantly decreased mean arterial pressure and urinary protein to creatinine ratio compared to vehicle. Glomerular and interstitial lesions were modestly reduced across all treatment groups.

**Conclusions:** In summary, the ZSF1 obese rat constitutes a preclinical model of diabetic nephropathy in which an ACEi both prevents and reverses renal damage.

*Funding:* Pharmaceutical Company Support - Boehringer Ingelheim Pharmaceuticals, Inc.

**SA-PO741**

**Cardiorenal Syndrome Type 5 Mechanism: A New Hypothesis for Organs Damage** Alessandra Brocca, Grazia Maria Virzì, Giacomo Mason, Massimo de Cal, Claudio Ronco. *Nephrology Dep-IRRIV, Vicenza, Italy.*

**Background:** Cardiorenal Syndrome Type 5 (CRS5) is characterized by the presence of combined cardiac and renal dysfunction due to systemic disorder. Severe sepsis represents the most common condition which can damage both organs. Activation and induction of cytokines, leukocytes and toll receptors are well established in organs damage in CRS5. CRS5 mechanism is not well-known, although specific cellular and molecular changes with time-specific pattern are reported. Our aim was to examine in vitro that CRS5 plasma was able to trigger a response in renal tubular cells (RTCs), resulting in apoptosis and in cytokine-release.

**Methods:** We enrolled 11 patients with CRS5 (68.4±10.8yrs), and 16 controls (CTR) (52.0±7.7yrs). Plasma from different groups were incubated with RTCs for 24h and, subsequently, cell apoptosis was evaluated by Annexin-V/Propidium Iodide assay and quantitative levels of IL-6 in plasma was performed by ELISA.

**Results:** In RTCs treated with CRS5 plasma, a quantitative analysis showed significantly higher apoptosis and necrosis rates compared to CTR (p<.001). A significantly lower viability was observed in RTCs incubated with CRS5 plasma compared to CTR (p<.001).

| | Viability (%) | Apoptosis (%) | Necrosis (%) |
|---|---|---|---|
| **CRS5** | 82.80 (81.20-86.20) | 15.10 (13.80-17.80) | 4.20 (1.60-12.20) |
| **CTR** | 96.60 (94.75-97.60) | 1.51 (1.20-2.00) | 0.98 (0.70-1.31) |

In CRS5 plasma, IL-6 levels (64.6pg/ml, IQR 59.1-96.3) were significantly higher compared with CTR plasma (6.17 pg/ml IQR 3.50-7.78) (p<.001). Moreover there were significant positive correlation between IL-6 levels and cellular apoptosis (rho .74, p<.001) and necrosis (rho .56, p<.01). A negative correlation (rho -.74, p<.001) was observed for viability.

**Conclusions:** Our study demonstrated the induction of cellular death, by apoptosis and necrosis pathways, in RTCs incubated with CRS5 plasma. Furthermore, we observed an increase of IL-6 plasma levels in CRS5 patients. In conclusion we could hypothesise a possible implication of inflammatory damage on the pathophysiology of CRS5. It is necessary to increase the patients sample size to validate our hypothesis.

**SA-PO742**

**Tubular Overexpression of Gremlin in Transgenic Mice Induces Renal Damage Susceptibility** Sergio A. Mezzano,[1] Alejandra M. Droguett,[1] Daniel Carpio Paniagua,[1] Bredford Kerr,[2] Raquel Rodrigues-Diez,[3] Jesus Egido,[3] Marta Ruiz-Ortega.[3] *[1]Nephrology, Universidad Austral de Chile, Valdivia, Los Rios, Chile; [2]Centro de Estudios Científicos, CECS, Valdivia, Los Rios, Chile; [3]Fundacion Jimenez Diaz, Universidad Autonoma, Madrid, Spain.*

**Background:** Gremlin is an embryogenic gene with a key role in nephrogenesis that is reexpressed in many human renal diseases, including diabetic nephropathy, pauci inmune glomerulonephritis and chronic allograft nephropathy. Some authors have proposed that gremlin could be involved in renal damage, acting as a downstream mediator of TGF-b.

**Methods:** To examine the *in vivo* role of Gremlin in the kidney we generated seven specific proximal tubular epithelial cells human gremlin (GREM1) transgenic mouse lines, presenting 1.2 to 200-fold increase of GREM-1 gene expression levels. These GREM1 transgenic mice presented a normal phenotype and non-proteinuria or renal function involvement.

**Results:** In response to acute renal damage cause by folic acid injection, tubular-specific GREM1 transgenic mice developed higher proteinuria after 7 and 14 days than wild type mice. Tubular GREM1 overexpression was associated to renal upregulation of profibrotic factors, such as TGF-b and a-SMA, and increased proliferating cells compared to wild type mice.

**Conclusions:** Our results suggest that GREM1-overexpressing mice might have an increased susceptibility to develop renal failure supporting the involvement of gremlin in renal damage progression.

**SA-PO743**

**Xylene Induces DNA Methylation Changes in Podocytes and Tubular Epithelial Cells** Zhongxiu Xu, Wei-song Qin, Xianghua Cao, Cai-hong Zeng, Zhi-hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing Univ School of Medicine, Nanjing, China.*

**Background:** To determine if there is an epigenetic mechanism underlying organic solvent-induced renal injury, we investigated the change of DNA methylation in conditionally immortalized human podocytes and proximal tubular cell line HK2 treated with xylene.

**Methods:** DNA methylation changes in cultured human podocytes and proximal tubular cells were identified by comparing DNA methylation profiles of the cells treated with xylene and the untreated control. Illumina human 450k CpG DNA methylation microarray was used to analyze DNA methylation of the cells. Bisulfite sequencing PCR and pyrosequencing were used to validate the microarray results. Quantitative real-time PCR (qRT-PCR) was carried out to examine the correlation between the mRNA expression and methylation level of a gene.

**Results:** We identified 51 probes that displayed significant methylation level changes in xylene-treated podocytes compared with untreated control cells, among which 25 probes showed increased, while the remaining 26 decreased, methylation levels. mRNA qRT-PCR analyses of the corresponding genes revealed the correlations of IL-20 and p53 expressions with their methylation levels, respectively. For HK2 cells, there were 243 probes that displayed significant methylation change, of which 109 showed increased, while 134 decreased, methylation level. qRT-PCR analyses confirmed the correlation between the mRNA expression and the methylation level of EIF1AY or KDM5D. The results of pyrosequencing were well consistent with the microarray data.

**Conclusions:** Xylene can induce DNA methylation change in podocytes and tubular cells, which may be part of the mechanism by which xylene causes injury of these cells.

*Funding:* Government Support - Non-U.S.

**SA-PO744**

**Inhibition of Cyclooxygenase-2 Does Not Ameliorate Lithium-Induced Renal Microcystic Injury and Polyuria in Adolescent Rat** Kirsten Madsen,[1,2] Gitte Kjaersgaard,[1] Niels Marcussen,[2] Boye Jensen.[1] *[1]Dept of Cardiovascular and Renal Research, Univ of Southern Denmark, Odense, Denmark; [2]Dept of Pathology, Odense Univ Hospital, Odense, Denmark.*

**Background:** In human patients, chronic treatment with lithium leads to tissue injury with multiple microcysts that originate in cortical collecting duct and nephrogenic diabetes insipidus (NDI). In this study it was hypothesized that renal COX-2 activity promotes microcyst formation.

**Methods:** Microcystic kidney injury was induced in male adolescent rats by feeding dams with lithium [50 mmol Li/kg chow] from postnatal days 7 to 34.

**Results:** Lithium treatment induced cortical microcysts and dilatations in the distal nephron parts; it increased cortical cell proliferation and increased inactive pGSK-3β; it lowered AQP2 expression and induced polyuria with decreased ability to concentrate the urine and it increased COX-2 protein level in thick ascending limb. Concomitant treatment with lithium and a specific COX-2 inhibitor, parecoxib (5mg/kg/day, P10-P34) did not prevent lithium-induced microcystic injury and polyuria, but improved urine concentrating ability transiently after a dDAVP challenge. COX-2 inhibition did not reduce reno-cortical lithium-induced cell proliferation or inactivating phosphorylation of GSK-3β. COX-1 protein abundance increased in kidney cortex in response to lithium and was associated with microcysts and dilatations in collecting ducts in both rats and humans.

**Conclusions:** In summary, COX-2 is marginally stimulated in cortical loop of Henle cells in chronic lithium-treated adolescent rats; COX-2 is not colocalized with microcystic epithelium; mitotic activity and inactivated pGSK-3β in collecting duct; a blocker of COX-2 does not prevent cell proliferation, cyst formation or GSK-3β inactivation. It is concluded that COX-2 activity is not the primary cause for microcystic injury and polyuria in a NaCl-substituted rat model of Li-nephropathy while COX-1 is a likely candidate to affect the injured epithelium.

**SA-PO745**

**The Effect of Pioglitzone on Mitochondrial Biogenesis in the Kidney of Dahl Salt Sensitive Hypertension Rat** Yoshimitsu Hayashi, Yuki Kusano, Kimio Watanabe, Makoto Kanno, Hiroshi Kimura, Kenichi Tanaka, Koichi Asahi, Hiroyuki Terawaki, Shigeatsu Hashimoto, Masaaki Nakayama, Tsuyoshi Watanabe. *Fukushima Medical Univ, Nephrology and Hypertension, Fukushima, Japan.*

**Background:** Thiazolidines (TZDs) improve insulin sensitivity but also appear to have antihypertensive effects in obesity. Increases oxidative stress in renal outer medulla by salt loading is thought to be one of the causes of hypertension and kidney damage. To closely examine the antihypertensive and renoprotective effects of TZDs, we used non-obese salt sensitive hypertension rat with pioglitazone (pio).

**Methods:** Aged 6week Dahl salt sensitive (DSS) rats were divided into the four groups: LS (0.3% Low salt fed n=10), LSP (LS fed containing pio n=10), HS (4.0% High salt fed n=20) and HSP (HS fed containing pio n=20). The concentration of pio in chow is kept at 0.005%. Rats were sacrificed at 12$^{th}$ week. Nitrotyrosine, SOD1 and SOD2 in kidney were observed by immunohistochemistry or western blot. We also determined two subunits (COX-I and SDH-A) of oxidative phosphorylation enzyme complex to elucidate mitochondrial biogenesis of kidney by western blot. COX-I is mitochondrial DNA-encoded, and SDH-A is nuclear DNA-encoded.

**Results:** Between HS and HSP groups, significant improvement were observed in systolic blood pressure (171 vs 156 mmHg), creatinine clearance (2.3 vs 3.1 ml/min) in HSP. No significant differences were observed in body weight, serum glucose and insulin levels, and urinary protein excretion. Serum triglyceride levels was decreased (96 vs 67 mg/dl, p<0.01), and adiponectin levels was increased (3.3 vs 5.2 mg/ml, p<0.01) in HSP. Nitrotyrosine was detected in fibrosis area in renal outer medulla and nitrotyrosine levels were significantly reduced (1.0±0.3 vs 0.71±0.3) in HSP. Expression of SOD2 levels (1.0±0.1 vs 1.3±0.2, p<0.05) and ratio COX-I / SDH-A (1.0±0.1 vs 1.3±0.4, p<0.05) were increased in HSP.

**Conclusions:** Pioglitazone suppressed salt sensitive hypertension, renal damage in DSS rat without apparent changes in serum glucose and insulin levels. Increased adiponectin to induce mitochondrial biogenesis might be involved in these renoprotective effects of pioglitazone.

## SA-PO746

**Alpha-1-Microglobulin Protects Renal Proximal Tubule Epithelial Cells from Apoptosis and Cell Damage following Hemoglobin-, Heme-, and Oxidative Overload** Magnus Gram, Sara Davidsson, Maria Johansson, Bo Akerstrom. *Infection Medicine, Clinical Sciences, Lund, Sweden.*

**Background:** Intravascular hemolysis, following e.g. cardiac surgery, with the release of large amounts of extracellular hemoglobin (Hb), is a highly pathogenic event causing substantial and sometimes non-reversible damage to the kidneys. Removal, scavenging, or neutralization of extracellular Hb and its down-stream metabolites may therefore represent a plausible strategy of protection of the kidney function and structure. The aim of this study was to investigate the structural and functional damage and characterize the inflammatory response in human primary renal proximal tubule epithelial cells following Hb, heme and oxidative insults and to evaluate the protective effects following treatment with the heme- and radical scavenger alpha-1-microglobulin (A1M).

**Methods:** Following exposure to Hb and Hb-metabolites we characterized the cellular and molecular response in human primary renal proximal tubule epithelial cells (HPRPTEC) with or without the addition of A1M.

**Results:** Exposure to oxyHb, metHb, heme, or ROS led to upregulation of interleukin-1β (IL-1β), heme oxygenase-1 (HO-1), ICAM-1 and p21 mRNA expression at 4 and 24 hours. Furthermore, results showed an increased necrosis (LDH), and apoptosis (caspase activation) in epithelial cells exposed to metHb and heme but not in cells exposed to oxyHb. Treatment with A1M reversed the metHb, and heme-induced effects on gene expression as well as necrosis and apoptosis responses.

**Conclusions:** Following systemic hemolysis, e.g. as a result of cardiac surgery or blood transfusion, there is a distinct increase of extracellular Hb-metabolites that have potential pathophysiological effects on the kidneys, sometimes rendering irreversible damage to the kidneys. We show that treatment of the Hb-, heme-, and ROS-induced inflammatory and stress response in the kidney cell line HPRPTEC could be inhibited by the heme- and radical scavenger A1M. Our studies therefore present a therapeutic opportunity and a means of decreasing the damage to the kidneys following intravascular hemolysis.

## SA-PO747

**Podocyte Injury with Hypercholestelemia Promotes Intraglomerular Lipid Deposition** Satoshi Hara,[1] Kazuo Sakamoto,[2] Yasutoshi Takashima,[1] Namiko Kobayashi,[1] Toshiharu Ueno,[3] Noriko Uesugi,[1] Taiji Matsusaka,[4] Michio Nagata.[1] *[1]Kidney and Vascular Pathology, Univ of Tsukuba, Tsukuba, Ibaraki, Japan; [2]Nephrology, Iizuka Hospital, Fukuoka, Japan; [3]Nephrology, Toranomon Hospital, Tokyo, Japan; [4]Internal Medicine, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.*

**Background:** Focal segmental glomerulosclerosis (FSGS) cellular variant is characterized by endocapillaly proliferation mainly composed of foam cells which are derived from macrophage. The lesion is often associated with extracapillary proliferation. The present study aimed to investigate how foam cells infiltrate into the glomerulus in the setting of podocyte injury.

**Methods:** By mating low density lipoprotein receptor knockout (LDLRKO) mice with NEP25 mice which expressed human CD25 in podocyte, we generated NEP25;LDLRKO mice. In this model, immunotoxin injection provokes podocyte-specific injury leading to FSGS under hypercholesteremia. We compared NEP25;LDLRKO mice with LDLRKO mice and NEP25 mice as control. Mice have fed with Western-type diet or normal diet from 8 weeks old. At 12 weeks, immunotoxin for human CD25 or vehicle intravenous infusion was performed, and mice were perfused after 12 days. We performed Oil red O staining and immunohistochemically analyzed macrophage infiltration (CD68 staining), monocyte chemoattractant protein-1 (MCP-1).

**Results:** NEP25;LDLRKO and NEP25 mice revealed severe glomerular collapse with extracapillary proliferation. All groups showed macrophage and foam cells infiltration, although no significant differences were noted. Oil red O positive area in the glomeruli significantly increased in NEP25;LDLRKO mice ($p < 0.05$). Although MCP-1 was dominantly expressed at podocytes, MCP-1 expression were absent in the glomeruli with extracapillary proliferation in NEP25;LDLRKO and NEP25 mice.

**Conclusions:** Under hypercholesteremia, acute podocyte injury promotes excessive lipid deposition within the glomeruli probably due to injury of filtration barrier and mesangium. However, hypercholesteremia with podocyte loss did not cause macrophage attraction, suggesting mechanism of podocyte loss, but not podocyte loss per se may contribute to glomerular foam cell infiltration in FSGS.

## SA-PO748

**Vascular Eicosanoid Generation in Experimental Uremia** David Bishop-Bailey,[1] Julius Edward Kieswich,[2] Kieran McCafferty,[2] Scott Thomson,[1] Matthew L. Edin,[3] Darryl Zeldin,[3] Magdi Yaqoob.[2] *[1]Comparative Biomedical Sciences, Royal Veterinary College, London, United Kingdom; [2]William Harvery Research Institute, TMT, Queen Mary, Univ of London, London, United Kingdom; [3]Environmental Cardiopulmonary Disease Group, NIEHS, NIH, NC.*

**Background:** Cardiovascular disease is the leading cause of death for patients with moderate to severe chronic kidney disease. Eicosanoids and related lipids (EARLs), are products of cyclooxygenase, lipoxygenase and epoxygenase enzymatic pathways, and have established and emerging roles in renal and cardiovascular physiology. Here we examined the changes in vascular EARL production after experimental uremia in the rat.

**Methods:** Male Wistar rats (n=5 per group) underwent a 2-stage subtotal nephrectomy (SNx) or a sham procedure. The left kidney was two thirds resected with right total nephrectomy. After a further 4 weeks, blood was taken for serum analysis, and aorta's were removed and placed in serum free organ culture for 30min. The resulting conditioned media was analysed by LC-MS/MS for patterns of cyclooxygenase, lipoxygenase and epoxygenase: arachidonic acid and linoleic acid metabolites.

**Results:** Subtotal nephrectomy resulted in increases ($P<0.05$) in serum urea (sham 6.1±0.2; SNx 17.4±1.6 mmol/l), creatinine (sham 42.0±1.5; SNx 85.2±3.0 umol/l), $Ca^{2+}$ (sham 2.712±0.019; SNx 2.846±0.020 mmol/l) and mean arterial blood pressure (sham 137±26; SNx 157±19.6) but albumin, $Na^{+}$ and $K^{+}$ were unchanged. Sham and SNx aorta released an almost identical pattern of eicosanoids with prostacyclin the major EARL produced by both groups (sham 65±12; SNx 58±9 ng/ml). The one exception was a significant increase in the epoxygenase arachidonic acid metabolite 14,15-EET (sham 131±13; SNx 233±104 pg/ml, $P<0.02$).

**Conclusions:** 14,15-EET acts as a vasodilator and anti-inflammatory EARL which may represent a novel biomarker and mediator of possibly inadequate compensatory cardiovascular response to chronic kidney disease. The usefulness of drugs that elevate 14,15-EET levels, e.g. soluble epoxide hydrolase inhibitors, to limit the adverse cardiovascular outcomes associated with CKD remains to be determined.

## SA-PO749

**Sickle Nephropathy Is Mediated via ET-1 Upregulation of NOX2 and p47phox** Brett Heimlich, Joshua S. Speed, David M. Pollock. *Experimental Medicine, Georgia Regents Univ, Augusta, GA.*

**Background:** Sickle cell nephropathy (SCN) is a chronic manifestation of sickle cell disease (SCD) for which the mechanism is unknown. We previously found that reactive oxygen species (ROS) were elevated in the glomeruli of SCD mice. In vitro administration of the NADPH oxidase inhibitor apocynin prevented glomerular ROS production and importantly, in vivo treatment with ABT-627, a selective ET-A receptor antagonist, reduced glomerular ROS to levels observed in controls. Since ET-1 is elevated in patients with SCD, we hypothesized that ET-1 mRNA is elevated specifically in the glomeruli of SCD mice, which subsequently causes increased ROS creation via NOX2.

**Methods:** Renal tissues were carefully dissected and glomeruli were harvested from 14-week-old, knock-in HbS only sickle and C57BL/6J mice and were assessed for relative ET-1, NOX2, and p47phox mRNA.

**Results:** We found that sickle mice have 401±89% more glomerular ET-1 mRNA when compared to C57 control mice ($p<0.01$, n=6). Furthermore, we found that SCD mice have significant increases in both NOX2 and p47phox but not NOX4 mRNA in their glomeruli (186±21 and 301±64 % of control respectively, $p<0.01$, n=6). These results were recapitulated in the renal cortex of the same animals with the exception of NOX2. ET-1 mRNA was 269±36% of control while p47phox was 172±15% of control mice ($p<0.01$, n=6).

**Conclusions:** Combined with our previous experiment, these data support the hypothesis that chronically elevated ET-1 leads to the creation of ROS via NADPH oxidase in the glomeruli of sickle animals, contributing to renal damage in the progression of SCN.

## SA-PO750

**Clinical Assessment of Urine Magnesium Excretion Rate as a Predictor for Tubulo-Interstitial Disorders** Hajime Hasegawa, Chie Noiri, Taisuke Shimizu, Kunihiko Yasuda, Yoshimi Okada, Tatsuro Sano, Yuta Kogure, Tota Kiba, Tetsuya Mitarai. *Nephrol & Hypertens, Saitama Med Center, Saitama Med Univ, Kawagoe, Saitama, Japan.*

**Background:** Elevated urine magnesium excretion and its correlation with histological damage have been demonstrated in patients with tubulo-interstitial disorders. Present study aimed to assess the clinical significance of fractional excretion of magnesium (FEMg) for the prediction of interstitial disorders.

**Methods:** Adult patients of 94 cases with various renal diseases, including glomerulonephritis (41.5%), interstitial nephritis (23.4%), hypertensive nephrosclerosis (22.3%), diabetic nephropathy (6.4%), lupus nephritis (5.3%) and others, were enrolled and assessed cross-sectionally.

**Results:** Stratified analysis based on NAG-to-Cr ratio (NCR), which is a parameter for organic damage of proximal tubule cells, showed that high NCR group demonstrated significantly high FEMg although beta-2 microglobulin-to-Cr ratio (MCR) were not different. Univariate analysis using NCR as a predictor variate demonstrated that FEMg showed significant correlation with NCR ($R=0.596$, $p=0.0316$) but other parameters did not. Multivariate regression analysis confirmed the significance of FEMg as a effective predictor of NCR. FEMg also showed significant correlation with estimated GFR but NCR did not. Additionally, the correlation of FEMg with NCR was independently analyzed in patients with glomerulonephritis (G: glomerulus-predominant disorder, n=38), nephrosclerosis (N: disorders with both glomerulus and interstitium, n=21) and tubulo-interstitial nephritis (T: interstitium-predominant disorders, n=22), and FEMg demonstrated significant correlation with NCR in N ($R= 0.839$, $p<0.001$) and T ($R=0.743$, $p=0.002$) but not in G.

**Conclusions:** FEMg was only parameter showing significant correlation with both NCR and estimated GFR in all patients. In addition, clinical reliability of FEMg was more sensitive in patients with interstitium-predominant renal disorders. The present study might indicate that FEMg is a beneficial parameter to predict the severity of interstitial impairment.

**SA-PO751**

**Evaluation of Various Dendritic Cell Markers in Renal Biopsy Specimens of 48 Patients with Various Renal Diseases**

Hanako Takechi,[1] Takashi Oda,[1] Kojiro Yamamoto,[1] Naoki Oshima,[1] Yutaka Sakurai,[2] Hiroo Kumagai.[1] *[1]Dept of Nephrology and Endocrinology, National Defense Medical College, Tokorozawa, Saitama, Japan; [2]Dept of Preventive Medicine and Public Health, National Defense Medical College, Tokorozawa, Saitama, Japan.*

**Background:** Dendritic cells (DCs) are the most potent antigen-presenting cells, and their participation in the pathogenesis of glomerulonephritis has been suggested. We therefore investigated subtypes of DCs in kidneys of patients with various renal diseases.

**Methods:** We examined renal biopsy specimens from fifty-six patients with renal diseases or renal specimens of normal controls; 7 with ANCA-associated vasculitis (AAV), 9 with IgA nephropathy (IgAN), 5 with minimal change nephrotic syndrome (MCNS), 5 with focal segmental glomerulosclerosis (FSGS), 10 with membranous nephropathy (MN), 5 with membranoproliferative glomerulonephritis (MPGN), 8 with tubulointerstitial nephritis (TIN) and 8 normal control kidneys. Five distinct markers of DCs (CD1c, CD209, CD208, CD1a and CD303) and T cell subtypes (CD4, CD8) were analyzed immunohistochemically. The clinical data and histological features of renal biopsy were statistically evaluated for possible relation with immunostaining results.

**Results:** Among the five markers of DCs, three markers, i.e., CD1c (a marker of conventional DCs), CD209 (DC-specific ICAM3-grabbing nonintegrin; DC-SIGN, a marker of monocyte-derived DCs) and CD208 (DC-lysosome-associated membrane glycoprotein; DC-LAMP, a marker of interdigitating DCs), positive cells significantly increased in interstitium of the kidneys of AAV and TIN. The numbers of these interstitial DCs per area correlated with the number of interstitial CD4 positive cells and the grade of tubulointerstitial injury. Generally, DCs are rarely found in the glomeruli of most renal diseases, however, a few CD208+ DCs were observed in glomeruli in the patients with AAV.

**Conclusions:** These observations suggest that interstitial myeloid DCs may interact with CD4+ T cells and may induce tubulointerstitial injury in the patients of AAV and TIN. In addition, CD208+ DCs may induce inflammation not only in interstitium but also in glomeruli of patients with AAV.

**SA-PO752**

**The Protective Effect of Substance H in Chlorhexidine Gluconate-Induced Peritoneal Fibrosis Animal Model**

Kyung Don Ju,[3] Eun Kyoung Shin,[3] Seungmi Lee,[1] Miseon Park,[1] Hyo-jin Kim,[1] Tai Yeon Koo,[2] Curie Ahn,[1] Kook-Hwan Oh.[1] *[1]Div of Nephology, Dept of Internal Medicine, Seoul National Univ Hospital, Republic of Korea; [2]Transplantation Center, Seoul National Univ Hospital, Republic of Korea; [3]Biomedical Research Institute, Seoul National Univ Hospital, Republic of Korea.*

**Background:** Peritoneal fibrosis (PF) is a complication of long-term peritoneal dialysis. Inhibitory action of adenosine-monophosphate-activated protein kinase (AMPK) on the mTOR and smad-3 system has been suggested. Substance H is a novel and potent AMPK activator. The present study was implemented to investigate the protective effect of substance H against the development and progression of peritoneal fibrosis in an in-vivo and in-vitro models.

**Methods:** Peritoneal fibrosis rat were prepared by injecting 0.1 % chlorhexidine gluconate (CG) intraperitoneally. CG-treated rats without substance H treatment and vehicle-treated rats were used for control. Rat peritoneal mesothelial cells (RPMC) cultured primarily from wistar male rat using 0.25 % trypsin-EDTA and were treated in high glucose (HG, 30 mM) and normal glucose (NG, 5 mM) conditions.

**Results:** Substance H-treated peritoneal fibrosis rats exhibited marked decrease of peritoneal thickness, and cocoon formation compared with CG-treated control rat. The mRNA expression levels of Akt, mTOR and smad-3 in the peritoneal membrane were also ameliorated. From RPMC experiment, HG increased mRNA and protein expressions of Akt, mTOR and smad-3 in a time dependent manner. Substance H decreased the mRNA and protein levels of Akt, mTOR, smad-3 in a dose dependent manner.

**Conclusions:** Our findings suggest that substance H protects against peritoneal membrane fibrosis in the CG-induced peritoneal fibrosis model.

**SA-PO753**

**Renal Protective Effects of DPPIV Inhibition (LC15-0444) on Experimental UUO Model**

Hye Sook Min,[1] Mi Jin Lee,[1] Young Sun Kang,[1] Jin Joo Cha,[1] Young Youl Hyun,[2] Ji Eun Lee,[3] Hyunwook Kim,[3] Jung Eun Kim,[1] Hye Kyoung Song,[1] Mihwa Lee,[1] Jee-young Han,[4] Dae R. Cha.[1] *[1]Nephrology, Korea Univ Ansan Hospital, Ansan, Kyunggido, Republic of Korea; [2]Nephrology, Sungkyunkwan Univ Kangbuk Samsung Hospital, Seoul, Republic of Korea; [3]Nephrology, Wonkwang Univ Sanbon Hospital, Gunpo, Republic of Korea; [4]Pathology, Inha Univ Hospital, Incheon, Republic of Korea.*

**Background:** DPP IV is known to modulate substrates involved in metabolism, glucose regulation, inflammation, cell migration, and cell differentiation. However, the roles of DPP4 and its inhibitors are not fully understood in the renal setting. Therefore, we investigated the role of DPP4 inhibitor in experimental renal fibrosis model.

**Methods:** 8-week-old C57/BL6 mice were divided into 3 groups : I) sham II) vehicle + UUO, III) DPP4 inhibitor (LC15-0444) + UUO group. After inducing UUO C57Bl/6J mice were placed on a normal chow diet with DPP4 inhibitor (LC15-0444, 150mg/kg/day) as a food admix for 2 weeks.

**Results:** Interestingly, DPPIV activity was significantly increased in the obstructed kidney, which was ameliorated by DPPIV inhibition. Administration of LC15-0444 resulted in a significant decrease of microalbuminuria and proteinuria. However, there were no significantly changes of DPP4 activities in the heart and plasma. Gene expressions of MCP-1, PAI-1, Type IV collegen and TGF beta 1 in kidney were significantly decreased in DDP4 inhibitor (LC15-0444) group. In addition, Urinary excretion of 8-isoprostane was markedly increased in UUO, and DPPIV inhibition significantly decreased urinary excretion of 8-isoprostane. In cultured proximal tubule cells, DPPIV expression was upregulated by angiotensin II stimulation, and suppressed by DPPIV inhibition.

**Conclusions:** Altogether, these results suggest that activation of DPP4 in kidney has a role in the progression of renal disease and DPPIV inhibition may provide renoprotective effects independent of its hypoglycemic effects. In our study showed that DDP4 inhibitors have anti-inflammatory and anti-fibrotic processes in the kidney.

**SA-PO754**

**HIV-Induced Podocyte Ang II Production Sustains Downregulation of Vitamin D Receptor (VDR) through Upregulation of Snail**

Nirupama Chandel, Tejinder Singh, Noopur Goel, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

**Background:** Ang II plays an important role in the development and progression of HIV-associated nephropathy (HIVAN). Recently, we reported that HIV enhances the activation of renin angiotensin system (RAS) in podocytes through down regulation of VDR (Am J Physiol, 2013). We hypothesize that HIV may be sustaining podocyte Ang II production through up regulation of Snail.

**Methods:** Protein blots were prepared form renal tissues of age and sex matched control and HIV transgenic mice (Tg26; n=4) and probed for TGF-β, Snail, and VDR; the same blots were reprobed for actin. Renal tissue lysates of control and Tg26 mice were also assayed for their Ang II content by ELISA. Conditionally immortalized human podocytes (CIHP) were transduced with either empty vector (EV/CIHP) or NL4-3 construct (HIV/CIHP). Protein blots of cellular lysates EV/CIHPs and HIV/CIHPs were probed for VDR, renin, and TGF-β. Ang II content was measured in cellular lysates of EV/CIHP and HIV/CIHPs by ELISA. To determine the contribution of Ang II, EV/CIHPs and HIV/CIHPs were incubated in media containing either buffer or losartan ($10^{-7}$M, an Ang II blocker) for 24h (n=3). Subsequently, protein blots were probed for TGF-β, Snail and actin. To establish cause and effect relationship, podocytes transfected with Snail plasmid (Snail/CIHP) were evaluated for the expression of Snail, VDR and actin. To further confirm link between Snail and VDR, ChiP assay was carried out.

**Results:** Renal tissues of Tg26 mice displayed increased Ang II content and enhanced expression of TGF-β and Snail, but down regulation of VDR. HIV/CIHPs displayed down regulation of VDR but up regulation of renin; moreover, HIV/CIHPs showed enhanced generation of Ang II when compared to EV/CIHPs. HIV/CIHP also exhibited enhanced expression of TGF-β and Snail. Snail/CIHP also exhibited down regulation of VDR. Interestingly, losartan not only attenuated HIV-induced podocyte expression of TGF-β and Snail but also upregulated VDR.

**Conclusions:** HIV sustains generation of Ang II through down regulation of podocyte VDR and upregulation of Snail.

**SA-PO755**

**Hedgehog Pathway Plays a Vital Role in HIV-Induced Podocyte Epithelial-Mesenchymal Transition (EMT)**

Xiqian Lan, Kang Cheng, Partab Rai, Nirupama Chandel, Andrei Plagov, Ashwani Malhotra, Pravin C. Singhal. *Medicine, North Shore LIJ Medical School, New York, NY.*

**Background:** HIV-associated nephropathy (HIVAN) is characterized by heavy proteinuria, progressive renal insufficiency, and distinct morphological changes in the form of collapsing glomerulopathy, microcystic dilatation of tubules, and tubulointersititial fibrosis. HIV-induced EMT and proliferation of renal cells are important involved mechanisms contributing to the development of HIVAN phenotype. We hypothesized the role of hedgehog pathway in the HIV-induced kidney cell EMT and associated fibrosis.

**Methods:** Protein blots were prepared and RNAs were extracted from renal tissues of 4 weeks old control and HIVAN (Tg26) mice (n=4) and probed for molecules involved in hedgehog pathway, including sonic hedgehog (SHH), PTCH, gli1, and gli2. For *in vitro* studies, human podocytes (HP) were transduced with either empty vector or HIV (NL4-3) and treated with either buffer or Grant58 (an inhibitor of gli1 transcription) for 48 hours. Subsequently, protein blots of EV/HP and HIV/HPs were probed for molecules involved in hedgehog, EMT (α-SMA, vimentin, FSP1,and Snail), and proliferative pathways. Additionally, effect of hedge pathway was studied in modulation of podocyte monolayer permeability by utilizing albumin flux assay.

**Results:** Western blot and real time PCR analysis showed enhanced expressions of SHH, PTCH, gli1, and gli2 in renal tissues of Tg26 mice. In vitro studies, HIV not only activated the hedgehog pathway but also enhanced the expression of EMT and proliferation markers in podocytes. On the other hand, the blockage of hedgehog pathway with Gant58, decreased expression of HIV-induced kidney cell EMT markers. Albumin flux assay showed that HIV infection increased podocyte monolyer permeability, which could be partially attenuated by Gant58.

**Conclusions:** These results indicate that hedgehog pathway plays a vital role in the development of HIVAN; additionally, it provides insight into a new target for HIVAN therapeutic strategy.

## SA-PO756

**The Role of MicroRNAs in Podocyte Differentiation and Injury**
Christopher P. Carrington,[1] Robert H. Jenkins,[1] Moin Saleem,[2] Timothy Bowen,[1] Donald Fraser.[1] *[1]Institute of Molecular and Experimental Medicine, Cardiff Univ, Cardiff, United Kingdom; [2]Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom.*

**Background:** Wholesale deletion of microRNAs (miRs) within murine podocytes is associated with proteinuria and progressive glomerulosclerosis. However little is known about the role of specific miRs in the maintenance of human podocyte phenotype.

**Methods:** Using a laser capture micro-dissection (LCM) based approach we have isolated and array profiled (Taqman Low Density Array (TLDA)) the miR expression patterns in glomeruli from 8 nephrotic patients with idiopathic membranous nephropathy (IMN). We then performed a miR array (Torey 3D Gene microarray) on conditionally immortalized podocytes stimulated with TGFβ. Using this approach we identified several miRs that were highly expressed in glomeruli of patients with IMN and altered with TGFβ stimulation.

**Results:** TGFβ treatment was associated with widespread and significant changes in podocyte phenotype including loss of podocyte specific markers, up-regulation of matrix associated genes and increased motility as assessed by scratch wound assay consistent with de-differentiation. MicroRNA array profiling on podocytes treated with 1.0ng/ml TGFβ for 24 hours revealed 20 microRNAs that were significantly down regulated with a de-differentiated phenotype, of these 2 miRs (miR 30a-5p and miR 26a) were also highly expressed in glomeruli from patients with IMN.

The expression of both miRs was confirmed by qPCR to be up regulated with the acquisition of a differentiated podocyte phenotype and down regulated in response to TGFβ induced de-differentiation. *In silico* analysis of these miRs revealed putative targets associated within the control of the actin cytoskeleton specifically the activation/ inhibition of the Rho GTPases, RhoA, Rac1 and cdc42.

**Conclusions:** MiRs 30a-5p and 26a are down regulated during podocyte de-differentiation and are also highly expressed in the glomeruli of patients with nephrotic syndrome caused by IMN. These microRNAs are predicted to target elements of the Rho GTPase signaling cascade controlling podocyte cytoskeleton rearrangement implicated in the development of podocyte foot process fusion and proteinuria.

## SA-PO757

**2-Photon Microscopy Reveals Stationary Podocytes in Living Zebrafish Larvae**
Nicole Endlich,[1] Ole Simon,[1] Ahmed Kotb,[1] Eric Schordan,[1] Henny Wegner,[1] Marcus J. Moeller,[2] Achim Goepferich,[3] Elisabeth Rumpel,[1] Karlhans Endlich.[1] *[1]Anatomy and Cell Biology, Univ Medicine Greifswald, Greifswald, Germany; [2]Internal Medicine, Div of Nephrology and Immunology, RWTH Aachen Univ Hospital, Aachen, Germany; [3]Pharmaceutical Technology, Univ of Regensburg, Regensburg, Germany.*

**Background:** Podocytes are an essential component of the glomerular filtration barrier and cover the outer aspect of glomerular capillaries. They form a complex actin-based cytoskeleton in vivo and show a prominent motility in vitro. Since a long time it has been speculated whether podocytes are stationary or mobile in vivo.

**Methods:** To address this question we performed two-photon microscopy (2PM) of the pronephros of translucent zebrafish larvae (casper) expressing eGFP specifically in podocytes (wt1a:eGFP larvae) over extended periods of time.

**Results:** By intravital 2PM, podocyte cell bodies as well as the interdigitating branching pattern of major processes could be resolved in zebrafish larvae at 5-7 dpf (days post fertilization) with a resolution of about 1 µm in the xy-plane. Time-lapse imaging demonstrated that podocytes neither migrated nor changed their branching pattern of major processes over a time period of up to 18 h. Podocyte motility was neither detected by recording at low rates (2-5 images per h) nor at high rates (up to 5 images per s). By contrast, weakly GFP-positive cells close to the pronephric glomerulus that were presumably of neural crest origin exhibited vigorous motility in 2PM time-lapse recordings.

**Conclusions:** In summary, we have generated a translucent zebrafish with fluorescently labeled podocytes for intravital 2PM revealing that podocytes are stationary cells in the intact glomerulus.

## SA-PO758

**Increased Glomerular Water Permeability in Human and Streptozotocin-Induced Diabetes Mellitus**
Amy Russell, Yan Qiu, Kenton Arkill, Andy Salmon. *Microvascular Research Laboratories, Physiology & Pharmacology, Univ of Bristol, Bristol, United Kingdom.*

**Background:** Diabetic nephropathy patients show endothelial dysfunction, albuminuria and increased glomerular filtration rate. We hypothesised that glomeruli from humans and animals with diabetes would have increased water permeability.

**Methods:** Male Sprague Dawley rats were injected intravenously with streptozotocin (45 mg/kg) or citrate buffer alone. 7 days later, streptozotocin-injected rats were hyperglycaemic (before: 6.0±0.13 mmol/L; after: 27±1.7 mmol/L, p<0.0001) and proteinuric (sham: 11.6±0.9 mg/day; diabetic: 25.3±6.7 mg/day, p = 0.005). Kidneys were perfused via the abdominal aorta with 4% bovine serum albumin (BSA) under anaesthesia (sodium pentobarbital). Glomeruli were isolated via a sieving procedure. Human glomeruli were isolated from kidneys not suitable for transplantation, from donors with and without diabetes. Glomeruli were aspirated onto a micropipette and equilibriated in 1% BSA. The perifusate was exchanged to 8% BSA causing fluid efflux. The resultant glomerular volume decrease was used to calculate volume-corrected glomerular volume permeability ($L_pA/V$i: $min^{-1}$ $mmHg^{-1}$).

**Results:** $L_pA/V$i was significantly elevated in diabetic animals (sham: 1.00±0.09 (90/9); streptozotocin: 1.54±0.16(74/9)) {mean±sem (glomeruli/animals)} p<0.01). Human glomerular $L_pA/V$i was also increased in diabetes (healthy: 1.0±0.1 (25/3; diabetic donors {2.3±0.4 (16/3)} (p<0.001).

**Conclusions:** These are the first measurements of single glomerular permeability in diabetic humans. Glomerular $L_pA/V$i is elevated in early diabetes in humans and rats.

## SA-PO759

**Podocyte Hypertrophy Is Regulated by Ubiquitin C-Terminal Hydrolase-L1 Induced Cytoplasmic $p27^{Kip1}$ Accumulation in Rat Membranous Nephropathy**
Catherine Meyer-Schwesinger,[1] Tobias N. Meyer,[2] Maja Lindenmeyer,[3] Thorsten Wiech,[4] Clemens D. Cohen,[3] Rolf A. Stahl.[1] *[1]Nephrology, UKE, Germany; [2]Nephrology, AKB, Germany; [3]Nephrology, UZH, Switzerland; [4]Renal Pathology, UKE, Germany.*

**Background:** Podocytes are terminally differentiated and react to injury with hypertrophy and loss of barrier function. $p27^{Kip1}$ is a key regulator of cellular hypertrophy through induction of $G_1$ arrest. Subcellular localization of $p27^{Kip1}$ in tumours is influenced by ubiquitin C-terminal hydrolase L1 (UCH-L1), a key neuronal protease in the ubiquitin-proteasome pathway. We recently demonstrated *de novo* UCH-L1 expression and activation in podocytes of patients with membranous nephropathy (MGN) and in rodent models of MGN. Here, we investigated the role of UCH-L1 in podocyte $p27^{Kip1}$ homeostasis and hypertrophy.

**Methods:** UCH-L1 and $p27^{Kip1}$ co-localization studies were performed in human MGN and in the rat model of MGN, the passive Heymann nephritis (PHN). The effects of UCH-L1 overexpression, knockdown and inhibition of hydrolase function on podocyte hypertrophy and $p27^{Kip1}$ homeostasis were evaluated in cultured podocytes and in PHN.

**Results:** In human and rodent MGN, podocyte hypertrophy correlated with up-regulation of UCH-L1 and cytoplasmic $p27^{Kip1}$ protein in podocytes. In cultured podocytes, over-expression of UCH-L1 (1) increased levels of $p27^{Kip1}$ and $p27^{Kip1}$ phosphorylation at $thr^{198}$, which serves as a nuclear export signal, and (2) decreased poly-ubiquitination and proteasomal degradation of $p27^{Kip1}$. These altered post-translational modifications of $p27^{Kip1}$ resulted in cytoplasmic accumulation of $p27^{Kip1}$ protein in podocytes *in vitro* and *vivo*. UCH-L1 activity in podocytes decreased the percentage of cells in $G_1$ arrest, increased cellular turnover, hypertrophy, migration and cytoskeletal rearrangement, which are associated with known oncogenic functions of cytoplasmic $p27^{Kip1}$ in cancer. Inhibition of UCH-L1 hydrolase activity in rat MGN, and knockdown or inhibition of UCH-L1 *in vitro*, decreased cytoplasmic $p27^{Kip1}$ protein levels and attenuated podocyte hypertrophy, loss and proteinuria.

**Conclusions:** We demonstrate that podocyte hypertrophy and loss was induced by UCH-L1 through stabilization of $p27^{Kip1}$ in the cytoplasm of podocytes.

## SA-PO760

**Regulation of Apolipoprotein-1L Splicing by Wilms Tumor-1 Protein**
Hidefumi Wakashiu, Jeffrey B. Kopp. *NIDDK, NIH, Bethesda, MD.*

**Background:** Apolipoprotein L1 (*APOL1)* genetic variants are associated with increased glomerular disease risk. ApoL1 has several RNA splice variants, producing distinct protein isoforms: APOL1-A is encoded by exons 1, 3-7; APOL1-B is encoded by exon 1-7; and APOL1-C is encoded by exons 1, 3, 5-7. Wilms tumor 1 (WT1) plays crucial roles in kidney development and podocyte differentiation.

**Methods:** We raised a rabbit antiserum against APOL1-B exon 2 peptide, which is specific for this isoform. We examined the expression of *APOL1* splicing variants, using by TA cloning,, RT-PCR and WT1 knockdown, and subcellular localization, using immunofluorescence (IF), Flag tagged vector transfection, in cultured human podocytes , WT1 inducible human osteosarcoma cells and human kidney.

**Results:** Seven APOL1 splicing variants (classed as V1-V4) were cloned from immortalized human podocytes. These include three splicing variants that contain exon2: APOL1-V2-1, V2-2 and V2-3, which encode ApoL1-B-1, B-2 and B-3 respectively. APOL1-V2-1 consists of exon 1-7. V2-2 is distinguished by having a longer exon 3. V2-3 lacks exon4, which contains a signal sequence. Human kidney expressed 5 APOL1 splicing variants. Using IF, we found that ApoL1-B was expressed by podocytes in normal human kidney and was decreased in FSGS kidney. Transfected C-terminal Flag-tagged ApoL1-B-3 was detected by both ApoL1-B ab and Flag ab, and co-localized with F-actin in immortalized human podocytes. ApoL1-B-1 and B-2 were not detected by ApoL1-B ab but were detected by Flag ab. In WT1-expressing UB27 human osteosarcoma cells, the APOL1-V2-3 RNA level was increased compared to control cells lacking WT1. WT1 expression dramatically increased ApoL1-B protein expression, assessed by WB and IF. Further, WT1 knockdown reduced the expression of APOL1-V2-3 in immortalized human podocytes while other APOL1 variant RNAs were reduced or unchanged.

**Conclusions:** ApoL1-B variants were expressed in the human podocytes. WT1 regulates ApoL1 splicing variants, and selectively increases expression of ApoL1B protein and APOL1-V2-3. A better understanding of the complexity of APOL1 RNA and protein isoforms will be required to define the role of APOL1 in podocyte function.

## SA-PO761

**Podocyte Slit-Diaphragm Protein Nephrin Associates with the Actin Cytoskeleton through Interacting with IQGAP1** Yipeng Liu,[1] Wei Liang,[1] Qian Yang,[1] Pravin C. Singhal,[2] Guohua Ding.[1] *[1]Div of Nephrology, Renmin Hospital of Wuhan Univ, Wuhan, Hubei, China; [2]Medicine, North Shore-Long Island Jewish Health System, Manhasset, NY.*

**Background:** Nephrin plays a crucial role in maintaining the structural and functional integrity of the glomerular filtration barrier. Nephrin is reported to contribute to dynamics of actin cytoskeleton in podocyte through several adaptor and effector proteins. IQGAP1 is a newfound scaffolding protein that is expressed in the slit-diaphragm (SD) and contains a F-actin biding domain. We evaluated the role of IQGAP1 in linking nephrin to the actin cytoskeleton.

**Methods:** Kidneys were harvested from male Sprague-Dawley rats (n=6) for isolation of glomeruli and immunofluorescence analysis. In vitro, mouse podocytes were cultured. The distribution and interaction of nephrin and IQGAP1 was detected by fluorescent microscopy and co-immunoprecipitation. Differential detergent extraction was used to evaluate the connection mode of nephrin and IQGAP1 to F-actin in the presence or absence of potassium iodide in vivo or cytochalasin D in vitro. HEK-293T cells were co-transfected with nephrin plasmid and IQGAP1plasmid containing full-length or domains (CHD, IQGAP repeat, WW, IQ, GRD and RasGAP-C) to assess the specific domain of IQGAP1 interacting with nephrin.

**Results:** Neprin and IQGAP1 are co-localized in the cellular membrane of cultured podocytes and along the capillary loops of glomeruli in a linear model. Analysis of differential detergent extraction indicated that nephrin co-precipitated with actin filaments and IQGAP1.Co-precipitation between nephrin and actin was prevented by potassium iodide or cytochalasin D which are able to depolymerize F-actin. However, the complexes of nephrin and IQGAP1 were not disrupted by the actin depolymerization. Co-transfection analysis in HEK-293T cell demonstrated that the IQ domain of IQGAP1 is the target module interacting with nephrin.

**Conclusions:** IQGAP1, as an adaptor protein, mediates the link of nephrin to actin cytoskeleton in podocyte.

## SA-PO762

**PDZ and LIM Domain Protein 2 Forms a Protein Complex with Podocin and Nephrin at the Slit-Diaphragm** Liliana Garmendia,[1] Mariana Quiroz-munoz,[2] Stephanie Carol Acuña,[1] Eduardo A. Machuca.[1] *[1]Centro de Investigaciones Médicas, P.Universidad Católica de Chile, Chile; [2]Escuela de Medicina, P.Universidad Católica de Chile, Chile.*

**Background:** Nephrin and Podocin are main structural and functional components of the slit-diaphragm (SD). Inherited defects affecting Podocin and Nephrin encoding genes are the leading causes of congenital and early-onset nephrotic syndrome, respectively. Thoughtful knowledge of the SD structure and its signaling pathways is essential to understand glomerular filtration. Furthermore, understanding SD structure may lead to the discovery of targets to modulate its function in diseases known to be cause by disruption of the glomerular filtration barrier.

**Methods:** We used a proteomic approach to identify novel SD proteins. We isolated murine glomeruli, then, glomerular protein extracts were subjected to immunoprecipitation (IP) studies with anti-nephrin or anti-podocin antibodies coupled to Protein A-magnetic beads. Eluted proteins were analyzed by nano-LC/MS/MS. Mascot and Scaffold were used to validate MS/MS based peptide and protein identifications.

**Results:** We found novel podocyte actin-cytoskeleton components that interact with nephrin and podocin. One of them, PDZ and LIM domain protein 2 (Pdlim2), has been previously identified as a SD-related protein, although its interaction with nephrin or podocin has not been shown before. We validated Pdlim2 interaction with nephrin through *in vivo* and *in vitro* co-immunoprecipitation studies. Pdlim2 was shown to localize in glomerular capillaries by using double-staining immunofluorescence. In addition, we found that Pdlim2 partially co-localized with actin cytoskeleton components such as Synaptopodin, β -actin and Phalloidin. Using double-labeling electron microscopy we showed that Pdlim2 localizes in close proximity with Nephrin in foot-processes.

**Conclusions:** Our results suggest that Pdlim2 interacts with Nephrin at the SD. It has been shown that Pdlim2 is adapter protein located at the actin cytoskeleton that promotes cell attachment, and which may potentially interact with alpha-actinins, FLNA and MYH9. Further functional analyses are desirable to elucidate the role of Pdlim2 in the maintenance of the glomerular filtration barrier.

## SA-PO763

**Formin-Binding Protein 1-Like Is a Novel Interacting Protein at the Glomerular Slit-Diaphragm** Mariana Quiroz-Munoz,[1] Liliana Garmendia,[2] Stephanie Carol Acuña,[2] Eduardo A. Machuca.[2] *[1]Escuela de Medicina, P. Universidad Católica de Chile, Chile; [2]Centro de Investigaciones Médicas, P. Universidad Católica de Chile, Chile.*

**Background:** The preservation of glomerular permselectivity relies critically on the podocyte and the architecture of its actin cytoskeleton. Podocytes intertwining to cover the capillary loops with interdigitating foot processes, which are connected through actin-based cell-cell adhesion proteins, forming a structure called slit diaphragm (SD). Nephrin is the major structural component of the SD, and is know to interact with podocin and CD2AP among others. Little is known about other interacting proteins within this complex which may connect the SD to the actin-cytoskeleton.

**Methods:** We isolated murine glomeruli by a modified sieving method. Then, protein lysates were immunoprecipitated with anti-podocin antibodies. Eluted proteins subjected to 1D-SDS PAGE, gels were stained with Coomassie blue and each lane was excised into ten segments. Gel bands were digested with trypsin and then they were analyzed by nano-LC/MS/MS.

**Results:** We identified a novel podocyte protein known as Formin-binding protein 1-like (Fnbp1l). We performed western blot analysis of protein lysates showing that Fnbp1l is ubiquitously expressed in mice. Using RT-PCR, we assessed whether a particular isoform of Fnbp1l isoform was express in kidney, finding that mRNA isoform 2 was predominantly expressed in kidney. We also performed immunofluorescence studies of frozen kidney tissue to locate Fnbp1l, resulting in Fnbp1l localization mainly in podocyte. Fnbp1l strongly colocalized with synaptopodin and partially with β-actin and phalloidin. Immuno-gold electron-microscopy showed partial Fnbp1l localization at the SD. Immunoprecipitation assays showed that Podocin co-immunoprecipitated with Fnbp1l.

**Conclusions:** We have shown that Fnbp1l interacts with Podocin at the SD. It has been previously shown that the function of Fnbp1l probably involves the coordination of actin assembly by promoting CDC42-induced actin polymerization. Thus, Fnbp1l-Podocin complex may link the SD to actin-cytoskeleton. Further work is necessary to elucidate the role of Fnbp1l in the maintenance of the glomerular filtration barrier.

## SA-PO764

**Mechanism of CLIC5A-Mediated Ezrin Phosphorylation** Abass Almomany, Laiji Li, Barbara J. Ballermann. *Medicine, Univ of Alberta, Edmonton, Canada.*

**Background:** CLIC5A deficiency in mice potentiates hypertension- and adriamyin-induced glomerular injury. CLIC5A is highly and uniquely expressed at the apical plasma membrane (PM) of podocyte foot processes as part of the Ezrin-Podocalyxin complex (*Am. J. Physiol. 298: F1492, 2010*). Phosphorylated ezrin ($^{P}$Ezrin) links podocalyxin to cortical actin. In podocytes of CLIC5A deficient mice, $^{P}$Ezrin abundance is reduced. This study explored the molecular mechanisms by which CLIC5A regulates ezrin function.

**Methods:** CLIC5A cDNA or vector (control) were introduced into Cos-7 cells, which express ezrin but not CLIC5A at baseline. Protein abundance was evaluated by immunoblot (IB) and protein localization by immunofluorescence (IF) confocal microscopy (CF). Since ezrin phosphorylation requires its binding to phosphatidylinositol 4,5-bisphosphate (PIP2), the distribution of the PIP2 reporter RFP-PH-PLC was evaluated with live-cell CF.

**Results:** CLIC5A expression induced surface ruffles (Scanning EM) and actin polymerization. The ratio of $^{P}$Ezrin : Total Ezrin was greater in Cos-7 cells expressing CLIC5A than in control cells (0.84±0.06 vs. 0.38±0.06, mean±SE, n=3, $p<0.01$), and $^{P}$Ezrin redistributed to the cytoskeleton. Ezrin phosphorylation was protein kinase C (PKC) dependent, but CLIC5A did not alter PKC activity, nor did CLIC5A block $^{P}$Ezrin de-phosporylation. The ratio of apical PM : cytosolic RFP-PH-PLC was much higher in CLIC5A expressing cells than in control cells (3.46±0.62, vs. 1.56±0.06; mean±SE, n=8, $p<0.01$), indicating increased apical PM PIP2 content. Activation of phospholipase C (with m-3M3FBS), which depletes PIP2, blocked CLIC5A-dependent ezrin phosphorylation. CLIC5A strongly co-localized with the PIP2 reporter and PIP5K1α (which generates PIP2) in discrete apical PM patches. GST-CLIC5A but not GST pulled down PIP5K1α from cell lysates.

**Conclusions:** Hence, CLIC5A may activate and/or recruit PIP5Kinase, resulting in localized PIP2 generation, ezrin phosphorylation and cell-surface re-organization. We postulate that in podocytes, where it is so highly expressed, CLIC5A maintains high, apical PIP2 and $^{P}$Ezrin concentrations, in turn contributing to the unique podocyte architecture and podocyte-dependent integrity of glomerular capillaries.

## SA-PO765

**Caveolae May Enable Albumin to Enter Human Renal Glomerular Endothelial Cells** Takahito Moriyama, Yasuko Oshima, Kayu Tanaka, Chihiro Iwasaki, Ken Tsuchiya, Kosaku Nitta. *Medicine, Kidney Center, Tokyo, Shinjyuku-ku, Japan.*

**Background:** The pathophysiology of albuminuria remains unclear. We previously reported that caveolae on human renal glomerular endothelial cells (HRGECs) are increased in glomerular disease and correlate with the degree of albuminuria, suggesting that the proliferation of caveolae on HRGECs contributes to albuminuria(J Clin Pathol 2011; 64: 504-9). To assess the mechanism by which caveolae contribute to albuminuria, we investigated whether albumin enters into HRGECs through these caveolae.

**Methods:** HRGECs were incubated with Alexa Fluor 488 labeled bovine serum albumin (BSA), followed by immunofluorescence localization with antibody to caveolin-1 (Cav-1), the main structural protein of caveolae, to assess time course study of albumin internalization and whether BSA colocalizes with Cav-1. HRGECs were also incubated with albumin and caveolae disrupting agents, such as methyl beta cyclodextrin (MBCD) and nystatin, to determine whether disrupting the caveolae interfered with albumin endocytosis into HRGECs by western blot and immunofluorescence analysis. Albumin internalization into HRGECs transfected with Cav-1 small interfe-ring RNA (SiRNA) was also analyzed.

**Results:** Labeled BSA was expressed soon after the start of incubation, increasing gradually from 5.81±0.98 $\mu m^2$/cell at 5 minutes to 82.9±13.6 $\mu m^2$/cell at 6 hours after incubation. The ratio of BSA co-localized with Cav-1 was 17.3±3.06% at 5 minutes, and it was increased to about 50 at 15 minutes and remained 50 to 65 % during 6 hours after incubation. Incubation of HRGECs with MBCD or nystatin significantly decreased the intracellular amount of albumin and Cav-1 expression, relative to normal HRGECs, as

shown by western blotting and immunofluorescence. Also albumin and Cav-1 expression in HRGECs transfected with Cav-1 SiRNA were significantly decreased in comparison to normal HRGECs.

**Conclusions:** These findings indicate that albumin enters HRGECs through the caveolae. Caveolae on HRGEC play an important role in the pathogenesis of albuminuria by providing a new pathway through which albumin can enter glomerular endothelial cells.

*Funding:* Government Support - Non-U.S.

## SA-PO766

**Qualitative Changes in Vascular Endothelial Growth Factor A Expression in Kidney Disease** Rosanne Jane Turner, Ingeborg M. Bajema, Michael Eikmans, Jan A. Bruijn, Hans J. Baelde. *Pathology, LUMC, Leiden, Netherlands.*

**Background:** The cytokine vascular endothelial growth factor A (VEGF-A) is a key regulator in the maintenance of the glomerular filtration barrier by promoting survival of podocytes and endothelial cells. There are seven proangiogenic VEGF-A splicing variants. Longer isoforms containing heparin and neurophilin binding sites, such as VEGF-A 165 and 189, have a more prolonged and more effective mode of action than shorter isoforms, such as VEGF-A 121. In various kidney diseases quantitative changes in VEGF-A expression play an important role. In this study, we set out to investigate the renal splicing pattern of VEGF-A in various kidney disease entities in humans and mice.

**Methods:** Kidney biopsies from patients with acute rejection after kidney transplantation, patients with diabetic nephropathy, and from healthy controls were collected. Also kidney samples from mice with graft versus host disease and controls were collected. Lung, lymph node, spleen and thymus tissue samples from healthy mice were obtained. The relative expression of each individual splice variant was measured by RT-PCR followed by quantitative fragment analysis with capillary electrophoresis.

**Results:** In the healthy human kidney VEGF-A 121 was the dominant isoform with a relative expression of 75.08%. VEGF-A 165 and 189 showed relative expression levels of 21.66% and 3.26%. The splicing pattern in diabetic nephropathy and in transplanted kidneys with acute rejection and in graft-versus-host disease did not differ from that in control kidneys. In rodent kidneys VEGF-A 164 was the dominant isoform with a relative expression of 48.84%. VEGF-A 120 and 188 showed relative a expression of 43.24% and 7.74%, respectively. Different splicing patterns of VEGF-A were detected in samples from different organs.

**Conclusions:** VEGF-A splicing in the glomeruli is different between humans and rodents. Although it has been described that there are quantitative changes of VEGF-A in transplanted kidneys with acute rejection and in diabetic nephropathy, the splicing pattern does not change in these disorders. Apparently quantitative rather than qualitative changes of VEGF-A mRNA levels play an important role in renal diseases.

## SA-PO767

**Molecular Mechanism of Steroid-Induced Thrombus Formation in Kidney Disease** Noritaka Kawada,[1] Toshiki Moriyama,[1] Harumi Kitamura,[2] Hiromi Rakugi,[2] Yoshitaka Isaka.[2] *[1]Osaka Univ, Health Care Center, Toyonaka, Osaka, Japan; [2]Dept of Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

**Background:** The use of exogenous steroid positively associates with the risk of thromboembolism (Johannesdottir-SA et. al. *JAMA Intern Med*. 2013; 1, 1-10). Plasminogen activator inhibitor-1 (PAI-1) inhibits plasminogen activator (tPA), plasmin and matrix metalloproteinase (MMP) and is known as an established risk marker for cardiovascular disease and thrombus formation. We tested the effects of exogenous steroid on the PAI-1 expression in cultured cells originated from rat kidney.

**Methods:** Rat primary cultured mesangial cells (rMSC), renal fibroblast cells (NRK49F), and renal tubular cells (NRK52E), were exposed to dexamethasone (Dex) and/or TGFβ. The mRNAs were quantitated and the collected cultured mediums were processed to test the induction of PAI-1 protein and MMP activity.

**Results:** rMSCs exposed to Dex (10-6M) or TGFb (2ng/ml), 6 hours for mRNA and 16 hours for protein, induced both mRNA and protein for PAI-1 (mRNA: Dex +130%, $p<0.01$. TGFβ +190%, $p<0.01$; n=6 each). At the same experiment, the mRNA for tPA were reduced only in Dex (Dex -36%, $p<0.01$. TGFβ -20%, n.s.; n=6 each). The rMSCs exposed to both Dex and TGFβ further induced PAI-1 protein and mRNA (PAI-1 mRNA: +640%, $p<0.001$. tPA mRNA: -40%, $p<0.01$; n=6). This was accompanied by the inhibition of MMP activity ($p<0.01$, n=6). The induction in PAI-1 and the reduction in tPA were also observed in NRK49F and 52E cells exposed to Dex and/or TGFβ. The effects of Dex and TGFβ on PAI-1 and tPA expression in rMSCs were blunted by enhanced cAMP production with adenylate cyclase activator (Forscolin) or β2 stimulant (Salbutamol).

**Conclusions:** Steroid may promote thrombus formation in kidney disease through the induction of PAI-1 and the inhibition of tPA and MMP activity. Enhanced cAMP production has potential to moderate these unwilling side effects.

## SA-PO768

**PDGF Launches Mesangial Cell Proliferation via a Positive Feed-Back Loop Involving Erk5 and Akt Downstream of PI 3 Kinase** Falguni Das,[1] Amit Bera,[1] Nandini Ghosh-choudhury,[2] Balakuntalam S. Kasinath,[1] Hanna E. Abboud,[1] Goutam Ghosh-Choudhury.[1] *[1]Medicine, UTHSCSA, San Antonio, TX; [2]Pathology, UTHSCSA.*

**Background:** PDGF-forced proliferation of mesangial cells is an ominous feature of mesangioproliferative glomerulonephritis. The mechanistic underpinning of MC proliferation is not clear. We probed the role of most recently identified MAPK, Erk5.

**Methods:** Glomerular mesangial cells (MCs) were used.

**Results:** PDGF increased activating phosphorylation of Erk5 concomitant with enhanced tyrosine phosphorylation of several proteins including PDGF receptor in a time-dependent manner. XMD-8-92, an inhibitor of Erk5, attenuated PDGF-stimulated Erk5 phosphorylation, DNA synthesis and MC proliferation in the absence of any effect on Erk1/2 phosphorylation. Similarly, expression of dominant negative (DN) Erk5 or siRNA-mediated downregulation of Erk5 significantly inhibited PDGF-induced DNA synthesis and proliferation. Inhibition of Erk5 markedly blocked cyclin D1 mRNA and protein expression induced by PDGF, resulting in inhibition of its target cyclin-dependent kinase 4 (CDK4) phosphorylation and its substrate pRb inactivating phosphorylation. Interestingly, exogenous expression of wild type cyclin D1 or CDK4 reversed DN Erk5- and siErk5-mediated suppression of DNA synthesis and proliferation of mesangial cells induced by PDGF. As we have shown previously that PI 3 kinase/Akt axis regulates PDGF-induced MC proliferation, we interrogated its role. Inhibition of PI 3 kinase significantly blocked Erk5 phosphorylation. Since Akt is a downstream target of PI 3 kinase, we examined the contribution of Erk5 in its activation. XMD-8-92, DN Erk5 and siErk5 inhibited PDGF-stimulated Akt phosphorylation. Interestingly, MK2206, a specific inhibitor of Akt kinase and DN Akt abrogated Erk5 phosphorylation by PDGF.

**Conclusions:** Together our results provide the first evidence demonstrating the presence of a micro-circuitry mechanism involving Erk5 and Akt to instruct cyclin D1/CDK4 to drive cell cycle progression and proliferation of MC in response to PDGF.

## SA-PO769

**Vitamin D Receptor Participate in the High Glucose-Induced Epithelial-Mesenchymal Transition of Mouse Podocytes through Wnt/GSK-3β/β-Catenin Signaling Pathway** Guo Jia.[1,2] *[1]Nephrology, The First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China; [2]Key-Disciplines Laboratory Clinical-Medicine Henan, Zhengzhou, Henan, China.*

**Background:** Proteinuria, closely related with the disease development, is the main clinical symptoms of diabetic nephropathy. Previous studies and our previous results were all confirmed that epithelial-mesenchymal transition (EMT) of mouse podocyte cells was the major pathophysiological mechanism of proteinuria in diabetic nephropathy. It has been reported that the Wnt/GSK-3β/β-catenin signaling pathway involved in the EMT process of renal tubular epithelial cell induced by high glucose. Vitamin D receptor was reported involving in the EMT of renal tubular epithelial cells of end-stage renal diseases. And decreased expression of VDR could lead the expression of β-catenin increased. The purpose of this study is to testing whether VDR participate in the EMT process of mouse podocytes caused by high glucose through Wnt/GSK-3β/β-catenin pathway.

**Methods:** The expressions of key molecules in Wnt/GSK-3β/β-catenin signaling pathway, as well as VDR expression, were detected in mouse podocytes with high glucose treatment and the normal control group by western blot and RT-PCR. Co-localization of the key molecules of Wnt/GSK-3β/β-catenin signaling pathway and VDR were observed by Immunofluorescence.

**Results:** High glucose cultured mouse podocytes had obvious EMT phenomenon. The activity and expression of GSK-3β were significantly increased compared with the normal control group ($P<0.05$). The expressions of β-catenin and its downstream snail were also up-regulated companied with glucose concentration increasing ($P<0.05$), while the VDR expression declined. By using the immunofluorescence assay, β-catenin in high glucose cultured mouse podocyte was found translocation to nuclear, showing less co-localization with GSK-3β and more co-localization with the VDR compared with the normal group.

**Conclusions:** Decreased expression of VDR may be involved in the EMT process caused by high glucose of mouse podocytes through Wnt/GSK-3β/β-catenin signaling pathway.

*Funding:* Government Support - Non-U.S.

## SA-PO770

**The Role of Dynamin in the Development of Proteinuria** Ramzi Khalil,[1] Reshma Lalai,[1] Rosalie Bor,[1] Reinhold Kreutz,[2] Emile De Heer,[1] Jan A. Bruijn,[1] Hans J. Baelde.[1] *[1]Pathology, Leiden Univ Medical Center, Leiden, Netherlands; [2]Institute of Clinical Pharmacology and Toxicology, Charité - Univ Medicine, Berlin, Germany.*

**Background:** Dynamin has been established as a protein essential in membrane scission, vesicular transport and interaction with actin in cytoskeleton regulation. Rats with a podocyte-selective knock out of Dynamin showed proteinuria, renal failure and foot process effacement. In a previous microarray experiment, we identified dynamin mRNA as differentially expressed in spontaneously proteinuric Dahl SS rats. This study aims to investigate the role of dynamin in the time course of the development of proteinuria and the direct relationship between dynamin deficiency and loss of glomerular permselectivity.

**Methods:** The involvement of dynamin in the development of proteinuria was studied in a time course experiment. Dynamin mRNA expression and urinary albumin excretion (UAE) were measured at 2, 4, 6, 8 and 10 weeks of age in Dahl SS rats. Additionally, dynamin mRNA expression was investigated in microdissected glomeruli of patients with various proteinuric kidney diseases. To clarify the direct relationship between dynamin and loss of glomerular permselectivity, a functional assay using dextran tracers was performed in zebrafish embryos, microinjected with a morpholino construct targeting the zebrafish homologue of dynamin.

**Results:** In the time course experiment, Dahl SS rats started showing significant and increasing albuminuria from week 6. Dynamin mRNA upregulation was seen at 4 and 6 weeks of age. Moreover, a statistically significant increase in dynamin mRNA expression was found in glomeruli of lupus nephritis and minimal change disease patients. The functional assay of the morpholino injected zebrafish demonstrated a loss of glomerular permselectivity.

**Conclusions:** Strong evidence is shown for the role of dynamin in the time course of proteinuria development, as dynamin mRNA expression was upregulated 2 weeks before onset of albuminuria. Also, the direct relationship between loss of dynamin and loss of glomerular permselectivity is shown in the functional assay using zebrafish embryos. The results from the human biopsies further confirm these results.

## SA-PO771

**EphB-Receptors Mediate Nephrin Tyrosine Phosphorylation – Mechanism for Adhesion and Repulsion** Eva Koenigshausen, Nils Tim Haep, Magdalena Woznowski, Ivo Quack, Lars C. Rump, Lorenz Sellin. *Nephrology, Heinrich Heine Univ, Duesseldorf, Germany.*

**Background:** Proteinuria is a hallmark for glomerular disease and results from disruption of the glomerular filter with the glomerular slit diaphragm. The slit diaphragm's major component is nephrin which is endocytosed upon the binding to beta-arrestin controlled by tyrosine phosphorylation. Eph-receptor family kinases are the largest group of tyrosine kinases and mediate cell adhesion and repulsion. Eph-receptor kinases bind to their cell-membrane bound ligands - ephrines. Ephrinb1 and EphB4 have been localized at the slit diaphragm. The molecular function of the EphB1 and B2 receptors in podocytes is unknown.

**Methods:** Murine and human podocytes were differentiated. After cell lysis, qPCR was performed. Cells expressing nephrin, beta-arrestin2 and Nck1/2 were lysed and co-immunoprecipitation was performed. For phosphorylation experiments cells were serum starved. Tyrosin phospho-specific antibodies were used. Preclustering was performed by incubation of IgG-Fc or ephrinb1-Fc with anti-human IgG with a final concentration of 1µg/ml.

**Results:** EphB1, B2, ephrinb1 and b2 are expressed in murine and human podocytes. EphB1 and EphB2 interact with the extracellular domain of nephrin. Expression of EphB1 and B2 results in a strong phosphorylation on nephrin at the Nck1/2 binding sites Y1176/1193 and Y1217. Stimulation with the ligand ephrinb1 leads to a decrease of nephrin-Y-phosphorylation. Expression of EphB1 and B2 increases the interaction of nephrin with nck2 and reduces the binding of nephrin with beta-arrestin2. Expression of an EphB2-kinase inactive mutant abolishes the enhancement of nephrin-Y-phosphorylation demonstrating that the kinase function is crucial for nephrin. PP2, a src family kinases inhibitor, decreases nephrin-Y-phosphorylation. EphB receptor induced nephrin-Yphosphorylation is reproduced in murine podocytes.

**Conclusions:** Like in other cell types EphB receptors may mediate adhesion and repulsion at the glomerular slit via modulation of nephrin-Y-phosphorylation. The understanding of adhesion and repulsion at the slit could help to understand pathophysiology in glomerular disease and identify new therapeutic targets.

## SA-PO772

**Proteomic Analysis of Formalin-Fixed Paraffin-Embedded (FFPE) Glomerular Tissue Suggests Depletion of Glomerular Filtration Barrier Proteins in Two-Kidney One-Clip (2K1C) Hypertensive Rats** Kenneth Finne,[1] Heidrun Vethe,[1] Trude Skogstrand,[1,2] Olav Tenstad,[2] Sabine Leh,[1,3] Rolf K. Reed,[2] Bjorn Egil Vikse.[1,4,5] *[1]Dept of Clinical Medicine, Univ of Bergen, Bergen, Norway; [2]Dept of Biomedicine, Univ of Bergen, Bergen, Norway; [3]Dept of Pathology, Haukeland Univ Hospital, Bergen, Norway; [4]Dept of Medicine, Haukeland Univ Hospital, Bergen, Norway; [5]Dept of Medicine, Haugesund Hospital, Haugesund, Norway.*

**Background:** It is well known that hypertension may cause glomerular damage, but the mechanisms are still incompletely understood. In the present study we investigated changes in the proteome of the glomerular filtration barrier in the non-clipped kidney of 2K1C hypertensive rats.

**Methods:** 2K1C hypertension was induced with a 0.2 mm silver clip in 6-weeks-old Wistar rats (n=6) that was sacrificed 23-weeks later and compared to age-matched sham operated controls (n=6). After sacrifice, the non-clipped kidney was fixed in formalin and embedded in paraffin. Using this tissue, we microdissected 100 glomeruli cross-sections that were trypsin digested and analyzed in a label-free manner using LC-MS/MS (Orbitrap system).

**Results:** While podocyte cytoskeletal proteins such as synaptopodin and α-actinin-4 remained unchanged in 2K1C compared to controls, we found reduced abundance of slit-diaphragm complex proteins in 2K1C. These included, but were not limited to, nephrin, podocin, neph1, dendrin and ZO-1. We also found lower abundance of important glomerular basement membrane (GBM) proteins including collagen IV, laminin and nidogen-1. Interesting glomerular markers of damage were desmin, heat shock 70kDa protein 1A/1B and transgelin.

**Conclusions:** In conclusion, we have demonstrated reduced abundance of proteins involved in the glomerular filtration barrier in FFPE tissue from the non-clipped kidney of 2K1C rats with proteinuria compared to non-proteinuric controls.

## SA-PO773

**Effect of Rho Kinase (ROK) Inhibition on Rho A Induced Podocyte Injury** Liming Wang,[1,2] William Eisner,[1,2] Robert F. Spurney.[1,2] *[1]Medicine, Duke Univ, Durham, NC; [2]Medicine, Durham VA Medical Center, Durham, NC.*

**Background:** We previously created transgenic (TG) mice that expressed a constitutively active Rho A construct (V14Rho) specifically in glomerular podocytes in a doxycycline inducible fashion. In these TG mice, induction of V14Rho caused albuminuria and foot process (FP) effacement (Kidney Int 81:1075, 2012). In this same study, V14Rho promoted apoptosis of cultured podocytes and this apoptotic effect was attenuated by treatment with the ROK inhibitor Y27632.

**Methods:** To determine if Y27632 attenuated V14Rho induced podocyte injury in vivo, we treated V14Rho TG mice with doxycycline for 2 wks followed by doxycycline and either Y27632 or saline for an additional 2 wks.

**Results:** Treatment with doxycycline alone caused albuminuria (43±3 vs 102±11 µg/24H; P<0.01). The addition of saline vehicle to doxycycline treatment had little effect on albuminuria (85±10 µg/24H; P=NS) but Y27632 increased the albuminuric response (142±26 µg/24H; P<0.05). Because abnormal podocyte motility may be associated with albuminuria and FP effacement, we determined the effect of Y27632 on podocyte motility using a wound-healing assay. We found that V14 Rho alone had little effect on wound closure. In contrast, Y27632 enhanced wound closure in either the presence or absence of V14Rho suggesting that Y27632 increased podocyte motility. We next determined the molecular signature of Y27632 induced motility by investigating the effects of V14Rho and Y27632 on the actin and microtubule cytoskeleton. In cultured podocytes, V14Rho promoted formation of detyrosinated and deacetylated tubulin as well as phosphorylation of both myosin light chain (MLC) and cofilin. Incubation with Y27632 inhibited V14Rho induced MLC phosphorylation, cofilin phosphorylation and tubulin deacetylation but not formation of detyrosinated tubulin. With the exception of cofilin, the effects of Y27632 were similar in V14Rho-expressing TG mice treated with Y27632.

**Conclusions:** The molecular signature of a motile podocyte in vitro was largely recapitulated in vivo. These data suggest that ROK inhibition promotes podocyte motility which, in turn, may diminish the beneficial effects of ROK inhibitors in glomerular diseases.

## SA-PO774

**Urinary Microvesicles Differentiate Patients with Diabetic Nephropathy from Those with Active Glomerulonephritis** Ladan Zand, Muthuvel Jayachandran, Stephen T. Turner, M. Regina Castro, Joseph P. Grande, Vesna D. Garovic. *Mayo Clinic, Rochester, MN.*

**Background:** Microvesicles (MVs) are small membrane-enclosed sacs that are shed from activated or injured cells and have been identified in different body fluids including urine. They contribute to a variety of pathophysiological processes involving cell-cell interaction. We hypothesized that urinary MVs may serve as a diagnostic marker in differentiating between glomerulonephritis (GN) and diabetic nephropathy.

**Methods:** Digital flow cytometry was used to characterize urinary MVs expressing podocyte markers in patients with type 2 diabetes mellitus (DM) (n=31, male=19, female=12) and biopsy-proven GN (n=9, male=6, female=3) including focal segmental glomerulosclerosis (n=4) and membranous nephropathy (n=5). Of 31 patients with DM, 23 had urine albumin <300mg/L (Group I) and 8 had urine albumin >300 mg/L (Group II). For diabetic patients, other etiologies causing proteinuria including autoimmune diseases, hepatitis B, C, or monoclonal gammopathy were excluded. Data were analyzed by non-parametric Kruskal-Wallis test. Results are shown as median. Units for urinary MVs are expressed as MVs/µL of urine.

**Results:** Median age in GN group was 52 vs. 64.5 years in Group II (P=0.03) and protein to creatinine was 3.5 vs. 1.4 mg/mg (P=0.05). There was no difference in the GFR between the two groups (43 vs. 64 ml/min/1.73m$^2$). GN patients compared to Group II had significantly higher number of urinary MVs expressing podocyte markers such as nephrin (618 vs. 335 P=0.03), & podocalyxin (1376 vs. 587, P=0.04). There were also significantly greater number of parietal cell specific markers, claudin-1 plus CK-8 positive MVs (761 vs. 310, P=0.01). There were no differences in the number of urinary MVs expressing podocyte markers between GN group and Group I. There was no association between degree of proteinuria or GFR and presence of urinary MVs (data not shown).

**Conclusions:** The high number of urinary MVs found in GN patients is suggestive of active ongoing injury to the podocytes in contrast to patients with advanced diabetic nephropathy. Urinary MVs may be used as a novel biomarker in distinguishing GN from DM with macroalbuminuria.

## SA-PO775

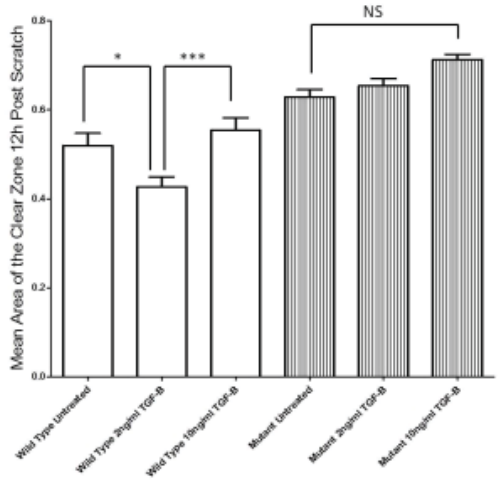
**Transforming Growth Factor Beta Signalling Impairment in *PLCE1* Mutant Podocytes** Carl James May, Gavin Iain Welsh, Moin Saleem. *Academic Renal Unit, Univ of Bristol, Bristol, Avon, United Kingdom.*

**Background:** *PLCE1* is a gene mutated in inherited nephrotic syndrome, causing diffuse mesangial sclerosis. It is unusual in not having a known role at the podocyte slit diaphragm or in actin regulation. We generated a conditionally immortalised cell line from a child with a PLCε1 mutation, and studied its biology.

**Methods:** Wild type and *PLCE1* mutant human podocytes were treated with 2ng/ml recombinant TGF-B1. Podocyte markers and TGF signalling activity were measured by western blot and IF. Podocyte motility and barrier function were assessed by scratch assays and Electric Cell-substrate Impedence Sensing (ECIS) respectively.

**Results:** The mutant podocytes expressed typical podocyte markers at similar levels to wild type cells, Interestingly, the mutant cell line appeared mesenchymal in culture, and significantly overexpressed mesenchymal markers such as fibronectin and α-SMA. Despite expressing TGFBR1 and TGFBR2 there was no phosphorylation of SMAD2 in the mutant cell line. Non-canonical TGF-B1 signalling pathways were similarly impaired. This lack of SMAD2 signalling in response to TGF-B1 treatment also had functional consequences. Wild type podocytes became significantly more motile in response to 2ng/ml TGF-B: the mutant podocytes were unresponsive. This has clear implications for TGF-B signalling *in vivo*.

TGF-B Treated Scratch Assay of Wild Type and *PLCE1* Mutant Human Podocytes



The wild type podocytes also demontrated a very tight dose response to TGF-B. Following 24 hour treatment with 2ng/ml TGF-B1, the wild type podocytes upregulated the EMT regulators *slug* and *snail*. There was no such upregulation in the mutant podocytes.

**Conclusions:** In the mutant cell line there are equivalent amounts of SMAD2 and SMAD3. Compared to the wild type podocytes which express significantly more SMAD2. the antagonism of SMAD2 and SMAD3 leads to impaired responses to TGF-B1 in the mutant cell line. In this way PLCε orchestrates the podocyte's response to TGF-B1.

## SA-PO776

**Sypl2 Ablation Causes Congenital Nephrotic Syndrome** Ling-Mei Chiang,[1] Pu Duann.[2] *[1]Paediatrics, Chang-Gung Memorial Medical Center, Keelung, Taiwan; [2]DHLRI, Ohio State Univ, Columbus, OH.*

**Background:** Synaptophysin-like 2 (Sypl2), originally cloned from transverse tubules in muscle. It also expressed subtle abundance in kidney. It was newly identified to podocytes. Although some deformity was found in Sypl2-null mices, i.e. disarrayed T- tubule and reduced mitochondria amount, there is no muscle dystrophy. In this abstract, we report ablation of Sypl2(-/-) on kidney function and pathophysiology.

**Methods:** renal function on Sypl2 null mice were studied in terms of protein filtration and Adriamycin-mediated glomerulonephropathy. The interaction between Sypl2 and other Slit diaphragm genes was explored.

**Results:** Sypl2 expression was further localized to podocytes. Immuno-colocalization with nephrin (Nphs1) or podocin (Nphs2) was not detected. Foot process syncytium and defects was found in both scanning and transmission electromycroscopy. Intracytoplaqsmic lipid droplets (1-5 μm), was found abundant in tubular epithelium cells suggests the pathognomic hyperlipidemia in nephrotic syndrome. Adult Sypl2-null mice displayed proteinuria (UpUc 0.52 ± 0.23 ) compared to their wild type littermates (0.22 ± 0.14). Genetic ablation of Sypl2 results in no abnormalities in fertility, litter sizes and Mendelian ratios. The pathohistology studies revealed distinct glomerular deformity in homozygous 21d-pups and 28d-heterozygotes in a esser extent. To test whether ablation of Sypl2 injured the integrity of the slit-diaphram thus interfere podocyte normal function, Adriamycin-mediated glomerulopathy was explored. Sypl2-null mice with C57BL/6 as parental strain, was anticipated to be adriamycin resistant. High dosage (17mg/KgBW) Adriamycin administration failed to give conclusive answer. Abnormal Glut-4 translocation and oral glucose intolerance were observed in Sypl2-null mice.

**Conclusions:** Sypl2 has no direct intermolecular contact with any known slit diaphragm molecules is not prone todevelop the Finnish-type nephrotic syndrome. Sypl2-null mice with intact slit diaphragm genes still develop pathognomic footprocess deformity and hyperlipidemia instead of the Finnish type nephrotic syndrome. It provide an animal model to study the metabolic-mediated nephrotic syndrome.

## SA-PO777

**Pathophysiology of Reductions in Renal Blood Flow (RBF) and Glomerular Filtrate Rate (GFR) in Sepsis** Ruben M. Sandoval,[1] George Rhodes,[1] Silvia B. Campos-bilderback,[1] Sarah E. Wean,[1] Bruce A. Molitoris.[1,2] *[1]Medicine/ Nephrology, IU School of Medicine, Indianapolis, IN; [2]Roudebush VAMC, Indianapolis, IN.*

**Background:** It is well known that the reduction in GFR in sepsis far exceeds the fall in RBF yet the mechanism(s) remain unknown.

**Methods:** We used the cecal ligation and puncture (CLP) sepsis model in Munich Wistar Frömter rats with surface glomeruli to evaluate glomerular vascular alterations during ongoing sepsis at 24 hours.

**Results:** Serum creatinine increased from 0.3 to 0.8 mg/dl at 24 hours and was associated with a marked reduction in glomerular capillary RBC flow rates from 1,771 ±467μm/sec in untreated rats to 576 ±327μm/sec (P≤0.01). At 24 hour post injury, WBC adherence increased from 0.42 ±0.33/25μm volume in untreated rats to 7.25 ±5.82/25μm 24Hrs post CLP (p≤0.05). Most noticeable was the heterogeneous nature of RBC flow within the glomerular capillaries. Areas of markedly reduced or stagnant flow were observed with channeling of flow into adjacent areas. We quantified capillary loop branching points, which we determined to occur at approximately 48 ±8.8 points per glomeruluar volume. Shunting of RBC flow was measured using changes in RBC density within the capillary loops showing a decrease in RBC density within occluded loops. Untreated rats had a visual RBC density of 80.8 ±3.5% while rats imaged 24HR post CLP had a decreased RBC density of 56.2 ±15.8% (p≤0.01). Glomerular permeability was measured using a 150kDa Rhodamine dextran which increased from 0.007 ±0.003 in untreated rats to 0.096 ±0.046 (p≤0.05) 24HR post CLP.

**Conclusions:** These data imply the marked dissociation between GFR and RBF during sepsis is due to a reduction in the glomerular surface area available for filtration and shunting of blood flow around the glomerulus via intraglomerular capillary branch points allowing for small decreases in RBF resulting from marked reductions in GFR.

## SA-PO778

**Slit2-Robo2 Signaling Decreases Non-Muscle Myosin IIA Activity in the Podocyte** Xueping Fan, Anna Pisarek-Horowitz, Hila Milo Rasouly, Stefanie Chan, David J. Salant, Weining Lu. *Renal Section, Dept of Medicine, Boston Univ Medical Center, Boston, MA.*

**Background:** We have recently discovered that Robo2 is a novel podocyte protein localized to the basal cell surface of

the podocyte. Slit2-Robo2 signaling inhibits nephrin-induced actin polymerization and regulates podocyte foot process structure. However, the downstream signaling components of the Slit2-Robo2 pathway in podocytes are unknown.

**Methods:** Yeast two-hybrid screen and protein precipitation assays were performed to identify novel downstream signaling components of Slit2-Robo2 pathway in podocytes. Immunocytochemistry was used to verify protein expression of novel components in podocytes. We also performed genetic interaction studies in podocyte-specific knockout mice of Robo2 and the newly identified gene.

**Results:** Using yeast two-hybrid screen, we find that the myosin II regulatory light chain (MRLC), a subunit of non-muscle myosin IIA heavy chain (NM IIA, encoded by Myh9 gene), interacts directly with Slit-Robo Rho GTPase activating proteins (srGAPs). Protein precipitation assays show that NM IIA, MRLC, srGAPs, and Robo2 receptor form a protein complex that is enhanced by Slit2 ligand. Immunocytochemistry indicates that NM IIA, MRLC and srGAPs are expressed in podocytes. In vitro functional study demonstrates that Slit2-Robo2 signaling decreases NM IIA activity in podocytes. In vivo studies show that Myh9 and Robo2 podocyte-specific double knockout mice have fewer podocyte numbers compared with Robo2 single knockout mice.

**Conclusions:** We have identified srGAPs, MRLC and NM IIA (Myh9) as novel downstream protein components of the Slit2-Robo2 signaling in the podocyte. NM IIA activity is down-regulated by Slit2-Robo2 signaling, which may play a role in regulating podocyte cell adhesion and dynamics.

## SA-PO779

**ERK1/2 Are Dispensable for Normal Podocyte Function and Initial Response to Injury In Vivo** Johannes S. Schlondorff, Eliyahu V. Khankin. *Div of Nephrology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.*

**Background:** The Erk pathway in one of the canonical mitogen activated protein kinase signaling pathways and plays a central role in critical cellular functions, including survival and differentiation. Erk activation is a common manifestation in multiple human glomerular diseases and mouse models. However, it remains unclear whether its role is as a mediator or mitigator of disease, with conflicting results from in vitro studies. Here we present data that deletion of Erk1/2 in podocytes is dispensable for normal glomerular function.

**Methods:** Mice with a germline deletion of ERK1 (ERK1 -/-), a flox allele of ERK2 (ERK2 flox/flox), and podocyte specific Cre expression were generated. These podocyte ERK1/2 deficient animals were compared to littermates without the Cre allele, or with at least one wild-type ERK1 allele. Urinary microaolbumin-to-creatinine ratios and renal histology were examined at various ages. Age and sex matched mice were injected with a single dose of nephrotoxic serum (NTS) to induce transient massive proteinuria with subsequent repair.

**Results:** Mice with ERK1/2 deficient podocytes demonstrate no gross or histologic renal abnormalities at 6 weeks of age and have no significant albuminuria at that time. At 8 months of age, male mice showed a trend toward mildly elevated microalbumin/Cr ratios. Podocyte ERK1/2 deficient mice did not differ from their littermates with regard to peak proteinuria after NTS injection, nor with initial recovery at 11 days post-NTS. However, one month after NTS, podocyte ERK1/2 deficient animals showed approximately two fold higher residual albuminuria.

**Conclusions:** Podocyte development and function is not dependent upon ERK1/2 in vivo. Similarly, podocyte ERK1/2 deficient animals show a similar initial response to acute, transient podocyte injury in the NTS model, though there is evidence that they do not recover as well from the injury. In summary, these findings suggest that ERK1/2 do not play an essential role in baseline podocyte function and likely has only a minor role in podocyte response to injury or stress.

## SA-PO780

**Cyclosporine A Protects Podocyte via Upregulating the Expression of Cofilin-1** Xiaoyan Zhang,[1] Xiaoyan Li,[1] Youfei Guan,[2] Jie Ding.[1] *[1]Pediatric, Beijing Univ First Hospital; [2]Physiology and Pathophysiology, Beijing Univ Health Science Center.*

**Background:** Podocyte foot process is dysregulated in nephrotic syndrome. The effacement of podocyte foot processes typically arises owing to perturbations in the actin cytoskeleton. Calcineurin inhibitor Cyclosporien A (CsA) is currently used in the treatment of nephrotic syndrome. Recent data suggest that the effects of CsA on nephrotic syndrome are independent of its effects on the immune system. They identified that CsA can stabilize the actin cytoskeleton through stabilizing synaptopodin in podocytes and thereby reduce proteinuria directly. Other studies also showed that CsA induced cofilin phosphorylation and promoted stress fiber generation in proximal tubular cells. However, whether the antiproteinuric role of CsA is played by regulating cofilin-1 in podocyte has not been studied.

**Methods:** Acute podocyte injury and nephrotic syndrome were induced by puromycin aminonucleoside (PAN) injection in rats with or without CsA. Cultured podocytes were exposed to PAN with or without CsA treatment. Cofilin-1, nephrin, synaptopodin expression were determined by western blot or immunofluorescence. The cofilin-1 specific effect was determined using cofilin-1 siRNA.

**Results:** CsA reduced proteinuria, restored expression of cofilin-1, nephrin, syanptopodin and repaired foot process effacement of PAN induced nephropathy *in vivo*. *In vitro* studies showed that exposure of CsA restored the expression of cofilin-1 and nephrin which decreased by PAN. CsA also repaired actin cytoskeleton impaired by PAN. The protective effect of CsA was disappeared partially when cultured podocytes were exposed to cofilin-1 siRNA.

**Conclusions:** The antiproteinuric effect of CsA is derived from the stabilization of the podocyte actin cytoskeleton by upregulating expression of actin-binding protein cofilin-1.

*Funding:* Government Support - Non-U.S.

## SA-PO781

**Calbindin-1 (28kDa) Inactivation Leads to Proteinuria – Studies in Zebrafish (*Danio rerrio*), Mice and Mammalian Podocytes** Nils Hanke,[1,2] Laura L. Beverly-Staggs,[2] Patricia Ann Schroder,[2] Konstantin Deutsch,[1,2] Michelle P. Winn,[5] Gentzon Hall,[5] Ron Korstanje,[3] Christoph Kornauth,[4] Hermann G. Haller,[1,2] Mario Schiffer.[1,2] *[1]Div of Nephrology, Hanover Medical School, Hannover, Germany; [2]Mount Desert Island Biological Laboratory, Salisbury Cove, ME; [3]The Jackson Laboratory, Bar Harbor, ME; [4]Dept of Pathology, Medical Univ of Vienna, Vienna, Austria; [5]Div of Nephrology, Duke Univ Medical Center, Durham, NC.*

**Background:** Calbindin-1 (Calb-1) is an intracellular calcium-binding protein containing four active calcium binding domains. As calcium homeostasis is important for podocyte survival, we examined the effects of Calb-1 knockdown on the integrity of the glomerular filtration barrier and proteinuria in zebrafish.

**Methods:** Knockdown of Calb-1 was performed using morpholino injections in zebrafish *(Danio rerio)* eggs. We examined proteinuria development in the embryos by cardinal vein injection of 70 kDa FITC-labeled dextran and knockdown in a transgenic fishline (l-fabp:DBP-EGFP) expressing a 78kD GFP labelled protein. Pronephros structure was evaluated by TEM. Calb1 protein expression was analyzed in human biopsies as well as in wildtype and calreticulin deficient mice. Moreover proteinuria development was examined in aging Calb1-knockout mice.

**Results:** We found edema, proteinuria and foot process effacement in zebrafish embryos after knockdown of Calb-1.

Immunohistochemistry showed a strong expression of Calb1 protein in tubular cells and in addition we detected a cytoplasmatic vesicular expression pattern of Calb-1 in human podocytes. On immunofluorescence we detected a vesicular expression pattern in cultured human podocytes. Moreover we detected an upregulation of Calb1 in tissues with a calreticulin deficiency. Calb-1 knockout mice did not develop a spontaneous proteinuria indicating an indepence from Calb-1 in unchallenged mice.

**Conclusions:** In summary we found that Calb-1 knockdown results in a podocyte phenotype in zebrafish. In contrast in a rodent model the knockdown did not lead to proteinuria but to an upregulation of calreticulin indicating a delicate balance of calcium binding proteins in the podocyte.

*Funding:* Private Foundation Support

## SA-PO782

**Prostaglandin E2 Upregulates Olfactory Genes in Podocytes with Recovery from Nephrotoxic Serum Induced Injury** Nino Kvirkvelia, Maggie McMenamin, Afu Abdul, Michael P. Madaio. *Medicine, Georgia Regents Univ, Augusta, GA.*

**Background:** $PGE_2$ promotes resolution of Nephrotoxic Serum Nephritis in mice, and this was due, at least in part, to promoting glomerular cell recovery. In cell culture, $PGE_2$ reduced nephrotoxic serum (NTS) induced apoptosis of glomerular cells and promoted cell reproliferation after NTS-mediated injury.

**Methods:** To define the pathways involved, microarray analysis (Affymetrix oligonucleotide chips) was used to investigate $PGE_2$ regulated gene expression profiles in mouse glomerular epithelial cells after NTS treatment. Genes with a minimal 1.5-fold change and $P < 0.05$ were selected for network generation and pathway analyses by Ingenuity Systems. GenBank IDs of the selected genes were then mapped to the functional networks available in the Ingenuity Pathway Knowledge Base.

**Results:** A total of 237 genes with 3.5-1.5 changes ($p<0.05$) were identified, and the top 3 networks included functional categories of: a) Cell cycle, cell development, cell signaling; b) RNA post-translational modification, cell morphology, cellular assembly and organization; c) Cell-to-cell signaling and interaction, cellular compromise, cellular function and maintenance. The scores, reflecting the negative logarithms of the significant p values for these networks were 34, 29 and 27 respectively. The top upregulated $PGE_2$ targets included: NR4A2; NR4A1; OR5M11; TRDN; Olfr765/Olfr767; Olfr1085; Olfr582; Olfr948; OR10G2; Svs3a/Svs3b genes, with expression values of: 2.807; 2.681; 2.464; 2.229; 2.208; 2.110; 2.052; 1.951; 1.901; 1.893 respectively.

**Conclusions:** Among the highest $PGE_2$ regulated genes, a majority belong to an olfactory group of receptors, which are members of large family of G-coupled receptors, and share 7-transmembrane domain structure with many hormone and neurotransmitter receptors. Olfactory receptors have been shown to be expressed in the kidney at the RNA and protein levels. The hypothesis that $PGE_2$ acts as a specific ligand recognized by podocyte olfactory receptors to regulate podocyte survival and proliferation after injury are under investigation. The study will aid further understanding of signaling pathway regulated by $PGE_2$ in podocytes.

*Funding:* NIDDK Support

## SA-PO783

**Synaptopodin Limits Cell Surface Expression of TRPC6 in Podocytes** Hao Yu,[1] Andreas D. Kistler,[1] Stuart E. Dryer,[2] Jochen Reiser.[3] *[1]Nephrology, Univ of Miami, Miami, FL; [2]Biology and Biochemistry, Univ of Houston, Houston, TX; [3]Medicine, Rush Univ, Chicago, IL.*

**Background:** TRPC6 mutations have been shown to cause familial FSGS and increased TRPC6 in podocytes is found in acquired glomerular diseases. Synaptopodin (synpo) is a stabilizer of actin cytoskeleton in podocytes and it can be preserved by Cyclosporine A (CsA). We show that synpo interacts with TRPC6 and this interaction is functionally important and may have a role in regulating membrane localization of TRPC6.

**Methods:** Immunogold labeling and co-immunoprecipitation (co-IP) were performed to examine co-localization and interaction of TRPC6 and synpo, respectively. Cell surface biotinylation assay in synpo knock-down mouse podocytes was carried out to measure cell surface TRPC6 levels. Knockdown of synpo in podocytes and overexpression of wt TRPC6 and expression of FSGS-causing mutant $TRPC6^{M131T}$ in cultured and primary mouse podocytes were achieved by lentiviral system.

**Results:** Close co-localization of TRPC6 and synpo was observed in podocyte FPs by immunogold double labeling in mouse kidney sections. Interaction between TRPC6 and synpo was observed by co-IP in HEK293, cultured podocytes and mouse glomeruli. This interaction is significant because surface TRPC6 in synpo down-regulated podocytes showed a 2.4 fold increase in TRPC6 membrane expression suggesting synpo limits cell surface expression of TRPC6. Moreover, synpo was upregulated by ~2 fold in podocytes overexpressing wt TRPC6 or $TRPC6^{M131T}$, and decreased by ~70% in mouse $TRPC6^{-/-}$ glomeruli and $TRPC6^{-/-}$ primary podocytes. Reduction of synpo was rescued by expressing wt TRPC6 in $TRPC6^{-/-}$ primary podocytes. These data may reflect a feedback mechanism for podocytes to counteract the effect of malfunctioning or excessive TRPC6.

**Conclusions:** We demonstrate that synpo negatively regulates TRPC6 expression on cell membrane, presumably by direct binding. CsA, a drug that has been used to treat FSGS, was shown to stabilize synpo in podocytes. We propose a mechanism that CsA protects podocytes from excessive TRPC6 or FSGS-causing TRPC6 mutants by lowering cell surface expression of TRPC6 through stabilization of synpo.

*Funding:* NIDDK Support

## SA-PO784

**Dynamin1 Regulates Actin Cytoskeleton in Podocytes in a Phosphorylation Dependent Manner** Changkyu Gu, Sanja Sever. *Nephrology, Massachusetts General Hospital, Charlestown, MA.*

**Background:** Dynamin is an essential actin regulatory protein in podocytes, and loss of its function is closely connected to podocytes damage and proteinuria. Recently, our data has shown that dynamin directly regulates actin cytoskeleton via its oligomerization state. This dynamin oligomerization can be regulated through interaction with diverse cellular proteins, and it is reported that dynamin1 can differentially alter the affinity for its protein binding partners via phosphorylation by two different serine/threonine kinases, GSK3b and CDK5, in neurons. Based on these data, we hypothesize that phosphorylation-dependent dynamin1 oligomerization is an important molecular mechanism that regulates actin dynamics in podocytes.

**Methods:** Various phospho-dynamin1 mutants were generated by site-directed mutagenesis, and adenoviruses carrying these mutants were produced using Adenoviral Expression System (Invitrogen). Actin and paxillin in podocytes were stained to observe actin structures and focal adhesions. FLIM assay was done to detect oligomerization state of different phospho-dynamin1 mutants in podocytes.

**Results:** 1. Inhibition of GSK3b or CDK5 alters actin structures in podocytes.

2. Dynamin1 is phosphorylated by GSK3b and CDK5 in podocytes.

3. Overexpression of dynamin1 mutants lacking PRD domain inhibited the effects of GSK3b inhibitor on actin structures in podocytes.

4. Dynamin1 mutants which cannot be phosphorylated by GSK3b stimulate the formation of actin stress fiber and focal adhesions in podocytes.

5. FLIM assay showed that ablation of the GSK3b-specific phosphorylation site on dynamin1 induces dynamin1 oligomerization in podocytes.

**Conclusions:** The role of dynamin in actin cytoskeleton is essential to maintain the filtration barrier function of podocytes. Dynamin directly regulates actin structures via its oligomerization state. Our data show that dynamin1 oligomerization can be modulated by its phosphorylation state, and phosphorylation-dependent dynamin1 oligomerization contributes to regulation of actin dynamics in podocytes.

**Paricalcitol Ameliorates TGF Beta-Induced Glomerulopathy via Notch Pathway Activation** Taichi Murakami, Koji Okamoto, Shashi Shrivastav, Hidefumi Wakashiu, Jeffrey B. Kopp. *NIDDK, NIH, Bethesda, MD.*

**Background:** Vitamin D (VitD) is a promising approach to renoprotection. TGF-β induces kidney injury, and VitD antagonizes TGF-β signaling. TGF-β is engaged in cross-talk with the Notch pathway, with system-dependent agonistic and antagonistic effects. We tested whether VitD amplifies Notch signaling and thereby antagonizes TGF-β pro-fibrotic effect.

**Methods:** We investigated the effect of paricalcitol, a 1,25-OH VitD analog, on Notch activation in Alb/TGF-β transgenic (TG) mice, in which elevated plasma TGF-β, driven by the albumin promoter, induces progressive glomerulosclerosis. Paricalcitol was subcutaneously administered, beginning at 2 wk of age, when glomerular injury is mild, until 4 wk of age.

**Results:** Two-wk old TG mice exhibited the following: mild albuminuria, assessed as urine albumin/creatinine ratio (ACR), of 227 μg/mg; glomerular ECM accumulation; increased Smad3 phosphorylation; and down-regulation of VitD receptor protein. Notch pathway mRNA expression was significantly increased: Notch4 by 1.7 fold, Hey2 by 1.7 fold and HeyL by 4.0 fold. Immunostaining revealed a nuclear pattern of HeyL expression in glomeruli and tubules. Four-wk old TG mice had progressive kidney disease (table, mean±SD, * denotes significant compared to wild-type mice). Paricalcitol-treated mice exhibited less kidney damage, which reached statistical significance for urine ACR, glomerulosclerosis score, and HeyL/actin RNA ratio (#).

| | Urine ACR (μg/mg) | Glomerulo-sclerosis | FN/actin mRNA | COL1/actin mRNA | PAI-1/actin mRNA | HeyL/actin mRNA |
|---|---|---|---|---|---|---|
| Wild-type mice | 96±41 | 80±25 | 0.015± 0.0018 | 0.04±0.01 | 0.0011±0.00031 | 0.0014±0.00037 |
| TG mice | 4872±1733 * | 151±15 * | 0.038± 0.015 * | 0.22±0.077* | 0.013±0.0072* | 0.0047±0.0012* |
| TG mice + paricalcitol | 1187±1316 # | 125±12# | 0.027± 0.01 | 0.14±0.029 | 0.0077±0.0046 | 0.0074±0.0016# |

Paricalcitol did not alter Smad3 phosphorylation. The effect of paricalcitol plus TGF-β to increase HeyL mRNA expression was replicated in cultured mouse podocytes.

**Conclusions:** Paricalcitol may ameliorate glomerulopathy in part by amplifying Notch signaling and thereby antagonizing TGF-β signaling.

## SA-PO786

**Effect of Angiotensin II on Podocyte Autophagy** Imane Bensaada,[1,2] Carole Hénique-Gréciet,[1,2] Pierre-Louis F. Tharaux.[1,2] *[1]Paris Cardiovascular Research Centre - PARCC, INSERM, Paris, France; [2]Univ Paris Descartes, Sorbonne Paris Cité.*

**Background:** Injury and loss of podocytes are leading factors of glomerular diseases and renal failure. Angiotensin II (AngII) promotes albuminuria, aggravates non hypertensive glomerulosclerosis and severe hypertension nephropathy (HTN). Recently, autophagy has been identified as a major mechanism that delivers damaged proteins and organelles to lysosomes in order to maintain cellular homeostasis. Podocytes exhibit an unusually high level of constitutive autophagy.

**Methods:** The aim of this study was to evaluate the role of AngII on autophagy in podocytes. Expression of LC3 II, an autophagosomal membrane protein, was measured in kidney homogenates and in podocytes from HTN mice after chronic infusion of AngII or in vitro, in primary cultures of podocytes from mice with normal or constitutive activation of the AT1 receptor.

**Results:** Mice with chronic HTN presented decreased autophagy activity in podocytes. Furthermore, podocyte culture from mice with constitutively active AT1 mutant (CAM) displayed lower autophagy flux than wild type mice. Chronic activation of the AT1 receptor induced significant podocyte loss, as demonstrated by WT1 and podocin staining in aged mice. In primary podocyte culture, autophagy regulation is independent of the PI3-kinase-mTOR pathway, as shown after rapamycin treatment. To further investigate the importance of autophagy in podocyte survival, we used a mouse model with podocyte specific deletion of Atg5 alleles, that is required for autophagosome formation and maturation (Pod-Atg5 mice). Pod-Atg5 mice developed more severe glomerular injury than wild type counterparts upon chronic AngII infusion, with severe albuminuria and glomerulosclerosis.

**Conclusions:** In conclusion, these data indicate that chronic activation of the AT1 receptor promotes decrease in autophagy activity and unravel a protective function for podocyte autophagy in AngII-mediated glomerulosclerosis.

## SA-PO787

**TGF–β1 and VEGFa Differentially Regulate Notch Signaling in Podocytes** Mariya T. Sweetwyne, Katalin Susztak. *Renal, Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia, PA.*

**Background:** The Notch family is comprised of receptors (N1-4) and the Jagged (Jag1-3) and Delta-Like (DLL1, 3, 4) ligands. The regulation of these receptors and ligands suggests that they are not functionally redundant in podocytes. We previously showed that loss of N1 from podocytes (via floxed Notch1/podocin Cre) protects glomeruli from diabetic injury in vivo. Conversely, expression of Notch2 is critical for podocyte development. To understand this specificity in podocytes, we investigated Notch signaling in response to growth factors TGF-β1 and VEGFa as they both regulate glomerulosclerosis.

**Methods:** Murine podocytes were cultured with either TGF-β1 or VEGFa (+/- gamma secretase Notch inhibitor - GSI) for 0, 1, 4, 8, 12, 24, 48hrs. Notch-related gene regulation was determined by qRT-PCR and protein expression confirmed by immunoblot (WB) and immunofluorescence (IF).

**Results:** Direct TGF-β stimulation of the ligand, Jag1, was detected (WB, mRNA) by 1-8h. We detected TGF-β/Jag1-induced Notch1, but not Notch2, cleavage by WB at 4-24h. Interestingly, we observed a second wave (24-48 hr) of Jag1 gene expression that was GSI sensitive/Notch cleavage dependant. TGF-β suppressed expression of the Notch ligand Dll1, while inducing expression of another ligand, Dll4, at 4-48h, which was also dependent on Notch activation. Examining individual cells, we found that the protein expression of Dll4 and Jag1 (IF) was increased heterogeneously, with cells expressing either Jagged1 or Dll4. Furthermore, TGF-β also induced Notch dependent Vegfa expression in podocytes. Direct stimulation of podocytes with VEGFa induced Notch dependent expression of Dll4 but not other ligands, suggesting that TGF-β-induced Dll4 expression is downstream of Jagged1 and Vegfa.

**Conclusions:** TGF-β directly induces Jagged1 expression and Notch1 activation in podocytes. At later time points Notch activation sustains the expression of different ligands including Jagged1 and Dll4, as well as growth factor Vegfa. Stimulation of podocytes with VEGFa is sufficient to induce Dll4. Our results reveal an important ligand-specific response to TGF-β1/VEGFa cross-talk converging on the Notch signaling pathway.

## SA-PO788

**Melanocortin 1 Receptor Protects against Puromycin Induced Actin Stress-Fiber Rearrangement** Johannes Elvin,[1] Annika Lindskog Jonsson,[1] Lisa Maria Buvall,[2] Anna Granqvist,[1] Jenny C. Nystrom,[3] Borje Haraldsson.[1] *[1]Dept of Molecular and Clinical Medicine, Institute of Medicine, Univ of Gothenburg, Sweden; [2]Dept of Nephrology, Massachusetts General Hospital & Harvard Medical School; [3]Dept of Physiology, Institute of Neuroscience and Physiology, Univ of Gothenburg, Sweden.*

**Background:** Drugs targeting the melanocortin 1 receptor (MC1R) have shown to possess beneficial properties in treatment of patients with nephrotic syndrome. We have earlier demonstrated reduction of proteinuria in combination with improvement in glomerular morphology following MC1R treatment in a nephrotic rat model. We are currently investigating the mechanisms behind the beneficial effects of MC1R stimulation, with focus on actin dynamic regulatory pathways in podocytes.

**Methods:** Conditionally immortalized mouse podocytes over-expressing human MC1R were subjected to the nephrotic agent puromycin aminonucleoside (PAN) and simultaneously treated with a selective synthetic MC1R agonist (SA) or a non-selective MC1R agonist (α-MSH). Following PAN and MC1R agonist treatment, F-actin was visualized with Rhodamine-Phallodin and stress fiber content in cells were calculated and compared between treatment groups.

**Results:** The MC1R agonists SA or α-MSH were both able to restore stress fibers in podocytes with disrupted actin cytoskeleton due to PAN treatment. Stress fiber analysis following MC1R agonist treatment, revealed restoration of up to 40% of the actin stress-fibers in cells compared to PAN treatment alone.

**Conclusions:** MC1R stimulation hereby demonstrates the ability to restore stress fibers in podocytes when exposed to nephrotoxic agents such as PAN. Adding to our previous work, we know that MC1R signals through a cyclic AMP-dependent (cAMP) pathway. These data could propose that MC1R protects glomerular podocytes by regulating the actin cytoskeleton through a cAMP dependent pathway.

**SA-PO789**

**Tumor Necrosis Factor-α, Interleukin-6 and High Insulin Disrupt Podocyte Insulin Responses *In Vitro*** Abigail Charlotte Lay, Gavin Iain Welsh, Moin Saleem, Peter W. Mathieson, Richard Coward. *Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom.*

**Background:** We have previously demonstrated that podocytes are insulin-responsive cells *in vitro* and the podocyte-specific depletion of the insulin receptor (IR) *in vivo* results in glomerular dysfunction. It is recognised that insulin resistance is associated with albuminuria and type 1 and type 2 diabetic patients with insulin resistance are more at risk of developing nephropathy. Hyperinsulinaemia and increased circulating levels of the pro-inflammatory cytokines TNF-α and IL-6 are factors associated with insulin resistance. Here, the effects of Tumor Necrosis Factor-α (TNF-α), Interleukin-6 (IL-6) and high insulin concentrations on podocyte insulin responses *in vitro* were examined.

**Methods:** Conditionally immortalised mouse podocytes were grown in the presence of insulin, TNF-α and IL-6, and the effects on podocyte insulin responses investigated. Insulin-stimulated glucose uptake was assessed via a 2-deoxyglucose uptake assay, western blotting was performed to determine changes in protein expression and insulin-stimulated phosphorylation cascades and focused insulin signalling PCR arrays were performed to determine any changes at the mRNA level.

**Results:** Prolonged exposure to TNF-α and IL-6 reduces insulin-stimulated glucose uptake in podocytes. Western blotting demonstrated no significant reduction in IR protein levels and insulin-stimulated phosphorylation of IGF-IRβ (Tyr1131)/IRβ (Tyr1146) and Akt (Ser473, Thr308). Other aspects of the insulin signalling cascade are currently being investigated in a focused insulin signalling PCR array. Preliminary data suggests podocyte exposure to high concentrations of insulin *in vitro* reduces IR protein expression and phosphorylation of IGF-IRβ (Tyr1131)/IRβ (Tyr1146). Furthermore, Akt phosphorylation (Ser473, Thr308) also appears reduced.

**Conclusions:** Prolonged exposure of mouse podocytes to insulin and the pro-inflammatory cytokines TNF-α and IL-6 *in vitro* disrupts podocyte insulin responses. Investigating factors contributing to podocyte insulin insensitivity will enhance our understanding of the causes of glomerular disease in settings of insulin resistance.

**SA-PO790**

**HIV Induces Podocyte Epithelial Mesenchymal Transition (EMT) through Modulation of Telomerase Reverse Transcriptase (Tert)** Tejinder Singh, Nirupama Chandel, Partab Rai, Gautam Kishore Valecha, Rivka Lederman, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

**Background:** HIV-associated nephropathy (HIVAN is charcterized by podocyte proliferative phenotype in the form of collapsing glomerulopathy. HIV induces podocyte proliferative phenotype through podocyte expression of TERT in a HIV transgenic mouse model. We earlier reported that proliferative phenotype of kidney cells in HIVAN was the consequence of HIV-induced epithelial mesenchymal transition (EMT). In the present study, we hypothesized that HIV induces EMT in podocytes through the modulation of kidney cell Tert expression.

**Methods:** Renal cortical sections of control and HIVAN mice (Tg26) were immunolabeled for Tert, and EMT markers. In in vitro studies, conditionally immortalized human podocytes (CIHP, these podocytes constitutively Tert) were transduced with either HIV(NL4-3, HIV/CIHP) or empty vector (EV/CIHP). CIHP proliferate at 33°C and differentiate at 37°C. To determine the effect of HIV on Tert expression and occurrence of EMT, EV/CIHPs and HIV/CIHPs were incubated in media at 33°C for 72h, followed by differentiation at 37°C for 72h (CIDHP) further followed by dedifferentiation at 33°C for 72h (CIDDHP). Cellular lysates of control and experimental cells were probed for Tert, vimentin, α-SMA, p-cadherin, and FSP-1. To probe relationship between Tert and podocyte EMT, HIV/CIDDHP were silenced for Tert and evaluated for vimentin, SMA and FSP-1.

**Results:** Renal cortical sections of Tg26 mice displayed enhanced Tert expression by podcytes. In in vitro studies, HIV/CIHP exhibited enhanced expression of Tert and robust expression of vimentin, α-SMA and FSP-1 when compared to EV/CIHPs. HIV/CIDHPs displayed moderate expression of Tert, vimentin, α-SMA, and FSP-1 but decreased expression of nephrin and synaptopodin. HIV/CIDDHP displayed robust expression of Tert, α-SMA, and FSP-1 and decreased expression of nephrin, synaptopodin and WT1. siRNATert/CIHP and siRNATert/CIDHP demonstrated attenuated expression of vimentin, α-SMA, and FSP-1.

**Conclusions:** These findings indicate that HIV-induced podocyte EMT is mediated through HIV-induced Tert expression.

**SA-PO791**

**ERK5 Involvement in the Regulation of Human Podocyte Phenotype** Irbaz Isaac Badshah,[1,2] Deborah L. Baines,[2] Mark Edward Dockrell.[1] *[1]SWT Institute for Renal Research, Surrey, United Kingdom; [2]St. George's Univ of London, London, United Kingdom.*

**Background:** Podocytes are specialised cells integral to the normal functioning kidney, however in diabetes injury occurs leading to podocyte dysfunction and a compromised phenotype. ERK5 is an atypical MAPK involved in pathways modulating cell survival, proliferation and phenotype. Previously we have demonstrated the expression and activation of ERK5 in human podocytes, the role of which remains largely unknown in these cells.

**Methods:** Conditionally immortalised human podocytes were stimulated with EGF (10ng/ml) and TGF-β1 (2.5ng/ml); inhibition of ERK5 activation was conducted with the chemical inhibitor BIX02188 (10μM) directed to the upstream MEK5. Intracellular signalling proteins were investigated by western blotting; phenotype was explored with markers of podocytes, epithelia and mesenchymal cells by immunofluorescence; proliferation was assessed with an MTS assay; motility was examined with a scratch assay; barrier function was studied using electric cell-substrate impedance sensing.

**Results:** TGF-β1 decreased P-cadherin staining and increased the myofibroblast marker α-SMA which was prevented by BIX02188; BIX02188 alone and co-incubation with EGF led to increased nuclear staining of P-cadherin. EGF and TGF-β1 increased podocyte proliferation which was prevented by BIX02188. Podocyte motility was reduced by BIX02188 alone and co-incubation with EGF and TGF-β1. Integrity of the podocyte barrier at 6h was impaired by TGF-β1, EGF and BIX02188; co-treatment of EGF and BIX02188 further reduced impedance, however BIX02188 co-incubation with TGF-β1 restored impedance to vehicle control levels.

**Conclusions:** We have previously demonstrated activation of ERK5 isoforms by TGF-β1 in human podocytes; here we provide strong evidence that TGF-β1-induced transition to a more mesenchymal phenotype, enhanced motility and reduced barrier function were all prevented by pan-inhibition of ERK5 activation. Furthermore, inhibition of ERK5 activity prevented EGF-induced proliferation. These results implicate ERK5 as a critical regulator of growth factor-induced pathological and physiological responses in human podocytes.

**SA-PO792**

**ERK5 Involvement in the Regulation of Human Podocyte Survival** Irbaz Isaac Badshah,[1,2] Ekram Nabi,[1] Deborah L. Baines,[2] Mark Edward Dockrell.[1] *[1]SWT Institute for Renal Research, Surrey, United Kingdom; [2]St. George's Univ of London, London, United Kingdom.*

**Background:** Podocytes are highly focused cells central to kidney physiology, however in diabetic conditions injury occurs leading to an impaired function which is critically due to podocyte loss. ERK5 is an atypical MAPK involved in pathways modulating cell survival and apoptosis. Previously we have established the expression and activation of ERK5 in human podocytes, the role of which remains largely unknown in these cells under conditions associated with diabetic nephropathy.

**Methods:** Conditionally immortalised human podocytes were stimulated with the diabetic stimuli 30mM D-glucose and 200μg/ml advanced glycation end-product (AGE)-BSA. Inhibition of ERK5 activation was conducted with 10μM of the chemical inhibitor BIX02188 that targets the upstream MEK5. Intracellular signalling proteins were investigated by western blotting and protein modifications by immunoprecipitation; apoptosis was studied by western blot detection of cleaved caspase-3 and annexin V-FITC flow cytometry.

**Results:** High glucose treatment decreased p-ERK5 levels at 30min and over 48h increased apoptosis relative to the osmotic control of L-glucose as demonstrated through flow cytometry and raised cleaved caspase-3 protein levels. BIX02188 increased apoptosis, but co-incubation with D-glucose augmented the apoptosis observed with either treatment alone. AGE-BSA similarly decreased p-ERK5 at 30min, but did not cause apoptosis at 48h; contrariwise, AGE-BSA decreased the level of apoptosis relative to the non-glycated BSA control which was abolished following BIX02188 co-treatment. Immunoprecipitation revealed ERK5 to be SUMOylated in response to AGE-BSA treatment.

**Conclusions:** ERK5 is permissive for cell survival and inhibiting its activity leads to podocyte apoptosis under non-stimulated and diabetic conditions. ERK5 is SUMOylated under the diabetic stimulus of AGE-BSA treatment where there was no increase in apoptosis. This suggests that SUMOylation of ERK5 alters its localisation or activity in a manner not related to apoptosis. Manipulation of ERK5 signalling can be exploited to preserve the loss of podocytes that is observed in diabetic kidney injury.

**SA-PO793**

**Effects of Serum Amyloid A on Glomerular Podocyte Inflammatory Responses** Robert J. Anderberg,[1] Rick L. Meek,[1] Sheryl K. Cooney,[1] Katherine R. Tuttle.[1,2] *[1]Providence Medical Research Center, Providence Sacred Heart Medical Center & Children's Hospital, Spokane, WA; [2]Div of Nephrology, Dept of Medicine, Univ of Washington School of Medicine, Seattle, WA.*

**Background:** Inflammatory mediators promote kidney damage that plays an important role in the pathogenesis of diabetic kidney disease (DKD). Acute phase serum amyloid A (SAA) is a family of apolipoprotein isoforms that likewise promote inflammation. We previously discovered that SAA isoform 3 (SAA3), a major acute phase reactant in mice, was increased in the glomeruli of mouse models of both type 1 diabetes/early DKD and

type 2 diabetes/advanced DKD. Notably, SAA3 was prominently expressed in glomerular podocytes. The aim of this study was to evaluate direct effects of SAA on podocyte inflammatory responses that may contribute to DKD.

**Methods:** Mouse podocytes were treated with SAA (human SAA isoform 1), advanced glycation end products (pro-inflammatory control), or normal control conditions for 6, 24 and 48 hours. Nuclear Factor kappa B (NF-kB) activity was measured in cell lysates. Podocytes were also treated with SAA for 1 day and mRNA measured (quantitative real-time PCR) using pathway arrays featuring NF-kB and inflammation-related genes. Mouse SAA3 protein was also measured from conditioned media (ELISA).

**Results:** Mouse podocytes exposed to SAA or AGE increased NF-κB activity. SAA exposure produced strong increases in expression of NF-κB gene targets comprising numerous inflammatory alpha and beta chemokines including ENA-78, RANTES, and MCP-1. Inflammatory cytokines were also induced, including IL-6, G-CSF, and SAA3 itself. SAA3 protein production was also augmented in podocytes exposed to SAA.

**Conclusions:** SAA induces a wide-ranging inflammatory response in podocytes, making it a likely candidate to instigate inflammatory mechanisms in diabetic glomeruli. Increased expression of an SAA gene, and consequent mRNA translation, in response to exposure to an SAA isoform suggests up-regulation via an autocrine positive feedback loop in podocytes.

## SA-PO794

**Blockade of AT1 Receptor Upregulates Vitamin D Receptors in Podocytes through Downregulation of CYP24A1** Tejinder Singh, Nirupama Chandel, Rivka Lederman, Partab Rai, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

**Background:** Blockade of AT1R leads to the slow down in the progression of renal lesions in several kidney disease models. We hypothesized that blockade of AT1R would provide protection against podocyte injury by *de nov*o up regulation of vitamin D receptor (VDR).

**Methods:** Control and HIV transgenic mice (Tg26) were evaluated under control and Telmisaratan treatment (2 wks, Tg/Tel) for renal tissues expression of VDR and CYP24A1. Human podocytes (HP) incubated in media containing either buffer, losartan ($10^{-7}$M) ± Ang II ($10^{-6}$M), or Ang II-stimulating miiieus (HIV, high glucose,30 mM) (n=3). To determine the role of AT1, CIHPs transfected with siRNA-AT1R or scrambled siRNA (SCR) in the presence/absence of losartan.To determine the role of tyrosine kinase, HPs were treated with either buffer or genistein ($10^{-7}$M) ± Ang II. To determine the role of Vit D3, CIHPs were incubated in serum free media (SFM) containing either buffer, vit D3 (10 pM) or losaratan for 24h (n=3). All Protein blots were probed for VDR and CYP24A1 expression.

**Results:** Renal tissues in Tg/Tel mice displayed attenuated VDR but enhanced CYP24A1 expression. In *in vitro* studies Ang II, glucose and HIV down regulated podocyte VDR expression; whereas, losartan enhanced podocyte VDR expression under basal as well as Ang II-, glucose-, and HIV-stimulated conditions. HP/siRNA-AT1 also displayed enhanced VDR but attenuated CYP24A1 expression. Ang II, HIV and glucose stimulated podocyte expression of CYP24A1. Interestingly, losartan enhanced VDR expression only in the presence of media containing either serum or vitamin D3. These findings suggested that AT1 blockade-induced down regulation of CYP24A1 prevented degradation of vitamin D3, which might have resulted in the up regulation of VDR. Since losartan treated HIV/podocytes silenced for VDR displayed greater apoptosis, it appears that losartan-induced de novo up regulation of VDR also contributed partially to the protection offered by AT1R blockade.

**Conclusions:** AT1 blockade upregulates VDR through down regulation of CYP24A1 and the former provides protection against HIV-induced podocyte injury.

## SA-PO795

**Rapid Multiplex Detection of *E. coli* and *K. pneumonae* by Loop Mediated Isothermal Amplification in Urine** Ashish Yeri,[2] Ishwad Chandra,[1] Abhay N. Vats.[1] *[1]Nephrology, Children's Hospital of Pittsburgh; [2]Chemical and Petroleum Engineering, Univ of Pittsburgh.*

**Background:** The need for rapid point-of-care diagnostics for infectious diseases has been steadily increasing globally, especially in low resource settings. *E. Coli* and *K. pneumonae* are responsible for a large proportion of urinary tract infections (UTI) as well as other infections. Detection of these organisms is generally done by bacterial culture which usually takes 48 hours or more. Recently, a loop mediated isothermal amplification (LAMP) technique has been developed which amplifies the DNA at around 63-65 °C with high specificity in 30-60 minutes or less. We utilized LAMP protocols and lateral flow display to detect these two common UTI associated organisms in a multiplex reaction.

**Methods:** The LAMP procedure utilizes 6 primers and can be performed on a regular water bath or a heating block maintained at a constant temperature of 60-65 C. The detection of the LAMP *E. Coli* and *K. pneumonae* amplification product was performed on lateral flow display (LFD) strips LFD primarily consists of a nitrocellulose membrane with antibodies immobilized at specified locations. Labeled primers, namely biotin, digoxigenin (*K. pneumonae)* and FITC labeled (*E. Coli* ) outer primers were and the detection is performed using a sandwich type immunoassay. We analyzed 98 de-identified residual urine samples from patients with suspected UTI with LAMP and LFD and compared results with culture and PCR.

**Results:** LAMP amplification took about 30 minutes or less which was followed by LFD detection in 5 minutes or less. LFDs showed a clear visible lines for *E. Coli* and *K. pneumonae* at the immobized anti-FITC or anti-digoxigenin locations and easy distinction between the positive and negative samples. LAMP had a higher sensitivity (98%) when compared to culture and was similar to PCR, making this assay a reliable, rapid and inexpensive diagnostic tool.

**Conclusions:** LAMP is an efficient and cost effective method for rapid detection of common UTI associated organisms. The technique reuires no sample preparation and can yield fast and precise results in appx 30 minutes. The technique is amenable for use in low resource settings as well as ER and out patient clinics.

## SA-PO796

**Pseudohyperphosphatemia during Exposure to Liposomal Amphotericin B Therapy** Nicole Bohm,[1] Katherine Hoover,[1] Amy E. Wahlquist,[3] Juan Carlos Q. Velez.[2] *[1]Dept of Pharmacy, Medical Univ of South Carolina; [2]Div of Nephrology, Medical Univ of South Carolina; [3]Dept of Public Health Sciences, Medical Univ of South Carolina.*

**Background:** Reports have emerged linking exposure to liposomal amphotericin B (L-AmB) therapy with artifactually elevated serum phosphorus (sPhos) levels (pseudohyperphosphatemia) caused by interference of the phospholipid component of L-AmB with the kinetic-based clinical assay. However, this phenomenon remains under-recognized.

**Methods:** We reviewed records of adult hospitalized patients treated with L-AmB or fluconazole (Fcz, control) at our institution in the last 5 years, excluding those with estimated glomerular filtration rate (eGFR) < 20 ml/min.

**Results:** Among those without chronic kidney disease (CKD) [eGFR > 59] and no concomitant acute kidney injury (AKI) [50% rise in serum creatinine], *de novo* high sPhos [>5.0 mg/dL] occurred more often during L-AmB therapy compared to Fcz therapy [36% (12/33) vs 13% (63/491), respectively, p<0.01]. Very high sPhos [>7.0 mg/dL] was also more common during L-AmB therapy [6% (2/33) vs <1% (2/491), respectively, p<0.01]. Among those with CKD [eGFR 20-59] and no concomitant AKI, high sPhos also occurred more often during L-AmB therapy [60% (12/20) vs 24% (45/184), p<0.01]. Similarly, very high sPhos was more common during L-AmB therapy [15% (3/20) vs 3% (6/184), p=0.02]. None of the L-AmB-treated subjects with high sPhos received phosphorus supplements. After adjustment for a reciprocal drop in serum calcium, use of phosphorus binders and baseline eGFR, L-AmB-treated patients remained more likely to have high sPhos than the Fcz group [4.0 (95% CI: 1.9 to 8.6) times in non-CKD and 4.3 (95% CI: 1.6 to 11.7) times in CKD, p<0.01]. In the presence of concomitant AKI, no differences were observed. In addition, we identified 6 cases where unexpectedly high sPhos levels during L-AmB therapy prompted a re-run of the sera utilizing a confirmatory endpoint-based assay. In all 6 cases, re-run values were normal [median spurious rise in sPhos: 1.7 (0.6 - 3.6) mg/dL].

**Conclusions:** We conclude that pseudohyperphosphatemia may not be uncommon during L-AmB therapy. Awareness of this phenomenon should be raised.

## SA-PO797

**Utility of the Urinalysis in the Diagnosis of Primary Glomerular Disease: Report of the NEPTUNE Collaborative Study** Howard Trachtman,[1] Richard A. Lafayette,[2] J. Troost,[3] Debbie S. Gipson,[3] Matthias Kretzler,[3] Peter J. Nelson,[4] Marie C. Hogan,[5] John C. Lieske,[5] Sharon G. Adler,[6] Heather N. Reich,[7] Kevin E.C. Meyers.[8] *[1]NYU Langone Medical Center, New York, NY; [2]Stanford Univ, Stanford, CA; [3]Univ of Michigan, Ann Arbor, MI; [4]Univ of Washington, Seattle, WA; [5]Mayo Clinic, Rochester, MN; [6]Harbor-UCLA Medical Center, Torrance, CA; [7]Toronto General Hospital, Toronto, Canada; [8]Children's Hospital of Phila., Philadelphia, PA.*

**Background:** Urinalysis (UA) is a key screening test in patients with primary glomerular disease (PGD) and proteinuria. Although differences in UA findings have been reported in patients with the various forms of PGD, there is little information about the utility of the UA in the diagnosis of PGD in a large unbiased disease population. Therefore, we assessed the value of the UA in making the diagnosis of minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS) and membranous nephropathy (MN) in patients enrolled in the NEPTUNE cohort study with a confirmed histopathological diagnosis (n=376).

**Methods:** Dipstick testing results were recorded for hematuria (n=189) and leukocyturia (n=167). All patients had proteinuria (> 500 mg/d) and required a diagnostic kidney biopsy. Hematuria or leukocyturia above trace was considered positive. UA results were compared between patients in the three categories of PGD and those with other diseases, predominantly IgA nephropathy, immune complex glomerular disease, and diabetic nephropathy.

**Results:** There were 56 cases of MCD, 47 of FSGS, 34 of MN, and 52 with other glomerular disease with UA testing. Hematuria was less frequent in those with MCD/FSGS (32%) vs MN (59%) or other glomerular diseases (67%) (P<0.01). Leukocyturia was generally absent in patients with MCD, FSGS, and MN but low-grade leukocyturia was more common (15%) in those with other glomerular diseases (P<0.05).

**Conclusions:** Patients with MCD and FSGS are less likely to have hematuria compared with MN. Although hematuria can be used to assess the probability of MN vs. MCD or FSGS, it is not a discriminating factor. The presence of leukocyturia was indicative of other PGD.

## SA-PO798

**Short Synacthen Test: Outcome in Patients with Glomerulonephritis on Long Term Steroids** Roshni Rathore, Michael Venning. *Dept of Renal Medicine, Central Manchester Univ Hospitals NHS Trust, Manchester, United Kingdom.*

**Background:** Although potency, dose and duration of steroid use are important predictors of presence of hypothalamic-pituitary axis suppression, the preferred method to assess adrenocortical function is the response to synthetic ACTH. Short synacthen test is widely used for assessing adrenal function prior to weaning off long term steroids.

In our regional renal vasculitis clinic, we see a large population of renal patients with glomerulonephritides requiring long term immunosuppression. We specifically looked at our practice of performing short synacthen test before completely stopping steroids in this population.

**Methods:** We retrospectively analysed data obtained from biochemistry database at University Hospitals of South Manchester along with patients' case notes. We gathered data on 50 patients who had one or subsequent short synacthen test between 1993 and 2007. These patients were in remission and had been maintained at 5 mg daily or less of Prednisolone for some weeks or months. We divided them into those that had been successfully weaned, those that are still on steroids and those that were back on steroids after complete withdrawal.

**Results:** Time taken to completely come off steroids ranges from 3 months to 30 months. Three different regimes are being used for tapering the dose-1) Reduction by 1 mg every month 2) Missing dose a day and subsequently longer in a week 3) Alternate day dosing and reduction. Relapse or presence of active disease has been the main reason for prolonged continuation of steroids. There was no documented evidence of major complication in the form of addisonian crisis when steroids were weaned after adequate cortisol response to synacthen. Most patients have required 60 min test to confirm adequate response.

**Conclusions:** 1. A 60 minute cortisol rise of > 250 nmol/l can adequately predict safe steroid withdrawal if undertaken over several months; 2. An adequate cortisol rise of > 250 nmol/l at 30 min is not necessary for subsequent safe steroid withdrawal; 3. With this protocol, a peak rise in cortisol to >550 nmol/l is not necessary for subsequent safe steroid withdrawal as traditionally described.

## SA-PO799

**Exosomal mRNA for Biomarkers of Renal Injury Is Not Increased after Renal Transplantation** Zoltan H. Endre, Philip Peake, Timothy J. Pianta, Lena Succar. *Dept of Nephrology, Prince of Wales Hospital, Randwick, NSW, Australia.*

**Background:** mRNA extracted from urinary exosomes may provide a snapshot of altered renal cell metabolism after injury, preceding or paralleling changes in urinary biomarker protein concentrations.

**Methods:** Exosomes were isolated using nanomembrane concentrators from urine obtained immediately following renal transplantation, from patients with stable kidney transplant function, from healthy volunteers, and from patients with CKD complicated by proteinuria. The expression of exosomal mRNA for neutrophil gelatinase-associated lipocalin (NGAL), interleukin-18 (IL-18), cystatin C and kidney injury molecule-1 (KIM-1) was compared with levels of the corresponding urinary protein and18S RNA.

**Results:** Urinary protein concentrations of all biomarkers of injury increased after kidney transplantation, and exosomal18S RNA increased after transplantation and in CKD. Exosomal mRNA for NGAL, IL-18 and cystatin C was detected in all subjects with CKD and in some subjects in all groups, except in patients with stable transplant function. However, mRNA for KIM-1 was mostly undetectable. mRNA expression did not correlate with urinary protein concentrations. NGAL mRNA was lower following acute transplantation than in normal subjects and those with CKD, although urinary NGAL had risen by 4h post transplantation, and was high in CKD. IL-18 mRNA in CKD was higher than after transplantation, or in normal subjects, while urinary IL-18 levels in CKD were normal.

**Conclusions:** mRNA for NGAL, IL-18 and cystatin C is present in urinary exosomes, but levels do not reflect urinary protein concentration or acute injury. This may result from selective sorting of mRNA to exosomes by the parent cell, or by immunosuppression acting on these cells.

## SA-PO800

**Induction of Chitotriosidase in Human Macrophages by Incubation with Cystine Crystals: Clinical Utility in Nephropathic Cystinosis** Mohamed A. Elmonem,[1] Lambert Van den Heuvel,[2] Neveen Soliman,[3] Elena N. Levtchenko.[2] *[1]Clinical and Chemical Pathology, Inherited Metabolic Disorder Laboratory (IMDL), Faculty of Medicine, Cairo Univ, Cairo, Egypt; [2]Pediatric Nephrology, Growth and Retardation, Univ Hospital Leuven, KU Leuven, Leuven, Belgium; [3]Pediatrics, Center for Pediatric Nephrology and Transplantation (CPNT), Faculty of Medicine, Cairo Univ, Cairo, Egypt.*

**Background:** Nephropathic Cystinosis (NC) is an inherited autosomal recessive disorder. Mutations of the *CTNS* gene, coding for cystinosin, lead to accumulation and crystallization of cystine inside different cells. The aminothiol cysteamine is the only specific treatment for cystinosis, and so far, cystine content in white blood cells (WBC) is the main diagnostic tool and the only therapeutic monitor. Chitotriosidase enzyme is a human chitinase produced by activated macrophages. Its elevation was documented in many lysosomal disorders, and is used as a therapeutic monitor for enzyme replacement in Gaucher disease.

**Methods:** Different concentrations of cystine crystals were incubated with control human macrophages in-vitro to detect macrophage activation by assaying TNF-α in culture supernatant and chitotriosidase induction by measuring enzyme activity and mRNA expression in the cell lysate. Chitotriosidase activity was also measured in the plasma of 45 NC patients, and compared with matched 54 normal controls and 24 renal disease patients. Chitotriosidase levels were also correlated with cystine in WBC for 33 patients on cysteamine therapy.

**Results:** TNF-α, released in supernatant, increased up to ten folds after cystine crystal incubation and correlated with crystal concentration. Chitotriosidase activity and mRNA expression were also significantly increased. Enzyme activity (nmol/ml/h) in NC patients (0-3880, median 163) was significantly elevated compared to normal controls (0-72, median 14) and renal patients (2-144, median 39), $P<0.001$ for both groups. Chitotriosidase activity also correlated with cystine content in WBC ($r = 0.8$).

**Conclusions:** Chitotriosidase enzyme is a promising screening marker for NC patients among the clinically suspected and a probable therapeutic monitor for cysteamine therapy.

## SA-PO801

**Urinary microRNAs Are Stabilised by Association with Argonaute 2 Protein** Donald Fraser, Cristina Beltrami, Timothy Bowen. *Section of Nephrology, Cardiff Univ School of Medicine, Cardiff, United Kingdom.*

**Background:** microRNAs (miRs) are endogenous, short, non-coding single-stranded RNA transcripts that regulate gene expression at the post-transcriptional level. Recent work has shown that miRs found in serum and plasma are present in microvesicle-free and microvesicle-associated form, in each case showing a resistance to RNase activity that enhances their disease biomarker utility. Urinary miRs represent a potentially novel source of biomarkers for chronic kidney disease (CKD), but their localisation to microvesicles and sensitivity to degradation remain poorly characterized. The purpose of this study was to identify the location of miRs in urine, and to investigate their stability.

**Methods:** Microvesicle-free and microvesicular urinary fractions were prepared by sucrose gradient ultracentrifugation prior to analysis by flow cytometry, immunoblotting and RT-qPCR. Endogenous urinary miR stability was then compared with that of spiked-in, exogenous, C. elegans-specific cel-miR-39 using RNase or proteinase K digestion followed by RT-qPCR. Protein:miR associations were analysed by RNA-immunoprecipitation (RNA-IP).

**Results:** Over 95% of urinary miRs were present in microvesicle-free urine, with the majority of the remainder associated with exosomes. Endogenous miRs had significantly greater resistance to RNase degradation than cel-miR-39 in urine samples from both control subjects and proteinuric diabetic nephropaths. Proteinase K digestion significantly decreased endogenous miR stability, suggesting protection by protein binding partners. Investigation of putative partners using RNA-IP showed association between urinary miRs and Argonaute 2, a protein component of the RNA-induced silencing complex, but not albumin.

**Conclusions:** Our data demonstrate that the majority of urinary miRs are not associated with microvesicles, provide a mechanism by which their stability is enhanced, and suggest that miRs do not freely cross the glomerular filtration barrier. These findings have important implications for the use of urinary miRs as a novel class of CKD biomarkers.

## SA-PO802

**Phospholipase A2 Receptor Staining in Biopsies of Stage I Primary Membranous Glomerulonephritis** Margaret Ryan, Gyongyi Nadasdy, Anjali A. Satoskar, Sergey V. Brodsky, Tibor Nadasdy. *Pathology, The Ohio State Univ Wexner Medical Center, Columbus, OH.*

**Background:** Most patients with primary membranous glomerulonephritis (MGN) have circulating IgG4 antibodies directed against the phospholipase A2 receptor (PLA2R) with positive glomerular capillary deposits for IgG4 and PLA2R by immunofluorescence. We recently described that the deposits in early (glomerular stage I) primary MGN tend to be IgG1 dominant (Huang et al., Mod Pathol 26: 799-805, 2013). To better characterize the role of PLA2R in primary early stage MGN, we evaluated the reactivity of glomerular stage I primary MGN biopsies with antibodies to the PLA2R.

**Methods:** From our biopsy archives, we identified fifteen cases of primary (by clinical history) glomerular stage I MGN. We stained the biopsies for the IgG subclasses by direct immunofluorescence on frozen sections and for PLA2R by indirect immunofluorescence on paraffin-embedded sections.

**Results:** The majority (n=11) of these cases were IgG1 dominant or codominant. Six cases were IgG1 dominant, four codominant for IgG1/IgG4, one codominant for IgG1/IgG2, and four IgG4 dominant. Two of the cases (one IgG1 dominant and one IgG1/IgG4 codominant) did not have glomeruli available for evaluation for PLA2R staining. All cases with IgG1 dominant glomerular deposits (n=5) were negative for PLA2R. One of these cases had serum PLA2R testing, which was also negative. Because of the retrospective nature of the study, we were unable to compare serum PLA2R antibodies with the histologic findings for the other cases. Three of the four cases with dominant glomerular IgG4 and the three cases with codominant IgG1/IgG4 staining were positive for PLA2R. The biopsy with IgG1/IgG2 codominant glomerular staining was negative for PLA2R.

**Conclusions:** The lack of PLA2R staining in all cases of IgG1-dominant early stage MGN suggests that in very early stage primary MGN antigens other than the PLA2R may be the target antigens. Alternately, it is possible the PLA2R initially evokes an IgG1 response which later may switch into an IgG4 response, but serial biopsies to prove this are unavailable.

## SA-PO803

**Biomarkers of Interstitial Kidney Pathology in Lupus Nephritis – The CKD Biomarker Consortium** Brad H. Rovin,[2] Huijuan Song,[2] Cassandra L. Hines,[2] Haifeng M. Wu,[2] Vasan S. Ramachandran,[4] Paul L. Kimmel,[3] John W. Kusek,[3] Harold I. Feldman,[5] Michael Merchant,[1] Jon B. Klein.[1] *[1]Univ of Louisville; [2]Ohio State Univ; [3]NIDDK; [4]Boston Univ; [5]Univ of Pennsylvania.*

**Background:** Interstitial inflammation (INF) correlates with long-term renal outcomes in lupus nephritis (LN). Monitoring the interstitium during therapy to determine if INF is resolving or interstitial fibrosis (FIB) is increasing could improve outcomes.

**Methods:** Discriminant analysis was used to design non-invasive biomarker panels that could distinguish INF and FIB in > 25% of interstitium. Urine biomarkers tested were chosen as plausible candidates from literature, or from differentially-expressed urine proteins identified by mass spectrometry followed by ELISA from LN patients with varying levels of INF and FIB on biopsy (n=81). Combinations of MCP-1, hemopexin (HPX), endothelial protein C receptor (EPCR), serum creatinine (SCr), and proteinuria were tested for the ability to discriminate between levels of INF and FIB ≤ and >25% involvement.

**Results:** The function that best discriminated ≤25% INF from >25% INF was Y=1.2*log(uMCP-1) + 3.7*log (SCr) + 1.2*log (uHPX) – 3.6, where Y≥0 identified >25% INF with 82% accuracy and an area under the ROC curve of 0.89. The discriminant function best distinguishing ≤25% FIB from >25% FIB was Y= -2.8*log (EPCR) + 1.8*log (uHPX) +10.2, where Y≥0 identified >25% FIB with 78% accuracy and an area under the ROC curve of 0.85. To determine discriminant functions' specificity for interstitial changes, they were applied to inflammatory or fibrotic glomerular lesions. The INF equation had only 63% accuracy identifying glomerular necrosis or cellular crescents in ≥ 25% of glomeruli. The FIB equation had 65% and 60% accuracy in identifying glomerulosclerosis or fibrous crescents in more than 25% of glomeruli, respectively.

**Conclusions:** These data demonstrate the potential value of combining biomarkers into diagnostic panels that discriminate between levels of interstitial pathology in LN with good accuracy and specificity. If validated, these panels can be of potential use to follow interstitial injury prospectively, and guide therapy.

## SA-PO804

**Urinary Podocyte Specific mRNA in Alport Syndrome** Larysa T. Wickman, Farsad Afshinnia, Su Qing Wang, Mahboob A. Chowdhury, Ryuzoh Nishizono, Jocelyn E. Wiggins, David B. Kershaw, Roger C. Wiggins. *Univ of Michigan.*

**Background:** There is increasing evidence that podocytes may play an important role in pathophysiologic mechanism leading to progression in Alport syndrome. It was shown that type IV collagen originates solely from podocytes. Studying urinary expression profiles of podocyte specific mRNA podocin may help to understand pathophysiologic mechanisms of Alport disease progression, guide treatment and lead to biomarker discovery that can aid assessment of novel therapies.

**Methods:** Urine pellet RNA is isolated and reverse-transcribed to cDNA using High-Capacity cDNA Reverse Transcription Kits. Quantitation of podocin mRNA was performed using the 7900 HT Fast Real-Time PCR System. All assays were performed against cDNA standards to allow data to be expressed in moles per gram of creatinine. Normal range was derived from single samples of urine from individuals without kidney disease and compared to average values for each clinic patient with Alport.

**Results:** We have collected and analyzed 20 urine samples from 10 patients with Alport syndrome and 291 urine samples from controls. This included 6 patients with biopsy proven Alport, 3 patients with hematuria/ proteinuria and family history of Alport and 1 patient with hematuria/proteinuria and thin GBM on biopsy. Majority of the patients (80%) were treated with Renin-Angiotensin System (RAS) inhibitors. Urine samples from Alport patients contained 23 fold elevated amounts of podocin mRNAs when compared to controls (P<0.001).

**Conclusions:** We have shown that podocin mRNA levels are significantly higher in representative samples of patients with Alport compared to normal controls. We need to extend the observation to examine whether this methodology can be used to identify Alport disease progression at an early stage before development of significant proteinuria and to determine whether initiation of RAS inhibition on early stages can slow the rate of podocyte detachment.

*Funding:* NIDDK Support, Other NIH Support - NIH T32DK065517 training grant and by a NEPTUNE Career Development Award U54 DK083912 from the NIDDK and the NIH Office of Rare Diseases Research (ORDR)/NCATS

## SA-PO805

**Urinary Podocalyxin Excretion Levels and Podocyte Damage** Masahiro Hagiwara,[1] Akira Hiwatashi,[1] Hirayasu Kai,[1] Joichi Usui,[1] Naoki Morito,[1] Chie Saito,[1] Keigyou Yoh,[1] Hiroyuki Kurosawa,[2] Kunihiro Yamagata.[1] *[1]Nephrology, Clinical Medicine, Univ of Tsukuba, Tsukuba, Ibaraki, Japan; [2]Denka Seiken Co., Ltd., Niigata, Japan.*

**Background:** Podocalyxin (PCX), the major sialoprotein of glomerular epithelial cells (podocytes) is expressed on apical membrane, and helps maintain the architecture of the foot process and the patency of the filtration slits. PCX was excreted in urine as vesicle form in various glomerular diseases and this vesicle was originated from microvilli of podocyte membrane by shedding.

**Methods:** We examined urinary level of PCX and ultrastructural podocyte changes in rat animal models of membranous nephropathy (active Heymann nephritis (AHN)), minor change nephrotic syndrome (early phase of puromycin aminonucleoside nephritis (PAN)) and focal segmental glomerulosclerosis (late phase of PAN). AHN was induced by ip injection of Freund's complete adjuvant and renal cortex homogenate. PAN wad induced by 4 times (day 1, 28, 35, 42) ip injection of PA, and early phase (day 10) and late phase (day 52) were studied.

**Results:** Urinary PCX levels were higher in AHN and early phase PAN rats than normal control rats and late phase PAN rats.

| | n | proteinuria (mean ± SD, mg/day) | urinary PCX (mean ± SD,ug/day,) |
|---|---|---|---|
| active Heymann nephritis | 10 | 251 ± 100 | 20.1 ± 10.3 |
| early phase of PAN | 5 | 183 ± 69 | 6.3 ± 3.2 |
| late phase of PAN | 5 | 224 ± 74 | 1.3 ± 1.2 |
| normal control | 10 | 8 ± 6.5 | 2.3 ± 1.5 |

AHN rats showed a significantly higher level of urinary PCX than early and late phase PAN rats with same level proteinuria. Numerous microvilli formations of podocytes were observed in AHN than both phase PAN rats. Although, the podocyte numbers of late phase PAN rats showed only 10% decrease than early phase PAN, urinary PCX levels of late phase were markedly decreased to 20% of early phase PAN.

**Conclusions:** Among the proteinuric glomerular diseases, urinary PCX excretion was affected by podocyte microvilli formation, podocyte number and additional podocyte dysfunction.

## SA-PO806

**Light Microscopic Identification of Urinary Podocytes Using Latex Particles Bound with Anti-Podocalyxin Antibody** Masanori Hara,[1] Hiroyuki Kurosawa.[2] *[1]Pediatrics, Yoshida Hospital, Tsubame, Niigata, Japan; [2]Research and Development, Denka Seiken Co., Ltd., Gosen, Niigaata, Japan.*

**Background:** One of the causes for podocytopenia is detachment of podocytes from the GBM and leakage into the urine. While urinary podocytes are usually detected using immunofluorescence (IF), in the current study we developed a reliable light microscopic procedure using latex particles bound with an anti-podocalyxin (PCX) antibody.

**Methods:** An anti-PCX monoclonal antibody was coupled with latex particles (0.4-3.0 um) with various latex colors, and the particles checked for binding to PCX using an ELISA plate bound with purified PCX from isolated glomeruli. These particles were thenfurther examined for binding to PCX-transfected HEK cells, as well as urine samples from patients with glomerulonephritis. Optimal conditions for light microscopic identification were determined by comparing various factors, such as the types of anti-PCX antibodies, particle sizes, colors, pretreatment of the samples and incubation conditions. Quantitation of urinary podocytes counted by this new procedure was then directly compared with that by IF.

**Results:** The best conditions for the identification of urinary podocytes were as follows; 1) the antibody which reacts with sugar components of PCX, 2) 1 um of particle size, 3) blue color for particles, 4) 30 minutes for incubation period with two-way shaking, 5) pretreatment of urine samples by EDTA buffer. When 60 urine samples containing various densities of urinary podocytes were compared using these two detection methods, a significant positive correlation (rs=0.85 by Spearman; $P$<0.001) was found, which had both good specificity and sensitivity (0.90 and 0.80, respectively). The time needed for the entire new procedure, including microscopic examination, was ~ 60 min., compared to ~150 min. for the IF procedure.

**Conclusions:** We have developed a new method to detect urinary podocytes using antibody-bound latex beads that is faster, simpler, and equally reliable to the historical IF-based method. This new approach thus offers great advantages for the expansion of the use of semi quantitative podocyturia measurement as a practical biomarker for podocyte injury.

## SA-PO807

**Cytokines Profile in ICU Patients with Sepsis and AKI** Anna Clementi,[1] Grazia Maria Virzì,[2] Massimo de Cal,[2] Claudio Ronco,[2] Antonio Granata.[1] *[1]Nephrology Dep, Agrigento; [2]Nephrology Dep-IRRIV, Vicenza, Italy.*

**Background:** Sepsis, defined as systemic inflammatory response syndrome associated with an infectious disease, is a primary cause of morbidity and mortality in ICU patients (pts) with mortality rates 20-60% for septic shock. Sepsis is also a contributing factor for AKI, with cases requiring renal replacement therapy (RRT). Several mechanisms contribute to AKI development.

We examined the inflammatory profile in ICU pts and investigated the possible correlation between cytokines and the development of sepsis and AKI requiring RRT(AKI_ RRT), as well as the outcomes (out) in these pts.

**Methods:** 56pts (37Male, 63±15yrs) were recruited for the study at admission in ICU. 38/56pts had Endotoxin value higher than .40 units, used as cut-off value, 25/56pts had AKI_RRT. 40/56pts had negative out during ICU stay. We measured TNFα, IL6, IL18 in ICU pts sera. Mann-Whitney test was used for cohort comparisons. Statistical significance was set at p <.05.

**Results:**

| | No septic | Septic | NoAKI_RRT | AKI_RRT | Positive_out | Negativa_out |
|---|---|---|---|---|---|---|
| TNFα pg/ml | 28.7, 18.3-142.4 | 89.9, 34.2-135.7 | 131.7, 90.8-148.9 | 30.9, 19.5-70.1 | 44.1, 21.8-132.6 | 109.1, 81.8-186.2 |
| IL6 pg/ml | 407.7, 286-461 | 297.3, 177-449 | 332.6, 230.5-449 | 237.3, 183.9-445.1 | 305.6, 205.1-464.7 | 309.5, 195.6-439.7 |
| IL18 pg/ml | 398.4, 265-1189 | 1752, 1283-2597 | 933.5, 733.9, 1211.7 | 1886.9, 1470.7-2942.7 | 1586.3, 879-2156 | 2409, 1567-3125 |

There was no significant difference in TNFα and IL6 levels between septic and non septic pts, while IL18 resulted to be significantly higher (p<.01) in septic pts. TNFα and IL18 levels were significantly higher in AKI_RRT pts compared with NoAKI pts(p<.01),

while IL-6 did not differ significantly. TNFα and IL18 levels were significantly higher (p=.012 and p=.017, respectively) in pts with poor out, while there was no significant difference in IL6 levels.

**Conclusions:** Our study suggests that IL6 may be considered an unspecific inflammatory index, whose levels may increase in critically ill pts, independently on the development of sepsis or AKI. TNFα and IL18 levels seem to correlate sepsis and AKI in ICU pts and their increase is associated to poor out.

## SA-PO808

**Evaluation of Endogenous Insulin Secretory Capacity in Patients with Advanced Chronic Kidney Disease** Yukinari Yamaguchi,[1] Koji Harada,[1] Juri Tukahara,[1] Yuto Kasahara,[1] Kouichi Sumida,[1] Yasuhiro Akai.[2] *[1]Dept of Nephrology and Rheumatology, Rakuwakai Otowa Hospital, Yamashina, Kyoto, Japan; [2]Center for Diabetes Care and Research, Nara Medical Univ, Kashihara, Japan.*

**Background:** Diabetes is one of the major causes of ESRD, and adequate glycemic control is important to prevent the progression of diabetic nephropathy. Accurate evaluation of endogenous insulin secretory capacity (EISC) is important in choosing proper diabetic medications because the efficacy of these medications in lowering blood glucose could be dependent on the degree of EISC. There were few reports regarding EISC in advanced CKD patients. We conducted this study to investigate the methods to evaluate EISC in advanced CKD patients.

**Methods:** Thirty-four non-dialysis CKD patients were divided into 2 groups as follows: DM group (DM), patients with 2-h plasma glucose ≥ 200 mg/dl during the 75-g oral glucose tolerance test (OGTT); non-DM group (non-DM), 2-h plasma glucose < 200 mg/dl. To assess the EISC, we evaluated fasting serum insulin, plasma C-peptide, 24h-urinary C-peptide, and glucagon stimulation test (GST). Furthermore the insulinogenic index (II) or incremental area under the curve of insulin [ΔI(AUC)] divided by the incremental area under the curve of glucose [ΔG(AUC)] was calculated during the 0- to 30-min and 0- to 120-min time period of OGTT.

**Results:** Twenty-three patients were in DM and 11 in non-DM. There was no significant difference in the eGFR, HbA1c, and 24h-urinary C-peptide between DM and non-DM (22.0±9.7 vs 24.1±11.2 ml/min/1.73 $m^2$, $p$=0.64, 7.2±1.7 vs 6.2±0.9%, $p$=0.0525, 20.9±12.6 vs 25.9±24.6 μg/day, $p$=1.0). In 75-g OGTT, fasting serum insulin and C-peptide were not significantly different between 2 groups (7.1±6.1 vs 6.4±3.1 μU/ml, $p$=0.94, 3.4±1.7 vs 2.9±1.2 ng/ml, $p$=0.57). However, II, ΔI(AUC)/ΔG(AUC), and the difference of C-peptide after GST were significantly lower in DM than in non-DM (0.46±1.50 vs 0.70±0.68, $p$=0.0016, 0.12±0.11 vs 0.31±0.17, $p$=0.0010, 1.74±0.96 vs 3.41±1.99, $p$=0.0194).

**Conclusions:** Whereas the estimation of EISC using fasting blood sample is inappropriate, OGTT and/or GST should be performed to properly evaluate EISC in advanced CKD patients.

## SA-PO809

**A National Survey of the Availability and Use of Urine Microscopy in the UK** Shafi Malik.[1] *[1]Nephrology, Toronto General Hospital, Toronto, Canada; [2]Nephrology, Wrexham Maelor Hospital, Wrexham, North Wales, United Kingdom.*

**Background:** Urine microscopy has been used as a diagnostic tool since the 17th century,its use has been steadily declining.Studies have shown its use in differentiating between the causes of Acute Kidney Injury.Urine microscopy findings are found to correlate to renal histology.Urine microscopy is considered a basic and essential skill for a Nephrologist.We conducted a national survey of all the renal centers both adult & pediatric in the UK,aiming to study the availability and use of urine microscopy by Nephrologists. We also aimed to study whether its use helped in management decisions and the importance of it being included in the Nephrology training curriculum as an essential skill.Current Nephrology trainees(2011 - 2012)were also surveyed to get their view on urine microscopy being included in the training curriculum.

**Methods:** A web based survey was created.A link to the survey was sent by email to clinical directors of renal units and to Nephrology trainees in the country.All answers were anonymously collected.

**Results:** Of 70 Renal units,26 responded(37%).42% of respondents were from district general hospitals and 58 % from University teaching hospitals.In 5(20%)of the 26 hospitals,Nephrologists routinely performed urine microscopy.In 8(38%) of hospitals where Nephrologists did not perform urine microscopy,urine specimens were sent to Microbiology for microscopy.In centers where urine microscopy was done,63% said it helped in management decisions.In 80% of the hospitals that responded Nephrology trainees were not encouraged to learn and do urine microscopy.53% of Renal Unit clinical directors thought that urine microscopy should be part of the renal training curriculum.78 % of trainees who responded said that urine microscopy helped in management decisions and 57 % said it should be included in the training curriculum.

**Conclusions:** This is the first national survey studying the use of urine microscopy in the UK.Only 20 % of the hospitals that responded currently use urine microscopy.When performed, majority felt it helped in management decisions and more than 50% of trainees and Nephrology leads want it included in the Nephrology training curriculum.

## SA-PO810

**Renal Thrombotic Microangiopathy Associated with Chronic Graft versus Host Disease after Hematopoietic Stem Cell Transplantation** Akiko Mii,[1,2] Akira Shimizu,[2] Seiichiro Higo,[1,2] Shuichi Tsuruoka.[1] *[1]Dept of Nephrology, Nippon Medical School, Tokyo, Japan; [2]Dept of Pathology, Nippon Medical School, Tokyo, Japan.*

**Background:** Thrombotic microangiopathy (TMA) is one of the major complications after hematopoietic stem cell transplantation (HSCT). The pathogenesis of HSCT-associated TMA is controversial but considered to involve various factors such as irradiation, use of calcineurin inhibitors (CNI), infection, and GVHD. Previously, we reported the cases, which involve chronic GVHD after HSCT. The pathologic feature showed severe endothelial injury with glomerular's and peritubular capillary's C4d deposition, and we termed it chronic humoral GVHD.

**Methods:** We examined the clinical and pathologic findings of five renal biopsy cases with pathological TMA, in order to clarify the relation between GVHD and HSCT-associated TMA.

**Results:** All cases showed renal impairment. Acute and chronic GVHD occurred in four and three cases, respectively. Clinical evidence of TMA was detected in only one case. The predominant histologic findings were diffuse endothelial injury such as glomerular capillary collapse, GBM duplication with enlarged subendothelial space, and mesangiolysis. Hyalynosis was notable in small arteries. All cases showed glomerulitis, tubulitis and peritubular capillalitis (PTC-itis) with CD3+ cells infiltration. These suggest that GVHD is involved in the development of TMA. Furthermore, C4d deposition on glomerular capillaries and PTCs was evident, indicating that our cases may be mediated by antibody deposition and complement activation in chronic GVHD. In the clinical course, three cases were treated with prednisolone for renal GVHD, renal function ameliorated gradually. In one case, at that time, he was diagnosed as CNI toxicity. Renal impairment progressed by decreasing the dose of CNI, and finally he required dialysis.

**Conclusions:** Our cases were probably associated with the antibody-mediated renal endothelial injury in chronic GVHD. Three cases had an excellent course by treatment for renal GVHD. Kidney is one of the target organs of GVHD that may be associated with the development of TMA after HSCT. We need to take into consideration increase the dose of immunosuppressive drugs.

## SA-PO811

**Random Urine Protein to Creatinine Ratio (UPCR) Is a Relatively Poor Predictor of 24 hr Protein Excretion in Patients with Glomerular Disease** Marie C. Hogan, Heather N. Reich, Peter J. Nelson, Sharon G. Adler, Daniel C. Cattran, Gerald B. Appel, J. Troost, Debbie S. Gipson, Matthias Kretzler, John C. Lieske. *For the Nephrotic Syndrome Study Network.*

**Background:** A random UPCR is often used to estimate 24 hr urine protein excretion (24P). However, little data is available regarding sensitivity (SE) and specificity (SP), especially for specific glomerular diseases.

**Methods:** The multicenter Nephrotic Syndrome Study Network (NEPTUNE) applies standardized urine collections at defined study visits in the proteinuric diseases minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), and membranous nephropathy (MN). Total protein (by pyrogallol red) and creatinine (by enzymatic creatinase) are measured in random and 24 hr urine collections at a centralized biobank at baseline (postbiopsy) and subsequent protocol visits within 2 yrs of diagnosis.

**Results:** Paired baseline random UPCR and 24P data were available from 177 participants (72% adults, 62% male). Mean (median, SD) UPCR = 3.8, (2.4, 4.6) g/g Cr and 24P = 1.8 (0.9, 2.8) g/ 24 hr. 24P was > 1 g in 45% and > 3.5 g in 12%. Biopsies revealed FSGS/MCD in 47%, MN in 12%, and other diseases in 40%. There was a significant relationship between UPCR and 24P (p<0.01) with correlations (r) of 0.51 and 0.84 before and after log transformation (P<0.001). The correlation was stronger in adults (r=0.65) than in children (r=0.36) and stronger in males (r=0.73) than in females (r=0.35). There was no difference by histopathological group. The correlation was particularly weak among those with 24P <1g (r=0.13) compared to those 1-3.5g (r=0.38) and >3g (r= 0.40). Nevertheless, UPCR was a reasonable predictor of a 24P > 1g (AUC by ROC analysis=0.86; SE 79% and SP 80% at UPCR of 2.2 g/g as well as >3.5g (AUC=0.85; SE 86% and SP 74% at UPCR of 1.4 g/g).

**Conclusions:** Among patients with MCD, FSGS, and MN, UPCR correlates moderately with 24P. The correlations are poorer in children, females, and those with 24P< 1g. Nevertheless, our data suggest UPCR can be used with caution to identify those patients with 24P above the clinically relevant cutpoints of 1g and 3.5g.

**Cross-Species Transcriptional Analysis of Human and Rat Experimental Membranous Glomerulonephritis Reveals Shared Mechanisms at the Gene and Coexpression Network Level** Viji Nair,[1] Sebastian Martini,[1] Clemens D. Cohen,[2] Matthias Kretzler,[1] J. B. Hodgin.[3] *[1]Internal Medicine, Univ of Michigan, Ann Arbor, MI; [2]Klinische Immunologie, Staedtisches Klinikum Muenchen Harlaching, Munich, Germany; [3]Pathology, Univ of Michigan, Ann Arbor, MI.*

**Background:** Passive Heymann nephritis (PHN) in the rat is the best characterized animal model of membranous glomerulonephritis (MGN). As seen in human MGN, the rat PHN model is distinguished by subepithelial immune deposits, diffuse podocyte foot

process effacement, and proteinuria. In order to elucidate the molecular similarities between human MGN and the rat PHN model, we compared differentially expressed genes (DEGs) from glomeruli of humans with MGN to DEGs from rat PHN glomeruli at the transcript and coexpression network level.

**Methods:** Microarray analysis on the human glomerular mRNA (AffymetrixHGU133A) from 21 participants of the European Renal cDNA Bank and 31 living donors revealed 2179 DEGs (FDR<0.05). Rat glomerular DEGs (2251, FDR<0.05) were obtained from publically available data [Hauser PV et al., Nephron Exp Nephrol 2009;112(2):e43-e58] (5 PHN rats versus 5 untreated controls, AffymetrixR230A).

**Results:** We found an overlap of 931 DEGs between human and rat glomeruli, of which 510 were concordantly upregulated and 223 concordantly downregulated. Pathway analysis revealed significant enrichment of upregulated genes in several KEGG canonical pathways including proteasome regulation, extracellular matrix-receptor interaction, cell cycle, and focal adhesion, whereas the downregulated genes were mainly involved in amino acid and fatty acid metabolism, glycolysis, and PPAR signaling pathways. Cytoskeleton organization, protein transport and localization were among the top enriched biological processes for the upregulated genes. Downregulated DEGs reflected similar metabolic processes. Coexpression network analysis revealed a highly significant conserved co-expression network enriched again for amino acid and fatty acid metabolic processes.

**Conclusions:** Our approach will lead to a better understanding of glomerular disease pathogenesis in human and animal models at the transcriptional and network level.

### Preservation of HIF-1 and ERK Phosphorylation Are Involved in Hypothermic Protection of Renal Ischemia-Reperfusion Injury

Dae Eun Choi,[1] Jin Young Jeong,[1] Sarah Chung,[1] Yoon-Kyung Chang,[2] Ki Ryang Na,[1] Kang Wook Lee,[1] Young Tai Shin.[1] *[1]Internal Medicine, Chungnam National Univ Hospital, Daejeon, Republic of Korea; [2]Internal Medicine, Daejeon Saint Mary Hospital, Daejeon, Republic of Korea.*

**Background:** Although hypothermia attenuates renal injury induced by ischemia-reperfusion (IR), precise molecular pathways have not been known yet. Our previous study showed ERK phosphrylation plays an important role in hypothermic protection in renal IR injury. Hypoxia-inducible factor-1(HIF-1) has been known as one of the potent protective proteins in IR injury. We evaluated the role of HIF-1 and interaction with ERK phosphorylation in hypothermic protection of renal IR injury.

**Methods:** C57Bl/6 mice were divided into four groups; sham operated mice, cold IR mice(30°C), warmIR mice(37°C) and PD98059(MAP kinase kinase inhibitor) treated cold IR mice(IR injury; reperfusion 27 minutes after clamping of both renal artery and vein). Kidneys were harvested at 10min and 27min after both renal artery ischemia and 24hr after IR injury. Renal HIF-1, Peroxisome proliferator-activated receptor gamma coactivator 1-alpha(PGC 1-alpha), AMP-activated protein kinase(AMPK), and 8-hydroxydeoxyguanosine(8-OHdG) were evaluated by western blot and immuohistochemical stain. BUN and serum creatinine(s-Cr) were measured 24 hrs after IR injury. TUNEL staining of kidneys was performed.

**Results:** Serum creatinine(s-Cr), tissue injury score, and 8-OHdG and TUNEL positive cells in cold IR mice were significantly lower than those of warm IR mice (all, $p<0.01$).s-Cr, and tissue injury score,8-OHdG and TUNEL positive cells in kidneys of PD98059 treated cold IR mice were significantly higher than those ofuntreated cold IR mice(all, $p<0.05$). Renal HIF-1, PGC 1-alpha, and AMPK expression were significantly increased in the kidneys of cold ischemic mice at10min and 27min after both renal artery clamping compared to sham operated mice. PD98059 treatment in cold IR mice decreased renal HIF-1 significantly ($p<0.01$). However, PGC-1 alpha and AMPK were not changed.

**Conclusions:** In conclusion,HIF-1 preservation induced by ERK phosphorylation may be involved in hypothermic protection of renal ischemia-reperfusion injury.

## SA-PO814

### Multiorgan Involvement and Detection of Tissue Gadolinium in a Rodent Model of Nephrogenic Systemic Fibrosis

Tareq Issa Nassar,[1] Brent Wagner.[2] *[1]Internal Medicine Dept, Univ of Texas Health Science Center at San Antonio; [2]Nephrology Dept, Univ of Texas Health Science Center at San Antonio.*

**Background:** Nephrogenic systemic fibrosis (NSF) is an irreversible systemic disorder that is associated with exposure to gadolinium-based magnetic resonance imaging (MRI) contrast in patients with compromised renal function. Gadolinium (Gd) has been detected in many organs in patients with NSF, including the spleen (on autopsy). Although rodent models have been established, to date no laboratory has assayed for tissue gadolinium content in an experimental MRI contrast-induced fibrosis model.

**Methods:** Control-matched Hannover-Wistar rats with 5/6 nephrectomy were treated with 20 doses of gadodiamide/caldiamide (Omniscan, 2.5 mmol/kg IP) over 4 weeks. Sacrifice time points were week 1, week 3 and week 16 in order to follow the evolution and chronicity of the disease. Formalin-fixed and embedded tissues (e.g., skin, spleen, liver) were analyzed with scanning electron microscopy equipped with an energy-dispersive x-ray spectroscopy (EDS) silicone detector (EDAX Genesis). Spectra were obtained under low vacuum (30 Pa), 600 x, 10 mm working distance, 20 kV accelerating voltage. Estimated gadolinium content was compared.

**Results:** Skin and spleen demonstrated pathologic changes evident by light microscopy. In the contrast-treated animals, (normalized for controls), the estimated Gd in spleen (arbitrary, mean ± SD) was 0.01 ± 0.15, 0.51 ± 0.48 and 0.13 ± 0.53 for week 1, week 3 and week 16.

**Conclusions:** Spleens from MRI contrast-treated animals demonstrate pathology evident by light microscopy. This is the first prospective, experimental report to detect gadolinium in an NSF model. Together, these results suggest that gadolinium accumulation in specific tissues can elicit pro-fibrotic effects.

### Hydrostatic Dialysis: A New Method to Enrich Urinary Vesicles for Clinical Analytics

Luca Musante,[1] Dorota Ewa Tataruch,[1] Alberto Benito Martin,[1,2] Dongfeng Gu,[1,3] Giulio Calzaferri,[1] Harry B. Holthofer.[1] *[1]Centre for Bioanalytical Sciences, Dublin City Univ, Dublin, Ireland; [2]Hematology/ Oncology Dept, TWeill Medical College of Cornell Univ, New York; [3]The Third Affiliated Hospital of Southern Medical Univ, Guangzhou, China.*

**Background:** Secreted vesicles in urine are released from all nephron segments and the epithelial lining the urinogenital tract and have been proposed as valuable source of disease biomarkers. Typically the vesicles contain specific signature proteins reflecting their cellular origin as well as DNA, and a variety of RNA species which suggest of important regulatory and communication functions. Despite their proposed importance, there are still significant challenges to overcome for successful clinical application, starting from simple method which allow to process large volumes of urine to enrich material for both proteomic and transcriptomic analysis. Here we show the full characterization of a novel easy method to simplify and enrich urinary vesicles and extract its transcript content.

**Methods:** In the enrichment method urinary vesicles are first concentrated and dialysed by a simple hydrostatic dialysis system which offers the following advantages: First, handling of large volumes of urine (~ 400mL) within a working day. Second, concentration of vesicle fraction up to 100 times. This easily meets the needs for the biobanking storage of urine sample material in smaller volumes Third, introduction of dialysis step necessary to equalize the physical-chemical features, like electrolyte concentration of the samples and thus to reduce the technical inter-individual variability.

**Results:** Application of this method mimicking a clinical pilot study has revealed that the minimum volume of urinary necessary to perform a proteomic analysis for a discovery phase is not less than 200ml and at least 100ml for a transcriptomic profiling. About 50ml of urine is needed for a validation analysis. Finally, 10ml of urine routinely collected may be utilised for specific targeted approaches including Western blots.

**Conclusions:** Our protocol for vesicle isolation paves the way to utilization of full diagnostic potential of urinary vesicles.

## SA-PO816

### Intraoperative Cell-Saver Blood Product: *In Vitro* Effect on Renal Tubular Cells

Grazia Maria Virzì,[1] Tommaso Hinna Danesi,[2] Alessandra Brocca,[1] Massimo de Cal,[1] Loris Salvador,[2] Claudio Ronco.[1] *[1]Nephrology Dep-IRRIV, Italy; [2]Cardiosurgery Dep, Italy.*

**Background:** The hazards of transfusions has led to an emphasis on blood conservation in cardiac surgery. Mediastinal shed blood has high inflammatory properties, related to the development of post-operatory complications as AKI and renal failure. Many modalities including intraoperative cell-saver (CS) have emerged as alternatives to avoid immunomodulatory effects. The aim of this study was to investigate the effect of CS product on renal tubular cells (RTCs).

**Methods:** 14 patients (64±14yrs) underwent on-pump cardiac surgery were enrolled. An intraoperative CS device was used in each patient. We collected 2 blood samples for each patient: one at the end of cardiopulmonary by-pass (CPB) from the venous reservoir and one from the CS treated blood pack. For each patient, CPB and CS product were incubated with RTCs for 24h and, subsequently, apoptosis and necrosis was evaluated by cytometer. Quantitative analysis of IL6, TNFα and oxidative stress (Endogenous Peroxidase Activity-EPA; Myeloperoxidase-MPO) were performed in CPB and CS samples.

**Results:**

| | %Vitality | %Apoptosis | %Necrosis | IL6 pg/ml | TNFα pg/ml | EPA U/l | MPO pg/ml |
|---|---|---|---|---|---|---|---|
| CPB | 93(89.6-94.6) | 2.5(1.8-6) | 2.9(2.2-7.0) | 136.3 (75.3-375.3) | 28.6 (26.2-31.3) | 49.5 (31.5-55.8) | 276.8(200.6-330.5) |
| CS | 74.9(62.1-79.7) | 21.3(13.9-37.4) | 7.1(4.4-9.2) | 24.8 (19.7-29.8) | 33.4 (33.1-35.2) | 65.2 (55.4-82.2) | 370.6(246.0-405.1) |

A quantitative analysis of cell viability showed significantly higher apoptosis and necrosis rates in RTCs incubated with CS group compared to CPB(both,$p<.01$) with a median Δapoptosis(CS-CPB) from the same patient of 19.5(IQR 11-28.5)and a median Δnecrosis(CS-CPB) of 3.3(IQR 0.7-7.1). IL6 and TNFα were lower in CS($p<.05$). An increase of oxidative stress was observed in CS($p<.05$).

**Conclusions:** Cell viability analysis indicated that CS product induces RTCs death by apoptosis and necrosis. CS product was able to induce a damage on RTCs and systemic disequilibrium caused by oxidative stress. In these patients, there could be injury to nephrons, which may lead to subclinical or recognized AKI with post-operatory complications and poor outcomes.

**SA-PO817**

**Metal-Ion Complexation to Serum Carnosinase Is Increased upon Hemodialysis** Sibylle Jenny Hauske, Shiqi Zhang, Sarah Kabtni, Emmanouil Ntasis, Eleni Stamellou, Bernhard K. Krämer, Benito Yard. *Vth Medical Dept, Medical Faculty Mannheim, Univ of Heidelberg, Mannheim, Germany.*

**Background:** We have previously shown that in serum the carnosinase (CN1) protein is only partly complexed with metal ions and that the relative proportion of not complexed (nc) CN1 negatively correlates with CN1 activity. ncCN1 can be detected by ELISA using RYSK173 (monoclonal IgG) antibody which we have raised against recombinant CN1.

**Methods:** In the present study we evaluated the relevance of Zinc binding to CN1 for detection by RYSK173. Since changes in divalent metal ion concentrations (conc.) have been reported to occur during hemodialysis (HD) we also assessed if HD affects the quality of CN1 by measuring total CN1 and ncCN1 conc. before and after HD.

**Results:** By making use of myc-tagged CN1 fragments we were able to narrow-down the RYSK173 epitope to a stretch of 40 amino acids in close vicinity to the metal binding region of CN1. While in serum ncCN1 constituted only 5% of total CN1, for recombinant CN1 expressed in Cos-7 cells approximately 50 % of total CN1 was recognized by RYSK173. When recombinant CN1 was spiked into human serum, it was poorly detected by RYSK173. Similarly, addition of $ZnCl_2$ to either serum or recombinant CN1 strongly diminished its detection by RYSK173. In HD patients (N=30) we measured both total CN1 and ncCN1 conc. before and after HD. While total CN1 conc. were significantly increased after HD, ncCN1 conc. were decreased. The increased total CN1 conc. positively correlated with the percentage of plasma fluid depletion during HD.

**Conclusions:** In conclusion our data further demonstrate the presence of different qualities of CN1 in human serum. These qualities are due to the extent of metal-ion complexation to CN1. Since the RYSK173 epitope is in close vicinity to the metal binding region of CN1 our data indicate that occupation of this region by metal-ion prevents RYSK173 binding. Interestingly, ncCN1 conc. as detected by RYSK173 significantly decrease after HD suggesting an increased concentration of divalent metal-ions that have complexed to CN1 after HD. The identity of the metal-ions as well as the consequence for CN1 activity remains to be assessed.

**SA-PO818**

**Osteoprotegerin in Exosome-Like Vesicles from Human Cultured Tubular Cells and Urine** Alberto Benito Martin,[1] Alvaro C. Ucero,[1] Irene Zubiri,[1] Maria Posada Ayala,[1] Beatriz Fernández,[1] Maria Concepción Izquierdo,[1] Marta Ruiz-Ortega,[3] Jesus Egido,[1] Gloria Alvarez Llamas,[1] Alberto Ortiz.[1] *[1]IIS - Fundacion Jimenez Diaz; [2]IDIPAZ; [3]Universidad Autonoma de Madrid.*

**Background:** Urinary exosomes have been proposed as potential diagnostic tools. TNF superfamily cytokines and receptors may be present in exosomes and are expressed by proximal tubular cells. We have now studied the expression of selected TNF superfamily proteins in exosome-like vesicles from cultured human proximal tubular cells and human urine and have identified additional proteins in these vesicles byLC-MS/MS proteomics.

**Results:** Human proximal tubular cells constitutively released exosome-like vesicles that did not contain the TNF superfamily cytokines TRAIL or TWEAK. However, exosome-like vesicles contained osteoprotegerin (OPG), a TNF receptor superfamily protein, as assessed by Western blot, ELISA or selected reaction monitoring by nLC-(QQQ)MS/MS. Twenty-three additional proteins were identifiedin tubular cell exosome-like vesicles, including three (zinc finger protein 40, isopentenyl-diphosphate delta-isomerase and vitamin D binding protein) that had not been previously reported in exosome-like vesicles. Twelve were extracellular matrix proteins, including the basement membrane proteins type IV collagen, nidogen-1, agrin and fibulin-1. Urine from chronic kidney diseasepatients contained a higher amount of exosomal protein and exosomal OPG than urine from healthy volunteers. Specifically OPG was increased in autosomal dominant polycystic kidney disease urinary exosome-like vesicles and expressed by cystic epithelium in vivo.

**Conclusions:** OPG is present in exosome-like vesicles secreted by proximal tubular epithelial cells and isolated from Chronic Kidney Disease urine.

**SA-PO819**

**Laser Capture Microdissection Enables mRNA and microRNA Quantification of Parietal Epithelial Cells (PECs) and Cellular Crescents from Paraffin Embedded Renal Biopsy Tissue** Clemens L. Bockmeyer, Karen Säuberlich, Stephanie Zell, Philip Zeuschner, Jan U. Becker. *Institute of Pathology, Hannover Medical School, Hannover, Lower Saxony, Germany.*

**Background:** Crescents develop from PECs and indicate a dismal prognosis. So far, studies on PECs were limited because PECs could not be analyzed by quantitative real time-PCR (qRT-PCR) for mRNAs and miRNAs.

This proof-of-principle study shows that our techniques can overcome this limitation and enable mRNA and miRNA expression analysis of PECs and the crescents derived thereof.

**Methods:** Patients with IgA glomerulonephritis (n=4), Schoenlein-Henoch purpura with cellular crescents (n=2) and mild tubulointerstitial nephritis with normal glomeruli (n=3) were analyzed. Four different compartments glomeruli (n=9), PECs (n=9), crescents (n=2) and periglomerular tubulointerstitium (n=9) were isolated from paraffin embedded renal biopsies. For quantitive mRNA and microRNA analysis we used real time quantitative PCR after preamplification (Applied Biosystems). We quantified the compartment markers WT1, PAX2, GLEPP1, CD44, CD45, CD68 against two reference genes (GAPDH, PGK1). microRNAs RNU48 and snRNU6 were also quantified. Results are given as mean value and standard deviation of the relative expression level.

**Results:** Relative expression of WT1 was 18.5±19.3 in glomeruli, 3.6±2.2 in PECs, 0.2±0.4 in periglomerular interstitium, 0.9±0.1 in crescents; of PAX2 0.2±0.3, 2.4±1.8, 3.8±6.2, 1.5±0.7; of GLEPP1 5.6±5.3, 0.8±0.6, 0.1±0.1, 0.2±0.1; of CD44 3.1±5.4, 1.3±0.9, 1.7±1.1, 1.5±0.6; of CD68 3.2±3.6, 3.4±1.9, 3.5±2.5, 4.7±2.8; of CD45 9.3±11.1, 5.3±2.7, 4.8±4.8, 3.6±1.3; of snRNU6 17.6±4.0, 20.1±3.6, not detectable, 17.2±5.6 and of RNU48 19.4±3,7, 21.6±3.0, not detectable, 18.7±1.8.

**Conclusions:** Our results show that it is possible to isolate PECs from other kidney compartments for mRNA and miRNA expression studies. WT1, PAX-2 and GLEPP-1 are the best compartment markers for the identification of PECs. mRNAs and microRNAs can be quantified in PECs and crescents with our method allowing advances in the research on PEC pathology and crescent formation not only in patients with Schoenlein-Henoch purpura.

**SA-PO820**

**Optimal Level of Proteinuria Reduction for Renoprotection in Patients with IgA Nephropathy** Ki Heon Nam,[1] Fa Mee Doh,[1] Hyung Jung Oh,[1] Tae-Hyun Yoo,[1] Shin-Wook Kang,[1,2] Seung Hyeok Han.[1] *[1]Dept of Internal Medicine, College of Medicine; [2]Brain Korea 21, Yonsei Univ, Seoul, Korea.*

**Background:** Proteinuria is a target for renoprotection in various glomerular diseases. However, the optimal level of proteinuria reduction is not clearly defined in patients with IgA nephropathy (IgAN). In this study, therefore, we conducted a retrospective observational cohort study to investigate whether reducing proteinuria below the levels suggested by the current guideline may confer a more renoprotective advantage.

**Methods:** Among 644 patients, who were pathologically diagnosed with IgAN between 2000 and 2010, 500 subjects were eligible for the study. Time-averaged proteinuria (TA-P) was calculated as the mean of every 6-month measurements of spot urine protein-to-creatinine ratio. The study endpoints werea doubling of the baseline serum creatinine concentrations (D-sCr) and the onset of ESRD.

**Results:** There were 221 (44.2%), 135 (27.0%), 96 (19.2%), and 48 patients (9.6%) with TA-P of <0.5, 0.5-0.99, 1.0-1.99, and ≥2.0 g/g, respectively. During a median follow-up duration of 65 (12-154) months, D-sCr was observed in 1 (0.5%), 3 (2.2%), 18 (18.8%), and 30 patients (62.5%) of each group (P<0.001).There was no difference in the development of D-sCr between patients with TA-P <0.5 g/g and those with TA-P of 0.5-0.99 g/g. ESRD did not occur in these two groups, while 11 (11.5%) and 23 patients (47.9%) with TA-P of 1.0-1.99 and ≥2.0 g/g, respectively, progressed to ESRD. In a multivariable Cox model after adjustment for age, estimated glomerular filtration rate, blood pressure, pathologic findings, and treatment, the risk of D-sCr did not differ between patients with TA-P of <0.5 g/g and those with 0.5-0.99 g/g (HR, 3.67; 95% CI, 0.34-36.2; P=0.281), whereas itwas significantly higher in patients with TA-P of 1.0-1.99 g/g (HR, 27.6; 95% CI, 3.30-230.5; P=0.002) and those with TA-P >2.0 g/g (HR, 140.6; 95% CI, 16.4-1209.1; P<0.001).

**Conclusions:** The results of our study suggest that the optimal proteinuria levels are <1.0 g/g in patients with IgAN. Further studies are required to clarify whether reduction of proteinuria of <0.5 g/g may confer a more renoprotective advantage.

**SA-PO821**

**Development and Validation of a Prediction Rule Using the Oxford Classification in IgA Nephropathy** Shigeru Tanaka,[1] Toshiharu Ninomiya,[1] Ritsuko Katafuchi,[2] Kosuke Masutani,[1] Akihiro Tsuchimoto,[1] Hideki N. Hirakata,[3] Kazuhiko Tsuruya,[1] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Kidney Unit, National Fukuoka-Higashi Medical Center, Fukuoka, Japan; [3]Div of Nephrology and Dialysis Center, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan.*

**Background:** The risk assessment for developing end-stage kidney disease (ESKD) remains limited in patients with IgA nephropathy (IgAN). The aim of our study was to develop and validate a prediction rule for estimating the individual risk of ESKD in patients with IgAN.

**Methods:** We followed retrospectively 698 patients with IgAN diagnosed by renal biopsy at Kyushu University Hospital (derivation cohort). The Oxford classification was used to evaluate the pathologic lesions. The risk factors for developing ESKD were evaluated using a Cox proportional hazard model. Furthermore, we verified the prediction rule using the data of 702 patients diagnosed at Japanese Red Cross Fukuoka Hospital (validation cohort). The validation of the goodness-of-fit of the prediction model was assessed using a c-statistic and Hosmer-Lemeshow test (H-L test).

**Results:** In the derivation cohort, 73 patients developed ESKD during the median 4.7-year follow-up. As independent risk factors for developing ESKD, proteinuria, estimated glomerular filtration rate, mesangial proliferation, segmental sclerosis and interstitial fibrosis/tubular atrophy were selected. To create a prediction rule, the score for each variable were weighted by the regression coefficients calculated using the relevant Cox model. The incidence of ESKD was linearly increased with elevating the total risk scores (P for trend <0.001). Furthermore, the prediction rule demonstrated good discrimination (c-statistic: 0.89) and calibration (H-L test, P = 0.78) in the validation cohort.

**Conclusions:** We developed and validated a new prediction rule using clinical parameters and the Oxford classification for developing ESKD in patients with IgAN.

## SA-PO822

### Clinical Implication of Crescentic Lesion in Patients with IgA Nephropathy

Mi Jung Lee,[1] Tae ik Chang,[2] Hyung Jung Oh,[1] Seung Hyeok Han,[1] Dae-Suk Han,[1] Shin-Wook Kang.[1] *[1]Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea; [2]Internal Medicine, NHIC Ilsan Hospital, Gyoeonggi-do, Korea.*

**Background:** Early case series showed that the presence of crescents was associated with proteinuria and rapid deterioration of renal function in patients with IgA nephropathy (IgAN). To date, however, there has been much controversy about the role of crescentic lesions as a significant prognostic factor. In this study, therefore, we elucidated whether crescentic lesions predicted adverse renal outcomes in IgAN patients.

**Methods:** A total of 430 patients with biopsy-proven IgAN diagnosed between January 2001 and December 2010 were included. Histologic variables of the Oxford classification (Oxford-MEST) and the presence of crescents were assessed. The primary endpoint was a 50% decline in estimated glomerular filtration rate (eGFR).

**Results:** Among 430 patients, 81 (18.8%) had crescentic lesions. During a mean follow-up duration of 61 months, the primary outcome was significantly more observed in patients with crescents (19 patient, 23.5%) compared to patients without crescents (40 patients, 11.5%) ($P$ = 0.01). A Kaplan-Meier plot showed that the 10-year renal survival rates were significantly lower in patients with crescents than patients without crescents ($P$ = 0.01). However, in a multivariable Cox regression analysis including clinical factors and the Oxford-MEST score, crescents were not significantly associated with an increased risk of the primary outcome (HR, 0.78; 95% CI, 0.40-1.51; $P$ = 0.48). Moreover, adding crescents to the Oxford classification did not improve the discriminative ability for the prediction of renal outcomes [c-statistic: 0.86 (0.81-0.91) vs. 0.86 (0.80-0.91), $P$ = 0.35].

**Conclusions:** Crescentic lesions were not an independent prognostic factor in patients with IgAN, suggesting that crescents had limited value in predicting renal outcome in these patients. Further studies are required to clarify the clinical implication of crescentic lesions in patients with severe IgAN or IgAN with rapidly progressive nature.

*Funding:* Government Support - Non-U.S.

## SA-PO823

### Microbiota in Patients with Immunoglobulin A Nephropathy

Maria De Angelis,[1] Eustacchio Montemurno,[2] Maria Piccolo,[1] Gabriella Lauriero,[2] Lucia Vannini,[3] Valentina Maranzano,[2] Giuseppe Dalfino,[2] Sonya Siragusa,[1] Marco Gobbetti,[1] Loreto Gesualdo.[2] *[1]DiSSPA, Univ of Bari; [2]DETO, Nephr Unit, Univ of Bari; [3]Inter-departmental Centre for Industrial Agri Food Research, Univ of Bologna.*

**Background:** Immunoglobulin A nephropathy (IgAN) is one of the most common forms of primary glomerular disease. Along structural IgA abnormalities, hyperproduction of poorly galactosylated IgA1 is thought to play a role in the pathogenesis of primary IgAN. The downstream effector mechanisms triggered by mesangial IgA1 deposition and its etiology are poorly understood. Recently, it was showed a probable role of the enteric microbiota in educating the immune system and disease development. This study aimed at comparing the differences of the fecal microbiota between IgAN pts and Healthy Controls (HC).

**Methods:** Based on clinical data, IgAN pts were grouped into "non-progressors" (NP) and "progressors' (P). Each group was composed by 16 volunteers. The total and active faecal microbiota was characterized through an integrate approach of culture-dependent and -independent methods and metabolomic analyses. Bacterial tag-encoded FLX-titanium amplicon pyrosequencing (bTEFAP) and Biochrom 30 series Amino Acid Analyzer were carried out for genomic and phenotypic analyses.

**Results:** The main bacterial phyla (Firmicutes and Bacteroidetes) significantly (P<0.05) changed between the fecal microbiota of NP, P and HC. Overall, a decreased level of metabolically active and cultivable bacteria was found in NP and, especially, in P compared to HC. In addition, the composition of some genera mainly differed among NP, P and HC. Metabolites produced by intestinal microbes play a direct role in health and disease. According to the differences in the composition of the microbiota, the metabolome also differed in NP and P patients compared to HC. As shown by multivariate statistical analyses, the levels of free amino acids and volatile organic compounds of fecal and urine samples were markedly affected in NP and, especially, P pts.

**Conclusions:** The microbiota differences among NP , P and HC pointed out in this study, may have implications regarding specific diagnostic test, and/or for treatment and prevention.

## SA-PO824

### Glomerular IgG Staining on Immunofluorescence Microscopy Is Associated with Progression to ESRD in IgA Nephropathy

Andrew S. Bomback,[1] Pietro A. Canetta,[1] Blake M. Butler,[1] Ana Huerta,[2] Jonathan J. Hogan,[1] Jai Radhakrishnan,[1] Leal C. Herlitz,[1] Michael B. Stokes,[1] Vivette D. D'Agati,[1] Gerald B. Appel,[1] Glen S. Markowitz.[1] *[1]Columbia Univ College of Physicians and Surgeons, New York, NY; [2]Hospital Universitario 12 de Octubre, Universidad Complutense de Madrid, Madrid, Spain.*

**Background:** Autoantibodies against galactose-deficient IgA1 (Gd-IgA1) have been postulated as mediators in the progression of IgA nephropathy. Circulating IgG autoantibodies have been shown to predict this progression, but the predictive role of glomerular IgG staining on immunofluorescence (IF) microscopy remains unclear.

**Methods:** We reviewed clinical, histopathologic, and laboratory data in 95 patients with biopsy-diagnosed IgA nephropathy followed at the Center for Glomerular Diseases at Columbia University from 2005 through 2010. We used Cox proportional hazards models to evaluate whether IgG staining on IF was associated with progression to ESRD.

**Results:** The cohort was comprised of 61 men and 34 women with mean (SD) age of 35.7 (12.4) years. The majority of patients were either white (58%) or Asian (27%). At time of diagnosis, mean (SD) serum creatinine was 1.6 (1.0) mg/dl, mean estimated GFR was 66 (31) ml/min/1.73m$^2$, and mean proteinuria was 3666 (3393) mg/day. Staining for IgG on IF microscopy was positive in 37 (39%) patients: 1+ IgG in 32 cases and 2+ IgG (co-dominant with IgA) in 5 cases. Over a mean follow-up period of 58.8 months, 18 patients progressed to ESRD, including 8 of the 37 (22%) with IgG staining by IF and 10 of the 58 (17%) without IgG staining (p=0.6 for unadjusted comparison). In multivariate Cox proportional hazards models, adjusting for age, gender, race, baseline eGFR, and baseline proteinuria, the presence of IgG on IF microscopy was associated with significantly greater risk for progression to ESRD (HR 7.07, 95% CI 1.69-29.56, p=0.007).

**Conclusions:** The presence of IgG staining on IF microscopy, like serum levels of IgG autoantibodies, may predict outcomes in IgA nephropathy. These findings further support the pathophysiologic role of autoantibodies against Gd-IgA1 as mediators of disease progression and should be further examined in larger cohorts.

## SA-PO825

### Effect of Tonsillectomy Plus Steroid Pulse Therapy on Clinical Remission of IgA Nephropathy with Mild Proteinuria: A Multicenter Study

Hiroyuki Komatsu,[1,2] Yuji Sato,[1,2] Tetsu Miyamoto,[2] Takeshi Nakata,[2] Tomoya Nishino,[2] Masahito Tamura,[2] Tadashi Tomo,[2] Masanobu Miyazaki,[2] Shouichi Fujimoto.[1,2] *[1]First Dept of Internal Medicine, Univ of Miyazaki Hospital, Miyazaki, Japan; [2]Steering Committee for IgA Nephropathy from Four Univs (IgAN-4U), Japan.*

**Background:** Our previous multicenter cohort study of 323 patients (*JASN* 2012: 23; 58A) found that tonsillectomy plus steroid pulse therapy (TSP) can result in clinical remission (CR) for patients with IgA nephropathy and mild to moderate histological damage. Medical intervention for patients with IgA nephropathy and mild proteinuria (< 1.0 g/day) is controversial, and the effectiveness of TSP for such patients remains obscure.

**Methods:** Fifty-five patients who had mild proteinuria (0.4 to 1.0 g/day) at diagnosis and who were initially treated with steroid were eligible to participate in this study. We used univariate and multivariate analysis to evaluate the decline in renal function defined as a 100% increase in serum creatinine (sCr) and CR defined as the disappearance of hematuria and proteinuria (UP/Ucr < 0.3) between groups treated with TSP and steroid without tonsillectomy (ST).

**Results:** Background factors at diagnosis including age (mean, 31.9 vs. 34.0 y), ratio (%) of patients with hypertension (19.6% vs. 22.2%), sCr (mean, 0.74 vs. 0.86 mg/dL), proteinuria (mean, 0.62 vs 0.69 g/day), and histological severity did not statistically differ between the TSP and ST groups. None of the patients achieved a 100% increase in sCr during mean followed–up periods of 4.5 years. At the final observation, 69.6% and 44.4% of patients in the TSP and ST groups, respectively, achieved CR. Cox proportional hazards models revealed that CR was achieved about six-fold more effectively by TSP than SP (HR for CR; 5.85, p = 0.028).

**Conclusions:** TSP is a potential modality for inducing CR in patients with IgA nephropathy and mild proteinuria.

## SA-PO826

### Kidney Transplant following Crescentic IgA Nephropathy

Ziad S. Zaky, Jonathan J. Hogan, Gerald B. Appel, Andrew S. Bomback, Eric D. Braunstein, Demetra Tsapepas, Pietro A. Canetta. *Columbia Univ Med. Center, New York, NY.*

**Background:** Crescentic IgA Nephropathy (IgAN) represents an aggressive form of IgAN that often leads to ESRD. Little is known of the clinical course of patients (pts) with crescentic IgAN who undergo kidney transplant.

**Methods:** We reviewed the charts of 153 IgAN pts who underwent kidney transplant at CUMC between Jan-2000 and Jan-2013. Native kidney biopsy reports were available for n=70. Crescentic IgAN was defined as ≥30% glomeruli with cellular, fibrous, or fibrocellular crescents.

**Results:** Crescentic IgAN was found in 15 pts (21%), of whom 8 were male. Race/ethnicity included white (n=8), Af-Am (n=4), Asian (n=2), and Hispanic (n=1). Two pts had a second transplant. Of 17 transplants, 7 were living-related, 6 living-unrelated, and 4 deceased-donor. Mean ±SD age at first transplant was 36±11 yrs (range 22-55 yrs). Induction agents used were anti-thymocyte globulin (n=11), pulse steroids alone (n=5), and basiliximab (n=1). Mean follow-up after transplant was 55±44 mos (range 8.5-137 mos). All pts were alive at last follow-up (May-2013). 3/17 grafts (18%) eventually failed: 1 from interstitial fibrosis after 17 mos, 1 from BK virus at 8.5 yrs, and 1 from recurrent crescentic IgAN (see below). Mean ±SD serum creatinine in surviving grafts was 1.5±0.4 mg/dl. At last followup, 1 patient had significant (3+) proteinuria and 3 had (3+) hematuria. Routine surveillance biopsies were not done, but 9/17 (53%) grafts were biopsied for graft dysfunction or proteinuria. Recurrent IgAN occurred in 4/15 pts and 5/17 allografts, diagnosed at mean 9.2 mos post-transplant (range 0-23.4 mos), and characterized by IgA deposits without proliferation or crescents. One patient lost his first graft to recurrent crescentic IgAN. He had histological evidence of recurrent IgAN at 6 weeks and crescentic IgAN at 26.5 months. He was retransplanted at 48 mos and reperfusion biopsy of the 2nd transplant showed recurrent IgA deposition, but normal light microscopy.

**Conclusions:** 4/15 (27%) pts with native crescentic IgAN had recurrent IgAN in the allograft. Only 1/15 (7%) pts had histologic evidence of recurrent crescentic disease. Most pts had favorable outcomes following transplant.

## SA-PO827

**Circulating Tumor Necrotizing Factor α Receptors Predict the Outcome of Human IgA Neprhopathy** Yun Jung Oh,[1] Jung Pyo Lee,[2] Su Mi Lee,[3] Jin Ho Hwang,[3] Hyuk Huh,[3] Seung Hee Yang,[3,4] Dong Ki Kim,[3,4] Hajeong Lee,[3] Yun Kyu Oh,[2] Chun Soo Lim,[2] Yon Su Kim.[3,4] *[1]Internal Medicine, Cheju Halla General Hospital, Jeju, Korea; [2]Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea; [3]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [4]4 Kidney Research Institute, Seoul National Univ, Seoul, Korea.*

**Background:** The circulating TNF receptors (TNFRs) levels could predict the long-term renal outcome in diabetics, but the role of circulating TNFRs in other chronic kidney disease has not been investigated. Here, we investigated the correlation between circulating TNFRs and renal histologic findings in IgA nephropathy (IgAN) and assessed the notion that the circulating TNFRs could predict the clinical outcome.

**Methods:** 187 consecutive biopsy-proven IgAN patients between 2009 and 2012 were prospectively enrolled. Circulating TNFR levels were measured using serum samples stored at the time of biopsy. The primary clinical endpoint was the decline of estimated glomerular filtration rate (eGFR; ≥30% decline compared to baseline).

**Results:** Mean eGFR decreased and proteinuria worsened proportionally as circulating TNFR1 and TNFR2 increased (p<0.001). Interstitial inflammation and interstitial fibrosis were significantly more severe as TNFR1 levels increased regardless of eGFR levels. Also, the severity of interstitial fibrosis and tubular atrophy worsened with increasing TNFR2 levels. The risk of reaching the primary endpoint was significantly higher in the highest TNFR1 quartile compared with other quartiles by the Cox proportional hazards model (HR 12.924, p<0.001), but the risk was not evident in the highest TNFR2 quartile (HR 1.949, p=0.211).

**Conclusions:** In conclusion, the circulating TNFR1 and TNFR2 levels reflect the histologic and clinical severity of IgAN. Moreover, TNFR1 at the time of initial diagnosis may predict the long-term outcome of IgAN.

## SA-PO828

**Clinical and Histological Parameters Associated with the Recurrence of Proteinuria after Steroid Therapy in IgA Nephropathy Patients** Keita Hirano,[1] Tetsuya Kawamura,[2] Nobuo Tsuboi,[2] Hideo Okonogi,[2] Kazushige Hanaoka,[2] Takashi Yokoo.[2] *[1]Internal Medicine, Ashikaga Red Cross Hospital, Ashikaga, Tochigi, Japan; [2]Div of Nephrology, Jikei Univ School of Medicine, Minato, Tokyo, Japan.*

**Background:** We recently reported that the achievement of proteinuria <0.4 g/day at one year after six months of steroid therapy is associated with favorable renal survival in Japanese patients with IgA nephropathy (IgAN)(Clin Exp Nephrol 2012). However, the predictive factors of recurrence remain obscure.

**Methods:** Employing a historical cohort design, we enrolled 93 IgAN patients, who received six months of steroid therapy and achieved a reduction in the urinary protein excretion volume (UPE) to <0.4 g/day at one year. To evaluate the event of recurrence, the end point was defined as an increase in the UPE level of ≥1.0 g/day after the first one year following the initiation of steroid therapy. Concerning pathological predictors, we adopted the Oxford classification and the histological grades (HG) recently proposed in Japan, in which HG1, HG2 and HG3+4 correspond to <25%, 25-49% and ≥50% of glomeruli exhibiting cellular and/or fibrocellular crescents, global sclerosis, segmental sclerosis or fibrous crescents, respectively (J Nephrol 2012).

**Results:** During a median follow-up of 2.3 years after the first one year following the initiation of treatment, 18 patients (19.4%) reached the end point. Of note, mesangial hypercellularity and HG2 were significant pathological predictors of an increased risk of recurrence in the multivariate model (M1 vs. M0, HR: 2.98, 95%CI: 1.08-8.26; HG2 vs. HG1, HR: 8.58, 95%CI: 1.08-68.4). Moreover, females and tonsillectomy as concurrent treatment were associated with relatively reduced risk of recurrence (HR: 0.29, 95%CI: 0.10-0.85; HR: 0.20, 95%CI: 0.07-0.62).

**Conclusions:** Our data indicate that mesangial hypercellularity based on the Oxford classification and the histological grade in Japanese classification predict recurrence in Japanese IgAN patients that have received six months of steroid therapy. Tonsillectomy prior to the steroid therapy can protect them from the recurrence.

## SA-PO829

**Comparison of the Predictability of Renal Outcome between the Oxford and the Haas Classifications in Patients with IgA Nephropathy** Kyoung Sook Park,[1] Chan Ho Kim,[1] Hyang Mo Koo,[1] Fa Mee Doh,[1] Hyung Jung Oh,[1] Tae-Hyun Yoo,[1,2] Shin-Wook Kang,[1,2] Seung Hyeok Han.[1] *[1]Dept of Internal Medicine, College of Medicine; [2]Brain Korea 21, Yonsei Univ, Seoul, Korea.*

**Background:** The Oxford classification, a new classification of IgA nephropathy (IgAN), has recently been proposed and gained worldwide acceptance. However, it is uncertain whether the Oxford classification can predict renal outcome better than the previous ones.

**Methods:** We conducted a retrospective cohort study to compare the predictability of renal outcome between the Oxford and the Haas classification in 500 Korean patients with biopsy-proven IgAN between January 2001 and December 2010. Primary outcome was a doubling of the baseline serum creatinine concentrations (D-SCr).

**Results:** During a mean follow-up duration of 68 months, D-SCr occurred in 52 patients (10.4%), and 35 patients (7.0%) progressed to ESRD. There was a significant stepwise increase in the development of D-SCr as the Haas classes increased (P < 0.001). In addition, the primary endpoint of D-SCr occurred significantly more in patients with the Oxford M and T lesions than those without such lesions (P < 0.001). In multivariable Cox regression analyses adjusted for age, blood pressure, proteinuria, and eGFR, the Haas class V (HR, 12.19; 95% CI, 2.61-63.8; P = 0.002) and the Oxford T1 (HR, 6.68; 95% CI, 2.86-15.6; P < 0.001) and T2 (HR, 12.16; 95% CI, 4.78-30.9; P < 0.001) lesions were independently associated with a higher risk for reaching D-SCr. Harrell's C indices of each multivariable model with the Haas and the Oxford classifications were 0.867 (P = 0.015) and 0.881 (P = 0.004), respectively, which was significantly higher compared to the model with clinical factors only (c-statistic = 0.819). However, there was no difference in c-statistics between the two models with the Haas and the Oxford classifications (P = 0.348).

**Conclusions:** Both pathologic classifications were comparable in predicting the progression of IgAN. Further studies are required to delineate relationship between pathologic features and treatment responsiveness in patients with IgAN.

## SA-PO830

**Urinary Angiotensinogen, a New Biomarker in Primary IgA Nephropathy Patients?** Danxia Zheng, Yimu Zheng. *The Renal Dept, Peking Univ 3rd Hospital, Beijing, China.*

**Background:** Urinary angiotensinogen (AGT) was supposed as a useful local marker of intrarenal Renin Angiotensin System (RAS) activity in renal injury. To investigate the inapporated increased RAS in IgA nephropathy, urinary AGT was measured, and its correlation with clinical and pathological injury index was investigated.

**Methods:** 73 IgA nephropathy patients (16-69 years, 44 male ) were recruited. All the patients were diagnosed by pathologist from renal biopsy, and any known secondary IgA nephropathy was excluded. The controls are 19 age-matched healthy volunteers. Urinary AGT (normalized by urine creatinine) levels on the biopsy day were measured by ELISA method.

**Results:** Urinary AGT was significantly higher in IgA nephropathy patients than in controls (162±234 vs 6.6±5.0μg/g, p<0.05). Urinary AGT was significantly lower in patients treated with RAS inhibitors compared with in patients not treated with RAS inhibitors (87±105 vs 217±284 μg/g, p=0.018). But even with the treatment of RAS inhibitors, urinary AGT level was still higher in IgA nephropathy than in the controls (87±105 vs 6.6±5.0μg/g,p<0.05). Urinary AGT was correlated positively with 24-h urinary protein(r=0.703, p=0.000) and renal crescent percent (r=0.428, p=0.000). This correlation was confirmed by multiple regression analysis. Urinary AGT was not correlated with gender, age, blood pressure, serum creatinine, serum albumin, or glomerulosclerosis percent. Taking hypertension and if RAS inhibitors being used before biopsy day into account, these IgA patients were divided into 4 subgroups.

| RAS inhibitors | + | + | - | - |
|---|---|---|---|---|
| hypertension | - | + | - | + |
| n | 14 | 17 | 25 | 17 |
| urinary AGT(μg/g) | 29±25 | 135±122 | 203±231 | 236±355 |

Urinary AGT in normotensive patients receiving RAS inhibitors treatment was lowest among 4 subgroups (p<0.05), but it is still higher than in controls (29±25 vs 6.6±5.0μg/g,p<0.05); which supported the necessary of earlier RAS inhibitors treatment in IgA nephropathy.

**Conclusions:** Our data support intrarenal RAS is elevated in IgA nephropathy, and correlated with renal injury activity. Earlier RAS inhibitors may never mean early in IgA nephropathy.

## SA-PO831

**Serum Under-*O*-Glycosylated IgA Level Does Not Correlate with Glomerular IgA Deposition Based upon Heterogeneity in the Composition of Immune Complexes in IgA Nephropathy** Yoshio Shimizu, Hitoshi Suzuki, Yusuke Suzuki, Yasuhiko Tomino. *Juntendo Univ Faculty of Medicine, Tokyo, Japan.*

**Background:** Although serum under-*O*-glycosylated IgA1 in IgA nephropathy (IgAN) patients may deposit more preferentially in glomeruli than normal IgA1, through self-aggregation and the formation of immune-complexes with autoantibodies, the relationship between glomerular IgA deposition level and *O*-glycan profiles of serum IgA1 remains obscure.

**Methods:** Serum total under-*O*-glycosylated IgA was quantified in 32 IgA nephropathy patients (11 males/22 females) by ELISA with *Helix aspersa* (HAA) lectin. Serum under-*O*-glycosylated polymeric IgA (pIgA) was selectively measured by a method that was developed by our group (pIgA trap). Immunofluorescence of biopsy specimens and image analyses were used to quantify the percentage area of IgA deposition in the whole glomeruli (Area-IgA). Correlations were assessed between the Area-IgA and data from HAA-ELISA or pIgA trap.

**Results:** While the under-*O*-glycosylated-IgA levels were significantly higher in IgAN patients than in healthy controls, when measured by HAA-ELISA (p<0.05), there was no significant difference in under-*O*-glycosylated-pIgA. There was no linear correlation between Area-IgA and data from HAA-ELISA or the pIgA trap.

Decision tree analysis was performed to determine the cause of the lack of a linear correlation between the Area-IgA and data from ELISA or the pIgA trap. The patients were initially classified into groups, A, B, C and D. based upon the gradual increases in the HAA-ELISA titers from A to D, and group C was divided into C1 and C2 groups, based on the pIgA trap. The area-IgA of each group (A, B, C1, C2 and D) (%) was 7.8±1.7, 12.5±1.7, 4.5±2.0, 5.9±3.4, 10.7±5.5 with significant differences. The backgrounds of the patients

in each group suggested that dominant immune complexes in the glomeruli consisted of 1. IgA-IgG and complement in groups A and B, 2. pIgA and complement in groups C1 and C2 and 3. monomeric IgA-IgA or aggregated monomeric IgA in group D.

**Conclusions:** Serum under-*O*-glycosylated IgA levels do not correlate with glomerular IgA deposition based upon heterogeneity in the composition of glomerular immune complexes in IgAN patients.

*Funding:* Pharmaceutical Company Support - Novartis, Tanabe-Mitsubishi, Kowa, Kyowa-Kirin

## SA-PO832

**Endothelial Nitric Oxide Synthase (eNOS) Gene Polymorphism and Risk for Progression in IgA Nephropathy** Dimitrios Xydakis,[1] Georgios Goulielmos,[2] Kostas Stylianou,[2] Antonia N. Papadaki,[3] Apostolos Papadogiannakis,[1] Eugenios Daphnis.[2] *[1]Nephrology, Venizeleio Hospital, Greece; [2]Univ Hospital of Crete, Greece; [3]Nephrology, Hospital of Chania, Greece.*

**Background:** Several studies have shown the influence of eNOS gene polymorphism on the progression of kidney disease. IgA nephropathy has a variable natural history. The aim of this study is to investigate any association between eNOS gene intron 4a/b polymorphism and clinical presentation and progression of IgA nephropathy patients in a geographical region.

**Methods:** We included in our study 103 patients with biopsy-proven IgA glomerulonephritis and a median follow up period of 5.1±2.8 years. All subjects where genotyped for the intron 4a/b polymorphism. The end-points were doubling in baseline serum creatinine and/or initiation of dialysis.

**Results:** At baseline, M/F 68/35, age was 41.5±13.5 years, creatinine 1.21±0.74 mg/dl, proteinuria 1094±1201 mg/24H, 78% of the patients had a baseline creatinine of ≤ 1.3 mg/dl, 57% had a proteinuria of <1000mg/24H. During follow up time, 12 patients (11%) have doubled serum creatinine and 7 of them (8%) started dialysis in a period of 5.1±4.2 years.

40(39%) patients presented eNOS intron 4 polymorphism a (6 aa,34 ab) and 63 (64%) polymorphism b. Patients reaching the outcome exhibited higher systolic blood pressure (144±20 vs 130±20 mmHg, p=0.02), diastolic blood pressure (82,1±13 vs 72,3±15mmHg, p=0.028), higher baseline creatinine (2.18±2,7 vs 1.34±0,8 mg/dl, p=0.009) and more extended tubulointertitial fibrosis (21% vs 13% , p=0.1)

In a multivariate Cox proportional hazard analysis, the presence of (a) allele of eNOS gene, showed an 8-fold hazard to reach the outcome (HR=8.09, p=0.04) after adjusting for age, sex, presence of hypertension, proteinuria and ACE inhibitors treatment.

**Conclusions:** A significant proportion of patients, present impaired renal function at baseline. The classical risk factors for progression of renal disease also apply to our population. Additionally, the genotype (a) of eNOS gene appears to be associated with a worse outcome. The early detection of (a) allele could indicate those patients at increased risk of renal impairment.

## SA-PO833

**Association between Low Plasma Renin Activity and Renal Interstitial Fibrosis in Patients with IgA Nephropathy** Hitomi Nishimoto, Hirofumi Ikeda, Yoriko Ura, Masaru Nakayama. *Div of Nephrology and Clinical Research Institute, Dept of Internal Medicine, National Kyushu Medical Center Hospital, Fukuoka City, Fukuoka Pref., Japan.*

**Background:** IgA nephropathy (IgAN) is the most common cause of glomerulonephritis. Renal interstitial fibrosis (RIF) is considered a poor prognostic factor in IgAN. An association between the renin-angiotensin system and RIF has been suggested, with low plasma renin activity (PRA) reflecting increased renal renin-angiotensin system activity. To date, no studies have evaluated the relationship between RIF and PRA in IgAN patients. Our aim was to determine whether PRA is associated with RIF in IgAN patients.

**Methods:** Forty-four patients (mean age, 42±15 years)with biopsy-proven IgAN were enrolled in this cross-sectional study. Subjects taking angiotensin-converting enzyme inhibitors and/or angiotensin II receptor blockers or with estimated glomerular filtration rates (eGFRs) lower than 30 ml/min/1.73m$^2$ were excluded from the study. Mean eGFR and daily proteinuria of subjects were 76.2±20.5 ml/min/1.73m$^2$ and 1.1±1.4 g/day, respectively. Blood was drawn in a supine position early in the morning to measure PRA. PRA was log-transformed to achieve a normal distribution for analysis. We quantitated RIF by a point counting method and assessed the glomerular sclerosis index using semi-quantitative scoring.

**Results:** The mean percentage of RIF in subjects was 30±8 and the mean glomerular sclerosis index was 0.78±0.67. Univariate linear regression analysis showed that RIF was associated with age (β=0.38, p=0.01), systolic blood pressure (β=0.37, p=0.01), daily proteinuria (β=0.31, p=0.04), and log PRA (β=-0.54, p<0.01). In multivariate analysis, log PRA was the only independent predictor of RIF (β=-0.48, p=0.01). In univariate analysis, eGFR was associated with the glomerular sclerosis index (β=-0.42, p<0.01), but log PRA was not (β=-0.25, p=0.11).

**Conclusions:** In patients with IgAN, low PRA was independently associated with RIF. We speculate that low PRA might reflect enhanced tissue renin-angiotensin system activity, which activates RIF.

## SA-PO834

**The Role of Plasmin in the Development of Tubulointerstitial Change in IgA Nephropathy** Takahiro Uchida, Takashi Oda, Atsushi Watanabe, Hanako Takechi, Kojiro Yamamoto, Naoki Oshima, Hiroo Kumagai. *Dept of Nephrology and Endocrinology, National Defense Medical College, Tokorozawa, Saitama, Japan.*

**Background:** Plasmin activity has recently been reported to be associated with renal fibrosis in experimental models. However, the role of plasmin in human renal diseases is unclear. We therefore examined the renal plasmin activity in IgA nephropathy (IgAN).

**Methods:** Fifty seven patients with IgAN who were diagnosed by renal biopsy were retrospectively evaluated. Plasmin activity was assessed by in situ zymography with the use of plasmin sensitive synthetic peptide, and the percentage of positively stained area was calculated with image analysis software (LuminaVision Ver. 2.04). The relationships between the results of plasmin activity and the renal histological or clinical parameters were evaluated.

**Results:** Plasmin activity was observed only in tubulointerstitial (TI) space (and mainly in interstitium). Regarding the correlation with histological features, plasmin activity was significantly stronger in patients with TI change than those without TI change ($P$<0.05), and it was significantly correlated with the global glomerulosclerosis rate ($r$=0.45, $P$=0.0004). Regarding the correlation with clinical parameters, plasmin activity at the time of renal biopsy was significantly correlated not only with serum creatinine concentration (sCr) or estimated glomerular filtration rate (eGFR) at the time of renal biopsy ($r$=0.58, $P$<0.0001; $r$=-0.44, $P$=0.0005, respectively) but also with SCr and eGFR at the time of the end of the follow-up ($r$=0.58, $P$<0.0001; $r$=-0.46, $P$=0.0003, respectively). Double stainings for plasmin activity and CD68, and plasmin activity and neutrophil erastase in selected patients revealed the infiltration of CD68+ macrophages and neutrophils in TI space with upregulated plasmin activity.

**Conclusions:** These data suggest that TI plasmin activity may promote renal fibrosis by inducing inflammatory cells infiltration in human IgAN as well as in experimental models. Targeting to antagonize plasmin activity in situ may be a promising therapeutic approach to slow renal fibrogenesis and improve renal function.

## SA-PO835

**Crescentic IgA Nephropathy (C-IgAN) in Children** Yuko Shima,[1] Koichi Nakanishi,[1] Taketsugu Hama,[1] Hironobu Mukaiyama,[1] Hiroko Togawa,[1] Masashi Sato,[1] Kandai Nozu,[2] Ryojiro Tanaka,[3] Kazumoto Iijima,[2] Norishige Yoshikawa.[1] *[1]Pediatrics, Wakayama Medical Univ, Wakayama, Japan; [2]Pediatrics, Kobe Univ, Kobe, Hyogo, Jordan; [3]Pediatric Nephrology, Hyogo Prefectural Kobe Children's Hospital, Kobe, Hyogo, Japan.*

**Background:** Crescentic glomerulonephritis (CN) is defined as nephritis with more than 50% of glomeruli presenting crescents. IgAN is one of causes of CN.

**Methods:** We analyzed retrospectively consecutive 515 children newly diagnosed as having biopsy-proven IgAN from June 1976 to May 2010. There were 25 children (4.9%) with C-IgAN. We compared clinical and pathological findings between cases with C-IgAN and the remained 490 cases.

**Results:** Among 25 C-IgAN, 16 children (64%) were referred to hospitals by annual school screening program for urinary abnormalities, 7 children for gross hematuria, a child for acute nephritic syndrome, and a child for nephrotic syndrome. There was no significant difference about gender and blood pressure. There were significant differences in ratio of gross hematuria (76 vs. 50%), excretion of proteinuria (1.9 vs. 0.5 g/day/m$^2$), eGFR (102 vs. 108 ml/min/m$^2$), and duration from onset to renal biopsy (4.0 vs. 8.0 M). As to the pathological findings, degree of tubular atrophy showed significant difference (IQR[5-10] vs. [0-5]%). Sixteen children of C-IgAN (64%) were treated with combination therapy including PSL and immunosuppressant. Mean observation period was 6.0±3.6 yrs. Four cases (16%) reached chronic renal failure (eGFR<60) at the latest observation. One case was treated with dipyridamole and warfarin, two cases were with combination therapy, and the last one's treatment was unknown. The Kaplan-Meier analysis showed that the cases with C-IgAN demonstrated significantly lower renal survival curve than the rest (p<0.001). But they showed significant better preservation of renal function compared with the previous reports and renal survival rates for 5 yr was 84.1%.

**Conclusions:** We confirmed the importance of school screening program to find even children with C-IgAN. In our study, most crescents were cellular/fibrocellular crescents, which are acute lesions. That may be the reason why the combination therapy is effective in children with C-IgAN.

## SA-PO836

**Tonsillectomy in a Pan-European Cohort of 1147 Patients with IgA Nephropathy** Rosanna Coppo, Roberta Camilla, Shubha Bellur, Ian Roberts, Daniel C. Cattran, John Feehally, Stephan Troyanov, Luca Vergano, Laura Morando. *On Behalf of VALIGA Study Group.*

**Background:** The beneficial effect of tonsillectomy in patients with IgA nephropathy (IgAN) is controversial.

While in Asia benefits have been claimed, in Europe small studies failed to show benefits.

**Methods:** The 1147 patients with IgAN enrolled in the European validation study of the Oxford Classification of IgAN (VALIGA), from 55 Centers of 13 Countries, offered a unique opportunity to investigate the effect of tonsillectomy in histologically and clinically well characterized IgAN patients followed in mean for 5 years.

**Results:** Tonsillectomy was performed in 62(5.9%), 10 children; e-GFR was calculated (MDRD and Schwartz formula). The e-GFR slope was calculated; end-points were ESRD and 50% loss of e-GFR. Values in 62 tonsillectomized and 987 non-tonsillectomized patients in Table 1.

| | NO tonsillectomy | YES tonsillectomy | P value |
|---|---|---|---|
| Age at renal biopsy (years) | 35.8 ± 16.5 | 37.4 ± 16.2 | ns |
| Follow-up (years) | 5.71 ± 4.48 | 5.62 ± 4.12 | ns |
| eGFR at renal biopsy (ml/min/1.73 m2) | 76.7 ± 34.6 | 73.4± 31.76 | ns |
| Proteinuria at renal biopsy (g/day/1.73 m2) | 1.20 (0.52-2.56) | 1.35 (0.59-2.83) | ns |
| Mean proteinuria over follow -up (g/day/1.73 m2) | 0.78 (0.40-1.62) | 0.73 (0.37-1.68) | ns |
| Loss of eGFR during follow-up (ml/min/1.73 m2/year) | -2.08 ±8.08 | -1.01± 7.75 | ns |
| ESRD | 112/987 (11.3%) | 9/62 (14.5 %) | ns |
| 50% loss of initial GFR | 137/987 (13.9%) | 9/62 (14.5%) | ns |
| combined end -point (ESRD or 50% loss of initial GFR) | 156/987 (15.8%) | 10/62 (16.1%) | ns |

**Conclusions:** A propensity score estimating the probability of receiving tonsillectomy paired 41 patients with tonsillectomy and 41 without tonsillectomy with similar risk of progression (gender, age, race, mean blood pressure, proteinuria, e-GFR at renal biopsy, previous treatments and Oxford MEST scores). No significant difference was found in the combined end point, nor in eGFR loss over follow-up.

## SA-PO837

**Proteomic Analysis of Whole Glomeruli in Patients with Immunoglobulin A Nephropathy Using Micro-Sieving** Shigeki Kojima, Kenichiro Koitabashi, Yugo Shibagaki, Takashi Yasuda, Kenjiro Kimura. *Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan.*

**Background:** Immunoglobulin A (IgA) nephropathy (IgAN) is one of the most common primary glomerular disorders in the world. Pathogenesis of IgAN is still unclear. We recently established a method to isolate glomeruli from renal samples obtained by single needle biopsy, named as "micro-sieving". To identify glomerular proteins related to the pathogenesis of IgAN, we analyzed protein profiles of glomeruli obtained by micro-sieving in patients with IgAN.

**Methods:** Glomeruli were obtained by micro-sieving from renal biopsy samples of five patients with IgAN and five patients with minimal change nephrotic syndrome (MCNS). Then proteins, extracted from the isolated glomeruli, were separated by two dimensional fluorescence differential gel electrophoresis (2D-DIGE). By this method protein spots intensity of which was different between the IgAN and MCNS groups were detected and further identified by matrix-assisted laser desorption-ionization time-of-flight mass spectrometry (MALDI-TOF/MS). Some of the identified proteins were evaluated by immunohistochemistry.

**Results:** By 2D-DIGE, we detected in total 1170 protein spots matched among the samples. We found that intensity of 22 out of the 1170 spots was significantly higher in the patients with IgAN than in those with MCNS. Similarly, we found that intensity of 12 out of the 1170 spots was significantly lower in the patients with IgAN than in those with MCNS. Fifteen out of the 34 spots were successfully identified by MALDI-TOF/MS. Among them, we focused on two proteins, α-actinin-4 and glycine amidinotransferase, which intensity was significantly higher in IgAN. Also in immunohistochemistry, the expression of α-actinin-4 increased in the patients with IgAN than in those with MCNS.

**Conclusions:** Use of micro-sieving enabled us to obtain only glomerular proteins from renal biopsy samples and thus to analyze protein profiles of glomeruli. Future analysis of the identified proteins would help understanding of the pathogenesis of IgAN as well as MCNS.

## SA-PO838

**Adverse Events Associated with Immunosuppressive Therapy and Tonsillectomy in IgAN: The Nationwide Retrospective Cohort Study in IgAN in Japan** Yoshinari Yasuda,[1] Takashi Yasuda,[2] Sachiko Ohde,[3] Osamu Takahashi,[3] Tetsuya Kawamura,[4] Seiichi Matsuo.[1] *[1]Nephrol, Nagoya Univ, Nagoya, Japan; [2]Nephrol & Hypertens, St. Marianna Univ, Kawasaki, Japan; [3]Clin Epidemiol, St. Luke's Life Sci Inst, Tokyo, Japan; [4]Kid & Hypertens, Jikei Univ, Tokyo, Japan.*

**Background:** IgA nephropathy (IgAN) is one of progressive renal diseases requiring immunosuppressive therapy with/without tonsillectomy (Tx) when the prognosis is expected to be worse, however adverse events and complications associated with specific treatments have not been well documented. Thus, adverse events associated with immunosuppressive therapy and complications of Tx were analyzed in The Nationwide Retrospective Cohort Study in IgAN in Japan.

**Methods:** Study subjects were all IgAN patients diagnosed by the first renal biopsy in 49 collaborating hospitals during 2002 to 2004. Patients under 18 years old were excluded. Data at the time of renal biopsy and during the follow-up were collected, including death, complications of Tx and the following adverse events requiring specific treatment; infection, psychiatric disorder, aseptic necrosis, peptic ulcer, de novo diabetes, osteoporosis and others. Total 1,103 cases were registered till Dec. 1, 2012. Among them, we analyzed 931 cases which have sufficient data for the analysis.

**Results:** The median observation period was 5.4 years. Choice of therapy was as follows; conservative therapy (Cons) 475, oral steroids (Oral) 174, pulse methylprednisolone (mPSL) 121, and Tx with pulse methyprednisone (Tx+mPSL) 161. In this period, 11 patients died (6 malignancy, 2 CVD, 1 COPD, 1 druhg-induced lung injury and 1 unknown), and death cases were not obviously association with immunosuppressive therapy. Age (mean +- SD years old) and gender (female %) distributions were significantly different (Cons: 42.5 +- 16.8, 45.5%, Oral: 38.4 +- 15.0, 45.4%, mPSL: 39.6 +- 15.1, 43.0%, Tx+mPSL: 33.8 +- 15.8, 58.4%). Adverse event rates were significantly lower in Cons (2.3%) and in Tx+mPSL (3.7%) groups compared to Oral (12.6%) and mPSL (14.0%) groups. Complication of Tx was occurred in 3 out of 290 (1.1%) cases.

**Conclusions:** Adverse event rate was low in Cons and Tx+mPSL groups and complication of Tx was rare among Japanese IgAN patients.

## SA-PO839

**Enhanced Urinary Angiotensinogen Is Correlated with the Impaired Reabsorption Capacity of Proximal Tubular Cells in Children with the Severe Henoch-Schonlein Purpura Nephritis** Yanjie Huang, Xiaoqing Yang. *Pediatrics, The First Affiliated Hospital of Henan Univ of Tranditional Chinese Medicine, Zhengzhou, Henan, China.*

**Background:** The mechanism of enhanced urinary angiotensinogen (UAGT) in hypertension and some kidney diseases remains to be clarified. The aim of this study was to investigate the levels of UAGT in children with Henoch-Schonlein purpura nephritis (HSPN), and the correlations of UAGT with urinary albumin (ALB), Cystatin C (CysC), and beta2-microglobulin (beta2-MG). Urinary CysC and beta2-MG have been recognized as the markers of the reabsorption capacity of proximal tubular cells.

**Methods:** Patients were classified into three groups, according to the initial clinical presentation. 1) HSPN 1, n=20, hematuria, 5 or more red blood cells in per high power field in a centrifuged specimen, urine protein/creatinine ratios (UPCR)<200mg/g; 2) HSPN 2, n=30, 200mg/g<UPCR<1000mg/g, with hematuria; 3) HSPN 3, n=30, UPCR>1000mg/g, with hematuria. We measured urinary creatinine (Cr), ALB, AGT, CysC, beta2-MG, and plasma CysC levels. The urinary levels of these parameters were expressed in ratios with Cr.

**Results:** The UAGT levels in HSPN 3 (11.74±3.14ug/gCr) were significantly increased, compared with HSPN 1 (versus 3.39±2.43ug/gCr, p<0.01 )and HSPN 2 (versus 5.76±1.84ug/gCr, p<0.01). The levels of urinary CysC and beta2-MG were also enhanced in HSPN 3, compared with other groups. However, the concentration of plasma CysC had no difference among groups. In HSPN 3, there were the significant positive correlations between UAGT and UCysC (r=0.794, p<0.01), also between UAGT and beta2-MG (r=0.757, p<0.01). But, the UAGT levels did not correlated with UALB (r=0.303, p>0.05) in HSPN 3.

**Conclusions:** These results suggest that the higher levels of UAGT in severe HSPN may mainly reason from the impaired reabsorption capacity of proximal tubular cells, when the molecular barrier function of the glomerular capillary wall is injuried, and massive AGT protein is leaked into the tubular lumen. Upregulation of UAGT may lead to the elevated generation of intrarenal angiotensin II along the nephron.

## SA-PO840

**Predicting End-Stage Renal Disease or Death in Henoch Schønleins Purpura Patients Using Predictive Model Absolute Renal Risk Developed for IgA Nephropathy** Ann-merethe Vaagane,[5] Thomas Knoop,[1] Bjorn Egil Vikse,[2] Einar Svarstad,[1] Sabine Leh,[3] Rune Bjoerneklett.[1] *[1]Dept of Medicine, Haukeland Univ Hospital, Bergen, Norway; [2]Dept of Medicine, Haugesund Hospital, Haugesund, Norway; [3]Dept of Pathology, Haukeland Univ Hospital, Bergen, Norway; [4]Dept of Transplant Medicine, Oslo Univ Hospital Rikshospitalet, Oslo, Norway; [5]Institute of Clinical Medicine, Univ of Bergen, Bergen, Norway.*

**Background:** The glomerulonephritis in Henoch Schønlein Purpura (HSP) is morphologically similar to primary IgA nephropathy (IgAN). It is however not well studied whether the clinical prognosis also is similar. Recently, a prognostic model to predict end-stage renal disease (ESRD) or pre-ESRD death in IgAN called absolute renal risk (ARR) was published (Berthoux et al, JASN 2011). With ARR, IgAN patients are scored from 0-3 based on the presence/absence of proteinuria ≥ 1gram/24 hours, hypertension and the severity of the histological findings.

**Methods:** We identified a cohort of HSP patients diagnosed with kidney biopsy in the Norwegian Kidney Biopsy Registry and cases with ESRD or pre-ESRD deaths in the cohort during follow-up were identified through record linkage with the Norwegian Nephrology Registry (ESRD) and the Norwegian Population Registry (deaths). We scored the patients according to ARR. We used Kaplan Meier statistics and log-rank test to compare risk of ESRD/death in the different prognostic groups. We also calculated 10-year cumulative risk of ESRD/death and compared our results with the findings of Berthoux et al.

**Results:** We identified 120 HSP patients with mean follow-up time 8.4 years (range up to 20 years). During follow-up, ESRD occurred in 13 and pre-ESRD death in 7 patients. Risk of ESRD/death significantly increased with increasing ARR score. Ten-year cumulative risk of ESRD/death were 0% if ARR was 0, 4% if ARR was 1, 11% if ARR was 2 and 66% if ARR was 3.

**Conclusions:** ARR is applicable also to risk stratify HSP patients. Ten-year risk of ESRD/death in each ARR group of HSP patients is fairly similar to what Berthoux et al observed in IgAN patients.

## SA-PO841

**Attenuated Megalin Expression in Proximal Renal Tubules Is Associated with Tubular Atrophy/Interstitial Fibrosis by Oxford Classification in IgA Nephropathy**

Ikue Kobayashi,[1] Yasuo Imanishi,[1] Masayo Yamagata,[2] Toshimi Michigami,[3] Eiji Ishimura,[1] Masaaki Inaba.[1] *[1]Metabolism, Endocrinology and Molecular Medicine, Nephrology, Osaka City Univ Graduate School of Medicine, Japan; [2]Pharmacology, Osaka Ohtani Univ, Tondabayashi, Japan; [3]Bone and Mineral Research, Osaka Medical Center and Research Institute for Maternal and Child Health, Izumi, Japan.*

**Background:** Although vitamin D receptor activator (VDRA) have been reported to have a beneficial effect on IgA nephropathy (IgAN) possibly via inhibiting renin-angiotensin system, vitamin D (VD) metabolism in IgAN is not well determined. Megalin, a multiligand endocytotic receptor involving in the reabsorption of 25-hydroxyvitamin D in renal proximal tubules, plays an important role in VD metabolism. To elucidate the role of megalin in IgAN, its interstitial expression was examined in IgAN kidneys and was compared to Oxford classification of IgAN.

**Methods:** Renal biopsy specimens were collected from histologically proven 43 IgAN patients (serum creatinine 1.13 ± 0.74 mg/dl, urinary protein 1.24 ± 1.19 g/day) with informed consent. Interstitial megalin expression was determined by immunohistochemistry using ScanScope Aperio Slide Scanner.

**Results:** In tubular atrophy and interstitial fibrosis (T) by Oxford classification, the megalin expression in T1/2 significantly decreased compared to T0(P=0.03 by Mann-Whitney U test). Other Oxford categories such as mesangial hypercellularity, endocapillary hypercellularity or segmental sclerosis did not make any difference in the interstitial megalin expression. No significant relationship was observed between interstitial megalin expression and biochemical parameters such as serum creatinine, eGFR, urinary protein, or urinary β2-microglobulin.

**Conclusions:** Advanced T classification, one of determinants for worse renal prognosis in IgAN, suppressed interstitial megalin expression in IgAN. The suppression of intrinsic VD activation may contribute to the progression of IgAN possibly via renin-angiotensin system.

## SA-PO842

**Different Impact of Proteinuria on Renal Outcomes in IgA Nephropathy and Membranous Nephrpathy**

Natalia I. Polanco Fernandez, Eduardo Gutierrez-martinez, Elena Gutierrez-solis, Paula Jara Caro Espada, Manuel Praga. *Grupo de Enfermedades Glomerulares de la SEN (GLOSEN), Spain.*

**Background:** Reduction in proteinuria in chronic glomerular diseases is considered to be a crucial therapeutic objective. However, a clear proteinuria target (mean proteinuria during follow-up below which no renal outcomes will develop) has not been established for all glomerular diseases. Some studies have shown a high number of negative renal outcomes in IgA nephropathy (IgAN) with proteinuria persistently > 1 g/24h, but if the same target could be applied to other diseases like idiopathic membranous nephropathy (IMN) is unknown.

**Methods:** Retrospective, multicenter study performed in 14 Spanish Hospitals that collected two cohorts of patients: biopsy-proven IgAN (n=77) and biopsy-proven IMN (n=129), with a long follow-up (129 and 96 months, respectively). All patients with IMN had achieved remission of nephrotic syndrome (proteinuria <3.5 g/24h) spontaneously. Time-average proteinuria (TAP) throughout follow-up was determined in every patient along with clinical, biochemical and histologic parameters. Main outcomes were progression of renal insufficiency (measured by a >50% increase of baseline serum creatinine and the annual rate of GFR loss) and ESRD.

**Results:** Both IgAN and IMN patients were divided in two groups, according to TAP > or < 1 g/24h during follow-up. Whereas a clear difference in renal outcomes between both groups was observed in IgAN, there were no differences in IMN.

| | | IgAN | | | IMN | |
|---|---|---|---|---|---|---|
| | <1g/day | >1 <3.5 g/day | p | <1g/day | >1 <3.5 g/day | p |
| Final serum Creatinine (mg/dl) | 1.5 ± 0.9 | 3.4 ± 2.2 | < 0.0001 | 1 ± 0.33 | 1 ± 0.27 | 0.9 |
| >50% serum creatinine increase (%) | 4 | 52 | < 0.0001 | 8 | 11 | 0.6 |
| GFR loss (ml/min/1.73m2/yr) | -0.07 ± 2.1 | -2.5 ± 3.2 | < 0.0001 | -0.06 ± 4.4 | -0.2 ± 8.1 | 0.09 |
| ESRD (%) | 0 | 33 | < 0.0001 | 0 | 0 | 0.9 |

**Conclusions:** TAP >1 g/day is associated with a poor renal prognosis in IgAN, but IMN patients exhibit a significantly better tolerance to similar values of proteinuria. Pathogenic mechanisms explaining this different proteinuria impact are unknown.

## SA-PO843

**Quantitative Evaluation of Renal Cortical Fibrosis and Renal Prognosis in IgA Nephropathy and Focal Segmental Glomerulosclerosis**

Hidekazu Iida,[1] Kensuke Asaba,[2] Satoshi Kinugasa,[2] Yoshitaka Ishibashi,[1] Masaomi Nangaku,[2] Akihiro Tojo.[2] *[1]Div of Nephrology, Japanese Red Cross Medical Center, Tokyo, Japan; [2]Div of Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan.*

**Background:** Renal prognosis is generally correlated with interstitial fibrosis in chronic kidney diseases. However, previous scoring systems to evaluate interstitial fibrosis are subjective and may show inter-observer variability. Thus, we used computer image analyzer software to evaluate the ratio of fibrosis area to the area of renal cortex in Azan staining sections in patients with focal segmental glomerulosclerosis (FSGS) and IgA nephropathy, and evaluated its association with renal prognosis during 20 years follow up.

**Methods:** The ratio of fibrosis area to the area of renal cortex was evaluated quantitatively by an image analyzer software (Image Pro Plus®) in Azan staining kidney sections in 52 FSGS patients and 159 IgA nephropathy patients diagnosed by renal biopsy at the University of Tokyo. Induction of hemodialysis or doubling of serum creatinine was used as a combined end point, renal prognosis was evaluated with the Kaplan-Meier method, and risk factors were examined by Cox's proportional hazards model.

**Results:** After correction with age, sex, and blood pressure at renal biopsy, the fibrosis area ratio was found to be an independent risk factor for renal survival in both IgA nephropathy and FSGS patients by Cox's proportional hazards analysis. The cut off values of the fibrosis area ratio, determined from the ROC curve using the least-square method, were 14.5% for IgA nephropathy and 15.8% for FSGS. The mean length of renal survival in patients with a cortical fibrosis area ratio lower than 14.5% was significantly longer than those with a ratio higher than 14.5% (23.1 vs. 12.5 years, p<0.00001) in IgA nephropathy. Likewise, it was longer in patients with a cortical fibrosis area ratio lower than 15.8% (20.4 vs. 8.2 years, p<0.00001) in FSGS.

**Conclusions:** The renal cortical fibrosis area ratio calculated by computer image software is an objective index that enables estimation of long-term renal survival in IgA nephropathy and FSGS patients.

*Funding:* Government Support - Non-U.S.

## SA-PO844

**Long-Term Prognosis of Clinically Early IgA Nephropathy Is Not Always Favorable**

Hajeong Lee, Dong Ki Kim, Ho Jun Chin, Yon Su Kim, Chun Soo Lim, Jung Pyo Lee. *Internal Medicine, Seoul National Univ Hospital.*

**Background:** Long-term prognosis of clinically early IgA nephropathy (IgAN) patients remains to be clarified. In this study, investigated long-term outcome of IgAN patients with apparently benign presentation and evaluated the prognostic factor for renal survival.

**Methods:** We included biopsy proven IgAN patients with estimated glomerular filtration rate (eGFR) ≥60 mL/min/1.73m$^2$, normal blood pressure, and proteinuria (PU) < 0.5 g/day at the time of biopsy. Patients who were younger than 15 years old or with other systemic disease were excluded. Primary outcome was defined as end-stage renal disease (ESRD) progression. Secondary outcome was defined as 50% increase of serum creatinine or increased amount PU >1 g/day. During the follow-up, cases with loss of microscopic hematuria, PU < 0.2 g/day and stable renal function were categorized to remission group.

**Results:** A total of 142 patients met these criteria and analyzed. Median systolic blood pressure was 119 (110-121)mmHg, initial eGFR was 85.1 (74.9 – 100.4) mL/min/1.73m$^2$ and proteinuria was 0.25 (0.13 – 0.38) g/day at diagnosis. More than 13% of patients showed moderate or severe tubular atrophy or interstitial fibrosis. Among them, 4 patients were died, 5 reached to ESRD. Twenty-year renal survival rate was 88.6% during 92 (46 – 204) months of follow up. Increase of serum creatinine levels was found in 3 patients, and development of PU in 11 patients. Remission was demonstrated in 35 patients. No patients were treated by immunosuppressive agents and 61 (43%) of patients were taken renin-angiotensin-aldosterone. Moderate or severe degree of interstitial fibrosis (adjusted odd ratio (OR) 6.828, 95% confidence interval (CI) 1.512 – 30.801, P = 0.013) and mild renal insufficiency (eGFR < 90mL/min/1.73m$^2$) (adjusted OR 3.866, 95% CI 1.004 – 14.933, P = 0.049) were independent predictors for elevation of serum creatinine or increased amount of PU.

**Conclusions:** This study demonstrated that the prognosis of early IgAN was not always favorable. Besides mild renal insufficiency, pathologic changes including interstitial fibrosis also should be considered as an important prognostic factor for clinically early IgAN patients.

## SA-PO845

**Effect of Hematuria on the Outcome of IgA Nephropathy with Mild Proteinuria**

Kayu Tanaka, Takahito Moriyama, Chihiro Iwasaki, Yasuko Oshima, Kosaku Nitta. *Medicine, Tokyo Women's Medical Univ, Tokyo, Japan.*

**Background:** Heavy proteinuria has been widely recognized as the risk factor for progression of IgA nephropathy (IgAN), and hematuria recently has been recently recognized to be excreted from the active inflammatory lesion of glomerular capillaries in IgAN. However the effect of hematuria on the outcome for IgAN remains unknown and the treatment of IgAN with severe hematuria is still controversial.

**Methods:** We retrospectively examined 88 IgAN patients with proteinuria less than 0.5g/day and were not treated with corticosteroid, immunosuppressive agents or tonsillectomy. We divided them into two groups: the low urinary red blood cells (U-RBC) group (L group, n=48); U-RBC was less than 20 counts/high-power field (HPF), and the high RBC group (H-group, n=40); U-RBC was greater than 20 counts/HPF. We analyzed the clinical and histological findings and renal survival rate until progression to end-stage renal disease.

**Results:** Median U-RBC in H group was significantly higher than L group (L group: 5 vs. H group: 30 counts/HPF, p<0.0001), and the other laboratory data were similar between both groups [estimated glomerular filtration rate (L: 77.1 vs. H: 81.9 ml/min) and proteinuria (0.26 vs. 0.27 g/day)], though some clinical findings were significantly different between both groups [male to female ratio (L: 25:23 vs. H: 9:31, p=0.004), and systolic and diastolic blood pressure (122.8/76.5 vs. 116.1/69.4 mmHg, p=0.0179/0.0073)]. Histological findings were not significantly different between both groups. During the 5 years after renal biopsy, median amount of proteinuria remained less than 0.5g/g•creatinine in both groups, and median amount of U-RBC was decreased to less than 5/HPF in the L group and to 10/HPF in the H group without any intensive therapy. 25 years renal survival rate by the Kaplan-Meier method was 100 % in H group, but it was decreased to 85.5% in L group, though it was not significant.

**Conclusions:** Severe hematuria at the time of biopsy naturally improved without any intensive therapy, and there were no effect of hematuria on the outcome for IgAN.

**SA-PO846**

**Clinical Feature and Long Term Renal Outcome of IgA Nephropathy in China: A Retrospective Cohort Study of 1835 Cases** Wei Qin, Xiaolei Chen, Junming Fan, Zi Li, Ling Ji. *Div of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

**Background:** This study was conducted to clarify clinical feature and long term renal outcome of IgA nephropathy (IgAN) in China.

**Methods:** 1835 patients with IgAN were included in this study. The clinicopathological features, treatments, responses and renal outcome were analyzed.

**Results:** Of the 1835 patients, 586 presented with nephrotic syndrome (NS); 114 presented with hematuria without proteinuria; 303 presented with renal dysfunction at biopsy; the rest 832 presented with nephritic syndrome with normal renal function. The median followup time was 40.4 months. Renal function in 94.1% patients remain stable. Only 109 patients developed ESRD or GFR reduced>50%. Multivariate analysis indicated that estimated glomerular filtration rate (eGFR) <90 mL/min, uncontrolled hypertension, NS, severe pathological lesions were the independent risk factors of decreasing of renal function. In patients with NS, 392 cases (66.9%) were IgAN with minimal change disease. Corticosteroid achieved high complete remission (CR) rate (86.2%) with a considerable relapse rate (28.1%). In the other 440 patients with NS and mesangial proliferation, corticosteroids and immunosuppressants achieved 57% CR, 31% partial remission (PR) and 12% no response (NR). In patient with proteinuria between 1-3g/d with or without renal dysfunction, immunosuppressive treatment achieved 28% CR, 37% PR, and 35% NR. RAS inhibitors (RASi) were prescribed in most patients. However, significant effect could only be observed in patients with hypertension. Renal function remained normal in every patient with normal renal function and proteinuria <1g/d during following up. Treatment of RASi or immunosuppressants did not show any benefit regarding as decreasing of proteinuria or protecting of renal function in these patients.

**Conclusions:** Renal function decline was observed in 6% of IgAN patients during following up. The prognostic factor of renal survival were eGFR<90 mL/min, uncontrolled hypertension, NS, severe pathological lesions. Corticosteroids and immunosuppressant was effective in most patients. RASi only had a limited effect in Chinese patients.

**SA-PO847**

**The Nationwide Retrospective Cohort Study in IgA Nephropathy in Japan** Takashi Yasuda,[1] Yoshinari Yasuda,[2] Sachiko Ohde,[3] Osamu Takahashi,[3] Tetsuya Kawamura,[4] Seiichi Matsuo.[2] *[1]Nephrology & Hypertension, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; [2]Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan; [3]Center for Clinical Epidemiology, St. Luke's Life Science Institute, St. Luke's International Hospital, Tokyo, Japan; [4]Kidney & Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** We have started the Nationwide Retrospective Cohort Study in IgA nephropathy in Japan since Sep. 1, 2012. The main purpose is to clarify the choice of therapy, including tonsillectomy in combination with intravenous pulse methylprednisolone followed by oral prednisone (tonsillectomy with pulse), in patients with IgA nephropathy under various clinical presentations. In this interim analysis, we evaluated the therapeutic efficiency on renal outcome defined as 50 percent increase in the serum creatinine concentration from baseline between conservative therapy without steroids, oral steroids, pulse methyprednisone followed by oral prednisone (pulse methyprednisone), and tonsillectomy with pulse.

**Methods:** Adult patients with IgA nephropathy diagnosed by the first renal biopsy during the three years from 2002 to 2004 were eligible. Data at the time of renal biopsy and during the follow-up were collected, and total 1,103 cases from 49 facilities were registered till Dec. 1, 2012. Among them, we analyzed 931 cases which have sufficient data for the analysis.

**Results:** The median observation period was 5.4 years. Choice of therapy was as follow; conservative therapy 475, oral steroids 174, pulse methylprednisolone 121, and tonsillectomy with pulse 161. In this period, 103 patients reached the renal outcome. Cox regression analyses with adjustment for baseline covariates showed that, compared to the patients with tonsillectomy with pulse, the risk for those with other therapy was as follow; conservative therapy 3.74 (95%CI, 1.75-8.00), oral steroids 2.02 (0.87-4.68), pulse methyprednisone 2.76 (1.22-6.24).

**Conclusions:** This interim analysis seems to indicate the superiority of tonsillectomy with pulse in terms of improving renal prognosis. After registration of all cases, we will clarify proper choice of therapy by the propensity score analysis.

*Funding:* Government Support - Non-U.S.

**SA-PO848**

**Efficacy and Safety of Telmisartan, Clopidogrelin and Leflunomide in Patients with IgA Nephropathy — A Multicentre, Prospective, Randomized, Double-Blind, Double-Dummy Controlled Clinical Trial** Xiang-Mei Chen, Jie Wu, Shuwei Duan, Ying Zheng. *Dept of Nephrology, State Key Laboratory of Kidney Disease, Chinese PLA General Hospital, Beijing, China.*

**Background:** To evaluate the efficacy and safety of telmisartan combined with clopidogrelin and/or leflunomide for patients with lgA nephropathy and whether the combination therapy surpass telmisartan in decreasing proteinuria and protecting renal function.

**Methods:** We enrolled 400 patients aged 18–55 years from 13 centres in Beijing who had proteinuria 0.5~3.5g/d, baseline serum creatinine (SCr) <3mg/dl, All patients were eluted by taking telmisartan 80mg/d for 4 weeks and then randomly assigned to receive 24 weeks of treatment with telmisartan 80mg/d + clopidogrelin placebo + leflunomide placebo (group A), telmisartan 80mg/d + clopidogrelin 50mg/d + leflunomide placebo (group B), telmisartan 80mg/d + clopidogrelin placebo + leflunomide 20mg/d (group C), telmisartan 80mg/d + clopidogrelin 50mg/d + leflunomide 20mg/d (group D). Comparison of 24h urinary protein excretion, the serum creatinine, eGFR, albumin, cholesterol and uric acid after the therapy were assessed.

**Results:** After treatment for 24 weeks, proteinuria declined significantly in the four groups (P<0.05), while those in group C (1.20±0.76 vs 0.77±0.42 g/24h) and group D (1.16±0.63 vs 0.74±0.49 g/24h) were decreased more significantly than in group A (1.15±0.87 vs 0.92±0.58 g/24h) and group B (1.11±0.83 vs 0.89±0.42 g/24h) (P<0.05). Mixed effects model analysis showed that telmisartan, leflunomide and telmisartan combine leflunomide decreased proteinuria (P<0.01). The SCr declined in group C and group D more significantly than that in group A and group B (P<0.05). The level of eGFR in group C and group D were increased more than that in group A and group B. The serum uric acid in group C and group D decreased more significantly than group A and group B (P<0.05). There were no significant differences in the results of albumin and cholesterol among the four groups. No obvious adverse reactions were found in the four groups.

**Conclusions:** Telmisartan combined with leflunomide was safe and effective in decreasing proteinura and protecting short-term renal function.

**SA-PO849**

**Eculizumab (ECU) Inhibits Thrombotic Microangiopathy (TMA) and Improves Renal Function in Pediatric Atypical Hemolytic Uremic Syndrome (aHUS) Patients (Pts)** Larry A. Greenbaum, Marc Fila, Michel Tsimaratos, Gianluigi Ardissino, Samhar I. Al-Akash, Jonathan Evans, Paul H. Henning, Kenneth V. Lieberman, Silvio Maringhini, Lars Pape, Lesley Rees, Nicole Van De Kar, Johan Van de Walle, Masayo Ogawa, Camille L. Bedrosian, Christoph Licht. *C10-003 Investigators.*

**Background:** aHUS is a rare, genetic, life-threatening disease of uncontrolled complement activation leading to systemic TMAand severe end-organ damage. ECU, a terminal complement inhibitor, is approved for the treatment of aHUS, and was shown to be safe and effective in a retrospective pediatric study. Here, we report safety and efficacy results at 26 weeks (wks) from the first prospective trial of pediatric aHUS pts.

**Methods:** This was an open-label, single-arm, Phase 2 trial of ECU in pediatric pts with aHUS. The primary endpoint was complete TMA response at 26 wks. Dosing was based on weight cohorts.

**Results:** 22 pts (age 1 month to 17 yrs) were enrolled; 19 completed 26 wks. 16 pts (73%) were newly diagnosed (median duration of 6 days prior to ECU). At wk 26, 14 pts (64%) achieved the primary endpoint.

| **Table: Wk 26 Results (N=22)** | |
|---|---|
| **Baseline Demographics and Disease Characteristics** | |
| Age (years) – mean (SD) | 6.6 (6.1) |
| Female sex – n (%) | 10 (45) |
| Identified complement regulatory protein mutation or auto-antibody – n (%) | 11 (50) |
| Time from aHUS diagnosis until screening (months) – median (range) | 0.56 (0.03–191.3) |
| Newly diagnosed pts – n (%) | 16 (73) |
| Duration of current clinical manifestation of aHUS (months) – median (range) | 0.2 (0.0–4.3) |
| PE/PI at baseline – n (%) | 10 (45) |
| Dialysis at baseline – n (%) | 11 (50.0) |
| Prior renal transplant – n (%) | 2 (9) |
| Platelet count <150x10$^9$/L – n (%) | 22 (100) |
| LDH >ULN – n (%) | 19 (86) |
| eGFR ≤60 mL/min/1.73m$^2$ – n (%) | 18 (82) |
| **Efficacy Outcomes** | |
| Complete TMA response – n (%) | 14 (64) |
| Complete hematologic response – n (%) | 18 (82) |
| Platelet count normalization – n (%) | 21 (95) |
| eGFR improvement from baseline ≥15 mL/min/1.73m$^2$ – n (%) | 19 (86) |
| eGFR increase from baseline (mL/min/1.73 m$^2$) – mean (95% CI) | 64 (50; 79)<br>*P*<0.0001 (wk 25) |
| Serum creatinine ≥25% decrease from baseline – n (%) | 16 (73) |

**Complete TMA response:** normalization of platelets and LDH, and ≥25% improvement in serum Cr from baseline on 2 consecutive measurements >4 wks apart. **Complete hematologic response:** platelet and LDH normalization at ≥2 consecutive measurements ≥4 wks apart. **Platelet Count Normalization:** platelet count ≥150x10$^9$/L ≥2 consecutive measurements ≥4 wks apart.

9/11 pts (82%) on dialysis at BL discontinued dialysis. Of the 11 pts not on dialysis at BL, 11 (100%) remained dialysis free through 26 wks. Of 10 pts on PE/PI at BL, all discontinued. QoL was significantly improved. ECU was safe and well tolerated. No pts withdrew due to Aes, no pts had meningococcal infections, and no pts died.

**Conclusions:** In this first prospective trial of pediatric pts with aHUS, early intervention with ECU improved hematologic and renal parameters, and decreased the burden of dialysis. These results confirm that ECU inhibits complement-mediated TMA, and is safe and effective at the approved dose regimen in pediatric pts with aHUS, including those receiving first-line ECU. Treatment in the clinical trial is ongoing.

## SA-PO850

**Eculizumab (ECU) in Atypical Hemolytic Uremic Syndrome (aHUS) Patients (Pts) with Long Disease Duration and Chronic Kidney Disease (CKD): Sustained Efficacy at 3 Years**

Yahsou Delmas,[1] Chantal Loirat,[2] Petra Muus,[3] Christophe M. Legendre,[4] Kenneth Douglas,[5] Maryvonne Hourmant,[6] Birgitta Maria Herthelius,[7] Antonella Trivelli,[8] Tim Goodship,[9] Giuseppe Remuzzi,[10] Camille L. Bedrosian,[11] Christoph Licht.[12] *[1]CHU Pellegrin-Bordeaux; [2]Hôpital Robert-Debré; [3]Radboud Univ Nijmegen Medical Centre; [4]Univ Paris Descartes and Hôpital Necker; [5]Beatson West Scotland Cancer Centre; [6]CHU de Nantes-Hôpital Hotel Dieu; [7]Karolinska Univ Hospital; [8]Gaslini Institute; [9]Newcastle Univ; [10]Istituto Mario Negri; [11]Alexion Pharmaceuticals, Inc.; [12]The Hospital for Sick Children.*

**Background:** aHUS is a rare, genetic, life-threatening disease of chronic complement activation leading to systemic TMA. ECU was shown to inhibit TMA, eliminate PE/PI, and improve renal function in pts with long aHUS duration and CKD in 1- and 2-yr reports of this prospective study. Here, we provide a 3-yr update.

**Methods:** aHUS pts ≥12 yrs with CKD receiving chronic PE/PI were enrolled. After 8 wks of observation, pts stopped PE/PI and started ECU.

**Results:** 20 pts were treated—16 pts for ≥30 mos. Median (med) time from diagnosis was 48 mos. Med duration of ECU was 156 (26—176) wks. Baseline mean eGFR was 31 mL/min/1.73m$^2$, and 90% of pts had eGFR≤60. Efficacy outcomes were consistent with a 2-yr analysis.

Table

| Key Outcomes* (N=20; ITT) | 114 wk Median ECU Duration | 156 wk Median ECU Duration |
|---|---|---|
| TMA event-free status[†,‡], % pts (95% CI) (Primary) | 95 (75–100) | 95 (75–100) |
| Hematologic normalization[†,§], % pts (95% CI) (Primary) | 90 (68–99) | 90 (68–99) |
| Mean change in eGFR from baseline, mL/min/1.73m$^2$, (95% CI) | +7.2 (0.76–13.6) (wk 104) | +4.1 (-12.6–20.9) (wk 152) |
| eGFR increase of ≥15 mL/min/1.73m$^2$, % pts (95% CI) | 40 (19–64) | 40 (19–64) |
| CKD improvement of ≥1 stage, % pts (95% CI) | 60 (36–81) | 60 (36–81) |
| ≥25% reduction in serum creatinine, % pts (95% CI) | 55 (32–77) | 55 (32–77) |
| Mean change in health-related quality of life (EQ-5D score)[‖] (SD) | 0.12 (0.15) (wk 104) | 0.16 (0.24) (wk 152) |

ECU dosage: 900 mg/week for 4 wks, 1200 mg at wk 5, then 1200 mg every 2 wks thereafter.
*All analyses are compared with baseline values.
†LOCF analysis.
‡Normalization of platelet and LDH counts for 2 measurements ≥4 wks apart.
§≥12 wks with no platelet decrease >25%, no PE/PI, and no new dialysis.
‖Clinically meaningful threshold ≥0.06.

3 pts had serious Aes possibly or probably related to ECU. 1 death (unrelated) occurred in the extension.

**Conclusions:** Improvements in hematologic parameters and kidney function were maintained at 3 yrs. These results confirm sustained efficacy with long-term ECU treatment and resulting terminal complement inhibition in aHUS pts with CKD previously managed with PE/PI.

*Funding:* Pharmaceutical Company Support - Alexion Pharmaceuticals

## SA-PO851

**Successful Treatment of DEAP-HUS with Eculizumab**

Damien Gerard Noone,[1] Fred G. Pluthero,[1] Peter F. Zipfel,[3] Christoph Licht.[1] *[1]Nephrology, The Hospital for Sick Children, Toronto, Canada; [2]Immunology, Univ of Heidelberg, Heidelberg, Germany; [3]Leibniz Institute for Natural Product Research and Infection Biology, Jena, Germany.*

**Background:** DEAP-HUS (deficiency of CFHR proteins and CFH autoantibody positive) represents a unique subgroup of complement-mediated aHUS. CFH autoantibodies block CFH surface recognition and mimic aHUS causing mutations. CFH autoantibodies are found in up to 15% of aHUS patients and typically occur in the background of CFHR3/CFHR1 deletions. The principal treatment concept for complement-mediated aHUS hinges on restoring alternative pathway regulation via plasma-based treatments or eculizumab, a monoclonal C5 antibody. Clinical practice guidelines for DEAP-HUS are lacking; strategies have been adopted from genetically-determined forms of aHUS and other autoimmune diseases. The literature supports PLEX initially, but with the addition of an antibody-suppressing or depleting agent with varied success reported.

**Methods:** We present a retrospective report of the successful use of eculizumab in 2 DEAP-HUS patients and their follow up.

**Results:** We show eculizumab to be safe and effective in the management of DEAP-HUS in 2 patients with confirmed CFHR3/CFHR1 deletion. One was dependent on bi-weekly plasma infusions. Successful induction of aHUS remission was achieved in the acute phase in the other. Immunosuppressive agents and midterm discontinuation of eculizumab are considered. We propose a biphasic treatment concept for DEAP-HUS with eculizumab used acutely to arrest the complement mediated damage and continued for at least 6 months (Phase 1), followed by the use of immunosuppressive agents targeting ongoing antibody production (Phase 2), with antibody titre measurement.

**Conclusions:** The complement C5 inhibitor eculizumab is safe and effective in maintaining a disease-free state in DEAP-HUS in the presence of ongoing anti-CFH autoantibodies. While immunosuppression alone may sufficiently address the autoimmune component of DEAP-HUS, the predisposing lack of CFHR1 – an identified C5 convertase inhibitor – and possible additional but unrecognized complement mutations would be left untreated.

## SA-PO852

**Eculizumab (ECU) Maintains Efficacy in Atypical Hemolytic Uremic Syndrome (aHUS) Patients (Pts) with Progressing Thrombotic Microangiopathy (TMA): 3-Year (Yr) Update**

A. Osama Gaber,[1] Chantal Loirat,[2] Larry A. Greenbaum,[3] Sunil Babu,[4] Richard R. Furman,[5] Neil S. Sheerin,[6] David J. Cohen,[7] Frank Eitner,[8] Yahsou Delmas,[9] Camille L. Bedrosian,[10] Christophe M. Legendre.[11] *[1]The Methodist Hospital; [2]Hopital Robert Debre; [3]Emory Univ; [4]Fort Wayne Medical Oncology and Hematology; [5]Weill Cornell Medical College; [6]Newcastle Univ; [7]Columbia Univ; [8]Bayer Pharma AG; [9]CHU Pellegrin-Bordeaux; [10]Alexion Pharmaceuticals, Inc; [11]Univ Paris Descartes & Hôpital Necker.*

**Background:** aHUS is a rare, genetic, life-threatening disease of chronic complement activation leading to systemic TMA. In 1 and 2 yr reports from this prospective study (C08-002), ECU was shown to inhibit TMA, prevent or reverse organ damage, and reduce the need for dialysis in aHUS pts. Here we provide a 3-yr update.

**Methods:** aHUS pts ≥12 yrs with progressing TMA (platelet decrease of ≥25% despite ≥4 PE/PI sessions 1 week [wk] before screening) entered an open-label, Phase 2 trial and long-term extension. Primary endpoints were platelet count change and hematologic normalization.

**Results:** 17 pts enrolled and 13 pts continued in the extension. Median duration of treatment was 100 wks, with a range of 2 to 186 wks. 5 pts remained enrolled for >130 wks. Continuous, long-term ECU treatment sustained or improved key hematologic and renal endpoints at 3 yrs.

Table

| Key Outcomes* (N=17; ITT) | 2-yr analysis | 3-yr analysis |
|---|---|---|
| Mean change in platelet count, x10$^9$/L (SD) (primary endpoint) | 94 (56) *P*=0.001 (wk 104) | 136 (41) *P*=0.007 (wk 156) |
| Hematologic normalization[†,‡], % pts (95% CI) | 88 (64–99) | 88 (64–99) |
| TMA-event-free status[†,§], % pts (95% CI) | 88 (64–99) | 88 (64–99) |
| Mean change in eGFR, mL/min/1.73m$^2$ (95% CI) | 35.2 (17.4–53.1) *P*=0.0005 (wk 104) | 54.0 (11.8–96.1) *P*=0.03 (wk 156) |
| eGFR increase of ≥15 mL/min/1.73m$^2$, % pts (95% CI) | 59 (33–82) | 59 (33–82) |
| CKD improvement of ≥1 stage, % pts (95% CI) | 71 (44–90) | 76 (50–93) |
| Serum creatinine decrease of ≥25%, % pts (95% CI) | 76 (50–93) | 76 (50–93) |
| Mean change in health-related quality of life[‖], EQ-5D score (95% CI) | 0.31 (0.28–0.34) *P*<0.0001 (wk 104) | 0.29 (0.28–0.30) *P*<0.0001 (wk 152) |

ECU dosage: 900 mg/wk for 4 wks, 1200 mg at wk 5, 1200 mg q2w thereafter.
*All analyses are compared with baseline values.
†LOCF analysis.
‡Normalization of platelet and LDH counts for 2 measurements ≥4 wks apart.
§≥12 wks with no platelet decrease >25%, no PE/PI, and no new dialysis.
‖Clinically meaningful threshold ≥0.06.

ECU was generally safe and well tolerated. 4 pts had serious Aes judged to be possibly drug related. No pts died.

**Conclusions:** The data demonstrate the safety and continued efficacy of ECU therapy in aHUS pts, highlighting the ongoing inhibition of TMA at this 3-yr update.

## SA-PO853

**An Observational, Non-Interventional, Multicenter, Multinational Registry of Patients (Pts) with Atypical Hemolytic Uremic Syndrome (aHUS): Initial Pt Characteristics**

Christoph Licht,[1] Gianluigi Ardissino,[2] Gema Ariceta,[3] Jon Beauchamp,[4] David J. Cohen,[5] Larry A. Greenbaum,[6] Sally A. Johnson,[7] Masayo Ogawa,[8] Franz S. Schaefer,[9] Johan Van de Walle,[10] Veronique Fremeaux-bacchi.[11] *[1]The Hospital for Sick Children; [2]Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico; [3]Hospital Vall d' Hebron; [4]Alexion Pharmaceuticals International; [5]Columbia Univ; [6]Emory Univ; [7]Newcastle upon Tyne Hospital; [8]Alexion Pharmaceuticals; [9]Univ of Heidelberg; [10]UZ Gent Dienst Nefrologie; [11]Assistance Publique-Hopitaux de Paris.*

**Background:** aHUS is a rare, genetic, life-threatening disease of chronic complement activation leading to systemic thrombotic microangiopathy, with renal and other end-organ damage. The global aHUS Registry, initiated in April 2012, prospectively collects information on pts with aHUS. Here, we report baseline demographics from the initial pts in the aHUS Registry.

**Methods:** aHUS pts (regardless of treatment) are eligible for enrollment. Demographic, medical and disease history, treatments, efficacy and safety outcomes data are collected initially and every 6 months thereafter.

**Results:** By March 31, 2013, 53 pts from 8 countries were enrolled in the aHUS registry. 32 (60%) were treated with eculizumab [ECU], and 47 (89%) were ≥18 yrs.

Family history of aHUS, prior kidney graft, dialysis, and PE/PI were observed in ECU and non-ECU treated groups.

Table

| Demographics | | | |
|---|---|---|---|
| | Treated with Eculizumab (N=32) | Never Treated with Eculizumab (N=21) | Total (N=53) |
| Mean age at registry enrollment (SD), yrs | 38.1 (18.38) | 33.0 (15.62) | 36.1 (17.36) |
| Age at registry enrollment, n (%) | | | |
| ≥2 to <5 yrs | 2 (6.3) | 2 (9.5) | 4 (7.5) |
| ≥5 to <12 yrs | 1 (3.1) | — | 1 (1.9) |
| ≥12 to <18 yrs | — | 1 (4.8) | 1 (1.9) |
| ≥18 yrs | 29 (90.6) | 18 (85.7) | 47 (88.7) |
| Sex, n (%) | | | |
| Female | 22 (68.8) | 7 (33.3) | 29 (54.7) |
| Male | 10 (31.3) | 14 (66.7) | 24 (45.3) |
| Year of registry enrollment, n (%) | | | |
| 2012 | 17 (53.1) | 4 (19.0) | 21 (39.6) |
| 2013 | 15 (46.9) | 17 (81.0) | 32 (60.4) |
| **aHUS Disease Characteristics** | | | |
| | Treated with Eculizumab (N=32) | Never Treated with Eculizumab (N=21) | Total (N=53) |
| Mean age at initial symptoms (SD), yrs | 37.7 (19.84) | 24.2 (13.63) | 33.1 (18.94) |
| Mean age at diagnosis (SD), yrs | 39.2 (19.00) | 25.8 (15.97) | 34.5 (18.95) |
| Family history of aHUS, n (%) | 4 (12.5) | 6 (28.6) | 10 (18.9) |
| Prior kidney graft, n (%) | 4 (12.5) | 1 (4.8) | 5 (9.4) |
| Prior dialysis, n (%) | 15 (46.9) | 4 (19.0) | 19 (35.8) |
| Prior PE/PI, n (%) | 17 (53.1) | 4 (19.0) | 21 (39.6) |
| **Treatment Characteristics** | | | |
| | Treated with Eculizumab (N=32) | | |
| Mean age at eculizumab treatment initiation (SD), yrs | 38.1 (18.38) | | |
| Median dose at initiation of eculizumab (mg) | 900.0 | | |
| Mean time on eculizumab(SD), yrs | 0.9 (0.85) | | |
| Discontinuation of eculizumab, n (%) | 2 (6.3) | | |
| Restart of eculizumab (among those who discontinued), n (%) | 1 (50.0) | | |

Mean age at treatment initiation was 38 yrs, and mean time on ECU was 0.9 yr. Two pts discontinued ECU, with 1 of 2 restarting.

**Conclusions:** Analyses of data obtained through the aHUS Registry will increase our understanding of the history and progression of aHUS, and may help optimize pt care and quality of life. New clinical sites are encouraged to participate.

*Funding:* Pharmaceutical Company Support - Alexion Pharmaceuticals

## SA-PO854

**Spectrum of HIV-Associated Kidney Disease in the Era of Combination Antiretroviral Therapy**

John W. Booth,[1] Stephen Paul McAdoo,[2] Emil A. Kumar,[2] Tabitha Turner-stokes,[1] Partha Das,[3] Claire Melinda Naftalin,[3] Nadia Khatib,[5] Catherine Horsfield,[3] Patrick J. O'Donnell,[3] Deborah I. Williams,[4] Ed Kingdon,[4] Jyoti B. Baharani,[5] Bruce M. Hendry,[3] Rachel Hilton,[3] Jeremy B. Levy,[2] Rachael Jones,[6] John O. Connolly,[1] Frank A. Post.[3] *[1]UCL; [2]Imperial College; [3]King's Health Partners; [4]Brighton; [5]Birmingham; [6]Chelsea & Westminster NHS Trust, London, United Kingdom.*

**Background:** The spectrum of kidney disease in HIV positive patients has changed as a result of effective combination anti-retroviral therapy (cART) and ageing but remains poorly described.

**Methods:** We reviewed consecutive renal biopsies (2000-2012) of HIV+ patients attending eight clinics in the UK. We describe the clinical characteristics of 199 of 250 patients with HIVAN/FSGS (67), immune complex kidney disease (ICKD, 86) and tubulo-interstitial disease (TID, 46). Kruskall-wallis test was used to compare medians, chi squared test for proportions, and log-rank test to compare Kaplan-Meier estimates of end-stage kidney disease (ESKD).

**Results:** Patients with HIVAN and primary FSGS (NOS) were indistinguishable. ICKD encompassed membranous (16), undifferentiated immune complex disease (NOS) (34), IgA (26), MPGN (5) and SLE nephritis (5). TID included TIN (18), acute tubular injury (16) and interstitial fibrosis with tubular atrophy (12). Patients with HIVAN/FSGS, ICKD and TID differed by ethnicity (black: 97, 48, 36 %), median known duration of HIV (0.1, 6.3, 9.6 years), degree of immunodeficiency (median CD4 nadir 56, 128, 117; median CD4 at biopsy 122, 389, 289) and severity of CKD (median eGFR 23, 55, 33) ($p<0.001$ for all). At biopsy, 35, 68, 76 % of patients had initiated cART and 19, 53, 72 % had HIV RNA <200 c/mL; at 1 and 5 years post-biopsy, 28, 7, 7 % and 54, 21, 14 % of patients had progressed to ESKD ($p<0.001$ for all).

**Conclusions:** In this cohort, HIVAN/FSGS was typically present at HIV diagnosis. Patients with ICKD and TID were frequently stable on ART with suppressed HIV replication at biopsy. All forms of CKD were associated with a history of advanced immunodeficiency suggesting that early HIV diagnosis and appropriate cART initiation may constitute a renal risk reduction strategy.

## SA-PO855

**Tubulointerstitial Fibrosis Not Glomerular Sclerosis Predicts 1 Year Kidney Function after Donation**

Daisuke Ichikawa,[1] Sayuri Shirai,[1] Yugo Shibagaki,[1] Atsuko Ikemori,[2] Masahiko Yazawa,[1] Kayori Tsuruoka,[1] Naohiko Imai,[1] Takashi Yasuda,[1] Kenjiro Kimura.[1] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Japan; [2]Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Japan.*

**Background:** Studies have shown that the risk of end-stage renal disease in kidney donors appears to be similar to that in the general population; however, very little isknown about which histological findings correlate well with the prognosis of kidney function in healthy adults with a unilateral kidney. Here we investigated which parameters affected prognosis 1 year after donation.

**Methods:** This was a retrospective observational cohort study. The study included 41 consecutive adult living-related kidney donors who underwent kidney biopsy at the time of kidney grafting (0-hour donor kidney biopsy: 0hB) between 2009 and 2012. Data of kidney function by estimated glomerular filtration rate (eGFR) and risk factors at the time of donation were obtained from the medical records, and the kidney function of the donors was followed for 1 year. Biopsy tissues were evaluated for glomerular sclerosis (GS) rate (%),interstitial fibrosis (IF) rate (%), grade of arteriosclerosis (AS), and existence of arteriolosclerosis (ALS).

**Results:** A high IF rate was associated with a low eGFR at the time of 0hB ($r = 0.46$, $P < 0.01$), while a high GS rate was not with a low eGFR ($r = 0.08$). Grade of AS and existence of ALS did not affect eGFR. This association between the 4 histological findings and eGFR persisted at least for a year after donation. A decreasing eGFR a year after donation was only associated with a high IF rate. IF was evaluated, and the donors were divided into 4 quantile groups. The decreasing eGFR a year after donation was significantly higher in the highest IF group (> 10.5%) than in the lowest IF group (< 5.18%) ($P< 0.05$).

**Conclusions:** IF affected the progression of renal dysfunction 1 year after donation, while GS did not affect it. In healthy adults with a unilateral kidney, it is necessary to carefully check for severe IF.

## SA-PO856

**Syk Activation in Leucocytes in Acute Human Glomerulonephritis**

Jessica Ryan,[1,2] John Kanellis,[1,2] David J. Nikolic-Paterson.[1,2] *[1]Dept of Nephrology, Monash Medical Centre, Clayton, Victoria, Australia; [2]Dept of Medicine, Monash Univ, Clayton, Victoria, Australia.*

**Background:** Spleen tyrosine kinase (Syk) plays an important role in Fc-γ receptor signaling. Syk inhibition is protective in rodent models of antibody-dependent glomerular disease; however, the potential role of Syk in human glomerulonephritis (GN) has not been investigated. Therefore, we examined activation of Syk in a range of human GN biopsies bydetecting phosphorylation of Tyr525/526 in the Syk activation loop (p-Syk).

**Methods:** Immunostaining for p-Syk, neutrophils and CD68+ macrophages was performed in renal biopsy sections in a cohort of 96 patients, which included: MCD (3), TBMD (8), post-infectious GN (5), Class IV SLE (19), ANCA vasculitis (13), IgAN (31), membranous nephropathy (7) and FGS (10).

**Results:** MCD and TBMD, which are diseases generally not associated with leucocytic infiltration or antibody deposition, had no infiltrating p-Syk+ cells. Likewise membranous GN and FGS had few glomerular p-Syk+ cells. In contrast, the proliferative GNs had numerous glomerular p-Syk+ cells (PIGN>ANCA vasculitis>Class IV SLE>IgA Nephropathy). p-Syk was seen in infiltrating glomerular leukocytes, mainly neutrophils and some macrophages, in 36/40 cases of crescentic GN. Glomerular p-Syk+ cells had a strong correlation with infiltrating neutrophils ($r = 0.85$, $P < 0.001$), and a weaker correlation with macrophages ($r = 0.22$, $P < 0.05$). Likewise interstitial p-Syk+ cells correlated with neutrophils and macrophages ($r = 0.63$ and $r = 0.35$ respectively, both $P < 0.01$). Glomerular and interstitial p-Syk+ cells correlated with renal function (GFR ml/min $r = -0.25$ and $-0.22$ respectively, both $P <0.05$) and systemic inflammation (C-reactive protein $r = 0.28$ and $r = 0.35$ respectively, both $P < 0.05$), but not proteinuria.

**Conclusions:** Syk is activated in infiltrating neutrophils and macrophages in acute forms of antibody-dependent glomerular disease. These findings support the therapeutic use of Syk inhibitors in rapidly progressive crescentic glomerulonephritis.

*Funding:* Government Support - Non-U.S.

## SA-PO857

**Baseline Immunosuppression Exposure in Neptune Study Cohort**

Keisha L. Gibson,[1] J. Troost,[2] Howard Trachtman,[2] Christine Sethna,[2] Alessia Fornoni,[2] Richard A. Lafayette,[2] Susan L. Hogan,[2] Michelle A. Hladunewich,[2] Matthias Kretzler,[2] Debbie S. Gipson.[2] *[1]UNC Kidney Center, Univ of NC at Chapel Hill, Chapel Hill, NC; [2]The Nephrotic Syndrome Network (NEPTUNE).*

**Background:** The Nephrotic Syndrome Study Network (NEPTUNE) includes a multicenter, prospective cohort of adults and children with proteinuria and a clinical indication for initial renal biopsy. We aimed to characterize the pre-biopsy immunosuppressive therapy (IST) and clinical features associated with therapy among the initial 313 enrollees.

**Methods:** IST was categorized as steroids only, calcineurin inhibitor, mycophenolate, cytoxan, multiple (MIST), and none. Indications for biopsy were classified as steroid dependent (SDNS), frequently relapsing (FRNS), steroid resistant (SRNS), or diagnosis. ANOVA and chi-squared tests were used for analysis. Data are presented as n(%) and median(interquartile range).

**Results:** 51(24%) of adults and 69(71%) of children were treated with IST ($p<0.01$). Median months cumulative IST was 2.0(14.0) adults and 6.0(10) children, $p <0.01$. Compared to adults without IST, adults with IST did not differ in terms of age of onset, obesity or race. Adults with IST compared to those without IST were more likely to have FRNS, SDNS or SRNS as the biopsy indication (8% v 0%, p=0.02), less likely to have FSGS (14% v 39%, $p <0.01$), and more likely to have MCD (27% v 7%, $p <0.01$). Children had greater exposure to second line or MIST compared to adults (37% v 7%, $p<0.01$). Children without IST were more likely to be black (64% v 36%, p =0.01), over age 12 years (68% v 20%, $p <0.01$) and obese (46% v 34%, p=0.04) and differed by histopathology (FSGS 44% v 25%; MCD 19% v 68%; other 38% v 5%, $p<0.01$) compared to children treated with IST.

**Conclusions:** In this contemporary prospective longitudinal cohort, a surprising 24% of adults with proteinuria are exposed to IST prior to initial clinically indicated kidney biopsy. Only a fraction of these have a history of childhood onset disease. Conversely, 29% of children did not have IST pre-biopsy. These children were more commonly of black race, older age, and obese. Pre-biopsy therapy in these pediatric settings is consistent with North American Clinical Practice Guidelines.

## SA-PO858

**A Noninvasive Biomarker for Aristolochic Acid Exposure Detected in Exfoliated Urinary Cells** Tao Su,[1] Xiaomei Li,[1] Li Yang,[1] Byeong Hwa Yun,[2] Robert Turesky,[2] Arthur P. Grollman,[3] Kathleen G. Dickman.[3] *[1]Peking Univ First Hospital, Beijing, China; [2]NY State Dept of Health, Albany, NY; [3]Stony Brook Univ, Stony Brook, NY.*

**Background:** Aristolochic acid (AA), a nephrotoxin and upper tract urothelial carcinogen, is a component of all *Aristolochia*-based herbal drugs. In cases of suspected exposure, analysis of blood or urine for the presence of AA is not useful, as CKD and/or urothelial cancer can appear months to years following drug withdrawal. However, reactive AA metabolites form stable adducts with DNA that are resistant to repair and persist in cells with low turnover rates. Here we test the feasibility of detecting aristolactam (AL)-DNA adducts in urinary cells and evaluate their utility as a noninvasive biomarker of AA exposure in CKD patients with a documented history of *Aristolochia* use.

**Methods:** Cells were collected by centrifugation of 12-24 hour urine specimens from 40 patients; six cases were excluded due either to insufficient DNA for analysis or incomplete clinical data. AL-DNA adducts extracted from these cells were measured by $^{32}$P-postlabeling methodology or mass spectrometry.

**Results:** Based on eGFR, 32/34 patients had CKD, the majority at stages 4 or 5. All but two patients reported using *Aristolochia;* urinary AL-DNA adducts were absent in these two cases. Adducts, with levels ranging from 0.3-581 adducts/$10^8$ nucleotides, were detected in 28/32 of the remaining cases, representing a wide range of AA exposure times (2 mo-20 yrs), cumulative doses (0.14-19 g), and time following withdrawal (2 d-8 yrs). Adducts were found in 13/13 of cases with recent discontinuation of *Aristolochia* use (‹3 mo), and could still detected for as long as 8 yrs after the last exposure. Upper tract urothelial cancer was present in three patients at the time of sampling (adducts in 2/3) and developed in three additional adduct-positive patients during an 8-yr follow-up.

**Conclusions:** AL-DNA adducts can be detected in urinary cells several years after discontinuation of *Aristolochia* use. This noninvasive biomarker can be used to screen for persons at risk of developing AA nephropathy and upper tract urothelial cancer, providing an opportunity for early detection and intervention.

## SA-PO859

**GQ-16, a New Peroxisomal Proliferator Activated, Receptor Gamma Represses Cell Proliferation and Tumor Necrosis Factor Alpha Promoter in Human Mesangial Cells** Alexandre Martini,[1] Michela Soares Coelho,[1] Francisco R. Neves.[1] *[1]Molecular Pharmacology Laboratory, Faculdade De CiêNcias Da Saúde, Universidade de Brasília, Brasilia, DF, Brazil; [2]National Institute of Science and Technology for Pharmaceutical Innovation, Universidade Federal de Pernambuco, Recife, PE, Brazil.*

**Background:** Tumor necrosis factor (TNF-α) induces mesangial proliferation and participates in kidney disease. Peroxisome proliferator activated receptor gamma (PPAR¡) agonists (pioglitazone –PIO and rosiglitazone - ROSI) improve insulin sensitivity and also ameliorate renal disease by their antiinflammatory action. Unfortunately, these ligands have been beset by side effects including weight gain, edema and cardiovascular toxicity. We developed a new compound (GQ-16) that exhibits partial PPARγ agonism, and a robust anti-diabetic activity in mice, yet did not elicit weight gain or edema. Here we investigate the role of GQ-16 on transcriptional activity of TNF-α promoter and mesangial cells (MC) proliferation upon TNF-α treatment.

**Methods:** Human MC were incubated at 37°C in DMEM supplemented with 10% fetal calf serum, treated with TNF-α (10 ng/mL) and GQ-16 (1μM to 50 μM) or PIO and ROSI at 1 μM. Thymidine incorporation assay was performed to evaluate mesangial cell proliferation. Gene reporter assays were carried out using luciferase reporter driven by human TNF-α promoter (fragment from -125 to -82), and the activity was measured in a luminometer. The data were analyzed by one-way ANOVA.

**Results:** In MC, GQ-16 significantly impaired TNF-α induced cell proliferation, in a dose-response curve (1μM -32%; 10μM -35% and 50 μM -52%). These results were similar to PIO (10μM -39%) and ROSI (10μM -35%). Also, GQ-16 significantly reduced transcriptional activity of human TNF-a promoter in a dose response manner. The IC50 of GQ-16 (91,98 nM) was 26 times higher than ROSI (3,46 nM), but at the highest concentration this response was comparable to ROSI.

**Conclusions:** These results suggest that in human MC, GQ-16 exerts an antiproliferative and represses the transcriptional TNF-α promoter activity through PPAR¡ suggesting an antiinflammatory effect similar to ROSI.

## SA-PO860

**Glomerulonephritis (GN) in a Chronic Kidney Disease (CKD) Population** Andrew John Mallett,[1,2,3] Anne Salisbury,[1,2,3] Zaimin Wang,[1,2] Helen G. Healy,[1,2,3] George T. John,[1,3] Wendy E. Hoy.[1,2] *[1]CKD.QLD; [2]Centre for Chronic Disease, School of Medicine, Univ of Queensland, Brisbane, Queensland, Australia; [3]Dept of Renal Medicine, Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia.*

**Background:** GN is a heterogenous group of disorders accounting for 23% of Australian and New Zealand patients commencing renal replacement therapy in 2011. The characteristics of this group in Australian CKD populations requires require definition.

**Methods:** Aim: To define characteristics of CKD patients with glomerulonephritis. CKD.QLD is a registry and research platform involving all consenting patients in public renal practices in Queensland. Primary Renal Disease coding on the 2359 patients enrolled from 5 sites were searched for GN patients according to ANZDATA GN codes. These patients were compared to all patients in the CKD.QLD registry for age, gender and CKD stage.

**Results:** 286 GN patients were identified, representing 12.1% of the total. Of these 87 (30.5%) had Miscellaneous GN (MiscGN), 64 (22.5%) had GN with Systemic Involvement (GNSI), 63 (22.1%) had IgA Nephropathy (IgAN), 45 (15.8%) had Focal Segmental Glomerulosclerosis (FSGS), 21 (7.4%) had Membranous Nephropathy (MN) and 5 (1.8%) had Membranoproliferative GN (MPGN). There was similar prevalence among the 5 sites (9.6-13.3%).

CKD Stage 2 was most common for MN (38%) and FSGS (31%) whereas CKD Stage 4 was most common for MiscGN (27.6%), MPGN (60%) and GNSI (23.4%). CKD Stage 3b was most common for all GN combined (22.1%) and IgAN (27%).

48% of GN patients were female compared to 45% in the whole CKD.QLD registry. Females were most prevalent in GNSI (59.4%) and FSGS (51%), but males were more common in MN (76.2%).

Mean age was similar in all GN groups (51.6-58.8 years) with a mean of 54.2 years. Mean age for the whole CKD.QLD registry was 65.5 years. The most common age group for all GN was 55-64yrs (24.6%) compared to 65-74 years (29.2%) for all CKD.QLD.

**Conclusions:** There are significant numbers of patients with GN in these Australian CKD populations. They are younger than the aggregate CKD population. Stage and gender differ among several GN subgroups. Continued patient registration will allow enhanced GN subgroup analysis.

## SA-PO861

**The Spectrum of Glomerular Diseases in Central Region of Saudi Arabia: A 5 Year Retrospective Study** Naveed Aslam, Ebadur Rahman, Dujanah Hassan Mousa, Seddeg Younis, Ahmed Soliman, Raees Farhan Mushtaq. *Nephrology, Prince Sultan Military Medical City, Riyadh, Saudi Arabia.*

**Background:** Glomerular diseases continue to be the leading cause of end-stage renal disease globally. Hence it is important to recognize the glomerular disease pattern in any given geographical area to understand the pathobiology, incidence and progression of the disorder in that region.

**Methods:** A total of 348 native renal biopsies performed on patients with proteinurea > 1 gm, haematuria or renal impairment during a period of 5 years (between January 2005 and December 2009) in a tertiary care hospital of Kingdom of Saudi Arabia. All the biopsies were studied by histopathologist by (light microscopy, immunofluorescence and electron microscopy) and categorized. SAS version 9,2 was used for statistical analysis.

**Results:** Primary glomerular disease accounted for 55.1% of all renal biopsies. The most common histological lesion was focal segmental glomerulosclerosis (FSGS) (27.6%). Minimal change disease (MCD) was the second most common lesion (17.7%) followed by membrano-proliferative glomerulonephritis (MPGN)(13.0%) and IgA nephropathy (IgAGN) 11,5%. Secondary glomerular disease contributed to 37.9% of glomerular diseases with lupus nephritis (LN) as the commonest lesion (54.5%) followed by hypertension (HTN) (22%), post-infectious (7.5%), diabetic nephropathy (DN) (6.8%) and vasculitides (4.5%). We came across14 cases of crescentic glomerulonephritis (5 vasculitic, 2 post-infectious, 1 lupus nephritis, 1 IgA nephropathy, 1 mesangioproliferative, 1 diffuse proliferative and 3 not specified). ESRD accounted for 4 % of all renal biopsies whereas inadequate biopsies constituted 2.8 % of all the tissues.

**Conclusions:** This study demonstrates FSGS as the most common primary GN encountered in the studied cases, the second most frequent is MCD. Lupus nephritis is the most common secondary GN. The results of this study were compared with surveys from other studies in same region and rest of the world. Pattern of glomerulonephritis seems to vary in different regions of Saudi Arabia. We believe that Renal Biopsy Registry is mandatory to better understand the pattern of glomerular disease and to follow any trend change.

## SA-PO862

**Glomerular Descriptors Enhance Standard Renal Biopsy Diagnoses** Cynthia C. Nast,[1] L. Barisoni,[2] J. Troost,[3] A. Gasim,[4] Gerald B. Appel,[5] Daniel C. Cattran.[6] *[1]Cedars-Sinai; [2]U Miami; [3]U Mich; [4]UNC; [5]Columbia U; [6]U Toronto.*

**Background:** The Nephrotic Syndrome Study Network (NEPTUNE) has characterized a cohort with proteinuria, including FSGS and minimal change disease (MCD). In addition to standard morphologic diagnoses, biopsies are assessed using "descriptors" of renal lesions. Based on this evaluation, MCD was subclassified into MCD with only glomerular foot process effacement (FPE) (MCD-) and MCD with any other glomerular lesion (global sclerosis, ischemia, hypercellularity) (MCD+). These 3 groups (FSGS, MCD-, MCD+) were analyzed to discern whether presenting clinical features and FPE extent correlate with this descriptor-based subclassification.

**Methods:** 75 FSGS, 41 MCD- and 17 MCD+ patients had biopsies evaluated for FPE by two semiquantitative systems (3 or 5 grades), and analyzed relative to patient age, sex, baseline hypertension (HTN), urine Pr/Cr ratio, eGFR, and pre-biopsy steroid treatment.

**Results:** Sex ratio was similar, but ages differed in the groups (FSGS 36.3 yrs, MCD+ 27.9 yrs, MCD- 12.8 yrs, $p<.0001$). Urine Pr/Cr ratios were not different, but eGFR was lower in FSGS (73.6) vs. both MCD groups (MCD+ 111.6, MCD- 115.5; both $p<.0001$ vs FSGS). HTN was more common in FSGS and MCD- vs. MCD+ ($p<.02$). Overall, FPE extent and proteinuria correlated when groups were combined ($p<.0001$); however, there was no significant correlation when groups were separated regardless of the score system used.

Pre-biopsy steroid exposure was more frequent in MCD- (71%), less in MCD+ (56%) and least in FSGS (22%) ($p<.0001$); this difference occurred in children but more prominently in adults. Prior steroid treatment correlated with FPE extent only in MCD- ($p<.05$).

**Conclusions:** At baseline, FSGS patients were older with lower eGFR, more frequent HTN, and were less likely to receive pre-biopsy steroids. MCD+ had features between FSGS and MCD- including HTN, and intermediate age and pre-biopsy steroid exposure, with FPE similar to FSGS. This suggests morphologic glomerular descriptors may be used to identify a distinct clinical cohort in MCD. FPE overall correlated with degree of proteinuria, but did not discriminate among these diagnostic groups.

## SA-PO863

### Masked Monoclonal Membranous-Like Glomerulopathy

Christopher Patrick Larsen, Nidia Cordeiro Messias, Larry N. Cossey, Josephine M. Ambruzs, Patrick D. Walker. *Nephropath, Little Rock, AR.*

**Background:** Routine direct immunofluorescence on fresh tissue is the gold standard for the detection and characterization of immune deposits. We recently have observed an unusual form of glomerulonephritis in which the deposits are "masked" and require an antigen retrieval step to be visualized. Correlation with the patient information reveals this to be a unique clinicopathologic syndrome not previously described. We have termed this entity masked monoclonal membranous-like glomerulopathy (MMMG).

**Methods:** We identified 14 cases of MMMG in our case files over the past two years. LM, IF, and EM was performed in all cases. Retrospective analysis of clinical information was also gathered.

**Results:** The cases were characterized by subepithelial deposits and C3-predominant staining by routine immunofluorescence with weak to negative immunoglobulin staining. Repeat immunofluorescence after pronase digestion of the FFPE tissue demonstrated strong IgG with kappa restriction. Four patients had evidence of crescent formation without endocapillary proliferation. The remaining cases showed no proliferative changes. The patients were most commonly female (12/14) with a mean age of 24.8 years and 8/14 (62%) had evidence of vague autoimmune phenomenon. The clinical and demographic findings in MMMG patients do not correspond with those typically found in patients with monoclonal membranous glomerulopathy or proliferative glomerulonephritis with monoclonal IgG deposition as these patients were significantly older (mean age of 69.2 and 67.3, respectively) and rarely showed evidence of autoimmune phenomenon. Follow-up data in 9 patients showed one complete remission, 2 partial remissions and 6 with persistent disease (mean 14.9 months, range 2– 46 months).

**Conclusions:** We present the first description of a novel form of glomerulopathy that occurs predominantly in young females with vague autoimmune symptoms and proteinuria. The specific glomerulopathy is only revealed after addition of antigen retrieval. Previously, MMMG has likely been misdiagnosed as an atypical form of membranous glomerulopathy, infection-related glomerulonephritis, or C3 glomerulopathy.

## SA-PO864

### Quantitative T2 MRI to Measure Kidney and Liver Disease Progression in Autosomal Recessive Polycystic Kidney Disease (ARPKD)

Ying Gao,[1,2] Bernadette O. Erokwu,[1] Lan Lu,[1] Chris Flask,[1,2,3] Katherine MacRae Dell.[3,4] *[1]Depts of Radiology; [2]Biomedical Engineering; [3]Pediatrics; [4]CWRU Center for the Study of Kidney Disease and Biology, Case Western Reserve Univ, Cleveland, OH.*

**Background:** ARPKD is associated with significant morbidity and mortality in affected patients; however, there are no clinically-available methods to measure kidney and/or liver disease progression except in advanced stages, severely limiting the study of novel therapies in patients. We previously utilized quantitative T2 MRI to assess kidney and liver disease in the PCK rat. In the current study, we used T2 MRI to longitudinally examine disease progression.

**Methods:** Eight PCK rats were scanned at 1-, 2- and 3-mos of age in a 7T Bruker Biospec MRI scanner. Multislice, coronal kidney and sagittal liver images were obtained with a flow-saturated, respiration-gated, multiecho spin echo acquisition. For kidneys, T2 values were calculated using a linear least squares regression of a monoexponential decay model. Cysts (↑T2 values) and normal tissue (↓T2 values) were distinguished by manual thresholding. For liver, T2 values were calculated based on mean values of whole regions of interest via a nonlinear least squares fitting of a biexponential decay model. Means and standard deviations (SD) for disease and normal tissues were calculated at each time point and analyzed using 2-tailed Student's t-tests.

**Results:** For kidneys, the cystic volume increased over the 2 month study period. Mean±SD (%cystic) at 1,2,and 3 mos were 27.4±4.2%, 31.1±4.5% and 43.8±4.3%. Significant differences ($p=0.00006$) were seen in the 2-3 mos interval but not the 1-2 mos interval. For livers, mean T2 values (indicating increased biliary duct dilatation vs.normal parenchyma) also increased. Mean±SD values (msecs) at 1, 2, and 3 mos were 54.3±9, 64.4±7.8 and 74.6±9. Significant differences were seen at both the 1-2 mos ($p=0.032$) and 2-3 mos ($p=0.035$) intervals.

**Conclusions:** Quantitative T2 MRI assessments of PCK rats detected significant kidney and liver disease progression over the relatively short time intervals studied. These techniques, which are readily translatable to human imaging, may provide a useful assessment of disease progression in ARPKD patients as well.

## SA-PO865

### Maternal Anti-Human Laminin α5 IgG Causes Anti-GBM Disease in Perinatal Transgenic Mice Expressing Human Laminin α5

Brooke M. Steenhard, Larysa Stroganova, Adrian T. Zelenchuk, Patricia St. John, Dale R. Abrahamson. *Anatomy and Cell Biology, and the Kidney Institute, Univ of Kansas Medical Center, Kansas City, KS.*

**Background:** Mammalian immune systems do not mature until well after birth, but transfer of maternal IgG to the fetus and newborn usually provides sufficient immunoprotection from infectious diseases. This IgG transfer occurs before birth in humans across the placenta and in many mammalian species, including rodents, continues after birth across the intestine. The transfer is selective and occurs by transcytosis across placental syncytiotrophoblasts and intestinal epithelium, which is mediated by the neonatal IgG Fc receptor (FcRn). Although maternal IgG is generally beneficial, maternal autoimmunity can be transferred to the fetus/infant, causing diseases such as myasthenia gravis, bullous pemphigoid, thrombocytopenic purpura, and systemic lupus erythematosus, including lupus nephritis.

**Methods:** Previously, we generated transgenic (Tg) mice that express human laminin α5 (huLama5) in basement membranes throughout the body (Steenhard et al., PLoS ONE 6(9): e23926, 2011). These Tg mice suppress murine Lama5 mRNA transcription and mouse laminin α5 protein deposition, but heterozygous animals have no renal phenotype.

**Results:** When we crossed huLama5 Tg males with wildtype (wt) females, we discovered development of a maternal anti-huLama5 immune response (presumably induced by embryonic Tg basement membranes) and maternal sera contained IgG that bound linearly to basement membranes of human kidney cryosections. Maternal alloantibody also crossed the placenta in vivo and bound in bright, linear patterns to glomerular basement membranes (GBMs) of Tg fetuses but not those of wt siblings. Foster nursing of Tg pups showed post-natal transfer of maternal anti-huLama5 IgG through suckling as well, which also bound to GBMs of Tg pups but not wt. By 18d, most Tg mice had glomerular C3 deposits. Electron microscopy showed neutrophil and monocyte infiltrates, thickened and split GBMs, and podocyte foot process effacement.

**Conclusions:** This novel model of perinatal anti-GBM disease may be useful for determining effects of autoantibodies on glomerular development in vivo.

## SA-PO866

### Remodeling of Renal Urothelium Characterizes Renal Adaptation to Congenital Obstructive Nephropathy in the Megabladder Mouse

Ashley R. Carpenter,[1,2] Brian Becknell,[3] Jordan Allen,[4] Kirk M. McHugh.[1] *[1]Center for Molecular and Human Genetics, Nationwide Children's Hospital; [2]Biomedical Sciences Graduate Program, The Ohio State Univ; [3]Div of Nephrology, Nationwide Children's Hospital; [4]College of Medicine, The Ohio State Univ.*

**Background:** The *megabladder* (*mgb*) mouse model of congenital obstructive nephropathy (CON) presents the opportunity to describe renal adaptation to urinary tract obstruction. *Mgb*$^{-/-}$ mutants develop functional lower urinary tract obstruction due to a lack of proper detrusor muscle organization *in utero*, which leads to chronic kidney disease and death in early adulthood. To better understand the molecular mechanisms responsible for renal adaptation in CON, we performed transcriptome analysis of *mgb*$^{-/-}$ kidneys compared to controls.

**Methods:** Kidneys from age-matched male *mgb*$^{-/-}$ and wild type control mice were evaluated by ultrasound, Agilent cRNA microarray, qPCR and immunohistochemistry (IHC).

**Results:** Microarray analysis comparing severe *mgb*$^{-/-}$ kidneys with controls identified upregulation of urothelium-specific genes. These genes encompassed uroplakins (*Upk1a*, *1b*, *2*, *3a* and *3b*), cytokeratins (*Krt5*, *14*, and *19*), urothelial transcription factors (*Grhl3*, *Foxa1*) and additional genes with proposed functions in maintaining the urine permeability barrier (*Sprr1a*, *Gjb6*, and *Gsdmc4*). We confirmed increased expression of each of these transcripts by qPCR ($p<0.05$). Notably, *Upk1b* and *Krt14* mRNA were found to statistically differ in control versus mildly hydronephrotic *mgb*$^{-/-}$ kidneys. We characterized expansion of Upk3a and Krt14 protein expression and a significant increase in the number of Ki-67-positive proliferating cells along the renal urothelium as hydronephrosis worsened.

**Conclusions:** In the *mgb* mouse model of CON, proliferation and upregulation of urothelium-specific genes reflect an early adaptive response in the obstructed kidney. Further understanding of the molecular pathways responsible for urothelial proliferation and remodeling during renal adaptation will yield insights into the pathophysiology of chronic kidney disease as well as identify early diagnostic and prognostic markers of CON.

*Funding:* NIDDK Support

## SA-PO867

### Molecular Basis of Renal Adaptation in a Murine Model of Congenital Obstructive Nephropathy

Ashley R. Carpenter,[1,2] Brian Becknell,[1,3] Melissa Scott,[1] Michael Wilhide,[1] Susan E. Ingraham,[1,3] Kirk M. McHugh.[1] *[1]Research Institute, Nationwide Children's Hospital; [2]Biomedical Sciences Graduate Program, The Ohio State Univ; [3]Div of Nephrology, Nationwide Children's Hospital.*

**Background:** Congenital obstructive nephropathy (CON) is a common cause of pediatric chronic kidney disease (CKD) and a leading indication for renal transplant in children. The cellular and molecular responses of the kidney to CON are incompletely

characterized. In this study, we evaluated global transcription in kidneys with graded hydronephrosis in the *megabladder* (*mgb*$^{-/-}$) mouse.

**Methods:** Kidneys from age-matched male *mgb*$^{-/-}$ and control mice were graded by ultrasound, evaluated by Agilent cRNA microarray, and validated by qPCR and immunohistochemistry.

**Results:** This analysis indicates that CKD in the *mgb*$^{-/-}$ mouse model of CON involves a delicate balance between three canonical pathways including TGFβ directed pathogenesis, retinoic acid (RA) mediated remodeling/repair and steroid hormone modulation. Over half of the top twenty canonical pathways identified in this study involved renal response to injury, an observation that confirms our prior morphological and biochemical studies. The role of RA in kidney development has been well characterized and the results of this study suggest that these developmental functions are recapitulated during pathogenesis as a transient repair mechanism. Steroid hormones appear to play a dual modulatory role during renal adaptation that includes suppression of an acute inflammatory response as well as modulation of the genetic programs controlling cellular differentiation. Finally, this study identified the skewed expression of a group of sexually dimorphic genes in male *mgb*$^{-/-}$ kidneys as well as de-repression of Hdac target genes. These observations provide a potential mechanism for gender-based differences in renal pathogenesis.

**Conclusions:** The results of this study indicate that CKD in *mgb*$^{-/-}$ mice results in a highly orchestrated adaptive response that is designed to prevent permanent renal injury and permit rapid morphological and functional recovery. These observations will permit the development of novel biomarkers and therapeutic approaches to progressive renal injury in the context of CON.

## SA-PO868

**Global and Gene-Specific Hypomethylation by Maternal Undernutrition in Rat Embryonic Kidney** Midori Awazu, Mariko Hida. *Dept of Pediatrics, School of Medicine, Keio Univ.*

**Background:** Maternal undernutrition leads to low nephron number. We reported that ureteric bud branching is reduced and that genes involved in ureteric branching are methylated by maternal nutrient restriction in rat embryonic kidney. On the other hand, maternal undernutrition decreases global methylation in the baboon kidney. Since increased methylation traditionally decreases gene expression, we examined whether genes involved in negative regulation of kidney development are hypomethylated by maternal undernutrition.

**Methods:** The kidneys of embryonic day 18 fetuses from dams given food ad libitum (CON) and those subjected to 50% food restriction throughout pregnancy (NR) were examined. Global methylation was assessed by methylated DNA quantification kit. The methylation landscape around promoter CpG islands was analyzed using methylated DNA immunoprecipitation (MeDIP) coupled with microarray (NimbleGen Rat ChIP-chip 385K Promoter array) comparing methylated fractions of CON and NR. MeDIP probe significances were generated using the Kolmogorov–Smirnov test as implemented by NimbleScan. These values were transformed (-log10) to give peak scores, which reflect the probability of methylation at a p-value of less than 0.01.

**Results:** Global methylation was reduced in NR compared with CON by 30%. Of 15911 promoter regions included in the array, 7330 were hypomethylated in NR. Genes categorized into negative regulation of biological process were more frequently hypomethylated in NR vs CON (338 vs 262). The number of hypomethylated genes in the categories of pro-apoptosis was not different between CON and NR. Hypomethylated genes in NR known as negative regulators of kidney development were, in descending order of peak score, activin A receptor type IC, axin 1, STAT1, Osr1, TACSTD2, spry1, TGF-ß receptor II, activin A receptor type I, sema3a, noggin, and GSK3ß, most of which are implicated in branching morphogenesis. Pro-apoptotic genes that were hypomethylated in NR included Fas ligand, PKCδ, and TNFα.

**Conclusions:** Maternal nutrient restriction reduces global DNA methylation and the methylation of genes involved in negative regulation of branching morphogenesis, which may contribute to the reduced nephron number.

*Funding:* Government Support - Non-U.S.

## SA-PO869

**The Switch of Proteasome to Immunoproteasome in Peripheral Lymphomonocytes of Children with Henoch Schoenlein Purpura Differs from Primary IgA Nephropathy (IgAN)** Maria Elena Donadio, Elisa Loiacono, Licia Peruzzi, Alessandro Amore, Roberta Camilla, Luca Vergano, Giuliana Guido, Rosanna Coppo. *Nephrology Dialysis Transplanation, Città della Salute e della Scienza, Turin, Italy.*

**Background:** The proteasome (PS) plays a key role in activating transcriptional factors, cytokines and in presenting antigens; moreover, under the action of interferons, becomes immunoproteasome (iPS), by substituting beta1, beta2, beta5 catalytic uniots with low molecular weight proteins (LMP2 and LMP7) and endopeptidase-like complex (MECL-1). This modification confers optimal catalytic properties for professional presentation of peptides to MHC Class I. We previously demonstrated that adult patients with IgA-Nephropathy (IgAN) have an increased expression of iPS catalytic subunit, which correlated with severity of renal disease. Aim of this study was to investigate the switch from PS to iPS in children with primary IgAN and Henoch-Schoenlein purpura (HSP), sharing several immune system abnormalities.

**Methods:** Peripheral Lymphomonocytes (PBMC) from 18 children with IgAN, 57 with HSP and 33 healthy control subjects (HC), isolated by centrifugation gradient, were tested with real time PRC (Taqman) to assess quantitatively the mRNA levels of PS alpha subunit (constitutive), of the active subunit of PS (beta1, beta2, beta5) and of iPS (LMP2, LMP7 and MECL-1).

**Results:** The normalized values and the ratio between mRNA of corresponding subunit of PS and iPS are reported in the table. Differences between means were calculated with Student t test.

| | LMP2/beta1 | LMP7/beta5 | MECL-1/beta2 |
|---|---|---|---|
| Healthy control | **0.91 ± 0.42** | 1.08 ± 0.33 | 1.02 ± 0.29 |
| IgAN | **0.82 ± 0.39** | 1.44 ± 0.92 | 1.35 ± 0.70 |
| HSP | **1.23 ± 0.66** [a,b] | 1.45 ± 1.02 | 2.34 ± 3.92 |

**Conclusions:** A significantly higher switch from LMP2/beta1 subunits of PS/iPS was observed in children with HSP in comparison to IgAN and HC, which might indicate a more active antigen presentation and increased interaction between innate and adaptative immune system in this acute condition in comparison to chronic primary IgAN.

## SA-PO870

**Novel TNXB and ROBO2 Mutations Confirm Genetic and Phenotypic Heterogeneity of Hereditary VUR** Rasheed A. Gbadegesin,[1] Alison Homstad,[1] Gentzon Hall,[1] Andrew F. Malone,[1] Guanghong Wu,[1] Indra R. Gupta,[2] Patrick D. Brophy,[2] Michelle P. Winn.[1] *[1]Pediatrics, Medicine and Center for Human Genetics, Duke Univ, Durham, NC; [2]Pediatrics and Human Genetics, McGill Univ, Montreal, Canada; [3]Pediatrics, Univ of Iowa, Iowa, IA.*

**Background:** Vesicoureteral reflux (VUR) is the most common congenital anomaly of the kidney and the urinary tract and reflux nephropathy is a major cause of chronic kidney disease (CKD) in children. The gold standard for the diagnosis of VUR is VCUG, an invasive and unpleasant diagnostic procedure. VUR shows high heritability in family studies, however the genetic causes remain elusive and opportunities for non-invasive molecular and radiologic diagnosis of VUR have not been explored.

**Methods:** The objective of this study is to identify genetic causes for VUR as a first step towards identification of non-invasive molecular tools for diagnosis. We have ascertained and obtained clinical data and biologic samples from over 330 individuals with VUR, of these; we identified 27 kindreds with hereditary VUR. As a proof of principle that molecular diagnosis is feasible in VUR, we carried out genome-wide linkage analysis (GWLA) and/or whole-exome sequencing on two families with hereditary VUR.

**Results:** We identified a missense mutation T3257I in TNXB and a novel missense mutation A304D in ROBO2. The two mutations segregated with disease in the two families. Both mutations are conserved in evolution and are predicted to be deleterious with a polyphen score of 0.99 and 1 respectively. Some affected individuals with TNXB mutation demonstrated asymptomatic joint hypermobility while the phenotype in the family with ROBO2 is isolated VUR with no underlying renal dysplasia or extra renal manifestations.

**Conclusions:** Whole exome sequencing analysis identified novel mutations in TNXB and ROBO2 in two families with hereditary VUR showing that non-invasive molecular diagnosis may be feasible in a subset of patients with VUR. Our results highlight the genetic and phenotypic heterogeneity of VUR.

**DNA Copy Number Variations in Human Alpha-Defensin 1-3 Gene Locus Are Associated with Urinary Tract Infections in Patients with Vesicoureteral Reflux** David S. Hains,[1,2] Huanyu Wang,[2] John David Spencer,[1,2] Brian Becknell,[1,2] Kirk M. McHugh,[2] Andrew L. Schwaderer.[1,2] *[1]Pediatrics, Nationwide Children's Hospital, Columbus, OH; [2]The Research Institute at Nationwide Children's Hospital, Columbus, OH.*

**Background:** DNA copy number variations (CNVs) can have profound effects on gene dosage. Specifically, CNVs in innate immunity genes, such as the alpha-defensin gene family, are associated with diseases involved with infection like HIV susceptibility. The *DEFA1A3* locus varies ranging from 2-12 copies per diploid genome. Despite the importance of alpha defensins in the immune response, CNVs in the alpha-defensin gene family have not been evaluated in patients with UTI. This study was designed to quantitate DNA copy number of alpha-defensin 1-3 (*DEFA1A3*) in patients with vesicoureteral reflux (VUR) and UTI enrolled in the RIVUR study.

**Methods:** Standard individual copy type: Southern blot and pulsed-field gel electrophoresis were performed to copy-type multiple individuals at the *DEFA1A3* locus. RIVUR study patients: 310 individuals from the RIVUR study (children with VUR and at least one UTI) were copy typed using multiplex real-time PCR and normalized to *ZNF80.* 310 age/ethnicity/gender-matched controls were also copy-typed. DNA copy calls: Exact *DEFA1A3* copy numbers were determined for each individual using known copy-typed individuals for standard curve. Tissue gene expression: Using validated exon-spanning primers for *DEFA1A3* mRNA, we copy-typed DNA and and quantitated *DEFA1A3* mRNA using real-time PCR on human kidney samples.

**Results:** On average, we identified that RIVUR patients had one less copy of *DEFA1A3* compared to controls ($p < 0.0001$). Furthermore, copy number distribution showed a significant overall skewing toward a lower copy number of *DEFA1A3* in RIVUR patients. Finally, DNA copy number correlated with mRNA message in the human kidney.

**Conclusions:** We present data in this study that suggests that lower DNA copy number in the gene for DEFA1A3 is associated with increased risk for UTI in children with VUR. Ultimately, decreased DNA copy number results in less transcribed mRNA. These findings serve as a potential risk factor when determining risk of UTIs in these patients.

**SA-PO872**

**APOL1 Variants Are Associated with LVH in the CKID Study**
Robert Woroniecki,[1] Cheryl Ann Winkler,[2] George W. Nelson,[2] Craig S. Wong,[3] Mark Mitsnefes,[4] Bradley A. Warady,[4] Susan L. Furth,[5] Frederick J. Kaskel,[6] Jeffrey B. Kopp.[2] *[1]Columbia U; [2]NIH; [3]U New Mexico; [4]Cincinnati Childrens' Hosp; [5]U Pennslyvania; [6]Albert Einstein U.*

**Background:** Left ventricular hypertrophy (LVH) is common among adults and children with chronic kidney disease, and is more common among African Americans (AA). We wished to determine whether APOL1 kidney risk alleles might contribute to this disparity.

**Methods:** We carried out a case/control study among AA subjects enrolled in the Chronic Kidney Disease in Children (CKiD) study to assess a role for *APOL1* variants in LVH. GFR was determined by plasma iohexol disappearance. Hypertension was defined according to Fourth Report for subjects ≤18 years and JNC7 for older subjects. LVH was defined by echocardiographic parameters. Proteinuria was assessed as first morning urine protein/creatinine ratio. *APOL*1 variants G1 (rs73885319, S342G) and G2 (rs71785313, NY deletion) were genotyped.

**Results:** DNA was available for 89 AA subjects, 43 (48%) had been diagnosed as ever having had hypertension and 62 underwent echocardiography. LVH was present in 9/33 (27%) of hypertensive children and 7/29 (24%) normotensive children (p=1). As expected, APOL1 risk alleles were common, with 23% of CKID subjects having 2 risk alleles compared to 12-15% in the general AA population. Two APOL1 risk alleles were present in 6/16 (38%) children with LVH and 5/45 (11%) without LVH, p=0.028. After adjustment for hypertension history, baseline GFR, and baseline proteinuria, the p value was 0.031. Among subjects with 2, compared to 0 or 1 risk alleles, the average GFR decline rates during the study were similar (10.4% vs. 8.8% respectively, p=0.82).

**Conclusions:** *APOL1* kidney risk alleles are associated with LVH in pediatric CKD. *APOL1* variants have been also associated with increased heart size at autopsy, in the absence of kidney disease (Hoy et al, Int Soc Hyperternsion 2012). It remains unknown whether the apparent effect of the *APOL1* variants on the heart arise from APOL1 gene expression in the heart or in the kidney. Further data on the duration and severity of hypertension will be required to exclude a role for hypertension as a mediator of cardiac damage.

**SA-PO873**

**Mutations in the Insulin Receptor INSR Are Associated with Hypercalciuria and Nephrocalcinosis**
Arabella Simpkin,[1] Velibor Tasic,[4] Detlef Bockenhauer.[1] *[1]Great Ormond Street Hospital, London, United Kingdom; [2]Endocrinology, Addenbrookes Hospital, Cambridge, United Kingdom; [3]NIDDK, NIH; [4]Children's Hospital Skopje, Macedonia, The Former Yugoslav Republic of.*

**Background:** The insulin receptor INSR is expressed in kidney and studies in mice suggest a role in proximal sodium reabsorption as well as in podocyte function. Yet its physiological role in human kidney is unclear. Recessive mutations in INSR lead to Rabson-Mendenhall (RMS) or Donohue syndrome (DS). Observations in such patients can illuminate the role of INSR.

**Methods:** Retrospective review of patients with confirmed biallelic INSR mutations. Data for blood pressure, renal ultrasound, plasma creatinine and electrolytes, as well as urine protein, albumin and calcium excretion were sought from the referring clinicians.

**Results:** Clinical data were provided on 13 RMS and 5 DS patients, age 2-24 years (mean±SD: 10.5±6.5 years). All patients had low normal plasma creatinine for age (mean±SD: 0.24±0.11mg/dl) and plasma electrolytes were within the normal range in all. Blood pressure centile data (N=13) ranged between the 48th and 98th percentile for age, sex, height and weight (mean±SD: 65±23). 24-h urinary data (N= 13) revealed markedly elevated urinary calcium (mean±SD: 9±6 mg/kg/d; normal <4). 24-h urinary protein excretion (N=9) was borderline high (mean±SD: 5.5±4.7 mg/kg/h; normal <4) and urinary albumin excretion (N=9) ranged from 5.7-122.5 μg/min (normal <20). Renal ultrasound (N=10) showed nephrocalcinosis in all.

**Conclusions:** In contrast to mice with targeted Insr deletion, key renal abnormalities identified in humans are hypercalciuria and nephrocalcinosis, suggesting a role for INSR in tubular calcium handling. There was no obvious glomerular dysfunction. Whilst protein and albumin excretion rates were borderline elevated, it is unclear whether this reflects a primary role of INSR in podocyte function or just the long-standing hyperglycemia in these patients.

**SA-PO874**

**In Situ Evaluation of INF2 in Normal and Glomerular Diseases in Children**
Hiroshi Tamura. *Pediatrics, Graduate School of Medical Sciences, Kumamoto Univ, Kumamoto, Japan.*

**Background:** Mutations of the inverted formin 2 gene (INF2) are common causes of autosomal dominant focal and segmental glomerulosclerosis (FSGS). Its encodes a member of the formin family, which regulates actin and microtuble cytoskeletons. This study investigated the expression of INF2 in glomerular diseases.

**Methods:** We generated rabbit polyclonal antibodies against conjugated peptides from human INF2, and studied glomerular expression of INF2 and synaptopodin using kidney tissues of normal humans and those with glomerular diseases in children.

**Results:** Anti INF2 antibodies detected the original 135kD fragment by Western blot analysis using human isolated mature glomeruli. Immunohistochemically, INF2 was detected in a linear pattern along the glomerular capillary loop. Anti INF2 antibody stained the smooth muscles of renal arterioles and aorta. Among 42 patiennts, INF2 was normally expressed in glomeruli in purupura nephritis, IgA nephropathy, lupus nephritis and minimal change disease (MCD), while it was either decreased or absent in most subjects with focal and segmental glomerulosclerosis (FSGS). The expression of synaptopodin was similar to that of INF2, although some discrepancy existed.

**Conclusions:** Although indirect, our data suggest the existence of a vascular isoform of INF2 with a different molecular mass. We propose that examination of INF2 expression may help differentiate MCD from FSGS.

**SA-PO875**

**Epidermal Growth Factor Receptor Gene Polymorphisms in Childhood IgA Nephropathy**
Byoung-Soo Cho,[1] Jin-Soon Suh,[2] Yumi Choi.[3] *[1]Dept of Pediatrics, TheAll Medibio Research Institute, Seoul, Korea; [2]Dept of Pediatrics, Bucheon St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea, Bucheon, Korea; [3]Dept of Pediatrics, School of Medicine, Kyung Hee Univ, Seoul, Korea.*

**Background:** Recent studies indicated that epidermal growth factor receptor (EGFR) activation contributes to development and progression of renal diseases in animal models of obstructive nephropathy, diabetic nephropathy, and glomerulonephritis through mechanisms involved in activation of renal interstitial fibroblasts, induction of tubular injury, overproduction of inflammatory factors and/or promotion of glomerular and vascular injury. We investigated the association between single nucleotide polymorphisms (SNPs) of the *EGFR* gene and childhood IgA nephropathy (IgAN).

**Methods:** Three synonymous SNPs (rs1140475, rs2293347 and rs1050171) and one promoter SNP (rs6965469) were analyzed in 196 patients with childhood IgAN and in 288 healthy controls. The IgAN patients were divided and compared with respect to the presence of gross hematuria as a initial symptom, proteinuria and nephrotic-range proteinuria during disease course, and the presence or absence of podocyte foot effacement and pathologically advanced disease markers, such as interstitial fibrosis, tubular atrophy or global sclerosis at the renal biopsy.

**Results:** Significant differences in SNP frequencies between IgAN patients and healthy controls were observed for rs2293347 in the codominant model [p=0.027, OR (95% CI)=1.35 (1.03-1.77)] and the recessive model [p=0.028, OR (95% CI)=1.82 (1.07-3.12)]. Moreover, rs2293347 of *EGFR* gene was found to be associated with the presence of podocyte foot process effacement at the renal biopsy. In addition, rs1140475 was found to be associated with the presence of pathologically advanced disease markers and the presence of gross hematuria.

**Conclusions:** Our results suggest that the polymorphism of *EGFR* gene may associated with increased susceptibility to IgAN in children. They also suggest that the polymorphism of *EGFR* gene may be related to the development of proteinuria and the presence of foot process effacement or pathologically advanced states in IgAN patients.

**SA-PO876**

**Premature Immunologic Aging, Associated with Inflammation in Children with Chronic Renal Insufficiency and Dialysis**
Roshan P. George,[1,2] Aneesh K. Mehta,[1] Sebastian D. Perez,[1] Jean Kwun,[1] Brandi E. Johnson,[1] Stephanie A. Monday,[1] Jennifer Cheeseman,[1] Linda L. Stempora,[1] Barry L. Warshaw,[1,2] Allan D. Kirk.[1,2] *[1]Emory Transplant Center, Emory Univ; [2]Pediatric Nephrology, Children's Healthcare of Atlanta, Atlanta, GA.*

**Background:** Chronic Renal Insufficiency (CRI) and dialysis are known to be associated with chronic inflammation. Persistent antigen stimulation drives T cells toward exhaustion and senescence but the influence of non-specific inflammation such as that present in dialysis, has not been defined, particularly in children. We studied T cell maturation, senescence and inflammatory markers in children with CRI and those on dialysis.

**Methods:** Serum obtained from 100 children, [CRI or dialysis (n=80) and normal controls (NC, n=20)] was analyzed for proinflammatory cytokines using multiplex luminex assay. Multiparameter flow cytometry, specifically interrogating cells for indices of T cell maturation, exhaustion and senescence was done. Telomere length using PCR in DNA was studies to assess cell aging.

**Results:** Of the 80 children with CRI, [35 on dialysis, 19 with CRI and prior organ transplantation (pTx), and 26 with CRI, not on dialysis]; 20% had reversal of CD4/CD8 ratio. There was significant reduction in naïve CD4 T cell frequencies in dialysis vs. NC (p =0.04) and in the naïve CD8 T cell percentage in pTx vs. NC (p= 0.0004). Senescent $CD57^+$, CD8 T cells were also elevated in dialysis vs. NC (p= 0.05). $CD28^-$ late differentiated, CD8 T cells were significantly higher in patients with CRI and pTx (p= 0.002). $CD28^-$ T cells were associated with shorter telomere length (p=0.04). There was significant elevation of inflammatory cytokine IL-5 (p=0.04), IL-6 (p= 0.02) and VEGF (p=0.008) in children on dialysis compared to NC. Elevated ferritin correlated to higher percentage of $CD57^+$, CD8 T cells and $CD28^-$ T cells (p=0.008 and 0.03 respectively).

**Conclusions:** Children on dialysis have elevated markers of inflammation and a T cell repertoire skewed towards terminal differentiation, immune senescence and exhaustion. These data may form the basis for further studies, needed to assess the clinical impact of this immune phenotype with regards to risk for infections and cardiovascular morbidity.

**Management of Hypertension in Pediatric Pheochromocytoma/Paraganglioma** Mauricio Romero Olvera,[1] Gaurav Kapur,[2] Rossana Baracco,[3] Tej K. Mattoo,[4] Amrish Jain.[5] *[1]Pediatric Nephrology, Children's Hospital of Michigan (CHM), Detroit, MI; [2]Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI; [3]Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI; [4]Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI; [5]Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI.*

**Background:** Surgical manipulation of pheochromocytoma/paragangliomas(PH/PG) while being removed can cause hypertensive crisis and post resection hypotension. Guidelines on management of blood pressure (BP) in pediatric patients with PH/PG are lacking. We report our experience with preoperative adrenergic blockade.

**Methods:** This retrospective study included 7 patients, aged 1-18 yrs old with biopsy proven PH/PG at Children's Hospital of Michigan from 2003-13. Excluded were patients with elevated catecholamines due to other diagnosis(neuroblastoma). All patients had urinary/plasma catecholamines, imaging, genetic testing & multidisciplinary evaluation. BP was controlled with α blockade for 2-4 weeks and β blockade for 2-3 days before surgery. High salt diet was encouraged after 3 days of α blockade. Intraoperative esmolol/nitroprusside infusion ± fluid resuscitation was used for cardiovascular stability.

**Results:** Of 7 patients (10.4±5.8 yrs; 5 male), 6 had PH & 1(14.2%) PG. Bilateral disease was noted in 4 (57.1%) & 1 had 2 recurrences. Altogether 9 surgical removals were done in 7 patients. Plasma normetanephrine, urine normetanephrine and VMA were elevated in 6, 4, and 3 patients respectively. Adrenal mass was seen on CT scan (2/9)& MRI (7/9); confirmed by MIBG Scan(8/9). Nitroprusside used transiently(<2h) during surgery in 2; esmolol in 2. Five needed albumin/PRBC. All anti-hypertensives were discontinued immediately after surgery(72%) or within 4 days (28%).

| Intervention | Number | Mean dose (mg/kg/day) | Mean duration(days) |
|---|---|---|---|
| α blockade- Phenoxybenzamine | 7 | 0.64 | 33±16.5 |
| β blockade- | | | |
| Atenolol | 3 | 0.3 | 33 ±14.3 |
| Propranolol | 2 | 0.63 | 3 ±3 |
| Labetalol | 2 | 0.86 | 12 ±8.6 |
| Volume expansion | 7 | - | 14.8±11.4 |

**Conclusions:** A systematic and multidisciplinary approach of BP control with α blockade, volume expansion and β blockade ensures excellent outcome.

**SA-PO878**

**Podocyte Differentiation Arrest Is Associated with Aberrant Response of Notch to Down-Regulated Wnt Signaling** Haichun Yang,[2] Taiji Matsusaka,[3] Iekuni Ichikawa,[1] Agnes B. Fogo,[2] Ji Ma.[1] *[1]Pediatric Nephrology, Vanderbilt Univ, Nashville, TN; [2]Pathology, Microbiology and Immunology, Vanderbilt Univ, Nashville, TN; [3]Internal Medicine, Tokai Univ, Isehara, Kanagawa, Japan.*

**Background:** Forced re-entry of mature podocytes into the cell cycle by inducing Simian Virus 40 T antigen (SV40T) gene expression causes podocyte and glomerular damage, while induction of SV40T in podocytes of developing mice results in complete differentiation. Upregulated Wnt and Notch signaling are associated with podocyte damage in glomerulopathies. In contrast, during development, down-regulation of Wnt and activation of Notch suppresses proliferation and promotes differentiation. In the present study, we tested the possibility that coordinated interaction between Wnt and Notch pathways determines the fate of differentiated podocytes.

**Methods:** Primary podocytes from *Nphs2-rtTA:TRE-SV40T* (SV40T) and *Nphs2-rtTA* (Cont) mice were pre-treated with doxycycline to induce SV40T expression and incubated with Wnt inhibitor Dkk1.

**Results:** SV40T podocytes showed increased proliferation compared with Cont. Dkk1 increased p-β-catenin in both Cont and SV40T podocytes, indicating inhibition of Wnt/β-catenin pathway. Dkk1 did not change the proliferation profiles in these two genotypes of podocytes. Expression of PAX2, a transcriptional factor expressed in primitive podocytes, was significantly down-regulated by Dkk1 in Cont but not in SV40T cells. While there was no significant difference in the number of podocyte processes between Cont and SV40T at baseline, Dkk1 increased the process number in Cont (5.8±0.3 *vs.* 7.5±0.5 /cell, $P<0.05$) but not in SV40T (6.4±0.5 *vs.* 7.4±0.5). Dll4, a ligand for Notch signaling pathway, was significantly reduced by Dkk1 in Cont (1.03±0.07 *vs.* 0.39±0.05, $P<0.05$) while increased in SV40T (0.85±0.07 *vs.* 1.24±0.04, $P<0.05$).

**Conclusions:** Actively proliferating podocytes with induced SV40T have limited commitment for differentiation in response to inhibition of Wnt/β-catenin signaling. The concurrent proliferation-differentiation processes underlying complete podocyte differentiation requires coordinated interaction between the Wnt and Notch signaling pathways.

**SA-PO879**

**A Polymorphism of Interleukin 10 and Its Receptor Polymorphism Is Associated with the Development of Childhood IgA Nephropathy** Jin-Soon Suh,[1] Yumi Choi,[2] Byoung-Soo Cho.[3] *[1]Dept of Pediatrics, Bucheon St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea, Bucheon, Korea; [2]Dept of Pediatrics, School of Medicine, Kyung Hee Univ, Seoul, Korea; [3]Dept of Pediatrics, TheAll Medibio Research Institute, Seoul, Korea.*

**Background:** Recent studies suggest that dysregulated innate immunity plays an important role in the pathogenesis of immunoglobulin A nephropathy (IgAN). The interleukin-10 and its receptor complexes elicit diverse hose defense mechanisms during many infectious and inflammatory diseases. In the current study, we investigated the association between the polymorphisms of IL-10 and its receptors, IL-10RA/IL-10RB genes and childhood IgAN.

**Methods:** 196 patients with IgAN and 288 normal controls were genotypes for two polymorphisms of the IL-10 gene (rs1518111 and rs1554286), two polymorphisms of the IL10RA gene (rs2256111 and rs4252243), and three polymorphisms of the IL10RB (rs2228054, rs999788 and rs2834167).

**Results:** Our case-control analysis showed that genotypes of rs4252243 in IL10RA gene were associated with IgAN. Individuals with genotypes containing the T allele (TC or TT) of rs4252243 had about 2-fold reduced risk of IgAN compared with those with the CC genotype in the codominant model (0=0.011) and in the recessive model (p=0.014). Furthermore, rs2228054 and rs999788 in the IL10RB gene were associated with the presence of proteinuria and nephrotic-range proteinuria during disease course, respectively.

**Conclusions:** Our data suggest that rs4252243 polymorphism in the IL10RA gene is associated with the reduced risk of IgAN and polymorphisms in the IL10RB are associated with the disease severity in IgAN patients.

**SA-PO880**

**Risk Factors for Progression in Children with IgA Nephropathy: Data from a European Cohort** Roberta Camilla, Rosanna Coppo, Shubha Bellur, Daniel C. Cattran, John Feehally, Francesco Emma, Kostantinos Giannakakis, Alessandro Amore, Stephan Troyanov, Ulla B. Berg, Magnus Soderberg, Gianna Mazzucco. *On Behalf of VALIGA Study Group.*

**Background:** The European validation study of Oxford classification of IgA nephropathy (IgAN) (VALIGA) has enrolled 1147 patients.

**Methods:** Children account for 174 cases, from 20 centers of 11 countries. Proteinuria was adjusted for body surface area and mean arterial pressure for gender and age. Schwartz formula estimated eGFR and the functional decline was defined as slope of eGFR.

**Results:** Mean age at renal biopsy was 12.7±3.7 years; median follow-up was 4.7 years (IQs 2.4-7.8 years); > 80% presented with normal renal function (eGFR > 90 ml/min/1.73m$^2$).

End-stage renal disesase (ESRD) was reached by 4%, 50% loss of eGFR by 5%; 7% reached the combined end point (ESRD or 50% loss of initial eGFR).

At renal biopsy 57% presented with mesangial proliferation (M1), 24% endocapillary proliferation (E1), 35% segmental glomerulosclerosis (S1) and 9% tubular atrophy/interstitial fibrosis (TA/IF; T1/2). Patients with segmental sclerosis and TA/IF showed a significantly worse eGFR slope (S0 vs S1 p=0.04; T0 vs T1/2 p=0.003).

At univariate linear regression, clinical data at renal biopsy (eGFR, proteinuria and MAP) were not associated with renal function decline, while data at 6-12 and 12-24 months and TA-proteinuria and MAP significantly predicted eGFR slope.

A multivariate linear regression model (including proteinuria and MAP at 12-24 months together with the difference of eGFR at renal biopsy and at 12-24 months as independent variables) performed well in predicting eGFR slope ($R^2$=0.39). This model was used to derive a formula able to estimate eGFR slope in ml/min/1.73m$^2$/year, which performs well in the VALIGA pediatric population (mean bias between estimated and really observed eGFR slope of 0.05 ± 6.6 ml/min/1.73m$^2$).

**Conclusions:** The Oxford classification of IgAN showed that in children segmental glomerulosclerosis and tubular-atrophy/interstitial fibrosis being more significantly associated with renal outcome. A formula was developed that predicts renal function decline based on clinical data after 1-2 years from renal biopsy.

*Funding:* Government Support - Non-U.S.

**Enhanced Functional Complement Regulatory Proteins (CD46)-Induced Regulatory T Cells by High-Dose Pulse-Intravenous Meyhylprednisolone in Lupus Nephritis Patients** Ching-Yuang Lin. *Clinical Immunology Center, China Medical Univ Hospital, Taichung, Taiwan.*

**Background:** Defective suppressive regulatory T cell (Treg) function is crucial in lupus nephritis (LN) pathogenesis. Complement regulatory protein (CD46) is a newly defined co-stimulatory molecule for Treg activation; together with IL-10 production, it may help suppress kidney inflammation. We examine chemotaxis and adhesion molecule expression on CD3/CD46$^+$-activated CD4$^+$ T cells (Tregs) from Class III or IV LN patients to ascertain whether five-day pulse intravenous methyl-prednisolone (IVMP) therapy enhances CD3/CD46-activated Tregs suppressive function.

**Methods:** During 2009-2011, 40 active LN patients (Class III or IV) with heavy proteinuria, aged 12-18 years, were recruited. Peripheral blood mononuclear cells (PBMCs) were isolated, both from LN patients (before/after IVMP) and from healthy controls.

**Results:** Diminished IL-10 and CCR4 or CCR7 expression from CD3/CD46-activated Tregs appeared in LN patients. Therapy significantly increased CD3/CD46-activated Tregs with intracellular IL-10 and suppressed $CD4^+$ T cell proliferation. Percentage of CCR4 and CCR7 in CD3/CD46-activated Tregs significantly decreased in patients compared to healthy controls. IVMP therapy enhanced CCR4, CCR7, and CCR4 ligand-medicated migration and phosphorylation of protein kinase B expression of CD3/CD46-mediated Tregs.

**Conclusions:** Lower migratory capacity of suppressive CD3/CD46-activated Tregs might be involved in LN pathogenesis.

## SA-PO882

**Investigation of Principal Mechanism for Renal Sodium Retention in Children with Idiopathic Nephrotic Syndrome** Takeshi Ninchoji,[1] Hiroshi Kaito,[1] Kandai Nozu,[1] Taketsugu Hama,[2] Koichi Nakanishi,[2] Norishige Yoshikawa,[2] Kazumoto Iijima.[1] *[1]Pediatrics, Kobe Univ Graduate School of Medicine, Japan; [2]Pediatrics, Wakayama Medical Univ, Japan.*

**Background:** Renal retention of sodium is one of the principal mechanisms that leads to edema in children with idiopathic nephrotic syndrome (INS). Some animal experiments have documented that it is the epithelial sodium channel (ENaC) at collecting ducts or the sodium-hydrogen exchanger (NHE3) at proximal tubules that may contribute to sodium retention in INS. However, there are various theories of renal sodium retention and opinion is divided. In addition, another problem is that no structured studies have elucidated possible contributor to renal sodium retention in human with INS.

**Methods:** We retrospectively analyzed 10 patients with INS group and 10 with age-matched control (CON) group. All cases in INS underwent kidney biopsy during nephrosis, and those in CON underwent during complete remission. Paraffin-embedded serial sections were stained with immunostaining procedure, and the number of positive cells was counted by a single researcher. NHE3 was evaluated with CD10, a specific marker of proximal tubule, and both α- and β- subunit of ENaC with CK34βE12, a specific marker of collecting tubule. The ratios of NHE3 to CD10 and ENaC to CK34βE12 positive cells were compared each between two groups.

**Results:** The mean age at kidney biopsy was 5.3±1.9 years old in INS and 5.3±1.2 in CON. All cases showed no interstitial and tubular damage, and no cases deteriorated kidney function at biopsy. Serum albumin level in INS was significantly lower than that in CON (2.4±0.3 g/dl vs 3.5±0.3 g/dl; p=0.027). The ratio of NHE3 to CD10 positive cells in INS was significantly higher than that in CON (0.85±0.06 vs 0.77±0.06; p=0.013). On the other hand, there was no change in the proportion of α- and β-ENaC to CK34βE12 positive cells. Distribution of each channel had also no difference between two groups.

**Conclusions:** We could first elucidate the distribution and the trend of the sodium channel in children with INS. We demonstrated that it may not be ENaC, or collecting ducts, but NHE3, or proximal tubules, that contributes to sodium retention in INS.

## SA-PO883

**Patient Reported Outcomes in Pediatric Nephrotic Syndrome** David T. Selewski,[1] J. Troost,[2] Susan F. Massengill,[2] Rasheed A. Gbadegesin,[2] Larry A. Greenbaum,[2] Ibrahim Shatat,[2] Yi Cai,[2] Gaurav Kapur,[2] Diane Hebert,[2] Michael J. Somers,[2] Howard Trachtman,[2] Priya J. Pais,[2] Michael E. Seifert,[2] Jens W. Goebel,[2] John D. Mahan,[2] Heather E. Gross,[2] Emily G. Herreshoff,[2] Courtney L. Harkness,[2] Darren Dewalt,[2] Debbie S. Gipson.[2] *[1]Univ of Michigan; [2]PROMIS Pediatric Study Network.*

**Background:** PROMIS-II is a prospective longitudinal study evaluating patient reported outcomes (PRO) in pediatric chronic diseases. We report the initial PRO results for the nephrotic syndrome (NS) cohort.

**Methods:** 126 children (8-17 yo) with active NS were enrolled at 14 centers from 9/2010-3/2013 including incident and prevalent (mean 68 months from diagnosis) patients. Children completed PROMIS and PedsQL instruments. For PROMIS higher scores indicate more of a domain and population norms are not defined. For PedsQL, higher scores indicate better function (normative range 100±15).

**Results:** As shown in Table 1 (incident vs. prevalent unadjusted analysis, mean±sd), PedsQL scores were below the normative range (p<0.05). Multivariate analysis evaluating the unadjusted significant domains controlling for BMI, edema, and recent hospitalization showed that prevalent NS predicted worse PROMIS Pain (p=0.009), PROMIS Peer Relationships (p=0.048), PedsQL Social (p=0.004) and PedsQL School (p=0.008) scores.

**Conclusions:** PedsQL scores in children with active NS are well below population norms. Children with prevalent NS have increased burden in the domains of peer, pain, social and school functioning showing that disease duration negatively impacts PRO in these areas.

| **PROMIS** | | | |
|---|---|---|---|
| Domain | Incident (N=58) | Prevalent (N=68) | *p* |
| Anxiety | 49±11 | 50±10 | 0.57 |
| Peer Relationships | 51±10 | 47±11 | 0.02 |
| Fatigue | 49±13 | 50±12 | 0.6 |
| Mobility | 47±10 | 46±8 | 0.8 |

## SA-PO884

**Vitamin D in Pediatric Incident Idiopathic Nephrotic Syndrome** David T. Selewski,[1] Ibrahim Shatat,[2] Ashton Chen,[2] Priya J. Pais,[2] Larry A. Greenbaum,[2] Pavel Geier,[2] Raoul D. Nelson,[2] Stefan Kiessling,[2] Patrick D. Brophy,[2] Alejandro Quiroga,[2] Michael E. Seifert,[2] Caroline E. Straatmann,[2] John D. Mahan,[2] Maria E. Ferris,[2] Courtney L. Harkness,[2] J. Troost,[2] Debbie S. Gipson.[2] *[1]Univ of Michigan; [2]Midwest Pediatric Nephrology Consortium.*

**Background:** Idiopathic nephrotic syndrome (iNS) is a common kidney disease in children. While studies of children with prevalent NS have shown 25-Vitamin D (VitD) deficiency rates of 20-100%, there has not been a longitudinal study of 25-VitD levels in incident iNS. We assessed 25-VitD deficiency in children with iNS at diagnosis and over time (within 2 weeks of and 2-4 mos. after diagnosis).

**Methods:** Preliminary analysis of a longitudinal study of children (2-18yo) from 14 centers with incident iNS designed to investigate 25-VitD. 25-VitD deficiency defined as < 20 ng/mL. Exclusion criteria: evidence of secondary NS at diagnosis. Follow-up completes in 8/2013.

**Results:** 57 children are enrolled, 54 children have completed initial labs and 38 completed 2nd visit labs. Their characteristics are: males 70%; white 56%, black 35%, other race 9%, median age 5 yo. Table1 shows lab data by visit (mean±sd). All 54 (100%) had 25-VitD deficiency at diagnosis. 21 (55%) children had 25-VitD deficiency at follow-up. 81% of children were steroid responsive and 19% were steroid resistant. Children prescribed VitD supplements were less likely to have VitD deficiency at follow-up compared to those without (OR 0.2, 95%CI 0.1, 1.0). Steroid response, age, race, and season did not predict 25-VitD deficiency at follow-up.

**Conclusions:** In this incident iNS cohort, all children at diagnosis have 25-VitD deficiency and the majority continue to have a deficiency at 2-4 months. Furthermore, supplemental VitD decreases the odds of 25-VitD deficiency supporting a potential role for supplementation in incident NS.

| | Diagnosis (N=54) | 2-4 mos. Follow-up (N=38) |
|---|---|---|
| 25-VitD ng/mL | 9.0±3.7 | 22.4±19.5 |
| 1,25-VitD pg/mL | 23.3±14.4 | 54.5±27.9 |
| Int PTH pg/mL | 73.2±45.7 | 58.1±28.9 |
| Alb g/dL | 1.6±0.6 | 3.7±0.9 |
| Ca mg/dL | 7.9±0.8 | 9.1±1.2 |
| VitD Supplement (N) | 0 | 8 |

## SA-PO885

**An Evaluation of a 6 Month versus 4 Month Steroid Protocol in Childhood Onset Nephrotic Syndrome** Andra Diana Popescu, Allison Dart. *Pediatrics and Child Health, Univ of Manitoba, Winnipeg, Canada.*

**Background:** Standard therapy for a first presentation of nephrotic syndrome is a course of corticosteroid, however there exists considerable practice variation in the duration of initial course. This study aimed to evaluate the effect of a 6-mo vs. 4-mo steroid protocol on clinical outcomes at 1 year.

**Methods:** This is a retrospective analysis of all children (1-18 yrs) with a first presentation of nephrotic syndrome treated at the Children's Hospital of Winnipeg with a 6-mo course of prednisone (July 2009 to Sept 2011) (Group B) compared to historical controls treated with a 4-mo course (Jan 2005 to June 2009) (Group A). Children with biopsy confirmed FSGS were excluded. Data was obtained from an electronic medical record. Differences in number of relapses, total steroid dose, time to first relapse and second line agent were evaluated between groups. Logistic regression models evaluating the association of clinical factors with 0 vs. >1 and 0-1 vs. >2 relapses were conducted. Follow-up time was 12 months.

**Results:** In Group A (n=20) 3 had 0, 4 had 1 and 13 patients had >1 relapse. In Group B (N=18) 5 had 0, 6 had 1 and 7 patients had >1 relapse. There were no differences in clinical characteristics between groups. The odds of any relapse (A vs. B) was not different between groups (odds ratio (OR)=2.8; 95% CI 0.5-14.9) and for 0-1 vs. >1 relapse the OR = 4.4 (CI 0.9-20.3). Sex, age, and initial albumin were not associated with outcome in either analysis. Survival analysis showed a mean of 4.8 mo to first relapse for Group A and 7.1 mo for Group B (NS), and 8.1 mo to initiation of second line therapy for Group A and 9.9 mo for Group B (NS). There was no difference in the total cumulative steroid dose at 12 months in mg/kg (p=0.3). The rates of steroid toxicity were low in both groups.

**Conclusions:** Our findings suggest that a 6-mo course of steroids for the first presentation of nephrotic syndrome may decrease the odds of frequent relapses, and delay the time to first relapse and time to initiation of a second line agent compared to a 4-mo course without increasing total steroid exposure. A randomized study with a larger sample size is required to confirm these identified trends.

## SA-PO886

**Vertebral Fractures in the 3 Year Period following Steroid Initiation among Children with Chronic Illnesses** Maury N. Pinsk, Monica Taljaard, Steven Arora, Lorraine E. Bell, Tom D. Blydt-Hansen, Guido Filler, Joanne Grimmer, Diane Hebert, Janusz Feber, Julian Paul Midgley, Veronique Phan, Leanne M. Ward, and The Canadian Stopp Consortium. *Canadian Pediatric Bone Health Working Group, Canada.*

**Background:** To describe the frequency of incident vertebral fractures (IVF) in steroid-treated children.

**Methods:** IVF were assessed prospectively each year following steroid initiation for 3 years, according to the Genant semi-quantitative method. To examine associations with baseline clinical factors, the 3-year total number of IVF was analyzed using multivariable Poisson regression.

**Results:** 404 children were enrolled at a median age of 6.2 years, range 1-17; 50% boys; 188 (46%) had leukemia, 136 (34%) rheumatic conditions, and 80 (20%) nephrotic syndrome. The baseline study visit occurred at a median of 18 days following steroid initiation (inter-quartile range 11-24 days). Overall, 17% of children (95% CI 13-22) had at least one incident VF over the 3 years. Among those with IVF, 24/55 children (44%) had 1 or more moderate or severe fracture. The proportions of children with IVF over 3 years were as follows: Leukemia: 24% (95% CI 16-32); rheumatic disorders: 13% (95% CI 6-19); nephrotic syndrome 9% (95% CI 1-17). The annual proportion of children with IVF peaked at 12 months and declined thereafter (p=0.04). In Poisson multivariable modeling assessing baseline clinical factors, the following were associated with higher, 3-year VF incident rates: the presence of VF at baseline (incidence Rate Ratio (RR) 6.3, 95% CI 3.2-12.4), female gender (RR 1.8; 95% CI 1.0-3.3), pre-pubertal status (RR 2.1; 95% CI 0.8-5.4), and lower BMD Z-scores (RR 1.4; 95% CI 1.1-1.7).

**Conclusions:** Within 3 years of steroid initiation, 17% of children had IVF. VF incidence peaked at 12 months, and almost half of the IVF were moderate or severe. Of the factors measured at baseline, prevalent VF were most strongly associated with IVF over the ensuing 3 years.

### Thrombosis in Childhood Nephrotic Syndrome: Contributory Risk Factors

Rezan Topaloglu,[1] Fehime Kara Eroglu,[1] Betul Tavil,[2] Fatih Ozaltin,[1] Mualla Cetin,[2] Fatma Gumruk.[2] *[1]Pediatric Nephrology, Hacettepe Univ Faculty of Medicine, Ankara, Turkey; [2]Pediatric Hematology, Hacettepe Univ Faculty of Medicine, Ankara, Turkey.*

**Background:** The aim of this study was to evaluate the prevalence and contributory risk factors for development of thrombosis in children with Nephrotic syndrome (NS).

**Methods:** Among 188 children with NS followed up at Pediatric Nephrology Unit in last seven years; 17 children (9%),identified as having thromboembolic complications and screened for thrombotic risk factors.

**Results:** The mean age of patients was 4.5±3-2 years at the diagnosis of NS and that was 7.1± 4.9 at the time of thrombosis. The mean time from NS diagnosis to the first thrombosis development was 2.6±2.3 years. More than half of the thrombosis (53%) occurred during the first year of NS. Among these children;14 (82%) had FSGS, 2 (14%) had congenital NS and 1 had minimal change disease. 88% of the thrombosis was venous and in regards to the localization; 6 deep venous thrombosis, 4 sino venous thrombosis, 2 portal venous thrombosis, 2 intracardiac thrombosis, 1 intracardiac thrombosis and cerebral infarct, and 2 had cerebral infarct. Among screened thrombotic risk factors high factor VIII levels (16.5%) was the leading risk factor followed by decreased antithrombin III level (29%) and high homocystein level (23.5%). The distribution of the hereditary risk factors were; factor V Leiden heterozygote mutation in 12.5%, MTHFR 677 heterozygote mutation in 37.5%, MTHFR 677 homozygote mutation in 6.2%, MTHFR 1298 heterozygote mutation in 23%, MTHFR 1298 homozygote mutation in 7.6%, PAI (4G/5G) polymorphism in 15.3% and PAI (4G/4G) polymorphism in 7.6%. Thrombotic risk factors were found in all children while 14 had multiple risk factors. Most of the children (70.5%) treated with only low molecular weight heparin ranging 3 to 12 months.

**Conclusions:** Unlike previously reported studies, in our cohort FSGS is associated with the highest incidence of venous thrombosis. All of our patients had predisposition to thrombosis that shows underlying genetic background influences the likelihood of thrombosis in nephrotic syndrome.

## SA-PO888

### Intermittent High-Dose Mizoribine Therapy Is Effective for Children with Steroid-Dependent Nephrotic Syndrome

Takayuki Okamoto, Takeshi Yamazaki, Asako Hayashi, Yasuyuki Sato. *Pediatrics, Hokkaido Univ Graduate School of Medicine, Sapporo, Hokkaido, Japan.*

**Background:** Daily high-dose mizoribine (MZB) for children with steroid-dependent nephrotic syndrome (SDNS) has been reported to be effective. Unlike preceding studies, we retrospectively investigated the efficacy of intermittent high-dose MZB therapy for children with SDNS within insurance support that means the maximum weekly dose of MZB was limited up to 1050mg.

**Methods:** Nine children (7 boys, 2 girls) who had SDNS with (n=5) or without (n=4) calcineurin-inhibitor (CNI)-dependency were enrolled in the present study to clarify the efficacy of limited-dose MZB therapy for sparing steroid and CNI. All patients were undergoing treatment at our hospital and associated hospitals between Jan 2009 and May 2013. The dosage of MZB was started at a single daily dose of 5mg/kg administered after breakfast and gradually increased to achieve the target concentration (3-h levels of 3 ug/ml) within 1050mg per week, such as daily (up to 150mg/day) and intermittent high-dose therapy; once in two days (300 mg alternate-day) and twice a week (550mg-500mg per week). The median dose of prednisolone (PSL) and CNI, the median number of relapses, the change in stature and body-weight were statistically analyzed before and after MZB therapy.

**Results:** 7 out of the 9 patients (78%) achieved the target concentration of MZB. In the 7 patients, all patients took intermittent high-dose MZB such as 6 patients (86%) took medication of MZB once in two days and 1 patient (14%) took twice a week. Intermittent high-dose MZB treatment (n=7) over a period of 12 months resulted in reduction of the mean PSL dose from 0.36 to 0.32 mg/kg/day and the median 12-month number of relapses from 2.1 to 1.3 episodes/12 months. In the 5 patients who had SDNS with CNI dependency, 3 patients (60%) could wean off CNI. No significant side effects such as hyperuricemia, liver dysfunction and leukopenia were revealed during the administration of MZB therapy.

**Conclusions:** Our retrospective study demonstrated that intermittent high-dose MZB therapy is effective for eliminating steroid or CNI to children with SDNS.

## SA-PO889

### Role of Early Volume Expansion in Mitigating Shigatoxin-Associated Hemolytic Uremic Sindrome. North Italian HUS Network

Gianluigi Ardissino, Francesca Tel, Sara Testa, Stefania Salardi, Rosaria Colombo, Ilaria Possenti, Silvana Tedeschi, Erminio Torresani. *Center for HUS Prevention, Control and Management, Fondazione IRCCS Ca' Granda Osp Maggiore Policlinico, Milan, Italy.*

**Background:** STEC-HUS is a severe acute illness for which there is no specific treatment. Among supportive therapy, the management of fluids has been traditionally concentrated on avoiding fluid overload because patients often present with oligo/anuric AKI. Hemoconcentration at disease onset is associated with more servere disease, however it is still unclear if early volume expansion can improve disease's outcome.

**Methods:** Since May 2010 a Network connecting pediatric hospitals in Northern Italy (10 millions gp) was developed aimed at early diagnosis and referral of STEC-HUS with the working hypothesis that prompt volume expansion with saline solution 0.9% may revert disease severity. All children with STEC-HUS referred to our Center from Jan. 2012 were addressed to intravenous hydration aimed at inducing an overhydration (+10-15% of the working weight within 48 hrs). The outcome was compared with an equal and sequential group of historical patients (group A) referred to our Center during 2007-2009 when patients were usually restricted in fluid intake.

**Results:**

| | Group A | Group B |
|---|---|---|
| N. | 22 | 22 |
| Gender (M/F) | 11/11 | 9/13 |
| Age (yrs) | 4.9 | 4.8 |
| sCreatinine at diagnosis (mg/dL) | 3.6 | 1.7 |
| Peak sCreatinine (mg/dL) | 5.6 | 2.9 |
| RRT (% of total) | 64 | 18 |
| Days of hospitalization | 14.1 | 9.4 |

**Conclusions:** Our data showed that early hydration of STEC-HUS can improve the outcome. It can be speculated that hypovolemia (due to diarrhea, reduced food intake, endothelial leakage and reduced onchotic pressure), if uncorrected, favours trombi formation and hipoxic/ischemic tissue damage.

## SA-PO890

### Discontinuation of Eculizumab Maintenance Treatment in Patients with Atypical Hemolitic Uremic Syndrome

Gianluigi Ardissino, Sara Testa, Francesca Tel, Ilaria Possenti, Fabio Paglialonga, Samantha Griffini, Massimo Cugno, Stefania Salardi, Silvana Tedeschi. *Center for HUS Prevention, Control and Management, Fondazione IRCCS Ca' Granda Osp. Maggiore Policlinico, Milan, Italy.*

**Background:** Atypical haemolytic uremic syndrome (aHUS) is a rare, systemic, life-threatening thrombotic microangiopathy (TMA). As many as 70% of aHUS patients have mutations in the genes encoding complement regulatory proteins. Since 2009, Eculizumab, a humanised recombinant monoclonal antibody targeting C5, that prevents the generation of membrane-attack complex C5b-9, has been successfully used in patients with aHUS. The standard maintenance treatment schedule requires administration of the drug every two weeks lifelong, but the possibility to and the risk of discontinuing the treatment has not yet been tested.

The present study analyzes the safety of treatment discontinuation with the rational of: 1. improving the quality of life; 2. minimizing the risk of adverse reactions; 3. reducing the risk of meningitis; 4. reducing the theoretical risk of development of neutralizing antibodies and 5. reducing the heavy costs of the treatment.

**Methods:** All patients with aHUS treated with Eculizumab at our Center, in stable remission were considered eligible to drug discontinuation. Strict routine home monitoring of indicators of disease activity was performed after treatment discontinuation: detection of blood in the urine with dipstick three times per week.

**Results:** Over a cumulative observation period of 59 months, three (2 CFH, 1 CFH+CFI) out of eleven patients (1 MCP, 2 Ab AntiFH, 3 CFI, 2 idiopathic) addressed to treatment discontinuation, relapsed. The recurrences occurred within 2 months from treatment discontinuation. Relapses were detected thanks to home urine dipstick that showed hematuria. Patients immedtely restarted the treatment with a complete recovery and return of serum creatinine to baseline level.

**Conclusions:** Our experience supports the possibility of discontinuing Eculizumab treatment in patients with aHUS in stable remission with a strict home monitoring of early signs of relapse.

*Funding:* Private Foundation Support

**SA-PO891**

**Interval Extension of Eculizumab Maintenance Treatment in Patients with Atypical Haemolitic Uremic Syndrome** Gianluigi Ardissino, Sara Testa, Donata Cresseri, Francesca Tel, Fabio Paglialonga, Ilaria Possenti, Samantha Griffini, Massimo Cugno, Stefania Salardi, Silvana Tedeschi. *Center for HUS Prevention, Control and Management, Pediatric and Adult Nephrology and Laboratory Unit, Fondazione IRCCS Ca' Granda Osp. Maggiore Policlinico, Milan, Italy.*

**Background:** Atypical haemolytic uremic syndrome (aHUS) is a rare, systemic, life-threatening thrombotic microangiopathy (TMA). As many as 70% of aHUS patients have mutations in the genes encoding complement regulatory proteins. Since 2009, eculizumab, a humanised recombinant monoclonal antibody targeting C5, that prevents the generation of membrane-attack complex C5b-9, has been successfully used in patients with aHUS. The standard maintenance treatment schedule requires administration of the drug every two weeks but the best treatment schedule is not yet defined. We tested alternative treatment schedule for prevention of relapses with the rational of improving the quality of life, reducing the risk of adverse reactions and reducing the heavy costs of the treatment.

**Methods:** All pts undergoing eculizumab treatment for aHUS in our Center (n: 22) were addressed to an extension of the interval between doses from the standard 2 weeks to 3 or 4 wks with a strict monitor of global complement activity. AP50 was routinely determined towards a target AP50 <25 before subsequent eculizumab dose. Strict home monitoring of disease reactivation with blood in the urine with dipstick, was performed at home.

**Results:** In the 12 pts (9 CFH, 1 CFH+CFI, 1 idiopathic, 1 C3) addressed to interval extension (five at 3 weeks and seven at 4 weeks), no aHUS relapses were observed over a cumulative observation period of 130 mos.

**Conclusions:** Our experience supports the possibility of tailoring eculizumab schedule for maintenance treatment in patients with aHUS based on global complement activity.

**SA-PO892**

**Eculizumab Hepatotoxicity – When to Change Therapy?** Wesley N. Hayes,[1] Sibylle Tschumi,[1] Simon Ling,[2] Janusz Feber,[1] Christoph Licht.[1] *[1]Div of Nephrology, Hospital for Sick Children, Toronto, Canada; [2]Div of Gastroenterology, Hepatology and Nutrition, Hospital for Sick Children, Toronto, Canada.*

**Background:** Eculizumab is a first-in-class humanized anti-C5 antibody approved for treatment of paroxysmal nocturnal hemoglobinuria and atypical Hemolytic Uremic Syndrome (aHUS) in adults and children. Its use is increasing in children following reports of its safety and efficacy in inducing thrombotic microangiopathy response. No hepatic side effects have been reported to date.

**Methods:** We performed a retrospective review of case notes and investigations for patients treated with eculizumab for aHUS in a single pediatric center. A standard dosing regimen based on patient weight was used.

**Results:** Seven of 11 children aged 6 to 11 years experienced elevated aminotransferases following eculizumab treatment for aHUS. One patient with no pre-existing liver disease developed tender hepatomegaly 3 days following the first dose. Alanine transaminase (ALT), hepatic alkaline phosphatase (ALK), aspartate aminotransferase (AST) and gamma-glutamyl transpeptidase (GGT) rose to over 20 times the upper limit of normal. Bilirubin, INR and albumin remained within normal limits. Liver biopsy taken following improvement in liver enzymes showed mild hepatocellular injury with no evidence of infectious or autoimmune hepatitis. Recurrent progressive elevation of ALT following re-dosing of eculizumab necessitated its discontinuation and transition to plasma therapy for aHUS. In 6 other children transient elevation of liver enzymes following eculizumab was observed. Infectious and other causes were excluded in each case.

**Conclusions:** Hepatotoxicity is a potentially important yet previously unreported and so far unexplained adverse effect of eculizumab. We recommend monitoring liver enzymes in all patients receiving eculizumab. In patients with excessive hepatic enzyme disturbance or clinical symptoms of hepatitis in association with eculizumab we would change to plasma therapy. Further research is required to clarify the magnitude of the issue, to characterize the mechanism of hepatotoxicity and to identify which patients are most at risk.

**SA-PO893**

**Frontline Treatment for Atypical Hemolytic Uremic Syndrome: Plasma-Exchange or Eculizumab?** Gianluigi Ardissino, Fabio Paglialonga, Sara Testa, Francesca Tel, Ilaria Possenti, Silvia Consolo, Silvana Tedeschi, Stefania Salardi. *Center for HUS Prevention, Control and Management, Fondazione IRCCS Ca' Granda Osp. Maggiore Policlinico, Milan, Italy.*

**Background:** The introduction of Eculizumab for atypical haemolytic uremic syndrome (aHUS) has quickly changed the management and the outcome of the disease. It is not clear what is the role left for "old" treatment, mainly plasma exchange (PEX) in the management of aHUS. The aim of the study is to retrospectively assess the outcome of treatment with PEX vs Eculizumab at our Center.

**Methods:** All patients with aHUS treated with PEX or Eculizumab since 2000 where considered for the present analysis. Patients who either remained dialysis dependent or who were switched to the other treatment modality because they did not reach remission, were considered non responders. PEX was performed with FFP in all cases, with an exchange volume of 50-150% (depending on the historical period) with a variable number of sessions (2-29).

**Results:** Twenty-eight patients underwent PEX for aHUS (16 CFH, 4 CFI, 2 MCP, 1 C3, 1 AbAntiFH, 4 Idiopathic) and since 2009, 26 patients were treated with Eculizumab (12 CFH, 4 CFI, 1 MCP, 1 C3, 2 AbAntiFH, 6 Idiopathic). Overall, the responders were 32 and 88% with PEX and Eculizumab, respectively. The response rate was not substantially different when analyzed separately for specific etiology: CFH Defect + AntiCFH Antibodies (41 Vs 100%), CFI Defect (25 Vs 75%), MCP (50 vs 100%), Idiopathic (0 Vs 66%).

**Conclusions:** In our experience, PEX was of limited efficacy for preventing ESRD in patient with aHUS compared to Eculizumab. Based on this finding, Eculizumab should be considered as the first-line treatment for aHUS.

*Funding:* Private Foundation Support

**SA-PO894**

**Presentation of Apolipoprotein L-1 (APOL-1) Nephropathy in Pediatric (Ped) and Young (Yg) Adult African American (AA) Patients (Pts)** Elizabeth I. Anyaegbu, Keith A. Hruska, Andrey S. Shaw, Sanjay Jain. *Washington Univ in St. Louis, St. Louis, MO.*

**Background:** 2 coding variants in the APOL1 gene have recently been found to associate with increased incidence of ESRD in the adult AA population (pop). Prevalence of 2 APOL1 risk variants (rvs) in the general AA pop is 9% compared to 0.04% in Caucasians. These rvs associate with hypertension (HTN) attributed ESRD, FSGS and HIVAN in adult AA pts. We hypothesized that as a genetic disease, *APOL1* nephropathy (APOL1N) has a ped phenotype, but it remains unclear if the *APOL1* rvs influence progression to ESRD in yg AA pts with HTN or FSGS and a family history (FHx) of ESRD.

**Methods:** We conducted a case-control study of 85 ped and yg AAs who presented with HTN or FSGS to determine the association with *APOL1* rvs, G1 and G2, using custom made TaqMan based alleic discrimination assays.

**Results:** Ped and yg AA pts presenting with either HTN (n= 39) or FSGS (n= 22) with a FHx of ESRD were cases. 24 healthy AA participants without a FHx of ESRD were controls. Mean ages (SD) for the FSGS and HTN pts were 24.3 (7.4) and 23.6 (6.9) years respectively; 27% of pts were < 18 years old. 66% of pts (40/61) had 2 APOL-1 rvs; significantly higher than the prev in the general AA pop ($p < 0.001$). 24/29 pts with HTN attributed ESRD had 2 APOL1 rvs while none of the HTN pts who presented without kidney disease had more than 1 APOL1 rvs. Of the ped pts, 35% (6/17) had 2 APOL-1 rvs; with majority of these rvs in the ped FSGS pts.

**Conclusions:** We demonstrated for the first time that 2 APOL1 rvs in HTN yg AA with a FHx of ESRD are strongly associated with ESRD ($p< 0.01$). We also found that 2 APOL1 rvs in yg AA with a FHx of ESRD were significantly associated with FSGS and not essential HTN in ped and yg AA pts. This study demonstrates that the ped presentation of APOL1N is not primary HTN. Prevalence of 2 APOL1 rvs in our controls (4/24) and ped HTN pts (1/11) were not significantly different from the general AA pop. Although a small cohort, our findings strongly suggest that APOL1N presents with kidney disease- FSGS or CKD in pts with a FHx of ESRD. Screening yg HTN AA with a FHx might aid in early identification of pts at risk for progression to ESRD.

**SA-PO895**

**Cytoskeletal Changes in the Proteins of Podocytes by Interleukin-13** Se Jin Park,[1,4] Moin Saleem,[2] Tae-Sun Ha,[3] Jae Il Shin.[4] *[1]Dept of Pediatrics, Ajou Univ Hospital, Ajou Univ School of Medicine, Suwon, Republic of Korea; [2]Children's and Academic Renal Unit, Southmead Hospital, Univ of Bristol, Bristol, United Kingdom; [3]Dept of Pediatrics, Chungbuk National Univ College of Medicine, Cheongju, Republic of Korea; [4]Dept of Pediatrics, Severance Children's Hospital, Yonsei Univ College of Medicine, Seoul, Republic of Korea.*

**Background:** The aim of this study was to determine whether pathologic changes in the cytoskeletal proteins of podocytes are induced by interleukin-13 (IL-13) in the experimental minimal-change nephrotic syndrome (MCNS) model and to investigate whether montelukast, a leukotriene receptor antagonist, has an effect on the production of the cytoskeletal proteins in cultured human podocytes.

**Methods:** Human podocytes cultured on bovine serum albumin-coated plates were treated with different doses of IL-13 and montelukast and examined for permeability using monolayer semi-permeable membranes, for distribution using confocal microscopy, and for ZO-1 protein levels using Western blotting.

**Results:** As the concentration of IL-13 increased, the contents of ZO-1 and synaptopodin were decreased and their redistribution and rearrangement were observed in immunofluorescence studies. The redistribution of α-actinin & CD2AP by IL-13 were also found around the nucleus of the cell. α-actinin & CD2AP significantly decreased at 20 ng/mL IL-13 (both $P < 0.05$), whereas β-catenin and p130Cas significantly increased (both $P < 0.05$). At higher doses, IL-13 gradually increased the permeability of monolayered podocytes. ZO-1 was internalized and shown to accumulate in the cytoplasm of human podocytes in an IL-13 dose-dependent manner. High doses (50 and 100 ng/mL) of IL-13 decreased the levels of ZO-1 protein at 12 and 24 hr (both $P < 0.01$; n=3), which were significantly reversed by a high dose (0.5 μM) montelukast treatment ($P < 0.01$, n=3).

**Conclusions:** Our results indicate that IL-13 may increase podocyte permeability through the modulation of several cytoskeletal proteins in podocytes, and such alterations in the content and localization of the molecules may be relevant to the pathogenesis of proteinuria in the IL-13-induced MCNS model.

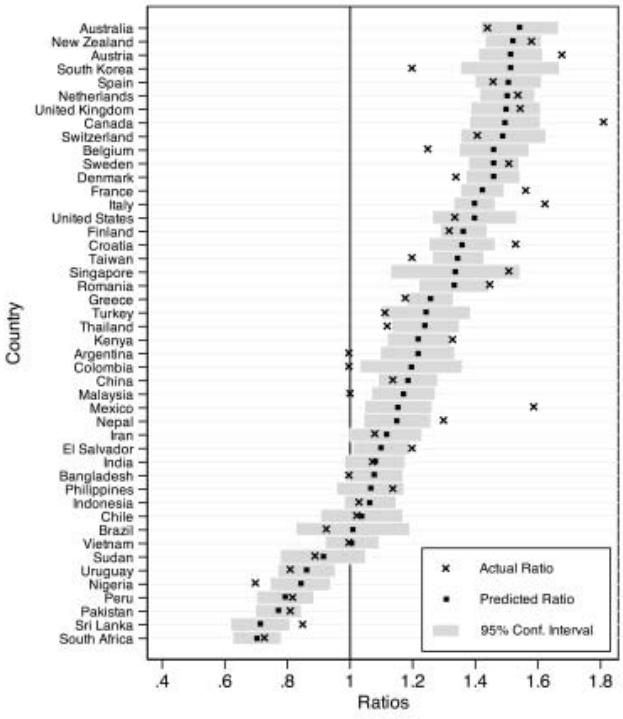
## SA-PO896

**Economies of Scale and Cost of Dialysis across the World: A Macroeconomic Perspective** Akash Nayak Karopadi,[2] Giacomo Mason,[1] Enrico Rettore,[3] Claudio Ronco.[1] *[1]Dept Nephrology - IRRIV, S Bortolo Hosp, Vicenza, Italy; [2]Dept Chem Eng and Dept Econ, BITS, Pilani, India; [3]Dept Statistical Sciences, Uni Padua, Padua, Italy.*

**Background:** ESRD treatment is a large expense in most health systems. The main dialysis methods, hemodialysis (HD) and peritoneal dialysis (PD), have significant differences in cost composition and production factors. In this paper we identify macroeconomic variables that influence the relative cost of such modalities across a sample of 51 countries, and finally draw policy-relevant conclusions.

**Methods:** We retrieved 75 articles from PUBMED and EMBASE estimating PD and HD costs in a 46 countries. We augmented this data with targeted surveys to prominent nephrologists in countries not covered by available literature. For each country, we estimated the ratio between cost of HD and PD. We finally conducted a multivariate regression analysis using the HD/PD cost ratio in each country as dependent, with several country-level indicators as regressors.

**Results:** We found a strong effect of the following variables on the HD/PD ratio: positive effect of a country's development (approximated by minimum wage or HDI); large positive effect of a country's economies of scale in PD equipment (presence of local manufacturing or absence of tariff restriction on PD equipment imports); negative effect of the percentage of private healthcare expenditure and APD usage. Actual and model-predicted ratios are in Figure 1.



**Conclusions:** Ceteris paribus, local manufacturing and the absence of import duties on PD equipment imply less costly PD: local manufacturing and no duties have very similar effects on the HD/PD cost ratio (0.42 vs. 0.33). The policy implication is that, in the absence of a market large enough to make local production of PD equipment feasible, a country can still reap the benefits of economies of scale by eliminating restrictions on import such as tariffs or quotas.

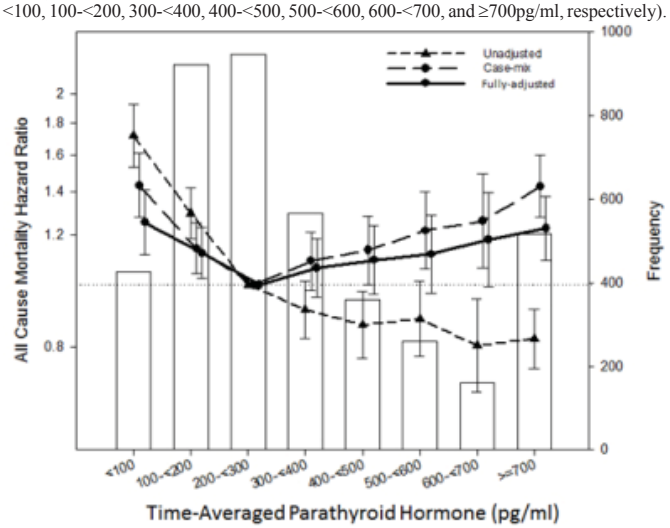
## SA-PO897

**Mortality-Predictability of Parathyroid Hormone in Peritoneal Dialysis Patients** Connie Rhee,[1] Wei Ling Lau,[1] Vanessa A. Ravel,[1] Elani Streja,[1] Csaba P. Kovesdy,[2] Rajnish Mehrotra,[3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmon Center, Orange, CA; [2]Memphis VA Medical Center, Memphis, TN; [3]Harborview Medical Center, Seattle, WA.*

**Background:** In hemodialysis (HD) patients, parathyroid hormone (PTH) derangements are associated with mortality. Prior studies examining the mortality-predictability of PTH in peritoneal dialysis (PD) patients have been limited and mixed, and the outcome-predictability of PTH in this population remains unclear.

**Methods:** In a cohort of 9,244 adult PD patients from a large national dialysis organization (entry period 2001-2006, with follow-up through 2009), we examined associations between time-averaged PTH with all-cause mortality using multivariable Cox models adjusted for case-mix and laboratory covariates. We then compared the mortality-predictability of time-averaged PTH among 9,244 PD vs. 99,323 HD patients.

**Results:** In PD patients, there was a U-shaped association between PTH and death risk, with PTH levels <200pg/ml and ≥700pg/ml associated with increased mortality (reference: PTH 200-<300pg/ml): HRs (95% CI) 1.25 (1.12-1.41), 1.12 (1.02-1.23), 1.06 (0.96-1.18), 1.09 (0.97-1.24), 1.12 (0.97-1.29), 1.18 (0.99-1.40), and 1.23 (1.09-1.38) for PTH levels <100, 100-<200, 300-<400, 400-<500, 500-<600, 600-<700, and ≥700pg/ml, respectively).



In analyses comparing the mortality-predictability of PTH among HD vs. PD patients, there was a U-shaped association among both HD and PD patients, with a greater magnitude of risk observed among HD patients particularly in lower and higher PTH categories (ref: PD patients PTH 200-<300pg/ml).

**Conclusions:** In PD patients, both lower and higher PTH levels are associated with increased mortality. Further studies are needed to confirm findings, elucidate underlying mechanisms, and to determine if correction of PTH to target ranges improves outcomes in PD patients.

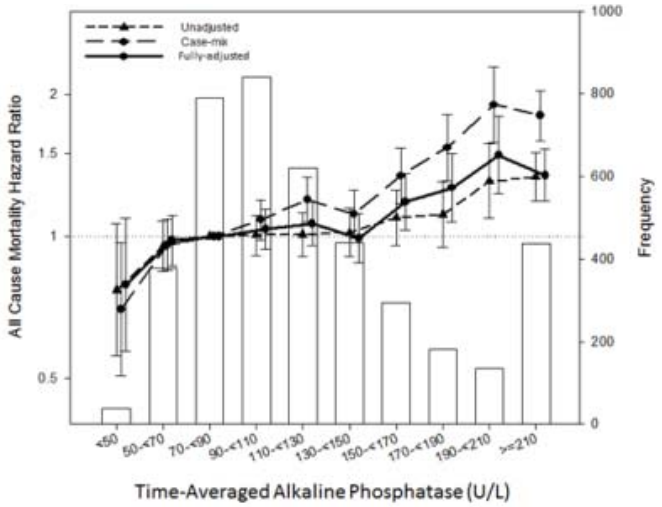
## SA-PO898

**Mortality-Predictability of Alkaline Phosphatase in Peritoneal Dialysis Patients** Connie Rhee,[1] Wei Ling Lau,[1] Vanessa A. Ravel,[1] Elani Streja,[1] Csaba P. Kovesdy,[2,3] Rajnish Mehrotra,[4] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmon Center, Orange, CA; [2]Univ of Tennessee Health Science Center, Memphis, TN; [3]Memphis VA Medical Center, Memphis, TN; [4]Harborview Medical Center, Seattle, WA.*

**Background:** Kidney Disease Improving Global Outcomes guidelines recommend alkaline phosphatase (AP) as an adjunctive test in bone turnover assessment. Mounting evidence suggests AP derangements are associated with coronary artery calcification, cardiovascular events, sudden cardiac death, and increased mortality in chronic kidney disease and hemodialysis (HD) patients. However, the mortality-predictability of AP in peritoneal dialysis (PD) patients has not been well-studied.

**Methods:** In a cohort of 9,244 adult PD patients from a large national dialysis organization (entry period 2001-2006, follow-up through 2009), we examined associations between time-averaged AP with all-cause mortality using Cox models adjusted for case-mix and laboratory covariates. We then compared the mortality-predictability of time-averaged AP among 9,244 PD vs 99,323 HD patients.

**Results:** In analyses adjusted for case-mix and laboratory covariates ("fully-adjusted"), higher AP levels were associated with increased death risk in PD patients (ref: AP 70-<90U/L).



In analyses of time-averaged AP measurements, HD patients had increased mortality at all levels with the greatest risk in the highest and lowest AP categories, whereas PD patients had increased mortality with AP>150U/L only (ref: PD patients with AP 70-<90U/L). Sensitivity analyses adjusted for AST were qualitatively similar.

**Conclusions:** Higher AP levels are associated with increased mortality in PD patients. Further study of AP as a marker and/or mediator of vascular calcification and other underlying mechanisms, as well as the utility of AP in the management of chronic kidney disease-mineral bone disorders is needed.

## SA-PO899

**Prevalence of High Parathyroid Hormone and Alkaline Phosphatase Levels among Peritoneal Dialysis versus Hemodialysis Patients**

Connie Rhee,[1] Wei Ling Lau,[1] Vanessa A. Ravel,[1] Elani Streja,[1] Csaba P. Kovesdy,[2,3] Rajnish Mehrotra,[4] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Orange, CA; [2]Univ of Tennessee Health Science Center, Memphis, TN; [3]Memphis VA Medical Center, Memphis, TN; [4]Harborview Medical Center, Seattle, WA.*

**Background:** Bone metabolism and morphology may be inherently different in peritoneal dialysis (PD) vs. hemodialysis (HD) patients, owing to heightened risk of vitamin D deficiency (ie, peritoneal effluent losses) and differences in mineral bone disorder management in PD (ie, greater oral vs. IV vitamin D use). Early studies suggested PD patients have a disproportionately higher prevalence of adynamic bone disease and low parathyroid (PTH) levels compared to HD patients, but were largely conducted prior to the adoption of lower calcium concentration peritoneal dialysate solutions. We thus compared the distribution of alkaline phosphatase (AP) and PTH levels according to modality in a contemporary cohort of dialysis patients.

**Methods:** Among a 2001-2006 cohort of 9,244 adult PD and 99,323 HD patients from a large national dialysis organization, we compared the distribution of AP and PTH levels. Using logistic regression adjusted for case-mix and malnutrition-inflammation-complex (MICS) markers, we then examined the association between dialysis modality and risk of higher PTH levels.

**Results:** Distributions of AP levels among PD vs. HD patients were similar, and >60% of patients receiving either modality manifested AP<110U/L. However, PD patients manifested a higher prevalence of PTH>300pg/dl (39.4% vs 48.1% of HD and PD patients, respectively) and PTH>600pg/dl (13.8% vs 20.1% of HD and PD patients, respectively). Compared to HD, PD was associated with higher risk of having a PTH>300pg/dl and a PTH>600pg/dl, after adjusting for case-mix and MICS covariates: ORs 1.68 (95% CI) 1.60-1.76 and 1.73 (95% CI) 1.62-1.84, respectively.

| PTH Level | Multivariable adjusted OR (95% CI) |
|---|---|
| PTH>300pg/dl | 1.68 (1.60-1.76) |
| PTH>600pg/dl | 1.73 (1.62-1.84) |

**Conclusions:** Contrary to earlier data, for a given level of AP and after adjustment for case-mix and MICS markers, PD patients have disproportionately higher PTH levels than HD patients.

## SA-PO900

**NT-proBNP Is a More Significant Prognostic Biomarker for Mortality among Three Cardiac Biomarkers in Incident Peritoneal Dialysis Patients**

Fa Mee Doh,[1] Hyung Jung Oh,[1] Chan Ho Kim,[1] Tae-Hyun Yoo,[1,2] Shin-Wook Kang.[1,2,3] *[1]Dept of Internal Medicine, College of Medicine; [2]Brain Korea 21, Yonsei Univ, Seoul, Korea; [3]On Behalf of the Clinical Research Center for ESRD Investigators.*

**Background:** Given multifactorial pathogenesis of cardiovascular (CV) disease in ESRD patients, integrated assessment using different biomarkers is required in risk stratification. In this study, we conducted a comprehensive analysis to identify the impact of three biomarkers (NT-proBNP, cTnT, and hsCRP) on mortality in incident continuous ambulatory peritoneal dialysis (CAPD) patients.

**Methods:** A prospective cohort of 335 incident CAPD patients from 36 centers of the CRC for ESRD in Korea was followed up to 33 mo. According to the baseline values of three biomarkers, patients were stratified into tertiles, and CV and all-cause mortality were compared among the three groups. Cox proportional analysis was performed to determine the independent prognostic value of each biomarker for mortality.

**Results:** During a mean follow-up duration of 21.5 mo, all-cause deaths were significantly more observed in the third tertile of NT-proBNP (29 patients, 25.7%) compared to the first (6 patients, 5.4%) and second tertiles (4 patients, 3.6%) (P<0.001). In addition, the third tertile of hsCRP had significantly higher all-cause mortality rates compared to the other tertiles (P<0.05). In contrast, there was a trend for higher mortality rates in the third tertile of cTnT, but this difference did not reach statistical significance. In multivariate Cox models, natural log values (Ln) of NT-proBNP and hsCRP, but not cTnT, were significantly associated with increased risks of all-cause mortality (Ln NT-proBNP, HR=12.81, P=0.001; and Ln hsCRP, HR=1.489, P=0.037), while NT-proBNP only significantly predicted CV mortality (HR=14.35, P=0.007). Moreover, among these biomarkers, NT-proBNP provided the highest positive predictive value for CV (AUC=0.826, P=0.004) and all-cause mortality (AUC=0.865, P<0.001).

**Conclusions:** NT-proBNP predicted CV and all-cause mortality better than hsCRP and cTnT in incident PD patients, suggesting that NT-proBNP could be a useful biomarker for adverse outcomes in these patients.

*Funding:* Government Support - Non-U.S.

## SA-PO901

**Serum Beta-2 Microglobulin Significantly Predicts Survival in Association with the Residual Renal Function in Japanese Patients on Peritoneal Dialysis – A Prospective Multicenter Cohort Study (PDR-CS)**

Hiroshi Morinaga,[1] Hitoshi Sugiyama,[1] Yasuhiko Ito,[2] Kazuhiko Tsuruya,[3] Hisako Yoshida,[3] Hiroki Maruyama,[4] Shin Goto,[4] Tomoya Nishino,[5] Hiroyuki Terawaki,[6] Masaaki Nakayama,[6] Hidetomo Nakamoto,[7] Seiichi Matsuo,[2] Hirofumi Makino.[1] *[1]Okayama Univ, Okayama, Japan; [2]Nagoya Univ, Nagoya, Japan; [3]Kyushu Univ, Fukuoka, Japan; [4]Niigata Univ, Niigata, Japan; [5]Nagasaki Univ, Nagasaki, Japan; [6]Fukushima Medical Univ, Fukushima, Japan; [7]Saitama Medical School, Saitama, Japan.*

**Background:** Beta-2 microglobulin (B2M) is an 11,800-molecular-weight polypeptide that is generated at a constant rate and eliminated by the kidneys. An elevated serum level of B2M is a potential risk factor predicting mortality in predialysis patients. However, it remains unknown whether B2M has an impact on the outcomes of patients with peritoneal dialysis (PD).

**Methods:** Five university hospitals participated in the PDR-CS and 188 PD patients were enrolled in the study, as of December 2011 (mean age, 58.0 years; male, 68.0%; diabetic nephropathy, 31.3%).

**Results:** The analysis showed that the group with a total Kt/V of 1.7 or higher to exhibit significantly lower levels of serum B2M than the group with a total Kt/V under 1.7 (23.1 vs. 27.3 mg/L; p<0.01). Dividing the patients based on whether they had a daily urinary volume of under 400 mL or 400 mL or higher revealed dramatic differences in the serum B2M levels (33.5 vs. 20.0 mg/L, p<0.0001). During the 24 months of follow-up, the group with serum B2M levels of less than 30 mg/L exhibited significantly better patient survival (p<0.01) and technique survival (p<0.05) than the group with serum B2M levels of at least 30 mg/L. The most significant determinant of the B2M level was the renal Kt/V (p<0.0005), as observed in a multivariate analysis after adjusting for the age and PD duration.

**Conclusions:** This study suggests that PD patients with a serum B2M level of less than 30 mg/L exhibit significantly better patient survival and technique survival in association with the residual renal function based on the renal Kt/V. The serum B2M level is thus considered to be a potential prognostic indicator in PD patients.

## SA-PO902

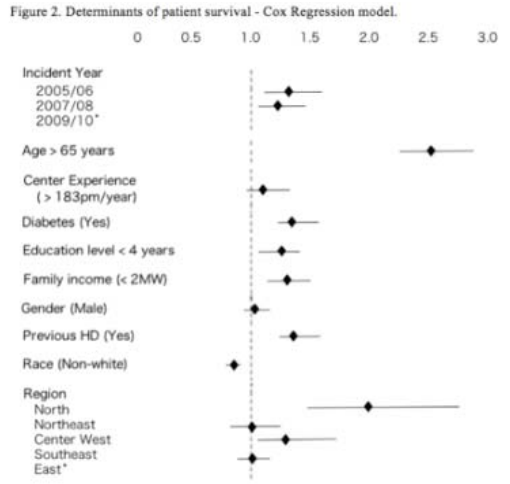
**Vintage-Related Improvement in Peritoneal Dialysis Patient Survival in the BRAZPD II Cohort**

Thyago Proença de Moraes,[1] Marcia Olandoski,[1] Ana Figueiredo,[2] Pasqual Barretti,[3] Roberto Pecoits-Filho.[1] *[1]Pontificia Universidade Catolica do Parana, Brazil; [2]Pontificia Universidade Catolica do Rio Grande do Sul, Brazil; [3]Universidade do Estado de Sao Paulo, Brazil.*

**Background:** Recent reports describe a trend to outcomes improving in peritoneal dialysis (PD) patients in the developed world. However, most of the recent growth in PD has been in the developing world, and studies looking at trends of outcomes in these regions are lacking. Our aim was to analyze temporal trends in patient and technique survival (TS) in BRAZPD II study.

**Methods:** This is a nationwide prospective study, in which incident adult patients on PD for at least 90 days from 122 centers were included between Dec 2004 - Jan 2011. Patients were divided based on the year of PD initiation: 2005/6, 2007/8, and 2009/10. Groups were compared using multivariate Cox regression.

**Results:** A total of 7007 patients (60±16 years old and 39% diabetics) were included. Main cause of dropout: death (51%); Main cause of death: cardiovascular disease(36%). Main cause of technique failure: peritonitis (63%). TS at 1, 2, 3, 4, and 5 year were 91%, 84%, 77%, 68%, and 58%. There was no change in TS over the years. Overall patient survival (PS) were 85%, 74%, 64%, and 54% at 1, 2, 3, and 4 years. PS improved with a striking 24% reduction of risk when 2005/6 was compared to 2009/10 (HR 0.76, CI95% 0.65-0.89).



Independent mortality predictors were: age ≥ 65 years (HR 2.55, CI95% 2.27-2.85), previous HD (HR1.41, CI95% 1.26-1.58), diabetes (HR 1.36, CI95% 1.22-1.52), White race (HR 1.25, CI95% 1.10-1.42), lower education level (HR 1.68, CI95% 1.11-1.44), low family income (HR 1.34, CI95% 1.19-1.51) and region (p<0.05).

**Conclusions:** A positive significant trend to patient survival improvement was observed throughout the vintages, even with no changes in technique survival and after adjusting for multiple covariates.

## SA-PO903

**Switching to Hemodialysis without a Functioning Arteriovenous Shunt Increased Risk of Mortality in Peritoneal Dialysis Patients** Shin Hung Tsai,[1] Jinn-Yang Chen.[2] *[1]Div of Nephrology, Cheng Hsin General Hospital, Taipei, Taiwan; [2]Div of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan.*

**Background:** Switching to hemodialysis was frequently encountered in peritoneal dialysis (PD) treatment. Whether switching to Hemodialysis without a functioning arteriovenous shunt will increase risk of mortality has not been fully addressed in the literatures.

**Methods:** Incident PD patients, aged ≥ 20 y/o, started dialysis therapy between January 2006 and December 2009, and had stayed on PD for ≥ 180 days were reviewed for our study. Switching to HD for ≥ 60 days was defined as a successful switching. Acute cardiovascular event (defined as admission due to acute heart failure, acute myocardial infarction or angina pectoris) and first peritonitis were analyzed as time-dependent covariates in the regression.

**Results:** Among 4333 incident PD patients, 163 (3.8 %) patients switched with a functioning arteriovenous shunt, 479 (11.1 %) switched with a central venous catheter (CVC) and 442 (10.2%) patients died within 60 days of hemodialysis with a CVC. Patients who switched with CVC were older (55.3±14.4 years), had higher prevalence of cardiovascular disease (41.3%) at baseline and had more episodes of acute cardiovascular events and peritonitis after initiating PD. After adjusting acute cardiovascular events, peritonitis and other baseline covariates in the Cox model, patients who switched with CVC had increased risk of mortality (HR:1.41, 95% CI: 1.07-1.86, *P*=0.014) than those who switched with functioning arteriovenous shunt (HR: 1.01, 95% CI: 0.59-1.74, *P*=0.97). Patients who switched with CVC also had higher non-dialysis out-patient and in-patient medical cost.

| USD/patient/month | Dialysis cost | OPD, non-dialysis | In-patient, non-dialysis |
|---|---|---|---|
| Switching a functioning AV shunt | 1629.6 | 127 | 293.6 |
| Switching with a central venous catheter | 1619.8 | 165.6 | 482.5 |

**Conclusions:** Switching to hemodialysis without a functioning arteriovenous shunt increased risk of mortality in PD patients. A planned arteriovenous shunt creation for patients not doing well in PD would avoid the increased mortality risk after initiating hemodialysis with a central venous catheter.

*Funding:* Government Support - Non-U.S.

## SA-PO904

**High Serum Cholesterol and Low Density Lipoprotein Predicted a Lower Early Death but Higher Late Death in Peritoneal Dialysis Patients** Qionghong Xie,[1] Xiaoling Ge,[1] Da Shang,[1] Rong Xu,[2] Yue Wang,[3] Yeping Ren,[4] Jianghua Chen,[5] Huiping Zhao,[6] Jie Dong,[2] Hai Yan Wang,[2] Chuanming Hao,[1] Tongying Zhu.[1] *[1]Huashan Hospital, Fudan Univ; [2]Peking Univ First Hospital; [3]Peking Univ Third Hospital; [4]Second Affiliated Hospital of Harbin Medical Univ; [5]The First Affiliated Hospital, Zhejiang Univ; [6]Peking Univ People's Hospital.*

**Background:** This study aimed to examine whether serum lipids were associated with all-cause mortality in PD patients.

**Methods:** Two retrospective cohorts were analyzed in this study. In the first cohort, 2,028 adult PD patients from seven PD centers in China were included and their lipids data at the beginning of PD were collected. The primary endpoint was all-cause mortality. In the second cohort, 171 PD patients who survived >24 months were included from one of seven centers. Their lipids were measured at the 1st, 3rd, 6th, 12th, 18th and 24th month and average levels were used to analyze their effect on mortality. Cox regression was used to analyze the association between lipids and all-cause mortality. Hazard Ratio was expressed as per 1 mmol/L increasing.

**Results:** The first cohort showed that higher cholesterol (p<0.001, HR=0.867), LDL (p<0.001, HR=0.823) and HDL (p<0.001, HR=0.606) but not triglyceride (p=0.073, HR=0.942) predicted a better prognosis in PD patients, consistent with a reverse epidemiology phenomena. When we analyzed the association between lipid and mortality using time-stratified Cox regression dividing follow-up time into 2 intervals: <1 year and > 1 year, we found that cholesterol (p<0.001, HR=0.719) and LDL (p<0.001, HR=0.052) were associated with the first-year death of the PD patients but not the late death (death after 1 year). To examine the association of lipid levels with later mortality, we analyzed the patients from second cohort who survived for more than 2 years and had two-year lipids available. The results: higher average cholesterol (p=0.008, HR=1.535) and LDL (p=0.002, HR=2.024) were associated with an increasing late mortality.

**Conclusions:** High lipid levels at beginning of PD predict a lower early death while high lipid levels are associated with late death in PD patients.

## SA-PO905

**Comparison of Three Comorbidity Indices as Predictors of Survival in Chinese Peritoneal Dialysis Patients** Terry Kw Ma, Cheuk-Chun Szeto. *Div of Nephrology, Dept of Medicine and Therapeutics, Prince of Wales Hospital, The Chinese Univ of Hong Kong, Shatin, New Territories, Hong Kong, China.*

**Background:** In patients undergoing peritoneal dialysis (PD), various indices have been used to quantify the burden of comorbid conditions. The aim of this study is to compare the performance of three commonly used comorbidity indices in incident Chinese PD patients.

**Methods:** The cohort included 461 incident PD patients (245 males). Clinical information and presence of comorbid conditions were obtained by review of medical records. Comorbidity scores using the original Charlson Comorbidity Index, Brenda's modified Charlson Comorbidity Index, and Liu's Comorbidity Index were calculated. Patients were followed up for 45.5 ± 33.0 months for survival analysis.

**Results:** The mean age of our patients was 57.3 ± 13.5 years and 36.4% had diabetes. The median (inter-quartile range) of the Charlson, Brenda's, and Liu's scores were 6 (4-7), 1 (0-2), and 4 (2-5), respectively. There was a strong internal correlation between all three scores (p < 0.0001 for all comparisons). By univariate analysis, all three comorbidity scores significantly correlated with patient survival, with unadjusted hazard ratios (HR) 1.34, 1.31 and 1.21, respectively (p < 0.0001 for all). Multivariate analysis showed that only the original Charlson's score was independent predictor of patient survival (adjusted HR 1.34, 95% confidence interval 1.26-1.43, p < 0.0001).

**Conclusions:** When used alone, all three comorbidity scores have satisfactory performance in predicting patient survival of Chinese incident PD patients. However, the original Charlson's score appears to be the best predictor of patient survival amongst the three.

## SA-PO906

**Visit-to-Visit Variability in Systolic Blood Pressure Is Associated with Mortality in Incident Peritoneal Dialysis Patients** Han Ro,[1] Ae Jin Kim,[1] Hyung Soo Kim,[1] Chungsik Lee,[2] Sun Moon Kim,[3] Ji Yong Jung,[1] Jae Hyun Chang,[1] Hyun Hee Lee,[1] Wookyung Chung.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Gachon Univ Gil Medical Center, Gachon Univ of Medicine and Science, Incheon, Republic of Korea; [2]Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea; [3]Div of Nephrology, Dept of Internal Medicine, Chungbuk National Univ Hospital, Cheongju, Republic of Korea.*

**Background:** Visit-to-visit blood pressure variability has been well known to be associated with mortality in general population. However, the relationships between the variability in blood pressure and mortality have not been studied in peritoneal dialysis (PD) patients.

**Methods:** In 98 patients who started PD in Gachon University Gil Medical Center between May 2007 and December 2011, 84 patients who continued PD until 36 weeks were retrospectively analyzed. The coefficient of variation (CV) of systolic blood pressure (SBP) was calculated from office blood pressures between 12 week and 36 week after PD. The patients were divided in to low and high BP variability groups according to the median value of CV of SBP.

**Results:** Higher BP variability predicted all cause mortality (log-rank test, P=0.008). Diabetes mellitus, congestive heart failure, history of previous cardiovascular event, serum sodium at 12 week, serum albumin at 12week, and use of β-blockers were the main correlates of CV of SBP. Higher BP variability was an independent risk factor of death after adjusting for confounding factors (hazard ratio 12.363, 95% confidence interval 1.017-150.293).

**Conclusions:** Peritoneal dialysis patients with high visit-to-visit variability in systolic blood pressure increased all cause mortality.

**SA-PO907**

**Ankle-Brachial Index Is Correlated with Mortality, Morbidity and Peritoneal Transport in Peritoneal Dialysis Patients**
Ana Rita Mateus Martins, Ricardo Vizinho, Patricia Quadros Branco, Maria Augusta Cabrita Silva Gaspar. *Nephrology, Santa Cruz Hospital, Carnaxide, Portugal.*

**Background:** Peripheral artery disease (PAD) is highly prevalent among patients with end stage renal disease. PAD is associated with high cardiovascular risk and is often unrecognized in peritoneal dialysis pts. Ankle-Brachial Index (ABI), a non-invasive method to diagnose PAD, show a U-shaped association with mortality. The ABI is highly correlated with subclinical PAD, but little is known about its association with morbidity and peritoneal transport in peritoneal dialysis pts.

**Methods:** We studied 72 pts (65,8% male, 27,4% diabetic, mean age 55±13,8 years) during 36±26,8months. Measurements of ABI were performed in supine position. Blood pressure was measured in the both arms (brachial artery) and ankles (posterior tibila arteries). Highest ankle SBP/Highest brachial SBP was used to calculate ABI. An ABI value greater than 0.9 was defined as normal. Subclinical PAD was defined as an ABI less than 0.9 in either extremity. ABI> 1.3 is a false negative caused by noncompressible arteries. ABI was correlated with functional parameteres of peritoneum, residual renal function, vascular calcification (Adragao Score) and cardiovascular events.

**Results:** A normal ABI were found in 84,9 %. Vascular calcification were found in 20 pts (27,4%).

During the follow up period, 7 pts died. In a multivariate analysis abnormal ABI (p=0,04) and high peritoneal transport (p=0,03) were independent predictors for amputation events, adjusted to diabetes and age. A survival cox regression showed that C reactive protein (p=0,02) and diabetes (p=0,05) were independent predictors for the survival, even when adjusted to BMI (body mass index), baseline cardiovascular disease and abnormal ABI.

**Conclusions:** ABI is correlated with peritoneal transport level, C reactive protein, diabetes, albumin and BMI in PD patients.

**SA-PO908**

**Metabolic Syndrome Investigation and the Risk Factors Analysis in Peritoneal Dialysis Patients: A Clinical Cohort Study in a Mono-Center**
Yiwen Li. *Kidney Disease Dept, ZheJiang Province Hospital.*

**Background:** To investigate metabolic syndrome status in peritoneal dialysis patients. To observe the effects of glucose-based peritoneal dialysate on the prevalence of metabolic syndrome in peritoneal dialysis patients. To identify the risk factors in peritoneal dialysis patients with metabolic syndrome.

**Methods:** A retrospective self-controlled study was performed with 77 peritoneal dialysis patients who had been long-term peritoneal dialysis treated in Division of Nephrology, the First Affiliated Hospital, Zhejiang University School of Medicine during January 1, 2009 to February 23, 2012. According to time after peritoneal dialysis (0 months, 6 months, 12 months, 18 months and 24 months) they were divided into 5 groups.

**Results:** 1. The prevalence of obesity was 14.86% in ESRD patients at the initiation of PD. There were no significant differences in the prevalence of obesity in PD patients with PD duration. 2. The FPG level of PD patients rose significantly with their prolonged dialysis duration, especially at 1 year after PD treatment (P<0.05), but there were no significantly high incidence rate of hyperglycemia.3.The prevalence rate of high TG was 98.68% in ESRD patients, and had increased significantly with PD duration (P<0.01). 4. The level of HDL-C increased significantly with PD duration (P = 0.005), but the prevalence rate of high HDL-C level decreased (P = 0.032). 5. The level of LDL-C increased significantly with PD duration (P <0.01). 6. The baseline prevalence rate of MS in ESRD patients was 59.21%. It increased up to 73.68% at 2 years after the initiation of PD therapy, though did not reach statistical significance. 7. FPG(B=4.549, P<0.01), BMI (B=9.338, P=0.002), FPG (B=6.983, P=0.008) , Systolic blood pressure (B=3.921, P=0.048), LDL-C(B=4.549, P=0.033), HDL-C(B=5.968, P=0.015), albumin (B=4.42, P=0.035) and dialysis additional energy (B=4.42, P=0.035)were the risk factors of MS.

**Conclusions:** The prevalence of obesity, dysglycaemia, dyslipidemia and MS were high in PD patients. ESRD and PD patients were high risk groups of MS. Long PD duration did not affect the incidence of MS. Dialysis additional energy and BMI along with FPG, Systolic blood pressure, LDL-C, HDL-C and albumin were the risk factors of MS.

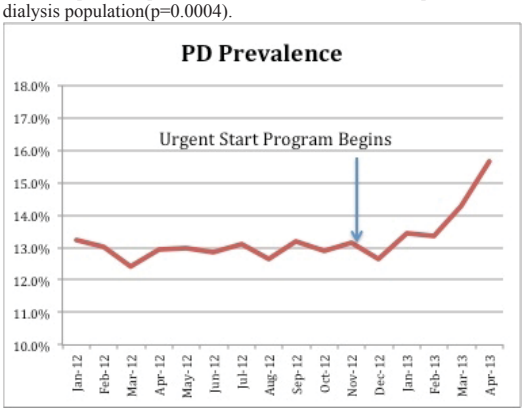
**Urgent Start Peritoneal Dialysis Increases Peritoneal Dialysis Utilization without Compromising Outcomes**
Eric L. Wallace, Tarek Darwish, Russell Griffin, Gaurav Jain. *Univ of Alabama at Birmingham.*

**Background:** Peritoneal dialysis (PD) utilization remains low. A contributing factor is that until recently urgent dialysis required initiation using an intravascular catheter (IVC) on hemodialysis (HD) accounting for 60% of HD initiations. IVC usage is associated with increased morbidity and mortality, thus decreasing IVC use may lead to improved outcomes. Urgent start PD (UPD) allows for urgent initiation on PD by using the PD catheter prior to the standard 2 week healing time. We studied short term effects of UPD at a large academic center.

**Methods:** Clinical and outcomes data were collected on concurrent incident UPD and traditional patients using chart review. Incident PD patient was defined strictly as a patient having attended 1 day of PD training. Effect of UPD on PD prevalence (PD census/total dialysis census)was evaluated using Poisson regression. Outcomes were analyzed comparing UPD versus traditional cohorts. Pearson correlation was used to analyze IVC prevalence (total patients with IVC/total HD census) with relation to PD prevalence.

**Results:** UPD (N=11) and traditional (N=27) cohorts were similar in clinical characteristics. PD prevalence 6 months prior to UPD was stable at 13% (SD 0.002). After inception PD prevalence increased over a 6 month period to 15.7% of the total UAB dialysis population(p=0.0004).



Outcomes including need for a second PD related operation, major leaks, peritonitis, admissions, and patient retention were similar (p values 0.55, 0.52, 0.20,0.65, and 0.61 respectively). For every 1% increase in PD prevalence, there was a 0.6% decrease in IVC prevalence, though not statistically significant (p=0.25).

**Conclusions:** UPD increases PD utilization.Short-term clinical outcomes of urgent versus traditional start are similar. Increased PD prevalence may decrease IVC catheter prevalence although longer follow up will be needed to evaluate for significance.

**SA-PO910**

**Urgent Start PD: A Viable Mode of Dialysis Delivery to Increase PD Patients in the United States**
Heather L. Henderson, Quresh T. Khairullah, Heather M. Stamat, Robert Provenzano. *Nephrology, St. John Hospital and Medical Center, Detroit, MI.*

**Background:** There are over 500,000 people in the US with ESRD, of which only 7% use PD. There are many reasons for this low PD percentage, but the fact 60% of patients progressing to ESRD lack dialysis education or planning is a major factor. We developed an "Urgent-Start" PD program to address these issues.

**Methods:** Encouraged by Ghaffari and others showing urgent start PD (using the catheter earlier than 2 weeks) is a safe and viable option to initiate dialysis a protocol was devised involving a dedicated surgeon/nephrologist to place the Tenckhoff catheter, education of nurses, nephrologists, and one participating outpatient dialysis unit to deliver urgent start PD. All new start dialysis patients without prior dialysis education or plan were offered PD as their initial dialysis modality to avoid placement of a tunneled central venous catheter (CVC). After consent was obtained, a Tenckhoff catheter was placed and low volume exchanges were initiated immediately inpatient or at the outpatient unit as clinically appropriate. Once they were transitioned to the outpatient unit they received intermittent PD (IPD) thrice weekly until full fill volumes were tolerated and training was complete. After learning more about dialysis options those that chose to change to HD, an AVF was placed. While awaiting AVF maturation they continued in center IPD to avoid CVC placement.

**Results:** 19 new dialysis patients were enrolled in the program from May 2012 through May 2013. Two patients developed catheter complications requiring replacement or repositioning of their catheter and two patients developed a minor leak which resolved with holding PD temporarily. At six months of follow up, 6 patients (32%) transitioned or plan to transition to hemodialysis once their AVF has matured. No episodes of peritonitis and one exit site infection were observed.

**Conclusions:** Our urgent start PD program has resulted in increased PD growth (urgent and non-urgent starts) by 46% over last year with acceptably low incident complication rates. We believe our program should be considered to increase the use of PD by incident patients as well a method of CVC avoidance.

**Urgent Start Peritoneal Dialysis: A Centre's Experience**
Sunita K. Nair,[1] Rajinder S. Singh.[2] *[1]Dept of Nephrology, St. Paul's Hospital, Vancouver, Canada; [2]Dept of Nephrology, Vancouver General Hospital, Vancouver, Canada.*

**Background:** Traditionally, Hemodialysis ( HD)is the usual adopted initial modality for patients who need urgent unplanned dialysis. Peritoneal dialysis allows better quality of life than incentre hemodialysis and gives the option to dialyse at home. It offers an early survival advantage over HD (1). PD is cost effective (2). Recently it was shown by Gaffari that starting PD in unplanned patients needing urgent start is safe and feasible (3).

**Methods:** Retrospective study that looked at the urgent starts who were offered PD in the year Jan 2012- Feb 2013. These patients may or may not be followed up in the CKD clinics. PD catheter was inserted either at bedside by a Neprhologist or in the operating room by a Surgeon. Intermittent low volume PD (IPD) was commenced within three weeks of insertion. The study aimed to look at modality retention at 90 days since commencing on IPD and the complications encountered during their treatment.

**Results:** A total of 22 patients received PD as initial modality of dialysis in the period between Jan 2012-Feb 2103. IPD was commenced within three weeks of PD catheter insertion. 20 of these catheters were inserted bedside and 2 were surgical catheters. 11 patients remained on CCPD ( Continuous Cycler Peritoneal Dialysis), 5 patients stayed on CAPD ( Continuos Ambulatory Peritoneal Dialysis). So a total of 16 out of 22 ( 72%) patients retained PD modality beyond three months of commencing therapy. 2 patients died on PD and 1 patient moved territory. 3 patients were transitioned to HD. Of the patients, 2 developed Exit site leaks and 2 aptients had peritonitis. 1 patient needed brief HD for a hernia repair in between IPD and training for CAPD/CCPD. 2 patients had bloody effluent which subsequently cleared up.

**Conclusions:** PD can certainly be the initial modality for patients needing urgent start in a centre that has support in terms of bedside catheter insertion, space for allowing IPD within the hospital and rooms and staff for training at the earliest.

## SA-PO912

**Impact of a Dedicated Laparoscopic Peritoneal Dialysis Access Program on Clinical Outcomes** Tarek M. Alzahrani,[1] Mina Kashani,[2] Daniela Ghiculete,[1] Benjamin Shiff,[3] Philip McFarlane,[2] Jeffrey Perl,[2] Jason Y. Lee.[1] *[1]Urology, St. Michael's Hospital, Univ of Toronto; [2]Nephrology, St. Michael's Hospital, Univ of Toronto; [3]Faculty of Medicine, Univ of Toronto.*

**Background:** The success of peritoneal dialysis (PD) rests on the establishment of a functional access at time of PD initiation. Optimal methods of PD catheter insertion, which include laparoscopic (LAP), open surgical (OS), and fluoroscopic-guided (FG) techniques, continue to be debated. After the addition of a dedicated laparoscopic surgical access program, we compared the outcomes of PD catheters inserted at our institution using LAP, OS, and FG techniques.

**Methods:** After REB approval, a retrospective chart review was conducted on all PD catheters inserted at St. Michael's Hospital between January 2007 and March 2013. Patient demographic data, operative details, and clinical outcomes data were collected and analyzed for all 3 different insertion techniques.

**Results:** A total of 235 PD patients were included in the study (40 LAP, 36 OS, 159 FG) and each group had comparable patient populations; mean age, gender, BMI, prior history of abdominal surgery. The LAP group had a lower rate of early (<2 months post-insertion) mechanical complications (2.5% vs 39% OS vs 20% FG, p<0.001), a higher rate of successful PD initiation (94% vs 84% OS vs 79% FG, p<0.01), a higher rate of catheter technical survival (87% vs 39% OS vs 38% IR, p<0.01), and a lower rate of late (>2 months post-insertion) mechanical complications (5% vs 33% OS vs 18% FG, p<0.01The LAP group also had a lower rate of catheters requiring surgical/fluoroscopic revision (8% vs 40% OS vs 18% FG, p<0.01).

**Table 2 - PD Catheter Outcomes**

| | LAP | OS | FG | p-value |
|---|---|---|---|---|
| Mean Follow-up Duration (days) | **267.7** | 1331.7 | 987 | **<0.01** |
| Successfully Initiated PD | | | | |
| No<br>Yes<br>Still Buried | 2 (6%)<br>**31 (94%)**<br>7 | 5 (16%)<br>27 (84%)<br>3 | 33 (21%)<br>121 (79%)<br>0 | **<0.01** |
| Technical Survival of catheter * | | | | |
| No<br>Yes | 4 (13%)<br>**26 (87%)** | 22 (61%)<br>14 (39%) | 95 (62%)<br>59 (38%) | **<0.01** |
| Mechanical Complications ** <2 months from Insertion | **1 (2.5%)** | 14 (39%) | 32 (20%) | **<0.01** |
| Mechanical Complications ** >2 months after Insertion | **2 (5%)** | 12 (33%) | 28 (18%) | **<0.01** |
| PD catheter Manipulation *** Required | **3 (8%)** | 14 (40%) | 28 (18%) | **<0.01** |
| Manipulation Successful **** | 2 (67%) | 12 (43%) | 9 (69%) | 0.25 |

* Technical Survival defined as having started PD and still on PD at time of review
** Mechanical complication includes exit site infection, fluid leakage, mechanical obstruction, bleeding, tunnel infection
*** Manipulations performed by Interventional Radiologist or Laparoscopically
**** Successful manipulation defined as started on PD successfully

**Conclusions:** Our single-centre, retrospective review of 3 different PD insertion techniques demonstrated better outcomes using the laparoscopic technique, in comparable patient populations. Further follow-up is required to validate these promising early findings.

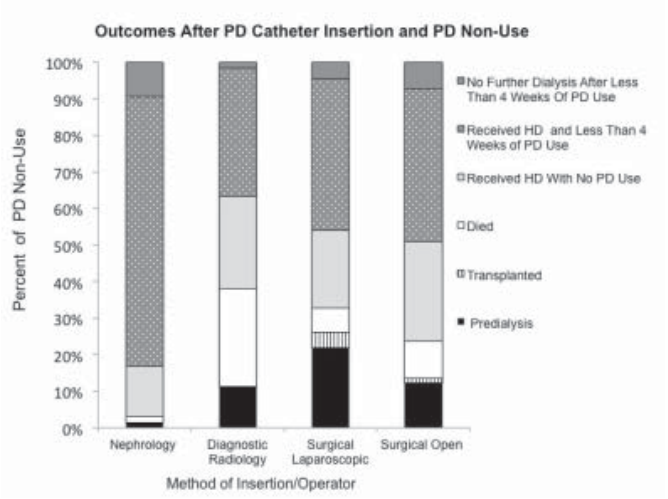
## SA-PO913

**Peritoneal Dialysis Use after Peritoneal Dialysis Catheter Implantation: A Population-Based Study** Jeffrey Perl,[1] Michael Paterson,[4] Arsh Jain,[2] Andreas Pierratos,[1] Brendan McCormick,[3] Gokulan Kandasamy,[5] Matthew J. Oliver.[1] *[1]Nephrology, Univ of Toronto, Tor, Canada; [2]Nephrology, Univ of Western Ontario, London, Canada; [3]Nephrology, Univ of Ottawa, Ottawa, Canada; [4]Chronic Disease Program, ICES, Tor, Canada; [5]Ont. Renal Network, CCO, Tor, Canada.*

**Background:** Llittle is known regarding outcomes of patients after peritoneal dialysis (PD) catheter implantation and predictors of the successful initiation of PD. We examined receipt of PD after catheter implantation exploring outcomes of PD non-use stratified by the method of catheter insertion.

**Methods:** Administrative data from Ontario identified 3886 predialysis adults with a first PD catheter implanted between 2002 and 2010. Patients were stratified by the method of PD catheter insertion: surgical-open (Su-O, n=1 884), surgical-laparoscopic (Su-L, n=1 154), nephrology-inserted (N-I, n=498), radiology-inserted (R-I, n=350). Patients were followed for at least 1 year to the successful receipt of PD (4 consecutive weeks of PD).

**Results:** The percent PD use among inserted catheters was: 85% of Su-O, 79% of Su-L, 87% of N-I and 79% of R-I. Diabetes, age, prior hemodialysis (HD) were associated with a lower risk of PD use. Relative to the Su-O group, the adjusted hazard ratio (AHR) of PD utilization was greater for N-I PD catheters AHR 1.4 (95% CI 1.2-1.5), similar for R-I inserted catheters AHR 1.0 (95% CI 0.9-1.2) but lower for the Su-L- group, AHR 0.8 (95% CI 0.7-0.8). Across groups, the majority of PD non-use resulted in the receipt of HD. More PD non-use in the Su-L, Su-O and in the R-I groups was driven by patients who remained predialysis and died prior to dialysis initiation.



**Conclusions:** Across all insertion methods, most PD catheter insertions result in successful PD use. N-I was associated with higher PD use. This may relate to the timing of insertion rather than the technical success of the technique.

## SA-PO914

**Six Years Experience with Blind Percutaneous Insertion of Peritoneal Dialysis Catheters at a Brazilian Interventional Nephrology Center** Ricardo Franco,[1] Marcelo M. Nascimento,[1,2] Natasha Silva Constancio,[1] Joao otavio Ribas Zahdi,[1] Luciana Schmitt Cardon De Oliveira,[1] Leonardo Claudino Ribeiro,[1] Itamara P. Danucalov,[1] Tobias August Siemens,[1] Margarete Mara Da Silva,[1] Marcia Tokunaga De alcantara,[1] Miguel C. Riella,[1,3] Domingos Candiota Chula.[1,2] *[1]Interventional Nephrology Center, Pro-Renal Brazil Foundation, Curitiba, Parana, Brazil; [2]Internal Medicine, Federal Univ of Parana, Curitiba, Parana, Brazil; [3]Catholic Univ of Paraná, Curitba, Parana, Brazil.*

**Background:** Percutaneous peritoneal catheter insertion can be performed by trained nephrologists although the ideal method for inserting peritoneal dialysis catheters (PDC) remains controversial. This study was performed to evaluate the efficiency, the complication profile and the outcome of percutaneously placed PDC.

**Methods:** Our study population comprised 455 patients (55±17 years; 51%males) in whom 532 PDC were inserted blindly with a Tenckhoff trocar between January 2006 and December 2011 at our Interventional Nephrology Center (*Pro-Renal Brazil Foundation*).

**Results:** Early complications related to insertion included: four (0,7%) placement failures, three cases (0,5%) of bowel perforation , eight (1,5%) significant surgical wound bleeding and fifty five (10%) tip catheter migration (twenty-six out of them (47%) were successfully repositioned). Most common late complication and frequent cause for catheter removal was intractable and recurrent peritonitis which has been verified in eighty one patients (15%). In addition, exit site infection was present in twenty two patients (4%). Technical survival at 1 and 2 years was 80% and 60%, respectively. After 72-months follow-up, the survival rate by Kaplan–Meier analysis was significantly different according

to the presence of peritonitis ($\chi^2$=13.85; p<0,001). Finally, in the multivariate analysis only the presence of peritonitis was a significant risk factor for decreased catheter survival (HR=1.83; 1.35-2.47; IC (95%)).

**Conclusions:** PDC inserted percutaneously, by trained nephrologists, was associated with a very low complication rate and high primary success rate. This approach had reduced waiting time for PDC insertion and increased PD penetration in our dialysis population.

## SA-PO915

**Evaluating Outcomes of Patients with Bedside Peritoneal Dialysis Catheters Placed by Nephrologists Compared to Surgeons** Bhanu Prasad Tikkisetty,[1] Cathy Nadiger,[1] Jennifer St.onge.[2] *[1]Nephrology, Regina Qu Apelle Health Region, Regina, Canada; [2]Research and Health Information Service, Regina Qu Apelle Health Region, Regina, Canada.*

**Background:** Limitations in allocated OR time and staff resources in the RQHR have created long wait-times for patients to receive a catheter placement. Since 2007, nephrologists have also begun to perform PD catheter placements for non-complex patients. The purpose of this project was to evaluate whether nephrologists can also successfully insert PD catheters in non complex patients and therefore improve access.

**Methods:** We reviewed data from 78 charts of patients who received a PD catheter placement from 2007-2012 (Surgeon n=39; Nephrologist n=38). Our primary analyses examined the wait-time from referral to physician consult and the wait-time from physician consult to procedure between patients treated by a surgeon compared to a nephrologists. We also examined the percentage of patients with immediate (within one-month) and delayed complications following the procedure.

**Results:** The complication rate for nephrologists was 18% for immediate and 16% for delayed. Patients had to wait significantly less time to see a nephrologist (median 1.36 weeks) compared to seeing a surgeon (5.71 weeks; $p$<.05). Similarly, patients only waited a median 1.14 weeks from the time of consult to have the procedure by a nephrologist but 6.29 weeks for a surgeon placement ($p$<.05).

**Conclusions:** This research shows that nephrologists can successfully insert PD catheters with few patients experiencing immediate or delayed complications. The rates of complications were similar or lower than previous studies examining insertion of PD catheters. Given the current discrepancies in access to OR time and resources, this research suggests that nephrologists could continue to place PD catheters in non-complex cases, which would reduce wait-times without increasing the risk of complications for these patients. Surgeons should continue to handle complex cases. Decreasing the wait-time for PD catheters could also avoid some patients having to go on hemodialysis in the meantime, which is more costly to the region and disruptive to the patient.

## SA-PO916

**Long Term Results of Fluoroscopy-Guided Placement of Peritoneal Dialysis Catheter** Joo Hee Cho, Hong Joo Lee, Dongyoung Lee, Ju Young Moon, Sang Ho Lee, Chun-Gyoo Ihm, Kyung Hwan Jeong, Taewon Lee. *Depts of Nephrology, Kyung Hee Univ School of Medicine, Seoul, Korea.*

**Background:** Percutaneous fluoroscopy-guided insertion of peritoneal dialysis catheter provides accurate placement with little waiting time. Limited data suggest that this approach provides similar outcomes compared with more invasive techniques. Therefore, we report our experience with fluoroscopy assisted placement of PD catheters.

**Methods:** A Single- center, retrospective review of 401 consecutive PD patients from July 2001 to July 2012. We assessed post procedure pain scores using a 10-point visual analogue pain score scale, time to hospital discharge, complications related to PD catheters, causes of catheter removal and catheter survival. We also reviewed 89 PD patients undergoing fluoroscopic manipulation for mechanical failure of their PD catheter.

**Results:** We placed 537 PD catheters in 401 patients using fluoroscopy. There were 3 placement failures (0.56%). The average post procedure pain scores were 1.61 and 177 (44.13%) subjects had pain score of zero by 24 hours after procedure. Early complications defined as those occurring within 14 days of catheter insertion. Early complications related to PD catheter insertion occurred in 29 patients (7.23%) included 8 cases of leakage (27.58%) and 7 cases of peritonitis (24.13%). The most common cause of catheter removal was recurrent peritonitis (27.79%). 89 patients underwent fluoroscopic manipulation of PD catheters because of mechanical failure of PD catheters. The success rate of fluoroscopic manipulation was 86%. The 1- year catheter survival was 84%.

**Conclusions:** Percutaneous fluoroscopy assisted placement and manipulation of PD catheters are safe and effective. The survival rate of PD catheters placed using fluoroscopy was comparable to that of more invasive method. Radiological insertion of PD catheters to be available to a large proportion of patients who require PD.

## SA-PO917

**Outcomes of Fluoroscopic and Ultrasound Guided Placement versus Laparoscopic Placement of Peritoneal Dialysis Catheters** Dalia Dawoud,[1] Ahmed Elsayed,[2] Ahmed Kamel Abdel Aal.[3] *[1]UAB; [2]UAB; [3]UAB.*

**Background:** Peritoneal Dialysis (PD) is a renal replacement modality, with overall survival benefits that is higher or at least similar to hemodialysis. The timely and successful placement of PD catheters is crucial for the success of PD, especially in the urgent-start setting. Our aim is to compare the outcomes of PD catheter placement using fluoroscopy (FL) and ultrasound guidance (UG) with those placed using laparoscopic (LAP) technique.

**Methods:** We retrospectively compared the outcome of two groups of patients who initiated PD from January 2005 to December 2012: (1) Those who received (PD) catheter insertion using FL and UG under local anesthesia by Interventional Radiologists/ Nephrologists, and, (2) those who received PD catheter insertion using LAP under general anesthesia by surgeons. Patients with history of prior surgery were excluded from both groups. The primary endpoint was the occurrence of dialysis catheter complications at 1 year. Catheter complications including; technical, mechanical, and infectious complications were recorded. Differences between groups were analyzed using the Chi-square test.

**Results:** The overall complications at 1 year was significantly higher for the second group (p = 0.0019). The LAP approach is more likely to be complicated by catheter malfunction and peritonitis. The other complications occurred at a higher rate in the second group but the difference e was not statistically significant (Table).

| | ***FL and UG*** | ***LAP*** | ***p-value*** |
|---|---|---|---|
| ***N pts*** | 27 | 35 | |
| *Exit Site Infection* | 1 (4%) | 5 (14%) | 0.0923 |
| *Peritonitis* | 3 (11%) | 8 (23%) | 0.0570 |
| *Catheter malfunction* | 1 (4%) | 4 (29%) | 0.0326 |
| *Hernia* | 1 (4%) | 10 (11%) | 0.1559 |
| *Catheter removal* | 2 (7%) | 7 (20%) | 0.1585 |

**Conclusions:** The FL and UG technique is a minimally invasive technique that can be performed safely, and provides a significantly more favorable outcome compared to the LAP technique. The results may be due to lesser breach of the peritoneum with the former technique. This technique may allow for expeditious PD catheter placement in the late-referred patients with end-stage renal disease, thus facilitating urgent-start PD, and avoiding the need for temporary vascular access catheters.

## SA-PO918

**Vasopressin-2-Receptor Antagonist, Tolvaptan Preserved Residual Renal Function on Peritoneal Dialysis Patients with Diabetes Mellitus** Takeyuki Hiramatsu. *Dept of Nephrology, Konan Kosei Hospital, Konan-City, Aichi, Japan.*

**Background:** The contribution of residual renal function(RRF) as an independent predictor of survival or better cardiovascular health in dialysis patients has been confirmed by many observational studies. Vasopressin-2-receptor antagonist, tolvaptan was reported to augment water excression without changes in renal function. So we evaluated the short-term effect of tolvaptan on peritoneal dialysis (PD) patients with DM.

**Methods:** We studied 20 incident PD patients with DM. Patients were divided into group A and group B. Patients in group B received 15 mg/day of tolvaptan 2 weeks after PD initiation for 12 months, but not in group A. During study period, diuretics and PD prescription were not changed in both groups. Urine volume (UV), weekly Kt/V and weekly creatinine clearance (Ccr) were evaluated at baseline, 3 days, 6, and 12 months after PD initiation.

**Results:** RRF in group B were significantly increased from baseline to 3 days after PD initiation, (UV; P=0.005, renal Kt/V;P=0.0014, for at baseline and 3 days after PD initiation, respectively). After 6 and 12 months, RRF in group B were significantly greater than that in group A(*:P<0.005,**:P<0.001, ***P<0.05).

| category | Group | baseline | 6 months | 12 months |
|---|---|---|---|---|
| UV (ml/day) | A | 1406.8 ± 457.5 | 613.6 ± 282.0 | 218.2 ± 210.1 |
| | B | 1025.8 ± 225.2 | 1147.3 ± 462.3* | 816.0 ± 374.5** |
| renal KT/V | A | 0.706 ± 0.258 | 0.355 ± 0.280 | 0.320 ± 0.410 |
| | B | 0.659 ± 0.325 | 0.674 ± 0.401*** | 0.462 ± 0.302*** |
| renal Ccr (L/W) | A | 42.21 ± 17.05 | 20.39 ± 11.49 | 11.21 ± 14.14 |
| | B | 46.16 ± 23.36 | 45.83 ± 20.91* | 27.02 ± 13.68*** |

**Conclusions:** Short term treatment with tolvaptan preserved residual renal function, suggesting that tolvaptan might prevent cardiovascular events and improve quality of life in PD patients with diabetic end stage renal disease.

## SA-PO919

**Predictors of Residual Renal Function Decline in Patients Undergoing Continuous Ambulatory Peritoneal Dialysis** Chi-bon Leung, Bonnie Kwan, Cheuk-Chun Szeto. *Carol and Richard Yu Peritoneal Dialysis Research Centre, Dept of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, Hong Kong.*

**Background:** Residual renal function (RRF) is an important prognostic indicator in continuous ambulatory peritoneal dialysis (CAPD) patients. We determine the predictors of RRF loss in a cohort of new CAPD patients.

**Methods:** We reviewed the record of 645 new CAPD patients. RRF loss is represented by the slope of decline of residual glomerular filtration rate (GFR) as well as the time to anuria.

**Results:** The average rate of residual GFR decline was -0.083 ± 0.094 ml/min/month. The rate of residual GFR decline correlated with proteinuria (r=-0.506, p<0.0001) and baseline residual GFR (r=-0.560, p<0.0001). Multivariate analysis showed that proteinuria, baseline residual GFR, and the use of diuretics had independent correlations with residual GFR decline. Cox proportional hazard model showed that proteinuria, baseline residual GFR, body weight, and the number of peritonitis episode were independent predictors of progression to anuria. Each 1 g/day of proteinuria is associated with 22.3% excess in the risk of progressing to anuria, each 1 ml/min higher baseline GFR is associated with 11.3% reduction in risk, while each peritonitis episode confers 7.9% excess in risk.

**Conclusions:** We conclude that proteinuria, baseline residual GFR, and the use of diuretics are independently related to the rate of RRF decline in CAPD patients, while proteinuria, baseline residual GFR, body weight, and the number of peritonitis episode are independent predictors for the development of anuria. The role of anti-proteinuric therapy and measures to prevent peritonitis episodes in the preservation of RRF should be tested in future studies.

## SA-PO920

**V2 Receptor Antagonist Tolvaptan Ameliorates Left Ventricular Mass Index (LVMI) and Urinary Output without Reduction in Residual Renal Function in Patients on Peritoneal Dialysis (PD)** Kenji Koizumi, Takefumi Mori, Ikuko Oba, Sadayoshi Ito. *Nephrology, Endocrinology and Vascular Medicine, Tohoku Univ Graduate School of Medicine.*

**Background:** Left ventricular (LV) hypertrophy is commonly observed in PD patients with poor control in volume overload. Loop diuretics and/or enhanced ultrafiltration are the common treatments for volume overload in PD patients, which may results in a decrease in residual renal function (RRF) and deterioration in peritoneal function, respectively. The V2 receptor antagonist, tolvaptan has been available for the treatment of heart failure to control volume overload in Japan. This study was conducted to examine whether tolvaptan could control volume status without reduction of RRF and improve left ventricular mass index (LVMI) in PD patients.

**Methods:** We studied 7 patients on peritoneal dialysis whose urinary volume (UV) increased more than 400mL/day after treatment with tolvaptan at Tohoku University hospital (Sendai, Japan). Body weight (BW), UV and weekly renal Kt/V (rKt/V) were compared before and after the first administration of Tolvaptan for volume control. Left ventricular mass index (LVMI), left ventricular ejection fraction (LVEF), E/E' and brain natriuretic peptide (BNP) were examined before and at least 18 weeks after the treatment. The difference of $p<0.05$ was considered as statistical significance.

**Results:** A significant increase in UV was observed in all patients. BW and BNP were not significantly reduced. An increase in rKt/V was observed and maintained over 4 to 6 months. On the other hand, significant reductions in LVMI and E/E' were observed ($p<0.05$) without changes in LVEF.

**Conclusions:** Tolvaptan increased urinary output and improved LVMI in patients on PD without deterioration in cardiac functions or residual renal function. This could be an effective novel strategy for volume control in PD patients.

*Funding:* Government Support - Non-U.S.

## SA-PO921

**Overhydration among Patient's Undergoing Peritoneal Dialysis in Relation to Age** Dorota Sikorska, Justin Nealis, Krzysztof Hoppe, Krzysztof Schwermer, Maria Wanic-kossowska, Krzysztof Pawlaczyk, Andrzej P. Oko. *Poznan Univ of Medical Sciences, Poland.*

**Background:** Overhydration is a prevalent problem in peritoneal dialysis (PD) patients and is associated with numerous complications. Multi-frequency bioimpedance analysis (BIA) offers the potential to accurately determine a patient's dry body weight (DBW). The main aim of this study was to assess the impact of age on fluid overload, and its' relationship with markers of cardiovascular risk in PD patients.

**Methods:** The study was performed on 70 PD patients. The cohort was divided into two subgroups according to gender (group A, 45 patients, <65 YO, mean age 47.98±12.76; group B, 25 patients, ≥65 YO, mean age 74.16±6.02). In both subgroups the degree of overhydration was assessed with BIA and clinical criteria. NT-proBNP and troponin T (TnT) concentration in the serum and the patient's nutritional status (SGA) was measured. Echocardiography and chest X-ray examinations were performed.

**Results:** There is a correlation between age and overhydration in BIA ($r=0.30$;$p=0.01$). The older group of patients had higher BIA overhydration (1.37±2.15 vs.2.08±2.21kg; $p=0.059$) and higher SGA (8.64±2.03 vs.9.20±1.29; $p=0.01$). The SBP and DBP (136.6±18.79 vs.140.36±22.92 mmHg; 82.66±12.06 vs.76.00±14.71mmHg) was comparable in both subgroups. The data revealed a tendency for higher NT-proBNP (3118.7±6872.7 vs.11377.2±13341.5 pg/ml; $p=0.03$) and TnT (0.04±0.03vs.0.17±0.17ng/ml;$p<0.01$) concentration in the older group. There was a correlation between BIA overhydration and NT-proBNP ($r=0.40$;$p=0.02$), TnT ($r=0.48$;$p=0.01$), SGA ($r=0.28$;$p=0.02$) and ejection fraction (EF,$r=-0.31$;$p=0.04$). The older group of patients were more overhydrated and presented with more aortic atherosclerotic changes (10vs.16;$p=0.02$) and had a reduced EF (58%vs.49%;$p=0.05$).

**Conclusions:** Older age may be a risk factor determining a higher tendency for overhydration. Overhydration seems to be a potential predictor for the development of cardiovascular complications. BIA appears to be a super technique for monitoring the hydration status, DBW and cardiovascular risk among PD patients as compared with clinical assessment alone.

**Is N-Terminal Pro-Brain Natriuretic Peptide a Useful Marker of Cardiovascular Disease or Volume Status in Peritoneal Dialysis Patients?** Ruth J. Pepper, Debbie Falconer, Andrew Davenport. *Centre for Nephrology, Royal Free Hospital, London, United Kingdom.*

**Background:** N-terminal pro-brain natriuretic peptide (NTproBNP) is used to diagnose heart failure in general medicine, and has been associated with both left ventricular hypertrophy (LVH) and extracellular water (ECW) expansion in haemodialysis (HD) patients. However whether NTproBNP has a role in peritoneal dialysis (PD), who typically have residual renal function remains to be determined.

**Methods:** Serum NTproBNP was measured in 287 PD patients and correlated with factors such as ejection fraction, echocardiogram findings and Kt/V. A linear regression model was used to delineate the relationship between the significant variables and log NTproBNP.

**Results:** The mean serum BNP was 776 pmol/l (SD 1883), and log NTproBNP 2.34 pmol/l (SD 0.64). Using the linear regression model, logNTproBNP was demonstrated to significantly correlate with logCRP [B co-efficient (B) = 0.184 ($p=0.002$)], low dialysis adequacy as measured by total Kt/V [B=-0.168] [$p=0.000$]. To assess for fluid overload the ratio of extracellular water to total body water (ECW/TBW) was calculated and was also significant [B=7.711] [$p=0.01$]. With respect to gender, logNT-proBNP was significantly associated with males [B=0.202] [$p=0.001$]. Although there was a significant correlation with ejection fraction [B=-0.017] [$p=0.000$]. However no relationship was observed with left ventricular mass index, urine output or residual renal function.

**Conclusions:** Serum NTproBNP was associated with reduced left ventricular ejection fraction, over hydration with ECW expansion, systemic inflammation as measured by CRP, reduced dialysis adequacy (total weekly Kt/V), and male sex. Therefore, serial NTproBNP measurements in stable PD outpatients may aid the clinical assessment of volume status, in the context of adequately dialysed patients with stable cardiac function and absence of systemic inflammation.

## SA-PO923

**Comparison of Cardiac Function via Echocardiography between Icodextrin and Glucose-Based Peritoneal Dialysis Patients: A Prospective One-Year Study** J. B. Chen. *Nephrology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan.*

**Background:** Icodextrin dialysis solution had been demonstrated effective ultrafiltration in a long dwell time in peritoneal dialysis (PD) patients. However, it is uncertain whether cardiac function preservation will be resulted from icodextrin ultrafiltration capacity. The aim of study was to assess the cardiac function in incident PD patients with icodextrin-based PD solution.

**Methods:** The study design was a prospective, open-label, parallel control groups. The incident PD patients were enrolled with 1:1 ratio by assigned dextrose and icodextrin-based PD solutions. Thirty patients were in icodextrin group, twenty-nine patients in dextrose group. The enrolled patients received echocardiography examinations at baseline and one-year apart. The variables of echocardiography including systolic and diastolic parameters were compared between two groups.

**Results:** At baseline cardiac examination, patients in icodextrin group showed inferiority in the variables of cardiac systolic function than those in dextrose group, i.e. LVESV (left ventricular end-systolic volume)($mm^3$), LVEF (LV ejection fraction)(%), ET(ejection time)(ms), decelceration time (ms). The trend approached to similar pattern in one-year apart. The similar phenomenon was observed in the variables of cardiac diastolic function, i.e. left atrium diameter (mm), aorta diameter, LVESD (LV end-systolic diameter)(mm). The comparison of variables at baseline and one-year apart in each groups demonstrated patients in dextrose group had significantly decrease LVEDD (47.7 vs 45.5 mm) and LVEDV (109.5 vs 98.1 $mm^3$) values at one-year period. In contrast, only one variable was found significantly increased in icodextrin group at one-year period, i.e. decelceration time (172.4 vs 201.3 ms).

**Conclusions:** Icodextrin-based PD solution could improve cardiac function both in systolic phase and in diastolic phase when those compared to dextrose-based PD solution in incident PD patients.

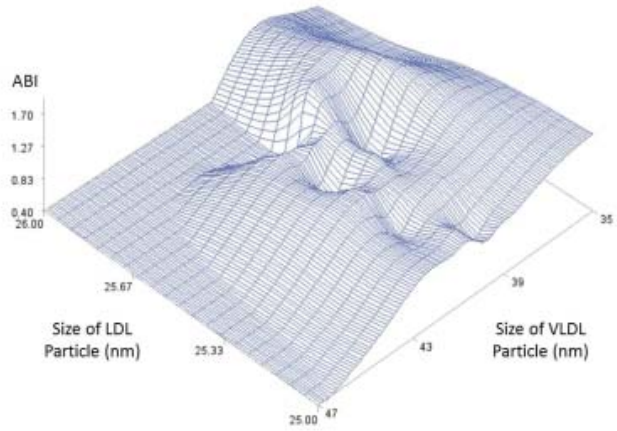
## SA-PO924

**Very-Low-Density Lipoprotein Affects Atherosclerosis of Peripheral Artery in Peritoneal Dialysis Patients** Eiichiro Kanda,[1] Masumi Ai,[3] Mitsuyo Okazaki,[3] Yoshitaka Maeda,[2] Sei Sasaki,[3] Masayuki Yoshida.[3] *[1]Nephrology, Tokyo Kyosai Hospital, Meguroku, Tokyo, Japan; [2]Nephrology, JA Toride Medical Center, Toride, Ibaraki, Japan; [3]Tokyo Medical and Dental Univ, Bunkyoku, Tokyo, Japan.*

**Background:** Peripheral artery disease (PAD) represents atherosclerotic disease and is a risk factor for death in peritoneal dialysis (PD) patients, who tend to show an atherogenic lipid profile. In this study, we investigated the relationship between lipid profile and ankle-brachial index (ABI) as an index of atherosclerosis.

**Methods:** Thirty-five PD patients were enrolled in this cross-sectional study in Japan. The proportions of cholesterol level to total cholesterol level (cholesterol proportion) in 20 lipoprotein fractions and the mean size of lipoprotein particles were measured using an improved method, high-performance gel permeation chromatography.

**Results:** The mean (standard deviation) age was 61.6 (10.5) years; PD vintage, 38.5 (28.1) months; ABI, 1.07 (0.22). A low ABI (0.9 or lower) was observed in 7 patients (low-ABI group). The low-ABI group showed significantly higher cholesterol proportions in the chylomicron fraction and large very-low-density lipoproteins (VLDLs) (Fractions 3-5) than the high-ABI group (ABI>0.9). Adjusted multivariate linear regression analysis showed that ABI was negatively associated with serum VLDL cholesterol level ($p=0.0074$) and the cholesterol proportions in large VLDLs (Fractions 4, $p=0.038$; 5, $p=0.0039$) and medium VLDL (Fraction 6, $p=0.014$). ABI was also negatively associated with the size of VLDL particles ($p=0.032$), which was associated with serum triglyceride level (Pearson's correlation coefficient $r=0.798$, $p=0.0001$).



**Conclusions:** This study showed that, among PD patients, the characteristics of VLDL particles were associated with atherosclerosis. Lowering serum VLDL level may be an effective therapy against atherosclerosis in PD patients.

## SA-PO925

**Overhydration in Peritoneal Dialysis: Clinical Perception versus Bioimpedance** Lourdes de la Vara Iniesta, Agustín Ortega-cerrato, Carmen Gómez Roldán, Juan Pérez-martínez. *Hospital of Albacete.*

**Background:** Overhydration is associated with increased morbimortality in peritoneal dialysis (PD) patients. Health professionals are capable of estimating our patients' hydration volume through clinical perception but, using other tools such as bioimpedance, it is possible to assess it more objectively. Objectives:Determine if there is a correlation between the hydration status of the PD patients treated in our unit when estimated using bioimpedance and when estimated by health professionals' clinical perception. Evaluate whether it is possible to improve the professional's clinical perception.

**Methods:** Descriptive, observational study. 37PD patients were included. 1resident,1nephrologist and 4nurses took part in the study. The estimation of the patients' hydration status was compared using the two methods. The data are given as mean±SD and percentage over/underhydration with respect to the Urea distribution volume(V). Pearson's correlation and the Bland-Altman plot were used for the statistical analysis.

**Results:** 111 determinations performed on PD patients were analysed. The mean overhydration estimated by bioimpedance was 2.77±2.05litres vs 2.04±1.67litres by the health professionals. The correlation between the two methods was significant (r:0.33;p<0.003). As can be seen in figure1A, there is no significant scatter between the estimations by the two methods, showing a tendency to underestimate our patients' hydration status. My clinical perception, as resident, became increasingly accurate as the 4-month study progressed [B].

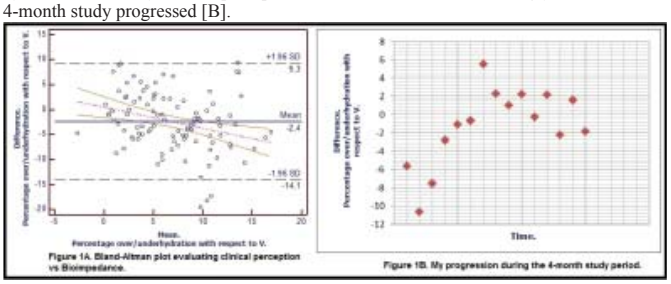


Figure 1A. Bland-Altman plot evaluating clinical perception vs Bioimpedance.

Figure 1B. My progression during the 4-month study period.

**Conclusions:** We found a high correlation between the two methods. Although bioimpedance may help the clinician to identify more objectively minor changes in volemia, it does not replace the professional's clinical perception. Furthermore, this perception can improve with input from all of the patient's clinical parameters, helping to give a more accurate estimation.

## SA-PO926

**The Effects of Paricalcitol on Cardiac Fibrosis in a Peritoneally Dialysed Uremic Rat Model** Zeynep Kubilay,[1] Arzu Velioglu,[1] Halil Tugtepe,[2] Deniz Filinte,[3] Izzet Hakki Arikan,[1] Mehmet Koc,[1] Serhan Tuglular,[1] Cetin Ozener.[1] *[1]Nephrology, ; [2]Pediatric Surgery, ; [3]Pathology, Marmara Univ.*

**Background:** VitaminD receptor activators are promising agents in mitigating cardiovascular complications in chronic renal disease. Herein, we evaluated effects of paricalcitol on cardiac fibrosis in a peritoneally dialysed uremic rat model.

**Methods:** 30 Wistar male rats were randomized to 4 groups. GroupN:Sham operation(n=6), GroupU:5/6 Nephrectomized(n=8), GroupPD:5/6 Nephrectomized+PD(n=8), Group PD-P:5/6 nephrectomized+PD+paricalcitol(0.24 µg/kg/day IP)(n=8).After 6 weeks, blood Cr, Ca,P,PTH levels, blood pressure, ultrafiltration capacity, cardiac fibrosis and media/lumen ratio of the intracardiac arteries, TGF-β and Collagen III staining were evaluated.

**Results:** When compared to Group U, Group PD and PD-P showed a decrease in cardiac fibrosis, media/lumen ratio and cardiac TGF–β expression, but significance was only found between Group PD-P and U for the studied variables.

| | N(n=6) | U(n=8) | PD(n=8) | PD-P(n=8) |
|---|---|---|---|---|
| Ca(mg/dL) | 10.8±0.13 | 10.9±0.14 | 9.6±0.13[c] | 9.7±0.52[b] |
| P(mg/dL) | 4.4±0.16 | 6.1±0.34 | 6.9±0.39 | 7.8±0.69[b] |
| PTH(pg/mL) | 372.5±54.1 | 244.9±41.8 | 478.7±50[c] | 605.8±76[b] |
| Ultrafiltration | 6.5±0.4 | 8.1±0.8 | -7.1 ±1.1[c] | -2.3 ±1.2[a,b] |
| Blood Pressure | 120±3.6 | 150±0.4 | 173±1.3 | 163±1.7[a,b] |
| Cardiac Fibrosis | 0.17±0.16 | 1.25±0.16 | 1.00±0.26 | 0.50±0.18[b] |
| Media/Lumen | 1.83±0.3 | 2.63±0.27 | 2.25±0.25 | 1.75±0.25[b] |
| Collagen III | 1.17±0.16 | 2.20±0.2 | 1.38±0.5[c] | 1.63±0.26 |
| TGF-β | 1.67±0.33 | 2.00±0.8 | 1.25±0.16 | 1.13±1.25[a] |
| a:p<0.05 group PD-Pvs.group PD,b:p<0.05 group PD-P vs.group U, c:p<0.05 group PDvs.group U | | | | |

**Conclusions:** Paricalcitol was found to decrease cardiac fibrosis. PD treatment alone did not improve this finding, whereas addition of paricalcitol significantly reduced cardiac fibrosis. Due to its beneficial effects on heart, paricalcitol could be preferred in peritoneal dialysis patients.

## SA-PO927

**Relation between Volume Status and Health-Related Quality of Life in Peritoneal Dialysis Patients** Yun Jung Oh, Chungsik Lee. *Internal Medicine, Cheju Halla General Hospital, Jeju, Korea.*

**Background:** Volume status is an important predictor of outcomes in patients with end stage renal disease, and chronic fluid overload contributes to the high mortality in dialysis patients. However, it has not yet been identified whether to achieve euvolemia contributes to improve health-related quality of life(HRQOL) in peritoneal dialysis(PD). We investigated the relationship between volume status and HROQL in PD patients.

**Methods:** This study is a cross-sectional, noninterventional, and observational. We enrolled 41 prevalent PD patients, and accessed volume status using Body Composition Monitor(BCM). Korean version of Kidney Disease Quality of Life short form(KDQOL-SF), version 1.3 was used to evaluate HRQOL. We determined scores of three components summary of HRQOL; Kidney Disease Component Summary(KDCS), Physical Component Summary(PCS), and Mental Component Summary(MCS). The hydration status(HS) was normalized to extracellular water(ECW)(Relative hydration=HS/ECW) for the analysis, and overhydrated status was defined as OH/ECW value greater than 0.15.

**Results:** Mean values of HS, ECW, and relative hydration were 2.80±2.20L, 17.4±3.84L, and 0.151±0.101, respectively. In correlation analysis, relative hydration(HS/ECW) was negatively correlated with the scores of KDCS and MCS(r=-0.410; P=0.008 and r=-0.309; P=0.049 respectively). Among disease-specific KDCS domains, relative hydration was significantly associated with two subscales including burden of kidney diseases and cognitive function(ß=-82.813, P=0.018 and ß=-40.670, P=0.033, respectively). The result of multiple linear regression analysis showed that relative hydration had significant negative association with KDCS(ß=-37.565, P=0.033). Mean value of KDCS score was lower in overhydrated patients compared to normohydrated patients, but the difference was not significant(61.1±9.25 vs 66.7±17.17, P=0.075).

**Conclusions:** Overhydrated status showed a significant negative association with scores of KDCS and MCS, indicating that volume status is an important factor affecting HRQOL in PD patients. Close monitoring of volume status and a correct dialysis prescription to maintain euvolemia seem to be warranted to improve HRQOL in PD patients.

## SA-PO928

**Sympathetic Overactivity in Chronic Peritoneal Dialysis Patients** Dan Sapoznikov, Aharon Bloch, Haya Assayag, Dvora Rubinger. *Nephrology and Hypertension Services, Hadassah Univ Medical Center, Jerusalem, Israel.*

**Background:** Sympathetic overactivity is not well defined in chronic peritoneal dialysis (PD) patients.

**Methods:** Continuous beat-to-beat intervals (IBI) and systolic blood pressure (SBP) were monitored in 13 PD patients (pts.), 112 chronic hemodialysis (HD) pts. and in 32 control subjects (C).IBI and SBP oscillations in the low frequency range (LF, 0.04-0.15 Hz) were considered to be indicative of sympathetic activation. The prevalence of baroreflex and nonbaroreflex episodes (in which heart rate and SBP change in opposite or in the same direction) was interpreted as representative of vagal or central sympathetic activation, respectively.

**Results:** Mean SBP and IBI, sdIBI (a measure of overall autonomic activity), LF IBI (power spectrum of IBI in LF range), LF IBI/HF IBI (the ratio between amplitudes of IBI oscillations in LF and HF (high frequency) ranges, an index of sympatho-vagal balance) and LFα (baroreflex sensitivity in LF range) were (median and interquartile range):

| | C | HD | p vs.C | PD | p vs.C | p vs.HD |
|---|---|---|---|---|---|---|
| Age*(y) | 54±11 | 58±15 | NS | 55±14 | NS | NS |
| SBP (mm Hg) | 125 (25) | 137 (32) | 0.031 | 130 (33) | NS | NS |
| Mean IBI (msec) | 832 (172) | 838 (166) | NS | 712 (142) | 0.040 | 0.006 |
| sd IBI (msec) | 32 (15) | 20 (13) | 0.001 | 20 (14) | 0.001 | NS |
| LF IBI (msec$^2$/Hz) | 2327 (3048) | 739 (1569) | 0.001 | 520 (1409) | 0.001 | NS |
| LF IBI/HF IBI | 6.89 (3.60) | 3.15 (3.40) | 0.001 | 4.40 (7.20) | NS | NS |
| LFα (msec/mm Hg) | 5.06 (2.76) | 3.24 (2.57) | 0.001 | 3.13(1.37) | 0.002 | NS |

*mean±SD.

Baroreflex activity was predominant in HD, while in PD the prevalence of nonbaroreflex episodes was increased. The proportion of pts. With predominant (>90%) nonbaroreflex activity was higher in PD than in HD (p=0.013).

**Conclusions:** These results show: 1.Decreased IBI variability and baroreflex sensitivity are suggestive of sympathetic overactivity in both HD and PD. 2. The increased heart rate, the higher LF IBI /HF IBI and the increased prevalence of nonbaroreflex episodes point to a more pronounced sympathetic tonus in PD. The prognostic significance of these findings remains to be defined.

## SA-PO929

**An Analysis of Factors Predicting Peritoneal Catheter Tunnel and Exit-Site Infection in a Low Incidence Setting** Miguel Perez Fontan, Ana Rodriguez-carmona. *Nephrology, Univ Hospital A Coruña, A Coruña, Spain.*

**Background:** Catheter tunnel and exit-site infection (TESI) causes morbidity and Peritoneal Dialysis (PD) technique failure. Between 1990-2012 our Unit has kept homogeneous practices for prevention of TESI, including catheter design, insertion techniques, exit-site care, screening and management of Staphylococcus aureus (SAu) carriers, and diagnostic criteria of TESI.

**Methods:** We have explored the baseline profile for TESI in 665 patients initiatiating PD 1990-2010. Statistics: univariate tests, Kaplan-Meier and Cox models. We also applied time-dependent multivariate analysis to disclose the potential association between the risks of TESI and peritonitis.

**Results:** We observed 230 episodes of TESI (170 patients, 1631 patient-years). Univariate analysis disclosed PD intiated before 2000 ($p<0.0005$), kidney transplant before PD ($p=0.02$), SAu carriage ($p<0.0005$), short delay catheter insertion-PD initiation ($p=0.001$), lower GFR ($p=0.02$), fast peritoneal transport ($p=0.005$), lower hemoglobin ($p=0.008$) and higher C-reactive protein levels ($p=0.008$) as predictors of TESI. 68.3% of patients with TESI suffered peritonitis too, versus 49.8% of those without TESI ($p<0.0005$).

Multivariate analysis identified SAu carriage (HR 1.67, $p=0.03$), kidney transplant before PD (HR 2.58, $p=0.017$), fast peritoneal transport (HR 1.03, $p=0.001$) and delay <7 days between catheter insertion and PD (HR vs >30 days 3.45, $p=0.002$) as predictors of TESI. Time-dependent Cox analyses disclosed an independent association between TESI and peritonitis ($p=0.023$); there was a trend to a higher risk of peritonitis in patients with >1 TESI ($p=0.061$), while the time lapse to the first episode of TESI did not appear to modify this association ($p=0.30$).

**Conclusions:** Adequate catheter rest after insertion has a definite impact on the later incidence of TESI. Systematic screening and treatment of SAu carriers does not prevent an increased incidence of TESI in this subgroup. Our results confirm a strong time-dependent association between the risk of TESI and peritonitis.

## SA-PO930

**Rapid Progression of Brain Atrophy in Patients on Peritoneal Dialysis: A Longitudinal Study** Kazuhiko Tsuruya,[1] Hisako Yoshida,[1] Tohru Mizumasa,[2] Hideki N. Hirakata,[2] Takanari Kitazono.[3] *[1]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Div of Nephrology and Dialysis Center, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan; [3]Dept of Medicine and Clinical Sciences, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

**Background:** Brain atrophy has been reported in chronic kidney disease (CKD) patients, although its mechanism remains to be elucidated. We previously demonstrated that cerebral ischemia and dialysis-related hypotension play a role in brain atrophy in hemodialysis patients (Yoshimitsu T, et al., 2000, Mizumasa T, et al., 2004). On the other hand, to date, it has not been reported as to brain atrophy in patients with peritoneal dialysis (PD). Thus, we examined the progression rate of brain volume by a two-year longitudinal observation in the present study.

**Methods:** Thirty-two PD patients aged 37–79 (60 ± 11) years (men 19, diabetes 10) and 58 predialysis CKD patients aged 37–79 (61 ± 10) years (men 30, diabetes 15, eGFR 38.9 ± 11.6 mL/min/1.73m$^2$), who had no history of cerebrovascular disease, were recruited and underwent MRI scanning at baseline and after two years. T1-weighted MRI images were analyzed with statistical parametric mapping software. Total gray matter (GM), total white matter (WM), and cerebrospinal fluid were segmented and each volume was quantified using MRI voxel-based morphometry. GM volume (%GMV) and WM volume (%WMV) were normalized as percentages of intracranial volume to adjust for variations in head size. We compared the reduction rate of %GMV between PD patients and predialysis CKD patients.

**Results:** The percentage of GMV was lower in PD patients than predialysis CKD patients at baseline (39.09 ± 2.91% vs. 41.13 ± 2.47%). Annual reduction rate of %GMV was significantly higher in PD patients than predialysis patients (0.68 ± 0.42 vs. 0.26 ± 0.41 percentage-point/year). This significant difference remained even after stratification by age, gender, and diabetes.

**Conclusions:** Progression of brain atrophy is significantly higher in PD patients than predialysis CKD patients independent of age, gender, and diabetes.

## SA-PO931

**Does Peritoneal Dialysis Confer a Higher Risk for Calciphylaxis?** Sagar U. Nigwekar, Maria B. Luongo, Ravi I. Thadhani, Nina E. Tolkoff-Rubin. *Massachusetts General Hospital.*

**Background:** Calciphylaxis is a rare but highly fatal condition seen in dialysis patients. Prior literature speculates that peritoneal dialysis (PD) patients are at a higher risk for calciphylaxis compared to hemodialysis (HD) patients. However, no study has compared distribution of calciphylaxis risk factors in these populations to determine whether PD as a modality increases calciphylaxis risk.

**Methods:** Dialysis unit and pathology department records from two large academic centers were searched to identify calciphylaxis cases diagnosed between January 2002 and December 2012. Demographics, co-morbidities, dialysis adequacy, laboratory and medication data were compared between PD and HD calciphylaxis patients using a Fisher exact test (categorical variables) or a Wilcoxon test (continuous variables).

**Results:** We identified 69 cases of calciphylaxis; 7 were on PD (all on continuous ambulatory PD) and 62 were on HD. PD calciphylaxis patients were younger than HD calciphylaxis patients (median age 50 vs. 62 years, $p=0.03$) and were more likely to be non-Caucasian (62% vs. 36%, $p=0.04$). There were no significant differences between calciphylaxis patients on PD vs. HD for dialysis vintage (median 5.1 vs. 4.8 years), diabetes mellitus (28% vs. 35%, $p=0.10$), macrovascular disease (31 vs. 34%, $p=0.10$), calcium based phosphate binder use (29 vs. 33%, $p=0.13$), and vitamin D therapy (45% vs. 49%, $p=0.11$). Warfarin use (71% vs. 44%, $p=0.01$), obesity (57% vs. 37%, $p=0.01$), and hypoalbuminemia (100% vs. 65%, $p=0.02$) were more prevalent in PD calciphylaxis patients compared to HD calciphylaxis patients. Dialysis adequacy and serum calcium, phosphorous, and parathyroid hormone levels were similar.

**Conclusions:** Higher prevalence of calciphylaxis risk factors (such as warfarin, obesity and hypoalbuminemia) rather than dialysis modality likely explains calciphylaxis development in PD patients. Prospective studies are needed to confirm these findings. More judicious warfarin use and attention to malnutrition-inflammation complex may prevent calciphylaxis in PD patients.

## SA-PO932

**Metabolic Syndrome and Body Fat Content of Peritoneal Dialysis Patients** Cheuk-Chun Szeto,[1] Terry Kw Ma.[2] *[1]Dept of Medicine & Therapeutics, The Chinese Univ of Hong Kong, Shatin, Hong Kong; [2]Dept of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, Hong Kong.*

**Background:** In the general population, metabolic syndrome (MES) is strongly associated with cardiovascular risk. However, the definition of MES and its prognostic implication amongst patients undergoing peritoneal dialysis (PD) remains controversial.

**Methods:** We studied 329 prevalent PD patients and compared 4 sets of diagnostic criteria: the original WHO criteria, the International Diabetes Federation (IDF) criteria, the original National Cholesterol Education Program (NCEP) criteria, and the modified NCEP criteria. Nutritional status, body composition, and arterial pulse wave velocity were measured. Patients were followed for 31.7 ± 15.5 months for survival and hospitalization.

**Results:** Amongst the 329 patients, 175 (53.2%) fulfilled the WHO criteria, 177 (53.8%) by the IDF criteria, 199 (60.5%) by the original NCEP criteria, and 218 (66.3%) by the modified NCEP criteria. In general, the agreement between the 4 sets of criteria was fair to moderate (Cohen's kappa 0.352 to 0.580). Patients with MES defined by all 4 criteria had higher adipose tissue mass than the others, although the difference was most pronounced with the IDF criteria (18.2 ± 7.9 vs 10.7 ± 5.9 kg, $p<0.0001$), and the IDF criteria was least affected by overhydration. Furthermore, patients with MES, as defined by the IDF criteria, were hospitalized longer than those without MES (3.82 (inter-quartile range [IQR] 0.00 – 12.61) vs 1.07 (IQR 0.00 – 6.43) days per year of follow up, $p = 0.010$). There was no difference in overall survival, cardiovascular survival, or technique survival between patients with and without MES, irrespective to the diagnostic criteria after adjusting for diabetic status.

**Conclusions:** We conclude that the IDF criteria is probably the preferred choice for the definition of MES in PD patients as it best reflects the adipose tissue mass, least affected by overhydration, and best associated with the need of hospitalization during follow up.

*Funding:* Clinical Revenue Support

## SA-PO933

**Does Increased Peritoneal Dialysis Adequacy Correlate with Physical Activity and Energy Expenditure?** Sally Salah El-kateb,[1] Sivakumar Sridharan,[2] Kirsten L. Rennie,[3] Ken Farrington,[2] Andrew Davenport.[1] *[1]Royal Free Hospital; [2]Lister Hospital; [3]Univ Hertfordshire.*

**Background:** Whereas there is an established relationship between dialysis adequacy, nutrition and survival for haemodialysis patients, the same relationship has not been demonstrated for peritoneal dialysis (PD) patients. We therefore looked at the relationship between total energy expenditure (TEE), resting energy expenditure (REE), active physical energy expenditure (AEE), and dialysis adequacy and body composition.

**Methods:** All patients included are receiving PD treatment at the Royal Free hospital. Patient demographics, body composition measured using bioimpedance and PD adequacy (Total weekly urea KT/V and weekly litres of creatinine cleared (CrCl), along with residual urine output assessed by 24-hour urine collection) were recorded. Dietary protein intake (nPNA) and albumin serum levels were used as an indicator of the nutritional status. TEE, REE and PEE were calculated such that (TEE = REE * Mean daily MET) and REE = -2.497 * Age * (age) + 0.011 * height$^{2.023}$ + 83.573 * weight$^{0.6291}$ + 68.171. A physical activity assessment questionnaire was designed to determine daily MET.

**Results:** Seventy five patients (M=43,F=32) were included in this study, of which 25 were diabetic. Average age was 59.99±17.32(21-88) years. There was a significant association between AEE and age(β= -17.66, CI 95% (-34.8 --.47), $p=0.044$) and log vintage (β=-770.32, CI 95% (-1346.56 - -194.09), $p=0.01$). REE was significantly associated with skeletal muscle mass(SMM) (β= 88.51, CI 95% (72.23-104.79), $p<0.0001$), extracellular weight/total body weight(β= 66.78, CI 95% (24-109.5), $p=0.003$), BMI(β=-35.373, CI 95% (-59.39 - -11.35), $p=0.005$) and body fat mass(β=20.21, CI 95% (8.81 – 31.61), $p=0.001$). Finally, a significant association was depicted between TEE and SMM(β=129.84, CI 95% (25.56 – 234.11), $p=0.016$). No significance was detected between any EE and nPNA, CCr or total weekly urea KT/V.

**Conclusions:** There is no relationship between nPNA or dialysis adequacy measured by total weekly urea KT/V or litres of creatinine cleared per week or residual urine output and either total, resting or activity energy expenditure in PD patients.

### SA-PO934

**Leptin as a Key Factor in Obesity Pathophysiology: Clinical Relevant Associations in PD Patients** Ana Paula Bernardo,[1,2] Silvia Coelho,[1] Maria João Carvalho,[1] António Manuel Nunes Cabrita,[1] Anabela Rodrigues.[1,2] *[1]Nephrology, CHP; [2]UMIB/ICBAS/UP.*

**Background:** In peritoneal dialysis, obesity is assumed to result from intraperitoneal glucose absorption, and doubts still remain about its impact on patient survival, since most studies are simply based on body mass index (BMI) to characterize obesity.In general population, adipokines are known to play an important role in obesity pathogenesis and their associated metabolic complications such as dislipidemia and inflammation.Until now, no study explored body composition assessment with adipokines and inflammation in peritoneal dialysis.Our aim was to explore in a PD prevalent population the link between leptin and adiponectin, lipids, IL6 and fat mass evaluated with body composition monitor(BCM®).

**Methods:** We performed multifrequency bioimpedance assessment in 66 prevalent PD patients. We assessed lean tissue index (LTI), fat tissue index(FTI), relative lean tissue mass(Rel.LTM), relative fat mass(Rel.Fat), body cell mass(BCM), BMI, leptin, adiponectin, IL-6, triglycerides (Tg), HDL and LDL cholesterol, albumin and nPCR(protein catabolic rate).

**Results:** 48.5% female, 18.2% diabetics, 28.1% anurics, 20% fast transporters, mean age 50.3 years, PD vintage 18.7 months.Leptin correlated better with FTI and Rel.Fat than with BMI (r=0.67, r=0.63 and r=0,45, p<0.0001,respectively).Leptin also correlated with adiponectin(r=-0.24, p=.04), Tg(r=0.39, p=0.001) and nPCR(r=-0.41, p=0.004) but no correlation was found with IL-6, albumin, peritoneal membrane small solute transport or residual renal function in our population.Patients with leptin > median (17.25ng/mL) had lower adiponectin(15.7±7.3 vs 18.9±7.6µg/mL,p=0.034), lower LTI(12.4±2.7 vs 14.3±3.2Kg/m$^2$,p=0.025), lower BCM(18.4±6.1 vs 22.7±7.9Kg,p=0.018), higher FTI and Rel.FAT (14.1±4.9kg/m$^2$ vs 8.5±3.9Kg/m$^2$ and 37.5±8.4% vs 26.3±10.5%,respectively, both p<0.0001), higher Tg(190 vs 131mg/dl,p=0.008) lower HDL(38±9 vs 47±16mg/dl,p=0.013) and lower nPCR(1.0±0.3 vs 1.2±0.3g/kg/day,p=0.026).

**Conclusions:** Leptin shows better correlation with FTI and Rel.FAT assessed by bioimpedance than with BMI, and has important and clinically relevant associations with dislipidemia and nutrition parameters in PD patients.

### SA-PO935

**Body Composition Evaluation and Adipokines Profile in Risk PD Patients** Ana Paula Bernardo, Olivia Santos, Maria João Carvalho, António Manuel Nunes Cabrita, Anabela Rodrigues. *Nephrology, CHP, Porto.*

**Background:** Peritoneal dialysis has improved clinical results in the last decade. However aged patients, diabetics, anurics and fast transporters, leading to less favorable outcomes, still challenge therapy.Our aim was to document relevant corporal composition changes and adipokines profile alterations amenable to intervention in specific risk PD patient subgroups.

**Methods:** We performed multifrequency bioimpedance assessment in 66 prevalent PD patients, under updated PD therapy, treated with low-GDPs solutions, elective automated PD and free icodextrin use.We assessed relative fluid overload(RelOH), lean tissue index(LTI), fat tissue index(FTI), relative lean tissue mass(Rel.LTM), relative fat mass(Rel.Fat), body cell mass(BCM), leptin and adiponectin.

**Results:** 18.2% diabetics, 28.1% anurics, 20% fast transporters, mean age 50.3 years, 48.5% female, PD vintage 18.7 months. Diabetic patients had higher RelOH(15.3±8.1vs6.3±7.5%,p=0.001) but notably similar fat and lean tissue mass as well as adipokine profile. Anuric patients did not present significantly higher volume overload but had lower LTI (11.9±2.3vs 13.8±3.2Kg/m$^2$,p=0.04), and lower BCM (17.2±5.2 vs 21.7±7.5Kg,p=0.035), without other significant differences, namely adipokines.Fast transporters had no significant differences concerning adiponectin [19.3(11)µg/mL vs 15.9(10)µg/mL], leptin [13.8(42) ng/mL vs 19.5(56)ng/mL], FTI (10.5±5.3 vs11.4±5.2Kg/m2) and Rel.Fat(30.7±12.9 vs32.0±10.6%);additionally RelOH was similar(8.3±9.9 vs 7.8±8.0%).Aged patients (≥ 65 years) had significantly higher RelOH(12.5±6.4vs6.8±8.4%,p=0.018),without other differences concerning body composition or adipokines profile.

**Conclusions:** Updated PD schedules are able to avoid clinically relevant complications in risk patients: fast transport status and diabetes were not associated with increased fat mass or with a dismal adipokine profile; both anuric and fast transporters achieved good volume control but risk of protein malnutrition should be managed in anurics; older patients were prone to higher volume overload but preserved fat and lean tissue mass. Carefully body composition evaluation in risk PD patients is mandatory to adjust therapy and improve PD outcomes.

### SA-PO936

**Gabapentin Therapy for Pruritus in Automated Peritoneal Dialysis Patients: A Randomized Controlled Trial** Arturo R. Marin. *Nephrology, Hospital Regional ISSEMYM-Tlalnepantla., Mexico, Estado de Mexico, Mexico.*

**Background:** Uremic pruritus is a common and unpleasant symptom in patients with chronic kidney disease (CKD), the incidence is 42-52% and impact on quality of life in peritoneal dialysis and hemodialysis patients. Available treatments are not completely effective. Evidence with gabapentin and antihistamines indicate variable effects in dialysis patients.

Objective. To compare efficacy and side effects of gabapentin and loratadine in uremic pruritus in patients on automated peritoneal dialysis (APD).

**Methods:** We did a randomized, prospective, open, comparative clinical trial in APD patients with uremic pruritus. 60 patients were randomized to receive 12 weeks of treatment with gabapentin (n=30) 300 mg and loratadine (n=30) 10 mg every 24 hours, at night. To assess the severity of pruritus was used visual analogue scale (VAS), a reduction of pruritus of 50% was considered effective. To assess other features of pruritus was used 5D itch scale; a reduction of 2 points on the scale used was considered as effective.

**Results:** The gabapentin group were 22 male and 8 female patients, with 56.7+12.4 years old and the loratadine group were 21 male and 9 female patients, with 48.5+14.6 years old (p >0.05). All patients completed 12 weeks of treatment. Effectiveness was reported in 20 patients in the gabapentin group vs 10 patients in loratadine group (P = 0.025). With respect to the intensity of pruritus was found effective in 18 patients in the gabapentin group vs 9 in the loratadine group (P = 0.006), in terms of effectiveness duration was found in 15 patients in the group with gabapentin vs 7 in the loratadine group (P = 0.025). In the loratadine group was reported good tolerance to treatment and in the gabapentin group the more important adverse effect was somnolence (8 patients) but well tolerated in 6 patients, 2 decreased the dose. No statistically significant differences were found between ages, sex, underlying cause of CKD, PTH, and laboratory parameters between groups.

**Conclusions:** The use of gabapentin for treatment of uremic pruritus, in patients on APD is better than loratadine and is a good option for use in the treatment of uremic pruritus, in APD population of patients.

### SA-PO937

**Use of the Mid-Day Exchange in a Large USA Peritoneal Dialysis Cohort** Bethany Greer Costello, Sue A. Tendering, Steven Guest. *Baxter Healthcare.*

**Background:** In peritoneal dialysis (PD), a mid-day exchange (MDE) is performed to increase total daily solute clearance or prevent ultrafiltration (UF) loss during the long dwell of automated PD (APD). The potential benefits of a MDE are offset by the additional burden of requiring patients to perform an additional daytime exchange. We sought to better understand the use of a MDE in US PD therapy.

**Methods:** The data used is maintained in a custom, purpose built, data warehouse containing PD supply shipment information for US patients using Baxter PD solutions, disposables, and cycler devices. The parameters were APD patients who ordered supplies from Nov 2012-Jan 2013, and ordered CAPD supplies (48,232 individual orders by 13,489 patients) implying a MDE. Three months of data were used to smooth fluctuation in ordering due to number of days in the month and patient ordering patterns. APD patients with a three month average of 15-36 CAPD solution bags per month were included.

**Results:** 971 clinics with a total APD population of 20,161 patients were analyzed. 16% were receiving CAPD solution shipments consistent with a MDE. 16% of APD patients translated to 3,226 patients in the database performing a MDE. Average number of CAPD solutions ordered per month was 26- suggesting the patients were consistent in the use of the MDE. Discussion: This analysis has revealed that 16% of APD patients in this USA cohort received CAPD solution shipments implying use for a MDE. This estimate may be conservative as it would not capture patients using the cycler for a MDE. If the MDE is used to improve long-dwell UF, use of icodextrin could favorably impact the therapy as it is indicated for a single daily exchange for the long (8-to-16-hour) dwell for APD or CAPD.

**Conclusions:** Analysis of a large USA PD cohort has suggested 16% of APD patients are prescribed a MDE and reasons for the MDE should be clarified. A significant number of these patients would be considered candidates for a prescription change to icodextrin.

### SA-PO938

**Peritoneal Dialysis Prescriptions during the Third Trimester of Pregnancy: A Meta-Analysis** Steven Guest,[1] Rodolfo Batarse,[2] Ralph M. Steiger.[3] *[1]Baxter Healthcare Corporation, Deerfield, IL; [2]Nephrology, Hypertension, Transplant Medicine, Rancho Mirage, CA; [3]Desert Regional Medical Center, Palm Springs, CA.*

**Background:** Management of the pregnant patient on PD is complicated by the uterine enlargement that may restrict dwell volumes and/or create catheter dysfunction or discomfort. A variety of publications describe successful outcomes of pregnancy in the PD literature. A meta-analysis of the 3rd trimester PD prescription was performed to describe prescription options.

**Methods:** A systematic review and meta-analysis was performed of the English literature to identify ESRD patients managed by PD in which sufficient information was provided to determine the PD prescription used during the 3rd trimester of pregnancy to the end of gestation. Pregnancy outcomes were also determined.

**Results:** Twenty-five publications describing 37 pregnancies were reviewed. Twenty-nine pregnancies were included in the analysis. These were selected as they were deemed to provide sufficient clinical and prescription information. Both APD and CAPD modalities were reported. --Five of 29 pregnancies were managed with dwell volumes of 2L or greater per exchange. The remaining 83 % of pregnancies were managed by lower volume dwells with increased number of exchanges, either manually or with a cycler device. Patients hospitalized in the last trimester often received extended APD shorter dwells in lieu of a long day dwell.

**Conclusions:** Pregnant PD patients have been managed thru full term gestation and delivery. Whether managed by CAPD or APD, most reports describe reduced dwell volumes with increased number of daily exchanges with dialysate dwelling throughout the 24-hour period. APD patients often had increased number of cycles prescribed with

an extended time connected to the cycler. Empiric increases in the total daily dialysate volume to enhance the delivered solute clearance but employing reduced dwell volumes is frequently reported in this literature.

### SA-PO939

**Peritoneal Dialysis for Stage 5 Chronic Kidney Disease Patients in China: Twenty-Seven Years of Experience in a Single Centre** Huiling Wang. *Div of Nephrology, Jimin Hospital, Shanghai, China.*

**Background:** We present the demographics, patient and technique survival as well as peritonitis rates of 841 stage 5 chronic kidney disease (CKD5) patients, who started continuous ambulatory peritoneal dialysis (CAPD) between 1 January 1985 and 31 December 2011 at renal division of Shanghai Jimin Hospital in China.

**Methods:** A retrospective cohort study of individuals 15 years of age and older, divided into three cohorts according to the year they started peritoneal dialysis (PD): the first cohort (1985-1994), the second cohort (1995-2004) and the third cohort (2005-2011). Demographic and biochemical variables, clinical outcomes, patient and technique survival, peritonitis rate, and factors affecting mortality were analyzed.

**Results:** Mean age at the start of PD was 58.5±16.7years. Chronic glomerulonephritis (CGN) was the most common cause of end stage renal disease (ESRD) (52.4%); ESRD incidence as a result of diabetes ($p<0.05$) and hypertension ($p<0.05$) were significantly more frequent in the second and third as compared with the first cohort. Cardiovascular disease was the main cause of death (41.9%); the common cause of transfer to haemodialysis (HD) was peritonitis (59.2%), psychosocial causes of technique failure were reported in only 3.9%. Patient and technique survival at 1, 3 and 5 years were estimated by Kaplan-Meier for each of three cohorts. The patients in the third cohort had significantly better 5-year survival rate ($p=0.000$) and longer technique survival ($p=0.000$). The peritonitis rate reduced to an average of 0.25 episodes per year at risk in the third cohort from 1.33 episodes per year at risk in the first cohort. In the Cox proportional hazards model analysis, age,diabetic nephropathy,transfer to PD from HD,serum albumin level, serum C-reaction protein (CRP) level,Total creatinine clearance (Ccr) and dialysate-to-plasma creatinine ratio (D/P creatinine) predicted mortality.

**Conclusions:** Patient and technique survival have significantly improved, and peritonitis rate has reduced in the most recent cohort compared with earlier periods. The causes of this improvement are likely to the appointment of dedicated PD nurses, a standardized follow-up system, and a "PD first" principle since 2005.

### SA-PO940

**Physical Activity: Peritoneal Dialysis versus Hemodialysis Patients** Daniel Teta,[1] Marie Paule Guillodo,[2] Anne Kolko-Labadens,[3] Catherine Deforges-lasseur,[4] Martial Levannier,[5] Marine Panaye,[6] Denis Fouque.[7] *[1]Nephrology, Univ Hospital, Lausanne, Switzerland; [2]AUB Santé, Brest, France; [3]Hémodialyse, AURA Nord, Saint Ouen, France; [4]AURAD Aquitaine, Gradignan, France; [5]Amgen, Neuilly/Seine, France; [6]Néphrologie, Hôpital H.E.Herriot, Lyon, France; [7]Néphrologie, U1060 CHLS, Pierre Bénite, France.*

**Background:** Physical inactivity, a risk factor for mortality in maintenance dialysis (MD) patients, has been essentially studied in hemodialysis patients (HD). We aimed to assess physical activity from peritoneal dialysis (PD) patients included in the Step by Step initiative, a large cohort of MD patients.

**Methods:** All French nephrologists were invited to participate in a national prospective multicenter observational trial. 149 investigators included 1163 adult prevalent (> 3 months) MD patients. Physical activity was assessed by the number of daily steps using a pedometer (NO PE317C, USA) for 7 consecutive days. All PD patients from the cohort (n=63, 5.4%) were analyzed and compared with randomly-matched computer-selected HD patients (n=123), 1:2 ratio, by age (10-year intervals) and dialysis vintage (3-months intervals), which mostly determined daily step number in the whole cohort.

**Results:** Median age (57 yr) and dialysis vintage (1 yr) were not different in PD vs HD patients, as expected. Sex ratio (males: 60% in PD vs 68% in HD), prevalence of diabetes (30% vs 25%), ischemic heart, peripheral arterial, neurological and joint diseases were comparable. The groups only differed by the prevalence of hypertension (89 vs 63%, p: 0.0002) and median body mass index (25.9 vs 24.2 kg/m$^2$, p: 0.036). Median daily step number was comparable in PD vs HD patients (3321: Q1 1478-Q3 5926 vs 3903: Q1 2156-Q3 7346; p: 0.193). 64% PD vs 61% HD patients were sedentary (< 5000 steps/d), and 22% PD vs 16% HD patients had a low physical activity (> 5000 and < 7500 steps/d).

**Conclusions:** This study is the first to compare physical activity of PD vs matched HD patients. Despite a less immobilizing treatment, 86% of PD patients had a sedentary/low activity profile, similar to HD patients. These data confirm the need to promote physical activity in all MD patients, independent of the dialysis technique.

### SA-PO941

**The Relationship of Follow-Up Frequency and Peritoneal Dialysis Quality** Yan-ru Chen, Hui Peng, Jun Zhang, Tan-qi Lou. *Div of Nephrology, Dept of internal Medicine, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

**Background:** To investigate the relationship offollow-up frequency and quality of peritoneal dialysis.

**Methods:** 110 continuous ambulatory peritoneal dialysis(CAPD)patients were collected for retrospective analysis from October 2011 to December 2012. All patients were divided into two groups according to different follow-up frequency: group A(every 1~2 months) or group B(every 3~6 months).The dialysis quality of the two groups was compared. The dialysis quality including blood pressure, fluid balancing, nutritional status, serum calcium and serum phosphate, iPTH, peritonitis, exit infection were observed.

**Results:** Hemoglobin in group A (106.82±16.35)g/L was significantly higher than that in group B (94.32±20.77)g/L ($P=0.003$). Systolic pressure(141.73±27.12)mmHg, serum parathyroid hormone(335.85±187.36)pg/ml (iPTH), serum phosphate(1.37±0.36)mmol/L of group A were all lower than those of group B, which were respectively(156.87±22.36) mmHg,(463.95±354.65)pg/ml and(1.72±0.58)mmol/L. Thedifference of two groups was statistically significant (respectively $P=0.027$,0.033,0.001). The compliance of patients in group A is superior to those in group B ($P = 0.035$). In group A, patients with lower educational status, medical insurance covered less than 50% and patients whose home was far from the hospital (>50 km) were significantly less than in group B (respectively $P=0.025$,0.000,0.000).

**Conclusions:** According to our results, follow-up frequency affects quality of peritoneal dialysis. Short follow-up interval is better to ameliorate blood pressure, iPTH, serum phosphorus levels, anemia or patient compliance. Follow-up Frequency may be related to educational status, medical insurance coverage and the distance to the hospital.

### SA-PO942

**Prognostic Value of Blood Pressure at Initiation of Renal Replacement Therapy in Peritoneal Dialysis** Farsad Afshinnia, Jonathan H. Segal. *Internal Medicine, Univ of Michigan.*

**Background:** Reverse epidemiology manifested as higher mortality associated with lower blood pressure is described in patients with end stage renal disease (ESRD) on hemodialysis, but is not well described in peritoneal dialysis (PD). We evaluated the effect of baseline blood pressure at initiation of PD on all-cause mortality.

**Methods:** This is a retrospective observational study in a cohort of ESRD patients from the outpatient PD clinic of the University of Michigan from January 2007 to July 2012. Inclusion criteria were 18 years of age or older and having had at least one measured weekly KT/V. Baseline characteristics including demographics, comorbidities, medications, laboratory values as well as KT/V, PD prescription, and complications at follow up. The primary outcome is all-cause mortality. Multivariable Cox-regression survival models with increasing degree of adjustment by the background variables were applied for the analysis.

**Results:** Overall 88 patients were included and contributed to 2136 patient-months. There were 47 male- (53.4%), and 66 (75.0%) white patients. Median follow up time after initiation of PD was 35 months (interquartile range: 18 to 36 months). 22 patients reached the primary end point. There was a graded decrease in mortality from 38.9% to 13.2% for systolic blood pressure (SBP) <120 mmHg to SBP ≥160 mmHg. The first multivariable model revealed a 3.6 fold (95% CI: 1.1 to 12.7) higher risk of mortality with SBP <120 mmHg compared to SBP of 140-159 mmHg after adjusting for age, sex, and race. Subsequent models with stepwise addition of baseline albumin, KT/V, normalized protein catabolic rate, and etiology of ESRD further strengthened the association of SBP <120 mmHg with higher mortality as compared to SBP of 140-159 mmHg by stepwise increase in hazard ratio.

**Conclusions:** Reverse epidemiology manifested as higher mortality associated with lower blood pressure is observed in PD. This association may be representative of poor cardiac function in those patients with lower blood pressures. Randomized controlled clinical trials are needed to identify an optimal target of blood pressure control in patients performing PD.

### SA-PO943

**Tolvaptan Increases Urine and Ultrafiltration Volume for Patients with Oliguria Undergoing Peritoneal Dialysis** Toru Iwahori,[1,2] Shinya Nagasaka,[2] Akira Shimizu.[2] *[1]Immunology & Nephrology, Koyukai Memorial Hospital, Chiba, Japan; [2]Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

**Background:** Hypoalbuminemia caused by peritoneal dialysate protein loss, frequently occurs in patients on peritoneal dialysis (PD) and is associated with an increased risk of death. We investigate whether PD dialysis exchange volume (PD volume) could be reduced with Tolvaptan (TVP) through increased urine volume (UV).

**Methods:** In 23 stable patients with oliguria undergoing, the following parameters were examined diuretic response and the effect of TVP on peritoneal ultrafiltration (UF), body weight (BW), serum albumin, sodium, arm muscle area (AMA), PD volume, Kt/V, and urine and serum osmolarity (OSM).

**Results:** The average UV increased from 428 ± 178 mL to 906 ± 285 mL ($p = 0.018$ by paired t-test). Average weekly PD volume decreased from 28,836 ± 5,699 to 23,872 ± 3,569 mL ($p = 0.04$ by paired t-test). Average UF increased from 283 ± 147 to 575 ± 135 mL ($p = 0.019$ by paired t-test). On the other hand, there was no significant difference in the average dialysate Kt/V before and after TVP treatment. Serum sodium, AMA, and serum albumin levels were not statistically different before and after TVP treatment. The urine and serum OSM (us OSM) ratio of effective cases before TVP treatment was higher than that of ineffective cases ($p = 0.024$ by unpaired t-test).

**Conclusions:** Our results indicate that TVP is useful for patients on CAPD who have oliguria and high urine osmolarity. Furthermore, we can reduce PD volume to maintain their nutritional status.

**SA-PO944**

**The Effect of Folic Acid Therapy on Anemia in Patients with End Stage Renal Disease on Peritoneal Dialysis** Subir K. Paul, Shejuti Paul, Rajesh Boorgu, Jamie N. Cockrell, Narasimha Rao Boorgu, Cassandra (cassie) A. Miller. *Shoals Kidney and Hypertension Center, Florence, AL.*

**Background:** Despite maintenance of adequate iron saturation with intravenous iron and utilization of appropriate dose of Epogen therapy, anemia management remains sub-optimal in some patients with End Stage Renal Disease (ESRD) on peritoneal dialysis. We found macrocytosis and folic acid deficiency in some patients on peritoneal dialysis. This study tests the effect of folic acid treatment on plasma hemoglobin concentration in peritoneal dialysis patients with anemia.

**Methods:** 16 patients with ESRD on peritoneal dialysis with plasma hemoglobin concentration less than 11g/dl, folic acid level of 5 ng/ml or less, and iron saturation more than 20% were treated with 3 to 5 mg of oral folic acid daily. All patients had adequate KT/V and were free of infections or known inflammatory conditions. Vitamin B12 level was found to be normal in all patients. Mean age was 47.81 years. 7 were male and 9 were female. 9 were white, and 7 were black. Serum folic acid level and plasma hemoglobin concentration were evaluated at 4 weeks prior, initiation, and 4 weeks after initiation of therapy. Maintenance therapy with intravenous iron and Epogen were continued according to standard protocol. No subject received blood transfusion. Statistical analysis was done with student's t test.

**Results:** At four weeks prior to initiation, and at initiation mean folic acid level was 3.93 +/- 0.20 ng/ml and 3.96 +/- 0.22 ng/dl respectively (p=0.89). Following therapy with folic acid, mean folic acid level increased from 3.96 +/- 0.22 ng/dl to 19.26 +/-0.53 ng/dl (P<0.0001). During pre-treatment phase, mean plasma hemoglobin concentration remained unchanged from 10.42 +/-0.25 g/dl to 10.29+/- 0.25g/dl (P=0.97). Following treatment with folic acid, mean plasma hemoglobin concentration improved from 10.29 +/-0.25 g/dl to 11.30 +/-0.22 g/dl (P=0.005). Following treatment with folic acid, mean Epogen dose decreased from 14875+/-4968 units to 10437+/- 3407 units every 2 weeks (P=0.043).

**Conclusions:** We conclude that oral folic acid therapy may be a cost-effective addition to anemia management in patients with ESRD on peritoneal dialysis.

**SA-PO945**

**Change in Body Composition Measurements in Peritoneal Dialysis Patients According to Dialysate** Seokhui Kang,[1] Tae woo Kim,[2] Kyu-hyang Cho,[1] Jong-Won Park,[1] Kyung woo Yoon,[1] Jun-Young Do.[1] *[1]Internal Medicine, Yeungnam Univ Hospital, Daegu, Republic of Korea; [2]Internal Medicine, Soonchunhyang Univ Gumi Hospital, Gumi, Republic of Korea.*

**Background:** The accurate estimation of body composition is associated with prediction of morbidity or mortality in peritoneal dialysis patients. The aim of this study is to evaluate change in body composition measurements according to dialysate.

**Methods:** A total of 41 patients on maintenance peritoneal dialysis were enrolled in the study. Body composition analysis using bioimpedance spectroscopy (BIS) and multi-frequency bioimpedance analysis (MF-BIA) were performed in all patients, first with an empty abdomen (D-) and then with a full abdomen (D+, 2 liter). Differences in body compositions with D- and D+ were investigated. Biases were calculated as follows: measurement in D- – measurement in D+.

**Results:** In BIS, there were significant differences in fat mass and extracellular water between D- and D+. In MF-BIA, there were significant differences in free fat mass and extracellular/intracellular water between D- and D+. Bland-Altman analysis was performed. The mean biases in fat mass were 1.3 for BIS and -0.3 for MF-BIA. The mean bias in lean mass was 1.3 for BIS. That in free fat mass was -1.8 for MF-BIA. BIS underestimated the fat mass in D+. MF-BIA underestimated the lean mass in D+ and BIS overestimated the free fat mass in D+.

**Conclusions:** This study demonstrates that MF-BIA may be useful to evaluate fat mass, regardless of dialysate. Lean mass or free fat mass can be reliably done without dialysate.

**SA-PO946**

**Urinary Tract Infections in Kidney Transplant Recipients: Incidence and Risk Factors in a Contemporary Cohort** Joseph Kim, Stacey V. Konidis, Olusegun Famure, Yanhong Li, Shahid Husain. *Multi-Organ Transplant Program, Toronto General Hospital, Univ Health Network, Toronto, Canada.*

**Background:** Urinary tract infections (UTI) are a common cause of morbidity in kidney transplant recipients. This study aimed to evaluate the incidence, risk factors, causative organisms, and burden of urinary tract infections following kidney transplantation.

**Methods:** A retrospective cohort study of 907 kidney transplant recipients in Toronto, Canada from January 1, 2000 to December 31, 2010 was conducted. Time-to-first UTI was assessed using the Kaplan-Meier product limit method. Potential risk factors for the development of UTIs post-transplant were assessed using Cox proportional hazards regression models.

**Results:** Overall, there were 264 patients who had at least one UTI over a median of 3.0 years of follow-up, yielding an incidence rate of 7.5 (95% CI: 6.7 to 8.5) per 100 person-years. The cumulative incidence of UTI was 21.3% for male patients and 69.8% for female patients at 10-years post-transplant. The Cox proportional hazards model revealed that advanced age, female sex, and the presence of a structural urologic diagnosis were independently predictive of UTI post-transplant (hazard ratios 1.1 [95% CI: 1.0, 1.3], 4.8 [95% CI: 3.7, 6.2], and 1.5 [95% CI: 1.1, 2.0], respectively). Interestingly, ESRD due to polycystic kidney disease was associated with a reduction in the adjusted relative hazard of first UTI (hazard ratio 0.6 [95% CI: 0.4, 0.9]). Gram-negative bacteria were more common than gram-positive bacteria as the causative organisms for UTI events.

**Conclusions:** This observational cohort study found that kidney transplant recipients experience a significant burden of UTIs post-transplant. There are identifiable risk factors in this patient population that may help target preventive strategies to reduce the burden of this complication after kidney transplantation.

**SA-PO947**

**The Evolving Risk Factor Profile of New-Onset Diabetes Mellitus after Kidney Transplantation** Joseph Kim, Laura Rivera, Roman Zyla, Yanhong Li, Olusegun Famure. *Multi-Organ Transplant Program, Toronto General Hospital, Univ Health Network, Toronto, Canada.*

**Background:** New-onset diabetes after transplant (NODAT) is a common complication in kidney transplant recipients (KTR). The incidence of NODAT in KTR is high in the immediate post-transplant period and falls with time until it approaches that of diabetes in the general population, suggesting potential differences in the mechanism of diabetogenesis. An understanding of different risk factors for early- and late-onset NODAT may increase opportunities for prevention and/or early treatment.

**Methods:** The study population is composed of all individuals over the age of 18 who received a first kidney transplant between 1 Jan 2000 and 31 Dec 2011 at the Toronto General Hospital and were free of diabetes mellitus at the time of transplant. Patients were considered to have early-onset NODAT if they developed diabetes between day 14 and day 180 post-transplant inclusive, and late-onset NODAT if they developed diabetes after 180 days. A multivariable Cox proportional hazards model was used to identify risk factors for early- and late-onset NODAT.

**Results:** The study cohort was composed of 840 kidney transplant recipients, with a median follow-up of 3.53 years.Overall, 89 patients in the cohort developed early-onset diabetes, and 112 developed late-onset NODAT. Risk factors for early-onset NODAT were recipient age (HR 1.05 [95% CI: 1.03, 1.07]), deceased donor kidney (HR 2.04 [95% CI: 1.32, 3.13]) and expanded criteria donor kidney (HR 1.92 [95% CI: 1.15, 3.18]). Risk factors for late-onset NODAT were recipient age (HR 1.04 [95% CI: 1.03, 1.06]), non-white donor race (HR 2.04 [95% CI: 1.12, 3.85]), HLA mismatches (HR 1.21 [95% CI: 1.06, 1.39]), positive CMV serostatus (HR 1.69 [95% CI: 1.16, 2.50]), and deceased donor kidney (HR 1.69 [95% CI: 1.16, 2.50]).

**Conclusions:** The differences in risk factors for early- and late-onset NODAT suggests that they are likely the product of both shared and distinct mechanisms. Based on these results, the targets for diabetes risk reduction may partially depend on the timing of NODAT occurrence.

**SA-PO948**

**Transplant Renal Artery Stenosis in Kidney Transplant Recipients: Incidence, Risk Factors, and Outcomes** Joseph Kim, Ching Lucy Chau, Yanhong Li, Olusegun Famure. *Multi-Organ Transplant Program, Toronto General Hospital, Univ Health Network, Toronto, Canada.*

**Background:** Transplant renal artery stenosis (TRAS) has been implicated in poor allograft function and survival. As such, the prevention and early detection of TRAS may prove to benefit patient outcomes. This study aims to define the incidence, risk factors, and outcomes of kidney transplant recipients with TRAS in a large Canadian patient cohort.

**Methods:** This is a retrospective cohort study of 1224 kidney transplant recipients from 1 Jan 2000 and 31 Dec 2010 (followed until 31 Dec 2011). TRAS was confirmed through Doppler ultrasound indices (peak systolic velocity > 200 cm/second at mid-artery). Multivariable Cox proportional hazards models were fitted to examine the association between various risk factors at the time of transplant and the occurrence of TRAS over follow-up. In addition, the impact of TRAS as a time-varying exposure on the risk of total graft failure (i.e., return to dialysis or death with graft function) was also studied.

**Results:** A total of 106 incident cases of TRAS were observed over a median follow-up of 3.24 years. The incidence rate of TRAS was 0.46 cases per 100 person-years. The relative hazard for TRAS was significantly associated with living donor transplant [HR 2.69 (95% CI: 1.59, 4.56)] and male sex [HR 1.80 (95% CI: 1.16, 2.78)]. Our analysis showed an era effect with a lower relative hazard of TRAS in the most recent eras [HR 0.62 (95% CI: 0.41, 0.95) for 2005-2007 vs. 2000-2004 and HR 0.29 (95% CI: 0.15, 0.58) for 2008-2011 vs. 2000-2004]. TRAS was associated with an increased risk for total graft failure [HR 1.41 (95% CI: 0.58, 3.44)], although this failed to reach statistical significance.

**Conclusions:** Our results suggest that male sex and living donor recipients are at an increased risk for TRAS. A decrease in the risk of TRAS was also observed with the most recent transplant era. Further study is required to confirm and explore these associations in other kidney transplant populations.

**SA-PO949**

**Infection-Related Mortality Is Higher for Kidney Allograft Recipients with Diabetes Mellitus – A Population Based Cohort Study** Manvir Kaur Hayer, Daniela Farrugia, Adnan Sharif. *Renal Institute of Birmingham, Queen Elizabeth Hospital, Birmingham, United Kingdom.*

**Background:** Strong epidemiological evidence linking diabetes with risk for serious infections is lacking despite sufficient experimental evidence. The risk for infection-related mortality in kidney allograft recipients with diabetes, on immunosuppression, is unknown. This study investigates whether diabetes mellitus predicts mortality from infection post kidney transplantation.

**Methods:** We identified all kidney alone transplants done in England from April 2001 to March 2012 through a national database called Hospital Enquiry Statistics. Patient demographics were collected, and all deaths in the study group were identified via data linkage analysis with the Office for National Statistics. The primary outcome was death from infection post transplantation in diabetics versus non-diabetics. Cox proportional hazard models identified independent factors associated with infection-related mortality ($p<0.05$ was significant).

**Results:** 19,103 kidney allograft recipients were analysed, of whom 2,968 had diabetes at the time of transplantation. Diabetic allograft recipients were often older, male, non-white, of deprived socio-economic areas, received deceased-donor kidneys and had co-morbidities. 2,085 deaths occurred post transplantation; 433 were due to infection. Table 1 compares the risk of death in diabetics and non-diabetics.

| Risk for death (p<0.010) | % Diabetic | % Non-diabetic |
|---|---|---|
| Post kidney transplant | 16 | 10 |
| 1 year post kidney transplant | 4.9 | 2.6 |
| Due to infection post transplant | 3.3 | 2.1 |

Increasing age, deceased-donor kidneys, area socioeconomic deprivation, peripheral vascular disease and diabetes were independently associated with death from infection.

**Conclusions:** Infection-related mortality is common post transplantation especially in kidney allograft recipients with pre-existing diabetes mellitus. Diabetes is a risk factor for infection-related death post kidney transplantation independent of confounders. Further work is needed to decide whether personalised immunosuppression is beneficial for diabetic kidney allograft recipients.

### Distinct Localization of HCMV-Encoded Chemokine Receptor US28 and Immediate Early Antigen after Renal Transplantation Suggests Microenvironment-Specific Expression

Wouter Lollinga,[1] Afsar Rahbar,[2] Martine J. Smit,[3] Annelies Riezebos-brilman,[4] Cecilia Söderberg-naucler,[2] Willem Van Son,[1] Johannes S. Sanders,[1] Jacob van den Born.[1] *[1]Nephrology, UMCG, Groningen, Netherlands; [2]Medicine, Karolinska Institutet, Stockholm, Sweden; [3]Medicinal Chemistry, VU Univ, Amsterdam, Netherlands; [4]Medical Microbiology, UMCG, Groningen, Netherlands.*

**Background:** Human cytomegalovirus (HCMV) is associated with decreased renal graft function and survival, possibly through expression of chemokine receptor US28. US28 enables HCMV to benefit from the host cellular machinery and modify intracellular signaling. We hypothesized US28 to be expressed in vascular, inflammatory and tubular epithelial cells, linking HCMV infection to transplant dysfunction.

**Methods:** Recipient renal transplant biopsies (n=50) from HCMV-seropositive donors were obtained pre-transplantation, on indication or by protocol one year post-transplantation. Immunohistochemical staining was performed for US28 and immediate early antigen (IEA). Localization of both HCMV antigens was semi-quantitatively scored in renal compartments and analyzed by Spearman rank correlation.

**Results:** Both HCMV antigens were detected during recipient active and latent HCMV infections, with IEA exclusively localized in the nucleus and US28 mainly in the cytoplasm. Localization can overlap in renal compartments, but is regularly distinct. IEA displays widespread distribution but prevails in vascular endothelium and inflammatory cells. US28 distribution is more restricted and most prevalent in vascular smooth muscle and tubular epithelial cells ($r=0.557$, $p<0.001$). Strikingly, IEA and US28 expression within a single compartment didn't correlate.

**Conclusions:** We are the first to demonstrate US28 in renal transplant biopsies, and its specific localization. More pronounced than for IEA, the distinct localization of US28 in vascular smooth muscle and tubular epithelium suggests microenvironment-specific expression. Since these compartments frequently display histopathology, HCMV could instigate (chronic) transplant dysfunction through US28. The effect of US28 on transplant histopathology and recipient clinical outcome parameters are currently under investigation.

## SA-PO951

### Long-Term Impact of CMV Infection on the Allograft and on Patient Survival in Renal Transplant Patients with Protocol Biopsies

Uta Erdbruegger,[1] Irina Scheffner,[2] Michael Mengel,[3] Anke Schwarz,[2] Hermann G. Haller,[2] Wilfried Gwinner.[2] *[1]Univ of Virginia; [2]Hannover Medical School, Germany; [3]Univ of Alberta, Canada.*

**Background:** The impact of CMV infection on allograft and patient survival is controversial.

**Methods:** We studied 594 patients with a protocol biopsy (pBx) at 6 weeks, 3 & 6 months post transplant (Tx). Chronic allograft changes were graded by the Banff classification (cGrade, cv, cg lesions). CMV infection was diagnosed by CMV antigenemia test. Follow up data was available up to 10 years.

**Results:** CMV infection was diagnosed in 153 of 594 patients (26%) in the first year after Tx, mostly within the first 3 months. In patients with CMV infection between the pBx at 6 weeks and 6 months, 11.5% of the biopsies had a cGrade>0 at 6 weeks compared to 3.5% in patients without CMV ($p=0.005$). At 6 months, the prevalence of a cGrade>0 rose to 40.6% in patients with CMV and to 34.2% in patients without CMV ($p=0.24$). In patients with CMV infection within the first 6 weeks post-Tx, 13% of the biopsies had a cGrade>0 at 6 weeks compared to 3.5% in patients without CMV ($p=0.06$). At 6 months, the prevalence of a cGrade>0 rose to 55% in patients with CMV and 34% in the group without CMV ($p=0.09$). Chronic vascular and glomerular changes were rarely seen and were not different. The annual GFR loss was greater in patients with CMV infection (median: 3.6 vs 2.4ml/min per year, $p=0.017$). Allograft survival was reduced in patients with CMV ($p=0.03$) as well as the combined allograft/patient survival ($p=0.008$). Clinical and laboratory factors that differed between patients with and without CMV were recipient and donor age, pre-Tx coronary heart disease, CMV donor/recipient IgG serostatus, and initial graft function. In multivariate analyses, higher donor age, lower initial graft function, and coronary heart disease were significant for graft loss whereas patient age and initial graft function were significant for death. In none of these analyses, CMV viremia or disease was a significant factor.

**Conclusions:** Patients with CMV post-Tx show more chronic allograft changes early-on, even before CMV infection. Thus, allograft loss and death is apparently not related to CMV.

## SA-PO952

### Effect of HIV and HIV/ HCV Coinfection in Kidney Transplant Recipients

Anjali Gupta, Graciela De Boccardo, Enver Akalin, Liise K. Kayler. *Montefiore Medical Center/Albert Einstein College of Medicine, NY.*

**Background:** Reports of kidney transplantation in human immunodeficiency virus seropositive (HIV+) recipients with or without hepatitis C (HCV+) are scarce and lack long-term outcomes.

**Methods:** We evaluated paired deceased-donor kidneys (derived from the same donor transplanted to different recipients) in which one kidney was transplanted into an HIV+ (n=207) or HIV+/HCV+ (n=43) patient and the other transplanted to a recipient without HIV or HCV (HIV-;n=250) using Scientific Registry of Transplant Recipients (SRTR) data between 2000 and 2010.

**Results:** While univariable analysis revealed death-censored graft survival (DCGS) was significantly worse in HIV+ patients compared to HIV- patients ($p=0.0331$), on multivariable analysis (adjusted for recipient risk factors), there was no significant difference (aHR 0.34, 95% CI 0.03, 3.91). There was no difference in patient survival by univariable ($p=0.7329$) or multivariable analysis (aHR 0.80, 95% CI 0.29, 2.18] between the two groups. HCV co-infection was a significant independent risk factor for DCGS (aHR 2.51; 95%CI 1.23, 5.14) and patient survival (aHR 3.03; 95%CI 1.31, 6.98). Acute rejection at one year occurred in 9.2%, 15.9%, and 16.3% of the patients in the HIV-/HCV-, HIV+/HCV-, and HIV+/HCV+ groups, respectively ($p=0.0724$). Acute rejection was significantly associated with African-American race (aOR 2.26, 95% CI 1.17-2.38) and HLA mismatch > 3 (aOR 2.18, 95%CI 1.01-4.66); however, neither HIV+(aOR 1.36, 95%CI 0.72-2.58) nor HCV coinfection (aOR 1.02, 95%CI 0.39-2.62) were risk factors for acute rejection.

**Conclusions:** Where as kidney transplantation in HIV+ recipients is associated with similar long term outcomes relative to non-infected recipients, HCV co-infection confers poor patient and graft survival. The higher rates of acute rejection amongst HIV+ kidney transplant recipients relative to HIV- recipients is at least partially due to the predominance of African-Americans in the HIV+ cohorts.

## SA-PO953

### The Impact of Hepatitis C Virus Infection on the Incidence of Post-Transplant Lymphoproliferative Disorder among Epstein-Barr Virus and Cytomegalovirus Seropositive Kidney Transplant Recipients: An Analysis of UNOS/OPTN Data

Hoang Anh Nguyen,[1] P.C. Pham,[2] P.T.T. Pham.[3] *[1]UCI Dept of Internal Medicine; [2]UCLA-Olive View Dept of Medicine, Nephrology Div; [3]UCLA Dept of Medicine, Nephrology Div & Kidney Transplant Program.*

**Background:** Post-transplant lymphoproliferative disorder (PTLD) is a serious complication after organ transplantation. Hepatitis C virus (HCV) infection is a well-established risk factor for the lymphoproliferative syndrome type II mixed cryoglobulinemia. In this study, we hypothesize that pre-transplant HCV infection increases the risk of PTLD among kidney transplant recipients who have Epstein-Barr virus (EBV) and Cytomegalovirus (CMV) seropositivity.

**Methods:** Adult kidney transplant recipients (≥ 21 years old), of a deceased or living donor kidney transplant in the U.S., with PTLD diagnosis between 1999 and 2011 from the UNOS/OPTN data, were included the analysis using SAS. The difference of distributions of categorical variables between groups was investigated using chi-squared tests. Effect modifications of HCV antibody status on PTLD risk by selected demographic characteristics (age, sex, ethnicity) and clinical factors (CMV serology, EBV serology, pre-transplant malignancy, HLA mismatch, acute rejection episodes, use of medications for induction and maintenance of immunosuppression) were evaluated under the multiplicative model in the Cox regression models.

**Results:** There were a total of 923 PTLD cases (incidence, 1.78 patients per 1000 person-years) among 169,196 primary kidney transplant recipients between 1999 and 2011 (accrued 517,739.76 person-years at risk during the follow-up period). HCV prevalence at transplantation was 5.58% (N = 9,445). HCV infection did not increase PTLD risk in the total cohort even after adjusting for demographic and clinical risk factors. No significant effect modifications were found for HCV infection on the incidence of PTLD among EBV and CMV seropositive kidney transplant recipients.

**Conclusions:** Our findings suggest that HCV is not a major risk factor for PTLD among kidney transplant recipients, which is consistent with previous studies among other solid organ transplant recipients.

**SA-PO954**

**Prevalence and Risk Factor of Epstein-Barr Virus Viremia in Kidney Transplant Patients** Keun Suk Yang, Byung Ha Chung, Bum Soon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea.*

**Background:** Epstein-Barr Virus (EBV) infection is an important risk factor for post-transplant lymphoproliferative disease and increase in viral load of EBV also associated with the development of chronic allograft injury. In this study, we evaluated the prevalence and risk factors for the development of EBV viremia in renal transplant recipients.

**Methods:** One hundred ninety three patients were included in this study. The follow-up period from KT was 82.26±68.09 months and the mean age was 46.88±11.19 years. Plasma EBV loads were measured by real-time quantitative polymerase chain reaction and EBV Viremia was defined as having at least 500 copies EBV/ml.

**Results:** EBV viremia developed in 35.23% (68/193) of study population. Donors for the majority of patients in this study were living (74.1%). The patients with proteinuria showed significant difference in both groups ($p<0.01$). EBV viremia were more frequent in the patients treated with cyclosporine than with tacrolimus ($p<0.01$). Glomerular filatration rate was lower in EV group (53.74±21.39 ml/min/BSA) than NV group (60.54±17.58 ml/min/BSA) ($p<0.05$) and immunosuppression period was longer in EV group (124.92±83.63 months) than NV group (78.33±73.45 months) ($p<0.01$). No significant difference was shown between EV group and NV group on age at transplant, pre-transplant dialysis type, donor type, rejection history, ABO incompatible transplantation proportion.

**Conclusions:** The prevalence of [/bold]EBV viremia in stable renal transplant recipients was 35.23 % and follow up period and the type of immunosuppressant may be associated with the development of viremia.

**SA-PO955**

**BANFF Scores in Polyomavirus Nephropathy: How Do They Change over Time?** Harsharan Kaur Singh,[1] Rachel Cianciolo,[1] Carlos Jimenez,[1] A. Gasim,[1] Randal K. Detwiler,[2] Volker Nickeleit.[1] *[1]Div of Nephropathology, Univ of North Carolina, Chapel Hill, NC; [2]Nephrology and Hypertension, Univ of North Carolina, Chapel Hill, NC.*

**Background:** The morphology of Polyomavirus Nephropathy (PVN) resolution has not been systematically studied. It is unclear whether PVN contributes significantly to the development of chronic allograft injury over time.

**Methods:** Paired renal biopsies for cause from 14 patients (total biopsies n=28) were evaluated at time of initial PVN diagnosis and at time of PVN clearance following standard protocols (weeks between biopsies:mean=128; range=3.4-392). At time of index biopsy,9 cases were PVN stage A (miminal virally induced injury) and 5 were stage B (florid virally induced injury). Biopsies were scored using BANFF criteria. Renal function was assessed by serum creatinine titers (SCr). PVN clearance was defined as no staining for the SV40 T antigen. Statistical analysis: Wicoxon rank-sum test.

**Results:** No significant differences were seen in index and clearance biopsies for Banff acute lesion scores; all cases C4d negative. In clearance biopsies, overall inflammation decreased with new onset rejection induced changes (g,v,ptc); 15% C4d positive. Comparative analysis of chronic Banff lesion scoring showed increased chronic changes in clearance biopsies due to rejection (cg), and hypertension and/or calcineurin inhibitor toxicity (ci, ah, cv, ct) (figure 1B). PVN likely only contributed as a minor factor to chronic injury. Renal function-index biopsy: SCr(mg/dL) mean=2.79, range 0.43-11.3; clearance biopsy:SCr mean=1.98, range=0.59-4.4.

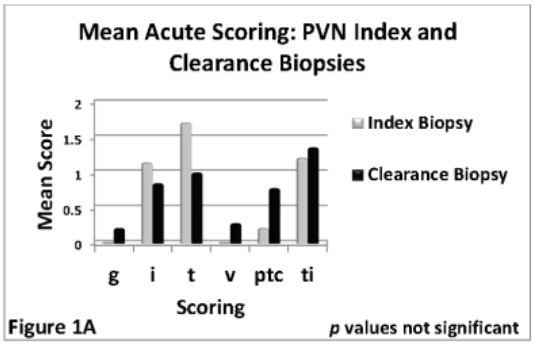

Figure 1A *p* values not significant

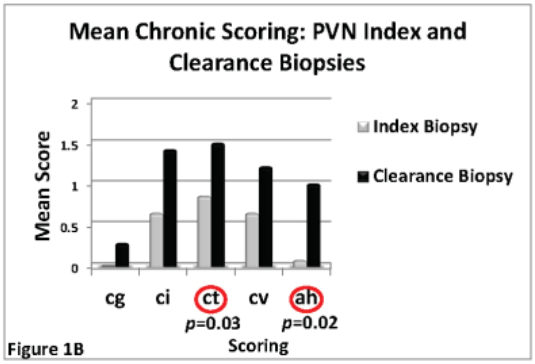

Figure 1B

**Conclusions:** In healed PVN stages A & B, renal function improved compared to time of PVN diagnosis. PVN does not necessarily contribute significantly to acute or chronic graft injury during disease resolution.

**SA-PO956**

**Bk-Virus and the Impact of Transient versus Persistent BK Viremia on Graft Function and Survival after Kidney and Kidney/Pancreas Transplantation – 5-Year Results** Nissreen S. Elfadawy,[1] Stuart M. Flechner,[1] Jesse D. Schold,[2] Titte Srinivas,[3] Emilio D. Poggio.[1] *[1]Glickman Urological and Kidney Institute, The Cleveland Clinic; [2]Dept of Quantitative Health Sciences, The Cleveland Clinic, Cleveland, OH; [3]Div of Nephrology, Medical Univ of South Carolina, Charleston, SC.*

**Background:** BK virus (BKV) reactivation is a serious complication after kidney transplantation. Currently there are limited data regarding long-term impact of transient BK viremia.

**Methods:** 609 patients who had kidney or kidney/pancreas transplant from 2007 to 2011 were screened for BKV infection. 130 patients (21.7%) developed positive BKV infection in blood during the first year post transplant. BKV positive patients were classified according to duration of infection from onset to clearance - if any (≥or < 3 months), and BK peak viral loads (≥ or < 10000 copies/mL) into: transient low viremia(n=42), transient high viremia (n=18), persistent low viremia (n=23), and persistent high viremia (n=47). Patients were followed up for a median of 36 months (3-66). BKV associated nephropathy (BKVAN), acute rejection, and the 1-year graft function were assessed and compared with the negative group.

**Results:** Patients and graft survival were comparable among the groups ($p>0.05$). Transient high viremia and persistent high viremia groups showed higher incidence of acute graft rejection (50% and 34% respectively vs 21.5%, p=0.01), and worse 1-year post transplant graft function (eGFR 42.1 and 44.9 vs 53.1, p= 0.01, 0.005 respectively). Tacrolimus and MMF blood levels were not significantly lower after diagnosis of transient viremia compared to the negative group (p= 0.3, 0.1).The 7 patients developed BKVAN were exclusively limited to the persistent high viremia group ($p<0.0001$). No graft loss occurred related to BKV.

**Conclusions:** Low BKV infection does not have a negative impact on graft outcomes. Although transient high viremia was not associated with BKVAN, poor graft function and high incidence of graft rejection in this patient group may suggest a new mechanism for the negative impact of BKV. In general, BK viremia and BKVAN are associated with excellent patient and graft survival in the era of BKV screening.

## SA-PO957

**The Genomics of BK Viremia and Nephropathy in Kidney Transplant Recipients Reveal a Heightened T Cell and Natural Killer Cell Response**

Michelle L. Lubetzky, Yi Bao, Maria Ajaimy, Graciela De Boccardo, Enver Akalin. *Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY.*

**Background:** The genomics of polyomavirus BK viremia and nephropathy (BKVN) have not been well described. We aimed to study gene expression profiles of BK viremia and BKVN samples using microarrays.

**Methods:** 17 biopsy and 40 whole blood PAXgene samples from patients enrolled in our IRB approved "Immune Monitoring Study" were used for analysis. Biopsy samples were divided into 3 groups, Group 1: Normal biopsy,n=11, Group 2: BKVN, n=3, and Group 3: BK viremia with normal biopsy,n=3. Whole blood PAXGene samples were divided into 3 groups, Group 1: Stable renal function, n=14, Group 2: BK viremia, n=19, and Group 3: samples taken 1-2 months prior to BK viremia, n=7. All samples were analyzed using Affymetrix Human Gene 1.0 ST Arrays.

**Results:** When comparing BKVN biopsy samples to Group 1 and 3, there were 1442 and 1325 differentially expressed genes, respectively (FDR<0.05 and fold change >2). There was no significant difference between Group 1 and 3. Pathogenesis based transcript (PBT) analysis revealed a significant increased expression of interferon-gamma and rejection induced (GRIT), cytotoxic T-cell (CAT), constitutive and alternate macrophage, B cell and natural killer cell-associated transcripts (NKAT), indicating an active inflammatory immune response in BKVN biopsies. The top 50 differentially expressed genes were involved in immune activation such as toll-like receptor 10, CD40 ligand, B and T lymphocyte associated, CD4, and MHC-Class II DO Beta. Gene ontology analysis revealed pathways involved in immune activation, T cell activation and costimulation, B cell activation, and defense response to virus. While there were no significant differentially expressed genes in whole blood gene expression profiles of Group 1 and 3, the PBTs of BK viremia revealed significant increased expression of GRIT, QCAT and NKAT when compared to Groups 1 and 3.

**Conclusions:** Our results showed increased activity of cytotoxic T cells and natural killer cells in BKVN and viremia samples resembling acute rejection. Whether such response is to alloantigens or virus requires further studies.

## SA-PO958

**BK Nephropathy: A Paired Kidney Analysis from a Single Center**

Marilda Mazzali, André Ba Esteves, Luiz R.S. Ulisses, Leonardo F. Camargo, Gabriel G. Rivelli. *Renal Transplant Program–Div of Nephrology, School of Medical Sciences- State Univ of Campinas–UNICAMP, Campinas, Brazil.*

**Background:** Polyomavirus nephropathy (PVAN) has a negative impact on graft survival, and is related to donor and recipient risk factors. In order to identify recipient related factors, we analyzed a series of renal transplants from deceased donor, where one recipient developed PVAN and compared to their controls, recipients from a paired kidney, with persistent negative BKV viruria.

**Methods:** From the Transplant Unit database, 16 patients with biopsy proven PVAN, recipients from a deceased donor kidney were identified. For analysis, we considered 12 pairs of kidneys, one with biopsy proven PVAN (PVANs) and the paired kidney (Controls) with persistent negative BKV viruria. Two pairs, were both kidneys developed PVAN were excluded. All patients were screened for BK viruria every 3 months during the first 3 years post transplant.

**Results:** PVANs and Controls were comparable for age at transplant, primary renal disease, % PRA, induction therapy, and baseline immunosuppression, with a higher prevalence of male recipients in PVANs (91.6% *vs.* 66.6%, p<0.05). Despite a trend to a lower cold ischemia time (p=0.08) in PVANs, the incidence of delayed graft function and CMV infection were similar to Controls. However, incidence of acute rejection and severity of Banff grade were higher in PVANs (41% *vs.* 8%, p<0.05). Positive BKV viruria was observed 14±9 months post transplant, and biopsy diagnosis of PVAN was done 24±11 months post transplant. While serum creatinine in controls remained stable (1.2±0.3 mg/dL), renal function deteriorated over time in PVANs (1.8±0.8 mg/dL at viruria and 2.6±0.6mg/dL at biopsy, p<0.05 *vs.* controls). The mean follow up after diagnosis was 34.2 months for PVANs (Controls, 41 m, p=ns), with a significantly lower graft survival, starting one year after diagnosis (5 year graft survival 50% PVANs *vs.* 83% Controls, p<0.05).

**Conclusions:** In this series, PVAN was associated with male gender, number and severity of acute rejection. After a 5 year follow up, 50% of the grafts in PVAN group remained functioning, with a mean serum creatinine of 3.3 ± 1.6 mg%.

## SA-PO959

**Evolution of BK Viremia, Intragraft Inflammation and Tubulointerstitial Fibrosis following BKVN Diagnosis**

Jun B. Lee,[1] Surya V. Seshan,[3] John R. Lee,[2] Steven Salvatore,[3] Thangamani Muthukumar,[2] David Serur,[1] Manikkam Suthanthiran,[2] Darshana Dadhania.[2] *[1]Nephrology, Rogosin Institute, New York, NY; [2]Nephrology, Weill Cornell Medical College, New York, NY; [3]Pathology, Weill Cornell Medical College, New York, NY.*

**Background:** BKV Nephropathy (BKVN) is associated with greater than 50% risk of graft loss and earlier studies have mostly evaluated graft function and viral load following BKVN diagnosis, and the evolution of histological features following BKVN diagnosis has not been well-characterized.

**Methods:** We performed a systematic review of index and surveillance renal allograft biopsy findings in individuals with biopsy proven BKVN. We evaluated the change in the histology scores associated with inflammation and fibrosis following a decrease in BK viral load.

**Results:** We studied 22 patients with BKVN; 12 with BKVN stage A, 7 with stage B, and 3 with stage C. The surveillance biopsies were performed at mean of 9 months following BKVN diagnosis. Histological scores, renal function, and BK viral load at the time of BKVN diagnosis and at surveillance biopsy are summarized in the Table.

Table 1: Laboratory Data and Histology Scores

| Variable (mean+SD) | BKVN Biopsy | Follow-up Biopsy | P Value* |
|---|---|---|---|
| Creatinine (mg/dL) | 2.04+0.57 | 2.10+0.89 | 0.48 |
| Serum BKV PCR (copies/ml) | 1,299,158+2,535,182 | 1663+2650 | 0.03 |
| Post Transplant Months | 15.5+12.7 | 24.5+12.9 | |
| **Tubulitis Score** | | | |
| Stage A (N=12) | 0.58+0.90 | 1.00+0.95 | 0.34 |
| Stage B/C (N=10) | 1.50+1.18 | 0.40+0.52 | 0.03 |
| **Interstitial Inflammation** | | | |
| Stage A (N=12) | 1.17+0.72 | 1.42+0.90 | 0.52 |
| Stage B/C (N=10) | 2.00+0.82 | 0.90+0.57 | 0.003 |
| **Tubular Atrophy Score** | | | |
| Stage A (N=12) | 0.58+0.67 | 1.42+0.67 | 0.02 |
| Stage B/C (N=10) | 1.30+0.68 | 1.20+0.63 | 0.67 |
| **Interstitial Fibrosis Score** | | | |
| Stage A (N=12) | 0.50+0.52 | 1.08+0.90 | 0.09 |
| Stage B/C (N=10) | 1.20+0.63 | 1.20+0.63 | 1.0 |

* P Value calculated using paired T-test

**Conclusions:** The striking decrease in BK viral load was associated with a significant decrease in intragraft inflammation but tubulointerstitial fibrosis either increased (in BKVN stage A) or remained the same (in BKVN Stage B/C). Our new findings, in addition to providing a mechanistic basis for the poor long-term outcome in BKVN patients, suggest the hypothesis that anti-fibrosis therapy ( e.g., anti-TGF-beta antibody) may retard the progression of BKVN.

## SA-PO960

**Utility of ImmuKnow Assay in BK Infection after Kidney Transplantation**

Nashat Burhan Imran, Phuong M. Truong, Venkataraman Ramanathan. *Baylor College of Medicine.*

**Background:** By quantifying cellular ATP production after mitogenic stimulation, ImmuKnow assay values(IKAV) can provide an estimate of immune function. We studied the utility of this assay in patients with and without BK viremia (BKV) after kidney transplantation.

**Methods:** In this retrospective case-control study, IKAV and BK PCR was obtained in kidney transplant recipients at 1 month post-transplantation and then quarterly for a year. BKV was subdivided into groups based on PCR values: A<$10^3$, B:$10^3$-$10^4$, C:$10^4$-$10^5$ and group D>$10^5$. Delta IKAV was defined as IKAV on the date that BK was first ≥$10^3$ minus immediate previous IKAV. General linear mixed model was used to compare IKAV between different BK infection groups over time. Paired t-test was used to test the null hypothesis (i.e. no significant change in delta IKAV in incident BKV patients).

**Results:** We had 79 BKV cases and 99 of selected controls. Time-group interaction term was significant (P<0.0001) indicating that differences between groups depend on time. In BK cases, IKAV were significantly lower at months 3, 6, 9 and 12 months when compared to first month IKAV and BK PCR Groups appear have an inverse relationship. This appears to be consistent across time points; however, the association appears to dissipate by month 12. IKAV for group D were significantly lower than Group A (P=0.056) and Group B (P=0.015). Using paired t-test, we found that incident BKV was associated with a significant decrease in delta IKAV from month 1 to 3 (P<0.0001). On an average, there is a 367 point decrease in IKAV (SD=346, 95% CI: 269,486). Beyond 3 months, delta IKAV was not associated with incident BKV (P≥0.07).

| Effect | Time 1 (months) | Time 2 | Mean Difference (*Step-down Bonferroni P<0.0001)* |
|---|---|---|---|
| Time*Infection | 1 | 3 | -308 |
| | 1 | 6 | -315 |
| | 1 | 9 | -249 |
| | 1 | 12 | -273 |

**Conclusions:** Compared to controls, kidney transplant recipients who develop BKV have significantly lower IKAV after 3 months when compared to first month. Also, incident BKV is associated with a significant decrease in delta IKAV only in the first 3 months. Beyond that period, delta IKAV did not correlate with incident BKV.

## SA-PO961

**BK Viremia in Kidney Transplant Recipients**

Gopal Basu, Margabandhu Saravanan, Anjali Mohapatra, Anna T. Valson, Vinoi George David, Suceena Alexander, Shibu Jacob, Santosh Varughese, Chakko Korula Jacob, Veerasamy Tamilarasi. *Nephrology, Christian Medical College, Vellore, India.*

**Background:** BK virus associated nephropathy is a threat to kidney transplant (KT) graft survival.BK viremia precedes BKV nephropathy. We aimed to study the risk factors and outcome BK viremia in KT recipients with graft dysfunction.

**Methods:** KT Recipients who underwent transplantation at Christian Medical College, Vellore from January 2006 to December 2011 were included. Patients underwent BK viremia screening for evaluation of graft dysfunction [by Qualitative BK PCR (VP1 region Primers, Qiagen) with limit of detecting 100 genome copies/ml] and tissue histopathology. The risk factors, and outcomes were analysed using standard statistical methods.

**Results:** Of the 458 KT recipients (mean age 35.1±11.7 years; M:F=3.2:1) followed up for 23±14 months on predominantly prednisolone, tacrolimus and mycophenolate based regimen, BK PCR was tested in 196 individuals either for evaluation of graft dysfunction [Evaluation group] (n=165) or as routine screening [Screening group] (n=32). Among evaluation group, 33 patients had BK viremia at 18.0±13.7 months post transplant. Acute rejections [p=0.07] was a significant risk factor for BK viremia and use of basiliximab [p=0.032] had a protective effect. CMV disease [p=0.067] was associated with BK viremia. The decline in GFR with BK viremia was significantly higher than in non viremic patients (-1.48±1.46 ml/min/1.73m$^2$/month vs. -0.44±0.91 ml/min/1.73m$^2$/month [p=0.000]). All patients with BK viremia were treated with immunosuppression reduction and Leflunomide. With therapy, GFR stabilized and 15 patients became BK PCR negative after 6 months. Among patietns with graft dysfunction, BK viremia resulted in significantly poor graft survival and patient survival.

**Conclusions:** Among KTRs with graft dysfunction, BK viremia occurred in 20% of patients and was associated with acute rejections and CMV disease. Basiliximab use had a protective effect. Graft dysfunction patients with BK viremia had rapid decline in GFR, graft loss and mortality. Immunosuppression reduction and leflunomide cleared BK viremia or stabilized GFR in a considerable number of patients.

## SA-PO962

**HLA-A2, HLA-B44 and HLA-DR15 Associate with Lower Risk of BK Viremia while BK Viruria Is HLA Independent** Kosuke Masutani,[1,2] Parmjeet S. Randhawa.[1] *[1]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Medicine and Clinical Science, Kyushu Univ, Graduate School of Medical Sciences, Fukuoka, Japan.*

**Background:** Human leucocyte antigens (HLA) modulate immunity to polyomavirus BK (BKV). Identification of HLA-antigens that alter the course of infection will facilitate risk stratification, and customization of pre-emptive intervention strategies.

**Methods:** We performed a retrospective cohort study with 998 kidney transplant patients with BKV infection status confirmed by polymerase chain reaction (PCR). Clinical parameters and donor-recipient matching for specific HLA-antigens were examined in relation to occurrence of viremia and viruria. Emphasis was placed on donor-recipient matching rather than the actual frequency of specific HLA-alleles, since a successful immune response requires sharing of HLA antigens between a virus infected target cell and the anti-viral effector cell.

**Results:** In multivariate statistics incorporating known risk factors of BKV, low risk of BK viremia was independently associated with matching of HLA-A2 (hazard ratio [HR] 0.51, 95% confidence interval [CI] 0.28-0.85), HLA-B44 (HR 0.31, 95%CI 0.076-0.85) and HLA-DR15 (HR 0.35, 95%CI 0.084-0.93) ($p<0.05$), whereas high risk of viremia was associated with male gender (HR 2.38, 95%CI 1.46-4.09, $p<0.001$). We did not find any difference in the distribution of HLA matching between BK viruria and BKV negative patients.

| | No BKV replication (n=515) | Viruria (n=381) | Viremia (n=102) | p-value |
|---|---|---|---|---|
| HLA-A2 match | 154 (29.9%) | 122 (32.0%) | 21 (20.6%) | 0.08 |
| HLA-B44 match | 56 (10.9%) | 42 (11.0%) | 3 (2.9%) | 0.04 |
| HLA-DR15 match | 55 (10.7%) | 30 (7.9%) | 3 (2.9%) | 0.03 |

**Conclusions:** HLA-A2, HLA-B44 and HLA-DR15 mismatches are associated with a lower risk of BK viremia. Control of low grade BK viruria not complicated by viremia may require HLA-independent mechanisms.

## SA-PO963

**Polyoma-BK-Virus Associated High Grade Carcinomas in Renal Allografts** Daniel J. Kenan, Harsharan Kaur Singh, Volker Nickeleit. *Div of Nephropathology, The Univ of North Carolina, Chapel Hill, NC.*

**Background:** Although polyoma-BK-virus (BKV) induced allograft nephropathy is seen in 2-4% of kidney transplant recipients, the role of BKV as a potential oncogenic pathogen is poorly understood.

**Methods:** Two transplant nephrectomies with high grade invasive transitional cell and collecting duct-like carcinomas were analyzed. Laser capture microdissection on formalin fixed normal and tumor tissue was performed and DNA was extracted. Tissue sections were analyzed by immunohistochemistry (SV-40 large T and VP antigens), in-situ hybridization and electron microscopy. Molecular studies were based on quantitative PCR assays, and targeted genomic DNA sequencing.

**Results:** Both study tumors strongly expressed SV40-T antigen (a proliferation marker) in tumor cell nuclei but not in adjacent normal tubules/parenchyma; no signals were seen for VP capsid antigens, by in-situ hybridization or electron microscopy in any tissue compartment (no evidence of productive viral replication). A TaqMan PCR assay showed BKV sequences (encoding T and VP ) in relatively low copy numbers in both the in situ and invasive tumor components but not in the adjacent normal tubular epithelial cells/ normal parenchyma. No PCR amplification products were detected with primers specific for polyoma-JC-virus. Conventional PCR further demonstrated the presence of the full length BKV genome. Sequencing of the PCR fragments proved the presence of BKV genotypes.

**Conclusions:** These new findings demonstrate that polyoma-BK-virus is closely associated with high grade carcinomas occurring in kidney transplants. The presence of BKV is restricted to tumor cells, and it is not associated with BKV replication or a productive infection. It is tempting to speculate that BKV is incorporated into the genome and promotes tumor growth. BKV: a potential tumorigenic pathogen?

## SA-PO964

**Efficacy of Ciprofloxacin for Prophylaxis of BK Virus Infection in Kidney Transplant Recipients** Tariq Shah,[1,2,3,4] Don Vu,[1,2,3] Elizabeth Cadag,[1] Yasir A. Qazi,[4] Robert Naraghi,[1,2] Caron Hutchinson,[2] David I. Min.[3] *[1]Saint Vincent Medical Center, Los Angeles, CA; [2]Transplant Research Institute, Los Angeles, CA; [3]Western Univ of Health Sciences, Pomona, CA; [4]Univ of Southern California, Los Angeles, CA.*

**Background:** BK virus nephropathy (BKVN) is a common viral infection that affects up to 10% of renal transplant recipients (RTRs), causing allograft dysfunction and graft loss. Fluoroquinolones have been shown in vitro to inhibit BK viral replication by direct inhibition of the BKV-encoded DNA gyrase. The aim of the study is to investigate the efficacy of prophylactic administration of ciprofloxacin for prevention of BK viremia after renal transplantation.

**Methods:** We retrospectively collected patient and transplant data for 104 patients undergoing kidney transplantation between April 2010 and January 2012 at St. Vincent Medical Center (SVMC). Forty-four patients received ciprofloxacin prophylaxis of 250 mg daily for 30 days (CP) and sixty patients received no ciprofloxacin prophylaxis (NP). Quantitative BK virus (BKV) DNA surveillance in plasma was performed at 1,3,6,9, and 12 months after transplantation.

**Results:** Baseline characteristics, transplant demographics, and 1-year incidence of acute rejection were similar between the two groups. The cumulative incidence of BK viremia at one year after transplantation was significantly reduced in CP (11.3% versus 28.3%, OR =3.07, p=0.036). Among recipients who developed BK viremia, the median time to BKV was 145 days in CP group, compared to 120 days in NP ($P>0.05$), however the CP group developed a significantly lower peak BK viral load, versus the NP group (median, 10.8 x $10^3$ copies/mL vs. 10.4 x $10^4$ copies/ml, p=0.044). The overall incidence of BKVN was 2.2 % in CP group and 6.7 % in NP group (P=0.39, OR=3.1). Additionally, patients in CP group were not found to experience a higher risk of fluoroquinolone-resistant infection.

**Conclusions:** Ciprofloxacin prophylaxis appears to be effective in preventing BK viremia within one year after transplantation. Future prospective, randomized studies are needed to determine the impact of ciprofloxacin prophylaxis for BKVN.

## SA-PO965

**Efficacy of Intravenous Immunoglobulinin the Treatment of BK Virus Nephropathy in Renal Transplant Recipients** Tariq Shah,[1,2,3,4] Robert Naraghi,[1,2] Don Vu,[1,2,3] Cameron Sheth,[5] Yasir A. Qazi,[4] Elizabeth Cadag,[1] Caron Hutchinson,[2] David I. Min.[3] *[1]Saint Vincent Medical Center; [2]Transplant Research Institute; [3]Western Univ of Health Sciences; [4]Univ of Southern California; [5]Univ of California, Santa Babara.*

**Background:** BK virus can cause clinically significant viral infection in the renal transplant recipients. The outcome may be BK virus associated nephropathy (BKVAN), leading to renal allograft dysfunction and the loss of the graft. The usual management of BKVAN involves reduction of immunosuppression and the addition of leflunomide, quinolones and cidofovir, but the rate of graft loss remains high. The aim of this study was to assess the impact of treatment with intravenous human immunoglobulin (IVIG) on the outcome of BKVAN in renal transplant recipients.

**Methods:** Upon diagnosis of BKVAN, patients remained on anti-polyomavirus strategy consisting of reduction of immunosuppression and the use of leflunomide therapy. Treatment with IVIG was given only to patients who did not respond to adjustment of immunosuppression and leflunomide. Response to IVIG therapy was monitored by measuring the viral load, serum creatinine level and repeated allograft biopsy if needed clinically. Clearance of viremia (<500 copies/mL) was considered a positive response to IVIG treatment.

**Results:** All 30 patients had persistent BKV viremia and BKVN with their mean BK viral loads higher than the baseline (range 15,000 – 2 million copies/mL). Mean peak BK load was 205,314 copies/mL compared to 697 copies/mL after one year follow up. Twenty seven patients (90%) had a positive response in clearing viremia. The actuarial patient and graft survival rates after 12-months were 100% and 96.7 %, respectively. The average total amount of IVIG was 102.4 ± 52.1 g per patient and the average cost per patient was $7,657.00.

**Conclusions:** IVIG administration appeared to be safe and effective in treating BK viremia, BKVAN and preventing graft loss in patients who had inadequate response to immunosuppression reduction and leflunomide therapy.

## SA-PO966

**The BK:KIDNI Trial – BK Viremia: Kinase Inhibition to Decrease Nephropathy Intervention Trial** Pietro Ravani, Brenda Hemmelgarn, Lee Anne Tibbles. *Medicine, Univ of Calgary, Calgary, Canada.*

**Background:** Although infection with human BK virus is common, this polyomavirus remains dormant in the kidney of affected individuals. However, following kidney transplant, BK viremia and nephritis are increasing problems as with immunosuppression BK virus reactivates and replicates, causing progressive interstitial nephritis in the renal allograft.

Observational studies suggest that reduction of immunosuppression can lead to clearance of BK viremia. However, reducing immunosuppression may also increase the risk of rejection. In addition, no consensus regarding how to reduce immunosuppression has been reached and studies on treatments other than reduction of immunosuppression are not available to inform clinical practice.

**Methods:** We are conducting a Phase III multi-centre randomized, parallel-group trial involving 300 patients (150 per arm), at 15 sites in Canada. De novo kidney transplant patients with positive PCR for plasma BK (viremia) are randomized to either reduced immunosuppression (control arm) or Sirolimus/Leflunomide (treatment arm). Biopsies are taken at first viremia and one year follow-up. Biopsy proven rejection is treated according to site-specific guidelines. The study period is at least one year in duration (last subject randomized will be followed for one year). Since recruitment will occur over approximately 3 years, the total duration of the trial and thus follow-up of first patients will be an estimated 4 years.

**Results:** To date we have screened 146 patients and recruited 27 across Canada.

**Conclusions:** The BK:KIDNI trial will test whether specific kinase inhibition is superior to standard therapy in reducing the risk of the multiple outcome of doubling of serum creatinine, need for renal replacement therapy for graft failure and death (primary objective). Secondary outcomes include rate of decline in renal function based on decline in eGFR, time to 50% increase in serum creatinine, time to clearance of viremia, biopsy proven acute rejection, grade of BK nephropathy on biopsy at 12 months, chronic allograft nephropathy at 12 months, change in Health Related Quality of Life measures, and differences in health care costs between the two strategies (secondary objectives).

*Funding:* Government Support - Non-U.S.

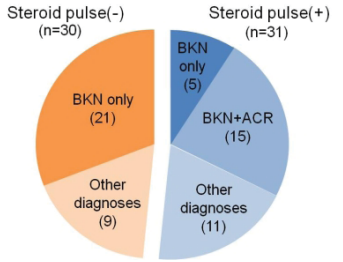
## SA-PO967

**The Outcome of Steroid Pulse Therapy in BK Viremia Patients Who Demonstrated Acute Rejection Like Lesion** Hyosang Kim,[1] Jong Cheol Jeong,[2] Jaeseok Yang,[2] Wonseok Yang,[1] Curie Ahn,[2] Duck Jong Han,[3] Su-Kil Park.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea; [2]Transplantation Center, Seoul National Univ Hospital, Seoul, Republic of Korea; [3]Dept of Surgery, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea.*

**Background:** To investigate the change of renal function on renal transplant recipients with high BK viremia who received steroid pulse therapy for pathologic diagnosis of acute cellular rejection(ACR) along with BK nephropathy(BKN).

**Methods:** The study population consisted of 112 kidney transplant recipients with high BK viremia (defined as serum BKV load > $1x10^4$ copies/mL) detected more than once from January 1, 2004 to December 31, 2011 at Asan Medical Center and Seoul National University Hospital.

**Results:** Kidney biopsies were performed in 61 patients and 31 received steroid pulse therapy (>500mg) around the time of kidney biopsy.



Estimated GFR (eGFR) were 31.8±14.3 ml/min/1.73m² in steroid(+) group (n=31) at the time of steroid treatment and 47.9±26.9 in steroid(-) group (n=81) when serum BK load>$10^4$ ($p$<0.001). After 1 year, the difference of eGFRs has maintained (32.8±20.5 and 52.8±34.9, $p$<0.001). In Kaplan-Meier analysis for 50% decline of eGFR from baseline, renal function in steroid(+) group tended to deteriorate more rapidly.

Comparing between 15 BKN+ACR patients who received steroid pulse therapy and 21 BKN patients without steroid treatment, eGFRs were changed to 22.4±12.7 vs 31.7±13.2 after 1 year ($p$=0.05) from initial eGFRs 28.7±9.0 vs 31.3±9.4 ($p$=0.39) without any difference of BK viral loads. The renal function in BKN+ACR group tended to become aggravated earlier in Kaplan-Meier analysis.

**Conclusions:** In BK viremia patients who received steroid pulse therapy, the renal function tended to deteriorate more rapidly.

## SA-PO968

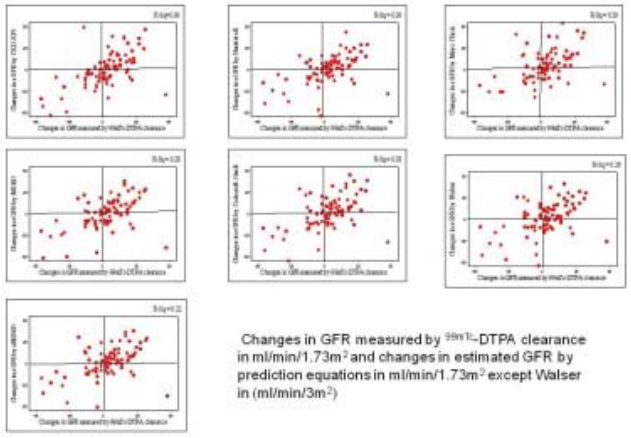
**Precision of Current Formulae to Detect Changes of GFR in Middle Eastern Kidney Transplant Recipients** Osama M. El-minshawy, Eman Elbassuoni. *Internal Medicine, School of Medicine, Univ of Tabuk, Tabuk, Saudi Arabia.*

**Background:** Assessment of graft function is crucial in kidney transplantion (Tx); Most formulae were developed for estimation of GFR in white and African Americans, Australian and Canadian people, Also their accuracy to detect changes of GFR in kidney Tx has not well studied. Aim of this work is to find out the precision of current formulae to detect GFR changes in kidney Tx recipients.

**Methods:** the study included 79 kidney Tx recipients; 46 (58%) were males, 45 (57%) were Egyptian, 34 from different Arab countries age 46±13 years, body weight 70±7 Kg, BSA 1.8±0.1m², BMI 25±4 Kg/m². serum creatinine 1.8±1 mg/dl, blood urea nitrogen 29±11 mg/dl. Serum albumin 3.7±0.6 g/dl. Their immunosuppression: prednisone, CNI, and MMF in 70 patients (89%), prednisone, and MMF in 9 patients (11%). GFR was measured by $^{99m}$Tc- DTPA clearance twice for each patient after follow up time 14±3 months and estimated twice at the same days of measurements by MDRD, abbreviated MDRD, Walser, Nankivell, Mayo clinic, Cockroft-Gault and CKD-EPI formula.

**Results:** measured GFR were: 8-90 ml/min/1.73m² (44±21) , absolute changes of measured GFR between 1st & 2nd measurement range from -45 to 46. changes of estimated GFR range from -52 to 48 by CKD-EPI, from -57 to 44 by Cockroft-Gault from -92 to 57 by Mayo Clinic formula, from -60 to 37 by MDRD, from -82 to 37 by aMDRD, from -53 to 43 by Nankivell, and from -53 to 40 by Walser.

| | No of Concordant | No of Discordant | % of concordance | $R^2$ |
|---|---|---|---|---|
| CKD-EPI | 58 | 21 | 73% | 0.39 |
| Nankivell | 57 | 22 | 72% | 0.29 |
| Mayo Clinic | 55 | 24 | 70% | 0.29 |
| MDRD | 55 | 24 | 70% | 0.28 |
| Cockcroft-Gault | 53 | 26 | 67% | 0.28 |
| Walser | 51 | 28 | 65% | 0.26 |
| aMDRD | 52 | 27 | 66% | 0.22 |



**Conclusions:** we conclude lack accuracy of current formulae to detect changes in GFR in kidney Tx.

## SA-PO969

**How to Estimate Kidney Function in Kidney Transplant Recipients with Mild to Moderate Kidney Impairment** Makoto Tsujita, Daijo Inaguma. *Kidney Disease Center, Nagoya Daini Red Cross Hospital, Nagoya, Japan.*

**Background:** With the recent increase in renal transplantations in Japan, accurate assessment of renal function is required.

**Methods:** This study included 73 patients who had undergone renal transplantationat Nagoya Daini Red Cross Hospital at least 6 months previously and had stable renal function for more than 3 months. Glomerular filtration rates (GFRs) were measured by inulin clearance (mGFR) and compared with estimated cystatin C-based GFRs (eGFRcys), estimated creatinine-based GFRs (eGFRcre) and their averaged values (eGFRave).

**Results:** mGFR was 43.3 ± 14.1 mL/min/1.73 m² and, eGFRcre was 39.6 ± 11.7 in eGFRcre, eGFRcys was 56.0 ± 17.1, and eGFRave was 47.8 ± 13.7 mL/min/1.73 m² , respectively.Serum cystatin C was 1.39±0.37 mg/L and serum creatinine was 1.58±0.51 mg/dL.The correlation coefficients between mGFR and eGFRcre, eGFRcys, and eGFRave was 0.768, 0.831, and 0.841, respectively (p <0.001, for all).The intraclass correlation coefficients were 0.754, 0.816, and 0.840, respectively (p <0.001,for all).The mean differences between measured and estimated GFR values were - 3.74 mL/min/1.73 m² with a root-mean square error (RMSE) of 9.06 for eGFRcre, + 12.64 with RMSE of 9.48 for eGFRcys, and + 4.45 with RMSE of 7.86 for eGFRave. Bland–Altman plots showed that eGFRcys overestimated GFR values compared with mGFR values in most cases and that eGFRave overestimated GFR values in 53 of 73 cases, whereas eGFRcre underestimatedthe values in 53 of 73 cases.

**Figure 1. Relation between measured GFR and estimated GFR**

| Estimated | Correlation Parameters | | | | | Mean | Accuracy |
|---|---|---|---|---|---|---|---|
| GFR | ICC | 95%CI | P values | Pearson's r | P values | differences | with 30% |
| eGFRcre | 0.754 | 0.635 – 0.838 | <0.001 | 0.768 | <0.001 | - 3.74 | 82.2 |
| eGFRcys | 0.816 | 0.722 – 0.881 | <0.001 | 0.831 | <0.001 | + 12.64 | 52.1 |
| eGFRave | 0.840 | 0.757 – 0.897 | <0.001 | 0.841 | <0.001 | + 4.45 | 86.3 |

GFR indicates glomerular filtration rate; ICC, intraclass correlation coefficient; eGFRcre, estimated creatinine-based GFR; eGFRcys, estimated cystatin C-based GFR; eGFRave, average of eGFRcre and eGFRcys

**Conclusions:** eGFRave may be the best marker to estimate kidney function in Japanese renal transplant recipients with mildly reduced or normal kidney function.

## SA-PO970

**Can Renal Function Equations Substitute for the Standard Method in the Measurement of the Glomerular Filtration Rate of Kidney Transplant Recipients?** Xiaoying Du, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

**Background:** Accutate estimate of glomerular filraton rate (GFR) is crucial in the care of kidney transplant recipients. Since the reference methods to measure GFR cannot be easily implemented, several formulas for estimating GFR have therefore been developed. However, little is known about their diagnostic value in kidney transplant recipients. The aim of this study is to evaluate the performance of four creatinine-based formulas for estimating the GFR in this population.

**Methods:** Performances of the modified abbreviated Modification of Diet in Renal Disease (aMDRD) equation, aMDRD for Chinese chronic kidney disease patients (c-aMDRD), Cockcroft and Gault (CG) formula, Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula were compared with the dual plasma sampling $^{99m}$Tc-DTPA plasma clearance method as the gold standard for measuring GFR in 155 stable patients after kidney transplantation. Correlation, bias, precision and accuracy within 15%, 30% and 50% of true GFR were determined.

**Results:** Though each GFR test displayed a significant correlation (P<0.0001) with $^{99m}$Tc-DTPA clearance, Pearson's correlation coefficients (r) were only 0.596 for aMDRD, 0.584 for c-aMDRD, 0.583 for CKD-EPI, and 0.556 for CG. Bias ranged from -46.07 to 34.39 ml/min/1.73m$^2$for aMDRD ,-45.13 to 49.33 ml/min/1.73m$^2$for c-aMDRD, -40.36 to 41.73 ml/min/1.73m$^2$for CKD-EPI, and -49.68 to 36.97 ml/min/1.73m$^2$for CG. The 15,30 and 50% accuracies were 44.5%, 83.9% and 98.1% for aMDRD respectively; 41.9%, 79.4% and 94.2% for c-aMDRD respectively; 47.7%, 79.4% and 94.8% for CKD-EPI respectively; 51%, 86.5% and 98.1% for CG respectively.

**Conclusions:** All of these equations can just roughly estimate the GFR of kidney transplant recipients. None of them can substitute for $^{99m}$Tc-DTPA plasma clearance. In clinical trials, renal graft function should be measured by a standard method.

## SA-PO971

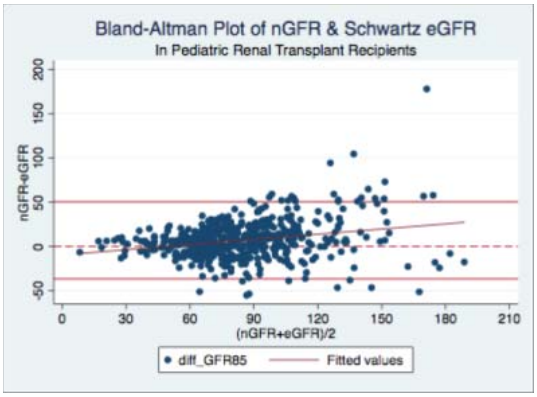
**Modified Schwartz Formula Accurately Reflects GFR in Pediatric Renal Transplant Recipients** Omar M.A.A. Alkandari,[1] Diane Hebert,[1] Valerie Langlois,[1] Lisa Robinson,[1] Rulan S. Parekh.[1] *[1]Hospital for Sick Children; [2]Hospital for Sick Children; [3]Hospital for Sick Children.*

**Background:** Kidney function is best assessed by measured GFR, however, this is impractical, complex, and costly especially in children. Our aim is to assess the validity of modified Schwartz formula in a pediatric renal transplant recipients.

**Methods:** We conducted a retrospective cross-sectional data analysis of pediatric kidney transplant patients less than age 18 (n=174) followed at our center between 2001-2012. We compared estimated GFR using modified Schwartz with enzymatic measured serum creatinine (SCr) to the two point $^{99m}$Tc-DTPA nuclear GFR (nGFR) and determined bias, precision, accuracy (within 30%), and agreement by Bland-Altman analyses in 505 paired measures. The eGFR was also determined using Counahan and Leger formulas.

**Results:** The study population included 62% males, 70% between ages 10 and 18 years , 46% with CAKUT as

cause of ESRD and 45 % of patients were living donor transplant recipients. Baseline median eGFR and nGFR were 77 and 86 ml/min/1.73m2, respectively. Out of the 505 nGFRs, 83% had a nGFR ≥ 60 ml/min/1.73m2. Overall, the modified Schwartz formula has a bias of 6.9 ml/min/1.73m$^2$ and accuracy within 30% of 83.6%. Bland-Altman analyses demonstrates good agreement across the range of GFR especially in the normal range of GFR.



Bias and accuracy within 30% vary for females (4.8; 86.7%), children less than 5 years (-3.0; 80%), older than 15 years (10.1; 77.7%), nGFR ≥ 90 ml/min/1.73m$^2$ (16.7;81.7%) and measurements done in first 3 months post-transplant (5.8; 78.3%). Cause of ESRD or CKD stage did not influence bias or accuracy. When compared to other SCr-based formulae, modified Schwartz and Counahan have better accuracy than Leger.

**Conclusions:** Modified-Schwartz is a useful bedside tool and a valid measure of GFR in pediatric kidney transplant recipients.

## SA-PO972

**Increased Risk of Late Graft Dysfunction from Rejection in New Onset Diabetes after Transplantation** Joseph B. Lockridge,[1] Kirsten L. Johansen,[2] F. Vincenti.[3] *[1]Div of Nephrology, Univ of California San Francisco, San Francisco, CA; [2]Nephrology Section, San Francisco VA Medical Center, San Francisco, CA; [3]Kidney Transplant Service, Univ of California San Francisco, San Francisco, CA.*

**Background:** New Onset Diabetes after Kidney Transplant (NODAT) is an independent predictor of graft loss and mortality. The mechanisms leading to graft loss in these patients remain unclear. Further, late allograft outcomes have not been specifically addressed in this population.

**Methods:** We screened 1949 patients transplanted at UCSF between July 16, 1997 and Dec 28, 2004. Of these, we identified 156 patients with stable graft function for one year and underwent biopsy for late onset graft dysfunction after one year. Participants were divided according to diabetes status into three groups: NODAT (n=45), pre-existing diabetes (n=38) and no diagnosis of diabetes (n=73). We used univariate and multivariable logistic regression analysis to determine whether NODAT was associated with rejection compared to those with pre-existing diabetes and those with no diabetes.

**Results:** Baseline characteristics were similar in all three groups with respect to donor status, gender, race, induction therapy, and panel reactive antibody. Patients with pre-existing diabetes had a higher age at transplant, while patients with no diabetes had a higher time post-transplant at the time of biopsy. We found that both patients with pre-existing DM and those without a diagnosis of DM had lower odds of rejection than patients with NODAT (OR 0.21, 95% CI 0.07-0.59 for pre-DM and OR 0.38, 95% CI 0.18-0.83 for no DM). Multivariable regression analysis confirmed a higher rejection rate in patients with NODAT compared to patients with no diabetes (OR 3.4 95% CI 1.01-11.50;p = 0.05) and to pre-existing DM when adjusted for allograft age, creatinine, and calcineurin inhibitor level.

**Conclusions:** Our study shows that in this cohort, NODAT was associated with a significantly higher risk of late allograft dysfunction from rejection. Larger studies are needed to determine the mechanism of disease and to guide immunosuppression management in this selected group.

## SA-PO973

**Outcomes of Bisphosphonate Therapy in Kidney Transplant Recipients—A Meta-Analysis of Randomized Controlled Trials** Stephanie M. Toth, Jean M. Francis, Craig E. Gordon. *Renal Section, Boston Univ School of Medicine, Boston, MA.*

**Background:** Mineral and bone disorders that precede kidney transplantation are worsened in the post-transplant setting by immunosuppressive regimens and tertiary hyperparathyroidism. Bone mineral density (BMD) rapidly decreases following transplantation, leading to increased fracture risk. The benefits and risks of bisphosphonates in kidney transplant recipients are not well defined. The aim of this study is to evaluate changes in BMD and fracture rates in bisphosphonate-treated transplant recipients by meta-analysis.

**Methods:** We performed a systematic review of Cochrane, Embase, and Medline to identify studies that evaluated bisphosphonate therapy in kidney transplant recipients (last search 4/14/13). Randomized controlled trials comparing bisphosphonate therapy to standard of care in adults were included if follow-up duration was >6 months. We performed a random effects meta-analysis to determine the effect of bisphosphonates on BMD and fracture incidence.

**Results:** Of 793 retrieved studies, sixteen met inclusion criteria comprising a total of 748 patients. Mean age was 45.1 years, 69.8% were male, and mean baseline creatinine was 1.5 mg/dL. Treatment with bisphosphonates was associated with improvement in

lumbar and femoral neck BMD compared with controls (0.061 g/cm$^2$, 95% CI 0.039-0.082 and 0.056 g/cm$^2$, 0.020-0.093, respectively). This corresponded to an unweighted improvement in BMD of 7.8% in lumbar spine and 7% in femoral neck. Bisphosphonate therapy had no effect on serum creatinine or calcium. There was no difference in fracture incidence in the two groups.

**Conclusions:** Bisphosphonate therapy was associated with improved lumbar and femoral neck BMD in kidney transplant recipients without adversely affecting serum creatinine or calcium. Although there was no difference in fracture rates, this may have been due to short follow-up times or the small number of studies reporting clinical outcomes. Future studies should report fracture rates and plan for longer follow-up intervals to better evaluate whether bisphosphonates reduce fracture incidence in kidney transplant recipients.

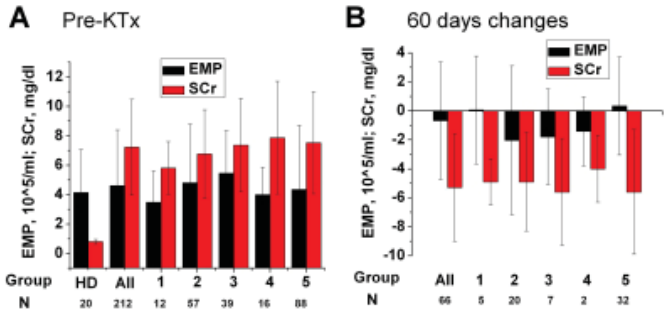
## SA-PO974

**Comparison of Endothelial Microparticles and Serum Creatinine after Kidney Transplantation** Zahida Qamri, Ronald Pelletier, Jon R. Von Visger, Kyle M. Ware, Anjali A. Satoskar, Tibor Nadasdy, Sergey V. Brodsky. *Dept of Pathology and Comprehensive Transplant Center, The Ohio State Univ, Columbus, OH.*

**Background:** Endothelial microparticles (EMP) are membrane vesicles shed from endothelial cell in response to injury, activation or apoptosis. Kidney transplantation (KTx) is the treatment of choice for patients with end-stage kidney disease (ESKD). The aim of this study was to compare changes in EMP and serum creatinine (SCr) in patients following KTx.

**Methods:** Blood was periodically collected from patients the day before (pre-KTx) and two months after KTx. EMP were identified as 1 µm CD31$^+$/CD42b$^-$ microparticles and quantified by fluorescence-activated cell scanning.

**Results:** This study included 212 KTx or kidney/pancreas (KPTx) recipients and 20 healthy donors (HD) (for comparison) prior to donation. The recipients were divided into 5 groups based on the cause of ESRD: 1: ESRD due to diabetes mellitus (DM) type I that received a KPTx; 2: ESRD due to DM (type I or type II) that received a KTx only; 3: congenital/obstructive causes of ESRD; 4: ESRD due to immune complex disease; 5: ESRD due to unknown causes. No differences in the quantity of circulating EMP were seen in the pre-KPTx or KTx recipient sera and HD sera (Figure 1, A). At day 60 after KTx, Groups 2, 3 and 4 had a reduction in both circulating EMP and SCr from pre-KTx values (Figure 1, B).



**Conclusions:** In our patient cohort the quantity of circulating EMP were similar in HD and ESRD patients before KPTx or KTx. Reduction in both circulating EMP and SCr was seen after KTx in selective groups. Mechanisms of these variations in post-KTx EMP in different patient groups are not clear yet, but may be related to an underlying systemic disease or immune suppression therapy.

## SA-PO975

**Oral Paricalcitol Ameliorates Post-Transplant Hyperparathyroidism and Proteinuria in Kidney Transplantation** Matias Trillini, Jorge Arturo Reyes Loaeza, Karen Courville, Claudia Ferrer Siles, Silvia Prandini, Flavio Gaspari, Antonio Cannata, Alessandro Villa, Annalisa Perna, Eliana Gotti, Norberto Perico, Piero Ruggenenti, Giuseppe Remuzzi. *IRCCS Istituto di Ricerche Farmacologiche Mario Negri, Italy.*

**Background:** Secondary hyperparathyroidism (SHPT) is a major clinical problem in renal transplant recipients. In renal patients Paricalcitol (PAR) ameliorates SHPT and even reduces proteinuria, a major determinant of disease progression. Effects of PAR in SHPT renal transplant recipients are unknown.

**Methods:** In a randomized (1:1 computer-generated sequence), cross over trial (NCT01220050) we compared the effect of 6-month oral PAR added-on standard therapy vs 6-month standard therapy alone on serum intact parathyroid hormone (iPTH, primary outcome), markers of bone remodeling and proteinuria in 43 stable renal transplant recipients aged 54±9 yrs with iPTH persistently >80 pg/ml and no vitamin D therapy. PAR was started at 1 µg/d and, if tolerated, at 3 months was up-titrated to 2 µg/d. We compared treatment effects by repeated measures ANOVA, with participants as random and treatment and period as fixed factors.

**Results:** Serum creatinine averaged 1.39±0.33 mg/dl at baseline and was stable thereafter. Compared to standard therapy, PAR significantly reduced iPTH, ostase and osteocalcin levels, without affecting calcium and phosphate levels. Proteinuria significantly decreased on PAR, but not on standard treatment (Table). Reductions in iPTH, ostase and osteocalcin levels vs standard therapy were already significant at 3 months with PAR 1 µg/d. PAR was well tolerated.

Table. Outcome variables at baseline and at the end of each treatment period

| | Baseline | PAR 2 µg | Standard treatment |
|---|---|---|---|
| iPTH *(pg/ml)* | 115 (95 -152) | 63 (52 - 78)$^{\#\,\circ}$ | 128 (94 -166) |
| Ostase *(µg/l)* | 11 (8 - 14) | 9 (7 - 11)$^{\#\,\circ}$ | 13 (10 - 18) |
| Osteocalcin *(ng/ml)* | 25 (15 - 33) | 18 (10 - 28)$^{\#\,\circ}$ | 25 (16 - 38) |
| Calcium *(mg/dl)* | 9.6 (9.2 - 9.9) | 9.8 (9.5 - 10) | 9.6 (9.3 - 9.9) |
| Phosphate *(mg/dl)* | 3.2 (2.8 - 3.6) | 3.3 (2.8 - 3.9) | 3.2 (2.7 - 3.5) |
| Proteinuria *(g/24 h)* | 0.27 (0.13 - 0.60) | 0.14 (0.10 - 0.41)$^{\S}$ | 0.23 (0.10 - 0.54) |

Data are median (interquartile range)

$^{\#}p < 0.001$ vs standard therapy, $^{\circ}p<0.01$ vs. baseline, $^{\S}p < 0.05$ vs baseline

**Conclusions:** In renal transplant recipients oral paricalcitol safely ameliorates secondary hyperparathyroidism and may have beneficial effects on proteinuria that need confirmation in ad-hoc trials.

## SA-PO976

**Functional Status Predicts Hospital Length of Stay and Rehospitalizations following Kidney Transplant (KTx)** Elizabeth C. Lorenz, Hatem Amer, Andrea L. Cheville, Fernando G. Cosio. *Mayo Clinic, Rochester, MN.*

**Background:** Decreased functional status has been associated with increased hospital length of stay (LOS) and rehospitalizations (RH) in patients with CKD. The goal of this study was to determine whether functional status predicts LOS and RH following KTx.

**Methods:** We performed a prospective cohort study involving all patients receiving KTx at our center between 12/2011 and 1/2013 (n=141). Providers assessed functional status with the following scoring system: A=regular exercise and no limitations, B=no regular exercise and no limitations, C=no regular exercise and slight limitations, D=no regular exercise and significant limitations. Providers assigned scores during the pre-KTx evaluation. The relationship of score to initial hospital LOS and number of RH during the first 4 months post-KTx was studied.

**Results:** Mean age was 51.0±13.6 yrs, 57.2% were male, 84.8% were Caucasian, 85.8% received LD KTx and 26.9% were diabetic (DM). Overall, 34.0% received a score of A, 46.1% a score of B, 16.3% a score of C and 3.5% a score of D. Scores of C or D were associated with DM (38.5% vs 12.8%, p=0.0006) but not with age, gender or dialysis status. Median initial hospital LOS was 4 days (range 3-13). A score of C or D independently predicted a hospital LOS longer than 4 days (OR 3.4, CI 1.4-8.1, p=0.003).

| | Univariate analysis | | Multivariate analysis | |
|---|---|---|---|---|
| Variable associated with hospital LOS | OR (CI) | p | OR (CI) | p |
| Age (per 10 yr decrease) | 0.7 (0.6-0.9) | 0.03 | 0.7 (0.5-0.9) | 0.006 |
| Male | 1.6 (0.8-3.1) | 0.20 | | |
| Preemptive | 0.9 (0.5-1.9) | 0.90 | | |
| DM | 1.3 (0.6-2.7) | 0.53 | | |
| Functional status score of C or D | 3.4 (1.5-8.1) | 0.003 | 3.8 (1.6-9.9) | 0.003 |
| Thymoglobulin | 2.2 (1.1-4.5) | 0.03 | 3.6 (1.6-8.3) | 0.001 |
| BMI (per kg/m$^2$) | 0.9 (0.9-1.0) | 0.28 | | |

Overall 24.8% (n=35) underwent RH during the first 4 months post-KTx. Scores of C or D were independently associated with more RH (0.6 ± 0.1 vs 0.2 ± 0.1, p=0.02).

**Conclusions:** Functional status independently predicts morbidity following KTx. Limitations in functional status were associated with longer hospital LOS and more RH early post-KTx. Further study is needed to determine whether improving functional status prior to KTx could decrease hospital utilization post-KTx.

## SA-PO977

**A Pedometer-Based Exercise Prescription Is Associated with Improved Metabolic Parameters following Kidney Transplant (KTx)** Elizabeth C. Lorenz,[1] Hatem Amer,[1] Fernando G. Cosio,[1] Andrea L. Cheville.[2] *[1]Nephrology and Hypertension, Mayo Clinic; [2]Physical Medicine and Rehabilitation, Mayo Clinic, Rochester, MN.*

**Background:** Exercise is associated with improved metabolic parameters in patients with chronic kidney disease. However, studies of exercise in KTx recipients are lacking. The aim of this study was to examine the effect of a pedometer-based exercise prescription on metabolic parameters following KTx.

**Methods:** We performed a prospective cohort study involving all patients who received KTx at our center between 12/2010 and 1/2013 (n=307). Patients transplanted between 12/2010 and 12/2011 received usual care (n=162) while patients transplanted between 1/2012 and 1/2013 received a 90-day pedometer-based exercise prescription beginning at KTx (n=145). Weight gain, glucose, lipids and automated office blood pressures (BP) were assessed 4-months post-KTx.

**Results:** Mean age was 51.5±13.3 yrs, 57% were male, 87% were Caucasian, 83% underwent LD KTx, 48% underwent preemptive KTx and 25% were diabetic. Mean BMI was 28.1±5.5 kg/m$^2$ and steroid-containing maintenance immunosuppression was used in 80%. Baseline demographics were not significantly different between cohorts. At 4 months post-KTx, patients in the pedometer cohort had lower BP and less impaired fasting glucose.

| Variable | Pedometer cohort (n=145) | Non-pedometer cohort (n=162) | p |
|---|---|---|---|
| Systolic BP (mmHg) | 122.5±18.1 | 125.8±15.6 | 0.049 |
| Diastolic BP (mmHg) | 73.1±10.4 | 76.8±9.2 | 0.004 |
| Number antihypertensive medications | 1.2±1.0 | 1.1±1.0 | 0.58 |
| Weight change (kg) | 1.5±5.3 | 1.0±5.7 | 0.44 |
| Triglycerides (mg/dL) | 152.1±81.8 | 154.4±85.9 | 0.77 |
| HDL (mg/dL) | 56.9±19.4 | 54.3±19.5 | 0.16 |
| Fasting glucose (mg/dL) | 112.0±31.6 | 113.6±33.8 | 0.43 |
| Impaired fasting glucose | 21.8% (n=31) | 33.3% (n=49) | 0.029 |
| NODAT | 4.2% (n=6) | 4.1% (n=6) | 0.95 |
| eGFR (ml/min/1.73m$^2$) | 53.9±15.4 | 54.6±15.1 | 0.56 |

Adherence to the prescription was 44.8%.

**Conclusions:** A pedometer-based exercise program was associated with lower BP and less impaired fasting glucose early post-KTx. Further study of personalized exercise prescriptions following KTx is needed.

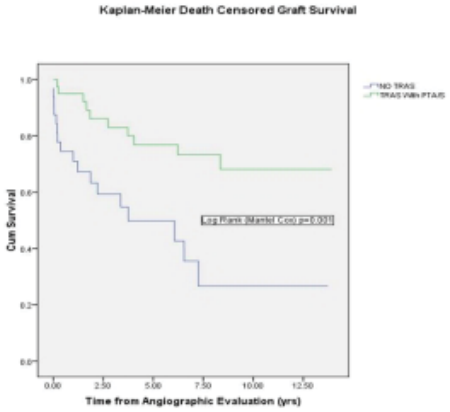
## SA-PO978

**Long-Term Outcomes of Angiographic Evaluation for Transplant Renal Artery Stenosis** Anum Ali, Muhammad Ahmad Mujtaba, Dennis P. Mishler, Tim E. Taber, Muhammad S. Yaqub, Asif A. Sharfuddin. *Nephrology/ Transplant, Indiana Univ.*

**Background:** The purpose of the present study was to evaluate graft survival, patient survival and long-term outcomes after angiographic evaluation and treatment for suspected transplant renal artery stenosis (TRAS).

**Methods:** From January 1999 to Aug 2012, 74 patients had an angiographic evaluation for suspected TRAS. Outcome measures were death-censored graft failure,all-cause mortality and long-term effects of TRAS treatment on efficacy,blood pressure (BP) control and graft function.

**Results:** TRAS was angiographically confirmed in 42 (56.7%) of the patients. The median time to angiographic evaluation in the TRAS group was 8.8 months, as compared to 48.3 in those who did not have TRAS (p<0.05). The median follow-up in the TRAS group was 67 months (range, 7-166) with a mean pre-procedure creatinine level of 2.2 ± 0.8 mg/dL. Systolic and diastolic BP fell from 166.2±19.7mm Hg to 137.9±5.8 mm Hg and 83.0 ± 14.5mm Hg to 68.6 ± 12.9 mm Hg (P<0.05).Post-procedure number of anti-hypertensive drugs was reduced from 3.5±0.9 to 2.7±1.0 (P<0.05). Primary Angioplasty (PTA) alone was performed in 57% of patients with TRAS, while the remaining had PTA with stent (PTAS). 8 cases of primary PTA treated had recurrent TRAS as compared to only 1 treated with primary PTAS. Death-censored graft survival after PTA/PTAS was significantly higher in TRAS group as compared to those without TRAS.



Overall transplant graft and patient survival was similar. Graft function at last follow up in TRAS treated group was 1.9±0.7mg/dl, as compared to 2.2±0.9 in those without TRAS treated with conventional medical therapy (p<0.05).

**Conclusions:** The long-term graft and patient survival were as good in TRAS treated patients as those without TRAS, but with particular benefit in superior graft survival post-intervention. Suspected TRAS should be intervened early with PTA/S as initial treatment.

## SA-PO979

**Urinary Clusterin Predicts Poor Recovery of Renal Function within Four Hours of Transplantation** Timothy J. Pianta,[1,2] Philip Peake,[2] Nicholas Buckley,[1] John W. Pickering,[3] Michaela Kelleher,[2] Zoltan H. Endre.[1,2,3] *[1]Prince of Wales Clinical School, Univ of New South Wales, Australia; [2]Dept of Nephrology, Prince of Wales Hospital, Sydney, Australia; [3]Dept of Medicine, Univ of Otago, New Zealand.*

**Background:** Impaired graft function is common after renal transplantation. We compared four urinary biomarkers of kidney injury, clusterin, neutrophil gelatinase-associated lipocalin (NGAL), interleukin-18 (IL-18) and kidney injury molecule-1 (KIM-1) with creatinine for early prediction of impaired recovery.

**Methods:** Serial urine and plasma biomarkers were measured before and for 7 days after transplantation in a single centre. Urinary biomarkers were normalised to creatinine excretion.

**Results:** Of 75 patients, 30 (40%) had immediate graft function, while 22 (29%) had delayed graft function requiring dialysis and 23 (30%) slow graft function. Urinary clusterin was increased at 4h in the 45 patients with non-immediate graft function (NIGF) (p=0.01). IL-18, KIM-1, and NGAL were increased (p< 0.05) by 8h, 1d and 2d respectively. At 4h only an elevated urinary clusterin [area under the curve (AUC): 0.68 (95% CI: 0.57 to 0.83)] and a low serum creatinine reduction ratio [AUC: 0.70 (0.59 to 0.82)] predicted NIGF. On multivariable analysis, only clusterin and the creatinine reduction ratio remained independently predictive of NIGF. Integrated discrimination improvement analysis demonstrated that elevated clusterin was independently additive to creatinine reduction ratio but a combined metric [clusterin or anuria] performed best. Addition of the combined metric of clusterin or anuria to a clinical model increased prediction of events (NIGF) by 0.05 (95% CI: 0.01 to 0.13); and of non-events (immediate function) by 0.08 (0.01 to 0.19). Clusterin performed best at 12h [AUC:0.72 (0.59 to 0.84)]. At this time [clusterin or anuria] also improved risk prediction independent of clinical factors and creatinine reduction ratio.

**Conclusions:** Urinary clusterin adds value to assessment based on creatinine, urine output and clinical factors in predicting poor recovery of renal graft function after transplantation.

*Funding:* Government Support - Non-U.S.

## SA-PO980

**Urine Liver-Type Fatty Acid-Binding Protein (L-FABP) Predicts Graft Outcome up to 2 Years after Kidney Transplantation** Myung-gyu Kim, Sang-Kyung Jo, Won-Yong Cho, Hyoung-kyu Kim. *Internal Medicine, Korea Univ Anam Hospital, Seoul, Republic of Korea.*

**Background:** In kidney transplant (KT) recipient, several new biomarkers have been investigated for predicting early tubular injury and our recent study identified day 2 urinary neutrophil gelatinase associated lipocalin (NGAL) to be useful in predicting slow graft function and adverse 1-year outcome. Here in this study, we further investigated the value of urinary NGAL and liver type fatty acid binding protein (L-FABP) in predicting long term graft outcome up to 2 years.

**Methods:** This was a single-center, prospective observational study. Serial urinary NGAL and L-FABP levels at 0 hrs, 2 days and 6 days after KT were measured and the clinical outcomes including acute allograft rejection, proteinuria and estimated glomerular filtration rate (eGFR) were collected during the 2-year period after KT.

**Results:** Of the 69 patients investigated, 14 and 7 experienced slow and delayed graft function (SGF and DGF), and urinary NGAL on day 2 after KT was significantly associated with SGF and DGF development, but L-FABP was not. During the 2-year follow up period, 13 (18.8%), 4 (5.8%) and 1 (1.4%) were diagnosed with acute T-cell mediated rejection, acute antibody mediated rejection (AMR) and chronic AMR, respectively. In addition, 10 (14.3%) developed calcineurin inhibitor toxicity and 6 (8.7%) developed BK viremia. The mean eGFRs at 1 and 2 years after KT were 65.1±19.1 and 58.5±22.6 ml/min/1.73m2. When poor long-term graft outcome was defined as eGFR at 2 year less than 50 mL/min/1.73 m2, elderly donor, AR and higher level of urinary L-FABP at 0hr were found to be significant risk factors. Furthermore, among the patients who did not develop AR, L-FABP showed more strong association with 2-year poor graft function (p=0.006). In the multivariate logistic regression analysis, higher L-FABP at 0 hr (p=0.015) as well as acute rejection (p=0.006) was also independent factor for predicting poor long-term graft function and ROC analysis showed that area under the curve (AUC) of urinary L-FABP was 0.692 (P=0.036).

**Conclusions:** Our results demonstrate the possibility that urinary L-FABP might be useful in predicting adverse longterm outcome in KT patients.

## SA-PO981

**Treatment of New Onset Diabetes after (Renal) Transplantation (NODAT) by Linagliptine and Insulin, a Comparative Analysis** Pratik Das,[1] Soumava Gupta.[2] *[1]Nephrology, Rtiics, Kolkata, West Bengal, India; [2]Nephrology, Rtiics, Kolkata, West Bengal, India.*

**Background:** NODAT has negative impact on renal allograft survival, cardiovascular risk and patient survival.Adequate glycemic control may alter the outcome.New generation dipeptidyl peptidase-4(DPP4) inhibitor linagliptine is now increasingly used to treat type2 DM. The present study has evaluated the safety & efficacy of linagliptine monotherapy in renal transplant recepients with NODAT,in comparison to insulin.

**Methods:** 200 renal allograft recepients with stable renal function & without past history of diabetes were evaluated for NODAT by routine 2 hrs oral glucose tolerance test.Those having a 2 hours glucose value more than 200mg/dl were randomly selected for either linagliptine monotherapy (5mg/d single dose) or insulin treatment.Fasting blood sugar was measured at 4 weekly interval &HbA1c at 12,24,36 &48 weeks. hypoglycemic &other treatment related events were noted.

**Results:** 67 patients fulfilled criteria for NODAT were randomly assigned to either linagliptine monotherapy(n=35) or insulin only(n=31).Fasting blood sugar level were comparable in 2 ggroups (124.56+_23.78 vs 118.69+_18.88 mg/dl,p>0.05), so also HbA1c %(7.6+_1.1 vs7.3+_0.88%,p>0.05).Weight gain was significantly lower in linagliptine group(0.88+_0.35 vs4.23+_1.79 kg,p<0.01). Hypoglycemic episodes were much lower in linagliptine group(1.01+_0.21 vs 8.76+_2.39 episodes,p<0.05).abnormal liver function test & sinnusitis were founnd in 2 linagliptine group.

**Conclusions:** Linagliptine monotherapy is as effective as insulin for glycemic control in NODAT with a much better safety profille.

## SA-PO982

### Febuxostat in Renal Transplant Recipients with Hyperuricemia

Youngjoo Jang, Su-Kil Park, Wonseok Yang. *Nephrology, Internal Medicine, Asan Medical Center, Seoul, Republic of Korea.*

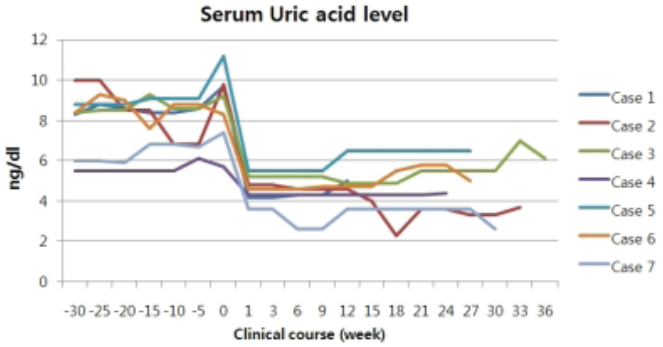
**Background:** Febusoxtat might be an alternative agent for the patient who cannot use allopurinol, because of more selective and less allergenic. However, information concerning the effectiveness and safety of this drug among renal allograft recipients is not well known.

**Methods:** Seven renal allograft recipients whose eGRF above 30 ml/min/1.73m$^2$ and need urate lowering therapy started febuxostat considering side effects or anxiety of using allopurinol. Febuxostat was administered 40mg daily in 6, 20mg daily and tapered on alternate days in 1 who is on Imuran. Uric acid, serum creatinine, hepatic enzyme, and serum cyclosporine or tacrolimus levels were monitored.

**Results:** The patients mean age was 60 ± 6.05 years. At the first visit after starting febuxostat ( Median duration 1.18 weeks, Range, 0.18 - 3 weeks ), UA levels ( mg/ml ) were lowered from 8.6 ± 1.74 to 4.6 ± 0.64 ( P = 0.018 ) and the other laboratory changes were not significant.

| | Before febuxostat | 1'st F/U | P value |
|---|---|---|---|
| Uric acid level ( mg/dl ) | 8.61 ± 1.75 | 4.60 ± 0.64 | 0.018 |
| Serum creatinine ( mg/dl ) | 1.42 ± 0.35 | 1.36 ± 0.30 | 0.141 |
| AST ( UI/L ) | 21.00 ± 4.08 | 21.14 ± 4.53 | 0.893 |
| ALT ( UI/L ) | 20.29 ± 7.50 | 19.86 ± 10.42 | 0.498 |
| Cyclosporine level ( ng/dl ) | 56.85 ± 26.68 | 52.68 ± 19.93 | 0.593 |
| Tacrolimus level ( ng/dl ) | 6.75 ± 2.62 | 8.50 ± 0.14 | 0.655 |

The UA level under 6.0 mg/dl was achieved in all subjects at first visit and maintained around 6.0 mg/dl ( 27.35 ± 7.57 weeks, Range 12.7- 36 weeks ).



Febuxostat was well tolerated and no adverse effects were noted.

**Conclusions:** Low dose febuxostat may effectively and promptly reduce serum uric acid level and maintained therapeutic serum uric acid level in renal transplant recipients without significant side effect.

## SA-PO983

### Cinacalcet Use at the Time of Transplantation Is Associated with a Significant Risk of Delayed Graft Function in Kidney Transplant Recipients

Laurent E. Weekers,[1] Stéphanie M.J.G. Grosch,[1] Catherine Bonvoisin,[1] Oliveir Detry,[2] Jean-marie H. Krzesinski,[1] Francois Jouret.[1] *[1]Nephrology, CHU ULg, Liege, Belgium; [2]Surgery, CHU ULg, Belgium.*

**Background:** The calcium-sensing receptor (CaSR) has been implicated in the ischemia/reperfusion cascade in cardiomyocytes and neurons. Renal ischemia/reperfusion occurs at the time of transplantation (Tx), with a deleterious impact on early graft function. Here, we retrospectively investigated whether the use of cinacalcet, a CaSR agonist, in kidney transplant recipients (KTR) influences early graft recovery.

**Methods:** All KTR from 2007 to 2012 were prospectively included in a database. Patients actively treated with cinacalcet on the day of Tx were retrospectively identified and matched with controls on (i) type of donor: living (LD), deceased after brain or circulatory death (DCD); (ii) cold ischemic time (CIT) ± 1 hour; (iii) residual diuresis ± 500 mL; and (iv) donor age ± 5 years. Delayed graft function (DGF) was defined as dialysis requirement after Tx. Baseline characteristics were compared between groups with t-test or Chi-2 as appropriate. The endpoint was the percentage of DGF in both groups.

**Results:** Among 337 KTR, 36 (10.7%) were treated with cinacalcet at Tx, they were matched with 61 controls. on the previously defined criteria. Characteristics of patients and donors are summarized in the table. DGF occurred in 42 % and 23 % of cinacalcet-treated and control groups, respectively (p=0.05).

| | | | Cinacalcet (n=36) | Controls (n=61) | p |
|---|---|---|---|---|---|
| Recipient | Age at Tx | years | 50.2±10.3 | 49±13.5 | 0.92 |
| | Sex ratio | % female | 47 | 41 | 0.55 |
| | Dialysis vintage | years | 3.7±2.1 | 3.3±3.8 | 0.57 |
| | Residual diuresis | ml | 430±655 | 444±541 | 0.91 |
| | Multi-organ Tx | % | 5.6 | 1.7 | 0.28 |
| Donor | Age | years | 46.8±11.4 | 47±11.4 | 0.93 |
| | Sex ratio | % female | 42 | 46 | 0.67 |
| | LD | % | 2.8 | 1.6 | 0.70 |
| | DCD | % | 30.6 | 21.3 | 0.31 |
| Transplantation | CIT | min | 779±297 | 825±255 | 0.43 |

**Conclusions:** These retrospective observations suggest that CaSR activation at the time of Tx impairs early graft recovery.

## SA-PO984

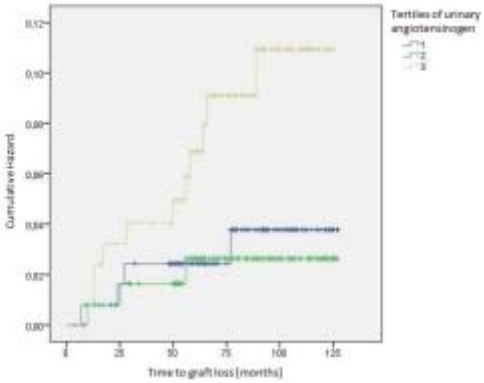
### Urinary Angiotensinogen Levels Are Associated with Graft Survival in Renal Transplant Recipients

Bernhard M.W. Schmidt, Wilfried Gwinner, Irina Scheffner, Mario Schiffer, Hermann G. Haller, Daniel Kayser. *Dept of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

**Background:** Intrarenal activity of the renin angiotensin aldosterone system (RAAS) is an important pathophysiological factor for the progression of renal disease. Urinary angiotensinogen (uAGT) levels have been shown to be a measure of intrarenal RAAS activity. We hypothesized that uAGT levels three months after renal transplantation (rTx) may predict long term graft survival.

**Methods:** We assessed uAGT in patients participating in our rTx protocol biopsy program using a commercially available assay (IBL, Japan). All samples had been stored at -80°C for at least five years to assure long term follow up of patients. Primary endpoint of our analysis was death censored graft survival. Tertiles of uAGT were built, Kaplan-Meier curves and log-rank test were used for analysis.

**Results:** The highest tertile of uAGT levels was associated with worse graft survival (figure), p=.048, log-rank test. Mean graft survival in the highest tertile was 117.0 (95% CI 112.4, 121.6) months vs. 124.5 (95% CI 121.7, 127.3) and 123.8 (95% CI 120.7, 126.9) in the middle and lowest tertile, respectively. uAGt was weakly correlated with donor age (r= .16 , p= .002) and best creatinine (r= .21, p< .001) but not modulated by treatment with ACE inhibitors or angiotensin receptor blockers.



**Conclusions:** In conclusion higher uAGT levels reflecting intrarenal RAAS activity are associated with worse graft survival. This reflects a potential pathophysiological role in graft failure e.g. due to profibrotic effects of angiotensin II and aldosterone. Therapeutic strategies to reduce intrarenal RAAS activity e.g. high dose RAAS blockade might be useful to improve long-term graft survival.

## SA-PO985

### Adherence to Phosphate Binders and Low-Phosphorus Diet in Pediatric Kidney Transplant Candidates Is Associated with Post-Transplant Adherence to Immunosuppressant Medications

Oleh M. Akchurin,[1] Anita V. Tambay,[2] Frederick J. Kaskel,[1] Marcela Del Rio.[1] *[1]Albert Einstein College of Medicine / Children's Hospital at Montefiore; [2]Ponce School of Medicine and Health Sciences.*

**Background:** Non-adherence to treatment regimens is common in pediatric and adolescent transplant recipients and is the major cause of graft loss. During the transplant selection process, it is desirable to identify patients at high risk for non-adherence. Non-adherence to low-phosphorus diet and phosphate binders in patients with CKD and on dialysis is commonly used as a predictor of their post-transplant non-adherence. However, little evidence exists to support this assumption.

**Methods:** This is a retrospective IRB-approved study. Pre-transplant adherence to diet and phosphate binders was assessed by serum phosphorus levels during the last 2 years before transplant. Patients were categorized into non-adherent (NA) vs adherent (A) using the median serum phosphorus value as a cutoff. Post-transplant adherence was assessed by the number of sub-therapeutic and/or undetectable tacrolimus levels (UTL). Post-transplant adherence was analyzed for a 1-year period starting 1 year post transplant. Statistical methods included Chi-square and Mann-Whitney tests.

**Results:** Fifty three patients who received their first kidney transplants in our Center between 1990 and 2011 were included in the analysis. In the group that was NA to phosphate binders and low-phosphorus diet before the transplant, 69% of patients had at least one UTL during the time of post-transplant observation, which was statistically significantly higher than in the A group (40%, p=0.037). The median number of UTL episodes was also statistically significantly higher in the NA group compared with the A group: 2 [0.0-4.3] vs 0 [0.0-3.0] episodes respectively, p=0.04.

**Conclusions:** Pre-transplant adherence to low-phosphorus diet and phosphate binders was statistically significantly associated with post-transplant adherence to tacrolimus in our cohort. Analyses of the relationship between post-transplant adherence and other measures of pre-transplant adherence (e.g., interdialytic weight gain in hemodialysis patients), as well as multivariate analyses are ongoing.

## SA-PO986

**Adherence and Graft Survival in Pediatric Kidney Transplant Recipients Who Transition to Adult Services** Oleh M. Akchurin,[1] Anita V. Tambay,[2] Frederick J. Kaskel,[1] Rebecca Hashim,[1] Marcela Del Rio.[1] *[1]Albert Einstein College of Medicine / Montefiore Medical Center; [2]Ponce School of Medicine and Health Sciences.*

**Background:** Adolescent kidney transplant recipients have a high rate of graft loss. Transition of these patients from pediatric to adult care has been proposed as a risk factor for non-adherence and graft failure. However, data about adherence and graft survival after transition are limited and conflicting.

**Methods:** Retrospective IRB-approved study. Undetectable and/or sub-therapeutic serum tacrolimus levels and their variability were used to measure adherence and were compared between 2 years before and 2 after transition. Graft survival for pediatric patients during 4 years after transition was compared with 4 years before transition and also with post transplant of young adults starting 1-year post transplant.

**Results:** Three groups of patients were analyzed: (1) pediatric patients older than 18 years of age prior to their transition to the adult program (n=71), (2) those who were actually transitioned to the adult program (n=25), and (3) young adults 20-25 years of age who received their first transplant in the adult program (n=62). The median age of group 2 at transition was 22.5 [21.7–23.3] years. Overall, there were no significant differences in adherence within group 2 before and after transition, however patients with lowest tertile of baseline adherence showed improvement of their adherence after transition, which was significantly different from the patients with highest tertile of baseline adherence, p=0.02. The peak of graft loss in all pediatric transplant recipients occurred at 18.3±5.7 years. The rate of graft loss was 0.10 in group 1 (19 losses in 185.6 person-years), 0.06 in group 2 (4 losses in 67.9 patient-years), and 0.07 in group 3 (14 losses in 194.7 person-years). The differences in rate of graft loss between the groups were not statistically significant.

**Conclusions:** Transition of pediatric transplant recipients to the adult program was not statistically associated with worsening adherence and graft loss rate was not significantly different between the groups. Large-scale studies are needed to assess the nationwide impact of transition on adherence and graft loss.

## SA-PO987

**SHROOM3, a SNP and Renal Allograft Fibrosis** Madhav C. Menon,[1] Peter Y. Chuang,[1] Zhengzhe Li,[1] Weijia Zhang,[1] Yi Luan,[1] Philip O'Connell,[3] Robert B. Colvin,[2] Bernd Schroppel,[1] John C. He,[1] Barbara T. Murphy.[1] *[1]Icahn School of Medicine, Mount Sinai, NY; [2]Harvard Medical School, MA; [3]Westmead Clinical School, Sydney.*

**Background:** The Genomics of Chronic Allograft Rejection (GoCAR) is a multicenter study to understand the mechanisms of chronic allograft nephropathy (CAN).

**Methods:** Serial allograft biopsies were performed on 589 GoCAR participants. To identify molecular drivers of CAN, we examined genes whose expression level in the allograft 3 months after transplantation correlated with indices of allograft dysfunction(chronic allograft dysfunction index score(CADI), eGFR) at 12 months after transplantation in 160 participants.

**Results:** Higher allograft levels of *SHROOM3* transcript, antedated and correlated with CADI and, inversely with eGFR ($P<0.01$). Genome wide association studies have previously identified an intronic polymorphism (SNP) in *SHROOM3* (rs1731972) as associated with CKD. G and A are the major and minor alleles at this site respectively. We observed that allograft *SHROOM3* expression was higher with the A/G or A/A genotypes, compared to G/G **in the donor** ($P=0.02$). Recipients who received allografts from A/G or A/A donors were more likely to have a CADI≥2 at 12-mths than recipients of G/G allografts (OR-1.98; p=0.02). rs173192 is located within a consensus binding sequence for transcription factor 4 (TCF4/TCF7L2) downstream of Wnt-ßCatenin signaling, and overexpression of TCF4 increased *SHROOM3* expression in HK2 cells. The A-allele alone had enhancer activity compared to the G-allele with SHROOM3 promoter-enhancer reporter assays. TGF-β up-regulated *SHROOM3* expression through a ßCatenin-TCF4 mediated mechanism, while SHROOM3 facilitated canonical TGFβ-signaling (Smad3 phosphorylation) and Collagen-1 production.

**Conclusions:** In summary, we found that *SHROOM3* expression preceded the development of chronic allograft injury and demonstrated that SHROOM3 facilitates TGF-β signaling. The A-allele of rs173192 exhibited a TCF4-dependent enhancer function, and confers increased risk for CAN at 12-mths. This is the first description of any CKD-associated SNP that modulates gene expression. *SHROOM3* may serve as a novel therapeutic target common to both CAN and CKD.

## SA-PO988

**A Model to Identify Patients at Risk for Post-Transplant Kidney Disease after Liver Transplantation** Mario Schiffer,[1] Christian Lerch,[1] Eleni Evangelidou,[2] Hermann G. Haller,[1] Tobias J. Weismüller.[2] *[1]Nephrology, Hannover Medical School, Hannover, Germany; [2]Dept of Internal Medicine 1, Univ of Bonn, Bonn, Germany.*

**Background:** Following liver transplantation (LT) a significant subgroup of the recipients develops chronic kidney disease (CKD) ranging from mild impairment of kidney function to need for chronic hemodialysis treatment. Since CKD aftrer liver transplantation is multifactorial, so far no reliable models exist to predict the development of CKD in liver graft recipients. The goal of this study was the development of a predictive model to estimate the development of renal function after LT based on parameters known before LT.

**Methods:** We retrospectively analysed clinical and biochemical pre- and perioperative parameters of 328 liver recipients transplanted between 2004 - 2008 and developed ordinal logistic regression models which predict CKD stage 3 or CKD stage 4 or worse after LT. The five most important variables of this model were taken to build a more simplified model for clinical use. These variables were diagnosis of PSC, Hepatitis C, Age, GFR before LT and history of diabetes.

**Results:** The full model allowed with high accuracy the prediction of CKD stage 3 or CKD stage 4 or worse. The simplified model includes 5 parameters (diabetes mellitus, primary sclerosing cholangitis, hepatitis C, recipient-age, cystatin-c based glomerular filtration rate before LT) and showed a good accuracy in the prediction of CKD ≥ stage 3 (AUC =0.739) resp. CKD ≥ stage 4 (AUC = 0.774). To validate these data we performed an external validation and tested the model in a prospective cohort and confirmed an acceptable accuracy for the prediction of CKD ≥ stage 3 (AUC =0.716) resp. CKD ≥ stage 4 (AUC = 0.639).

**Conclusions:** In conclusion our model allows based on five parameters known before LT the identification of patients at risk to develop CKD Stage 3, 4 or worse after LT.

## SA-PO989

**Serum Cystatin C in Renal Transplantation: Beyond GFR Estimation, a Prognosis Marker?** Ingrid Masson, Nicolas Maillard. *Nephrology Dialysis Renal Transplantation, Univ Hospital, Saint-Etienne, France.*

**Background:** In renal transplantation, death with a functioning graft remains one of the main causes of graft loss. In the general population, renal function impairment is strongly associated with cardiovascular and all cause mortality. Whether this association holds true for kidney transplant recipients (KTR) is unclear. This uncertainty is likely to be due, in part, to the fact that glomerular filtration rate (GFR) estimation based on serum creatinine (SCr) does not always provide an accurate evaluation of the graft function in KTR. As compared to SCr, we have recently shown in a large cohort of KTR that serum cystatin C (SCysC) is a much better marker of GFR.

Herein, we sought to study the ability of the 1-year-post-transplant renal function to predict all cause mortality according to the methods used to assess GFR.

**Methods:** Three hundred and forty two consecutive KTR for whom a measurement of GFR by inulin clearance was available at 1 year post-transplant were included. SCr and ScysC were measured with standardised methods. The association of the 1-year inulin clearance value the 1-year MDRD Study equation value and the 1-year CKD-EPI ScysC equation value with all cause mortality was studied by ROC analysis and Cox model.

**Results:** During a median follow-up of 145 months, 70 KTR died. Mean (±SD) inulin clearance at 1-year-post-transplant was 46 (±19) mL/min/1.73m$^2$. Aeras under the ROC curves were similar for inulin and CKD-EPI ScysC equation values (0.564 and 0.550, respectively, NS), and were both significantly superior to that of the MDRD equation (0.483, $p<0.01$). In Cox analysis, while all types of GFR evaluations were significantly associated to graft loss, only an inulin and a CKD-EPI ScysC equation values below 45 mL/min/1.73m$^2$ were associated with an excess risk of mortality (HR of 1.85 vs 1.01 for both inulin and CKD-EPI ScysC vs MDRD, respectively).

**Conclusions:** We conclude that ScysC-based GFR estimation might better predict KTR outcome as compared to a traditional SCr-based estimation. The one year-post transplant GFR value given by the CKD-EPI ScysC equation should be further evaluated as a potential surrogate marker for both graft and patient survival.

## SA-PO990

**The Performance of Cystatin C (CystC) and Creatinine Based CKD-EPI Equations to Estimate GFR in Kidney Transplant (KTx) Recipients** Mira T. Keddis, Hatem Amer, Nick Voskoboev, Andrew D. Rule, John C. Lieske. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

**Background:** Performance of CystC- and creatinine-based CKD-EPI equations published in 2012 have not been evaluated in a large cohort of stable KTx recipients.

**Methods:** A prospective cross-sectional cohort of KTx patients presenting for routine annual visits and who are more than 1 year from transplant were actively recruited. GFR was measured by iothalamate clearance (mGFR). Plasma CystC was analyzed by particle-enhanced immunoturbidimetry assay, while serum creatinine (Cr) was measured by enzymatic assay, both traceable to international reference materials. eGFR was calculated using published 2012 CKD-EPI equations. Overall bias and accuracy (within 10% and 30%) for each eGFR equation were calculated.

**Results:** 1151 KTx patients were studied. Mean age was (mean+SD) 56.0 ± 14.2 years; 56.5% were male and 85.6% were Caucasian. mGFR was 55.7 ± 20.7 ml/min/1.73m$^2$.

| eGFR equations | GFR mean, median (range) | Percentage bias (95% CI) | Bias (log-logscale) (95% CI) | Accurate within 10% (P10) | Accurate within 30% (P30) |
|---|---|---|---|---|---|
| CKD-EPI Creatinine | 55.1, 52.8 (9.3, 168.1) | 4.1% (2.2, 6.1) | 0.1% (1.6, -1.5) | 34% | 80% |
| CKD-EPI CystatinC | 44.8, 43.2 (3.39, 113.9) | -17.5% (-18.8, -16.3) | -19.9 % (-18.8, -21.0) | 23% | 72% |
| CKD-EPI Creatinine-CystatinC | 48.6, 47.3 (9.93, 128.2) | -9.9% (-11.2, -8.6) | -12.1% (-13.2, -11.0) | 30% | 84% |

**Conclusions:** The creatinine-based CKD EPI equation outperformed CystC and CystC-Cr equations in a large cohort of stable KTx patients. CystC and CystC-Cr equations had significant negative bias.

*Funding:* Pharmaceutical Company Support - Gentian

## SA-PO991

**Endothelin-1 and Kidney Function in Renal Allograft Recipients** Rupesh Raina,[1] Michael S. Simonson,[2] Beth A. Vogt,[1] Joshua J. Augustine,[2] Donald E. Hricik.[2] *[1]Dept of Pediatrics, Nephrology, Univ Hospitals Rainbow Babies and Children's Hospital, Cleveland, OH; [2]Dept of Medicine, Nephrology, Univ Hospitals Case Medical Center and Case Western Reserve Univ, Cleveland, OH.*

**Background:** Endothelin-1 (ET-1), a vasoconstrictor and pro-inflammatory peptide, is elevated in chronic allograft nephropathy, and studies in experimental models suggest that ET-1 is a determinant of graft loss. However, whether elevated ET-1 is associated with allograft dysfunction in humans is unclear.

**Methods:** We examined the association between urinary ET-1, a non-invasive surrogate for ET-1 in kidney cortex, and renal function in an exploratory cross-sectional study of 28 renal allograft recipients 3 to 56 months post-transplant. ET-1was measured by ELISA in spot urine specimens and corrected for urinary creatinine. Glomerular filtration rate was estimated (eGFR) by the simplified MDRD equation.

**Results:** ET-1correlated inversely with eGFR ($r$=-0.599, $P$=0.01) independent of recipient age, sex, and donor age. ET-1 did not correlate with urinary albumin/creatinine ratio nor with IgG/creatinine, a marker of increased glomerular permselectivity. ET-1 was modestly elevated in patients with posttransplant hypertension (Systolic Blood Pressure > 140 mm Hg) compared to normotensive allograft recipients (5.4 ± 2.6 vs. 3.2 ± 1.5pg/mg creatinine, $P$=0.02). Consistent with findings in experimental models, ET-1correlated with a urine biomarker of allograft inflammation, macrophage chemoattractant protein-1 ($r$= 0.638, $P$<0.01). ET-1 was higher in participants with prior acute rejection (6.5 ± 1.6 vs. 3.9 ± 2.3 pg/mg creatinine, P=0.002) compared to those without rejection but not in those with prior delayed graft function (4.4 ± 2.5 vs. 4.3 ± 2.2, $P$=0.937).

**Conclusions:** These cross-sectional data are consistent with the hypothesis thatelevated ET-1is associated with low eGFR and inflammation in kidney transplant recipients, particularly in patients with prior episodes of acute rejection.

## SA-PO992

**Tubular Biomarkers in Serum and Urine of Stable Kidney Transplant Patients – Prospective Observational Study** Bertram Hartmann, Frieder Keller. *Internal Medicine 1, Nephrology, Univ Hospital, Ulm, Germany.*

**Background:** The surveillance and control of kidney function relay on serum creatinine and glomerular filtration rate (GFR) while interstitial fibrosis and tubular atrophy are leading pathological findings in kidney transplant biopsies.

**Methods:** This is a prospective observational study in a cohort of 39 stable kidney transplant patients. Lisa Schupp and the authors measured on routine appointments standard laboratory markers (e.g. serum creatinine, eGFR) as well as 8 different biomarkers in serum and urine: Kidney injury molecule-1 (TIM1/KIM1), monocyte chemotactic protein-1 (MCP-1), cysteine-rich protein 61 (Cyr 61), neutrophil gelatinase-associated lipocalin (NGAL), liver-type fatty acid-binding protein (L-FABP), fetuin A, interleukin-18 binding protein (IL-18 BP), retinol-binding protein 4 (RBP4). All specimens were measured with the ELISA method and the results were correlated with the eGFR (MDRD2 Formula) by linear regression analysis (SPSS).

**Results:** The eGFR was on average at 40 +/- 16 ml/min (range 6 – 76) but stable for the last 3 months. RBP4, Fetuin A, NGAL, Cyr61, MCP1 are higher concentrated in serum than in the urine. Urine and serum biomarkers were significancantly correlated to the eGFR ($p < 0.01$). Thus, urine and serum biomarker exhibit a perplexing pattern, the worse the kidney function the higher are the concentrations of urine as well as of serum biomarkers.

**Conclusions:** Since only patients with stable transplant function were investigated, the elevated biomarkers less likely can be correlated to cellular or humoral rejection. However, biomarkers that are high in serum and in urine could indicate interstitial fibrosis and tubular atrophy.

## SA-PO993

**Application of an Established CKD Biomarker Signature to Predict Chronic Renal Impairment after Solid Organ Transplantation** Jens Drube,[1] Eric Schiffer,[2] Harald Mischak,[2] Christian Lerch,[1] Hermann G. Haller,[3] Mario Schiffer.[3] *[1]Pediatrics, Hannover Medical School; [2]Mosaiques Diagnostics GmbH; [3]Nephrology, Hannover Medical School.*

**Background:** After solid organ transplantation (SOT) some patients develop CKD. This is a serious clinical problem as CKD negatively affects the survival of organs and patients. Momentarily, it is impossible to predict prior to transplantation patients at risk to develop CKD after SOT. Therefore, therapies cannot be adjusted to individual CKD risk profiles. The aim of this study was to test the ability of a CKD biomarker-pattern to detect previously published by *Good et al. 2010* to predict CKD after transplantation using prior transplantation urine samples.

**Methods:** From the prospective German RECAST register we generated two groups of transplanted subjects, a case group (lung n=5, heart n=5, liver n=1) and a control group (lung n= 7, heart n=3, liver n=2) who had a GFR below 55 or above 70 ml/min/1,73m² three months after transplantation, respectively. We conducted a capillary electrophoresis and mass spectrometry proteome analysis on urine obtained before transplantation. Each proteome profile was compared to the pattern published by *Good et al. 2010*. Additionally, we analyzed which individual biomarkers of the pattern correlated strongest with CKD outcome after transplantation.

**Results:** The biomarker-pattern published by >*Good et al.* was able to predict renal impairment three months after SOT with a sensitivity of 91% and specificity of 67%. The AUC of the ROC analysis was 0.71. Four of the 273 previously defined biomarkers showed a significant correlation with the GFR three months after SOT, another ten showed a significant trend, when P-values corrected for multiple testing.

**Conclusions:** This study shows that the biomarker-pattern published by *Good et al. 2010* can predict the development of CKD three months after SOT from urine obtained before transplantation. These results can be used to refine the biomarker pattern so it can be used in clinical practice.

*Funding:* Government Support - Non-U.S.

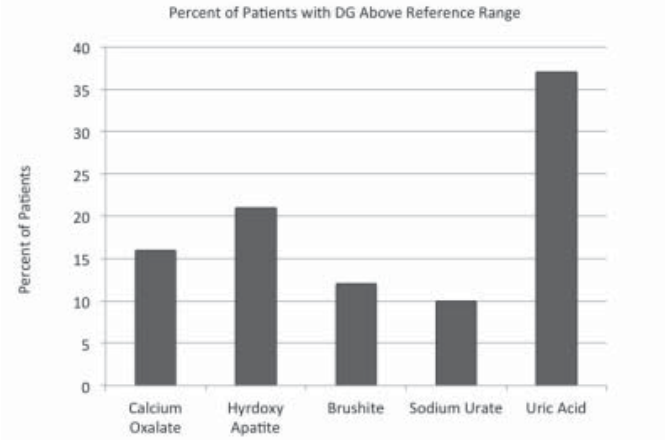
## SA-PO994

**Urinary Super Saturation in Newly Transplanted Kidney Transplant Recipients: Cause for Concern and Action** Hatem Amer,[1] Elizabeth C. Lorenz,[1] Dawn S. Milliner,[1] Andrew D. Rule,[1] Eric J. Bergstralh,[2] John C. Lieske.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Health Sciences Research, Mayo Clinic.*

**Background:** Renal allograft are vulnerable to calcification compared to native kidneys whichis a cause for decreased renal allograft function. Risk factors include pre transplant duration of dialysis and secondary hyperparathyroidism. Urinary composition plays a significant role. No systematic evaluation of post-transplant urine supersaturation has been performed.

**Methods:** Funded by the Rare Kidney Stone Consortium we prospectively enrolled a cohort of 100 consecutive incident kidney only transplant recipients. The study subjects completed a 24-hour urine collection for a super saturation profile 2-4 weeks from transplant.

**Results:** Age 52.4± 13.3 years, males 61%, Caucasian race 90%, pre-emptive transplants 51%, deceased donor organ source 14%, and first transplant 94%. Serum PTH 146 ± 168 [28-1269] pg/ml, serum calcium 9.5± 0.5 [7.9-11.2] mg/dL, serum phosphorus 3.0± 0.7 [1.1-5.3] mg/dL. 24-hour urine volume was mean 2540 ± 1028 ml, urine pH 5.9± 0.6 [4.9-7.8]. Daily urine excretion of sodium was 165± 73 [12-416], phosphorus 865± 373 [74-1868], oxalate 0.38± 0.14[0.05-0.84] mmol, calcium 112± 78[6-446], citrate 269±176 [24-881] mg.The Delta G (DG) as the measure of super saturation with positive values indicating super saturation was Brushite -1.9±1.6, Hyrdroxy apatite 1.8± 2.4, sodium urate 0.26±1.1, uric acid -0.5±2.9 and oxalate 0.9±0.9. More importantly figure 1 shows the proportion of patients with DG > reference limit for non-stone formers.



**Conclusions:** For the first time we present a series of urine super saturation profiles in incident kidney transplant recipients. A significant proportion of transplant recipients have urines super saturated above the reference for a variety of crystals putting them at risk for intra graft calcification and crystal deposition.

## SA-PO995

**Vitamin D Status and Long-Term Outcomes after Kidney Transplantation** Charlotte A. Keyzer,[1] Ineke J. Riphagen,[1] Michel M. Joosten,[1] Gerjan Navis,[1] Anna Muller Kobold,[2] Ido Peter Kema,[2] Stephan J.L. Bakker,[1] Martin H. De Borst.[1] *[1]Nephrology; [2]Laboratory Medicine, Univ Medical Center Groningen, On Behalf of NIGRAM, Netherlands.*

**Background:** Recent studies linked 25OH but not 1,25OH2 vitamin D deficiency to lower GFR one year after kidney transplantation (KTx), but whether this discrepancy also holds for long-term hard outcomes is unclear. We investigated the value of circulating 25OH and 1,25OH2 vitamin D levels as risk factors for graft failure and mortality in stable renal transplant recipients (RTR).

**Methods:** 25OH and 1,25OH2 vitamin D levels were measured by LC-MS/MS in a cohort of stable RTR transplanted in our center between 2001 and 2003, with a functioning graft for ≥1 year. Associations between vitamin D status and the risk of death-censored graft failure or all-cause mortality were investigated by multivariate Cox regression analyses adjusting for known risk factors.

**Results:** 448 RTR (51% men, age (mean±SD) 51.9±11.9 years, median 6.4 [IQR 3.1-11.8] years after KTx, eGFR (CKD-EPI) 47±16 mL/min) were followed for 7.1 [6.2-7.5] years. Median 25OH and 1,25OH2 vitamin D levels were respectively 50.3 [35.7-68.0] nmol/L and 104.4 [76.0-128.6] pmol/L. In multivariable Cox regression analyses, neither 25OH nor 1,25OH2 vitamin D was associated with graft failure (44 events). In univariate Cox regression, 25OH vitamin D was associated with all-cause mortality (HR 0.83 (95% CI 0.76 to 0.92) per 10 nmol/L increase; P<0.001; 99 events). Adjustment for potential confounders including renal function, seasonal variation and Framingham risk factors did not materially change this association. In univariate Cox-regression, 1,25OH vitamin D was associated with all-cause mortality (HR 0.92 (0.88 to 0.97) per 10 pmol/L increase; P=0.002). However, this association lost significance after adjustment for renal function.

**Conclusions:** Low circulating 25OH but not 1,25OH2 vitamin D is an independent risk factor for all-cause mortality after KTx. Given the abundant presence of 1α-hydroxylase in renal and extra-renal tissues, our findings supports a protective role for autocrine/paracrine vitamin D activation. Future studies should address whether vitamin D supplementation improves outcome after KTx.

**Initial Bone Mineral Density Status Predicts the Development of New Vertebral Fractures during Kidney Transplantation** Carlo M. Alfieri,[1] Brigida Brezzi,[1] Fabio Massimo Ulivieri,[2] Maria Meneghini,[1] Riccardo Floreani,[1] Anna Regalia,[1] Francesco Barretta,[3] Manuela Curreri,[1] Maria Daniela Croci,[1] Maria Pia Rastaldi,[1] Piergiorgio Messa.[1] *[1]Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca'Granda Osp. Maggiore Policlinico, Milan, Mi, Italy; [2]Osteporosis Centre, Fondazione IRCCS Ca'Granda Osp. Maggiore Policlinico, Milan, Mi, Italy; [3]Clinical Sciences and Community Health,Epidemiology Unit, Dept of Preventive Medicine, Fondazione IRCCS Ca'Granda Osp. Maggiore Policlinico, Milan, Mi, Italy.*

**Background:** Bone disorders and related skeletal fractures are common events during kidney transplantation (KTx). In our study we evaluated: 1) the prevalence of asymptomatic vertebral fractures (VFx) at baseline and 1 year after KTx; 2) the factors associated with the occurrence of new VFx during the first year after KTx; 3) the role of bone mineral density (BMD) in the prediction of new VFx.

**Methods:** 109 consecutive KTx patients (57 M–age range 17-73 years) were evaluated at the 1st and 12th mth for VFx by vertebral X-ray (Genant et al, J Bone Miner Res. 1993 Sep;8(9):1137-48). In addition to the routine biochemical evaluation, FGF-23, Fetuin, Osteoprotegerin (OPG) and 25OH-VitD levels were also evaluated at 1, 6 and 12 mths after KTx. In 87 of these patients BMD, assessed by dual energy X-ray absorption (DEXA),was also performed.

**Results:** VFx were present in 22% and 37% of pts at 1st and 12th mth resp. VFx at 1 mth correlated only with serum phosphorus (P) (directly) and PTH (inversely), whereas at 12 mths only with the number of fractures at baseline. Of the studied patients, 25% had one or more new VFx during the first 12 mths of KTx (VFx-PROG+). VFx-PROG+ had lower BMD at baseline, which was a good predictor for new VFx (ROC:AUC 0,6962), with no difference in PTH, Vit-D status, cumulative steroid doses, FGF-23, Fetuin, and OPG levels compared with VFx- non progressors.

**Conclusions:** According to our results: 1) the prevalence of VFx is high in KTx patients and 25% of them have at least one new VFx during the first year after KTx; 2) baseline BMD might be predictive of the occurrence of new VFx; 3) mineral metabolism related parameters do not seem to play a major role in the occurrence of new VFx.

## SA-PO997

**Can Steroids Be Withdrawn Safely in Routine Practice? Prospective, Four-Year Data from the Mycophenolic Acid Observational REnal Transplant (MORE) Study** V. Ram Peddi,[1] Kimi Ueda Stevenson,[1] Anne Wiland,[2] Kevin M. McCague.[2] *[1]California Pacific Medical Center, San Francisco, CA; [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ.*

**Background:** Corticosteroid withdrawal (CSW) after kidney transplantation is widespread, but prospective data are lacking on the long-term implications for acute rejection, graft survival and graft function vs corticosteroid continuation (CSC) in routine clinical practice.

**Methods:** Prospective data were analyzed from the observational, four-year MORE study of de novo adult kidney transplant patients receiving mycophenolic acid at 40 centers in the US, managed according to local practice. Cox regression analysis adjusted efficacy outcomes for recipient gender, African vs non-African American, deceased vs living donor, PRA status (<30% vs ≥30%), delayed vs immediate graft function and baseline mycophenolic acid dose (<2g/day vs ≥2g/day).

**Results:** 363 CSW and 509 CSC patients were analyzed. All patients received tacrolimus, with similar trough levels in the CSW and CSC cohorts. The observed four-year incidence of efficacy events in the CSW vs CSC groups was 10.1% vs 14.3% for biopsy-proven acute rejection (BPAR, p=0.12), 3.1% vs 6.3% for graft loss (p=0.030) and 4.4% vs 5.0% for death (p=0.65). Cox regression analysis showed hazard ratios (HR) for CSW vs CSC to be 0.75 (95% CI 0.46, 1.21; p=0.25) for BPAR, 0.35 (0.12, 0.86; p=0.032) for graft loss and 0.82 (0.31, 2.09; p=0.68) for death. Mean estimated GFR (CKD-EPI formula) for CSW vs CSC was 59.5 vs 57.5mL/min/1.73m$^2$ (p=0.84) at one year post-transplant, 59.7 vs 60.3mL/min/1.73m$^2$ (p=0.42) at two years, and 57.7 vs 58.1mL/min/1.73m$^2$ (p=0.44) at three years (numbers at four years were too low for meaningful analysis).

**Conclusions:** After adjustment for confounding variables, CSW by month 3 after kidney transplantation was associated with significantly higher four-year graft survival than CSC, with no increase in BPAR or reduction in graft function vs CSC in routine practice.

## SA-PO998

**Impact of Maintenance Steroids versus Rapid Steroid Withdrawal in African-American Kidney Transplant Recipients: Comparison of Two Centers** Divya Jain Arwindekar,[2] Revathi C. Belur,[1] Woojin James Chon,[2] Amishi S. Desai,[1] Ignatius Yun-Sang Tang,[1] Michelle A. Josephson,[2] Sanjeev Akkina.[1] *[1]Medicine, Univ of Illinois at Chicago, Chicago, IL; [2]Medicine, Univ of Chicago, Chicago, IL.*

**Background:** Rapid steroid withdrawal (RSW) is used increasingly in kidney transplantation but long-term outcomes in African-American (AA) recipients are not well known. Our objective was to compare 5 year transplant outcomes in a large cohort of AA patients who underwent RSW to those who were maintained on steroids (CS).

**Methods:** Post-transplant courses of AA receiving a kidney allograft between 2003-2011 at two urban transplant centers were followed. Both centers use thymoglobulin induction with tacrolimus and mycophenolate mofetil as maintenance therapy. The patients at Center 1 (C1) underwent RSW with completion of therapy by day 5. At Center 2 (C2), patients were generally tapered to a maintenance dose of 5 mg of prednisone daily by 1 month post-transplant. The data were analyzed to compare death-centered graft survival, graft survival, patient survival, and MDRD GFR at 1 and 5 years post-transplant between the RSW and CS groups. Additionally, biopsy-proven acute rejections (BPAR) in the first year were compared between the two groups. An intention-to-treat analysis was used with C1.

**Results:** There were 381 AA recipients at C1 and 299 at C2. C1 recipients were younger (48.6 vs. 50.6, p = 0.048), had more living donors (64% vs 20%, p < 0.0001), more expanded criteria donors (9.5% vs. 5.0%, p=0.03), more hypertensive kidney disease (68% vs. 32%, p<0.0001), and less diabetic kidney disease (6.6% vs 22%, p<0.0001) compared to C2. Death-censored and patient survival was similar between the two centers. Other outcomes are shown in the table.

| Outcome | C1 | C2 | p-value |
|---|---|---|---|
| 1 Year Graft Survival | 97% | 96% | NS |
| 1 Year GFR(mL/min/1.73m2) | 53.4±17.8 | 58.9±25.0 | 0.002 |
| 1 Year Biopsy Proven Rejection | 19.4% | 11.4% | 0.004 |
| | | | |
| 5 Year Graft Survival | 75% | 72% | NS |
| 5 Year GFR (mL/min/1.73m2) | 52.5±20.4 | 56.4±23.2 | 0.18 |

**Conclusions:** Graft survival and GFR were similar between the two centers but BPAR was higher in the RSW group. Our findings suggest RSW regimens can be used in AA with similar outcomes to CS regimens.

## SA-PO999

**The Impact of the Transplant Pharmacists on Cardiovascular Risk Reduction in Kidney Transplant Recipients** Caitlin R. Musgrave, David J. Taber, Nicole A. Pilch, Beje S. Thomas, Titte Srinivas. *Medical Univ of South Carolina, Charleston, SC.*

**Background:** Reductions in acute rejection have not translated into comparable improvements in long-term graft survival in kidney transplant (KTX) pts. Cardiovascular (CV) disease is the leading cause of late graft loss following KTX, and control of HTN, DM, and hyperlipidemia is an essential strategy to prevent CV events. The aim of this study was to determine the impact of txp PharmD interventions on the management of CV risk factors in KTX.

**Methods:** This prospective controlled pilot study involved 2-3 mos of enrollment followed by 6 mos of intervention. Patients were 3 mo-3 yr post-KTX and enrolled into the control group (CG) or intervention group (IG). IG pts participated in a pharmacist-run clinic during which the PharmD evaluated and modified CV-related medications through collaborative practice agreements. The control group received standard of care post-KTX.

**Results:** There were no significant differences in baseline characteristics between the two groups aside from more pts in the IG being on baseline ASA (p=0.05, tables 1-2). At study end, significantly more pts in the IG were started on CV meds for compelling indications (p=0.042, table 3) and started on ASA (p<0.001, table 2). Pts in the IG were also more likely to be started on an ACE I/ARB, ASA, or statins during follow-up (OR 2.4, 4.7, 5.9, respectively). No statistically significant changes in lipids, A1C, or pulse were noted; however, paired repeated measures analysis demonstrated that patients in the IG had significant reductions in SBP, which was not demonstrated in CG pts (-8.4±18.0 vs 5.7±31.6, p<0.05).

| Diastolic blood pressure | 73.5 ± 11.6 | 81.1 ± 14.1 | 71.5 ± 10.0 | 74.4 ± 10.9 | 0.143 |
| Pulse | 71.2 ± 12.7 | 74.0 ± 15.3 | 70.6 ± 11.4 | 78.5 ± 13.3 | 0.216 |

***p-value for change from baseline to follow up in the control group vs. change from baseline to follow up in the intervention group**

**Conclusions:** The involvement of txp PharmDs in CV risk factor management led to improved prescribing of medications with compelling indications and lowers SBPs. Further studies are warranted to determine the impact of txp PharmD involvement on long-term KTX outcomes.

## SA-PO1000

### Patient Survival in Simultaneous Pancreas Kidney Transplant Recipients and the Paired Kidneys

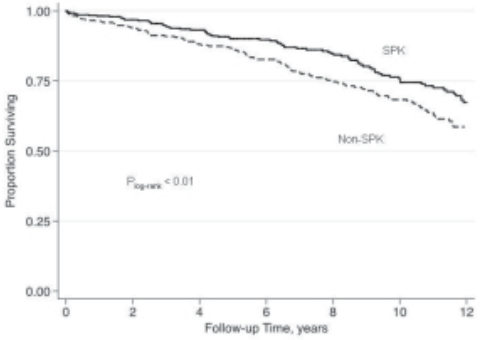
Brenda L. Muth,[1] Brad C. Astor,[1] Hans Sollinger,[2] Jon S. Odorico,[2] Arjang Djamali.[1] *[1]Nephrology, Univ of Wisconsin, Madison, WI; [2]Surgery, Univ of Wisconsin, Madison, WI.*

**Background:** Survival after simultaneous pancreas kidney (SPK) transplantation is better than deceased donor transplantation. However, it is unclear what roles donor and recipient factors play in this advantage.

**Methods:** We conducted a paired-organ analysis to examine patient and kidney graft survival in 453 pairs of recipients transplanted at the University of Wisconsin between 1994 and 2010.

**Results:** Non-SPK recipients were older, more likely to be sensitized and have DGF, less likely to be white and to recieve a pre-emptive transplant, and had longer cold ischemia time (CIT) than those with SPK.

93 (20.5%) SPK and 108 (23.8%) non-SPK recipients died over a median of 5.9 years.



SPK was associated with a lower risk of death (adjusted hazard ratio [HR]=0.50; 95% CI: 0.30, 0.82). Donor (0.49; 0.28,0.76) and recipient age <45 years (0.59; 0.43, 0.80) were also associated with improved patient survival. DGF was associated with a two-fold higher risk of death (2.04; 1.35,3.10).

| | SPK | Non-SPK | p |
|---|---|---|---|
| Age (Mean ± SD) | 40 ± 7 | 44 ± 12 | <0.001 |
| Female (%) | 39 | 44 | 0.08 |
| Diabetes | 100 | 13 | <0.001 |
| PRA > 10% (%) | 4 ± 21 | 27 ± 44 | <0.001 |
| Pre-emptive Transplant (%) | 33 | 12 | <0.001 |
| CIT (hr ± SD) | 14 ± 5 | 19 ± 7 | < 0.001 |
| DCD (%) | 12 | 12 | |
| Donor Age (Mean ± SD) | 30 ± 13 | 30 ± 13 | |
| DGF (%) | 10 | 20 | <0.001 |

Kidney grafts failed in 179 (39.5%) non-SPK vs 147 (32.5%). SPK (0.59; 0.39, 0.88) and white race (0.59; 0.42, 0.83) were associated with lower risk of failure, whereas donor age >45 years (1.74; 1.36, 2.23) and DGF (1.79; 1.32, 244 were associated with greater risk of failure. Adjustment for CIT did not change these associations.

**Conclusions:** Both donor (age) and recipient (SPK vs non-SPK, age, race) characteristics as well as DGF are related to patient and kidney graft survival.

## SA-PO1001

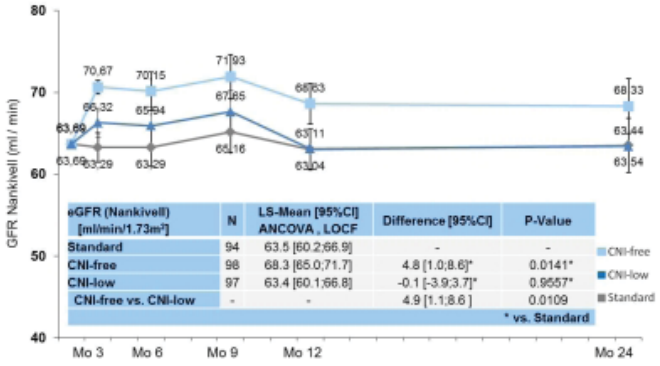
### HERAKLES at Month 24: Maintained Superior Renal Function in Patients on an Everolimus-Based Calcineurin Inhibitor Free Regimen Compared to Standard Cyclosporine/Mycophenolate and Low Cyclosporine/Everolimus

Martin G. Zeier,[1] Wolfgang Arns,[1] F. Lehner,[1] Markus Guba,[1] Claudia Sommerer,[1] Hans-Hellmut Neumayer,[1] Johannes Jacobi,[1] Peter Weithofer,[1] Daniel Baeumer,[2] Christoph May,[2] Eva-Maria Paulus,[2] Oliver Witzke,[1] Klemens Budde.[1] *[1]HERAKLES Study Group, Germany; [2]Novartis Pharma Nuremberg, Germany.*

**Background:** To follow up(FU) on the evolution of renal function(RF) of 3 different immunosuppressive regimen with different calcineurin inhibitor(CNI) exposure at month(Mo)24 post renal transplantation(Tx).

**Methods:** 802 patients (pts) were included in an 1year, prospective, open-label, randomized (RDZ), controlled multi-center study. After induction with basiliximab pts received cyclosporine A(CsA), enteric-coated mycophenolate sodium(EC-MPS) + steroids. 3Mo post Tx 499 pts were RDZ 1:1:1 to either continue standard (STD) CsA(100-180ng/ml) + EC-MPS(n=166), or to convert to a CNI-free regimen+ everolimus(EVR;5-10ng/ml) + EC-MPS(n=171) or to convert to CNI-low regimen+ EVR(3-8ng/ml) and reduced CsA(50-75ng/ml)(n=162). Mo24 FU visit was performed by 131(96%)STD, 132(96%) CNI-free and 125(93%) CNI-low pts. RF (primary endpoint) was assessed as Glomerular Filtration Rate (cGFR;Nankivell).

**Results:** Trough levels: CsA 99±32ng/ml in STD, 83±34ng/ml in CNI-low pts; EVR 6.7±3.1ng/ml in CNI-free, 6.2±2.3ng/ml in CNI-low pts. RF was similar at RDZ and had significantly improved at Mo12 by +5.6mL/min/1.73m2(95%CI:[+2.9;+8.3];p<0.001) in favor of CNI-free regimen and remained significantly improved by +4.8mL/min/1.73m2 at Mo24 (ITT;p=0.014). Rejections since RDZ were similar in all 3 groups (12%STD,14%CNI-free,12%CNI-low), safety profile was overall comparable.



| eGFR (Nankivell) [ml/min/1.73m²] | N | LS-Mean [95%CI] ANCOVA , LOCF | Difference [95%CI] | P-Value |
|---|---|---|---|---|
| Standard | 94 | 63.5 [60.2;66.9] | - | - |
| CNI-free | 98 | 68.3 [65.0;71.7] | 4.8 [1.0;8.6]* | 0.0141* |
| CNI-low | 97 | 63.4 [60.1;66.8] | -0.1 [-3.9;3.7]* | 0.9557* |
| CNI-free vs. CNI-low | - | - | 4.9 [1.1;8.6 ] | 0.0109 |
| | | | | * vs. Standard |

**Conclusions:** Reduced CsA in combination with EVR did not result in better RF compared to STD regimen with EC-MPS. However, CNI-free regimen lead to better RF maintained for 2years, confirming previous reports.

## SA-PO1002

**HERAKLES at Month 24: Follow-Up Results on Efficacy and Safety of Three Different Treatment Regimens in De Novo Renal Transplant Patients Demonstrate Options for Individualized Immunsosuppression**

Martin G. Zeier,[1] Volker Kliem,[1] Wolfgang Arns,[1] Oliver Witzke,[1] Claudia Sommerer,[1] Hans-Hellmut Neumayer,[1] F. Lehner,[1] Johannes Jacobi,[1] Daniel Baeumer,[2] Christoph May,[2] Eva-Maria Paulus,[2] Markus Guba,[1] Klemens Budde.[1]
*[1]HERAKLES Study Group, Germany; [2]Novartis Pharma Nuremberg, Germany.*

**Background:** To follow-up (FU) on safety and efficacy of 3 different immunosuppressive (IS) regimen at 24 months (Mo) after renal transplantation (Tx).

**Methods:** 802 patients(pts) were included in this 1year, prospective, open-label, randomized (RDZ), controlled, multi-center study. After induction therapy with basiliximab all pts received cyclosporine A(CsA), enteric-coated mycophenolate sodium(EC-MPS)+steroids. 3Mo post Tx 499pts were RDZ 1:1:1 to either continue standard(STD) treatment CsA(100-180ng/ml)+EC-MPS(n=166) or convert to a calcineurin inhibitor (CNI)-free regimen with everolimus(EVR;5-10ng/ml) +EC-MPS(n=171) or to a CNI-low regimen with EVR(3-8ng/ml) +reduced CsA(50-75ng/ml) (n=162). All pts continued on steroids. Mo24FU visit was performed by 131(96%)STD, 132(96%)CNI-free and 125(93%) CNI-low regimen pts of the FU-population.

**Results:** From RDZ to Mo24 BPAR was reported in 17/144(12%) STD, 20/146(14%) CNI-free and 17/141(12%) CNI-low pts (ITT). Two (1%) deaths occurred in the CNI-low, none in the other groups. 1(1%) graft loss was observed in the STD and 4(3%) in the CNI-free group. Premature discontinuation due to AEs occurred in 1/147(1%) STD, 3/148(2%) CNI-free and 1/141(1%) of CNI-low pts (safety-pop) from Mo12 to Mo24. Renal function expressed as cGFR (Nankivell) was significantly improved by +4.8mL/min/1.73m2(95%CI:[+1.0;+8.6]) in favor of CNI-free regimen at Mo24(ITT;p=0.014).

## SA-PO1003

**APOLLO after 4 Years: Outcome on Renal Function of an Everolimus Based Therapy after Calcineurin Inhibitor Withdrawal in Maintenance Renal Transplant Recipients**

Wolfgang Arns,[1] Petra Reinke,[1] Claudia Sommerer,[1] Hermann G. Haller,[1] Oliver Witzke,[1] Barbara M. Suwelack,[1] Thomas Rath,[1] Daniel Baeumer,[2] Christoph May,[2] Eva-Maria Paulus,[2] Klemens Budde.[1]
*[1]APOLLO Study Group, Germany; [2]Novartis Pharma Nuremberg, Germany.*

**Background:** To assess renal function(RF), safety and efficacy of an Everolimus(EVR) regimen after Calcineurin-Inhibitor(CNI) withdrawal in maintenance kidney allograft recipients.

**Methods:** In this open-label, randomized(RDZ), controlled, multi-center trial 93 patients(pts) on stable immunosuppression consisting of CNI, Enteric-Coated Mycophenolate Sodium(EC-MPS) with or without steroids were RDZ to either continue CNI treatment + EC-MPS or convert to EVR + EC-MPS based regimen. After 12Mo core study pts were included in an observational follow-up(FU).

**Results:** 93 pts (mean time since last transplantation(Tx): 6.4years) were RDZ to either EVR(n=46) or CNI(n=47) regimen. 72(77%)pts completed Mo48visit. At Mo48 mean adj. GFR(Nankivell) in EVR pts was higher by +5.6 mL/min/1.73m2(95%CI:[-0.6;+11.8];p=0.08) vs CNI pts (ITT); mean GFR change from RDZ to Mo48: +5.7(95%CI:[-0.1;+11.5]) in EVR vs +0.1(95%CI:[-5.1;+5.3])mL/min/1.73m2 in CNI group (p=0.08). Mean eGFR of pts who remained to Mo48 on the assigned EVR regimen: +8.7ml/min(95%CI:[+16.0;+1.4]n=20;p=0.02) over CNI pts (n=31).

| eGFR Nankivell (ml/min/1.73m²) | EVR | CsA | Difference EVR/CsA | P-value |
|---|---|---|---|---|
| ITT pop. | n=32 | n=33 | Δ | |
| eGFR mean ± SD | 66.3 ± 17.6 | 60.6 ± 15.5 | 5.7 | 0.1307[b] |
| eGFR change[a], LS-mean[c] | +5.7 [-0.1;11.5] | +0.1 [-5.1;5.3] | 5.6 [-0.6;11.8] | 0.0762[c] |
| eGFR LS-mean[c] | 67.1 [61.3;72.9] | 61.5 [56.3;66.7] | 5.6 [-0.6;11.8] | 0.0762[c] |
| On-therapy pop. | n=20 | n=31 | Δ | |
| eGFR mean ± SD | 69.2 ± 14.9 | 60.8 ± 15.9 | 8.4 | 0.0704[b] |
| eGFR change[a], LS-mean[c] | +9.9 [2.5;17.2] | +1.2 [-4.1;6.4] | 8.7 [1.4;16.0] | 0.0216[c] |
| eGFR LS-mean[c] | 71.1 [63.8;78.4] | 62.4 [57.2;67.7] | 8.7 [1.4;16.0] | 0.0216[c] |
| [a]RandomizedTreatmentPeriod; [b]Wilcoxon Rank-Sum test; [c]ANCOVA LS-mean [95%CI] | | | | |

Mean trough levels: 84±44ng/ml CsA, 5.9±2.4ng/ml Tacrolimus, 6.7±2.0ng/ml EVR. 2deaths and 1graft loss occurred in CNI, 1death and 3graft losses in EVR, no BPAR in either group. Infections after Mo12: 23(50%) pts in EVR vs 20(43%) in CsA group. Of these were 3(7%) severe in EVR group vs 1(2%) in CNI group; none lead to hospitalization. No malignancy occurred in EVR group, 1(2%) in CNI group.

**Conclusions:** Late conversion to an EVR/EC-MPS regimen in maintenance KTx patients after CNI withdrawal is safe and associated with tendency towards better RF maintained for 4 years.

## SA-PO1004

**Outcome on Renal Function, Efficacy and Safety in Living-Donor Kidney Transplant Recipients after Conversion from a Calcineurin Inhibitor to an Everolimus Based Regimen: Post Hoc Subgroup Analysis from the ZEUS Study**

Claudia Sommerer,[1] F. Lehner,[1] Wolfgang Arns,[1] Petra Reinke,[1] Ute Eisenberger,[1] Rudolf P. Wuthrich,[1] Martina Porstner,[2] Christoph May,[2] Eva-Maria Paulus,[2] Anja Susanne Muhlfeld,[1] Heiner H. Wolters,[1] Katharina M. Pressmar,[1] Rolf A. Stahl,[1] Oliver Witzke,[1] Klemens Budde.[1] *[1]ZEUS Study Group, Germany; [2]Novartis Pharma Nuremberg, Germany.*

**Background:** To study renal function and patient outcome in subgroup of living-donation (LD) kidney *de novo* transplant recipients after conversion from calcineurin inhibitor (CNI) therapy to an everolimus (EVR) based regimen.

**Methods:** *Post hoc* subgroup analysis on LD recipients from a prospective, open-label, controlled, multi-center study on renal transplant (Tx) patients that were randomized (RDZ) at month (Mo) 4.5 post Tx to an immunosuppressive regimen consisting of either EVR + enteric coated-mycophenolate sodium (EC-MPS ) or cyclosporine (CsA) plus EC-MPS.

**Results:** 300 kidney transplant recipients were RDZ to continue CsA or convert to EVR at 4.5Mo post Tx. Results from 80 LD recipients (EVR: N=42; CsA: N=38) were analyzed *post hoc*. In this subpopulation, adjusted estimated GFR at Mo12 (Nankivell formula) was 74.2 (95%CI [70.5;78.0]) mL/min/1.73m² for EVR pts vs 63.6 (95%CI [59.5;67.8])mL/min/1.73m²) for CsA pts, resulting in a difference of 10.6mL/min/1.73m² in favor of EVR group (p<0.001). From RDZ to Mo12, adjusted estimated GFR increased by a mean of 9.9 (95%CI [6.2, 13.7]) mL/min/1.73m² with EVR vs -0.6 (95%CI [-4.8, 3.5])mL/min/1.73m²) (p<0.001) in CsA subgroup. Mean trough levels at Mo12: 7.1±2.1ng/ml for EVR, 117±32ng/ml for CsA pts. In EVR group 6 BPAR episodes (5 of them Banff I), occurred vs 1 (Banff I) in the CsA group (p=0.109). One graft loss occurred in the CsA group, none with EVR. Discontinuation due to AEs occurred in 6 EVR pts (14.3%) and 5 CsA pts (13.2%) between RDZ and Mo12. Overall safety profile was similar between treatment groups.

**Conclusions:** These findings suggest that initiation of EVR with early elimination of CNI therapy in LD kidney transplant recipients is associated with a significant renal benefit at 12Mo post Tx without compromising safety and efficacy.

*Funding:* Pharmaceutical Company Support - Novartis Pharma Germany

## SA-PO1005

**Living Renal Donation: Emotional Status of the Donor** Claudia Sommerer,[1] Ralf A. Dikow,[2] Matthias Schaier,[1] Christian Morath,[1] Vedat Schwenger,[1] Martin G. Zeier.[1] *[1]Nephrology, Univ Hospital, Heidelberg, Germany; [2]Dialysis, Renal Center, Bruchsal, Germany.*

**Background:** The benefits of living kidney donation for recipients are well-known. Nevertheless, donor safety is of importance at all time. Data on the impact of living donation on the emotional status including depression and anxiety are rare.

**Methods:** In an open, prospective observational study, renal allograft donors were evaluated with respect to psychosocial and emotional outcome after living donation. Standardized questionnaires (HADS, SF-12) as well as additional questions related to living donation were used.

**Results:** Altogether, 128 renal allograft donors were evaluated (86 male, median age 49.1 ± 11.4 years, mean time after transplantation 3.7±3.8). None of the donors had any serious post-transplant complications and the renal function was stable. 13 donors (13%) assessed general health worse compared to prior to transplantation. Emotional role function was decreased in 8% of the donors. Concerning the emotional status, most of the patients demonstrated normal HADS anxiety scores, with pathological results in 6 patients (5%). Depression scale showed pathological results in 15 donors (13%). Patients with pathological anxiety scores were more likely to be parents, foreign origin and living alone. There was no difference concerning gender, age or renal function. Concerning the HADS depression scale no difference in the patient cohort with and without depression symptoms could be noticed. Health status was more often judged as worse in patients with pathological results in one of the sub-scales. Renal allograft function or recipient health had no relevant impact on the emotional status of the donor.

**Conclusions:** A minority of renal donors demonstrated and impact of renal donation on the emotional status or anxiety and depression symptoms. Health status was impacted by pathological results. Parenthood, foreign origin and living alone were identified as risk factors for anxiety symptoms.

## SA-PO1006

**Evolution of Allograft Fibrosis and Related Markers in Kidney Transplant Patients under Treatment with Cyclosporine and Everolimus** Luis Eduardo Becker,[1] Ruediger Waldherr,[2] Martin G. Zeier,[1] Claudia Sommerer.[1] *[1]Nephrology, Univ of Heidelberg, Heidelberg, Germany; [2]Pathology, Univ of Heidelberg.*

**Background:** In kidney transplant, protocols to avoid calcineurin inhibitor chronic toxicity are continuously developed in order to prevent allograft fibrosis and function loss. We analyzed the histological evolution of fibrosis and the expression of related markers after conversion from cyclosporine (CsA) to everolimus performed in stable kidney transplant patients.

**Methods:** Forty patients maintained on prednisone, sodium mycophenolate and CsA were included in our analysis. After 4.5 months of transplantation, patients were randomised to either continue the current CsA regimen (n = 21) or gradually convert from CsA to everolimus (n = 19). Histological sections of kidney biopsies obtained prior (baseline) and at least 6 months after randomization were digitally analyzed for kidney fibrosis (Masson's trichrome, Sirius Red) and for the immunohistochemical expression of related markers (transforming growth factor ß (TGFß), hypoxia inducible factor 1alpha (HIF1A) and platelet derived growth factor (PDGF)). Results are given as percent (%) of variation/year and presented as mean±SEM. Analysis was performed using the Student's t-test, $p<0.05$ was considered significant.

**Results:** Baseline characteristics were similar between groups. Time on target immunosuppression was 22±5 and 25±4 months in the CsA and in the everolimus groups, respectively. A tendency for a higher increase in the fibrotic area was seen in the CsA (8.5±5.5 %variation/year) compared to everolimus (0.4±2.5 %variation/year, p=0.2), which was confirmed by Sirius red. TGFß tubular expression reduced significantly in the everolimus group compared to baseline (-2.2±0.9% variation/year, p=0.03); the variation was also significantly different compared to the CsA group (+0.5±0.9% variation/year, p=0.04). Expression of both PDGF and HIF1A remained stable and was similar in both groups.

**Conclusions:** Conversion from CsA to everolimus in kidney transplant patients was associated with a tendency for a lower development of allograft fibrosis and a significant reduction of tubular TGFß expression on patients with stable allograft function.

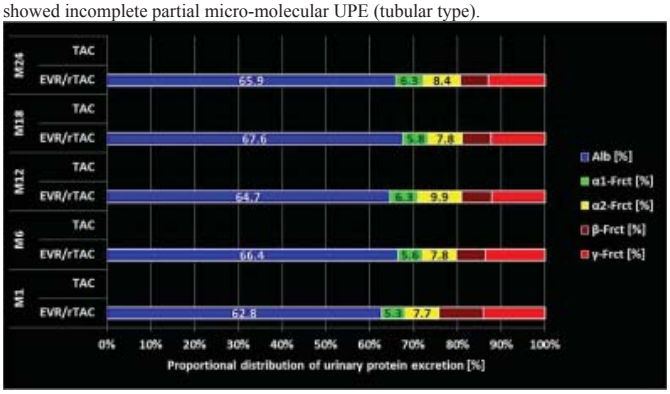
## SA-PO1007

**mTOR Inhibition and Evolution of Urinary Protein Excretion in Non-Renal Tranplant Patients – 24 Month Results from 719 De Novo Liver Transplant Patients** G. Junge, Sven Kohler, Ute Eisenberger, Heike Schwende, Wolfgang Arns. *H2304 Study Group.*

**Background:** The interplay of glomerular filtration and tubular absorption of proteins with various molecular weights defines pattern/magnitude of urinary protein excretion(UPE). Increased UPE(proteinuria) serves as clinical surrogate for renal injury and progressive damage affecting different parts of the nephron. mTOR-inhibitor(i) treatment has also been associated with increased UPE not only in KTx but also non-renal Tx recipients(R).

**Methods:** Data from study H2304(NCT00622869), a 24-month(M), randomized, multicenter study in 719 de novo LTxR comparing everolimus(EVR 3-8ng/mL) plus reduced tacrolimus(rTAC 3-5ng/mL) to standard TAC(sTAC-C 6-10ng/mL). Total daily UPE, measured as UP/UC ratio, as well as a set of different urinary proteins is described to allow a more detailed investigation of the origin/course of UPE in de novo LTxR receiving EVR.

**Results:** UPE was higher with EVR+rTAC compared to sTAC with highest values at M6 (290mg/d) followed by decrease to M12 and M24 (194mg/d) compared to 158mg/day in TAC-C at M24. UPE >500mg/d occurred in 18.1% of TAC-C vs 23.6% in EVR+rTAC (18.9% when EVR C0 was 3-8ng/mL). Analysis of urinary protein electrophoresis and levels of b2MG(12kDa), a1MG(26 kDa), Alb(70 kDa), TF(80 kDa), and IgG(150 kDa) suggest mixed glomerular/tubular UPE for TAC while patients on EVR with new proteinuria showed incomplete partial micro-molecular UPE (tubular type).



**Conclusions:** Clinical observations suggest that mTOR inhibition might be associated with increased UPE, potentially due to enhanced cell wall permeability and podocyte dysregulation. However, in case of mTORi facilitated CNI reduction the improvement in glomerular blood flow and consequently higher overall protein filtration in combination with mTOR-dependent reduction in tubular protein reabsorption may also contribute to increased UPE.

## SA-PO1008

**Surrogate Renal Function Endpoints for Predicting Long-Term Allograft Survival in Kidney Transplantation** G. Junge, Peter Bernhardt, Cesar Escrig, Helio Tedesco Silva. *For the A2309 Study Group, Novartis Pharma AG, Basel, Switzerland.*

**Background:** Despite the improvement of short-term kidney transplant (KTx) survival over the last decades, the main concern remains about the long-term outcome. However, classical primary endpoints in KTx clinical trials are still highly focused on short-term efficacy. A new approach to define study endpoints with clinical relevance in the current KTx setting is needed. We retrospectively examined different endpoints in the study A2309 to gain information on potential parameters that may predict long-term allograft survival for future verification.

**Methods:** This 24-month, multicenter, A2309 study randomized 833 de novo KTx patients to compare two regimens of everolimus (EVR; 1.5mg/day or 3.0mg/day) with reduced dose cyclosporine A (CsA) *vs.* enteric-coated mycophenolate sodium (EC-MPS; 1.44g/day) with standard dose CsA. Renal function was measured by estimated glomerular filtration rate (eGFR) using MDRD-4. The retrospective analyses used different cut-offs for eGFR to define renal function impairment. Efficacy was assessed as either treated biopsy-proven acute rejection (tBPAR), or the occurrence of any event of tBPAR, graft loss, or death. Different combinations of renal function and efficacy endpoints were analyzed.

**Results:** Fewer patients in the EVR group experienced the composite endpoint of impaired renal function or tBPAR and composite endpoint of eGFR cut-off or tBPAR, graft loss, or death (Table).

Table: Exploratory endpoints at mo 12 post-KTx

| Event at mo 12 | EVR 1.5 mg N=277 n/M (%) | EC-MPS N=277 n/M (%) | Risk Difference EVR 1.5 mg vs. EC-MPS (%) (95%CI) |
|---|---|---|---|
| eGFR ≤ 40 or tBPAR | 84/277 (30.3) | 96/277 (34.7) | -4.3 (-12.1, 3.5) |
| eGFR ≤ 50 or tBPAR | 117/277 (42.2) | 156/277 (56.3) | -14.1 (-22.3, -5.8) |
| eGFR ≤ 60 or tBPAR | 178/277 (64.3) | 205/277 (74.0) | -9.7 (-17.4, -2.1) |
| eGFR ≤ 40 or tBPAR/graft loss/death | 91/277 (32.9) | 99/277 (35.7) | -2.9 (-10.8, 5.0) |
| eGFR ≤ 50 or tBPAR/graft loss/death | 122/277 (44.0) | 157/277 (56.7) | -12.6 (-20.9, -4.4) |
| eGFR ≤ 60 or tBPAR/graft loss/death | 182/277 (65.7) | 206/277 (74.4) | -8.7 (-16.3, -1.1) |

CI, confidence interval; EC-MPS, enteric-coated mycophenolate sodium; eGFR, estimated glomerular filtration rate (mL/min/1.73m²); EVR, everolimus; KTx, kidney transplantation; mo, month; tBPAR, treated biopsy-proven acute rejection.

**Conclusions:** Endpoints to assess renal function impairment events in composite with efficacy failure allowed for the differentiation of the EVR 1.5 mg group *vs.* the EC-MPS group in the retrospective analysis of the A2309 study. These composites may provide a clinically meaningful approach to discriminate between immunosuppressive regimens in KTx. These endpoints need to be further explored in prospective trials.

**SA-PO1009**

**The Risk Factors for mTOR Inhibitors Associated Proteinuria in Kidney Transplant Recipients** Hung-Tien Kuo, Hung-Chun Chen. *Nephrology, Kaohsiung Medical Univ Hospital, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

**Background:** The use of mammalian target of rapamycin inhibitor (mTORI) after kidney transplantation has been associated with an increased risk of proteinuria. The purpose of this study is to investigate the risk factors for proteinuria after mTORI treatment in kidney transplant recipients in a Taiwan medical center.

**Methods:** A total of 55 adult (46.7±10.6 years old) deceased donor kidney transplant recipients who received mTORI treatment (sirolimus/everolimus 47/8, started at 351 days post-transplant in median) were enrolled. They had no overt-proteinuria before the initiation of mTORI treatment. The risk factors for mTORI-associated proteinuria were investigated using multivariate logistic regression analysis. The impact of mTORI-associated proteinuria on overall graft survival was investigated using multivariate Cox-regression analysis.

**Results:** Median follow-up after the initiation of mTORI treatment was 1603 days. During this time, there were 15 outcomes of new-onset proteinuria (27.3%) and 2 outcomes of overall graft failure (3.6%). After adjusting for major confounding factors in the logistic regression model, the independent risk factors for mTORI-associated proteinuria included renal function impairment (initial eGFR<30 vs. ≥60ml/min, odds ratio=91.7, $P<0.01$; 30-60 vs. ≥60ml/min, 3.1,$P=0.20$) and high body mass index (BMI≥25 vs. <25 Kg/m$^2$, 7.84, $P<0.05$). In the multivariate Cox regression model, mTORI-associated proteinuria was not significantly associated with the risk of overall graft failure.

**Conclusions:** In our study cohort, renal function impairment and obesity at the initiation of mTORI treatment were strong predictors for proteinuria. However, the impact of mTORI-related proteinuria on overall graft survival in kidney transplantation cannot be supported in the current analysis.

**SA-PO1010**

**Medication Safety: The Next Big Challenge to Improving Long-Term Outcomes in Kidney Transplantation?** David J. Taber, Justin Spivey, Nicole A. Pilch, John McGillicuddy, Kenneth Chavin, Frank Treiber, Prabhakar Baliga, Titte Srinivas. *MUSC, Charleston, SC.*

**Background:** Immunosuppressant regimens have significantly decreased acute rejection, but have potentially increased the risk of graft loss driven by infections, over-immunosuppression, adverse drug reactions, and medication errors.

**Methods:** This was a post-hoc analysis of a prospective randomized controlled trial that included adults that had a solitary renal transplant between 3/09-7/11. Data collection and analysis included sociodemographics, medications, adverse drug reactions, and medication errors. Patients were divided into groups based on the development of a clinical significant medication error, defined as a significant or severe medication error contributing to hospitalization, and analyzed for post-transplant clinical outcomes.

**Results:** 200 patients were included in this analysis; 233 medication errors were identified, with 64% of the cohort having at least one error. Immunosuppressant medications were associated with 48% of these errors. There was a total of 327 significant adverse drug events. Patients that experienced at least one med error had 1.8 times the risk of developing an adverse drug event (90% vs. 82%, p=0.128). 28 patients (12%) experienced a clinically significant medication error (CSME). Patients that experienced CSMEs had a statistically higher number of readmissions, cost of readmissions, and overall length of stay for these readmissions. These patients were more likely to experience graft failure (see Figure 1, CSME 22% vs. 10%, p =0.05); CSME was more strongly associated with graft loss as compared to acute rejections.

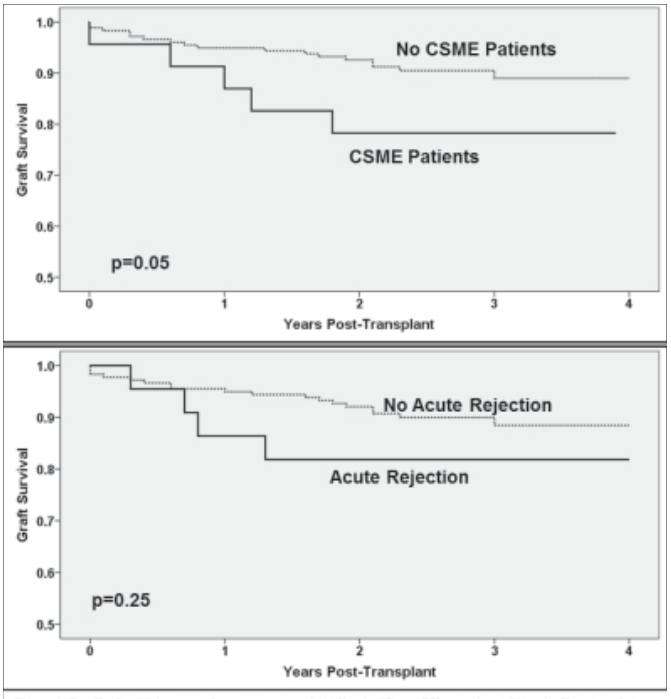


**Figure 1.** Top Kaplan-Meier curve demonstrates a statistically significant difference in graft survival between the CSME group and Non-CSME group. The bottom graph shows the lack of a strong association between acute rejection and graft survival suggesting a stronger association with medication errors and graft loss.

**Conclusions:** Clinically significant medication errors occur in one out of every eight kidney transplant recipients and lead to an increased risk hospital readmissions, cost of care and graft loss.

**SA-PO1011**

**Are Thiazide Diuretics Safe and Effective Antihypertensives in Kidney Transplantation?** David J. Taber, Titte Srinivas, Nicole A. Pilch, Beje S. Thomas, Maria N. Salazar, Kenneth Chavin, Prabhakar Baliga, Leonard Egede. *MUSC, Charleston, SC.*

**Background:** There is limited data assessing the safety and efficacy of thiazides as antihypertensives in kidney transplant (KTX) recipients.

**Methods:** This was a longitudinal retrospective cohort study of all KTX recipients transplanted between 2000-08 with follow-up through 2012. Patients were grouped based on receiving thiazide therapy. Safety and efficacy comparisons were made within thiazide patients and between groups.

**Results:** 1,093 KTX were included in this study (thiazide group: 108, control group: 985). KTX that received thiazides had a more aggressive HTN phenotype, demonstrated by being older (53±11 vs 48±13 yrs, p<0.001), more pre-KTX hypertension (97% vs 88%, p=0.004), diabetes (36% vs 27%, p=0.035), more post-KTX HTN medications (2.1±0.9 vs 1.4±1.0, p<0.001) and more HTN medication changes (10.9±4.4 vs 5.7±4.9, p<0.001, see Table 1). Despite this, means BPs were similar between thiazide and controls (139/77 vs 136/77) while receiving thiazide therapy. Safety analysis revealed thiazide patients were more likely to be readmitted to the hospital (70% vs. 53%, p<0.001), develop hyperkalemia (56% vs. 38%, p<0.001) or hypokalemia (28% vs. 18%, p=0.010), but had similar rates of hypotension, eGFRs, graft loss and death. After controlling for age and comorbidity differences, hospital readmissions were fairly similar between groups (OR 1.49, 95% CI 0.92–2.40). Within the thiazide cohort, paired repeated measures analysis demonstrated SBP (147±17 to 139±18, p<0.001) and DBP (79±9 to 77±11, p<0.001) were reduced after thiazide initiation.

| Outcome | Thiazide Patients n=108 | Control Patients n=985 | p-Value |
|---|---|---|---|
| Patient Survival | | | |
| One Year | 100% | 100% | |
| Three Year | 100% | 95% | 0.346 |
| Five Year | 95% | 91% | |
| Ten Year | 77% | 77% | |
| Graft Survival | | | |
| One Year | 100% | 100% | |
| Three Year | 97% | 90% | 0.160 |
| Five Year | 90% | 83% | |
| Ten Year | 67% | 65% | |
| Delayed Graft Function | 10% | 14% | 0.249 |
| Acute Rejection | 22% | 22% | 0.837 |
| Readmitted to Hospital Post-Transplant | 70% | 53% | **<0.001** |
| Reasons for Hospital Readmissions | | | |
| Infectious Issue | 26% | 18% | **0.030** |
| GI Issue | 11% | 9% | 0.535 |
| Rejection | 20% | 16% | 0.303 |
| Surgical Issue | 9% | 8% | 0.609 |
| Cardiovascular Event | 13% | 11% | 0.581 |
| Other | 50% | 35% | **0.003** |
| Developed at least one Episode of Hypotension (<90/60) | 13% | 10% | 0.384 |
| Hyperkalemia (>5 mEq/L) | 56% | 38% | **<0.001** |
| Severe Hyperkalemia (>6 mEq/L) | 5% | 5% | 0.985 |
| Hypokalemia (<3.5 mEq/L) | 28% | 18% | **0.010** |
| Severe Hypokalemia (3 mEq/L) | 6% | 4% | 0.299 |
| Mean Estimated GFR (mL/min/1.73 m$^2$) | 48±15 | 50±19 | 0.124 |
| Mean Serum Creatinine (mg/dL) | 1.7±0.5 | 1.8±0.7 | 0.177 |
| Mean Number of Anti-HTN Medications Used | 2.1±0.9 | 1.4±1.0 | **<0.001** |
| Total Number of Anti-HTN Medication Changes | 10.9±4.4 | 5.7±4.9 | **<0.001** |
| Number of Anti-HTN Medication Changes Per Year | 1.6±1.1 | 1.2±1.5 | **0.007** |
| Systolic BP at Transplant (mmHg) | 144±27 | 143±25 | 0.556 |
| Diastolic BP at Transplant (mmHg) | 77±15 | 78±15 | 0.577 |
| Mean Follow-Up Systolic BP (mmHg) | 142±15 | 136±16 | **<0.001** |
| Mean Follow-Up Diastolic BP (mmHg) | 78±8 | 77±9 | 0.861 |
| Follow-Up BP <130/80 mmHg | 32% | 36% | 0.219 |

**Conclusions:** Based on long-term outcomes, thiazides appear to be safe and effective antihypertensives in kidney transplantation; in the short-term, thiazides may increase the risk of hospitalization and potassium disturbances. Prospective RCT are warranted to confirm results.

## SA-PO1012

**Improving or Maintaining Renal Function over 5 Years with Belatacept or Cyclosporine (CsA): Insights from the BENEFIT and BENEFIT-EXT Long-Term Extension (LTE) Studies** F. Vincenti,[1] L. Rostaing,[2] A. Durrbach,[3] K. Rice,[4] L. Pupim,[5] J. Grinyo.[6] *[1]UCSF, USA; [2]Univ Hosp Toulouse, France; [3]Bicêtre Hosp, France; [4]Baylor Univ Med Ctr, USA; [5]Bristol-Myers Squibb, USA; [6]Univ Hosp Bellvitge, Spain.*

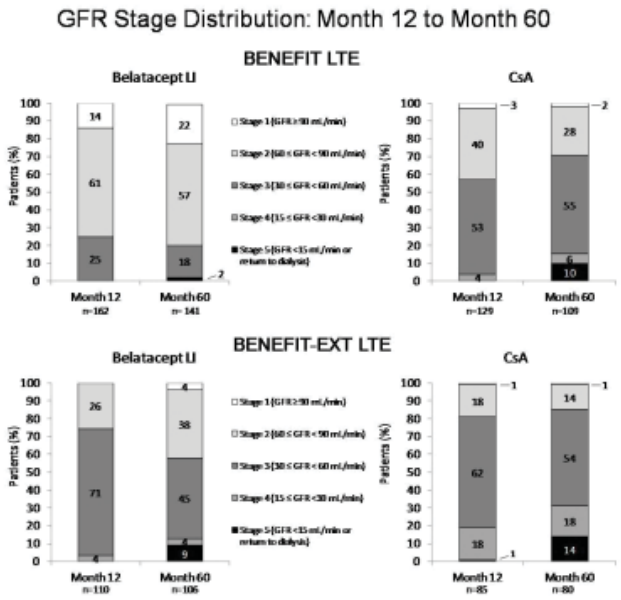
**Background:** In BENEFIT and BENEFIT-EXT, the early renal function benefit observed in belatacept(bela)-treated patients (pts) was maintained over 3 years with a consistent safety profile. Here we report renal function outcomes over 5 years in the LTE of both studies.

**Methods:** In both Phase III studies, adult kidney transplant recipients (living or SCD in BENEFIT; ECD in BENEFIT-EXT) were randomized to a more or less intensive (LI) regimen of bela or CsA. Pts entered the LTE after 3 years. GFR stages at Months (Mos) 12 and 60 are shown in the Figure. Post hoc analyses reported here assessed shifts in cGFR stage between Mos 12 and 60 in the LTE cohort, with the approved LI regimen vs. CsA. To be analysis eligible, patients in the LTE had to have a GFR value at Mo 12 and Mo 60. In BENEFIT, 139 of 165 pts in bela LI and 102 of 136 in CSA were eligible; in BENEFIT-EXT, 103 of 113 LI and 79 of 87 CSA were eligible.

**Results:** In BENEFIT, from Mo 12–60, 77 of 85 LI pts and 21 of 43 CsA pts in Stage 2 maintained or improved their GFR stage. Among Stage 3 pts, 33 of 35 LI and 40 of 52 CsA maintained or improved their GFR stage.

In BENEFIT-EXT, from Mo 12–60, 20 of 25 LI pts and 7 of 15 CsA pts in Stage 2 maintained or improved their GFR stage. Among Stage 3 pts, 63 of 74 LI and 38 of 50 CsA maintained or improved their GFR stage. Among Stage 4 pts, 3 of 4 LI and 7 of 12 CsA maintained or improved their GFR stage.

**Conclusions:** Despite modest sample sizes, these results suggest that patients treated with belatacept were more likely than CsA-treated patients to maintain or improve renal function over 60 Mos in both studies.



## SA-PO1013

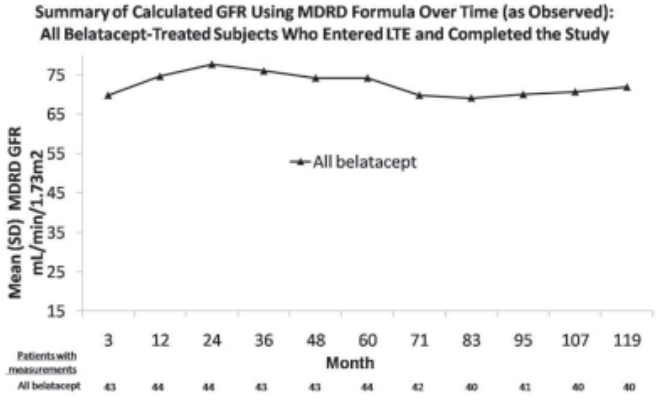
**A Decade of Treatment with Belatacept in Renal Transplantation: Final Results from the Long-Term Extension (LTE) of the Phase 2 Study** F. Vincenti,[1] C. Larsen,[2] J. Grinyo,[3] F. Mühlbacher,[4] G. Blancho,[5] Y. Vanrenterghem,[6] F. Lehner,[7] C. Jones-burton,[8] B. Charpentier.[9] *[1]UCSF, US; [2]Emory Univ; [3]Univ Hospital of Bellvitge, Spain; [4]Medical Univ of Vienna, Austria; [5]Univ Hospital, Nantes, France; [6]Univ Hospital Gasthuisberg, Belgium; [7]Medizinische Hochschule Hannover, Germany; [8]Bristol-Myers Squibb, US; [9]Univ Hospital of Bicêtre, France.*

**Background:** Results of the Phase 2 LTE of belatacept in kidney transplantation demonstrated a favorable safety profile & improved renal function vs cyclosporine (CsA) at 5 years (Vincenti F et al, *JASN* 2010;21(9):1587–96). Here we report the safety & efficacy of belatacept in the LTE up to study closure (9–13 years).

**Methods:** 218 patients were randomized to receive a more or less intensive regimen of belatacept (n=145) or CsA (n=73), with belatacept patients receiving treatment at 4- or 8-week intervals (5 mg/kg after 6 months). Only 9 CsA patients remained at the end of the study. 44 belatacept patients completed the study, & their results are presented here.

**Results:** Mean belatacept treatment duration for these 44 patients was 9.7± 0.4 years. Mean(SD) MDRD cGFR was 70(21) mL/min/1.73m$^2$ at Month 3 & 72(17) mL/min/1.73m$^2$ at the end of the study (Figure). There was 1 acute rejection episode in Year 9 (8-week dosing interval), & there were no deaths or graft losses. From randomization to study end, 82% of belatacept patients had serious AEs, 36% had serious infections, & 18% had malignancies (with no cases of PTLD). From randomization to end of study, 30% of patients missed no infusions, & 16% missed only 1 infusion.

**Conclusions:** While the sample sizes are limited in this self-selecting cohort, data suggest that the profile of belatacept is consistent over nearly a decade. Patients maintained renal function over ~10 years with no new safety findings & high treatment compliance.



GFR=glomerular filtration rate, MDRD=modification of diet in renal disease

## SA-PO1014

**Accuracy of Kidney Failure Risk Equations among Kidney Transplant Recipients** Brad C. Astor,[1,2] Brenda L. Muth,[1] Arjang Djamali.[1,3] *[1]Dept of Medicine, Univ of Wisconsin School of Medicine and Public Health, Madison, WI; [2]Dept of Population Health Sciences, Univ of Wisconsin School of Medicine and Public Health, Madison, WI; [3]Dept of Surgery, Univ of Wisconsin School of Medicine and Public Health, Madison, WI.*

**Background:** Accurate prediction of graft failure among kidney transplant recipients may identify patients at greatest risk and allow improved management and preparation for return to dialysis. Kidney failure risk equations have recently been developed and validated in native chronic kidney disease (CKD), but their utility in transplant recipients is unknown.

**Methods:** We tested the accuracy of the 3-variable (age, sex, estimated glomerular filtration rate) and 4-variable (urinary protein:creatinine ratio) to predict 3-year and 5-year graft survival in a cohort of 1,673 patients who received a kidney transplant at the University of Wisconsin from 1990-2009 and had survived one year post-transplant. C-statistic, net reclassification index (NRI) and integrated discrimination improvement (IDI) are reported. The NRI was calculated for risk groups of <5%, 5-10% and >10% for 3-year survival and <10%, 10-20%, and >20% for 5-year survival.

**Results:** A total of 91 grafts failed within 3 years and 134 failed within 5 years. The 4-variable model resulted in a significantly positive NRI for 3-year survival, but the C-statistics did not differ significantly. The 4-variable model resulted in a higher C-statistic and significantly positive NRI and IDI for 5-year survival.

| | C-statistic (3-variables) | C-statistic (4-variables) | p | NRI | IDI |
|---|---|---|---|---|---|
| 3-year graft survival | 0.7827 | 0.8052 | 0.14 | 7.7% (-2.7, 18.1) | 8.3% (5.2, 11.4) |
| 5-year graft survival | 0.7426 | 0.7746 | 0.01 | 18.4% (7.6, 29.3) | 10.1% (7.4, 12.9) |

**Conclusions:** The accuracy of both kidney failure risk equations was substantially lower in this population of kidney transplant recipients (C-statistics ≤ 0.80) than reported for native CKD populations (C-statistics ≥ 0.90). While the 4-variable equation, with the addition of urinary protein:creatinine ratio, significantly improved risk prediction, additional factors must be considered to provide accurate risk prediction in kidney transplant recipients.

## SA-PO1015

**Effect of Mycophenolate Mofetil Dose on Long-Term Kidney Allograft Function** Karlo K. Mihovilovic, Matija Pavlovic, Bojana Maksimovic, Mladen Knotek. *Clinical Hospital Merkur, Zagreb, HR, Croatia.*

**Background:** Studies have reported significant improvement in kidney function in patients on MMF with lower exposition to calcineurin inhibitors.The optimal long-term MMF dosing in patients maintained on contemporary low-dose calcineurin inhibitors is still undetermined. The aim of our study was to determine effect of MMF dose on kidney function over five years post-transplant.

**Methods:** A cohort of 171 transplant patients with kidney, kidney-pancreas and kidney-liver transplantation was included. Immunosuppression consisted of anti-IL2 or antithymocyte immunoglobulin induction with MMF, calcineurin inhibitors ± steroids. Estimated creatinine clearence (eCrcl) was calculated using Cockroft Gault formula. MMF dose at 1,2,3,4 and 5 years was correlated with eCrcl at respective time point. Univariate and multiple regression analyses were done to test relationship between independent variables and eCrcl. Data are shown as mean±SD, or median with range.

**Results:** 105 patients had kidney transplantation and 58 kidney-pancreas transplantation. Recipients were a mean of 42.3 ± 12.03 years old at the time of transplantation, 63 percent of them were male and all were Caucasians. Donors were a mean of 42.8 ± 16.2 years old. There were 46 living donor transplantations.

| | 1 yr | 2 yrs | 3 yrs | 4 yrs | 5 yrs |
|---|---|---|---|---|---|
| eCrcl (ml/min) | 61.5 (49-74.4) 171 | 68 (53.7-80.5) 169 | 67.8 (53.9-81) 130 | 67 (52.7-79.7) 92 | 72.2 (58-82.1) 61 |
| MMF dose (mg) | 2000 (500-4000) 171 | 2000 (500-4000) 164 | 2000 (500-3000) 123 | 2000 (720-3500) 87 | 2000 (500-3000) 59 |
| Tac. conc. (µg/L) | 7.7 ± 2.9 125 | 7 ± 7.5 123 | 6.1 ± 2.1 87 | 5.8 ± 2.3 53 | 5.1 ± 1.6 28 |
| Cyclo. conc. (µg/L) | 173 ± 54 43 | 127 ± 53 23 | 101 ± 43 41 | 80 ± 30 38 | 77 ± 25 33 |

eCrcl at 1,2,3,4 and 5 years post-transplant positively correlated with average MMF dose ($p<0.01$ for each time point). There was no correlation of eCrcl with tacrolimus or cyclosporin concentration at any time point. In multivariate analysis MMF dose remained strongly positively correlated with kidney function at all time points.

**Conclusions:** Higher MMF dose with lower calcineurin concentration is associated with better long-term renal function and may increase long-term survival of transplanted kidney.

## SA-PO1016

**Are We Reducing Tacrolimus Exposure Adequately after Kidney Transplantation? A 3-Year Analysis of the Mycophenolic Acid Observational REnal Transplant (MORE) Study** Fuad S. Shihab,[1] Ali Olyaei,[2] Anne Wiland,[3] Kevin M. McCague,[3] Larry Chan.[4] *[1]Univ of Utah School of Medicine, Salt Lake City, UT; [2]Oregon State Univ and Oregon Health & Science Univ, Portland, OR; [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [4]Univ of Colorado School of Medicine, Aurora, CO.*

**Background:** It is unclear if tapering of tacrolimus (Tac) exposure in routine practice after kidney transplantation is adequate to minimize calcineurin inhibitor-related nephrotoxicity.

**Methods:** MORE was a prospective, observational study of *de novo* kidney transplant recipients receiving mycophenolic acid (MPA) at 40 US centers, and managed according to local practice. Tac $C_0$ levels and estimated GFR (eGFR, CKD-EPI) were analyzed up to 3 years post-transplant. Tac $C_0$ was graded as low, moderate or high (<6, 6–8 or >8ng/mL) and eGFR analyzed as <60 or ≥60mL/min/1.73m$^2$. Risk of eGFR <60 at 1, 2 or 3 years was analyzed based on Tac $C_0$ at 1 year and was adjusted for living donor, ethnicity, gender, delayed graft function, recipient age, PRA, HLA mismatches, expanded criteria donor, MPA dose at month 1 and CMV serology.

**Results:** 904 patients were analyzed. The % of patients with low/moderate/high Tac $C_0$ was 29%/36%/34% at year 1, 37%/36%/27% at year 2 and 39%/35%/27% at year 3. Incidence of biopsy-proven acute rejection at month 12 was 8.5%, 8.3% and 6.5% (n.s.) with low, moderate and high tac $C_0$. eGFR<60 was present in 55%, 51% and 54% at 1, 2 and 3 years. The adjusted odds ratio (AOR) for eGFR <60 at years 1, 2 and 3 in patients with high vs low Tac $C_0$ was 1.28 (95%CI 0.83-1.96, p=0.263), 1.75 (1.05-2.92; p=0.033) and 1.69 (0.88-3.25, p=0.115), respectively. AORs for eGFR<60 at years 1, 2 and 3 in the high vs moderate Tac $C_0$ groups were 1.24 (0.84-1.84; p=0.282), 1.13 (0.71-1.81; p=0.605) and 1.14 (0.62-2.08; p=0.680).

**Conclusions:** Over a quarter of patients were exposed to high Tac $C_0$ (>8ng/mL) up to 3 years after kidney transplantation, resulting in a lower eGFR at 2 years. Risk of low eGFR may be adversely affected by maintenance of unnecessarily high Tac exposure.

*Funding:* Pharmaceutical Company Support - Novartis

## SA-PO1017

**Pregnancy Outcomes in Kidney Recipients Who Discontinued Mycophenolic Acid Products prior to Conception** Serban Constantinescu,[1] Peter Axelrod,[1] Lisa Coscia,[2] Michael J. Moritz,[3] Vincent T. Armenti.[2] *[1]Temple Univ School of Medicine, Philadelphia, PA; [2]Gift of Life Institute, Philadelphia, PA; [3]Lehigh Valley Health Network, Allentown, PA.*

**Background:** The FDA changed the pregnancy category for mycophenolic acid products (MPA) from C to D in 2007. Transplant centers report discontinuing MPA in female kidney recipients anticipating pregnancy.

**Methods:** Data were collected by the National Transplantation Pregnancy Registry (NTPR) via questionnaires, phone interviews and medical records.

**Results:** 114 pregnancies were conceived on MPA, and in 163 pregnancies MPA was discontinued preconception (69% switched to another agent).

| | MPA exposure during early pregnancy | MPA discontinued preconception | p value |
|---|---|---|---|
| **Maternal Factors** | **n=114** | **n=163** | |
| Unplanned pregnancies | 62% | 19% | <0.001 |
| Transplant-to-conception (yrs) | 4.2±3.6 | 5.4±3.5 | 0.004 |
| Creatinine before pregnancy | 1.3±0.5 | 1.1±0.3 | <0.001 |
| Creatinine during pregnancy | 1.4±0.6 | 1.2±0.4 | 0.003 |
| Creatinine after pregnancy | 1.5±0.9 | 1.2±0.5 | 0.001 |
| Biopsy-proven rejection during pregnancy | 3% | 1% | NS |
| Graft loss within 2 yrs of delivery | 5% | 3% | NS |
| **Outcomes** | | | |
| Livebirth | 43% | 79% | <0.001 |
| Miscarriage | 52% | 19% | <0.001 |
| Stillbirth | 2% | 1% | NS |
| **Livebirths** | **n=50** | **n=133** | |
| Gestational age (wks) | 35.3±3.3 | 35.7±3.5 | NS |
| Birth weight (g) | 2344±753 | 2590±716 | 0.02 |
| **Birth defects** | 14%* | 6% | NS |

* 1 stillbirth with birth defects, not included

Recipients who discontinued MPA preconception had significantly longer transplant to conception intervals and lower creatinine levels before, during and after pregnancy. Pregnancy resulted in significantly higher rate of livebirths and lower incidence of birth defects. Rejection rate during pregnancy and graft loss within 2 yrs of delivery were similar between groups.

**Conclusions:** Pregnancy in kidney recipients who discontinued MPA preconception resulted in a significantly higher rate of livebirths, without an increase in rejection, graft loss or birth defects.

## SA-PO1018

**Differences in Long-Term Kidney Transplantation Outcomes between Hispanic and Non-Hispanic Whites in the United States** Maria Cristina Arce,[1] Colin R. Lenihan,[1] Maria E. Montez-Rath,[2] Wolfgang C. Winkelmayer.[1] *[1]Div of Nephrology, Stanford Univ, Palo Alto, CA; [2]Div of General Medical Disciplines, Stanford Univ, Palo Alto, CA.*

**Background:** For most patients who develop kidney failure, kidney transplantation offers the greatest promise for restoring a healthy, productive life. It is widely known that disparities in long-term outcomes persist among racial and ethnic minorities in the United States, but little is known about the Hispanic minority population.

**Methods:** Using the U.S. Renal Data System, we identified 105,250 Caucasian patients who received their first kidney transplant between 1/1/1996-12/31/2010 and investigated long-term kidney graft survival by Hispanic ethnicity. Death and death-censored graft failure were analyzed using Cox proportional hazards model, stratified by year of transplant, to estimate unadjusted and adjusted cause-specific hazard ratios ($HR_{CS}$) and subdistribution (competing risk analysis) hazard ratios ($HR_{SD}$) with corresponding 95% confidence intervals (CI).

**Results:** A total of 11,003 (10.5%) patients experienced kidney graft failure during 544,257 person-years of follow-up. In the unadjusted analysis, the incidence rate of death-censored graft failure was 2.25/100 person-years in Hispanics versus 1.97/100 person-years in non-Hispanics. The incidence rate of death occurred in 3.04/100 person-years in Hispanics versus 4.13/100 person-years in non-Hispanic whites. In the adjusted analysis, we found that Hispanics undergoing kidney transplantation experienced improved survival (adjusted $HR_{CS}$=0.69; 95%CI, 0.66-0.72) but similar death-censored graft survival ($HR_{CS}$=0.96; 95%CI, 0.91-1.01) compared to non-Hispanic whites. When accounting for competing risks, the graft survival by ethnicity remained similar ($HR_{SD}$=0.99; 95%CI 0.94-1.05). The presence of diabetes and level of education did not modify this association.

**Conclusions:** Few studies have described long-term transplantation outcomes in this rapidly growing minority population burdened with not only socioeconomic challenges but cultural and language barriers as well. Overall, Hispanics were found to have similar kidney graft survival compared to non-Hispanic whites.

*Funding:* Other NIH Support - T32 DK007357-26

## SA-PO1019

**Changes in Graft Survival among Pediatric and Young Adult Recipients, 1992-2010** Bethany J. Foster,[1] Mourad Dahhou,[1] Xun Zhang,[1] Susan M. Samuel.[2] *[1]McGill Univ Health Centre, Montreal, Canada; [2]Alberta Children's Hospital, Calgary, Canada.*

**Background:** Adult kidney transplant recipients had significant improvements in graft survival from the late 1980s to mid-1990s, but only very modest changes thereafter. We aimed to determine if graft failure rates among pediatric recipients changed between 1992 and 2010.

**Methods:** Using United States Renal Data System (USRDS) data, we studied individuals who received a 1st kidney transplant at ≤21 years old between 1992 and 2010. We used Cox models to compare graft failure (death or graft loss) rates in individuals transplanted in 1992-1997 with those transplanted in 1998-2005, and 2006-2010. Models were stratified by age at transplant, and adjusted for sex, race, donor source, age, primary disease, socioeconomic status, and duration of dialysis before transplant.

**Results:** Graft failure rates were significantly lower in more recent time periods compared with 1992-1997. Improvements over time were significantly larger for those <5 years at transplant (interaction p=0.001).

| | 1992-1997 | 1998-2005 | 2006-2010 |
|---|---|---|---|
| **Age <5 years at transplant** | | | |
| **All patients** (n) | 601 | 926 | 630 |
| Graft failures per 100 person-years | 4.7 | 2.8 | 3.2 |
| Adjusted HR [95% CI] | 1.00 | 0.64 [0.52, 0.78] | 0.38 [0.27, 0.56] |
| **Patients with ≥1 year of graft function (n)** | 522 | 860 | 511 |
| Graft failures per 100 person-years | 3.8 | 2.1 | 1.7 |
| Adjusted HR [95% CI] | 1.00 | 0.68 [0.52, 0.87] | 0.52 [0.29, 0.91] |
| **Age ≥5 years at transplant** | | | |
| **All patients** (n) | 4011 | 5960 | 3736 |
| Graft failures per 100 person-years | 7.2 | 5.9 | 4.3 |
| Adjusted HR [95% CI] | 1.00 | 0.78 [0.74, 0.84] | 0.51 [0.46, 0.58] |
| **Patients with ≥1 year of graft function (n)** | 3599 | 5581 | 3033 |
| Graft failures per 100 person-years | 6.8 | 5.7 | 3.9 |
| Adjusted HR [95% CI] | 1.00 | 0.82 [0.76, 0.87] | 0.52 [0.45, 0.61] |

**Conclusions:** Graft failure rates have decreased substantially over calendar time among young recipients.

*Funding:* Clinical Revenue Support

## SA-PO1020

**Renal Transplantation in the Older Populations: 5 Years Single Centre Experience** Asmaa Y.M. Al-Chidadi, Mark Harber. *Centre for Nephrology, Royal Free Hospital Univ College London, Hampstead, London, United Kingdom.*

**Background:** Elderly patients are increasingly being considered for renal transplantation due to the ageing population. However there may be associated short term morbidity and mortality that is more apparent in the elderly.

**Methods:** We reviewed the course of 47 recipients, 65 years or older transplanted between the 1st of January 2008 and the 31st of December 2010. One year patients and graft survival were compared with 367 patients aged 64 years or younger transplanted during the same time period.

**Results:** Survival was significantly higher in the younger group at 97.55% vs. 91.67%, p=0.028. Graft loss was not significantly different between the two cohorts (4.92% vs. 4.17% in the older group, p=0.819). Initial hospitalization was not significantly different between the two groups as well as hospital stay in the first 3 months and the number of admissions in the first year. E-GFR on discharge was significantly higher among the younger cohort 43.26±24.1 vs. 32.22±20.3, p=0.03. E-GFR at one year however did not achieve significance; 52.35±22.25 vs. 46.06 ±21.28 in the older cohort, p=0.077. Delayed graft function was indicated in 60% in the older versus just over 30% in the younger group, p<0.001. On bivariate analysis the mean number of rejection episodes was nearly identical in the 2 cohorts (0.26±0.80 Vs. 0.25±0.48).

**Conclusions:** Perhaps surprisingly the initial length of hospitalization in the first year among the older cohort was only a little different from younger recipients, however there was a significant higher rate of mortality and delayed graft function in the older cohort. The slightly poorer eGFR among the older cohort although it wasn't statistically significant at one year might have been a reflection of allocating more marginal and significantly older donors compared to younger cohort. The significant increase in mortality is an important consideration when listing older patients for transplantation.

*Funding:* Government Support - Non-U.S.

## SA-PO1021

**Long Term (Visit to Visit) Instability Is an Independent Predictor of Progressive Renal Function Loss in Transplant Patients** Francesca Mallamaci, Pasquale Fabio Provenzano, Graziella D'arrigo, Rocco Tripepi, Giovanni Tripepi, Carmine Zoccali. *Clin. Epid. and Physiopath. of Renal Dis. and Hypert., CNR-IBIM, Reggio Calabria, Italy.*

**Background:** Hypertension is an established risk factor for renal function loss in transplant pts but it is unknown whether BP instability is an independent risk factor for the same outcome.

**Methods:** We tested the relationship between long term, visit-to-visit BP variability [expressed in terms of standard deviation (SD)] and the evolution of the GFR over-time (eGFR slope) in an unselected series of 154 clinically stable renal transplant patients followed up for a median time of 3.2 years (IQ range: 2.2-4.9 years). In a sub-sample of 86 pts, we also investigated the association between short term (24h) BP variability (assessed by ambulatory BP monitoring, ABPM) and the same renal outcome.

**Results:** Office BP was on average 131±10 /78±7 mmHg and the visit to visit variability (SD) was 7.1±5.1/5.2±3.2 mmHg. Visit to visit systolic BP (SBP) variability was inversely related to baseline eGFR (rho=-0.21, P=0.007) but was independent of average BP and other classical risk factors. During the follow-up, the eGFR decreased in 64 pts (-2.8±3.4 ml/min/1.73m2/year, range:-20.6 to -0.01) and increased in the remaining 90 pts (3.7±3.2, ml/min/1.73m2/year, 0.01 to 15.6). Overall, there was an inverse relationship between visit to visit SBP and DBP variabilities and renal function deterioration over time (rho=-0.17, P=0.035 and rho= -0.19, P=0.02) and these associations held true also after data adjustment for the average BP and baseline eGFR (partial rho=-0.19, P=0.02 and partial rho=-0.19, P=0.02). Short term systolic and diastolic BP variability was largely unrelated to eGFR slope.

**Conclusions:** Visit to visit BP systolic variability predicts GFR loss over-time in transplant pts. Such an effect is independent of underlying average BP and other risk factors. In contrast short term (24h) variability does not predict renal outcomes. These observations have prognostic and therapeutic implications. Trials aimed at minimizing visit to visit BP variability are needed to establish whether attenuation of visit to visit variability may improve renal outcomes in transplant pts.

*Funding:* Government Support - Non-U.S.

## SA-PO1022

**Communication between Community Nephrologists and the Transplant Centers: A Survey of Nephrologists** Sreedhar Devathi, Ahmad Aswad, Shahed Abbasi, Nasrollah Ghahramani. *Dept of Medicine, Div of Nephrology, PennState Hershey Medical Center, Hershey, PA.*

**Background:** Interactive communication between the primary nephrologist and the transplant center (TC) is crucial to the optimal care of the patient pre- and post- kidney transplant (KT). Ideally, the TC and the nephrologist should discuss the plans for transition of care prior to KT. We examined nephrologists' current practice and experience regarding patient-related communication with the TC.

**Methods:** Invitations were sent to 3180 nephrologists in the eastern US. 822 expressed interest, and 250 were randomly invited to complete a questionnaire about demographics, practice characteristics, and their communication with TC. A total of 216 surveys with complete responses were analyzed. Univariate analysis and stepwise logistic regression were performed.

**Results:** 90% indicated access to an attending physician in the TC to discuss patient-related issues. 50% call the TC about patients they are referring, 57% call to provide updates on new events about listed patients, and 81% to discuss the care of their transplanted patients. 87% are informed in a timely manner when their patient undergoes KT. 79% consider the information they receive from TC about their transplanted patients as adequate. In multivariate analysis, attending at least one yearly transplant-related CME was associated with higher likelihood to call the TC to refer patients (OR:3.77; p<0.0001) and to discuss the care of patients post-KT (OR:3.35; p=0.002). Nephrologists who attended more than 2 national nephrology meetings in a 5-year period were more likely to call to provide updates on listed patients (OR:3.25; p=0.0005). Nephrologists are less likely to call with updates if more than half of their patients are not employed (OR:0.43; p=0.02). Practice in groups of more than 10 increased the likelihood that a nephrologist will call the TC to refer patients (OR:2.30; p=0.03).

**Conclusions:** The majority of nephrologists are satisfied with the communication with the TC. The likelihood of communication is related to participation in continuing educational meetings, the overall composition of the patients and the number of nephrologists in the practice.

*Funding:* NIDDK Support

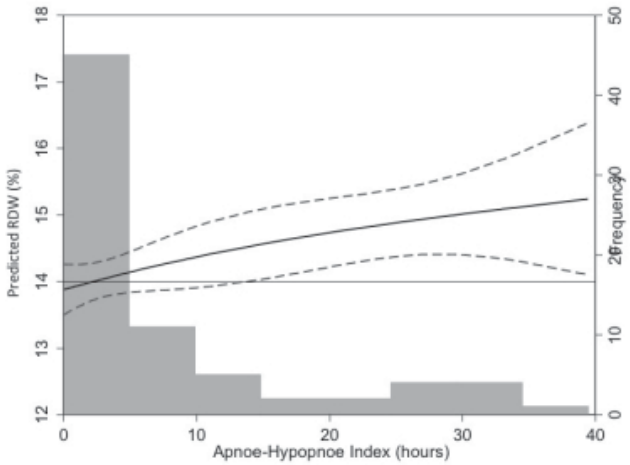
## SA-PO1023

**Red Cell Distribution Width Is Associated with Obstructive Sleep Apnea in Kidney Transplant Recipients** Miklos Zsolt Molnar,[1,2] Akos Ujszaszi,[3] Katalin Fornadi,[3] Marta Novak,[1,3] Istvan Mucsi.[4] *[1]Univ of Toronto, Toronto, Canada; [2]Nephrology and Hypertension, Univ of California, Irvine, Irvine, CA; [3]Semmelweis Univ, Budapest, Hungary; [4]McGill Univ Health Centre, Montreal, Canada.*

**Background:** Red cell distribution width (RDW), a marker of heterogeneity in the size of circulating erythrocytes. It is associated with mortality in various patient populations. We assess the association between Obstructive Sleep Apnea (OSA) and RDW in stable kidney transplant recipients to demonstrate if RDW is associated with intermittent hypoxemia generated by OSA.

**Methods:** Cross-sectional study of 100 kidney transplant patients who underwent polysomnography. Socio-demographic information and data about medication, comorbidity and laboratory parameters were collected.

**Results:** The mean age was 51±13 years, 43% were women, and the prevalence of diabetes was 19%. The mean RDW was 14±1%, and the median (interquartile range) Apnoe-Hypopnoe Index (AHI) was 3 (13). We found an incremental linear association between the AHI and RDW in unadjusted (B=0.027, 95%CI:0.012-0.04; p<0.001) linear regression models.



After adjustment for relevant factors, such as age, gender, eGFR, comorbidity, abdominal circumference, serum albumin, serum CRP, blood hemoglobin and soluble transferrin receptor levels, AHI was still associated with RDW (B=0.022, 95%CI:0.007-0.037; p=0.005).

**Conclusions:** RDW is associated with the apnoe-hypopnoe index, the objectively assessed measure of the severity of OSA. It is tempting to speculate RDW is increased in response to intermittent hypoxemia (a hallmark of OSA). Further studies will need to unravel if the link between RDW and mortality is a reflection of underlying OSA.

## SA-PO1024

**Prevalence of Primary Hyperaldosteronism in Renal Transplantation Is More Common Than Reported** Mahendra V. Govani, Cara Crone, Russell A. White, Alvin Wee, Islam A. Ghoneim, Joseph Whelan, Jay H. Weiss. *Kidney and Pancreas Transplantation, St. Vincent Hospital, Indianapolis, IN.*

**Background:** Despite several case reports of primary Hyperaldosteronism (PHA) diagnosed after renal transplantation, prevalence of this condition has not been studied in detail.

**Methods:** Between 1/1/2009 and 4/31/2013, 186 kidney alone transplants (146DD and 40LD) were performed at our center in 184 patients. On longitudinal follow-up, 7 patients were found to have refractory hypertension (≥3 antihypertensive drugs) and refractory hypokalemia (no potassium (K) restriction and supplemental K>40 mEq/day) without any obvious non-urinary K loss. Plasma aldosterone to renin ratio (PARR) was performed on these 7 patients; at the time all of them were on tacrolimus, and only one patient was on furosemide for CHF due to diastolic dysfunction. Demographics and outcomes were studied, and the patients were followed until 5/31/2013.

**Results:** PARR was >30 in 4 of 7(57.1%) patients (definite PHA), >20 in 2(28.6%) patients (probable PHA), and <5 in the remaining one.

| Variable | PHA Patients (N=6) |
|---|---|
| Age in years, median±SD(range) | 56.4±13.5(47.5-81.4) |
| African-American, n(%) | 3(50) |
| Male, n(%) | 4(67) |
| DM, n(%) | 6(100) |
| SCR, mg/dL, median±SD (range) | 1.5±0.3(1.4-2.2) |
| MDRD GFR, ml/min, median±SD (range) | 47.1±8.5(38.2-59.7) |
| PARR, median±SD (range) | 47±75(23-219) |

All 6 patients with PARR >20 were started on spironolactone; BP improved markedly(>30/15), and it was possible to stop or reduce other antihypertensive drugs in all of them. No patient had adrenal mass on CT scan of abdomen. Patient and graft survival were 100%; median serum creatinine (SCR) and GFR were 1.5 mg/dL and 47.1 ml/min respectively at median follow-up of 28.6±21.6 (range 1.7-53.5) months respectively. The patient with CHF improved (NYHA class III to class I), and furosemide was reduced from 80 to 20 mg/day.

**Conclusions:** Prevalence of PHA (definite and probable) is 3.3% in our cohort. All posttransplant patients with both refractory hypertension and hypokalemia (especially when patients are on tacrolimus) need to be tested for PAH.

## SA-PO1025

**The Change of Circadian Rhythm of Blood Pressure after Successful Kidney Transplantation in End Stage Renal Disease** Myung Hyun Lee, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, Seoul, Republic of Korea.*

**Background:** The change of circadian rhythm after kidney transplantation (KT) is not fully studied. In this study, we prospectively investigated circadian rhythm before and after KT.

**Methods:** We performed 24 hour ambulatory blood pressure monitoring (ABPM) in 48 patients before KT and at 1 year after KT. Circadian rhythm was presented as dipper(ΔSBP ≥10%), non-dipper (0 < ΔSBP ≤10%), and reverse dipper (SBP nocturnal rise) according to the nocturnal reduction of systolic blood pressure (ΔSBP). We evaluated the pattern of circadian rhythm and mean blood pressure before and 1 year after KT.

**Results:** Mean blood pressure did not differ between before and after KT(124±19/81±13 vs.121±10/81±9 mmHg, P>0.05), but the number of anti-hypertensive medication was significantly decreased (1.7±1.2 vs 0.6 ±0.9, P <0.05). Before KT, 41 out of 48 patients (85%) showed abnormal circadian rhythm (non-dipper was 58% (28/48) and reverse dipper was 27% (13/48)) and dipper was only 13% (7/ 48). At 1 year from KT, the abnormal circadian rhythm did not improve in most patients. The proportion of non-dipper did not change compared to before KT and reverse dippers showed increasing pattern (27%(13/48) to 31%(15/48)). However, the proportion of dipper showeddecreasing pattern (15%(7/48) to 10%(5/48)). In individual analysis, 27 out of 28 non-dippers before KT still showed abnormal circadian rhythm (18 non-dippers and 9 reverse dippers at 1 year after KT) and only 1 changed to dipper. In 13 revere dippers before KT, only 2 patients converted to dipper and 11 patients still showed non-dipper(n=6) and reverse dipper(n=5). In 7 dippers before KT, only 2 patients remained in dipper, and another 5 showed abnormal circadian rhythm after KT (4 non-dippers and 1 reverse dipper).

**Conclusions:** In conclusion, overall status of blood pressure improved, but circadian rhythm showed deteriorating pattern at 1 year after transplantation.

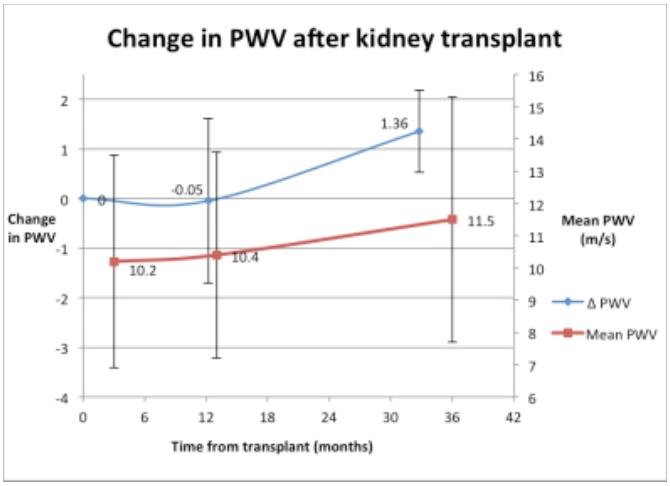
## SA-PO1026

**Initial Stabilization in Pulse Wave Velocity Is Followed by Rapid Worsening One Year after Kidney Transplantation** Fadi Tohme, Eduardo Cruz, Harald M. Stauss, Roberto S. Kalil. *Univ of Iowa Hospitals and Clinics, Iowa City, IA.*

**Background:** Cardiovascular (CV) disease is the leading cause of mortality in advanced CKD and after kidney transplantation (KT). Pulse wave velocity (PWV) is a highly sensitive and non-invasive predictor of CV risk. Our aim was to identify factors associated with a significant change in PWV after KT.

**Methods:** Kidney transplant recipients at an academic center were recruited between 2009 and 2012. Visits occurred at 3, 12, 24 or 36 months after transplant. Patients who did not have at least 2 sequential measurements of PWV were excluded. Data collected at each visit included age, gender, eGFR, blood pressure (BP), weight and carotid-femoral PWV, measured using the SphygmoCor system. Correlations were calculated using nonparametric Spearman's coefficient. Visits at 11-14 months and 21-37 months after transplant were compared using ANCOVA.

**Results:** 56 visits corresponding to 25 patients were included. Mean age was 50 [36-64] years and 72% were males. The absolute value of PWV had a positive correlation with age, SBP and weight (p<0.001) but not with gender (p=0.37), eGFR (p=0.7) or time elapsed from transplant (p=0.154). Sequential change of PWV (Δ-PWV) correlated with the time elapsed from transplant (p=0.01), but not with the change in SBP, eGFR or weight. ANCOVA analysis (using time between sequential measurements as a covariate) showed a significantly lower Δ-PWV in the 11-14 months group compared to the 21-37 months group (p=0.049.



**Conclusions:** PWV, a good marker of CV risk, initially stabilizes after KT but rapidly increase within a year of transplant. Those changes seen in PWV can not be explained by changes in SBP, GFR or weight after transplant. Persistent elevated PWV after 1 year from transplant may play a role in high rates of CV events post KT.

*Funding:* Other NIH Support - NHLBI

## SA-PO1027

**Arterial Stiffness and Changes in QTc Interval in Renal Transplantation Patients** Mehtap Erkmen Uyar,[1] Ugur Bal,[2] Zeynep Bal,[1] Emre Tutal,[1] Burak Say?n,[1] Orhan Guliyev,[1] Begum Erdem?r,[3] Siren Sezer.[1] *[1]Dept of Nephrology, Baskent Univ Faculty of Medicine, Ankara, Turkey; [2]Dept of Cardiology, Baskent Univ Faculty of Medicine, Ankara, Turkey; [3]Dept of Internal Medicine, Baskent Univ Faculty of Medicine, Ankara, Turkey.*

**Background:** Arterial stiffness plays an important role in cardiovascular diseases and is an independent predictor for cardiovascular mortality. The QTc interval has been reported to be increased and to be associated with high-risk ventricular arrhythmias and sudden death. Although renal transplantation improves survival, cardiovascular morbidity and mortality still remain as a significant problem compared with nonrenal populations. The aim of this study is to evaluate the association between the QTc interval changes and arterial stiffness in kidney transplant recipients.

**Methods:** 100 kidney transplant recipients from our renal transplant outpatient clinic were enrolled into the study. All patients were evaluated for clinical and biochemical parameters. Anthropometric and body composition analyses were performed for all patients. Body compositions were analyzed by using the Body Composition Analyzer (Tanita BC-420MA). PWv was determined from pressure tracing over carotid and femoral arteries using the SphygmoCor system. Pre- (retrospectively) and post-transplant electrocardiographic (ECG) evaluations were performed. Each QT interval was corrected for the patient's heart rate using Bazett's Formula.

**Results:** After renal transplantation maxQTc intervals (456.7 ms to 414 ms) and QTdc (54 ms to 34 ms) of all patients were significantly decreased. In post transplantation period, patients with high QTc intervals had significantly higher PWv (p:.009) and higher serum CRP levels (p:.001) than patients with QTc<440 ms. Patients with PWv≥7 m/s had significantly higher maxQTc interval decline than patients with PWv<7 m/s (p:.05, r:-.206).

**Conclusions:** High QTc interval after renal transplantation could be a predictor of arterial stiffness in renal transplant recipients. Electrocardiographic evaluation is seem to be a cheap and reliable way to detect arterial stiffness.

## SA-PO1028

**Anti-PLA2R Monitoring in Relapsing Membranous Nephropathy after Kidney Transplantation** Miguel Seras,[1] David San Segundo,[2] Marcos Lopez-Hoyos,[2] Emilio Rodrigo,[1] Juan Carlos Ruiz,[1] Gema Fernandez-Fresnedo,[1] Angel Luis M. De Francisco,[1] Manuel Arias-Rodriguez.[1] *[1]Nephrology, Univ Hospital Marques de Valdecilla, Santander, Spain; [2]Inmunology, Univ Hospital Marques de Valdecilla, Santander, Spain.*

**Background:** Idiopathic membranous nephropathy (MN) is an important cause of chronic kidney disease with relatively high incidence of relapse after transplantation. The antibodies against the phospholipase A2 receptor (anti-PLA2R) seem to play a key role in the pathogenesis and diagnosis of idiopathic MN. The aim of our study was to know the postransplant evolution of anti-PLA2R in patients with MN.

**Methods:** We selected 13 transplanted patients from our database with histological diagnosis of MN before transplantation and biopsies done under clinical suspicion of relapse or other pathologies after transplantation: 3 of them had histological confirmation of MN relapse, 2 in the first year and one after 5 years. We analyzed the sera of the 13 patients (from a prospectively updated sera bank) with indirect immunofluorescence for anti-PLA2R, on the day before transplantation, after 3 months and on the day of the confirmatory biopsy. We also analyzed the sera of 2 out of 3 MN relapsed cases after the administration of rituximab.

**Results:** 2 of the 3 MN relapses were positive before transplantation, maintaining high titles of anti-PLA2R in the 3rd month and when the biopsies confirming the relapses were done (11 and 13 months respectively). The test became negative after the administration of rituximab in both, with no correlation with proteinuria or clinical outcomes. The 3rd MN relapse was negative before and in the 3rd month after transplantation but became positive after five years, at the moment of histological diagnosis. Only 3 of the 10 patients who did not relapse had positive pretransplant anti-PLA2R, although at low titles, and they became negative in the first months after grafting.

**Conclusions:** Persistently high titles of anti-PLA2R after kidney transplantation are a good predictor of MN relapse. Monitoring after using rituximab is somewhat uncertain, because of no correlation with proteinuria or clinical outcomes.

## SA-PO1029

**The Natural History and Risk Factors Identified for Development of Skin Cancer in Renal Transplant Recipients** Rosa M. Montero,[1] Donald Choi,[2] Christopher Harland,[1] Mona Wahba.[1] *[1]Epsom & St. Helier Univ Hospitals NHS Trust, London, United Kingdom; [2]St. George's Univ of London, London, United Kingdom.*

**Background:** There is no consensus regarding the guidance and recommendations of skin cancer surveillance in Renal Transplant Recipients (RTRs). In this cross-section observational study all RTRs attending skin surveillance clinic were reviewed to determine the natural history of skin lesions occurring in RTRs and identify risk factors associated with development of these lesions.

**Methods:** A total of 125 RTRs were reviewed for diagnosis of de novo skin lesions in nurse led clinics between Sep 2010 and Nov 2011. Immunosuppressive regimen, Age, gender, and skin type were looked as potential risk factors. Spearman's correlation was used for data analysis.

**Results:** 13 Non Melanoma Skin Cancer (NMSC) and 17 Premalignant lesions (PMLs) were found in this cohort. Increasing age significantly correlated with the development of Bowens disease (BD) (p=0.03,r=0.20). Basal cell carcinoma (BCC) had a predilection for male RTRs (p=0.01). A bimodal distribution appeared in both NMSC and PML at <5yrs (mode for BCC: 3 yrs) and >10yrs post 1st renal transplant (RT). RTRs on Prednisolone (P)+ Cyclosporin correlated with development of PML; BD (p=0.01,r=0.246). The combination of P + Tacrolimus (FK) + Mycophenolate Mofetil correlated with the development of BCC (p=0.03,r=0.197). FK+ Azathioprine developed cases of BCC (p=0.03,r=0.194) and Actinic Keratosis (AK) (p=0.03,r=0.19). All of the skin lesions found occurred in those with skin types I-IV with BCC, AK and BD predominantly in the lower skin type (Spearman's correlation p<0.001,p=0.001,p=<0.01, respectively). NMSC and PML develop before 5 years and rise steadily with a similar rate of growth by 20 yrs post 1st RT.

**Conclusions:** Early screening is recommended in view of high detection rates <5yrs of NMSC and PML in RTRs post 1st RT. The high incidence of BCC in <5yrs post 1st RT suggests a role for rigorous pre-transplant screening as BCC are slow growing lesions. Risk factors for NMSC include skin types I-IV, length and combination of immunosuppression. We recommend skin surveillance from 3 years to 20 years should occur as a minimum in RTRs post 1st RT.

## SA-PO1030

**Clinical and Genetic Predictors of Cutaneous Squamous Cell Carcinoma in Kidney Transplant Recipients** M. Lee Sanders, Jason Karnes, Joshua C. Denny, Dan M. Roden, T. Alp Ikizler, Kelly A. Birdwell. *Vanderbilt Univ Medical Center.*

**Background:** Cutaneous squamous cell carcinoma (cSCC) occurs 100 times more frequently in kidney transplant recipients (KTRs) compared to the general population with more aggressive metastasis, a higher rate of recurrence, and an increased morbidity and mortality. We set out to identify clinical and genetic predictors which confer an increased risk for cSCC in this patient population.

**Methods:** We retrospectively identified 78 cSCC cases and 246 controls among Caucasian KTRs using a DNA biobank linked with de-identified electronic medical records (EMRs). We performed a genome wide association study (GWAS) for cSCC with 711,021 single nucleotide polymorphisms (SNPs) using the Illumina OMNI1 and OMNI5 platforms. Logistic regression was used to determine adjusted odds ratios for clinical predictors and SNP effects in a dominant model using SAS and PLINK.

**Results:** Age (OR 1.11 [1.08-1.15], p<0.0001), months of immunosuppression (OR 1.02 [1.01-1.024], p<0.0001) and inhaled tobacco use (OR 2.10 [1.07-4.09, p=0.030) were significant clinical predictors of cSCC development while gender and duration of dialysis were not. No SNPs reached nominal genome-wide significance ($p<10^{-8}$). The two top associations were rs2135976 in *TRPC3*, previously associated with glomerulonephritis and proteinuria (OR 9.13, $p=7.04x10^{-6}$) and rs373610, a nonsynonymous SNP in *OBSCN* previously associated with tobacco addiction (OR 5.90, $p=1.58x10^{-5}$).

**Conclusions:** Age, immunosuppression duration, and inhaled tobacco use were significant predictors for the development of cSCC in an EMR-based cohort of Caucasian KTRs. Genetic analysis suggests a role for the biologically plausible genes *TRPC3* and *OBSCN* in cSCC. Replication and better-powered studies are required to analyze these and other potential genetic predictors.

**SA-PO1031**

**Six Years Posttransplant Follow-Up of the First Case Who Underwent Partial Bladder Transplantation with *En Bloc* Kidney Transplant in a Human** Noriko Sugawara,[1] Tatsuo Asano,[1] Kei Nishiyama,[1] Shoichiro Kanda,[1] Kiyonobu Ishizuka,[1] Masataka Hisano,[1] Hiroko Chikamoto,[1] Yuko Akioka,[1] Rie Yago,[2] Motoshi Hattori.[1] *[1]Dept of Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan; [2]Dept of Urology, Tokyo Women's Medical Univ, Tokyo, Japan.*

**Background:** We have reported a 12-month-old girl who underwent partial bladder transplantation with *en bloc* kidney transplant (Kato et al. Am J Transplant 8: 1060, 2008). Because her native bladder was extremely small, bilateral kidneys were transplanted *en bloc* with their ureters connected to a patch of the donor bladder, which encompassed the bilateral ureterovesical junction (bladder patch technique). That was the first case report of transplanting a vascularized segment of the human urinary bladder.

Although this technique has several potential benefits including preserving the natural anti-reflux mechanism, there are some concerns. One potential concern is the inadequacy of blood supply to the donor bladder wall. Another concern is that the donor bladder wall is denervated and is not likely to contract. So, her bladder function was followed carefully.

**Methods:** She is routinely examined at our facility. At 6 years post transplant, a voiding cystourethrogram(VCUG), magnetic resonance urography, cystoscopy were performed. Here, we report a 6-years posttransplant follow-up of this case, especially focusing on her bladder function.

**Results:** Her native bladder capacity was 3 ml at the time of transplantation. At 6 years posttransplant, VCUG revealed that the bladder capacity increased to 140 ml, though the bladder deformed asymmetric shape. Both native and grafted bladders showed coordinate contractions, voiding pressure was 10 $cmH_2O$ and there were no residual urines. Reflux to the bilateral grafted kidneys was not observed. Cystoscopy revealed that the bladder had an adequate blood flow. She gained normal urinary continence and her serum creatinine was 0.4 mg/dl.

**Conclusions:** In conclusion, the bladder patch technique worked well in this child. Longer follow-up is needed to prove the efficacy of this technique. Also, additional cases with this technique are required to provide more accurate insight on its safety and efficacy.

**SA-PO1032**

**Do Outcomes of Living Donor Renal Allograft Recipients Differ in Patients on Peritoneal or Hemodialysis** Amit Gupta, Harsh Vardhan, Narayan Prasad, Anita Saxena, Raj K. Sharma. *Dept of Nephrology, SGPGIMS, Lucknow, Uttar Pradesh, India.*

**Background:** Studies in deceased donor renal transplantation show that patients on peritoneal dialysis (PD) have reduced incidence of post transplant delayed graft function (DGF) compared to patients on hemodialysis (HD). This study was undertaken to compare the outcomes of ***living donor renal transplantation*** in recipients who were on PD or HD in the pretransplant period.

**Methods:** This is a retrospective observational study.Inclusion criteria were end stage renal disease (ESRD) patients on PD who received living donor renal transplantation betweenJanuary 2002 to December 2011 at our institute and age & gender matched renal transplant patients who were on HD prior to transplantation.

**Results:** 45 patients on PD & HD were included in the study. Both groups were similar in terms of recipient's age & gender, donor's age & gender, diabetic & non diabetic status of the recipients & proportion of different blood groups. Immunosuppression protocol was similar in both groups. Duration of dialysis was significantly longer in PD patients. In the pretransplant period the infectious complications similar (15.4% in PD vs 17.8% in HD). Comorbidities was more in the PD patients but they had better residual renal function.Surgical complications (20% in PD vs 13.3% in HD), DGF (8.8% in PD vs 11% in HD), acute rejections [AR] (13.3% in PD vs 15% in HD) were similar. The mean eGFR values at 1 month (86.1±23.8 vs 77.9±15.3,p=0.22) and at last follow up (60.9±23.5 vs 60.3±18.8,p=0.94) was similar in both groups. Post transplant infections were similar. The mean cumulative patient survival was similar (PD : 84 mths vs HD : 85 mths). The 1, 2, 5 & 8 year patient survival in PD patients was 98%, 93%, 86% & 80% and in HD patients was 100%, 95%, 87% & 80% respectively. The overall mean cumulative death censored graft survival was similar (PD : 83 mths vs HD : 84 mths). The 1,2,5,& 8 years death censored graft survival of PD patients was 98%, 95%, 85% & 75% and in HD patients was 100%, 93%, 84% & 79% respectively.

**Conclusions:** The short & long term outcomes, AR & DGF of renal allograft recipients do not differ with modality of dialysis in living donor renal transplantation.

**SA-PO1033**

**Family Income and the Risk of Rejection, Graft Loss, and Death of Pediatric Renal Transplant Recipients** Gregory H. Gorman,[1] John C. McDonnell,[1] Brent L. Lechner,[1] Robert Nee,[2] Lawrence Agodoa,[3] Kevin C. Abbott.[2] *[1]Pediatrics, Walter Reed National Military Medical Center, Bethesda, MD; [2]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [3]NIDDK, National Institutes of Health, Bethesda, MD.*

**Background:** Socioeconomic status influences health outcomes and access to care. Children with renal transplants have complex medical needs and may be particularly susceptible to income disparities.

**Methods:** Pediatric (<18 yrs old) renal transplant recipients from 1997-2006 were identified from United States Renal Data Service files and follow-up data through 2009 was obtained. Subjects were linked by zip code to median household income from the 2000 U.S. Census. Median family income was stratified by quintiles. Primary outcomes were death, graft loss due to rejection and all causes. Proportional hazards regression and Kaplan-Meier curves modeled risk based on income. Covariates considered included race, etiology of ESRD, age, race, gender, and donor type (deceased-donor vs. living-related).

**Results:** There were 7,781 pediatric renal transplants identified. Maximum follow-up was 11.7 years. 59% were male, 19% black, and congenital/urologic conditions accounted for 50% of ESRD etiologies. Mean age at transplant was 11.4 ± 5.1 yrs. 55% had living-related donors. Median annual household income was $39,359 (IQR $31,187-$51,101.) 1,951 (25%) lost their graft and 442 (5.6%) died. Of graft loss, (4.6%) were due primarily to rejection. In unadjusted regression with the highest income group as the reference, there was a 17% increased risk of mortality (HR 1.17 [95%CI 1.09-1.25; p<0.001]) and a 13% increase in risk of graft loss (HR 1.13 [95%CI 1.1-1.17; p<0.001]) for each successive decrease in income quintile. There was no relationship between graft loss due to rejection and median family income [HR 0.98 [95%CI 0.85-1.14; p=0.78]).

**Conclusions:** Those with the lowest income had increased risk of death and graft loss compared to those with the highest income. Differences in rates of graft rejection are not the primary mediators of this relationship. Policy makers should consider the effect of income when determining benefits for pediatric kidney transplant recipients.

**SA-PO1034**

**Mortality in Patients with a Failed Transplant after a Return to Dialysis** Zhyiar Abdulrahman, Nassim Kamar, Laure Esposito, F. Sallusto, I. Cardeau-desangles, Arnaud Dell Bello, Lionel Rostaing. *Dept of Nephrology, Dialysis, Transplantation, Toulouse Univ Hospital, Toulouse, France.*

**Background:** It is not clear whether mortality increases among those with kidney-allograft failure relative to those who start dialysis but have never received a transplant.

**Methods:** We compared mortality rates and its causes among 136 patients with a failed kidney allograft who returned to dialysis between January 2006 and December 2012 (at Toulouse University Hospital, France) with 532 *de novo* hemodialysis patients who had never received a transplant. Within failed-allograft patients, we also compared mortality rates of those who had lost their graft before or after the end of the first year post transplant, and of those who were or were not on a waiting list for a kidney transplant.

**Results:** Overall mortality was comparable between failed-allograft patients (22.8%) and *de novo* hemodialysis patients (24.1%; $p$=0.79). Mortality rates were also similar between patients who lost their allograft within 1 year post transplant (22.9%) and those who lost their allograft at >1 year (22.8%; $p$ =0.92). Failed-allograft patients who were not relisted for a kidney transplant had the highest mortality rate (40.8%) when compared to those patients who had been relisted (12.6%; $p$=0.0002) and hemodialysis transplant-naïve patients (24.1%, $p$=0.001). The lowest mortality rate (6%) was observed in failed-allograft patients who had a re-transplant when compared to those patients who were still on a waiting list (21.6%) and those who were not relisted (40.8%; $p$=0.0002). The major causes of mortality in the failed-allograft group ($n$=31) were cardiovascular (29%), others are cancer, gastrointestinal complications, and sepsis caused equal mortality rates (13% each). Causes of mortality in *de novo* hemodialysis patients ($n$=128) were similar.

**Conclusions:** Patients with a failed kidney allograft and transplant-naïve patients undergoing *de novo* hemodialysis had equivalent mortality risks and the causes of mortality were similar; the most frequent being cardiovascular. Failed-allograft patients who underwent re-transplantation had the lowest mortality rate regardless of their status vis-à-vis kidney transplantation.

**SA-PO1035**

**Elevated Fibroblast Growth Factor 23 Levels Are Associated with Chronic Rejection and Declining Kidney Transplant Function** Michael E. Seifert,[1,2] Aftab S. Chishti,[3] Myra L. Chiang,[4] David T. Selewski,[5] Debbie S. Gipson,[5] Keith A. Hruska.[2] *[1]Southern Illinois Univ; [2]Washington Univ; [3]Univ of Kentucky; [4]West Virginia Univ; [5]Univ of Michigan.*

**Background:** Chronic rejection (CR) is characterized by cumulative vascular injury that leads to kidney transplant failure. Chronic kidney disease-mineral bone disorder (CKD-MBD) contributes to vascular injury in native CKD, but its importance in CR is unknown. Circulating CKD-MBD factors such as fibroblast growth factor 23 (FGF23) have been associated with remote transplant loss and mortality but not directly with CR. We hypothesized that FGF23 and other biomarkers of CKD-MBD would serve as non-invasive biomarkers of CR.

**Methods:** Preliminary analysis of 26 pediatric kidney transplant recipients enrolled in an ongoing multicenter, case-control study of biomarkers of vascular injury in CR. Subjects with biopsy-proven chronic rejection were assigned to the CR group. Subjects were assigned to the No CR group if a recent biopsy (<6 months prior) revealed no abnormality or estimated glomerular filtration rate (eGFR) was > 90 mL/min/1.73$m^2$ (Schwartz calculation). We measured plasma FGF23, Dickkopf-related protein 1 (Dkk1), and sclerostin (SOST) levels at enrollment using ELISA and correlated levels with eGFR and CR.

**Results:** 10/26 (38%) of subjects had biopsy-proven CR. We detected variable FGF23 levels in the CR group but the mean plasma FGF23 was significantly higher vs. No CR (104 ± 93 pg/ml vs. 47 ± 19 pg/ml, p=0.03). FGF23 levels were inversely correlated with transplant function ($r^2$ -0.365, p=0.02). Using logistic regression we found that for every 5 pg/mL increase in FGF23 the risk for CR increased nearly two-fold, after adjusting for age and gender [OR 1.994 (95% CI 1.725, 5.175)]. FGF23 was a superior biomarker of CR when compared to eGFR [OR 0.737 (95% CI 0.516, 1.053)]. Dkk1 and SOST levels were similar between groups.

**Conclusions:** Plasma FGF23 is inversely correlated with eGFR and is a better non-invasive biomarker for CR. These findings will be further validated as we complete enrollment and analysis for this study. We speculate that FGF23 is a modifiable risk factor for CR that must be explored in a prospective study.

## SA-PO1036

**The Fall in FGF-23 Levels at One Year following Kidney Transplantation Ameliorates Acute Allograft Rejection Risk** Monique E. Cho,[1] William H. Chong,[2] Michael S. Ring,[1] Xiongce Zhao.[3] *[1]Kidney Disease Branch, NIDDK, NIH, Bethesda, MD; [2]Skeletal Clinical Studies Unit, NIDCR, Bethesda, MD; [3]Office of the Director, NIDDK, NIH, Bethesda, MD.*

**Background:** Although increased serum levels of fibroblast growth factor 23 (FGF23) predict progression of CKD and increased mortality risk, no published studies have addressed the role of FGF23 in incident renal transplant (tx) population.

**Methods:** In all 163 kidney and kidney/pancreas transplants performed in our center from 1999 -2007, 82 stored serum samples taken 0-3 months prior to tx (baseline) were available for analysis. Sixty of the 82 samples had repeat serum samples at one yr. We tested the hypothesis that the greater decline in FGF23 levels during the first yr is associated with decreased risk of allograft rejection and favorable allograft function. Because of non-parametric distribution of the data, Kruskal-Wallis test was used to investigate the relationship between FGF23 and renal allograft outcome.

**Results:** The median (IQR) baseline intact FGF23 was 4873 (589, 16041) pg/mL. At one-yr post tx, it decreased to 53 (36, 85) pg/mL, with a median reduction of 3305 (515, 15453) pg/mL. During the mean follow-up of 5.7±2 yrs, there were a total of 31 rejections (77% 1A/B, 23% 2A/B) in 24 patients (87% in the 1st yr). Of the 31 rejection episodes 18 were included in the analysis (6/24 patients did not have FGF23 decline data and those with multiple rejections were treated as one episode). The 5-yr median serum Cr was 1.5 (1.2, 1.8) mg/dL in 70 patients.Patients who experienced rejection had a median FGF23 decline of 1022 pg/mL while those without rejection had a median FGF23 decline of 4804 pg/mL, P=0.037. The baseline or 1-yr FGF23 level was not associated with the rejection risk. Those with greater reduction in FGF23 levels at 1 yr showed a trend for lower serum Cr at 5 yrs. There was no difference in the baseline serum PTH or phosphorus levels in the rejection vs. non-rejection group.

**Conclusions:** While greater FGF23 fall in the 1st yr may be associated with decreased allograft rejection risk, a larger study is needed to determine if FGF23 change independently predicts renal allograft outcome.

## SA-PO1037

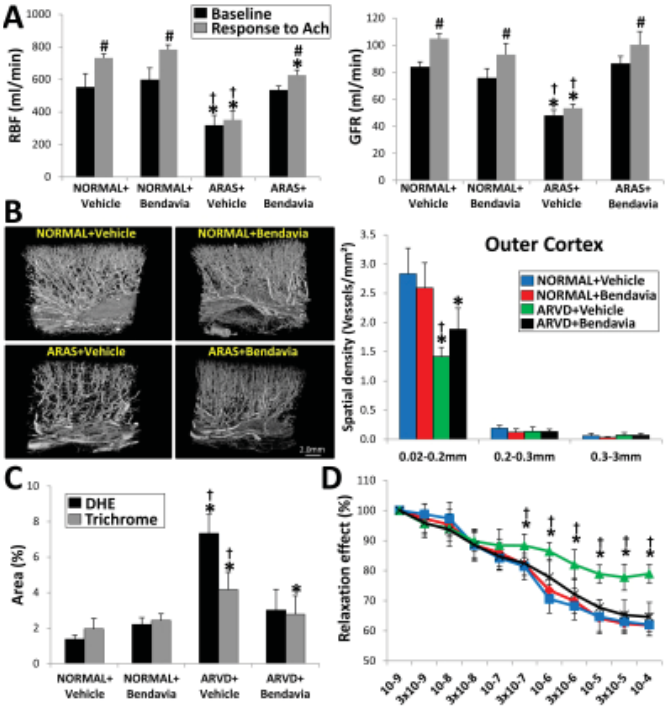
**Chronic Treatment with Bendavia Restores Renal Function in Swine Atherosclerotic Renal Artery Stenosis** Alfonso Eirin, Xin Zhang, James D. Krier, John A. Crane, John R. Woollard, Xiang-Yang Zhu, Stephen C. Textor, Amir Lerman, Lilach O. Lerman. *Mayo Clinic.*

**Background:** Few therapeutic options are available to blunt kidney injury in patients with Atherosclerotic Renal Artery Stenosis (ARAS). Bendavia, a novel tetrapeptide that prevents cardiolipin peroxidation in the inner mitochondrial membrane, improves renal outcomes in swine ARAS when infused adjunctively during revascularization. However, whether chronic treatment with Bendavia alone attenuates stenotic-kidney structural and functional deterioration remains unknown. We hypothesized that daily treatment with Bendavia would attenuate tissue injury and improve renal function in swine ARAS.

**Methods:** Four groups of pigs (n=7 each) after 6 weeks of ARAS or sham were treated for 4 additional weeks with SC injections of Bendavia (0.1mg/kg) or vehicle (5d/week). Single-kidney hemodynamics and function were studied using fast-CT, and microvascular architecture (micro-CT), oxidative stress (DHE), and fibrosis (trichrome) ex-vivo. Renal endothelial function (responses to acetylcholine [Ach]) was studied in vivo (CT) and ex vivo (renal arteries, organ bath).

**Results:** All ARAS pigs developed hypertension (mean arterial pressure=137.4±13.2mmHg). Renal blood flow (RBF) and glomerular filtration rate (GFR) were blunted in ARAS+Vehicle, but improved in ARAS+Bendavia. Loss of small outer cortical microvessels, oxidative stress, and fibrosis were ameliorated in Bendavia-treated pigs. Furthermore, Bendavia normalized renal endothelial function both in vivo and in vitro.

**Conclusions:** Chronic treatment with Bendavia in ARAS pigs improved stenotic kidney hemodynamic and function, and normalized vascular endothelial function in-vivo and ex-vivo. Microvascular loss, oxidative stress, and fibrosis were attenuated in ARAS+Bendavia, uncovering a unique therapeutic potential for Bendavia in restoring renal function in chronic experimental ARAS.



**A:** Single-kidney renal blood flow (RBF), glomerular filtration rate (GFR), and their responses to acetylcholine (Ach). **B:** Representative micro-CT images (left) and spatial density of outer cortical microvessels (right). **C:** Quantification of renal production of superoxide anion [dihydroethidium (DHE)] and tubulointerstitial fibrosis (trichrome). **D:** Endothelial-dependent relaxation of renal arterial segments from the study groups in response to increasing doses of Ach. *p<0.05 vs. NORMAL+Vehicle, †p<0.05 vs. ARAS+Bendavia. #p<0.05 vs. Baseline.

## SA-PO1038

**Mitochondrial Targeted Peptide Attenuate Myocardial Damage in Experimental Atherosclerotic Renovascular Disease** Alfonso Eirin, Xin Zhang, James D. Krier, Xiang-Yang Zhu, Stephen C. Textor, Amir Lerman, Lilach O. Lerman. *Mayo Clinic.*

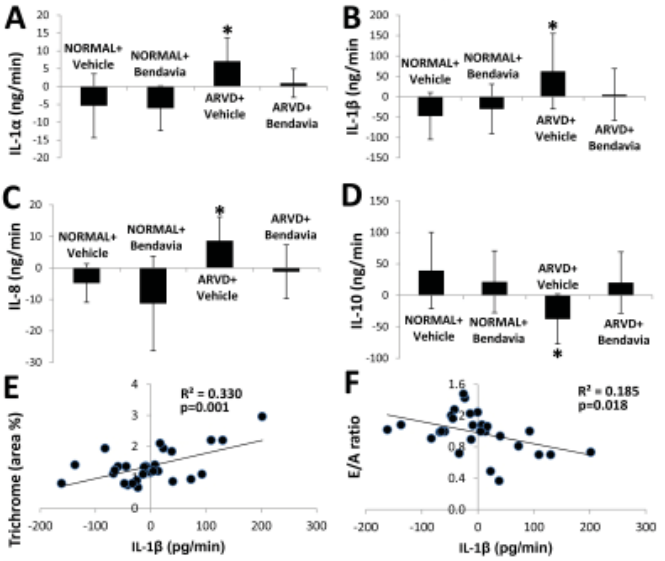
**Background:** Atherosclerotic renovascular disease (ARVD) leads to hypertension and abnormalities in cardiac structure and function, partly due to release of inflammatory cytokines from the post-stenotic kidney. Mitochondrial-targeted peptides (Bendavia) have shown novel reno- and cardio-protective properties in experimental ischemic disease. We hypothesized that chronic treatment with Bendavia would decrease cardiac remodeling and dysfunction in swine ARVD.

**Methods:** After 6 weeks of ARVD (unilateral renal artery stenosis and high-cholesterol diet) or control, pigs were treated for another 4 weeks with Bendavia (0.1mg/kg SC, 5d/week) or vehicle (n=7 each). Single-kidney and cardiac function were assessed by multidetector CT, and myocardial fibrosis by trichrome. Renal vein and inferior vena cava levels of interleukins (IL)1-α, 1β, 8, and 10 were measured by ELISA, and their net release calculated from their gradient.

**Results:** Blood pressure was similarly elevated in both ARVD groups, yet glomerular filtration rate (GFR), left ventricular muscle mass (LVMM), E/A ratio, and myocardial fibrosis normalized only in Bendavia-treated pigs (Table). Release of inflammatory IL was higher in the ARVD+Vehicle and correlated with myocardial fibrosis and diastolic dysfunction, but decreased in ARVD+Bendavia pigs (Figure).

**Conclusions:** Chronic treatment with Bendavia improved stenotic kidney function, and prevented myocardial hypertrophy, fibrosis, and diastolic dysfunction. These effects might be mediated partly by ameliorating renal dysfunction and inflammatory cytokines release, underscoring ubiquitous protective properties of Bendavia in chronic experimental ARVD.

| | NORMAL+ Vehicle | NORMAL+ Bendavia | ARVD+ Vehicle | ARVD+ Bendavia |
|---|---|---|---|---|
| Mean arterial pressure (mmHg) | 82.2±41.6 | 84.4±23.7 | 136.5±5.0* | 138.4±5.8* |
| GFR (ml/min) | 84.0±3.8 | 75.8±6.8 | 48.0±4.0*† | 86.6±11.2 |
| Ejection fraction (%) | 58.5±10.0 | 58.1±4.4 | 60.0±7.0 | 60.8±6.1 |
| LVMM (g/kg body weight) | 1.7±0.3 | 1.6±0.1 | 2.5±0.4*† | 1.8±0.1 |
| E/A ratio | 1.2±0.3 | 1.0±0.1 | 0.7±0.3*† | 1.0±0.2 |
| Trichrome (area %) | 0.9±0.2 | 1.2±0.2 | 2.2±0.5*† | 1.2±0.2 |



Net release of the inflammatory IL1-α, IL1-β, and IL-8 was higher in the ARVD kidney, and decreased in Bendavia-treated pigs (A-C). Anti-inflammatory IL-10 showed an opposite pattern. *p<0.05 vs. Normal; †p<0.05 vs. ARVD+Bendavia. Net release of IL1-β correlated directly with myocardial fibrosis (E), but inversely with diastolic dysfunction (F).

## SA-PO1039

**Renal and Vascular Safety after Renal Denervation Using the Symplicity Catheter in a Porcine Preclinical Model** Stefan Tuney, Robert J. Melder. *Cardiovascular Integrative Sciences, Medtronic Cardiovascular, Santa Rosa, CA.*

**Background:** Renal denervation (RDN) by radio frequency (RF) energy using the Symplicity Flex™ catheter significantly reduces blood pressure in patients with resistant hypertension. Preclinical studies to support the safety of RDN are necessary.

**Methods:** The renal and vascular safety following RDN by RF energy was evaluated quantitatively in normal swine at 7, 14, and 28 days by histological morphometric analysis and blood biochemistry. The success of RDN was confirmed by the significant drop in tissue norepinephrine values measured in the renal cortex. Naïve animals were used as controls for all time points.

**Results:** Histologically, the average circumferential extension of the RF lesion in the arterial media at 7 days was estimated at 28%. Quantitative morphometric analysis of the medial lesion extension confirmed this observation and yielded an average value of 26% (N=415 histological sections). Endothelialization was scored for each histological section semi-quantitatively and showed scores of 4 (>95% of the luminal surface covered by endothelium) for all sections at 7, 14 and 28 days. Quantitative morphometric analysis of endothelialization confined to the areas of RF lesions was performed using CD31 immunohistochemistry and demonstrated that the average percent endothelialization of the lesion area only at 7 days is >99%. Thin caged mural thrombi (completely endothelialized) were noted histologically in 5 out of 54 vessels at day 7 whereas none of the vessels at day 14 of 28 contained any thrombi. Histological assessment of serial kidney sections from all time points (N=1260 sections) failed to demonstrate presence of renal thrombo-embolization, infarction, foreign bodies, hemorrhage, microgranulomas and fibrosis. Furthermore, blood chemistry analysis showed that the treated animals did not develop significant deviations in renal physiological blood parameters (BUN, Creat, Ca, P, Na, K, Cl, BUN/Creat).

**Conclusions:** The data demonstrated that RDN via the Symplicity catheter results in consistent RF lesions with no compromise in vascular integrity, followed by a rapid vascular healing with no downstream anatomical or physiological consequences to the kidney.

*Funding:* Pharmaceutical Company Support - Medtronic, Inc

## SA-PO1040

**Angiotensin-(1-7) Modulates Renal Vascular Resistance through Inhibition of Mitogen-Activated Protein Kinase p38 in Apolipoprotein E Deficient Mice** Sebastian Alexander Potthoff, Lars C. Rump, Johannes Stegbauer. *Dept of Nephrology, Medical Faculty, Univ Düsseldorf, Düsseldorf, Germany.*

**Background:** ApoE KO mice are characterized by increased vasoconstrictor response. Previously, we have shown that chronic Ang-(1-7) treatment ameliorates endothelial dysfunction in apoE KO. However, the impact of Ang-(1-7) on vasoconstrictor response to Ang II is unknown.

**Methods:** To examine the role of Ang-(1-7) in vascular resistance in atherosclerosis, apoE KO and wild type (WT) mice fed on western diet were treated via osmotic minipumps either with Ang-(1-7) (82µg/kg/hr) or saline for 6 weeks. Mas/apoE double KO mice were used to investigate the role of the Ang-(1-7) recepter, Mas.

**Results:** Ang II induced renal pressor response was significantly increased in apoE KO compared to WT mice. Chronic Ang-(1-7) treatment attenuated AngII induced pressor response in apoE KO mice. Accordingly, phospho-MLC20 was increased in preglomerular vessels of apoE KO and reduced after Ang-(1-7) treatment. Ang-(1-7) treatment significantly decreases renal p47phox and urinary isoprostane-8 excretion. In addition, it reduced superoxide production in renal cortext tissue ex vivo. ROS is known to activate the MAPK p38. To test the role of p38-activation, we measured p38-activity and renal pressor response to AngII in the presence of SB203580, a p38-inhibitor. In preglomerular vessels, chronic Ang-(1-7) treatment restored the level of phospho-p38 almost to WT levels. Moreover, administration of SB203580 (5µmol/L) reduced renal pressor response to Ang II in apoE KO but not in Ang-(1-7) treated mice. Hence, chronic inhibition of p38 with BIRB796 (50mg/kg/day) attenuated the increased pressor response to Ang II in apoE KO mice. Chronic Ang-(1-7) treatment did not attenuated AngII induced pressor response nor did it decrease urinary isoprostane-8 excretion in in Mas / apoE double KO mice.

**Conclusions:** In summary, p38 plays a crucial role in regulating renal vascular resistance in apoE KO mice. Moreover, Ang-(1-7) attenuates pressor response to Ang II by reducing p38 activity mediated by reduction in ROS abundance, which is Mas-receptor dependent. Thus, this study reveals a new pathway how Ang-(1-7) modulates vascular function.

*Funding:* Government Support - Non-U.S.

## SA-PO1041

**The Macula Densa (Pro)renin Receptor Functions as an Amplifier of Renin Synthesis and Release** Anne Riquier-brison, Karie G. Villanueva, James L. Burford, Janos Peti-Peterdi. *Dept of Physiology and Biophysics, Univ of Southern California, Los Angeles, CA.*

**Background:** The (pro)renin receptor (P)RR was initially thought to be a new addition to the renin angiotensin system (RAS), but a recent paradigm shift questioned its association with the RAS and suggested new roles for (P)RR in organ development and cell differentiation. Recently, we found (P)RR expression in the basolateral cell membrane and signaling via MAP kinases ERK1/2 and p38 in macula densa (MD) cells which regulate renal hemodynamics and renin. Exogenous renin or prorenin added to the in vitro microperfused juxtaglomerular apparatus (JGA) preparation induced renin release which was inhibited by removing the MD or by the administration of the (P)RR blocker decoy peptide suggesting a role of MD (P)RR in renin control.

**Methods:** Here, we aimed to study the role of MD (P)RR in stimulating renin synthesis in vivo. We established a new mouse model with MD-specific conditional knockout (cKO) of the (P)RR by intercrossing nNOS-CreERT2 and floxed (P)RR mice.

**Results:** At baseline, blood pressure was not affected by removal of MD (P)RR (10 days following tamoxifen induction, SBP=112±9 mmHg in WT, 107±14 mmHg in (P)RR cKO). However, after 1 week on a combined low salt + captopril treatment (in order to challenge the RAS), normalized renin expression in whole kidney homogenates was significantly lower in (P)RR cKO animals (1.00±0.11 in wild type, 0.58±0.09 in (P)RR cKO, p=0.003). Similarly, microsomal prostaglandin E synthase (mPGES-1), a critical element of the MD renin release signaling cascade, was also lower in (P)RR cKO mice (1.00±0.10 in wild type, 0.58±0.08 in (P)RR cKO, p=0.005). A 20% decrease in COX2 expression in (P)RR cKO mice did not reach significance. Renin immunofluorescence confirmed reduced JGA renin expression in (P)RR cKO versus wild-type mice.

**Conclusions:** These results suggest the key role of the MD (P)RR in amplifying renin synthesis in vivo when the RAS is challenged. Also, this study confirmed the direct role and involvement of the (P)RR in the RAS consistent with the original paradigm.

## SA-PO1042

**Renal Distal Cortex Perfusion Reflects Cardiac Function in Chronic Kidney Disease** Arkadiusz Lubas, Robert Ryczek, Jerzy Smoszna, Stanislaw Niemczyk. *Military Institute of Medicine.*

**Background:** Disturbances of renal perfusion deregulate renal tissue oxygenation and nutrition causing the decrease of organ function. Properly preserved cardiac hemodynamic function is a key-factor for maintaining sufficient renal perfusion. The aim of the study was to evaluate a relationship between the renal cortex perfusion and cardiac functional and structural markers in patients with stable chronic kidney disease (CKD).

**Methods:** Twenty six patients (4 F; 22 M; age 50 ±17) with stable CKD (Cre-CKD-EPI 48.8 ±26.5 ml/min/1,73m$^2$) and a history of hypertension or heart failure were enrolled in the study. Serum Creatinine (Cre), Cystatin C (Cys), NT-pro brain natriuretc peptide (NTpBNP), Troponin I (TnI) were tested. Renal function was estimated according to Cre-

and Cys- based CKD-EPI formula. Echocardiographic examination, ABPM, estimation of Intima-Media Thickness (IMT), and mean arterial Perfusion intensity in Color Doppler (PixelFlux, Chameleon Software, Germany) of Total (TCP), Proximal (PCP) and Distal (DCP) renal Cortex were collected.

**Results:** DCP was significantly lower than PCP and TCP (0.071 ±0.66 cm/s vs 0.464 ±0.334 cm/s and 0.273 ±0.188 cm/s; p<0.001). TCP was significantly correlated with age (r=-0.47), Cys (r=-0.43), NTpBNP (r=-0.48), Cys-CKD-EPI (r=0.43), IMT (r=-0.43) and SBP (r=0.42). PCP was associated with age (r=-0.47), Cys (r=-0.50), Cre (r=-0.43), NTpBNP (r=-0.45), Cys-CKD-EPI (r=0.48), IMT (r=-0.42) and SBP (r=0.43). Whereas, only DCP was significantly correlated with left ventricle hemodynamic parameters: stroke volume (LVSV) (r=-0.59); cardiac output (LVCO) (r=-0.53), cardiac index (LVCI) (r=-0.56). In addition, DCP was associated with left ventricular mass index (LVMI) (r=-0.43) and NTpBNP (r=-0.45). In multiply stepwise regression analysis model (TnI, NTpBNP, Cre-CKD-EPI, Cys-CKD-EPI, LVEF, LVMI, LVSV, LVCO, LVCI, IMT and MAP) NTpBNP, LVCO and Cys-CKD-EPI independently influenced DCP ($R^2$=0.66, p=0.001).

**Conclusions:** Renal cortical perfusion is significantly associated with cardiac function in CKD patients. Ultrasound measurement of renal perfusion should be considered as a new tool in diagnosing cardio-renal interactions.

*Funding:* Clinical Revenue Support

## SA-PO1043

**Beraprost Sodium Suppresses Progression of Chronic Renal Failure by Protecting Renal Capillary Endothelial Cells and Improving Renal Hypoxia in Glomerulonephritis Rats** Shinichi Yamaguchi, Yasufumi Goto, Nahoko Sato, Hajimu Kurumatani, Mitsuko Miyamoto, Masateru Yamada. *Pharmaceutical Research Laboratories, Toray Industries Inc., Kanagawa, Japan.*

**Background:** Beraprost sodium (BPS), a chemically stable prostacyclin analog, has been reported to suppress the progression of chronic renal failure (CRF) in glomerulonephritis (GN) rats (Kidney Week 2012). Also, an international P-IIb/III study of BPS using a renal composite endpoint is on-going in Asia (China, Hong Kong, Japan, Malaysia, Republic of Korea, Taiwan and Thailand). In order to clarify the mechanism of the suppression of CRF progression, we examined whether BPS protects renal capillary endothelial cells and improves renal hypoxia in GN rats.

**Methods:** GN was induced to rats by injecting anti-glomerular basement membrane antibody. BPS administration (0.6mg/kg/day, p.o.) was started from day 15 after GN induction when serum creatinine levels were increased significantly. Glomerular flow rate (GFR) was measured by inulin clearance method. The number of renal capillary endothelial cells was quantitatively measured by immunohistochemistry with anti-aminopeptidase P antibody-positive area. Renal hypoxic region was evaluated by immunohistochemistry with anti-pimonidazole antibody-positive area.

**Results:** At day 15 after GN induction, GFR in GN rats was significantly decreased to 57% of normal rats, and further decreased to 11% at day 50. In BPS-treated GN rats, the decrease in GFR was completely inhibited until day 50. Anti-aminopeptidase P antibody-positive area in GN rats was decreased to 60% of normal rats at day 15, and further decreased to 44% at day 50. The decrease in the number of renal capillary endothelial cells was significantly prevented in BPS-treated GN rats. Furthermore, the anti-pimonidazole antibody-positive area was increased in GN rats at day 50. And, the increase in renal hypoxic region was also prevented by BPS administration.

**Conclusions:** In this study, BPS inhibited the decrease of GFR, protected renal capillary endothelial cells and improved renal hypoxia associated with CRF in GN rats. Therefore, it is suggested that the improving effect of BPS on renal hypoxia contributes to the suppression of CRF progression.

## SA-PO1044

**Renal Vein Inflammatory and Injury Biomarkers Are Associated with Net Renin Release and Persist Despite ACE/ARB Therapy in Human Atherosclerotic Renal Artery Stenosis (ARAS)** Sandra Herrmann, Ahmed Saad, Alfonso Eirin, Lilach O. Lerman, Stephen C. Textor. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

**Background:** ARAS is known to reduce renal blood flow(RBF) and induce renin release, but the relationships between tissue inflammation and injury and renin release are poorly understood. The purpose of this study was to examine the renin release and renal injury as reflected by systemic and renal vein(RV) levels of the neutrophil gelatinase associated lipocalin(NGAL) and the inflammatory cytokines TNF-α and MCP-1 which are induced in inflammation and ischemia.

**Methods:** Inpatient studies were performed in ARAS(n=39), with more than 60% occlusion, or in essential hypertensives(EH)(n= 32), during fixed Na+ intake and ACE/ARBRx. We measured IVC and RV levels of NGAL,MCP-1 and TNF-α. Plasma renin activity(PRA) was measured and net contribution of renal vein renin(RVR) was determined as(Renal vein PRA-IVC PRA)/IVC PRA X 100%. RBF was measured with multidetector CT and GFR by iothalamate clearance.

**Results:** Renal blood flow, perfusion, and GFR were reduced in the STK. Renal vein levels of NGAL, TNF-α and MCP-1 were higher in ARAS than EH (Table). Net renin contribution was elevated in the STK and correlated with IVC NGAL (r=0.5, p=0.02) and MCP-1 (r=0.4, p=0.02) levels in the STK but not with TNF-α.

**Conclusions:** Occlusive renovascular disease triggers pressor mechanisms including renin release. These results demonstrate an association of net renin contribution of the STK and activation of inflamatory and injury pathways, despite therapeutic blockade of the renin-angiotensin system(RAAS). We interpret these data to indicate that RAAS blockade alone fails to inactivate inflammatory injury in this condition that likely requires additional anti-inflammatory measures to restore post-stenotic kidney function.

| | | ARAS | | |
|---|---|---|---|---|
| | EH | Stenotic Kidney | Contra-lateral Kidney | P value |
| Net Renin Contribution(%) | 23.1±36.2 | 86.42± 98.6* | 23.9±52.2* | 0.0005 |
| RV NGAL(ng/mL) | 66.9±37.5 | 134.1±52.3* | 129.7±48.3* | <0.0001 |
| RV MCP-1(pg/mL) | 152.8±72.1 | 188.4±67.6* | 171.7±68* | 0.05 |
| RV TNF-α (pg/mL) | 4.6±4.3 | 16.6±26.5* | 11.5±8.2* | <0.0001 |
| IVC NGAL(ng/mL) | 83.5±46.8 | 121.1±55.5* | | <0.027 |

P≤ 0.05 versus EH.

## SA-PO1045

**Contrast-Enhanced Ultrasound Using Perflubutane Microbubble Agent Is Useful to Evaluate the Degree of Tubulointerstitial Injury** Kayori Tsuruoka, Takashi Yasuda, Tsutomu Sakurada, Sayuri Shirai, Yugo Shibagaki, Kenjiro Kimura. *Div of Nephrology and Hypertension, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan.*

**Background:** Although we evaluate kidney function mostly by glomerular filtration rate, the degree of tubulointerstitial injury (TII) is more predictable of renal prognosis, but is harder to assess.We have reported that kidney contrast-enhanced ultrasound (CEUS) using Perflubutan is useful to evaluate renal microcirculation inpatients with chronic kidneydisease (CKD). To evaluate the possibility of assessing TII by CEUS, we reexamine the result of our previous study, by comparing CEUS parameters with kidney functional and histological findings.

**Methods:** We examined the parameters of CEUS in total of 23 CKD patients who underwent kidney biopsy. We first obtained the data of PSV (peak systolic velocity), EDV (end diastolic velocity), RI (resistive index) using color Doppler. For CEUS, we administered bolus i.v. (0.0075mg/kg) of perflubutane from median vein, then flushed with saline and recorded the data for ten minutes. We evaluated the contrast intensity using image analysis software, and drew a time intensity curve (TIC). Percutaneous kidney biopsy was obtained within one month after a CEUS and calculated the degree of tubuointerstitial injury.

**Results:** In patients with CKD, the time to reach the peak was delayed, peak intensity was low, intensity decreased earlier, and TIC was gentle, compared to those in patients with normal renal function.Because the change in the first 3 seconds from the start of cortical enhancement was remarkable, we assessed the slope of the TIC during this 3 seconds (CS-3 slope) that represents the intensity of the rising gradient. CS-3 slope had a strong correlation with the degree of tubulointerstitial injury (r=0.70, p<0.0001), and a mild correlation with eGFR (r=0.48, p=0.022). By multivariate analysis, CS-3 slope had significant correlations with RI, PSV, EDV.

**Conclusions:** Contrast-enhanced kidney ultrasound with perflubutane may be a useful tool to assess the degree of tubulointerstitial injury.

## SA-PO1046

**Involvement of ACE and ACE2 in Kidney and Cardiac Dysfunction in Rats with Heart Failure** Ravit Cohen,[1] Hoda Awad,[1] Niroz Abu-saleh,[1] Zaher Armaly,[2] Zaid Abassi.[1,3] *[1]Physiology, Faculty of Medicine, Technion, Haifa, Israel; [2]Nephrology, EMMS, Nazareth Hospital, Nazareth and Galilee Medical School-Bar Ilan Univ, Zafad, Israel; [3]Rambam Medical Center, Haifa, Israel.*

**Background:** The role of Angiotensin II (Ang II) in the pathogenesis of CHF has been well established. However, the involvement of Angiotensin 1-7 (Ang 1-7) and ACE2 in this phenomenon is largely unclear. This study examined (a) Expression of ACE and ACE2 in the renal and cardiac tissues of CHF rats, and (b) Acute and chronic renal and cardiac effects of Ang 1-7, AVE0991 (Ang 1-7 agonist), and A779 (Ang 1-7 antagonist) in these rats.

**Methods:** CHF was induced by surgical creation of aorto-caval fistula. ACE and ACE2 immunoreactivities were determined in the renal and cardiac tissues of CHF rats and their sham controls. In the acute protocol, the effects of incremental doses of Ang 1-7, AVE0991, or A779 on glomerular filtration (GFR), renal plasma flow (RPF), urinary flow (V), urinary sodium excretion (UNaV), and urinary excretion of cyclic GMP (UcGMP) were determined in these rats. In the chronic protocol, the effects of 4-week treatment with the above described compounds on kidney function and cardiac hypertrophy were evaluated in these animals.

**Results:** ACE and ACE2 immunoreactivities in the heart and kidney were ~2 fold higher in CHF rats. Acute infusion of either Ang 1-7 or AVE0991 at a high dose into CHF rats evoked significant increases in V, UNaV, GFR and RPF along enhanced UcGMP. In the chronic protocols, untreated CHF rats displayed lower cumulative V and UNaV than their controls. Chronic administration of Ang 1-7 and AVE0991 exerted significant diuretic and natriuretic effects in CHF rats, but not in sham. Serum Cr and Aldo levels were significantly higher in vehicle-treated CHF rats. Treatment with Ang 1-7 and AVE0991 reduced these parameters. Noteworthy, chronic administration of Ang 1-7 to CHF rats caused reduction of cardiac hypertrophy.

**Conclusions:** This study demonstrates that ACE and ACE2 are activated in CHF. Upregulation of ACE2 and Ang 1-7 with their beneficial actions may compose a compensatory response in face of the deleterious classic RAAS to prevent worsened renal and cardiac dysfunctions.

## SA-PO1047

**Long-Term Administration of Type-I Interferon Leads to Premature Atherosclerosis** Yanpeng Diao, Pui Lee, Rajesh Mohandas, Mark S. Segal. *Medicine, Univ of Florida, Gainesville, FL.*

**Background:** Disease states such as SLE, CMV, and HIV are associated with elevated type I interferon (IFN-I) and increased cardiovascular risk. We have demonstrated that IFN-I has detrimental effects on endothelial progenitor cells that could contribute to the atherosclerosis (AS). However, the relationship between IFN-I and smooth muscle progenitor cells (SMPC), cells derived from the bone marrow that can differentiate into mature SMC, has not been determined. We hypothesized that IFN-I could induce premature AS by increasing the number of SMPC in the bloodstream and increasing the number of immature SMC within the vasculature.

**Methods:** In vitro, SMPC isolated from wild-type (WT) and IFN receptor knock-out (IFNR-KO) animals, were cultured in medium plus or minus IFN-1. In vivo, two mice models of long-term IFN-I exposure (electroporation of an IFN-I plasmid, or Q 3 day IFN-I i.p. injection for 3 months) were studied and the number of SMPC and degree of AS were analyzed.

**Results:** The number of SMPC from WT mice was significantly increased when cultured in medium plus IFN-I. However, IFN-I had no effect in the SMPC from IFNR-KO mice. Increased SMPC numbers were also observed in mice treated with or that expressed IFN-I. In addition, atherosclerotic-like lesions were found in the arterial wall in WT mice expressing IFN-I. Within the lesions we observed CD34+/SM α-actin+ expressing cells.

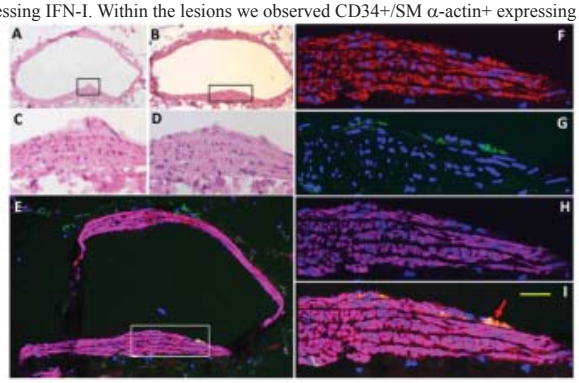

**Figure:** Atherosclerosis plaque-like lesion apparent in IFN-I treated mice. The aorta of mice whose gastrocnemius muscle were transduced with an IFN-I expressing plasmid were examined by H&E and confocal analysis, 3 months after transduction. Shown are low (20X, **A&B**) and high (40X, **C&D**) magnifications of the H&E stain from cross sections of the aortic bifurcation. Plaque-like lesions (**A&C**) and thickening of the vessel walls (**B&D**), indicated by the black box, were seen in IFN-I treated mice at much higher frequency (p=0.011) than in control mice. Immunohistochemical stain (with anti-smooth muscle(SM)-α-actin (red), anti-CD34 (green) and anti-SM myosin heavy chain (purple)) of an adjacent section to **B** was examined under low (20X, **E**) and high (63X, **F-I**) magnification by confocal analysis. A yellow, immature SMC, a cell that expresses SM-α-actin (red) and CD34 (green), but does express SM-MHC (purple), is indicated by the red arrow in I. Bar=25 μm.

These cells did not express SM myosin heavy chain, suggesting that they were immature SMC.

**Conclusions:** For the first time we demonstrated that elevated IFN-I levels could lead to an atherosclerosis-like lesion. In concert with our previous work, this work suggests a complex interplay between the bone marrow, circulating cells, and the vessel wall leading to IFN-I mediated atherosclerosis. This has profound implications for cardiovascular disease in a number of disease states.

## SA-PO1048

**Aryl Hydrocarbon Receptor Plays a Crucial Role for Uremic Toxin-Induced Vascular Inflammation** Shunsuke Ito,[1,2] Yoshiharu Itoh,[2] Masayuki Yoshida.[1] *[1]Tokyo Medical and Dental Univ; [2]Kureha Corporation.*

**Background:** Indoxyl sulfate has been know as one of the major components of uremic toxin in chronic kidney disease patients. The aryl hydrocarbon receptor (AhR) is a ligand-inducible transcription factor known to mediate the toxic effects of numerous environmental contaminants including indoxyl sulfate. In the present study, we investigated a potential role of AhR in indoxyl sulfate-induced leukocyte-endothelial interaction.

**Methods:** Human umbilical vein endothelial cells (HUVEC) were transfected with siRNA of AhR (siAhR) and then treated with indoxyl sulfate for 20 h, followed by stimulation with TNF-α for 4 h. Leukocyte (HL-60) adhesion assay was carried out under physiological flow condition. Protein expression and phosphorylation was evaluated by western blotting. Reactive oxygen species (ROS) production was investigated with CM-$H_2$DCFDA staining.

**Results:** siAhR significantly decreased indoxyl sulfate-enhanced leukocyte adhesion. Western blotting analysis revealed that siAhR abrogated indoxyl sulfate-enhanced expression of adhesion molecule such as E-selectin. To our surprise, though indoxyl sulfate enhanced activation of JNK and NF-κB, siAhR did not suppress their induction. siAhR did not affect indoxyl sulfate-induced ROS production. To assess the functional role of AhR in the indoxyl sulfate stimulated E-selectin gene induction, we conducted luciferase promoter assay. We found that the promoter region of E-selectin, corresponding to -153 to -146 bps, was essential for the effect of indoxyl sulfate mediated by AhR. Because the indoxyl sulfate response region is similar to AP-1 response element and cAMP response element (CRE), we investigated which transcription factors were activated by indoxyl sulfate. Mutation in the indoxyl sulfate response region to AP-1 response element did not affect indoxyl sulfate-induced E-selectin promoter activity, however, mutation to CRE decreased it. We also found that indoxyl sulfate induced AP-1 transcriptional activity but not that of CRE.

**Conclusions:** Our data suggest an important role for AhR in indoxyl sulfate-enhanced leukocyte-endothelial interaction and provides a novel mechanistic insight into the CKD-related vascular inflammation.

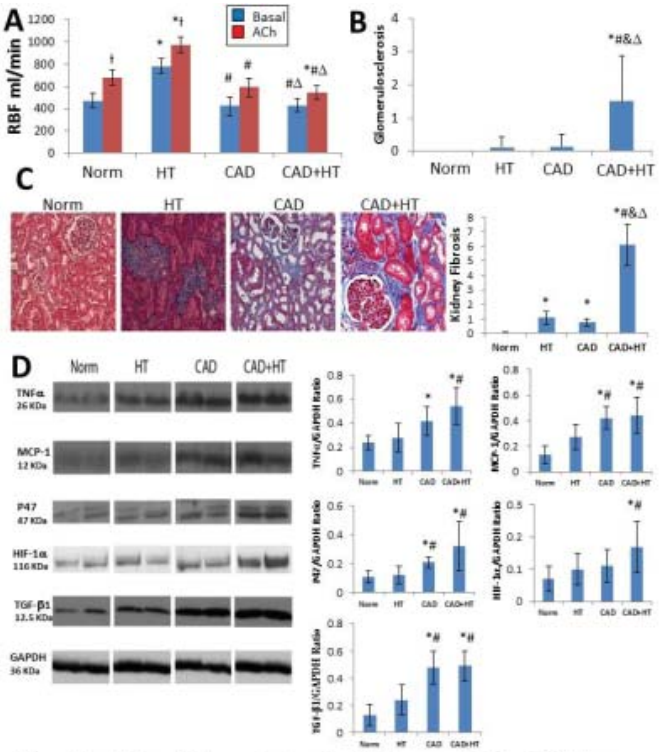
**Experimental Coronary Artery Disease Accelerates Kidney Fibrosis in Hypertensive Swine** Dong Sun, Alfonso Eirin, Xiang-Yang Zhu, Xin Zhang, John A. Crane, John R. Woollard, Amir Lerman, Lilach O. Lerman. *Mayo Clinic.*

**Background:** Patients with coronary artery disease (CAD) often have hypertension (HT). Cardiac dysfunction can impair kidney function, but if CAD aggravates renal injury is unknown. We hypothesized that CAD elicits kidney inflammation, which is exacerbated by HT.

**Methods:** Domestic pigs were randomized to normal, CAD, renovascular HT or CAD + HT (n=7, each). Cardiac and non-stenotic kidney function were measured by multidetector CT. Renal fibrosis and glomerular score were assessed by trichrome staining. Tumor necrosis factor (TNF)a, monocyte chemoattractant protein (MCP)-1, p47, hypoxia inducible factor (HIF)-1a and transforming growth factor (TGF)-b1 expressions were analyzed by western blotting.

**Results:** Mean arterial pressure increased in both HT and CAD+HT, and serum creatinine was elevated in CAD, HT and CAD+HT. Urine protein increased significantly in CAD+HT compared to normal and CAD. The levels of isoprostane were increased in CAD and CAD+HT compared to normal and HT. Compared with HT, basal renal blood flow (RBF) and cortical perfusion decreased in CAD and the non-stenotic kidney of CAD+HT, but their response to acetylcholine (ACh) was blunted only in CAD and CAD+HT. Basal medullary perfusion was similar among the four groups, but its response to Ach was blunted only in CAD+HT. MCP-1, p47 and TGF-b1 expressions were elevated in both CAD and CAD+HT compared with normal and HT, whereas TNFα and HIF-1a were increased only in CAD+HT than normal and HT. Furthermore, both glomerulosclerosis and fibrosis increased synergistically in CAD+HT compared to normal, CAD and HT (Figure).

**Conclusions:** CAD augments inflammation and increases systemic and renal oxidative stress and synergistically interacts with HT to impair RBF and increase kidney fibrosis. This interaction may contribution to the increased incidence of renal failure seen when CAD and HT coexist.



**A**-Renal Blood Flow; **B**-Glomerulosclerosis; **C**-Trichrome staining ; **D**-Western Blotting. $^{*}P<0.05$ compared with Norm; $^{\#}P<0.05$ compared with HT; $^{\&}P<0.05$ compared with CAD; $^{\dagger}P<0.05$ compared with baseline, $^{\Delta}P<0.05$ for synergistic interaction CAD*HT. Norm=Normal; HT=Hypertension; CAD=Coronary Artery Disease.

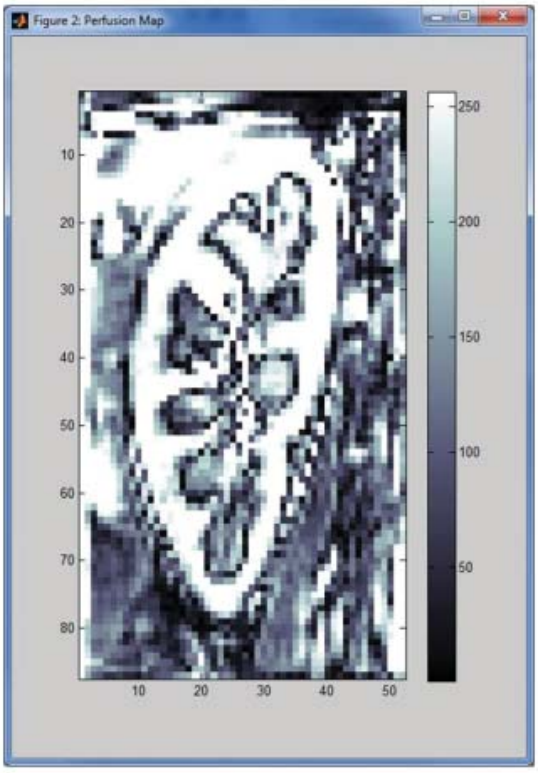
**Reproducibility of Renal Perfusion Measurements Using Arterial Spin Labelling MRI – A Healthy Volunteer Study** Keith Gillis,[2] Christie McComb,[2] Scott Morris,[2] Christian Delles,[2] Patrick B. Mark.[2] *[1]Glasgow Renal and Transplant Unit, Western Infirmary Glasgow, Glasgow, United Kingdom; [2]Univ of Glasgow, Glasgow, United Kingdom.*

**Background:** Accurate assessment of renal perfusion is a crucial part of measuring kidney function and allows assessment of renal hemodynamics in health and disease. Arterial spin labelling magnetic resonance imaging (ASL MRI) is a novel non invasive method of measuring renal function using paramagnetic properties of blood as endogenous contrast. We studied the reproducibility of ASL MRI in normal volunteers.

**Methods:** ASL MRI was performed in 12 healthy volunteers on 2 occasions 4-28 days apart on a 3 Tesla MRI scanner along with measurement of routine serum biochemistry. A flow sensitive alternating inversion recovery perfusion and true fast imaging with steady precession sequence (FAIR True-FISP) was utilised to obtain 5 kidney images on each occasion. Cortical and whole kidney perfusion was then calculated on 24 kidneys on 2 visits using automated analysis software.

Automated analysis of ASL MRI images



**Results:** All subjects (5 male, mean age 44 years) completed 2 ASL MRI studies. Mean estimated glomerular filtration rate was 98.3 ml/min by CKD-EPI formula. Mean cortical perfusion (CP) on visit 1 was 321 ml/min/100g whilst on visit 2 was 336ml/min/100g. Whole kidney perfusion (WKP) was 227ml/min/100g on visit 1 and 230ml/min/100g on visit 2. There was no significant difference between perfusion values measured in visit 1 and visit 2 (CP p=0.167; WKP p =0.659). Bland Altman plots showed no systematic bias when comparing perfusion measured at each visit, whilst the mean difference between visits was 13ml/min/100g for CP and 2.6ml/min/100g for WKP.

**Conclusions:** ASL MRI provides a repeatable method of measuring renal perfusion in healthy volunteers. Further research is required to determine if this is also the case in renal impairment, and if findings correlate with renal function.

**SA-PO1051**

**Influence of Klotho Gene Polymorphisms on Vascular Klotho Expression and Cardiovascular Disease** Javier Donate,[1] Rafael Martínez,[2] Ernesto Martín,[1] Carmen Mora,[1] Mercedes Muros,[3] Violeta Cazaña,[1] Juan F. Navarro-Gonzalez.[1,4] *[1]Research Unit, Univ Hospital Ntra. Sra. de Candelaria, Santa Cruz de Tenerife, Spain; [2]Cardiac Surgery Service, Hospita Universitario de Canarias, La Laguna, Spain; [3]Clinical Analysis Service, Univ Hospital Ntra. Sra. de Candelaria, Santa Cruz de Tenerife, Spain; [4]Nephrology Service, Univ Hospital Ntra. Sra. de Candelaria, Santa Cruz de Tenerife, Spain.*

**Background:** Klotho protein has been associated with beneficial effects on cardiovascular (CV) health. The aim of our study was to analyze the relationship between Klotho gene polymorphisms, mRNA expression levels in the vascular wall and the presence of vascular disease.

**Methods:** We analyzed three single nucleotide polymorphisms (SNPs) of *Klotho* locus [F352V (rs9536314) (exon 2), G-395A (rs1207568) (promoter) and C1818T (rs564481) (exon 4)] in 111 patients undergoing coronary or valve replacement surgery. Gene expression studies were performed in fragments of thoracic aorta.

**Results:** G-395A polymorphism is related to Klotho levels in vascular tissue: Klotho mRNA levels were significantly lower in allele A carriers as compared with homozygous carriers of the G allele [0.19 ± 0.1 vs. 0.97 ± 0.17 (log relative units), P<0.0001]. These differences were not observed for the other two polymorphisms. When comparing the vascular klotho expression levels with clinical characteristics of patients, we observed a higher incidence of coronary artery disease (CAD) in subjects with lower mRNA Klotho expression (P=0.06). However, the G-395A polymorphism was not related with the incidence of CAD. By contrast, CAD and atherosclerotic disease were more frequent in patients carrying the minor allele of the F352 polymorphism (77.9%, P=0.08 and 89.8%, P=0.01, respectively). Finally, the incidence of valve calcification was higher in homozygous carriers of the C allele of C1818T polymorphism compared to carriers of the T allele (43% vs 19%, P=0.01).

**Conclusions:** Polymorphisms of the Klotho gene may influence tissue expression levels of this protein as well as may be related to the incidence of atherosclerotic vascular disease and valvular calcification.

**SA-PO1052**

**Protamine Sulfate and Hyaluronidase Reduce the Size-Selectivity, but Not the Charge-Selectivity, of the Rat Glomerular Filtration Barrier In Vivo** Kristinn Sverrisson, Josefin Axelsson, Anna Rippe, Bengt Rippe. *Dept of Nephrology, Clinical Sciences, Lund, Sweden.*

**Background:** The proteinuric actions of protamine sulfate (PS) have classically been, at least partly, attributed to alterations of the negatively charged glomerular endothelial glycocalyx (GC). To investigate whether the charge-selective properties of the glomerular filtration barrier (GFB) would be altered by PS we assessed the glomerular sieving of conventional, uncharged, polydispersed Ficoll (n-Ficoll) compared to charge modified, conformationally intact, anionic (carboxymethylated) Ficoll (a-Ficoll) before and after systemic infusions of PS in rats. For comparison we also investigated the impact of hyaluronidase (Hyase), postulated to partially degrade the glomerular GC, on GFB permeability.

**Methods:** In anaesthetized Wistar rats blood access was achieved and the left ureter was cannulated for urine collection. Rats were infused with either n-Ficoll or a-Ficoll before and during systemic infusions with either PS or Hyase in doses that minimally affected systemic blood pressure or the glomerular filtration rate. Plasma and urine samples were taken repeatedly and analyzed by high performance size exclusion chromatography (HPSEC) for assessing glomerular sieving coefficients (θ) for Ficoll (radius 13-80Å).

**Results:** As reported previously, we found a significant glomerular charge selectivity for Ficoll molecules of radius 20-45Å ($Ficoll_{20\text{-}45Å}$). PS infusions increased θ for $Ficoll_{50\text{-}80Å}$ markedly, and partly reversibly, for both n-Ficoll and a-Ficoll. For a-$Ficoll_{70Å}$ θ thus increased from $2.47 \times 10^{-5} \pm 1.1$ to $7.25 \times 10^{-5} \pm 1.1$ ($p<0.05$) at 15 min. However, neither PS nor Hyase had any effect on θ for n-$Ficoll_{20\text{-}45Å}$ or a-$Ficoll_{20\text{-}45Å}$, and thus had no effect on glomerular charge selectivity. Furthermore, contrary to PS, Hyase did not affect θ for a-$Ficoll_{50\text{-}80Å}$, whereas it caused a moderate increase in θ for large n-Ficoll molecules.

**Conclusions:** Systemically administered PS and Hyase decreased the size-selectivity of the rat GFB, but did not affect its charge selectivity, as indicated by the unaltered θ for a-$Ficoll_{20\text{-}45Å}$ after PS or Hyase infusions.

**Continuous Erythropoietin Receptor Activator (C.E.R.A.) Improves Endothelial Function in Anemic Rats with Chronic Kidney Disease** Michinori Hirata, Ken-ichi Serizawa, Kenji Yogo, Yoshihito Tashiro, Koichi Endo. *Product Research Dept, Chugai Pharmaceutical Co., Ltd., Gotemba Shizuoka, Japan.*

**Background:** Endothelial dysfunction is closely associated with cardiovascular events in chronic kidney disease (CKD) patients. Continuous erythropoietin receptor activator (C.E.R.A.) is widely used for the treatment of anemia in CKD patients, but it is unclear whether C.E.R.A. has any endothelial protective effect. Therefore, in the present study, we assessed the influence of C.E.R.A. on endothelial function in 5/6 nephrectomized (Nx) rats.

**Methods:** C.E.R.A. (0.6 μg/kg, once every 2 weeks) was subcutaneously administered from 1 week after Nx. After 8 weeks of treatment, endothelial function was evaluated by

measurement of flow-mediated dilation (FMD) in the femoral artery of anesthetized rats by using a high-resolution ultrasound system. FMD was calculated from the change in diameter of the femoral artery (relative to baseline diameter) following reperfusion after 5 min ischemia of the iliac artery.

**Results:** Urinary protein (uTP) and blood pressure (BP) were increased in Nx rats. Femoral blood velocity instantaneously increased (i.e. reactive hyperemia) at reperfusion after 5 min of hind limb ischemia. Following reactive hyperemia, maximum arterial dilation (i.e. FMD) was observed at 0.5–1 min after reperfusion. FMD tended to negatively correlate with uTP and BP. In Nx rats treated with C.E.R.A., Hb increased to within the normal range, but uTP and BP did not show any significant change. C.E.R.A. significantly increased FMD in the femoral artery without changing reactive hyperemia. C.E.R.A. significantly decreased nitrotyrosine (a marker of peroxynitrite) in the femoral artery. In addition, C.E.R.A. enhanced phosphorylation of endothelial nitric oxide synthase (eNOS) in the femoral artery.

**Conclusions:** These results demonstrated that, in Nx rats, C.E.R.A. improved endothelial function with reduction of oxidative stress and improvement of eNOS activity.

## SA-PO1054

**Klotho Is Not Expressed Endogenously in Healthy and Uremic Vascular Tissue** Rik Mencke,[1] Joyce Struik,[2] Joris van Ark,[1] Melissa Verkaik,[3] Martin H. De Borst,[4] Marc G. Vervloet,[3] Jan-luuk Hillebrands.[1] *[1]Pathology, UMCG, Netherlands; [2]Physiology, VUmc, Netherlands; [3]Internal Medicine - Nephrology, VUmc, Netherlands; [4]Internal Medicine - Nephrology, UMCG, Netherlands.*

**Background:** Cardiovascular disease (CVD) is the leading cause of death in patients with chronic kidney disease (CKD), a disease state that is strongly associated with loss of renal klotho. Reversely, murine klotho deficiency also causes marked medial calcification. It is thought that klotho conveys a vasculoprotective effect, inhibiting calcification and the development of atherosclerosis. Klotho expression in the vessel wall itself, however, is still disputed.

**Methods:** We assessed klotho expression in healthy renal donor arteries (N=6), CKD (renal graft recipient) arteries (N=10), carotid endarterectomy specimens (N=4), healthy elastic arteries (N=9), and human aortic smooth muscle cells (HASMCs, N=3), using immunohistochemistry and immunofluorescence, Western blotting (WB), qRT-PCR, and mass spectrometry. We extensively validated antibody specificity, using multiple antibodies to compare staining patterns, and competition assays and WB with recombinant human klotho (RhKlotho).

**Results:** Using anti-klotho antibody KM2076, we detected strongly positive specific staining in healthy renal tissue, which was blocked by incubation with RhKlotho, and which co-localized partially with distal tubule marker Epithelial Membrane Antigen. In addition, renal klotho and RhKlotho could be detected with KM2076 on Western blot. However, we could not detect klotho with immunohistochemistry, immunofluorescence or Western blotting in any type of vascular tissue or in HASMCs. We could also not detect klotho by mass spectrometry in healthy donor and CKD arteries, nor find klotho mRNA with qRT-PCR.

**Conclusions:** In contrast to recently published data, using several independent and validated methods, we conclude that klotho is not expressed in healthy or atherosclerotic vascular tissue, nor in cultured HASMCs.The putative vasculoprotective effect of klotho most likely results from circulating klotho levels.

## SA-PO1055

**Serum Cystatin C Is a Significant Diagnostic Marker of the Renal Resistive Index Detected on Doppler Ultrasound in Patients with Chronic Kidney Disease** Ayu Ogawa, Hitoshi Sugiyama, Masashi Kitagawa, Hiroshi Morinaga, Toshio Yamanari, Akifumi Onishi, Yoko Kikumoto, Shinji Kitamura, Yohei Maeshima, Hirofumi Makino. *Okayama Univ Graduate School of Medicine, Okayama, Japan.*

**Background:** Cystatin C (CysC) is a cysteine protease inhibitor produced by nearly all human cells whose serum level is a stronger predictor of the risk of cardiovascular events than that of creatinine. The resistive index (RI) on renal Doppler ultrasonography is a good indicator of renal vascular resistance as well as renal outcomes in patients with chronic kidney disease (CKD). However, it is unclear whether the serum CysC level is associated with signs of vascular dysfunction, such as renal RI in CKD patients.

**Methods:** We determined the levels of serum CysC in 73 CKD patients (median age: 57.0 years, male: 67.1%, diabetes: 9.6%) and investigated the relationship between the level of CysC and markers of vascular dysfunction, including the renal RI, ankle-brachial pulse wave velocity (baPWV), a marker of arterial stiffness, and intima-media thickness (IMT), a marker of atherosclerosis.

**Results:** The serum CysC level was significantly correlated with the renal RI ($P < 0.0001$), mean IMT ($P = 0.0499$) and baPWV ($P < 0.0001$). The serum CysC level was a significant determinant of the renal RI ($P = 0.0281$), but not the baPWV or mean IMT, in a multivariate regression analysis using a biomarker model. The multivariate odds ratio of the serum CysC level for a renal RI of 0.70, a level that predicts worse renal outcomes, was significant (4.04, $p = 0.0030$); however, the odds ratios for the baPWV and mean IMT were not significant. The area under the receiver-operating characteristic curve comparing the sensitivity and specificity of CysC for predicting the RI 0.70 was 0.926 ($P < 0.0001$) (cutoff value: 2.04 mg/L). The serum CysC level was significantly correlated with the level of albuminuria and inversely correlated with the eGFR, as previously reported.

**Conclusions:** The serum CysC level is independently associated with signs of vascular dysfunction, such as the renal RI, in patients with CKD. The study suggests that the serum CysC level serves as a significant marker of the renal RI in CKD patients.

## SA-PO1056

**Quantitative Measurement of Vascular Occlusion Is Associated with Tissue Hypoxia and Inflammatory Cytokines in Human Atherosclerotic Renal Artery Stenosis** Ahmed Saad, Sandra Herrmann, Alfonso Eirin, John A. Crane, Michael A. McKusick, James Glockner, Lilach O. Lerman, Stephen C. Textor. *Mayo Clinic.*

**Background:** Atherosclerotic renal artery stenosis (ARAS) reduces renal blood flow (RBF) and amplifies kidney hypoxia, but the relationship of degree of arterial stenosis and RBF reduction and renal injury remains poorly understood. We tested the hypothesis that RBF reduction and renal injury as reflected by renal vein levels of neutrophil gelatinase associated lipocalin (NGAL) would be magnified with more severe occlusive vascular disease in humans with ARAS.

**Methods:** Inpatient studies were performed in patients with ARAS (n=40, 71.3±11% (Range 48 , 89) occlusion by quantitative CT angiography) or essential hypertension (EH) (n=30), during fixed Na+ intake and ACE/ARB Rx. Single-kidney(SK) cortical/medullary perfusion, volume and RBF were measured using multidetector CT, and glomerular filtration rate (GFR) by iothalamate clearance. Tissue deoxyhemoglobin levels (R2*) and fractional kidney hypoxia (% of axial area with R2*>30/s) were measured by BOLD-MRI at 3T.

**Results:** SK-RBF, volume, cortical and medullary perfusion were reduced in the post-stenotic kidney, as was GFR. Renal vein NGAL and fractional hypoxia were higher in patients with ARAS than EH. The degree of arterial stenosis correlated directly with NGAL levels ($r = 0.49$, $P=0.0004$) and fractional hypoxia ($r= 0.33$, $P=0.01$) and inversely with the RBF, GFR, and kidney volume ($r=-0.59$, $P<0.0001$; $r =-0.66$, $P<0.0001$, and $r= -0.54$, $P<0.0001$).

| SK | ARAS N=40 | EH N=30 | *P-value* |
|---|---|---|---|
| NGAL (ng/ml) | 139±72 | 69.7±34 | <0.0001 |
| RBF(ml/min) | 215.9±135 | 399.2±174 | <0.0001 |
| Cortical perfusion (ml/min/mL tissue) | 2.4 ±0.8 | 3.4±1 | <0.0001 |
| Kidney volume (CT) mL | 104.6±44.3 | 143±32.8 | <0.0001 |
| Kidney hypoxia(R2*> 30/s) | 18.6±15 | 9.6±6.9 | 0.001 |
| GFR(ml/min/1.73m2) | 24.6±14 | 44.3±13.5 | <0.0001 |

**Conclusions:** Our results demonstrate that elevated renal venous markers of kidney injury (NGAL) and RBF in ARAS are correlated with the severity of arterial stenosis measured by CT. Therefore, although moderate blood flow reduction is often tolerated, severe stenosis is associated with active inflammatory injury in renovascular disease.

## SA-PO1057

**Early Detection of Renal Hemodynamic Dysfunction Using Sonographic Analysis in Drug-Induced Nephrotoxicity Rat Models** Tzongshi Lu,[1] Vivian Y. Chan,[2] Li-Li Hsiao.[1] *[1]Renal Div, Brigham and Women's Hospital, Boston, MA; [2]Harvard College, Cambridge, MA.*

**Background:** Drug-induced nephrotoxicity consists 19-25% of all cases of acute kidney injury (AKI). Conventional metrics such as serum creatinine (sCr) has been shown inadequate to detect nephrotoxicity before significant renal function loss and there is no robust method to accurately early detect hemodynamic in the course of drug-induced nephrotoxicity. To detect drug-induced kidney hemodynamic dysfunction in the early discovery phase would provide great benefit for better decision-making about candidate compounds and dose selection, as well as better design for clinical trials that will provide clear information about product benefit and safety. Real-time sonography combined with Color-Doppler imaging technique is the most advanced non-invasive tool to evaluate kidney status, and it is particularly useful for detecting early vascular occlusions and arterial stenosis in renal function analysis.

**Methods:** Rats were treated with Cisplatin (5 mg/kg b.w., single dose, i.p.) to induce AKI. Nephrotoxicity was assessed 6 days after Cisplatin treatment by measuring sCr and histopathology of kidney. Hemodynamic evaluation using Sonography combined with Color-Doppler imaging via Vevo2100 system (VisualSonic, Toronto, Canada).

**Results:** Our data showed successful drug-induced proximal tubular kidney injury by histological examination. Color-Doppler ultrasound study of AKI rats showed that resistive index (RI) and pulsatile index (PI) were increased; and peak-systolic velocity (mm/s), end-diastolic velocity (mm/s) and velocity-time integral (VTI, mm) were decreased at renal arteries. Importantly, these hemodynamic changes preceded the rise of sCr, the current gold-standard for renal function.

**Conclusions:** These observations suggest that RI, PI, VTI, peak-systolic velocity and end-diastolic velocity may serve as hemodynamic parameters to evaluate early phase of kidney injury. We suggest that this technical advance will provide an unprecedented opportunity for a non-invasive and sensitive method. Furthermore, the combination of these parameters (with histopathology and sCr) suggest their potential utility to study drug-induced dysfunction and nephrotoxicity.

*Funding:* Private Foundation Support

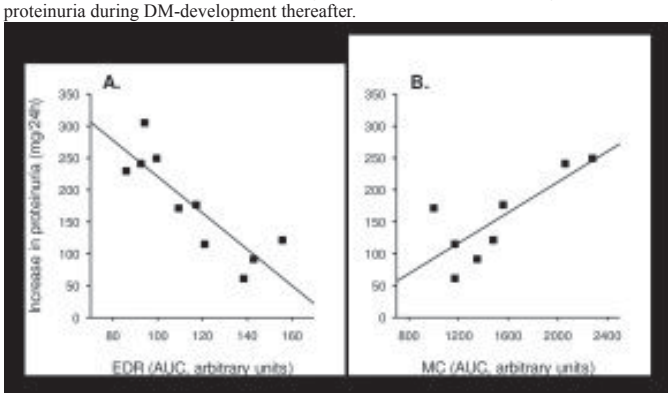
## SA-PO1058

**Proteinuria in Zucker Diabetic Fatty Rat Predicted by Small Renal Artery Function at Young Age** Mahdi Hamidi Shishavan, Leo E. Deelman, Sjoerd W. Landheer, Robert H. Henning, Hendrik Buikema. *Dept of Clinical Pharmacology, Univ Medical Center of Groningen, Groningen, Netherlands.*

**Background:** Severity of chronic kidney disease varies considerably among patients with similar risk profiles, such as obesity, diabetes (DM) and also be dependent on intrinsic factors.Early occurrence of vascular dysfunction in progressive renal disease has led us to question whether renal vascular function might condition the susceptibility of obese individuals to renal damage.

**Methods:** Obese Zucker diabetic fatty (ZDF) rats (n=10) at pre-DM state were subjected to unilateral nephrectomy (UNx) and followed for development of proteinuria until 10 weeks thereafter. At the moment of UNx, intrarenal arteries were isolated from extirpated kidneys and individually studied for endothelium-dependent relaxation (EDR) to acetylcholine and pressure-induced myogenic constriction (MC) responses. Linear regression analysis was performed of baseline EDR and MC (both expressed as AUC in arbitrary units) with increase in proteinuria (mg/24h).

**Results:** At the end, ZDF-UNx rats showed DM - i.e. increased blood glucose (18.5±3.2 mmol/L), $HbA_{1c}$ (5.9±0.6 %), cholesterol (5.4±0.6 mmol/L) and urinary glucose leakage (2.6±1.1 mmol/24h)- and associated renal injury including marked urinary protein excretion (190±25 mg/24h). Proteinuria was significantly predicted by renal artery function such that individuals with low EDR and/or high MC at baseline showed a higher increase in proteinuria during DM-development thereafter.



**Conclusions:** Proteinuria in ZDF rat is predicted by intrarenal artery function at young age. This seems of relevance as our society is becoming increasingly obese and developing associated health problems, such as diabetic nephropathy. Hence, tools that help to monitoring intrarenal vascular function could be useful to identify the individuals prone to the renal damage.

*Funding:* Government Support - Non-U.S.

## SA-PO1059

**Far-Infrared Induces Autophagy to Inhibit Advanced Glycation End Product-Induced Apoptosis in Vascular Endothelial Cells** Yung-Ho Hsu,[1] Tso Hsiao Chen,[2] Cheng-hsien Chen.[1,2] *[1]Div of Nephrology, Dept of Internal Medicine, Shuang Ho Hospital, Taipei Medical Univ, New Taipei, Taiwan; [2]Div of Nephrology, Dept of Internal Medicine, Wan Fang Hospital, Taipei Medical Univ, Taipei, Taiwan.*

**Background:** Diabetic vascular complication accounts for disabilities and high mortality rates in diabetic patients. The accumulation of advanced glycation end products (AGEs) in diabetic patients can trigger apoptotic changes in vascular endothelial cells and involves in the development and progression of micro- and macroangiopathy. Far-infrared radiation (FIR) therapy has been proved to be effective in increasing patency of dialysis vascular access.

**Methods:** Our study is to investigate the biological effects of FIR on AGEs-induced apoptosis in human umbilical vein endothelial cells (HUVECs).

**Results:** We found FIR exposure for 30 min significantly inhibited AGE-bovine serum albumin (BSA)-induced apoptosis in HUVECs. FIR exposure inhibited AGE-BAS-induced apoptotic signals, including cleaved caspase-3 increase and Bcl-xL decrease. We found that FIR exposure induced nuclear translocation of promyelocytic leukaemia zinc finger (PLZF) and phosphatidylinositol-3 kinase (PI3K) class III expression. PLZF siRNA transfection inhibited FIR-induced antiapoptotic effect and PI3K class III expression. Fluorescent staining showed that FIR exposure significantly increased autophagic activity in HUVECs. FIR exposure also induced the expression of autophagic markers, such as Beclin-1, Lamp1 and LC3-II. PLZF siRNA transfection reduced FIR-induced autophagic activity and the expression of Beclin-1, Lamp1 and LC3-II. Beclin-1 siRNA transfection and wortmannin, a PI3K inhibitor, blocked FIR-induced autophagic activity and the antiapoptotic effect of FIR in HUVECs. Additionally, we also found that autophagy promoted HUVECs to engulf AGE-BSA as revealed by immunofluorescence staining.

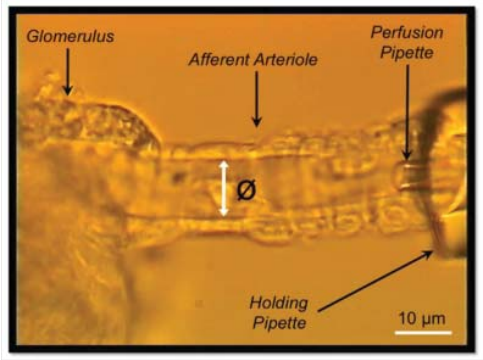
**Conclusions:** Our data suggest that FIR therapy induces autophagy to inhibit AGE-BSA-induced apoptosis in HUVECs.

## SA-PO1060

**Src Homology 2 Domain-Containing Protein B Deficient Mice Display an Increased Glomerular Filtration Rate and Augmented Renal Arteriolar Contractions to Both Adenosine and Ang II** Xiang Gao.[1] *[1]Medical Cell Biology, Uppsala Univ, Uppsala, Sweden; [2]Karolinska Institute, Stockholm, Sweden.*

**Background:** Src homology 2 domain-containing protein B (Shb) is an adapter protein whichregulates several signal transduction cascades and endothelial cell functions. The adenosine-angiotensin II (Ado-Ang II) interaction plays an important role in the regulation of glomerular filtration rate (GFR), vascular resistance and tubuloglomerular feedback. We used Shb-knockout ($Shb^{-/-}$) and wild-type ($Shb^{+/+}$) mice to investigate their GFR and effectiveness of Ado and Ang II to constrict renal resistance vessels.

**Methods:** GFR was measured in conscious $Shb^{-/-}$ and $Shb^{+/+}$ mice using FITC-inulin. Isotonic contractions were measured in isolated and perfused renal afferent arterioles from $Shb^{-/-}$ and $Shb^{+/+}$ mice.



Concentration responses to Ang II ($10^{-12}$ to $10^{-6}$M; 2 minutes each) doses or low-dose Ado ($10^{-8}$ mol/l; 15 min) alone, as well as Ado ($10^{-8}$ mol/l)in combination with cumulative application of Ang II ($10^{-12}$ to $10^{-6}$ mol/l; 2 minutes each) were studied in both genotypes.

**Results:** There was a significantly increased GFR (371 ± 12 µL/min, n=11) in $Shb^{-/-}$ comparing to $Shb^{+/+}$ (321 ± 11 µL/min, n=8) mice. The maximal arteriolar contraction to Ang II was significantly larger in $Shb^{-/-}$ (87 %; n=8) than in $Shb^{+/+}$ (54 %; n=8) mice. Low-dose Ado alone contracted afferent arterioles in both genotypes (6% in $Shb^{-/-}$ and 7% in $Shb^{+/+}$). Ado significantly enhanced Ang II constriction in afferent arterioles in both genotypes (to 93% in $Shb^{-/-}$ and to 72 % in $Shb^{+/+}$).

**Conclusions:** Low-dose adenosine augments Ang II arteriolar constriction effectiveness, which indicates Ado-Ang II interaction in both $Shb^{-/-}$ and $Shb^{+/+}$ mice. The absence of Shb increases GFR The underlying mechanisms remain to be resolved.

*Funding:* Government Support - Non-U.S.

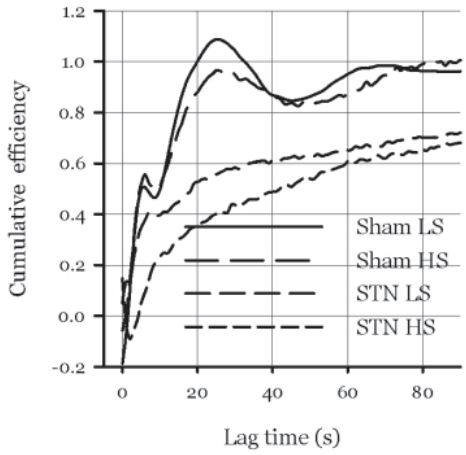
## SA-PO1061

**Dynamics of Renal Blood Flow Autoregulation in Early Remnant Kidney** Scott C. Thomson, Hai Pham, Prabhleen Singh. *Medicine, Univ of California and VASDHS, San Diego, CA.*

**Background:** Previous micropuncture data revealed that the early remnant kidney adapts to high NaCl diet by suppressing tubuloglomerular feedback (TGF), which permits distal delivery to increase. TGF normally accounts for half of RBF autoregulation.

**Methods:** Current studies tested for a signature of TGF suppression on dynamic RBF autoregulation at the whole kidney level in rats fed high (HS) or low (LS) NaCl diets for one week after 5/6 nephrectomy (STN) or sham surgery. (n=7-9 per group). RBF (Transonics transit time) and blood pressure (BP) were recorded at 1 Hz for 90-120 minutes. Impulse response functions were generated in MATLAB by best fit of current RBF to a linear combination of the last 240 values of BP. Autoregulatory step responses (same as accumulated fractional compensation for a unit step in BP) were obtained by integrating and normalizing to mean conductance. Values <0, 0, 1, >1 correspond to dilation, rigid conduit, perfect autoregulation, and super-autoregulation, respectively.

**Results:**



Several distinct features of the response varied among the groups as shown in the figure. Transient peaks and/or damped oscillations are consistent with simple negative feedback control with intrinsic delay and gain exceeding some threshold. Peaks at Lag<15s and >25s presumably owe to myogenic and TGF responses, respectively. Most of the difference among Sham LS, Sham HS, and STN LS can be explained by quantitative adjustment of the TGF gain. Unique to STN HS was a 3s vasodilatory phase followed by sluggish autoregulatory response.

**Conclusions:** Simple systems analysis revealed distinct components to the autoregulatory response that are individually affected by STN and dietary salt. Overall, the autoregulatory response is slower and salt-sensitive in STN.

## SA-PO1062

**Diffusion Tensor Imaging: A Useful Tool in the Evaluation of Renal Artery Stenosis** Emiliana Ferramosca,[1] Laura Patregnani,[1] Caterina Gaudiano,[2] Fiorenza Busato,[2] Valeria Clementi,[3] Rita Golfieri,[2] Antonio Santoro.[1] *[1]Nephrology, Dialysis and Hypertension, S.Orsola-Malpighi Univ Hosp., Bologna, Italy; [2]Radiology Inst, S.Orsola-Malpighi Univ Hosp., Bologna, Italy; [3]GE Healthcare, Clin. Science Development Group, Bologna, Italy.*

**Background:** Diffusion Tensor Imaging (DTI) is an MR imaging technique used to show molecular diffusion.The apparent diffusion coefficient (ADC) combines the effects of capillary perfusion and water diffusion in the extracellular space. Fractional Anisotropy (FA) is a quantitative value that provides information on direction of water molecules flow within a tissue. DTI provides information on perfusion and diffusion simultaneously.

Aim of this study was to evaluate feasibility of DTI in detecting unilateral kidney alteration in pt with renal artery stenosis (RAS).

**Methods:** We studied 13 patients (pt) with RAS and 15 control subjects without any kidney disease. All subjects underwent morphological MRI followed by DTI sequence. Mean ADC and FA values of cortical and medullary Regions of Interest were calculated. The reference range for ADC and FA on cortex and medulla in the control group was defined as mean value±2SD. For each kidney in the pt with RAS the corresponding parameters were compared with the reference range.

**Results:** Reference ranges on controls were: 2.55±0.18 $\times 10^{-3}$ mm$^2$/s for cortical ADC, 2.25±0.24 $\times 10^{-3}$ mm$^2$/s for medullary ADC, 0.308±0.071 for cortical FA and 0.389±0.067 for medullary FA.

In 7 pt DTI parameters confirmed the unilateral alteration showed by the CE-MRI. In 1 pt DTI confirmed the bilateral alteration showed by the CE-MRI. In the other 5 pt DTI parameters suggested functional alterations but not corresponding to the side involvement showed by the CE-MRI.

**Conclusions:** DTI of the kidneys is a new application that allows us to study renal alterations. Previous studies demonstrated the feasibility of DTI in pt with CKD, showing lower ADC than in control subjects. This preliminary results suggest to increase the number of data to investigate the DTI ability to measure the functional alteration of each kidney, also by adding percentage of RAS and kidney volume data.Based on these data DTI could be useful on RAS study by evaluating functional alteration of each kidney.

## SA-PO1063

**Regulation of Mitochondrial Function and Dynamics in Early CKD** Prabhleen Singh, Hai Pham, Joanna Thomas, Scott C. Thomson. *UCSD&VASDHS.*

**Background:** Available therapies for CKD are inadequate in halting the progression of disease Intrarenal hypoxia has been identified as a major culprit in CKD progression. We have reported a high nephron oxygen consumption (QO2) leading to hypoxia in subtotal nephrectomy (STN) model of CKD.

**Methods:** In 1-week STN rats, mitochondrial QO2, ROS generation, ATP generation, mitochondrial dynamics (fission/fusion) and morphology were examined. Effects of HIF-1α activation by DMOG treatment were examined. Data presented as mean±sem.

**Results:** Cortical mitochondrial QO2 were not different between STN and controls, but mitochondria isolated from whole kidneys, showed elevated rates of both coupled and uncoupled respiration, $p<0.05$. ATP generation was not different despite elevated QO2, but increased superoxide production was seen in STN mitochondria, $p<0.05$. HIF-1α activation lowered both mitochondrial QO2 and ROS production. Imaging revealed longer lengths and elongated phenotype (fusion) in STN cortical (912±32 nm) vs. medullary (547±16 nm) mitochondria, which were fragmented (fission), $p<0.001$. STN cortical mitochondria had increased volume density (29±1%) compared to STN medullary (22±1%) or control cortical mitochondria (22±1%), $p<0.01$. Lastly, the cristae abundance, normalized to mitochondria outer membrane was increased in the STN cortical (2±0.1) compared to STN medullary (1.3±0.1) or control cortical mitochondria (1.3±0.1), $p<0.01$. Western blotting revealed increased mitofusin 2 (fusion protein) expression in STN cortex compared to control cortex and STN medulla ($p<0.05$) and decreased Fission 1 (fission protein) expression in STN vs. control cortex, but higher expression in STN vs. control medulla, $p<0.05$. Beclin-1 expression was significantly elevated in STN medulla vs. cortex and was lowered by DMOG treatment.

**Conclusions:** Elevated mitochondrial QO2 is observed in early STN medullary mitochondria, without expected increase in ATP generation, but associated with elevated ROS levels. Significant alterations in mitochondrial morphology and dynamics were also observed in STN medullary mitochondria, which could explain the mitochondrial dysfunction. HIF-1α activation ameliorated mitochondrial dysfunction, and its effects on mitochondrial dynamics are being examined.

## SA-PO1064

**Interferon-Gamma Increases Connexin-40 Expression and Affects Electrical Properties of Endothelial Cells** Branko Braam,[1,2] Wenqing Zhuang,[1] Steve Kulak,[1] R. Todd Alexander,[2,3] William A. Cupples.[4] *[1]Medicine/Nephrology, Univ of Alberta; [2]Physiology, Univ of Alberta; [3]Pediatrics, Univ of Alberta, Edmonton; [4]Physiology and Kinesiology, Simon Fraser Univ, Vancouver, Canada.*

**Background:** Connexin(CX)-37, -40 and -43 are part of the gap junctions between and participate in the electrochemical coupling of endothelial cells (EC). These properties have been implicated in vascular regulation, since the EC seem to form the 'electrical cable' for axial signal transmission in the microvasculature. We investigated whether CX expression responds to stimuli known to be involved in endothelial dysfunction.

**Methods:** Interferon-gamma (IFNγ) strongly induced CX-40 expression and subsequently was tested with respect to transcellular impedance. Human microvascular EC-1 (HMEC-1, CDC) in culture were subjected to partial vs. full confluence, normal vs. high glucose (5 vs. 25 mM), IL-6, IFNγ, TNFa, Ang II and DETA-NONOate. After 4h and 8h cells were harvested for RNA isolation, DNA degradation and RT-qPCR with specific primers.

**Results:** Of all those stimuli, IFNγ (1-30 ng/ml) consistently induced CX-40 expression at 4h and 8h dose dependently to 10-20 fold when corrected for the control (HPRT). TNFa and IL6 resulted in a small, significant depression of CX-37 expression at 4h. The induction of CX-40 by IFNγ was reproduced in HUVEC (less pronounced) and glomerular EC in culture. All other stimuli did not change expression of CX-37, CX-40 or CX-43. Two JAK inhibitors, EGCG (100-250 uM) and A-490 (100-250 uM) dose-dependently inhibited the induction of CX-40 expression by IFNγ. Subsequently, HMEC-1 were subjected to 10-30 ng/ml IFNγ for up to 48h and transcellular cell impedance monitored by cell-substrate impedance sensing (ECIS, Applied BioPhysics). IFNγ dose-dependently increased cell impedance significantly after 24h and this was blunted by A-490 (25 uM).

**Conclusions:** These experiments point to an important role of IFNγ to induce CX40 expression. IFNγ also seems to increase EC electrical impedance, which could 'insulate' the electrical cable. Experiments testing intercellular conductance are ongoing.

## SA-PO1065

**Comparison of Combination Therapy with Irbesartan/Amlodipine and Irbesartan/Cilnidipine for Attenuation of Albuminuria in Rats with Streptozotocin-Induced Diabetic Nephropathy** Minoru Satoh, Yuko Nishi, Hiroyuki Kadoya, Tamaki Sasaki, Naoki Kashihara. *Dept of Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

**Background:** Managing hypertension is important for decreasing the risks of cardiovascular and renal diseases. Calcium channel blockers (CCBs) have varying suppressive effects on urinary albumin excretion. However, it is unknown whether this effect differs in combination therapy with angiotensin receptor blockers (ARBs). This study aimed to compare the efficacy of the combination therapy of irbesartan/amlodipine and irbesartan/cilnidipine on diabetic nephropathy.

**Methods:** Male Sprague-Dawley rats with streptozotocin–induced diabetes were treated with CCBs, amlodipine (2.0 mg/[kg·day]) or cilnidipine (2.0 mg/[kg·day]), with or without the ARB, irbesartan (20.0 mg/[kg·day]). In the acute protocol, changes in the diameters of glomerular afferent and efferent arterioles were examined by a charge-coupled device video microscope. In the chronic protocol, urinary albumin excretion, glomerular reactive oxygen species, and endothelial surface layer were evaluated.

**Results:** In the acute protocol, cilnidipine monotherapy caused a greater dilation in glomerular efferent arterioles than amlodipine monotherapy. In both groups, combination therapy with irbesartan induced comparable dilation in the glomerular efferent arterioles. In the chronic protocol, cilnidipine monotherapy suppressed albuminuria more than amlodipine monotherapy. However, the addition of irbesartan reduced the albumin excretion in both groups. In a group initiated on irbesartan monotherapy, addition of cilnidipine or amlodipine had no further effect on albuminuria reduction.

**Conclusions:** Cilnidipine monotherapy suppressed increased albuminuria more than amlodipine monotherapy. However, combination therapy with irbesartan led to a greater reduction in albuminuria in both treatment groups and with equal effectiveness. The combinations of irbesartan with cilnidipine or amlodipine are equally effective in reducing albuminuria in diabetic nephropathy.

## SA-PO1066

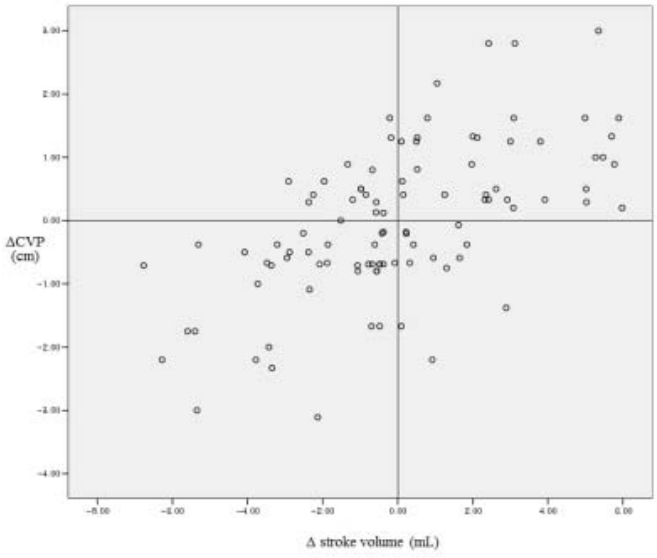
**Comparison of Central Venous Pressure with Cardiac Output Measured by Non-Invasive Cardiac Output Monitoring during Anesthesia for Kidney Transplant Surgery**

Joon Seok Oh,[1] Jin Ho Lee,[1] Seong Min Kim,[1] Yong Hun Sin,[1] Yong Ki Park,[2] Joong Kyung Kim.[1] *[1]Div of Nephrology, Internal Medicine, Bong Seng Memorial Hospital, Busan, Korea; [2]Div of Nephrology, Internal Medicine, Dongnae Bong Seng Hospital, Busan, Korea.*

**Background:** Patients with end-stage renal disease (ESRD) can be hemodynamically unstable because of frequent changes in peripheral resistance and blood volume during kidney transplant surgery. Cardiac output (CO) is a key variable when describing and treating the cardiovascular system. Thermodilution via a pulmonary artery catheter is the most frequently used method, but it lacks accuracy. Non-invasive cardiac output monitoring (NICOM) measures CO based on chest bioreactance. Validated data of NICOM in patients with kidney transplant surgery are lacking. So we compared central venous pressure (CVP) with cardiac output monitored via NICOM system during anesthesia for renal transplant surgery.

**Methods:** Stroke volume (SV) values using NICOM were recorded during anesthesia in patients with renal transplant surgery and CVP values were measured at the same time. The difference between measured and average values of CVP (ΔCVP) and SV (ΔSV) were calculated in each subject, because CVP values may be different depending on the person who measured. Correlation analysis was performed ΔSV with and ΔCVP.

**Results:** Twenty subjects were enrolled and the SV and CVP values were measured 100 times. There werepositive correlation with ΔSVand ΔCVP (R = 0.61, P = 0.00).



**Conclusions:** Stroke volume measured by NICOM and CVP showed a positive correlation. NICOM may be effective as non invasive method for circulating volume monitoring in patients with renal transplant surgery.

## SA-PO1067

**Angiotensin II Type 2 Receptor Activation Counteracts Angiotensin II-Induced Loss of Glomerular Permselectivity – A Multiphoton Microscopy Study**

Ina Maria Schiessl, Hayo Castrop. *Univ of Regensburg, Institute of Physiology, Regensburg, Germany.*

**Background:** In this study, we assess the acute effects of angiotensin II (AngII) on glomerular permselectivity for albumin.

**Methods:** Experiments were performed in Munich Wister Froemter rats using intravital microscopy. Alexa-Fluor-594 albumin was injected i.v. and fluorescence intensities were determined in glomerular capillaries and in Bowman's space to calculate the albumin glomerular sieving coefficient (GSC). GSC was measured before and during constant infusion of AngII (10 ng/min/kg BW).

**Results:** Baseline MAP averaged 99±5 mm Hg and stabilized at 137±5 mm Hg during AngII infusion. GSC averaged $0.00044\pm5*10^{-5}$ at baseline and increased by 386±44% after AngII infusion (p<.0001). During saline infusion, no changes in MAP or GSC were observed. Proximal tubular Alexa-Fluor-594 albumin uptake was markedly elevated during AngII infusion (518% of baseline vs. 218% in controls; p<.0001). Changes in GSC were abolished and reversed, when the AT1 antagonist losartan (9.9 µg/g BW) was injected before and after the start of the AngII infusion, respectively. Contrary to losartan, the AT2 antagonist PD123319 increased baseline GSC from $0.00052\pm4*10^{-5}$ to $0.00074\pm8*10^{-5}$ (p=.02), without altering MAP. During infusion of AngII in the presence of losartan, PD123319 increased albumin GSC from $0.00037\pm5.8*10^{-5}$ to 0.00115±.00015 (p=.001). There was a minor correlation between GSC and MAP, with the two variables increasing in parallel ($r^2$= .26). Pressure-independent effects of AngII on GSC were assessed after normalization of the renal perfusion pressure by pulling on a string loop, which was implanted around the aorta upstream of the branching of the renal arteries. With renal perfusion pressure kept constant (measurement in the femoral artery), GSC increased from 0.0007±.0002 to 0.0025±.0006 during AngII infusion, similar to what was seen without controlled pressure.

**Conclusions:** In summary, AngII increases the permeability of the glomerular filtration barrier for albumin. This effect is AT1 receptor-dependent and largely independent of changes in the renal perfusion pressure. AT2 receptor activation partially counteracts the proteinuric effects of the AT1 receptor.

## SA-PO1068

**The Vascular Smooth Muscle Cell Calcium-Sensing Receptor Is Involved in Blood Pressure Regulation, Calcium-Homeostasis and Protection from Calcification**

Martin Schepelmann,[1] Polina L. Yarova,[1] Tom Davies,[1] Sarah C. Brennan,[1] Joao Z. Graca,[1,2] Wenhan Chang,[3] Daniel Bikle,[3] Donald T. Ward,[4] Ann E. Canfield,[4] William G. Richards,[5] David H. Edwards,[1] Sally A. Price,[2] Paul J. Kemp,[1] Daniela Riccardi.[1] *[1]Cardiff Univ, United Kingdom; [2]Astra Zeneca, Macclesfield, United Kingdom; [3]Dept of Medicine, Univ of California, San Francisco, CA; [4]Univ of Manchester, United Kingdom; [5]Amgen, Thousand Oaks, CA.*

**Background:** The extracellular Calcium-sensing Receptor (CaSR) is expressed in the vasculature, but the roles of the CaSR in vascular physiopathology still remain unclear.

**Methods:** We studied the phenotype of a mouse model of vascular smooth muscle cell (VSMC) targeted CaSR deletion by breeding exon 7 LoxP CaSR mice with SM22α-Cre mice.

**Results:** CaSR wild-type (WT) and knock-out (KO) mice showed no difference in weight, lifespan or reproductive capability. However, compared to WT control, 9 month old KO mice were hypotensive (90.3±2.8 vs. 80.5±2.8 mm Hg mean arterial pressure, p<0.05, N=6-11). Wire myography showed reduced phenylephrine-induced contraction and increased acetylcholine-induced relaxation of isolated KO aortae compared to WT control, suggesting a role for vascular CaSR in the control of arterial tone and hence blood pressure. $Ca^{2+}$ and FGF23 levels were significantly elevated in KO mice compared to WT ($Ca^{2+}$: 3.05±0.27 vs. 2.28±0.09 mM; FGF23: 384.4±83.5 vs. 145.0±11.0 pg/ml, p<0.01, N=6-11) indicating an influence of the vascular CaSR on $Ca^{2+}$/Pi homeostasis, a notion supported by the observation that KO mice showed significantly impaired bone mineral density. *In vitro*, VSMC cultured from KO mice – which show a ~60% reduction of CaSR staining intensity compared to WT (quantitative immunofluorescence) – exhibited a significantly greater predisposition to calcify in mineralising conditions (3 mM Pi and 1.8 mM $Ca^{2+}$) compared to WT control (24.60 vs. 0.99 AU, alizarin red densitometry, p<0.001, N=6-8).

**Conclusions:** These data point to an important physiological role of the vascular CaSR in blood pressure regulation and electrolyte homeostasis and to a possible protective role against vascular calcification in pathophysiology.

*Funding:* Government Support - Non-U.S.

## SA-PO1069

**Tubular Vegfa Is Required for Renal Microvasculature and Oxygen Sensing**

Henrik Dimke,[1] Matthew A. Sparks,[2] Sebastian Frische,[3] Thomas M. Coffman,[2] Susan E. Quaggin.[4] *[1]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, Canada; [2]Div of Nephrology and Dept of Medicine, Duke Univ, Durham, NC; [3]Dept of Biomedicine, Univ of Aarhus, Aarhus, Denmark; [4]Northwestern Univ, Feinberg School of Medicine, Chicago, IL.*

**Background:** Adequate renal oxygenation is pivotal for maintaining essential functions of the kidney. Vascular endothelial growth factor A (VEGFA) plays a key role in vascular formation and maintenance, processes that are critical for sufficient tissue perfusion and oxygenation.

**Methods:** Using a range of targeted transgenic mice models we determined the intrarenal localization of the Vegfa system and the functional consequences of *Vegfa* ablation in renal tubules.

**Results:** Here we show that *Vegfa* is expressed in select tubular epithelial cells, while expression of its receptor (*Kdr/Vegfr2*) is restricted largely to capillary beds. Early genetic ablation of tubular *Vegfa* allows the formation of a grossly normal kidney. However, microvascular density is markedly reduced, leading to increased renal hypoxia. As a consequence the mice develop pronounced polycythemia, elicited by an augmented renal production of erythropoietin. In kidney, expression of classical hypoxia-inducible factor-1 responsive transcripts remains unaltered; suggesting that erythropoiesis partly compensates the capillary rarefaction. An increase in diastolic blood pressure (112 ± 3.7 vs. 104 ± 1.6 mmHg) is present in mice lacking tubular Vegfa maintained on a normal diet, while systolic blood pressure (139 ± 2.8 vs. 135 ± 2.8 mmHg) does not change. The difference in diastolic pressure is ablated when dietary NaCl content changed or when angiotensin II is infused. Moreover, renal electrolyte excretion remains unperturbed by reductions in tubular Vegfa.

**Conclusions:** Tubular Vegfa is critical for adequate development of renal microvasuculature, a prerequisite for proper oxygenation of the kidney. Compensatory polycythemia likely prevents severe perturbations of renal function in this model. In addition, increased diastolic blood pressure may occur as a consequence of capillary rarefaction within the kidney.

*Funding:* Government Support - Non-U.S.

**SA-PO1070**

**Role of MicroRNA-126 in Asymmetric Dimethylarginine Induced Endothelial Dysfunction**

Filippo Martino,[1] Jan T. Kielstein,[2] Thomas Thum,[1] Johan M. Lorenzen.[2] *[1]Insitute of Molecular and Translational Therapeutic Strategies, Hannover Medical School, Hannover, Germany; [2]Dept of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

**Background:** Asymmetric Dimethylarginine (ADMA), an endogenous inhibitor of NOS, is elevated in patients with chronic kidney disease and is known to contribute to endothelial dysfunction. It remains unclear if microRNAs have an impact on these detrimental effects. We investigated the role of microRNA-126, which is essential for endothelial biology in ADMA induced endothelial dysfunction.

**Methods:** We measured ADMA-Plasma levels in 39 patients with coronary artery disease (CAD) by ELISA assay and correlated them with circulating miR-126 levels assessed by qRT-PCR. We infused ADMA into healthy rats (250µMol ADMA/kg/day) and healthy human volunteers (0.1mg ADMA/kg/min, 40 minutes) and quantified plasma levels of different microRNAs. We investigated the underlying molecular mechanisms in vitro by using HUVECs. Stimulating them with ADMA, we quantified extra- and intracellular levels of miR-126. Transcriptional activation was assessed by electrophoretic mobility shift assay (EMSA).

**Results:** Plasma Levels of ADMA in CAD patients correlated inversely with levels of circulating miR-126 ($r=-0.52$; $p<0.001$). ADMA infusion reduced circulating levels of miR-126 in rats. Levels of circulating miR-126 in healthy human volunteers were significantly decreased after ADMA infusion ($p<0.05$), whereas other microRNAs were not significantly altered. We could detect a time dependent alteration of extra- and intracellular amounts of miR-126 (extra: decrease 24h $p<0.05$; intra: increase 2h $p<0.05$) in vitro. Changes of intracellular levels of miR-126 were not related to transcriptional activiation by ETS-1, which is known to regulate miR-126.

**Conclusions:** We were able to show that, miR-126, which is known to convey alarm signals to injured endothelium and thereby contribute to repair mechanisms and cellular survival, is regulated by ADMA. Therefore, detrimental effects of ADMA on endothelial function might be partly mediated by miR-126. These effects are rather a consequence of altered miR-126 trafficking (e.g. through exosomes/microvesicles) than transcriptional regulation.

**SA-PO1071**

**Angiopoietin-2 Induced Arterial Stiffness in Chronic Kidney Disease**

Fan-Chi Chang,[1,2,3] Yu-hsiang Chou,[1,4] Szu Yu Pan,[1] Yi-Ting Chen,[1,2,5] Wen-Chih Chiang,[1] Shuei-Liong Lin.[1,3] *[1]Renal Div, National Taiwan Univ Hospital, Taipei, Taiwan; [2]Dept of Internal Medicine, National Taiwan Univ Hospital Chu-Tung Branch, Hsin-Chu, Taiwan; [3]Graduate Institute of Physiology, College of Medicine National Taiwan Univ, Taipei, Taiwan; [4]Dept of Internal Medicine, National Taiwan Univ Hospital Yun-Lin Branch, Yun-Lin, Taiwan; [5]Dept of Internal Medicine, E-DA Hospital, Kaohsiung, Taiwan.*

**Background:** Arterial stiffness is recognized detrimental to cardiovascular outcome. Given increased arterial stiffness in chronic kidney disease (CKD), we hypothesize that abnormal endothelial cell growth factor is implicated.

**Methods:** The cohort of CKD patients and animal models of CKD were studied.

**Results:** In the cohort of 416 CKD patients, plasma level of angiopoietin-2 was independently correlated with the severity of arterial stiffness assessed by pulse wave velocity. Using murine CKD models induced by 5/6 subtotal nephrectomy or unilateral ureteral obstruction, we demonstrated the increase of plasma angiopoietin-2. Angiopoietin-2 expression markedly increased in tubular epithelial cells of fibrotic kidney but decreased in other tissues including aorta and lung. Expression of collagen and pro-fibrotic genes in aortic vascular smooth muscle cells was increased in CKD mice or mice producing human angiopoietin-2. Angiopoietin-2 stimulated endothelial expression of monocyte chemokines and adhesion molecules, increased $Ly6C^{low}$ macrophage in aorta. Pro-fibrotic cytokine transforming growth factor b1 was increased in aortic endothelial cells and $Ly6C^{low}$ macrophages by angiopoietin-2. Angiopoietin-2 blockade not only attenuated expression of monocyte chemokines, pro-fibrotic cytokines, and collagen in aorta, but also decreased pulse pressure of mice after 5/6 subtotal nephrectomy.

**Conclusions:** This study identifies a link between fibrotic kidney and arterial stiffness through angiopoietin-2. Targeting angiopoietin-2 to attenuate inflammation and collagen expression may provide a novel therapy for cardiovascular disease in CKD.

**SA-PO1072**

**The Identification of a Robust, High Capacity Albumin Transcytosis Pathway in Isolated Perfused Rabbit Tubules**

Yuehan Zhou,[1] Leileata M. Russo,[2] Lisa M. Satlin,[1] Wayne Comper.[2] *[1]Mount Sinai School of Medicine; [2]Exosome Diagnostics.*

**Background:** A high capacity tubular retrieval pathway for filtered albumin has long been proposed on the basis of the lack of charge selectivity of the glomerular filter, albumin excretion with the use of chemical tubular knock outs, chase studies of filtered albumin in vivo, and more recent studies of the high glomerular sieving coefficient measured for albumin by 2-photon microscopy. The aim of this study was to examine the ability of proximal tubules to efficiently take up and transcytose albumin at relatively high concentrations in the tubular lumen.

**Methods:** Following a 40min equilibration period, the isolated rabbit S1 proximal tubules, approximately 1mm in length, were perfused with Burg's solution containing Alexa 488 labelled albumin at a concentration of 3mg/ml and $^{14}$C-inulin at 10-15nl/min. The basolateral perfusion rate was 10ml/h and fractions were collected every 10min for 1h. The fractions were concentrated by a 30kD-cut-off membrane and both the retentate (intact albumin) and filtrate (degraded albumin) measured for fluorescence. Leakage from the basolateral bath to the lumen was estimated by volume flow Jv as measured by the difference in $^{14}$C-inulin concentration in the luminal collection fluid vs luminal perfusate and leakage from the lumen to the bath was estimated by radioactivity in the basolateral perfusate.

**Results:** In all studies we found significant amounts of intact albumin in the basolateral bath giving a mean±SD for steady-state transcytosis of 8.9±9.7ng/mmtubule.min (n=3). There was no detectable presence of $^{14}$C-inulin in the basolateral fractions nor was there negative Jv indicating no leakage. The presence of degraded albumin or free label in the basolateral perfusate was <5% of the intact albumin.

**Conclusions:** The proximal tubule has the capacity to efficiently retrieve relatively high concentrations of filtered albumin that are predicted to occur because of its high glomerular sieving coefficient. The mechanism of retrieval is not associated with fluid phase endocytosis.

**SA-PO1073**

**Renin Vein Sampling in Patients with Refractory Hypertension and Non-Occlusive Renal Artery Stenosis**

Saravanan Balamuthusamy,[1,3] Bijin Thajudeen,[1] Raul Medina,[3] Evamaria Anvari,[1] Nishant B. Jalandhara.[2] *[1]Dept of Medicine, Univ of Arizona, Tucson; [2]Nephrology, Kansas Nephrology Physicians; [3]Nephrology and Hypertesnion, Angiocare, Tucson.*

**Background:** Less than 40% of patients with hypertension are being treated to target levels established by JNC-7. Refractory hypertension has been documented in atleast 10% of the patients with chronic hypertension. Elevated renin level under optimal conditions has been recorded in patients with refractory hypertension. The clinical significance of elevated renin in the absence of renin secreting tumors and occlusive RAS has not been analyzed in the past.

**Methods:** Three year retrospective comparative analysis of patients with refractory hypertension with elevated renin levels with non-occlusive RAS (NO RAS) and no RAS (no RAS) from two Nephrology and Hypertension practices was performed. Renal arteriogram was performed if there was evidence of renal artery stenosis on arterial Doppler based on flow or renal-aortic ratio criteria. Renin sample was obtained by selectively catheterizing the renal vein in an interventional lab. Renin angiotensin aldosterone blockers (RAAS) were discontinued 7 days before the procedure. Patients in the non-occlusive RAS group had <50% stenosis. Renal renin ratio (RRR) is calculated by dividing the renin level from the elevated to non-elevated side in patients with no RAS. The ratio in the NO RAS group was calculated by dividing the stenotic by non-stenotic side renin value.

**Results:** 22 patients met inclusion criteria for the analysis. The mean age was 61.7. There were more diabetics in the NO RAS group. The mean renin ratio in the NO RAS group was 3.1 as opposed to 0.8 in the non RAS group ($p<0.001$).

**Conclusions:** Renin ratio was significantly increased in refractory hypertension patients with non-occlusive renal artery stenosis when compared to patients who did not have any stenosis despite having elevated peripheral renin levels. The optimal treatment for NO RAS is unclear at this point with the exception of RAAS blockade and dihydropyridine calcium channel blockers.

**SA-PO1074**

**The Effect of Empagliflozin on Arterial Stiffness and Heart Rate Variability in Patients with Type 1 Diabetes**

David Cherney,[1] Bruce A. Perkins,[2] Nima Soleymanlou,[3] Ronnie Lok-Hang Har,[1] Nora M. Fagan,[4] Odd Erik Johansen,[5] Hans-Juergen Woerle,[5] Maximilian von Eynatten,[4] Uli Christian Broedl.[5] *[1]Univ Health Network, Univ of Toronto, Canada; [2]Mount Sinai Hospital, Univ of Toronto, Canada; [3]Boehringer Ingelheim Canada Ltd./Ltée, Canada; [4]Boehringer Ingelheim Pharmaceuticals, Inc.; [5]Boehringer Ingelheim Pharma GmbH & Co.KG, Germany.*

**Background:** Patients with type 1 diabetes (T1D) are at high risk for the development of hypertension. Hyperglycemia-mediated neurohormonal activation increases arterial stiffness, and is an important contributing factor for hypertension. Since the sodium glucose cotransport 2 (SGLT2) inhibitor empagliflozin lowers blood pressure and HbA1c, we hypothesized that this agent would reduce arterial stiffness and markers of sympathetic nervous system activity.

**Methods:** Blood pressure, arterial stiffness, heart rate variability (HRV) and circulating adrenergic mediators were measured during clamped euglycemia and hyperglycemia in 40 normotensive patients with T1D (NCT01392560). Studies were repeated after 8 weeks of empagliflozin (25 mg daily).

**Results:** During clamped euglycemic conditions, empagliflozin reduced systolic blood pressure (111±9 to 109±9 mmHg, p=0.0187), and augmentation indices at the radial (-52±16 to -57±17%, p<0.0001), carotid (+1.3±17.0 to -5.7±17.0%, p<0.0001) and aortic positions (+0.1±13.4 to -6.2±14.3%, p<0.0001) declined. Similar effects on arterial stiffness were observed during clamped hyperglycemia; however, blood pressure effects were not significant. Carotid-radial pulse wave velocity decreased significantly under both glycemic conditions (p≤0.0001), while declines in carotid-femoral pulse wave velocity were only significant during clamped hyperglycemia (5.7±1.1 to 5.2±0.9 m/s, p=0.0017). HRV, plasma noradrenaline and adrenaline remained unchanged under both glycemic conditions.

**Conclusions:** Empagliflozin reduces arterial stiffness in patients with uncomplicated T1D. The mechanisms responsible for this decline in arterial stiffness require further study and may relate to pleiotropic actions of SGLT2 inhibition, including glucose lowering, antihypertensive and weight reduction effects.

### Differential Effects of Indoxyl Sulfate and Inorganic Phosphate in Murine Cerebral Endothelial Cells

Andréa Marques Stinghen,[1,2] Jean-marc Chillon,[1] Ziad Massy,[1,3] Agnes Boullier.[1] *[1]Inserm U1088, UPJV, Amiens, France; [2]UFPR, Curitiba, Brazil; [3]A.Paré Hospital, Paris, France.*

**Background:** Endothelial dysfunction, partly due to nitric oxide (NO) unavailability and increased oxidative stress, plays a key role in stroke in CKD patients. To explore the mechanisms, we evaluated the effects of two uremic toxins on cerebral endothelium function.

**Methods:** A murine cerebral endothelial cell line (bEnd.3) was treated with various concentrations of indoxyl sulfate (IS) and inorganic phosphate (Pi). Cell viability was assessed by MTT. NO, ROS and $O_2^{\circ-}$ productions were measured using DAF-FM (0.1µM), DCFH-DA (1µM) and DHE (10µM), respectively. N-acetyl-L-cysteine (NAC,10mM) and vitamin E (10µg/mL) were added prior to IS or Pi treatment. Peroxynitrite ($ONOO^-$) involvement was evaluated using ebselen, a peroxide scavenger. eNOS uncoupling was analyzed by adding 10µM tetrahydrobiopterin ($BH_4$).

**Results:** Cell viability decreases after 24h of IS or Pi treatment (P<0.01). Both toxins significantly reduce NO production (IS, P<0.05; Pi, P<0.001). IS dose-dependently induces ROS production in treated cells (P<0.001). Pi mediates a significant oxidative stress with an highest effect at 3mM (P<0.001). Antioxydants pretreatments significantly reduce ROS levels in cells treated with either IS or Pi (P<0.05 and P<0.001 respectively). IS reduces $O_2^{\circ-}$ production in a dose-dependent manner compared to control cells (P<0.001). This effect is also observed with 2mM Pi (P<0.001). Both antioxydants decrease $O_2^{\circ-}$ production compared to control cells with a greater effect in Pi-treated cells (P<0.001) than in IS-treated cells (P<0.05). Ebselen reduces ROS production induced by both toxins (P<0.001) suggesting a role of $ONOO^-$ in this process. Whereas BH4 addition has no effect on $O_2^{\circ-}$ and NO levels in IS-treated cells, it significantly reduces $O_2^{\circ-}$ and increases NO production in Pi-treated cells (P<0.001) suggesting an eNOS uncoupling induced by Pi.

**Conclusions:** This study shows for the first time that 2 uremic toxins induce cerebral endothelial dysfunction by two different mechanisms. They both decrease NO levels by inducing an oxidative stress. However, Pi seems to be more deleterious since it also induces eNOS uncoupling.

**Effect of Adipose-Derived Stem Cells Cultured with Astragaloside IV on the Cisplatin-Induced Renal Tubular Cells** Huiling Wang. *Div of Nephrology, Jimin Hospital, Shanghai, China.*

**Background:** To investigate the role and possible mechanisms of human adipose-derived mesenchymal stem cells (hADSCs) cultured with Astragaloside IV(Ast) to human renal tubular epithelial cells line (HKC) induced by cisplatin in vitro.

**Methods:** HKC cells were induced by different concentrations of cisplatinfor 24 hours. The proliferation activity and apoptosis of HKC were evaluated with CCK-8 and Flow Cytometer assay respectively. The influence of hADSCs on HKC was detected by transwell culture system, which was used to co-culture for 48 hours. After that,the apoptosis rate and proliferating of HKC were detected by TUNEL and PCNA assay respectively. Transwell culture system was used to test the migration effect of hADSC. The number of migrating cell was counted under a fluorescence microscope .

**Results:** As the increasing of concentrations of cisplatin, the number of HKC was decreasing, meanwhile the apoptosis and necrosis proportion of HKC was enlarging. ,When the density of cisplatin was smaller than 10umol/L,Compared to model group (no co-culture), the apoptotic rates of HKC co-cultured with hADSCs were decreased and the cell number increased obviously($P<0.05$). The effects on HKC were even more pronounced when hADSC cultured with 20mg/L Ast. When the density of cisplatin was bigger than 10umol/L, the proliferation activity and apoptotic rates of HKC were no significant difference between co-cultured group and model group ($P>0.05$). *f*Crystal violet staining show that hADSCs cultured with 20mg/L Ast can increase the number of cells crossing the membrane in the transwell culture system($P<0.05$) after co-cultured.

**Conclusions:** As the increasing of concentrations of cisplatin, the degree of HKC injury was increasing. Cisplatin-indcued HKC can facilitate the migration of hADSC in vitro and hADSCs cultured with 20mg/L Ast can increase the number of cells crossing the membrane. The hADSCs could lessen the apoptosis of HKC induced by cisplatin, especially cultured with 20mg/L Ast, when the density of cisplatin was smaller than 10umol/L. However,when the density was bigger than 10umol/L, it had no obvious effect on HKC.

**Urinary Neutrophil Gelatinase Associated Lipocalin (uNGAL) Is the Most Sensitive Biomarker of Acute Kidney Injury** Peter Hamar, Mária Godó Godó, Csaba Revesz, Tamás Kaucsár. *Institute of Pathophysiology, Semmelweis Univ, Budapest, Hungary.*

**Background:** Acute tubular necrosis (ATN) is the most common cause of ischemic acute kidney injury (AKI). Neutrophil gelatinase associated lipocalin (NGAL) is an accepted early biomarker of tubular epithelial cell injury and inflammation. We aimed to analyse the diagnostic role of NGAL in ischemia-reperfusion (IR) injury in detail.

**Methods:** We performed 10, 20 and 30 minutes of ischemia on the left kidneys with right nephrectomy in C57BL/6 mice. After 1, 3, 6, 15, 24, 48, 72 and 96 hours of reperfusion we examined NGAL renal expression (real-time PCR), localization (immunohisto on tissue microarray), plasma and urine protein levels (ELISA), tubular histology (PAS stain) and renal function by BUN. Inflammation was monitored by plasma IL-6 and p40 (IL-12, IL-23) (ELISA).

**Results:** After ischemia NGAL appeared in a punctuate form in juxtamedullary tubular cells (TEC) at the luminal pole and in tubular lumina. After 1 day reperfusion, NGAL mRNA and 24h urine protein level raised significantly (1.7 fold, $p<0.05$ and 6.3 fold, $p<0.01$, respectively) already after 10 minutes ischemia: not inducing any other renal damage marker. ATN ($p<0.01$), blood urea (BUN) (5.4 fold, $p<0.001$) and plasma NGAL (3.2 fold, $p<0.05$) was elevated only if the ischemia was minimum 20 min. Thirty min. ischemia lead to anuria and to severe ATN already after 1h ($p<0.01$), BUN at 3h (1.8 fold, $p<0.05$), renal NGAL mRNA at 6h (10 fold, $p<0.01$), plasma NGAL at 15 reperfusion (5.2 fold, $p<0.01$). In sham, NGAL renal mRNA and plasma level also increased (the most at 15h), but this elevation was minor vs the IR grop (50 and 5 times lower, respectively). Plasma inflammatory cytokines increased only temporarily. After 20 min ischemia, BUN and plasma NGAL returned to baseline, but renal NGAL mRNA remained elevated longer (13.9 fold, $p<0.05$).

**Conclusions:** NGAL was upregulated by IR and accumulated in apical vesicles of renal TEC. Thus, urine NGAL (if obtainable) is the most sensitive biomarker of tubular ischemic injury. As plasma NGAL could be influenced by other inflammatory processes, it should be used only in the absence of available urine sample.Funding:OTKA, K 81972.

**PUB003**

**Activation of Proximal Tubule Sphingosine 1-Phosphate Receptor-1 Preserves Mitochondrial Function in Cisplatin-Induced Nephrotoxicity in Mice** Amandeep Bajwa,[1] Piotr Chroscicki,[1] Brandon M. Kenwood,[2] Hong Ye,[1] Diane L. Rosin,[2] Kyle L. Hoehn,[2] Mark D. Okusa.[1] *[1]Dept of Med./CIIR, Univ of Virginia, Charlottesville, VA; [2]Pharm., UVA.*

**Background:** S1P is a sphingolipid that is the natural ligand for a family of five G-protein coupled receptors (S1P1-5Rs), regulates cell survival and lymphocyte circulation. The pan S1PR agonist, FTY720 (fingolimod), attenuates ischemia-reperfusion injury by directly activating S1P1 on PT cells. In the current study we hypothesized that S1P1 activation protects kidneys from the nephrotoxic effects of C by preserving PT mitochondrial (Mt) function.

**Methods:** Renal proximal tubule (PT) S1P1KO (*PEPCK-CreS1pr1$^{fl/fl}$*) and control mice (*PEPCK-Cre)* received cisplatin (Cis-27 mg/kg; 20mcM) and renal injury was assessed on day 3 by monitoring plasma creatinine (Cr), inflammatory cell infiltration (by flow cytometry) and changes in pro-inflammatory cytokines (by real time RT-PCR). TKPTS cells were used for over-expression of S1P1.

**Results:** Compared to control mice (Cr: 0.79±0.02 mg/dl) C induced more kidney injury in PT S1P1 KO mice (1.22±0.13, $p<0.05$), and FTY720 reduced injury in control mice (0.47±0.06, $p<0.01$) but not in PT S1P1 KO mice (1.32 ±0.22, n.s.). Control or PT S1P1 KO mice treated with Cis had significantly higher levels of pro-inflammatory cytokines (CXCL1, MCP-1, TNF-$\alpha$ and IL-6) and increased neutrophil and macrophage infiltration in kidneys compared to vehicle-treated mice on day 3. FTY720 attenuated the increased immune cell infiltration and expression of cytokines in control but not PT S1P1 KO mice. Over-expression of S1P1 in TKPTS cells rendered cells resistant to Cis-induced cell death compared to empty vector controls. S1P1-overexpressing TKPTS cells had higher Mt respiratory capacity, Mt numbers (MitoSox/JC-1/Mitotracker) and more Mt fusion compared to control cells after Cis.

**Conclusions:** In summary, activation of S1P1 expressed in PT attenuates C-induced AKI by preserving Mt function. We conclude that FTY720 administration or increasing S1P1 expression might represent a novel strategy in the prevention of C-induced AKI. We are currently examining the mechanism of Mt control by S1P1 activation.

**The Role of Autophagy in Radiocontrast Induced Nephropathy** Gang Jee Ko, So Yeon Bae, Mi-yeon Jung, Yu ah Hong, Heui-jung Pyo, Young-Joo Kwon. *Dept of Internal Medicine, Korea Univ College of Medicine, Seoul, Korea.*

**Background:** Radiocontrast induced nephropathy (CIN) is the third common cause of acute renal failure among inpatients. Although the number of patients taken the exams using radiocontrast is increasing, little has been progressed in the treatment for CIN. The pathophysiology of CIN was known as tubular injury with toxic effect by oxidative stress. Autophagy, which regulates cell death in physiological as well as in pathological conditions with various stress, was known to have a role in tubular injury of acute kidney injury related to cisplatin and ischemia. We investigated the role of autophagy in radiocontrast induced nephropathy.

**Methods:** Radiocontrast nephropathy was induced with male C57BL/6J mice by intraperitoneal injection of iohexol (Omnipaque). Prostanoids and nitric oxide (NO) synthesis was inhibited prior injection of iohexol with indomethacin and NO synthase inhibitor to accentuate tubular injury by radiocontrast. Mannitol was used for osmotic control of iohexol, and 3-methyladenine (MA) was used as an autophagy inhibitor. Tubular injury caused by iohexol was also examined in vitro model using rat tubular cells (NRK-52E).

**Results:** Increased autophagy after iohexol administration was demonstrated with increased LC3 II expression in damaged tubules of kidney. Serum creatinine and tubular injury measured in PAS staining were significantly increased at 24hrs after iohexol administration compared to controls, and they were worsen with autophagy inhibition by 3-MA (creatinine: saline *vs* manntol *vs* iohexol *vs* iohexol+3-MA, 0.26±0.01 *vs* 0.36±0.04 *vs* 0.91±0.19 *vs* 1.31±0.40 mg/dL, $p<0.05$). In vitro study also showed that decreased cell viability measured by MTT assay after iohexol treatment was accentuated with 3-MA pretreatment. Increased caspase 3 and 9 expression after iohexol administration was augmented by autophagy inhibition.

**Conclusions:** Autophagy was associated with radiocontrast induced nephropathy.

**PUB005**

**Evaluation of Ischemic Renal Injury after Nephron-Sparing Surgery Using Dynamic Renal Scintigraphy and L-Type Fatty Acid Binding** Tokunori Yamamoto, Hideki Mizuno, Norihisa Matsukawa, Momokazu Gotoh. *Urology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.*

**Background:** Renal scintigraphy is an established method to quantitatively assess split renal function. L-type fatty acid binding protein (L-FABP) is a novel urinary biomarker to reflect acute kidney injury and may play a role in predicting the extent of ischemic renal injury following nephron-sparing surgery. We evaluated ischemic renal injury after nephron-sparing surgery using dynamic renal scintigraphy and urine level of L-FABP in treated kidney.

**Methods:** We performed open and laparoscopic nephron-sparing surgery for 7 patients with small renal mass and inserted ureteral catheter into the treated renal pelvis. Ischemic renal injury of the treated kidney was evaluated by comparing effective renal plasma flow (ERPF) estimated by radionuclide technetium Tc 99m-mercaptoacetyltriglycine (99mTc-MAG-3) renal scintigraphy before and 1 week after the operation. We calculated a previously described variable called baseline weighted differential (b-WD) of ERPF that represent the percentage of loss of kidney function, considering the baseline value with b-WD of ERPF= (1 week Postoperative ERPF- baseline ERPF)/ baseline ERPF. Urine was obtained from the ureteral catheter 4 hours and 24 hours after de-clamping of the renal artery. We defined induction rate of L-FABP by dividing the 24-hour level by the 4-hour level. The correlation between b-WD of ERPF and induction rate of L-FABP obtained from the ureteral catheter was assessed.

**Results:** There was a strong correlation($R2=0.633$) between b-WD of ERPF and the logarithm of induction rate of L-FABP. The proximal tubuli were stained by L-FABP.

**Conclusions:** The results of the present study show that L-FABP is an effective urinary biomarker to predict the extent of ischemic renal injury following nephron-sparing surgery.

**The Expression of Canonical Transient Receptor Potential Channels 6 in Renal Cortex and Hippocampus of Rats after Intraperitoneal Injection of Silver Nanoparticles** Ye Liu, Zhuo Yang. *Medical College, Nankai Univ, Tianjin, China.*

**Background:** The canonical transient receptor potential channels (TRPC) are members of a large channel family known as TRP channels. TRPC6 serves a variety of functions in both brain and kidney. Recent years, the discovery that the TRPC6 mutation causes familial focal segmental glomerulose sclerosis (FSGS) has aroused great attention to the investigation of this ion channel. The aim of the present study was to observe the expression of TRPC6 in renal cortex and hippocampus during early postnatal development of normal rats, and after exposure to silver nanoparticles.

**Methods:** A dosage of 3mg/kg Ag-NPs was applied to 16 post weaning rats through intraperitoneal injection (Ag-NPs treated group). Other 16 rats of the same age were given the same volume of normal saline to treat as the control group. Eight rats from each group were randomly chosen and executed at the end of the first week, and then the kidneys and hippocampus were removed. Other rats kept on with the treatment of either Ag-NPs or normal saline until the end of the fourth week. Then the rats were executed and the samples were removed as before. Immunofluorescence and Western blotting methods were used to detect the expression alteration of TRPC6 in rats.

**Results:** Results showed that the expression of TRPC6 was detected in glomerulus and tubules of both control group and Ag-NPs treated group. A stable expression was detected in the rat renal cortex during postnatal maturation in control group , while in Ag-NPs treated group, the expression of TRPC6 was increased in rat kidney cortex, and this increased tendency was getting more obvious in rats, which exposed to Ag-NPs for 4 weeks. The expression of TRPC6 didn't show an obvious variation in hippocampus between control group and Ag-NPs treated group.

**Conclusions:** These in vivo experiments suggested that the expression of TRPC6 underwent very little change with the development of kidney and hippocampus in normal post weaning rats, while an increased expression of TRPC6 was found in Ag-NPs exposure rat group, which may be a potential threat for the renal function.

**In Vitro and In Vivo Study of Necropotosis in Renal Tubular Epithelial Cells** Xinling Liang, Jialun Luo, Yuan Han Chen, Fen Jiang. *Div of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

**Background:** Recently research show that there are 4 but not 3 major morphologies of cell death: apoptosis, autophagy, necrosis and a new way described recently: necroptosis which was our major concern that may lead us to a new target point of protecting tubular epithelial cells. Necroptosis death receptor signaling with receptor-interacting protein 1 or 3(RIP1 or RIP3) activation, with no caspase 8 activation and can be inhibited by necrostatins or genetic alteration of RIP1 and RIP3.

**Methods:** We have used a human HK-2 renal tubular epithelial cell line to investigate the necroptosis phenomenon in vitro. HK-2 cells were subjected to TNF-a followed by ATP depletion, and benzyloxycarbonyl-Val-Ala-Asp-fluoro-methylketone (zVAD–fmk) was added to block the activity of caspase-8. And tried to interfere the process. Based on the in vitro result, we made a further research with SD mouse. We used a unilateral nephrectomy+ischemia-reperfusion model (I/R model) and pretreated the mouse with nec-1, NSA and mdivi respectively and combined in different groups, along with parallel control groups were sited. Blood and tissue samples were drawn after the model conducted.

**Results:** Without interfere, the cells showing organelles inflation, fragmentation. However, if we pretreated the cells with a specific blocker nec-1, these phenomenon were inhibited obviously and cell viability were greatly improved ($P<0.05$) with a parallel lower expression in LC3-II. Electron microscopy conform that necroptosis exist and can be block.

We observed the result through pathology, western blot, laser scanning confocal microscope and found that the situation in vitro can be duplicated in vivo, the renal tubular epithelial cells did not commit autophagy, and will mainly behave a necroptosis like in the group which the I/R model animal were treated with mdivi.

**Conclusions:** By this research we establish a way to build a necroptosis cell line model and proved necroptosis blocking can be a protective factor to human HK-2 renal tubular epithelial cell line. Furthermore, nec-1 can also show its protective effects in vivo and play an import role in the AKI of SD mouse I/R model.

**PUB008**

**Trps1 Promotes Kidney Repair following Ischemia-Reperfusion Injury by Regulating Proliferation and Re-Differentiation of Renal** Kehong Chen, Jurong Yang, Yani He. *Nephrology, Daping Hospital, Third Military Medical Univ, Chongqing, China.*

**Background:** Renal tubular epithelium cells (RTECs) are the main victims of acute kidney injury (AKI). Tubule repair following AKI involves epithelial de-differentiation followed by cell proliferation and re-differentiation. Trps1 is a transcription factor which plays a crucial role in the regulation of mesenchymal-epithelial transition in early stage of embryonic kidney development. The purpose of this study is to investigate the role of Trps1 in kidney repair following AKI.

**Methods:** Kidney IRI model was established by clipping bilateral renal pedicles for 45 min (moderate) or 60 min (severe). Ultrasound-microbubble-mediated adenovirus transfer technique was applied to contruct the Trps1 knockdown or over-expression rat model.

**Results:** Moderate and severe IRI rats showed similar renal dysfunction and the degree of renal tissue injury at 1d after injury. Renal tissue damage in severe IRI rats, not in moderate rats, continued to increased and reached the peak at 3d after ischemia. Trps1 expression and renal dysfunction and tubulointerstitial injury scores were negatively correlated. The number of $Trps1^{+}Idu^{+}$ cells and $Trps1^{+}Idu^{+}CldU^{+}$ cells was significantly higher than the predicted value. In severe IRI model, the percentage of PCNA-positive cells in Trps1 overexpression group was significantly higher than that of the control group at 5d after injury. Scr, BUN levels, renal injury scores and vimentin expression ascended significantly in Trps1 overexpression group while α-catenin expression descended at 3d and 7d after injury. In moderate IRI model, the percentage of PCNA-positive cells in Trps1 overexpression group was significantly lower than that of the control group at 3d after injury. Scr, BUN levels, renal injury scores and vimentin expression were attenuated significantly in Trps1 overexpression group while α-catenin expression were enhanced at 1d and 3d after injury.

**Conclusions:** Trps1 regulates proliferation and re-differentiation of renal tubular dedifferentiated cells and promotes kidney repair after AKI.

**Risk Prediction Models for Acute Kidney Injury Requiring Continuous Renal Replacement Therapy after Off-Pump Coronary Surgery** Hiromichi Suzuki,[1] Youhei Tsuchiya,[2] Isao Tsukamoto,[2] Hirokazu Okada,[1] Tsutomu Inoue,[1] Tsuneo Takenaka.[1] *[1]Nephrology, Saitama Medical Univ, Moroyama Machi Iruma Gun, Saitama, Japan; [2]Medical Engineering, Saitama Medical Univ, Moroyama Machi Iruma Gun, Saitama, Japan.*

**Background:** Patients who undergo coronary artery bypass grafting (CABG) are at increased risk for acute renal injury requiring continuous renal replacement therapy. Accurate models are needed to predict the individual risk. Recently, off-pump coronary artery bypass (OPCAB) grafting without cardiopulmonary bypass has become a less stressful surgical procedure for CABG. However, there are only a few papers on OPCAB. The purpose of this study was to assess the impact of OPCAB on the incidence of AKI requiring CRRT.

**Methods:** An observational study of 371 consecutive non dialysis patients who underwent isolated CABG using OPCAB was conducted. Among them, 42 patients needed CRRT due to AKI. Variables with $P<0.05$ in bivariate analysis collected from pre-operative data were entered in the multivariate and proportional hazards regression analysis for risk factors of independent AKI's requiring CRRT after OPCAB was carried out.

**Results:** The risk factors that were independently associated with AKI requiring CRRT were: presence of diabetes mellitus, estimated glomerular filtration rate (less than 45 ml/min/1.73 m2), serum albumin level (less than 3.6 g/dL), hemoglobin level (less than 11.5 g/dL) and use of intra aortic balloon pump.

**Conclusions:** In conclusion, our study will provide a decision aid for OPCAB and highlight the need for further validation and clinical testing of the risk prediction models for AKI requiring CRRT in patients undergoing OPCAB.

**PUB010**

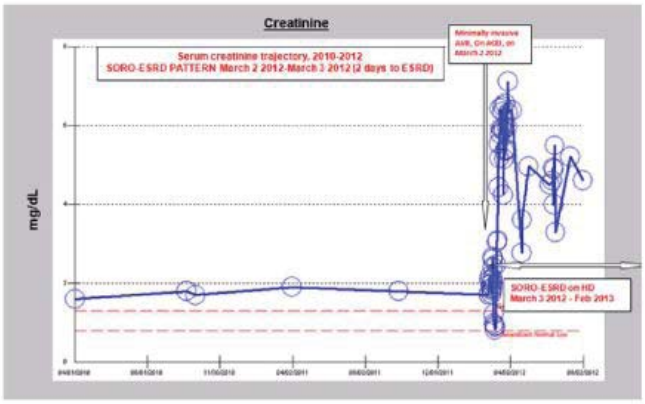
**The Rainbow Syndrome of AKI on CKD: From Full Recovery to Acute Irreversible Renal Failure or the Syndrome of Rapid Onset End-Stage Renal Disease – A Mayo Clinic Perspective** Macaulay A. Onuigbo,[1,2] Ngozi J. Achebe.[3] *[1]Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI; [3]Internal Medicine, Capital Medical Center, Olympia, WA.*

**Background:** Whereas nephrologists and physicians are aware of the phenomenon of acute kidney injury (AKI) on chronic kidney disease (CKD), the common consensus of usual full renal recovery is misguided. Anecdotal and objective evidence demonstrate that quite often, the reverse is the case, and renal recovery is either only partial, or worse still, never occurs, leading to rapid onset yet irreversible ESRD. The latter represents the new previously unrecognized syndrome of rapid onset end-stage renal disease (SORO-ESRD), that we first described in 2010, in the journal ***Renal Failure***. We describe four main patterns of renal outcomes of AKI on CKD as observed in a Mayo Clinic Health System Renal Unit.

**Methods:** Four case reports.

**Results:** Four patterns of renal outcomes following AKI on CKD:

- Full rapid recovery, in days to a few weeks, with terminal eGFR within ≤10% of baseline eGFR, or even higher.
- Partial recovery, in days to a few weeks, with terminal eGFR >10% below baseline eGFR.
- Rapid-onset yet irreversible ESRD, usually within 2-4 weeks, in native kidneys.
- Rapid-onset yet irreversible ESRD, usually withing 2-4 weeks, in renal allografts.



**Conclusions:** We have shown that renal outcomes following AKI on CKD is a spectrum of a continuum from quick complete recovery through to the rapid, unpredictable and precipitate progression to irreversible ESRD without any renal recovery ever. The latter pattern is the syndrome of rapid onset end-stage renal disease (SORO-ESRD), a previously unrecognized syndrome, that we first described in 2010. Undeniably, the variable renal outcomes following AKI on CKD is best described as the several colors of the rainbow.

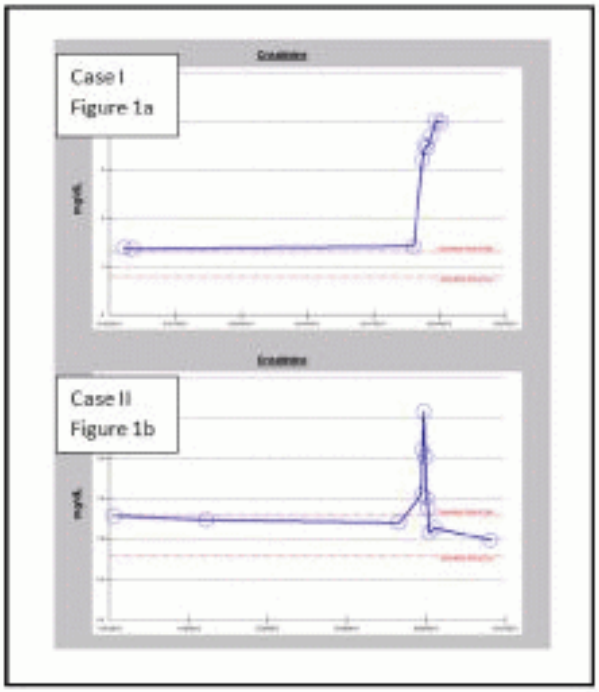
## PUB011

**Quadruple Whammy – A New Preventable Syndrome of Peri-Operative AKI on CKD in Patients on Concurrent Combination Triple Whammy Medications** Macaulay A. Onuigbo,[1,2] Belmarie P. Roman-maradiaga,[3] Ngozi J. Achebe.[4] *[1]Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, Eau Claire, WI; [3]Hospital Medicine, Mayo Clinic Health System, Eau Claire, Eau Claire, WI; [4]Internal Medicine, Capital Medical Center, Olympia, WA.*

**Background:** The potential nephrotoxicity from combination diuretics-ACEIs-NSAIDs, the 'triple whammy', is often unrecognized. In early 2013, we described accelerated post-operative AKI in patients on triple whammy, named 'quadruple whammy', in the ***British Medical Journal***.

**Methods:** Case reports.

**Results:** I. A 59-year old morbidly obese Caucasian male, hypertension, serum creatinine (SCr) 1.42 mg/dL (eGFR 54), developed accelerated oliguric AKI after elective right nephrectomy, peri-operative hypotension and anemia. He was on Lisinopril-Hydrochlorothiazide 20/25, Nabumetone (NSAID) 1000 mg daily. Within 24-hours, SCr more than doubled to 3.2 mg/dL (eGFR 22) with metabolic acidosis and hyperkalemia (Figure 1a). He was transfused; hypotension corrected. He was discharged on Metoprolol and Furosemide. SCr was 1.96 mg/dL (eGFR 37) three months later. II. A 46-year old morbidly obese Caucasian male, hypertension, SCr 1.21 mg/dL (eGFR 70), developed accelerated AKI after elective right hip arthroplasty, peri-operative hypotension and anemia. He was on Lisinopril 40 mg, Hydrochlorothiazide 25 mg daily, and had a preoperative dose of Celecoxib (cox II inh.). Within 36 hours, SCr more than doubled to 2.58 mg/dL (eGFR 28) with metabolic acidosis (Figure 1b). Hypotension was corrected. He was discharged on Amlodipine and Furosemide. SCr was 0.99 mg/dL (eGFR 85), one month later.



**Conclusions:** 'Quadruple Whammy', a new syndrome of preventable AKI with 'triple whammy', due to superimposition of peri-operative stressors especially hypotension is preventable, not uncommon, and calls for more pharmacovigilance.

## PUB012

**Contrast Induced Nephropathy after Transcatheter Arterial Chemoembolization in Hepatocellular Carcinoma** Kenichi Ishizawa,[1] Takamasa Ohki,[2] Takafumi Kanemitsu,[1] Tomoko Honda,[1] Masatomo Chikamori,[1] Ayako Tsuchiya,[1] Rika Miura,[1] Mai Sugahara,[1] Nobuo Toda,[2] Naobumi Mise.[1] *[1]Dept of Medicine, Div of Nephrology, Mitsui Memorial Hospital, Tokyo, Japan; [2]Dept of Medicine, Div of Gastroenterology, Mitsui Memorial Hospital, Tokyo, Japan.*

**Background:** The aim of this study was to determine the incidence and risk factors for contrast induced nephropathy (CIN) after transcatheter arterial chemoembolization (TACE) in patients with hepatocellular carcinoma (HCC) and coexisting chronic liver disease.

**Methods:** We retrospectively investigated 126 patients(97 male, age 70±9 years, estimated glomerular filtration rate (eGFR) 78±21 ml/min)with HCC who underwent TACE between January 2003 and January 2011. The first TACE treatment session of each patient was examined. CIN was defined as an increase in serum creatinine of ≥ 0.5mg/dl or ≥ 25% over baseline within 72 hours after TACE. Low-osmolality contrast medium, iopamidol, was administered in all patients.

**Results:** CIN developed in 4 patients (3.2%) and all recovered without renal replacement therapy. In a univariate analysis, age ($P<0.05$), HCC diameter more than 5-cm ($P<0.05$) and total bilirubin ($P<0.05$) influenced the development of CIN. Multivariate analysis including these 3 variables demonstrated that HCC diameter more than 5-cm ($P<0.05$) was a significant predictor of CIN. Between patients with and without CIN, the prevalence of chronic kidney disease (eGFR less than 60ml/min/1.73m$^2$, 50% vs. 18%, $P=0.11$) and diabetes (50% vs. 20%, $P=0.14$) was comparable. The mean dose of contrast medium was 100±45 ml.

**Conclusions:** CIN after TACE was associated with HCC size, but not with underlying kidney dysfunction. In the present study, the incident rate of CIN was lower than previously reported (9 ~ 24 %).

## PUB013

**M13-796 Study Design – A Phase 2b, Randomized, Double-Blind, Placebo-Controlled, Safety and Efficacy Trial of Multiple Dosing Regimens of ABT-719 for Prevention of Acute Kidney Injury in Patients Undergoing High Risk Cardiac Surgeries** Samina Khan,[1] Peter A. McCullough,[2] Lakhmir S. Chawla,[3] Thomas M. Beaver,[4] Elliott Bennett Guerrero,[5] Deli Wang,[1] Mark T. Houser.[1] *[1]AbbVie, IL; [2]Providence Park Hospital, MI; [3]George Washington Univ Medical Center, Washington, DC; [4]Univ of Florida, FL; [5]Duke Univ Medical Center, NC.*

**Background:** Prevention and treatment of acute kidney injury (AKI) is a significant unmet medical need. Patients undergoing high risk major surgeries are at increased risk for ischemia reperfusion (I/R)-induced AKI. ABT-719 is a novel melanocortin receptor agonist in development for prevention and treatment of AKI. In a Phase 2 study (CS007), 800 μg/kg of ABT-719 reduced the incidence of AKI defined by AKIN and RIFLE criteria, as well as

the 90 day composite outcomes. We describe the study design of M13-796 (ClinicalTrials.gov Identifier NCT01777165), a Phase 2b trial of ABT-719 in patients undergoing high risk on-pump cardiac surgeries.

**Methods:** This is a double-blind, placebo-controlled study. Subjects will be randomized at a 1:1:1:1 ratio into 4 treatment groups: placebo and ABT-719 at 800, 1600 or 2100 μg/kg (3, 5 or 6 bolus infusions, respectively). AKI will be evaluated according to the AKIN, RIFLE and KDIGO criteria with additional clinical outcomes of interest.

**Results:** The primary efficacy endpoint is the proportion of subjects developing AKI based on the AKIN criteria. The key secondary efficacy endpoint is the proportion of subjects developing at least one of the composite events: death, need for renal replacement therapy, or having a ≥ 25% reduction in eGFR at 90 days.

**Conclusions:** M13-796 is designed to further evaluate the efficacy of ABT-719 and optimal dosing strategy for prevention of AKI in patients undergoing high risk on-pump cardiac surgeries.

## PUB014

**Pseudo-Acute Renal Failure after Abdominal Hysterectomy** Muhammad K. Shakeel. *Nephrology and Internal Medicine of Anderson, Anderson, SC.*

**Background:** Intraperitoneal urinary leak from either urinary bladder or ureteral perforation should be considered in the diagnosis of acute kidney injury after gynaecological surgery.

**Methods:** I present a case of reversible acute renal failure after total abdominal hysterectomy. Patient developed intraperitoneal urinary bladder perforation. Subsequently she was noted to have elevated BUN and creatinine after 48 hours of surgery. Elevated creatinine occurred as a result of intraperitoneal urine leak and reabsorption through the peritoneum. Patient was taken to the OR and the leak was repaired.

**Results:** There was a prompt recovery of the serum biochemistry. Early recognition and surgical repair as opposed to dialysis therapy are warranted in such clinical setting. Nephrologist and gynaecologist should be aware of this diagnosis since pseudo-renal failure which may resolve without dialysis.

**Conclusions:** Early recognition and surgical repair as opposed to dialysis therapy are warranted in such clinical setting. Nephrologist and gynaecologist should be aware of this diagnosis as this condition may resolve without dialysis.

## PUB015

**ANA Negative Patient with Lupus Nephritis** Muhammad K. Shakeel. *Nephrology and Internal Medicine of Anderson, Anderson, SC.*

**Background:** I present a case of a 44-year-old male who presented with acute kidney injury and nephrotic syndrome.

**Methods:** Patient underwent a native kidney biopsy which showed immune complex mediated focal proliferative glomerulonephritis with 10% crescents consistent with lupus glomerulonephritis. Initial serology including ANA, complement levels and double stranded anti DNA antibodies were negative. Patient was treated with monthly pulse cyclophosamide and corticosteroids. Patient failed Cyclpphosamide and a repeat kidney biopsy was done which again showed cresentic glomerulonephritis consistent with lupus nephritis. Repeat serology including ANA complements were again negative. Patient was treated with rituximab times two doses. Patient remained nephrotic and there was no improvement in kidney function. Patient was started on haemodialysis and is doing well.

**Results:** The diagnosis of a SLE depends on patient's clinical and laboratory abnormalities. ANA is a diagnostic hallmark of SLE having a frequency of 95% in SLE patients. There are previous case reports of patients with clinical features of SLE having negative test for ANA. These patients appear to represent 1 to 5% of the SLE population. The age of onset and the female predominance are the same for ANA negative SLE as for ANA positive SLE. There are several possible explanations for negative ANA but there is no definitive explanation at this time.

**Conclusions:** My patient may be a rare case of ANA negative lupus nephritis and this suggests that ANA may not be required in the diagnosis of lupus nephritis.

## PUB016

**Acute Kidney Injury and Severe Hypokalemia in McKittrick-Wheelock Syndrome: Report of Two Cases** Claudio Angelini, Elisa Merizzoli, Paola Arosio, Manuel Alfredo Podesta', David Cucchiari, Salvatore Badalamenti. *Nephrology, Humanitas Clinical and Research Center, Rozzano, Milan, Italy.*

**Background:** McKittrick-Wheelock Syndrome (MWS) is a rare disorder characterized by the pentad: (1)secretory diarrhea induced by a colorectal villous adenoma, (2)pre-renal acute kidney injury (AKI), (3)metabolic acidosis, (4)hypokalemia and (5)hyponatremia.

**Methods:** Retrospective analysis of biochemical parameters from two patients admitted for AKI who were previously diagnosed with colorectal adenomas.

**Results:** Laboratory results were consistent with AKI, associated to dehydration, metabolic acidosis and hyponatremia in patients who had a previously normal renal function.

| | Case 1 | Case 2 |
|---|---|---|
| Age/Sex | 72/F | 83/M |
| Adenoma size | 15 cm | 15 cm |
| Creatinine | 11.7 | 4.8 |
| $Na^+$ | 122 | 124 |
| $K^+$ | 2.9 | 2.4 |
| $Cl^-$ | 96 | 94 |
| $HCO^{3-}$ | 14 | 13 |
| Anion Gap | +12 | +16 |

These parameters were rapidly corrected by intravenous infusion of saline. Both cases also showed severe hypokalemia, which was treated with intravenous KCl supplementation (80-90 mEq/day). All the attempts to wean the patients off this therapy resulted in hypokalemia relapse. Extra-renal potassium loss was confirmed by low urinary potassium levels: this finding, along with medical history and biochemical tests, led to MWS diagnosis.

**Conclusions:** MSW clinical picture ensues from the secretory diarrhea induced by colorectal villous adenomas. The adenomatous cells undergo a switch from an absorptive to a secretory phenotype, leading to ions and water loss. Non-anion gap metabolic acidosis results from the equal secretion of sodium, chloride and bicarbonate. When AKI develops, retention of organic acids can increase the anion gap. Patients can remain stable for years, until tumor secretion exceeds renal compensation, determining symptoms onset. MWS severity is proportional to the size and distal localization of adenomas, which prevents the reabsorption of secreted fluids. Although hypokalemia correction can only be achieved by surgical resection, prompt rehydration is usually enough to recover from AKI. Nevertheless, owing to MWS rarity, the diagnosis is often delayed, thus increasing the risk of complications.

## PUB017

**Effect OF Dialysate Fflow Direction on Solute Clearances during Continuous Rrenal Replacement Therapy** Jeong Chul Kim,[1,2] Flavio Basso,[1,2] Mauro Neri,[1] Alessandra Brendolan,[1] Massimo de Cal,[1,2] Monica Zanella,[1] Claudio Ronco.[1,2] *[1]Dept of Nephrology, St. Bortolo Hosp, Vicenza, Veneto, Italy; [2]IRRIV (International Renal Research Institute), Vicenza, Veneto, Italy.*

**Background:** Continuous renal replacement therapy (CRRT) is commonly used in critically ill patients with acute kidney injury (AKI). During CRRT, dialysate can be used to increase solute removal by diffusion. The connection of the dialysate fluid to the filter is usually applied such that dialysate fluid (Qd) flows in the opposite direction (counter-current) of blood to guarantee the maximum solute clearance by diffusion. However, there is no evidence about the superiority of counter-current on co-current configuration in CRRT. We performed a clinical study to investigate the effect of the direction of Qd on urea and creatinine removal.

**Methods:** We conducted a prospective study on adult patients admitted in ICU requiring CRRT. At this point ultrafiltration rate was set as zero and Qd was set as 2000 ml/h. Details of blood sampling procedure was represented in fig 1.

The CVVHDF were randomly initiated with co- or counter-current configuration for the first 50 minutes until it was switched to CVVHD. Urea (Ucl) and creatinine (CrCl) clearance were calculated to each flow configuration.

**Results:** Median value of UCl, CrCl and E/P ratio in co-current vs counter-current configuration were: 27.4 vs 33.3 ml/min, 26.7 vs 33.3 ml/min and 0.82 vs 1.0 respectively ($p< 0.001$).

**Conclusions:** Counter-current dialysate flow configuration during CRRT provides a higher solute clearance. However, advantages of each configuration should be balanced against the overall performance of the treatment and its simplicity in terms of treatment delivery and circuit handling procedures.

**PUB018**

**Modelling Acute Kidney Injury (AKI) Biomarkers** John W. Pickering,[1] Zoltan H. Endre.[1,2] *[1]Christchurch Kidney Research Group, Dept of Medicine, Univ of Otago, Christchurch, New Zealand; [2]Dept of Nephrology, Prince of Wales Clinical School, Univ of New South Wales, Sydney, Australia.*

**Background:** Many factors may modify the temporal profile of urinary AKI biomarkers, including type of biomarker and underlying CKD. We modelled these physiological differences to explore the effect of increased (hyperfiltration) or reduced GFR (CKD) on the biomarker time-course profiles.

**Methods:** Single nephron models of the time-courses of pre-formed (eg GGT) or, induced (eg NGAL) in tubular epithelial cells, or filtered and normally reabsorbed (eg Cystatin C) biomarkers were modelled based on known physiology. Excretion rates were combined using multiples of single nephron urine flow rates to compute urinary concentrations under scenarios of hyperfiltration, normofiltration, and reduced GFR. Whole kidney scenarios were then constructed for kidneys with normal or reduced nephron number.

**Results:** Preformed biomarker concentrations peaked earliest after insult with total excretion limited by pre-injury mass of biomarker, which in turn depended on the number of available nephrons and the rate of biomarker regeneration. Induced biomarkers peaked later and were influenced by nephron number but not limited by this. Filtered biomarker profiles varied with nephron number and GFR with extended time courses compared to other biomarkers.

**Conclusions:** Preformed biomarkers concentrations can directly quantify tubular injury, but must be measured very soon after renal insult. Induced biomarkers provide a longer window of assessment. Filtered biomarkers have the longest window of opportunity, and measure injury directly and indirectly measure reduced GFR.

**Epidemiology of Acute Kidney Injury in Indian Intensive Care Unit – Single Centre Study** Piyush Mathur,[1] Rajasekara Chakravarthi Madarasu,[1] Rusheendra Kambhampati,[1] Vikranth Reddy,[1] Santosh Hedau.[1] *[1]Nephrology, Care Hospital, Banjara Hills, Hyderabad, AP, India; [2]Nephrology, Care Hospital, Banjara Hills, Hyderabad, AP, India; [3]Nephrology, Care Hospital, Banjara Hills, Hyderabad, AP, India; [4]Nephrology, Care Hospital, Banjara Hills, Hyderabad, AP, India.*

**Background:** The incidence of acute kidney injury in intensive care units has increased in past few years but exact incidence is not known in because of many confounding factors.

**Methods:** Material: Single centre study conducted at tertiary care centre from March 2010 till May 2013. Method: Patients admitted in ICU, who developed AKI in 48 hours were included in study after taking consent. Demographic data was collected and patients younger than 18 years, patients with end stage kidney disease on maintenance hemodialysis, renal transplant recipients were excluded from study. Risk factors for AKI and APACHE score was calculated at enrollment.

**Results:** 350 patients were screened during study period for AKI in ICU's and 300 were included in study as they met AKIN criteria for AKI. 261 patients completed the follow up period of study. Out of these 261 patients who had AKI, 80 required renal replacement therapy. Of the 80 patients who required RRT, 40 were managed on hemodialysis, 37 on SLED and 3 were on CVVHDF. Major risk factors for AKI were old age and diabetes. APACHE 3 score was higher in those who had dialysis requiring AKI as compared to those who had AKI but not dialysis requiring. Multiple factors were responsible for AKI but most common etiology for AKI in Indian ICU setting was sepsis with septic shock. Others being drugs, cardiac surgery, contrast agents. The mortality of septic AKI and AKI due to other causes like cardiogenic, drug induced was significantly different.

**Conclusions:** Indian ICUs has high incidence of AKI which is mostly multifactorial. Sepsis is the most common etiology for AKI in a tertiary care ICU. Higher APACHE 3 score at admission to ICU is associated with higher incidence of dialysis requiring AKI.

**PUB020**

**Predictors of Contrast Induced Nephropathy after Coronary Angiogram in Nepalese Population** Sanjib Kumar Sharma. *Dept of Cardiology, College of Medical Sciences, Bharatpur.*

**Background:** The implications of radio-contrast induced nephropathy (CIN) are disastrous. In Nepal there is no published data on CIN**.** This study was undertaken to study the incidence of CIN and to identify risk factors (predictors) for the development of CIN in patients undergoing coronary angiography in tertiary care hospital.

**Methods:** The subject group consists of 540 patients undergoing coronary angiogram/ PCI in 2011 and 2012 enrolled by convenient sampling technique. Two hundreds ten patients were excluded from the study due either to incomplete data or death of the patients before completion of the study duration. Therefore, a total of 330 patients were enrolled in the study and analyzed. Serum creatinine values were measured before and at 24 hours, 48 hours and at 2 weeks of administration of contrast agents. Further measurements were performed in all CIN patients. Contrast-induced nephropathy was defined as an increase of >25% or >0.5 mg/dl in pre-PCI serum creatinine at or after 48 h after PCI. E-GFR was calculated by applying the 4 variables MDRD equation. Standard definitions were used to define the variables.

**Results:** Among the 330 patients studied, diabetes mellitus was present in 84 (28.81%), anemia in 120 (36.36%), e-GFR <60ml/min in 33 (10%), hypertension in 162 (49.09%), and heart failure in 48 (14.54%) patients at baseline. Twenty seven (8.18%) patients experienced CIN. The incidence of CIN in patients with baseline creatinine clearance < 60 ml/min was 45.45.9%. CIN developed in 10% of anemic and 12.5% diabetic patients. The amount of the contrast agent administered was similar for CIN and non-CIN patients (138.20±91.34ml vs. 175.56±118.86 ml; p =0.254). No correlation was found between the amount of contrast agent administered and the change of serum creatinine concentration. Multivariate logistic regression analysis found that baseline e-GFR and baseline hemoglobin were independent predictors for CIN.

**Conclusions:** In this first study of CIN in Nepal, the incident of CIN was 8.18%. Patients with preexisting kidney disease and anemia were at high risk of CIN.

**PUB021**

**A Case of Shunt Nephritis: Early Diagnosis and Management with a Complete Resolution of Acute Kidney Injury** Ibrahim Qaqish,[1] Pratik Shah.[2] *[1]St. Joseph's Hospital & Medical Center; [2]St. Joseph's Hospital & Medical Center.*

**Background:** Shunt nephritis is an immune-complex mediated glomerulonephritis associated with chronically infected ventriculoatrial shunts inserted for treatment of hydrocephalus. Renal outcome is good with early diagnosis and treatment. Delay in diagnosis can lead to irreversible ESRD.

**Methods:** 31-year-old male presented with two day history of worsening of his chronic headaches, blurry vision and fever.His past medical history was significant for ventriculoperitoneal shunt at age 16 weeks secondary to congenital hydrocephalus. His last revision was done 9 months ago when his ventriculoperitoneal shunt was changed to ventriculoatrial shunt. On physical examination only remarkable finding was temperature of 38.6 C. Labs showed hemoglobin of 10 gm/dl and serum creatinine of 2.2 mg/dl. Urine dipstick was positive for hematuria and proteinuria. Urine microscopy showed RBC casts. 24 hour urine protein was 590 mg/24hr. Cerebrospinal fluid (CSF) analysis revealed 172 nucleated cells with predominantly PMN. CSF culture and blood culture were positive for Propionibacterium acnes.Complement levels were low with C3 of 73 mg/dl and C4 of 12 mg/dl.Patient was treated with intravenous vancomycin and infected shunt was removed. Temporary external ventricular drain (EVD) was placed. Once infection cleared, a new shunt was placed and EVD was removed.At the time of discharge his serum creatinine was 1.4 mg/dl which normalized at 0.8 mg/dl two months as outpatient follow up.

**Conclusions:** Shunt nephritis was first described by Black et al in 1965. The overall incidence of ventricular shunt infection varies between 0.7 to 2.2 %. Patients with shunt infection typically present with fever, anemia, and cerebral manifestations i.e. headaches, blurry vision, and seizures. Renal manifestations include hematuria, proteinuria, renal insufficiency, and hypertension.Predominant finding on renal biopsy is membranoproliferative glomerulonephritis (MPGN). Decreased serum complement levels, presence of cryoglobulins or autoantibodies support the diagnosis of shunt nephritis. Treatment of shunt nephritis includes prompt removal of infected shunt and intravenous administration of antibiotics.

**PUB022**

**Protective Effect of N-Acetylcysteine on Contrast Induced Nephropathy in Patients with Stage 2-4 Chronic Kidney Disease** Irem Ari,[1] Mehmet T. Sezer,[2] Salih Inal,[2] Veysel Kidir,[2] Atila Altunta?.[2] *[1]Internal Medicine, Suleyman Demirel Univ School of Medicine, Isparta, Turkey; [2]Nephrology, Suleyman Demirel Univ School of Medicine, Isparta, Turkey.*

**Background:** There is a considerable interest in strategies to prevent contrast induced nephropathy (CIN) because of the increasing prevalence of renal insufficiency and the increasing use of imaging studies using contrast media (CM). The efficacy of N-acetylcysteine (NAC) for preventing CIN is uncertain. We aimed to investigate whether NAC might have a preventive role against the development of CIN in chronic kidney disease (CKD) patients.

**Methods:** The study included 60 stage 2-4 CKD patients undergoing investigations with CM. Patients were randomized into two groups. 2x1200 mg/day iv NAC and 1500 ml/day iv salin infusion were administered for three days starting one day before the procedure in the study group (n:30). Salin infusion was only given to the control group without altering other treatments of patients. Before the CM injection and two days after the procedure serum Cr, daily protein excretion, KIM-1, NGAL and MCP-1 levels were measured and Cr clearances were calculated.

**Results:** Baseline clinical and laboratory findings were similar in two groups.Although serum Cr levels were not significantly different between the two assessments in both groups; KIM-1 and MCP-1 levels increased significantly in the control group (253.03 ± 183.41 vs 388.57 ± 353.59 ; p:0.018 and 185.05 ± 114.66 vs 295.13 ± 274.49; p:0.026, respectively).In the study group, there was only a slight but not significant increase in MCP-1 and KIM-1 levels.

**Conclusions:** In conclusion, we assume that in CKD patients who are undergoing investigations with contrast medium administration, the use of NAC + iv salin infusion significantly reduces the risk of developing CIN. Secondly, KIM-1 and MCP-1 seem to be good surrogate markers for predicting renal tubulary injury.

**PUB023**

**A Strange Case of Hyperphosphatemia during Acute Kidney Injury** Davide Ricci, Raffaella Rizzo, Elena Mancini, Antonio Santoro. *Nephrology Dialysis Hypertension, Policlinico S.Orsola-Malpighi, Bologna, Italia, Italy.*

**Background:** Hyperphosphatemia (HPh) frequently accompanies acute kidney injury (AKI), due to the reduced urinary excretion. A severe HPh is rare, but may appear during cytolytic syndromes, often resulting in overt AKI. An inaccurate definition of the cause of HPh may lead to a wrong diagnosis of AKI.

**Methods:** A 77-y F patient was admitted in the Cardiology Unit because of NSTEMI. Renal function was normal (creatinine 0.85 mg/dl). The patient had a history of chronic obstructive pulmonary disease (COPD) and diverticulosis. After near 1 week, the patient needed enemas. After the administration, she developed copious diarrhoea, hypotension, bradycardia and syncope. In the following 24 hours urine output decreased and blood tests revealed stage 2 AKI (creatinine 1.97 mg/dl, urea 143 mg/dl, uric acid 9.9 mg/dl) with severe hyperphosphatemia (24.2 mg/dl). Inflammatory markers were elevated (leucocytes 23,950/mmc, N91%, PCT 121 ng/ml, PCR 12 mg/dl), as well as cytolysis parameters (CK 181 U/L, myoglobin 1384 ng/mL, LDH 318 U/L). An ultrasound scan showed a solid mass (8 cm) in the left kidney. A thorax scan excluded pulmonary infections.The patient appeared dehydrated.

**Results:** AKI secondary to a cytolytic syndrome and sepsis due to diverticulitis was supposed. In spite of the therapeutic measures, renal function further worsened. The patient was moved to our nephrological department where she was treated with hemodiafiltration. An accurate examination of the clinical history highlighted the administration of 2 enemas with high phosphate content (22 g/100 mL of sodium phosphate). Despite this therapeutic approach, the patient's general conditions worsened rapidly and she died 24 hours after, because of acute abdomen with septic shock (diverticulitis with intestinal perforation was the hypothesis).Autopsy was declined by the family.

**Conclusions:** Acute Phosphate Nephropathy (APN) was the final diagnosis. We can hypothesize a role of inflammation and altered intestinal wall permeability due to diverticulitis that could have favoured phosphate hyperadsorption. A major caution in the use of sodium containing enemas should be used, especially in patients with risk factors and several comorbidities.

**PUB024**

**Incidence, Risk Factors and Prevention of Contrast-Induced Nephropathy in a Medicine In-Patient Setting: Analysis of Current Practices at Veteran Administration Hospital** Aileen P. Tlamsa, Margaret Duffy, Shyam Patel, Osama El Shamy, Tekchand Ramchand, Jin K. Jung, Rakesh Malhotra. *UMDNJ-NJMS, Newark, NJ.*

**Background:** Contrast-induced nephropathy (CIN) is a form of acute kidney injury that occurs after administration of radio-contrast material. The aim of the study was to assess how well current CIN prevention guidelines are being adhered to in clinical practice.

**Methods:** We conducted a retrospective analysis of 245 patients admitted to the medicine floors at the Veteran Affairs (VA) hospital from Sept 2010 – Dec 2012 who received radio-contrast material during their stay. Serum creatinine (sCr) was measured at least once per 24 hour before and within 2 weeks after the radio contrast study. Only patients with minimum of 3 sCr readings were included in the analysis. CIN was defined as rise in serum creatinine ≥ 0.5 mg/dL or 25% relative increase from baseline sCR within 48 hours. The primary endpoint was to calculate the incidence of CIN in our study population. Secondary endpoint was to examine the adherence of CIN prevention guidelines which included use of IV Fluids and N-aceytylcysteine (NAC).

**Results:** The mean (SD) age of the study population was 66.4±12.1 years and 100% were male. The mean (SD) baseline sCr was 1.1±0.9 mg/dL and 14.7% had an eGFR <60 ml/min. Twenty four patients (24/245, 9.8%) developed CIN. The mean increase in sCr levels was 0.42±0.24 mg/dL. The patients who developed CIN had greater prevalence of chronic kidney disease, heart failure and liver disease (20.8% vs. 14.0%; 12.5% vs. 5.9% and 20.8% vs. 16.0%, respectively). 15/24 (62.5%) of the patients who developed CIN were documented to be on IV fluids. None of the 24 CIN patients was prescribed NAC prior to radiographic contrast procedure.

**Conclusions:** Based on our preliminary data, the incidence of CIN in hospitalized male VA medicine patients is high. Furthermore, the adherence to CIN prevention guidelines was suboptimal. Future studies would involve the implementation of a computerized reminder system in accordance with CIN prevention guidelines when ordering IV contrast studies in high risk patients.

**PUB025**

**Immunomodulation with a Selective Cytopheretic Device (SCD) Reduces Injury in a Pig Model of Intracranial Hemorrhage (ICH)** H.D. Humes,[1,2,3] D. Buffington,[1] A. Westover,[1] K. Johnston,[1] P. Smith.[1] *[1]Innovative BioTherapies; [2]Univ of Mich; [3]CytoPherx.*

**Background:** Inflammation has recently been recognized as a central contributor to the pathobiology of stroke and traumatic brain injury (TBI), indicating that therapies that target inflammation may provide a new approach to the treatment of the acute phase of this disease process, particularly for ICH as there are currently no interventive therapies for this subset of stroke patients. The SCD is a novel biomimetic device that has shown efficacy in preclinical models of acute and chronic diseases for which inflammation is an exacerbating factor. When placed in an extracorporeal blood circuit (EBC) with regional citrate anticoagulation (RCA), the low ionized calcium environment provides a simultaneous combination effect to sequester and alter the activity of the transiently bound leukocyte (LE). The safety/efficacy of this device has been demonstrated in clinical studies in ICU patients with ARF and MOF and is currently being evaluated in a US multicenter, randomized pivotal IDE trial. Pilot studies were initiated to determine the SCD effect on the acute inflammatory cascade in ICH.

**Methods:** The acute effects of SCD therapy were evaluated in a pig model of ICH for which thrombin was used as the inflammatory nidus. ICH was induced simultaneously to SCD therapy using an EBC with RCA. Therapy continued for 24 additional hours during which systemic inflammation was monitored by assay of systemic cytokines. Platelet activation and CD11b expression of LE populations were determined using flow cytometry. Most mortem coronal sections of frozen brain tissue were evaluated for LE infiltration, and neuronal injury was evaluated by histology. SCD effects on lesion size and brain edema were evaluated in treated animals (n=3) and compared to a contemporaneous control.

**Results:** SCD therapy resulted in a reduction in edema, reduced expression of neuronal injury markers and reduced LE infiltration as evaluated in animals sacrificed at 24h post ictus.

**Conclusions:** Pilot studies demonstrate that immunomodulation with the SCD represents a novel therapy that has the potential to improve outcomes associated with ICH.

**The Role of p66shc in Renal Toxicity of Oleic Acid** Istvan Arany,[1] Dustin Reed,[1] Luis A. Juncos,[2,3] Mehul P. Dixit.[1] *[1]Pediatrics, Div of Peditric Nephrology, Univ of Mississippi Medical Center, Jackson, MS; [2]Medicine, Univ of Mississippi Medical Center, Jackson, MS; [3]Physiology and Biophysics, Univ of Mississippi Medical Center, Jackson, MS.*

**Background:** Adult and childhood obesity is a growing problem: it is an independent risk factor in development of chronic kidney disease (CKD) and progression to end-stage kidney disease (ESRD). Pathologic consequences of obesity include non-esterified fatty acids (NEFAs)-induced oxidative stress and consequent injury of the kidney. Since the serine36 phosphorylated p66shc is a novel mediator of oxidative stress-dependent kidney injury we studied its role in oleic acid (OA)-induced oxidative stress and consequent injury in cultured renal proximal tubule cells (RPTCs).

**Methods:** Impact of OA or BSA-bound OA (OA-BSA) on production of reactive oxygen species (ROS), mitochondrial depolarization and cell injury (LDH release) was determined in RPTCS that harbor wild type (wt), knockdown (kd), Ser36-phosphorylation-(S36A) or cytochrome c binding-deficient (W134F) p66shc.

**Results:** OA increased ROS production via the mitochondria –and in less extent via NADPH oxidase- resulting in ROS-dependent mitochondrial depolarization. Further studies demonstrated that mitochondrial depolarization is responsible for injury of cultured cells. Knockdown of p66shc, mutation of its Ser36 or cytochrome c binding sites (S36A or W134F, respectively) attenuated adverse effects of OA. Interestingly, OA also stimulated the promoter of p66shc.

**Conclusions:** Our results revealed that OA increased expression, Ser36 phosphorylation and mitochondrial cytochrome *c* binding of p66shc that resulted in mitochondrial depolarization and consequent injury of RPTCs. Hence, these data may offer a novel mechanism by which obesity could lead to development of CKD and ultimately ESRD. Thus, manipulating this pathway may help to prevent obesity-associated renal lipotoxicity.

**Hirsutella Sinensis Antagonize Aristolochic Acid-Induced Epithelial-Myofibroblast Transition through Inhibition of Snail** Xiao-yi Xu, Hong-liang Rui, Yan-yan Wang, Hong Cheng, Yi-Pu Chen. *Div of Nephrology, Beijing Anzhen Hospital, Capital Medical Univ, Beijing, China.*

**Background:** Cordyceps sinensis extracts were shown to inhibit aristolochic acid (AA)-induced renal fibrosis in rodent model. However, the molecular mechanism underlying this process has remained unclear. Hirsutella sinensis (HS) is the anamorphic mycelial form of cordyceps sinensis. This study is to investigate if HS could inhibit AA-induced renal tubular epithelial-myofibroblast transition (EMT) and the role of transcriptional factor, snail, in this process.

**Methods:** Cultured Human renal proximal tubular epithelial cells (HKC) were divided into the following four groups: control group, AA group, AA+ HS group and AA+HS+ SB415286 group. The effects of AA or/and HS on HKC proliferation and cytotoxicity were determined by MTT assay and LDH release assay, respectively. After treatment with AA or/and HS for 12h, the mRNA expression of α-smooth muscle actin, (α-SMA), cytokeratin-18 (CK-18), transforming growth factor-β1 (TGF-β1) and Snail was measured by real time RT-PCR. After treatment for 36h, the protein expression of α-SMA, CK-18, TGF-β1 and snail was measured by Western Blot.

**Results:** 1. 10umM AA or/and 10mg/L HS do not affect cell proliferation and have cytotoxicity on HKC. 2. Compared with the control group, AA stimulation up-regulates the expression of α-SMA and TGF-β1 and down-regulates the expression of CK-18. 3. AA stimulation also up-regulates the expression of snail, which is the key molecular involved in EMT. 4. HS could inhibit AA-induced overexpression of α-SMA, TGF-β1 and snail. HS also up-regulates expression of CK-18. 5. GSK-3β could mediate degradation of snail through phosphorylation of snail. SB415286 up-regulates of expression of snail through inhibiting GSK-3. Compared with AA+HS group, the protective effects of HS on AA stimulation were blocked in AA+HS+ SB415286 group.

**Conclusions:** HS could inhibit AA-induced renal tubular epithelial-myofibroblast transition and interstitial fibrosis. Such effect maybe exert through inhibition of Snail.

**Oxidized High-Density Lipoprotein Impairs Function of Human Proximal Tubular Cells via CD36** Changlin Mei, Xiang Gao. *Kidney Institute of PLA, Changzheng Hospital, Second Military Medical Univ, Shanghai, China.*

**Background:** The participation of tubular lesions in the progression of chronic kidney disease (CKD) is widely recognized, in which inflammation plays an important role. Previous studies reported the presence of oxidatively modified high-density lipoprotein (HDL) in the serum of CKD patients. Unlike native HDL, oxidized HDL is thought to be an adverse factor and may increase the production of inflammatory in chronic diseases, but the effect of oxidized HDL on renal tubular cell remains unclear.

**Methods:** Human proximal tubular cell line (HK-2) was cultured and stimulated with different concentrations of oxidized HDL (0-50 μg/mL) in the absence and presence of CD36 siRNA. Intracellular reactive oxygen species (ROS) levels, proinflammatory factors, apoptosis and migration in HK-2 cells were assayed. The expression of Src (tyr527 and tyr416), MAPK protein (p38, JNK and ERK) and NF-κB activity were also detected.

**Results:** Oxidized HDL enhanced ROS production and upregulated expression of proinflammatory factors including TNF-α, MCP-1 and RANTES in HK-2 cells dose-dependently. Incubation with oxidized HDL also increased apoptosis of HK-2 cells and reduced the ability of migration in a dose-dependent manner. Src-family kinase tyr527, MAPK and NF-κB were activated post oxidized HDL stimulation. All oxidized HDL-mediated effects on HK-2 cells could be significantly attenuated by pretreatment with CD36 siRNA transfection.

**Conclusions:** These findings suggest that oxidized HDL enhances proinflammatory properties and impairs HK-2 cells function largely via scavenger receptor CD36, which might be one of the major players responsible for the progression of chronic kidney disease.

**Inflammation Contributes to Podocyte Injuries and Exacerbates the Progression of Diabetic Nephropathy via HIPK2 Signal Pathway** Kun Ling Ma,[1] Yang Zhang,[1] Chang Xian Wang,[2] Jing Liu,[1] Wu Yu,[1] Bi-Cheng Liu.[1] *[1]Institute of Nephrology, Southeast Univ School of Medicine, Nanjing, China; [2]Infection Mamagement Dept, Southeast Univ School of Medicine, Nanjing, China.*

**Background:** Inflammation plays central roles in the progression of diabetic nephropathy. Homeo-domain interacting protein kinase 2 (HIPK2) is a conserved serine/threonine nuclear kinase. In response to infection, DNA damage, and oxidative stress, HIPK2 is activated and plays a crucial role in renal injuries. This study aimed to investigate whether inflammation exacerbates the progression of diabetic nephrology (DN) via HIPK2 signal pathway.

**Methods:** Twenty male db/db mice were randomly divided into two groups: Control (distilled water injection) or inflamed group (10% casein injection). Body weight and 24-hour urinary protein were measured every week. The plasma levels of serum amyloid A (SAA) and tumor necrotic factor-a (TNF-a) were checked by enzyme-linked immunosorbent assay. The morphological changes of renal pathology and ultra-microstructures were checked by pathological staining and electron microscope. Immunofluorescent staining and Western blotting were used to check the expression of podocyte specific proteins, inflammatory cytokines, and HIPK2 pathway related protein in kidneys.

**Results:** The 24-hour urinary protein, plasma levels of SAA and TNF-α, as well as the protein expression of inflammatory cytokines in kidneys were significantly increased in inflamed group compared to the control. Moreover, there were more significant mesangial expansion, collagen accumulation, and foot process effacement in inflamed group compared to the control. Further analysis showed that inflammation markedly decreased the expression of wilims tumor-1 and nephrin, which were specific biomarkers of podocyte, suggesting accelerating injuries of podocyte induced by inflammation. Interestingly, inflammation increased the expression of HIPK2 and decreased the expression of SIAH1, which was closely associated with accelerated renal injuries.

**Conclusions:** chronic inflammation contributes to podocyte injuries and exacerbates the progression of DN via the activation of HIPK2 signal pathway.

**CCN3 Inhibits TGFβ1-Induced Non-Canonical Smad Signalling in Human Podocytes** Tarunkumar H. Madne,[1] Iain Macphee,[2] Mysore Keshavmurthy Phanish,[1] Mark Edward Dockrell.[1] *[1]SWT Institute for Renal Research, London, United Kingdom; [2]St. Georges, Univ of London, London, United Kingdom.*

**Background:** The pleiotropic growth factor TGFβ1 mediates some of its diverse effects by regulation of multiple signaling cascades as well as the recruitment of other growth factors such as CCN2/CTGF. Recently CCN3 has been identified as putative antagonist to CCN2/CTGF. ]In our work investigating the mechanism of TGFβ's effect on podocytes we have investigated novel signaling pathways activated by TGFβ1 in human podocytes in culture and their regulation by CCN3.

**Methods:** Experiments were conducted on conditionally immortalised human podocytes incubated with TGFβ1 (1.25 & 2.5 ng/mL). Western blotting analysis was performed to detect different levels of Smad and p38 expression and activation. Cells were co-incubated +/- CCN3 (360ng/mL).

**Results:** TGFβ1 induced canonical Smad signaling significantly phosphorylating Smad 2 & 3 at 1h ($p<0.05$). As we have previously reported p38 MAP kinase was also significantly activated by TGFβ1 [ASN 2012]. In addition significant phosphorylation of Smad1/5/8 was also observed ($p<0.05$). Following reports of a requirement for CCN2/CTGF for TGFβ1 activation of Smad1, we co-incubated the cells with the putative CCN2/CTGF antagonist CCN3. Incubation with CCN3 had no effect on activation of Smad2, 3 or p38 but significantly reduced Smad1/5/8 activation ($p<0.05$).

**Conclusions:** To our knowledge this is the first report of the activation of Smad1/5/8 in podocytes by TGFβ1. Our work with CCN3 suggests that endogenous CCN2/CTGF is expressed by podocytes and can mediate the activation of Smad1/5/8. Previous research demonstrated that Smad 1/5/8 activation can regulate collagen IV promoter activity. Hence, we are currently investigating the role of CCN2/CTGF mediated collagen IV expression in podocytes and propose this as a mechanism for glomerular basement membrane thickening observed in renal disease.

**Molecular Mechanisms of TNF-Receptor 1 Mediated Signaling Pathways in Human Peritoneal Mesothelial Cells** Julia Ranzinger,[1] Willie Lüdemann,[1] Danijela Heide,[1] Peter E. Scheurich,[2] Martin G. Zeier,[1] Vedat Schwenger.[1] *[1]Nephrology, Univ of Heidelberg, Heidelberg, Germany; [2]Institute of Cell Biology and Immunology, Univ of Stuttgart, Stuttgart, Germany.*

**Background:** Cellular apoptosis is involved in several physiological processes such as immunological responses and can be induced by the activation of death receptors including tumor necrosis factor receptor 1 (TNFR1). Human peritoneal mesothelial cells (HPMCs) play a central role in the context of inflammatory responses during peritoneal dialysis (PD) caused peritonitis. Although TNFR1 is expressed on HPMCs, TNF-induced apoptosis is inhibited in these cells. The aim of our present study is to investigate the molecular mechanisms of TNF-signaling in HPMCs.

**Methods:** HPMCs were isolated from omentum of healthy donors and dialysis fluid from patients undergoing PD. Flow cytometry was applied to determine the expression of TNFR1 on HPMCS from healthy donors in absence or presence of TNF and dialysis solution in comparison to the TNFR1 expression on cells from PD-patients. To investigate TNFR1-mediated signaling, HPMCs were either treated with dialysis solution or TNF and expression patterns of proteins involved in the TNFR1-signaling pathway (NFĸB, IĸBα, Caspase-3, $cFLIP_L$) were assessed by Western Blot and Immunocytochemistry.

**Results:** We show that incubation of HPMCs with dialysis solution leads to a significant up-regulation of TNFR1 on the cell surface. This correlates with elevated TNFR1-numbers on HPMCs from PD-patients. Concerning the molecular mechanisms of TNFR1-signaling, Western Blot experiments and Immunocytochemistry showed that incubation of HPMCs with dialysis solution results in increased levels of IĸBα protein. Furthermore, dialysis solution caused a reduction of $cFLIP_L$ protein amounts in the cells. In contrast, stimulation of the cells with TNF led to an increase in phosphorylated IĸBα and Procaspase-3.

**Conclusions:** This study shows that dialysis solution used in PD-treatment significantly up-regulates TNFR1 in HPMCs. Moreover, we demonstrate that the presence of dialysis solution affects TNF signaling at the proapoptotic signaling pathway by enhancement of IĸBα and reduction of $cFLIP_L$.

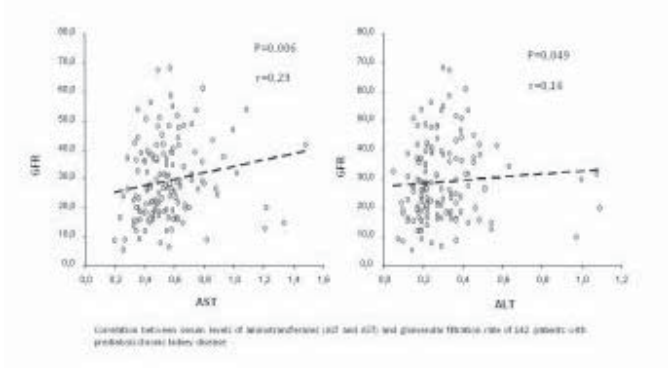
**PUB033**

**Evaluation of Serum Aminotransferases in Patients with Predialysis Chronic Kidney Disease** Luis H.B.C. Sette, Edmundo Pessoa Lopes. *Universidade Federal de Pernambuco.*

**Background:** Pacientes with chronic kidney disease (CKD) on hemodialysis have lower serum levels of aminotransferase than those with normal renal function and such a profile may compromise the diagnosis, clinical management and treatment of patients with CKD and liver disease.However, it is not known the behavior of these enzymes in patients with CKD and its relations with the GFR or the stages of CKD.

**Methods:** From September 2011 to December 2012, was held an observational and cross-sectional study in patients with chronic kidney disease (CKD) attended at the ambulatory of Nephrology at the Hospital of Clinics of the Federal University of Pernambuco (HC-UFPE).Renal function was assessed by estimated GFR using the formula proposed by Cockcroft-Gault. Patients were classified into stages of CKD, according to the definition of the Kidney Disease Outcomes Quality Initiative (K / DOQI).

**Results:** We evaluated 142 patients with CKD, 72 male (52.1%) with a mean age of 64 ± 16 years. The mean GFR was 29.1 ± 13 mL/min/1, 73m2. Patients showed the following distribution according to the stages of CKD: 15 (10.5%) patients stage 5; 70 (49.3%) stage 4, 54 stage 3 (38%) and 3 (2.1%) patients stage 2. The mean serum ALT and AST reduces in proportion to the decrease of GFR ($p = 0.006$ and $p = 0.049$, respectively).



Serum ALT levels were higher in the 57 patients with stages 2 and 3 compared to 85 patients at stages 4 and 5 ($p < 0.03$).

| | CHRONIC KIDNEY DISEASE | | |
|---|---|---|---|
| AMINOTRANSFERASES[a] | STAGES 2-3 | STAGES 4-5 | p-value |
| AST / ULN* | 0.546 (0.454; 0.632) | 0.494 (0.411; 0.603) | **0.066** |
| ALT / ULN* | 0.273 (0.212; 0.394) | 0.219(0.181; 0.341) | **0.030** |
| [a] Mann-Whitney test * Upper limite of normal | | | |

**Conclusions:** Serum ALT and AST correlated with GFR and the reduction of these enzime levels were in accordance with the progression of CKD.

## PUB034

**NGAL and NT-proBNP Levels in Type II Diabetic Patients with Macroproteinuria** Hulya Taskapan,[1] Mehmet Cagatay Taskapan,[2] Özkan Ulutas.[1] *[1]Nephrology, Inonu Univ Medical Faculty, Malatya, Turkey; [2]Biochemistry, Inonu Univ Medical Faculty, Malatya, Turkey.*

**Background:** In patients with heart failure plasma N terminal-pro brain natriuretic peptide (NT-proBNP) levels are correlated to urine Neutrophil gelatinase-associated lipocalin (NGAL) levels. We prospectively evaluated the relationship among glomerular filtration rate (eGFR), urine albumin to creatinine ratio, urine and serum NGAL levels and NT-proBNP in 20 tip 2 diabetic patients with macroalbuminuria at 4-month intervals.

**Methods:** In 20 diabetic patients with macroproteinuria, serum creatinine, albumine, N terminal-pro brain natriuretic peptide (NT-proBNP), serum and urine NGAL levels, urine microalbumin, urine creatinin were measured at the baseline, at the 4th month and at the 8th month. The baseline results of the patients were compared with those of 20 healthy, age and sex matched controls.

**Results:** Diabetic patients had higher urine and serum NGAL, NT-proBNP levels, and lower eGFR. The eGFRs at the baseline, the 4th and the 8th month were 29,6±12,0, 27,8±13,7 and 22,9±10,4mL/min/1.73 $m^2$, respectively. No significant change in urine NGAL levels was detected (p>0,05), wherease there were significantly increases in NTproBNP, serum NGAL levels, and urine albumin to creatinine ratio and significantly decrease in eGFR as the study progressed. (p<0,05). The baseline and the 4th month urine albumin to creatine ratio were positively correlated to NT-proBNP levels measured at the same periods (r:0,451; p:0,046; r:0,489; p:0,029 respectively). In all measurements urine albumin to creatine ratio were negatively correlated to serum albumin levels measured at the same periods (r:-0,792; p:0,000; r:-0,716; p:0,000; r:-0,531; p:0,016 respectively). The 4th month microalbumin to urine creatine ratio was positively correlated with serum NGAL (r:0,478; p:0,033). The 8th month eGFR was negatively associated with urine NGAL (r:-0,471; p:0,039). None of eGFR measurements was correlated with NT-proBNP (p>0,05). Neither serum NGAL nor urinary NGAL levels is associated with NT-proBNP levels(p>0,05).

**Conclusions:** Our findings showed an association between serum NT-proBNP levels and proteinuria in diabetic patients with macroalbuminuria but not with NGAL levels.

## PUB035

**Iron Management in Non Dialysis CKD Patients: The Italian Multicenter Prospective Study in Renal Clinics** Roberto Minutolo,[1] Francesco Locatelli,[2] Giuseppe Conte,[1] Luca De Nicola.[1] *[1]Nephrology, Second Univ of Naples, Naples; [2]A.Manzoni Hospital, Lecco, Italy; [3]For the RECORD-IT Study Group.*

**Background:** Knowledge on iron management in non-dialysis CKD (ND-CKD) patients regularly seen in renal clinics is scarce.

**Methods:** We prospectively evaluated iron management in two visits, performed 6 months apart, in 734 ND-CKD stage 3b-5 patients followed in 19 renal clinics from ≥6 months. Iron deficiency (ID) was defined as TSAT<20% and/or ferritin<100 ng/mL. Endpoints were the change of ID prevalence between basal and month-6 visit (primary) and the prevalence of clinical inertia to iron therapy, that is, the lack of iron prescription despite ID (secondary).

**Results:** Age was 69±13 yrs, GFR 28±10 mL/min/1.73$m^2$ and male gender, diabetes and prior CVD accounted for 57%, 30% and 30%, respectively. CRP [3.0 mg/L (0.5-3.8)], TSAT [24.3±9.5%] ferritin [102 ng/mL (54-193)] did not change at month 6. Table shows changes between the two visits by iron status at baseline (§P<0.05 vs ID, *P<0.05 vs basal).

| | No ID (N=292) | | ID (N=442) | |
|---|---|---|---|---|
| | Basal | Month 6 | Basal | Month 6 |
| Hb (g/dL) | 12.6±1.7§ | 12.5±1.7§ | 12.2±1.5 | 12.2±1.5 |
| Hb<11 g/dL (%) | 16.1 | 18.2 | 19.7 | 20.6 |
| TSAT<20% (%) | 0.0 | 23.3 | 55.9 | 48.0* |
| Ferritin<100 (%) | 0.0 | 12.7 | 81.1 | 69.3* |
| ESA use (%) | 29.1 | 33.2* | 26.9 | 30.1* |
| Iron use (%) | 14.0 | 16.8 | 26.2 | 29.4 |
| Clinical inertia to iron therapy (% of ID pts) | 0.0 | 80.0 | 75.7 | 89.6 |

ID was prevalent at baseline and month 6 (60% and 61%) and was associated to lower Hb (0.4 and 0.5 g/dL, respectively).While ESA use increased at month 6, iron supplementation (91±41 mg/day, oral in 97%) did not change in either group. Among ID patients only a minority received iron therapy at either visit despite low rates of intolerance (13%); consequently, 81% of patients had low TSAT and/or low ferritin at month 6. Clinical inertia to iron therapy was detected in 80% of patients developing ID and involved about 4 out of 5 ID patients at either visit.

**Conclusions:** Therefore, abating clinical inertia for iron therapy likely represents a main area of improvement in the nephrology management of renal anemia.

## PUB036

**25(OH)Vitamin D and Calcitriol: Dissimilar Actions on Left Ventricular Hypertrophy** Bruno C. Silva, Rosa M.A. Moyses, Manuel C. Castro, Rosilene M. Elias. *Nephrology Div, Univ of Sao Paulo, São Paulo, Brazil.*

**Background:** Hypovitaminosis D has been associated to cardiovascular (CV) morbidity and mortality both in general population and in patients with chronic kidney disease. Observational studies have shown that receiving any vitamin D (25(OH)vitamin D or calcitriol) reduced CV risk. Whether the effect of 25(OH)vitamin D (VitD) is independent of calcitriol is still controversial. The aim of this study was to evaluate the role of VitD levels on left ventricular hypertrophy (LVH) in patients on hemodialysis.

**Methods:** We performed a cross-sectional study, including 46 patients who underwent conventional chronic hemodialysis program at a single center facility (University of São Paulo). Clinical, laboratorial, demographic, and echocardiographic data were collected. LVH was categorized as LVH index (LVHI) > or < than 125g/$m^2$. Comparison between these 2 groups was performed using unpaired t tests. Multivariate analysis was also undertaken with LVHI as dependent variable.

**Results:** Of 46 patients, 26 were male, mean age of 47±18 years and dialysis vintage of 8.7 years (1 to 30 years). Mean hemoglobin levels were 11.3±1.5 g/dl and VitD levels of 26.1±12.4 ng/ml (82.6% had levels below 30ng/ml, and 41.6% below 15ng/ml). Nineteen patients (41.3%) were using calcitriol. In univariate analysis, VitD was the only significant variable associated to LVH, showing that levels were lower in patients with LVMI >125gm$^2$ (22.1±13.3 vs 29.1±10.8ng/ml, p=0.046). In backward stepwise logistic regression, VitD deficiency (<15ng/ml) was independently associated to LVH, when adjusting for calcitriol use, hemoglobin levels, and gender (HR 73.06, p=0.006).

| Variable | B | Sig. | Exp(B) |
|---|---|---|---|
| Gender | -0.319 | 0.678 | 0.727 |
| Hemoglobin | 0.485 | 0.086 | 1.62 |
| Calcitriol use | 1.934 | 0.114 | 6.92 |
| 25(OH) vitamin D deficiency | 4.291 | 0.006 | 73.06 |

Table 1. Logistic regression: dependent variable: LVHI

**Conclusions:** 25(OH)vitamin D deficiency is associated to reduced LVH, and its action seems to be independent of active vitamin D3 (calcitriol). Our results are supportive of prescribing VitD to patients on hemodialysis, even for those patients already taking calcitriol.

## PUB037

**The Efficacy and Usefulness of Darbepoetin Alpha in Patients with Chronic Kidney Disease: An Observational Clinical Trial** Noriaki Iino, Junichiro J. Kazama, Ichiei Narita. *Clinical Nephrology and Rheumatology, Niigata Graduate School of Medical and Dental Sciences, Niigata, Japan.*

**Background:** Conventional treatment with epoetin to manage anemia in chronic kidney disease, (CKD) is sometimes hard to reach target hemoglobin level defined by KDIGO guidelines. The aim of this study was to confirm the effectiveness of darbepoetin alpha (DA) on hemoglobin control in patients with CKD with preserved kidney function and to examine the relationship between anemia correction and occurrence of adverse events (i.e., cardiovascular disease, progressive decline in GFR).

**Methods:** An observational study was conducted in 202 patients with CKD who had anemia of hemoglobin levels below 11 g/dl. Patients with a malignancy, or an active gastrointestinal hemorrhage were excluded. Patients received darbepoetin alpha once every 4 weeks for 36 months intravenously or subcutaneously. Physicians adjusted a dose of DA based on manufacturer protocol for hemoglobin target (11-13 g/dl).

**Results:** At 3 months after starting darbepoetin alpha, the mean hemoglobin level increased from 9.6 g/dl to 10.4 g/dl. During follow up period, mean hemoglobin level maintained within target hemoglobin levels defined by KDIGO. To maintain target hemoglobin levels, physicians administered 80 to 100 μg of DA to the patients once every 4 weeks. During the study period, blood pressure remained relatively stable and good control. The mean change in hemoglobin from baseline at 3 months after initiating the study was significantly different between ESA-naive patients and those with previous epoetin-treatment. In the ESA-naive group, mean hemoglobin level rapidly raised to target levels and was maintained during the study period. On the other hand, mean hemoglobin levels slowly increased in previously epoetin-treated group. After 12 months of the investigation, differences of mean hemoglobin levels in the two groups finally diminished. However, to maintain same levels of hemoglobin, requirement dose of DA was significantly different between them.

**Conclusions:** Darbepoetin alpha once every 4 weeks successfully maintained stable hemoglobin levels in patients with CKD with preserved renal function,for prolong period.

**Prescribing in Renal Impairment within the Acute Hospital Setting – A Prospective, Observational Study** Michelle M. O'Shaughnessy,[1] Niamh Allen,[1] John O'Regan,[1] Edwina Louise Payne-danson,[2,3] Lise Mentré,[2,3] Dawn A. Davin,[2] Peter J. Lavin,[1] Tamasine C. Grimes.[2,3] *[1]Dept of Nephrology, Trinity Health Kidney Center, Tallaght Hospital, Dublin, Ireland; [2]Dept of Pharmacy, Tallaght Hospital, Dublin, Ireland; [3]Trinity College Univ, Dublin, Ireland.*

**Background:** Patients with renal impairment (RI) are susceptible to adverse drug reactions. We studied the nature and frequency of potentially inappropriate prescribing (PIP) amongst hospitalised patients with RI. We examined trends in, and risk factors for, PIP and measured agreement between renal prescribing guidelines.

**Methods:** This was a single-centre, prospective, observational study conducted between October 2012 and March 2013. Hospitalized patients with RI were stratified according to estimated GFR and randomly selected for study inclusion. Prescriptions were reviewed at three time-points (pre-admission, admission, discharge) and according to two renal prescribing guidelines, the British National Formulary (BNF) and the Renal Drug Handbook (RDH). Renal Risk Drugs (RRDs) and PIP were identified. Data were analysed using SPSS v20.

**Results:** 173 patients were studied, mean age 71, 52% male. During admission, 2,096 medications including 995 RRDs were prescribed. 93 cases of PIP by RDH (prevalence 39.8%) and 204 by BNF (prevalence 62.2%) were identified. Agreement between guidelines was fair, Cohen's k-coefficient 0.4, $p<0.05$. PIP prevalence increased as renal function deteriorated by BNF, but was similar across renal sub-groups by RDH. For patients with chronic kidney disease, PIP prevalence was lower prior to admission (26.7%) and at discharge (21.8%) than during admission (39.7%). Moderate RI was less commonly recognized and reported than severe RI. Pain, gout and diabetes were independent risk factors for PIP, whereas severity of RI, recognition of RI by treating team, and clinical pharmacy input were not.

**Conclusions:** PIP is common amongst hospitalized patients with RI, although prevalence rates vary depending upon severity of RI, referenced prescribing guideline, timing of assessment and patient co-morbidity. In particular, the impact of disagreement between renal prescribing guidelines upon clinical outcomes requires further study.

**PUB039**

**Anemia Management Practice in Chronic Kidney Disease in Eastern Europe** Andrzej Wiecek,[1] Lyudmila Biriukova,[2] Ivan Rychlik,[3] Gabriel Mircescu,[4] Jacek Lange,[5] Daniell Mitchell.[5] *[1]Medical Univ Silesia, Katowice, Poland; [2]RNRMU, Moscow, Russian Federation; [3]Fresenius Medical Care, Prague, Czech Republic; [4]Medical Univ, Bucharest, Romania; [5]Vifor Pharma, Glattbrugg, Switzerland.*

**Background:** Anemia and iron deficiency (ID) are frequent in chronic kidney disease (CKD) and should be managed with an erythropoiesis-stimulating agent (ESA) and iron. This study evaluated current practice in diagnosis and treatment of CKD-associated anemia in Eastern Europe.

**Methods:** Nephrologists from Bulgaria, Czech Republic, Poland, Romania, Russia, Slovakia, and Slovenia were surveyed (Jan-Feb 2012) for the use of diagnostic tests and therapies in their last 5 CKD patients (stage 3 or 4) that were treated for anemia in the prior 6 months. Data shown for all patients and range across countries.

**Results:** 163 nephrologists reported data of 855 anemic CKD patients (stage 3: 47% [26-59%], female: 52% [44-57%], mean age: 58y [52-65y]). At anemia diagnosis, 97% (94-100%) were tested for hemoglobin (Hb); 48% (23-71%) for serum ferritin and 46% (26-69%) for transferrin saturation (TSAT). Median Hb, ferritin and TSAT were 100g/L (88-110g/L), 84µg/L (12-102µg/L) and 19% (15-24%), respectively. Moderate-to-severe anemia (Hb ≤100g/L) was diagnosed in 67% (42-85%) of patients; 11% (1-36%) presented with Hb <80g/L. Insufficient iron for erythropoiesis (TSAT <20%) was seen in 65% (37-84%) and depleted iron stores (ferritin <100µg/L) in 56% (43-100%) of tested patients. Within 12 months prior the survey, 86% (80-94%) received iron treatment. Despite ESA use in 58% (37-87%), only 27% (9-53%) received intravenous iron. Notably, 17% of patients in the Czech Republic and 14% in Russia received intramuscular iron. Blood transfusions were given to 7% (1-11%) of patients.

**Conclusions:** Current anemia and iron status management in CKD patients varies substantially across Eastern Europe and is often not in line with recommendations. The high proportion of moderate-to-severe anemia and ID suggest insufficient iron status management. Similar findings in Western Europe suggest that improving awareness and implementation of guidelines for management of CKD-related anemia and ID is a pan-European if not a global need.

**Posterior Reversible Encephalopathy Syndrome in Patients with Chronic Kidney Disease** Marta Pereira, Maria Alice Gonçalves Fortes, Hugo Mário Silva, Natacha Rodrigues, Estela Nogueira, Antonio Gomes da Costa. *Nephrology and Kidney Transplantation, Hospital de Santa Maria, Lisbon, Portugal.*

**Background:** Posterior reversible encephalopathy syndrome (PRES) is a clinicoradiologic entity characterized by neurologic symptoms and typical neuroimaging transient changes. PRES is consequence of an endothelial dysfunction of the cerebrovascular barrier. It is associated with many conditions such as hypertension and uremia, and patients with chronic kidney disease (CKD) may have an increased risk for this syndrome.

**Methods:** We report three cases of PRES in patients with CKD on renal replacement therapy.

**Results:** The patients were three women, had a mean age of 20 years, two were in peritoneal dialysis and one in hemodialysis. The patient didn't have an autoimmune disease and weren't receiving immunosuppression. The presenting symptoms were bilateral blindness, loss of consciousness and seizures. All cases progressed to generalized tonic-clonic seizures and one patient was in status epilepticus at admission. All patients had abrupt increases in blood pressure. Hypertension was consequence of anti-hypertensive therapy withdraw in hemodialysis patient. In patients on peritoneal dialysis coexisted signs of failure of the technique with significant hypervolaemia. Brain magnetic resonance imaging (MRI) was performed in all patients and showed extensive bilateral white-matter abnormalities suggestive of edema, not only in the posterior regions of the cerebral hemispheres, but also in other cerebral areas, in the brain stem, and in the cerebellum. The patients were treated with hemodialysis, antihypertensive and antiepileptic drugs. Resolution of seizures occurred in three to four hours and complete neurologic symptoms were resolved in average after five days. In two patients the follow-up MRI revealed imagiologic significant improvement.

**Conclusions:** These cases emphasize the role of hypertension and hypervolaemia as inducing mechanisms of PRES and stress the importance of considering this syndrome in the differential diagnosis of seizures in CKD patients. This is essential since the early diagnosis and treatment may allow complete resolution of neurologic changes, without persistent cognitive sequelae.

**PUB042**

**Low Formic Acid Maybe Involved with Decreased ATP Production in ESRD Patients** Emiko Miyazawa,[1] Hiroyuki Terawaki,[2] Sadayoshi Ito,[1] Masaaki Nakayama.[2] *[1]Dept of Nephrology, Endocrinology, and Vascular Medicine, Tohoku Univ, Sendai, Japan; [2]Dept of Nephrology and Hypertension, Fukushima Medical Univ, Fukushima, Japan.*

**Background:** Formic acid (FA) is an essential substance for de novo synthesis of purine nucleotides. FA is combined with folic acid and incorporated into purine synthesis pathway as formyl-tetrahydrofolate. FA is used as a constituent of C2 and C8 of purine bodies. We previously reported that endogenous FA exists in human plasma. But only a limited number of reports examined about level of FA in ESRD and its physiological role.

**Methods:** Patients with ESRD (CKD 5 and CKD 5D; n=111) and predialysis (CKD 3a-4; n=51) were subjected for analysis of plasma FA and tryptophan (precursor of FA). FA and tryptophan were measured by high-performance liquid chromatography (HPLC). Adenosine triphosphate (ATP) levels were measured by luciferase luminescence method in (a) whole blood, (b) mononuclear cell, and (c) neutrophil after incubation for three hours with the addition of FA, and examined differential rates of increase.

**Results:** The levels of FA (mean ± SD) were 3.04 ± 1.09 mg/L in ESRD, 1.57 ± 1.10 mg/L in predialysis CKD, and 3.71 ± 1.16 mg/L in control ($P<0.05$). Rates of ATP change after incubation for 3 hours with the addition of FA were (a) 2.52 times, (b) 0.97 times, (c) 1.16 times the controls. Significant increases were seen in whole blood and neutrophil ($P=0.011$ and $P=0.0007$respectively), but ATP was not changed in mononuclear cell by t-test.

**Conclusions:** Taken together the result that plasma FA was lower in ESRD, and ATP level was significantly increased when cultured with the addition of FA to isolated neutrophil in healthy subject. It suggests that FA enhances not only purine metabolite but also ATP production. Lower FA maybe involved with the decreased ATP production in ESRD. The clinical relevance of this pathology needs to be addressed.

**PUB043**

**Clinical Utility of Reticulocyte Hemoglobin, a Parameter Obtained on High-End Hematology Analyzers, in the Diagnosis and Assessment of Functional Iron Deficiency in Predialysis Chronic Kidney Disease** Alan F. Almeida,[1] P. Gudsoorkar,[1] J. Kothari,[1] R. Sirsat,[1] S. Khodaiji,[2] K. Sehgal.[2] *[1]Nephrology, P.D.Hinduja Hospital, Mumbai, India; [2]Hematology, P.D.Hinduja Hospital, India.*

**Background:** Functional iron deficiency (FID) can complicate the management of the anemia of CKD. This study evaluates the utility of reticulocyte hemoglobin(Ret-He) as a marker for the assessment of FID.

**Methods:** CKD predialysis patients (Stage 3-5) with hemoglobin <11g%, transferrin saturation ≥20 % and Serum Ferritin >100ng/ml were included. They received intravenously 500 mg of ferric carboxymaltose. Soluble transferrin receptor assay (sTfr), Ret-He (Sysmex XE-2100), Ultrasensitive CRP, serum folate vitamin B12 measured before and Hb, Ret-He and sTfr was checked 1 month after IV iron therapy.

**Results:** 180 patients with CKD (stage 3-5) were screened. 47 enrolled in the study [19(40%) males, 28(60%) females] had a mean age of 46.6 years (S.D 13.7yrs).The most common renal diagnosis was CTID(36%) followed by CGN(32%). A majority were CKD stage 4(45%),followed by stage 5(38%). 4 weeks following iron infusion, a statistically significant increment in Hb ($p<0.001$), Ret-He increased from 23.58 (pre-infusion) to 24.55 (post-infusion)($p< 0.001$). sTfr assay showed a significant decrease with iron treatment ($p<0.001$). Further analysis of 7 patients with definite FID (confirmed by generating Thomas plot) showed a significant improvement in Hemoglobin and Ret-He.

**Conclusions:** Ret-He is a useful test to assess the status of hemoglobinization of RBC. A combination of Ret-He, Sr ferritin and sTfr assay along with the Thomas plot can help categorize the patients as FID. After categorization, the patients can be subjected to intervention in the form of oral iron / IV iron / Erythropoetin alone / Erythropoetin plus IV iron. The Thomas plot will help in the diagnosis and also the follow up of patients of anemia of renal disease. Whether Ret-He alone or in combination with other parameters, like sTfr assay and Sr ferritin, will require further studies with larger sample sizes.

## PUB044

### The Activation of Mineralocorticoid Receptor in Adipose Tissues in CKD Rat Impaired Glucose Metabolism through Tissue ADMA Increase

Kozi Hosoya, Shu Wakino, Ayumi Yoshifuji, Hitoshi Minakuchi, Kazuhiro Hasegawa, Naoki Washida, Koichi Hayashi, Hiroshi Itoh. *Internal Medicine, Keio Univ School of Medicine, Tokyo, Japan.*

**Background:** Recent studies revealed the influence of mineralocorticoid receptor (MR) activation by aldosterone (Aldo) and asymmetric dimethylarginine (ADMA) on the glucose metabolism.We examined whether the activation of MR and ADMA affected insulin resistance (IR) in chronic kidney disease (CKD).

**Methods:** We rendered SD rats renal insufficiency with 5/6th nephrectomy (Nx group) and were treated with MR blockade spironolactone (Spi group). The results of oral glucose tolerance test (OGTT) and intraperitoneal insulin tolerance test (IP-ITT) were compared among the groups. Tissue ADMA levels were measured by ELISA. In *in vitro* analysis, 3T3-L1 fibroblasts were differentiated with/without the addition of Spi.

**Results:** In OGTT, rats in Nx showed impaired glucose tolerance. In ITT, the decline in blood glucose was blunted. These changes were partially reversed in Spi. The phosphor-Akt level after insulin stimulation was attenuated in adipose tissue, which were restored in Spi. These changes were not observed in muscle and liver tissue. MR expression in the nuclear fraction was increased in the adipose tissues in Nx. The expression of SGK1 (Serum/glucocorticoid regulated kinase 1), MR target molecule was upregulated in Nx. These increase were blocked in Spi. The adipose tissue Aldo and ADMA levels were increased in Nx that were reduced in Spi. Both isoforms of DDAH1 and 2, ADMA-degrading enzymes, were downregulated in adipose tissues, which were reversed in Spi. In *in vitro* analysis, Aldo downregulated DDAH1 and DDAH2, which were reversed by the pretreatment with Spi. ADMA inhibited the increase in phospho-Akt levels after insulin stimulation in adipocytes.

**Conclusions:** In CKD, the activation of Aldo/MR pathway in the adipose tissue affected at least in part the insulin resistant state. The activation of adipose tissue MR downregulated DDAH and increased the levels of ADMA, which blocked the insulin signaling.

## PUB045

### Inflammatory Cytokine TNFalpha/IL-6 Related to Muscle Wasting and Up-Regulated Expression of Myostatin and Atrogin-1

Huiling Wang. *Nephrology Div, Jinmin Hospital, Shanghai, China.*

**Background:** Although plenty of research confirmed elevated systemic inflammation related to malnutrition in advanced chronic kidney disease (CKD), few clinic research revealed the mechanism of inflammatory cytokines impacted muscle wasting in patients with CKD. This study investigates the serum cytokines level and muscle wasting of patients with underlying maintenance hemodialysis (HD) and the expression of genes involved in the regulation of muscle mass and that for the inflammatory cytokine TNF-alpha/IL-6 in muscle biopsies.

**Methods:** HD patients were selected according to the enrolled standard as HD group, 30 healthy adults with gender and age matched as control(Ctl). We collected the biochemical and anthropometry data, measured inflammatory cytokine such as C-reactive protein( CRP), interleukin-6(IL-6) and tumor necrosis factor alpha(TNF alpha) by ELISA with their serum samples. Then we got muscle sample from 8 HD patients and 6non-HD patients, observed the muscle histology by light scope after HE staining, and analyzed the transcriptional levels of myostatin and Atrogin-1, TNFalpha; and IL-6 by real-time PCR.

**Results:** 42 patients enrolled in the study. The HD patients kept low level of body weight (68.8+-17.90Kg Ctl vs 58.16+-14.82Kg HD,P=0.003)and body mass index(BMI 23.56+-1.69Kg/m2 Ctl vs 21.52+-178Kg/m2 HD, P=0.026) ; and the plasma albumin showed lower in HD (45.47+-1.91g/L Ctl vs 42.35+-3.62g/L HD, P=0.006) though still in normal limits. The serum inflammation markers such as high sensitive C-protein, TNF alpha; and IL-6 showed elevated in HD compared with Ctl,which showed as hs-CRP1.32(0.11-10.21)mg/L Ctl vs 7.28(2.6-29.68)HD, P<0.001),TNFalpha; 154.8(74.8-298.1) pg/mL Ctl vs 92.6(220.1-1474.7)pg/mL HD, P<0.001); IL-6 1.37(0.03-6.31) Ctl pg/mL vs 2.55(0.13-28.37) pg/mL HD, P=0.004) The morphologic observation showed muscle fibers were tenuous and atrophy in an extent, the space between fibers was widen. The muscle fiber diameter was decreased compared with Ctl. We analyzed mRNA transcription of the muscle myostatin and Atrogin-1,the results showed myostatin mRNA levels was elevated 5.96 fold ; and the Atrogin-1 mRNA increased 2.43 fold respectively; and the TNFalpha;, IL-6 mRNA increased 8.37 fold and 3.36 fold respectively measured by RT-PCR.

**Conclusions:** CKD patients underlying hemodialysis present elevated inflammatory cytokines level and obviously muscle wasting. Up-regulation of TNFalpha and IL-6 expression, stimulating the transcription of myostatin and Atrogin-1, might be an important mechanism of muscle wasting in CKD.

## PUB046

### Assessment of Coronary Artery Calcification in Patients of Coronary Artery Disease with and without Chronic Kidney Disease

Anil Kumar Yadav, Abhishek Kumar, Sunil Agarwal, Alpana Raizada, Shuchi Bhatt, Basu Dev Banerjee, Om Parkash Kalra. *Univ College of Medical Sciences and Guru Teg Bahadur Hospital, Delhi, India.*

**Background:** Cardiovascular disease (CVD) is the main cause of morbidity and mortality in patients with chronic kidney disease (CKD). Vascular calcification, such as coronary artery calcification (CAC) is considered to be the causal link between them; however the role of Multidetector Computed Tomography (MDCT) for assessment of CAC is less well studied. In this study, we assessed CAC in patients of CAD with and without CKD using MDCT.

**Methods:** We conducted a cross sectional study, comprising of 75 patients, 25 in each of the 3 groups: Group I- CAD without CKD, Group II- CAD with CKD stage 3/4,and Group III- CAD with CKD stage 5 on maintenance hemodialysis (MHD) ≥3 months. Patients with diabetes mellitus were excluded. Assessment of CAC was done using MDCT by assigning a scoring system by Agatston as a CAC score. In addition, CAC score was correlated with calcium phosphorus product, intact parathyroid (iPTH) level, duration of CKD and duration of MHD.

**Results:** The mean CAC score was 75.05±193.35 (median 0), 163.62±399.17 (median 1) and 142.48±701.12 (median 0) in patients of Group I, II and III respectively. The CAC score was higher in patients with CKD; however, the difference was not significant ($p=0.792$). We found a positve correlation between CAC and duration of CKD in group II ($r=0.554$, $p=0.004$). Patients having CKD for ≤12 months duration had mean CAC score 24.56±65.17 and those having CKD for >12 months duration had mean CAC score 410.82±602.19. We also found a positive correlation of CAC with duration of dialysis ($r=0.605$, $p=0.001$). Patients who were on MHD for ≤12 months had mean CAC score 3.36±7.70 and those on MHD >12 months had mean CAC score 390.78±1168.99; however, in our study, there was no correlation between CAC and calcium phosphorus product and iPTH levels.

**Conclusions:** The coronary artery calcification was found to have a positive correlation with the duration of CKD and duration of maintenance hemodialysis. Further no correlation was found between CAC score and calcium phosphorus product and iPTH levels.

## PUB047

### Does Impaired Renal Function Interfere with the Development of Coronary Collateral Circulation in Patients with Acute Myocardial Infarction?

Sang Heon Suh, Ha Yeon Kim, Yong Un Kang, Chang Seong Kim, Joon Seok Choi, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Depts of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea.*

**Background:** It has been suggested that low estimated glomerular filtration rate (eGFR) was associated with poor collateral flows in patients with acute myocardial infarction (AMI). We investigated the association of impaired renal function with coronary collateral development. The association of coronary collateral circulation and impaired renal function with clinical outcomes of AMI was also examined.

**Methods:** We retrospectively analyzed 1,760 patients diagnosed with AMI between November, 2005 and March, 2009. eGFR < 60 mL/min/1.73m$^2$ was defined as impaired renal function. According to Rentrop classification, collaterals were considered present with scores ≥ 1 and were considered adequate with scores ≥ 2.

**Results:** Univariate analysis revealed eGFR was lower in patients with visible collateral circulation, while other high risk features of coronary artery disease (CAD), such as elevated hsCRP, N-terminal pro-brain natriuretic peptide, low thrombolysis in myocardial infarction (TIMI) grade before revascularization and low ejection fraction (EF) were also associated with the development of visible collateral flow. Multivariate logistic regression analysis, however, showed there is no significant association between impaired renal function and coronary collateral development, although other factors such as low TIMI grade before revascularization and low EF exerted significant impact on the development of coronary collateral vessels even after the adjustment of confounders. Cox proportional regression analysis for 24-month survival demonstrated impaired renal function, but not the development of any visible collateral, was one of the independent risk factors for all-cause mortality.

**Conclusions:** It is supposed the development of coronary collateral circulation is independent of renal function. Coronary collateral circulation might be mere a reflection of the severity of CAD rather than a guardian of myocardium against AMI.

**PUB048**

**Weekend Weight Gain in Late Stage Chronic Kidney Disease**
Steven Fishbane, Shailaja Chidella, Candice Halinski, Sofia Agoritsas. *Div of Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.*

**Background:** Patients with late stage CKD (stages 4-5) are at high risk for volume related hospitalizations. Reduced salt and water excretion make control of oral intake important. We hypothesized that over weekends patients would have greater weight gain compared to weekdays because of a greater propensity to eat meals at restaurants, attend parties and other functions where dietary intake is difficult to manage.

**Methods:** This analysis is of patients participating in the Healthy Transitions in Late Stage Kidney Disease Program of the Janet and John Raggio Nephrology Institute of the North Shore-LIJ Heath System. Patients with CKD stages 4-5 are monitored, and one aspect is daily weights with computerized tracking of weight changes. Weight changes that reflect the weekend period (Saturday, Sunday and Monday weights) were compared to weight gain on weekdays. Patients were excluded if they did not weigh themselves more than 50% of eligible days.

**Results:** 96 patients with CKD stages 4-5 had 8,821 weights recorded during evaluation periods of 60-182 days. Most patients recorded weights on 70-90% of total possible days (44.4%), another 27.1% had weights on >90% of days and 28.5% between 50-70% of possible days. The mean weight change on weekend days was 0.14±0.16 lb/d compared to -0.10±0.11 lb/d during weekdays ($p<0.0001$). A weight gain greater than 2 pounds occurred on 10.6% of weekends (Sat-Mon) compared to 4.2% of weekdays (Tues-Fri) ($p<0.004$). A weight gain greater than 4 pounds occurred on 3.6% of weekends and 0.8% of weekdays ($P=0.004$).

**Conclusions:** We found that in late stage kidney disease (CKD stages 4-5) that weight gain on weekend days was greater than on weekdays. The risk for excessive weight gain (>2 pounds) was greater over weekends than during the week. Because fluid weight gain is poorly tolerated in late stage CKD, and may increase hospitalization risk, our findings suggest a need for further study of interventions for weekend fluid management.

**Test Battery to Assess Physical and Cognitive Function in Stage 3-4 Chronic Kidney Disease**
Kristen L. Jablonski,[1] Jamie Justice,[2] Douglas R. Seals,[2] Michel Chonchol.[1] *[1]1Div of Renal Diseases and Hypertension, Univ of Colorado Denver, Aurora, CO; [2]Dept of Integrative Physiology, Univ of Colorado Boulder, Boulder, CO.*

**Background:** Physical and cognitive function is impaired in non-dialysis dependent chronic kidney disease (CKD), but has not been well characterized using a battery of tests evaluating multiple domains in a given cohort. Furthermore, there is limited published data available regarding the utility of these tests in patients with CKD not requiring dialysis, despite wide validation in the general gerontology literature.

**Methods:** We compared 10 patients with stage 3-4 CKD (estimated glomerular filtration rate [eGFR] 29+4 mL/min/1.73 $m^2$) matched for age (59+3 years) and gender (8M/2F) to 10 healthy controls (eGFR 89+3 mL/min/1.73 $m^2$).

**Results:** Patients performed worse than controls on the 400 m walk (endurance; 196+5 vs. 308+25 seconds; $p<0.001$), timed up and go (TUG) (mobility; 5.6+0.3 vs. 9.3+0.6 seconds; $p<0.001$), rapid step test (balance; 41.2+1.3 vs. 70.1+6.2 seconds; $p<0.001$), hand-grip strength (strength; 43.6+2.2 vs. 30.5+3.2 kg; $p<0.005$), grooved pegboard (dexterity; 67.3+5.1 vs.125.9+24.3 seconds; $p<0.05$), and trailmaking test part A and B (cognitive function; A: 29.9+3.5 vs. 52.8+9.6 seconds; B: 64.4+8.2 vs. seconds 132.3+30.7; both $p<0.05$).

**Conclusions:** These results confirm physical and cognitive function impairments across multiple domains in patients with stage 3-4 CKD and establish the need for intervention strategies.

**Fibroblast Growth Factor 23 and Pulmonary Hypertension in Patients with Chronic Kidney Disease and Hemodialysis**
Farid M. Nakhoul,[1,3] Nadia Thawho, Ana Roth,[1] Farber Evgeny,[1] Aviva Peleg. *[1]Nephrology, Poriya Medical Center, Israel; [2]Diabetic Nephropathy Lab, Poriya Medical Center, Israel; [3]Faculty of Medicine, Bar Ilan Univ Galilee, Israel.*

**Background:** The pathogenesis of Pulmonary Hypertension in advanced chronic kidney disease and Hemodialysis is hypothesized to be explained by different mechanisms. A-V fistula, parathyroid hormone and hyperphosphatemia. A new player, the Fibroblast growth factor 23(FGF 23) regulates phosphorus metabolism and is a strong predictor of mortality in dialysis patients. FGF 23 is thought to be an early biomarker of disordered phosphorus metabolism in the early stages of chronic kidney disease (CKD), and can cause pulmonary hypertension propably via vascular calcification. our group had described high incidence pulmonary hypertension and increased mortality in HD patients.

**Methods:** Forty one CKD patients on hemodialysis treatment( CKD-D group), and 44 patients with CKD not on dialysis therapy and healthy group (21), were measured for total FGF-23, comparing to healthy control, by using ELISA ( Millipore, St. Charles, MI , USA ) , and arterial pulmonary pressure (PAP) by transthoracic echocardiography.

**Results:** FGF-23 was significantly higher in the CKD-D group compare to control (502.67 ± 575.93 pg/ml vs 8.58 ± 0.92 pg/ml, $p<0.0001$ (Mann-Whitney test). The CKD group had increased FGF-23, at 37.12 ± 90.633pg/ml, significantly higher than the control ($p<0.0001$). Between the CKD groups there was a significant difference ( $p<0.0001$). Both CKD groups, had significantly higher FGF23 level than the control ( $p<0.0001$).

CKD patients had a significantly lower PAP (33.281 ± 12.44 mmHg) than the CKD-D patients (39.23 ± 13.23 mmHg, $p=0.035$), creatinine (2.73 ±1.7 dl mg/dl, vs 6.8 mg/dL $p<0.0001$). Both with the same LVEDD and serum phosphate ($p=0.4$).

**Conclusions:** 1.Patients with CKD express increased levels of plasm FGF-23 compare to healthy control; 2. FGF-23 can be used as a biomarker for early CKD and high incidence of pulmonary hypertension and increased cardiovascular mortality; 3. CKD patients must be followed annualy for pulmonary hypertension by echocardiography.

**PUB051**

**Barriers to Angiotensin Inhibitor Use in Advanced Chronic Kidney Disease**
Shayan Shirazian, Candace D. Grant, Joseph Mattana. *Medicine, Winthrop Univ Hospital, Mineola, NY.*

**Background:** Angiotensin inhibition with an ACEi or ARB is recommended for the treatment of hypertension (HTN) in patients with chronic kidney disease (CKD) and proteinuria regardless of GFR or presence of diabetes (DM). In patients with advanced CKD, angiotensin inhibitors (Ais) may be more conservatively utilized due to known adverse effects. The objective of this study was to determine the frequency with which Ais are used in patients with HTN, proteinuria and stage 4 or 5 CKD and to identify reasons why they are not utilized.

**Methods:** In this cross-sectional study, electronic charts from patients with stage 4 or 5 CKD and HTN seen at an outpatient nephrology practice were reviewed. Eligible patients had moderately or severely increased albuminuria or urine protein to creatinine ratio greater than 150 mg/g at least once during the year prior to study. The frequency of AI use was determined and documented reasons for not using these medications were collected. Groups receiving and not receiving an AI were compared using chi-squared tests for categorical variables and unpaired t-tests for continuous variables.

**Results:** Two-hundred and four charts were reveiwed and 89 patients with HTN, stage 4 or 5 CKD and proteinuria were identified. Fifty-three percent had DM, 57% were male, 75.3% were white, the average age was 70 and the average estimated GFR was 20 mL/min/1.73$m^2$. Of these patients, 46 (52%) were not taking an AI. Documented reasons for not being on an AI included: hyperkalemia (15/46), AKI (9/46), cough or allergy/anaphylaxis (4/46) and no documented reason (18/46). There were no significant differences between the groups on and off an AI with regards to DM status, gender, ethnicity, age, or average estimated GFR.

**Conclusions:** In this study the frequency of AI use among patients with stage 4 or 5 CKD and proteinuria was low, with hyperkalemia and AKI being the most commonly documented reasons for non-use and for a substantial number no reason is given. These findings suggest that there may be substantial opportunities to increase AI use, and future efforts should focus on strategies for increasing tolerance to AI therapy in patients with advanced CKD rather than simply recommending their use.

**PUB052**

**Variables Associated with Increased Proteinuria in Patients with Advanced Chronic Kidney Disease**
Shayan Shirazian, Candace D. Grant, Joseph Mattana. *Medicine, Winthrop Univ Hospital, Mineola, NY.*

**Background:** Reducing proteinuria is an important aim of therapies to slow the progression of chronic kidney disease (CKD) and typically entails aggressive use of ACEi/ARB therapy and blood pressure reduction. With advanced CKD however, markedly altered mineral, acid-base and hormone metabolism among other abnormalities might also exert adverse effects on proteinuria and contribute to CKD progression. Knowledge of such associations might help improve antiproteinuric strategies in this population.

**Methods:** We carried out a cross-sectional study of 187 adult patients with CKD-4 and 5 in an outpatient nephrology practice utilizing an electronic health record and examined the relationship between urine protein excretion and several laboratory variables which are commonly affected by advanced CKD.

**Results:** Urine protein-to-creatinine ratio (UPCR) was positively correlated with serum phosphorus ($r=0.218$, $p<0.01$) and serum intact parathyroid hormone levels ($r=0.181$, $p<0.01$). A negative correlation was found for UPCR and serum bicarbonate ($r=-0.242$, $p<0.01$) and serum 25-hydroxy vitamin D levels ($r=-0.283$, $p<0.01$). Serum albumin levels were negatively correlated with UPCR, both for the population as a whole ($r=-0.366$, $p<0.01$) as well as for patients with UPCR greater than or equal to 0.5 ($r=-0.389$, $p<0.01$), suggesting that the relationship with albumin is not restricted to only those patients with significant proteinuria.

**Conclusions:** These findings suggest that lower vitamin D levels, reduced serum bicarbonate, lower serum albumin levels, elevated phosphorus levels and elevated parathyroid hormone levels may be associated with higher urine protein excretion in patients with CKD-4 and 5. It is plausible that treating these abnormalities in the advanced CKD population might have additive favorable effects on urine protein excretion, though a cause and effect relationship is not clear. Future interventions, possibly through dedicated CKD clinics, should focus on intensive combined therapies to reduce proteinuria in patients with advanced CKD.

## PUB053

**Epoxyeicosatrienoic Acid Prevents Renal Fibrosis and Inflammation via Peroxisome Proliferators-Activated Receptor Activation in Obstructive Nephropathy** Jinu Kim,[1] Babu J. Padanilam.[1,2] *[1]Cellular and Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE; [2]Medicine, Div of Nephrology, Univ of Nebraska Medical Center, Omaha, NE.*

**Background:** Epoxyeicosatrienoic acids (EETs), lipid metabolites produced from arachidonic acid, have anti-inflammatory and profibrinolytic functions in the cardiovascular system. Soluble epoxide hydrolase (sEH) converts EETs to inactive dihydroxyeicosatrienoic acids. Based on previous studies, we hypothesized that genetic or pharmacological inhibition of sEH would attenuate tubulointerstitial fibrosis and inflammation induced by unilateral ureteral obstruction (UUO) in mouse kidneys.

**Methods:** UUO was performed by ligation of the left ureter near the kidney pelvis in sEH-knockout (*Ephx2*-KO) and wild-type (WT) male mice. In WT mice, sEH inhibitor *trans*-4-{4-[3-(4-trifluoromethoxy-phenyl)-ureido]-cyclohexyloxy}-benzoic acid (*t*TUCB, 0.2 mg/d) or vehicle was administered by oral gavage.

**Results:** Genetic or pharmacological inhibition of sEH abolished tubulointerstitial fibrosis as demonstrated by attenuated profibrotic protein expression and myofibroblast formation. Inflammatory response was attenuated as demonstrated by decreased leukocyte influx and proinflammatory protein expression during UUO. Consistently, chronic administration of 11,12- or 14,15-EET regioisomers reduced tubulointerstitial fibrosis and inflammation in UUO-subjected WT mice kidneys. Activity in subtypes of peroxisome proliferators-activated receptor (PPAR), especially PPARγ, were decreased by UUO, but sEH inhibition or 11,12/14,15-EET treatment enhanced PPAR activity.

**Conclusions:** These data demonstrate that EETs anti-inflammatory and fibroprotective effects are mediated via PPAR activation. Our data suggest the potential use of sEH inhibitors or EETs in treating fibrotic diseases.

## PUB054

**Soap Bar Placebo for the Treatment of Nocturnal Leg Cramps in a Chronic Kidney Disease Clinic** Martin Sedlacek. *Dartmouth Hitchcock Medical Center, Lebanon, NH.*

**Background:** Nocturnal leg cramps are a frequent complaint in the chronic kidney disease (CKD) population that we screen for in our specialized CKD clinic. Putting a soap bar under the bed cover is a popular remedy which most likely acts as a placebo. In the absence of a specific treatment for leg cramps we suggest that our patients try the soap bar placebo. As there is no generally accepted objective assessment of leg cramps we record the assessment that patients make of their symptoms.

**Methods:** The electronic medical records of the most recent 100 consecutive patients with chronic kidney disease seen in our CKD clinic by one physician were analyzed.

**Results:** Of 100 patients there were 47 women and 53 men with a mean age of 71 years and an age range of 31 years to 93 years. 15% were in stage 3 CKD, 56% in stage 4 CKD and 29% in stage 5 CKD. 44% had diabetes mellitus. 58 patients had leg cramps (58%) and 30 of these tried out the soap bar and 7 were interested but had not tried yet. Of the remaining 21 patients some were content to use other remedies (tonic water, ice, magnesium, vitamin E, oxycodone, and saltine crackers) and some had only mild symptoms or had other reasons not to try the soap bar. There was a statistical tendency for muscle cramps to be more frequent in women and patients with diabetes mellitus and electrolyte abnormalities. Of the 30 patients who tried the soap bar 18 (60%) reported improvement of the leg cramps. The response was variable, ranging from mild to dramatic.

**Conclusions:** The pathogenesis of nocturnal leg cramps is unknown and likely involves muscle, peripheral and central nervous system. We found that besides correction of metabolic abnormalities and changing possible offending medications, soap bar placebo was an effective treatment for leg cramps in most patients who tried it. Interestingly, there was improvement of symptoms even though the placebo was suggested to patients openly as a placebo.

## PUB055

**Myoclonus in Renal Failure: Two Cases of Gabapentin Toxicity** Lili Chan,[1] Milisha Shah,[2] Mary M. Bridgeman,[2] Kenneth Kaufman,[1] Amay Parikh.[1] *[1]UMDNJ-Robert Wood Johnson Medical School; [2]Robert Wood Johnson Univ Hospital.*

**Background:** Antiepileptic drugs (AEDs) are used in the treatment of epilepsy, pain, and psychiatric disorders. Renal status may impact the efficacy and toxicity associated with AEDs. Gabapentin is an AED that is cleared solely by renal excretion and dosing requires consideration of the patient's renal function. We report 2 cases of myoclonic activity associated with gabapentin toxicity in the setting of renal disease and address treatment with dialysis.

**Methods:** Case 1: 78-year-old woman with congestive heart failure, history of thromboembolism, hypertension, diabetes mellitus, asthma and diabetic peripheral neuropathy presented with tremors involving her upper extremities for 3 days prior to admission. Evaluation revealed acute kidney injury (AKI) secondary to increased furosemide and lisinopril with hyperkalemia and azotemia. The patient was noted to have severe myoclonus. Prior to admission, the patient was being treated with gabapentin 900 mg total daily dose. The patient did not have any history of renal disease, but presented with an estimated glomerular filtration rate of 13 mL/min/1.73 m$^2$. With discontinuation of gabapentin and initiation of hemodialysis, marked improvement in her myoclonus occurred. Case 2: 55-year-old man with end-stage renal disease on peritoneal dialysis (PD), diabetes mellitus, hypertension, neuropathic pain, and peripheral vascular disease with toe gangrene on long term antibiotics presented for evaluation of diffuse body tremors, altered mental status and worsening leg infection. Gabapentin 600 mg total daily dose was initiated 3 days prior to presentation with myoclonus. The patient's PD treatment was increased from 4 to 6 exchanges daily. With increased dialysis and discontinuation of gabapentin, mental status and myoclonus improved.

**Conclusions:** Myoclonic spasms may occur as a complication of gabapentin toxicity, especially in the setting of renal dysfunction. In the cases reported, both hemodialysis and PD were effective in treating myoclonic activity in acute and chronic renal dysfunction. Gabapentin dosing needs to be adjusted in patients with chronic kidney disease and in patients at risk for developing AKI.

## PUB056

**Lithium Induced Chronic Tubulointerstitial Nephropathy; Rate of Progression and Prognostic Markers towards ESRD in the North-Eastern Part of the Netherlands: The Case for Early Referral** Annika M.A. Berends,[1] Frank G.H. van der Kleij,[1] Riko Nap,[1] Casper F.M. Franssen,[2] Judith J. Dasselaar.[1+2] *[1]Dept of Internal Medicine, Div of Nephrology, Scheper Hospital Emmen; [2]Univ Medical Center Groningen, Netherlands.*

**Background:** Lithium, the treatment of choice for bipolar disorder, is known for its renal toxicity. Current guidelines advise a nephrologic consult when kidney function becomes moderately impaired (CKD stage 3A, GFR 45–59 ml/min/1.73m$^2$). The purpose of this study was to examine the course of renal function, and the effects of nephrologic interventions on renal function of patients on lithium.

**Methods:** In this, partially, retrospective study, we included all patients using lithium that were referred to our hospital for renal function decline from 1995 up until now. Subjects are prospectively followed. CKD was defined as eGFR <60 mL/min/1.73m$^2$.

**Results:** Data on thirteen patients (30.8% male) was available up until now. At referral, mean age was 51 years (range 44-71), mean duration of lithium therapy 18±10 years, and mean follow up time 35 months (range 8-132). eGFR was inversely related to duration of lithium use at referral (r: -0.57 (95%CI [-0,85--0,025]), and to last follow-up (r: -0.73 (95%CI [-0,95--0,054]). CKD stage, after correction for age, gender and hypertension, was strongly associated with cumulative lithium exposure (p=0.0037). In 8 patients, lithium therapy was ceased (mean eGFR at cessation: 26±15); renal function improved in none, and four progressed to ESRD.

**Conclusions:** Lithium induced nephropathy proofs to be irreversible, despite cessation of lithium even at CKD stage 3A. Our data might entail an underestimation of known incidence rates of lithium induced chronic tubulointerstitial nephritis and its progression towards ESRD. Future studies are therefore indicated to evaluate the effects on renal function when the CKD stage threshold for nephrologic evaluation is lowered. And, because preserving mental wellbeing is a factor to keep in mind when caring for these patients, those studies should include continuation of lithium as well, since no acceptable alternative to lithium is available as yet.

## PUB057

**Estimating Glomerular Filtration Rate in Chinese Patients with Type 2 Diabetes: A of Creatinine-Base Equations** Jin-xia Chen,[1] Chenggang Shi,[1] Jianhua Huang,[2] Xilian Qiu,[3] Cailian Cheng,[1] Xun Liu.[1] *[1]Div of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guanghzou, China; [2]Dept of Laboratory Medicine, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China; [3]Dept of Laboratory Medicine, The First Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China.*

**Background:** Diabetes has become a major cause of end-stage renal disease (ESRD). The aim of our study is to evaluate the equations based on serum creatininin type 2 diabetic patients in China.

**Methods:** A totle of 454 patients who were diagnosed with type 2 diabetes participated in the study. Comparisons of their efficiency to estimate GFR in the subjects were made between Cockcroft-Gault equation(CG), 6-variable Modification of Diet in Renal Disease equation(MDRD-1), 4-variable MDRD equation (MDRD-4), Reexpressed 6-variable MDRD equation (R-MDRD1), Reexpressed 6-variable MDRD equation (R-MDRD4), Mayo Clinic quadratic equation (MCQ), Chronic Kidney Disease Epidemiology Collaboration equation(CKD-EPI), Chinese equation, previously Japanes equation (Japan-1), new Japanese equation (Japan-2) by using the $^{99m}$Tc-DTPA –GFR to act as the standard GFR (sGFR).

**Results:** None of the equations had accuracy up to the 70% level with a deviation less than 30% from sGFR. The agreement limits of all the equations exceeded the prior acceptable tolerances defined as 60 ml/min per 1.73 m$^2$. When the overall performances were compared, GFR estimated by Japan-1 and Japan-2 demonstrated better results. Area under curve (AUC) of CKD-EPI is the largest. In the subgroup of sex, the accuracy of male is all higher than the female.When sGFR >60 mL/min per 1.73 m2, Japan-1 demonstrate higher accuracy. When sGFR <60 mL/min per 1.73 m2, the CG equation perform a better result.

**Conclusions:** This results displays that Japan-1 andJapan-2 is better than the other equations in overall performance. When sGFR is more than 60 mL/min per 1.73 m2 , the use of Japan-1 and Japan-2 may have better prediction of the GFR in diabetic patients, while if the patients sGFR is less than 60 mL/min per 1.73 m2 , the use of the CG equation is more accurate.

**PUB058**

**The Renal Survival of Post-Nephrectomy in Kidney Cancer and Non-Kidney Cancer Patient – East Cost Malaysian Experiences**
Azreen Syazril Adnan, Azhar Amir Hamzah, Nurul Jannah Ambak, Nik Zamli Nik Jid. *Chronic Kidney Disease Resource Center, School of Medical Sciences, Kota Bharu, Kelantan, Malaysia.*

**Background:** Chronic Kidney Disease (CKD) is a recognized worldwide public health issue. It is associated with increased morbidity, mortality and poor quality of life. Nephrectomy remains the standard of care in treatment of renal masses, however its risks in developing CKD have not been widely studied in our population. This study id meant to examine postoperative CKD and acute kidney injury (AKI) in patients post nephrectomy.

**Methods:** 31 patients from Hospital Universiti Sains Malaysia, whom underwent nephrectomy from 1st January 1998 until 31st December 2011 were enrolled and followed by one year follow-up. Patients' medical records were retrieved and reviewed. Socio-demographic, clinical characteristics and onset of CKD (primary end point) and secondary end point was AKI status were recorded. The duration of freedom from onset of disease was measured from the date of surgery until the onset of event.Survival probabilities were analyzed using the Kaplan Meier Product-limit Estimates (percentages with 95% confidence intervals) and comparison of survival probability used log-rank test. Data entry and analyses were done using SPSS version 20 and Stata version 11 software.

**Results:** Patients age ranged from 2 to 72, with mean ± SD was 43.48 ±3.55 years old. Majority were Malays 26 (83.9%) and 29 (93.5%) underwent open surgery. Overall proportion of CKD was 3.2% and AKI 6.5%. The five-year overall, freedom from the CKD and AKI onset were 100% and 90.5% (95% CI: 67.0%, 97.6%) respectively. The median freedom of CKD and AKI onset cannot be determined because, the survival curve still higher than 50% cumulative survival probabilities. The freedom from CKD and AKI in non cancer nephrectomy group was significant compared to kidney cancer nephrectomy group with log-rank statistics: 4.00 (*p*-value: 0.046) and log rank statistics: 4.21 (*p*-value: 0.040) respectively. Patients underwent surgery because of non kidney cancer had better survival rates.

**Conclusions:** Non-kidney cancer nephrectomy patient shave better renal survival rates from CKD and AKI onset compared to kidney cancer nephrectomy.

**Correlation of 25(OH)D3 Levels with Diet, Serum Calcium, Phosphorus, and Parathyroid Hormone in Normals and in People with Chronic Kidney Disease Stages 1-4 from NHANES 2003-2006**
Linda W. Moore, A. Osama Gaber, Wadi N. Suki. *Surgery, The Methodist Hospital, Houston, TX.*

**Background:** Little is known about the prevalence of low vitamin D [25(OH)D3] levels in stages of chronic kidney disease (CKD) or the correlation of 25(OH)D3 with diet, serum calcium (Ca), phosphorus (P), or intact parathyroid hormone (iPTH) for level of kidney function. We examined 25(OH)D3 levels in a large sample of people with normal kidney function (NL) and CKD subjects, and explored its relationship to kidney function, diet, serum Ca, P, and PTH.

**Methods:** Subjects were from NHANES 2003-2006. Renal function was estimated using the CKD-Epi equation. Intake of dairy product servings, according to the Academy of Nutrition and Dietetics method, was estimated from a 24-hour dietary recall taken the morning of fasting blood sample collection for serum Ca, P, iPTH, and 25(OH)D3. Mean, SE, median, range, correlation (r), and p-value were calculated using complex survey statistics.

**Results:** Only 45% of NL (26.9% US adults) had a 25(OH)D3 level ≥30. 25(OH)D3 and iPTH levels in CKD were different from NL (Table). A positive correlation was present between the level of 25(OH)D3 and number of servings of dairy products (r=0.14), serum Ca (r=0.12) and P (r=0.03). Correlation with iPTH was negative (r=-0.25); all p<0.0001.

| Variable | NL | CKD1 | CKD2 | CKD3a | CKD3b | CKD4 | p-value |
|---|---|---|---|---|---|---|---|
| n | 5,644 | 219 | 252 | 1,116 | 452 | 123 | |
| 25(OH)D3, ng/mL, mean±SE | 23.5±0.4 | 21.3±0.9 | 20.2±0.5 | 25.1±0.4 | 24.2±0.6 | 20.7±1.0 | <.0001 |
| median, range | 23, 2-86 | 20, 4-68 | 19, 3-53 | 25, 3-72 | 24, 6-53 | 20, 3-51 | |
| iPTH, pg/mL, mean±SE | 41.3±0.4 | 44.5±1.9 | 47.4±1.6 | 48.7±0.9 | 60.4±2.1 | 110.9±10.7 | <.0001 |
| median, range | 38, 6-315 | 40, 12-156 | 42, 12-138 | 43, 6-306 | 52, 6-320 | 81, 10-491 | |

**Conclusions:** We conclude that 1) low 25(OH)D3 levels are prevalent in NL and CKD, 2) low levels are associated with elevated levels of iPTH and may explain the hypophosphatemia observed in NL, and 3) dietary intake of dairy products contributes significantly to serum 25(OH)D3.

**PUB061**

**Prevalence of Cardiovascular Risk Factors and Kidney Function Progression among a Developing World Chronic Kidney Disease Sample**
Jafar Al-Said, Teerath Kumar, Soni Murdeshwar. *Nephrology and Internal Medicine, Bahrain Specialist Hospital.*

**Background:** CKD patients had high cardiovascular (CV) mortality and morbidity. Identifying the specific population CV risk factors is detrimental in implementing a successful preventive medical plan. The eGFR drop 3-5 ml/min annually in CKD patients. Reduction in kidney function increases the CV burden. The aims of this study were to identify the CV risk factors profile among CKD outpatient population, and to determine the progression of kidney function and its related factors.

**Methods:** This is a retrospective analysis of adult CKD patient followed in our nephrology department, from Oct. 2003, for 8.5 years. Primary Glomerulonephritis, transplant recipients, and pregnant patients were excluded. Demographic variables and CV risk factors were collected from electronic charts. Calculated eGRF by CKD EPI was used as an estimate for kidney function on the first and last OPD visit. SPSS 18 was used for analysis.

**Results:** Total patients were 245. Mean follow up was 23.6 months (SE 1.6), mean age 58.7 years (SE 0.9), mean BMI 30.5 kg/m2 (SE 0.5). Male form 61% of the total population. Mean eGFR was 45.4 ml/min (SE1.4), and 51% of the populations were having CKD stage III. The average number of CV risk factors was 4 and 95% of the population was having two or more CV risk factors. Hypertension was the most common CV risk factor present among 91% of the population. DM was present among 60%. Hypertension was more prevalent with advanced CKD stage. Uric acid levels increases significantly with the stage of CKD. The eGFR over 2 years of management was stable for the total population. Improvement in eGFR was noticed of 2ml/min among CKD stage III and IV and eGFR increased 4ml/min in non-Hypertensive patients. Certain factors were related to final eGFR.

**Conclusions:** High Cardiovascular risk was found in CKD patients. HTN was the most common CV risk factors present in our CKD population. For the total population eGFR did not decline over two years of treatment; moreover it improved in non-HTN patients and patients with CKD stages III and IV.

**PUB062**

**Long-Term Mortality and Its Risk Factors in Patients with Lupus Nephritis: A Cohort of 158 Patients at a Single Center in Japan**
Ken Kayakabe, Keiju Hiromura, Hidekazu Ikeuchi, Noriyuki Sakurai, Toru Sakairi, Yoriaki Kaneko, Akito Maeshima, Yoshihisa Nojima. *Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.*

**Background:** Lupus nephritis (LN) is a major cause of morbidity and mortality in SLE patients. Although the mortality of LN patients has been reported from various countries, little is known about mortality and its risk factors in Japan.

**Methods:** One hundred fifty-eight LN patients who received renal biopsy at our hospital from 1975 to 2012 were retrospectively analyzed.

**Results:** The mean age was 36.2±13.4 years; 86.7% was female. The mean observation period was 9.8±7.6 years. Urinary protein was 4.0±4.1 g/gCr and eGFR was 79±33 ml/min/1.73m$^2$ at biopsy. ISN/RPS class was as follows; II 12.7%, III 14.6%, IV 41.8%, V 14.6%, III/IV+V 14.6%. During observation periods, 18 patients died; infection (n=5), uncontrolled lupus (n=3; CNS lupus, pulmonary hemorrhage and renal failure), malignancy (n=3), cardiovascular disease (n=2), gastrointestinal disease (n=2), and others (n=3; uncertain, suicide and traffic accident). Early death within 3 years after renal biopsy occurred in 4 patients; 2 in uncontrolled lupus (CNS lupus and pulmonary hemorrhage) and 2 in others (uncertain and suicide). The 5, 10 and 20-year survival rates were 95.5, 93.1 and 76.1%, respectively. The log-rank test showed that older age, complication with CNS lupus, diabetes mellitus and progression of kidney dysfunction (doubling serum creatinine or ESRD) were significantly associated with increased mortality. Neither eGFR at biopsy nor ISN/RPS class was associated with mortality. A multivariate stepwise Cox hazard model revealed independent risk factors for death as follows; older age [per 1-year increase; Hazard Ratio (HR) 1 .09], complication with CNS lupus [HR 14.1] and progression of kidney dysfunction [HR 5.49].

**Conclusions:** Long-term survival rate of our facility is comparable to those of previous reports. From our cohort, older age, complication with CNS lupus and progression of kidney dysfunction were found as independent risk factors for increased mortality of LN.

**PUB063**

**Epidemiology of Nephropathies in Irregular Immigrants in Northern Italy**
Francesco Quarello,[1] Cristiana Rollino,[1] Rosanna Coppo.[2] *[1]Nephrology, Osp. S. G. Bosco, Turin, Italy; [2]Nephrology, Osp. Inf. Regina Margherita, Turin, Italy.*

**Background:** There are about 544.000 irregular immigrants in Italy (out of 60 millions inhabitants). Nephropathies epidemiology in the birth areas of these people is unknown.

Aim of this study was to evaluate the prevalence of renal disease among irregular immigrants in Turin.

**Methods:** The survey was conducted in the health reception center for immigrants from January to December 2012. It was based on: 1) anamnestic evaluation through a questionnaire in 7 languages; 2) serum creatinine (SCr); 3) glomerular filtration rate (GFR-EPI); 4) urine examination; 5) blood pressure.

**Results:** Data of 494 people (287 women, 207 men), mean age 36.9±12 years, 167 black, 11 Asians, were examined. 50 subjects reported hematuria, 90 dysuria, 21 infectious diseases, 67 previous malaria. 23 patients were diabetic (4.6%); in 1 case diabetes was a new diagnosis. Familiarity for kidney disease was found in 4 patients (2 stones, 2 polycystic

nephropathy), hypertension in 29 (5.8%). 63 patients (12.7%) had microhematuria, 67 (13.5%) proteinuria, 15 (3%) both hematuria and proteinuria. Mean SCr was 0.79±0.25 mg/dl (GFR 109±23.7 ml/min/1.73mq); 13 patients had SCr >1.3 mg/dl (10of these also had urinary abnormalities and/or hypertension). We also found: 1 renal glycosuria, 1 schistosomiasis (Schistosoma mansoni), 4 renal stones. 99 patients (20%) were recalled: 69 came. Eventually, 10 patients (2%) were sent to the GP to monitor blood pressure or diabetes; 41 (8.2%) were integrated in a nephrologic follow-up: of these only 8 turned up to the second visit.

**Conclusions:** This survey on irregular immigrants in Northern Italy identified 10 patients (2%) to be monitored by the GP because of hypertension or diabetes and 41 (8.2%) to follow in a nephrologic context for possible ongoing nephropathies or for polycystic disease or stones. Moreover, 1 schistosomiasis, 1 new diabetes and 1 renal glycosuria were detected. The studied people are young: Italian peolple in the same age range have a lower frequency of nephropathy. Poor patients compliance prevented a correct survey and diagnosis. This represents a main issue for the outcome and for the consequent wasted resources.

## PUB064

**Chronic Kidney Disease and Risk of Cardiovascular Events and Death among Asian Adults** Cynthia Ciwei Lim,[1] Boon Wee Teo,[2] Wan Ting Tay,[3] Carol Y. Cheung,[3] Su-chi Lim,[4] Khuan Yew Chow,[5] Jeannette Lee,[6] E. Shyong Tai,[2] Tien Yin Wong,[7] Charumathi Sabanayagam.[3] *[1]Dept of Renal Medicine, Singapore General Hospital; [2]Dept of Medicine, National Univ of Singapore; [3]Singapore Eye Research Institute, Singapore; [4]Diabetes Center, Khoo Teck Puat Hospital; [5]National Registry of Diseases Office, Singapore; [6]School of Public Health, Yong Loo Lin School of Medicine, National Univ of Singapore; [7]Dept of Ophthalmology, National Univ of Singapore.*

**Background:** To examine the association between chronic kidney disease (CKD) and adverse outcomes in a multi-ethnic Asian population using data from two independent studies in Singapore.

**Methods:** A prospective cohort study of 7098 individuals who participated in two population-based studies conducted from 2004-2007: the Singapore Malay Eye Study (n=3148 Malay adults aged 40-80 years) and the Singapore Prospective Study Programme (n= 3950 Chinese, Malay and Indian adults aged ≥40 years) was conducted. CKD was assessed from estimated glomerular filtration rate (eGFR) and urinary albumin-to-creatinine ratio (ACR). eGFR was categorized into ≥60, 45-59.9, <45 ml/min/1.73 $m^2$ and ACR into <30, 30-299, ≥300 mg/g. Outcomes were (1) combined incident cardiovascular disease (CVD) and CVD mortality, and (2) all-cause mortality identified by linkage with national disease/death registries.

**Results:** Over a median follow-up of 4.3 years, 4.6% developed CVD outcome and 6.1% died. Lower eGFR and higher ACR were associated with both outcomes in a dose-dependent manner. Compared to eGFR≥60, the adjusted HR (95% CI) of incident CVD/CVD mortality and all-cause mortality were 1.57 (1.08-2.77) and 1.99 (1.51-2.61) for eGFR<45; compared to ACR<30, the HR (95% CI) were 3.68 (2.10-6.47) and 2.01 (1.13-3.57) for ACR ≥300. In analysis stratified by age, the associations for both outcomes were stronger among those aged <65 years.

**Conclusions:** This study in a large multi-ethnic Asian cohort confirmed that eGFR and albuminuria were independent risk factors for CVD and mortality. Interventional studies are required to assess if modifying these factors will improve adverse outcomes.

## PUB065

**Cardiovascular Risk Factor Profile, Hypertension Control, and Progression of Renal Function among Diabetic and Non-Diabetic in a Developing World Sample** Jafar Al-Said, Teerath Kumar, Soni Murdeshwar. *Nephrology and Internal Medicine, Bahrain Specialist Hospital, Bahrain.*

**Background:** CKD population has high CV risk factors. The major cause of death in CKD patients is Cardiovascular. Diabetes increases further the CV risk. In this study we wanted to:

1- Determine the CV risk factors among diabetic CKD patients and Compare them with non-diabetic patients.

2- Study the progression of kidney function among both subgroups and identify the factors correlated with the final kidney function.

**Methods:** All patients with CKD followed between Oct. 2003 and April 2012 were identified. Demographic and CV risk factors were collected from electronic files. Seventy seven matched diabetic and non-diabetic patients, for age, Gender and BMI, were selected.

| Variables | Diabetic CKD, Mean (SE) | Non Diabetic CKD, Mean (SE) | P |
|---|---|---|---|
| Age | 56.7(1.3) | 57.5(1.8) | NS |
| BMI | 29.2(0.8) | 28.3(0.6) | NS |
| Follow up months | 26.3(2.9) | 26.1(2.9) | NS |
| Urea mg/dl | 57.5(1.8) | 52.2(3.3) | NS |
| Creatinine mg/dl | 1.8(0.1) | 1.7(0.1) | NS |
| eGFR CKD EPI ml/min | 48.4(2.7) | 49.1(2.9) | NS |

The eGFR on the first and last clinic visit were estimated using CKD EPI equation. Progression of CKD over the follow up period was identified. The prevalence of CV risk factor and the renal function progression were tested using SPSS version 18.

**Results:** Total patients were 245. Mean follow up was 23.6 months (SE 1.6). In each subgroup 52 were males. Diabetic CKD subgroup has a mean of 5 CV risk factors as compared to 3 in non-DM. Hypertension was the most common risk factor. Hypertension and hyperlipidemia were more common in DM subgroup. Urea, Creatinine and eGFR in both subgroups were not significantly different on the first visit. There was no significant change in eGFR over the follow up. Certain factors were related with the last eGFR.

**Conclusions:** Diabetic CKD population has higher CV risk factors. Hypertension and Hyperlipidemia are the most common CV risk and more prevalent in diabetic CKD. The eGFR did not decrease over the follow up for both subgroups. We would like to share our population data with the global nephrology group.

## PUB066

**Ratings of Executive Functioning in Children and Young Adults with CKD** Stephen R. Hooper,[1] Jerilynn Radcliffe,[2] Divya Ganeshmurthy Moodalbail,[2] Nina Laney,[2] Abbas F. Jawad,[2] Susan L. Furth.[2] *[1]Univ of North Carolina School of Medicine, Chapel Hill, NC; [2]Children's Hospital of Philadelphia, Philadelphia, PA.*

**Background:** Cognitive deficits in individuals with mild to severe CKD are well documented; however, few studies have examined executive function in children and young adults with CKD. Such measurement approaches may provide a cost effective strategy for nephrologists working with this population and provide useful clinical information with respect to health care management for individuals with CKD.

**Methods:** Cross sectional observational study of 42 children and young adults with CKD (eGFR below 90 ml/min/1.73m2), ages 8 to 25 years. The primary instrument was the Behavior Rating Inventory for Executive Functioning (BRIEF) completed by either the parent, for subjects (ages 8 to 18), or the adolescent/young adult (ages 19 to 25). Scores across the two versions of the BRIEF were combined for comparison purposes. Initial data analyses included descriptive findings of the CKD sample, with elevated ratings of at least one standard deviation above the normative mean reflecting risk for impairment.

**Results:** Mean(SD) age and eGFR were 15(3) yrs and 42(23) ml/min/1.73m2. The sample was 64% male and 67% Caucasian. 29% had transplant and 5% were on dialysis after a failed transplant. Results showed that none of the Behavior Regulation scales were significantly elevated when compared to normative expectations, with the Behavioral Regulation Index (BRI) falling within the average range (BRI T-Score = 54.39). The Metacognitive Index (MI) and Global Executive Composite (GEC) were also within average range (MI T-Score = 59.64, GEC T-Score = 59.64), although weaknesses were noted for Working Memory, Initiate, and Monitoring scales with associated effect sizes greater than 0.5 SD.

**Conclusions:** These findings indicated the presence of mild executive dysfunction, particularly for behavioral initiation, self-monitoring, and working memory. It will be important for nephrologists to be aware of the executive capabilities of their patients, especially with respect to how these capabilities affect adherence to medical care and ongoing medical management.

## PUB067

**Cross Sectional Findings from the German Chronic Kidney Disease Cohort** Stephanie Titze, Matthias Schmid, Anna Kottgen, Martin Busch, Katharina Paul, Claudia Sommerer, Georg Schlieper, Johan M. Lorenzen, Jan T. Kielstein, Thomas Sitter, Elke Schaeffner, Seema Baid-Agrawal, Karl F. Hilgers, Wolfram Gronwald, Jürgen Floege, Christoph Wanner, Florian Kronenberg, Kai-Uwe Eckardt. *On Behalf of the GCKD Investigators.*

**Background:** Chronic kidney disease (CKD) is increasingly recognized as a global health problem. Causes and prognosis differ markedly, but the reasons for the heterogeneity remain poorly understood. Throughout the recent years registry data have become available, but prospectively obtained data in patients with moderate CKD are still scarce.

**Methods:** The German Chronic Kidney Disease (GCKD) Study is a national cohort study with CKD of various etiologies; patients have been enrolled prospectively in cooperation with 169 nephrologists in Germany. A structured interview and clinical examination were performed and data from medical records obtained. Biosamples were acquired in standardized fashion. At the time of screening, male and female patients had to have an estimated GFR of 30-60 ml/min x 1.73 $m^2$ or overt proteinuria in the presence of an eGFR > 60 ml/min x 1.73 $m^2$.

**Results:** GCKD enrolled a total of 5217 CKD patients, 60% male and 40% female, with a mean age of 59 years and mean eGFR of 45 ml/min. Approx. 8% of the cohort were included due to overt proteinuria. Roughly 26% had undergone kidney biopsy. A significant proportion of patients had several underlying causes or unclear diagnosis. The most common causes were nephrosclerosis (38%) and diabetic nephropathy (27%). Immunological diseases were more present in younger patients. There was a high cardiovascular disease burden with approx. 20% history of CAD and approx. 10% of cerebrovascular or peripheral artery disease.

**Conclusions:** The GCKD Study has established one of the largest cohorts of non-dialysis dependent CKD patients worldwide. Baseline analysis confirms a high cardiovascular disease burden and shows uncertainties in identification of the underlying primary cause of kidney disease. The comprehensive data set of the GCKD-study will allow comparative and pooled analyses with other renal cohorts worldwide to validate observations and to identify important regional differences.

## PUB068

### Incidence of Proteinuria Is a Simple Sign of Poor Outcome in Cancer Patients Receiving Gemcitabine

Masaki Hara,[1] Minoru Ando,[1] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Renal Div, Dept of Medicine, Tokyo Metropolitan Komagome Hospital, Bunkyo-ku, Tokyo, Japan; [2]Dept IV of Internal Medicine, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan.*

**Background:** Gemcitabine (Gem) is a widely used as an anti-cancer drug. Gem administration induces glomerular thrombotic microangiopathy, resulting in the emergence of proteinuria and/or kidney dysfunction. This study attempted to ascertain both incidence of proteinuria and an association between incident proteinuria and mortality in Gem recipients.

**Methods:** A prospective cohort study was conducted in 60 non-proteinuric patients with pancreatic or biliary cancer (mean age, 67 years), who received the first single therapy of Gem and who lived over 6 months following the administration. Incident proteinuria was defined as dipstick test ≥ 1 +, persistent in at least two consecutive examinations within 6 months. Cumulative mortality was analyzed by the Kaplan-Meier method, stratified by presence and absence of incident proteinuria. Multivariable proportional hazards regression analysis was used to calculate hazard ratio (HR) with its 95% confidence interval (CI) for all-cause mortality, adjusted for age, gender, disease severity, and estimated glomerular filtration rate (eGFR).

**Results:** Incidence of proteinuria was 23.3% in the first 6 months, and mortality rate was 45.0% in the follow-up period (median, 251; range, 20 – 550 days). Cumulative mortality was significantly greater in patients who developed proteinuria (82.4%) than those who did not (38.2%) at the time of 450 days following the Gem administration. The HR (95% CI) of proteinuria incidence was 3.36 (1.44 – 7.49; P = 0.0060), as compared with the absence of incident proteinuria.

**Figure. Kaplan-Meier curves stratified by presence and absence of incident proteinuria**

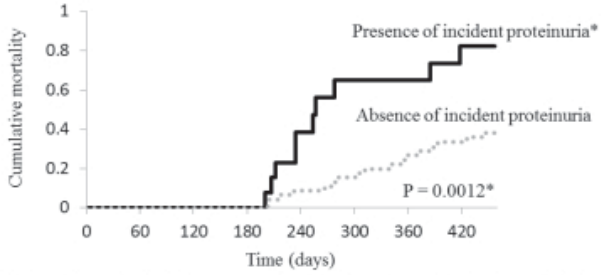

**Table. Adjusted risks of incidence of proteinuria for time to mortality in Gem recipients**

| | Univariable analysis | | Multivariable analysis | |
|---|---|---|---|---|
| Variable | HR (95% CI) | P value | HR (95% CI) | P value |
| Age | 0.99 (0.94 - 1.04) | 0.7213 | 1.02 (0.97 - 1.09) | 0.3857 |
| Gender, men | 2.17 (0.99 – 5.07) | 0.0508 | 1.94 (0.86 – 4.69) | 0.1098 |
| Stage of the disease | 1.62 (1.03 - 2.91) | 0.0349 | 1.65 (1.02 – 3.01) | 0.0411 |
| eGFR | 1.01 (0.99 – 1.04) | 0.2184 | 1.01 (0.98 – 1.03) | 0.4533 |
| Incidence of proteinuria | 3.43 (1.49 – 7.45) | 0.0046 | 3.36 (1.44 – 7.49) | 0.0060 |

**Conclusions:** Incidence of proteinuria may be a harbinger of near-term death in Gem recipients.

## PUB069

### Sex and Racial Differences in End-Stage Renal Disease Risk in Diabetes

Margaret K. Yu,[1] Xiaobo Ding,[1] Bessie A. Young.[1,2] *[1]Univ of Washington; [2]VA Puget Sound Health Care System.*

**Background:** Chronic kidney disease (CKD) is more common in women than in men, however few studies have examined the relationship between sex and risk of end-stage renal disease (ESRD). Furthermore, although racial/ethnic minority women have a high burden of CKD risk factors, there is little information regarding ESRD risk by sex and race. The objective of this study is to assess sex and racial differences in 10-year incident ESRD risk in a primary care diabetic population.

**Methods:** The Pathways Study is a prospective, observational cohort of ambulatory, diabetic patients from a large managed care population in Seattle, WA. Self-reported race/ethnicity was used to categorize subjects as non-Hispanic white, non-Hispanic black, Asian, or other. Subjects were followed for 10 years for incident ESRD. Cox proportional hazards regression was used to estimate the risk of incident ESRD by sex and race/ethnicity, after adjustment for age, marital status, education, smoking, diabetes duration, hemoglobin A1c, baseline estimated glomerular filtration rate (eGFR), microalbuminuria, body mass index (BMI), and depression, taking into account mortality as a competing risk.

**Results:** Of the 3877 total subjects, 1864 (48.1%) were women. Racial composition did not vary by sex (79.4% non-Hispanic white, 8.4% non-Hispanic black, 8.0% Asian, and 4.2% other races). Women were less likely to be married or have a high school education and had higher BMI and baseline eGFR compared to men. 78 subjects developed ESRD over 10 years. Amongst women, Asians had the highest unadjusted incidence rates of ESRD (4.99 per 1000 person-years vs 3.51 in non-Hispanic blacks and 2.82 in non-Hispanic whites). Amongst men, non-Hispanic blacks had the highest incidence of ESRD (6.55 per 1000 person-years vs 3.45 in Asians, 3.37 in other races, and 2.62 in non-Hispanic whites). In the fully adjusted model, Asian women had an increased risk of incident ESRD (sub-hazard ratio 2.75, 95% CI 1.20-6.30) compared to non-Hispanic white men.

**Conclusions:** In this primary care diabetic population, Asian women had a greater risk of incident ESRD at 10 years compared to non-Hispanic white men. Asian women with diabetes may represent a high risk subgroup for ESRD.

## PUB070

### Long-Term Outcome and Prognostic Factors of Idiopathic Membranous Nephropathy: Looking Back on the past Twenty Years

Rika Sakai,[1] Masao Kikuchi,[1] Yuji Sato,[1] Kazuo Kitamura,[1] Shouichi Fujimoto.[2] *[1]First Dept of Internal Medicine, Univ of Miyazaki, Miyazaki, Japan; [2]Dept of Hemovascular Medicine and Artificial Organs, Univ of Miyazaki, Miyazaki, Japan.*

**Background:** Idiopathic membranous nephropathy (IMN) is common cause of adult onset nephrotic syndrome. Although 30% patients showed spontaneous remission, 30-40% patients progress end-stage renal disease. This study addressed the long-term outcome and prognostic factors of IMN.

**Methods:** From 1992 to 2012, we diagnosed 100 patients with biopsy-proven IMN. 74 patients were followed up at least 1 year. We checked their drug history (prednisolone, cyclosporine, cyclophosphamide, angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, statin, aspirin and warfarin) and complications (cerebrovascular accidents, cardiovascular accidents, malignancy). Present patient's status was divided into three groups by degrees of proteinuria: complete remission (CR), partial remission (PR) and nephrotic syndrome (NS).

**Results:** The mean age of studied patients was 59±13 years. The 5, 10 and 15 years of renal survival rate of IMN were 94%, 91% and 85%. During the follow up (average 107 months), 5(7%) patients reached end-stage renal disease. They significantly showed high levels of serum creatinine and total cholesterol at renal biopsy. In present, 39 patients (53%) are in CR, 19 patients (26%) in PR, 9 patients (12%) in NS. Patients in NS were significantly used more immunosuppressant. 5(7%) patients developed cardiovascular accidents and these patients had higher level of serum creatinine at renal biopsy, no drug history of cyclosporine, more drug history of aspirin or warfarin and more malignant disease. 7(9%) patients developed malignant disease and these patients had more cerebrovascular and cardiovascular accidents.

**Conclusions:** In our study, IMN patients with higher level of serum creatinine and total cholesterol at renal biopsy showed poor renal prognosis. Although there was no relationship between their drug histories with poor renal prognosis, non-use of cyclosporine was associated with cardiovascular accident. Further studies are necessary to clarify the effectiveness of treatment.

## PUB071

### Prevalence of Heart Failure in a Cohort of Patients with Chronic Kidney Disease: Results from the German Chronic Kidney Disease Study

Anna Kottgen,[1] Hanna Beck,[1] Stephanie Titze,[2] Silvia Huebner,[2] Martin Busch,[3] Florian Kronenberg,[4] Vera Krane,[5] Kai-Uwe Eckardt.[2] *[1]Univ of Freiburg, Germany; [2]Univ of Erlangen-Nürnberg, Germany; [3]Univ of Jena, Germany; [4]Univ of Innsbruck, Austria; [5]Univ of Würzburg, Germany.*

**Background:** Reduced kidney function is a risk factor for the development and progression of heart failure, but there is limited data on the prevalence of heart failure from large cohorts of patients with chronic kidney disease (CKD) of moderate severity. In this initial analysis, we examined the prevalence and correlates of self-reported heart failure in the German Chronic Kidney Disease (GCKD) Study.

**Methods:** The GCKD Study is a prospective observational cohort. Between 2009 and 2012, 5217 CKD patients aged 18 to 74 years with an eGFR of 30 to <60 ml/min/1.73m² or eGFR ≥60 and overt proteinuria during screening were enrolled. As part of a detailed standardized interview including cardiovascular disease history, patients were asked if they were suffering from heart failure. Patients not meeting inclusion criteria or with missing information were excluded from analysis. GFR was estimated from serum creatinine by the 4-variable MDRD Study equation. Factors associated with heart failure were identified using logistic regression.

**Results:** The overall prevalence of self-reported heart failure was 18% (18% among men and 17% among women). Heart failure prevalence was considerably higher in patients with coronary heart disease (43% vs. 11% without) and those with diabetes (26% vs. 13% without). Overall, heart failure prevalence increased with lower eGFR from 5% among patients with eGFR of ≥90 ml/min/1.73m², 13% for eGFR 60-89, 17% for eGFR 60-89, 20% for eGFR 30-44, to 21% for eGFR <30 ml/min/1.73m². The strongest associations of prevalent heart failure were observed with older age, presence of coronary heart disease, valvular heart disease, higher BMI, hypertension and diabetes.

**Conclusions:** Heart failure is common among patients with CKD, and constitutes a large burden of disease. Alternative definitions of heart failure using information from signs and symptoms of heart failure as well as from biomarkers will be evaluated.

## PUB072

**Improved In-Hospital Morbidity and Mortality for Patients Treated by Hemodialysis Undergoing Orthopedic Procedures** David Bennett,[1] Ting-jung Pan,[3] Steven K. Magid,[3] Stephen Lyman,[3] Mayu Sasaki,[3] Jeffrey I. Silberzweig.[2] *[1]New York-Presbyterian Hospital-Weill Cornell Medical College; [2]The Rogosin Institute; [3]Hospital for Special Surgery.*

**Background:** The in-hospital post-operative medical course for patients with Chronic Kidney Disease (CKD) treated by hemodialysis (HD) undergoing orthopedic procedures has not been well reported. The few published reports document high rates of morbidity (up to 100%) and mortality (up to 28.5%), but have not clearly defined the patient population or focused on the in-hospital period.

**Methods:** We identified patients at a single institution between 2005-2008 and reviewed their charts for age, sex, comorbidities, complications, mortality, length of stay (LOS), cause of CKD, and discharge disposition. We compared our patients to the New York State (NYS) administrative database for mortality and LOS. Data was analyzed using two-sample t-tests for continuous variables and Fisher's exact tests for categorical data.

**Results:** 38 patients underwent 58 orthopedic procedures, most on the hip (46.6%) or knee (19.0%). Patients had been previously treated with HD for an average of 6.8 +/- 9.6 years. The most common causes of CKD were diabetic nephropathy (20.7%), hypertensive nephropathy (15.5%), and collagen vascular disease (13.8%). There were 17 post-operative complications in 14 patients (24.1%) and 1 in-hospital death occurred (1.7%). The average LOS was 9.1 +/- 5.0 days. Most patients were discharged to rehab (44.8%), but many went home (31.0%). The mean LOS was 2.2 days less than the NYS hospital average (95% CI: 0.8, 3.6, p-value=0.003) but the difference in mortality was not statistically significant (p-value >0.05).

**Conclusions:** The in-hospital post-operative medical course for patients with CKD treated by HD undergoing orthopedic procedures has not been well reported. By studying patients at a single institution, we have better defined the patient population and their post-operative course. Our results do not corroborate the high morbidity/mortality rate previously reported. Our mortality results do not significantly differ from other NYS hospitals.

## PUB073

**Albuminuria Is Associated with Diabetic Retinopathy in Ethnic Minorities** Amit J. Joshi,[1] Albert M. Osei,[1] Imran Tahir,[2] Bhavi Paresh Pandya,[3] Peter D. Hart.[1] *[1]Section of Nephrology, Stroger Hospital of Cook County, Chicago, IL; [2]Dept of Medicine, Stroger Hospital of Cook County, Chicago, IL; [3]Staten Island Univ Hospital, Staten Island, NY.*

**Background:** Diabetic nephropathy remains the most frequent cause of end-stage kidney disease (ESKD) in the United States. The association between the presence of diabetic retinopathy and diabetic nephropathy is well described; however, there are no data on whether presence of diabetic retinopathy is associated with progressive renal disease (defined as degree of albuminuria ± interval change in serum creatinine). We examined and herein describe the clinical characteristics of such patients at a large inner city hospital.

**Methods:** We retrospectively examined medical records of adult patients (≥18 years) with diabetes seen in the Ophthalmology clinic of our institution from Jan. and Feb. 2012. Data on baseline demographics, duration of diabetes, type of retinopathy, renal function, degree of albuminuria, use of renin-angiotensin-aldosterone system (RAAS) blockers, and other clinical parameters was collected.

**Results:** 245 patients had adequate data for clinical analysis. Mean age was 59.9 (±9.4) years and women accounted for 47% of the study cohort. Hispanics constituted 41%, African Americans 38%, Caucasians 9%, and other races 12%. 144(59%) patients had proliferative retinopathy, 73(30%) had nonproliferative retinopathy, 16(7%) patients had both proliferative and nonproliferative retinopathy; and 12 (4%) patients had no retinopathy. Longer duration of diabetes was associated with increased severity of retinopathy (P=0.0018). No difference was noted with respect to retinopathy severity and cerebrovascular disease, coronary artery disease or statin use. Degree of albuminuria influenced the severity of retinopathy (P 0.037). The presence of retinopathy had no impact on initial creatinine or interval change in creatinine (p value was insignificant) Also no ethnic difference was noted in terms of glycated hemoglobin level, age, initial creatinine, duration of diabetes, or use of RAAS blockers.

**Conclusions:** Albuminuria and longer duration of diabetes are associated with increased severity of retinopathy in ethnic minority patients.

## PUB074

**Risk Factors Associated with End-Stage Renal Disease and Fatality in Patients with Chronic Kidney Disease** Ya-Wen Chuang,[1,2] Cheng-Hsu Chen,[1] Fung-chang Sung.[2] *[1]Div of Nephrology, Dept of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan; [2]Dept of Public Health, China Medical Univ, Taichung, Taiwan; [3]Taichung Tzu Chi General Hospital, Taichung.*

**Background:** With the highest prevalence of end-stage renal disease (ESRD) worldwide, there is no study for patients in Taiwan on the prognosis of chronic kidney disease (CKD) by stage. This study evaluated the risk of ESRD and fatality for patients with stage 3, 4 and 5 of CKD.

**Methods:** We identified 4702 patients with CKD of stages 3-5 from nephrology clinics at the Taichung Veteran General Hospital from December 2001 to December 2011. Patient prognosis data were extracted from the baseline to July 31, 2012, ESRD diagnosed, death or loss to follow-up. We used Cox models to identify risk factors associated with ESRD and deaths by CKD stage and age, and Kaplan-Meier method to measure the cumulative events of ESRD and death.

**Results:** Patients with CKD consisted of 64% of males, with 60% of patients aged >65 years and 39% having diabetes. The incidence of ESRD in CKD patients of stages 3, 4, 5 were 1.95%, 10.6%, 46.7%, with the fatalities of 4.56%, 6.23%, 4.69%, respectively. The elderly were at a lowered risk for ESRD, but at an elevated risk for death. Diabetic patients were at higher risk than non-diabetic patients for ESRD and death.

**Conclusions:** The risk of ESRD for patients with CKD increases rapidly with the advance of stage; but the differences in fatality are not so acute among the 3 stages of patients. The elderly CKD patients are less prone to ESRD, but at an elevated risk of death.

## PUB075

**The Asymptomatic Ankle-Brachial Index Abnormality Can Predict Poor Prognosis of Arteriosclerosis-Based Chronic Kidney Disease Patients** Yuji Kamijo, Koji Hashimoto, Makoto Harada, Taro Kanno, Makoto Higuchi. *Dept of Nephrology, Shinshu Univ School of Medicine, Matsumoto, Japan.*

**Background:** World Health Statistics 2013 indicated that average life of Japanese is the longest. Furthermore, Ministry of Health, Labour and Welfare reported that average life of Nagano prefecture's people is the longest in Japan; therefore characteristics of chronic kidney disease (CKD) in Nagano might differ, greatly be affected by arteriosclerotic lesions by ageing.

**Methods:** To reveal the arteriosclerotic effects, we investigated the ankle-brachial index (ABI) of CKD patients in Nagano (n=144, mean age 70) and followed up prospectively (2.3 years). We analyzed hazard ratio (HR) of ABI abnormality (ABI<1.0 or ABI≥1.3) influencing incidence of cardiovascular diseases (CVD) and worsening of kidney function, mortality, CVD-free survival, and all event-free survival, using multivariate Cox regression analyses. We analyzed also ABI-abnormality-related factors using multivariate logistic regression analyses.

**Results:** The mean eGFR and proteinuria were 41 ml/min/1.73m$^2$ and 0.5 g/gCr, respectively. Twenty six percent patients had well controlled diabetes mellitus (DM, mean HbA1c 6.1%), indicating a little contribution of DM nephropathy. We detected ABI abnormality in high rate (24%), and most patients were asymptomatic. Multivariate analyses demonstrated that ABI abnormality was the strongest risk factor of incidence of CVD (adjusted HR 5.3, 95%CI 1.8-16.2), CVD-free survival (adj-HR 4.4, 95%CI 1.7-11.5), and all event-free survival (adj-HR 3.1, 95%CI 1.3-7.0). The strongest risk factor of worsening of kidney function and that of mortality were GFR reduction and age, respectively. ABI abnormality was greatly related to the GFR reduction (Odds ratio 1.84, 95%CI 1.2-2.8), while it was not related to presence of DM.

**Conclusions:** This study suggests that asymptomatic ABI abnormality is highly detected in arteriosclerosis-based CKD patients, and strongly relates to lethal events and survival rate. GFR reduction is a very important independent risk factor of ABI abnormality; therefore we should conduct ABI measurement for all CKD patients regardless of presence of DM.

## PUB076

**Discontinuation of Angiotensin Converting Enzyme Inhibitors in Advanced Chronic Kidney Disease** Silvia Gonzalez S, Ines Castellano, Pedro J. Labrador, Jesús P. Marin, Clarencio Javier Cebrian andrada, Maria C. Jimenez, Vanesa Garcia-Bernalt, Sandra Gallego, Juan R. G?mez-Martino. *Nephrology, San Pedro de Alcántara Hospital, Cáceres, Spain.*

**Background:** Renin-angiotensin-aldosterone system (RAAS) inhibition has been used to slow chronic kidney disease (CKD) progression in diabetic (DN) and non-diabetic proteinuric nephropaties.

However, in advanced CKD, their withdrawal can delay the onset of renal replacement therapy (RRT).

The aim was to evaluate the effect of discontinuation of RAAS inhibitors in patients with CKD stage 4-5 and to assess K levels.

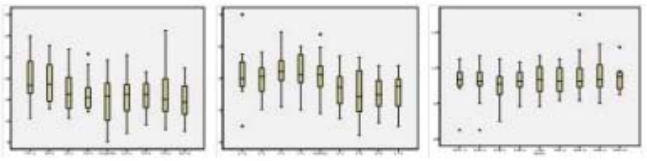
**Methods:** Observational prospective study made in patients who were being treated with angiotensin converting enzyme inhibitors (ACEi)/angiotensin receptors blockers (ARB) and whose estimated glomerular filtration rate (GFRe) was lower than 25 ml/min. We recorded creatinine and K in serum, GFRe (MDRD-4 IDMS) and mean arterial blood pressure (MAP) every 3 months for 1 year before and after stopping treatment. When it was necessary an alpha-adrenergic blocker or a calcium channel blocker was introduced.

**Results:** 27 patients were included (7 females, 20 males), mean age 73.7 ± 9.4 years. The aetiology of CKD was: vascular nephropathy (n = 10, 37%), DN (n = 9, 33.3%) chronic glomerulonephritis (n =2, 7.4%), chronic tubulointerstitial nephritis (n =2, 7.4%), autosomic policystic kidney disease (n =2, 7.4%), unknown aetiology (n =2, 7.4%).

Three patients started RRT 1, 2 and 11 months after stopping RAAS inhibitors, and one was lost to follow-up.

MAP, GFRe and K level when ACEi/ARB were stopped was 5.06 ± 0.59 mmol/l, 12.9 ± 4.8 ml/min and 92.3 ± 8.7 mmHg respectively.

MAP, GFRe and K levels 12 months before and after discontinuation of ACEi/ARB are shown in Figure 1.



[Figure 3]

**Conclusions:** Discontinuation of ACEi/ARB in patients with CKD stage 4-5 stabilized GFRe and improved K levels. There were no differences in MAP after stopping RAAS inhibitors.

## PUB077

**Renoprotective and Antiproteinuric Effect of Mineralocorticoid Receptor Blockers in Obese Patients with Proteinuric Nephropathy** Enrique Morales, Jorge Enrique Rojas-Rivera, Eduardo Gutierrez-martinez, Manuel Praga. *Nephrology, Hospital 12 de Octubre, Madrid, Spain.*

**Background:** Obesity is a risk factor for the development of renal failure (RF). Proteinuria (P) is an independent determinant of the progression of chronic kidney failure. Adipose tissue is a recognized source of components of the renin-angiotensin-aldosterone system (RAAS). The use of drugs which block the RAAS is unable to inhibit aldosterone long term. The aim of our study was to analyze the renoprotective effect of mineralocorticoid receptor blockers (MRB) in combination with other drugs that block the RAAS in obese patients with proteinuric nephropathy.

**Methods:** In January 2004, we began a prospective observational study in our hospital-based consultation. The management of spironolactone (S) patients with P> 1 g/24 hours being treated with other drugs blocking RAAS were divided according to body mass index (BMI): the group of obese (Ob) (BMI> 30 kg/m2) and a control group (C).

**Results:** Seventy-one patients were included. The mean age was 56.7 ± 15.1 years. The percentage of diabetics in both groups was greater than 50%. Thirty-two patients found within the Ob group, and 39 in group C. Initially there were no significant differences in renal function, P, blood pressure (BP), serum potassium levels and the percentage of drugs that block RAAS in both groups. After a follow-up of 28.9 (14-84) months, there was a reduction of 59.4% P in the Ob group (2.8 ± 2.1 to 1.3 ± 1.6 g/24hr, p <.05). The reduction of P was greater than 50% in 70 cases. The mean BP showed a significant decrease in their numbers (100.6 ± 9 to 92.1 ± 7.4 mmHg, p<.05). Renal function remained stable throughout the follow-up (56.8 ± 27 to 54.1 ± 30.9 ml/min). A slowing of renal function was observed since the introduction of E (3 to 1.4 ml/min/year, p 0.39). There gynecomastia in 9 cases (28.1%) in the Ob and only 2 cases (5.1%, p 0.008) in group C. The incidence of hyperkalemia was similar in both groups (6.3%).

**Conclusions:** MRB treatment in obese patients with different proteinuric kidney diseases induces a significant slowing in the progression of renal failure associated with a remarkable and sustained reduction in proteinuria with a few adverse events.

## PUB078

**Preliminary Examination of Chronic Kidney Disease Shared Medical Appointement Outcomes** Mohsen M. Elramah,[1] Henry N. Young,[2] Micah R. Chan.[1] *[1]UW Hospital and Clinics Dept of Nephrology; [2]Univ of Wisconsin School of Medicine and Public Health.*

**Background:** Chronic kidney disease(CKD) care can be challenging for multiple reasons . Our nephrologists implemented shared medical appointments (SMA) for CKD care in an effort to overcome such challenges. We examined if CKD SMAs resulted in similar outcomes in comparison to individual visits.

**Methods:** After IRB approval, we conducted a retrospective analysis of data from our database. Patients who received care in CKD shared medical appointments and individual visits from January 2011 to March 2013 were included. We compared the two groups on outcomes of,dialysis, mortality, transplantation, the change over time in CKD stage, glomerular filtration rate, intact parathyroid hormone , creatinine, phosphorus, proteinuria, and blood pressure.

**Results:** We analyzed 75 records; 23 SMA and 52 individual visits. SMA patients had a greater mean difference in PTH (M=40.1, SD=98.3) compared to individual visit patients (M=-4.9, SD=10.0) from 2011 to 2013 (t=-21, p=0.04).

| | **Group Visits (n=23)** n(%) or M(SD) | **Individual Visits (n=52)** n(%) or M(SD) |
|---|---|---|
| Dialysis in 2013 | 5 (22%) | 10 (19%) |
| Deceased in 2013 | 2 (9%) | 2 (4%) |
| Transplant | 1 (4%) | 1 (2%) |
| Change (2011 to 2013) | | |
| CKD stage (progression) | 5 (22%) | 13 (25%) |
| eGFR | -1.2 (10.2) | -2.5 (6.9) |
| iPTH | 40.1 (98.3) | -4.9 (61.7) |
| Creatinine (mg/dl) | 0.4 (1.0) | 0.3 (0.9) |
| Proteinuria (Ur P/C) | 0.2 (1.5) | 0.6 (3.0) |
| Phosphorus (mg/dl) | 0.3 (1.3) | 0.4 (1.1) |

Adjusting for potential confounders, this difference was no longer statistically significant. There were no differences in the proportions of patients who were on dialysis, deceased, or received a transplant between the two groups in 2013. Results also failed to indicate any differences in the changes across time for any other assessed outcome between the two groups.

**Conclusions:** This study demonstrates that CKD shared medical appointment clinical outcomes may be similar to individual visit outcomes. larger study designs are needed to confirm these initial findings.

## PUB079

**Chronic Kidney Disease (CKD) Is Distinct from End Stage Kidney Disease (ESKD)** Helen G. Healy,[1,2] Andrew John Mallett,[1,2,3] Zaimin Wang,[1,3] Anne Salisbury,[1,2,3] Robert G. Fassett,[1] Wendy E. Hoy.[1,3] *[1]CKD.QLD; [2]Dept of Renal Medicine, Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia; [3]Centre for Chronic Disease, School of Medicine, Univ of Queensland, Brisbane, Queensland, Australia.*

**Background:** CKD is the most common chronic disease in Australia. Inferences about its natural history have largely relied upon hypotheses from mortality and Renal Replacement Therapy (RRT) datasets.

**Methods:** Aim: To describe how characteristics of Australian CKD patients differ from those of Australian RRT populations. Primary diagnosis, age and sex of the first 2139 patients from 5 sites in the CKD.QLD Registry (CKD.QLD) were analysed and compared with the 2005-2010 (n=15,514) and 2011 (n=2,760) Australia and NewZealand Incident RRT cohorts. (ANZ RRT 2005-10, ANZ RRT 2011). Comparison was also made with the Australian dataset of people dying with ESKD not on RRT (n=10421, AIHW ESKD/nonRRT).

**Results:** The most common primary renal diagnoses in the CKD.QLD cohort were Miscellaneous (Misc, 26%), Diabetic Nephropathy (DN, 23%), Hypertension (HTN, 18%) and Uncertain (15%). In ANZ RRT 2005-10 and 2011 the most common primary renal diagnoses were DN (36%, 38%), Glomerulonephritis (GN, 23%, 22%), Misc (13%, 11%) and HTN (10%, 13%).

Mean age in CKD.QLD was 65.5 years and in ANZ RRT 2011 it was 60.3 years. The most common age group in both cohorts was 55-74 years (47%, 47%) however in AIHW ESKD/nonRRT cohort it was ≥75 years (87%).

45% of the CKD.QLD cohort, 39% of the ANZ RRT 2005-2010 and 53% of the AIHW/nonRRT ESKD cohorts were female.

**Conclusions:** There are differences in proportion and ranking of primary renal diagnoses between these CKD and RRT/ESKD cohorts. CKD patients are older and more frequently female then those undergoing RRT. Extrapolation from RRT cohorts for characterisation of CKD should be replaced with direct study of CKD cohorts. When paired with RRT and mortality cohort data this will provide information of greater accuracy and translational impact.

## PUB080

**Left Atrial Volume Index as Useful Predictor for Decline of Kidney Function in CKD G3b and G4** Takeshi Yokoyama,[1] Mikako Hisamichi,[1] Masahiko Yazawa,[1] Nagayuki Kaneshiro,[1] Katsuomi Matsui,[2] Yusuke Konno,[1] Yugo Shibagaki,[2] Kenjiro Kimura.[2] *[1]Nephrology and Hypertension, Kawasaki Municipal Tama Hospital, Kawasaki, Kanagawa, Japan; [2]Nephrology and Hypertension, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan.*

**Background:** Several studies have documented a strong relationship between CKD and accelerated cardiovascular disease. Although heart failure is known to associate with progression of CKD, little is known which parameters of ultrasound cardiography (UCG) are helpful to predict decline of kidney function (KF).

The aim of present study is to clarify the relationship between the rate of decline of KF and the parameters of UCG.

**Methods:** UCG was performed in 38 CKD G3b and G4 patients from April 2011 to December 2012, and the following parameters such as left atrial dimension (LAD), left atrial volume index (LAVi), end-diastolic wall thickness of the interventricular septum (IVSTd) and posterior wall (PWTd), and left ventricular mass index (LVMi) were measured. We calculated estimated GFR (eGFR) by the japanese GFR equation, and defined the rate of decline of KF as [(the latest eGFR – intial eGFR) / follow-up period]. We examined the correlations between the rate of decline of KF and the parameters of UCG.

**Results:** Average eGFR at UCG was 29.23 ± 8.47 ml/min/1.73m2 and average rate of decline of KF was -0.29± 0.74 ml/min/1.73m2/month. Rate of decline of KF was significantly correlated with LAD(r = -0.381), IVSTd + PWTd(r = -0.425), LVMi(r = -0.394) and LAVi(r = -0.455). Multiple regression analysis revealed that only LAVi was an independent predictor for decline of KF.

**Conclusions:** Among the parameters of UCG, LAVi was the most useful predictor for decline of KF in CKD G3b and G4.

**PUB081**

**The "Opt-Out" Recruitment Strategy: The SNORE Study**
Muna T. Canales,[1,2] Nicole Kay,[1] Areef Ishani,[3] I. David Weiner,[1,2] Richard Berry,[1,2] Rebecca Beyth.[1,2] *[1]Malcom-Randall VAMC, Gainesville, FL; [2]Univ of Florida, Gainesville, FL; [3]Minneapolis VAMC, Minneapolis, MN.*

**Background:** Recruitment in an unbiased fashion of adequate numbers of human subjects is key for scientifically sound and generalizable studies. We report initial results of an IRB-approved "opt-out" recruitment strategy that involves primary care provider (PCP) approval and easy "opt-out" options as part of the SNORE Study, an ongoing prospective study of sleep apnea and CKD progression.

**Methods:** With IRB approval, we identified veterans age 18-99 in the N. FL/S. GA Veterans Health System (NF/SGVHS) (2/12/2012-present) with at least 2 MDRD eGFRs between 15-44, at least 3 months apart; target enrollment = 250 over 2 years. We excluded those with dialysis, kidney transplant, PAP or $O_2$ therapy, active cancer, solid organ transplant or inability to give consent. Via e-mail, we requested permission from every PCP in the NF/SGVHS to contact their patient for enrollment; non-responders were contacted again by e-mail and then by phone. We invited eligible veterans in random order to participate via a letter with follow-up call within 1 week if no response. Letters stated that the PCP gave permission for us to contact them and provided a 1-800 number and an email to facilitate communication. Interested subjects presented for initial baseline visit during which they completed informed consent and baseline assessments.

**Results:** Of 141 PCPs across 13 clinical sites 103 gave approval, 6 refused, 11 wanted to be contacted for each patient, and 21 have not responded. To date 560 letters have been mailed. 130 veterans called in and, of these, 37 were interested in participation. We contacted the remaining 430 veterans and, of these, 222 were not interested, 105 were interested and 103 we could not reach. 75 study visits have been scheduled (13% of letters mailed out). Of those who scheduled a study visit, 86% completed enrollment as planned, 8% rescheduled and 6% cancelled before the visit. On average, 3-4 visits occur each week with anticipated completion of enrollment in < 2 years as planned.

**Conclusions:** An "opt-out" recruitment strategy with PCP approval and easy "opt-out" options met expectations of IRB and yielded adequate enrollment numbers for this study.

**PUB082**

**Wine Intake Is Associated with Fewer Cardiovascular Events in the National Health and Nutrition Examination Survey (NHANES)**
Tapan Mehta,[1] Pamela Mettler,[2] Kim McFann,[2] Diana I. Jalal.[1] *[1]Div of Renal Diseases and Hypternsion, Univ of Colorado, Aurora, CO; [2]Colorado Biostatistics Consortium and Colorado School of Public Health, Univ of Colorado Denver, Aurora, CO.*

**Background:** Chronic Kidney disease (CKD) is associated with an increased risk of cardiovascular disease. Wine intake is associated with a lower risk of cardiovascular disease in non-CKD populations. Although kidney and cardiovascular disease share many risk factors, such as insulin resistance and inflammation, no study to this date has examined the potential relation between wine intake and CVD in individuals with CKD.

**Methods:** This was a cross sectional analysis of 5876 participants in NHANES 2003-2006. Wine intake was categorized as: none, <1 glass/day, ≥1 glass/day. Cardiovascular disease (CVD) was defined as history of: cardiovascular disease, angina, myocardial infarction, or stroke. The analysis was then stratified based on presence of CKD defined as estimated GFR < 60 mL/min/1.73m$^2$ or albumin/creatinine ratio ≥30 mg/g.

**Results:** Of the 5876 participants, 671 had a history of CVD, 187 ingested <1 wine glass/day, and 20 ingested ≥1 wine glass/day. The group with CVD was older, had lower HDL- cholesterol, greater waist circumference, and a greater proportion of males, in addition to a greater prevalence of diabetes, kidney disease, and hypertension. Those who drank less than <1 glass/day had 0.5 odds (95% CI 0.4, 0.62) of having CVD than those who drank no wine ($p < 0.0001$). This relation remained significant after adjusting for demographics and other CVD risk factors (OR 0.63; 95% C.I. 0.50, 0.79; $p<0.0001$). Among individuals with CKD (n=1263), the odds of CVD was 0.72 (95% C.I. 0.54, 0.96; $p=0.03$) for those drinking <1 wine glass/day compared to non- drinkers after adjusting for demographics and CVD risk factors. The odds of CVD were not significantly different for those who drank ≥ 1 wine glass/ day compared to non- wine drinkers.

**Conclusions:** These data suggest that wine intake is associated with reduced odds of CVD in the general population with and without CKD. Further studies are needed to understand the mechanisms underlying this association particularly in individuals with CKD.

**PUB083**

**Study of Apolipoprotein E Polymorphism across Different Stages of Chronic Kidney Disease**
Marcelo Costa Batista,[1,2,3] Andrei Alkmim Teixeira,[1] Mauro Sergio Martins Marrocos,[1] Maria Dalboni,[1] Beata Marie Redublo Quinto,[1] Maria Eugenia F. Canziani.[2] *[1]Nephrology Div, Universidade Federal de Sao Paulo, Sao Paulo, SP, Brazil; [2]Federal Univ of Sao Paulo, Sao Paulo, SP, Brazil.*

**Background:** The burden of chronic kidney disease (CKD) is epidemic. Apolipoprotein E (APOE) polymorphism has been associated with its progression although scarce data are available in South American ethnic groups. **Objective**: We aim to determine apolipoprotein E polymorphism (APOE) alleles and genotypes distribution across different stages of CKD patients.

**Methods:** In a single-center cross-sectional study, patients were divided into 3 groups. Group 1: estimated glomerular filtration rate (eGFR) higher than 60ml/min/1,73m$^2$ (n=189); Group 2: eGFR between 15 and 60ml/min/1,73m$^2$ (n=222); Group 3: patients on renal replacement therapy (RRT) (n=224). APOE alleles and genotypes distribution were analyzed in relation to the different stages of CKD. ApoE genotypes were determined by PCR-restriction fragment length polymorphism (RFLP) analysis.

**Results:** We studied 615 patients (317 men, 51.0%), 63.8% were white, 40.3% diabetic and 15.6% smokers. Mean age was 60 ± 14 years. The homozygous genotype e3/3 was the most frequent genotype in all three groups (Group 1: 121 (72.9%), Group 2: 161 (75.6%) and Group 3: 144 (71.6%), p: NS) and even after considering just CVD patients (Group 1: 31 (72.1%), Group 2: 62 (73.8%), Group 3: 58 (69%), p: NS). We did not observe difference on alleles or genotype distribution among the studied population along the different CKD stages. However, among diabetic patients, e2 allele was negatively associated with more advanced stages of CKD (Group 1: 7 (13.1%) OR: 3.36, 95%CI: 1.15,9.77; Group 2: 8 (7.1%) OR: 1.19, 95%CI:0.41,3.42; Group 3: 0 (0%) OR: 0.9, 95%CI:0.86,0.95. This progressive inclination was demonstrated across the 5 CKD stages.

**Conclusions:** In diabetic patients, the authors demonstrated a negative association between e2 allele prevalence and more advanced stages of CKD.

**PUB084**

**A Phase IV, Randomized, Blinded Single-Center Study of the Effects of Calcitriol and Paricalcitol on Vascular Calcification in Chronic Kidney Disease Stages 3 and 4-Vitamin D and Coronary Calcification Study (VCOR)**
Sylvia E. Rosas,[1] Wei Yang,[2] Harold Litt.[3] *[1]Medicine, Univ of Pennsylvania, Philadelphia, PA; [2]Biostatistics, Univ of Pennsylvania, Philadelphia; [3]Radiology, Univ of Pennsylvania, Philadelphia, PA.*

**Background:** In animal models, calcitriol significantly increased the serum calcium-phosphate product and aortic calcium content, while paricalcitol had no effect. The objective of this randomized clinical trial was to determine the differential effect of calcitriol and paracalcitol on vascular calcification in patients with chronic kidney disease (CKD).

**Methods:** Inclusion criteria included patients with CKD and secondary hyperparathyroidism (SHPT) with any CAC naive to activated vitamin D therapy. We used the Wilcoxon rank-sum test to compare CAC progression between groups using the absolute change in Agatston unit (AU)/time between scans. We also evaluated the square root difference in CAC volume [sqrt(post) – sqrt (pre)]. Progressors were defined as those with a difference in volume > 2.5.

**Results:** Forty-four participants were randomized. The mean age(standard deviation) was 65.6 (9.3). Fifty-nine were male and two-thirds were African American. Fifty-seven percent had a history of diabetes (DM). The mean and median CAC score were 318.2 (632.7) and 140.2 AU at baseline, respectively.

We did not find any difference in the median CAC progression between the calcitriol vs. paracalcitol arms (33.7 vs.64.1 31, p=0.75). The square root of the difference method yielded similar results (1.34 vs. 1.56, p=0.75). There were no statistical differences between progressors between groups [2(10.5%) vs. 7 (33.3%), p=0.09]. The median CAC progression in non-DM was similar between the two arms [57.3 vs. 38.3, p=1.0]. However, the median CAC progression in those with DM appeared higher in the paracalcitol group but did not achieve statistical significance. [31.6 vs. 111.1, p=0.2]. (p=0.04 for test of interaction).

**Conclusions:** In CKD patients with secondary hyperparathyroidism naïve to activated vitamin D therapy, we were unable to detect differences in CAC progression between the two therapies. The effect of diabetes on treatment group needs to be explored in future studies.

**Perceptions of Risks in Chronic Kidney Disease among Patients, Clinicians and Administrators**
Helen Chiu,[1] Navdeep Tangri,[2] Ognjenka Djurdjev,[3,4] Brendan J. Barrett,[5] Brenda Hemmelgarn,[6] Francois Madore,[7] Claudio Rigatto,[2] Norman Muirhead,[8] Manish M. Sood,[2] Catherine M. Clase,[9] Adeera Levin.[4,10] *[1]PHCRI; [2]U of M; [3]PHSA; [4]BCPRA; [5]MUN; [6]U of C; [7]U de M; [8]WU; [9]MU; [10]UBC, Canada.*

**Background:** Clinical trajectories of patients with chronic kidney disease (CKD) are highly variable. Understanding the appropriate risk thresholds and time horizons associated with predicting risks of key outcomes (renal failure, cardiovascular (CV) events & death) is important in facilitating decision-making and addressing the needs of the patients and care providers. We aimed to determine the importance of specific time frames for prediction of key outcomes from patients, nephrologists and renal administrators, and performed a needs assessment for risk prediction tools among these groups.

**Methods:** Online surveys were developed for each group of stakeholders and deployed nationally through the Kidney Foundation of Canada, provincial renal networks and the Canadian Kidney Knowledge Translation and Generation Network. Anonymous responses gathered over a 4-month period were descriptively analyzed.

**Results:** Over 270 respondents across Canada participated in the surveys. Patients deemed personal risks of needing renal replacement therapy and developing heart disease as similarly important over all time horizons (1-15 years). Both nephrologists and administrators felt that the time horizons of 1-5 years are the most relevant. The majority of nephrologists were not satisfied with their current ability to predict the progression to renal failure, CV events and death, with the ability to predict CV events and death being the most dissatisfying. All groups indicated willingness to use risk scores with improved accuracy, if available, to predict specific outcomes.

**Conclusions:** Patients, clinicians and administrators have slightly different time horizons that they deem important for predicting outcomes in CKD; however, all agree that there is a need to improve risk prediction. These perspectives from patients and other stakeholders provide valuable information for developing future research and tools for predicting patient-centered outcomes in the CKD population.

**PUB086**

**Patient Centered, Multidiciplinary Clinic for Pre-End Stage Renal Disease Care: A Process Improvement Project** Nicole Piero,[1] Julia Hennessy,[1] Loretta Simbartl,[1] Charuhas V. Thakar.[2] *[1]VA Medical Center; [2]Univ of Cincinnati.*

**Background:** Changes in U.S. healthcare system necessitates creative resource use while providing patient-centered care. A gap analysis within our hospital (2006-2010) revealed that 700/42,984 patients, who had ≥ 1 outpatient creatinine, had glomerular filtration rate (GFR) < 30 ml/min/1.73m2. 333/700 (48%) were evaluated in renal clinics, and 116/333 (35%) were seen by one additional clinic (nutrition, education, vascular access, social work) for ESRD preparation. We report a process improvement initiative by converting the need for multiple appointments to a multidisciplinary, pre-ESRD clinic.

**Methods:** Since Jan 2012, after a renal evaluation, patients with a GFR <30 are enrolled in this pre-ESRD clinic representing all disciplines, and led by a nurse practitioner. Patients learn about kidney disease, dialysis choices, transplant, nutrition, payment, advance directives, and conservative therapy. Since Oct 2012 patients also complete a quality of life (KDQOL) and nutrition evaluation.

**Results:** In a sample of 56 males mean age was 69 years, mean GFR of 20.5 ml/min/1.73m2. After pre-ESRD education, of the 56 patients 64% favored hemodialysis, 5% peritoneal dialysis, 7% no dialysis or hospice, and 24% were undecided. Outcomes for all 56 were: 25% have started hemodialysis (incident fistula rate = 36%), 7% died before dialysis, and remaining 68% are under follow-up care. 8/56 are being evaluated for kidney transplant. 19/56 completed the KDQOL of which 39% and 58% reported severe activity limitation or limitation to climb stairs respectively. 15/56 completed nutritional assessment: 67% ate out <2 times/week whereas 33% ate out 3 – 10 times per week; 34% ate > 4 oz meat portions/meal; and 60% ate frozen or canned food > 3 times/week. 15/56 patients completed 24-hour urine collection: Urea ranged 4.7-14.3 g/24h, sodium ranged 67-294 mmol/24h, and protein ranged 0-9.3 g/24h.

**Conclusions:** Over 1-year, such an initiative could result in an efficient use of resources by reducing the number of required appointments by over 50%. Moreover, a patient-centered program provides individualized care, and an avenue for nutritional intervention in patients with advanced CKD.

**PUB087**

**Primary Care Physicians' Own Exercise Habits Influence Exercise Counseling for Patients with Chronic Kidney Disease** Yoshiyuki Morishita, Yasuhiro Ando, Shigeaki Muto, Eiji Kusano. *Nephrology, Internal Medicine, Jichi Medical Univ, Shimotsuke, Tochigi, Japan.*

**Background:** We investigated primary care physicians' exercise counseling practices for chronic kidney disease (CKD), and the association of these physicians' own exercise habits with exercise counseling.

**Methods:** The population of this cross-sectional study was 3310 medical doctors who graduated from Jichi Medical University from 1978 to 2012. The study instrument was a self-administered questionnaire to investigate their age class, specialty, workplace, exercise habits, and practices of exercise counseling for CKD.

**Results:** 581 (64.8%) medical doctors practiced the management of CKD among a total of 933 responses. These 581 medical doctors were defined as CKD primary care physicians and Their answers were analyzed. CKD primary care physicians' own exercise habits (frequencies and intensities) were as follows: frequencies: daily, 71 (12.1%); ≥2–3 times/week, 154 (26.5%); ≥1 time/week, 146 (25.1%); and ≤1 time/month, 176 (30.2%); intensities: high (≥6 Mets), 175 (30.1%); moderate (4–6 Mets), 132 (22.7%); mild (3–4 Mets), 188 (32.3%); very mild (<3 Mets), 47 (8.1%); and none, 37 (6.4%). CKD primary care physicians' exercise recommendation (general) levels for CKD patients were as follows: high, 31 (5.3%); moderate, 176 (29.7%); low, 256 (44.0%); and none, 92 (15.8%). The details of exercise recommendations (frequency and intensity) were as follows: frequency: daily, 23 (10.8%); ≥2–3 times/week, 144 (70.4%); ≥1 time/week, 25 (12.3%); and ≤1 time/month, 0 (0%); intensity: high (≥6 Mets), 1 (0.5%); moderate (4–6 Mets), 62 (30.5%); mild (3–4 Mets), 132 (66.0%); very mild (<3 Mets), 3 (1.5%); and none, 3 (1.5%). The CKD primary care physicians' exercise recommendations (general) for CKD patients were significantly related to their own exercise frequency ($p<0.01$), but they were not related to their age, specialty, workplace, or exercise intensity. Furthermore, the CKD primary care physicians' exercise recommendations (frequency ($p<0.01$) and intensity ($p=0.01$)) were related to their own exercise frequency.

**Conclusions:** CKD primary care physicians' own exercise habits influence their exercise counseling for CKD patients.

**PUB088**

**Kidney Health in Volunteers Recruited as Study Controls** Samer Rateb Abbas,[1,2] Cassandra Cartagena,[1] Fansan Zhu,[1] Peter Kotanko,[1] Nathan W. Levin,[1] Mary Carter,[1] Stephan Thijssen,[1] Caroline M. Williams,[1] Cesar Flores-Gama.[1] *[1]Nephrology, Renal Research Institute, New York, NY; [2]Nephrology, Beth Israel Medical Center, New York, NY.*

**Background:** Little is known about kidney function in volunteers recruited as healthy controls. Here we report kidney function in such individuals.

**Methods:** We solicited the participation of healthy volunteers using posters and newspapers. Telephone callers underwent a structured 22 questions to explore their eligibility. Volunteers who passed the telephone interview underwent clinical assessment (, height, weight, blood pressure) and measurement of serum creatinine, BUN, urinalysis) 1-4 weeks later. Estimated glomerular filtration rate (eGFR) was computed with the CKD-EPI equation. Albumin-creatinine ratio (ACR) was calculated as urine albumin/urine creatinine (mg/g). Systolic blood pressure SBP was recorded three consecutive times in a sitting position; subjects with average SBP > 140 mmHg were considered hypertensive.

**Results:** Based on the phone interview, almost 50% of 180 volunteers were excluded because of kidney, cardiac, or malignancy-related conditions. Ninety-one participants (age 57±10 years; 49 female) were eligible. Of these 18 participants were excluded, mostly because of absent blood and urine samples. Results obtained in the remaining 73 participants are shown in Table 1.

| | eGFR>90 N=20 | eGFR 60-89 N=43 | eGFR<60 N=10 | ACR>30 N=5 | Hypertensive N=9 |
|---|---|---|---|---|---|
| Black [N]<br>White [N] | 10<br>10 | 17<br>26 | 2<br>8 | 1<br>4 | 6<br>3 |
| Male [N]<br>Female [N] | 10<br>10 | 21<br>22 | 4<br>6 | 1<br>4 | 5<br>4 |
| Age [year] | 50±7 | 60±9 | 69±9 | 62±9 | 63±12 |

eGFR in mL/min/1.73 m²

Age was significantly different between eGFR groups ($p = 0.001$, 1-way ANOVA).

**Conclusions:** Our results indicate the presence of unrecognized kidney impairment in a notable fraction of normal healthy volunteers who identify themselves as healthy and who pass a telephone interview screening aimed at identifying and excluding non-healthy volunteers. Since decreased function of unknown cause is frequent in older people this should be considered in recruiting apparently healthy volunteers. Laboratory tests are indispensable to define healthy controls.

**PUB089**

**Prevalence of Chronic Kidney Disease in an Adult Population from Southern Brazil: Results of Campo Largo Study** Marcelo M. Nascimento,[1,3] Ana Paula Piccoli,[3] Miguel C. Riella.[2,3] *[1]Dept de Clinica Médica, Universidade Federal do Parana, Curitiba, Brazil; [2]Post Graduation Program, Pontifícia Universidade Católica do Parana, Curitiba, Brazil; [3]Pro-Renal Foundation, Scribner Institution, Curitiba, Brazil.*

**Background:** There is a rising incidence of chronic kidney disease (CKD) worldwide. However, in Latin America there are few studies which could estimate the real prevalence of CKD in the general population.

**Methods:** From April 2009 to December 2011 the Pro-Renal Foundation screened 5216 individuals for the presence of CKD in the city of Campo Largo (a city situated in the southern Brazil, with an estimated population of two hundred thousand people). Individuals younger than 18 years were excluded from the study. Personal and medical history data through a specifically designed questionnaire was obtained as well as blood and urine samples were collected to estimate eGFR with microalbuminuria (MA) status. All participants were weighed and had their height measured. The eGFR was estimated by Modification of Diet in Renal Disease MDRD equation formula.

**Results:** The total cohort included in this analysis was 5216 subjects. The mean +/- SD age of all participants was 46+/- 15 years (range 18-87 yrs) and 64 % of them were females. The mean eGFR of whole cohort was 89 +/- 22 mL/min/1.73 m² and the prevalence of MA and reduced eGFR (stage 3-5) was 4 % and 9%, respectively. The prevalence of MA and CKD were all significantly higher among adults with diabetes and hypertension. Finally, in multivariate analysis only age (HR=5.25 (95% CI; 4.18-7.60) ($p<0.001$), DM (HR= 1.78 (95% CI (1.35-3.34) ($p<0.001$), hypertension (HR= 1.78 (95% CI;1.35-3.34) ($p<0.001$), BMI (>30kg/m2) (HR= 1.81(95% CI ;1.34-3.45) ($p<0.01$) were independently predictors for the presence of CKD.

**Conclusions:** CKD risk factors must be addressed to all primary care physicians who take care of hypertensive and diabetic patients. Moreover, in Brazil, it is necessary to establish a health national strategy for the treatment and prevention of CKD.

**PUB090**

**Improving Chronic Kidney Disease Detection and Care in a High Risk Underserved Population** Miguel A. Vazquez,[1] Ruben Amarasingham,[2] Adriana Valencia,[1] Beverley Adams-huet,[1] Adeola O. Jaiyeola,[2] Blake R. Barker,[1] Noel O. Santini,[2] Ying Ma,[2] Javier A. Velazquez,[2] Vibin Roy,[1] Zhiyi Zhou,[2] George Oliver,[2] Brett Moran,[2] Christopher Y. Lu,[1] Robert D. Toto.[1] *[1]Internal Medicine, UT Southwestern Medical Center, Dallas, TX; [2]Parkland Hospital and Health Systems, Dallas, TX.*

**Background:** Many patients with chronic kidney disease (CKD) are not receiving treatments shown to be effective for improving outcomes. The main purpose of this study is to facilitate detection of CKD and implement established treatments for slowing the progression of CKD and its associated complications.

**Methods:** We developed a collaborative primary care and nephrology model for CKD care enhanced by a novel technology information platform, PIECES (Parkland Intelligent e-Coordination Evaluation System), that makes it possible to use information in the electronic health record and electronic databases to identify patients with CKD, implement evidence-based therapies and evaluate responses to interventions. CKD was defined by eGFR <60 ml/min and/or albuminuria or proteinuria. The expected number of study participants is 500, and 72 patients have been enrolled so far and provided baseline data.

**Results:** Initial review reveals 62% of patients in clinic with established CKD had not been previously diagnosed with CKD. Among the 72 patients enrolled so far, at initiation of the study less than 40% with CKD have blood pressure control within established guidelines. More than 75% of patients are receiving ACEIs and statins. The table below summarizes achievement of goals on recommended clinical measures at baseline.

| Clinical Measures | Percent at Goal (n=72) |
|---|---|
| Systolic BP <130 mmHg | 37% (n=26) |
| Diastolic BP <80 mmHg | 62% (n=44) |
| ACEI/ARB | 86% (n=62) |
| Statin | 75% (n=54) |

**Conclusions:** Using a primary care and nephrology collaborative model enhanced by novel information technology, we detected previously undiagnosed CKD. We also found a large proportion of patients are not getting the potential benefit of BP control and ACEi/ARB known to slow progression of CKD and prevent cardiovascular complications. We are now implementing accepted practices for CKD in our patients and monitoring prospectively compliance with clinical management.

*Funding:* NIDDK Support

## PUB091

**Serving the Underserved: A Case Study of Community Screening by the Kidney Disease Screening and Awareness Program (KDSAP)**

Michael Ho-Young Ahn,[1] Manjinder Singh Kandola,[1] Laura C. Polding,[1] Andrew J. Pan,[1] Ryan Lindeborg,[1] Jennie Kuo,[2] Kenneth Lim,[2] Tzongshi Lu,[2] Li-Li Hsiao.[2] *[1]Harvard College, Cambridge, MA; [2]Brigham and Women's Hospital, Boston, MA.*

**Background:** Chronic Kidney Disease (CKD) is a public health problem affecting 27 million Americans. Early detection of CKD can prevent premature kidney failure. The prevalence of CKD and its risk factors, including diabetes, hypertension, and obesity, have increased within minorities, in part due to less access to care and no insurance. The Kidney Disease Screening and Awareness Program (KDSAP) strives to reduce the incidence of CKD by reaching out to underserved communities and providing kidney health screenings free of charge.

**Methods:** The screening was held in New Brunswick, NJ, and was modeled after the National Kidney Foundation's Kidney Early Evaluation Program. Diagnostic evaluations included body mass index, blood pressure, blood glucose, and urinalysis. Participants were also asked to report their health insurance status. Student T-test and Fisher's exact test were used for data analysis.

**Results:** A total of 70 community members participated in the screening (66% Chinese, 21% Hispanic, 9% African American, and 4% White). Among the participants, there was a high prevalence of CKD risk factors: overweight or obese 61% (19 and 24, respectively); hypertension 61% (42), hyperglycemia 64% (45), hematuria 46% (32), proteinuria 9% (6) and both hematuria and proteinuria 6% (4). 57% of the participants lacked health insurance (40). Furthermore, 56% (22) of uninsured individuals presented with hematuria versus 32% (10) of those insured. Lack of insurance coverage was associated with 2.6-fold greater odds of developing hematuria ($p<0.05$).

**Conclusions:** We detected a high prevalence of obesity, hypertension, hyperglycemia and hematuria at a single kidney health screening event in New Brunswick, NJ. There is a significant correlation between the lack of health insurance and hematuria in this unique population. Ultimately, the data support that KDSAP's free community kidney health screening efforts can serve as an effective tool to detect CKD risk factors early, especially among underserved communities.

## PUB092

**CKD Prevention: It Is Possible**

Maria Eva Baro-Salvador,[1] Carlos Sillero,[2] Sonia Baldoví.[2] *[1]Nephrology, Hospital de Torrevieja y Hospital de Vinalopo, Torrevieja/Elche, Alicante, Spain; [2]Nephrology, Hospital de Torrevieja.*

**Background:** Chronic Kidney Disease is an emerging problem that affect, by EPIRCE study , at the 10% of the adult spanish population. In our population, it represents more than 40,000 affected people and is for this reason that we needs to adapt to us at the new healthcare model scenario . Although various chronic diseases have developed chronic plans has not been so in the case of CKD as accurate a number of prerequisites such as continuity of care between primary and specialty, which is rarely given. We have developed a chronic patient care as the Pyramid of Kaiser, which stratifies the population by levels of chronicity. The correlation between these levels of chronicity and stages of CKD has allowed the development of a Plan for the ERC approach that collects from disease prevention to case management more complex levels.

Objective: Create a comprehensive plan for diagnosis, treatment and monitoring renal disease at its different stages from prevention to End-Stage Renal Disease (ESRD) homogeneously and to implement it in two departments of health (16 GP´s centers and two general hospitals).

**Methods:** We made a multidisciplinary working group for this purpose by defining a CKD Clinic Guide unified criteria and concise definition, treatment and referral of CKD easily accepted by all health personnel. Stratification of renal disease in different stages and their correlation with chronic patient stratification according to the Kaiser pyramid, has helped define and develop goals, interventions, algorithms and indicators.

**Results:** In February of 2013 took place the presentation to all health professionals in both departments (management staff, physicians and nurses). In March the program officially started and we hope to analyze initial results in August but in this moment , after 3 months, we have detected more than 700 news patients only in the Third Level .

**Conclusions:** Developing a comprehensive approach to Plan CKD which perform an adaptation of the diagnosis, treatment and monitoring early disease at all levels gets evenly reduce CKD progression from one stage to another with the resulting gain for the patient and the healthcare system.

## PUB093

**A Screening Model of Correlation Factors for Type 2 Diabetes Mellitus with Massive Proteinuria**

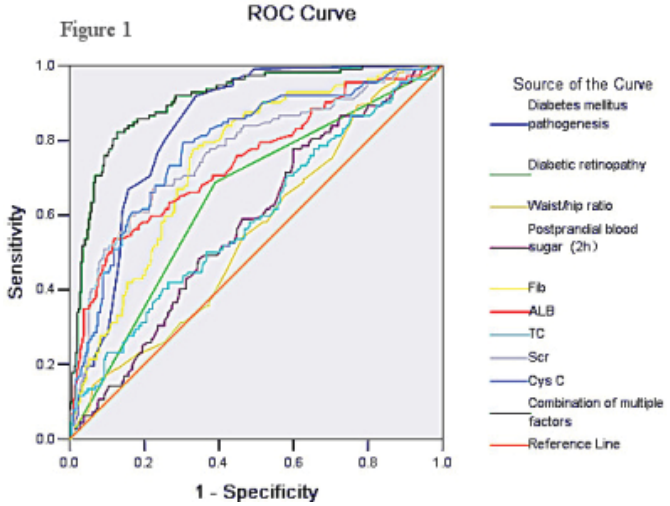
Wenbo Zhao, Yan-ru Chen, Jia-ling Rao, Hui Peng, Jun Zhang, Tan-qi Lou. *Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

**Background:** To establish the logistic regression screening model of the DKD with massive proteinuria crowd, and validate the effectiveness of the model.

**Methods:** Collected 605 type 2 diabete patients with microalbuminuria and massive proteinuria were treated during January 2008 to November 2012. 605 cases were randomized to the first group(404 cases) for modeling group, and the second(201 cases) to validation. The modeling group was including 292 cases with microalbuminuria and 122 with massive proteinuria. The eGFR was Calculated (MDRD Formula, all more than30 ml/min·1.73m$^2$). Statistical analysis used the SPSS15.0 software. Univariate and multivariate Logistic regression analysis were used to estabilsh regression equation.sensitivity and specificity of the model was analysised by ROC curves, diagnosis cut-off point was set on the maximum of youden index. Put the validation group into the model, to compare the difference of areas of ROC curve between model group and validation group with Z test.

**Results:** After multi-factor analysis, the duration of diabetes, DR, waist-to-hip ratio, postprandial blood glucose 2 h, Fib, ALB, TC, Scr, CysC were the 9 main relative factors for massive proteinuria. AUC of the combination of multiple main relative factors was largest (0.907), and the cut-off value was 0.3501 (Sensitivity 82.1%, Specificity 87.3%). The data of validation group applied to the model, the AUC was 0.850. To Compare the areas of ROC curves, that were no statistical difference (***P***>0.05).

Figure 1



**Conclusions:** The combination of multiple factors screening model of DKD with massive proteinuria was effective. The performance of the screening was stable. It can be used in clinical according to validation. Early prevention could be implement in the patients who are close to the diagnosis cut-off point.

## PUB094

**Healthy Behavior Is Low in Patients with Pre-Dialysis Chronic Kidney Disease**

Julie A. Wright Nunes,[1] T. Alp Ikizler,[2] Kerri L. Cavanaugh.[2] *[1]Nephrology, Univ of Michigan, Ann Arbor, MI; [2]Nephrology, Vanderbilt, Nashville, TN.*

**Background:** Preventing chronic kidney disease (CKD) progression and complications could be enhanced by patient engagement in healthy behaviors.

**Methods:** Adult patients with CKD Stages 1-5 not on maintenance dialysis were enrolled in a cross-sectional study from April 2009 to October 2010. Patients were asked how many days over the past week they performed health behaviors on topics including healthy eating, medication adherence, smoking, and physical activity.

**Results:** 556 patients were enrolled. The mean (SD) age was 57 (16) years. 53% were male, 81% were Caucasian, 19% had limited health literacy, and 78% had CKD Stage 3-5. Twenty-two percent reported eating healthy, 16% ate at least 5 servings of vegetables/fruits, 10% avoided high fat foods, 14% had at least 30 minutes of daily physical activity, 80% took their medications exactly as prescribed, and 91% did not smoke. In univariate analysis older patients had a higher odds of reporting eating healthy every day (OR 1.03[CI 1.01,1.04]; $p<0.01$), including eating at least 5 servings of fruits/vegetables (1.02[1.01,1.04]; $p<0.01$). Non-white patients were less likely to report eating healthy (0.50[0.30,0.90];$p=0.03$) and to take medications as prescribed (0.50[0.30,0.80];$p<0.01$) versus white patients. In analyses adjusted for age, sex, race, kidney function, income, and health literacy, older patients continued to show higher odds (1.03[1.01,1.04]; $p<0.01$), and non-white race lower odds (0.50[0.30,1.004];$p=0.05$) of healthy eating. Older patients were less likely to report daily physical activity (0.98[0.96,0.99];$p=0.02$). Non-white patients had 0.50[0.30, 0.80];$p=0.01$) lower odds of taking medications as prescribed. Patients with an eGFR>60 had higher odds (2.80[1.09,7.20];$p=0.03$) of not smoking vs. patients with a lower eGFR.

**Conclusions:** Adherence to many health behaviors were low for our cohort of Stage 1-5 CKD patients not on dialysis. Older patients were more likely and non-white patients less likely, to report healthy eating behaviors. More work is needed to determine reasons for the racial differences in health behaviors and potential strategies to improve healthy behavior patterns.

## PUB095

**Improving Care of Patients with Kidney Disease: Use of Mobile Telephony to Improve Lifestyle and Adherence** Alfonso M. Cueto-Manzano,[1] Hector Gallardo-rincon,[2] Héctor R. Martínez Ramírez,[1] Laura Cortes-sanabria,[1] Enrique Rojas-Campos,[1] Petra Martínez,[3] Jose I. Cerrillos,[3] Jorge Andrade-Sierra,[3] Miguel Medina Perez.[3] *[1]UIMER, Hospital Especialidades, CMNO, IMSS, Guadalajara, Jalisco, Mexico; [2]Dirección de Soluciones Operativas, Instituto Carlos Slim de la Salud, Mexico, DF, Mexico; [3]Dept Nephrology, Hospital Especialidades, CMNO, IMSS, Guadalajara, Jalisco, Mexico.*

**Background:** Opportunities for new technologies (as mobile phones) to play formal role in health services are increasing. However, no study has been performed in kidney disease (KD). Aim: To develop and test a mobile phone program to improve lifestyle, adherence and clinical outcome of KD patients.

**Methods:** In collaboration, and with technology developed by the Carlos Slim Health Institute, a program based on mobile phone text messages and reminders was developed, and tested in a pilot study (Jun-Oct 2012). Text messages about KD risk factors (50), healthy lifestyle (40), and to improve adherence and follow-up appointments (35) were generated and sent to patients agreed to participate (recipients of a functioning kidney transplant performed at our Hospital, included when they were discharged). Patients were treated by their nephrologists according to clinical practice standards. A satisfaction questionnaire was applied at end of follow-up.

**Results:** Twenty-three patients (age 33±13 yrs, 43% women) had a follow-up of 58 (41-76) days. Patients received 0.8 (0.3-1) text messages/day, 3 (2-3) medication reminders/day, and 1.1 (0.3-2) appointment reminders/month. Clinical and biochemical data are shown in the table.

| Variable | Baseline | Final |
|---|---|---|
| Hemoglobin (g/dL) | 11 (10-13) | 13 (12-14)* |
| Creatinine (mg/dL) | 0.9 (0.8-1.1) | 1.0 (0.9-1.2) |
| Systolic Blood Pressure (mmHg) | 130 (118-137) | 120 (115-125)* |
| Diastolic Blood Pressure (mmHg) | 80 (72-82) | 78 (70-80) |

*$p<0.05$ vs baseline

In a 0-10 scale, patients considered utility of messages as 9.6±0.7, medication reminders 9.8±0.5, and appointment reminders 9.8±0.6.

**Conclusions:** More than 100 mobile phone messages were successfully developed and tested to improve lifestyle, adherence and clinical outcome of KD patients. Future research should address scalability of this intervention and explore association with changes in attitudes and behaviors.

## PUB096

**Chronic Kidney Disease Education and Impact on Dialysis Modality Choice and Dialysis Access** Doris Sofia Galina Quintero, Clare Nichols Lyas, Russell Griffin, Jane S. Davis, Dana Rizk, Eric L. Wallace. *Univ of Alabama at Birmingham.*

**Background:** Despite the morbidity and mortality associated with the initiation of dialysis with intravascular catheters (IVC), IVC rates of incident patients remains over 60%. Home modalities utilization remains low despite the associated benefits. Perhaps a contributing factor for these data is patient education. There is limited information about how Chronic Kidney Disease Education (CKDE) affects modality selection and placement of permanent access. Although education may be documented, its effectiveness is unclear. We analyze the effects of the UAB CKDE class on modality selection and permanent access placement.

**Methods:** Clinical and demographic data on all patients who attended CKDE class from 2010 through 2012 were collected through chart review. Data on all dialysis accesses placed up until June 2013 was collected on these patients utilizing a preexisting dialysis access database. Chi-square test and ANOVA statistical analysis were used for categorical and continuous variables respectively.

**Results:** 174 patients were analyzed. At the time of class attendance, patients had a mean glomerular filtration rate (GFR) of 19 ml/min/1.73 $m^2$ (Standard Deviation (SD) of 6). 50.3% were diabetic. 70/174 (40.2%) had no access placed at the time of analysis.This group had higher GFR compared to all other access types ($p<0.05$). Length of time from class to first access was 174 days (SD 192). Of patients with access, 11.5% had an IVC,12.5% an AV graft; 51% an AV fistula; and 25% a peritoneal dialysis (PD) catheter as first access. There was no difference in age, gender, or race with regards to type of access placed.

**Conclusions:** When compared to USRDS data, patients who attended CKDE class were significantly more likely to choose PD as their modality of choice and much less likely than national average to have an IVC as their initial dialysis access.

## PUB097

**Cost Analysis of Participatory Educational Intervention for Prevention, Diagnosis and Treatment of Early Chronic Kidney Disease** Laura Cortes-sanabria, Victor Omar Frías-navarro, Héctor R. Martínez Ramírez, Alfonso M. Cueto-Manzano. *Unidad de Investigación Medica en Enfermedades Renales, Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.*

**Background:** Our group previously demonstrated that adequate training to family physicians (FP) successfully preserved renal function of patients with DM2. However, no previous study has evaluated the economic impact of such an educative intervention.

AIMS: To determine and evaluate the direct costs (DC) of an educative-participative intervention (EPI) to FP and a multidisciplinary team (MDT) addressed to increase their clinical competence (CC) in the management of patients with DM2 and early nephropathy (EN).

**Methods:** Economic evaluation study. EPI included review of Clinical Practice Guidelines of early CKD and discussion of real clinical cases, 5 h/wk during 3 months. CC was evaluated with a previously validated instrument, applied at the beginning and the end of the EPI (maximum value of CC 150 points). The pattern of service utilization was identified; costs were calculated for each activity, according to the Institutional Unit Cost System (IMSS). Only direct medical costs (DMC, all monetary costs incurred during the EPI) were considered, and they are shown in US dollar. *Statistical Analysis:* Mac-Nemar $Chi^2$, and Wilcoxon test. Bootstrap analysis to assess uncertainty in the estimates of CD. The cost-effectiveness ratio was estimated.

**Results:** The CC of the FP and MDT was significantly increased at the end of EPI (Basal 61 [41-71] vs final 89 [76-101], $P<0.0001$). The total CD distribution is shown in the table.

| Resource | Costs US Dollar | % |
|---|---|---|
| Time of doctor attendance visit | 32,714 | 95 |
| Printing of Clinical Practice Guidelines of early CKD | 1,279 | 2 |
| Office supplies | 378 | 0.6 |
| Printed materials | 257 | 0.4 |
| Teacher salaries | 403 | 1.0 |
| Audiovisual equipment | 721 | 1.0 |
| Total Cost | 35,746 | 100 |
| Average training cost per person | 760 | |

The cost-effectiveness ratio of the educational intervention was 0.89 (better result = 1.0).

**Conclusions:** Implementing an EPI in the primary health-care is a cost-effective measure to reduce the burden of kidney disease.

## PUB098

**National Kidney Centre Report on Kidney Screening Programm Risk Factor for Chronic Kidney Disease – A Survey from Ranibas, Gulmi Nepal** Rishi Kumar Kafle. *National Kidney Center, Kathmandu, Nepal.*

**Background:** National kidney center is providing dialysis to increasing numbers of patients every year. kidney disease screening programm along with awareness campaign is carried out from time to time.

**Methods:** Team of experts from National Kidney centre visited village Ranibas of Gulmi district to conduct kidney disease screening and awareness camp. Infrmation about camp was publishized through media before the team arrived there. On three consecutive days all who came for screening were evaluated. Every individual registered,his /her BMI, BP, was measured. Urine dipstick test for protein and sugar was done there only. survey form filled with the hep of volunteers to know medical history, personal habits especially water intake; smoking; tobacco chewing; alcohol consumption and exercise done by that individual. all data were entered into register for evaluation.

**Results:** More than 33 % of 731 persons examined were overweight
17 % of examined had raised blood pressure
around 5 % examined were suspected to have Diabetes
around 6% examined had proteinuria
majority had healthy kidneys
98% had access to aerated drinks and use it
94 % do not exercise except their regular work.

**Conclusions:** Even in a remote village of Nepal there are enough risk factors for development of kidney disease. Programm to educate not only about kidney diseases or others education to remain healthy is needed. Need to make people aware about their health and ways how they can prevent serious disease by simple screening method which is not costly.

## PUB099

**High Self-Efficacy Is Associated with More Self-Care in Patients with Chronic Kidney Disease** H. Omer Ikizler, Jillian Molli Berkman, Kenneth A. Wallston, T. Alp Ikizler, Kerri L. Cavanaugh. *Vanderbilt Univ.*

**Background:** Self-care behaviors, dietary and medication adherence, physical activity, and health care engagement, are important to optimize chronic kidney disease (CKD) treatment. To identify potentially modifiable factors to promote effective self-care, we investigated the relationship between patients' self-perceived efficacy and frequency of CKD self-management behaviors.

**Methods:** Adult patients with CKD (eGFR<60) from one academic nephrology clinic were enrolled in a cross-sectional study from May 2012 to July 2013. Patient surveys assessed kidney knowledge, health literacy, frequency of CKD self-care, and their self-perceived efficacy in managing their kidney disease using the Perceived Kidney Disease Self-Management Scale (PKDSMS).

**Results:** Among 252 patients enrolled, mean (SD) age was 58 (12) years. 42% were male, and 83% were Caucasian. Mean (SD) self-efficacy score was 2.58 (0.73) out of 5; mean self-care score was 26.7 (6.4) out of 39. In univariate analysis, higher subjective numeracy (rho(r)=0.15, p<.05), and greater perceived (r=0.19, p<0.01) and objective kidney knowledge (r=0.23, p<0.01) were correlated with higher self-efficacy. Self-care behaviors were also correlated with higher self-efficacy: healthier food (r=0.22, p<0.01), physical activity (r=0.20, p<0.01), adhering to a kidney diet (r=0.14, p<0.05), not missing doctor visits (r=0.13, p<0.05), and taking medications as prescribed (r=0.22, p<0.01). Total overall self-care score was also positively correlated (r=0.33, p<0.01). In an analysis adjusted for age, gender, race, education, perceived and objective kidney knowledge, the association between self-efficacy and overall self-care behaviors persisted [β (95%CI): 0.21 (0.10 – 0.31); p<0.001]. Furthermore, higher self-efficacy was also associated with greater satisfaction with physician communication (r=0.30; p<0.01).

**Conclusions:** Self-efficacy is easily assessed and is moderately to strongly associated with a variety of self-care behaviors in chronic kidney disease. Interventions to improve self-efficacy specific to CKD may increase participation and effectiveness of self-care, enhance patient-centered communication, and ultimately improve clinical outcomes.

## PUB100

**A Bioreactor as a Long Term Perfusion Model** Vera Jankowski,[1] Horst-Dieter Lemke,[2] Joachim Jankowski.[1] *[1]Charite, Berlin, Germany; [2]Excorlab, Obernburg, Germany.*

**Background:** Metabolic stimuli, pressures and hemodynamic flows are major mediators of vascular plasticity. In this study, we have developed an *in vitro* bioreactor to investigate cell-specific interactions, molecular mechanisms as well as time-dependent effects under physiological hemodynamic flow conditions. This bioreactor termed "*artificial artery*" can be used for screening of potential arterio-protective substances, pro-arteriogenic factors, and for investigating biomarkers of vascular diseases in CKD.

**Methods:** The bioreactor is built up out of 4 hollow fibre membranes colonised with primary human umbilical vein endothelial cells (HUVECs) on the inside and primary human arterial smooth muscle cells (HUASMCs) on the outside. By means of fluorescent staining as well as immunocytochemistry of reference proteins for endothelial cells and smooth muscle cells, a hydrophobic polypropylene membrane was identified as being the optimal polymer for co-colonisation.

**Results:** Applying defined arterial flow conditions, metabolic exchange, and cross-talk of endothelial and smooth muscle cells through the microporous structure of the hollow fibre, capillaries mimic physiological *in vivo* conditions of the vasculature and is therefore of high relevance for further studies. Chromatographic methods and subsequently mass spectrometry analyses as well as expression analyses of shear stress regulated genes proved our system to be viable and functional up to five days.

**Conclusions:** The "*artificial artery*" provides a solid *in vitro* model to test pharmacological active compounds for their impact on arterio-damaging or arterio-protective properties on vascular response in CKD.

## PUB101

**Renal-Coloboma Syndrome Associated with Arnold-Chiari Malformation Type 2 and Proximal Renal Tubular Acidosis** Heino R. Anto, Tatyana Tolchinsky, Fnu Jaipal. *Dept of Nephrology, St. John's Episcopal Hospital, Far Rockaway, NY.*

**Background:** A 28 y/o patient was admitted for corrective surgery involving Arnold-Chiari malformation type 2. Besides this malformation the patient also had optic disc dysplasia and syringomyelia and was treated with topiramate for seizures. On this admission laboratory serum values were as follows : sodium 140 mEq/L, potassium 3.9 mEq/L, chloride 116 mEq/L, co2 17 mEq/L, BUN 35 mg/dL, creatinine 2-3 mg/dL, and anion gap of 7. The patient was also found to have 3 + proteinuria, microhematuria, and hypoplasia of the left kidney on sonography.The patient ultimetly developed end-stage renal failure and was being evaluated for renal transplant.

This case exemplifies the characteristics of renal-coloboma syndrome. While this syndrome has been reported with Arnold-Chiari malformation type 1, we believe this is the first case reported with type 2. The progressive renal failure seen in this case was likely due to the development of focal segmental glomerulosclerosis, frequently seen in renal-coloboma syndrome and resulted from increased intra-glomerular pressure associated with renal hypoplasia, leading to ESRD and renal transplantation.

Renal coloboma syndrome is an autosomal dominant disorder due to a mutation of the PAX 2 gene located on chromosome 10 q 24.3- q 25.1.The PAX gene is vital for the proper development of both eyes and kidneys; and when mutated leads to improper development of these organs. The diagnosis is made by renal ultrasound, kidney biopsy, family history, opthalmologic exam, and genetic testing.

This patient also presented with renal tubular acidosis, a finding not associated with renal-coloboma syndrome, but likely due to topiramate; which inhibits carbonic anhydrase leading to reduced bicarbonate reabsorption by the proximal tubule.

## PUB102

**Evidence from Cytogenomic Aberrations Suggests Complicated Genetic Mechanisms in the Development of Multicystic Dysplastic Kidney** Tianjian Chen, Arivudainambi Ramalingam, Renfang Song, Adam T. Janssen, Graeme James Preston, Dominique Monlezun, Ihor V. Yosypiv. *Pediatrics, Tulane Univ, New Orleans, LA.*

**Background:** Multicystic dysplastic kidney (MCDK) is considered to be a nonheritable form of congenital anomaly of the kidney and urinary tract (CAKUT). However, several lines of evidence strongly suggested that genetic factors play a pathogenic contribution to the pathogenesis of MCDK. In our previous report (ASN 2012), three cytogenomic aberrations have been detected by arrayCGH in a pilot study from ten pediatric patients with isolated unilateral MCDK. In this work, we characterized the derivation of the aberrations.

**Methods:** DNA was isolated from patients and their biological parents. Primers and probes for quantitative PCR (qPCR) were designed for detection of the relative copy number on targeted regions within the aberrations. Two quantitative technologies, TaqMan assay and SYBR green assay, were performed on more than two targeted regions for each aberration with reference control. The relative copy number was calculated by ΔΔCt method.

**Results:** Deletion at 7p14.3 with size of 2.07 Mb was revealed to be inherited from patient's father. Duplication at 16p13.11-p12.3 with size of 3.28 Mb. This duplication was determined to derive from patient's mother. Parental origin of monosomy X was not studied.

**Conclusions:** The two aberrations were determined to be inherited from parents, indicating that much complicated molecular mechanisms play the role in kidney morphogenesis. The molecular products encoded in the two altered regions should be involved in the reciprocal interaction between the ureteric bud and the metanephrogenic mesenchyme, and be tightly regulated during kidney development. Thus, interpretation of cytogenomic alternations to be recessive or dominant is not enough. In addition to halploinsufficiency and dosage effects, incomplete penetrance, variable tissue expression, imprinting, and unmarked mutations in the deletion regions have to be explored. Detailed analysis of the embryonic transcription and interactions related to the genes located within these aberrations will provide a better understanding for the genetic mechanisms.

## PUB103

**Chronic Low-Level Lead Exposure in Young Mice Results in Abnormal Glomerular Development** John M. Basgen,[1] Christina Sobin.[2] *[1]Charles R. Drew Univ; [2]Univ of Texas, El Paso.*

**Background:** Long-term exposure to high levels of lead is a risk factor for chronic kidney disease. Few studies have examined glomeruli in children or in young mice exposed to low levels of lead. This study examines the effects of early chronic low-level exposure of lead on glomerular development in young mice.

**Methods:** Pups were exposed to 30 ppm (99.4% lead acetate) via dams' drinking water. Controls received water with sodium acetate. Pups were sacrificed at post-natal day 28 and organs fixed with 4% paraformaldehyde via transcardial perfusion. Kidneys were harvested, weighed, and processed for light and electron microscopy. Glomerular volumes were measured on light microscopy images using the Cavalieri priniciple. The volumes of the glomerular components podocyte, mesangium, and capillary lumen were calculated by first measuring the volume fraction of each glomerular component on low magnification electron microscopy images using manual point counting. Finally the respective volume fractions were multiplied by glomerular volume to obtain podocyte, mesangial, and glomerular capillary volumes. Twelve mice per group were studied with ten glomeruli per mouse measured.

**Results:** Mean lead blood levels in the control and 30 ppm groups were 0.03 and 3.42 μg/dl respectively. The mean kidney weight of the 30 ppm exposed mice (91±7 μg) was significantly less than that of the controls (105±16 μg), p<0.02. The mean glomerular volume of the 30 ppm exposed mice was significantly greater (86±8 $x10^3$ $\mu m^3$) than that of the control group (72±6 x $10^3$ $\mu m^3$), p<0.001. The mean podocyte volume of the lead exposed mice was significantly greater (26±4 $x10^3$ $\mu m^3$) than that of the control group (23±3 x $10^3$ $\mu m^3$), p<0.02. The mean mesangial volume of the lead exposed mice was significantly greater (17±3 $x10^3$ $\mu m^3$) than that of the control group (13±3 x $10^3$ $\mu m^3$), p<0.01. The mean glomerular capillary lumenal volume of the lead exposed mice was significantly greater (34±3 $x10^3$ $\mu m^3$) than that of the control group (27±3 x $10^3$ $\mu m^3$), p<0.001.

**Conclusions:** Early chronic exposure to low-level lead in mother's milk is associated with decreased kidney weight and abnormal glomerular development in young mice.

## PUB104

**Glomerular Development in the Chinese Experimental Miniature Pig** Xiang-Mei Chen, Yuansheng Xie, Qing-gang Li, Xueyuan Bai. *Dept of Nephrology, State Key Laboratory of Kidney Disease, General Hospital of Chinese People's Liberation Army, Beijing, China.*

**Background:** The pig, which shares more similarities in renal structure and function with humans than with other species, is an excellent model for the study of renal development. However, few studies have focused on glomerular development in pigs.

**Methods:** The morphological changes of glomerular development, the development of podocytes, endothelial and mesangial cells, and the interrelationship between these cells were systematically observed in Chinese experimental miniature pigs at 17 time points from embryonic day 28 (E28d) to postnatal day 21 (P21d).

**Results:** Immunofluorescence staining showed that diffuse WT1 expression was observed in the metanephric mesenchyme and then, in succession, in the renal vesicle, the comma-shaped body, the tail of the comma-shaped body, the lower aspect of the S-shaped body and the glomerular podocytes. CD31 was scattered throughout the fetal kidneys and then surrounded the developing renal vesicle and comma-shaped body. At the S-shaped body stage, CD31-positive cells migrated into the vascular cleft to form precapillary cords in the immature glomeruli and finally localized in the endothelium of mature glomeruli. α-SMA expression was not present in the early fetal kidney, renal vesicle or comma-shaped body, but appeared near the periphery of the S-shaped body at the early stage of the S-shaped body, streamed into the vascular cleft by the late S-shaped body stage, aggregated at the root of the developing glomerulus, migrated to the periphery of the glomerular tuft at the capillary loop stage, and finally localized to the mesenterium in the mature glomerulus.

**Conclusions:** Porcine podocytes arise from the metanephric mesenchyme and the development of podocytes and endothelial cells precedes the development of the mesangial cells. Cross-talk between cells in the glomerulus may be essential during the development of the porcine glomerular tuft.

## PUB105

### Atorvastatin Improve Effects of Mesenchymal Stem Cells Treatment for Kidney Ischemia/Reperfusion Injury through Down-Regulation of TLR4 Expression

Jieru Cai, Xiaofang Yu, Bingyng Zhang, Yi Fang, Xiaoqiang Ding. *Nephrology of Dept, Zhongshan Hospital, Fudan Univ, Shanghai, China.*

**Background:** Statin has been shown to attenuate ischemia/reperfusion (I/R) injury and enhance efficacy of mesenchymal stem cells (MSCs) treatment. However, the components of the mechanism remain largely unknown. We aim to investigate whether atorvastatin regulates the expression of Toll-like receptor 4 (TLR4), a potential mediator of innate activation and inflammation, and facilitates therapeutic efficacy of MSCs in renal I/R injury.

**Methods:** The model of I/R injury was induced by bilateral renal pedicles clamp for 45 min. Immediately after reperfusion, CM-Dil labeled MSCs ($1\times10^6$ cells) or vehicle were administered into the animals, pretreated with or without Ator for 3 days, through the carotid artery.

**Results:** After 24h systemically administration following I/R, the combined treatment with Ator and MSCs (Ator+MSCs) markedly decreased the elevated level of serum creatinine and blood urea nitrogen, reduced the severity of renal damage. In addition, inhibited renal tubular cell apoptosis, and reduced oxidative stress were observed in the Ator+MSCs group compared with control or mono-therapy group. Furthermore, TLR4 expression and high-mobility group box 1 (HMGB1) were decreased and survivals of implanted MSCs were increased within the kidney of Ator+MSCs animals.

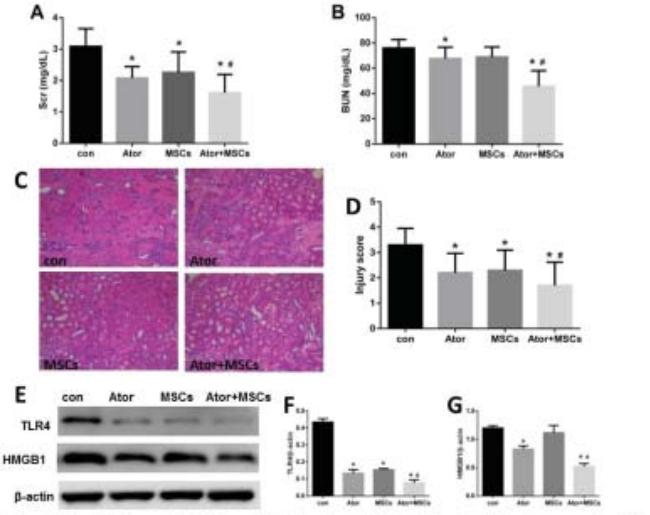

**Figure 1 Effect of Ator and/or MSCs on I/R-induced renal dysfunction.** Renal function was evaluated by determing (A) serum creatinine (Scr) and (B) blood urea nitrogen (BUN) levels post-I/R 24h. All the animals treated with Ator and/or MSCs showed less increasing in Scr and BUN levels than control group, especially in the combination of Ator and MSCs group. (C) representative photomicrographs of kidney sections showed that there were severe tubular injury occurred in the cortical and corticomedullary junction areas when the rat subjected to 45 min renal ischemia and 24 hours of reperfusion (HE staining, magnification×200). (D) The degree of renal injury was assessed via a semiquantitative method in the sections. Compared with control or MSCs alone, there were less injured score in group Ator+MSCs. (E-G) The inflammatory-regulating protein levels of TLR4 and HMGB1 were analyzed by Western blotting and representative scan of three independent experiments was shown. The expressions of HMGB1 and TLR4 were down-regulated in the treated group compared to the control group. The presence of the Ator further decreased the expression of the HMGB1 compared with the MSCs group ($P<0.05$) but not affected the TLR4 ($P=0.321$). *$P<0.05$, vs control group; #$P<0.05$, vs MSCs group.

**Conclusions:** Ator inhibit the apoptosis, oxidative stress, and inflammation in the kidney undergoing I/R injury, through down-regulate the expression of TLR4 and endogenous ligand HMGB1. Therefore, Ator pretreatment create a better environment for the survival of implanted MSCs and enhance their therapeutic potential.

## PUB106

### Secreted Factors from Adult Kidney Stem Cells Protect against Renal Ischemia-Reperfusion Injury

Kenji Tsuji, Shinji Kitamura, Hirofumi Makino. *Medecine and Clinical Science, Okayama Univ Graduate School of Medicine, Okayama, Japan.*

**Background:** Recently, stem cell therapies have been proposed as a novel therapy against acute kidney injury (AKI) on basic research. We have established adult stem / progenitor-like cells (KS cells) from S3 segment of renal proximal tubules (Kitamura S et al., FASEB J, 2005). We have previously reported that KS cells replaced in injured tubules directly and improved renal function after implantation in rat AKI models (Kinomura M et al., Cell transplantation, 2008). It is unclear whether the secreted factors from adult kidney stem / progenitor cells are effective or not. Here we examined whether the KS cell therapy system is not only the direct cell differentiation at injury place but also the secreted factors from KS cells.

**Methods:** SD rats were subjected to kidney ischemia/ reperfusion (I/R) injury. We separated the rats in three groups, KS cell supernatant (CS-KS) administrated group (Intraperitoneally administrated 3 hours after I/R; I/R-KS, n=3), vehicle group (I/R; n=3) and sham operated group (sham: n=3). They were sacrificed after 2 or 4 days, were evaluated renal function, tubulointerstitial injury, apoptosis, cell proliferation and inflammation.

**Results:** In I/R-KS group, we could observe significant suppression on urinary N-acetyl-b-D-glucosaminidase (NAG) level in 4 days compared to I/R group (I/R group v.s. I/R-KS group; 4.43±1.76 v.s.1.36±0.99 U/l, $p<0.01$). The cell proliferation increased significantly in I/R-KS group (I/R group v.s. I/R-KS group; Histone H3(+) cells: 24.3±7.9 v.s. 43.9±9.5/×40field).The apoptotic cells decreased in I/R-KS group (I/R group v.s. I/R-KS group; TUNEL(+) cells: 46.4±14.5 v.s. 25.3±13.0 / ×200field, $p<0.01$). Moreover, we could observe significant inflammation suppression in I/R-KS group compared to I/R group (F4/80(+) area: 4476±2433 v.s. 1577±1042 pixel/×40field, $p<0.01$). In addition, CS-KS significantly suppressed cisplatin-induced cell apoptosis in vitro. Immunoblot analysis revealed that CS-KS contained many factors, such as HGF.

**Conclusions:** Not only the direct cell differentiation but also secreted factors from adult kidney stem cells have the potential to protect against AKI and activate renal regeneration.

## PUB107

### Acute Hemodialysis Therapy in Neonates with Inborn Errors of Metabolism

Israel Eisenstein,[1,4] Mahdi Tarabeih,[1] Daniella Magen,[1,4] Shirley Pollack,[1,4] Hanna Mandel,[2,4] Gad Bar Joseph,[3,4] Israel Zelikovic.[1,4] *[1]Pediatric Nephrology, Rambam Medical Center; [2]Pediatric Metabolic Diseases, Rambam Medical Center; [3]Pediatric Intensive Care, Rambam Medical Center; [4]Faculty of Medicine, Technion, Haifa, Israel.*

**Background:** Inborn errors of metabolism (IEOM) can cause devastating damage to the neonatal brain if not promptly treated. The most efficient therapy for IEOM-induced metabolic crisis is hemodialysis (HD). Data on the use of HD in IEOM in neonates is scarce.

**Methods:** We analyzed the demographic, clinical, and biochemical data of all neonates with IEOM who were admitted to our Pediatric Intensive Care Unit between 2004-2013 with a metabolic crisis necessitating HD.

**Results:** Fourteen neonates (M:F 7/7; Arabs/Jews 13/1) with IEOM [6- Urea cycle defects (UCD), 4- maple syrup urine disease (MSUD), 2-mitochondrial cytopathies (MC), 2 - other] had uneventful delivery, and were admitted because of metabolic/neurological deterioration starting at 48h -14 days of age. Median age and weight of the infants at the initiation of HD was 6.3 days and 2999 g, respectively. HD was performed through double-lumen, 6.5- French, Gamcath® acute catheter inserted into the internal jugular vein; Gambro AK200 dialysis machine and tubing and Fresenius FXpaed® dialyzers were used. A total of 30 dialysis treatments (at least 2 per patient) were performed. The first (2 hrs) HD tretment markedly decreased (91.9%) mean plasma ammonia level in UCD and MC patients from 1071 to 86 μmol/L (nl: 53-90), and markedly decreased (90%) mean plasma leucine level in MSUD patients from 2408 to 230 μmol/L (nl: 70-240). The second (3-4 hrs) HD treatment decreased the mean rebounded ammonia and leucine levels from 433 μmol/L and 780 μmol/L to 69 μmol/L and 88 μmol/L, respectively. The HD procedure was free of complications, resulted in marked clinical improvement in 11 patients, and enabled the initiation of appropriate dietary/pharmacological therapy in all patients. Eleven (78.6%) of the infants survived, and 3 (21.4%) succumbed to their metabolic disease in the neonatal period.

**Conclusions:** HD in neonates with IEOM is safe, very efficient, and life-saving when performed by skilled personnel and in the appropriate setting.

## PUB108

### Predictive Factors of Graft Censored Failure in Pediatric Kidney Transplants

Ana Rocha, Liliana Rocha, Maria Faria, Conceição Mota. *Centro Hospitalar do Porto.*

**Background:** Kidney transplant in children's has shown steady improvement in graft survival outcome over the last decades. Using data obtained from the transplant registry of our Centre between 1984 and 2012, we assessed the independent determinants of graft failure using the Cox proportional hazards regression.

**Methods:** Altogether, 128 recipients aged <18 years at the time of kidney transplant and who had > 3 months graft survival were studied. Over 9.95 years of medium follow-up, 27 censored graft failures occurred. Censored graft survival at five, ten, fifteen and twenty years post-transplant was 93%, 82%, 70% and 63%, respectively. Studied factors included receptor and donor age, receptor gender, dialysis vintage, donor/recipient CMV

serology, panel reactive antibody percentage, human leucocyte antigen mismatching, previous transplant number, donor type [deceased vs. living donation], cold ischemia time, induction therapy with antithymocyte globulin, occurrence of acute tubular necrosis and development of acute rejection.

**Results:** Using univariate analysis, the significant predictors for graft censored failure were adult donor (P<0.001), higher receptor age (P=0.035), human leucocyte antigen mismatching (P=0.025), antithymocyte globulin induction (P=0.03) and development of acute rejection (P<0.001).Two factors independently predicted graft censored failure in multivariate analysis. The odds ratios for graft failure in patients with acute rejection and in children who received an organ of an adult were 3.744 and 4.962, respectively.

**Conclusions:** Pediatric recipients should receive the first priority for allografts from pediatric donors and acute rejection should be meticulously prevented.

## PUB109

### Efficacy and Safety of Eculizumab in Children with Dense Deposit Disease

Kiran K. Upadhyay, Richard N. Fine. *State Univ of New York at Stony Brook, NY.*

**Background:** Dense Deposit disease (DDD) is a rare cause of glomerulonephritis and is believed to result from dysregulated alternative complement pathway. Treatment options are limited and there is a high incidence of end stage renal disease if untreated. Eculizumab, a humanized monoclonal antibody, binds to the terminal complement, C5, and prevents formation of membrane attack complex (MAC) - C5b9, a potent proinflammatory agent.

**Methods:** We describe a 6 yo male with biopsy-proven DDD who was treated off-label with eculizumab soon after the diagnosis. The patient presented with nephrotic range proteinuria, microhematuria, C3 hypocomplementemia, with normal renal function and mild hypoalbuminemia without edema. Baseline serum soluble MAC (SC5b9) was elevated. Other tests included negative C3 nephritic factor, normal factor H & I levels, no autoantibodies to factor H & I, and no CD46, C3 or factor H mutation. After initial Rx with biweekly intravenous eculizumab, the proteinuria decreased from baseline urine protein to creatinine ratio (U P/C) of 5.6 to 0.7. SC5b9 normalized when checked after 3rd treatment. Subsequently, when the treatment frequency was changed to monthly after 5$^{th}$ treatment, the proteinuria started rising to U P/C of 3-4, necessitating initiation of ACE inhibitor therapy. SC5b9 level increased to pretreatment value when checked again during 10$^{th}$ infusion. The frequency was then changed back to biweekly and the treatment is ongoing. Renal function remains normal but the C3 hypocomplementemia persists. Repeat renal biopsy after 7$^{th}$ treatment showed no interval histopathological changes but with de novo staining for IgG in the same distribution as C3 and C5b9. Patient was fully immunized including meningococcal vaccine prior to the treatment. No serious adverse effects have been observed so far. To the best of our knowledge, this is the first youngest pediatric patient to receive eculizumab for DDD. It is yet to be seen whether eculizumab continues to be effective in this patient.

**Conclusions:** We conclude that biweekly eculizumab effectively inhibits the terminal complement cascade and may be useful in preventing progression of renal disease in DDD, especially in those who have elevated SC5b9 level.

## PUB110

### Typical or Atypical Hemolytic Uremic Syndrome? This Is the Question

Gianluigi Ardissino, Francesca Tel, Stefania Salardi, Sara Testa, Fabio Paglialonga, Nicolò Borsa, Ilaria Possenti, Silvana Tedeschi. *Center for HUS Prevention, Control and Management, Fondaz. IRCCS Ca' Granda Osp Maggiore Policlinico, Milan, Italy.*

**Background:** Hemolytic Uremic Syndrome (HUS) is commonly classified into 2 forms: typical HUS (tHUS) due to an infection by Shiga-toxin (Stx)-producing *E. coli* (STEC) and atypical HUS (aHUS), mainly caused by complement alternative pathway dysregulation. The classification relies upon the evidence or not of STEC infection: isolation of STEC, detection of Stx in stools and/or in blood and serotype specific LPS antibody. However, diarrhea can also represent a trigger for aHUS, leading to difficulties in identifying the most appropriate treatment. Herein, we report a case of HUS associated with bloody diarrhea, in which prompt lab investigations revealed a complement related protein gene mutation which guided the clinical choice of treating the patient with Eculizumab.

**Methods:** A 5-yrs-old girl, while on vacation on the Red Sea, was admitted to the local hospital with macrohematuria, severe bloody diarrhea and fever. Lab showed mild anemia, low PLT count and AKI. An antibiotic treatment was started. Two days later, for worsened clinical conditions, the child was referred to our Center. Bloody stools were negative for Stx *1 and 2*. Due to low C3 level (40 mg/dl) molecular biology for complement related genes was started and on day 6, a novel variant on MCP gene (p.Phe175Val) mutation was identified. The same day Eculizumab (600 mg) was administered with a rapid remission of the thrombotic microangiopathy and recovery of renal function. During the following 8 mos, no relapse occurred, despite the single dose of Eculizumab. The child is well with normal renal function.

**Conclusions:** This case suggests that proofs of STEC infection should be always actively seeked and documented. C3 level should also be determined in any patient with HUS. In diarrhea-associated HUS, if no clear evidence of STEC infection and/or if low C3 are found, aHUS triggered by diarrhea should be suspected and ruled in or out.

## PUB111

### Epidemiology of Hemolytic Uremic Syndrome in Children in Northern Italy

Gianluigi Ardissino, Stefania Salardi, Sara Testa, Silvana Tedeschi, Valentina Paracchini, Francesca Tel, Ilaria Possenti. *Center for HUS Prevention, Control and Management, Fondazione IRCCS Ca' Granda Osp Maggiore Policlinico, Milan, Italy.*

**Background:** HUS is a rare microangiopathy characterized by platelet (PTL) consumption, hemolysis and renal damage. The most frequent type of HUS in children is associated with shigatoxin (Stx)-producing E. coli infection (STEC-HUS), but other atypical forms (aHUS) are occasionally seen, including those related to complement dysregulation. Despite the severity of the disease and the fact that it represents a leading cause of AKI in children, the general epidemiology of HUS is all but well documented.The aim of the study is providing reliable, population-based epidemiological.

**Methods:** Between 2001 and 2011, all incident cases with a first episode of HUS <18 yrs who present these conditions, were included: 1.PLT <150,000/mm$^3$ or evidence of PLT consumption; 2.Evidence of hemolysis; 3.Signs of renal damage. Overall and age-related crude incidence rates per 100,000 people were calculated from 2001 to 2011 using the population estimates issued by the Italian Institute of Statistics (ISTAT). The population at risk was defined as Lombardy residents aged ≤18 years.

**Results:** Ninety-eight HUS cases were identified during the 10 yrs; the overall annual incidence was 0.55/100,000 children ≤18 years of age (range 0.44-0.66). The incidence in patients aged <5 yrs was 1.2 cases per 100,000. aHUS accounted for 11.2% of the cases (incidence:0.069/100.000); among the 11 aHUS patients, 4 (36.4%) were caused by complement gene dysregulation (2 CFH, 1 MCP, 1 CFI), 3 (27.2%) were associated with methyl-malonic acidemia, 2 (18.2%) were associated with pneumonia, and 2 (18.2%) were of unknown origin. The overall case fatality rate was 4.1% (3.4% in STEC-HUS).

**Conclusions:** Our findings provide epidemiological data useful to healthcare planning in the area of HUS, particularly in relation to estimating the financial burden that health care providers might have to face for treating atypical HUS.

## PUB112

### Pediatric Nephrotic Syndrome Practice Guidelines: Adoption and Outcomes

Debbie S. Gipson,[1] J. Troost,[2] Emily G. Herreshoff,[2] Courtney L. Harkness,[2] Susan F. Massengill,[2] Rasheed A. Gbadegesin,[2] Larry A. Greenbaum,[2] Ibrahim Shatat,[2] Yi Cai,[2] Gaurav Kapur,[2] Diane Hebert,[2] Michael J. Somers,[2] Howard Trachtman,[2] Priya J. Pais,[2] Michael E. Seifert,[2] David T. Selewski,[2] Jens W. Goebel,[2] John D. Mahan,[2] Heather E. Gross,[2] Darren Dewalt.[2] *[1]Univ of Michigan; [2]PROMIS Pediatric Study Network.*

**Background:** North American Clinical Practice Guidelines were published (2009) for childhood onset nephrotic syndrome (CONS). Based on systematic review, we expect 40% of incident patients to develop frequently relapsing/steroid dependent (FRNS/SDNS) and 25% steroid resistant (SRNS) disease. The objective of this study was to evaluate guideline adoption and outcomes.

**Methods:** 126 children with CONS, age 8 to 17 years, enrolled in the PROMIS II prospective longitudinal cohort from 14 institutions between 9/2010 - 3/2013, were included. Nephrologists were asked if they intended to follow the published guidelines and when the answer was 'no', the reason for alternate therapies was captured.

**Results:** In 103(82%) cases physicians reported the intent to follow guidelines, increasing from 73% in the initial 6 months to 100% at months 24-30(p=0.02). 23(18%) declined guideline recommendations secondary to provider preference (N=16), patient contraindications (N=3), secondary NS (N=2) and established resistance to guideline regimen (N=2). Outcomes are shown in Table 1.

**Conclusions:** Adoption of Clinical Practice Guidelines was high (82%) within 3 years from publication. The observed 69% combined FRNS/SDNS and SRNS outcomes in the setting of high guideline adoption rates, suggests focus areas for novel therapy development and generates estimates for standard of care outcomes for future trials.

| Patient Characteristics | Incident N=58 | Prevalent N=68 |

## PUB113

**The U.S. Pediatric Nephrology (PN) Workforce 2013** William A. Primack,[1] Kevin E.C. Meyers,[2] Suzanne Kirkwood,[3] Holly S. Ruch-Ross,[4] Carrie Radabaugh,[3] Larry A. Greenbaum.[5] *[1]UNC Kidney Center, Chapel Hill, NC; [2]CHOP, Philadelphia, PA; [3]AAP, Evanston, IL; [4], Chicago, IL; [5]Emory Children's Center, Atlanta, GA.*

**Background:** A shortage of pediatric nephrologists exists, yet the PN workforce is poorly characterized.

**Methods:** The AAP is conducting workforce surveys of all pediatric subspecialists (PSS). The first 44 questions are asked of all PSS to allow comparisons. Then 44 PN specific questions were created with help of the ASPN. The survey was sent electronically to all physicians who are either working as pediatric nephrologists or were ever US board eligible in PN.

**Results:** 500 responses (response rate 65.8%): 51% male. 68% US graduates. 396 are ABP Certified in PN. 409 practice PN full or part time. They spend 57% of their time in direct patient care, 14% administration, 12% clinical research, 11% teaching, 9% basic research. Mean work week is 54.5 ± 15.7 hrs (n=470). Respondents (n=405) spend 84% of their time in all aspects of PN with the rest of their time spent in non-nephrology administration, general peds, and in adult neph. 131 plan to decrease clinical work in the next 5 yrs due to 1 or more of the following: 59 are dissatisfied with work-life balance; 70 plan to retire; 13 for family reasons; 49 to increase nonclinical activities. 65% would probably or definitely choose PN as a career if they could do it over again, but 22% would not and 14% were unsure (n=455). 49% think that there should be a 2 year clinical as well as a 3 year academic track for fellowship, 34% did not and 17% were unsure (n=452). PN Division chiefs (n=110) and solo PN's (n=28) report that 52% have adequate PN staff, 47% inadequate. In the next 3 years, 92% anticipate recruiting for newly created PN positions, as well as 77% and 71% to replace retirees and departing PN's respectively.

**Conclusions:** 409 PN's spend 57% of their time in patient care, but 32% plan to decrease clinical work in next 5 yrs. Also 20% of trained PN's do not practice PN. An ongoing shortage of pediatric nephrologists is likely given the high numbers who will need to be replaced over the next 5 years. The PN workforce requires continuing needs assessment monitoring.

## PUB114

**Fighting Bloody Diarrhea for Shigatoxin-Associated Hemolytic Uremic Syndrome. Prevention and Mitigation: North Italian HUS Network** Gianluigi Ardissino, Francesca Tel, Sara Testa, Stefania Salardi, Rosaria Colombo, Ilaria Possenti. *Center for HUS Prevention, Control and Management, Fondazione IRCCS Ca' Granda Osp. Maggiore Policlinico, Milan, Italy.*

**Background:** Shigatoxin-associated Hemolytic Uremic Sindrome (STEC-HUS) still represents a major public health problem caused by an infection often presenting with bloody diarrhea.

**Methods:** Since May 2010 a Network connecting pediatric hospitals in Northern Italy (10 millions gp) was developed aimed at screening bloody diarrhea in children for Shigatoxin. Among the objectives of the Network is the early diagnosis of STEC-HUS thus reducing the time of referral to our Center and allowing the implementation of interventions measures to prevent or mitigate the renal complication. The present study compares the clinical characteristics at diagnosis of an equal number of STEC-HUS cases referred to our Center in the past (2007-2009) and during the last 2 years (2012-2013) in order to analyze the efficacy of the Network.

**Results:** Since Jan. 2012, 22 cases of STEC-HUS have been referred to our Center and these were compared to 22 historical cases (sequentially referred during 2007-2009). No significant difference was observed in gender and age distribution as well as in mean haemoglobin, LDH and platelet levels at onset while mean serum creatinine was significantly higher in the historical group (3.6 mg/dL with CI 1.8-5.4 vs 1.7 mg/dL with CI 1.1-2.4; $p < 0.05$).

**Conclusions:** The screening of bloody diarrhea, together with the increased awareness among pediatricians towards STEC-HUS, led to a remarkable advance in the diagnosis of the renal complication which can be estimated, based on creatinine, in as much as 24-48h. The anticipation in the diagnosis is the prerequisite for testing early intervention measures for mitigating the severity of STEC-HUS.

## PUB115

**Coinfection in Children with Bloody Diarrhea Caused by Shigatoxin Producing *Escherichia coli*** Gianluigi Ardissino, Ilaria Possenti, Stefania Salardi, Rosaria Colombo, Francesca Tel, Sara Testa, Erminio Torresani. *Center for HUS Prevention, Control and Management, Fondazione IRCCS Ca' Granda Osp. Maggiore Policlinico, Milan, Italy.*

**Background:** Hemolytic Uremic Syndrome (HUS) is characterized by the triad of microangiopathic hemolytic anemia, platelet consumption and renal damage. Bloody diarrhoea, caused by Shiga-toxin producing *Escherichia coli* (STEC), is the most frequent prodromic sign of HUS (at least 57% of cases). Although rarely, other microorganisms have been reported as cause of HUS in children but their responsibility in the thrombotic microangiopathy is not clearly defined.

**Methods:** Since May 2010 a Network connecting pediatric hospitals in Northern Italy (10 millions gp) was developed aimed at early diagnosis of STEC-HUS. 930 children with bloody diarrhoea were screened and the rate of bacterial coinfection was analyzed.

**Results:** In Shigatoxin positive patients (n:52) the rate of coinfection (with either Salmonella or Campylobacter) was as high as 34.6% while coinfection between Salmonella and Campylobacter was as low as 0.5%.

**Conclusions:** It is speculated that infection by Salmonella or Campylobacter increase the risk of STEC infectionor viceversa. Based on our finding, the isolation of microrganisms other than STEC in HUS cases is expected to be unrare and it should not be necessarily regarded to as the etiological agent. In conclusion, in all HUS case it is of paramount importance to perform the full panel of available diagnostic tools for STEC (shigatoxin in stools and blood and serum antiLPS) to clearly define the etiological agent.

*Funding:* Private Foundation Support

## PUB116

**The Effects of Hydroxyurea (HU) or Chronic Blood Transfusion (CTx) on Sickle Cell Nephropathy (SCN) in Children** Valeriya M. Feygina,[1] Kathy Rey,[2] Miho Hatano,[2] Bandana Paudyal,[1] Anil K. Mongia,[1] Morris J. Schoeneman,[1] Vaishali Bansilal,[1] Scott Miller,[2] Hanan K. Tawadrous.[1] *[1]Pediatric Nephrology, SUNY Downstate Medical Center, Brooklyn, NY; [2]Pediatric Hematology/ Oncology, SUNY Downstate Medical Center, Brooklyn, NY.*

**Background:** Renal complications of sickle cell anemia (HbSS) include: a concentrating and acidification defect, hyperfiltration, proteinuria, renal scarring. No treatment is proven to slow progression of SCN. **Hypothesis:** HU or/and CTx may slow SCN progression in children with HbSS.

**Methods:** Data collected: age, sex, Hb, HbF, MCV, eGFR, fractional excretion of sodium (FeNa), transtubular potassium gradient (TTKG), fractional reabsorbtion of phosphorus. Osmolality and microalbuminuria/proteinuria were measured in a first morning urine after at least 6 hours of fasting. Student's t-test was used to compare parameters.

**Results:** 26 patients (50 % female) with HbSS were enrolled. 9 patients on CTx for primary and secondary stroke prevention and 17 on HU for acute recurrent vaso-occlusive complications. Treatment duration 56.1±45.9 and 26.7±10.7 months, patients age 13.5±9.1 and 10.8±3.8 yrs in CTx and HU group, respectively. HU dose: 24.7±1.9 mg/kg/24hr. Comparison of HU and CTx groups.

| | HU | CTx | P value |
|---|---|---|---|
| HbF (g/dL) | 13.5 +5.8 | 4.5+3.9 | 0.0005 |
| Retic (%) | 9.6+4.0 | 8.4+0.02 | 0.02 |
| MCV (fL) | 103.5+14.5 | 91.8+7.2 | 0.02 |
| Urine osmolality (mOsm/kg) | 433.9+110.7 | 479.6+92.3 | 0.15 |
| FeNa (%) | 0.32+0.2 | 0.38+0.3 | 0.25 |
| Reabsorb of phosphorus (%) | 95.3+2.9 | 95.7+1.5 | 0.34 |
| TTKG (%) | 4.05+2.9 | 3.10+1.6 | 0.27 |
| Microalb /cr (mg/mg) | 70.3 +125.1 | 83.3+101.5 | 0.43 |
| Protein/cr (mg/mg) | 0.2+0.4 | 0.19+0.1 | 0.47 |
| eGFR (ml/min/1.73m2) | 150.2+31.7 | 172.0+37.8 | 0.06 |

There was no significant difference in renal function between the groups but a trend toward less hyperfiltration in the HU group. 18.75 % and 20.8 % of patients have microalbuminuria and proteinuria, respectively, prevalences similar to that reported in untreated children.

**Conclusions:** Renal function is similar in children with HbSS receiving either HU or CTx, and both groups have a high prevalence of SCN.

## PUB117

**Functional Magnetic Resonance Imaging on Pediatric Renal Disease Patients** Nobuaki Takagi, Takayuki Shibano, Kohei Maekawa, Hiromu Mae, Masuji Hattori, Takakuni Tanizawa. *Dept of Pediatrics, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

**Background:** We have been evaluated renal disease children by estimated glomerular filtration rate (eGFR) or by invasive renal biopsy, which sometimes require general anesthesia. But in adult patients, Inoue et al. reported (JASN, 2011) that they evaluated renal hypoxia and fibrosis using functional Magnetic Resonance Imaging (MRI). It is known that apparent diffusion coefficient (ADC) by Diffusion-weighted (DW)-MRI reflects fibrillation and T2* by blood oxygen level-dependent (BOLD)-MRI reflects renal tissue hypoxia. It is reported that chronic kidney disease (CKD) stage5 patients' renal MRI showed low ADC and T2* compared to normal kidneys. Therefore, we now test the possibility of functional MRI on pediatric renal disease patients. For this purpose, we compared the ADC and T2* value of normal and renal disease children.

**Methods:** We tested DW- and BOLD-MRI to 10 normal children, whose urinary test was normal and had no history of renal disease (median age 12.5 y.o.), and 18 children who underwent renal biopsy 2days before MRI because of abnormal urinary test (median age 13.0 y.o., 8 IgAN, 5 TBMD, 2 nephrotic syndrome, 3 others). All patients were not CKD.

**Results:** ADC value of renal cortex was 1729.9±114.8m2/sec (normal control) vs. 1765.8±96.4m2/sec (patients, $p>0.05$), and T2* value of renal cortex was 175.9±19.7msec (normal control) vs. 190.1±24.3msec (patients, $p>0.05$). ADC value of renal medulla was 1800.3±121.5m2/sec (normal control) vs. 1750.1±105.0m2/sec (patients, $p>0.05$), and T2* value of renal medulla was 165.3±20.1msec (normal control) vs. 176.5±20.4msec (patients, $p>0.05$).

**Conclusions:** These results reveal that children with normal renal function and abnormal urinary test (proteinuria and/or hematuria) show normal functional MRI. That may because the patients had no or little renal fibrosis or tissue hypoxia. We may distinguish CKD and non-CKD patients by functional MRI in children as well as in adults. Also, we may expect renal fibrosis and ischemic change by these non-invasive functional MRI, if we could show the usefulness in children.

## PUB118

### Development of Oxabact® for the Treatment of Primary Hyperoxaluria

Elisabeth Lindner. *OxThera AB, Stockholm, Sweden.*

**Background:** Primary Hyperoxaluria (PH) is a rare inborn error of the glyoxylate metabolism characterised by severe hyperoxaluria (Uox >0.8 mmol/day/1.73m$^2$) with clinical presentation of nephrocalcinosis with or without recurrent calcium-oxalate urolithiasis and deteriorating renal function leading to ESRD.

**Methods:** Oxabact® therapy consists of lyophilised *Oxalobacter formigenes* in an enteric-coated capsule for oral administration. *O. formigenes* is an anaerobic bacterium which only utilizes oxalate as its substrate and is naturally suited to degrade oxalate in the human GI tract. Based on extensive animal and clinical data it is hypothesised that Oxabact® treatment can remove endogenously produced oxalate in patients with PH by enteric elimination, thereby lowering the disease´s detrimental effect on kidneys.

**Results:** The Oxabact® treatment has been evaluated in a series of clinical studies in PH patients. Although earlier Phase I/II studies showed a significant reduction of urinary and plasma oxalate these results were not reproduced in larger multi-centric double blind placebo controlled trials. The outcome of the these studies was found to be related to significantly reduced biological potency of freeze dried bacteria used in said studies. Extensive research and improvement in the manufacturing process for Oxabact® was done in the last two years to produce the final formulation (OC5) which has a hundred fold improvement in its potency (increased concentration of live cells, faster regeneration from freeze dried state and higher oxalate degradation activity) as compared to the product used in unsuccessful studies.

**Conclusions:** OC5 has been tested for safety and efficacy in animal models and is currently being tested in a pivotal randomised, placebo-controlled, double-blind, multi-centre study in patients with PH type 1. Following screening and baseline evaluations eligible subjects have been randomised 1:1 to receive OC5 or placebo for a period of eight weeks. The study end points will evaluate reduction of oxalate in 24h urine and plasma; quantification of *O.formigenes* in the feces and the safety and tolerability of treatment. Successful outcome of this trial is expected to provide a significant unmet medical intervention for PH patients.

## PUB119

### Possible Pathogenic Roles of Granzyme B in Peripheral Blood Mononuclear Cells in Pediatric Patients with Idiopathic Nephrotic Syndrome

Yuko Akioka, Tatsuo Asano, Kei Nishiyama, Noriko Sugawara, Kiyonobu Ishizuka, Masataka Hisano, Hiroko Chikamoto, Motoshi Hattori. *Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

**Background:** Granzyme B (GrB) is a serine protease released from cytotoxic lymphocytes. Recently, increased research has focused on extracellular GrB activity which contributes to be a loss of structural integrity through the cleavage of extracellular matrix in a number of chronic inflammatory conditions. Several clinical studies showed a correlation between GrB expression and disease severity. The purpose of this study was to examine the possible pathogenic roles of GrB in idiopathic nephrotic syndrome (NS).

**Methods:** We examined 41 patients with steroid sensitive nephrotic syndrome (SSNS) and 10 patients with steroid resistant NS (SRNS). Sex- and age-matched 11 healthy subjects were also included. Peripheral blood mononuclear cells were isolated and polychromic flow cytometric analysis was performed to evaluate the expression of GrB in CD3, CD4, CD8, CD19, CD56 cells. Plasma GrB level was determined with ELISA.

**Results:** In both SRNS and SSNS patients in relapse, the percentages of GrB-positive CD3 cells were significantly higher than those in healthy controls (11.6±9.0%, 15.6±10.2% vs. 5.1±3.1%, P<0.01, P<0.05, respectively). There were no differences in the percentages of GrB-positive cells in CD19 and CD56 cells between NS patients and controls. GrB expression in CD3 cells decreased accompanied with the remission in SSNS patients. The plasma levels of GrB in both SRNS and SSNS patients in relapse were not different from those in controls. The positive correlation between GrB-positive CD3 cells and selectivity index of urine was observed in NS patients (r=0.556, p=0.041).

**Conclusions:** Although further studies including measurement of urinary levels of GrB are clearly needed, our preliminary results suggest possible pathogenic roles of granzyme B in CD3 cells in pediatric patients with idiopathic NS.

## PUB120

### Do Immunosuppressed Renal Patients with Fever Need Routine Hospitalization?

Mauricio Romero Olvera, Rossana Baracco, Amrish Jain, Gaurav Kapur, Tej K. Mattoo. *Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI.*

**Background:** Immunosuppressed patients with high fever are often hospitalized until cultures are negative and temperature settles down. The objective of this study was to assess the need for such practice in our renal patients on immunosuppression.

**Methods:** This retrospective study included children 2 to 18 years old who were on immunosuppressive medications for nephrotic syndrome (NS), systemic lupus erythematosus (SLE) and renal transplantation (RT), admitted to Children's Hospital of Michigan from 2009 – 2012 for fever >38.3ºC. Patients with diabetes, cardio-respiratory disease or lupus flares were excluded. Patients were considered as having a significant clinical presentation (SCP) if emergency department evaluation revealed low blood pressure, tachycardia, abnormal cardiac or chest auscultation, abdominal tenderness, and abnormal test results. Those with normal examination except for high fever were considered as having insignificant clinical presentation (ICP).

**Results:** The study included 60 patients with 103 admissions. Mean age was 9.28 (SD+/- 4.66) years; 59.2% were males. Of the103 admissions, 52 were in patients with NS, 32 had RT, and 19 had SLE. Twenty four admissions had SCP(23.3%), which included 4 to PICU; 79 (76.6%) admissions had ICP.

| Table1 | SCP N = 24 | ICP N = 79 | Total |
|---|---|---|---|
| Bacterial infections N (%) | 20 (83.3) | 9 (11.4) | 29 (28.15) |
| Viral infections N (%) | 4(16.7) | 70 (88.6) | 74 (71.84) |
| Tmax mean (SD) | 102.1 (0.9) | 102.0 (1.1) | 102.04(1.02) |
| White blood cell count mean (SD) | 12.4 (6.9) | 11.3 (5.7) | 12.23(6.11) |

Of the 20 patients with bacterial infections/SCP, 8 had pneumonia, 5 had abscesses/cellulitis, 4 had UTIs(1 had E.coli bacteremia), and 1 had bacterial peritonitis, 1 C. difficile infection, and 1 sepsis episode due to S. pneumoniae. Of the 9 patients with bacterial infections/ICP, 5 had strep pharyngitis, and 2 had otitis media and 2 UTI.

**Conclusions:** Immunosuppressed renal patients with high fever and insignificant clinical findings do not need routine hospitalization; they could be sent home with appropriate counseling/follow-up after culture specimens are collected.

## PUB121

### Renal Involvement in Children with Sickle Cell Disease, Sickle Cell Trait, and Sickle Beta Thalassemia in Southern Iran

Mohammad Hossein Fallahzadeh,[1] Yusof Mojtahedi,[1] Mohammad Kazem Fallahzadeh,[1,2] Mohammad Amin Fallahzadeh,[1] Mitra Basiratnia,[1] Ghamar Hosseini Al-hashemi.[1] *[1]Dept of Pediatric Nephrology, Shiraz Univ of Medical Sciences, Shiraz, Islamic Republic of Iran; [2]Dept of Nephrology, LSUHSC, Shreveport, LA.*

**Background:** Different types of renal involvement have been reported in children with sickle disease, sickle cell trait and sickle beta thalassemia. There is not enough information about the renal manifestations of these diseases in Iranian children. The aim of our study was to evaluate the manifestations of renal involvement in children with sickle disease, sickle cell trait and sickle beta thalassemia.

**Methods:** Over a period of 1 year (2011-2012), 97 consecutive children (30 with sickle cell disease, 31 with sickle trait and 36 with sickle beta thalassemia) who were referred to us by pediatric hematologists were enrolled in this cross-sectional study. These children were evaluated by history, physical examination and laboratory workups including renal function panel, urinalysis and albumin/creatinine measurement in spot urine.

**Results:** Mean age of the enrolled patients was 8.8 ± 3.4 years (range: 3-18 years). The prevalence of their renal manifestations is listed in the following table:

| Clinical findings | Sickle cell disease (n=30) | Sickle cell trait (n=31) | Sickle beta thalassemia (n=36) |
|---|---|---|---|
| Enuresis | 8 (27%) | 7 (23%) | 5 (14%) |
| Microalbuminuria (albumin/creatinine ratio: 30-300 mg/g) | 4 (13%) | 5 (16%) | 5 (14%) |
| Macroalbuminuria (albumin/creatinine ratio: >300 mg/g) | 0 | 0 | 0 |
| Hypertension | 2 (7%) | 4 (13%) | 1 (3%) |
| Hematuria | 1 (3%) | 0 | 0 |
| Chronic kidney disease (defined as GFR<60 ml/min/1.73m$^2$) | 1 (3%) | 0 | 2 (6%) |

**Conclusions:** In contrast to previous reports, hematuria and macroalbuminuria were rare in our patients with sickle cell disease and its variants while enuresis, microalbuminuria and hypertension were more common.

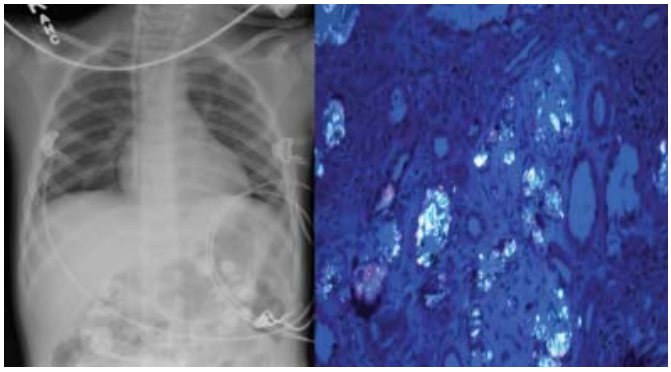
## PUB122

### Primary Hyperoxalosis Presenting with Anemia, Thrombocytopenia and Acute Renal Failure

Luis A. Ortiz. *Pediatric Nephrology - Pediatrics, Children's Hospital of Georgia, Augusta, GA.*

**Background:** Primary Hyperoxaluria (PH) is an AR inborn error of metabolism resulting in high oxalate production and excessive urine oxalate excretion, it is a deficiency in the liver peroxisomal enzyme alanine-glyoxylate aminotransferase that catalyzes the transamination of glyoxylate to glycine. Failure to detoxify glyoxylate results in its conversion into oxalate then the endogenous production and urinary oxalate and glycolate are elevated. It is 1% of pediatric ESRD.

**Methods:** Evaluation of a 5 y/o healthy w/g, she presented fatigue, abdominal pain and vomiting. Labs work-up showed Hgb 6.7, platelets 133; K 4.2, HCO3 14, BUN: 210mg, Cr 11.67mg**.** She was drinking one gallon of milk/day for the last 3 years. Her physical Exam was unremarkable with BP: 93/55 and UOP 2.3ml/kg/hr. CxR: bilateral nephrocalcinosis, DsDNAab, pANCA, cANCA were negative; Stool for E. coli 0157 H7 were negative; urine oxalate 335 [<129], glycoxylate (10.2 [<4]), Urine oxalate-creatinine ratio of 25.7 and serum oxalate level was 123.1 (<1.8). Renal biopsy on day # 3: abundant deposit of oxalate crystals compatible with Primary hyperoxaluria.



Serum Alanine: Glyoxylate Aminotransferase (AGXT) mutation full gene analysis was (+). Bone marrow biopsy, bone serial x-rays, eye exam were negative. Treatment with Low oxalate diet, PO fluid intake of 2 L/m2 day, pyrodixine (B6) 5mg/kg and daily hemodialysis (3-4 hours/day) avoided extra renal damage, but renal function was not recovered.

**Conclusions:** Clinical presentation in PH was very atypical. Nephrocalcinosis was a significant finding for the diagnosis. Early kidney Bx was the best procedure for final diagnosis (<36 hours). There was a delayed in the crystal precipitation in other tissues/organs because of the high amount of Calcium she was drinking with the milk. Aggressive dialysis with low oxalate diet was the best procedure to avoid oxalate crystal precipitation.

## PUB123

**Why Pediatricians Fail to Diagnose Hypertension: A Multicenter Survey**
Arend Bokenkamp,[1] Merijn Bijlsma,[2] Hester Blufpand,[2] Gert-jan Kaspers.[3] *[1]Pediatric Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Pediatrics, VU Univ Medical Center, Amsterdam, Netherlands; [3]Pediatric Oncology, VU Univ Medical Center, Amsterdam, Netherlands.*

**Background:** It has become clear that adult hypertension begins in childhood and contributes to the development of cardiovascular disease. Early recognition and intervention may slow down the progression of elevated blood pressure (BP) to cardiovascular disease. Recent studies indicate that the majority of hypertensive cases are unrecognized. The purpose of this study was to elucidate why pediatricians fail to diagnose childhood hypertension, with special emphasis to the use of reference data. We hypothesized that pediatricians frequently omit to measure BP and do not routinely relate BP measurements to reference data.

**Methods:** Multicenter questionnaire survey among 197 pediatricians, pediatric residents and medical students in the Netherlands about their daily practice of BP measurement and the use of pediatric BP reference tables. Furthermore, respondents were asked to estimate BP percentiles and classify BP readings in 12 short clinical cases (6 normal BP, 2 pre-hypertension, 4 hypertension).

**Results:** 71% of physicians only measure BP during ambulatory visits if a child has risk factors for hypertension. After measuring BP, 65% compares the reading to reference data only if they suspect it to be elevated. However, their ability to rate a reading at its true value was limited. Forty-seven percent of the physicians categorized one or more of the prehypertensive or hypertensive cases as normal.

**Conclusions:** Most pediatricians only measure BP in certain circumstances, contrary to recommendations. After obtaining a BP measurement, the majority does not compare the reading to reference standards. Without the use of reference data, however, they commonly underestimate the BP percentile and potentially miss childhood hypertension. The introduction of automated blood pressure monitors that directly report blood pressure percentiles might improve the recognition of childhood hypertension.

## PUB124

**Genetic Control of Renin Angiotensin System and Extracellular Matrix-Related Protein Polymorphismsin Obese Preschool Children**
Kee Hwan Yoo, Hyung Eun Yim, In Sun Bae, Young Sook Hong, Joo Won Lee. *Pediatrics, Korea Univ Medical Center, Seoul, Korea.*

**Background:** We have recently shown that postnatal overnutrition in male rats leads to obesity and the acquired reset of the intra-renal renin angiotensin system (RAS) and of extracellular matrix (ECM)-linked moleculesduring renal maturation. Long-standing obesity, renal functional and structural impairment, and hypertension were programmed later in adulthood. This study was designed to investigate whether genetic polymorphisms of RAS and ECM-linked proteins were associated with the susceptibility to obesity in childhood.

**Methods:** We performed the genotyping of angiotensin converting enzyme (ACE), angiotensinogen (AGT), angiotensin type 2 receptor (AT2), matrix metalloproteinase (MMP)-9, and plasminogen activator inhibitor (PAI)-1 proteins in 46 obese, 48 overweight, and 96 control children using PCR-restriction fragment length polymorphism analysis.

**Results:** The mean age was 22.3 ± 1.5 months in controls, 17.3 ± 2.19 months in overweight children, and 24.2 ± 2.96 months in obese children. No differences among the groups were found with respect to age, sex, gestational age, birth weight, blood pressure levels, and serum levels of glucose and cholesterol. Obese children showed a lower incidence of ACE II genotype, compared to the controls (Control 46.8% Vs. Obese 15.6%, $P < 0.05$). Overweight children had a higher incidence of MM genotype in the AGT M235T polymorphism (Control 2.1% Vs. Overweight 16.7%, $P < 0.05$). In overweight children, the MMP-9 C1562T polymorphism revealed an increase in CC genotype (Control 66.3% Vs. Overweight 90.7%, $P < 0.05$) and a decrease in CT genotype (Control, 30.5% Vs. Overweight 9.3%, $P < 0.05$). In the case of combination of overweight and obese children, a higher incidence of MM genotype in the AGT M235T polymorphism was found compared to the controls (Control 2.1% Vs. Overweight + Obese 10.6%, $P < 0.05$). There were no genotype differences of the AT2 C3123A and the PAI-1 4G/5G polymorphism among the groups.

**Conclusions:** The ACE I/D, AGT M235T, and MMP-9 C1562Tpolymorphisms could be suitable genetic markers for development of overweight or obesity of childhood.

## PUB125

**Eculizumab (Anti C5 Monoclonal Antibody) in a Child with Therapy Resistant Systemic Lupus Erythematodes**
Rosanna Coppo,[1] Alessandro Amore,[1] Licia Peruzzi,[1] Roberta Camilla,[1] Maria Elena Donadio,[1] Giuliana Guido,[1] Luca Vergano,[1] Silvana Martino,[2] Pier angelo Tovo.[2] *[1]Nephrology Dialysis Transplanation, Regina Margherita Hospital, Turin, Italy; [2]Pediatrics, Univ of Turin.*

**Methods:** A 4 y.o girl presented with extremely severe systemic lupus erythematodes (SLE) (SLEDAI score: 42; C4<4 mg/dl, C3 <20 mg/dl, ANA>1/640; anti DNA>400 UI/ml),lupus nephritis Class IV-G, e-GFR120ml/min/1.73m2, UP/UCr5mg/mg). The symptoms slightly improved after 3 MP pulses, prednisone, 9 plasmapheresis, cyclophosphamyde (withdrawn due to leukopenia) followed by cyclosporine. Three months later she worsened: e-GFR 60ml/min/1.73m2, UP/UCr 6 mg/mg. In spite of Rituximbab 1g/1.73m2 and MP pulse, SLEDAI increased to 63 (hypertension, seizures, numbness, O2 desaturation, pleural effusion). Platelets (Ptls) 55,000/mm3, aptoglobin <10 mg/dl, neg LAC, e-GFR 60ml/min/1.73 m2, UP/UCr 7mg/mg. After eculizumab 20 mg/Kg, she had impressive improvement in general conditions with normalization of Ptls, aptoglobin and e-GFR increase to 140 ml/min/1.73m2. Eculizumab was repeated over 2 months, then stopped. Rituximab was infused but immediately stopped for severe adverse reaction. A new attempt to use cyclophosphamyde was interrupted because of leukocytopenia. 9 plasmaphereses were performed, but renal conditions worsened (e-GFR 50 ml/min/1.73m2, UP/UCr 8) with a new drop in Ptls 70,000/mm3, aptoglobin <10 mg/dl (LAC neg). A repeated renal biopsy confirmed Class IV nephritis without any sign of thrombotic microangiopaty. However, when eculizumab was re-introduced (20 mg/Kg) a prompt improvement was observed with normalization of aptoglobin level, Ptls count and e-GFR. The child was followed for 4 months on maintenance treatment with cyclosporin, prednisone and eculizumab every other week. SLE data remained unchanged over the follow-up (C4 < 4 mg/dl, C3 30 mg/dl , ANA 1/640, Anti DNA >400 UI/ml), however e-GFR is 138 ml/min/1.73 m2, UP/Ucr 1 and SLEDAI score is reduced to 14 with good general conditions. Complement genetics and ADAMST are negative.

**Conclusions:** This is the first case reporting a beneficial effect of C5 inhibition as rescue therapy in a SLE refractory to the standard therapies.

## PUB126

**Hydrothorax, a Serious Complication of Infants on Peritoneal Dialysis – Can We Identify Risk Factors**
Michaela Gessner, Christina Taylan, Gesa Schalk, Rasmus J.C. Ehren, Lutz Thorsten Weber. *Dept of Child and Adolescent Medicine, Univ Hospital, Cologne, Germany.*

**Background:** Approximately 150 children suffer from end-stage renal disease requiring renal replacement therapy in Germany every year. Due to congenital kidney disease 2/3 of them are still in infancy at initiation of therapy, which is most commonly peritoneal dialysis (PD) in this age group. Besides infections another serious complication of this procedure is the development of a hydrothorax, possibly due to an embryonic remnant of a persisting pneumatoenteric recess or an infracardiac bursa, a passage connecting the peritoneal cavity to the right pleural space.

**Methods:** In this single center analysis all infants that had started PD in their first year of life between 2002 and 2012 were included (n=19). Infants with short-term PD treatment due to acute renal failure were excluded. All infants had a minimal duration of PD of four months. PD catheters were inserted by laparotomy. Median initiation of PD was at the ninth day of life (range: second day to ninth month).

**Results:** 3 of 19 infants were symptomatic with a hydrothorax at a median of 49.5 weeks (range: 33.6-72.1) after start of PD treatment, finally leading to long-term change of treatment modality in 2/3. All affected infants had been born prematurely. However, another 11 premature infants in this group did not show this complication. There was no hydrothorax in 5 term deliveries. Hydrothorax occurred independently from previous abdominal surgeries, the occurrence of catheter obstruction, birth weight, mode of delivery, APGAR score, age at initiation or duration of PD. However, this complication appeared in 3/6 preterm infants of Turkish origin.

**Conclusions:** This analysis failed to determine risk factors for the incident of hydrothorax after initiation of PD treatment in infants. The overall risk in our cohort was 15.9% and 21.4% in preterm infants, respectively, that is higher than reported in literature (3%), which reviews other cohort compositions regarding age of children. Since preventive actions do not exist, physicians must be aware of this serious complication for the purpose of early detection and treatment, especially in preterm infants.

## PUB127

**Reducing Central Venous Catheters in Children on Chronic Hemodialysis**
Rossana Baracco, Tej K. Mattoo, Amrish Jain, Gaurav Kapur, Rudolph P. Valentini. *Pediatrics, Children's Hospital of Michigan/Wayne State Univ, Detroit, MI.*

**Background:** Permanent vascular access is preferred over central venous catheters (CVC) for chronic hemodialysis (HD). However, CVCs remain the most commonly used access in children. The objective of this study was to assess the impact of increased arteriovenous fistula (AVF) use in our HD patients.

**Methods:** Retrospective chart review of children ages 1 to 18 on chronic HD from January 2001 to June 2012 at Children's Hospital of Michigan. Patients were divided into 3 time periods; 2001 to 2005; 2006 to 2009; and 2010 to 1012. A systematic approach to AVF placement was introduced in 2006 and a new, more experienced, vascular surgeon became available in 2010.

**Results:** There were 55 patients (67.3% male) that had an AVF placed. Of 65 AVF created, 41 (63.1%) were successfully used. AVF use rates increased and CVC use rates decreased with time; by the end of the third time period only 7.7% of HD patients were using a CVC. The number of successful AVF were significantly higher in the third time period. Primary patency rate was 42.9% at one year. Secondary patency rates were 96.8% at one year, 88.7% at 2 years and 76% at 5 years. Infection and hospitalization rates were higher for CVC compared to AVF (0.8 vs 0.1 infections per access-year and 1.0 versus 0.3 hospitalizations per access-year, respectively).

| | 2001 - 2005 | 2006 - 2009 | 2010 - 2012 |
|---|---|---|---|
| AVF use rates (%) | 33.3 | 42.9 | 76.9 |
| AVG use rates (%) | 16.7 | 35.7 | 15.4 |
| CVC use rates (%) | 50 | 21.4 | 7.7 |
| AVF N (%) | | | |
| Successful | 10 (52.6)* | 19 (57.6)* | 12 (92.3)* |
| Unsuccessful | 9 (47.4) | 14 (42.4) | 1 (7.7) |
| Demographics of successful AVF | | | |
| Age median in years (range) | 14 (10 - 17) | 15 (12 - 17) | 13.5 (3 - 18) |
| Weight median in kilograms (range) | 42.1 (27 - 82) | 61 (28 - 113.4) | 60.5 (14.7 - 110.7) |
| AVF=arteriovenous fistula, AVG=arteriovenous graft. *p≤0.05 | | | |

**Conclusions:** With a dedicated team committed to permanent vascular access placement, it is possible to decrease the use of CVCs and increase AVF use in children. Increased use of AVF decreases access related infection and hospitalization rates.

## PUB128

**Design of IM103-144: A Pediatric PK/Conversion Study with Belatacept to Assess PK, Safety, Tolerability, and Preliminary Efficacy in EBV-Seropositive Pediatric Renal Transplant Recipients**
Robert B. Ettenger,[1] Allan D. Kirk,[2] Sandra Amaral,[3] Vikas R. Dharnidharka,[4] Daniel Feig,[5] Bishu Ganguly,[6] Charlotte Jones-burton.[6] *[1]UCLA, US; [2]Emory Univ; [3]Children's Hosp Philadelphia; [4]Washington Univ, US; [5]Univ of Alabama, US; [6]BMS, US.*

**Background:** Belatacept(bela) is approved for use in prevention of acute rejection(AR) in adult EBV-seropositive(+) kidney transplant(TX) recipients. In Ph 3 trials, bela was associated with comparable pt & graft survival & superior renal function despite higher rates & grades of early AR vs cyclosporine. The current study, the first study of bela in children, will determine if similar results occur in pediatric kidney TX recipients. Study objectives are to establish dose & evaluate PK, efficacy, & safety in pediatric conversion.

**Methods:** In this global multicenter study, 54 kidney TX recipients, currently on CNI-based immunosuppression (IS), will be studied in 2 groups: adolescents(age 12-17y) & children(6-11y). Pts will be ≥1y post-TX, will have stable eGFR 45–75 ml/min/1.73m$^2$, & be EBV+ both at TX & start of study. Study will be conducted in 3 phases: 1) uncontrolled single dose phase(SD) to determine PK characteristics & appropriate dosing for bela in each age group; 2) multiple dose phase(MD): pts randomized 2:1 to convert from CNI to bela or remain on CNI for 12 months; 3) long term extension phase (LTE). Enrollment will be staggered, with adolescents (N=9) starting SD first; adolescent PK results will inform dosing in this group for MD & also in the younger group for SD (N=6). All pts in SD will continue to receive all maintenance IS (steroids optional). In MD, CNI will be discontinued for pts in the bela arm.

**Results:** PK & safety determinations will be assessed in all pts in SD & MD. Outcomes to be examined during MD & LTE include the evolution of the eGFR by the updated Schwartz formula, AR, graft loss, & safety (including PTLD) in bela & CNI arms. Medication adherence & quality of life will also be explored.

**Conclusions:** This controlled multicenter trial will provide dosing & PK information, as well as initial efficacy & safety information about bela use in stable EBV+ children & adolescents following kidney TX.

## PUB129

**Relationship between Birth Weight and Renal Volume in Children with and without Overweight**
Maria Eugenia V. Bianchi,[1] Gustavo A. Velasco,[1] Daniel Forlino.[2] *[1]Argentinian Northeast Kidney Foundation, Resistencia, Chaco, Argentina; [2]Radiology, Facultad de Medicina Unne, Corrientes, Argentina.*

**Background:** Determination of renal volume by ultrasound (ERV) is considered as an indirect indicator of the number of nephrons. As it know the low number of nephrons can be considered an independent risk factor for the development of hypertension, and taking into account that low birthweight has been associated with a low kidney volumen, we evaluate differences in renal volume in scholar children with and without overweight and its relationship to birthweight.

**Methods:** We performed a cross-sectional observational study with non-probability sampling, in children of school of the Province of Chaco, by his guardian consent. The variables considered were: Nutritional Status by BMI according to WHO tables (overweight and normal-weight), referred Birthweight, VRE and VRE corrected for body surface area (SC), used for them a portable ultrasound. Maximum diameters were recorded Right and Left Kidney in the longitudinal, transverse and anteroposterior axis. The VRE was calculated using the ellipsoid formula and SC was estimated by Du Bois formulation. Diameters and VRE, were associated with birthweight and actual nutritional status.

**Results:** We studied 84 children, after excluding those with morphologically abnormal kidneys and low weight. The mean age was 9.14 ± 2.36 (range 3-13 years), 36 were male (42.8 %), and the average SC was 1.20 ± 0.27 m$^2$, 46 were overweight (54,8%). The combined volume of both kidneys for children with overweight was 174.4 ± 40.9 ml and for those with normal weight was 134.4 ± 39.2 ml (p <0,05). Classified by birthweight (<3300 and ≥ 3300 g) in the normal weight group combined VRE were 148.6 ± 43.6 ml and 120.2 ± 29.0 ml (p <0.05) while in the overweigth group cambined VRE were 165.3 ± 29.6 ml and 180.8 ± 46.8 ml (p= NS).

**Conclusions:** .VRE differences found in the groups according to referred birthweight disappear in actually overweight children. We conclude, that overweigth enhanced the combined VRE masking the difference found in the low birthweigth.

## PUB130

**Disease Burden of Cystinosis**
Larry A. Greenbaum,[1] Ben Cadieux.[2] *[1]Pediatric Nephrology, Emory Univ, Atlanta, GA; [2]Raptor Pharmaceuticals, Novato, CA.*

**Background:** Cystinosis is a rare autosomal recessive disorder with a variety of renal (Fanconi syndrome and CKD) and extrarenal complications. Cysteamine, which reduces lysosomal levels of cystine, is the only specific therapy, and prevents, attenuates or delays disease complications. However, Q6H dosing may limit adherence. The disease burden of cystinosis has been assessed via single center studies and among patients who travel to the NIH. However, these approaches may lead to significant selection bias. We report the long-term trajectory of cystinosis-related and comorbid disease among 9 pediatric Medicaid enrollees.

**Methods:** We examined 12 years (7/1/97 to 6/30/09) of Florida Medicaid claims data and identified 9 newly-diagnosed pts (6 male) with cystinosis (based on ICD-9 270 and initiation of cysteamine at ages 12-43 mos).

**Results:** Duration of claims data was 3.5-12 years. There were 231 diagnostic, procedural or claims-related complications possibly or probably related to cystinosis (22, 9.5%) involved an ED visit). There was an average of 3.4 claims per year (range 1.7 to 5.7/yr). 29 claims were related to CKD (including CKD IV for 2 pts at 13 yr; ESRD in 2 pts at 9 and 11 yrs; hyperparathyroidism in 3 pts). There were 2 pts with obstructive hydrocephalus; 1 with heart failure at 11 yrs. The majority (6/9 pts) had feeding problems; 4 had complications from g-tubes. There were 72 claims related to infections (UTIs x 28 in 7 pts; otitis media x 24 in 6 pts). Developmental issues were common: speech/language difficulties in 2 pts (1 pt with additional conduct disorder); ADHD in 1 pt; mental retardation and epilepsy in 1 pt.

**Conclusions:** Claims data analysis provides a complementary approach for assessing disease burden and long-term complications of cystinosis. We observed substantial cystinosis-related disease burden and unexpected comorbidities, including obstructive hydrocephalus, heart failure, and frequent UTIs. Future analysis will assess disease burden following the recent introduction of q12h dosing cysteamine, which has been found to improve QOL and is expected to improve adherence.

## PUB131

**Adherence to Cysteamine Therapy in Cystinosis**
Larry A. Greenbaum,[1] Ben Cadieux,[2] David Lapidus.[3] *[1]Pediatric Nephrology, Emory Univ, Atlanta, GA; [2]Raptor Pharmaceuticals, Novato, CA; [3]LapidusData LLC, Brookline, MA.*

**Background:** Early initiation and adherence to cysteamine therapy are essential in delaying progression to ESRD in cystinosis. Immediate-release cysteamine (IR-C) requires chronic, lifelong Q6H dosing. Objective measures of long-term adherence are challenging to quantify.

**Methods:** We examined IMS data for adherence to IR-C in cystinosis patients. From 2002 to 2012, we identified 221 unique pts (104 male) ages 0 to 51 years with cystinosis (based on ICD-9 270.0 and claims for IR-C). Adherence was assessed by refill data and used to calculate a medication possession ratio (MPR).

**Results:** Twelve, 13, 11 and 9 new pts were diagnosed per year from 2008 to 2011. In a representative year (2011), 207 pts were distributed equally among younger age groups (born post IR-C): 0-10 (N = 75), 11-20 (N = 74); whereas it progressively declined for those born before IR-C approval: 21-30 (N = 52), 31-40 (N = 16), 41-50 (N = 3), 1 pt age 51.

The average duration of reliable IR-cysteamine claims data among all pts (N = 221) was 4.5 years, with an overall MPR of 79%. The MPR declined by age group: 88% (0-5 yrs), 83% (6-11 yrs), 79% (12-17 yrs), and 64% (>17 yrs). The percentage of pts who had a least 1 gap >180 days between IR-C fills increased by age group: 27%, 33%, 35% and 40%, respectively. In pts 0-5 yrs, a diagnosis of failure to thrive (22/34 pts) was associated with a higher MPR (95%) vs. those w/out this diagnosis (83%).

69 of 97 pts (71%) born before the approval of IR-cysteamine reached ESRD; 8 of 93 (9%) and 29 of 93 (31%) pts born from 1994 to 2006 achieved CKD stage IV and ESRD, respectively. The median age for ESRD post approval of IC-cysteamine was 12 yrs (range 1 – 16).

**Conclusions:** Claims data is a novel approach for assessing long-term adherence to cysteamine in patients with cystinosis. Adherence with IR-C according to IMS claims with cystinosis is low and declines with age. Future analysis will correlate adherence with health outcomes, and analyze changes in adherence following the recent introduction of delayed release cysteamine (q12h dosing formulation). Efforts to improve adherence in this population are needed.

## PUB132

**Anhydramnios in Fetal Nephropathy: A Non Conventional Indication to Amnioinfusion. Second Work of Mercy: To Give Drink to the Thirsty**

Gianluigi Ardissino,[1] Roberto Fogliani,[2] Sara Testa,[1] Nicola Persico,[2] Francesca Tel,[1] Simona Boito,[2] Sarah Salmona,[2] Fabietti Isabella,[2] Maria albina Galli.[3] *[1]Pediatric Nephrology, Fondazione IRCCS Ca' Granda Osp Maggiore Policlinico; [2]Obtetrics and Ginecology, Fondazione IRCCS Ca' Granda Osp Maggiore Policlinico; [3]Pediatric Cardiology, Fondazione IRCCS Ca' Granda Osp Maggiore Policlinico.*

**Background:** Oligohydramnios, complicating 4-5.5% of all pregnancies, may occur in some fetal nephropaties. When present in association with fetal kidney diseases, it predicts a more severe postnatal prognosis for it anticipates congenital reduction of renal function. Most of congenital nephropathies are characterized, soon after birth, by significant poliuria and, consequently, by increased needs of fluid which, if unmet, are responsible for worsening of renal function. In case of oligohydramnios the fetus might not count on an adequate amount of drinking fluid possibly leading to fetal dehydration and consequent further reduced renal function.

**Methods:** A pregnant woman who presented with anhydramnios from the 32nd wk of gestation, with severe fetal bilateral hypodisplastic kidney and repeatedly documented empty bladder, was addressed to 2 amnioinfusions (saline total 750cc) for providing the fetus with the fluid normally swallowed during late pregnancy (around 100 cc/kg/day) with the working hypothesis of rehydrating the fetus, improving renal perfusion, preventing further deterioration of renal function and eventually for reversing fetal anuria.

**Results:** Soon after the amnioinfusions a significant increase in the bladder volume (from 18 to 54 mm3) was observed indicating that fetal diuresis had restarted; this was associated with a doubling of both right (from 0.6 to 1.4 mL) and left (from 0.4 to 1.1 mL) cardiac ouput.

**Conclusions:** It is speculated that anhydramnios in fetal nephropathies may be responsible for further reduction of renal function secondary to fetal dehydration and that amnioinfusion may revert this functional worsening.

## PUB133

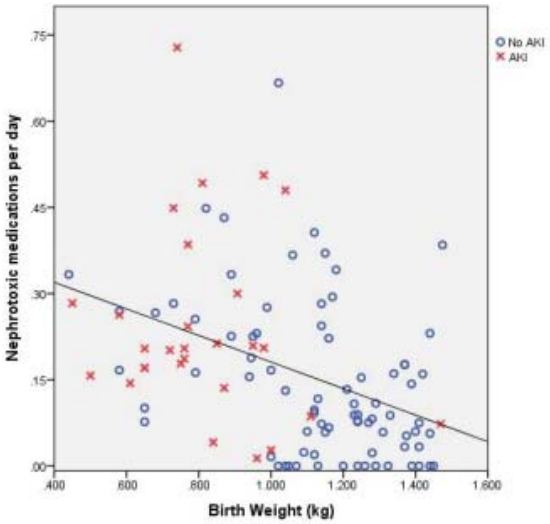
**Nephrotoxic Medication Exposure in Very Low Birth Weight Infants**

Erika Rhone,[1] J. Bryan Carmody,[1] Jonathan R. Swanson,[2] Jennifer Richardson Charlton.[1] *[1]Pediatrics, Div of Pediatric Nephrology, Univ of Virginia, Charlottesville, VA; [2]Pediatrics, Div of Neonatology, Univ of Virginia, Charlottesville, VA.*

**Background:** Nephrogenesis continues until 36 weeks gestation, meaning that many very low birth (VLBW) infants must complete development *ex utero*. While potentially nephrotoxic medications (NM) are commonly used in the neonatal intensive care unit, the extent of exposure among VLBW infants has not been established. We sought to quantify NM exposure among VLBW infants in a Level IIIc NICU.

**Methods:** We retrospectively reviewed the electronic medical record of VLBW infants (n=107) admitted from April 2011 to March 2012, excluding those admitted at >2 d of age or who died during hospitalization. Exposure to the following was calculated in person days: acyclovir, amikacin, amphotericin B, gentamicin, ibuprofen, indomethacin, iohexol, tobramycin, and vancomycin. AKI was assessed using the Kidney Disease: Improving Global Outcomes system, modified to include serum creatinine alone.

**Results:** Exposure to 1 or more NM occurred in 86.9%. The median number of NM was 2 (range 0-6). On average, each infant received 0.17 NM per day when accounting for length of stay. The most common exposures were gentamicin (86%), indomethacin (43%), and vancomycin (25%). Exposure to other NM occurred in <10%. There was an inverse linear relationship between birth weight and mean NM received per day ($\beta$=-0.231, $R^2$=0.169, p<0.001).



AKI occurred in 26.2%. Infants who experienced AKI received higher mean NM per day than those who did not (0.24 versus 0.15;p=0.003).

**Conclusions:** Exposure to NM in VLBW infants was common and occurred in nearly 90% of all NICU survivors. Infants received on average 1 NM per every 6 days spent in the NICU. The greatest nephrotoxic medication exposure occurred in the smallest, most immature infants and in those who experienced AKI.

## PUB134

**A Systematic Approach for the Management of Antenatal Hydronephrosis in Children**

Joana R. Dos Santos,[1] Tino D. Piscione,[1] Rulan S. Parekh,[1] Norman D. Rosenblum.[1] *[1]Nephrology, The Hospital for Sick Children, Toronto, Canada; [2]Urology, The Hospital for Sick Children, Toronto, Canada.*

**Background:** Hydronephrosis in children may require surgery to prevent deterioration in renal function; however, it is unclear which grading system will best predict outcomes. Our goal was to evaluate the accuracy of the Society for Fetal Urology (SFU) grading system compared to measurement of anteroposterior diameter of renal pelvis (APPD) at predicting need for surgery.

**Methods:** The study was a retrospective chart review of patients referred for antenatal hydronephrosis to Nephrology and/or Urology clinics between 2003-10 who had a first postnatal ultrasound < 3 months and at least minimum 1 year of follow-up.

**Results:** 1191 patients were screened; 526 met the inclusion criteria. In a subset of patients analyzed to date (N=416), 79.8% were male, 249 patients had unilateral, and 167 bilateral hydronephrosis. 115 patients underwent surgery (27.6%; mean age 454 ± 643 days; median 244; range 1-3764). APPD measurement at baseline demonstrated positive predictive value (PPV) for surgery of 50.8% (sensitivity 55.2%; specificity 79.7%) and SFU grading demonstrated a PPV for surgery of 54% (sensitivity 81.5% and specificity 73.7%). Logistic regression showed no statistical significance between APPD and SFU grading for predicting surgery at baseline (APPD: OR 2.72, CI 95% 2.06-3.06, p value 3; SFU: OR 3.1,CI 95% 2.5-3.8, p value 1.3). Combined APPD and SFU grading (Group 1: APPD <12 mm + SFU 0-2; Group 2: APPD< 12 mm + SFU 3-4; Group 3: APPD ≥ 12mm + SFU 0-2; and Group 4: APPD≥12mm+ SFU 3-4) showed higher PPV of 60% (sensitivity 34.2% and specificity 91.3%) but did not improve accuracy for predicting surgery when compared to SFU and APPD alone (OR 3.9, CI 95% 2.5-6.1, p value 1.9).

**Conclusions:** These data suggest that neither APPD or SFU grading alone, nor a grading system which combines both methods are good predictors for surgery at baseline. Our future analyses are aimed at determining whether accuracy for predicting surgery is improved by evaluating interval changes in APPD and/or SFU over time.

## PUB135

**Successful Remission of Treatment-Resistant Minimal Change Disease with Adrenocorticotropic Hormone Gel**

M. Khurram Faizan,[1] Ruchir S. Patel.[2] *[1]Dept of Pediatrics, Hasbro Children's Hospital; [2]Dept of Medicine, Rhode Island Hospital, Providence, RI.*

**Background:** Adrenocorticotropic hormone (ACTH) has historically been used to treat pediatric nephrotic syndrome (NS) and also received FDA approval for the treatment of NS in the 1950's. It fell out of favor with the advent of oral steroids. Recent case reports and small case series reporting the successful use of ACTH has rekindled interest in its use for treatment of NS resistant to conventional immunosuppression.

**Methods:** We report a 19 yr old Caucasian female with frequently relapsing, treatment resistant NS who achieved remission with purified porcine ACTH (ACTHAR Gel®) treatment. Patient was diagnosed with NS at age 10. Two renal biopsies 5 yrs apart showed minimal change disease. Clinical course was complicated by numerous relapses despite chronic steroid and CNI therapy, severe dyslipidemia, and episodes of anasarca requiring IV albumin/furosemide. PMH: Significant for splenic infarct at age 14 and restrictive eating disorder. ROS: Positive for intermittent swelling, fatigue, and anorexia. Medications: Prednisone 10 mg, Tacrolimus 4 mg BID, Losartan 25 mg, Lisinorpil 10 mg, Simvastatin

40 mg, Penicillin V 250 mg BID. Vital signs: BP 122/81, Pulse 104, afebrile. Wt 51 kg, BMI 20.64. Physical exam: No lower extremity edema. Table 1 shows labs at baseline and post-treatment. ACTH was started at 40 units SQ twice a week for 6 mths. Tacrolimus and prednisone were tapered.

**Results:** Our patient underwent prompt remission of proteinuria and marked improvement in lipid levels, did not experience any side-effects, and remains on ACTH (Table 1). Subjectively, she reported improvement in her mood, energy and self-esteem.

**Table 1:**

| | Before ACTH | 2 Wks | 4 Wks | 6 Wks | 10 Wks |
|---|---|---|---|---|---|
| Urine Protein/Creatinine Ratio | 5.35 | 0.66 | 0.68 | 0.24 | 0.12 |
| Albumin (g/dl) | 1.7 | | | 2.9 | 3.2 |
| Creatinine (mg/dl) | 0.82 | | | 1.01 | 0.69 |
| Cholesterol (mg/dl) | 506 | | | 403 | 240 |
| Triglyceride (mg/dl) | 717 | | | 324 | 172 |

**Conclusions:** Our report suggests that ACTH may be an important alternative in patients with challenging and difficult to treat NS due to minimal change disease. However, long term efficacy and side-effects remain unknown. Large scale prospective studies are needed to further validate our observation.

## PUB136

**Effect of AngiotensinII Type 1 Receptor Blocker on the 12-Lipoxygenase Activation and Slit Diaphragm Protein Expression in Type 2 Diabetic Rat Glomeruli** Zhong-gao Xu, Wan-ning Wang, Fu-zhe Ma, Tao Sun. *Dept of Nephrology, The First Hospital of Jilin Univ, Changchun, Jilin, China.*

**Background:** 12-lipoxygenase (12-LO) is implicated in the development of diabetic nephropathy, in which the proteinuria is thought to be associated with a decreased expression of glomerular slit diaphragm protein. Recently, it was demonstrated that nephrin expression, but not p-cadherin expression, varies among the different sizes of glomeruli under type 2 diabetic conditions. Furthermore, the decreased expression of nephrin in the hypertrophied glomeruli may be responsible for the albuminuria at the early stage of diabetes. In this study, we investigated the effect of angiotensinII(AngII) type 1 receptor blocker(ARB) on 12-LO activation and slit diaphragm protein expression in type 2 diabetic rat glomeruli.

**Methods:** Podocytes were stimulated by AngII for 24 hours. 12-LO product 12(S)-HETE and AngII were infused to rats by osmotic mini-pump for 1 week and 2 weeks respectively. Rats fed high fat diet were received low dose streptozotocin (STZ) to make type 2 diabetes and divided into 2 groups:low dose STZ(DN), low dose STZ+ARB treatment(Losartan). Rats fed regular chow were as control group (Ctrl). All rats were sacrificed after 6 weeks. Glomeruli were isolated with a sieving method, we used relative large glomeruli (on the 125μm sieve, not on the 75μm sieve). ELISA, RT-PCR and Western blot for related target were performed respectively.

**Results:** AngII increased 12(S)-HETE levels in podocytes and glomeruli. AngII levels in the glomeruli were significantly increased by 12(S)-HETE stimulation. Blood glucose, kidney/body weight and albuminuria were increased in DN compared with Ctrl. However, albuminuria, Kidney/body weight were decreased after Losartan treatment compared with DN. Increment of 12(S)-HETE content and decrement of nephrin and p-cadherin expression were observed in DN glomeruli compared with Ctrl.These abnormalities were prevented by administration of the Losartan.

**Conclusions:** These results indicate that ARB can ameliorate the progression of DN via upregulation of glomeruli nephrin and p-cadherin through inhibition of 12-LO activation in type 2 DN rat.

## PUB137

**The Effect of High Glucose Exposure on Iron Induced Cytotoxicity and the Protective Role of Carnosine** Sibylle Jenny Hauske, Emmanouil Ntasis, Eleni Stamellou, Shiqi Zhang, Bernhard K. Krämer, Benito Yard. *Vth Medical Dept, Medical Faculty Mannheim, Univ of Heidelberg, Germany.*

**Background:** It is generally believed that diabetic complications are oxidative stress mediated. The production of mitochondrial derived reactive oxygen species (ROS) seems to play a pivotal role herein. Recently it has also been discussed that increased intracellular iron accumulation, occurring under high glucose conditions (HGC) may lead to additional oxidative damage.

**Methods:** In keeping with the postulated protective role of L-carnosine (CAR) in diabetic complications we sought to asses in this study: 1) if HG exposure makes cultured human umbilical vein endothelial cells (HUVEC) more susceptible to metal induced toxicity, 2) if this correlates with increased expression of known iron transporters (DMT-1, IREG, TFR), 3) If CAR is able to protect HUVEC in this respect and if so, do HUVEC express CAR transporters (PEPT1, PEPT2).

**Results:** HUVEC were cultured for 2 days under normal glucose conditions (NGC) or HGC (30mM) in the presence or absence of 20mM CAR. Hereafter the cells were challenged for 24h with different concentrations of FeCl3 without changing the culture conditions. Cell viability was not impaired under HGC nor associated with increased susceptibility to FeCl3. HGC down regulated the expression of IREG1 but did not change DMT1 and TFR expression. CAR showed a strong protective effect under NGC or HGC. The protective effect only occurred if CAR was present during FeCl3 challenge but not if CAR was only applied as pre-treatment. CAR did not quench ROS. Both PEPT1 and PEPT2 were poorly expressed on HUVEC. The expression was not changed under HGC.

**Conclusions:** Our data indicate that metal induced cytotoxicity is not enhanced under HGC. This is compatible with an unaltered expression of the iron transporters DMT-1 and TFR and with down regulation of IREG1. CAR displayed a strong protective effect on iron mediated toxicity. The protective effect was not related to quenching of ROS. In keeping with the poor expression of PEPT1 and PEPT2 on HUVEC our data indicate that the protective effect of CAR most likely resides outside the cells, possibly via a mechanism that involves iron chelation.

## PUB138

**Aggravation of Diabetic Nephropathy in OLETF Rats with thy-1 Nephritis** Maho Watanabe, Hitoshi Nakashima, Kenji Ito, Yasuhiro Abe, Satoru Ogahara, Takao Saito. *Div of Nephrology and Rheumatology, Dept of Internal Medicine, Faculty of Medicine, Fukuoka Univ, Fukuoka, Japan.*

**Background:** OLETF rat was established as an animal model of human type 2 diabetes. We previously reported increase of urinary protein and aggravation of diabetic nephropathy when thy-1 nephritis was introduced into OLETF rats (Clin Exp Nephrol 15:22-29, 2011). In this study, we clarifiy the mechanisms for advance of diabetic nephropathy in OLETF rats by thy-1.

**Methods:** Forty week-old OLETF rats were divided into 2 groups. One mg/kg body weight of OX7, an anti-thy1.1 antibody, was administered in one group intravenously (Group T, n=14); the same volume of 0.9% saline in the other group as control (Group C, n=14). The rats were sacrificed after 25 weeks of the injection. Using the quantitative real-time polymerase chain reaction, we assayed the transcription levels of the Smad1, NF-κB,CREB(cAMP response element binding protein), GLUT1,RAGE as diabetic nephropathy related transcription factor , ICAM-1,MCP-1,Collagen type III, IV, VI, IL-6, IL-10, TGF-β, Angiotensin II,VEGF, collagens type IV and type VI, CD68 and TGF-beta in the kidney with immunohistochemical technique. The same procedures were peformed in 2 groups of LETO rats, a non-diabetic strain of OLETF rat.

**Results:** Relative abundance of ICAM-1 mRNA normalized by beta-actin were 0.52±0.06 and0.26±0.02 in Groups T and C, respectively ($p<0.05$). The abundances of Collagen type III expression were 0.57±0.11 and 0.35±0.05; Collagen typeVI were 0.18±0.03 and 0.12±0.01 , IL-6 were 2.2E-4±1.19E-4 and 5.19E-5±2.00E-5 in Groups T and C, respectively ($p<0.05$ in all assays). In Group T , Smad1, NF-κB, GLUT1, RAGE were higher than that in Group C, but they were not significant between groups T and C. Histologically, collagen type VI ollagen positive area were increased by OX7 administration.

**Conclusions:** The inflammatory changes induced by anti thy1.1 antibody may be irreversible in the diabetic conditions of OLETF rats and accerelate the production of collagens III and VI for aggravating diabetic nephropathy. These mechanisms may be applied to the advance of diabetic nephropathy by glomerulonephritis in human, eg., IgA nephropathy.

## PUB139

**Activation of Renin-Angiotensin System Is Involved in Fatty Acid Induced ER Stress in the Kidney** Chunling Li,[1] Yu Lin,[1] Renfei Luo,[1] Moshe Levi,[2] Tianxin Yang,[1,3] Weidong Wang.[1] *[1]Institute of Hypertension and Kidney Research, Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Renal Div, Univ of Colorado Denver, Aurora, CO; [3]Dept of Internal Medicine, Univ of Utah and Veteran Affairs Medical Center, Salt Lake City, UT.*

**Background:** Free fatty acids (FA) are critically involved in the pathogenesis of diabetic nephropathy (DN), and renal proximal tubule cells are an important site for the onset of DN. The objectives of this study were to elucidate the role of renin-angiotensin system (RAS) activation in FA-induced endoplasmic reticulum (ER) stress in cultured human proximal tubule epithelial cells (HK2) and in mice fed with high-fat diet.

**Results:** Treatment with saturated FA palmitic acid (PA, 1mM) for 24h induced HK2 ER stress, leading to an unfolded protein response as reflected by increased expressions of the ER chaperone BiP (4.23±0.54 in PA vs. 1.00±0.20 in controls, $p<0.05$) and proapoptotic transcription factor CHOP (9.06±0.36 in PA vs. 1.00±0.26 in controls, $p<0.05$) as evaluated by immunoblotting. PA treatment induced increased protein expression of IRE1alpha (3.44±0.46 in PA vs. 1.00±0.16 in controls, $p<0.05$) and phosphorylation of eIF2alpha. The mRNA levels of angiotensin type I receptor (AT1R), but not AT2R, was significantly increased in response to PA treatment. In contrast, unsaturated FA linoleic acid didn't induce ER stress in HK2 cells. The AT1R blocker valsartan or renin inhibitor aliskiren protected against PA-induced upregulation of BiP (1.70±0.36 in valsartan, 1.16±0.14 in aliskiren group), CHOP (2.27±0.14 in valsartan, 2.29±0.10 in aliskiren group) , IRE1alpha (1.18±0.18 in valsartan, 1.24±0.26 in aliskiren group), and phosphorylation of eIF2alpha in HK2 cells. The renal cortex of mice (C57BL/6) fed with high-fat diet for ten weeks showed increased protein expressions of BiP (4.73±0.27 in HF vs. 1.00±0.28 in control) and CHOP (1.43±0.15 in HF vs. 1.00±0.10 in control) in comparison to control mice, which were significantly blunted by the valsartan treatment.

**Conclusions:** It is suggested that the intrarenal RAS activation may play an important role in renal injury via mediating ER stress induced by fatty acid.

## PUB140

**mPGES-2 Deletion Improves Glucose Metabolism but Enhances Streptozotocin-Induced Liver Toxicity** Ying Sun,[1,2] Zhanjun Jia,[1,2] Kevin Yang,[1] Mi Liu,[1] Tianxin Yang.[1,2] *[1]Internal Medicine, Univ of Utah, Salt Lake City, UT; [2]VA Medical Center, Salt Lake City, UT.*

**Background:** Microsomal prostaglandin E synthase-2 (mPGES-2) deletion doesn't influence PGE2 production in vivo and the function of this enzyme remains elusive.

**Methods:** We examined a possible role of mPGES-2 in glucose metabolism using mPGES-2 KO mice.

**Results:** mPGES-2 KO mice had elevated blood insulin (WT: 1.34±0.18 vs KO: 2.37±0.38ng/dl, p<0.05), moderately reduced random blood glucose(WT: 119.0±5.4 vs KO: 106.1±2.84mg/dl, p<0.05) and significantly improved glucose tolerance(GTT). Interestingly, at day 4 of streptozotocin (STZ) (120 mg/kg, i.p.) administration, mPGES-2 KO mice exhibited severe lethality (6 of 9 died and 3 of 9 were near-death),, but WT controls had no noticeable abnormality. The near-death KO mice consistently presented pale liver and extremely enlarged stomach. To avoid lethality, another experiment was done at day 3 of STZ. The blood glucose levels were similar between STZ treated KO and WT mice (WT: 291.8±49.5 vs KO: 278.0±40.8 mg/dl, p>0.05). However, these KO mice showed pale liver with severe global ballooning degeneration (PAS staining), in parallel with markedly elevated liver enzymes (ALT: WTSTZ 72.7±18.1 vs KOSTZ 2910±862.1u/L, p<0.05; AST: WTSTZ 250±54.5 vs KOSTZ 5430±1539.5u/l, p<0.05), and remarkable stomach expansion with extremely thin stomach wall (PAS). However, the morphology of other organs including kidney, pancreas and heart are largely normal. By qRT-PCR and western blotting, inductions of caspase-3, Bak and Bax were much greater in KO indicating a severe liver apoptosis. Meanwhile, the inflammatory markers of IL-1β, TNF-α, MCP-1 were much higher in KO. More interestingly, a liver-specific 50% increase of Glut2, a key transporter of STZ uptake, was found in KO mice. Finally, liver PGE2 content in KO mice had high baseline (KO:747.6.23±107.2 vs WT470.2±89.2pg/mg protein: p<0.05) and greater induction after STZ (KOSTZ: 4247.6±1124.5 vs WTSTZ: 1751.9±388.8 pg/mg protein, p<0.01).

**Conclusions:** mPGES-2 deletion significantly enhanced the blood insulin and improved glucose metabolism, but enhanced STZ-induced liver toxicity possibly via Glut2-mediated STZ uptake, independently of diabetes mellitus.

## PUB141

**The Histopathology of Diabetic Nephropathy (DN) Emerges from Two Different Pathomechanisms: A Structure-Based Analysis** Wilhelm Kriz,[1] Hermann-Josef Groene.[2] *[1]Anatomy and Embryology, Medical Faculty Mannheim, Univ of Heidelberg, Mannheim, Germany; [2]Cellular and Molecular Pathology, German Cancer Research Center, Heidelberg, Germany.*

**Background:** The glomerular pathology of DN comprises a mesangio-capillary scenario presenting as diffuse or nodular mesangial sclerosis and a podocyte-parietal cell scenario consisting of the usual changes following podocyte loss. How these two manifestations are related to each other is poorly understood. We postulate that they emerge from different mechanisms.

**Methods:** Biopsies from patients with DN were compared with the histopathology of experimental glomerular diseases.

**Results:** Hyperfiltration, glomerular hypertension and growth are the challenges to which podocytes are exposed in DN. Podocytes have been considered as pericytes counteracting transmural pressure gradients. Based on the insight that podocytes are lost as viable cells by detachment we conclude that the podocyte cytoskeleton mainly serves to fix podocytes to the GBM; a pressure counteracting role is unlikely. The major part of hydraulic resistance must be located upstream in the GBM correlating with the synthesis of a thickened GBM in DN as a protective response to increased pressure and flow.

Inside the GBM the changes are highly specific for DN; experimentally, identical changes were found in response to high serum levels of VEGF (Hakroush et al 2009, Am J Pathol 175:1877). Normally, glomerular capillaries are located on the surface of a lobule facing Bowman's space. This placing of capillaries beneath podocytes is likely a consequence that growth stimulation by VEGF exclusively comes from podocytes. In patients with DN serum levels of VEGF are elevated likely alternating with episodes of low VEGF. We hypothesize that "diffuse mesangial sclerosis" is due to random stimulation of capillary growth by high serum VEGF associated with repression of podocyte VEGF. "Nodular sclerosis" develops during episodes of low serum VEGF. VEGF from podocytes cannot reach remote capillaries in the mesangium followed by capillary collapse and sclerosis.

**Conclusions:** Podocyte loss results from increased mechanical stress, diffuse and nodular sclerosis develop from disturbances in VEGF availability.

## PUB142

**The Researches on the Protection Mechanism of DanHong-Injection to Diabetic Rats** Li Wang. *Renal Dept, Sichuan Provincial People's Hospital.*

**Background:** To investigate the renoprotective effect of Dan Hong-injection on streptozocin (STZ)-induced diabetic rats, and explore the renoprotective mechanism by comparing the expression of vascular cell adhesion molecule-1(VCAM-1) and endothelial cell adhesion molecule (PECAM-1) in kidney before and after administration.

**Methods:** The unilateral nephrectomy model of SD rats were feed with high-fat diet for one month. 12 rats were used as the control group. The other rats were given a single dose of STZ. Forty rats with diabetic kidney disease model were randomly divided into two groups:Dan Hong-injection group (DH group, n=20), saline injection group (NS group, n=20). DH group were given Dan Hong-injection intravenously (2ml/kg) daily for two weeks; NS group, NR group were given saline intravenously (2ml/kg) daily for two weeks. After treatment, urine, blood and kidney were collected.

**Results:** At 2, 6, and 10 weeks after treatment, the blood glucose in both NS and DH groups were significantly increased. BUN, SCr , and Cys-C in DH group was lower than NS group at 2 weeks after treatment. At 2, 6, and 10 weeks after treatment, Cys-C in DH group was lower than NS group. 24h-TP in DH group was lower compared with that in NS group at 6,10 weeks after administration.The glomerular's volume of DH group significantly decreased compared with NS group at 6 (P=0.023),10(P=0.049)weeks after treatment. At 2, 6, and 10 weeks after administered, the IOD of VCAM-1 and PECAM-1 in DH group were significantly weaker than that in NS group(P5.The IOD of VCAM-1 was significantly positively correlated with both proteinuria (γ=0.59, P=0.001) and glomerular's volume. The IOD of PECAM-1 was also significantly positive correlated with both proteinuriaand glomerular's volume.

**Conclusions:** Danhong-injection alleviates the early renal injury, protects renal function and reduces urine protein, and has the potential to decrease the progress of kidney damage in DKD rats. Danhong-injection decrease the expression of PECAM-1 and VCAM-1 in kidney. It reveals that the renoprotective effect of Danhong-injection may be attributed to its anticoagulant effect, thus improving the hyper-filtration state in renal and the endothelial function of kidney.

## PUB143

**Down-Regulation of TRPM6 and NCC in Diabetic Nephropathy as a Principal Cause of Hypermagnesuric Hypomagnesemia in Diabetes** Kaori Takayanagi,[1] Hajime Hasegawa,[2] Takatsugu Iwashita,[2] Yosuke Tayama,[2] Juko Asakura,[2] Naohiko Anzai,[3] Yuya Shiota,[2] Saeko Seki,[2] Nobuyuki Onizawa,[2] Tetsuya Mitarai.[2] *[1]Kawagoe Ekimae Clinic, Kawagoe, Saitama, Japan; [2]Nephrol & Hypertens, Saitama Med Center, Saitama Med Univ, Kawagoe, Saitama, Japan; [3]Pharmacol & Toxicol, Dokkyo Med Univ School of Medicine, Mibu, Tochigi, Japan.*

**Background:** Hypermagnesuric hypomagnesemia is frequently appeared in diabetic patients, and is known to be highly related to the development of insulin resistance. The present study aimed to investigate the molecular mechanism of the hypermagnesuria in diabetic nephropathy, and the involvement of interstitial damage because renal interstitial damage is not rarely associated with hypermagnesuria.

**Methods:** Kidneys were obtained from male OLETF (F) and LETO (L) rats of 16, 24, and 34 weeks-old. Altered expression of Mg transporting molecules was assessed by immunohistochemistry and RT-PCR. Time-differential development of interstitial damage was assessed by histological and molecular biological analysis.

**Results:** Absolute Mg excretion in F were significantly high in 24 and 34 weeks (0.16±0.01 in 24L, 0.28±0.01 in 24F, 0.18±0.02 in 34L, 0.29±0.04 μg/min/100g BW in 34F), showing significant hypermagnesuria from the early stage of diabetic nephropathy. Gene expressions of TRPM6 and NCC were significantly reduced in F (reduction rate of TRPM6: 73.8% in 24 week, 78.3% in 34 week, NCC; 87.9% in 24 week, 75.3% in 34 week), whereas the expressions of claudin-16 in TAL were not significantly changed. Semi-quantitative analysis of immunohistochemical expression of both molecules were agreed with the reduced gene expression (reduction rate in TRPM6; 52.7% in 34 week, NCC; 40.8% in 34 week). Expression of molecular markers for interstitial damage, such as MCP-1, α-SMA were not different between F and L in all experimental periods in compatible with the histological assessment of interstitial damage.

**Conclusions:** Present study might show that down-regulated TRPM6 in DCT would be a principal cause of hypermagnesuria in diabetic nephropathy. Suppression of NCC might be involved in the TRPM6 down regulation. The elevation Mg excretion in diabetes might be independent of renal interstitial damage.

## PUB144

**Study of TGFB1 -509C>T Polymorphism Association with Diabetic Nephropathy Development in T1D Patients** Thamara R. de Melo,[1] Karla Souza,[1] Marcela Ururahy,[1] Yonara Monique Oliveira,[1] Melina Bezerra Loureiro,[1] Heglayne P. Silva,[1] João F. Bezerra,[1] Gustavo M. Oliveira,[1] Rosario D.C. Hirata,[2] Maria Das Graças Almeida,[2] Ricardo Fernando Arrais,[3] Sonia Q. Doi,[4] Mario Hiroyuki Hirata,[2] Adriana Augusto de Rezende.[1] *[1]Clinical and Toxicological Analysis, UFRN, Natal, RN, Brazil; [2]Clinical and Toxicological Analysis, USP, São Paulo, SP, Brazil; [3]Pediatrics, UFRN, Natal, RN, Brazil; [4]Medicine, USUHS, Bethesda, MD.*

**Background:** Diabetic nephropathy (DN) is the most commom cause of end-stage renal disease. DN manifestations may be a consequence of transforming growth factor beta 1 (TGF-β1) actions, since it promotes renal cell hypertrophy and stimulates extracellular matrix accumulation. In this way, we aimed to investigate *TGFB1* -509C>T polymorphism association with DN development patients with type 1 diabetes (T1D) from Natal-RN/Brazil.

**Methods:** *TGFB1* -509C>T polymorphism was analyzed in 156 T1D patients and 188 normoglycemic (NG) subjects, aged between 6 to 20 years. Glucose, glycated hemoglobin, creatinine, urea, albumin-to-creatinine ratio (ACR), serum lipids and *TGFB1* mRNA expression were evaluated.

**Results:** T1D patients showed increased levels of urea (mg/dL) [NG:22 (19-27) and T1D: 29 (22-33), p<0.001] and ACR (mg/g of creatinine) [NG:6 (4.7-7.9) and T1D: 7.7 (5.2-16.1), p<0.001], compared to NG subjetcs. No association was found for *TGFB1* -509C>T with markers of kidney damage development in T1D patients (Table 1).

Table 1 - Relationship between TGFB1 -509C>T genotypes and biochemical parameters of T1D patients

| Genotype | Glucose *mg/dL* | Glycated Hemoglobin *%* | Creatinine *mg/dL* | Urea *mg/dL* | RAC *mg/g of creatinine* | Total cholesterol *mg/dL* | *TGB1/Bactin* mRNA *fold-change* |
|---|---|---|---|---|---|---|---|

## PUB145

**Anti-Apoptotic Effects of Green Tea Extracts on Streptozotocin-Induced Diabetic Nephropathy in Mice** Byung Chul Shin, Jong Hun Back. *Dept of Internal Medicine, Chosun Univ Hospital, Gwangju.*

**Background:** Diabetic nephropathy is the most common cause of end-stage renal disease and is characterized by glomerulosclerosis and tubulointerstitial fibrosis, associated with apoptosis. Green tea extracts (GTE) have antioxidant properties and is responsible for the renoprotection. We examined whether GTE could ameliorate the development of diabetic nephropathy and its role of antiapoptotoic effects.

**Methods:** The mice (n=40) were divided into 4 groups. Control group (n=10) was intraperitoneal (IP) injected 0.9% saline, Streptozotocin (STZ) group (n=10) was IP injected STZ 200mg/Kg and induced diabetic nephropathy. GTE group (n=10) was received 0.1% GTE by oral rout from 4 weeks to 16 weeks. STZ plus GTE group (n=10) was received with same dose. Serum glucose, blood urea nitrogen, serum creatinine, urine volume and urine protein amounts were measured at 16 weeks. Western blot assay of p53, caspase-3, cleaved caspase-3, caspase-7 were compared for the different groups. Histopathologic examination and immunohistochemical staining of mice kidney were performed.

**Results:** Compared with control group, STZ-group showed an increase in blood glucose, blood urea nitrogen, creatinine levels and urine protein amounts, and a decrease in body weight. All the above parameters were significantly reversed with GTE treatment. After STZ injection, there were a diabetic glomerulosclerosis with increased caspase-3 and caspase-7 activities. GTE-treated mice kidney showed a reduced expression of above parameters and the reserved pathologic findings.

**Conclusions:** GTE can inhibit progression of STZ-induced diabetic nephropathy by reductions in caspase-3 and caspase-7 activities. These results suggest that GTE ameliorates STZ-induced diabetic nephropathy by apoptosis suppression.

## PUB146

**Remission of Diabetes and Hypertension Accompanying Rapid Weight Reduction following Bariatric Surgery** Anil K. Mandal,[1] Linda M. Hiebert.[2] *[1]Univ of Florida, Gainesville, FL; [2]Univ of Saskatchewan, Saskatoon, Canada.*

**Background:** Obesity and diabetes go hand in hand. Diabetes control is difficult to accomplish because of insulin resistance. Hypertension control also requires many and high doses of antihypertensive drugs. Remission of diabetes following gastric bypass surgery is reported (Arch Surg 2011; 146: 744-750).

**Methods:** This study reports a 52y obese male with progressive weight increase and uncontrolled diabetes of 10-12 years, despite intensive insulin therapy and variable hypertension control despite 4 line therapy. Gastric bypass surgery was recommended. Baseline weight of 207 lbs.; increased to 356 lbs., fasting blood glucose (FBG) and 2h postprandial blood glucose (2hPPG) increased from 131 and 181 mg/dL to 147 and 263 mg/dL respectively, despite 60 units of glargine insulin twice daily and regular insulin 5 units with each meal. Blood pressures (BP) ranged from low 130/80 to high 180/100 mmHg. Roux-en-y-Gastric bypass surgery performed in November 2011.

**Results:** At last visit, 18 months later, weight was 230 lbs. with a total weight loss of 126 lbs. Sitting BP was 120/60 with reduced BP medication. FBG and 2hPPG were reduced to 102 and 85 mg/dL respectively without insulin therapy. $HbA_1c$ varied from 7.8% to 9.3% with a mean 8.3% before surgery to mean 5.5% 18 months after surgery. Renal function is maintained normal.

**Conclusions:** Massive weight reduction following gastric bypass surgery restores normoglycemia even in insulin treated, long-term diabetes and simplifies BP control. Gastric bypass surgery is not a conventional therapy but should be considered when weight reduction, diabetes and BP control are at a crossroad situation.

## PUB147

**Circulating Irisin Level in Human Diabetic Cohorts; 11 Year Retrospective Cohort Study** Jin Joo Cha,[1] Mi Jin Lee,[1] Young Youl Hyun,[2] Dae R. Cha,[1] Jung Eun Kim,[1] Mihwa Lee,[1] Hye Kyoung Song,[1] Young Sun Kang.[1] *[1]Nephrology, Korea Univ Ansan Hospital, Ansan, Kyunggido, Republic of Korea; [2]Nephrology, Sungkyunkwan Univ Kangbuk Samsung Hospital, Seoul, Republic of Korea.*

**Background:** Irisin, a novel myokine, has been proposed to induce browning of subcutaneous adipocytes. In humans, circulating irisin level was significantly decreased in obese and diabetic patients. We therefore, examined circulating irisin level and its associations with various complications of diabetes.

**Methods:** We performed a retrospective cohort analysis of 161 diabetic individuals followed up for approximately 11 years. Baseline circulating plasma level of irisin was measured using commercially available EIA kit. The associations between the circulating irisin with variable metabolic parameters, microvascular and macrovascular complications were evaluated.

**Results:** Total 161 patients (n=14, type 1 diabetes, n=147 type 2 diabetes, mean age 43,6±4.6, 66.8±10.4 respectively) were analyzed. There were no significant associations with circulating irisin levels with gender difference, the type of diabetes, body mass index, age, Patients with hypertension (n= 66) showed significantly decreased level of circulating irisin (649.09 ±661.9 vs 884.01± 792.27, p=0.04). There was no significant difference in irisin level among the CKD stages (using CKD-EPI equation), however there was a trend toward decrement as the stage advanced. (stage 1(n=62) 806.97±793.70, stage 2(n=58) 925.31±849.83, stage 3a(n=20) 690.75±522.96, stage 3b(n=12) 547.5±460.7, stage 4(n=5) 627.30±464.73, stage 5(n=4) 207.48±75.89). Binary logistic regression was performed to evaluate the relative risks of irisin level with the development of micro- and macrovascular complications. The irisin level did not affect the risks of macrovascular complications. However, incre! Ased level of irisin (log irisin) significantly decreased the risk of retinopathy (Unadjusted RR 0.688, 95% CI 0.516-0.918, p=0.01, Adjusted RR 0.677, 95% CI 0.487-0.942, p=0.02).

**Conclusions:** Circulating irisin level of diabetic patients was not affected by renal insufficiency nor did not affect diabetic nephropathy. It might have a predictive role in diabetic retinopathy.

## PUB148

**The Association of Glypican-4 with Diabetic Complications in Korean Population** Mi Jin Lee,[1] Jin Joo Cha,[1] Young Youl Hyun,[2] Dae R. Cha,[1] Jung Eun Kim,[1] Mihwa Lee,[1] Hye Kyoung Song,[1] Young Sun Kang.[1] *[1]Nephrology, Korea Univ Ansan Hospital, Ansan, Republic of Korea; [2]Nephrology, Sungkyunkwan Univ Kangbuk Samsung Hospital, Seoul, Republic of Korea.*

**Background:** Glypican-4(Gpc4) is an adipokine, which is known to be important for adipocyte differentiation by interacting with and regulating insulin receptor activation and its downstream signaling. Serum Gpc4 is known as a marker for BMI and insulin sensitivity in mice and human. But it is uncertain that the association of Gpc4 with diabetic complications.

**Methods:** We investigated the association of serum Gpc4 level with diabetic complications in a prospective cohort of 161 Korean diabetic patients from 2002 to 2013.

**Results:** In Univariate regression analysis, glycemic variability, estimated GFR was negatively correlated and urine albumin excretion and use of ACE inhibitor was positively correlated with serum Gpc4 level (all $p<0.05$). In multivariate regression analysis, the increase of serum Gpc4 level was associated with the decrease of glycemic variability independently ($p =0.05$). And the increase of serum Gpc4 level was associated with the increase of urine albumin excretion ($p =0.02$). The serum Gpc4 level was not associated with retinopathy, neuropathy, nephropathy, cardiovascular disease, cerebrovascular events. Also serum Gpc4 level did not increase depending on the CKD-epi stage.

**Conclusions:** Taken together, there is no relationship between diabetic complications and serum Gpc4 level. But more research is needed on the relationship between Gpc4 and diabetic complications.

## PUB149

**Effect of Ultrafiltration on Plasma Hemoglobin Concentration in Patients with End-Stage Renal Disease on Chronic Hemodialysis** Subir K. Paul, Shejuti Paul, Rajesh Boorgu, Narasimha Rao Boorgu, Jamie N. Cockrell. *Shoals Kidney and Hypertension Center, Florence, AL.*

**Background:** Anemia is highly prevalent in patients with end stage renal disease. It is common practice to measure plasma hemoglobin concentration in patients on hemodialysis before HD treatment begins. Therapeutic interventions including adjustment of Epogen dose and intravenous iron administration are undertaken based on these meaurements. We have found considerable variation in plasma hemoglobin level in these patients without any apparent clinical change, except for interdialytic weight gain. We hypothesize that the pre-ultrafiltration hemoglobin concentration in this patient population is artificially low because of plasma volume expansion. We propose that plasma hemoglobin level should be measured after ultrafiltration is completed. This study compares the plasma hemoglobin level in patients on chronic hemodialysis before and following ultrafiltration.

**Methods:** Our study included twenty five patients with end stage renal disease on chronic hemodialysis for at least 6 months duration with minimum interdialytic weight gain of three kilograms. Mean age was 59.08 years. Twelve were male and thirteen were female. Ten were white and fifteen were African American. Pre and post hemodialysis plasma hemoglobin concentration was determined in a standard laboratory. Statistical analysis was done with student's t-test.

**Results:** The mean interdialytic weight gain was 4.6 kilograms. Pre-ultrafiltration hemoglobin concentration was 11.32 +/- 0.27 g/dL. Post-ultrafiltration hemoglobin increased to 12.14 +/- 0.28 g/dL (P=0.04).

**Conclusions:** This preliminary data suggests that pre-ultrafiltration hemoglobin concentration in chronic hemodialysis patients may be artificially low because of plasma volume expansion associated with interdialytic fluid gain. Measurement of hemoglobin in this patient population should be done after hemodialysis when ultrafiltration is completed and euvolemia is achieved. This strategy may reduce pharmacological interventions for anemia management in these patients.

## PUB150

**Effect of Ultrafiltration on Serum Albumin in Patients with End Stage Renal Disease on Chronic Hemodialysis** Subir K. Paul, Shejuti Paul, Rajesh Boorgu, Narasimha Rao Boorgu, Jamie N. Cockrell. *Shoals Kidney and Hypertension Center, Florence, AL.*

**Background:** Malnutrition is prevalent in many hemodialysis patients with end stage renal disease on chronic hemodialysis. It is common practice to measure serum Albumin before the initiation of ultrafiltration and hemodialysis. Serum albumin has been found to vary considerably without any apparent clinical change except for interdialytic weight gain. We hypothesize that serum albumin in these patients is artificially low because of plasma volume expansion and should be measured following ultrafiltration.

**Methods:** Our study included 65 patients with end-stage renal disease on chronic hemodialysis for at least 6 months with minimum weight gain of 1 kg. Mean age was 61.17years. Thirty two patients were male. Thirty three were female. Thirty three were White. Thirty two were black. Ultrafiltration was done to reach pre dialysis dry weight for each patient. Serum albumin was measured pre and post ultrafiltration. Statistical analysis was done with student t-test.

**Results:** The mean weight gain was 3.66 kg. Pre-ultrafiltration albumin was 3.77 +/- 0.04 g/dL. Post-ultrafiltration albumin increased to 4.145 +/- 0.05 g/dl (P=0.0001).

**Conclusions:** This preliminary data suggests that pre-ultrafiltration albumin measurements in hemodialysis patients may be artificially low in patients with plasma volume expansion associated with interdialytic fluid gain. We propose that serum albumin should be measured after ultrafiltration when patients are relatively euvolemic. This strategy may be valuable for assessment of malnutrition in patients of end stage renal disease on chronic hemodialysis.

## PUB151

**Clinical Factors and Renal Function at the Start of Dialysis; Impact on Mortality in Incident Hemodialysis Patients** Elvira Bosch,[1] Eduardo Baamonde,[1] German Perez Suarez,[1] Cesar Garcia-canton,[2] Rita Guerra,[2] Dolores Checa.[2] *[1]Centro de Hemodialisis Avericum, Las Palmas de Gran Canaria, Spain; [2]Servicio de Nefrologia, Hospital Insular de Gran Canaria, Las Palmas de Gran Canaria, Spain.*

**Background:** The goal of this study was to analyze whether clinical conditions and renal function at the start of renal replacement therapy (RRT) are related with mortality.

**Methods:** Retrospective study with 220 incident hemodialysis patients between 2007 and 2010 in Southern Gran Canaria. Patients' demographic, clinical and laboratory data were analyzed at the start of dialysis treatment. Glomerular filtration rate (GFR) was calculated by using the MDRD4 and Cockroft-Gault (CG) formula. Patients were classified into 3 different groups according to their GFR (MDRD4 > 15, 8-15 and < 8 mL/min). Survival rates were compared between groups.

**Results:** 65.5% male, 61.13 ± 13 years old, 58.6% diabetic and 17.7% with cardiovascular disease; 65.5% started with catheter, the mean age-adjusted Charlson comorbidity index (ACCI) was 6.2 ± 2.4 and the average MDRD4 at the start of hemodialyis was 10.67 ± 3.25 mL/min. Patients who started with MDRD4 < 8 mL/min were ($p< 0.05$) younger, with lower ACCI and higher incidence of catheter; they showed lower albumin and hemoglobin levels and higher urea and phosphorus levels. The median follow-up time was 30.9 months. Eighty patients died (17.7 % of them with early start and 3.8% with late start). The risk of death was significantly higher for patients with hypoalbuminemia, age > 65 years, higher ACCI, MDRD4 > 15 mL/min at the start, heart failure or history of ACV. After adjusting the model (Cox regression) the global risk of death was higher ($p< 0.05$) for patients who started with catheter (HR: 2.4 CI: 1.3- 4.4), higher ACCI (HR: 1.16 CI: 1.03-1.3), > 65 years (HR: 1.7 CI: 1.01-3.08) and for those who started with GF-MDRD4 > 15 mL/min (HR: 3.6 CI: 1.03-13).

**Conclusions:** Patients with a late RRT start were younger, with lower ACCI and with lower albumin and hemoglobin levels. Factors affecting the survival of incident hemodialysis patients are: early start, start with catheter, older age, the GF-MDRD4 and high ACCI.

## PUB152

**The Use of Continuous Measurement of Glucose Concentration in Interstitial Fluid in Hemodialysed Patients** Stanislaw Niemczyk,[1] Wojciech Klimm,[1] Katarzyna Pleskacz,[2] Bozena Pietrzak.[1] *[1]Internal Diseases, Nephrology and Dialysis, Military Institute of Medicine, Warsaw, Poland; [2]Information and Communication Technologies, Military Institute of Medicine, Warsaw, Poland.*

**Background:** Fluctuations of glucose concentration in serum are an important problem in hemodialysed (HD) patients with and without diabetes. The aim of this study is to compare the fluctuations of the glucose concentrations in interstitial fluid in hemodialysed patients with and without diabetes assessed by the method of continuous measurement.

**Methods:** The study involved 22 HD patients (9 women and 13 men) in two groups: with diabetes (GDM): 4 women and 8 men; and without diabetes (GN): 5 women and 5 men. The concentration of glucose was measured using a Real Time Guardian (Medtronic) monitoring system every 5 minutes. The study assumed 4-day monitoring.

**Results:** In the GDM 9319 measurements were performed (average 776.58/person). Total observation time was 752 hrs 35 min(average 62 hrs 42 min). In the GN 7079 measurements were performed (average 707.9).Total observation time was 589 hrs 55 min(average 58 hrs 59 min). In the GDM the average value of glucose concentration was 137.58 mg/dl and was higher than the GN by 30.28 ($p = 0.004$). The maximum values of glucose concentration were higher in the GDM. The duration of hyperglycemia in the GDM was by 61390 s significantly longer ($p = 0.0008$) compared with the GN. The groups of patients were analyzed for the frequency and the length of glycemia fluctuations. No differences in the number of hyperglycemia were observed.

**Conclusions:** Continuous measurement of interstitial glycemia seems to be a useful, accurate and safe method of the assessment of carbohydrate metabolism in HD patients. In patients with diabetes asymptomatic hyperglycemia are more frequent and longer. Episodes of hypoglycemia also occur in patients without diabetes.

## PUB153

**Lack of Effect of Standard or Adjusted Dialysate Potassium Concentration on Postdialysis Potassium Levels** Xenia P. Sumin, Michael F. Michelis, Maria V. DeVita. *Nephrology, Lenox Hill Hospital, New York, NY.*

**Background:** Controlling serum potassium concentration (K) is an important goal in maintenance hemodialysis (MHD) patients. Intermittent hemodialysis results in rapid fluctuations of serum K that can extend from pathologically high to low concentrations. Predialysis hyper- and hypokalemia have been implicated in increased death risk in MHD patients. Complications of dialysis in regard to serum K is largely a function of both K flux and the development of hypokalemia. The goal of this study was to examine the postdialysis serum K in patients with normal predialysis serum K when dialyzed against standard and adjusted K baths to assess the frequency and extent of postdialysis hypokalemia.

**Methods:** Monthly labs at a single outpatient dialysis center were screened to identify MHD patients with predialysis serum K in normal range (K≥3.7 and K<4.5mEq/L). Of 72 such patients identified, 11 patients were on 3K bath. Twenty-two of the remaining 61 patients, all on 2K bath, were chosen at random to compare to the 3K group. Postdialysis serum K levels were collected on all patients. Patient data on treatment time (min), blood flow (mL/min), and URR was also collected.

**Results:** Mean pretreatment K (4.05±0.22mEq/L) in 2K dialysate group was not different from the mean pretreatment K (4.00mEq/L±0.35mEq/L) in 3K dialysate group ($p=0.59$). Mean change between pre- and posttreatment serum K was -0.12 ±0.58 mEq/L for 2K dialysate group and -0.14±0.31mEq/L for 3K dialysate group ($p=0.94$). Mean posttreatment K (3.93±0.60mEq/L) in 2K dialysate group was not different from the mean postreatment K (3.86mEq/L±0.33mEq/L) in 3K dialysate group ($p=0.73$). Treatment time was longer in the 2K group, 214 versus 195 minutes ($p=0.04$). There was no difference in blood flow or URR between the groups. Though the 2K group had significantly longer treatment time, there was no correlation between change in K and either treatment time or blood flow.

**Conclusions:** There was no significant difference in postdialysis serum potassium levels among the 2K and 3K dialysate groups. It appears patients with normal predialysis K can be dialyzed against 2K bath with minimal risk for the development of severe hypokalemia.

## PUB154

**Performances of the New Revaclear High Flux Dialyzers for Conventional HD Treatments** Fulvia Caligaris,[1] Maria Roseo,[1] Adina Misca,[1] Francesco Guarnieri,[2] Denis Steckiph.[2] *[1]ASL AT Ospedale, Asti, Italy; [2]Gambro, Italy.*

**Background:** High-flux dialyzers may delay long term clinical complications of dialysis. Aim of this study: to evaluate if standard HD with high-flux dialyzers Revaclear (Gambro) improves the removal of uremic toxin in stable HD patients respect to other low and high flux dialyzers.

**Methods:** ESRD patients on dialysis (Qb>250 ml/min) were retrospectively enrolled in a single center, controlled and observational study. The patients were treated on conventional HD (CHD: 19 low-flux, 5 high-flux; n=17 1,7m2, n=7 2,1m2) for 6 months and on high-flux HD with Revaclear dialyzers (RevHD: n=5 1,4m2, n=19 1,8m2) for further 6 months. Revaclear is equipped with a high water permeability PAES/PVP membrane, efficient and compact in size thanks to fiber microondulation and bundle density. Primary end-point: to evaluate the monthly pre-dialysis level of blood urea (Ur) and phosphorus (P). Secondary end-points: to evaluate the monthly pre-dialysis value of hemoglobin, hematocrit, Epo dose and 2-month eKt/V (Daugirdas).

**Results:** We analyzed 24 patients(10 F, age 68.4±12.0 years, HD vintage 6.8±6.1years; vascular access:11 FAV, 13 Tesio CVC). Mean Ur among the whole evaluation period was lower during RevHD(156±37 vs. 142±35mg/dl, $p<0.05$) and a different trend was found between the two periods since by the first month of observation($p<0,05$, Fig.1A). P was significantly lower during the RevHD period, both as mean value(4.65±1.81 vs. 4.19±1.88mg/dl, $p<0.05$) and as time-related trend($p<0.05$, Fig.1B). Other parameters did not show any significant difference (Fig.1C).

| | | | |
| | | | |

**Conclusions:** Our findings in RevHD period were obtained with smaller surface filters on about 2/3 of the treatments respect to CHD, showing the high efficiency of Revaclear high-flux dialyzers on HD. Concerning the effect of Revaclear on hemoglobin levels and Epo dose, a further study on a larger population is needed.

## PUB155

**Is Acidosis Associated with a Better Survival in Hemodialysis Patients?**
Asmaa Y.M. Al-Chidadi, Abdelgalil Abdelrahman Ali. *Broomfield Hospital, Chelmsford, United Kingdom.*

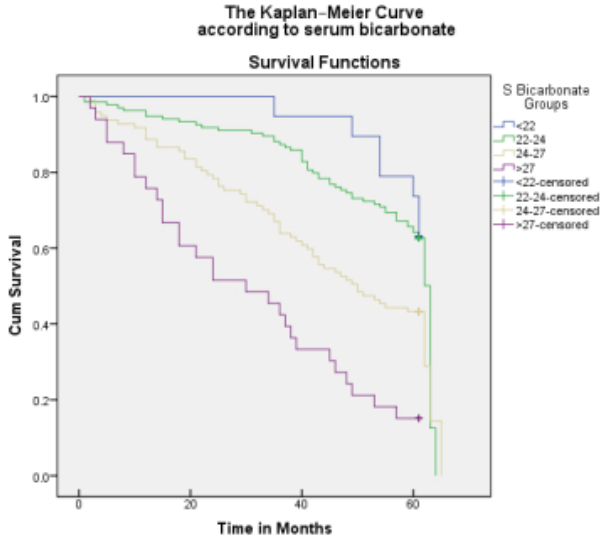
**Background:** Association between acidosis and survival in hemodialysis patients remains controversial.

**Methods:** Correlation between 5-years survival and time-averaged S. Bicarbonate (HCO3) among 293 adults on maintenance hemodialysis was studied. Patients were categorized into four groups according to S. HCO3 levels.

**Results:** CRP correlated positively while S. Phosphate correlated inversely with S.HCO3. Normalized protein nitrogen appearance (nPNA) showed an inverted U-shape correlation with S.HCO3. The mildly acidotic group were significantly younger and had a significantly higher BMI.

| S. HCO3 mmol/l | <22 | 22-24 | 25-27 | >27 | P-value |
|---|---|---|---|---|---|
| (n) | 19(6.5%) | 135(46.2%) | 97(33.2%) | 34(11.6%) | |
| S. HCO3 | 21.4±0.9 | 23.7 ±0.95 | 25.9±0.7 | 27.9±1.0 | **<0.005** |
| Age | 67.7 ± 10.8 | 64.9 ±15.8 | 69.6±15.3 | 73.1 ±12.1 | **0.01** |
| M(F) % | 4.6(2.1) | 32.6(14.7) | 24.2(9.8) | 6.3(5.6) | 0.26 |
| Mortality% | 2.5 | 19.6 | 20.4 | 10.2 | **<0.0001** |
| Kt/V | 0.95±0.2 | 1.1±0.4 | 1.2±0.4 | 1.0±0.2 | **0.009** |
| nPNA | 0.94±0.2 | 0.93 ±0.3 | 0.96±0.2 | 0.90±0.3 | 0.8 |
| BMI | 34.4±26.3 | 27.8±7.9 | 28.8±24.2 | 24.4±4.3 | **0.006** |
| CRP | 41.2±49.7 | 36.3±38.1 | 50.1±41.5 | 53.6±9.2 | **0.007** |
| S. Pi | 1.6±0.5 | 1.50±0.5 | 1.4±0.5 | 1.18±0.4 | **<0.005** |

**Survival was significantly higher** among the acidotic group, p<0.0001, despite a significantly lower Kt/V.



**Conclusions:** The higher survival among the acidotic group could be influenced by reverse epidemiology engendered by malnutrition and inflammation.

## PUB156

**Low Molecular Weight Heparin (LMWH) "Enoxaparin" as a Standard Anticoagulant in Hemodialysis Patients: A 15 Year Experience**
Bassam O. Bernieh,[1] Yousef Boobes,[1] Mohamed Raafat Al Hakim,[1] Qutaiba Hussain Daoud,[1] Hanan Eljack,[1] Nicholas T. Richards.[2] *[1]Nephrology, Tawam Hospital, Al Ain, United Arab Emirates; [2]SEHA Dialysis Services, Abu Dhabi, United Arab Emirates.*

**Background:** LMWHs are available since 25 years with wide use in the treatment and prevention of medical and surgical thromboembolic events. The use of LMWHs as anticoagulant in hemodialysis (HD) patients, is still not a routine or standard practice. We are using LMWH 'Enoxaparin' since 1998 as a standard anticoagulation in our HD unit, and in a previous publication (1), we defined the dose which would be used in HD (0.36 mg/kg), and the advantages of LWMH "Enoxaparin" over unfractionated heparin. **Aim of the study:** In the current study, we are reporting our 15 years experience of using "Enoxaparin" , evaluating the current used dose, the dose according to the type of vascular access, etiology of kidney disease (diabetic, none diabetic), and dialytic mode (HD, HDF).

**Methods:** This study includes 252 HD patients, mean age 56.6 (17) year, Male 145 (57.5 %). Mean duration on HD 50 (44.5) months. 139 (55%) were diabetics, 138 (55%) had AVF, 28 (11%) had AVG, and 86 (34%) had tunneled catheter (TC). 187 (74%) patients were on HD, and 65 (26%) were on line HDF.

**Results:** Total number of HD sessions during the 15 years use of "Enoxaparin" was 350,000. The average dose of "Enoxaparin" was 0.31 (0.14) mg/kg/session. 0.29 (0.13), 0.34 (0.17), and 0.34 (0.14) mg/kg/ session, were the average doses used in AVF, AVG, and TC respectively with ***p*=0.03**. The dose used in DM patients was 0.30 (0.13), and 0.34 (0.13) mg/kg in non DM, with ***p*=0.15**. Average dose in HD was o.31 (0.13), and in HDF 0.32 (0.15) mg/kg, ***p*=0.69**.

**Conclusions:** To the best of our knowledge this study is the longest, and the largest experience ever reported with the use of LMWH "Enoxaparin" as a standard anticoagulant in HD. The average dose used continued to be low and stable with time. Only the type of vascular access impact significantly the required dose.

## PUB157

**Successful Treatment of Metabolic Encephalopathy by Switching Peritoneal Dialysis to Hemodialysis**
Ayesha Waqar, Monalisa Joseph, Muhammad R. Syed, Azka Arif, Talal A. Khan, Muhammad W. Khattak, Sandeep Aggarwal, Nauman Shahid. *Drexel Univ College of Medicine, Philadelphia, PA.*

**Background:** End stage renal disease patients on dialysis can suffer from metabolic encephalopathy. More often than not the reason remains uncertain. We report a case of a patient in which the encephalopathy completely resolved by switching from peritoneal dialysis to hemodialysis.

**Methods:** Our patient was a 65-year-old Hispanic male, with history of end stage renal disease, diabetes mellitus type 2, hypertension, coronary artery disease, gout and peripheral vascular disease. He was on peritoneal dialysis for last one year and had been compliant with his treatment with adequate dialysis. He was admitted to the hospital with change in mental status. Prior to this admission he was completely independent and worked as mathematics teacher. As part of his work up, CT head did not reveal any new changes and lumbar puncture results were unremarkable. His EEG showed slowing of back ground activity suggestive of mild diffuse encephalopathy likely due to metabolic, toxic or infectious etiology. His TSH was elevated so he got IV synthroid . He had culture negative peritonitis which was treated with IV antibiotics to resolution. Despite treatment of the metabolic and infectious abnormalities and providing adequate dialysis (Kt/V 1.7), his mental status did not improve. He remained hospitalized for two months, without any improvement in mental status until his renal replacement therapy was switched to hemodialysis. We used F 180 dialyzer with Blood flow rate of 350 and Dialysate flow rate of 700 for his first session. Immediately after his first hemodialysis, a dramatic improvement of his mental status was noted. We continued hemodialysis and after his second session, he returned to his baseline, nine weeks after his initial presentation.

**Conclusions:** Although we do not have clear explanation for this but there is a possibility that hemodialysis may have some benefit in clearing middle molecules and some unknown substances in blood which may contribute to encephalopathy.

## PUB158

**Continuous Veno-Venous Hemodialysis (CVVHD) with Regional Citrate Anticoagulation (RCA) Is a Suitable and Safe Modality for Severe Acute Kidney Injury (AKI) Induced by Tumor Lysis Syndrome (TLS)**
Veronica T. Costa e Silva,[1] Elerson Costalonga,[1] Cilene Muniz de Alencar Soares,[1] James Hung,[1] Juliana Silva Bezerra,[1] Ana Paula Leandro Oliveira,[1] Luciane Oikawa,[1] Ludhmila Abrahão Hajjar,[2] Luis Yu,[1] Emmanuel A. Burdmann.[1] *[1]Nephrology Div, Sao Paulo State Cancer Institute - Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Intensive Care Dept, Sao Paulo State Cancer Institute - Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

**Background:** It has not been established which is the most suitable dialysis modality for TLS-induced AKI and there is no data on RCA protocol safety in these patients.

**Methods:** We prospectively analyzed 8 consecutive adult cancer TLS-induced AKI patients (Cairo-Bishop criteria) submitted to CVVHD for a minimum of 3 days in the Intensive Care Unit of a University tertiary hospital (Cancer Institute) from January 2010 to December 2011. RCA was performed according to an adaptation of Mehtas' protocol.

**Results:** Patients were 61±20 y, 55.6% male, 67% on vasopressors and none on mechanical ventilation. Six had hematologic diseases (leukemia or lymphoma) and 2 solid tumors (kidney cancer and hepatocellular carcinoma). Venous access was temporary triple lumen catheter (11 Fr). Blood flow was 180 (150 -180) ml/min, calcium cloride flow was 25ml/h (500mg/h), dialysis dose was 2000 ml/h and citrate dose was 21.5 (14.6 – 24.4) mmol/h. Laboratory tests at dialysis initiation were: uric acid (UA) 14.7 (10.5 – 20.6) mg/dL; phosphate (P) 7.25 (4.0 – 8.8) mg/dL; creatinine 5.3 (3.5 – 6.9) mg/dL; urea 166 (140 – 216 mg/dL); K 3.9 (3.6 – 4.7) mEq/L; bicarbonate (Bic) 19.4 (18.5 - 23) mEq/L; Cai 4.4 (4.0 – 4.7) mg/dL; lactic dehydrogenase 1107 (1012 – 1876) U/L. Laboratory tests after 24h of CVVHD were P 4.3 (3.7 – 5.8) mg/dL; Bic 23 (21.9 - 29.3) mEq/L. UA after 48 h of CVVHD was 3.7 (2.4 - 4.5) mg/dL. The Cai during CVVHD was maintained at 4.40 (4.1 – 4.9/minimum of 3.7 mg/dL). Low Ca (< 4.0 mg/dL) was observed in 66% of all measured Cai, but no patient presented related complications such as seizure or cardiac arrhythmias.

**Conclusions:** CVVHD with RCA was an efficient and safe dialysis modality for TLS-induced AKI.

## PUB159

**Adjusting Effective Replacement Fluid Sodium Level in Continuous Hemofiltration**
Carl P. Walther, Amber S. Podoll, Kevin W. Finkel. *Div of Renal Diseases & Hypertension, UTHealth Science Center at Houston, Houston, TX.*

**Background:** Management of dysnatremic patients with renal replacement therapy can be perilous because of rapid sodium correction if standard therapy fluids are used. We describe a means whereby patients receive CVVH with standard replacement fluid, and standard hypo- or hyperosmolar fluids are infused into the patient, either post-filter or at a separate venous access site, to adjust the effective replacement fluid sodium concentration.

**Methods:** A model was developed for calculating the "effective" sodium concentration of the replacement fluid in CVVH as the mean of the sodium concentrations of the input fluids, weighted for fluid rate. [$Na_{eff}$] represents desired effective replacement fluid sodium concentration, [$Na_R$] is the sodium concentration in the standard replacement fluid (usually 140 mEq/L), [$Na_A$] is the sodium concentration in the "adjustment" fluid, $Q_R$ is the standard replacement fluid rate, and $Q_A$ is the rate of "adjustment" fluid. [$Na_{eff}$] = ( [$Na_R$] x [$Q_R$] + [$Na_A$] x [$Q_A$] ) / $Q_R$ + $Q_A$. The equation can then be solved for the "adjustment" fluid rate: $Q_A = Q_R \times \{([Na_R] - [Na_{eff}]) / ([Na_{eff}] - [Na_A])\}$.

**Results:** By inputting values for the desired "effective" replacement sodium concentration, the replacement fluid flow rate, and the sodium concentration of the adjustment fluid used, the flow rate of the adjustment fluid is determined. As an example, the table below shows the calculated adjustment fluid rates for various desired effective sodium concentrations and CVVH replacement fluid rates where the adjustment fluid is 5% dextrose in water.

| Replacement fluid rate (ml/hr) | | 500 | 1000 | 2000 | 3000 | 5000 |
|---|---|---|---|---|---|---|
| | Effective Na concentration (mEq/L) | | | | | |
| 5% Dextrose infusion rate (ml/hr) | 100 | 200 | 400 | 800 | 1200 | 2000 |
| | 110 | 136 | 273 | 545 | 818 | 1364 |
| | 120 | 83 | 167 | 333 | 500 | 833 |
| | 130 | 38 | 77 | 154 | 231 | 385 |

**Conclusions:** We propose that using standard CVVH replacement fluid, and standard additional "adjustment" intravenous fluids (e.g., 5% Dextrose in water, 3% saline), the effective sodium concentration for CVVH can be easily adjusted to avoid excessive correction in dysnatremic patients.

## PUB160

### Metformin Associated Lactic Acidosis (MALA): A Long Term Single Center Experience

Andrea Angioi, Antonello Pani. *AOB Cagliari.*

**Background:** Metformin associated lactic acidosis (MALA) is a well-known side effect of Biguanides and in 13 years we observed an exponential increase in hospitalizations. Aim: investigate about the incidence in our area, the underlying causes, the survival in the short and long term.

**Methods:** We conducted a retrospective analysis retrieving 22 patients (pts) with MALA and acute renal failure admitted from Jan 2000 to Dec 2012. Inclusion criteria: type II diabetes, metformin intake, lactic acidosis (lactate≥5 mmol/L). Treatment: SLED hemodialysis(HD) with HCO3- buffer, based on lactate and electrolytes. In order to weigh the role of comorbid factors, we calculated a MALA risk score (MRS) to find relationships with mortality and survival curve dividing a low (MRS≤2-Gr.A) from a high risk group (MRS≥3-Gr.B). We followed them for a mean of 20.7 months; all discontinued the metformin. Then we obtained the MALA incidence in our area.

**Results:** Selected pts (M:F 1.4:1; mean age 67±9 yrs) showed: acute on chronic renal failure(59.1%); dehydration(86.4%); SIRS(50%); sepsis(27%); renal stones(13.6%); infusion of iodinated contrast(4.5%). Elevation of sCr(mean: 8.4±2.7mg/dL), BUN(mean: 104 ± 49.1 mg/dL), K+(mean: 6.0 ± 1.5 mEq/L), low pH(median: 7.06 ± 0.19) and serum lactate(median: 13.4 ± 6.2 mEq/L) were demonstrated at admission. Mortality was 22.7% after the 1st HD(100% of deaths), similar in both risk groups (2/5 in group B).

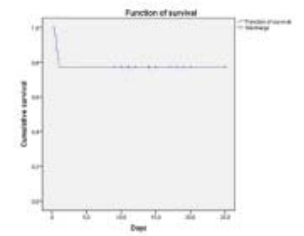

Figure 1A: Kaplan-Meier survival curve (admission – 25 days) of MALA patients. During the follow-up (mean 20.7 months), none of the patients who survived have experienced new episodes of lactic acidosis after discontinuing the drug.

Figure 1B: The MALA risk score: every shade of blue corresponds to a score, from +1 (light) to +8 (dark). Sepsis was considered as a SIRS (+1) plus an additional +1 score point. Red indicate deceased patients. CKD: Chronic Kidney Disease; SIRS: Systemic Inflammatory Response Syndrome

We found no absolute contraindications on drug use but none of pts was informed about the side effects. At follow-up, no episodes of lactic acidosis were observed. Incidence: lower=1.1/10.000(2000); higher=8.1/10.000 users(2010), especially in cold months (Jan-Mar).

**Conclusions:** Mortality(22.7%) was not related with the severity of the score. The lack in information of the patient facilitated the most of cases. The current spreading of MALA could be explained by renewed confidence in the drug, that is safe when properly prescribed.

## PUB161

### Multipass Hemodialysis (MPHD) – A Flexible Alternative in the ICU

James G. Heaf,[1] Mette K.M. Axelsen,[2] Robert Smith Pedersen.[3] *[1]Dept of Nephrology B, Copenhagen Univ Hospital at Herlev, Herlev, Denmark; [2]Institute of Public Health, Aarhus Univ Hospital, Aarhus, Denmark; [3]Flexdialysis A/S, Rungsted, Denmark.*

**Background:** Dialysis treatment of acute renal injury (AKI) varies between conventional HD for 4 hours to more gentle continuous renal replacement therapy (CRRT). We assessed available data to calculate whether MPHD, a batch system where the dialysate is recirculated, is a valid alternative.

**Methods:** Ten stable HD patients were dialyzed for 8 hours. The dialysate volume was 50% of the calculated water volume and the water flow 500 ml/min. Dialysate tests and blood tests before and after the filter, were taken at start and every hour thereafter. Dialysate volume and ultrafiltration was measured continuously.

**Results:** The initial S-Urea was 20.5 ± 7.6 mmol/l. Minimal S-Urea levels of 13.0 ± 4.7 mmol/l occurred after 5 hours, and thereafter rose to 14.0 ± 4.8 mmol/l. A total of 316 ± 131 mmol urea was eliminated. The dialysate volume was 22.9 ± 4.8 liter. The rise in S-Urea from 5 to 8 hours was 1 mmol/l corresponding to 0.33 mmol/hour. If MPHD had been used for 24 timer (CRRT), assuming constant urea generation, s-urea would have risen to 14 + (16 x 0.33) = 19.3 mmol/l. Assuming a terminal dialysate urea concentration of 19 mmol/l, a total of 435 mmol/ day can be removed. In cases of extreme hyperkalemia, e.g. rhabdomyolysis, a water flow of 500-800 ml/min and blood flow of 300-350 ml/min, with a dialysate potassium concentration of zero, is recommended. This would rapidly permit the removal of approximately 100 mmol of potassium. Continuing potassium problems would require new dialysate.

**Conclusions:** MPHD can be used both as CRRT and for intensive toxin elimination, with a very low water consumption. The principle is also applicable to areas where sustained low-efficiency daily dialysis (SLEDD) is used. Thus MPHD is not a low-efficiency system. This has logistical advantages.

## PUB162

### Comparison of 15% and 4% Citrate Anticoagulation in Plasma Exchange

Manja Antonic, Jadranka Buturovic-Ponikvar, Jakob Gubensek, Rafael Ponikvar. *Dept of Nephrology, Univ Medical Centre, Ljubljana, Slovenia.*

**Background:** To reduce infusion volume we introduced 15% citrate solution and compared its (micro)anticoagulant effect with 4% citrate solution in plasma exchange (PE).

**Methods:** In 18 patients, PE was performed using 4% or 15% trisodium citrate. Anticoagulant effect was evaluated by postfilter ionized calcium (iCa) (target range 0.2-0.4 mmol/l), postfilter hourglass clotting time and visually by assessing circuit after the procedure (on a 5-excellent anticoagulation to 1-total clotting scale). Sieving coefficient (SC) for immunoglobulin G was measured at the start and at the end of all procedures; the reduction of SC at the end was indicative of microanticoagulation failure at plasmafilter.

**Results:** 26 PEs were performed. Postfilter iCa was in a target range in both groups and was significantly lower in the 15% citrate group (0.37±0.02 vs. 0.4±0.02 mmol/l, p<0.05). The mean hourglass clotting time was similar (19±5 min in 15% citrate group vs. 16±2.3 min, p=0.22). Visual assessment showed excellent anticoagulation at plasmafilter and arterial bubble trap (score 4.9±0.3 in both groups) and almost excellent at venous bubble trap (4.6±0.8 and 4.7±0.6). On average, SC did not change significantly during the procedure in 15% citrate group (0.93±0.31 vs. 0.99±0.21, p=0.52) or in 4% citrate group (0.86±0.26 vs. 1.00±0.2, p=0.19). We observed a decrease in SC during 36% of procedures in 15% citrate group and during 50% of procedures in 4% citrate group (p=0.46). The infused volume of citrate per procedure was significantly lower in 15% citrate group (170±26 ml vs. 530±71 ml, p<0.001). No side effects were detected in either group.

**Conclusions:** 15% citrate showed similarly good anticoagulation as 4% citrate and allowed reduction of infused volume, which can be important in volume overloaded patients needing PE.

## PUB163

### Early Dialysis Initiation Based on Acute Kidney Injury Network Criteria in Critically Ill Asian Patients: A Prospective Cohort

Cynthia Ciwei Lim, Chieh-suai Tan, Manish Kaushik, Han Khim Tan. *Dept of Renal Medicine, Singapore General Hospital.*

**Background:** To compare patient mortality in intensive care unit (ICU) patients with acute kidney injury (AKI) and renal replacement therapy (RRT) initiated based on modified Acute Kidney Network (AKIN) creatinine and urine output criteria.

**Methods:** This was a single-center, prospective cohort study of medical and surgical ICU patients referred for AKI over 22 months. Indications for RRT were classified as Group A: "absolute" indications including serum potassium ≥6.0 mmol/L, serum urea ≥30 mmol/L, arterial pH <7.2, serum bicarbonate <10 mmol/L, acute pulmonary edema, acute uremic encephalopathy or pericarditis; Group B: modified AKIN stage 3 without "absolute" indications; Group C: AKIN Stages 1 or 2 without "absolute" indications. Demographic, clinical and biochemical data were collected prospectively from patient medical records. Patients with incomplete baseline data were excluded.

**Results:** There were 169 patients (mean age 59.2 ± 17.1 years; male 63.9%; diabetes mellitus 33.7%; hypertension 53.8%; ischemic heart disease 21.3%; medical ICU 72.2%; mean APACHE score 23.8 ± 6.0). Main AKI causes were sepsis (63.9%) and ischemia (34.9%). RRT was initiated in 121 patients. Complete data on RRT indications were available in 83 patients: Group A (n=26), B (n=26) and C (n=31). Those with RRT initiated in absence

of "absolute" indications were examined. Comparing Group B vs. C: baseline demographics and comorbidities were similar. There were no significant differences in premorbid MDRD eGFR (p=0.36); time from ICU admission to RRT initiation (p=0.51); CRRT modality (p=0.08); average CRRT effluent flow rate (p=0.23). There were no differences in ICU mortality (33.3% vs. 33.3%, p=0.85) or in-hospital mortality (35.7% vs. 28.6%, p=0.25).

**Conclusions:** In the absence of "absolute" indications, earlier RRT initiation based on AKIN criteria did not improve survival in critically ill patients. Controlled trials with well-defined dialysis criteria, including novel biomarkers, are required for further evaluation of optimal RRT timing.

## PUB164

**Predictors of Mortality in Patients Treated with Continuous Veno-Venous Hemodialysis** Tanush Gupta,[1] Sahil Agrawal,[1] Jalaj Garg,[1] Nikhil Agrawal,[1] Savneek S. Chugh,[1] Dipak Chandy.[2] *[1]Internal Medicine, New York Medical College; [2]Pulmonary and Critical Care Medicine, New York Medical College.*

**Background:** Continuous Veno-Venous Hemodialysis (CVVHD) is a mode of renal replacement therapy utilized in critically ill patients when intermittent hemodialysis is contraindicated due to hemodynamic instability. The purpose of our study was to determine predictors of 7-day and in-hospital mortality in patients treated with CVVHD.

**Methods:** Study cohort included 60 consecutive adult patients (age≥18 years) requiring CVVHD in our Medical Intensive Care Unit (MICU). Acute Physiology and Chronic Health Evaluation II (APACHE II) score was calculated at the time of MICU admission. Primary outcome of our study was in-hospital mortality.

**Results:** The mean age of our study population (65% males, 35% females) was 60.7±13.7 years. The mean APACHE II score was 23.6±6.6 with mean time to initiate CVVHD being 9.2±6.6 hours. Mean duration of CVVHD in our study cohort was 7.2±5.7 days. 77% patients were started on CVVHD due to Acute Kidney Injury while remaining 23% had pre-existing end stage renal disease. Only 17.39% patients eventually recovered their renal function. The 7-day mortality in our analysis was 28.3% while in-hospital mortality was 71.7%. In unadjusted analysis, duration of CVVHD (OR 0.70, p = 0.004) and vasopressor support (OR 2.18, p 0.01) were found to be predictors of 7-day mortality. However, only duration of CVVHD (OR 0.63, p 0.007) predicted mortality in multimodel regression analysis. Similarly, recovery of renal function (OR 0.03, p 0.003) and APACHE II score (OR 1.12, p 0.03) were found to be predictors of inpatient mortality in unadjusted analysis. But, only recovery of renal function (OR 0.01, p 0.001) was associated with decreased inpatient mortality in multimodel regression analysis. Interestingly, time to initiate CVVHD did not predict both 7-day (OR 1.04, p=0.32) and in-hospital mortality (OR 0.99, p=0.77).

**Conclusions:** Duration of CVVHD and recovery of renal function were found to be predictors of 7-day and in-hospital mortality in critically ill patients respectively. Time to initiation of CVVHD had no association with mortality.

## PUB165

**AKI Requiring Dialysis: Shift CVVHD Technique Dose Results** Luis A. Concepcion. *Medicine, Texas A&M Healthscience Center Scott&White Hospital, Temple, TX.*

**Background:** The treatment of AKI requiring dialysis is controversial regarding the modality and dose.

**Methods:** Analysis of 18 month cohort of AKI patients treated with shift CVVHD(Nx Stage 8 hours 40L bicarbonate based dialysate per session)and conventional HD(4-6h Fresenius 4008Bicarbonate) demographics, laboratory data and survival obtained from the EMR, technical and monitoring details from the dialysis run sheets, pre/post BUN,KT/V,Urea reduction (URR), CVVHD dose (ml/kg/hr),standardized KT/V and EKR(equivalent renal clearance)per standard methods. Data as mean and standard deviation.

**Results:** 166 patients with AKI requiring dialysis (37.3% sepsis, 24% CV surgery, 38.7% other) Mortality 43.9%(48.3%sepsis 57.5% CV surgery 31.25% other) 8.31 (9.1) days in dialysis received 6.06(6.05)dialysis, median of 23 days in the hospital. 800 treatments analyzed.91.9%of treatments done in the ICU,78.4% were CVVHD 21.6%conventional dialysis. Age 56.1(17.4) years, weight 95.2(39.4)kg, dialyzed for 6.9(1.6) hours QB300 (40) ml/min ,dialysate K 2.83(0.5) mEq/L,Venous pressure 193(46.9)mmHg,Heparin 596.2 (1267) units,hypotension/hour 0.18(0.33)MAP predialysis 83.2(16.4) mmHg MAP post 83.5(15.7) mmHg,UF 2.6(1.7)L,UF/hour 394.6(274)ml/h ,per sesionURR 47.6 (13.2) % ,Kt/V 0.88(0.36) ,CVVHD dose 59.4(20.9)ml/kg/h , standarized KT/V 3.5(0.8), EKR 9.8(3.6)ml/min. Non survivors (p<0.05) : Older (59 vs 54.1y)longer dialysis times(7.2vs6.7h)lower MAP pre dialysis (77.9vs86.6mmHg) less UF per treatment (3.1vs3.4L) lower pre dialysis BUN(64vs 70 mg/dl)lower creatinine(3.4 vs 4.6mg/dl) higher CVVHD dose (63 vs 56 ml/kg/h) lower EKR (9.2vs10.1ml/min)Good correlation between kt/v,dose CVVHD,standardized KT/V and EKR .Inverse correlation between weight and kt/v ,dose of CVVHD standardized KT/V and EKR.Heavier patients(>95kg) have a better survival despite receive a lower dose of of CVVHD.

**Conclusions:** Shift CVVHD is a method of RRT that can be used for AKI requiring dialysis,the survival is similar to other methods. The dose of dialysis as measured (URR kt/v EKR) was lower in non survivors,dose of CVVHD(ml/kg/min)was higher on nonsurvivors suggesting that other factors affect the survival outcome (weight).

## PUB166

**Renal Replacement Therapy in the Setting of Orthotopic Liver Transplant – A Retrospective Descriptive Study** Adetokunbo A. Taiwo, Amishi S. Desai, Jay L. Koyner. *Section of Nephrology, Univ of Chicago, Chicago, IL.*

**Background:** Electrolyte and acid-base disturbances are common during the intraoperative course of orthotopic liver transplantation (OLT) and are magnified in those with chronic kidney disease (CKD) or acute kidney injury (AKI). Some have argued that utilizing intraoperative continuous renal replacement therapy (CRRT) attenuates these fluctuations and improves patient outcomes.

**Methods:** We performed a retrospective, chart review on all OLT recipients receiving intraoperative CRRT between Sept. 1, 2010 and May 15, 2012 at the University of Chicago. Electrolyte and pH data were collected from different time points during OLT [the start of surgery (time 0), 25%, 50%, and 75% of the time into the surgery (time 25,50,75)], pre-op and post-op. Data was analyzed using paired t-test.

**Results:** Data from 11 OLT recipients was available for analysis). Patients were predominantly male (9, 82%), mean age was 51.5 years (range 38-70). Indication for CRRT was as follows: 5 AKI (45.4%), 2 AKI on CKD (18.2%), 2 hyperkalemia (18.2%), 1 volume overload (9.1%) and 1 ESRD (9.1%). Type 1 hepatorenal syndrome was diagnosed in 3 (27.3%) patients prior to OLT. Nine of eleven (81.8%) patients died prior to hospital discharge. With the exception of comparisons between sodium at time 0 and time 75 (P= 0.019), sodium at time 0 and post-op (P= 0.001) and ionized calcium at time 0 and time 25 (P=0.016), there were no statistically significant difference between the other electrolyte and pH values measured at the different time points. Table 1 – Mean solute and pH values (+/- standard deviation).

| | T0 | T25 | T50 | T75 | Pre-Op | Post-OP |
|---|---|---|---|---|---|---|
| Sodium | 139.27 (3.66) | 140.0 (4.49) | 140.64 (3.04) | 142.09 (4.25) | 138.82 (6.37) | 145.18 (4.26) |
| Potassium | 4.55 (0.83) | 4.80 (0.89) | 4.32 (0.57) | 3.98 (0.96) | 4.28 (0.51) | 4.07 (0.80) |
| Bicarb | 24.21 (2.94) | 22.65 (3.55) | 24.34 (5.01) | 26.0 (5.07) | 24.73 (4.29) | 25.82 (5.86) |
| Ionized Ca | 1.08 (0.09) | 0.89 (0.23) | 1.03 (0.18) | 1.10 (0.13) | | |
| pH | 7.36 (0.07) | 7.34 (0.86) | 7.32 (0.091) | 7.391 (0.06) | | 7.47 (0.07) |

**Conclusions:** Randomized control trials will be necessary to elucidate whether CRRT has a defined role intra-operatively in the outcomes of OLT.

## PUB167

**Improving AVF Rate: Effect on Hemodialysis Quality** Ayman Karkar,[1] Ahmed Chaballout,[2] Mohammed Abdelrahman,[1] Maher Haj ibrahim,[1] Mona Al Shubaili.[1] *[1]Kanoo Kidney Center, Dammam Medical Complex, 1, Dammam, Saudi Arabia; [2]Kidney Transplantation Dept, Riyadh, Saudi Arabia.*

**Background:** Vascular access (VA) is the life-line for patients on regular hemodialysis (HD), and the type of VA is associated with patient outcome. Tunneled catheters are associated with increased risk of luminal thrombosis, infection, hospitalization, and high cost. The native arterio-venous fistula (AVF) remains the best available VA option. The high catheter usage rate, increased incidence and prevalence of catheter-associated complications and the progressive increase in number of our ESRD patients in need for HD prompted us to follow the USA "Fistula First Initiative". Our aim was to avoid or reduce the rate of catheter insertion and improve the rate of AVF use, and study that effect on quality of dialysis and patient's outcome.

**Methods:** A vascular access program has been established in collaboration with an enthusiastic and professional vascular surgery team to manage 358 patients who have been on regular HD treatment for a period ranging from 1 to 252 months. The mean ± SD age of patients was 52±15 years with 62% male patients.

**Results:** Over a period of 2 years, 403 procedures were performed. These include 293 AVF and 56 AVG. Other procedures include 35 permanent catheter insertion, 8 AVF aneurysmectomy, removal of 6 AVG, embolectomy of 3 AVG, excision of 1 AVG lymphocele and ligation of 1 AVF. This program resulted in an increase in AVF rate from 35% to 82%, reduction in catheter rate from 62% down to 10%, reduction in infection rate from 6.6% to 0.6%, reduction in VA clotting from 5.1% to 1% and an increase in average blood flow rate from 214±32 to 298±37 ml/min (p<0.01). These results have been associated with improved average single pool Kt/V from 0.88±0.19 up to 1.28±0.2 (p<0.01), increased hemoglobin from 9.2±1.2 to 10.9±0.9 g/dl (p<0.01), improved serum albumin from 3.2±0.5 to 3.7±0.4 g/dl (p<0.05), reduction in administered erythropoietin dose by 16% and a significant drop in hospitalization rate from 6.1% down to 3.8%.

**Conclusions:** In conclusion, these results confirm the great benefit of AVF on quality of HD and patient outcome, and clearly affirm that AVF should always come first.

## PUB168

**Rates of Vessel Mapping prior to Arteriovenous Fistula Placement Vary across the Mid-Atlantic United States** Janet R. Lynch,[1] W.G. Schenk,[2] Kim Deaver,[2] Ryan D. Evans.[3] *[1]Mid-Atlantic Renal Coalition, Richmond, VA; [2]Univ of Virginia; [3]Valley Nephrology Associates.*

**Background:** The Fistula First Breakthrough Initiative (FFBI) is a population-based intervention by the Centers for Medicare & Medicaid Services to increase appropriate arteriovenous fistula (AVF) use. Early referral for surgical evaluation and timely placement of a fistula, including prior vessel mapping, is encouraged. This study examines geographic variation in vessel mapping rates among Medicare beneficiaries. The relationship of vessel mapping to subsequent prevalent AVF use is examined in a sub-group of hemodialysis patients >=66 years treated by large dialysis organizations.

**Methods:** Using Medicare Part B claims for Maryland, Virginia, West Virginia and Washington, D.C., we identified AVF placements in 2011, matched these with prior vessel mapping claims in 2010 and 2011, and calculated rates of vessel mapping in hospital referral regions (HRRs) defined by the Dartmouth Atlas of Health Care. To examine the relationship between vessel mapping and prevalent AVF use, we matched claims with April 2012 FFBI prevalent patient-level vascular access data from large dialysis organizations. These linked data met the following criteria: (1) 2011 claim for AVF placement, (2) matched with FFBI prevalent access record, (3) patient >= 66 years of age at access claim, and (4) patient started dialysis in 2011. Chi-square was used to examine association.

**Results:** 50.4% (1,990/3,948) of AVF claims were preceded by vessel mapping claims. Across 17 HRRs within our geographic boundaries, the range was 23.3% to 85.8% for all patients (n=3,948) and 27.0% to 84.1% for patients >= 66 years (n=2,206). Four hundred eighty six patients met all criteria for examination of association between prior vessel mapping and AVF use. Of these, 71.4% were using an AVF in April 2012. Those with prior vessel mapping (n=260) had 74.6% AVF use and those with no prior vessel mapping (n=226) had 67.7% AVF use (p<0.1).

**Conclusions:** There may be an opportunity to improve fistula prevalence both by increasing rates of pre-operative vessel mapping as well as by reducing geographic variation in mapping.

## PUB169

**Use of Gentamycin/Citrate Lock Solution Decreases Catheter Related Bacteremia** Grant Springman, John Hergenrother. *The Christ Hospital, Cincinnati, OH.*

**Background:** Infection remains a leading cause of morbidity and mortality in hemodialysis patients. Those particularly susceptible are accessed by tunneled hemodialysis catheters, which comprise a majority of the dialysis population. Antimicrobial lock solutions have previously demonstrated decreases in catheter related bacteremia (CRB) rates. An investigation of catheter related bacteremia rates with use of a gentamicin/citrate catheter locking solution (GCLS) was compared to the standard heparin catheter locking solution.

**Methods:** A prospective review evaluating all prevalent patients using a tunneled catheter for hemodialysis access was performed in an urban, tertiary care, hospital-based, outpatient hemodialysis unit from July 1 2008 to December 31 2008. Patients were assigned to the control group of the standard 2000 units/ml of heparin or the study group of a 5mg/dl gentamicin/4% trisodium citrate based on their dialysis schedule. Overall 53 patients were evaluated, 34 in the control group and 19 in the GCLS group. CRB was determined by positive blood cultures drawn on patients based on clinical suspicion for infection.

**Results:** Results demonstrated a CRB rate of 5.3% (1/19) in the experimental group compared to 26% (9/34) in the standard group, an absolute risk reduction of 21% ($p < 0.05$). Therefore, the GCLS was implemented for all patients treated in the hemodialysis unit. Data collection continued from 2009-2011, and CRB rates continued at low rates significantly less than historical controls. Rates decreased from 2.1 to 0.9 to 0.7 infections per 100 patient months of treatment, from 2009-2011 respectively.

**Conclusions:** Gentamicin/Citrate is an effective antimicrobial lock solution in tunneled dialysis catheters, significantly decreasing CRB rates.

## PUB170

**Tunneled Dialysis Catheter Infection and Troponin-I Levels in End-Stage Renal Disease Patients** Kamel A. Gharaibeh,[1] Mihaly B. Tapolyai,[2] Eva Csongradi,[1] Tibor Fulop.[1] *[1]Dept of Medicine, Univ of Mississippi, Jackson, MS; [2]Dept of Medicine, Semmelweis Univ.*

**Background:** Elevated troponin-I levels in end-stage renal disease (ESRD) patients on dialysis are commonly attributed to ESRD itself. Our hypothesis was that infection of tunneled hemodialysis catheters (TDC) may be associated with subtle troponin-I elevations.

**Methods:** We performed additional data analysis on our consecutive 3-year experience (01/2007 - 12/2009) with bedside TDC removal at the University of Mississippi Renal Fellowship Program. Data was already collected for multiple patients and procedure-related variables. Data was analyzed with SPSS 19. and reported with means ±SD or medians 25-75% IQR for descriptive data; Pearson's correlation and independent-samples T test was utilized for statistical comparisons. The study was reviewed and approved by the University of Mississippi Human Research Office.

**Results:** Indication at the time of removal included bacteremia, fever or clinical sepsis with hemodynamic instability or respiratory failure. Of the 55 TDC removed, 63.6% took place on general floor, 12.7% in Emergency Department and 16.3% in Intensive Care Units, with a median time of 3 days [IQR 1-13] elapsed since admission or TDC placement. Four (7.2%) patients were hypothermic, 33 (60%) febrile or subfebrile (T>37 C°) at time of removal; 7 (12.7%) on vasoactive pressors. Peak C-reactive protein (available in 63.6% of cohort) measured 12.9±8.4 mg/dl (nl<0.49); mean troponin-I (34% available) was 0.534 ng/ml [IQR 0.03-0.9] (nl<0.034) and they did not correlate with each other. Troponin-I had no association with temperature, systolic and diastolic BP or clinical sepsis. However, troponin-I, as a continuous variable had a strong trend of association with proven bacteremia (p=0.075); furthermore, the association of troponin-I as a bivariate variable (normal/abnormal) with bacteremia has reach significance (Pearson's chi-square 0.049).

**Conclusions:** Our results strongly suggest that some of the elevated troponin-I levels in ESRD patients may be attributed to TDC-induced bacteremia. Additional investigations are warranted on this subject for definitive conclusion.

## PUB171

**Comparison of Survival and Hospitalization of Hemodialysis Patients Who Started Hemodialysis via Tunnelled or Non-Tunnelled Central Venous Catheter** Ji In Park,[1] Jung Pyo Lee,[2] Ji-Young Choi,[3] Yong-Lim Kim,[3] Yun Kyu Oh,[2] Dong Ki Kim,[1] Yon Su Kim,[1] Chun Soo Lim.[2] *[1]Seoul National Univ College of Medicine; [2]Seoul National Univ Boramae Medical Center; [3]Kyungpook National Univ Hospital.*

**Background:** Some of end-stage renal disease (ESRD) patients inevitably start dialysis via central venous catheter (CVC). Tunnelled central venous catheter (TCVC) is well known to be superior to non-tunnelled central venous catheter (NTCVC) in terms of lower risk of infection and catheter failure. In this study, we investigated whether the difference in the use of these two different types of catheter shows difference in the survival and vascular access related hospitalization or not.

**Methods:** We enrolled newly diagnosed ESRD patients and collected the data prospectively from August 2008 to March 2013. Laboratory and clinical variables with the type of catheter were documented, and hosppitalization and mortality were recorded as the outcome events.

**Results:** Among 1770 patients, 810 patients started hemodialysis via CVC, 629 patients with TCVC and 181 with NTCVC. Hospitalization due to catheter-related infection were higher in NTCVC group (2.21%) than in TCVC group (0.47%) (p=0.048). TCVC group also showed significantly better survival rate than NTCVC. In the multivariate analysis adjusting for age, liver disease and congestive heart failure, the type of catheter was still significantly associated with survival (p=0.021).

**Conclusions:** The data demonstrate the TCVC has an association with the lower hospitalization rate due to catheter-related infection and has the higher survival rate than the NTCVC. TCVC should be firstly considered in the patients who start hemodialysis without functioning vascular access.

## PUB172

**Renal Outcomes in PICC Patients** Rita L. McGill, Tarik Noureldeen, Sushil Ratnaparkhe. *Div of Nephrology, Allegheny General Hospital, Pittsburgh, PA.*

**Background:** A 2012 quality-improvement study identified peripherally-inserted central catheters (PICC) in 85/375 (22.6%) of our inpatients.

**Methods:** The hospital data system was examined to identify renal outcomes in these patients over the next 365 days; external data was not sought. AKI events were defined by KDIGO criteria, with elevated serum creatinine for 3 days required. Outcomes were classified as: non-recovery with dialysis, recovery after dialysis, recovery/stabilization without dialysis, or indeterminate.

**Results:** At baseline, 7/85 PICC patients were in ESRD and 18/85 had acute kidney injury (AKI); 60/85 patients were at their CKD baseline or had estimated GFR>60 mL/min/1.73m2. At least one additional AKI was seen in 11/18 patients. 6/18 required dialysis for initial AKI and 1 for subsequent AKI; 3 of these recovered. 21/60 patients without AKI at baseline developed episodes of AKI over 12 months, 3 of which required permanent dialysis. Overall 39/78 (50%) non-ESRD patients had initial and/or subsequent AKI, and 10/78 (12.8%) required dialysis.

| | AKI at baseline | No AKI at baseline |
|---|---|---|
| N | 18 | 60 |
| Non-recovery with dialysis | 4 | 3 |
| Recovery after dialysis | 3 | 0 |
| Indeterminate; no dialysis* | 0 | 3 |
| Recovery/stabilization without dialysis | 11 | 15 |
| Never AKI | --- | 39 |

*patient lost to follow-up or early death. Among 39 patients with initial or subsequent AKI, recovery or stabilization with or without dialysis could be documented in 29 cases. Final serum creatinine was significantly higher than baseline for these patients, (0.95+/-0.30 vs. 1.73+/-0.84, P-value<0.0001 for paired t-test, 95% CI for difference: 0.48-1.09).

**Conclusions:** Inpatients requiring PICC have a 50% risk for AKI and a 12.8% rate of requiring dialysis within a 12-month time-frame, despite methodological potential for low ascertainment. PICC patients who sustain AKI are at risk for accelerated deterioration of renal function, even when dialysis does not occur. Given the negative impact of PICC placement upon future hemodialysis vascular access, it may be reasonable to place all PICC lines in dominant arms, even when advanced CKD is not present, especially in patients with AKI.

## PUB173

**Prospective Observation of Effect of Vascular Access Types on C Reactive Protein, ESR and Fibrinogen in 203 Hemodialysis Patients** Ebadur Rahman, Nader Mohamed Omran, Naveed Aslam, Raees Farhan Mushtaq, Ahmed Soliman, Seddeg Younis, Dujanah Hassan Mousa. *Nephrology, PSMMC, Riyadh, Saudi Arabia.*

**Background:** In this study effect of arteriovenous fistula (AVF) and Permanent hemodialysis catheters (PC) on common inflammatory markers were observed in patients without any local or systemic infection.

**Methods:** Out of 350 patients dialyzing in Prince Sultan military medical city (PSMMC) 200 patients were included in this study. Patients with arterivenous graft and who had documented local or systemic infection by repeated cultures were excluded from this study. The patients included in this study had monthly blood cultures. Total observation period was 180 days. The average of monthly C reactive protein( CRP), ESR and fibrinogen was taken for analysis. All patients were dialyzed with same dialyzer (Hemoflow FX8O)

and heparin was used as anticoagulant. Patients with Hemoglobin above 12 or bellow 10 gm/dl were also excluded. Hemodialysis mode was used for all patients. SAS version 9.3 software was used for the data analysis.

**Results:** Mean age of observed group was 59.49 years. 55% were dialyzing with fistula and the rest with PC. Mean Kt/v in these two groups were statistically insignificant. There was no statistical significance between the PC and AVF regarding ESR and CRP protein level (P 0.696). However fibrinogen level was significantly lower in PC group (p 0.0311 *).

**Conclusions:** In non infected patients, CRP and ESR are not affected by access types, if the patients are dialyzed by same dialyzer using same anticoagulant. Fibrinogen level is significantly lower in PC group.

## PUB174

### Presentation and Complications of Non-Thrombus-Related Fibrin Sheath Pulmonary Embolus following Tunnelled Dialysis Catheter Removal

Iain Moore, Mark Brady, Saeed Ahmed. *Renal Unit, City Hospitals Sunderland, Sunderland, United Kingdom.*

**Background:** We report an unusual complication of tunnelled dialysis catheter removal. Fibrin sheaths have a reported prevalence of 60-100% in association with tunnelled dialysis catheters. Fibrin sheath emboli have previously only been reported following line stripping, or in association with catheter related thrombus, whilst a prospective study has suggested that fibrin sheaths alone do not directly embolise following line removal.

**Methods:** A 25 year old male presented with advanced renal impairment of unknown cause. Dialysis was commenced via uncomplicated insertion of a right internal jugular tunnelled dialysis catheter. This remained his preferred choice of access whilst transplantation was pursued. After 9 months hemodialysis he presented with dialysis catheter sepsis. His line was removed without event. Temporary access was attempted via right internal jugular vein 24 hours later but failed; a temporary femoral dialysis catheter was inserted. Two days later he described left upper quadrant pain out of keeping with physical examination and observations. After several reviews, a computed tomography pulmonary angiogram (CTPA) was performed.

**Results:** CTPA demonstrated left sided pulmonary artery fibrin sheath embolus and no thrombus. Following involvement from the cardio-thoracic team he was managed conservatively and warfarinised. Within a week he reported new breathlessness. CTPA demonstrated unchanged sheath emboli, extended infarction and an expanded exudative pleural effusion. After a prolonged admission he recovered and was established on peritoneal dialysis.

**Conclusions:** Symptomatic non-thrombus-related fibrin sheath embolisation has not previously been reported. It is thought to be a rare complication; perhaps rarely diagnosed or clinically apparent. This episode may have been precipitated by access attempts at the site of recent removal. We recommend consideration be given to fibrin sheath embolisation in patients presenting with pleuritic chest pain, upper abdominal pain or new pleural effusions, after recent tunnelled dialysis catheter removal. A high index of suspicion should prevail if access attempts have been made at the recent removal site.

## PUB175

### Importance of Monitoring and Immediate Intervention for Vascular Access Optimization

Marco Mendes, Patricia Veigas, Fernanda Gomes, Ines Aires, Célia Gil, Patrícia Matias, Cristina Jorge, Manuel A. Ferreira. *Nephrology, Nephrocare Vila Franca de Xira, Lisboa, Portugal.*

**Background:** Programs of monitoring vascular access (VA), including angiographic and/or surgical intervention, have been performed in order to improve VA outcome. Our goal is to assess the impact of an immediate response from a vascular access center (VAC) on the VA of patients (pts) from a large hemodialysis center.

**Methods:** A retrospective analysis of the VA and their interventions in 2 periods (20 months each), before and after the implementation of an immediate response from VAC, was performed. Both populations were equivalent. 218 pts were included, with mean age (± SD) 67,2 ± 15,4 years, 50% female, 37,2% diabetics, with mean HD time of 61,5±58,4 months. Monthly determinations of VA flow (Qa) using the Blood Temperature Monitor-Fresenius Medical Care were performed. Indications for angiography were: A-V fistula (AVF)Qa < 200 ml/min; PTFE graft < 600 ml/min or a Qa drop > 50% in 2 consecutive months; significant high venous pressure (VP) and/or edema of VA limb and thrombosis of the VA.

**Results:** The results comparing Pre VAC with Post VAC are presented at Table 1.

| | Pre CAV | POS CAV | |
|---|---|---|---|
| Total average lengh of use of VA/AVF (years) | 2.76 (±3.85)/4.4 | 2.91 ( ±3.86)/4.1 | p>0.05 |
| VA in use | | | |
| Central venous catheter (CVC) (%) | 28.58 | 25.7 | |
| AVF (%) | 42.86 | 48.2 | |
| AV flow (Qa) (ml/min) | 1489.3 ( ±632.5) | 1164.7 ( ±448.4) | p<0.05 |
| Kt/v | 1.57 ( ±0.27) | 1.94 ( ± 0.35) | p<0.05 |
| Diagnostic angiography (%) | 0.82 | 2.22 | p>0.05 |
| Angiography without stent (%) | 13.47 | 24.76 | p>0.05 |
| Surgical review of the VA (%) | 18.37 | 26.98 | p>0.05 |
| Failure due to thrombosis (%) | 19.42 | 8.97 | p>0.05 |
| Hospitalization related to the VA (%) | 11.02 | 3.17 | p<0.05 |

**Conclusions:** Introduction of VAC was associated with decrease thrombosis rate (50%) and hospitalizations related to the AV (71%) at expenses of increased number of interventions. In the authors opinion, continuous monitoring of vascular access and a timely reference to the VAC is crucial for increasing AV longevity and reducing morbidity.

## PUB176

### Percutaneous Transluminal Angioplasty (PTA) for Dysfunctional, Non Maturing or Thrombosed AVF: A Local Experience

Silvia Mattei,[1] Gianluca Pignatelli,[2] Mattia Corradini,[1] Alfredo Stefani,[1] Achiropita Bovino,[1] Augusto Vaglio,[3] Francesco Iannuzzella,[1] Sonia Pasquali.[1] *[1]Nephrology and Dialysis Unit, Arcispedale Santa Maria Nuova, Reggio Emilia, Italy; [2]Interventional Cardiology, Arcispedale Santa Maria Nuova, Reggio Emilia, Italy; [3]Nephrology and Dialysis Unit, Univeristà Degli Studi, Parma, Italy.*

**Background:** The arteriovenous fistula (AVF) is considered the vascular access of choice and stenoses are the major cause of its dysfunction. Our study retrospectively evaluates the clinical course and treatment outcome of performing PTA for dysfunctional, non maturing or thrombosed AVF in our experience.

**Methods:** Between Jan. 2008 and Dec. 2012, 101 PTA procedures were performed on 73 patients (49 men; median age 67 years, range: 27-89) with dysfunctional (63%), non maturing (7%) or thrombosed (30%) AVF. 63 wrist radiocefalic [25 with latero-terminal (L-T), 38 with termino-terminal (T-T) anastomosis] and 10 elbow fistulae with median age of 12 months (range 1 month-13 years) were treated.

**Results:** In radiocefalic L-T AVF, stenoses were located in the iuxta-anastomotic segment in 11 patients, in anastomotic area in 5, in the venous outflow in 5, in central vein in 1, in multiple areas in 3; in radiocefalic T-T AVF the distribution was similar (iuxta-anastomotic 47%, anastomotic 21%, outflow vein 16%, central vein 5%, multiple areas (11%). In elbow fistulae the stenoses occurred in the outflow vein in 7 patients (70%) and around the anastomotic region in 3 patients (30%). Angiografic and clinical success was 88%; 17 patients required 28 repeat PTA for recurrent stenosis/thrombosis. 8 patients had small extravasation that required no further treatment, 1 patient had microembolism in second interdigital artery. Excluding initial failure, mean primary and secondary patency for AVF were 34.3 months (95% CI 26.4-42.1) and 41.1 months (95% CI 37.9-52.4); the primary and secondary cumulative patency rates at 12 months were 59% and 84% respectively.

**Conclusions:** PTA can effectively salvage dysfunctional, non maturing or thrombosed AVF. Since repeat angioplasty is often necessary to maintain function, careful surveillance is necessary.

## PUB177

### Doppler Window; Vascular Access Ultrasound Development Platform

William Weitzel,[1,2] Leo Koziol,[1] Joseph L. Bull,[1] John J. Pitre,[1] Alan Vollmer,[1] Grant H. Kruger.[1] *[1]Univ of Michigan, Ann Arbor, MI; [2]VA Medical Center, Ann Arbor, MI.*

**Background:** Extensive research using ultrasound has sought to improve vascular access care through pre-operative evaluation, post-operative monitoring, and dialysis access surveillance. With the vision of low-cost high-performance ultrasound becoming ubiquitous, we designed, fabricated, and tested a flexibly reconfigurable vascular access ultrasound development platform to further develop conventional Doppler and B-mode as well as advanced capabilities such as vascular elasticity imaging.

**Methods: Figure 1a** shows the transducer with magnetic drive sub-assemblies. The system includes transmit and receive circuits for signal capture, and wireless and USB communications hardware. A MIPS microcontroller (MCU) controls the high-level functions of the device, while complex programmable logic device (CPLDs) handle low-level sequencing of the ultrasound sub-systems. The MCU also controls the magnetic drive board, providing the sensor and feedback control for 2D scanning.

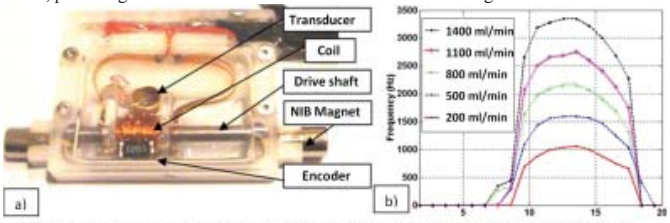

**Figure 1:** a) Vascular access ultrasound probe prototype, and b) gated-pulse wave Doppler flow measurements across flow phantom vessel using blood mimicking fluid.

**Results:** Velocity based measurements using the flow profile were obtained from our device in gated PW Doppler data acquisition mode; and PW flow estimation agreed with phantom flow for 4mm, 6mm, 8mm vessels from 0 to 1500 ml/min with an $R^2$ of 0.93, 0.93, and 0.96 respectively. **Figure 1b** illustrates the measured Doppler frequencies as the sample gate is transitioned across the vessel diameter at flow rates of 200, 500, 800, 1100 and 1400 ml/min. The expected parabolic profile can clearly be seen as well as a monotonic increase in frequency as volume flow is increased. The impact of pulsatility on flow measurement and edge detection algorithms were also tested and validated.

**Conclusions:** After accomplishing current engineering objectives, we are preparing to perform a pilot clinical study to validate our prototype for vascular applications for hemodialysis patients.

**PUB178**

**Use of Cefuroxime in Treatment of Methicillin Sensitive *Staphylococcus aureus* in Haemodialysis Patient – A Single Centre Experience** Vijay Sundaram Thanaraj, Ajay Prabhakar Dhaygude. *Dept of Renal Medicine, Lancashire Teaching Hospital, Preston, Lancashire, United Kingdom.*

**Background:** Infection is one of the most common causes of mortality in haemodialysis patient especially in patients who dialyse via catheter. It is common practice to use Vancomycin in management of Methicillin sensitive *Staphylococcus aureus* (MSSA) infection because of the broad-spectrum cover and convenience of administration in haemodialysis patients. Flucloxacillin is an effective alternative but q.i.d. dosing poses compliance problem. Use of Vancomycin however is associated with number of limitations. The incidence of Vancomycin resistant Enterococcus is on the rise.It is less bactericidal compared with the cephalosporins and penicillins.Cefuroxime, a second generation Cephalosporin is effective against MSSA and offers advantage over Vancomycin as above.

**Methods:** We used intravenous Cefuroxime; 1.5 grams given at the end of each dialysis session for a period of four weeks in patients with MSSA infection in haemodialysis patients. Root cause analysis and appropriate investigations were done for all the patients with MSSA infection to exclude other potential sources of infection other than dialysis catheter. Repeat blood cultures and exit site swab were taken following treatment to exclude ongoing bacteraemia. Ten patients were diagnosed with MSSA infection between December 2009 to March 2013.

**Results:** None of the 10 patients, who were treated with Cefuroxime, relapsed following completion of the course of treatment. The mean follow up period was 398 days.

**Conclusions:** In this study Cefuroxime appears to be safe and effective alternative in management of MSSA infection in haemodialysis patients. First generation cephalosporin (cefazolin) has been used successfully, use of second generation cefuroxime has not been reported before. Although small number of patients were treated with cefuroxime, unlike cefazolin, we did not find any treatment failure and it may be superior to 1st generation cephalosporins. **Limitation:** Our study has small number of patients however we are proactive with 'fistula first' policy and incidence of catheter associated infections are very low in our centre. Further large studies are recommended.

**PUB179**

**The Research of Anatomic Relationships between the Internal Jugular Vein and the Common Carotid Artery under CT Scan** Yimin Zhang.[1] *[1]Div of Nephrology, The Sixth Hospital of Sun Yatsen Univ, Guangzhou, Guangdong, China; [2]Div of Nephrology, The Sixth Hospital of Sun Yatsen Univ, Guangzhou, Guangdong, China; [3]Div of Nephrology, The Sun Yatsen Memorial Hospital of Sun Yatsen Univ, Guangzhou, Guangdong, China.*

**Background:** Central venous cannulation through the internal jugular vein is necessary for the management of a variety of clinical conditions. The aim of this study was to investigate anatomic relationships between the internal jugular vein and the common carotid artery under CT enhancement scan at a different plane.

**Methods:** A total of 226 patients who were checked the neck by CT enhancement scan since January 2010 to July 2012.All patients were supine position and the heads were normotopia.To collect the anatomic relationships between the internal jugular vein and the common carotid artery at the high plane(the upper edge of the thyroid cartilage) and the median plane(the level of the cricoids cartilage)of all patients.The relationships were classified as anterior,anterolateral,anteromedial,posterior,posterolateral,posteromedial,medial,lateral or partially overlap,complete overlap,parallel.Categorical variables were presented as counts and were compared by the chi-squared test.

**Results:** There were 116 male patients(mean age was 52.7±13.9) and 110 female patients(mean age was 49.5±14.5). No patients showd the image with the internal jugular vein and the common carotid artery placed conversely.Two cases were anterior complete overlap on the lefe side(0.9%).At the high plane,the internal jugular veins were mainly posterior and posterolateral position(78.6%-83.9%),the relationships with the common carotid artery were mainly partially overlap(70.5%-71.4%). While at the median plane ,the internal jugular veins were mainly anterior and anterolateral position(72.3%,P=0.00 for both),the relationships with the common carotid artery were mainly parallel(56.2%-63.4%,P=0.00 for both).

**Conclusions:** The relationships between the internal jugular vein and the common carotid artery at the median plane had more proportion of parallel than at the high plane.

**PUB180**

**Turolidine Catheter Locking to Prevent Catheter Related Bloodstream Infections (CRBSI) in New Patients Undergoing Hemodialysis through Temporary Hemodialysis Catheter** Omer Sabir,[1] Nauman Tarif,[1] Rizwan Muhammad Sheikh,[2] Kashif Rafique,[1] Nabiha Rizvi.[1] *[1]Dept of Nephrology, Fatima Memorial Hospital, Lahore, Pakistan; [2]Dept of Nephrology, Hashmat Medical and Dental College, Gujrat, Pakistan.*

**Background:** Temporary dialysis catheter for as long as 4 weeks, is unfortunately the first hemodialysis access in majority of patients initiating HD. Many patients will continue HD with same catheter beyond even 4 weeks due to cost and lack of permanent access. Several Interdialytic catheter locking strategies have been devised to prevent catheter related blood stream infection (CRBSI). Taurolidine is a nontoxic broad-spectrum antimicrobial agent that can potentially eradicate CRBSI and has generted recent interest to prevent CRBSI.

**Methods:** Open labelled, randomized controlled study in incident 38 patients initiating HD with non cuffed temporary HD catheter.

**Results:** Final analysis of 36 patients revealed one patient in heparin group had symptoms strongly suggestive of CRBSI, however refused further work up. The point incidence rates of CRBSI was 2.7% or 1.1 per 1000 catheter days. 5 patients in taurolidne group and 4 in heparin group continued HD beyond 30 days till they were shifted to AVF, except one in taurolidne group who continued on the same catheter and died of CRBSI on 100th day.

**Conclusions:** Taurolidine 2% and heparin compared to heparin alone as catheter lock solution are similar in terms of incidence of CRBSI over 4 weeks. Catheter survival may be prolonged with taurolidine, due to possible effect on biofilm and antibacterial activity however this needs further study in temporary vascular access.

**PUB181**

**Vascular Access Types at the Initiation of Hemodialysis** Kashif Rafique, Omer Sabir, Nabiha Rizvi, Nauman Tarif. *Nephrology, Fatima Memorial Hospital, Pakistan.*

**Background:** Initial vascular access dictates the short and long term survival patterns of hemodialysis patterns. Permanent vascular access arteriovenous fistula (AVF) is not the first access in majority of our patients. To stress the need to follow the AVF first slogan among our physicians and patients we conducted this study.

**Methods:** Retrospective review of hemodialysis patients by chart review and patient interview was conducted over a period of 6 months at four different hemodialysis (HD) centers.

**Results:** Total 80 patients took part in the study. Males were 51(63%), mean age was 53.9±15.34. Temporary hemodialysis catheter was the most common vascular access (86.3%) in majority of patients, whereas AVF in 13.7 % of patients. most of the patients were diabetics and or hypertensive (81.3%). The time from the diagnosis of Chronic kidney disease to initiation of HD was 24.73±25.9 months. At the time of interview 77.5% had AVF, and primary failure was only in two patients (2.5%), secondary failure in 17 (21.3%). 5(6.3%) patients had arteriovenous graft, and permcath in 4(5%) as current vascular access . Temporary vascular access was still used for HD in 9(11.3 %). Mean duration of functioning AVF was 24.25±23.8 months.

**Conclusions:** Temporary vascular access is still the primary vascular access in majority of our patients and once AVF is created continues to have a successful outcome. There is a need for patient education and more stress among the nephrology community in our setup to highlight the Fistula first initiative.

**PUB182**

**Do Taurolidine-Heparin-Citrate Line Locks Offer Improved Outcomes to Heparin? – Interim Analysis following a Cohort Switch** Mark E. McClure, Richard W. Corbett, Rachna Bedi, Bhavini Patel, Natasha Gunawardana, Damien Ashby, Neill D. Duncan. *Dialysis Research Group, West London Renal and Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom.*

**Background:** Catheter dysfunction and catheter-related infections remain a significant cause of morbidity in patients maintained on tunneled central venous catheters. Taurolidine-heparin-citrate line locks containing an antimicrobial (taurolidine) could potentially reduce the risk of catheter-related bacteraemia, although there are concerns that the reduced concentration of heparin (500 units/ml vs 5000 units/ml) may result in unacceptably high rates of catheter dysfunction. A small randomized control trial demonstrated increased catheter survival in the setting of catheter salvage, however, there is no published data relating to switching line locks in a prevalent haemodialysis population.

**Methods:** A retrospective comparison was performed of all patients in three dialysis units, who underwent a switch in their standard line lock from heparin to taurolidine-heparin-citrate. Patients who died or changed modality of renal replacement therapy were excluded. Comparison of a number of parameters including thrombolytic usage, line changes, catheter associated bacteraemia, Kt/V, blood flow rate and erythropoietin resistance was undertaken for three months prior to and following the switch.

**Results:** Data from 225 patients were included in the analysis over six months. There was a trend to a non-statistically significant reduction in catheter-related bacteraemia (8 vs 3 [pre- vs post]; p=0.12) and reduction in individuals requiring thrombolytic line locks (25 vs 18; p=0.26). There was also a low rate of catheter dysfunction requiring line change following the switch (2 vs 1). No difference could be demonstrated between any of the anaemia or dialytic parameters.

**Conclusions:** This retrospective study has not demonstrated any significant difference in a range of clinically relevant parameters following a switch from heparin to taurolidine-heparin-citrate line locks in a prevalent dialysis population. This study has not demonstrated increased levels of catheter dysfunction but requires further analysis at twelve months following the switch.

**PUB183**

**An Unusual Turn of the Wire** Roxana Neyra. *Ambulatory Surgery Center, Arizona Kidney Disease and Hypertension Center, Phoenix, AZ.*

**Background:** Every day, hundreds of hemodialysis (HD) catheters are inserted either electively or as an emergency to initiate HD and save patients from life threatening conditions. In the process, there are some immediate and long-term complications, such

as hematoma, bleeding, pneumothorax, and central venous stenosis respectively. A case of subcapsular hepatic hematoma post HD catheter insertion is presented.

**Methods:** 88-year-old female with past medical history significant for end stage renal disease on HD 3 times per week. She had refused arterio-venous fistula creation. Therefore, her vascular access was a right internal jugular hemodialysis catheter for about 4 years. Her catheter was exchanged about once a year. She presented to the outpatient surgery center once more for catheter exchange due to poor flows. The catheter was replaced successfully using two wires advanced to the Inferior Vena Cava (IVC). Shortly after the procedure she complained of abdominal pain, nausea and vomiting. At the same time hypotension and bradycardia was noted. Patient was immediately transferred to the hospital. She underwent emergent venogram of the IVC, and arteriogram of the hepatic artery that showed no bleeding or extravasation. A computerized tomography of the abdomen was performed and demonstrated a heterogeneous fluid collection in the right lobe of the liver suggestive of subcapsular hematoma. Patient was treated with supportive measures and was stabilized. Over the following days, she developed a myocardial infarction, sepsis and was transferred to hospice.

**Results:** An autopsy was performed, and showed no liver laceration, hepatic artery or IVC laceration, but confirmed the subcapsular hepatic hematoma.

**Conclusions:** a) Nontraumatic subcapsular hepatic hematoma is a rare complication of insertion of dialysis catheters due to the wire advancing through the hepatic veins. It can be managed by observation and supportive measures. It can be life threatening. b) There is a relative safety in advancing the wire to the (IVC) when inserting a catheter. The position of the tip of the wire needs to be monitored at all times during the procedure to prevent complications, like the one described here.

## PUB184

### Use of Rivaroxaban to Rescue Vascular Access in Hemodialysis Patients

Fabian A. Ortiz-Herbener. *Dept of Nephrology, Instituto Ecuatoriano de Dialisis y Trasplantes, Guayaquil, Guayas, Ecuador.*

**Background:** Rivaroxaban is a direct inhibitor of factor Xa. This novel oral anticoagulant has substantial renal clearance, with half-life prolonged in patients with chronic kidney disease. There is a lack of significant clinical experience of rivaroxaban use in hemodialysis patients.

**Methods:** This study aimed to investigate the effect of rivaroxaban as a compassionate treatment for vascular access dysfunction. A cohort of 5 patients with a history of at least four previous vascular access thrombosis was selected. Two patients received 10 mg QD and three patients received 15 mg QD with a follow up of four months. The INR was measured in a monthly basis, and the results were categorized as: “Good” (improvement in vascular access permeability), and “No Response” (when there is no improvement at all, and the patient required a new access). In addition, major side effects (bleeding from any cause) were stated as “Present” or “Not present”.

**Results:**

| | Dose (mg) | Baseline INR | Month 1 | Month 3 | Month 4 | Response | Side Effects |
|---|---|---|---|---|---|---|---|
| male (71) | 10 | 1.15 | 1.25 | 1.33 | 1.21 | No Response | Not Present |
| female (64) | 10 | 1.13 | 1.03 | 0.9 | 0.96 | No Response | Not Present |
| female (58) | 15 | 1.05 | 1.03 | 1.13 | 1.08 | Good | Not Present |
| male (53) | 15 | 0.98 | 1.13 | 1.12 | 0.97 | Good | Not Present |
| male (50) | 15 | 1.13 | 1.11 | 1.23 | 1.21 | Good | Not Present |

**Conclusions:** To our knowledge, this is the first clinical experience of Rivaroxaban in hemodialysis patients. Although it is a small number of cases, we found three patients with good response and no patients with major side effects. Larger studies are required to establish the safety profile of the drug in hemodialysis scenario.

## PUB185

### Persistent Variation in the Frequency of Payment for More Than Thrice Weekly Home Hemodialysis (HHD)

Richard Hirth, Adam S. Wilk, Wei Zhang, Tammie A. Nahra, John R.C. Wheeler, Kathryn Sleeman, Joseph M. Messana. *Univ of Michigan, Ann Arbor.*

**Background:** Regional fiscal intermediaries (FIs) and Medicare Administrative Contractors (MACs) that pay Medicare claims can authorize payment for >3 weekly treatments. Previous work showed FIs/MACs may contribute significantly to variation in HHD practice (Hirth et al. 2011). Due to bundling of drugs and lab tests on a flat, / treatment basis, each additional paid treatment results in greater incremental revenues under the expanded bundle dialysis prospective payment system (PPS) than under the prior system.

**Methods:** We examined trends in HHD payments and evidence that dialysis facilities may select FIs/MACs with favorable payment policies.We identified all Medicare HHD patients (pts) in 2009-2012 by FI/MAC. We used Ordinary Least Squares regression to relate FI/MAC with HHD pt treatments per month by year, adjusting for pt age, race, BMI, and 23 Medicare claims-derived comorbidities. We examined plots of this relationship and found heterogeneous trends, though most FIs/MACs authorized the same or fewer payments over time. We predicted modality choice in a linear probability model to test whether FI/MAC payment policy is associated with the likelihood of choosing HHD therapy.

**Results:** Despite significant variation across FIs/MACs in payments authorized for additional HHD treatments, persistence in these practices for some FIs/MACs, and stronger financial incentives for dialysis facilities, we find no evidence facilities with more favorable FIs/MACs provided more HHD. This suggests a HHD patient’s expected treatment frequency, conditional on clinical factors, may be a function of the FI/MAC processing his/her facility’s claims. This creates a natural experiment for identifying the effects of more frequent HHD treatment.

**Conclusions:** Average monthly HHD patient paid treatments peaked at 18.5 (12.1 for In-center HD pts) in 2010—ranging from 13.1 to 20.6 across FIs/MACs—and fell to 17.7 (12.3 IHD) in 2012—ranging from 12.8 to 21.2—perhaps due to increased scrutiny by FIs/MACs in light of the expanded PPS. The fraction of pts treated by HHD grew from 1.1% (0.3%-3.2%) in 2009 to 1.5% (0.7%-10.3%) in 2012.

## PUB186

### A New System for the Short-Daily Hemodialysis Using Slow Sterile Dialysate Flow Rate

Walid Arkouche,[1] Jacky Potier,[2] Maurice Laville.[3] *[1]AURAL, Lyon, France; [2]Centre Hospitalier, Cherbourg, France; [3]Univ de Lyon, Pierre Benite, France.*

**Background:** PHYSIDIA S[3] is a new system for hemodialysis using slow sterile dialysate flow rate, without needing of a processing of water treatment. The mechanical characteristics of this machine are based on a new concept for the control of a precise dialysate flow. This system is especially intended for the short-daily home hemodialysis and obtained the marking of the European Community.

**Methods:** A clinical pilot multicentric trial is led in France before the marketing. The object of the study is to control the clinical tolerance of the patients and to analyze the impact of low dialysate volumes on the removal of solutes of different molecules. The ethic committee approved the protocol.

**Results:** Four patients dialyzed in two different centers ended the study : mean age 53.3 ± 20.7 years (mean ± SD); dry weight 69.9 ± 11.9 kg; BMI 26.3 ± 4.7; dialysis protocol 6 times per week x 2 hours by session. Polyethersulfone membrane is used (surface 1.9m²; KUF 75 ml/h/mmHg). The results of 12 sessions by patient (total 48 sessions) are summarized below (mean ± SD):

Dialysis session duration 116 ± 5 minutes; the total of volume of spent dialysate and of ultrafiltration volume by session 24.8 ± 1.1 L; flow rate of dialysate 195 ± 5 ml/min; total UF by session 1554 ± 437 ml; total of urea recovered in the dialysate 317 ± 62 mmol by session; spKt/V by session 0.71 ± 0.15; eKt/V by session 0.53 ± 0.11; Std Kt/V by week 2.66 ±0.45; β2microglobulin (β2m) Reduction Rate (RR) by session 49.3 ± 6.4%; total of β2m recovered in the dialysate 110 ± 32 mg by session; Phosphorus RR by session 50.0 ± 8.2%; total of phosphorus recovered in the dialysate 17.6 ± 5.2 mmol by session.

**Conclusions:** The patient tolerance is very satisfactory without particular event, with a clinical evolution as the well-known evolution of a short-daily hemodialysis. Results are satisfactory and correspond to the results described for the short-daily hemodialysis with low flow dialysate rate. The machine is easy to use, and was reliable for all the periods of the essays.

## PUB187

### Adequacy of Glycemic Control in Diabetic Dialysis Patients: A Single Center Prospective Observational Study Using Continuous Glucose Monitoring

Siddharth Sharma, Thomas T. Titus, Talib Kasim Aljumaily. *Nephrology, Gold Coast Hospital, Gold Coast, Queensland, Australia.*

**Background:** Most international guidelines recommend targeting HbA1c of <7% irrespective of the presence of chronic kidney disease. However, the correlation of HbA1c with glycaemic control in dialysis patients is contentious due to shortened red cell survival, frequent blood transfusions, iron deficiency and use of erythropoietins. Paradoxically, a large retrospective analysis of diabetic dialysis patients has shown worse outcomes in dialysis patients with HbA1c <5%. Interstitial glucose measurements using Continuous Glucose Monitors(CGM) correlates well with blood glucose using a glucometer even in dialysis patients. Hence, Continuous Glucose Monitoring could identify periods of significant hypoglycaemia in dialysis patients.

**Methods:** This is a single center observational study, conducted on all in-center diabetic dialysis patients. CGM was applied to each patient for a total of 6 days continuously. Patients underwent routine dialysis and kept a diary to record their food intake and episodes of hypoglycaemia. HbA1c was measured along with routine monthly dialysis bloods on each patient.

**Results:** There were no episodes of asymptomatic hypoglycemia in the study patients. There appeared to be better correlation between regular venous blood sugar reading than with HbA1C.

**Conclusions:** Asymptomatic hypoglycemia does not appear to be a factor in this small study. Regular blood sugar monitoring may be better marker for adequacy of glycemic control than HbA1C, in diabetic haemodialysis patients.

*Funding:* Pharmaceutical Company Support - Medtronic- supplied Continuous Glucose monitors for duration of study only

## PUB188

### Increased Levels of Tissue Factor, Adhesion Molecules, Nitric Oxide and Adiponectin in End Stage Renal Disease

Vinod K. Bansal,[1] Jawed Fareed,[2] Kristiyana Kaneva.[2] *[1]Nephrology, Loyola Univ Medical Center, Maywood, IL; [2]Pathology, Loyola Univ Medical Center, Maywood, IL.*

**Background:** End stage renal disease (ESRD) represents the fifth (final) stage of chronic kidney disease characterized by an established kidney failure (GFR <15 mL/min/1.73 m²). To further understand the pathophysiology of ESRD, this study was designed to measure the circulating levels of tissue factor (TF), adhesion molecules, such as p-selectin (P-Sel), soluble ICAM (s-ICAM), nitric oxide and adiponectin (AD).

**Methods:** This study included 119 ESRD patients on maintenance hemodialysis in conjunction with an ongoing IRB approved protocol on the profiling of inflammatory markers in this syndrome. Citrated blood plasma samples were collected from these patients prior to the routine dialysis session. Nitric oxide levels (NO) were measured using a commercial kit from R&D systems (Minneapolis, Minnesota) and ELISA based methods for TF, P-Sel, s-ICAM and adiponectin were also purchased from R&D systems. Chromogenic and thrombin substrate method were used to measure the anti-Xa activity thrombin generation.

**Results:** Tissue factor levels were found to be increased in the ESRD group (20.4±6.1pg/ml) vs the control (11.9±2.8pg/ml). The nitric oxide level was markedly higher in the ESRD group (32±17uM) vs the controls (7±3uM). The p-selectin levels were also elevated in the ESRD group (46±20ng/ml) vs the control (31±3ng/ml). The soluble ICAM levels were higher in the ESRD group (250±112ng/ml) vs the control (180±19ng/ml). Interestingly, the adiponectin levels were also increased in the ESRD group (19.2±9.3ug/ml) vs the control (11.2±4.1ug/ml). The pre-dialysis samples of the ESRD patients exhibited detectable levels of heparin.

**Conclusions:** These studies suggest that TF, NO, p-selectin and s-ICAM levels are increased in the ESRD patient. Despite the fact that a significant number of ESRD patients being diabetic; the AD levels were increased in this group. These results suggest that while ESRD represents a pro-inflammatory/hypercoagulable state, the repeated administration of heparin and other drugs may contribute to the regulation of the hemostatic process and inflammatory balance.

## PUB189

**Optimal Serum Phosphate and Calcium for Hemodialysis Patients Judging from Fibroblast Growth Factor-23 and Parathyroid Hormone**

Hiroshi Tanaka,[1] Tomoyuki Kita,[2] Kumi Okamoto,[2] Maki Mikami,[2] Rumi Sakai.[1] *[1]Ashiya Sakairumi Clinic, Ashiya, Hyogo, Japan; [2]Sakairumi Clinic, Kobe, Hyogo, Japan.*

**Background:** High dose hemodialysis, HDD improves mortality, blood pressure control, anemia, quality of life of hemodialysis patients. We have reported that HHD significantly decreased serum fibroblast growth factor-23, FGF-23, interleukin-6, IL-6, $\beta_2$-microglobulin, $\beta_2$-MG than standard dose hemodialysis, SDD. In this study we analyzed correlations between the above serum parameters including routine laboratory data of the patients with different dialysis doses.

**Methods:** We selected 206 hemodialysis patients, whose treatment modes were not changed at least 3 months. They were divided in two groups, whose hemodialysis product, HDP was higher or lower than 54 (ex. 6 hours/session and 3 times weekly). SDD patients consisted of 129 patients (53 women and 76 men, 66.8 ± 12.8 years old, mean ± s.d., HDP 40.9 ± 4.1) and HDD patients did of 77 patients (27 women and 50 men, 61.1 ± 11.4 years old, HDP 68.4 ± 14.5). Serum FGF-23, IL-6 and routine laboratory tests were measured before hemodialysis on the day of the longest interval between consecutive dialysis sessions. Correlation between variables was analyzed using Pearson product moment correlation coefficient and Student's t-distribution.

**Results:** Serum phosphates of SDD and HDD patients were 4.9 ± 1.3 and 4.4 ± 1.0 mg/dl, respectively with a significant difference. Their serum calciums were 8.9 ± 0.6 and 8.9 ± 0.6 mg/dl, respectively. Table shows correlation coefficients and p values of each laboratory data of all, SDD and HDD patients.

| | All patients | SDD patients | HDD patients |
|---|---|---|---|
| FGF-23 : P | r = 0.553, P<0.001 | r = 0.564, P<0.001 | r = 0.529, P<0.001 |
| FGF-23 : Ca | r = 0.269, P<0.005 | r = 0.244, P<0.001 | r = 0.225, P<0.05 |
| PTH : Ca | r =−0.270, P<0.005 | r =−0.278, P<0.001 | r =−0.290, P<0.05 |
| $\beta_2$-MG : IL-6 | r = 0.200, P<0.05 | r = 0.209, P<0.005 | n.s. |

**Conclusions:** In order to decrease serum FGF-23, serum phosphate should be as lower as possible avoiding morbid hypophosphatemia. Serum Calcium should be kept higher within the normal range regarding FGF-23 and parathyroid hormone, PTH.

## PUB190

**Kinetics of Cystatin C during Single Hemodialysis Treatments: Determining Its Diffusional and Convectional Clearance, Equilibration Ratio, and Volume of Distribution**

Shih-Han S. Huang, Benjamin Ka Thomson, Robert M. Lindsay. *Medicine, Nephrology, Western Univ, London Health Sciences Centre, London, Canada.*

**Background:** Recent studies have demonstrated that cystatin C is cleared by hemodialysis. In this study, we assessed cystatin C kinetics during single hemodialysis treatments and estimated its volume of distribution.

**Methods:** Nine patients undergoing 10 hemodialysis sessions were studied. Each patient received a 3-4 hours hemodialysis session, which included a 1-hour dialysis only treatment, a 1-hour ultrafiltration only treatment plus 1-2 hours of combined dialysis and ultrafiltration. Arterial and venous blood sampling to measure cystatin C, creatinine, and urea levels at each treatment interval was done to calculate the diffusional, convectional and combined clearances of each solute. The clearance values of the three markers were compared with each other. The cystatin C clearance as calculated by solute clearance equations was compared with that obtained from a one-compartmental mass balance model. The cystatin C volume of distribution, its 30-minutes rebound ratio and its equilibration ratio were also calculated.

**Results:** The mean age ± standard deviation (SD) of the patients was 57 ± 9.3 years. The mean ultrafiltration volume (L) was 1.9 ± 1.05 L. There was a statistically significant difference between the cystatin C clearance values as estimated by the equations and by the model (p<0.014). There was also statistically significant differences between cystatin C, urea and creatinine clearances by all the treatment modes (p<0.05). The estimated cystatin C volume of distribution ratio was 0.33 ± 0.12 of total-body water. The rebound ratio at 30 minutes post-hemodialysis session was 0.085 ± 0.0059, and the equilibration ratio was 1.17 ± 0.227.

**Conclusions:** This study confirmed our previous hypothesis that cystatin C is cleared by both diffusion and convection during hemodialysis. It appears to be distributed mainly in the extracellular space. Larger studies to assess its clinical value as a marker of middle molecular weight toxin clearance in dialysis patients are needed.

## PUB192

**Continuous Erythropoietin Receptor Activator (C.E.R.A.) Improve Iron Dysregulation and Hypercytokinemia in Patients on Maintenance Hemodialysis (MHD)**

Yukiko Hasuike,[1] Naoto Kakita,[2] Kiyoko Yamamoto,[1] Aritoshi Kida,[1] Mana Yahiro,[1] Takeshi Nakanishi.[1] *[1]Div Kidney and Dialysis, Dep. Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; [2]Tanaka-Kitanoda Hospital, Sakai, Japan.*

**Background:** In MHD, the disturbance of iron regulation for erythropoiesis could cause hyporesponsiveness to erythropoiesis-stimulating agents (ESA). We previously reported the decrease in frataxin, an iron regulator, and an association between frataxin and inflammatory cytokines in MHD [Clin Exp Nephrol 2012]. In the present study, we evaluated whether the switching of ESA to C.E.R.A. affect frataxin expression as well as cytokines in MHD patients with ESA-hyporesponsive anemia.

**Methods:** In 92 MHD with low Hb (<10 g/dl), 50 patients who were treated with conventional ESA and 42 patients with darbepoetin alpha, ESA was switched to C.E.R.A. (Hb target level 10-11 g/dl). Hemoglobin, serum ferritin, hepcidin (HPLC-MS/MS), and interleukin-6 (IL-6, ELISA) and tumor necrosis factor-alpha (TNF-α, ELISA) as inflammatory makers were measured. Intravenous iron (iron sucrose 40 mg once) was administered when serum ferritin level was less than 75 ng/ml. In 34 patients, polymorphonuclear leukocytes were separated to measure the mRNA of ferroportin-1/GAPDH ratio and frataxin/GAPDH ratio (real-time PCR), and protein levels of frataxin (Dipstick assay).

**Results:** During 3 months, both mRNA and protein levels of frataxin were significantly increased (1.56: 1, p=0.0033; 1.18:1, p=0.0324; respectively), and ferroportin-1 mRNA was significantly elevated (2.91:1, p<0.0001) likewise. Serum hepcidin levels were significantly decreased compared with that at start (12.2±2.5 versus 45.3±5.9 ng/ml, p<0.0001), and serum levels of both IL-6 (11.0±2.2 versus 31.3±11.0 ng/l, p=0.0007) and TNF-α (6.29±0.70 versus 8.06±1.73 pg/ml, p=0.0148) were significantly reduced compared with the levels at start.

**Conclusions:** The intervention of switching to C.E.R.A. and iron might improve abnormality of frataxin expression, which could subsequently reduce inflammatory cytokines.

## PUB193

**Tryptophan Catabolism and Its Association with Sleep, Fatigue and Depressive Symptoms in Hemodialysis Patients**

Vanja Persic,[1] Rakesh Malhotra,[2] Laura Rosales,[2] Weifang Zhang,[3] Garry J. Handelman,[3] Caroline M. Williams,[2] Stephan Thijssen,[2] Fredric O. Finkelstein,[4] Mark L. Unruh,[5] Nathan W. Levin,[2] Peter Kotanko.[2] *[1]Univ Medical Center Ljubljana, Slovenia; [2]Renal Research Institute, New York; [3]Univ of Massachusetts, Lowell; [4]Yale Univ, New Haven; [5]Univ of New Mexico School of Medicine, Albuquerque.*

**Background:** Sleep and mood disorders are common in hemodialysis (HD) patients. Tryptophan (TRP) and its metabolites play prominent roles in neural pathways related to sleep, fatigue, and depressive symptoms. Here we report levels of TRP and its metabolite kynurenine (KYN) and their association with sleep health, non-physical fatigue and depressive symptoms in HD patients.

**Methods:** In this prospective pilot study we measured pre-dialysis levels of TRP and its metabolite kynurenine (KYN) by high-performance liquid chromatography with fluorometric detection. We performed a concurrent survey which included 3 self-reported questionnaires: the Medical Outcomes Study Sleep Scale (MOS-Sleep); the PROMIS Short form Fatigue 8a questionnaire (PROMIS-F); and the Patient Health Questionnaire (PHQ-9). Spearman rank correlation coefficient ($r_s$) was used to assess correlations.

**Results:** We enrolled 30 HD patients (age 58.8±13.3 yrs, 70% male, 63% African-American, 50% diabetics). Compared to levels reported in healthy controls, in our cohort TRP levels were decreased (35.3±8.1 μmol/L) and KYN levels were elevated (6.0±2.5 μmol/L). MOS-sleep scores confirmed poor sleep quality. PROMIS-F T score was 54.1±9.4, indicating a trend towards moderate fatigue. PHQ-9 score was 7.4±5.2, revealing the presence of mild depressive symptoms. TRP and KYN levels were not correlated with indicators of sleep health ($r_s$=0.045 and -0.027, respectively), fatigue ($r_s$=0.211 and 0.186, respectively), and depressive symptoms ($r_s$=0.181 and 0.046, respectively).

**Conclusions:** Our relatively small study indicates disturbed metabolism of the essential amino acid tryptophan, poor sleep health, fatigue, and depressive symptoms. A larger sample size is necessary to more comprehensively explore the potential spectrum of interactions between TRP status and patient reported outcomes.

**PUB194**

**Levocarnitine Administration Can Improve Left Ventricular Systolic Function in Hemodialysis Patients Diagnosed with Carnitine Deficiency** Masaki Aono, Yuzuru Sato. *Sato Junkankikanaika, Matsuyama, Ehime, Japan.*

**Background:** Since cardiac systolic dysfunction has been shown to be a risk factor for both mortality and the development of de novo CHF in patients on HD, a number of studies were performed to measure the effect of levocarnitine ( LC ) administration on systolic function in such patients. Cardiac dysfunction is also a contributing factor to the occurrence of dialysis-associated hypotension.

**Methods:** Over a three-month period, a daily dose of levocarnitine chloride (1800mg/day) was administered orally to 134 patients on HD who were diagnosed with carnitine deficiency. At the end of the three months, the patients were divided into 3 groups according to the concentration of plasma free carnitine (FC) as follows: group1: FC<30umol/L, N=22, group2:30<FC<72, N=13, group 3: FC>72, N=99. LVD and EF were measured by echocardiogram and PEP/ET was examined by systolic time interval using Vasera system in all patients before and after treatment. Blood pressure (BP) was measured at the start and the end of each HD session and averaged for a week before and after treatment. The lowest BP and maximum decrease of BP during HD were also measured. The frequency of use of vasopressors during the time of dialysis was compared among the patients in the groups.

**Results:** After administration of LC, the plasma concentration of FC increased in groups 2 and 3 significantly (from a mean ± SD of 22.5±4.7μmol/L to 45.8±11.3μmol/L in group 2, from 20.4±4.6μmol/L to 275.5±136.6μmol/L in group 3 ; paired t-test P<0.01). However, it did not increase significantly in group 1 (from 23.4±3.1 to 25.0 ± 4.6 μmol / L, n.s). PEP/ET improved significantly in group 3 (from 0.331 to 0.27, P<0.01), but remained unchanged in the other groups. LVD and LVEF did not change in any group. BP during dialysis did not show a significant change. The dosage of an occasional boosting agent to be used for dialysis hypotension significantly decreased in group 3, but remained unchanged in the other two groups.

**Conclusions:** This study suggested that levocarnitine administration can improve the left ventricular systolic function of patients on HD and reduce the frequency of HD-related hypotension.

**PUB195**

**Oral Iron Administration Corrects Renal Anemia Effectively without the Development of Adverse Reactions in Hemodialysis Patients Received Erythropoiesis-Stimulating Agents (ESA) at a Large Dose** Shigeru Miyazaki,[1] Noriko Saito,[1] Hiroki Takimoto,[1] Masaaki Shimotori,[1] Yutaka Tsubata,[1] Kozo Ikarashi,[1] Tetsuo Morioka,[1] Hisaki Shimada,[1] Tadashi Yamamoto.[2] *[1]Shinraku-en Hospital, Japan; [2]Niigata Univ, Japan.*

**Background:** ESA have an ability not only to stimulate erythropoiesis, but also decrease serum hepcidin, which disturbs iron utilization for erythropoiesis, resulting in anemia improvement and increase iron absorption. The additional intravenous iron, in association with an increase in ESA dose, can be effective in increasing hemoglobin levels over the short times. But efficacy of oral iron therapy is not well studied. We examined the effect of oral iron therapy on renal anemia and iron metabolism markers in hemodialysis(HD) patients receiving larger dose of ESA.

**Methods:** When ESA were increased in 18 HD patients from 8500±5200 to 22200±12500 U/week (Epoetin β equivalent) without iron supplementation, they developed microcytic anemia. Then they were treated with oral iron administration (Fe 100mg/day) for 12 weeks.We evaluated the following markers: hepcidin-25(HPC), growth differentiation factor 15(GDF15), soluble transfferin receptor(sTfR), 8-oxo-2'-deoxyguanosine (8-OHdG) and standard hematological parameters including high sensitive CRP (hs-CRP). Serum HPC level was determined by LS-MS/MS. GDF15, sTfR and 8-OHdG were measured by ELISA. Serum samples of 20 normal volunteers (N) were served as controls.

**Results:** Oral iron administration increased serum ferritin(ng/ml), Hb (g/dl) and MCV(fl) from 0W to 12W (14.6±9.2 to 39.1±14.9*, 8.5±1.3 to 12.4±2.1* and 79.6±5.7 to 90.7±6.5* respectively).HPC (ng/ml) was 0.6±0.8 at 0W in the HD, which was lower than N ( 11.1±11.9*). Then HPC was gradually increased to 17.5±30.5** at 12W. However, the level of HPC did not exceed that of N (17.5±30.5 vs 11.1±11.9, ns).Serum GDF15 (ng/ml) and sTfR (nmol/ml) levels were gradually decreased from 7.7±3.3 to 6.0±2.5* and from 48.0±13.4 to 39.5±8.8*, respectively.Hs-CRP (ng/ml) and 8-OHdG (ng/ml) levels were unchanged. *:p<0.01 **:p<0.05.

**Conclusions:** Oral iron therapy was very effective to improve renal anemia, and did not induce hyperferritinemia, hyperhepcidinemia nor oxidative stress state.

**PUB196**

**Do Patients on Chronic Hemodialysis Have a Suppressed Fever Response to S. aureus Bacteremia?** Eman Mohammad Shaban, George P. Bayliss, Leonard Mermel. *Dept of Medicine, Alpert Medical School, Brown Univ, Providence, RI.*

**Background:** We sought to determine whether hemodialysis patients with Staphylococcus aureus bacteremia have a suppressed febrile response compared to age matched, non-dialysis patients. We hypothesized that dialysis patients are more likely to have an afebrile bacteremia (<100.3°F) and lower maximal temperature over the first 48 hours than non-dialysis patients, potentially delaying treatment.

**Methods:** We identified patients on hemodialysis from the electronic medical record with methicillin-sensitive and methicillin-resistant S. aureus (MSSA and MRSA) bacteremia over a 5-five year period. We defined MSSA/MRSA bacteremia as a positive blood culture drawn either peripherally or from a dialysis catheter. Temperatures were recorded on presentation and over 48 hours. Cases included people age 18 or older on hemodialysis more than six weeks. We excluded as cases or controls patients on immunosuppressive drugs, with MSSA/MRSA infection other than in the bloodstream, or anyone who received antipyretic therapy within 6 hours before or 48 hours after the first positive blood culture.

**Results:** We identified 12 cases and 12 age- and gender-matched controls. Cases were more likely to suffer MRSA bacteremia than controls (7 cases versus 2 controls, p=0.04), but only 3 of 4 cases who screened positive for MRSA colonization developed MRSA bacteremia. Although mean temperatures were lower for dialysis patients with S. aureus bacteremia, the differences were not significant (temperature at initial blood draw = 99.8°F for cases versus 100.9°F for controls, p=0.2; Tmax over the next 48 hours = 99.4°F for cases versus 100.6°F for controls, p=0.13).

**Conclusions:** We found no significant difference in temperature at the time of presentation with S. aureus bacteremia or over the next 48 hours. But our study was underpowered for this outcome measurement. We found that chronic dialysis patients were more likely to present with MRSA bacteremia than non-dialysis patients, and this may have therapeutic implications for chronic dialysis patients in terms of initial selection of antimicrobial therapy.

**PUB197**

**Relationships between Hemoglobin Stability and Inflammation in the Treatment of Renal Anemia with Epoetin β Given during the Initiation Period of Hemodialysis Treatment** Yumi Furuno, Masahito Tamura, Tetsu Miyamoto, Akihiro Kuma, Kenichiro Bando, Yoko Fujimoto, Emi Hasegawa, Ryota Serino, Yutaka Otsuji. *Dept of Nephrology, Univ of Occupational and Environmental Health, Kitakyushu, Fukuoka, Japan.*

**Background:** In patients undergoing maintenance hemodialysis (HD), inflammation may cause resistance to erythropoiesis stimulating agents and is a high risk factor of cardiovascular diseases. Despite this relevance, relationships between inflammation and hemoglobin (Hb) stability during the initiation period of HD treatment have not been explored yet. We investigated correlations of Hb stability with inflammation in patients who newly initiated HD.

**Methods:** Epoetin β was administered to patients who initiated HD treatment in our university hospital, and the 1-year success rate of achieving the target Hb level and factors affecting the rate were prospectively examined.

**Results:** Among 139 patients initiating HD in our hospital from February 2008 to November 2010, 25 patients who provided written informed consent were involved in the study. The patients were consisted of 64% male, the average age was 61.4 years, and 60% had diabetic nephropathy. The mean values of laboratory tests at the initiation of HD treatment were as follows: Hb, 8.62 ± 1.47 g/dL; creatinine, 8.54 ± 1.41 mg/dL; albumin (Alb), 3.06 ± 0.71 g/dL; CRP, 0.78 ± 1.64 mg/dL; dose of epoetin β, 8460 ± 1492 IU/week. During the follow-up period, the mean Hb level was 10.70 ± 0.56 g/dL and the mean success rate of achieving the target Hb level (10-12 g/dL) was 70%. The high target Hb maintenance rate group had significantly higher mean Hb levels and significantly lower cardiothoracic ratio (CTR) during the period. Negative correlation was observed between the target Hb maintenance rate and CRP (r = -0.4445, p = 0.0296). Although the mean Hb change tended to exhibit an inverse relationship with Alb, the difference was not statistically significant.

**Conclusions:** Significant correlation of the target Hb maintenance rate with CRP and CTR suggested that inflammation may have effects on the management of renal anemia and prognosis even during the initiation period of HD treatment.

**PUB198**

**On-Line Hemodiafiltration and Control of Uremic Anemia** Ignace Mpio, Jean-christophe Szelag, Walid Arkouche. *AURAL, Lyon, France.*

**Background:** Control of anemia in chronic dialysis is a major regarding clinical outcomes. Nine months prospective cross-over study to determine if the advantages of the convective transfers of on line hemodiafiltration (ol-HDF) are associated with a better control of anemia than in conventional hemodialysis (CHD).

**Methods:** We studied 33 stable, dialyzed-patients transffered from CHD to ol-HDF (16 women (48%), mean age 73 ± 11 years, length of dialysis 7 ± 6 years). 24 (73%) were treated with erythropoiesis stimulating agents (ESA). Technical characteristics of CHD and ol-HDF: ultrapure water, blood flow ≥ 300 ml / min and high membrane permeability (area ≥ 1.9 m² and ultrafiltration coefficient ≥ 40 ml / h / mmHg). ol-HDF was mainly used in the post-dilution mode (volumes of substitution of 18 to 24 l.) Two phases were defined: phase A (CHD) and phase B (ol-HDF). Clinical and biological parameters of anemia were measured at Day 0 in phase A and after 9 months in phase B: ESA doses converted in doses of darbepoetin alpha (DA) per week, hemoglobin (Hb), erythropoiesis resistance index (ERI) (ERI = weekly dose of DA in μg / Hb in g/dl), CRP, albumin, ferritin, and delivered dialysis dose (KT).

**Results:** After 9 months in ol-HDF, the comparative analysis of the results phase A versus phase B reported: Hb (11.8 vs 11.7 g / dL); ERI (4.5 vs 4.1); doses of DA (53 vs 43 μg / wk, p <0.05); CRP (12 vs 9 mg / L, p <0.05); KT (47 vs 52 L); ferritin (353 vs. 453 μg / L); albumin (39 vs 38 g / L). In Phase B the ESA dose was decreased by 10 μg (20%) associated with a reduction of CRP, maintaining Hb and ERI levels equivalent to phase A without any difference in the martial and nutritional assessment. We found a significant correlation between delta DA and delta CRP but no correlation between KT and dose of DA.

**Conclusions:** ol-HDF is a non pro-inflammatory dialysis mode as reported by other authors and facilitates the response to ESA. The properties of the convective purification have implications in reducing other causes of erythropoietin resistance.

**PUB199**

**Impact of Angioaccess Type in Hemoglobin Levels, Iron Kinetics and Erythropoietin Dose in Two Hemodialysis Units of Fresenius Medical Care in Puebla City, Mexico** José Guillermo Pacheco Paredes, Carlos Colchero, Julio de León Ramirez Reyes, Karina Delfina Perez ayala. *Fresenius Medical Care, Puebla, Mexico.*

**Background:** An important issue in correcting anemia in hemodialysis patients is improving dialysis quality. It is demonstrated that in patients with chronic access has better outcome than patients with temporal access. The present study tries to demonstrate the relationship between hemoglobin levels, Epo alpha dose and iron kinetics with the type of angioaccess chronic or temporal in two separated units of hemodialysis in Puebla City, Mexico.

**Methods:** Data from medical files were analyzed that included hemoglobin levels, iron kinetics and recombinant erythropoietin (Epo) dose, by access type. STUDY DESIGN: Cohort longitudinal prospective study.

**Results:** 249 patients were studied in two-separated hemodialysis units with 6 months follow up from July 2012 to January 2013. The access type distribution was 47% with temporal angioaccess and 53% with chronic angioaccess. In patients with temporal access the hemoglobin levels were 10.6, g/dl serum ferritin were 434 and% transferrin saturation was 32%. For patients with chronic angioaccess the hemoglobin levels were 11g/dl, serum ferritin 396 and % ST 39. The distribution of Epo dose was not significantly different. 50 patients were lost for different causes. 209 patients with complete data were included in the study. The access type distribution was 75% with chronic angioaccess and 25% of the patients with temporal access. Hemoglobin levels for patients with temporal access were 10.9 ferritin levels 409 and %ST was 32%. For chronic access hemoglobin levels were 11.6 ferritin levels 361 and %ST 31%. 33 patients changed from temporal vascular access to chronic vascular access. These patients had an improvement in the hemoglobin levels and ferritin levels with no significantly change in Epo dose.

**Conclusions:** In our population the improvement of hemoglobin levels and the decrease in the ferritin levels were the most relevant factors associated to chronic angioaccess. Epo dose was not significantly changed during the 6-month follow up; nevertheless no patient with chronic angioaccess required an increase in Epo dose.

**Can the Use of a Novel Dialysis Bloodline Increase Haemoglobin and Reduce Erythropoetin Doses? Interim Results of an Ongoing Clinical Audit** Iain C. Macdougall,[1] Adam Rumjon,[1] Emmanuel Mangahis,[1] Thomas Ryzlewicz,[2] Franz-ferdinand Becker,[2] William Kilgallon.[2] *[1]Renal Unit, King's College Hospital, London, United Kingdom; [2]Oxyless Ltd, Reading, United Kingdom.*

**Background:** The Oxyless bloodline (patented in USA and Europe) has been designed to reduce the contact between blood and air during the haemodialysis (HD) process whilst still being able to remove additional air introduced during the set up and operation phases of dialysis, prior to entry to the dialyser. The hypothesis is that this novel design would reduce shear stresses on red cells and prolong their lifespan, potentially reducing dose requirements of ESAs as well as potentially other drugs such as iron and heparin.

**Methods:** A pilot audit was set up to test the hypothesis. Fifteen patients from the chronic haemodialysis unit were entered into a 12-month open-label, single cross-over, cohort prospective audit. The patients were all aged over 18 years, had been on HD for at least 3 months and all had A-V fistulae. Haemoglobin (Hb) was measured on a monthly basis and EPO doses were recorded. Clinical decisions regarding EPO doses were made independently in line with an established anaemia management protocol.

**Results:** Eight of the patients experienced intercurrent problems which let to them dropping out of the assessment. Drop out events included renal transplantation, gastrointestinal bleeding, episodes of acute inflammation, hospitalisation, and non-compliance. The remaining 7 patients demonstrated increases in haemoglobin (Hb) over a six month period of 1 g/dL. In 4 of the patients EPO requirements were reduced by 33% representing a total reduction of 9,000 IU/week, and a mean of 2,250 IU/week. Two patients have had no reduction to-date while one had a small increase at the start of the audit and has maintained that dose to-date. The patients have now entered into the cross-over phase.

**Conclusions:** As a result of these encouraging preliminary results, a Prospective European Multicentre Audit (PEMA) has been initiated to further evaluate the hypothesis that the use of the Oxyless bloodlines can improve the half-life of erythrocytes in dialysis patients and thereby reduce the requirements for ESAs, iron and heparin.

**PUB201**

**Hepatitis C Cirrhosis and Iron Load in End Stage Renal Disease** Nancy M. Tran,[2] Devasmita Choudhury,[1,2] Geri Brown,[1,2] Terri W. Crook.[3] *[1]Internal Medicine, Dallas Veterans Affairs Medical Center, Dallas, TX; [2]Internal Medicine, Univ of Texas Southwestern Medical Center, Dallas, TX; [3]Pathology, Dallas Veterans Affairs Medical Center, Dallas, TX.*

**Background:** Hepatitis C (HCV) in patients with end stage renal disease(ESRD) is associated with increased cirrhosis, carcinoma and all-cause mortality. Whether or not an iron load given as part of dialysis anemia management can exacerbate fibrosis is uncertain.

**Methods:** To evaluate liver disease progression, we retrospectively compared levels of aspartate aminotransferase(AST), platelet count(plt), AST/plt ratio, albumin, and iron load over a period of 20 years, from January 1992 through July 2012, in patients with ESRD alone(group 1,n= 18), ESRD and HCV(group 2,n=24), and HCV alone(group 3,n=20). Using SPSS 11.0, continuous variables were analyzed with t-test and ANOVA; non-parametric variables were analyzed with Mann-Whitney test. The 3 groups were matched in terms of age, race, and gender.

**Results:** No difference was found in AST/plt ratio within or between groups(p=0.06) at start time (dialysis initiation in groups 1 and 2; liver biopsy in group 3). Over study duration, the plt count was lower(p =0.04) but other biomarkers remained stable within group 2. Over time, there was no difference in biochemical markers within group 1, and none except for albumin within group 3. At completion of study, the AST/plt ratio in group 2 was not statistically different than values in group 1(p=0.86) or group 3(p=0.13). The total amount of iron received (intravenously or via packed red blood cell transfusions) was similar between groups 1(mean 8.0g) and 2(mean 10.6g) (U=171, p=0.72).

**Conclusions:** Preliminary findings show that while plt count was decreased within group 2, the remainder of the biomarkers was not significantly different between groups 1 and 2 even in the setting of similar iron administration, which suggests a stable level of fibrosis. This finding could indicate that, despite their pre-existing liver disease, patients with ESRD/HCV may be able to tolerate the iron load. However, a larger cohort and review of other parameters (ie.years of HCV exposure, HCV viral load, stage/grade of cirrhosis) will need to be further investigated.

**PUB202**

**Erythrocyte Indices Changes during Erythropoiesis Stimulating Agent Therapy in Hemodialysis Patients** Kyungyoon Chang, Hyung Wook Kim, Dong Chan Jin, Hoon Suk Park. *Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, St.Vincent's Hospital, Republic of Korea.*

**Background:** Macrocytosis occurs in chronic hemodialysis patients. It may be a manifestation of abnormal rapid cellular maturation in states of massive erythropoietic stimulation due to high doses of erythropoiesis stimulating agent (ESA). The aim of this study is to access the prevalence of macrocytosis and to identify its clinical associations.

**Methods:** We conducted a single-center, retrospective study of 104 chronic stable hemodialysis patients during ESA. Blood samples collected monthly from January through December 2012. Macrocytosis was defined as a mean corpuscular volume (MCV) > 98 fl.

**Results:** The mean MCV was 94.0 ± 4.6 fl (range 79-112 fl). We identified high prevalence of macrocytosis (16%).The ΔHb positively correlated with the ESA/dry weight (Pearson correlation coefficient= 0.477, P<0.001, $r^2$=0.2188), albumin (Pearson correlation coefficient= 0.143, P<0.001, $r^2$=0.0204 ) and negatively with iron (Pearson correlation coefficient= -0.178, P<0.001, $r^2$=0.0315 ). The ΔMCV positively correlated with ΔHb (Pearson correlation coefficient= 0.378, P<0.001, $r^2$=0.1473 ) and ESA/dry weight (Pearson correlation coefficient= 0.212, P<0.001, $r^2$=0.0619). The ΔMCHC positively correlated with iron (Pearson correlation coefficient= 0.119, P=0.017, $r^2$=0.0137 ). Macrocytosis is related to the increased Hb and the dose of ESAs requirement in hemodialysis patients. There were no significant correlation between serum iron level and macrocytosis.

**Conclusions:** Macrocytosis may be associated with the increased Hb in hemodialysis patients during ESAs. The measuring of MCV will help access the response of ESAs. Future studies will need the relationship between erythropoietin resistance.

**PUB203**

**The Association between Hemoglobin Variability and Morbidity/Mortality of Cardiovascular (CV) Events in Maintenance Hemodialysis (MHD) Patients: A Prospective Observation** Yong Gu,[1,2] Jianying Niu,[1] Xiaojing Zhong.[1] *[1]Div of Nephrology, The Fifth People's Hospital of Shanghai, Fudan Univ, Shanghai, China; [2]Div of Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China.*

**Background:** The study aims to find the relationship between morbidity/mortality of CV events with different hemoglobin level and variability in MHD patients.

**Methods:** 80 MHD patients were recruited into this 9-month period prospective study, from June 2012 to February 2013. Hb lecel was measured monthly, while the rest serum biochemical tests were preformed every 3 months. The observational end point was death, CV events.

**Results:** The mean age is 60.8±12.79 years, ratio of male to female is 1.2:1, dialysis age is 4.27±3.09 years, 74 cases had hypertension while 24 had diabetes.

During the period , 6 cases developed cardiovascular events, 4 cases developed cerebrovascular events and 10 cases died.

The mean Hb level was 101.62±15.24g/l, mean standard deviation was 8.91±4.4g/l, mean coefficient variation was 0.09±0.05, mean differences among 9 times results was 7.83±4.1g/l, residual standard deviation was 7.58±3.97g/l, and the standard deviation across thresholds (110-120g/l) was 19.97±14.67g/l.

Of six patterns of Hb level fluctuation, consistently low (<110g/l) is the most common pattern (43%). The proportion of Hb variability varies from 53.8% to 87% depending on the definition of Hb variability used.

Analysis of multiple stepwise regressions showed the independent risk factors were the Hb standard deviation (OR=1.162, P=0.030), coefficient variation (%) (OR=1.17, P=0.009), mean differences between 9 times results (OR=1.292, P=0.006), while the Hb level was protective factor (OR=0.95, P=0.02) .

The COX regression analysis showed that the mean differences between 9 times results was an independent risk factor (HR=3.13, P=0.006) of death, while the Hb level was protective factor (HR=0.849, P=0.012).

**Conclusions:** Hb variability is very common in MHD patients, and the consistently low (<110g/l) is the most common Hb level fluctuation pattern in our center. Hb level is a protective factor for total clinical adverse events and death, Hb standard deviation and coefficient variation are risk factors for CV events.

## PUB204

**Inflamation and CRP Chronic Haemodyalisis Patients** Cristobal Santacruz. *Nefrologia, Clinica de los Rinones Menydial, Quito, Pichincha, Ecuador.*

**Background:** We know that patients with CKD 5D have some conditions that predispose to be chronically inflamed and by this way their morbimortality is increased. Several markers of inflammation have been used to measure, but has not been able to determine which one of them are the best and which could be useful in our daily clinical practice to get decrease morbimortality. The aim of our study is to contribute in the interpretation of PCR and to determine patients in high risk.

**Methods:** 144 non selected patients 82 men (60%) and 62 women (40%), with a mean age of 53 years (range 16 to 83 years) treated with HD 44 months on average (range 3 to 161 months) were included in a base data when they began their treatments. All the personal data was fill in. They did treatments with standard bicarbonate, biocompatibility dialyzers, minimal heparinization. None reused dialyzer. We made some labs exams as ferritin, transferrin, albumin and quantitative CRP,EPO was used to maintain predialysis Hb level 11-12gr% . For this observational study we divided the patients into two groups:1. Not inflamed CRP <5 mg / L. 2.Inflamed CRP> 5 mg / L.

| VARIABLES | GROUP 1 CRP < 5 mg/dl | GROUP 2 CRP > 5 mg/dl | P |
|---|---|---|---|
| TOTAL | 74 (51%) | 70(49%) | |
| SEX DISTRIBUTION | 38 M (51%) 36 F (49%) | 44M (63%) 26 F (37%) | NS |
| AGES | 49 YEARS | 57 YEARS | 0,0086 |
| HAEMODIALYSIS TREATMENT TIME | 29 MONTHS | 58 MONTHS | NS |
| BMI | 23.7 | 23.8 | NS |
| FERRITINE | 1102 MG. % | 969 MG.% | NS |
| TRANSFERRIN | 369 MG.% | 361 MG.% | NS |
| ALBUMIN | 4.4 MG. % | 4.2 MG. % | NS |
| EPO UNITS MONTH | 16000 | 18000 | NS |

**Results:** 133 patients (94%) when assessed clinically were in good conditions regardless of the level of CRP, while 8 pctes (6%) considered clinically bad had an CRP average of 23. Associated comorbidities were: active lupus infection, severe heart disease and ischemic stroke.

**Conclusions:** 1. - 49% of HD patients specially men over 50 years old had high CRP level P=0,0086; 2. - The time spent in HD treatment, BMI, albumin, transferrin, ferritin and EPO doses doesn't have statistical significance to rise the CRP level; 3. - The clinical course of patients and complications are not related with CRP levels but help us to identify patients at risk.

## PUB205

**Anemia in Hemodialysis Patients: An Audit of Hemoglobin Targets and Erythropoiesis-Stimulating Agents Use** Samantha Jayne Owen, Adil Hazara, Sunil Bhandari. *Hull and East Yorkshire Hospitals NHS Trust, United Kingdom.*

**Background:** The objectives of anemia management in hemodialysis dependent (HD) patients have changed recently. We have reviewed the impact of Kidney Disease: Improving Global Outcomes (KDIGO) 2012 guidelines on anemia management in our HD population.

**Methods:** Hemoglobin concentration (Hb), Serum Ferritin (Fer), Platelet counts (PLT), ESA doses and blood pressures (BP) were reviewed retrospectively in all HD patients with reference to two separate time intervals: the last quarter of 2011 ('Oct-Dec 2011') and the same period in 2012 ('Oct-Dec 2012'). For Hb, BP and ESA doses, average values from multiple observations have been used whenever possible.

**Results:** 230 HD patients were studied. Mean age: 64 (range 19 – 91) years; Male 147 (64%); mean duration on hemodialysis: 7 (range 2 – 34) years.

Averages of Hb, Fer, PLT, ESA doses, BP and Hb/ESA are presented in table 1. There were no statistically significant differences in average Hb, Fer, systolic and diastolic BPs over the two time periods. ESA doses were lower by 0.5 micrograms(mcg)/patient/week. Reduction in PLT was statistically significant.

| | Oct-Dec 2012 | Oct-Dec 2011 | P value |
|---|---|---|---|
| Hemoglobin (grams/Litre) | 116 | 115 | 0.20 |
| Serum Ferritin (nanogram/millilitre) | 435.4 | 434.7 | 0.61 |
| Platelet count (x $10^6$ / Litre) | 221.6 | 233.1 | 0.02 |
| ESA dose/patient/week of Darbepoetin alfa (mcg) | 15.9 | 16.4 | 0.70 |
| Systolic BP (mmHg) | 132 | 129 | 0.11 |
| Diastolic BP (mmHg) | 73 | 71 | 0.09 |
| Haemoglobin/ESA [Hb/ESA] (g/L/mcg) | 7.32 | 7.04 | n/a |

**Table 1: Comparison of selected laboratory and clinical data in 230 haemodialysis patients over two time intervals (Oct-Dec 2012 versus Oct-Dec 2011).** The estimated annual cost saving on the account of lower ESA use was £36.40 (USD $56.94) per patient. Average Hb within the KDIGO recommended range of 90 to 115 grams/litre (g/L) was achieved in 127 (55%) patients during the most recent (Oct-Dec 2012) period.

**Conclusions:** KDIGO recommendations are gradually being implemented. Use of ESAs have declined slightly resulting in modest cost savings and possibly reduced PLT. Although average Hbs have not changed, guidelines may have helped focus attention towards reduced reliance on ESAs as demonstrated in our patients by increase in Hb/ESA ratio.

## PUB206

**Determining the Hemoglobin Target in Order to Avoid Transfusion** Romilkumar Patel, Adam E. Gaweda, Michael E. Brier. *Univ of Louisville.*

**Background:** The package insert for erythropoietin and recent comments from the FDA state "The goal is to individualize therapy and use the lowest ESA dose possible to reduce the need for red blood cell transfusion. We evaluate this goal through computer simulation.

**Methods:** We performed a simulation of hemoglobin (Hb) concentrations through time using the computer program Matlab. The following assumptions were made: 1) Hb level is chosen to buffer against routine blood loss 2) Routine blood loss is in the range of 1-3 grams Hb 3) Patients Hb cycle over a period of 6 months 4) Patients Hb cycle with an amplitude of 05. to 1.5 g/dL and 5) Transfusion threshold is 7 g/dL. Hb concentration was simulated usinga sin function with period 6 months and amplitudes of 0.5, 1.0 and 1.5 g/dL. Each week we applied a Hb drop of 1-3 g/dL and assessed the need for transfusion based on the Hb falling to the transfusion threshold. The probability of transfusion was then summed over 26 weeks.

**Results:** The results are shown in Table 1 as the Hb target needed to avoid any transfusion for routine blood losses.

| | | | Hb Buffer (g/dL) | | |
|---|---|---|---|---|---|
| Amplitude (g/dL) | 1.0 | 1.5 | 2.0 | 2.5 | 3.0 |
| 0.5 | 8.6 | 9.0 | 9.6 | 10.0 | 10.6 |
| 1.0 | 9.0 | 9.6 | 10.0 | 10.6 | 11.0 |
| 1.5 | 9.6 | 10.0 | 10.6 | 11.0 | 11.6 |

**Conclusions:** Defining the target Hb concentration for an individual patient requires the assessment of the patients variability in Hb concentration over time, likely blood loss one wishes to protect against, the threshold for transfusion for that patient, and for those patients with the highest variability, one must balance the risk of transfusion vs. high mean Hb concentrations. The results of this simulation can provide the necessary information to set individual targets.

## PUB207

**Playful Intervention Improves Nutritional Knowledge of Hyperphosphatemia in Hemodialysis Patients** Camila Machado de Barros,[1] Marina Pioltine,[2] Tânia Maria Marsulo Franciozi,[2] Thaís Barca Moraes,[2] Edeli Simioni Abreu,[2] Rosana Farah,[2] Bárbara Margareth Menardi Biavo,[1] Jacqueline Santos,[1] Elzo Ribeiro Júnior,[1] Carmen B. Tzanno-martins.[1] *[1]Nutrition, Grupo CHR, Brazil; [2]Nutrition, Universidade Presbiteriana Mackenzie, Brazil.*

**Background:** Chronic Kidney Disease (CKD) is a major public health problem and the control of serum phosphorus in these patients is recognized as an essential goal to be achieved in medical and nutritional treatment. This is due to the participation of this nutrient in the pathogenesis of secondary hyperparathyroidism, as well as in bone metabolism and bone mineralization. Objective: To evaluate the effects of a playful nutritional intervention on the knowledge regarding phosphorus of hyperphosphatemics patients undergoing dialysis.

**Methods:** A longitudinal study of 187 hemodialysis patients with hyperphosphatemia. In three nephrology clinics, located in São Paulo, Brazil. A nutrition dynamic was applied in the form of musical parody, composed by the researchers. All patients received, at the beginning of a given dialysis session, a pamphlet with the lyrics. The song featured guidelines on consumption of phosphorus in patients with CKD. The music was played and sung by patients and multidisciplinary team during the dialysis session. The impact of playful nutritional intervention was assessed by the questionnaire prepared by Nerbass et al. (2010). The questionnaire contains five questions of multiple alternatives on the knowledge of dietary phosphorus and it was applied before and after the dynamic.

**Results:** Knowledge regarding hyperphosphatemia increased in all three units when compared before and after nutritional intervention. There was an increase of 71.4% (± 16) to 80% (± 13), so that, in all questions, there was an increase in percentage of correct answers.

**Conclusions:** The nutritional intervention showed positive results on the knowledge of phosphorus in the diet, as well as the use of chelating agents to decrease the serum phosphorus level in hyperphosphatmics patients. In order to contribute to quality of life and life expectancy of these patients, we believe that further studies of nutritional intervention in dialysis patients are needed.

## PUB209

**Quantifying and Predicting the Effect of Infection and Erythropoietin Usage on Hemoglobin Level in Dialysis Patients** Jenny Feng, Adam E. Gaweda, Michael E. Brier. *Univ of Louisville.*

**Background:** Infection contributes to anemia in dialysis patients with End Stage Renal Disease (ESRD). Erythropoietin(EPO) is recommend for improving hemoglobin(Hb) levels in such cases. However, hypo-responsiveness to EPO is evident during infection and there is a lack of evaluation of appropriate EPO dosages during infection.

**Methods:** The Hb levels of 46 dialysis patients with ESRD at the University of Louisville Kidney Disease Program Dialysis Unit were studied. They had stable Hb levels pre-infection, had at least 1 infectious event, and received increased dosages of EPO following infection. Hb levels from pre-infection, infection, and post-infection were averaged for each time period. EPO resistance was calculated. Patients who were hospitalized for their infections were compared to non-hospitalized patients.

**Results:** There were 27 infectious events that resulted in hospitalization and 15 infectious events that were treated at the dialysis unit. Hb levels decreased in both groups

with a greater degree of decrease in hospitalized, -2.01±0.92 g/dL, versus 1.67±1.32 g/dL in non-hospitalized. Duration of decreased Hb level was longer for hospitalized, 66.7±27.07 days, when compared to 59.53±33.66 days in non-hospitalized. The amount of time it took for Hb concentrations to recover and reach peak Hb concentrations was also longer for hospitalized, 77.40±45.41 days, when compared to 69.23±20.93 days non-hospitalized.

**Conclusions:** Infection contributes to hypo-responsivity to EPO in both hospitalized and non-hospitalized patients. Compared to non-hospitalized patients, hospitalized patients suffered from greater Hb decline and longer duration of EPO hypo-responsitivity. Aggressive EPO dose adjustment during and immediately following an infectious event may lead to overcompensation post-infection and Hb overshooting the target range. EPO dosages may need to be held constant or at least limit the dose excalation that occurs due to an anemia management protocol. Ongoing work involves identifying factors associated with poorer EPO response and clinical outcomes, and simulating patterns of hgb response to EPO in infection.

*Funding:* NIDDK Support

## PUB210

**Dysregulation of Thrombotic and Hemostatic Factors in End Stage Renal Disease** Vinod K. Bansal,[1] Debra Hoppensteadt,[2] Syed Mustafa Ahmed,[3] Jawed Fareed.[2] *[1]Nephrology, Loyola Univ Medical Center, Maywood, IL; [2]Pathology, Loyola Univ Medical Center, Maywood, IL; [3]Medicine, Loyola Univ Medical Center, Maywood, IL.*

**Background:** Increased cardiovascular events occur in ESRD patients on maintenance hemodialysis. The objective of this study was to utilize newly introduced cardiac biomarker chips and immunoenzymatic methods, profiling various biomarkers of inflammation and thrombogenesis in a defined ESRD patient population.

**Methods:** Blood samples from seventy two ESRD patients were drawn prior to maintenance hemodialysis. Commercially available ELISA kits for Tissue Plasminogen Activator – Plasminogen Activator Inhibitor Type-1 complex (tPA-PAI-1 complex), Plasminogen Activator Inhibitor Type-1 (PAI-1), Myeloperoxidase, (MPO), Thrombomodulin, (TM), Interleukin-1 beta (IL-1β), Anti-Annexin V, human sL-selectin, and Inter-Cellular Adhesion Molecule 1 (ICAM-1). Functional methods were used for measuring Antithrombin and Von Willebrand factor (vWF) activity were used. The biochip arrays (Randox, Evidence System, United Kingdom)for cardiac markers, included creatine kinase-MB (CK-MB), Myoglobin (Myo), Heart-type fatty acid binding protein (hFABP) and cardiac troponin I (cTn1). The cerebral array included C-reactive protein (CRP), D-Dimer (DDMER), Neuron Specific Enolase (NSE), Neutrophil Gelatinase-Associated Lipocalin (NGAL), soluble Tumor Necrosis Factor Receptor 1 (TNFRI) and Thrombodulin (TM).

**Results:** ESRD patients showed assay dependent decrease in markers such as tPA-PAI-1, Anti-Annexin V, L-selectin and Antithrombin activity (ranging from 18 to 46%). The levels for MPO, TM, CK-MB, MYO, FABP, CRP, DDMER, NSE, NGAL, TNFR1, and vWF activity all showed a significant increase in the ESRD patients (ranging from 25%-5587%). No changes were observed in the IL-1B, ICAM1, or cTn1 in ESRD patients compared to normal groups.

**Conclusions:** These studies underscore the role of inflammatory and thrombotic mediators in ESRD. The cardiac biochip array revealed a remarkable elevation of the FABP and as well as a notable increase in MYO. The cerebral array revealed a remarkable elevation of the TNFR1.

## PUB211

**Stable Serum Magnesium Levels in Chronic Hemodialysis Patients** Eduardo K. Lacson,[1] Weiling Wang,[1] Chinu M. Jani,[2] Franklin W. Maddux.[1] *[1]Fresenius Medical Care, North America, Waltham, MA; [2]Spectra Laboratories, Rockleigh, NJ.*

**Background:** Serum magnesium (sMg) has been reported to be stable within one year in Japanese patients. We investigated the stability of sMg and prescribed dialysate magnesium (dMg) in chronic hemodialysis (HD) patients.

**Methods:** All in-center HD patients treated as of 1/1/08 at Fresenius Medical Care North America facilities with Mg measured for period 1 (4/1 - 6/30, 2007) and period 2 (10/1 – 12/31, 2007) were included. The 3-month mean sMg and weighted mean dMg for both periods were calculated and age, gender, race, diabetes mellitus, vintage, vascular access and hospitalization from the prior 30 days for each period. Spectra assay variability (represented by twice the SD) indicates that ~95% of re-test samples will fall between ±0.2 mEq/L.

**Results:** 16,768 patients had mean age of 61.9 ±14.6 years, 53.7% males, 46.2% whites, 46.6% blacks, 7.2% other races, and 52.8% with diabetes, and dialysis vintage of 4.1 ± 3.7 years. The interquartile range (IQR) of delta sMg was -0.1 – 0.2 (Table). Subgroup analyses for age (<45, 45-54, 55-64, 65-75, and > 75 years), gender, race, diabetes mellitus, vintage (<=120, 121-1095, and >1095 days) and prior 30 days hospitalization did not reveal effect modification.

Distribution of sMg, dMg, and the difference between periods (delta).

| Units: mEq/L | Mean (SD) | Median (IQR) |
|---|---|---|
| sMg of Period 1 | 1.86 (0.31) | 1.8 (1.7 – 2.0) |
| sMg of Period2 | 1.89 (0.31) | 1.9 (1.7 – 2.1) |
| sMg Delta (P2-P1) | 0.03 (0.25) | 0 (-0.1 – 0.2) |
| (prescribed) dMg of Period 1 | 0.95 (0.19) | 1 (0.9 – 1.0) |
| (prescribed) dMg of Period2 | 0.97 (0.15) | 1 (1.0 – 1.0) |
| (prescribed) dMg Delta (P2-P1) | 0.03 (0.16) | 0 (0.0 – 0.01) |

**Conclusions:** Serum and prescribed dialysate magnesium levels were stable over a 6-9 month period in a national sample of American HD patients. The observed differences in sMg were no greater than the expected assay variability of this test.

## PUB212

**Are There Differences in Treatment for Acute Myocardial Infarctions among Patients with Chronic Kidney Disease Stage 3-5, End Stage Renal Disease, and Patients with Normal Kidney Function?** Ninad D. Parekh, Chadi Saifan, Elie El-Charabaty, Suzanne E. El Sayegh. *Dept of Medicine, Div of Nephrology, Staten Island Univ Hospital, Staten Island, NY.*

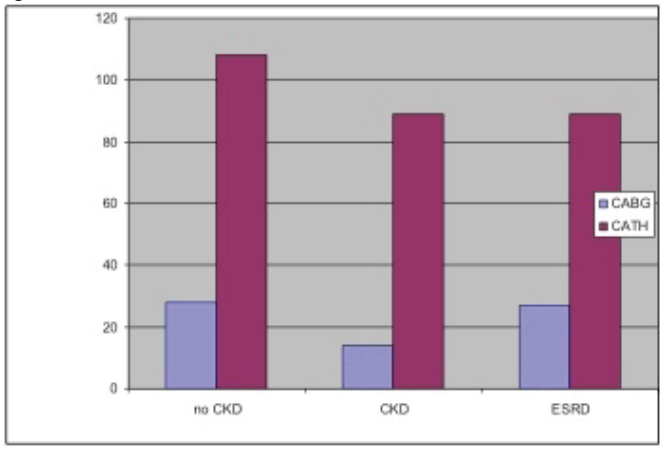
**Background:** Patients with CKD and/or ESRD have a higher risk of CAD and consequently higher morbidity and mortality from CAD. In this study, we aim to evaluate the differences in inpatient care of acute MI among patients with no CKD, patients with CKD and patients with ESRD.

**Methods:** All patient with ESRD on dialysis admitted with MI from 2007 to 2012 were matched with patients with CKD and patients with no CKD. The patients' characteristics including age, sex, risk factors, medications, length of stay, and need for a cardiac catheterization or CABG were collected.

**Results:** Mean ages were 68.2, 66.1 and 68.9 years, for the no CKD, CKD, and ESRD groups respectively. There were no statistically significant differences in medications, length of stay, and LVEF among all three groups. The admission diagnosis, the need for catheterization or CABG, and different risk factors are shown in table1.

| Category | N | NSTEMI | STEMI | Cath | CABG | DM | HTN |
|---|---|---|---|---|---|---|---|
| No CKD | 132 | 58% | 48% | 83% | 21.4% | 44.3% | 74% |
| CKD | 122 | 44.6% | 55.4% | 74.8% | 11.6% | 49.6% | 73% |
| ESRD | 122 | 62% | 38% | 73.6% | 22.% | 45.8% | 73.8% |

A t-test of two-sample assuming equal variances were done for the all three groups including the need for CABG or cardiac catheterization, and showed no statistically significant differences.



**Conclusions:** Contrary to other studies, our study did not show any statistical difference in treatment of MI among all three groups: patients with normal kidney function, with CKD or ESRD. We recommend that our finding should be verified in large multicenter study.

## PUB213

**Pulmonary Hypertension and Right Ventricular Dysfunction in Patients under Maintenance Hemodialysis** Lijun Zhao, Songmin Huang, Hong Tang, Ting Liang. *West China Hospital, Sichuan Univ, Chengdu, China.*

**Background:** When chronic hemodialysis treatment has been revealed to increased the systolic pulmonary artery pressure (sPAP),right ventricular dysfunction (RVD) is an important predictor of prognosis in patients with end-stage renal disease (ESRD).This study was to investigate the prevalence of pulmonary hypertension (PHT) and RVD among patients and the possible contributing factors for these clinical features.

**Methods:** Study population consisted of 67 patients under long-term hemodialysis (HD) therapy via arteriovenous (A-V) access in our HD center.Doppler echocardiography including myocardial performance index (MPI) of right ventricle and RV wall thickness were performed in all patients.The relationship of PHT and RV hypertrophy were analyzed by Pearson correltion analysis.The risk factors of PHT were analyzed by Logistic regression analysis.

**Results:** SPAP>35 mmHg which indicate PHT was found in 37.31% of patients,while 44.78% of patients had RVD.Patients were divided into non-PHT subgroup (n=42) and PHT group (n=25).Compared with the non-PHT subgroup, patients with PHT had a higher systolic blood pressure,while had lower levels of hemoglobin and Kt/V value.Patients in PHT subgroup demonstrated lower left ventricular ejection fraction (LVEF) than patients in non-PHT subgroup (65.5% *vs.* 60.1%,*p=0.04*). RVD,assessed by MPI,was higher in patients with PHT than those without PHT. Additionally,The former group showed a higher incidence of RV hypertrophy than those in non-PHT subgroup (9.5% *vs.* 32%,*p*=0.041). Pearson correlation analysis showed that sPAP was correlated with RV wall thickness positively (*r=0.394, p=0.01*).Logistic regression analysis revealed that LVEF contributed to the predictability of incidence of PHT ( regression coefficient *b*=-0. 096, *OR*=1.100, *p*=0. 01) as well as systolic blood pressure ( regression coefficient *b*= 0. 063,*OR*=0.940, *p*=0. 002).

**Conclusions:** The prospectively study demonstrated high incidences of PHT and RV dysfunction among ESRD patients under maintenance HD via surgically created native A-V access.The status of LV function,poor control of systolic blood pressure have played an important role in the mechanism of PHT,RVD in chronic uremia patients.

## PUB214

**The Association of Dental Health and All Cause and Cardiovascular Mortality in Hemodialysis Patients: Oral-D Study** Giovanni F.M. Strippoli,[1,2,3,4] Suetonia Palmer,[5] Marinella Ruospo,[1,2] Patrizia Natale,[1] Valeria Maria Saglimbene,[1,2] Michela Sciancalepore,[1] Letizia Gargano,[1] Fabio Pellegrini,[2] David W. Johnson,[6] Pauline J. Ford,[6] Jonathan C. Craig,[4] Paul Stroumza,[1] Luc Frantzen,[1] Miguel Rodrigues Leal,[1] Marietta Torok,[1] Anna Bednarek,[1] Jan Dulawa,[1] Eduardo Jorge Celia,[1] Ruben Gelfman,[1] Jorgen B.A. Hegbrant,[1] Charlotta Wollheim,[1] Staffan Schön,[1] Michele De Benedittis,[3] Massimo Petruzzi.[3] *[1]Diaverum; [2]Mario Negri Sud Consortium; [3]Univ of Bari; [4]Univ of Sydney; [5]Univ of Otago; [6]Univ of Queensland.*

**Background:** It has been hypothesized that oral disease may be associated with increased risks of death due to inflammation or as a general indicator of healthcare practices. We evaluated the association between dental status and the risk of all-cause and cardiovascular mortality in adults on hemodialysis.

**Methods: ORAL-D** is a multinational prospective cohort study of consecutive adults on hemodialysis in 75 outpatient clinics selected randomly from a dialysis network in Europe and South America. A dental surgeon evaluated dental status by using the DMFT (decayed, missing, filled, permanent teeth) score. Quality of dental health was defined based upon WHO criteria as low, moderate and high DMFT scores of <2.6, 2.7-4.4 and >4.4. We assessed survival at 8 months using centralized mortality data. We conducted analyses using Cox regression controlling for age, gender, previous cardiovascular events, income status, clinical performance measures, dialysis prescription and performance indicators, and depressive symptoms. Complete follow-up data at 12 months will be available by September 2013.

**Results:** 4720 hemodialysis patients in the participating clinics received a complete evaluation of their dental status and completed follow up. Median follow up was 8.0 (6.5 to 8.7) months and 344 (10%) died during follow up. Dental health (DMFT scores) had uncertain associations with all-cause or cardiovascular mortality.

**Conclusions:** Dental health has uncertain associations with all-cause and cardiovascular mortality in patients on hemodialysis. ORALD will be completed at the end of 1 year follow up by September 2013.

## PUB215

**Investigating the Relationship of Intradialytic BP Changed and ADMA** Aiqun Chen,[1] Hua Wu,[1] Ying Sun,[1] Deping Liu.[2] *[1]Nephrology, Beijing Hospital, Beijing, China; [2]Cardiology, Beijing Hospital, Beijing, China.*

**Background:** To observe the level of plasma asymmetric dimethylarginine (ADMA) and analyze the relationship between ADMA and the different intradialytic blood pressure change in MHD patients.

**Methods:** The blood pressure changed intra-dialysis was measured through ambulatory BP monitor. The 31 MHD patients with proper dry body weight were divided into intradialytic hypertention(BP increased >15mmHg, n=11), hypotention(BP decrease >20mmHg, n=12)and stable BP(n=8)groups. The plasma ADMA wsa detected by ELISA (Enzyme linked immunosorbent assay) method in pre- and post- HD. The possible effect factors were analysed and compared between the 3 groups.

**Results:** There were 17 male and 14 female in 31 MHD patients. The average age was 66.97±9.24 years. The average hemodialysis duration was 75.71±50.65 monthes. The plasma ADMA were markedly elevated in the beginning of HD and fell in the end of HD sessions (3.37±1.48umol/L vs 1.71±0.80 umol/L). Both before and after HD, the plasma ADMA levels were highest in intradialytic hypotensive patients (4.38±1.56 umol/L, 2.25±0.83 umol/L) than in stable BP and hypertensive patients(2.70±1.18umol/L, 1.32±0.60umol/L; 2.78±0.88umol/L and, 1.43±0.56umol/L; P=0.004 and 0.011). The pulse pressure was significantly higher in intradialytic hypertensive patients than that in stable BP and hypotensive patients (62.41±11.57mmHg, 47.98±13.30 mmHg and 44.56±8.30 mmHg, P=0.008 and 0.003). ALP, TC, LDL-C were higher in hypertensive and hypotensive patients than in stable BP patients (all P<0.05), but there was no significant difference between this two groups. Hs-CRP in hypotensive group was highest in 3 groups(8.43 ± 6.00mg/L, 4.85 ± 3.39 mg/L, 2.00±1.81mg/L, P= 0.092, 0.004).

**Conclusions:** ADMA are markedly elevated in MHD patients and with a significant fall in the end of the HD sessions. The plasma ADMA lever and hs-CRP in intradialytic hypotensive patients is the highest.

## PUB216

**Usefulness of NT-pro-BNP as a Marker of Overhydration and Alteration on Body Composition in Dialysis Patients. Effect of a Nutritional Intervention on NT-pro-BNP Levels** Maria astrid Rodriguez Gomez, María José Fernández-reyes, Manuel M. Heras, Alvaro Molina Ordas. *Nephrology, Hospital General de Segovia, Segovia, Spain.*

**Background:** NT-proBNP is a powerful predictor of risk of heart failure (HF) and mortality in patients with chronic kidney disease. Elevated levels of NT-proBNP in dialysis patients have been associated with heart disease and with extracellular water excess.

Analyze NT-proBNP to detect extracellular volume overload dependent on alterations in body composition and independent of cardiac history. Check if a nutritional intervention in malnourished patients would modify the body composition and NT-proBNP.

**Methods:** We evaluated the nutritional status in 40 stable dialysis patients, mean age 71 ± 10 years, time on dialysis of 49 ± 47 months, 40% with history of HF. Nutritional analysis included: biochemical parameters related to nutrition and inflammation; anthropometric parameters; body composition by electrical bioimpedance; and nutrient uptake. In 16 patients with nutritional deficiencies we started nutritional supplements. Two months later, the initial evaluation was repeated (including NT-proBNP).

**Results:** NT-proBNP correlates with history of HF (r = 0.30, p = 0.05) and with some body composition parameters related to extracellular water such as phase angle (r = -0.39 , p = 0.014), Na K exchange (r = 0.49, p = 0.001) and extracellular water percentage (r = 0.40, p = .01). In multiple regression analysis the model that better explains the levels of NT-pro-BNP is the one that includes the Na K exchange and the history of HF. There is a strong correlation between the NT-proBNP levels at baseline and after 2 months (r = 0.9, p <0.0001). Overall NT-proBNP did not change after the redetermination two months later. Excluding the 16 patients with HF history, we observed that proBNP levels in 10 patients with nutritional intervention significantly decreased, whereas in 14 patients without nutritional intervention remained stable.

**Conclusions:** NT-proBNP in dialysis patients is independently correlated with parameters of extracellular water overload. Nutritional intervention in malnourished patients without HF history can decrease the NT-pro-BNP levels.

## PUB217

**Preliminary Study on the Intradialytic Blood Pressure Variability and Influencing Factors in Maintenance Hemodialysis Patients** Aiqun Chen,[1] Ying Sun,[1] Hua Wu,[1] Deping Liu.[2] *[1]Nephrology, Beijing Hospital, Beijing, China; [2]Cardiology, Beijing Hospital, Beijing, China.*

**Background:** Objective To understand the blood pressure variability intra-dialysis and the influencing factors in MHD patients.

**Methods:** We enrolled 81 MHD patients into the study. Using dynamic BP monitor BP was measured intra-dialysis. BPV was estimated with the variation coefficient(CV) and standard deviation(SD). Patients are divided into two groups according to SBP-CV: high and low SBPV groups. The possible effect factors were analyzed and compared. And multivariate stepwise regression analysis was made between the SBPV and the influencing factor.

**Results:** There were 47 male and 34 female in 81 MHD patients. The average age was 62.8±13.1 years. The average dialysis duration was 62.00±47.50 monthes. The average SBP-CV in intradialysis was 8.12±3.16%. The patients were divided into CV>8.12% group(35 patients) and <8.12% group(46 patients). There were more female,longer dialysis duration,lower dry body weight in high SBPV group, but not significantly differences(P=0.13,0.11±0.08 respectively). Complicating of coronary artery disease(CAD) and T2 DM in low SBPV group(43.5%, 23.9%)was higher than in high SBPV group(25.7%, 20.0%)(P 0.099, 0.660). The incidence of intrahypertension and hypotension (20.0%, 25.7%) was higher in high SBPV group than in low SBPV group(8.7%, 6.5%)(P <0.009).The patients taking CCB were more (80.4%,65.7%)and lower dose of EPO(5358.7±4415.5U/ week, 6600.0±5270.0U/week)in low SBPV group than in high SBPV,but not statistical different(P 0.13±0.20). Serum creatinine, potassium, hs-CRP and ALP were higher in high SBPV group than that in low SBPV group (P 0.034, 0.005, 0.001 and 0.049 respectively). SBP-SD,CV and hsCRP were positively related (r = 0.756,0.464 ), SBP-CV and dialysis vintage were positively related (r = 0.211) by the multivariate stepwise regression analysis. There was no correlation between SD, CV and age, dry body weight, UF volume, dehydrate/ weight ratio, serume calcium, potassium, sodium, lipoprotein.

**Conclusions:** Intradialytic SBPV is positive associated with the inflammatory state and dialysis vintage in the MHD patients. There is no correlation between SBPV and UFV, dry weight.

## PUB218

**Association between Sleep-Disordered Breathing (SDB) and Brain Natriuretic Peptide (BNP) in Hemodialysis Patients** Fumiko Fukuuchi,[1] Takashi Kabaya.[2] *[1]Nephrology, Kumanomae Jin Clinic, Arakawa-ku, Tokyo, Japan; [2]Minmisenjyu Hospital, Japan.*

**Background:** A high prevalence of SDB has been reported in patients on hemodialysis. SDB has been associated with cardiovascular risk. SDB has important clinical implications in patients with congestive heart failure. Plasma BNP level is the independent prognostic factor in dialysis patients.

**Methods:** The aim of this study is to reveal the relationship between BNP and SDB.15 dialysis outpatients are included in this study and received sleep study with portable sleep apnea test equipment (LS-300, Fukuda Denshi Co., Ltd. Japan) for one night after dialysis. 4 dialysis outpatients are hospitalized and performed a sleep study with conventional Polysomunography (PSG) for two consecutive nights, before HD day and HD day. BNP, total protein, UN, creatinine, hematocrit were measured at the before and after dialysis. The echocardiography was also performed.

**Results:** Of 15 patients with LS-300, 13 patients were diagnosed as SDB. The average AHI was 26.7 ± 10.3 (mean ± SD)/ hour. Obstructive apnea was main. The BNP level was 418.2 ± 434.2 (mean ± SD) pg / ml, 278.8 ± 280.1 pg/ml, before and after dialysis, respectively. Correlation coefficient of BNP and AHI was 0.38, 0.37, before and after dialysis, respectively. In the case of whose pre-dialysis BNP level was more than 400pg/ml, the correlation coefficient of BNP and AHI was 0.72 ($p = 0.04$). Three of these patients were received sleep test again after Dry Weight reduction. AHI and BNP of them were improved. Of 4 patients with conventional PSG, all patients were diagnosed as SDB. 3 cases were severe, 1 case was mild grade of SDB. Obstructive apnea is main in both the day before dialysis and dialysis day. The AHI was improved after dialysis in three case of four. The BNP levels of 2 cases were more than 300pg/ml even after dialysis. In these 2 cases, AHI, maximum apnea time, minimum arterial oxygen saturation was improved in dialysis day.

**Conclusions:** Elevated BNP level is related to SDB in dialysis patients. Extracellular fluid volume overload is associated with SDB and the BNP level. SDB in dialysis patients can be expected to improve after dialysis if heart failure is suspected in the high level BNP.

## PUB219

**Diagnosis of Autonomic Dysfunction in Hemodialysis Patients Using Heart Rate Related Parameters in the Exercise Test** Jocemir R. Lugon, Maria A. Carreira, Marcio Galindo Kiuchi, Felipe M. Pena, Andre B. Nogueira, Ronaldo C. Rodrigues, Jorge P. Strogoff-de-Matos. *Medicine, Universidade Federal Fluminense, Niteroi, Rio de Janeiro, Brazil.*

**Background:** Hemodialysis (HD) patients have increased risk of sudden death problably due to impaired autonomic function. We aimed to evaluate the frequency of autonomic dysfunction in a cohort of HD patients in comparison to controls (C) employing the exercise test (ET).

**Methods:** Cross sectional study with HD patients from a single center. Sessions were performed thrice a week for 4 hours. ET was accomplished in a non-dialysis day using the treadmill ramp protocol. The test was symptom-limited with an active recovery period of 2 min. A set of heart rate (HR) related parameters were assessed at baseline, exercise and recovery.

**Results:** From 125 HD patients, 41 were selected for the study. They were 50±14 years old, 51% male, 66% non-white, and 7% diabetics. Forty-one non-dialysis C, age and gender matched were enrolled. At baseline, HR, systolic blood pressure (BP) and diastolic BP of HD and C patients were not different. At ET values were statistically different between HD and C groups for the following variables: chronotropic deficit (23.5±12.1 vs. 6.5±6.4%, P<0.001); chronotropic index (57.5±19.1 vs. 88.9±12.0, P<0.001); HR recovery (HRR) at the 1st min (11.9±9.1 vs. 19.6±8.6 bpm, P<0.001), 2nd min (21.3±12.3 vs. 34.1±10.5 bpm, P<0.001), 3rd min (33.8±21.3 vs. 53.2±18.0, bpm, P<0.001), and 5th min (40.8±21.3 vs.60.2±14.4 bpm, P<0.001); and R-R variability (SDNN) either during exercise (33.7±14.2 vs. 50.4±21.3 msec, P<0.001) or recovery (20.1±9.8 vs. 26.5±16.9, P=0.041). When patients under betablockers (HD 34% and C 17%) were analysed separately , chronotropic deficit (35.0±10.0 vs. 10.6±5.9bpm, P<0.001), chronotropic index (41.2±15.7 vs. 80.9±9.5, P<0.001) and HRR at the 3rd min (27.8±16.1 vs. 42.6±11.2 bpm, P=0.043) and 5th min (33.2±14.1 vs. 53.4±14.4, P=0,006) still discriminate between HD an C.

**Conclusions:** The ET was found useful for diagnosis of autonomic dysfunction in HD patients. The most discrimant parameters between HD and C groups were the chronotropic deficit, the chronotropic index and the HRR at the 3rd and 5th min, irrespective of the use of betablockers.

## PUB220

**Cinacalcet May Improve Oxidative DNA Damage in Maintenance Hemodialysis Patients – An Observational Study** Elif Ari Bakir. *Nephrology, Kartal Research and Training Hospital, Istanbul, Turkey.*

**Background:** The aim of the study was to evaluate the impact of cinacalcet on oxidative stress biomarkers, oxidative DNA damage (8-hydroxy-2'-deoxyguanosine/deoxyguanosine) (*8-OHdG/dG*) and endothelial function in HD patients.

**Methods:** Thirty chronic HD patients undergoing 60 mg/day cinacalcet treatment with a follow-up of 6 months and 30 healthy individuals were included in this prospective study. Plasma malondialdehyde (MDA) levels and *8-OHdG/dG* were determined as oxidative stress markers. Superoxide dismutase (SOD), paraoxanase (PON), catalase (CAT), carbonic anhydrase (CAN) and glutathione peroxidase (GPx) activites were measured as antioxidants.

**Results:** MDA levels were decreased; SOD, PON, CAT, CAN and GPx activites were increased after 6 months of cinacalcet treatment. Although CIMT remained stabile, there was a significant improvement in FMD% as well as a notable reduction trend in 8-OHdG/dG ratio after 6 months of treatment.

| | Hemodialysis Group-Baseline (n=30) | Hemodialysis Group-after 6 months (n=30) |
|---|---|---|
| Malondialdehyde (µmol/L) | 10,05 ± 5,74 | 5,71 ± 2,05¶ |
| 8-hydroxy-2´-deoxyguanosine/ deoxyguanosine | 2,47 ± 1,26 | 1,83 ± 0,83¶ |
| Superoxide dismutase (EU/mL) | 5,17 ± 1,82 | 7,29 ± 1,35¶ |
| Glutathione Peroxidase (EU/mL) | 7,62 ± 4,25 | 16,79 ± 7,63¶ |
| Paraoxanase (EU/mL) | 140,12 ± 18,54 | 183,95 ± 28,89¶ |
| Catalase (EU/gHb)–¹ | 24,60 ± 4,75 | 35,68 ± 4,48¶ |
| Carbonic anhydrase (EU/gHb)–¹ | 0,43 ± 0,22 | 1,45 ± 0,53¶ |
| Flow mediated dilatation (%) | 7,42 ± 2,08 | 9,64 ± 2,26¶ |
| Carotid artery intima-media thickness (mm) | 0,70 ± 0,11 | 0,69 ± 0,16 |

*¶: p<0.05 vs Hemodialysis group (Baseline).*

**Conclusions:** Cinacalcet improves oxidative stress, genomic damage, endothelial function and increases antioxidant protection in HD patients after 6 months of treatment.

## PUB221

**Left Ventricular Hypertrophy in End-Stage Renal Disease: Determinants and Impact on Myocardial Mechanics** Attila Kovács,[1] Mihaly B. Tapolyai,[2] Maria Faludi,[2] Klara Berta,[2] Bela Merkely.[1] *[1]Heart and Vascular Center; [2]Fresenius Medical Care.*

**Background:** Left ventricular (LV) hypertrophy is a major predictor of mortality in end-stage renal disease (ESRD). We sought to reveal the causes of increased LV mass in ESRD patients and to assess its influence on LV deformation using 3D echocardiography.

**Methods:** Forty-four patients (mean age 48±13 years, 54% men) with ESRD on maintenance hemodialysis (HD), without diabetes and any significant cardiac disease were investigated just before and immediately after HD, and compared to 46 controls (NC; 48±12 years, 48% men). Beyond conventional echo, 3D recordings were obtained using multi-beat reconstruction from 6 cardiac cycles (GE Vivid E9). LV mass indexed to body surface area (LVMi) were measured, and 3D speckle tracking analysis was performed to assess global longitudinal (LS), circumferential (CS), area (AS) and radial (RS) peak systolic strain (4D Auto LVQ). We also measured serum FGF-23 levels (Merck Millipore) and evaluated overhydration status by bioimpedance (Fresenius BCM). Data are presented as median(interquartile range).

**Results:** LVMi was remarkably increased in ESRD patients [136(46) vs. 71(8) g/m², p<0.001]. By multivariate linear regression ($R^2$=0.91, p<0.001), FGF-23 (β=0.41), total iron binding capacity (β=0.49), overhydration (β=0.29), systolic blood pressure (β=0.43) and bodyweight (β=0.39) were found to be independent predictors of LV mass. Strain values in all directions improved after HD [pre- vs. post-HD; LS: -20(3) vs. -21(6), CS: -20(4) vs. -22(7), AS: -33(5) vs. -35(10), RS: 50(12) vs. 53.5(20) %, all p<0.01]. While there was no difference in LS, the patients' pre-HD CS, AS and RS values were reduced, and after HD only CS increased enough to be similar compared to NC [NC LS: -20.5(3), CS: -21(3), AS -36(3), RS 61(8) %, all p<0.05]. LVMi inversely correlated with pre-HD CS (Spearman's ρ=0.63) and post-HD LS (ρ=0.64), CS (ρ=0.74) and AS (ρ=0.53, all p<0.05).

**Conclusions:** Beyond the chronic volume- and pressure overload, LV hypertrophy is determined by the endocrine effect of FGF-23. HD results in immediate improvement of LV function. The increase of LVMi correlates strongly with the reduction of 3D deformation parameters.

## PUB222

**Does This Adult Hemodialysis Patient without SIRS Require Blood Culture?** Daisuke Uchida,[1] Sho Sasaki,[1] Masahito Miyamoto,[2] Kenichiro Koitabashi,[4] Tomo Suzuki,[1] Hiroo Kawarazaki,[1] Yugo Shibagaki,[1] Kenjiro Kimura.[1] *[1]Internal / Div of Nephrology and Hypertension, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; [2]Nephrology, Shonan Kamakura General Hospital, Kamakura, Kanagawa, Japan; [3]Medicine / Div of Nephrology, St. Luke's International Hospital, Tokyo, Japan.*

**Background:** Bacteremia is one of the most common causes of death in hemodialysis patients in Japan, but it is often difficult to diagnose it at the first hospital visit. The systemic inflammatory response syndrome (SIRS) is a powerful predictor of bacteremia in general population. However, it is not known if SIRS is also predictive of bacteremia in patients on hemodialysis.

**Methods:** We designed a multi-center retrospective observational study of adult hemodialysis outpatients who had 2 sets of blood cultures drawn for suspected infection at their first hospital visit from August 2011 to July 2012. Antibiotics administered prior to first visit and access other than arterio-venous fistula (AVF), which is the main vascular access in Japan, was excluded. Bacteremia was diagnosed by positive blood culture after the exclusion of contamination by a pre-set criteria. Clinical, biological and microbial data were obtained to evaluate the usefulness of SIRS as a predictor of bacteremia at first visit to the outpatient setting.

**Results:** Data was obtained from 279 participants. Vascular access other than AVF (N=51) and antibiotics administered prior to first visit (N=36) were excluded. Mean age of participants was 70 years, 68.2% were male, 49.5% were diabetic, and 28.1% had indwelling artificial objects. Among the 192 participants, 17.7% (N=34) had bacteremia and the most common infectious sites were endocarditis, osteomyelitis and AVF infection (N=4). The most common microbe was Staphylococcus aureus (N=11). 22.9% of those who met the

criteria for SIRS, and 12.5% of those who did not meet the criteria for SIRS had bacteremia (p=0.09). SIRS had a low sensitivity for bacteremia in hemodialysis patients (sensitivity 64.7%, specificity 53.2%, positive LR 1.38, negative LR 0.66).

**Conclusions:** SIRS may not be helpful in distinguishing adult AVF hemodialysis patients to exclude bacteremia.

## PUB223

**Annual Update on Elimination of Hemodialysis Related Bacteremia and Vascular Access Infection** Jafar Al-Said, Aimee Pagaduan, Soni Murdeshwar. *Nephrology and Internal Medicine, Bahrain Specialist Hospital, Bahrain.*

**Background:** Hemodialysis related bacteremia and dialysis blood stream infection are the major causes of morbidity and the second cause of mortality in ESRD population. Great efforts are spent to control and reduce hemodialysis related bacteremia and access infection. We have been following strict infection control protocol since the beginning of our Hemodialysis service. The aims of this study were to update the prevalence of Hemodialysis related Bacteremia and vascular access infection and to identify the outcome of the tight infection control protocol we have been following.

**Methods:** This study is a retrospective analysis for the outcome of hemodialysis infection protocol over 112 months from January 2004 till May 2013. All Hemodialysis sessions performed were included during that period. Patients' demographic and vascular access types were collected from the electronic data. Hemodialysis induced bacteremic infection per 100 patient month, admission rates for Hemodialysis related bacteremia per 1000 patient year and admission for vascular access infection were estimated.

**Results:** Total Patients were 147. Total Hemodialysis sessions were 8641. Mean age was 57.6 years (SE 1.3). Male gender formed 55%. Types of vascular access were; 56.3% cuffed tunneled catheters, 19.5% AV fistula, 18.2 AV grafts and 5.8% vascath. Estimated infection prevalence is shown below.

| Calculated Variables | Ratio |
|---|---|
| Hemodialysis bacteremic infection per month | 0.001 |
| Hemodialysis related blood stream infection per 100 patient month | 0.016 |
| Admission for hemodialysis related bacteremia per 1000 patient year | 0.4 |
| Admission for vascualr access infection over 112 months | Zero |

**Conclusions:** The tight infection control protocol followed in our unit had persistently eliminate HD related infection and vascular access infection. We are reporting significant lower infection rate as compared to all published international data. We would like to present and share this infection control protocol with other HD centers.

## PUB224

**The Role of Pre-Dialysis N-Terminal Probrain-Type Natriuretic Peptide for Volume Estimation in Haemodialysis Patients** Arkom Nongnuch,[1,2] Andrew Davenport.[2] *[1]Renal Unit, Dept of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand; [2]Centre for Nephrology, Royal Free Hospital, Univ College London, London, United Kingdom.*

**Background:** N Terminal Probrain Type Natriuretic Peptide (NTproBNP) is used to aid the diagnosis of heart failure. In haemodialysis patients, NTproBNP could be increased due to pre-existent cardiac disease, volume overload, and reduced by residual renal function. We examined the effects of volume status on predialysis NT-proBNP, by measuring body water with bioimpedance and estimating over hydration using the Fresenius BCM In Body manufacturer's equations.

**Methods:** We prospectively studied 158 stable chronic HD patients, attending their midweek dialysis session who had predialysis bioimpedance measured (In Body). Serum biochemistry, relevant demographic, biochemical and bioimpedance data was collected prior to the session.

**Results:** Predialysis log NT-proBNP was correlation with age, sex, race, dialysis vintage, history of valvular heart disease, myocardial infarction, coronary stenting, peripheral vascular disease, number of anti-hypertensive medications, predialysis systolic blood pressure, mean arterial blood pressure, haematocrit, albumin, CRP, B2 microglobulin and volume overload estimated by the In Body equation, but not diabetes, stroke, hypertension, ratio of predialysis ECW/TBW, and volume overload estimated by the Fresenius BCM equation. On multiple linear regression analysis, NTproBNP was significantly associated with history of cardiac valve disease, myocardial infarction, coronary stenting, number of anti-hypertensive medications, predialysis systolic blood pressure and log B2 microglobulin, and negatively with serum albumin and haematocrit.

| Parameters | B coefficient | SD | t | P value |
|---|---|---|---|---|
| History of valve disease | 0.558 | 0.19 | 2.8 | 0.006 |
| Previous myocardial infarction | 0.25 | 0.12 | 1.9 | 0.049 |
| Previous coronary artery stenting | 0.43 | 0.14 | 3.1 | 0.002 |
| Total No hypertensive medications | 0.1 | 0.04 | 2.27 | 0.024 |
| Predialysis systolic blood pressure | 0.007 | 0.002 | 4.1 | 0.000 |
| Predialysis haematocrit | -2.47 | 1.07 | -2.3 | 0.022 |
| Predialysis serum Albumin | -0.032 | 0.01 | -3.1 | 0.002 |
| Log B2 microglobulin | 0.996 | 0.31 | 3.13 | 0.002 |

**Conclusions:** Predialysis NT-proBNP is associated with pre-existent cardiovascular morbidity, anaemia and hypoalbuminaemia rather than estimates of overhydration.

## PUB225

**Birth Weight and End-Stage Diabetic Nephropathy in Later Life: A Japanese Multicenter Study** Kei Nagai,[1] Chie Saito,[1] Soh Suzuki,[1] Masahiro Hagiwara,[1] Hirayasu Kai,[1] Joichi Usui,[1] Keigyou Yoh,[1] Shuichi Tsuruoka,[2] Kunihiro Yamagata.[1] *[1]Dept of Nephrology, Faculty of Medicine, Univ of Tsukuba, Tsukuba, Ibaraki, Japan; [2]Dept of Nephrology, Faculty of Medicine, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

**Background:** Low birth weight is a surrogate marker for low nephron number, and an important risk factor for both the progression of end-stage renal disease (ESRD). However, most participants of previous study have been younger than 40, because little well-organized information on birth weight is available for the old general population as comparison subjects.

**Methods:** In January 2010 in 9 centers in Japan, 1130 Japanese patients undergoing maintenance hemodialysis were identified. Data was obtained from 230 patients (20.3%) by using a self-completed questionnaire containing questions about birth weight. The race and age-matched mean birth weight was calculated by using well-organized data from nationwide surveys. We divided our subjects into those with and without DM and used the median ages in each group (53.0 y for DM and 43.5 y for non-DM) and birth weight of each group was compared with age-matched mean birth weight.

**Results:** Older patients with DM had significantly lower birth weight than age-matched mean birth weight ( 2963±674* vs 3129±28, mean±SD, respectively, *P<0.05), whereas no significant differences between them existed in younger patients in the DM group ( 3191±697 vs 3145±54 ) or in any patients in the non-DM (younger; 3107±401 vs 3140±54, older; 3048±517 vs 3114±40 ) group which consists of 101 patients with chronic glomerulonephritis and 45 with miscellaneous diseases.

**Conclusions:** We considered older diabetic patients with a small number of glomeruli due to significantly lower birth weight may have more severe long-term nephron damage than older non-diabetic patients. It was also suggested that the patients with young-onset diabetic nephropathy may develop ESRD with birth weight-independent manner. Therefore, we propose to notice that lower-than-mean birth weight would be a risk factor for ESRD in patients with DM in later life.

## PUB226

**Morbimortality in Incident Hemodialysis Diabetic Patients in Southern Gran Canaria** Elvira Bosch,[1] Eduardo Baamonde,[1] German Perez Suarez,[2] Cesar Garcia-canton,[2] Marta Riaño-ruiz,[3] Ana Ramirez Puga,[2] Batista Fatima Garcia,[2] Agustin Toledo Gonzalez,[2] Mar Lago alonso,[2] Dolores Checa.[2] *[1]Centro de Hemodialisis Avericum, Las Palmas de Gran Canaria, Spain; [2]Servicio de Nefrologia, Hospital Insular de Gran Canaria, Las Palmas, Las Palmas de Gran Canaria, Spain; [3]Servicio de Bioquimica Clinica, Hospital Insular de Gran Canaria, Las Palmas, Las Palmas de Gran Canaria, Spain.*

**Background:** To describe the characteristics and prognosis of patients with diabetes mellitus (DM) who are incident in hemodialysis and to compare them with those of non diabetic (NoDM).

**Methods:** Retrospective study of incident hemodialysis (2007-2010). Subjects' baseline clinical and laboratory data, as well as data on preexisting comorbidity were collected. Hospitalizations, causes of admission and causes of death were compared between DM and NoDM patients.

**Results:** 220 patients (58.6% DM – 41.4% NoDM) were included. Diabetic patients had higher average age, BMI and age-adjusted Charlson's index (ACCI); they started HD with higher GFR and incidence of catheter and with lower levels of albumin, proteins and creatinine; they showed higher prevalence of ischemic cardiopathy, cerebrovascular accident (CVA), peripheral artery disease (PAD) and heart failure. The median follow up was 31 months (DM: 30.1 vs NoDM: 32.7 months p: 0.064). No differences were found in hospitalization rate (DM: 2.23 vs NoDM: 1.84; p:ns) or in the number of days in hospital (DM: 17.4 vs NoDM: 24.7 days; p:ns). Admissions due to PAD were more frequent among DM patients (p:0.000). DM patients had shorter survival time (49.1 vs 57.2 months; p: 0.045) and higher rates of global mortality (45.2% vs 24.2%; p:0.002) and mortality of cardiovascular cause (47.3% vs 24%; p: 0.046). Preexisting cardiovascular disease (HR: 3.26 CI: 1.58-6.71), age > 65 years (HR: 2.53 CI: 1.15-5.56) and starting with catheter (HR: 2.6 CI: 1.42-4.91) were the main risk factors (p< 0.05).

**Conclusions:** Diabetic patients start hemodialysis with higher GFR, ACCI and percentage of catheter and with poorer nutritional control. They have poorer prognosis, mainly determined by preexisting cardiovascular disease, age and starting with catheter.

## PUB227

**Survival Analysis in Korean Elderly Patients Initiating Dialysis: A National Population-Based Study** Jung-hwa Ryu,[1] Shina Lee,[1] Hyunwook Kim,[2] Seung-Jung Kim,[1] Duk-Hee Kang,[1] Kyu Bok Choi,[1] Dong-Ryeol Ryu.[1] *[1]Internal Medicine, School of Medicine, Ewha Womans Univ, Seoul, Republic of Korea; [2]Internal Medicine, Wonkwang Univ College of Medicine Sanbon Hospital, Gunpo, Republic of Korea.*

**Background:** Although the proportion of the elderly among incident end-stage renal disease (ESRD) patients has been increasing in Korea, there has been a lack of information on their outcome. Furthermore, there are some controversies about the appropriateness of dialysis initiation in elderly patients due to the dismal survival. This study aimed to assess the survival and to delineate predictors influencing on the all-cause mortality among elderly Korean patients initiating dialysis.

**Methods:** We included 11,301patients(6,138 men) aged 65years or older who initiated dialysis from January 1,2005 to December 31,2008 and followed up(median 37.8months:3.0-84.0months). Baseline demographic data, comorbidities and the information on mortality were obtained using the database of the Health Insurance Review & Assessment Service. The survival rate and the factors associated with mortality were analyzed.

**Results:** Unadjusted 24-month survival rate was 59.3% in all subjects, and it was decreased with the increment of age;66.5% among patients aged 65-69years, 59.0% among patients of 70-74years, 52.5% among patients of 75-79years, 48.5% among patients ofd 80-85years, and 30.2% among patients of 85years or older. In addition, the survival rate was significantly higher in female and in patients on hemodialysis than patients on peritoneal dialysis in intention-to-treat analysis. Multivariate Cox proportional hazard model revealed that age,sex,type of healthcare security system, and comorbidities:diabetes mellitus, myocardial infarction, congestive heart failure, peripheral vascular disease, cerebrovascular disease, dementia, chronic pulmonary disease,hemiparesis, liver disease, and any malignancy were independent predictors for mortality.

**Conclusions:** The survival rate in Korean elderly patients initiating dialysis was significantly associated with age, sex, and various comorbidities.With these results, individual counseling to dialysis initiation could be possible in elderly patients with chronic kidney disease.

## PUB228

**Risk Factors and Outcomes of Unplanned Hospitalization in Haemodialysis Patients – A Prospective Study from Greater Manchester East Sector Renal Network, UK** Shiv Bhutani,[1] Leonard Ebah,[1] Emily R. Keating,[1] Sheetal Asrani,[2] Marie McNulty,[1] Andrew Stevens,[1] Arvind Ponnusamy,[1] Sandip Mitra.[1] *[1]Renal Medicine, Manchester Royal Infirmary, Manchester, United Kingdom; [2]Stockbridge Village Health Centre, United Kingdom.*

**Background:** Hospitalization is a key prognostic indicator in Hemodialysis (HD) patients and has significant financial burden on renal networks. Registry data has shown links of hospitalisation in HD to various modifiable & unmodifiable risk factors, however prospective studies are distinctly lacking. This study investigated risk factors,outcomes & financial impact of Hospitalization (HZ) & rehospitalization (rHZ) for HD patients.

**Methods:** HZ data were collected prospectively from 4 satellite & central hub HD unit (April-September 2012). Electronic notes were used to collect data on demographics, comorbidity, causes & outcomes for HZ episodes.

**Results:** Among 413 HD patients, 148 episodes of HZ were recorded in 92 patients. 56 rehospitalisation (rHS) episodes observed in 36 patients. The annual HZ rate was 0.7 episodes per patient-year (ppy) & 0.27 ppy for rHS. Cardiovascular(25.5%), Infections(20%) and access related (13.5%) were the leading causes of HZ. 12.3% admissions (n=18) were potentially avoidable: fluid overload (6.8%), blood pressure crisis (2.7%), Catheter related infection (2.7%). Diabetes as comorbidity was the strongest independent predictor of HZ;OR 3.3 [1.6-6.8, p=0.001]. The mean age of patients was 60.7±15 & 57.7±15 yrs with similar gender ratios (m:f,1.2) for HZ & rHS respectively. 21% died within a year, a higher than expected mortality quoted for HD patients. Patients who were functionally less dependent more likely to be hospitalized (p=0.002) but longer length of stay was associated with worse functional status (r=0.31, p=0.0001).During the study period, 2031 inpatient days were utilised with an estimated annual equivalent cost of $2 million.

**Conclusions:** This prospective study demonstrates a high incidence of HZ amongst HD patients, with younger & diabetic patients most at risk. The Total HZ was associated with an increase in mortality and However, a proportion were due to potentially preventable causes, with significant outcome & cost implications.

## PUB229

**Cancer Treatment for Patients under Dialysis Therapy; Single Center Surveillance** Tatsuo Tsukamoto, Makoto Araki, Takeshi Matsubara, Motoko Yanagita. *Nephrology, Graduate School of Medicine, Kyoto Univ, Kyoto, Japan.*

**Background:** Cancer is the growing cause of death (approximately 10% of all mortality) in Japanese dialysis patients, whose population becomes older along the better survival rate.

**Methods:** In order to clarify the therapeutic choice of the cancer treatment and the outcome, we examined actual conditions of the therapy by retrospective chart review in Kyoto University Hospital, which possess both cancer center and dialysis unit. From 2007 to 2012, fifty-seven dialysis patients, who were 63±13 y.o. and 63.2% was male, were admitted to our hospital to receive a surgical operation, chemotherapy and/or radiation therapy.

**Results:** 40% of cancers were found within 5 years after the initiation of dialysis therapy. The most frequent cancer was derived from atrophic kidney and urinary tract (19.4% of male and 19.0% of female). Fifty of 57 patients were undergone radical operations, whose performance statuses were mostly 1. 13 patients (26%) had been treated with percutaneous cardiac intervention therapy prior to the operation. All patients were dialyzed the next day with intermittent or continuous blood purification method without serious adverse effects, such as severe hypotension, thrombosis and bleeding. The dry weight were reduced approximately 3% before the discharge. The average hospitalization was 29.9 days. Post-surgical infection was found in 9 patients, which were not larger than those of non-dialytic population. Half of the advanced cases were also treated with chemotherapy after the operation, whereas others were avoided to prescribe the chemotherapy because of their dialysis dependency. Thus, most dialysis patients had been successfully treated with single or combination therapy with careful administration of blood pressure, fluid volume, and cardiac function under the co-operation of oncologist and nephrologist, instead of fewer clinical information of cancer treatment in dialysis patients.

**Conclusions:** Further study, such as an intensive registry, would be required to establish the effective as well as safety therapeutic protocol for cancer patients under dialysis therapy.

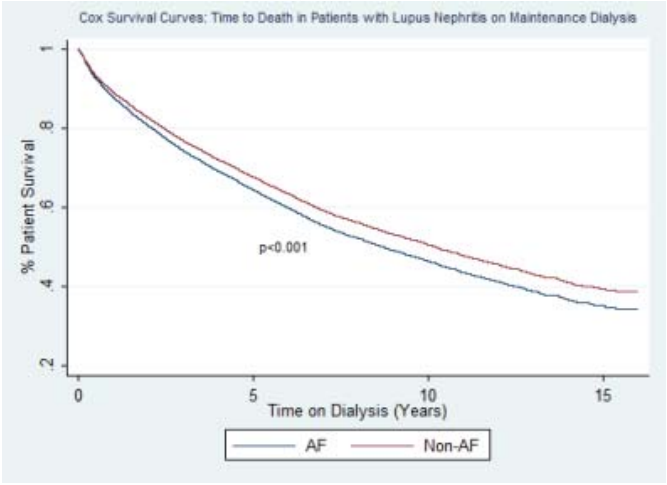
## PUB230

**The Impact of Race and Income on Mortality in Patients with Lupus Nephritis on Maintenance Dialysis** Robert Nee,[1] Jorge I. Martinez Osorio,[1] Lawrence Agodoa,[2] Christina M. Yuan,[1] Kevin C. Abbott.[1] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]NIDDK, National Institutes of Health, Bethesda, MD.*

**Background:** An analysis of racial and income disparities on mortality in end-stage renal disease (ESRD) patients with lupus nephritis (LN) on maintenance dialysis has not been reported. We analyzed the United States Renal Data System database to assess the impact of race and income on mortality in the LN and non-LN cohorts.

**Methods:** We identified 12,352 patients with LN as the cause of ESRD in a retrospective cohort of 1,132,217 patients, initiated on chronic dialysis between January 1,1995 to December 31, 2006, followed until December 2, 2010. We merged data on median household income from the United States Census based on the ZIP code.

**Results:** In multivariate Cox regression analyses, African-American (AF) patients with LN (vs. non-AF) had an increased risk of death (adjusted hazard ratio [AHR], 1.10; 95% confidence interval [CI], 1.04-1.17).



Without adjusting for income, this racial disparity in the LN cohort was greater with an AHR 1.19 (95% CI, 1.12-1.25). Furthermore, analysis of interactions demonstrated that higher income quintiles were significantly associated with lower mortality rate in both LN and non-LN populations, regardless of race.

**Conclusions:** Contrary to the lower mortality rate among AF patients in the general ESRD population, AF with LN were at increased risk of death. This risk was attenuated but remained significant after adjusting for income. Income as an effect modifier for mortality risk, however, was not unique to the AF cohort with LN.

## PUB231

**Effect of Bacteremia and Associated Risk Factors on Survival in Hemodialysis Patients** Puja Chebrolu,[1] Rhonda E. Colombo,[1] Stephanie L. Baer,[1,2] Mufaddal F. Kheda,[1] N. Stanley Nahman,[1,2] Kristina W. Kintziger.[1,2] *[1]Georgia Regents Univ, Augusta, GA; [2]Charlie Norwood Vet., Augusta, GA.*

**Background:** Bacteremia (BAC) is a major cause of morbidity and mortality in hemodialysis (HD) patients. We have previously shown that BAC in HD patients is significantly associated with many access-independent risk factors. However, the effect of BAC and/or associated risk factors on survival remains to be defined.

**Methods:** Incident HD cases from the United States Renal Data System for 2005-2008 were queried for a diagnosis of BAC and several potential clinical covariates using ICD-9 codes billed to Medicare. Cox proportional hazards regression was used to determine hazard of death in bivariable models. Covariates were classified by time of occurrence in relationship to a BAC diagnosis and HD initiation, and grouped according to infectious events, immunosuppressed conditions, demographic factors, and other comorbidities.

**Results:** In the 4-year period, 355,084 patients were available for analysis, and BAC was identified in 77,288 (21.8%). 208,397 patients (58.7%) were alive at the end of the period. Median time to death for patients with BAC was 455.7 days. Hazard ratio (HR) for death for BAC was 2.00 (95% CI 1.98, 2.02). Comorbidities which carried a higher HR than BAC were: age >65 years (HR 2.54 95% CI 2.51, 2.57), TPN (HR 2.29 95% CI 2.19, 2.39), pancytopenia (HR 2.11 95% CI 1.98, 2.25), and cirrhosis (HR 2.07 95% CI 2.01, 2.13), as well as infectious comorbidities such as candidemia and decubitus ulcer. These infectious conditions had the highest relative risks of bacteremia in our previous analyses as well. Among immunosuppressed comorbidities, diabetes was associated with a slight increase in hazard of death compared to non-diabetic patients (HR 1.22 95% CI 1.21, 1.23). In addition, SLE was negatively associated with hazard of death (HR 0.753 95% CI 0.71, 0.80) but carried a high relative risk of bacteremia (RR 1.77) in previous analyses.

**Conclusions:** Bacteremia is associated with a high risk of death in HD patients. Older age, TPN, pancytopenia, cirrhosis, and candidemia may carry a higher risk for mortality than bacteremia. Risk of bacteremia did not correlate with risk of death in patients with SLE.

## PUB232

**Can a Newly Started Dialysis Center Improve Patient's Quality of Life; Single Center Experience** Ihab El Madhoun, Rony Jose Pulikkan, Khalid Burghal, Omar Ahmad Alhasanat. *Renal Unit, Al Wakra Hospital, Al Wakra, Qatar.*

**Background:** Chronic diseases like chronic kidney disease can have a significant impact on patients quality of life (QoL)particularly when dialysis is indicated.

In our study, we assessed the impact of multidisciplinary approach on the QoL of haemodialysis patients in a new dialysis unit.

**Methods:** A multidisciplinary renal team of doctors, nurses, social worker and dietation managing patients in the newly started hospital. 13 patients were enrolled in the survey in a newly started dialysis center in Al Wakra Hospital, Qatar. All patients were assessed at the beginning of dialysis in the new unit using the WHOQOL-BREF questionnaire consisted of 26 questions representing 4 domains of physical health, psychological health, social relationship and environment. 7 patients reassessed after 3 months again.

| Domain | Facts Incorporated within domains |
|---|---|
| 1-Physical Health | Activities of daily living<br>Dependehnce on medicalinal substances and medical aids<br>Energy and fatigue<br>Mobility<br>Pain and discomfort<br>Sleep and rest<br>Work capacity |
| 2-Psychological | Bodily image and appearance<br>Negative feelings<br>Positive feelings<br>Self esteem<br>Spirituality/Religion/PersonalBeliefs<br>Thinking, Learning, memory and concentration |
| 3- Social relationships | Personal relationships<br>Social support<br>Sexual activity |
| 4- Environment | Financial resources<br>Freedom, physical safety and security<br>Health and social care; accessibilty and quality<br>Home environment<br>Opportunities for acquiring new informationa nd skills<br>Participation in and opportunities for recreation / leasure activities<br>Physical environment (pollution/ noise/ traffic/ climate)<br>Transport |

**Results:** 7 patients who had the chance to be assessed twice, have shown a significant improvement in their QoL after three months of treatment.

The remaining patients have shown a satisfactory level of QoL with space for some further improvement.

**Conclusions:** QoL is an important health care issue for dialysis patients. Newly established renal unit in a new hospital can still play a big role in improving patient's QoL. Multidisciplinary team approach is an important and strong tool in improving patients QoL.

## PUB233

**Impact of Changes in Dialysis Unit Structure and Procedures on Catheter Related Infections** Joseph Rossi Berger, Henry Quinones. *Nephrology, UT Southwestern Medical Center, Dallas, TX.*

**Background:** The Acute Dialysis Unit (ADU) at Parkland Health and Hospital System provides hemodialysis (HD) emergently to patients unfunded for outpatient dialysis. Catheter related bloodstream infections (CRBSI) are a significant source of morbidity in this group. We conducted this study to determine the impact of changes in ADU operational structure and procedures that were created to improve care and to decrease rates of CRBSI and infectious complications in our patients unfunded for outpatient dialysis.

**Methods:** We retrospectively analyzed all unfunded patients undergoing HD via a cuffed tunneled catheter during the 6 months before (period 1) and after (period 2) changes in the operational structure of the ADU. Changes included extended hours of operation, creation of an extra shift, increased levels of nursing staff, and hiring of 2 faculty nephrologists primarily responsible for care of unfunded patients. There was also a policy change that all CRBSIs requiring intravenous antibiotics be completed while inpatient rather than providing antibiotics when returning for urgent HD. We assessed the rates of overall CRBSI, Gram negative and polymicrobial infections, and complications (death, endocarditis, osteomyelitis) per 100 patient weeks of HD.

**Results:** There were 2392 patient weeks in perod 1 and 2578 patient weeks in period 2. There was a trend of reduction in overall CRBSI (3.22 v 2.33) and a significant reduction in Gram negative (2.30 v 0.85) and polymicrobial infections (1.30 v 0.27). There was not a significant difference in rate of complications (0.38 v 0.35).

| | Period 1 | Period 2 | P |
|---|---|---|---|
| Patient Weeks | 2392 | 2578 | |
| Overall CRBSI/100 pt weeks | 3.22 | 2.33 | 0.058 |
| Gram neagtive/100 pt weeks | 2.30 | 0.85 | <0.001 |
| Polymicrobial/100 pt weeks | 1.30 | 0.27 | <0.001 |
| Complications/100 pt weeks | 0.38 | 0.35 | 0.87 |

**Conclusions:** Changes in ADU structure and procedures were associated with a trend of reduced CRBSI rates and significant decrease in frequency of Gram negative and polymicrobial infections. These results support continued implementation of these practices and future study of other targeted interventions to further lower CRBSI rates.

## PUB234

**Symptom Cluster, but Not Single Symptoms, Predicts Mortality in Dialysis Patients** Bård Waldum,[1,2] Amin Amro,[1] Fredrik Barth Brekke,[2] Nanna von der Lippe,[2] Ingrid Os.[1,2] *[1]Dept of Nephrology, Oslo Univ Hospital, Ullevål, Oslo, Norway; [2]Faculty of Medicine, Univ of Oslo, Oslo, Norway.*

**Background:** Bothersome symptoms are frequent and often co-occur in dialysis patients. Symptom burden is related to both health related quality of life (HRQOL) and depression. As HRQOL and depression are associated with mortality in dialysis patients, our aim was to investigate if symptom clusters predicted mortality in prevalent dialysis patients in Norway.

**Methods:** In a prospective observational cohort study including 301 prevalent dialysis patients, Kidney Disease and Quality of Life Short Form version 1.3 (KDQOL), SF-36, and Beck Depression Inventory (BDI) questionnaires were used. Based on KDQOL, 11 kidney-specific self-reported physical symptoms were entered into principal component analysis with varimax rotation to generate symptom clusters. Patients were categorized using quartile limits of symptom scores. Kaplan-Meier and multivariate Cox regression analyses were used for the survival analysis.

**Results:** Three symptom clusters were identified. The "uremic" cluster (nausea, lack of appetite, dizziness, feeling squeezed out, shortness of breath and chest pain) and "skin" cluster (itching and dry skin) were associated with all-cause mortality (log-rank p=.0001 and p=0.043). In multivariate analyses the quartile with most "uremic" symptoms had higher mortality rates compared to the three quartiles with less perceived symptoms (HR 2.47, 95% CI 1.44-4.22, P=0.001). No single symptoms were independently associated with mortality, neither were the other two symptom clusters.

**Conclusions:** "Uremic" symptoms independently predicted mortality in prevalent dialysis patients. Assessing co-occuring symptoms rather than single symptoms might help to identify dialysis patients at high risk for all-cause mortality. Additional research is warranted to determine whether symptom treatment may affect mortality rate.

## PUB235

**The Prevalence and Risk Factors of Gallbladder Stone in Dialysis Patients** Xiaohong Tang, Ling Ji, Zi Li, Fei Liu, Wei Qin. *Div of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

**Background:** To investigate the prevalence of gallbladder stone in dialysis patients, clarify the prevalence difference between hemodialysis and peritoneal dialysis patients and analyzes the risk factors of it in dialysis patients.

**Methods:** 358 dialysis patients (126 hemodialysis patients and 232 peritoneal dialysis patients) and 376 pre-dialysis CKD stage 5 patients hospitalized in West China Hospital from January 2009 to October 2012 were included in this study. Abdominal ultrasound examination was performed to confirm the diagnosis of gallbladder stone. Data of hemoglobin (HGB), platelet (PLT), white blood cell (WBC), albumin (Alb), globulin (GLB), glucose (GLU), urea nitrogen (BUN), Creatinine (Cr), serum total cholesterol (CHOL), triglyceride (TG), low density lipoprotein (LDL), high-density lipoprotein (HDL), calcium (Ca), phosphorus (P) and parathyroid hormone (PTH) were collected. Prevalence of gallbladder stone in each team, then analysis risk factors of gallbladder stone in dialysis patients.

**Results:** The prevalence of gallbladder stone in dialysis patients was 23.5%, which is higher than the pre-dialysis CKD5 patients (14.4%, p=0.002) and the general population of China (10%, p<0.0005). The prevalence of gallbladder stone was higher in diabetic patients than non-diabetic patients, but with no statistical significance (p=0.076). Age, dialysis period, serum globulin and creatinine were significantly higher in dialysis patients with gallbladder stone (p<0.05). The prevalence of gallbladder stone in peritoneal dialysis patients was obviously higher than that of the hemodialysis patients (P < 0.05). The albumin level was significantly lower in peritoneal dialysis patients than the hemodialysis patients, while serum total cholesterol, low density lipoprotein cholesterol and low density lipoprotein cholesterol/high density lipoprotein were much higher. Logistic regression analysis showed that increasing age, women, diabetes mellitus and dialysis period were risk factors for gallbladder stone in dialysis patients

**Conclusions:** The prevalence of gallbladder stone in dialysis patients, especially the peritoneal dialysis patients, is higher than the general population. Risk factors for gallbladder stone in dialysis patients are: increasing age, women, diabetes mellitus, dyslipidemia, hypoalbuminemia and long dialysis period.

## PUB236

**Efficacy and Safety of Calcium Carbonate in Patients on Hemodialysis – A Pilot Study** Hui-juan Ma,[1] Yitong Yao,[2] Jianxiong Shi,[2] Ronglang Zhou,[2] Huanling Guo,[2] Xun Liu.[1] *[1]Div of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China; [2]Zhongshan School of Medicine, Sun Yat-sen Univ, Guangzhou, China.*

**Background:** Hyperphosphatemia in hemodialysis patients causes secondary hyperparathyroidism, and is associated with vascular calcification. Calcium carbonate ($CaCO_3$) is used broadly in China as phosphate binder to control the level of serum phosphorus.

**Methods:** A total of 19 hemodialysis patients with hyperphosphatemia (serum phosphorus > 5.5 mg/dL) were enrolled. All patients received a fixed dosage of $CaCO_3$ (3.0g/day, equivalent to 1.2g/day of elemental calcium). The effect and safety of $CaCO_3$ on serum phosphorus level were recorded at baseline and Weeks 4, 8 and 12. Statistical results are based on t-test (for one sample and two-group comparisons) and Fisher's Exact Test.

**Results:** Five patients were excluded including four of poor compliance and one receiving surgery. 14 patients completed the analysis. 10 were men and 4 were women, with a mean age of 48.7 ± 13.0 years who were on dialysis since 40 ± 26 months before the study. After 12 weeks of treatment, the mean level of serum phosphorus decreased significantly from 6.8 to 5.6 mg/dL (P <0.05). Eight patients (57.1%) achieved the NKF Kidney Disease Outcomes Quality Initiative target (serum phosphorus ≤ 5.5 mg/dL) and 4 (28.6%) achieved the Kidney Disease: Improving Global Outcomes target (serum phosphorus ≤ 4.5 mg/dL). In the subgroup with moderate hyperphosphatemia, the decreases of serum phosphorus in weeks 4, 8 and 12 were significantly relative to that in week 0, whereas in the subgroup with severe hyperphosphatemia, the respective changes revealed no significant differences. No serious adverse events related to treatment were reported.

**Conclusions:** $CaCO_3$ controlled serum phosphorus effectively in chronic hemodialysis patients with hyperphosphatemia. It may require larger dose of CaCO3 for the decrease of serum phosperus in the subgroup with severe hyperphosphatemia. The adverse events were mild in short term. Baseline serum phosphorus level affected the efficacy of $CaCO_3$.

HJM, YTY, JXS, RLZ, HLG contributed equally to the paper.

## PUB237

### Albumin and Age Are Predictors of Early Mortality in Incident Hemodialysis Patients

André Fragoso,[1] Ana Pinho,[1] Jose António Lopes,[2] Antonio Gomes da Costa.[2] *[1]Nephrology Dept, Hospital de Faro, Faro, Portugal; [2]Nephrology Dept, Hospital Santa Maria, Lisboa, Portugal.*

**Background:** Despite improvements in dialysis care, incident hemodialysis (HD) patients have the highest mortality in the first months, particularly, elderly patients with multiple comorbidities. Recent prognostic tools to estimate 6-month survival in elderly incident dialysis patients have been validated and showed that decreased albumin levels and older age are important independently factors. The purpose of this study was to evaluate predictors of early mortality in incident HD patients.

**Methods:** In this prospective cohort study we included 188 chronic kidney disease patients beginning, permanently or temporarily, unplanned HD after hospital admission in 2012. Clinical and several laboratory parameters were determined for each patient at admission and the follow-up period was timed for 6-months from the first HD session. Our population was divided in two groups accordingly to the mortality 6-months after beginning HD: G-I (n=55) non-survivors and G-II (n=136) survivors.

**Results:** We found that G-I was older than 80 years old (p=0.001), showed more than six comorbidities (p= 0.0001), higher occurrence of cardiovascular disease (p=0.001) and recent hospital admissions (0.002). G-I also showed albumin level below than 2.5g/dl (p= 0.010). No differences were found between the two groups regarding history of diabetes and analytic levels of Hemoglobin or C Reactive Protein. In a cox multivariate analysis, two variables were independently associated with early mortality: age more than 80 years (hazard ratio [HR] 2.375; p= 0.002; 95% CI 1.36 to 4.14) and albumin levels below 2.5g/dl (HR 2.045; p= 0.013; 95% CI 1.16 to 3.60). Area under the curve for the resulting prognostic analysis of 6-months mortality was 0.68 (p= 0.0001; 95% CI 0.59 to 0.78).

**Conclusions:** In our study, an integrated 6-month prognostic tool based on decreased levels of albumin (under 2.5g/dl) and older patients (above 80 years old) accurate estimate early mortality. The instrument may be of value for researchers and clinicians to identify patients who have poor prognosis and consequently provide better care.

## PUB238

### Mortality Risk by Early versus Late Start of Hemodialysis

Bruce M. Robinson,[1] Yun Li,[1,2] Yan Jin,[1] Alissa Kapke,[1] Jeffrey Pearson,[1] Friedrich K. Port.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Univ of Michigan, Ann Arbor, MI.*

**Background:** In the US there has been a trend to starting dialysis at a higher eGFR over the past decade and before. Observational studies have found a positive association between eGFR at dialysis start and mortality, perhaps due to confounding by indication (CBI). The IDEAL randomized trial showed no association of eGFR at start with mortality, but had limited separation between early vs. late start. We aimed to reduce CBI by studying the practice of early versus late start.

**Methods:** The US Renal Data System ESRD database was used to identify 163,424 patients who initiated hemodialysis at dialysis facilities with at least 10 new patients in each year between 2006 and 2009. Mortality risk by eGFR (adjusted for demographics and comorbidity) was assessed using standard Cox regression models and an instrumental variable (IV) approach using physician as the instrument. The IV first stage used a linear model to explain continuous eGFR as a function of physician dummy variables; the second stage used a Cox model to explain mortality as a function of categorized predicted eGFR (from stage 1).

**Results:** The Cox models confirmed prior findings of a strong positive association of eGFR at start with mortality risk (higher mortality at higher eGFR); the IV approach showed an attenuated association, presumably by reducing CBI (Figure 1). Sensitivity analyses limited to patients with nephrology care for six months prior to starting dialysis and excluding patients who died in the first two months of dialysis were corroborative.

**Conclusions:** Contrary to US trends in increasing eGFR at dialysis start over time, no survival benefit could be detected to support a practice of generally starting dialysis earlier.

## PUB239

### Peritoneal Dialysis in Nursing Home. Over 10 Years Experience

Valerio Vizzardi,[1] Massimo Sandrini,[1] Luigi Manili,[1] Laura Econimo,[1] Grazia Ventisette,[2] Giovanni Cancarini.[1] *[1]UO Nefrologia, Spedali Civili and Univ of Brescia, Brescia, Italy; [2]Fondazione di Cura, "Città di Gardone Val Trompia" ONLUS, Gardone Val Trompia, Italy.*

**Background:** Guests of nursing home (NH) often are extremely frail, poor self-sufficiency and high hospitalization rate. Hemodialysis (HD) in these patients faces several issues, e.g.: very old age, comorbidity, vascular access problems and logistic difficulties (mainly transportation). Peritoneal Dialysis (PD) is a possible treatment in not self-sufficient ESRD patients living in NH; in fact, trained health professionals are able to assist frail patients in these structures. In Italy there is a prevalence of about 40 patients (0,9%) doing PD in NH.

**Methods:** Retrospective analysis of clinical course and outcome in patients on PD treated in 2001 to 2013 in NH and followed-up by our Center.

**Results:** 24 pz (M/F=8/16) underwent PD in 8 NHs; mean age was 77±9 years (range: 56-94), median time on PD in NH was 5,5 months (I and III quartile: 1.9; 16.8; range: 1-81) with a total follow-up of 237 patient-months. Peritonitis occurred in 9 cases with a peritonitis rate of 1/26 patient-months; the causative microorganism were Gram negative in 67%, Gram positive in 11%, fungi in 11%, negative culture in 11%). The mean hospitalization was 10.8 days/patient year, but fourteen patients had no hospitalization during PD; the remaining 10 had a median of 14 days (I and III quartile: 14 and 37). Outcome: 21 deaths (age: 78±9 years; range: 56-95), 1 shift to HD (ultrafiltration failure). Today, two patients are still on PD.

| | |
|---|---|
| Albumin (g/dl) | 3.0±0.5 (range 2.2-3.7) |
| Hb (g/dl) | 10.8±1.6 (range 8.9-14) |
| Kt/V | 2.0±0.5 (range 1.5-3.4) |
| wCrCl (L/w/1.73 $m^2$) | 63±19 (range 34-121) |
| RRF (ml/min) | 2.1±2.1 (range 0-6.5) |

**Conclusions:** In patients on PD in nursing home, dialysis adequacy, nutrition and hemoglobin met targets acceptable for that kind of patients. Peritonitis rate was in the range suggested by ISPD. According to our experience, PD in NH is effective and safe. Moreover, PD allows the "home-management" of poli-comorbid and not self-sufficient ESRD patients.

## PUB240

### Intravenous Epogen in Peritoneal Dialysis: A Single Center Experience

Abdullah Hamad,[1] Kelly S. Jarvis,[2] Michelle G. Brickle,[2] Tarek M. Sobeih,[1] John Durham.[1] *[1]Palmetto Nephrology, Orangeburg, SC; [2]Davita Dialysis, Orangeburg, SC.*

**Background:** Epogen is commonly given subcutaneously (SQ) in Peritoneal Dialysis (PD) patients. The reason is being more potent and longer acting. We are reporting a retrospective evaluation of a single center experience with the use of Intravenous (IV) Epogen in anemia management in PD patients. The use of IV Epogen in anemia management has been the local practise at this center as a convenient way to deliver Epogen while having laboratory tests done with venous stick without having to do SQ stick. That practive provided an opportunity to evaluate its efficacy.

**Methods:** The records for all PD patients (total 34) were reviewed. 14 patients excluded (6 were not on any kind of erythropoietin stimulating agents and 3 had their Epogen on hold for over 1 month, 2 patients on PD less than one month, 2 patients on SQ Epogen). 20 PD patients were on PD more than a month and receiving IV Epogen weekly or every other week and included in the analysis. They were evaluated for Epogen dosing, Hemoglobin, Ferritin, Iron saturation, Albumin, Age and Sex.

**Results:** Their mean age was 48.3 years and were 9 males. Mean Ferritin was 683.6 mg/dL, iron sat was 41.5 % and albumin 3.52 mg/dL. Mean hemoglobin value for 1 month of follow up was 9.99 mg/dL, mean Epogen IV dose was 35400 units for PD patients on weekly dosing (7 patients) and 27600 units for the every other week dosing (13 patients).

**Conclusions:** It appears that IV Epogen provided for stable management of anemia and convenient dosing in PD patients. Most patients were maintained on an every other week schadule. Only one third of patients required more frequent and higher doses of Epogen. Despite what might be predicted, most patients can be successfully managed on every other week dosing regimine.

**PUB241**

**Kinetics of α-Amylase Activity in Mixture of Glucose Polymers: A Model for Degradation of Osmotic Agent** Jan T. Poleszczuk,[1] Elvia Garcia-lopez,[2] Bengt Lindholm,[2] Jacek Waniewski.[1] *[1]Nalecz Institute of Biocybernetics and Biomedical Engineering, Warsaw, Poland; [2]Depts of Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

**Background:** Glucose polymers (GP, as Icodextrin) are used as osmotic agents in peritoneal dialysis, and therefore the activity of α-amylase, the starch degrading enzyme, may have a substantial impact on the efficacy of the treatment. The kinetics of α-amylase activity is not easily predictable and the development of an experimental and mathematical framework for assessing α-amylase characteristics was necessary.

**Methods:** The reaction of porcine pancreatic α-amylase (PPA of 0, 25, 50, 100 U/L) and maltoheptaose (G7 of 2.5 and 5 mg/mL) in PBS was carried out *in vitro*. G7 and all its possible decay products were frequently measured by HPLC. Different hypothetical pathways of G7 decay were analyzed together with mathematical models for the second order reactions of PPA with GP and the derived generalized Michaelis-Menten equations. The model parameters were estimated.

**Results:** For all experimental conditions no trace of maltohexaose (G6) and only small quantities of glucose (G1) were found, what allowed us to eliminate a few possible G7 decay pathways. Further comparison of the experimental data with fitted model curves yielded a single decay pathway with maltotriose (G3), maltose (G2) and G1 as the final products and maltopentaose (G5), maltotetraose (G4) as both products and substrates for PPA. The corresponding mathematical model reproduced the experimental data with high accuracy. The cleavage of G4 was much slower than the digestion of higher oligosaccharides, G7 and G5, which had similar kinetic parameters. G4 was digested mostly to two G2 molecules, but also, with low rate, to G3 and G1. The intermediate products of the G7 decay (G5, G4), but not the final products, had substantial inhibition effect on PPA catalytic efficiency.

**Conclusions:** The proposed method with the application of mathematical modeling yielded important details about PPA activity without sophisticated experiments on oligosaccharides with labeled bonds. The obtained mathematical model may be generalized for describing the digestion of GP of arbitrary length.

**Make Peritoneal Dialysis Patient Driving Their Therapy: Cornerstone of Our Program** Piyatida Chuengsaman. *CAPD Service and Training Center, Banphaeo Hospital (Public Organization), Prommitr Branch, Bangkok, Thailand.*

**Background:** Our center was established since 2008, the same year as implementing Thai PD First Policy, which make dialysis be fully subsided thus more accessible in Thailand. We are the main referral PD center in Bangkok. Now we have provided PD therapy for about 1,500 ESRD patients. We recognized the cornerstone of our program: "making our patients driving their therapy". All the activities provided here, put this concept at the core. Under the limited healthcare professional resources and budget constraint, we can provide dialysis to save lives with good quality and affordable.

**Methods:** We retrospectively reviewed number of patients, survival analysis, infection-related peritoneal dialysis complication, and number of healthcare professional in each time period.

**Results:** As shown all the detail in Table 1, despite the rising number of our patients, compare with the number of staff, we can provide acceptable outcome. 1 and 2 year patient survival is 79 and 68 percent. 1 and 2 year technique survival is 77 and 64 percent. Our peritonitis and exit site infection rate is 1 episode per 27 patient-month and 1 episode per 24 patient month, respectively. We need to make our patients driving the therapy, this make the patient acting as part of the provider. Implementing concept of self-management (assessment, monitoring, reinforcement), ensure adequate and tailoring program of training & re-training, good data management which guiding to real time action plan, are the three main strategies for our program.

| Year | 2008 | 2009 | 2010 | 2011 | 2012 | 2013[March] |
|---|---|---|---|---|---|---|
| Patients | 113 | 373 | 673 | 1062 | 1426 | 1463 |
| Nephrologists[Full-, Part-time] | [1, 0] | [2, 1] | [2, 1] | [1, 6] | [2, 6] | [2, 6] |
| PD Nurses | 1 | 4 | 7 | 7 | 9 | 9 |
| Healthcare Workers | 2 | 2 | 2 | 4 | 3 | 6 |
| Volunteer Patients | 3 | 5 | 6 | 6 | 5 | 5 |

**Conclusions:** Driving their own therapy under good center management gives peritoneal dialysis a form of renal replacement therapy which can be implemented despite the limited healthcare professional resources.

**PUB243**

**The Clinical Investigation on Inflammatory Cytokine Profiles during Peritoneal Dialysis-Related Peritonitis** Guochun Chen, Jing Liu, Hong Liu, Feng Wen, Xiang Zhou, Fu-You Liu. *Dept of Nephrology, The Second Xiangya Hospital of Central South Univ, Changsha, Hunan, China.*

**Background:** Peritonitis is one of the key complications during peritoneal dialysis,this study was planned to detect new and sensitive inflammatory cytokines in order to improve its diagnosis.

**Methods:** 36 PD in and outpatient are enrolled in the study ,16 are with PD related peritonitis, others are in control.The overnight dialysate and other related clinical data are collected.Expression of IL-6,IL-17A, MCP-1,TNF-α,serum and dialysate hs-CRP were detected. pHPMC are cultured in vitro, then exposed respectively to different concentration(0, 2, 10, 20, 100ug/ml) of LPS and different time(10ug/ml 0, 3, 6, 12, 24h). The expression of CRP,IL-6,IL-8,IL-1β, TNF-α,LDH, ICAM-1 and TGF-β were examined.

**Results:** We found that, Compared with control, the dialysate concentration of IL-6, IL-17A, MCP-1, TNF-α and hs-CRP were significantly elevated in de novo PD patients with peritonitis. During recovery of peritonitis, expression of each above markers gradually decreased. The age, sex, BMI, primary disease, and dialysis duration showed no difference between peritonitis and control.The serum hs-CRP, white blood cell count, neutrophil ratio, dialyslate hs-CRP, LDH were significantly elevated in peritonitis PD patients compared with control (P< 0.05). The dialysate hs-CRP was significantly higher in the effluent of PD patients with peritonitis,which decreased significantly and rapidly after anti-infection therapy. And those patient withdrawed PD after peritonitis had relatively high hs-CRP level compared with normal.And dialysate hs-CRP was negatively correlated with serum albumin(>P=0.026), and serum hs-CRP was netively associated with BMI(P<0.05), serum albumin (r=0.665, P< 0.05) and total plasma protein(P<0.05).After HPMC was treated by series concentration of LPS, the mRNA expression of CRP,IL-6,IL-8,IL-1 β,TNF-α,LDH,ICAM-1and TGF- β were increased.

**Conclusions:** Our study indicated that dialysate hs-CRP,IL-6,IL-17A,MCP-1 and TNF-α may be early diagnosis markers of PD-related peritonitis,and dialysate hs-CRP could be a prognosis indicator.

**PUB244**

**Oral Ciprofloxacin and Intraperitoneal Cefazolin as Empirical Treatment for Peritoneal Dialysis (PD) Related Peritonitis: A 18 Years Experience** Tatiana Tanasiychuk, Daniel Kushnir, Alon Antebi, Jerome Marcusohn, Victor Frajewicki. *Dept of Nephrology and Hypertension, Carmel Medical Center, Haifa, Israel.*

**Background:** Peritonitis still remains a common and serious complication of PD. It is the primary cause of technique failure and it is associated with increased risk of death. According to the ISPD 2010 recommendations the most accepted empiric protocol includes a combination of Vancomycin/Cephalosporin for Gram-positive organisms and third-generation Cephalosporin or Aminoglycoside for Gram-negative bacteria. Cure rate widely varies between 44% to 85% but the initial empirical treatment of PD-related peritonitis is still under investigation.

**Methods:** We retrospectively evaluated all records of patients on PD with peritonitis between 1995 and 2012 treated in our Department. The protocol used in most of patients included an initial intraperitoneal instillation of Cefazoline (500 mg) and Ciprofloxacin (200 mg) or Ofloxacin (200 mg), followed by intraperitoneal Cefazoline (250 mg/bag) and oral Ciprofloxacin (500 mg) or Ofloxacin (200 mg) once daily.

**Results:** Records of 323 cases of peritonitis episodes in 143 patients on either Automated PD or Continuous Ambulatory PD were reviewed. More than one event was reported in 71 patients (250 cases). A single peritoneal infection was recorded in 72 (50%). Bacteriological data of 93 cases are missing. In 222 cases (97%) a single organism was isolated: 127 of Gram positive (57%) and 57 of Gram negative (26%) organisms. Methicillin resistant germs were detected in 69% of Gram positive and Pseudomonas in 33% of Gram negative infections. Fungal peritonitis was recorded in 9 cases. Thirty five cases were culture- negative. Overall treatment success rate was 73%. Total mortality was 4%, mainly (57%) related to Gram negative infection. Resolution rate was not significantly different in 98 cases with the use of Aminoglycosides (76%) than in the 211 cases where Quinolones were used(75.8%).

**Conclusions:** Empirical treatment with oral Quinolones and intraperitoneal Cefazolin is at least as good as the widely accepted combination of Vancomycin/Cephalosporin and third-generation Cephalosporin or Aminoglycoside in peritonitis catheter related.

**PUB245**

**Peritoneal Dialysis in HIV Seropositive End Stage Renal Disease Patients: Single Center Experiences** Piyatida Chuengsaman. *CAPD Service and Training Center, Banphaeo Hospital (Public Organization), Prommitr Branch, Bangkok, Thailand.*

**Background:** Our peritoneal dialysis program was established since 2008, now we have provided this therapy to about 1,500 end stage renal disease patients. In Thailand, HIV-seropositive end stage renal disease patients get limitation to access to hemodialysis, due to healthcare professional's concern about chance of viral transmission. Because peritoneal dialysis is a home-based therapy, this make the provider of this type of therapy feel more comfortable, thus make this therapy be more accesible for this group of patients.

**Methods:** We retrospectively reviewed our database. We compared the survival data, PD-related infection data, and other clinical parameter, between HIV -seropositive PD patients and overall center data.

**Results:** From February 2008 till September 2012, there were 1,366 patients which we have provided peritoneal dialysis. In this group of patients, there were 38 HIV-seropositive patients. At the end of September 2012, there were 13 active HIV-seropositive patients. Data about HIV status was available only for the ones who alive. According to HIV viral load, 11 out of 13 patients got very low copies of virus (less than 40 copies/ml). The patient's data is shown in Figure1.

| Patient number | Hb (g/dl) | HIV Duration (year) | ARV Duration (year) | BMI | Cholesterol (mg/dl) | Triglyceride (mg/dl) | HDL (mg/dl) | Albumin(g/dl) | Potassium (mmol/dl) | Lymphocyte (CD4+) Abs. Count | ViralLoad |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | 9.9 | 17 | 15 | 0 | 261 | 116 | 69 | 3.2 | 3.19 | 701 | <40 |
| 2 | 9.6 | 15 | 15 | 1 | 137 | 173 | 26 | 3.7 | 3.29 | 1365 | <40 |
| 3 | 11.1 | 1 | 1 | 0 | 215 | 206 | 61 | 4 | 4.36 | 1071 | <40 |
| 4 | 10.7 | 25 | 15 | 0 | 183 | 117 | 44 | 2.8 | 3.16 | 924 | <40 |
| 5 | 8.5 | 9 | 9 | 0 | 268 | 438 | 36 | 2.6 | 2.8 | 1080 | <40 |
| 6 | 7.6 | 9 | 0 | 1 | 121 | 99 | 38 | 3 | 3.43 | 527 | <40 |
| 7 | 8.4 | 1 | 1 | 0 | 222 | 238 | 23 | 3.1 | 2.46 | 1798 | 487 |
| 8 | 8.9 | 1 | 1 | 1 | 183 | 90 | 41 | 3.4 | 3.77 | 1239 | <40 |
| 9 | 14.9 | 1 | 1 | 0 | 320 | 71 | 131 | 4 | 4.21 | 1836 | <40 |
| 10 | 8.3 | 0 | 4 | 1 | 112 | 160 | 38 | 3.3 | 3.46 | 1150 | <40 |
| 11 | 9.8 | 18 | 17 | 0 | 242 | 411 | 42 | 3.8 | 3.79 | 1840 | <40 |
| 12 | 10.1 | 11 | 6 | 0 | 336 | 810 | 38 | 3.9 | 3.28 | 1096 | 186,339 |
| 13 | 9.6 | 2 | 2 | 1 | 181 | 128 | 28 | 3.1 | 2.8 | 2010 | <40 |
| 14 | 7.9 | 3 | 3 | 0 | 191 | 62 | 60 | 2.4 | 4.47 | 1333 | <40 |
| 15 | 9.6 | 10 | 10 | 1 | 283 | 268 | 32 | 3.7 | 2.56 | 2170 | <40 |

We also compare our overall center data with HIV-seropositive patients' data as shown in (Table 1).

| | Overal patients | HIV-seropositive patients |
|---|---|---|
| Number of Patients | 1,366 | 38 |
| 1,2 year patient survival | 81%, 69% | 68%, 60% |
| Peritonitis rate[1 episode per patient-month] | 28 | 56 |

**Conclusions:** HIV-seroposive ESRD patients, is an emerging problem in Thailand. Despite the concern about PD-related infectious complication. our data did not support this. Due to survival data is not as good as in HIV-seronegative ESRD patients, our program need to focus more to improve the outcome.

*Funding:* Government Support - Non-U.S.

## PUB246

**Combination Therapy with Peritoneal and Hemodialysis from the Initiation of Renal Replacement Therapy Preserve the Residual Renal Function and Peritoneal Function; Case Report** Atsushi Ueda,[1] Aki Hirayama,[2] Shigeru Owada,[3] Kei Nagai,[4] Kunihiro Yamagata.[4] *[1]Tsukuba Univ Hospital Hitachi Medical Education and Research Center, Japan; [2]Tsukuba Univ of Technology, Japan; [3]Asao Clinic, Japan; [4]Univ of Tsukuba, Japan.*

**Background:** In ASN 2012, we reported in a retrospective cohort study an advantage of the peritoneal and hemodialysis (PD+HD) combination therapy from the initiation of renal replacement therapy (RRT) on the patient's survival compared to PD or HD groups. We concluded this beneficial result was caused from the preservation of residual renal function (RRF) and serum albumin level.

**Methods:** This was the typical valuable case, a 51-year-old woman with diabetic nephropathy selected PD+HD therapy as the first dialysis method 10 years ago. The dialysis schedule consisted of five PD days and one HD without fluid removal a week. The Kt/V of RRF, PD and HD calculated by equivalent renal urea clearance were measured, and peritoneal equilibration test was performed every six months.

**Results:** At the beginning of this therapy, Kt/V of HD, PD and RRF was 0.81, 1.29, and 0.52, respectively. Interestingly, Kt/V of RRF increased to 1.29 at six months, it kept absolutely stable within 96 months and 0.44 at 120 months. The mean Kt/V of RRF, PD and HD was 0.85, 1.32 and 0.83, respectively. The mean for 10 years urine volume was 943 mL/day and the peritoneal fluid removal volume was 733 mL/day. The mean D/P Cr ratio was 0.52, peritoneal permeability did not increase for 10 years. Albumin level maintained stably, in addition anemia, inflammation and nutrition status kept as good control.

**Conclusions:** Since this combination therapy started at the initiation of RRT, fluid control could be kept well by urine and ultrafiltration of PD. A stable PET data indicated peritoneal resting might be expected to be beneficial on the preservation of peritoneal function. Finally, these effects could bring not only the long-term continuation of dialysis but also the improvement in anemia, inflammation and nutrition status. This case demonstrated that this new combination therapy was extremely useful for preserving both RRF and peritoneal function, indicating a good prognosis.

## PUB247

**Natural History of Cuff Externalization of Peritoneal Dialysis Catheter with Tunnel Infection** Ebadur Rahman, Nader Mohamed Omran, Naveed Aslam, Dujanah Hassan Mousa. *Nephrology, Prince Sultan Military Medical City, Riyadh, Saudi Arabia.*

**Background:** Patients with multiple access failure on peritoneal dialysis (PD),surgical externalization of catheter cuff was done and outcomes were observed.

**Methods:** Study included four cases two of which were unfit for reinsertion of (PD) catheter or fistula creation.Two patients refused for removal of catheter. All patients had positive cultures from exit site. Exit sites of two patients were positive for Methicillin sensitive staphylococcus aureus (MSSA). The exit sites of other two were positive for methicillin-resistant staphylococcus aureus (MRSA) and Pseudomonas Aeruginosa respectively. External Cuff was removed surgically followed by oral fluclaxacillin for MSSA positive Patients. Intra peritoneal vancomycin was prescribed for the MRSA positive patient whereas ciprofloxacillin was prescribed for pseudomonas positive patient. Along with continuation of PD, twice weekly dressing with 3% saline was done for all patients. Three months prospective observation was made regarding wound healing, persistence of exit site infection and any episode of peritonitis. PD fluid cell count, culture and exit site swab culture was done weekly to diagnose any infectious episodes during this period. Additional cultures were taken in case of any suspicion of peritonitis or tunnel or exit infection. Adequacy of dialysis was assesed monthly.

**Results:** Mean age of this group is 68 years and two of them were females. None of the 4 patients had wound healing within this observation period. Exit site cultures were persistanly positive for two cases who had MSSA in the exit site and of them one developed peritonitis. Eventually catheters were removed for this two cases. For the remaining two cases the repeated post procedure cultures were negative and they had no episode of peritonitis and remained on PD. Catheters were eventually removed because of poor wound healing. Mean Weekly Kt/V of these patients before and after the procedure was 1.87 and 1.8 respectively.

**Conclusions:** Catheter loss of this procedure is 100% .50% patients with this procedure can remain in PD. Procedure can be used for patients with high co morbidity and with very poor life expectancy.

## PUB248

**Urgent Start PD: Establishing a Center of Excellence as a Model of Delivery** Heather L. Henderson, Quresh T. Khairullah, Jukaku S. Tayeb, Robert Provenzano. *Nephrology, St. John Hospital & Medical Center, Detroit, MI.*

**Background:** PD is underutilized as a dialysis modality in the US. Currently ~7% of US dialysis patients use PD. First reported by Ghaffari and replicated by others, urgent start PD programs (catheter use ≤ 2 weeks post placement) have been shown to increase PD % with acceptable complication rates. Urgent start PD is difficult to deliver to all patients due to physician inexperience & commitment, adequate staffing (in hospital & PD units), and initial increased operational cost. Additionally, many argue that ESRD care in the US is structured around in-center HD and this places an undo burden on the majority of PD programs as to "ease of entry". To address this deficit, we developed a center of excellence (COE) to deliver urgent start PD and increase PD percentages in our region.

**Methods:** Successful PD outcomes are largely related to the experience of the nephrologists and PD nurses, which are typically higher in PD centers with larger patient populations. Unfortunately small PD centers far outnumber large centers making urgent start PD a nonviable option in many regions due to cost and staffing constraints. Our community based PD unit provides intermittent peritoneal dialysis (IPD) to urgent start patients referred by community based hospitals and nephrologists. Once tolerating full fill volumes, patients may be transferred back to their primary nephrologist at smaller PD units for continued care and management. Our intention is to increase patients into our urgent start program with plan for transfer back to their primary nephrologist once they no longer require IPD.

**Conclusions:** As integrated care penetrates the ESRD market, growing and maintaining PD populations will be critical. We have shown that instituting a centrally located PD COE gives more patients the opportunity to initiate PD that may otherwise not be possible and grow smaller PD centers nationwide. Transferring patients back to their primary nephrologist allows physician ownership and continuity of care, critical in an era of patient centered medical homes. Also by networking larger PD centers with smaller centers this may improve patient survival, outcomes, and drop-out rates.

## PUB249

**Status of 835 CAPD Patients in 6 Peritoneal Dialysis Center in Hunan Province in China** Liu Yan, Hao Zhang, Ke Zhang. *Nephrology, The Third Xiangya Hospital in Central South Univ, Changsha, Hunan, China.*

**Background:** Hunan is in the middle of China, the number of Continuous Ambulatory Peritoneal Dialysis(CAPD) patients here counted for more than 19% in China. This study is to investigate the status of CAPD patients in 6 peritoneal dialysis centers in Hunan Province.

**Methods:** Cross-sectional study of general data, nutriture, inflammatory state and dialysis adequacy of 835 CAPD patients in 6 peritoneal dialysis centers in Hunan Province during July, 2012 to December 2012, and analysis the datas.

**Results:** 1. General data:sex ratio is 1.2:1,age is 51.91±14.27, dialysis age is 23.64±19.71 months, and the primary disease before three were chronic glomerulonephritis (59.2%), diabetic nephropathy (15.6%), benign arteriolar nephrosclerosis (12.7%). 35.2% patients controlled their blood pressure under 140/90mmHg, and blood pressure of patients with dialysis age more than 36 months significantly higher than less than 36 months. 2. Nutiture: the rate of anemia is 83.3%, hypoproyeinemia is 55.7%, serum phosphorus beyond control is 47% and hyperlipemia is 54.7%. The BMI of the patients is 22.56±3.02kg/$m^2$, 90% patients with mild to moderate malnutrition, calcium-phosphorus product is 41.24± 10.16$mg^2/dl^2$, and PTH of 45.8% patients is higher than 300pg/ml. Patients with dialysis age more than 36 months compared with less than 36 months, Hb is significantly lower(P<0.05), TG and LDL is significantly higher(P<0.05), SGA score is significantly higher, PTH is significantly higher(P<0.05).3. Dialysis adequacy: BUN is 21.25±9.25 mmol/L, CR 953.72±369.32 μmol/L, Kt/V为1.53±0.44, and BUN and CRE of patients with dialysis age more than 36 months significantly higher than that of less than 36 months. 4. Inflammatory state: CRP is 3.39±3.37mg/L, patients with dialysis age more than 36months higher than less than that less than 36 months(P<0.05).

**Conclusions:** As the dialysis age increases, anemia, malnutrition and inflammation become more serious in CAPD patients in Hunan. 2. The analysis of CAPD datas is important and practical guidance for clinnical work. Key Words: CAPD, general data, nutriture, inflammatory state, dialysis adequacy.

## PUB250

**Simplifying the Identification of Changes in Residual Renal Function in Patients Treated with Peritoneal Dialysis** Matthew Miller,[1] K. Scott Brimble,[1] Chenglin Ye,[2] Brenda Hemmelgarn,[3] Arsh Jain,[5] Marcello Tonelli,[4] Michael Walsh.[1] *[1]Div of Nephrology, McMaster Univ, Hamilton, Canada; [2]Dept of Clinical Epidemiology and Biostatistics, McMaster Univ, Hamilton, Canada; [3]Div of Nephrology, Univ of Calgary, Calgary, Canada; [4]Div of Nephrology and Immunology, Univ of Alberta, Edmonton, Canada; [5]Div of Nephrology, Univ of Western Ontario, London, Canada.*

**Background:** Changes in residual renal function (RRF) may require changes in the peritoneal dialysis (PD) prescription. However, measuring RRF with a 24-hour urine collection is laborious for patients. In a retrospective multicentre cohort, we studied whether simplified measures of RRF adequately predict renal Kt/V (rKt/V) or significant changes in rKt/V.

**Methods:** We studied prevalent PD patients who had rKt/V >0.3 and at least 2 peritoneal adequacy tests done between 3 and 15 months apart without a change in modality of fill volume. We attempted to predict the follow-up rKt/V using multiple linear regression in which patient demographics, serum creatinine, serum urea and baseline rKt/V were potential predictors. We assessed candidate models by calculating mean bias of predictions and accepted the simplest model with a mean bias ≤0.2 as optimal. We also attempted to predict a clinically important change in rKt/V of 0.2 using only a change in serum creatinine using logistic regression.

**Results:** 388 patients were eligible for study. When predicting rKt/V, no model resulted in a mean bias of ≤0.2.

| Model Characteristics | Mean Aboslute Bias |
|---|---|
| Creatinine | 0.433 |
| Creatinine and BUN | 0.431 |
| Creatinine, BUN, age, and gender | 0.414 |
| Creatinine, BUN, age, gender, and initial rKt/V | 0.332 |

Change in serum creatinine was associated with a significant change in rKt/V (p<0.001) but had poor discrimination (area under the receiver operator curve 0.63).

**Conclusions:** We were unable to identify a simple method for accurately predicting Kt/V or significant changes in Kt/V. Further research is required to simplify the identification of patients with changes in RRF.

## PUB251

**Clincal Characteristics of Long-Term Survivors and Short-Term Survivors on Peritoneal Dialysis** Yiwen Li. *Kidney Disease Dept, ZheJiang Province Hospital.*

**Background:** To evaluate the characteristics of patients on long-term and short-term peritoneal dialysis (PD).

**Methods:** Patients who be treated with PD since 2006 to 2011 and received PD for at least one year in our Department of kidney disease were included in this study.According to dialysis duration, patients were divided into tree groups.Group A(long-term)was defined as patients survived on PD for more than 4 years.Group B(short-term)was defined as patients who died and Group C(short-term)was defined as switched to hemodialysis within less than 4 years.Demography, biochemical indexes, dialysis adequacy, residual renal function were compared between those groups.

**Results:** There were 50 patients in group A, 55 patients in group B and 90 patients in group C. Mean followed-up period of group A , group B and group C Was (58.33±10.03) months,(27.15±9.35) months and (41.65±12.80) months , respectively.Younger, fewer episodes of diabetic comorbidity(group A 4/50 vs group B 13/55, P<0.05) were found in group A.Compared to group B and gruopC, the level of semm albumin at the beginning of PD was much higher in group A [(38.74±4.65)g/L vs (36.15±4.85)g/L and vs (35.23±5.27) g/L, P<0.01)].Compared to group A and group B, the levels of blood sugar in group C is lower. The levels of CRP in group B is higher than in group A and group C(P<0.01 and P< 0.05). The levels of nPNA in group A is higher than in group B(P<0.05). The levels of TC, TG, hemoglobin, calcium, phosphate and iPTH were not significantly different between three groups. Renal Kt/V,renal Ccr and urinary volume at the beginning of dialysis were much higher in group A(P<0.05).Ultrafiltration volume and pulse pressure difference was less in group A(P<0.05). Peritonitis morbidity,peritoneal membrane transport,increased blood sugar morbidity were not significantly different between three groups.

**Conclusions:** In comparison to short-term survivors, long-term PD patients are characterized by being younger, less diabetic disease, higher level of serum albumin and Hemoglobin, higher volume of urine , lower level of CRP, better residual renal function , less ultrafiltraion volume and lower pulse pressure difference.

## PUB252

**Planned Dialysis, Not Early Referral, May Improve Quality of Life and Depression in Newly Diagnosed End Stage Renal Disease Patients: Comprehensive Prospective Study of the Clinical Research Center for End Stage Renal Disease (CRC ESRD) in Korea** Ji In Park,[1] Jin Ho Hwang,[1] Yong-Lim Kim,[3] Chun Soo Lim,[4] Yon Su Kim,[1] Jung Pyo Lee.[4] *[1]Internal Medicine, Seoul National Univ College of Medicine; [2]Internal Medicine, Hangang Sacred Heart Hospital; [3]Internal Medicine, Kyungpook National Univ Hospital; [4]Internal Medicine, Seoul Boramae Medical Center, Republic of Korea.*

**Background:** Health-related quality of life (HRQOL) has recently become an important issue, which was revealed to affect survival of end-stage renal disease (ESRD) patients. Few studies reported that early referral and planned dialysis improves HRQOL. Here, we investigated whether referral time and planned dialysis affects HRQOL by nationwide prospective cohort study.

**Methods:** We enrolled newly diagnosed 670 ESRD patients who responded to the survey on the HRQOL and depression at post-dialysis 3 month. We got follow-up data of 298 patients at post-dialysis 1 year. Early referral (ER) was defined as meeting with a nephrologist more than a year before dialysis, and planned dialysis as starting dialysis with functioning arteriovenous fistula or graft. Kidney Disease Quality of Life Short Form 36 (KDQOL-36) and Beck's Depression Inventory (BDI) were utilized to measure HRQOL and depression.

**Results:** Higher KDQOL-36 and lower BDI score correlate with significantly higher survival. Type of referral did not affect KDQOL-36 and BDI score at post 3 months and at post 1 year, neither. However, planned dialysis showed significant improvement in mental component score and symptom/problem list at 3 months (P<0.05). Furthermore, planned dialysis showed better quality of life at post dialysis 1 year in physical component score, symptom/problem list, and BDI (P<0.05). These associations were significant after adjusting for age, sex, laboratory results and social factors.

**Conclusions:** Planned dialysis significantly improved HRQOL and depression of ESRD patients in short and long period of time. However, timing of referral didn't affect them. This suggests that nephrologists should prepare dialysis at proper timing and make an effort to improve HRQOL of early referred patients.

## PUB253

**Value of Anion Gap, Serum Bicarbonate, Strong Ion Difference and Strong Ion Gap in the Diagnosis of Lactic Acidosis** Seyed-ali Sadjadi, Navin Jaipaul, James I. McMillan, Mohammad Sharif. *Nephrology, Jerry L Pettis VA Medical Center, Loma Linda, CA.*

**Background:** Timely detection of presence of lactic acidosis (LA) is of great importance in emergency rooms, operating rooms and intensive care units. Various methods have been proposed to look for LA, but none of them has been found to be reliable. Due to this, we decided to compare the utility of albumin corrected AG, serum bicarbonate, strong ion difference apparent(SIDa) and strong ion difference effective (SIDe) and strong ion gap (SIG) for the diagnosis of LA.

**Methods:** Our patient cohort included 299 patients, with LA who had a serum lactate ≥4 meq/L who were either seen in the emergency room or intensive care units. To simulate the acute care setting, we calculated SIDa as the sum of Na + K + Ca - Cl in meq/L and SIDe as, CO2 + albumin gram per liter * 0.3252, ignoring serum Mg, PO4 and arterial blood gases. Correction factor of AG for albumin was 2.5 meq/g/dL. SIG was the difference between SIDa and SIDe.

**Results:** AG, uncorrected for serum albumin was 13 ± 5.4(normal range 3 to 11), corrected for albumin 16.8 ± 5.6 meq/L, SIDa 41.5 ± 8.4 meq/L, SIG 13.5 ± 2 meq/L. Serum CO2 < 24 was present in 228/299, AG > 11 meq/L in 174/229, AG corrected for albumin (AGc) was >11 in 297/299, SIDa <40 meq/L in 122/279, SIG >5, in 281/299. Sensitivity of bicaronate <24, AG>11, AGc >11, SID <40, SIG >5 meq/L was 75.2, 58, 99.3, 40.8, and 93.9% respectively. The correlation between serum lactate and AGc was 0.521, lactate vs SIG 0.534, and SIG vs AGc was 86.35%. Table 1 shows patient characteristics.

| Parameter | Value |
|---|---|
| mean age, years | 67 |
| Na meq/L | 137.9 ±5.8 |
| K , meq/L | 4.5 ± 1 |
| Cl, meq/L | 105 ± 7.3 |
| CO2, meq/L | 19.9 ± 6 |
| Ca mg/dL | 8.3 ± 1.2 |
| Albumin g/dL | 2.5 ± 0.9 |

**Conclusions:** Although uncorrected anion gap has a low sensitivity for detecting lactic acidosis, AG corrected albumin and SIG have a high sensitivity for detecting LA. However the correlation between currently avaliable parameters with lactic acid level is poor. This emphasizes need to include several parameters rather than a single one.

## PUB254

**Hyponatremia in Hospitalized Patients: Management Discordance** Chelsea Estrada, Michael Petry, Adebayo Shakir Adewale, David L. Luftman, Nand K. Wadhwa. *Nephrology/Medicine, Stony Brook Medicine, Stony Brook, NY.*

**Background:** Hyponatremia is the most common electrolyte abnormality in hospitalized patients and carries significant morbidity and mortality.

**Methods:** We investigated if hyponatremia is managed appropriately in our academic tertiary care center. We reviewed 1344 serial electronic medical records retrospectively on 3 different medical services, over a six month period. Hyponatremia was defined as 2 or more serum sodium (Na) <135 mEq/L.

**Results:** 141 (10.5%) patients (85 M and 56 F, mean age 65.9 yrs) were found to be hyponatremic during their hospitalization. 84 (59.5%) had mild hyponatremia (Serum Na 131-134), 46 (32.6%) had moderate (Na 126-130) and 11 (7.8%) had severe (<126). In the hyponatremic group, mean serum sodium on discharge (133.8) was unchanged to admission (133.7, p=.56). Standard diagnostic criteria, serum osmolarity, urine osmolarity and urine electrolytes were not checked in 74/84 (88.1%), 34/46 (73.9%) and 6/11 (54.5%) of the hyponatremic patients in the mild, moderate and severe groups respectively. The mean lowest sodium was 128.6 in those that had any diagnostic work up done, compared to 130.9 in the group that had none (p<.001). At least one management discordance (either giving IV NaCl 0.9 % solution with diuretics or with a salt/fluid restricted diet) was seen in 52 (37%) of the hyponatremic patients. No significant difference in the management discordance was seen in the mild versus the severe groups. Length of stay was longer in the hyponatremic patients with management discordance than the patients without. Importantly, mean length of stay was 7.7 days in the hyponatremic groups compared to 4.3 days in the normonatremic group (P<.001).

**Conclusions:** Diagnostic workup was significantly less comprehensive for patients with mild hyponatremia compared to those with moderate or severe hyponatremia. Longer length of stay had both a positive correlation with lower serum sodium levels and with greater Δ Na levels, indicating that larger fluctuations in sodium levels may be an indicator of disease severity. Hyponatremia management remains suboptimal and further studies are needed to understand it and possible educational avenues to improve it.

## PUB255

**Interim Analysis of a Multi-National, Observational Safety Study of Tolvaptan in the Treatment of SIADH** Christian Stefan Haas,[1] Volker Rolf Burst,[2] Isabelle A. Runkle de la Vega,[3] Edward Jude,[4] Jayadave Shakher,[5] Duncan Gould,[6] Robert Goedde.[7] *[1]Univ of Luebeck, Luebeck, Germany; [2]Univ of Cologne, Cologne, Germany; [3]Hospital Clínico San Carlos, Madrid, Spain; [4]Tameside General Hospital, Ashton-under-Lyne, United Kingdom; [5]Birmingham Heartlands Hospital, Birmingham, United Kingdom; [6]Otsuka Pharmaceutical Europe Ltd., Uxbridge, United Kingdom; [7]Otsuka Frankfurt Research Institute GmbH, Frankfurt, Germany.*

**Background:** Hyponatremia (HN) is the commonest electrolyte disorder in in-patients with SIADH. Tolvaptan, a selective vasopressin-2 receptor antagonist, is the only vaptan approved in Europe for SIADH. Despite its good safety profile in prospective studies there is concern of possible rapid sodium correction in a real-life setting and increased risk of osmotic demyelination syndrome (ODS). Study objective was to assess tolvaptan drug utilization patterns and safety in clinical practice.

**Methods:** Prospective observational study in 7 European countries (65 sites). In-hospital prescription data and tolvaptan usage were studied. HN-associated symptoms, co-morbidities, co-medication and course of serum sodium were studied.

**Results:** Data from 664 prescriptions were available; 86% SIADH. The course of 252 patients was analyzed; 96% had a diagnosis of SIADH. Co-morbidities included neoplasms (47%), psychiatric disorders (21%), disorders of nervous (26%) or respiratory system (22%). Median age was 72 years (range 26-96). At baseline, 49% of patients had HN symptoms. Serum sodium at baseline, day 4 and week 4 was 123.2±6.5 (mean±SD), 131.8±5.6 and 134.0±6.5 mmol/L, respectively. Maximum daily dose ranged from 3.75 to 60mg (median 15mg). Most patients received tolvaptan daily, some received it less frequently. Treatment length varied from 1 to 857 days (median 17 days). Rapid correction of HN ($\Delta S_{Na} \geq 12$ mmol/L/24h) occurred in 15% of patients, no cases of ODS occurred.

**Conclusions:** In routine medical practice tolvaptan: is used for the indication of SIADH in the majority of cases; is an effective treatment for HN; may result in overly rapid correction of HN. Despite occurrence of rapid correction ODS has not been observed in this study to date.

## PUB256

**Aquaporin-10 May Not Be Physiologically Important in Mammals as Some Are Pseudogenes** Kenichi Ishibashi,[1] Ryouya Koma,[1] Kenma Nozaki,[1] Yasuko Tanaka,[1] Yoshiyuki Morishita.[3] *[1]Medical Physiology, Meiji Pharmaceutical Univ, Kiyose, Tokyo, Japan; [2]Nephrology, Jichi Medical School, Shimotuke, Tochigi, Japan.*

**Background:** The role of AQP10 is unclear as we reported previously that mouse AQP10 is a pseudogene (BBRC 294: 630, 2002). Human authentic AQP10 is located intracellularly at enterochromaffin cells of the small intestine, while its non-functioning splice-variant at the brush border membranes. We speculated that AQP10 will be a pseudogene in some other animals.

**Methods:** We searched genome databases for AQP10 orthologues and sequenced them with the analyses of their mRNA expressions by RT-PCR. We also analyzed the AQP10 gene of 100 people by direct exon sequencing from the genomic DNA.

**Results:** We found that the AQP10 of some mammals has insertions and deletions in the exons, including cattle (Bos taurus), sheep (Ovis aries) and goat (Capra hircus). In bovine AQP10, exon1 and 5 lack 'C' and 'CTT''CA' respectively to be frame-shifted and prematurely terminated, which was confirmed by the direct all exon sequencing of the genomic DNA. The PCR primer sets for exon1/2 and exon4/5 revealed only genomic bands without bands for mRNA in the duodenum and jejunum. Similar results were obtained by the analyses of the sheep and the goat AQP10s. Since above animals are derived from pig ancestors, swine (Sus scrofa) AQP10 was also analyzed to find that the exons were complete and expressed in the jejunum. Therefore, AQP10 might turn to a pseudogene around 65 million years ago when the cattle evolved. Although the rat (rattus norvegicus) AQP10 mRNA is complete, it was not detected in all the GI tracts, kidney, testis, uterus, eye, and skin, suggesting that rat AQP10 is also a pseudogene as mouse AQP10 is. The dog (Canis familiaris) AQP10 mRNA was detected not only in the small intestine and stomach but also in the cecum and colon where enterochromaffin cells are absent. No mutation was detected in the exons of AQP10 in hundred humans.

**Conclusions:** AQP10, selectively expressed in the GI tracts, may have lost its role or been replaced by other aquaglyceroporins, AQP3 and AQP7 in some branches of mammals.

*Funding:* Government Support - Non-U.S.

## PUB257

**Symptomatic Chronic Hyponatremia in a Young Female due to Nephrogenic Syndrome of Inappropriate Antidiuresis: Response to Tolvaptan** Vimal Chadha, Uri S. Alon. *Nephrology, Children's Mercy Hospitals and Clinics, Kansas City, MO.*

**Background:** First reported in 2005 in two unrelated male infants, nephrogenic syndrome of inappropriate antidiuresis (NSIAD) was found to be caused by gain-of-function mutations in the V2 vasopressin receptor (V2R). Since then a few other cases including two families with this syndrome have been reported. Transmitted in an X-linked mode, all reported cases so far have been of males, with abnormal water loading test in female relatives. All reported patients had missense mutations in the V2R gene and these patients did not respond to Tolvaptan (inhibitor of AVPR2) where it was tried.

**Methods:** Seventeen year old previously healthy girl presented with dizziness, and short-term memory loss, and was found to have serum sodium (S. $Na^+$) of 128 mEq/L. Her clinical picture was suggestive of SIADH (euvolemia, low serum osmolality, increased urinary osmolality and sodium level) but extensive investigations failed to delineate any underlying cause for SIADH. Kidney, thyroid and adrenal function tests were normal; urine drug screen was negative. Review of medical records revealed normal S. $Na^+$ of 142 mEq/L over a decade ago. She was managed as possible SIADH patient, with water restriction that resulted in modest improvement in S. $Na^+$ to 133 mEq/L. A month later her symptoms recurred with a drop in her S. $Na^+$ to 128 mEq/L. Serum ADH levels were undetectable on both occasions as confirmed in two different labs. Later, her S. $Na^+$ dropped to 119 mEq/L when she was given water prior to a renal ultrasound. She was suspected to have NSIAD and blood was sent for DNA sequencing of V2R gene, that did not show any mutation. She responded to Tolvaptan 7.5 mg daily and her current S. $Na^+$ is stable between 140 to 145 mEq/L with urine osmolality < 200 mOsm/kg.

**Conclusions:** All previously reported cases of NSIAD were males with activating mutations of V2R. Tolvaptan has not been effective when used. This is a first case report of NSIAD in a female with symptomatic hyponatremia that responded to Tolvaptan therapy. The case suggests (1) possible yet unknown mutations or mechanisms of water balance dysregulation resulting in NSIAD, (2) trial of Tolvaptan in cases of NSAID.

## PUB258

**Unexpectedly High Frequency of Reset Osmostat and Cerebral-Renal Salt Wasting in Nonedematous Hyponatremia: Value of Determining Total, Extracellular and Intracellular Water Volumes and Fractional Excretion of Urate** John K. Maesaka,[1] Louis J. Imbriano,[1] Joseph Mattana,[1] Dympna Gallagher.[2] *[1]Medicine, Winthrop-Univ Hospital, Mineola, NY; [2]Body Composition Unit, St. Lukes-Roosevelt Hospital, New York, NY.*

**Background:** The volume approach to the differential diagnosis of hyponatremia (HN) has hampered insights into its etiology.

**Methods:** We measured total body (TBW) and extracellular (ECW) water volumes by deuterium and sodium bromide, respectively, in 23 of 57 HN patients with a wide spectrum of comorbidities, fractional excretion (FE) of urate, normal 4-11%, and urine osmolality in random urine and during saline infusion. We used the following criteria: normal to high water volumes (WV) for reset osmostat (RO) and SIADH, low WV for renal salt wasting (RSW), normal FEurate and dilute random urine for RO, increased FEurate for SIADH and RSW, normalization of FEurate after correcting HN for SIADH, persistently increased FEurate after correcting HN for RSW and induction of dilute urine by saline for RSW because of removal of volume stimulus for ADH.

**Results:** The following data and conclusions with ample literature support were obtained: 1) 19 with normal FEurate had RO-8 with dilute random urine and 6 with increased WV. 2) 19 with increased FEurate had RSW-9 had decreased WV, 9 had dilute urines induced by saline (not seen in SIADH), 16 had no evidence of cerebral disease and 6 had persistently increased FEurate after correcting the HN. 3) 12 with increased FEurate had SIADH, 8 had increased WV, and 3 had normal FEurate after correction of HN. 4) 7 with high FEurate and HN did not have enough data to differentiate SIADH from RSW.

**Conclusions:** Determination of FEurate is superior to the volume approach in HN; RSW is known to be much more common than SIADH in neurosurgical patients; the unexpectedly high prevalence of RO and RSW in a non-neurosurgical population creates a need to change cerebral salt wasting to RSW because RSW would otherwise not be considered in the absence of cerebral disease; patients with RO and SIADH are hypervolemic, not euvolemic; RO is a separate clinical entity from SIADH because of a normal FEurate and predictable response to water-loading.

**PUB259**

**Ineffectiveness of Volume Approach to Hyponatremia: Proposal of New Approach** Louis J. Imbriano,[1] Dympna Gallagher,[2] Nobuyuki (Bill) Miyawaki,[1] Joseph Mattana,[1] John K. Maesaka.[1] *[1]Medicine, Winthrop-Univ Hospital, Mineola, NY; [2]Body Composition Unit, St. Lukes-Roosevelt Hospital, New York, NY.*

**Background:** There is awareness that the volume approach to evaluation of HN has been unsuccessful. We present 4 cases of hyponatremia (HN) that support this viewpoint.

**Methods:** Two females, ages 64 and 84 and 2 males, ages 71 and 73 yrs. met criteria for SIADH and renal salt wasting (RSW).

**Results:** Serum sodium (Na) ranged from 116-121 mmol/L, concentrated urine, urine Na 23-95 mmol/L, increased fractional excretion (FE) of urate, 16.8-22.7% (normal 4-11%) and normal renal, adrenal and thyroid function. Two non-edematous females, 1 had Lyme disease and 1 had hypertension; 1 male had 2+ edema of both legs due to inferior vena caval obstruction by stage IV B cell lymphoma. All 3 patients had postural hypotension and tachycardia. In 2 patients, saline infusion induced excretion of dilute urines, plasma ADH being appropriately undetectable in the edematous patient with lymphoma; FEurate remained increased after correction of HN in both females that was consistent with RSW as compared to normalization in SIADH. Total (TBW) and extracellular body water (ECW) as determined by deuterium and sodium bromide, respectively, were decreased in the 2 nonedematous females. The increased FEurate, which persisted after correction of HN, dilution of urine with saline infusion with appropriate inhibition of ADH in the edematous patient, postural hypotension with reflex tachycardia, and decreased TBW, ECW and intracellular water in the two nonedematous patients collectively support the diagnosis of RSW. The fourth patient had pleural effusion and edema after cardiac bypass surgery with increased FEurate of 19.3%, which normalized to 6% after correcting the HN as in SIADH and not RSW. A high FEurate is very unusual in edematous patients, usually <4%. None of the patients had cerebral disease.

**Conclusions:** RSW was noted in 3 patients-2 by critical volume studies and 1 had edema; SIADH can occur with edema and pleural effusion. None had clinical cerebral disease which justifies proposal to change cerebral to RSW. We demonstrate the superiority of determining FEurate to the volume approach in HN.

**Cost-Utility Analysis of Tolvaptan versus Water Restriction for Euvolemic or Hypervolemic Hyponatremia** David J. Yoo, Lisa K. Prince, Dustin J. Little, Robert Nee, Christina M. Yuan. *Walter Reed National Military Medical Center.*

**Background:** Hyponatremia is associated with increased morbidity and mortality. Tolvaptan, an oral vasopressin (V2) receptor antagonist, increases serum sodium concentration vs. placebo in subjects with mild to moderate hyponatremia (SALT-1/SALT-2 trials, NEJM 2006), with increased scores on the Mental Component Summary of the SF-12 General Health Survey. We performed a cost-utility analysis of tolvaptan vs. water restriction based on data from the SALT Trials.

**Methods:** A computer-based decision model was developed using TreeAge Pro software (Williamstown, MA) to represent the costs and effectiveness of tolvaptan 30 mg daily vs. water restriction alone for outpatient treatment of euvolemic/hypervolemic hyponatremia. Costs, utility indices, and probabilities were obtained from literature review. Model time horizon was 30 days. A one-day hospital admission was required for tolvaptan initiation. Probabilities of resolving hyponatremia, and utilities for resolved (0.68) and unresolved (0.55) hyponatremia were obtained from the SALT trials (Cyr, et al. Abstract 25379. ISPOR. 2009). The primary endpoint was the incremental cost-effectiveness ratio (ICER) in dollars per quality-adjusted year of life (QALY) gained.

**Results:** The ICER was $2,800,000 per QALY gained, using a cost of $250 per 30 mg tolvaptan. One-way sensitivity analysis, using an arbitrary willingness to pay (WTP) threshold of $1,000,000, demonstrated water restriction to be the cost-effective option unless the utility of resolved hyponatremia was > 0.902, or the cost of tolvaptan was < $71.22/day. Water restriction was more cost-effective than tolvaptan in 100% of model iterations using Monte-Carlo probabilistic sensitivity analysis. The expected value of perfect information was $0.00, at a WTP $1,000,000.

**Conclusions:** Tolvaptan is not cost-effective as compared to water restriction alone for the treatment of outpatient euvolemic/hypervolemic hyponatremia, because of the requirement for hospital admission and the daily cost of the drug. This analysis may help to guide decisions regarding adoption of tolvaptan in this setting.

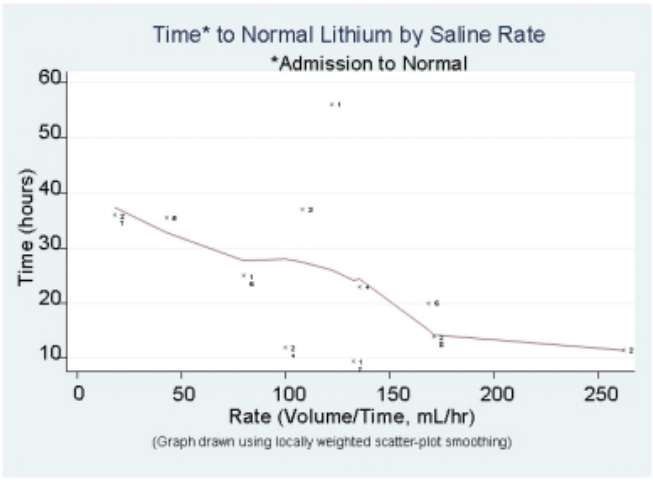
**Saline Diuresis for Lithium Intoxication Revisited 30 Years Later** Wei Boon Ooi, Francisco Hernandez Munoz, Alina Livshits, Monique Carreno, Alexander B. Knee, Anthony E. Poindexter, Gregory Lee Braden. *Dept of Medicine, Baystate Medical Center, Springfield, MA.*

**Background:** Reviews and textbooks do not recommend saline diuresis as therapy for lithium (Li) intoxication. Past case reports ('70s) showed forced saline diuresis (>250ml/hour 0.9% NaCl) may be helpful. We now describe patients with Li intoxication & correlate saline administration with clinical outcomes.

**Methods:** Patients were identified by ICD-9 codes from 2007-2012. Exclusion criteria included incomplete medical records & patients who were dialysed. Time from admission to normal serum Li level (≤1.0mmol/L), Tn, was used as surrogate marker for Li clearance. Main outcomes were rate of Li clearance due to saline diuresis & potential complications of saline diuresis.

**Results:** From 19 patients, 8 were excluded (4 dialysed, 4 incomplete records). Median age was 49 years. The majority (82%) were female & white. Bipolar disorder was the most common psychiatric diagnosis. Median baseline renal function was 132 ml/min (Cockroft-Gault). Five out of eleven patients had chronic intoxication. Symptoms at presentation included decreased level of consciousness, coarse tremors & tachycardia. Median peak Li level was 2.4 mmol/L. Median total saline administration from admission to Tn was 2400mL. Median saline rate from admission to Tn was 122.3ml/hour. Spearman correlation between saline rate & time to normal serum Li level was -0.546. Tn was less than 24 hours in 3 patients receiving >150ml/hr of saline. No patient had adverse complications from saline administration.



**Conclusions:** There was a trend for more rapid improvement of serum Li levels in lithium intoxicated patients with greater rates of saline administration although it was not statistically significant given our small sample size. Prospective studies are needed to re-examine the efficacy of forced saline diuresis in Li intoxication.

**Statistical Model for Evaluating Efficacy of Oral Zirconium Silicate in Treatment of Hyperkalemia** Philip T. Lavin,[2] Stephen R. Ash,[1] Henrik S. Rasmussen,[1] Alvaro F. Guillem,[1] Fiona Stavros,[1] Donald Jeffrey Keyser,[1] Robert Alexander,[1] Roland Winger.[1] *[1]ZS Pharma Inc., Coppell, TX; [2]Boston Biostatistics Research Fdn, Boston, MA.*

**Background:** A Phase 2 proof of principle RCT (ZS-002) was conducted by ZS Pharma to evaluate three doses (0.3g tid, 3g tid, 10g tid) of active therapy and placebo control in 90 patients with renal impairment to evaluate the reduction in serum potassium (s-K) during the first 48 hours following therapy initiation. A total of 12 post-baseline assessments were available for evaluation and modeling including an averaged baseline s-K over the prior 24 hours.

**Methods:** A longitudinal model (SAS PROC MIXED) was pre-defined in accordance with regulatory requirements. The model evaluated the log s-K as a means to stabilize variance and to represent the anticipated drug effect during the 48 hour assessment. The model included all post-baseline observations including the actual hour when the data were collected. Time and time-treatment interactions were included in the model with subject as a random effect. The model accommodated all available intent-to-treat data.

**Results:** The overall goodness of fit of the model was excellent with p<0.0001. The model-derived standard deviation (SD) estimate was 0.102, which was within 10% of the assumed SD. Statistical significance was established for the two highest doses relative to placebo control. The study power exceeded 80% to detect the preplanned 10% relative difference between active dose versus control in a pre-defined hierarchy from highest to lowest dose.Alternative post hoc models were investigated, however all other models were unable to match the goodness of fit of the following pre-defined model: */** Model for 48 hour endpoint **/ ods output Solutionf=mod_48; **procmixed**data=labs; class trtgrp subject; model val=timpnt trtgrp*timpnt/solution; random intercept timpnt/subject=subject*trtgrp type=un;**run**;* Data will be presented on the ability of the model to predict the patient-specific 48-hour outcome based on the pre-treatment baseline and the randomized dose group as a means to avoid hypokalemia.

**Conclusions:** A highly efficient model for the analysis of 48-hour s-K data has been identified.

**PUB263**

**Fractional Excretion of Urate Provides Insights into Pathophysiology of Hyponatremia in Addison's Disease and Myxedema** James Drakakis,[1] Louis J. Imbriano,[1] Naheed Ansari,[2] Joseph Mattana,[1] John K. Maesaka.[1] *[1]Dept of Medicine, Winthrop Univ Hospital, Mineola, NY; [2]Dept of Medicine, Jacobi Medical Center, Bronx, NY.*

**Background:** Fractional excretion (FE) of urate provides insights into the etiology of hyponatremia (HN). Low FEurate of <5% is most common in edematous states such as heart failure and in volume depleted patients with normal renal function. Normal FEurate

is most common in reset osmostat, while FEurate is increased in cerebral-renal salt wasting (RSW) and SIADH.

**Methods:** We present a patient with Addison's disease (AD) and another with myxedema (MX), where FEurate provided insight into the pathophysiology of HN. A 51 year old female with AD was admitted with low blood pressure, serum sodium (SNa) 119, potassium 5.4 mmol/L, low AM cortisol 3.1ug/dl, high ACTH 865.1 pg/ml, urine (U) Na 116 mmol/L, urine osmolality (Uosm) 537 mosm/kg and low FEurate of 2 and 3% (normal 4-11%). A 74 year old male with MX was admitted with SNa 116, UNa 44 mmol/L, Uosm 300 mosm/kg, high FEurate of 26.6%, TSH 39.7 mIU/L and free T4 0.53 ng/dL. Both had normal renal function.

**Results:** HN in AD is associated with an appropriate increase in plasma ADH secretion due to extracellular volume (ECV) depletion resulting from defective distal tubule (DT) Na transport with intact function of the proximal tubule (PT) where urate is exclusively transported. This induces a prerenal state with low FEurate. In MX, high FEurate is consistent with RSW and SIADH. Studies in MX rats demonstrate a 17.1% reduction in ECV as determined by inulin space and a 28% reduction in PT Na reabsorption by micropuncture methodology. These data are consistent with the increase in FElithium from 29 to 42% when plasma from patients with RSW was infused into rats. This suggests a major defect in PT Na transport in RSW since lithium is transported 1:1 with Na in the PT and no transport in the DT.

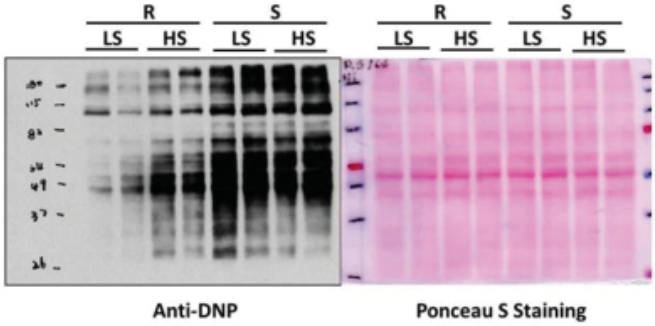
**Conclusions:** The HN in AD and MX is due to an appropriate increase in ADH induced by ECF volume depletion, defective Na transport in the DT in AD and PT in MX. The low FEurate in AD is consistent with intact PT function whereas the high FEurate in MX is consistent with a major defect in PT solute transport.

## PUB264

**The Implication of Overstimulation of Redox-Sensitive Na/K-ATPase Signaling in Dahl Salt Sensitivity** Yanling Yan,[1,3] Anna P. Shapiro,[2] Steven T. Haller,[2] Muhammad A. Chaudhry,[1] Jiang Tian,[2] Zi-jian Xie,[2] Deepak K. Malhotra,[2] Nader G. Abraham,[1] Joseph I. Shapiro,[1,2] Jiang Liu.[1] *[1]Marshall Univ JCE School of Medicine, Huntington, WV; [2]Univ of Toledo College of Medicine, Toledo, OH; [3]Yanshan Univ, Qinhuangdao, China.*

**Background:** Impairment of renal proximal tubule (RPT) Na/K-ATPase signaling contributes to Dahl salt-sensitive hypertension, but there is no difference in α1 gene coding, ouabain-sensitivity, and α1 expression between Dahl salt-resistant (R) and salt-sensitive (S) rats.

**Results:** A high salt diet (2% NaCl for 7 days) significantly stimulated RPT Na/K-ATPase signaling, protein carbonylation (whole cell lysate and Na/K-ATPase α1 subunit) and heme-oxygenase-1 (HO-1) expression in isolated RPTs in Dahl R but not S rats (12-14 week old). Compared to age- and gender-matched R rats fed with a low salt diet (0.3% NaCl), isolated RPTs from the S rats have a significantly higher basal level of protein carbonylation and HO-1 that do not respond to a high salt stimulation.



In isolated R rat PRTs, ouabain (10 μM)-stimulated α1 carbonylation, HO-1 expression and Na/K-ATPase signaling were significantly attenuated by pre-treatment with the antioxidant *N*-acetyl-L-cysteine (NAC, 10mM, 30min). However, the effect of ouabain on carbonylation was not observed in overstimulated S rats.

In porcine RPT LLC-PK1 cells, ouabain-stimulated protein carbonylation of the a1 subunit and HO-1 expression depend on Na/K-ATPase signaling, suggesting a redox-sensitive Na/K-ATPase signaling as well as a dynamic cellular adaptation (HO-1 and alike) to counterbalance ouabain-induced oxidative stress.

**Conclusions:** Oxidative stress affects RPT Na/K-ATPase signaling and sodium handling. Overstimulation of ROS/carbonylation in the S rats at baseline might desensitize the Na/K-ATPase signaling that is no longer responding to a high salt diet or ouabain.

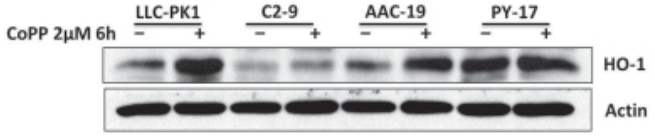
## PUB265

**The Involvement of the Na/K-ATPase in HO-1 Induction by Ouabain and CoPP** Yanling Yan,[1,3] Anna P. Shapiro,[2] Muhammad A. Chaudhry,[1] Zi-jian Xie,[2] Deepak K. Malhotra,[2] Nader G. Abraham,[1] Joseph I. Shapiro,[1,2] Jiang Liu.[1] *[1]Marshall Univ JCE School of Medicine, Huntington, WV; [2]Univ of Toledo College of Medicine, Toledo, OH; [3]Yanshan Univ, Qinhuangdao, China.*

**Background:** Both CoPP (Cobalt protoporphyrin, an inducer of heme-oxygenase-1, HO-1) and ouabain induce HO-1 expression in porcine renal proximal tubule LLC-PK1 cells.

**Results:** In LLC-PK1 cells, ouabain-stimulated c-Src activation, ROS generation and protein carbonylation of the Na/K-ATPase α1 subunit were significantly attenuated by the antioxidant *N*-acetyl-L-cysteine (NAC) and disruption of the Na/K-ATPase signaling. Interestingly, both ouabain and CoPP also significantly induced HO-1 expression in LLC-PK1 cells. To determine the role of the Na/K-ATPase and its signaling, we used three stable cell lines generated from LLC-PK1 cells, PY-17 (the Na/K-ATPase α1 subunit knock-down cells), C2-9 (caveolin-1 knockout cells), and AAC-19 (PY-17 cells only expressing rat α1) cells. Both PY-17 and C2-9 show disrupted Na/K-ATPase signaling. Both ouabain and CoPP significantly induced HO-1 expression in AAC-19 cell as seen in LLC-PK1 cells. However, depression of Na/K-ATPase expression and disruption of Na/K-ATPase signaling not only prevented ouabain-induced HO-1 expression, but also prevented CoPP-induced HO-1 expression.



Induction of HO-1 by CoPP partially but significantly attenuated ouabain-induced c-Src activation.

**Conclusions:** In LLC-PK1 cells, ouabain stimulated a dynamic antioxidant adaptation (HO-1 and alike) to counterbalance ouabain-induced oxidative stress. Furthermore, the Na/K-ATPase and its signaling function as a functional receptor of CoPP-induced HO-1 expression.

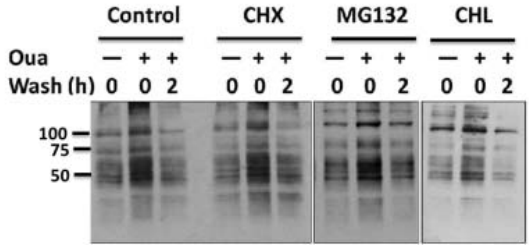
## PUB266

**Ouabain-Induced Protein Carbonylation of the Na/K-ATPase α1 Subunit Is Reversible in LLC-PK1 Cells** Yanling Yan,[1,3] Anna P. Shapiro,[2] Muhammad A. Chaudhry,[1] Zi-jian Xie,[2] Deepak K. Malhotra,[2] Nader G. Abraham,[1] Joseph I. Shapiro,[1,2] Jiang Liu.[1] *[1]Marshall Univ JCE School of Medicine, Huntington, WV; [2]Univ of Toledo College of Medicine, Toledo, OH; [3]Yanshan Univ, Qinhuangdao, China.*

**Background:** In LLC-PK1 cells, ouabain-induced protein carbonylation of the Na/K-ATPase α1 subunit is involved in the Na/K-ATPase signaling and sodium reabsorption.

**Results:** To assess whether ouabain-induced protein carbonylation is reversible, LLC-PK1 cells were treated with ouabain (100nM, 1h) to induce protein carbonylation of the α1 subunit, and then either collected as ouabain-treated (Oua) or washed to remove un-bound ouabain (by extensive washing with pre-warmed culture medium) and further cultured in ouabain-free medium for 2h (Oua+wash). Comparing to control and ouabain-treated (Oua) cells, ouabain-induced protein carbonylation of the α1 subunit was reversed by removal of un-bound ouabain.

To test if this carbonylation/decarbonylation process is due to *de novo* protein synthesis or degradation, LLC-PK1 cells were pre-treated for 2h with different inhibitors and aforementioned experiment was repeated in the presence of the inhibitors. The inhibitors used included protein biosynthesis inhibitor cycloheximide (20μg/ml), proteasome inhibitor MG132 (10μM), and lysosomotropic weak base agent chloroquine (100μM). In comparison with experiments without inhibitors, the decreased carbonylation of the α1 subunit was largely independent of *de novo* protein synthesis and degradation through lysosome and proteasome pathways, leading us to speculate a likely enzyme-driven mechanism of the removal of the carbonyl group, by either a known enzyme system or an unidentified enzyme-like protein.



**Conclusions:** Ouabain-induced protein carbonylation of the α1 subunit was reversible that is largely independent of *de novo* protein synthesis and degradation.

*Funding:* Other NIH Support - NIH RO1 HL-109015 to Z.X. and J.I.S.

## PUB267

**Abnormal Urinary Excretion of ENaCγ after Hypertonic Saline Infusion in Chronic Kidney Disease** Janni Majgaard Jensen,[1,2] Frank H. Mose,[1] Jesper N. Bech,[1] Erling B. Pedersen.[1] *[1]Depts of Medical Research and Medicine, Holstebro Regional Hospital, Holstebro, Denmark; [2]Aarhus Univ, Denmark.*

**Background:** Patients with chronic kidney disease (CKD) have a diminished capacity to concentrate urine. We wanted to test the hypothesis that this phenomenon is caused by abnormal activity in the aquaporin2 water channels and/or the epithelial sodium channels in the distal nephron.

**Methods:** The study comprised of 23 patients with CKD and 24 healthy controls, who consumed a 4- day standardized diet (120 mmol sodium/day) prior to the study day. At baseline conditions and after 3 % hypertonic saline infusion, we measured urinary

concentrations of AQP2 (u-AQP2) and gamma subunit of ENaC (u-ENaCγ,) free water clearance ($C_{H2O}$), urinary osmolality (u-Osm) and fractional excretion of sodium ($FE_{Na}$). GFR was measured by constant infusion clearance technique using $^{51}$Cr-EDTA as reference substance. Plasma concentrations of vasopressin (AVP), renin (PRC), Angiotensin II (AngII) and Aldosterone (Aldo) were determined by radioimmunoassay (RIA). Extracellular body fluid volume (ECV) was calculated by Body Composition Monitor.

**Results:** At baseline, GFR was 34 ml/min in patients and 89 ml/min in controls. CKD patients had a high u-ENaCγ, $FE_{Na,}$ PRC, p-Aldo and p-AVP and a low $C_{H2O}$compared to controls. No differences in u-AQP2 or ECV were measured between patients and controls. Hypertonic saline infusion caused an increase in u-ENaCγ in controls ($p<0.05$), but there was no change in u-ENaCγ in patients. Controls had a higher increase in u-osm and a larger decrease in $C_{H2O}$ compared to patients, but the increase in u-AQP2, $FE_{Na}$ and p-AVP were similar. PRC, AngII and Aldo decreased in both groups all though levels were higher in patients. ECV increased to the same extent in both groups.

**Conclusions:** In response to hypertonic saline, u-ENaCγ increased in controls and did not change in CKD patients. This abnormal response in u-ENaCγ in CKD patients might be caused by a less efficient decrease in reabsorption of sodium in the proximal tubules and subsequently no need for adjustment in the distal nephron via ENaC.

## PUB268

**Hypomagnesemia in Critically Ill Patients with Sepsis** Ashish Kataria,[1] Daniel W. Ross,[1] Nirav Mehta,[1] Myriam Kline,[2] Kenar D. Jhaveri,[1] Steven Fishbane.[1] *[1]Kidney Diseases and Hypertension, Hofstra NSLIJ School of Medicine, NY; [2]Biostatistics, Feinstein Institute of Medical Research.*

**Background:** Hypomagnesemia has been reported in 20% to 65% of patients in an ICU setting. Our study aimed to evaluate the frequency of hypomagnesemia in critically ill patients with sepsis, determine clinical predictors for its development, and to ascertain how hypomagnesemia affects patient outcomes in the ICU setting.

**Methods:** A single center, retrospective cohort study was conducted. All ICU patients with sepsis within the last year were evaluated. A group with normal Mg levels was compared to low Mg group. Baseline demographics, medications use, and lab data were collected. Primary outcome was the frequency of patients that developed hypomagnesemia. The adverse outcomes studied from were: ventilator requirement , days on ventilator, ICU length of stay and mortality during the hospital stay. Mg level of <1.6mg/dl was used as the cutoff level. Logistic regression was used to model hypomagnesemia as a function of key demographic clinical variables.

**Results:** Hypomagnesemia was observed in 23% of (n=99) studied patients. There were no significant differences between the groups at baseline on any demographic or laboratory variables. Risk factors in developing hypomagnesemia such as diarrhea, chemotherapy use, use of PPI's and diuretic were not significantly associated with the development of hypomagnesemia. Nevertheless, 77% patients who had low Mg levels were administered PPI's as compared to 53% in the normal Mg group, (p value=0.76). The development of hypomagnesemia was not associated with ventilator use, length of ventilator dependence, or length of stay in ICU and mortality.

**Conclusions:** While low Mg was extremely common in the ICU pateints with sepsis, it did not affect their overall ICU stay and mortality. Despite the absence of significant associations of low Mg levels with the studied risk factors and clinical outcomes, the development of hypomagnesemia in 23% of ICU patients having sepsis during their ICU stay warrants a prospective study with a larger sample size to ascertain its relationship to clinical outcomes in this specific patient population.

## PUB269

**The Effects of Tolvapton on Severe Chronic Kidney Disease Patients with Congestive Heart Failure** Kiyoto Koibuchi,[1] Kentaro Tanaka,[3] Toshiyuki Aoki,[1] Moriatsu Miyagi,[1] Ken Sakai,[2] Sonoo Mizuiri.[2] *[1]Dept of Nephrology, Saiseikai Yokohama-City Eastern Hospital, Yokohama, Kanagawa, Japan; [2]Dept of Nephrology, Toho Univ School of Medicine, Ota-ku, Tokyo, Japan; [3]Div of Diabetes and Metabolism, The Institute for Adult Diseases, Asahi Life Foundation, Chiyoda-ku, Tokyo, Japan.*

**Background:** Tolvaptan is a selective vasopressin receptor 2 antagonist and dose-dependent drug used to treat congestive heart failure (CHF) as diuretic. It is known that tolvaptan increases excretion of excess fluids and improves blood sodium levels in patients with heart failure without affecting renal function compared to conventional diuretics. However, few studies examined the effects of tolvaptan for patients with severe chronic kidney disease (CKD). The aim of the study is to examine the effect of tolvaptan on patients with severe CKD.

**Methods:** We analyzed CKD patients with less than 30 of estimated glomerular filtration rate (eGFR) who had CHF. Those of all patients have already treated conventional diuretics, but CHF worsened. We administrated tolvaptan for the patients with CHF in admission. In order to evaluate the effect of tolvapton, we examined urinary volume, body weight, serum sodium and eGFR for three days after administration. The patients who changed the dose of conventional diuretics in observation period were excluded.

**Results:** We evaluated 52 patients consisted of 32 men and 20 women with a mean age of 77.5 ± 10.9 years and a mean eGFR of 17.8 ± 7.4 ml/min/1.73m2 at admission. The mean dose of tolvaptan was 12.0±4.0mg. The urinary volume increased from 1141.1±539.5 ml/day to 1864.5±1008.2 ml/day ($p<0.001$, Wilcoxon signed-rank test). Body weight improved from 59.7 ± 17.6 kg to 57.8 ± 17.0 kg ($p<0.01$, Wilcoxon signed-rank test). Serum sodium elevated from 132 ± 6.3 mEq/l to 139.4 ± 6.4 mEq/l ($p=0.03$, ANOVA and Dunnett's testing). eGFR (17.8±7.4 at baseline) remained 17.1±8.7 after administration ($p=0.34$, Wilcoxon signed-rank test).

**Conclusions:** Tolvaptan is effective diuretic even in sever CKD patient , resistance to conventional diuretic, without worsening renal function.

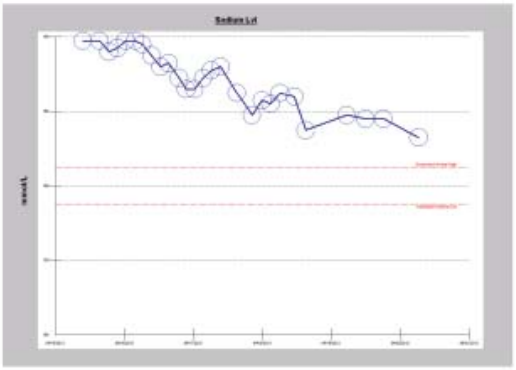
## PUB270

**A New Step-Ladder Approach to Treating Severe Symptomatic Chronic Hypernatremia to Mitigate Catastrophic Cerebral Events** Macaulay A. Onuigbo,[1,2] Ngozi J. Achebe.[3] *[1]Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI; [3]Internal Medicine, Capital Medical Center, Olympia, WA.*

**Background:** Hypernatremia is associated with hyperosmolality and hypertonicity of plasma and intracellular space. The brain and other tissues therefore adapt to avoid pathologic cell shrinkage/dehydration by synthesizing idiogenic osmoles. Severe hypernatremia is much less common than hyponatremia so physicians are less aware of the implications of over-rapid correction of chronic hypernatremia. We describe a new step-ladder approach to managing severe hypernatremia.

**Methods:** Case report.

**Results:** An unresponsive 80 year old Caucasian male patient, a Group Home resident, with cognitive developmental delay from birth, central diabetes insipidus with chronic hypernatremia was admitted with fever, pneumonia, volume depletion and severe hypernatremia (179 mEq/L). In addition to intravenous antibiotics, he required daily intermittent guided free water repletion therapy with intravenous 5% dextrose (100-250 cc/hr) to achieve a step-ladder correction of Na over 72-96 hours. Inhaled DDAVP was added about hospital day 4. This way, the over-rapid correction of chronic hypernatremia by >10-12 mEq/L/day was avoided, thus mitigating the potential but often unrecognized risk of cerebral edema. He was later discharged at baseline mental status, with a Na of 146 mEq/L.



**Conclusions:** With adaptive processes in severe hypernatremia, over-rapid correction produces rapid fluid movement into the brain cells and the development of cerebral edema. Most experts recommend 10-12 mEq/L/day correction. We have described a step-ladder approach of safely managing severe hypernatremia using guided intermittent intravenous 5% dextrose in an unconscious patient. Acute hypernatremia (<12 hours) should be corrected quickly; however, when in doubt, go slow.

## PUB271

**Aggressive Therapy Fails to Influence Outcomes in Hospitalized Hypernatremic Geriatric Patients** Muhammad R. Toor, Anjali Singla, Xenia P. Sumin, Maria V. DeVita, Michael F. Michelis. *Nephrology, NSLIJ-Lenox Hill Hospital, New York, NY.*

**Background:** Hypernatremia is a common electrolyte disorder and is associated with adverse outcomes such as increased length of stay and increased mortality. Prior studies have suggested a variety of factors that may result in undesirable outcomes.

**Methods:** A 3 month retrospective chart review was performed on hospitalized patients over the age of 18 with a serum sodium level >150 mmol/L. This study was designed to characterize the rate of sodium correction, the level of monitoring as indicated by ward setting, whether or not a nephrologist was involved in the case, the type of fluids used, and other relevant data and whether any of these variables influenced patient outcomes.

**Results:** Of 28 patients with hypernatremia, 5 were excluded because of data deficiencies. Of the remaining 23 patients studied, the mean age was 82.6 years old and the mean initial sodium level was 152.3 mmol/L (range: 151–156 mmol/L). Ten (43%) patients were demented and twelve (52%) were on tube feeding. The overall mortality rate was 65%. Sodium level was corrected (≤145 mmol/L) in 15 (65%) patients. Correction did not influence rates of survival (33% corrected vs. 38% not corrected, p=0.99). Seven patients corrected in ≤2 days and 8 in ≥3 days but these differences did not affect survival. Thirteen of 14 patients admitted to or transferred to the ICU expired whereas 2 of 9 patients not in the ICU expired (p=0.001, RR 6.93). Obtaining a nephrology consult did not affect patient mortality (p=0.69). The patients received various IVF and/or oral fluids, including NS, ½ NS, D5W, and oral water, which appeared appropriate to their clinical status. The mean length of stay for all patients was 20.4 days and longer for those who remained alive, 23.6 days.

**Conclusions:** Hypernatremia is associated with a poor prognosis and outcomes are still disappointing despite appropriate rates of correction, intensive monitoring, and the involvement of a medical specialist. This indicates that the disease state associated with hypernatremia appears to be of paramount importance in regard to patient outcomes and early attention to the primary process is essential.

## PUB272

### An Unusual Case of Hyperkalemia Refractory to Hemodialysis

Sindhu Mallik Arjun, Gary Noroian, Robert Mark Black. *Div of Nephrology, Saint Vincent Hospital, Worcester, MA.*

**Background:** Pseudohyperkalemia is typically caused by hemolysis, thrombocytosis or traumatic blood drawing. We report a case of a patient with severe hyperammonemia-associated hyperkalemia.

**Methods:** An 80 year old man presented to our institution with critical aortic stenosis. Before his aortic valve replacement, his serum creatinine was 1.02 mg/dL and his serum potassium concentration was 3.0 meq/L. His post-op course required pressor support and mechanical ventilation. He developed anuric acute kidney injury with a creatinine rise to 4.63 mg/dL. His urine sediment was consistent with acute tubular necrosis. Intermittent hemodialysis was initiated. His serum potassium level remained normal for the first two weeks of dialysis. It then rose to 6.1meq/L. He was dialyzed, but his potassium level two hours after hemodialysis was 6.7meq/L. A repeat potassium level was 7.3meq/L. The plasma level was also high. He was dialyzed again that evening. One hour into the dialysis treatment, the K fell to 5.7meq/L and it was 3.8meq/L at the end of the treatment. Blood pressure was lower and he had a very mild rise in the hepatic transaminases. An ammonia level was 572 umol/L (normal = 19–87). His ammonia level fell during the dialysis treatment, correlating with the decrease in the serum potassium level. While hepatic transaminases rose progressively over the next 24 hours, the acute hyperkalemia and hyperammonemia preceded these changes.

**Conclusions:** We hypothesize that the elevated ammonia (ammonium) level interfered with the serum potassium measurement in our patient. Extremely high serum ammonia levels (>400umol/L), were found to interfere with serum potassium measurements obtained using the OsmetechOPTI critical care analyzer[1]. The proposed mechanism is the cross reactivity of the $NH4^+$ ions with the $K^+$ selective ionophores. Pseudohyperkalemia should be considered in patients with refractory hyperkalemia and very high blood ammonia levels.

1. Carayannopoulos MO, Whilhite TR, Reddy L, Landt M, Smith CH, Dietzen DJ.Equimolar ammonia interference in potassium measurement on the Osmetech OPTI Critical Care Analyzer. ClinChem 2006;52:1603-1604.

## PUB273

### Factors Associated with Calf 100 kHz Impedance in Healthy Subjects

Samer Rateb Abbas,[1,2] Fansan Zhu,[1] Cesar Flores-Gama,[1] Cassandra Cartagena,[1] Caroline M. Williams,[1] Nathan W. Levin,[1] Peter Kotanko.[1] *[1]Nephrology, Renal Research Institute, New York, NY; [2]Nephrology, Beth Israel Medical Center, New York, NY.*

**Background:** Calf bioimpedance is used in hemodialysis patients to assess fluid status. Advantages of calf over whole body bioimpedance are ease of use and reliable evaluation of fluid status [Zhu, Physiol. Meas. 2008]. The aim of this study was to investigate associations between body weight, body mass index (BMI), age, gender and race and calf impedance (Zo) at 100 kHz in healthy subjects.

**Methods:** We measured Zo at 100 kHz (ZOE device; Noninvasive Medical Technologies; Las Vegas, NV) in adult subjects 40 to 80 years of age and eGFR > 60 mL/min/1.73 $m^2$ to create reference values. Zo was measured with leg horizontal in sitting subjects 5 minutes after placement of 4 electrodes; measurement took 30 seconds. Simple linear regression analysis was used to quantitate the associations between Zo and body weight, BMI, and age. Groups (genders; black vs. non-black) were compared by unpaired t-test.

**Results:** We studied 62 subjects (age 56±9 years; 31 males; 26 Blacks). Zo was not associated with body weight, BMI, age, gender and race figure A and B.

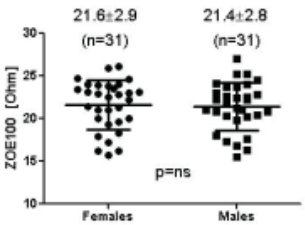


Figure A

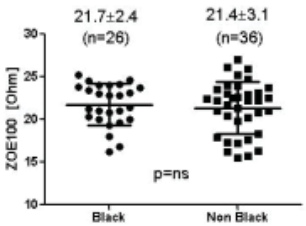

Figure B

**Conclusions:** In healthy subjects calf Zo measurement at 100 kHz is unrelated to key anthropometric and demographic characteristics, thus allowing the construction of Zo reference values irrespective of age, race, gender, body weight, and BMI.

## PUB274

### Dialysis Improved the Survival Rate of Patients with Severe Hyperkalemia

Do Hyoung Kim,[1] Jung Pyo Lee,[2] Jung Nam An,[3] Jin Ho Hwang,[3] Yon Su Kim,[3] Yun Kyu Oh,[2,3] Chun Soo Lim.[2,3] *[1]Dept of Internal Medicine, Chung-Ang Univ College of Medicine, Republic of Korea; [2]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Republic of Korea; [3]Dept of Internal Medicine, Seoul National Univ College of Medicine, Republic of Korea.*

**Background:** Severe hyperkalemia, with potassium levels ≥ 6.5 mEq/L, is a serious complication with high mortality in the hospitalized population. The purpose of this study is to evaluate the efficacy of renal replacement therapy (RRT) and the impact of the timing of RRT in patients with severe hyperkalemia.

**Methods:** We collected clinical data from 909 patients diagnosed with severe hyperkalemia. All were hospitalized between August 2007 and July 2010. The diagnosis of severe hyperkalemia was made either at the time of admission or during the period of hospitalization. Early dialysis (ED) was defined if RRT was started within 12 hours from the diagnosis of severe hyperkalemia. 135 patients (14.9%) who received RRT were compared with 774 patients who received only medical treatment.

**Results:** Of the 909 patients, 156 were end-stage renal disease (ESRD) patients with RRT and 753 were non-ESRD patients. The survival rate of RRT group was better than that of medical treatment group (Log Rank test, P=0.010). This association was also significant after adjusting for age, gender, disease severity, kidney function, and potassium level (HR 0.628, 95% CI 0.419-0.939, P=0.024). In subgroup analysis, RRT increased patients' survival rate in ESRD patients, however, it could not improve survival rate in non-ESRD patients. In non-ESRD patients, RRT group had significantly higher potassium levels and more comobidities than medical treatment group. The average time from diagnosis to dialysis was 9.1 ± 9.6 hours. The mortality rate of ED group was significantly higher than that of late dialysis (LD) group (P=0.007). Potassium level of ED group was higher that of LD group (ED vs. LD, 7.15 ± 0.74 vs 6.86 ± 0.53 mEq/L, P = 0.037).

**Conclusions:** Renal replacement therapy with medical treatment improved clinical outcomes in patients with severe hyperkalemia. But, timing of dialysis treatment could not affect the patients' survival.

## PUB275

### AVP-Induced Increase in AQP2 and p-AQP2 Is Blunted in Heart Failure during Cardiac Remodelling and Is Associated with Decreased AT1R Abundance in Rat Kidney

Sophie Constantin Lütken,[1] Jorgen Frokiaer,[2] Soren Nielsen.[1] *[1]The Water and Salt Research Center, Dept of Biomedicine -Anatomy, Aarhus Univ, Aarhus, Denmark; [2]The Water and Salt Research Center, Institute of Clinical Medicine, Aarhus Univ Hospital, Aarhus, Denmark.*

**Background:** The effects of early HF on a standard sodium diet, sodium restricted diet, and sodium restricted diet in combination with long-term 1-desamino-8-D-arginine vasopressin (DDAVP) treatment. Focus were the AVP-angiotensin II receptor (AT1R interactions with the (pro)renin receptor in regulation of the water channels AQP2, AQP1, AQP3 and AQP4 in the inner medullary (IM) collecting duct of rat kidney.

**Methods:** LAD-ligation was performed on male Wistar rats. 10 days after operation the rats were allocated to 6 groups for the last 7 days: Sham (N = 11), HF (N = 11), sodium restricted sham (LS-sham, N = 11), sodium restricted HF (LS-HF, N = 11), sodium restricted sham + DDAVP (LS sham+D, N = 12), and sodium restricted HF + DDAVP (LS-HF+D, N = 12). EF < 50% was the inclusion criteria for LAD ligated rats. DDAVP dose was 0.5 ng/h/day for 7 days. The rats were sacrificed after 17 days, before cardiac remodeling was completed.

**Results:** Early standard sodium HF and LS-HF increased AQP4 but blunted increase in AQP2 and p(Ser256)-AQP2 in the presence of hyponatremia, hypoosmolality and decreased fractional excretion of sodium in spite of increased V2R abundance. LS-HF+D exhibited decreased creatinine clearance, severe HF (EF = 41 ± 2), severe hyponatremia, and hypoosmolality. IM AQP2, p(Ser256)-AQP2, AQP3, and AQP4 decreased vs. LS sham and LS sham+D. LS-sham and LS-HF+D decreased (P)RR. (P)RR was only increased in LS-HF. All HF groups exhibited decreased AT1R levels compared with sham operated rats.

**Conclusions:** Early HF 17 days after LAD-ligation is associated with blunted increase in AQP2 and p(Ser256)-AQP2 in spite of hyponatremia, hypoosmolality, and increased inner medullary V2R expression. Decreased AT1R levels likely plays a role in the transduction of these effects. The present study also suggest an additional crosstalk between the renal collecting duct (P)RR and plasma AVP which might be of importance in development of chronic HF.

## PUB276

### Young Soul with Old Bones

Payaswini Vasanth, Amsalu Erko. *UT Southwestern Residency Program at Seton Family of Hospitals, Austin, TX.*

**Background:** Acid–base balance plays an important role in calcium homeostasis and bone metabolism. We present a case of osteoporosis with an objective to discuss partial defect in renal acidification as a preventable cause of osteoporosis.

**Methods:** A 37 year-old male was evaluated for fatigue for 2 years, was diagnosed for depression and was treated with fluoxetine. While on this medication, he developed insomnia which led to sleep deprivation seizure, and he experienced acute back pain after the seizures. The physical exam was unremarkable except for tenderness in lumbar spine. A lumbar x-ray revealed a T5-T6 compression fracture with diffuse osteopenia. A subsequent DEXA scan showed a T-score of -2.4 of lumbar spine. Urinary studies showed a pH of

7, calcium of 637 mg/24hr (normal range:100-300 mg/24hr), citric acid of 149 mg/24hr (normal range: 320-1240 mg/24hr), presence of amorphous and calcium phosphate crystals, and a positive urinary anion/gap. Serum chemistries were normal, except for a potassium level of 3.3 mmol/L and a bicarbonate of 22 mmol/L. A diagnosis of incomplete distal tubular acidosis was made based on the persistently high urine pH even after a trial of diuretics, and the presence of hypercalciuria and hypocituruia in the setting of mild non-gap acidosis. A workup for major causes of RTA and osteoporosis were negative. The patient received potassium citrate, calcium and vitamin D supplements. A DEXA scan after a year showed a increase of 3.8% in bone density of the lumbar spine.

**Conclusions:** Adults with incomplete distal RTA (iDRTA) have a partial defect in renal acidification. The relationship between iDRTA and low bone mineral density has been proposed but not proven based on current data. Although iDRTA patients do not have persistent systemic acidosis, they may develop mild to moderate acidosis episodically due to high acid load (as in high protein diet), and their limited ability to excrete it. Such excessive acid is buffered by the bone causing its resorption and demineralization. Treating these patients with alkaline therapy, like potassium citrate, has shown to prevent, delay or reverse metabolic bone disease. Incomplete iDRTA should be suspected in patients with unexplained osteopenia or osteoporosis.

## PUB277

**Traumatic Encephalopathy Leading to Cerebral Salt Wasting and Hyponatremia with Permanent Brain Damage** Allen I. Arieff. *Medicine, Univ of California, Sausalito, CA.*

**Background:** 1.5 to 2 million USA civilians per year suffer traumatic brain injury. 4.5% of these sustain a chronic and severe disabling condition. It has not been previously noted that cerebral salt wasting, which often complicates head trauma. could lead to hyponatremia, and severe brain damage.

**Methods:** 14 individuals who suffered acute traumatic encephalopathy {(motor vehicle accident (10), falls (7)} were admitted and had neuroimaging showing closed head injury.

**Results:** Brain lesions were subdural hematoma (6), diffuse cerebral edema (5), cerebral infarct (3). All received isotonic fluids and all developed hyponatremia after 57±32 hours. Plasma Na fell from 138±4 to 119±7 mmol/L. All were initially diagnosed as having SIADH (urine osmolality > 40400 mOsm/kg). All were initially treated with fluid restriction. Over 24 Hr the mean BP declined from 135/63 mm Hg to (92/48 mm Hg). Urine Na (184±66 mmol/day) was significantly above control (113±65 mmol/day, $p < 0.01$). The systolic BP was restored to above 100 mm Hg by IV infusion of 0.9% NaCl. Two patients suffered hypoxic brain damage and died while the other 12 recovered. The 12 surviving patients were eventually maintained on oral NaCl tablets (mean 2.5 gm/day).

**Conclusions:** Closed head trauma can lead to hyponatremia secondary to a Na wasting syndrome; b) fluid restriction can lead to shock, worsening of hyponatremia and hypoxic brain damage; c) the Na wasting can eventually be controlled with oral NaCl tablets.

## PUB278

**Downregulation of RAGE Suppresses Cyst Growth in an ADPKD Mouse Model** Jong Hoon Park, Eun Young Park, Bo Hye Kim, Eun Sun Chang. *Dept of Biological Science, Sookmyung Women's Univ, Seoul, Korea.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited renal disorder. Although a myriad of research groups have attempted to identify a new therapeutic target for ADPKD, no drug has worked well in clinical trials.

**Methods:** Our research group has focused on the receptor for advanced glycation end products (RAGE) gene as a novel target for ADPKD. This gene is involved in inflammation and cell proliferation. We have already confirmed that blocking RAGE function attenuates cyst growth *in vitro*. Based on this previous investigation, our group examined the effect of RAGE on cyst enlargement *in vivo*. PC2R mice, a severe ADPKD mouse model that we generated, were utilized. An adenovirus containing anti-RAGE shRNA was injected intravenously into this model.

**Results:** We observed that RAGE gene knockdown resulted in a loss of kidney weight and volume. Additionally, the cystic area that originated from different nephron segments decreased in size from downregulation of the RAGE gene. Blood urea nitrogen values tended to be lower after inhibiting RAGE, but the decrease was not significant.

**Conclusions:** We suggest that RAGE-related signaling may be closely associated with PKD and that RAGE could be a new potential therapeutic target for PKD.

## PUB279

**The Relationship between Liver Cyst Volume and QOL in ADPKD** Satoru Muto,[1] Masahiko Ando,[2] Saori Nishio,[3] Ichiei Narita,[4] Kouichi Kamura,[5] Toshio Mochizuki,[6] Ken Tsuchiya,[6] Kazuhiko Tsuruya,[7] Yoshifumi Ubara,[8] Kikuo Nutahara,[9] Shigeo Horie.[10] *[1]Urology, Teikyo Univ, Tokyo, Japan; [2]Center for Advanced Medicine and Clinical Research, Nagoya Univ, Nagoya, Japan; [3]The 2nd Dept of Internal Medicine, Hokkaido Univ, Sapporo, Japan; [4]The 2nd Dept of Internal Medicine, Niigata Univ, Niigata, Japan; [5]Urology, Chiba East Hospital, Chiba, Japan; [6]Nephrology, Tokyo Woman's Medical Univ, Tokyo, Japan; [7]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [8]Nephrology, Toranomon Hospital, Tokyo, Japan; [9]Urology, Kyorin Univ, Mitaka, Japan; [10]Urology, Juntendo Univ, Tokyo, Japan.*

**Background:** Although it is well known that ADPKD patients with large liver cysts have a significant decrement in QOL, there are few reports that clearly demonstrate the relationship between the size of liver cysts and QOL. Therefore, we started the prospective longitudinal study to clear the impact of liver cysts on QOL. We will report the compiling data at the time of enrollment in this study.

**Methods:** We divided the included ADPKD patients into 4 groups (group A;<25%, group B; 25-49%, group C; 50-75%, group D; >75%) according to liver cysts-parenchyma ratio. QOL was measured by FANLTC + FACT-Hep additional concerns. We compared QOL scores and several clinical parameters between groups during 3 years. We reported the compiling data at the time of enrollment in this study.

**Results:** We included 82 patients in this study. Number of patients in group A, B, C, and D was 31, 14, 14, and 23, respectively. Although there was no significant differences in AST (p=0.107), ALT (p=0.925), serum albumin (p=0.212) between 4 groups, platelet count was significantly decreased along with the extension of cysts volume (p=0.030). Overall, mean FANLTC score and FACT-Hep were 71.8 ± 12.5, and 32.4 ± 5.8, respectively. FANLTC (p=0.017) and FACT-Hep (p=0.003) were significantly decreased with the increasing cyst volume.

**Conclusions:** In this cross-sectional report, we could clear the relationship between liver cyst volume and QOL in ADPKD patients. We will show the long-term influence on QOL in this ongoing prospective longitudinal study.

## PUB280

**The Effect of Native Nephrectomy on Blood Pressure and Graft Outcome after Kidney Transplantation in ADPKD** Jo Hyung Ah,[1] Hayne C. Park,[1,2] Hyun Suk Kim,[1] Miyeun Han,[1] Hyuk Huh,[1] Jong Cheol Jeong,[1,2] Kook-Hwan Oh,[1] Jaeseok Yang,[2] Tai Yeon Koo,[2] Young-Hwan Hwang,[3] Curie Ahn.[1,2] *[1]Dept of Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [2]Transplantation Center, Seoul National Univ Hospital, Seoul, Korea; [3]Dept of Internal Medicine, Eulji General Hospital.*

**Background:** We often experience blood pressure decrement after nephrectomy in autosomal dominant polycystic kidney disease (ADPKD) patients. However, few studies have addressed the effect of native nephrectomy on blood pressure and graft outcome after kidney transplantation in ADPKD patients.

Purpose of this study was to determine the effect of simultaneous native nephrectomy on blood pressure and graft outcome after kidney transplantation in ADPKD patients.

**Methods:** We conducted retrospective study in ADPKD patients who underwent kidney transplantation from 1999 to 2012. Cases with simultaneous native nephrectomy (n=26) were compared with non-nephrectomy (n=16). Primary outcome was graft function 1 year after kidney transplantation. The secondary outcomes were patient and graft survival, post-operative hypotensive events and changes in blood pressure.

**Results:** Simultaneous native nephrectomy had no association with graft function at 3, 6, 12 months after kidney transplantation.

There were more frequent hypotensive events in the simultaneous nephrectomy group than controls (64.7% in unilateral, 77.7% in bilateral nephrectomy group vs. 37.5 % in controls; p=0.045). Graft function at post-transplant 1 year was higher in patients with hypotensive events than those without events (67.2 vs. 57.3 mL/min/1.73 $m^2$; p=0.02). The proportion of patients who had more than 3 anti-hypertensives was lower in patients with hypotensive events than those without events (5.5% vs.12.5% at 6 months; p=0.599).

**Conclusions:** Simultaneous native nephrectomy had no influence on graft outcome. Although hypotensive events occurred more frequently in the simultaneous nephrectomy group, patients with hypotensive events had better graft function than those without events. Better blood pressure control with fewer medication may explain the better graft function in patients with hypotensive events group.

## PUB281

**The Prevalence of Simple Renal Cyst in China and Its Correlative Factors** Jian Hui Yang. *Renal Div, Zhejiang Provincial People's Hospital.*

**Background:** Present study was to understand the prevalence of simple renal cysts in Jinan and to find the possible risk factors of them.

**Methods:** Abdominal sonography was performed in 10016 adults who received regular health check-up from February 2007 to May 2011. Their age, gender, blood pressure, BMI, values of serum cholesterol, glucose and creatinine, urine analysis, smoking habit and sonographic features were analyzed.

**Results:** The overall prevalence of simple renal cysts was 10.7%, ranging from 2.38% in the 2nd to 35.29% in the 7th or later decade of life. The incidence of simple renal cysts were associated with male gender, higher systolic blood pressure, older ages ($p < 0.001$). The age of individuals with cysts was significantly older than those without cysts (57.65 ± 13.35 vs. 47.78 ± 12.40 years; $p < 0.001$). Male-to-female ratio was 2.81 (15.14% vs. 5.38%; $p < 0.001$). The majority of cysts were solitary (82.3%). The diameter of cysts ranged from 40-8000 mm ( 20.89 ± 12.62 mm). The mean size of cysts in every age group was not statistically different. Factors significantly associated with simple renal cysts were age (odds ratio [OR], 4.37; $p < 0.001$), gender (OR, 0.32; $p < 0.001$), serum creatinine (OR, 11.77; $p = 0.001$), proteinuria (OR, 3.11; $p = 0.004$), renal stone (OR, 2.47; $p = 0.006$), and smoking (OR, 2.80; $p < 0.001$). However, in multivariate analysis, except proteinuria, all of the above factors were significantly related to the occurrence of simple renal cysts.

**Conclusions:** The overall prevalence of simple renal cysts in China was 10.7%. Age, sex, renal stone, serum creatinine, and smoking were found to be risk factors for the presence of simple renal cysts.

**PUB282**

**UMOD Polymorphism rs12917707 Is Not Associated with Severe or Stable IgA Nephropathy in a Large Caucasian Cohort** Miriana Dinic, Ingrid Masson, Nicolas Maillard. *Nephrology-Renal Transplantation Dept, CHU St. Etienne, St. Etienne, France.*

**Background:** The progression of IgA nephropathy (IgAN) varies among individuals and leads to a 20% global risk of End Stage Renal Failure. Genetic factors are involved in the physiopathology of IgAN. Genome-wide studies have recently addressed the genetic variants underlying impaired renal function and Chronic Kidney Disease (CKD) in the general population. Single Nucleotide Polymorphisms (SNPs) in UMOD gene were significantly associated with CKD and increased serum creatinine. The minor T allele of rs12917707 was linked with a 20% reduced risk of CKD. In this study,we tested the hypothesis that UMOD polymorphism rs12917707 is associated with severe outcome in IgAN.

**Methods:** We constituted two groups of Caucasian patients based on the disease phenotype. The first group was composed of IgAN cases with severe outcome as indicated by terminal renal failure requiring kidney transplantation. The second group was composed of stable cases of IgAN defined by a diagnostic made since at least 10 years and eGFR>60ml/min/1.73m². A third, control group, consisted of caucasian healthy volunteers.We performed TaqMan SNP genotyping assays and compared allele frequencies and genotype distributions.

**Results:**

| genotypes and allele of rs12917707 | severe cases (n,%)N=263 | stable cases (n,%) N=188 | controls (n,%) N=345 | p* | p** | p*** | p**** |
|---|---|---|---|---|---|---|---|
| GG | 180(68.4) | 133 (70.7) | 245 (69.9) | 0.91 | 0.69 | 0.88 | 0.85 |
| GT | 73 (27.8) | 49 (26.1) | 95 (27.5) | | | | |
| TT | 10 (3.8) | 6 (3.2) | 9 (2.6) | | | | |
| G | 80 | 84 | 84 | 0.69 | 0.58 | 0.84 | 0.58 |
| T | 20 | 16 | 16 | | | | |

Allele frequencies and genotype distribution among severe cases of IgAN,stable cases of IgAN and healthy volunteers.P*: comparison between the 3 cohorts; p**: comparison between severe cases and controls; p***: comparison between stable cases and controls; p****: comparison between severe and stable cases.

**Conclusions:** No difference in allele frequences of UMOD polymorphism rs12917707 was found between 2 groups of IgAN cases as to disease phenotype.This result tends to suggest that UMOD gene is not involved in IgAN progression.

**Enoxaparin-Induced Fatal Spontaneous Hemorrhage: The Case for Revising Dosing Guidelines for the Elderly** Tarek H. Naguib. *Internal Medicine, Texas Tech Univ Health Sciences Center, Amarillo, TX.*

**Background:** Enoxaparin-induced hemorrhage may prove fatal. The literature shows that elderly persons with kidney disease are especially at risk for this complication. They were previously recommended to receive individualized enoxaparin dosing. However, the dosing guidelines still recommend double dose for patients with eGFR of 30 compared to 29 mL/min, despite the lack of significant difference between the 2 values and the risk of bleeding from this abritrary dosing.

This case report reflects the complex factors that build the case for specific safety recommendations in the geriatric population with kidney disease.

**Methods:** A 78-year-old woman, who was admitted with heart failure due to aortic valve incompetence, was placed on enoxaparin due to atrial fibrillation. While on spironolactone and olmesartan, serum creatinine increased from 1.1 to 1.77 mg/dL and eGFR declined from 46 to 29 mL/min (Cockroft-Gault formula, weight is 69 Kg). Olmesartan was discontinued and the patient was discharged, on the same enoxaparin dose, to return in 1 week for valve replacement surgery. After 3 days, she was readmitted with severe retroperitoneal hemorrhage, confirmed by ultrasound. Despite fresh frozen plasma, 7 units of blood transfusion, intravenous fluids, and pressors, she expired within 24 hours.

**Conclusions:** This case highlights lack of safety of the current dosing guidelines for enoxaparin in elderly persons with chronic kidney disease. The following is recommended to decrease the risk of death in this population.

1. All persons aged 75 years or older shall be monitored with measuring anti-factor Xa levels. The same should be done for those aged 60 to 74, whenever the eGFR is at 35 mL/min (rather than below 30 mL/min, allowing for eGFR variability among different formulas). Clinicians are encouraged, but not required, to use anti factor Xa monitoring, whenever eGFR declines near 35 mL/min, regardless of age.

2. Clinicians shall avoid the use of intravenous contrast media and renin-aldosterone system antagonists, as possible, whenever enoxaparin is prescribed.

3. Pharmacy services shall flag medical records to ensure appropriate dosing that is consistent with the above recommendations.

**PUB284**

**Hyponatremia: When the Kidneys Flunk the Polypharmacy Tolerance Test** Jack Rubin, Heena M. Contractor. *Medicine, Los Alamitos Hospital, Los Alamitos, CA.*

**Background:** Depression in the elderly is common ranging in incidence up to 10%. Many new medications are available to treat the depressed patient and they are often used in combination. The elderly are often on medications for hypertension, diabetes, arthritis and congestive heart failure. We describe a patient who illustrates how rapidly and with the best of intentions one can move from routine care into a serious medical mishap.

**Methods:** Ms XX, age 74, was admitted from the emergency room with a diagnosis of depression. Her hospital medications and pertinent studies are listed by days from admission. Medications given between day 1 and 7 are listed below: Lexapro day 1 and 2; Zoloft day 1 to 4; Buproprion day 1 to 4; Buspar day 1 to 4; Protonix day 1 to 4; losartan day 1 to 4; Hydrochlorothiazide day 2 to 4; Amlodipine day 2 to 4 dicyclomine day 1 to 4; Lasix and 3% saline were given day 6. Lab studies: Na mmol/L: day 2: 144, day 4 : 127, day 5 : 109 , day 6 :129, day 7 : 137; Hg g/100 ml: day: 1: 12.5, day 4: 11.3, day 5:11.0, day 6: 11.5.

**Results:** Treatment was initiated by withdrawing the offending medications, restricting fluids and initiating Lasix and hypertonic saline. After return of her serum Na to the normal range Effexor (Venlafaxine) was introduced day 9 and and gabapentin day 20. The sodium remained stable throughout the remaining treatment. Although Lexapro, Zoloft, Protonix and hydrochlorothiazide are known to associate with hyponatremia and are all potentially implicated drugs, the rapidity of change in the serum sodium was eye-opening. The mechanism of hyponatremia remains speculative but the hemoglobin dropped approximately 10 % suggesting at least some element of hemodilution from acute fluid retention.

**Conclusions:** In summary we illustrate a case of a 74 year old female with psychiatric and medical co-morbidities whose treatment rapidly induced hyponatremia. Occasionally the kidneys fail the multiple medication test.

*Funding:* Clinical Revenue Support

**PUB285**

**Frail and Elderly Patient Outcomes on Dialysis (FEPOD): A 2-Part Study** Edwina A. Brown, Lina Johansson. *Imperial College Renal and Transplant Centre, London, United Kingdom.*

**Background:** The majority of frail older patients with ESRD are on haemodialysis (HD). In Europe, assisted peritoneal dialysis (aPD), with paid assistance or carers, is increasingly available for frail patients in their home. Little is known, though, about outcomes (mortality, morbidity and quality of life) of older people on aPD compared to HD.

**Methods:** Eligible patients on aPD (require assistance for PD and ≥60 years) are matched to HD patients by age + 2 years, sex, diabetes status, time on dialysis, ethnicity and Index of Deprivation. Study design: 2 Part study: Part 1 cross-sectional (11 UK centres, 50 aPD, completion August 2013) and Part 2 longitudinal (18 UK centres, 100 aPD). Both assess quality of life through questionnaires (including Hospital Anxiety and Depression Scale, SF-12, Palliative Outcome Symptom Scale), falls, social support, frailty and activities of daily living. Part 2 assesses healthcare use and survival over 2 years. Complete Part 1 data with multiple regression will be presented at meeting.

**Results:** Preliminary results for some measures from Part 1:

| | FEPOD 1 -aPD | FEPOD 1 - HD |
|---|---|---|
| Number | 25 | 14 |
| Age in years, mean (SD) | 71.7 (7.3) | 70.9 (7.2) |
| Diabetes, n (%) | 16 (64) | 9 (64) |
| Lives alone, n(%) | 6 (24%) | 2 (14%) |
| Frailty score, median (IQR); severely frail = 7 | 4.9 (1.0) | 4.4 (1.3) |
| Barthel Index (activities of daily living), mean (SD); normal = 100 | 83.0 (17.1) | 87.5 (11.1) |
| Timed up and go, mean (SD) (normal <10 sec) | 24.1 (13.6) | 23.4 (11.6) |
| Illness intrusion rating score, mean (SD); lower = less intrusion | 38.0 (17.2) | 52.4 (24.7) |
| HADS score >8 (probable depression) n, (%) | 11 (44%) | 4 (29%) |
| Renal Treatment Satisfaction, mean (SD); higher=greater satisfaction | 50.0 (9.5) | 53.1 (7.6) |

**Conclusions:** This is the first study to compare outcomes on aPD and HD. Results will provide valuable data to the understanding of how older frail patients manage on different dialysis options. Comparison of healthcare use and survival will be determined over the next 2 years in Part 2.

**Clinical Features of Elderly Patients with Diabetic Nephropathy Diagnosed by Renal Biopsy** Manuel M. Heras,[1] Ana Saiz,[2] Pedro Iglesias,[3] María José Fernández-reyes,[1] Maria astrid Rodriguez Gomez,[1] Alvaro Molina Ordas.[1] *[1]Nephrology, Hospital General, Segovia, Spain; [2]Pathology, Ramón y Cajal Hospital, Madrid, Spain; [3]Endocrinology, Hospital Ramón y Cajal, Madrid, Spain.*

**Background:** Diabetic nephropathy (DN) is the primary global cause of terminal nephropathy. Little is known about clinical features of elderly patients with DN diagnosed by renal biopsy (DNB).

**Methods:** A retrospective observational study at the General Hospital Segovia, between 2002-2012 was performed. 218 native renal biopsy (RB) patients were evaluated: 25 had DNB.

**Results:** Mean age of the entire NDB group was 66.0±11.0 years (range 39-83; 60% males). Hypertension 95.2%.The main indication for RB was nephrotic syndrome (NS) (68%) followed by acute kidney injury (AKI) (20%). Mean HbA1c was 7.1±1.0%, duration of the diabetes mellitus (DM) was 8.9±5.0 years. In 2 patients DNB was confirmed in dialysis. Study according to age in Table 1.

| Years | <65 (n=13) | ≥65 (n=12) | *p* |
|---|---|---|---|
| Age (years) | 57.0±7.0 | 75.8±4.0 | 0.000 |
| Gender (male/female) (%) | 77/23 | 42/58 | NS |
| Years evolution DM | 9.2±6.2 | 8.6±5.8 | NS |
| ACE inhibitors / ARB(%) | 77/54 | 58/33 | NS |
| ACE inhibitors+ARB (%) | 38 | 25 | NS |
| Oral antidiabetics (%) | 61 | 33 | NS |
| Insulin (%) | 46 | 58 | NS |
| Oral antidiabetics+insulin (%) | 23 | 8 | NS |
| Creatinine at diagnosis (mg/dl) | 2.1±1.3 | 2.2±1.2 | NS |
| Albumin (g/dL) | 3.3±0.7 | 3.0±0.8 | NS |
| Hemoglobin A1c (%) | 7.1±1.0 | 7.2±1.0 | NS |
| Proteinuria (g/24hours) | 5.7±3.0 | 7.7±6.0 | NS |
| Creatinine clearance (ml/min) | 53.4±41.0 | 35.2±12.0 | NS |

ARB: angiotensin receptor blocker; ACE: angiotensin-converting enzyme; NS: Not significant.

**Conclusions:** In our population, elderly NDB patients show the same clinical features than adult NDB patients. Both groups are patients with long-standing DM with nephrotic proteinuria, NS and/or AKI.

## PUB287

**Hematologic Parameters in Hemodialysis Patients Provide Insight on Anemia of Aging and Could Potentially Impact Anemia Treatment in End Stage Renal Disease** Namrata Baxi, Krystal Hunter, Amanda Logan, William D. Sirover. *Cooper Medical School of Rowan Univ.*

**Background:** Elderly patients comprise the most rapidly growing group of end stage renal disease (ESRD) patients. Unexplained anemia of the elderly (UAE) is also now recognized as a distinct clinical entity in this patient population. Decreased erythropoietin levels, impaired bone marrow activity, and increased inflammation have been implicated as possible causes.

Delineating the cause(s) may lead to a change in treatment practices. Increased erythropoietin (EPO) dose requirement in older ESRD patients could occur if bone marrow erythropoietic activity decreases and/or inflammation increases with age. In light of EPO-associated toxicity, if these two pathophysiologic changes occur, consideration of lowering hemoglobin (Hb) target may be warranted. We studied the effect of age on EPO dose requirement in a prevalent hemodialysis population.

**Methods:** Hematologic data on 179 hemodialysis (HD) patients was analyzed. Patients were 18 years or older and on HD for at least 3 months. Individual EPO dose was calculated as mean weekly dose over a 3-month period.Mann-Whitney was used to assess the relation between age (< and > 65 years old) and median EPO dose expressed as units/week (wk), units/wk/kg, or units/wk/Hb.

**Results:** No correlation existed between age and EPO dose expressed as units/wk (9,441 vs 10,560, p value = 0.48), units/wk/kg (107.83 vs 137.98, p= 0.22), or units/wk/Hb (827.66 vs 930.45, p= 0.57).

**Conclusions:** Building on previous literature, age does not appear to affect EPO dose or EPO resistance in HD patients. If impaired bone marrow activity or inflammation were causative factors in UAE, then age would have been expected to be associated with these EPO parameters. Therefore, by exclusion, these results indicate that UAE may be due to decreased EPO levels. Hypoxia inducible factor levels have been shown to decrease with age and may account for the decrease in EPO levels and subsequent development of UAE in general. In HD patients, exogenous EPO may effectively treat UAE.

## PUB288

**Masked Hypertension and White Coat Hypertension Are Common and Chronic Conditions in CKD Patients Receiving Antihypertensive Therapy: Implications for Hypertension Management if Hypertension Control Is Based Only on Clinic Blood Pressure** Christopher Valentine, Ravish Shah, Daniel J. Birmingham, Lee A. Hebert. *Medicine, Ohio State Univ Wexner Med Ctr, Columbus, OH.*

**Background:** Masked hypertension (MH) is defined as normal blood pressure (BP) in the clinic but hypertension at home (e.g., assessed by home BP monitoring (HBPM). White coat hypertension (WCH) is the opposite of MH. MH increases cardiovascular (CV) risk. The risk of WCH is less clear. However, there is recent evidence that treated WCH can increase risk because BP is overcontrolled.

**Methods:** We assessed MH and WCH in 33 pts followed in our Nephrology Clinical Trials Unit (NCTU) with a diagnosis of hypertension, receiving anti-hypertension therapy, and performing HBPM morning and evening at least 10 times per mo, using calibrated equipment and proper technique. NCTU BP was measured each 2-3 mo by Omron. There were 103 to 767 home BP measurements per pt, median 301. Follow-up was 4 to 15 mo, median 10 mo.

**Results:**

| | | Blood pressure, mm Hg | | | BP Difference | |
|---|---|---|---|---|---|---|
| H type | CKD | Clinic | Home AM | Home PM | Clinic-Home | |
| MH | | 128.3 | 136.7 | 143.1 | 11.6 | p = 0.002 |
| N=8 | N=3 | ±7.6 | ±10.0 | ±4.2 | ±6.5 | |
| WCH | | 139.0 | 124.2 | 122.0 | -15.9 | p = 0.040 |
| N=4 | N=3 | ±4.3 | ±8.7 | ±5.8 | ±9.1 | |
| Neither | | 124.7 | 125.2 | 123.9 | -0.2 | p = 0.89 |
| N=21 | N=13 | ±4.6 | ±8.4 | ±6.4 | ±5.3 | |

The table shows that MH and WCH are chronic and common in CKD and non-CKD pts receiving BP therapy. If hypertension control is based only on clinic BP, MH will go untreated and WCH may be over treated. The prevalence of MH and WCH and their association with CKD shown here is comparable to that of previous reports. In MH the difference between clinic and home BP is large and associated with increased 10-yr CV risk. In WCH the difference is also large. It could increase CV risk by BP overcontrol.

**Conclusions:** A BP control strategy that uses only clinic BP will undercontrol BP in MH and overcontrol BP in WCH, creating risk. HBPM should be used to direct BP therapy in both CKD and non-CKD patients.

## PUB289

**Metabolic Safety Profile of Thiazides in Patients with Diabetes Mellitus Type 2** R.P. Niraula,[1] A. Jittirat,[1] C.S. Huang,[1] S. Sarani,[1] D. Vo,[1] P.T.T. Pham,[2] P.C. Pham.[1] *[1]Nephrology and Hypertension, UCLA-Olive View Medical Center, Sylmar, CA; [2]Kidney and Pancreas Transplant Program, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

**Background:** Thiazides remain the mainstay of antihypertensive therapy in the general population. Traditional concerns for thiazide induced glucose intolerance and dyslipidemia may deter its routine use in patients with concurrent hypertension and diabetes mellitus type 2 (DM2). We analyze various metabolic indices among DM2 patients with and without chronic thiazide use.

**Methods:** In this retrospective study, electronic records from patients with both DM2 and hypertension who were evaluated for any reason at UCLA-Olive View Medical Center during the months of January 2011 – January 2012 were collected. Inclusion criteria: all patients with ICD-9 codes 250.00 to 250.93 for diabetes and 401.0 to 404.93 for hypertension, who had at least 3 documented blood pressure measurements, estimated glomerular filtration rates (eGFR) by the 4 variabled-MDRD formula, lipid profiles, hemoglobin, and A1C over the span of the previous 6 months and as available up to 24 months.

**Results:** 769 patients were included: 389 received thiazide diuretics; Thiazide group had significantly higher systolic blood pressure: 137+14 vs 131+12 mm Hg, p<0.0001, lower initial estimated glomerular filtration rate (eGFR): 93+27 vs. 100+26 mL/min/1.73m$^2$, and heavier weight: 87.4+21.2 vs 83.3+18.3 Kg, p=0.004. Differences in other biochemical values are as shown.

| | Follow-up duration (days) | Hb (gm/dL) | Initial A1C (%) | Final A1C (%) | HDL (mg/dL) | LDL (mg/dL) | eGFR change (mL/min/1.73m$^2$) over duration of follow-up |
|---|---|---|---|---|---|---|---|
| No thiazides (n=380; 65% female; Age=56±10 years) | 635±151 | 13.2±1.4 | 8.3±1.7 | 8.4±1.8 | 42±12 | 96±29 | -3.0±19 |
| Thiazides (n=389; 73% female; Age=58±8 years) | 621±151 | 13.2±1.3 | 8.3±1.8 | 8.3±1.8 | 43±12 | 97±26 | -3.8±18 |
| p-value | 0.2 | 0.7 | 0.9 | 0.3 | 0.3 | 0.6 | 0.6 |

**Conclusions:** There were no detectable adverse effects in terms of A1C change, lipid profile difference, hemoglobin, or decline in eGFR in diabetic patients treated with thiazides compared to those who did not receive the medication.

## PUB290

**Arterial Stiffness and Central Aortic Blood Pressure in Indian Chronic Kidney Disease Population** Ashok Kirpalani, Hardik Shah, Dilip Kirpalani, Ranveer Choudhary, Jay Patel. *Nephrology, Bombay Hospital, Mumbai, Maharashtra, India.*

**Background:** To estimate noninvasively arterial stiffness and central hemodynamics in CKD patients and analyse the epidemiological data in various subgroups.

**Methods:** 50 CKD patients included .Basic epidemiological and related information obtained. Brachial BP measured by sphygmomanometer. Applanation tonometer (Sphygmocor) device applied on the radial, carotid and femoral artery and measurements obtained.

**Results:** 48 % patients < 50 years (Group A), 52 % > 50 years (Group B) .13 patients had DM, 12 IHD ,12 had CVA.19 in CKD stages 1-4 ,31 on hemodialysis. Mean brachial Systolic BP (BSBP) 138.4 + 13.5 and Diastolic BP (BDBP) 86.1 + 6.2 mmHg. Mean Central Aortic Systolic BP (CASBP) 133.7 + 10.1 and diastolic BP (CADBP) 88.5 + 4.4 mmHg. Mean Central aortic Pulse Pressure(CAPP) - 45.4 + 5.1 mmHg. There was no significant difference between the mean brachial and central aortic pressures (p= 0.9). In 78% subjects, the CASBP was higher than the normal for age values. However, the CADBP was higher than normal for age values in only 56 %. Augmentation Index (AIx) was 24.7 + 3.4 while Mean Carotid-femoral pulse wave velocity (cf-PWV) was 11.1 + 3.2 m/s. In diabetics, AIx (33.5 + 3.1) and cfPWV (12.5 + 3.3 m/s) were significantly higher (p< 0.05) than the nondiabetic patients (AIx : 21.6 + 2.4 and cfPWV :10.6 + 2.9 m/s) although brachial blood pressures in both groups were similar. Group A had significantly higher (p < 0.05) CASBP(135.8 + 8.1 mmHg) as well as CADBP (91.6 + 5.8 mmHg) readings as compared to Group B (CASBP 131.8 +7.4 ; CADBP 85.7 + 5.1 mmHg).

**Conclusions:** 1. Patients with CKD have higher central aortic pressure, AIx well as higher cfPWV than the normal values in the general population. This first study done in Indian CKD patients confirms that CKD is associated with stiff arteries.

2.Diabetic CKD patients as well as the younger CKD population have accelerated vascular ageing. This predisposes them to greater risk of CVD inspite of similar brachial BP. Preventive CVD strategies can thus be aggressively targeted at this subgroup.

## PUB291

**Association between Renal Function (MDRD-4 versus CKD-EPI) and Cardiovascular Risk. Prospective Observational Study**

Francisco Javier Lavilla, Carmen Calderon Gonzalez, Nuria Garcia-Fernandez, Paloma L. Martin Moreno, Jose Maria Mora Gutierrez, Diana Lopez Espinosa, Pedro Errasti. *Nephrology, Univ Clinic of Navarra, Pamplona, Navarra, Spain.*

**Background:** To study the relationship between cardiovascular risk (CVR) and renal function in healthy people .

**Methods:** 235 patients were studied in prospective cardiovascular risk study (5 to 10 years). Mean age 48.39 years (SD 0.69). CVR (PROCAM-PR-, FRAMINGHAM-FR, SCORE score-SC-and cardiovascular-event probability-SCE),renal function (CKD-EPI and MDRD-4),metabolism parameters (cholesterol, triglycerides, glucose, uric acid), cardiovascular risk markers (von Willebrand factor-antigen-VWF, fibrinogen -F- and C- reactive protein -CRP-), albuminuria (albumin/creatinine urinary-IALBCR-), carotid intima-thickness(IM) and E/A echocardiography index were evaluated. Statistical analysis with SPSS 15.0.

**Results:** Observed greater association between CKD-EPI and CVR scores (PR r = -0.281, FR r = -0.432, SC r = -0.551, SCE r = -0.468) than with MDRD-4 ( PR r = -0.223, FR r = -0.235, SC r = -0.322, SCE r = -0.261) (p<0.005). CKD-EPI was better associated with IM thickness (r = -0.359), E /A ratio (r = 0.401) and uric acid (r = -0.357), than MDRD-4 (r = -0.170), (r = 0.308) and ( r = -0.249). The association of both formulas is similar with IALBCR. The best FG stratified according CKD-EPI stratified better GFR with CVR, showing significant increase below 90 ml / min (p <0.001). This effect depends on the age, associated with GFR (p <0.001), showing significant drop in people older than 50 years.

| CKD-EPI | >100 | 100-90 | 89-80 | 79-70 | <69 |
|---|---|---|---|---|---|
| PR | 0.64 | 1.7 | 5.23 | 6.61 | 8.12 |
| FR | 5.27 | 5.66 | 14.3 | 16.39 | 21.72 |
| SC | 19.3 | 23.7 | 31.2 | 32.6 | 39.1 |
| SCE | 0.46 | 0.59 | 1.41 | 1.76 | 3.10 |
| Age (years) | 41 | 40 | 50 | 52 | 67 |

PR: PROCAM. FR: FRAMINGHAN; SC: SCORE, CE: SCORE PROBABILITY CARDIOVASCULAR EVENT.

**Conclusions:** In healthy population there are association between CVR and renal function. GFR below 90 ml/min in aged over 50 years is associated with significant increase CVR. CKD-EPI allows better assessing the relationship between renal function and cardiovascular risk.

## PUB292

**The Decreased Expression of Nephrin and CD2-Associated Protein in Patients with Hypertensive Kidney Injury**

Zilong Li,[1,2] Wei Wang,[1] Juan Wang,[1] Hua Zhou,[3] Lining Wang.[1,2] *[1]Dept of Nephrology, First Affiliated Hospital of China Medical Univ, Shenyang, China; [2]Institute of Nephropathology, China Medical Univ, Shenyang, China; [3]NIDDK/NIH.*

**Background:** Given that nephrin and CD2-associated protein (CD2AP), podocyte associated proteins, play important roles in maintenance of glomerular structual integrity, the study focused on the expression changes of nephrin and CD2AP induced by hypertensive kidney injury in patients with proteinuria.

**Methods:** The involved patients were divided into two groups as following. Hypertensive group: patients with hypertension and proteinuria who were diagnosed as hypertensive kidney injury via kidney biopsy. Control group: kidney trauma patients without hypertension and proteinuria. Kidney biopsy section taken from hypertensive group and normal kidney tissues taken from control group via urologic surgical procedures were fixed with immersion-fixation method. Then immunohistochemistry stainings were performed with HE, DAB, immunofluorescence, uranyl acetate, and observed by light microscopy,confocal laser scanning microscopy and immunoelectron microscopy.

**Results:** In control group, the capillary loops were smooth and plump. Nephrin and CD2AP were observed staining along the glomerular capillary loops continuously and evenly. However, in hypertensive group the capillary loops became wizened, and the Bowman´s space and luminal spaces of the proximal or distal tubules became more widely opened in the renal cortices. Additionally, nephrin and CD2AP decreased and stained intermittently. Through the immunoelectron microscopy, different degrees of foot processes effacement were observed in hypertensive group, nephrin and CD2AP decreased and stained weakly along the podocyte basal membrane, while in control group, they distributed evenly in podocytes.

**Conclusions:** Desregulation of podocyte associated proteins induced by hypertension may be an important cause leading to development of proteinuria and decline of renal function in hypertensive kidney injury patients.

## PUB293

**Blood Pressure Control among Diabetic CKD Patient in a Developing World Sample**

Jafar Al-Said, Teerath Kumar, Soni Murdeshwar. *Bahrain Specialist Hospital.*

**Background:** Hypertension is the most common CV risk factor. The presence of Diabetes with Hypertension increases the risk further. Well control BP reduces the CV risk significantly. The aims from this study were to:

1. Identify the prevalence of Hypertension among CKD population.
2. Determine the percentage of successful BP control among diabetic and non-diabetic CKD patients and the factors correlated with uncontrolled BP.

**Methods:** In this retrospective study all CKD patient followed for 9.5 years in our Nephrology department were identified. Demographic factors were collected from electronic files. Matched diabetic and non-diabetic CKD samples for age, gender and BMI were selected. BP measurement on the last visit was recorded. Patients with BP more than 140/90 mmHg were considered uncontrolled. Independent variables correlated with uncontrolled BP were tested using SPSS 18. Multivariate regression equation was generated for these variables.

**Results:** Total CKD population was 245 patients. Mean follow up was 23.6 months (SE 1.6), mean age was 58.7 years (SE 0.9), mean BMI was 30.5kg/m2 (SE 0.5). Males constitute 61%. Mean eGFR was 45.4ml/min (SE 1.4) and 51% of the populations were CKD stage III. We matched 77 diabetic with non-diabetic patients. HTN was present in 88% of which 59% had controlled BP on the last visit. Uncontrolled BP was present in 47% of the diabetic as compared to 28% in non-diabetic (p 0.019). Factors related with uncontrolled BP are:

| Variables | Correlation Coefficient | P |
|---|---|---|
| Age | 0.188 | 0.024 |
| DM | 0.19 | 0.019 |
| Stroke | 0.19 | 0.017 |
| Systolic BP on first visit | 0.36 | 0.0001 |
| B-Blocker | 0.2 | 0.014 |
| Alpha / B-blocker | 0.2 | 0.013 |
| Total CV risk factors | 0.23 | 0.005 |
| Number of Anti HTN medications | 0.3 | 0.0001 |
| Vasodilators | 0.2 | 0.009 |
| Nitroglycerin | 0.3 | 0.0001 |

Systolic BP on presentation and Nitroglycerin, in multivariate regression model with RR 0.27, were the only significant factors correlated with uncontrolled BP.

**Conclusions:** Hypertension was highly prevalent among diabetic CKD patients. It was less controlled among this subgroup as compared to non-diabetic. Several factors were identified to correlate with uncontrolled BP.

## PUB294

**Usefulness of 24h-Ambulatory Blood Pressure Monitoring in Discharged Patients with Chronic Kidney Disease**

Patrick Saudan, Belen Ponte, Sophie M. De Seigneux, Pierre-Yves F. Martin. *Nephrology Unit, Dept of Medical Specialties, Geneva Univ Hospitals, Geneva City, Geneva, Switzerland.*

**Background:** Optimal blood pressure (BP) control is mandatory in patients with chronic kidney disease (CKD). These patients are often discharged from hospital with controlled BP based on ward measurements. Whether this control is satisfactory within the outpatient setting remains unknown.

**Methods:** 82 patients enrolled in the Implicate Study (ClinicalTrials.gov: NCT00929760) and with ward SBP < 140 mm Hg at discharge had an 24h-ambulatory blood pressure monitoring measurement (ABPM) within the following 3 months. Target BP values at daytime and nighttime were < 135/85 and 120/70 mm Hg respectively. Dipping was a night to day ratio < 0.90.

**Results:** There were 69% males and 27% diabetics**.** Mean age was 69 (9) years, mean eGFR was 33 (9) ml/mn. Seventy-one % of the patients were treated with ACEIs/ARBs and 62% with diuretics. Mean daytime ABP were 135/81(18/12) mm Hg and mean nighttime ABP were 124/72(18/13) mm Hg. Dipping was present in 45% of the patients. Target daytime and nighttime BP were met in 54% and 38% of the patients respectively. Only 28% could achieve both daytime and nightime BP targets.

**Conclusions:** In stage IIIB-IV CKD patients, ward good BP control did not predict the achievement of BP targets measured by ABPM within the outpatient setting. 24h-ABPM should be routinely used in CKD patients recently discharged from hospital in order to achieve BP targets, especially during nighttime.

## PUB295

**Influence of Central Blood Pressure on Significant Proteinuria in Chronic Kidney Disease**

Vinaya R. Soundararajan, Ramesh Soundararajan. *Nephrology, Associates in Nephrology, Chicago, IL.*

**Background:** Central aortic blood pressures are thought to be more reflective of the actual pressures the vital organs including the kidney and heart are subjected to rather than the brachial blood pressures. There is limited data regarding the effect of central aortic blood pressure on proteinuria in patients with chronic kidney disease (CKD).

**Methods:** We decided to study a selected population of our CKD patients in an office setting by evaluating the central aortic pressures, including systolic, diastolic, pulse pressure, and augmentation index, and their correlation to significant proteinuria. For this study, we defined significant proteinuria as having greater than 1 Gm of protein per Gm of creatinine. Central aortic blood pressure was measured using SphygmoCor XCEL PWA from ATCor Medical (Itasca, IL). The data set included 37 patients with CKD between the stages of II and IV, both diabetics and non-diabetics.

**Results:** The central diastolic pressure for patients without significant proteinuria was **68.9 mmHg**, which was found to be significantly lower than that for patients with proteinuria > 1gm/gm of creatinine **77.3 mmHg** (p=.039). However, the other central BP parameters did not display a significant correlation with significant proteinuria. We also studied the influence of antihypertensive medications (ace inhibitors, angiotensin receptor blockers, dihydropyridine calcium channel blockers, and non-dihydropyridine calcium channel blockers) on central systolic pressures and surprisingly found no significance between the type of medication and the resulting central pressure.

**Conclusions:** Unlike brachial pressures, where the control of systolic BP seems to correlate with proteinuria, this study determined that among the different central pressure parameters the central diastolic pressure is the best predictor of degree of significant

proteinuria in CKD patients. Further studies can be conducted with a greater sample size and for varying degrees of proteinuria to determine whether or not controlling central blood pressure can decrease the degree of proteinuria.

## PUB296

**Add-On Administration of HCTZ to the Preceding ARB Treatment Can Attain the Lower Sodium Balance Leading to the Successful Antihypertensive Effects for Daytime and Night-Time**

Daisuke Fuwa,[1] Michio Fukuda,[1] Toshiyuki Miura,[1] Shuichi Watanabe,[1] Hiroyuki Togawa,[1] Yoshiaki Ogiyama,[1] Yukako Isobe,[1] Hiroyuki Kobori.[2,3] *[1]Cardio-Renal Medicine and Hypertension, Nagoya City Univ, Japan; [2]Tulane Univ Hypertension and Renal COE; [3]Dept of Pharmacology, Kagawa Univ, Japan.*

**Background:** Previously, we have reported that the angiotensin receptor blockers (ARBs) or thiazide diuretics (HCTZ) can restore the circadian blood pressure (BP) rhythm. On this study, we investigated to demonstrate that an add-on administration of HCTZ to the preceding ARB treatment can further attain the lower sodium balance leading to the successful antihypertensive effects for daytime and night-time.

**Methods:** Major inclusion criteria were as follows: 1) chronic kidney disease (CKD, K/DOQI), 2) previous treatment with ARB (valsartan, 80 mg/day) for ≥ 2 months, and 3) office BP > 130/80 mmHg.

**Results:** At the interim analysis, two men and three women (69 ± 11 years old, GFR 65 ± 16 ml/min/1.73m$^2$), were studied before and 8-wk add-on treatment of HCTZ (12.5 mg/day) to the ARB. Filtered sodium load ($S_{Na}$ x GFR, 16,590 ± 6,310 → 10,510 ± 3,905 mmol/day, p = 0.01), tubular sodium reabsorption ($t_{Na}$, 16,430 ± 6,330 → 10,370 ± 3,890 mmol/day, p = 0.01), and fractional sodium reabsorption [$t_{Na}$/($S_{Na}$ x GFR), 98.9 ± 1.0 → 98.5 ± 1.1%, p = 0.009] were all decreased. Urinary excretions of protein (2.1 → 1.1 g/day, p = 0.03) was attenuated, but urinary excretion of angiotensinogen ($U_{AGT}V$, 610 ± 940 → 840 ± 1,138 mg/g Cr, p = 0.2) was increased. BP were lowered for both daytime [131/78 → 121/77 (SBP, p = 0.02; DBP, p = 0.01), and night-time [126/72 → 118/67 (SBP, p = 0.01; DBP, p = 0.01)]. Nocturnal BP dip was determined by the increase in daytime natriuresis.

**Conclusions:** Add-on administration of HCTZ to the preceding ARB treatment can attain the lower sodium balance leading to the successful antihypertensive effects for daytime and night-time, accompanied by the increase in $U_{AGT}V$, which was the indicator of the intrarenal renin-angiotensin system status. Careful studies are needed to investigate whether the increase in $U_{AGT}V$ is merely the result from lowering the sodium balance, or it is the risk for CKD progression.

## PUB297

**Increase in Daytime Natriuresis during the ARB Treatment Is Not Attributed to the BP Reduction of the Night before**

Toshiyuki Miura,[1] Daisuke Fuwa,[1] Shuichi Watanabe,[1] Hiroyuki Togawa,[1] Yoshiaki Ogiyama,[1] Yukako Isobe,[1] Tadashi Ichikawa,[1] Shirasawa Yuichi,[1] Yoshida Atsuhiro,[1] Michio Fukuda,[1] Genjiro Kimura.[2] *[1]Cardio-Renal Medicine and Hypertension, Nagoya City Univ, Japan; [2]Asahi Rosai Hospital, Japan Labour Health and Welfare Organization.*

**Background:** Previously, we have reported that the angiotensin receptor blocker (ARB), olmesartan can increase the natriuresis during the daytime to attain a lower sodium balance, and can restore the circadian blood pressure (BP) rhythm. However, the details should be pursued. The increase in daytime natriuresis can be explained by the two mechanisms as follows: 1) ARB can inhibit the tubular sodium reabsorption; and 2) ARB can lower the night-time BP resulting in the attenuation of the night-time natriuresis, and thus the daytime natriuresis compensatorily increase. If the latter holds, the decrease in the night-time BP can precede the increase in daytime natriuresis during the acute phase of the treatment (not steady state).

**Methods:** We studied which comes first the increase in daytime natriuresis, or the decrease in night-time BP, in seven patients with CKD (five men, two women, 52±19year-old, GFR 68±64 ml/min$^2$) before and within 2 days after commencing the ARB.

**Results:** At baseline, two out of the seven patients exhibited dipper circadian BP rhythm, whereas five had non-dipper BP rhythm. Although their BP rhythm had been dipper type before the treatment, the two patients exhibited the increase in daytime natriuresis on the first day after starting ARB. One of the five non-dippers demonstrated the increase in natriuresis first day of the treatment and on that day, the rhythm was restored into dipper pattern. Other four patients, who were non-dippers at baseline, remained as the non-dippers 2 days after the institution of treatment. However, all of these four patients demonstrated the increase in daytime natriuresis within 2 days after starting treatment (1 day for three patients; 2 days for one patient) even though circadian BP rhythm was not restored.

**Conclusions:** These findings suggest that the increase in daytime natriuresis during the ARB treatment is not attributed to the BP reduction of the night before.

## PUB298

**L-arginine Improves Endothelial Function, Independent of Arginine Transport System, in Chronic Renal Failure Female Rats**

Idit F. Schwartz, Doron Schwartz. *Nephrology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel.*

**Background:** Endothelial cell dysfunction (ECD) is a common feature of chronic renal failure (CRF). Defective nitric oxide (NO) generation due to decreased endothelial nitric oxide synthase (eNOS) activity is a crucial parameter characterizing ECD. Decreased activity of cationic amino acid transporter-1 (CAT-1), the selective arginine transporter of eNOS, has been shown to inhibit eNOS in uremia. Recently, we failed to demonstrate a decrease in glomerular arginine transport in uremic female rats. The current experiments were designed to determine whether the sexual dimorphism which characterizes the glomerular arginine transport system in uremia is a generalized phenomenon.

**Methods:** Contractile and vasodilatory responses, ultrastructural changes, and measures of the L-arginine NO system were performed in thoracic aortas of female rats subjected to 5/6 nephrectomy.

**Results:** Contractile response to KCl was significantly reduced in CRF dames when compared to healthy rats while arginine administration abolished this decline. Aortic rings contraction by Phenylephrine was unchanged in all experimental groups. Acetyl Choline induced vasodilation was significantly impaired in the aortas from CRF rats compared with controls. L-Arginine normalized the capacity of aortic vasodilation in CRF rats. The decrease in both cGMP generation, a measure of eNOS activity and abundance of aortic eNOS and phosphorylated eNOS observed in CRF rats were completely abolished by L-arginine while both arginine transport and CAT-1 protein abundance did not differ in all experimental groups.

**Conclusions:** Arginine administration has a profound beneficial effect on ECD independent of cellular arginine uptake, in CRF female rats.

## PUB299

**Relationship of Asymmetric Dimethylarginine and Whole Blood Viscosity in Normal Subjects and Patients with Chronic Renal Failure**

Mary S. Hammes,[1] Sydeaka Watson,[2] Fredric L. Coe,[1] Faris A. Ahmed,[1] Promila Dhar.[3] *[1]Nephrology, Univ of Chicago, Chicago, IL; [2]Health Studies, Univ of Chicago, Chicago, IL; [3]Biomedical Engineering, Univ of Chicago, Chicago, IL.*

**Background:** In chronic renal disease (CKD), vascular disease involves the microcirculation: Endothelial dysfunction as manifested by high vascular resistance and resultant hypertension. Key regulators of endothelial function include nitric oxide (NO), its antagonist, asymmetric dimethylarginine (ADMA), and whole blood viscosity (WBV). Since ADMA is a counter regulator of NO, and NO rises with increased blood viscosity, we reasoned that ADMA rises with WBV. The aim was to determine the relationship of ADMA and WBV in normal subjects and patients with CKD.

**Methods:** 51 subjects, 20 controls, 11 renal transplant recipients, 10 CKD and 10 end-stage renal disease (ESRD) patients had blood samples drawn for WBV, Hematocrit, and ADMA. WBV was measured using a Brookfield DV-II+ cone-plate viscometer. Hematocrit was measured using CritSpin. ADMA was assayed by ELISA. The significance between groups was compared by boxplots and analysis of variance. Tukey's test was used to examine pair wise comparisons. The linear relationship was shown by regression lines and correlation coefficients.

**Results:** ADMA was elevated in all groups with renal failure when compared to controls ($p < 0.05$). Control subjects showed a positive correlation ADMA and WBV($r = 0.56$, $p = 0.011$). Subjects who received a renal transplant had a negative correlation between ADMA and WBV ($r = -0.96$, $p < 0.01$). Extremely high ADMA values in subjects with ESRD and CKD were observed. The difference in ADMA comparing pre-dialysis to post-dialysis conditions was positive ($p < 0.05$.

**Conclusions:** There is a positive correlation of ADMA with WBV in normal subjects and conversely, an inverse relationship between ADMA and WBV in tansplant recipients with well-functioning grafts. There was a disruption of the ADMA–WBV relationship with high fixed values of ADMA in patients with CKD and ESRD. Dialysis uniformly increases ADMA. This investigation provides an understanding of factors that influence endothelial cell function.

## PUB300

**Parathyroid Hypertensive Factor Binds to Endothelial Type 1a Receptors In Vitro**

Larry A. Slomowitz,[1] Brian E. Peerce.[2] *[1]DuoPhos LP, Friendswood, TX; [2]Neuroscience and Cell Biology, UTMB, Galveston, TX.*

**Background:** Dahl salt sensitive rats fed a high salt diet (8% $Na^+$) did not develop hypertension when phosphorus (Pi) was restricted either by reduction in dietary phosphorus (from 0.67% to 0.2%) or when intestinal absorption was reduced with a NaPi 2b inhibitor (2'-fluorophosphophloretin). On a restricted Pi diet, the major hormonal effect of reduced dietary Pi was a 50% reduction in PHF (parathyroid hypertensive factor). Previous studies suggested that PHF affects $K^+$ channel activity and $Ca^{2+}$ channel activity therefore we examined the effect of PHF on SK channels (small conductance $Ca^{2+}$-activated $K^+$ channels), voltage gated $K^+$ channels, tetrodotoxin-sensitive $Na^+$ channels, and L-type $Ca^{2+}$ channels activities and hormone receptors involved in the regulation of blood pressure.

**Methods:** Hormone receptor or channel ligand binding (agonist or antagonist) was determined using a high-throughput system. Binding of radioactive ligand in the presence or absence of PHF was determined by liquid scintillation counting. Specific versus non-specific ligand binding was determined in the presence of a 100-fold excess of cold ligand. A single concentration of PHF (1 μM) was used in all of the experiments. The results are means + S.E. of triplicate determinations.

**Results:** Neither form of PHF ($PHF_S$ or $PHF_L$) affected agonist or antagonist binding to the channels examined. Neither form of PHF ($PHF_S$ or $PHF_L$) affected agonist or antagonist equilibrium binding (4 hours) to adrenergic receptors (α and β) to angiotensin receptors ($AT_1$ and $AT_2$), or to norepinephrine transporter. $PHF_S$ increased equilibrium [$^{125}$I] endothelin-1 binding to ET-A receptors (31% + 5%) but not to ET-B receptors. $PHF_L$ increased binding to ET-A receptors 22% + 3%.

**Conclusions:** $PHF_S$ increased endothelin-1 binding to ET-A receptors in equilibrium binding assays. ANG II and $PHF_S$ share greater than 80% amino acid homology. ANG-II has been reported to enhance ET-1 binding to ET-A receptors and it appears that $PHF_S$ may mimic this effect.

## PUB301

### Serum Asymmetric Dimethylarginine and Nitric Oxide Levels and Their Correlation with Kidney Functions in Turkish Patients with Acute Ischemic Stroke

Hakki Yilmaz, Huseyin tugrul Celik, Ali Akcay, Nuket Bavbek, Ayse Mukadder Bilgic. *Turgut Ozal Univ, School of Medicine, Ankara, Turkey.*

**Background:** Nitric oxide synthase (NOS) is present in the brain and cerebral arteries and enables the synthesis of nitric oxide (NO), which plays a critical role in brain perfusion. Asymmetrical dimethyl arginine (ADMA) is an endogenous NOS inhibitor. The goal of this study was to examine ADMA as an indicator of endothelial dysfunction of renal functions in patients with acute ischemic stroke and determine if a correlation between ADMA and NO levels or L-arginine/ADMA ratios exists.

**Methods:** Fifty-two patients and 48 healthy controls were included in this study. ADMA and Arginine levels were measured with an Applied Biosystems MDS SCIEX API 3200 LC-MS/MS system device in the ESI mode and an Aglient Eclipse XDB-C18 column. NO was measured with a Nitrate/Nitrite colorimetric assay kit.

**Results:** The mean serum ADMA level was 0.46 ± 0.13μM for the patients and 0.40 ± 0.11μM for the controls.The mean NO level was 2.78 ± 1.59 μM for the patients group and 4.34 ± 2.70 μM for the controls. The ADMA levels for the patient group were significantly higher than for the control group (p=0.011); the NO levels for the patients were significantly lower than for the controls (p<0.001).There was a negative correlation between the NO levels and age (r = -0.251), and a positive correlation between NO levels eGFR (r = 0.223). In addition, there was a positive correlation between ADMA and creatinine (r=0.224) and a negative correlation between ADMA and eGFR (r= -0.216).

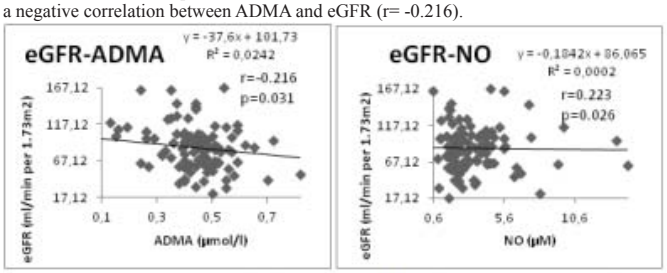

Figure 1. eGFR-ADMA correlation (left), eGFR- NO correlation (right).

**Conclusions:** Increased plasma levels of the NOS inhibitor ADMA and decreased levels of NO were found to be independent risk factors for ischemic stroke. Decreased NO levels cause vasoconstriction and may be important in the pathogenesis of ischemic stroke.

## PUB302

### Regulation of Human Endothelial Cells by Vitamin D Metabolites

Jessica L. Sea,[1] Tae Wuk Ko,[1] Eileen W. Tsai,[2] Isidro B. Salusky,[2] Martin Hewison.[1] *[1]Dept of Orthopaedic Surgery, Univ of California Los Angeles, Los Angeles, CA; [2]Dept of Pediatrics, Univ of California Los Angeles, Los Angeles, CA.*

**Background:** Vitamin D-deficiency in humans has been linked to aberrant vascular function but the possible mechanisms for this remain unclear. In human umbilical vein endothelial cells (HUVEC) effects of inactive 25-hydroxyvitamin D (25D) and active 1,25-dihydroxyvitamin D (1,25D) have been reported, but only following immune/inflammatory challenge. In current studies we have assessed 25D and 1,25D responses in HUVEC and human aortic endothelial cells (HAEC) and compared this to an established 25D/1,25D target cell, human monocytes.

**Methods:** Primary cultures of HUVEC, HAEC and human monocytes were cultured in the presence of 25D, 1,25, as well as native vitamin D (VitD) and 24,25-dihydroxyvitamin D for 6, 12 or 24 hrs. Cells were then lysed to extract RNA and expression of various target genes assessed by qRT-PCR. Western blot analysis were carried out to assess changes in protein expression.

**Results:** HAEC showed similar patterns of mRNA expression for the vitamin D-activation enzyme CYP27B1 and vitamin D receptor (VDR) relative to monocytes, whereas HUVEC exhibit lower levels of CYP27B1 and VDR. At 6 hours of culture, HAEC treated with LPS showed induction of CYP27B1 expression, whereas HUVEC treated with LPS led to a decrease in CYP27B1. Both HAEC and HUVEC treated with TNFα showed induction of VEGF with the effect taking place at 6 hours in HAEC but not until after 12 hours in HUVEC. At 6 hours HAEC showed little response to vitamin D metabolites but after 12 hours of culture HAEC treated with 25D, 1,25D and 24,25D showed decreased expression of VEGF. This was also seen in HUVEC with the effect being most pronounced after 24 hours.

**Conclusions:** These in vitro data suggest key differences between HAEC and HUVEC responses to LPS and suggest HAEC are more sensitive to vitamin D metabolites relative to HUVEC which exhibit more delayed responses to treatments of 25D, 1,25D and 24,25D. Direct effects of vitamin D metabolites on VEGF in both HAEC and HUVEC suggest that vascular endothelial cells may be highly sensitive to changes in patient vitamin D status.

## PUB303

### Association between Renal Microangiopathy and Brachial Artery Flow-Mediated Vasodilation in Patients with Chronic Kidney Disease

Tsuyoshi Miyagi,[1] Kentaro Kohagura,[1] Yusuke Ohya,[1] Kunitoshi Iseki.[2] *[1]Dept of Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus, Nishihara, Okinawa, Japan; [2]Dialysis Unit, Univ Hospital of the Ryukyus, Nishihara, Okinawa, Japan.*

**Background:** Endothelial dysfunction is associated with progression of chronic kidney disease (CKD) and cardiovascular disease (CVD). However, underlying mechanism of this association is unknown. Pre-glomerular microvessel damage could be responsible for albuminuria, and hypertension, both of which are risk factor for progression of CKD and CVD. We examined the cross-sectional association between renal microvessel damage and brachial artery endothelial function using renal biopsy specimen.

**Methods:** Small arterial intimal thickening and arteriolar hyalinosis were assessed by semi quantitative grading for small artery among 172 patients with CKD (95 men and 77 women), who underwent renal biopsy. Vascular endothelial cell function was assessed by flow mediated dilatation (FMD) of forearm.

**Results:** The mean of age, blood pressure (BP), estimated glomerular filtration rate (eGFR), urinary protein, %FMD, and mean grade of arterial intimal thickening were 45y.o, 120/74 mmHg, 71.4 ml/min/1.73m$^2$, 1.75 g/gCr, 5.9%, and 2.3, respectively. %FMD was positively correlated with eGFR and negatively correlated with age, uric acid, HbA1c, and index of arterial intimal thickening. Multivariate regression analysis showed that %FMD was negatively correlated with max grade of arterial intimal thickening or arteriolar hyalinosis, respectively even after adjustment for age, sex, mean arterial BP, eGFR and HbA1c.

**Conclusions:** The results of present study suggested that renal microangiopathy might be associated with systemic endothelial dysfunction of macro-vessel, independent of classical CVD risk factors. This association might be involved in the link between endothelial dysfunction and progression of CKD and CVD.

## PUB304

### Dysfunctional Contractility and Endothelium Dependent Relaxation Mediated by Reactive Oxygen Species and Nitric Oxide Insufficiency in Microvessels from Renal Failure Mice

Dan Wang,[1] Cheng Wang,[1,2] Christopher S. Wilcox.[1] *[1]Hypertension, Kidney and Vascular Research Center, Georgetown Univ, Washington, DC; [2]Div of Nephrology, The Third Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

**Background:** Cardiovascular disease (CVD) is major complication in chronic renal failure (CRF). Endothelial dysfunction is a starting point for vascular change. We hypothesized that reactive oxygen species (ROS) and insufficiency of nitric oxide (NO) mediated abnormal microvascular contraction and endothelial function in renal reduced mass (RRM) mice.

**Methods:** Mesenteric arterioles (MAs) were isolated from C57BL/6 mice after sham-operation (Sham) or RRM (5/6 nephrectomy) for 3 months (n=6/group), mounted on a wire myograph. Relaxations were tested to sodium nitroprusside (endothelium-independent relaxation, EIR) and acetylcholine (ACh) in preconstricted MAs for: endothelium-dependent relaxation (EDR); endothelium-derived relaxation factor (EDRF; NOS-dependent relaxation); endothelium-derived hyperpolarizing factor (EDHF; $K^+$ channel dependent relaxation). Contractions were tested to endothelium-derived contracting factor (EDCF; ACh induced contraction with blocked endothelial relaxation pathways); phenylephrine (PE); U-46,619 and endothelin-1 (ET-1). NO activity (DAF-FM fluorescence) and ROS generation (tempo-9-AC fluorescence) were measured by fluorescence microscope equipped with RatioMaster system. Data present as mean ±SEM.

**Results:** The MAs from RRM mice had diminished EDR (54 ±5 *vs.* 77±3%; P<0.01), EDRF (13±5 *vs.* 27±4%; P<0.01) and NO activity (0.18 ± 0.05 *vs.* 0.36± 0.04 units; P<0.05), but not in EDHF and EIR , and developed an EDCF (14±1 vs. 8±1%; P<0.05) and enhanced ACh-induced ROS (0.17±0.03 *vs.* 0.06±0.02 units; P<0.05). Contractions were enhanced to U-46, 619 (107±4 *vs.*87±6%, P<0.05) and ET-1 (108±7 *vs.* 89±4%, P<0.05), but not to PE.

**Conclusions:** Mice with RRM model developed defective microvascular EDR and EDRF, a new ACh-induced EDCF and enhanced contraction responses. These profound microvascular disturbances mediated by excessed ROS generation and diminished NO may contribute to the development of premature CVD in CRF.

*Equal contribution of work from DW and CW.

## PUB305

### Arteriovenous Fistula Leads to Elevated Pulmonary Vascular Resistance in Hemodialysis Patients with Pulmonary Hypertension

Saranya Buppajarntham,[1] Rapeepat Lekkham.[2] *[1]Medicine, Albert Einstein Medical Center, Philadelphia, PA; [2]Nephrology, Albert Einstein Medical Center, Philadelphia, PA.*

**Background:** An incidence of pulmonary hypertension in ESRD is rising along with the increment of mortality rate. The mechanism of pulmonary hypertension in hemodialysis patients has been proposed as the effects of high cardiac output, which cause by arterio-

venous fistula (AVF) that functions as an artificial shunt. We hypothesized that after AVF created, changing of systemic hemodynamics and circulating vasoactive substances leads to increase pulmonary vascular resistance and pulmonary hypertension subsequently.

**Methods:** We conducted a retrospective study in hemodialysis patients, who have had two right heart catheterization (RHC) from January 2002 through March 2013. After 71 charts reviewed, we recruited 19 patients with AVF and 13 patients with non-AVF as a dialysis access. The progression of hemodynamic parameters between two catheterizations was examined. Statistical analysis was done by paired two way t-test.

**Results:** In AVF group with mean pulmonary arterial pressure of second RHC more than 25 mmHg, pulmonary vascular resistance was increased (p=0.07), while mean arterial blood pressure and systemic vascular resistance were decreased (p=0.04 and 0.08 respectively). In both AVF and non-AVF groups, there was no difference in cardiac output or pulmonary capillary wedge pressure from two RHC. In non-AVF group, no difference between pulmonary vascular resistance from two RHC was observed.

**Conclusions:** Although, cardiac output was unchanged, pulmonary vascular resistance was elevated after AVF created. We proposed elevated pulmonary vascular resistance as a major mechanism of PHT in hemodialysis patients with AVF and the increase of pulmonary vascular resistance is not affected by increased cardiac output.

## PUB306

**Gone but Not Forgotten** Hyma V. Polimera,[1] Sachinkumar B. Kanagali,[2] Robert Pursell,[3] David Leh.[4] *[1]Internal Medicine, St. Luke's Univ Health Network, Bethlehem, PA; [2]Internal Medicine, St. Luke's Univ Health Network, Bethlehem, PA; [3]Nephrology, St. Luke's Univ Health Network, Bethlehem, PA; [4]Internal Medicine, St. Luke's Univ Health Network, Bethlehem, PA.*

**Background:** Fibromuscular dysplasia (FMD) is a non-inflammatory, non-atherosclerotic disorder of medium size arteries of unknown etiology that can lead to arterial stenosis, aneurysm, and dissection.

**Methods:** A healthy 40 year old man was admitted with acute onset of severe, sharp, left flank pain. CT scan of the abdomen, with contrast, revealed acute, left renal infarcts and subacute/chronic right sided infarcts. A digital subtraction angiogram showed duplication of the right renal artery and abnormal, beaded left renal arterial vasculature and multiple thrombi; findings consistent with FMD. Follow up abdominal aortogram showed an aneurysm and spontaneous dissection of the left renal artery. The aneurysm was successfully embolized using detachable bioactive coils. The patient was started on IV heparin and Coumadin, which was to be continued for 6 months, with close follow up of his kidney function. After an uneventful six year hiatus, the patient presented with severe, right flank pain. CT, with angiogram, of the abdomen revealed right, main renal artery dissection with infarction and abnormalities at the origin of the accessory right renal artery. A diffuse abnormality of the celiac artery, previously normal, was described. The patient was anticoagulated with IV heparin and Coumadin and conservatively managed for the arterial dissection. Follow up includes quarterly serum creatinine levels and annual renal duplex ultrasound.

**Conclusions:** Since first described in 1938, there has been little progress in understanding the pathogenesis and outcomes of FMD. The clinical course is highly variable, ranging from the asymptomatic to the symptomatic with hypertension or with grave complications like dissections, aneurysmal ruptures with organ infractions or stroke depending on the severity and arterial segment involved. Though more common in young women, FMD should be considered in male patients presenting with flank pain and hypertension.

## PUB307

**Oral Administration of Calcium Carbonate Is a Risk for Coronary Artery Disease in Japanese Hemodialysis Patients in a Dose-Dependent Manner** Chisako Nakano, Yoko Shima, Naoko Morikage, Masafumi Yamato, Akira Wada, Takahito Ito. *Div of Nephrology, Osaka National Hospital, Osaka, Japan.*

**Background:** Cardiovascular disease is the leading cause of hospital admission and death among patients with end-stage kidney disease. Several mechanisms are thought to contribute to vascular calcification and subsequent cardiovascular disease. It is known that calcium administration accerelates artery calcification and that cardiovascular events. In Japan, however, calcium carbonate is often prescribed as a phosphate binder to treat hyperphosphatemia.

We studied the relationship between cardiovascular disease (CVD) and oral calcium supplementation in Japanese patients under maintenance hemodialysis.

**Methods:** We performed a single-center case-control study using 90 individuals (68.6 ± 10.5 y, 67 males) who underwent maintenance hemodialysis while hospitalized in our hospital from December 1, 2011 to April 30, 2013. Blood analysis was done at the time of hospitalization or within one month prior to hospitalization. The case and control groups comprised 34 patients hospitalized for examination and/or treatment of coronary artery disease and 56 patients hospitalized for other medical issues, respectively. One with any previous history of CVD was excluded from the control group.

**Results:** More amount of calcium carbonate was administered in the case group than in the control at the time of hospitalization (2.25 ± 1.50 vs. 1.31 ± 1.19 g/day, P=0.0034), whereas there was no statistical difference regarding serum albumin, inorganic phosphate, albumin-corrected calcium, calcium-phosphate product, intact PTH or C-reactive protein. Dialysis vintage was significantly longer in the case than in the control (64.2 [29.0 – 132.7] vs. 35.7 [15.8 – 69.7], P=0.0458).</a> Male sex was a significant risk (P=0.0046) but diabetes was marginal (P=0.0612). Age was not significant. Odds ratio of calcium carbonate administration (per 1 gram increment) for CAD was 1.70 [95%CI: 1.22 – 2.45] (non-adjusted), and 1.65 [1.18 – 2.40] (adjusted by dialysis vintage and sex).

**Conclusions:** Calcium carbonate may be a risk factor of CVD-related hospitalization in a dose-dependent manner.

## PUB308

**Characteristics of Phosphate Binders Dissolution** Heather Busby,[2] John Durham,[1] Tarek M. Sobeih,[1] Abdullah Hamad.[1] *[1]Palmetto Nephrology, Orangeburg, SC; [2]Davita Dialysis, Orangeburg, SC.*

**Background:** Controlling hyperphosphatemia continues to be a challenge in dialysis patients. We evaluated for qualitative differences in the in-vitro dissolution times and characteristics of several calcium and non-calcium based phosphate binders in the acidic medium of vinegar to determine if these changes might correlate with the clinical responses to these binders.

**Methods:** Commercial phosphate binders were placed in 3 ounces of distilled white vinegar and observed for 20 minutes in transparent containers. Time to dissolution and its qualitative characteristics were visually monitored by two observers.

**Results:** Results are summarized in the attached table.

| | |
|---|---|
| Tums 1000 mg crushed | effervescent, very fast, mild increase in total volume, dissolved in 4 minutes |
| Calcium Acetate 667 mg powder (1) | slow and mild reaction, 8 minutes to dissolve |
| Renvela 2400 mg powder | effervescent, large volume expansion and dissolved in 1 minute |
| Fosrenol 1000 mg crushed | solution slowly became cloudy over 20 minutes |
| Phoslyra 667 mg (liquid) | immediatly dissolved woth no reaction |

1- calcium acetate was first removed the gel cap and crushed.

**Conclusions:** Different binders have different >in-vitro dissolution times and characteristics. That can affect the speed of binding to phosphorus and consequentially the importance of timing of taking medicine in relationship to food. In this regard the large and rapid expansion of volume with Renagel powder may explain some of its gastric and intestinal side effects.

## PUB309

**Hypomagnesemia Associated with Malignancy Induced Hypercalcemia** Wasay Humayun, Aparna Rao. *Vanguard Internal Medicine, Macneal Hospital, Berwyn, IL.*

**Background:** We report a case of a 81 y/o female patient who was admitted after a fall at home. Pt was found to have severe persistent hypomagnesemia despite attempts for repletion and hypercalcemia on labs.

**Methods:** Patient's detailed history was obtained a comprehensive physical exam was done. Patient's chart and records reviewed from an OSH as well. Daily labs and imaging were reviewed along with speaking to the Endocrinologist and Nephrologist on the case.

**Results:** Significant labs show her calcium was elevated at 11.1 and her magnesium level was 1.2. Her intact PTH was less than 7 and a Vitamin 1,25 OH level was 114. Patient also had a CT abdomen which showed a 8 cm mass near the pancreas which was biopsied to show a diffuse large B-cell lymphoma.

**Conclusions:** Patient's persistent hypomagnesemia was likely renal in etiology etiology. The utility of Fractional excretion of magnesium, which was calculated to be 3.7, helped differentiate renal from GI cause. The possible renal etiologies included: Loop diuretics, Barters syndrome, Familial hypomagnesemia with hypercalciuria and nephrocalcinosis (FHHNC), Autosomal Dominant hypocalcemia. . Patient's hypercalcemia likely secondary to the newly diagnosed lymphoma an interesting contributing factor. Hypercalcemia may result in hypomagnesemia at least in part from the fact that calcium and magnesium functionally compete for transport in the thick ascending limb of the loop of Henle. A variety of mechanisms may contribute to the reduction in magnesium reabsorption resulting from hypercalcemia. One well known mechanism is facilitated by the basolateral calcium-sensing receptor (CaSR) in the thick ascending limb: This leads to an inhibition of the apical ROMK channels. Also hypercalcemia can decrease in serum magnesium by decreased paracellular transport of calcium.

## PUB310

**Amphotercin Induced Pseudeohyperphosphatemia** Snezana H. Mijovic-Das,[1] Darius Mason,[2] Muhammad A. Ashraf,[1] Wadad S. Mneimneh.[1] *[1]Nephrology, Albany Medical College, Albany, NY; [2]Pharmacy, College of Pharmacy, Albany, NY.*

**Background:** Previous studies suggest that liposomal Amphoteracin-B (LAMB) may interfere with inorganic phosphate (Pi) lab measurements, causing pseudohyperphosphatemia (PHP). LAMB-associated PHP is not well recognized and may lead to unwarranted workup and therapy. We present a case of a previously healthy 47-year-old male patient with a baseline Scr of 0.9 mg/dl, who was diagnosed with cryptococcal meningitis. He was treated with LAMB and subsequently developed PHP.

**Methods:** Pi measurements were obtained by endpoint assay (EPA) using two different instruments (Beckman Coulter Unicel DXC and Dimension Vista 500). Lipid ultracentrifugation (LUC) was applied on one of the samples. For further quality control we serially measured Pi levels with LAMB-spiked calibration solutions, using both EPA and kinetic assay (KA), reproducing the variation pattern of Pi levels described in the literature.

**Results:** Table1 shows values of serum Pi, Scr and LAMB doses, throughout hospitalization.

| Day Post-admission | 2-7 | 8-9 | 10-11 | 12-15 | 16-17 | 18-24 |
|---|---|---|---|---|---|---|
| LAMB (mg/day) | 440 | 220 | 350 | 440 | 220 | 350 |
| Scr (mg/dl) | 1.5-2.9 | 2.9-2.3-2.0 | 2.0-1.7 | 1.7-2.0 | 2.0-2.2-2.0 | 2.0-1.8-1.5 |
| Pi (mg/dL) | 5.3-6.6 | 6.6-6.4-5.2 | 5.2-4.6 | 4.6-5.6 | 5.6-5.5-5.8 | 5.8-6.0-4.7 |

The patient's elevated Pi levels could not be explained by the degree of renal dysfunction reflected by Scr increase, whereas they directly correlated with LAMB doses, suggesting an interference effect. Previous studies had similarly shown erroneous linear elevation of Pi levels with increasing LAMB concentrations. The interference effect was supported by: Correction of PHP by either LUC or lipemic clearing agents (Microcon®, LipoCLear®); Concurrent Pi measurement using EPA and KA; Ineffectiveness of PO4 binders to resolve PHP. Of note, LUC failed to correct Pi level in our case, but this single-sample result is inconclusive.

**Conclusions:** LAMB-associated PHP can lead to extensive and unwarranted workup. Awareness of this drug-assay interaction can prevent inappropriate therapy such as dietary restriction, phosphate binders, hemodialysis, or altering the choice of ideal antifungal regimen.

## PUB311

**Ethanol Injections for Management of Severe Hyperparathyroidism: Case Reports** Ivana Lazich, Marc J. Alonzo, Carolyn Kirchgessner Donaldson, Stuart M. Sprague. *NorthShore Univ Health System, Univ of Chicago, Evanston, IL.*

**Background:** Uncontrolled hyperparathyroidism in the setting of CKD or primary hyperparathyroid adenoma remains a therapeutic challenge despite the developing pharmacotherapy. We evaluated the utility of percutaneous ethanol injection therapy (PEIT) for the management of severe hyperparathyroidism with hypercalcemia in patients with nodular parathyroid hyperplasia.

**Methods:** A total of nine patients with elevated PTH and calcium concentrations and discrete parathyroid nodules were evaluated. Parathyroid nodules were identified and localized via Doppler ultrasound (US) and 98% ethanol (<1 ml) was injected via US guidance. A successful procedure was defined as decrease in PTH > 50% over a minimum of 6 months. To determine if response was a function of nodular size, mean nodule size was compared between responders and nonresponders (T-test).

**Results:** Five patients had uncontrolled tertiary hyperparathyroidism (either ESRD on HD or post renal transplant) and four had primary hyperparathyroidism. This population included seven Caucasians and seven females with mean age of 56 ± 4.4 years. PTH concentrations, prior the procedure, ranged between 88 - 2922 pg/ml and serum calcium ranged 10 - 12.7 mg/dl. Five of the nine patients were considered responders. Mean nodule size in responder group was 1.28 mm and in nonresponder group was 1.86 mm (NS). Of the patients who responded to treatment only two had normalization of PTH, whereas all of them had normalization of serum calcium concentrations.

**Conclusions:** This preliminary experience demonstrates that some patients with severe hyperparathyroidism with hypercalcemia could be controlled with PEIT. The procedure, however, is limited to selective group of patients who have readily identified US evidence of parathyroid adenomas. Our evaluation did not show impact of nodular size on outcome as reported previously, however, our sample was small. The risk is minimal but the potential downside is the need for repetitive interventions until desired results have been achieved. Further studies should be performed to evaluate this as a viable option to surgery or in those who are not a surgical candidate.

## PUB312

**25-Hydroxy-Vitamin D3 Concentration Detection for Screening of Early Renal Damage in Diabetic Kidney Disease** Wenbo Zhao,[1] Bo Huang,[2] Cailian Cheng,[1] Xun Liu,[1] Zengchun Ye,[1] Tan-qi Lou.[1] *[1]Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Nephrology, The Sichuan Academy of Medical Sciences &Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

**Background:** To detect of the type 2 diabetic nephropathy patients' 25-hydroxy-vitamin D3 concentration, and analyze whether the concentration applies to screening of diabetic nephropathy early renal damage.

**Methods:** We collected the clinical data and blood samples of hospitalized patients with type 2 diabetes. The material is assessed according to eGFR (﹥30 ml/min·1.73m$^2$, MDRD Formula) and proteinuria combined diagnostic criteria of DKD. 52 cases were acquired, consisting of 23 males and 29 females, divided into normal proteinuria group (31 cases) with average (56.29±13.84) years old, and microalbuminuria group (21 cases) with average (60.29±13.24) years old. The quantitative determination of serum 25(OH) VitD3 level (IDS Corp., England) is further performed adopting ELISA. The 25(OH) VitD3 level of normal proteinuria group is (44.51±19.87)ng/ml, while that of (31.7±10.03) ng/ml for microalbuminuria group (P<0.05). SPSS 15.0 is used for statistical analysis. Multi-factors are brought into the variables, then applying the ROC curve method.

**Results:** Multi-factor analysis demonstrates that ALB, UA and 25 (OH) VitD3 are the three main relevant factors. The areas under the curves of these three main relevant factors are 0.698, 0.770 and 0.707 respectively. The underlying area of ALB+UA+ 25(OH) VitD3 combined curve (ALB+UA+ 25 (OH) VitD3) is 0.909, which is the maximum, and also greater than the area of 0.814 combining (ALB+UA).

figure1

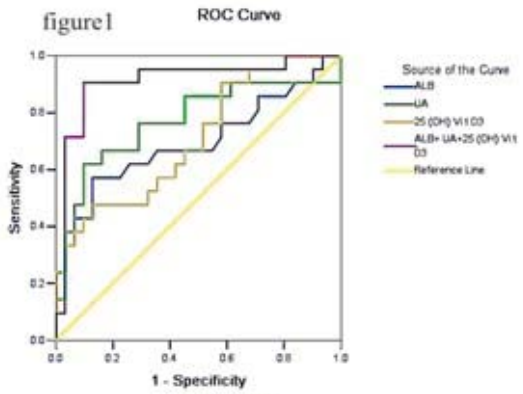

figure 2

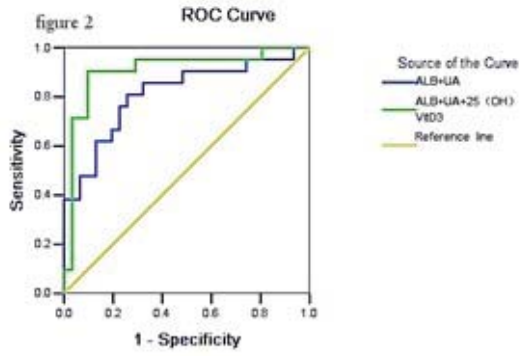

**Conclusions:** The concentration of 25(OH) VitD3 in microalbuminuria group is lower. Multi-factorial ROC curve has a larger area. 25(OH) VitD3 can be considered as a cofactor for early screening in the period of microalbuminuria.

## PUB313

**Dialysate-Magnesium Regulates Serum-Magnesium Regulates PTH** Bernd A. Winterberg. *Dept of Nephrology, Marienhospital, Emsdetten, Germany.*

**Background:** The magnesium balance is a function of absorption and excretion.

The excretion of Mg is almost exclusively renal, is determined by the glomerular filtration rate and decreases with increasing renal impairment. In dialysis patients, magnesium is eliminated via the dialysate.

Hemodialysis patients typically have a mild hypermagnesemia (1.03 to 1.5 mmol / l, normal range 0.62 to 1.03 mmol / l).

The serum magnesium in hemodialysis patients depends on the magnesium concentration in the dialysate. If you increase it, increases the serum magnesium. Hypermagnesemia below 1.5 mmol / l is usually asymptomatic, from 2-3 mmol / l connect symptoms such as lethargy and dizziness, at even higher values, loss of tendon reflexes, bradycardia, paralysis, apnea and cardiac arrest .

Positive effects of hypermagnesemia in dialysis patients: an increase in myocardial contractility, prevention of intradialytic hypotension, lowering elevated PTH levels, inhibition of vascular calcification.

Hypermagnesemia has a suppressive effect on PTH secretion. There is an inverse correlation between intact PTH and serum magnesium regardless of serum calcium and serum phosphate.

The PTH levels in dialysis patients can be regulated by modification of dialysate magnesium. If the PTH level is below the recommended lower limit of 150 micrograms / ml, it will increase by the use of low dialysate magnesium. If it is above the recommended upper limit of 300 micrograms / ml, it will decrease by increasing the dialysate magnesium.

**Methods:** In a separate investigation dialysis patients(n=24) were treated with a dialysate magnesium of 0.5 mmol / l ( or 1.0 mmol / l).

**Results:** In these patients before HD the mean serum magnesium was 0.81 + / - 0.22 mmol / l, n = 17 (or 1.3 + / - 0.19 mmol / l, n = 7) and after HD the mean serum magnesium was 0.77 + / - 0.14 mmol / l (or 1 , 37 + / - 0.05 mmol / l) .

**Conclusions:** Regulation of serum magnesium by modification of dialysate magnesium lead to serum magnesium concentrations (low or high) in the safe range, offering the chance to regulate PTH levels, to reduce vascular calcification, left ventricular hypertrophy and cardiovascular mortality.

**A Rare Cause of Tumor-Induced Osteomalacia: Metastatic Prostate Cancer**
Abdul Mubeen Mohammed,[1] Faheemuddin A. Ahmed.[2] *[1]Swedish Covenant Hospital, Chicago, IL; [2]Medical College of Wisconsin, Milwaukee, WI.*

**Background:** We present a rare case of severe asymptomatic hypophosphatemia in a patient with metastatic prostate cancer. It was associated with significant renal phosphate wasting as a consequence of high levels of fibroblast growth factor (FGF-23). We hypothesize that the metastatic prostate cancer caused high levels of FGF-23, resulting in tumor-induced osteomalacia.

**Methods:** A 63-year-old man with history of metastatic prostate cancer was evaluated for phosphorus level of less than 1 mg/dL for four months. He was asymptomatic. His past oncologic history was significant for Gleason 6 score prostate cancer diagnosed seven years ago. Patient subsequently underwent radical prostatectomy, adjuvant hormonal therapy and eventually radiation. PSA declined from a peak of 60 ng/mL to 0.08, but started increasing again. Adjuvant hormonal therapy was restarted with LHRH and bicalutamide. Follow-up staging scans revealed progressive metastatic disease and he was started on Docetaxel, three months prior to admission. Physical examination was unremarkable. Laboratory evaluation showed a calcium level of 8.4 mg/dL; 1,25 Vitamin D level 55 pg/mL and intact PTH level 182 pg/mL. Urine studies revealed renal phosphate wasting with fractional excretion of phosphorus of 60%. Serum FGF-23 levels were significantly elevated at 505 RU/ml (normal range of less than 180 RU/ml). Bone survey showed abnormal diffuse axial and proximal appendicular skeletal metastatic disease. Further work-up with Octreotide scintigraphy scan to locate for neuroendocrine tumor activity was negative. Patient was continued on potassium phosphorus supplements (10 tabs/day) with calcitriol. Subsequent phosphorus levels were at lower end of normal range.

**Conclusions:** Tumor induced osteomalacia due to metastatic prostate cancer is rarely described in literature. FGF-23 released from the tumor cells impairs phosphate reabsorption and 1α-hydroxylation of 25-hydroxyvitamin D. This leads to hypophosphatemia and usually low levels of 1,25-dihydroxy vitamin D. As the particular lesion could not be located with the octreotide scan, medical management was offered which included phosphate supplements and active vitamin D.

**PUB315**

**Phosphate Binder Powder Formulations: Perspectives from the Renal Care Community**
J. Brian Copley,[1] Elizabeth J. Lindley,[2] Maria Cruz Casal,[3] Susan Rogers,[4] Jitka Pancirova,[5] Jennifer Kernc,[1] Denis Fouque.[6] *[1]Shire Pharmaceuticals, Wayne, PA; [2]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [3]Hospital 12 de Octubre, Madrid, Spain; [4]Codia Waterland, Pumerend, Netherlands; [5]EDTNA/ERCA Secretariat, Prague, Czech Republic; [6]Centre Hospitalier Lyon-Sud and CENS, Lyon, France.*

**Background:** Phosphate binders are commonly used in tablet form to help patients with chronic kidney disease limit their absorption of dietary phosphorus. Alternative formulations, such as powders, provide choice and may facilitate medication adherence. A survey of renal nurses and dietitians was conducted in order to examine their perceptions of the relative benefits and drawbacks of a powder formulation.

**Methods:** Renal nurses and dietitians (n = 83) in the Netherlands, Spain, Sweden and the UK were asked to complete a survey in September and October 2012.

**Results:** The most frequently reported (38/83 responders, 46%) perception of powder formulations was that they are likely to be beneficial because they are easier for the patient to take, particularly if the patient experiences difficulties chewing or swallowing tablets. This perception was reported by a similar proportion of nurses (14/35, 40%) and dietitians (22/48, 46%). When a powder formulation is administered with food, the associated reduced need for additional fluid intake was perceived as another benefit (7/83, 8%). The most frequently reported perceived drawbacks of powder formulations were poor palatability (16/84, 19%) and administration of inaccurate doses (15/83, 18%). A greater proportion of dietitians than nurses perceived that the drawbacks of the powder were poor palatability (11/48, 23%, and 5/35, 14%, respectively) and administration of inaccurate doses (12/48, 25%, and 3/35, 9%, respectively). Another perceived drawback of powder was increased fluid intake required when a formulation is administered as an oral suspension (11/83, 13%).

**Conclusions:** Phosphate binder powder formulations were generally perceived favorably in the renal community surveyed, mainly because they were considered to be easier to take. The perceptions evaluated here may assist in the development of future phosphate binder formulations.

**Assessment of Serum Calcium (Ca), Phosphorous (P) and Parathyroid (PTH) Hormone Levels According to K/DOQI Guidelines in Hemodialysis Patients at a Tertiary Care Hospital of a Developing Country**
Ayesha Mahmood Malik,[1] Hafiz I. Ahmad,[1] Syed Rizwan Bokhari,[1] Muhammad Zaman Khan Assir,[1] Arif Asif.[2] *[1]Dept of Nephrology, Allama Iqbal Medical College/ Jinnah Hospital, Lahore, Punjab, Pakistan; [2]Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.*

**Background:** Studies have shown that achievement of bone mineral metabolism targets as recommended by K/DOQI guidelines is universally poor. Patients in developing countries receive less than optimal dialysis treatment. A cross sectional study was performed to assess these markers in our patient population receiving dialysis at a tertiary care hospital.

**Methods:** Demographic data of patients were collected and pre dialysis blood samples were drawn for serum calcium, phosphorous, alkaline phosphatase, intact PTH and albumin. Ca x P product was also calculated. The results were analyzed and compared with K/DOQI guidelines targets.

**Results:** Of the 66 ESRD patients, 41(62%) were males with mean age 42.3±5 years. The percentage of patients who achieved K/DOQI target ranges of calcium, phosphorus, PTH and CaxP product were 40.9%, 43.9%, 19.7% and 77.3% respectively. Values above the target ranges of calcium, phosphorus, PTH were seen in 12.1%, 36.4% and 59.1% respectively, while values below target ranges of calcium, phosphorus, PTH were found in 47%, 19.7% and 21.2% patients respectively. Abnormal Ca x P was seen in 23% patients.

**Conclusions:** Most of the patients receiving dialysis at our center have their values of calcium, phosphorus, alkaline phosphatase, PTH and Ca x P product out of the range recommended by K/DOQI guidelines. These results are similar to those achieved by the patients in developed countries.

**The Efficacy and Safety of Lanthanum Carbonate on Chronic Kidney Disease Mineral and Bone Disorder in Patients with Dialysis: A Systematic Review**
Ling Ji, Zi Li, Fei Liu, Xiaohong Tang, Junming Fan. *Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.*

**Background:** Hyperphosphatemia is a common complication in patients with end-stage renal disease (ESRD) requiring dialysis. Elevated serum phosphorus concentration is an established independent risk factor for increased mortality. Lanthanum carbonate (LC) is a potent new, non-aluminum, non-calcium phosphate binder. This systematic review evaluated the efficacy and safety of LC in dialysis patients.

**Methods:** Search methods: MEDLINE, EMBASE, the Cochrane Renal Group's Specialized Register and CENTRAL were searched from . 2000 to Dec. 2012 for relevant studies. Selection criteria: all randomized controlled trials (RCTs) and quasi-RCTs that assessed the efficacy and safety of LC in hemodialysis or peritoneal dialysis patients. Data collection and analysis: two authors independently reviewed search results and extracted data. Analysis was performed using the statistical software Review Manager 5.1.

**Results:** Twelve RCTs were identified and retained for this review, with 3029 patients included. There was no statistic difference between two groups in all-cause mortality. Due to the limited trials, there was not enough evidence to show the priority of LC in lowering vascular calcification or cardiovascular events, improving bone morphology or metabolism or improving bone turn over parameters. LC can significantly decrease serum phosphorus level and Ca×P product, increase the control rate of serum phosphorus compared with placebo. Nevertheless, there was no difference in phosphorus level, the control rate of serum phosphorus, iPTH and Ca×P product compared with calcium carbonate, but sith a significant lower level serum calcium. People treated with LC appeared a higher rate of vomiting and lower risk of hypercalcemia, diarrhea, intra-dialytic hypotension. For the incidence of other side-effects, meat-analysis showed no significant difference.

**Conclusions:** LC has a well efficacy in lowering serum phosphorus level and iPTH without increasing the serum calcium level. LC was safe for dialysis patients especially in patients with high risk of hypercalcemia except a higher incidence of vomiting.

**PUB318**

**Body Mass Index and Survival in Patients with Incident Kidney Stone Disease**
Jie Tang,[1] John R. Holmen,[2] Kim McFann,[1] Michel Chonchol.[1] *[1]Medicine, Univ of Colorado, Denver, CO; [2]Intermountain Health Care, Murray, UT.*

**Background:** Kidney stone disease is associated with obesity and metabolic syndrome. However, the impact of obesity on survival among kidney stone formers is not clear.

**Methods:** Incident kidney stone formers were identified from Intermountain Healthcare Data Warehouse and were defined as patients having first ever diagnosis of kidney stone disease using ICD9 codes 592.0, 592.1, 592.9 & 594.0 assigned from 1994 to 2013. Mortalities were determined using state and national death registries. Logistic regression models were used to test the associations of body mass index (BMI) with cardiovascular mortality (CVM) and all-cause mortality (ACM).

**Results:** Among 21,752 incident stone formers, 959 (5%) had BMI <20, 4,767 (22%) had BMI 20-24, 7,011 (32%) had BMI 25-29, and 9,015 (41%) had BMI ≥30. There were a total of 1,835 all-cause and 874 cardiovascular deaths during a median follow-up of 7.0 years. Higher BMI was associated with lower tobacco and alcohol use, lower glomerular filtration rate (GFR), and was associated with higher risk of prevalent hypertension, diabetes, and dyslipidemia. After adjusting for age, sex, race, tobacco history, alcohol history, diabetes, hypertension, cardiovascular disease history, dyslipidemia, and GFR, BMI <20 (vs. 20-24) was not associated with a significantly increased odds of CVM, odds ratio (OR) 1.5 (95% CI 0.9-2.5), p=0.11, but was associated with a significantly increased odds of ACM, OR 1.9 (95% CI 1.3-2.7), p=0.0005. BMI 25-29 (vs. 20-24) was associated with a reduced trend of CVM, OR 0.8 (95% CI 0.6-1.0), p=0.08, and was associated with a significantly reduced odds of ACM, OR 0.7 (95% CI 0.5-0.8), p=0.0002. BMI >30 (vs. 20-24) was associated with a significantly reduced odds of CVM, OR 0.6 (95% CI 0.4-0.8), p=0.0005, as well as ACM, OR 0.5 (95% CI 0.4-0.6), p<0.0001.

**Conclusions:** Higher BMI appears to be associated with better survival in patients with incident kidney stone disease. The cause of this finding remains to be determined.

**PUB319**

**Lithogenic Risks in Calcium Oxalate Nephrolithiasis Familial Members** Thasinas Dissayabutra,[1] Jakkaphan Rattanaphan,[1] Thanida Chiramongkolsiri,[1] Talerngsak Kanjanabuch,[2] Piyaratana Tosukhowong.[1] *[1]Biochemistry, Chulalongkorn Univ, Pathumwan, Bangkok, Thailand; [2]Medicine, Chulalongkorn Univ, Pathumwan, Bangkok, Thailand.*

**Background:** Many evidences suggested that nephrolithiasis familial members are at risk, although no pathologic gene has yet defined. This study aims to discover the epigenetic risk factors in calcium oxalate nephrolithiasis family.

**Methods:** 146 participants, including 28 stone-removed nephrolithiasis patients and 45 of their first-degree descendants, as well as 73 healthy volunteers were enrolled. Medical history about urologic disease, blood and 24-hour urine were collected. Urinary calcium, magnesium, potassium, and sodium were measured by inductively coupled plasma mass spectrometry (ICP), oxalate and citrate by capillary electrophoresis, and sulfated glycosaminoglycans (sGAGs) by dye binding assay. Statistical analyses were testing by SPSS (IBM, USA) version 16.0.

**Results:** Compared to healthy population, nephrolithiasis patients had elevated urinary protein (336.6 *vs.* 30.4 mg/day, $p$=0.002), calcium (5.8 *vs*. 3.1 mEq/day, $p$=0.005), oxalate (43.7 *vs*. 12.7 mg/day, $p$<0.001) together with decreased urinary citrate (66.2 *vs.* 185.9 mg/day, $p$<0.001) and sGAGs (5.3 *vs*. 48.5 µg/ml, $p$<0.001). While the nephrolithiasis descendants had the following parameters being in-between of 2 groups: proteinuria (67.0+7.0 mg/day, $p$<0.001), diminished urinary citrate (113.6 mg/day, $p$=0.001) and sGAGs (32.29 µg/ml, $p$<0.001), all of which were more obviously changed by age. The descendant also had lower kaliuria level (19.89 *vs*. 26.49, $p$=0.001) compared to the controls. No other urinary indices or clinical characteristics showed any significant differences. Adjusted odd ratios of the nephrolithiasis for urinary protein, citrate, and sGAGs were 1.024 (1.012-1.036), 0.993 (0.989-0.997) and 0.936 (0.914-0.958), respectively.

**Conclusions:** Nephrolithiasis patients and their first-degree descendants, although no stone-forming, have elevated proteinuria as well as depleted urinary citrate and sGAGs compared to healthy controls. Stone imaging and primary prophylaxis should be warranted in the relatives with abnormalities of urinary protein, citrate, or sGAGs.

**Serum 25-Hydroxyvitamin D Concentration and Survival among Incident Kidney Stone Formers** Jie Tang,[1] Pamela Mettler,[1] John R. Holmen,[2] Michel Chonchol.[1] *[1]Univ of Colorado, Denver, CO; [2]Intermountain Healthcare, Murray, UT.*

**Background:** Nutritional vitamin D deficiency is highly prevalent in kidney stone formers. However, its impact on survivial among incident kidney stone (IKS) formers is unknown.

**Methods:** IKS formers were identified from Intermountain Healthcare Data Warehouse and were defined as patients having first ever diagnosis of kidney stone disease using ICD9 codes 592 & 594.0 assigned from 1994 to 2013. All-cause mortalities were determined using state and national death registries. Logistic regression models were used to test the association of serum 25-hydroxyvitamin D (25D) concentration with all-cause mortality.

**Results:** Among 1,045 IKS formers, 569 (54%) had serum 25D concentrations ≤30 ng/ml (mean=21 ng/ml), 476 (46%) had serum 25D concentrations >30 ng/ml (mean=43 ng/ml). Lower serum 25D concentration was associated with lower body mass index and higher likelihood of tobacco & alcohol exposures, but was not associated with increased risks of prevalent hypertension, diabetes, dyslipidemia and cardiovascular disease. After adjusting for age, gender, tobacco & alcohol use, diabetes, hypertension, dyslipidemia, cardiovascular disease, and GFR, serum 25D concentration >30 ng/ml was not associated with a significantly reduced odds of all-cause mortality when compared to serum 25D concentration ≤30 ng/ml, odds ratio (OR) 1.74 (95% CI 0.88 - 3.45), p=0.11. Higher serum 25D concentration (per 1 ng/ml increase) was also not associated with a reduced odds of all-cause mortality, OR 1.02 (95% CI 1.00-1.04), p=0.06.

**Conclusions:** Higher serum 25D concentration does not appear to modify survival in patients with IKS disease. This is likely due to the fact that kidney stone formers often have normal or above-normal active vitamin D levels.

*Funding:* NIDDK Support

**PUB321**

**Taking into Consideration Migrant Patients' Cross-Cultural Features during Patient Educational Therapy for Patients** Abdallah Guerraoui,[1] Guillaume Jean,[2] Agnes Caillette-beaudoin,[1] Corinne Isnard-Bagnis.[3] *[1]Nephrologie Dialyse, Calydial, Vienne, France; [2]Nephrologie Dialyse, Nephrocare, Lyon, France; [3]Patient Education, Univ Pierre et Marie Curie, Paris, France.*

**Background:** This work is based on the results of a qualitative research dealing with the educational nurse's (EN) activity during a patient education session with migrant patients. More precisely, in this article we intend to report on the way the educational nurse takes into consideration all the cross-cultural factors and their repercussion/negative impact on the EN practice.

**Methods:** This research is uses a method which stems from social sciences called "the simple auto confrontation. The process consists in filming the interaction between the EN and the patients during the educational diagnosis. This video-taped interaction is recorded and coded according to L Bardin's method of content analysis. An auto confrontation between the EN and the researcher is carried out. This second interaction is also filmed, recorded and coded according to the same method.

**Results:** We demonstrate how difficulties stemming from differences in presentations, beliefs and cultures between the EN and the migrant patient have a significant impact on the consultation. We will highlight the ability of both the EN and the migrant patient to adapt their interactions to new cross cultural realities. The EN adaptation is closely linked to the individual's career path and their formation. Therefore, this work includes operationalizing the analysis in order to make the best use of educational therapy for patient (ETP) interviews.

**Conclusions:** When EN take into consideration each patient's culture, their life path and their individual itinerary, this enhances the success of an ETP programme. Hence, this qualitative research on the cross cultural aspects of the ETP falls within a more global dimension which enables us to better analyze how the medical culture influences relationships with both migrant and non-migrant patients. The differences between these two cultures (the doctor or nurse and the patient's cultures) lead to misunderstandings and divergences which complicate the health care provider the doctor-patient relationship.

**PUB322**

**Three Children Developing Enlarged and, Echogenic Kidneys while Receiving Circulatory Support from Pediatric Ventricular Assist Device** Atul Poudel,[1] Richard E. Neiberger.[2] *[1]Dept of Pediatric Nephrology, Univ of Florida, Gainesville, FL; [2]Dept of Pediatric Nephrology, Univ of Florida, Gainesville, FL.*

**Background:** In last decade pediatric ventricular assist device (VAD) specially designed for small children have been increasing implanted in North America. Prospective trials have shown pediatric VAD decreases the mortality of patient on heart transplant list and superior to extracorporeal membrane oxygenation (ECMO). After Food and Drug Adminstration approval of pediatric VAD, Berlin Heart EXCOR in 2011, more use of this device is expected in future. We are presenting unexpected renal findings developing in three children receiving circulatory support using Pediatric VAD ( Berlin Heart Excor).

**Methods:** The mechanisms of heart failure in these children included: 1) Hypoplastic ventricle with aortic stenosis; 2) Anomalous coronary artery arising from the pulmonary artery and 3) Idiopathic progressive heart failure. During circulatory support with VAD each child had coagulation times maintained at 2-3 times normal. Each child had normal or mildly reduced renal function.Each of these children had imaging studies (Ultrasound or Computed tomography) while receiving VAD support which demonstrated enlarged echogenic kidneys.These children subsequently died and autopsy studies of two children showed multiple bilateral kidney infracts, parenchymal congestion and arterial thrombosis.

**Conclusions:** Our case series shows that thromboembolism of renal artery may be a cause of enlarged echogenic kidneys in patients on pediatric ventricular assist device.

**PUB323**

**A Case of Warfarin Related Nephropathy** Nicole Bautista, William Whittier. *Rush Univ Medical Center, Chicago, IL.*

**Background:** Warfarin was approved in 1954 and currently is the most prescribed anticoagulant medication. Warfarin related nephropathy (WRN) is a recently described condition that involves acute kidney injury, supratherapeutic international normalized ratio (INR), and tubular obstruction with red blood cells (RBCs) and RBC casts. WRN is associated with significant morbidity as many patients progress to end stage renal disease (ESRD) despite normalization of the INR. We report a case of WRN where the acute kidney injury improves after cessation of warfarin.

**Methods:** A 64 year-old African American man presented with a two week history of gross hematuria. He had a history of chronic hepatitis C, CHF, well-controlled HIV, and an aortic arch atheroma and was initiated on warfarin 8 months prior to presentation. He had a baseline creatinine of 0.9 mg/dl and a urinalysis without blood or protein. Serial INR levels were in the therapeutic range. On presentation, he was found to have an INR of 7.3, acute kidney injury with a creatinine of 4.2 mg/dl, and his urinalysis showed large blood, >200 RBCs, and no protein. A renal biopsy revealed acute tubular necrosis, widespread tubular RBC casts, and no tubulointerstitial nephritis. There was mild mesangial hypercellularity and the IF had trace deposits of C3 and IgG. The EM showed normal glomerular basement membrane thickness (470 nm) without electron dense deposits, and normal endothelial and podocyte structures. There were no electron dense deposits in the mesangium. There were no clinical or pathologic etiologies that could explain the presence of tubular RBC casts and he was diagnosed with WRN. Warfarin therapy was discontinued, aspirin started, and at one year follow-up his creatinine had improved to 2.3 mg/dl. His urinalysis revealed no protein, trace blood, and 4-10 RBCs.

**Conclusions:** The diagnostic criteria for WRN includes acute kidney injury, supratherapeutic INR, and the presence of tubular RBCs and RBC casts on kidney biopsy. Often renal function does not recover and progression to ESRD is common, even after cessation of warfarin. This report highlights that cessation of warfarin therapy can be associated with improvement or stabilization in renal function.

## PUB324

**Heavy Chain Deposition Disease** Sarah Margaret Moran,[1] Maeve P. Crowley,[2] Marek J. Mazur.[1] *[1]Nephrology, Cork Univ Hospital, Ireland; [2]Haematology, Cork Univ Hospital, Ireland.*

**Background:** Heavy chain deposition disease (HCDD) is the least common of the plasma cell dyscrasias. 24 have been described in the literature to date. We report the presentation, diagnosis, treatment and complications of the 25th report patient. HCDD is an important but rare cause of renal impairment in association with plasma cell dyscrasia.

**Methods:** A 56 year old male was referred to Nephrology OPD for evaluation of hypertension and elevated creatinine of 2.9mg/dL (eGFR 26mls/min/1.73m2). History revealed a nine month history of hypertension and dyslipidemia treated with rosuvastatin and perindopril. Examination revealed BP 177/105mmHg, nil else of note. Urinary protein excretion was 6.4 g/24 hrs, serum total protein x g/L, albumin 31g/L. Thin-layer agarose electrophoresis revealed a monoclonal IgG kappa band, creatinine concentration 2.6mg/dL. Bone marrow aspiration showed 12% plasma cells, bone marrow biopsy 10-15% atypical plasma cell infiltrate. Renal biopsy revealed nodular glomerulosclerosis, PAS positive, Congo Red negative, electron microscopy reveals amorphous granular electron dense deposits. Treatment was initiated with bortezomib, cyclophosphamide and dexamethasone and subsequent stem cell harvest and transplantation. Stem cell harvest was complicated by AKI and urosepsis requiring renal replacement therapy. Repeat biopsy was morphologically similar to the initial biopsy, unfortunately baseline creatinine increased to 5.8mg/dL.

**Conclusions:** HCDD is rare cause of renal dysfunction in plasma cell dyscrasia, which is caused by a deletion of the CH1 domain. Series to date have been limited by small numbers. Reported treatments include bortezomib, cyclophosphamide, dexamethasone, chlorambucil, melphalan and stem cell transplantation.

## PUB325

**A Case of Minimal Change Disease in a Patient with Churg-Strauss Syndrome** Philippe Lachance, David Philibert. *Nephrology, CHUQ, Quebec, Canada.*

**Background:** Renal involvement in Churg-Strauss syndrome (CSS) ranges from 22 to 88%. Nephrotic syndrome is however rarely described and no case of minimal change disease (MCD) has ever been reported. We herein present the case of a young man who presented with this entity.

**Methods:** A 38 year-old male with a past medical history of CSS based on corticosteroid-dependant asthma, migrating pulmonary infiltrates, colitis, rash and peripheral eosinophilia presented to hospital on January 2012 with a two weeks history of leg edema. Laboratory studies revealed slight anemia, marked hypoalbuminemia, normal creatinine and a significant anti-PR3 level of 13.1 . The 24-hr urinary protein excretion was 13.4 g. The sediment revealed red cell casts. Renal biopsy was performed and showed 9 glomeruli with diffuse effacement of foot processes and no other anomaly, which was compatible with MCD. Prednisone 1mg/kg was instituted with improvement of proteinuria and edema but 2 relapses occurred within 6 months as corticosteroids were decreased to 40 mg/d. Cyclophosphamide was given for 3 months and then switched to azathioprine. Remission occurred while on Azathioprine.

**Conclusions:** The most common renal histological finding in CSS is necrotizing crescentic glomerulonephritis. Other forms of renal disease have also been reported including tubulointerstitial nephritis and IgA disease. Nephrotic range proteinuria in the context of CSS is extremely rare and the histopathologic lesion associated with this anomaly is focal and segmental glomerulosclerosis. To our knowledge it is the first case of MCD in the context of CSS reported in the literature. However, we cannot definitively exclude an unsampled FSGS. Regarding treatment, corticosteroids alone were first used as they are the mainstay of treatment in MCD. Because of established steroid dependance, cyclophosphamide and azathioprine were given as is usually done in ANCA associated vasculitis. Steroids were decreased to 10mg/d but to date the patient has not been weaned off. In conclusion, we herein reported the first case of MCD associated with CSS. Dual therapy with prednisone and cyclophosphamide and then Azathioprine seems more effective than prednisone alone at achieving remission in this scenario.

## PUB326

**Invasive Pulmonary Aspergillosis in a Patient with Kidney Transplant** Chadi Saifan, Elie El-Charabaty, Rabih Nasr, Chetana Rondla, Ninad D. Parekh, Suzanne E. El Sayegh. *Medicine, Staten Island Univ Hospital, Staten Island, NY.*

**Background:** Invasive pulmonary aspergillosis is a serious medical condition with a high morbidity and mortality (40%). Risk factors include immunosupprive therapy. While patients with solid organ transplants are at increased risk for such complication, it is thought to be lower in kidney transplant recipients.

**Methods:** A 56 year old female with history of deceased donor kidney transplant 3 months before presented complaining of low GI bleed. Patient's hospital course after her kidney transplant was complicated by an IVC tear and AAA aneurysm s/p repair that led to her graft loss and she was back on hemodialysis. By the time she presented to the hospital, she was still on tacrolimus, mycophenolate mofetil, prednisone, bactrim, and valgancilovir. Her physical exam revealed a BP of 85/50, temp101, with decreased breath sounds. Labs showed a BUN 74, Cr 1.92, K 2.8, WBC 0.96, Hb 10.7, and a platelet count 57,000. She was admitted to the ICU, was given blood transfusion, neupogen and was started on IV pressors. CT chest showed a bilateral basilar consolidation and a right pneumothorax. bronchoalveolar lavage grew fungal elements suggestive of aspergillus spp., and pseudomonas aeruginosa carbapenem sensitive. She was transferred to outside hospital and was treated with IV voriconazole, liposomal amphotericin B and wide spectrum antibiotics, but the patient subsequently expired after two weeks because of septicemia and respiratory failure.

**Conclusions:** Invasive aspergillosis appear to manifest in kidney transplant patients with pulmonary or CNS infection. A retrospective study by Abbott et Al in 2001 found that aspergillus pneumonia is the second cause of fungal infections in 33,479 of kidney transplant patients after candida esophagitis. No randomized clinical trials have been done regarding the treatment of invasive aspergillosis, but voriconazole and amphotericin B have been used in previous cases with relative success. Physicians should be aware of the interactions of the antifungal therapies with calcineurin inhibitors and should adjust the dose based on the creatinine clearance.

## PUB327

**Ifosfamide-Induced Nephrotoxicity: A Reversible Complication in Cancer Patients** Chadi Saifan, Rabih Nasr, Elie El-Charabaty, Ninad D. Parekh, Chetana Rondla, Suzanne E. El Sayegh. *Medicine, Staten Island Univ Hospital.*

**Background:** Ifosfamide is a synthetic analog of cyclophosphamide that is used in combination with other anti-neoplastic agents in the treatment of metastatic germ-cell testicular cancer and some sarcomas. Ifosfamide causes significant nephrotoxicity mainly due to direct tubular injury.

**Methods:** A 65 year old female with previous history of metastatic sarcomatous uterine cancer who was admitted to the hospital. She received ifosfamide chemotherapy 2 days prior. Her physical examination was benign. During the hospital stay she developed electrolyte abnormalities including hypokalemia, hypomagnesemia, and hypophosphatemia (see table) that required repletion. Urine analysis demonstrated increased 24 hours protein (1575mg/24hr) and a magnesium of (164.25 mg/24h) excretion. Phosphorus had normalized by the time of outpatient follow-up (4.1 mg/dl), as well as the serum creatinine. Patient's electrolyte abnormalities were thought to be due to proximal tubular dysfunction secondary to ifosfamide chemotherapy with associated acute kidney injury.

| | BUN | Creatinine | K | Mg | P |
|---|---|---|---|---|---|
| Day1 | 19 | 1.08 | 2.5 | 1.7 | 2.9 |
| Day2 | 20 | 1.16 | 3.4 | 1.9 | 1.8 |
| Day3 | 18 | 1.2 | 3 | 1.9 | N/A |
| Day4 | 14 | 0.96 | 2.8 | 2.2 | 1.9 |
| Day5 | 12 | 0.92 | 4.7 | 1.9 | 1.6 |

**Conclusions:** Nephrotoxicity caused by ifosfamide manifests by onset by one or more of the following tubular dysfunction sign including hypophosphatemia, glucosuria, aminoaciduria, hypokalemia and hypomagnesemia. Ifosfamide therapy can also cause a reduction in GFR which is usually mild unless given in conjunction with another nephrotoxin such as cisplatin. The risk factors for ifosfamide nephrotoxicity are cumulative dose, age under four to five years, and cisplatin therapy. Mesna and N-acetylcysteine, have been evaluated but their efficacy is unproven. For patients receiveing ifosfamide, we recommend telemetry monitoring and continuous intravenous hydration with electrolytes repletion to minimize the side effects. Physicians should be aware of the possible complications due to ifosfamide.

## PUB328

**Thrombotic Microangiopathy (TMA) and Lupus Nephritis: Two Hits, One Organ** Sumaira Talib Shaikh,[1] Ruthanna S. Seidel,[2] Micah R. Chan,[1] Laura J. Maursetter.[1] *[1]Div of Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI; [2]Div of Internal Medicine, Univ of Wisconsin School of Medicine and Public Health, Madison, Wi.*

**Background:** The prevalence of TMA in patients with systemic lupus erythematosus (SLE) is rare (1%). Recognizing TMA in patients with SLE is difficult because these 2 diseases have many overlapping features.

**Methods:** Our 28 year old patient with SLE, who was previously maintained on hydroxychloroquine, presented with confusion, platelet count of 5 K/uL and creatinine of 1.2 mg/dL. Her urinalysis revealed 21-50 RBCs, RBC casts and 3+ proteinuria(UPC 2.88). Antiphospholid antibody syndrome (APS) was ruled out based on negative antiphospholipid antibodies and later negative anticardiolipin antibodies. She was started on antivirals for possible encephalitis as lumbar puncture could not be performed. A lupus flare and TTP remained high on the differential. MRI findings were not consistent with lupus cerebritis and given there were schistocytes on peripheral smear, plasmapheresis was initiated. ADAMTS13 activity results, later confirmed the diagnosis of TTP (less than 5%). Her creatinine continued to rise and peaked at 2 mg/dl. A renal biopsy was performed on day 5 when platelet count improved to 100 K/uL. The biopsy revealed TMA and class III lupus glomerulonephritis. She was started on mycophenolate in addition to her prednisone. Her mental status improved. She was discharged on hospital day 9 with a creatinine of 1.1mg/dL and a platelet count of 182K/uL. At her follow up in the kidney clinic 1 month later, her Cr improved to 0.97, UPC decreased to 0.43, platelet count was 282 K/uL and ADAMTS 13 actvity improved to 96%. She continues to be treated with mycophenolate and hydroxychloroquine for her Lupus nephritis.

**Conclusions:** The incidence of TTP is increased in patients with SLE, although the mechanism of the association is not known. TTP can be difficult to differentiate from APS or a lupus flare. Early diagnosis is vital, as early treatment can be life saving.

**PUB329**

**Culture-Negative Subacute Endocarditis Presenting with Immune Complex Glomerulonephritis and Stroke in the Young** Ekamol Tantisattamo,[1] Royden S. Young,[2] Chuong Dinh.[2] *[1]Renal Div, Emory Univ School of Medicine, Atlanta, GA; [2]Medicine, Univ of Hawaii John A. Burns School of Medicine, Honolulu, HI.*

**Background:** Endocarditis is not only difficult to diagnose, but is responsible for considerable morbidity and mortality if not treated in a timely fashion. Negative blood cultures are not uncommon, and diagnosis is sometimes heavily reliant on a good history and physical examination. Although immunologic and embolic phenomena are rare, these classic clinical findings remain important clues to the diagnosis. We report a case of a man presenting with glomerulonephritis and embolic stroke. Echocardiography and positive blood cultures later confirmed the diagnosis of endocarditis.

**Methods: Case Description:** A 32-year-old man with recent stroke presented with seizures and right arm numbness 3 months ago. He had acute kidney injury (AKI), hematuria, and highly positive serum streptozyme. He had no residual weakness and was discharged with phenytoin. Renal function spontaneously returned to normal. Two months later, hemoglobin dropped to 5.3 g/dl. He had fevers and was empiricallytreated with piperacillin/tazobactam. Blood cultures later grew *Leuconostoc spp.* On the day of admission, he developed seizures, right hemiparesis, and expressive aphasia. Head CT scan revealed a large left MCA stroke. He again had a profound anemia consistent with anemia of chronic disease. He had AKI, positive streptozyme, and hypocomplementemia. Urine exam showed RBC cast and dysmorphic RBC. Therefore, transesophageal echocardiogram was performed and revealed mitral valve vegetations with perivalvular abscesses. He underwent mitral valve replacement. His renal function remained stable but did not return to baseline, and right-sided weakness persisted.

**Conclusions:** Our patient likely had endocarditis since 3 months ago when he developed AKI and positive streptozyme. In addition to embolic stroke, intermittent fevers and glomerulonephritis with elevated streptozyme raise a suspicion for endocarditis. Clinical presentations of endocarditis are varied. Stroke in the young with glomerulonephritis from immunologic phenomenon and unexplained positive streptozyme should prompt a search for endocarditis.

**PUB330**

**Idiopatic Retroperitoneal Fibrosis Successfully Treated with Rituximab** Carmela Pino, Andrea Guarnieri, Serena Bainotti, Elisabetta Moggia, Paola Inguaggiato, Alfonso Pacitti. *Nephrology and Dialysis Unit, S. Croce - Carle Hospital, Cuneo, Italy.*

**Background:** Retroperitoneal fibrosis (RF) is a rare condition characterized by the presence of inflammatory and fibrous retroperitoneal tissue that encases the ureters or abdominal organs. The goals of therapy are to relieve the obstruction caused by fibrosis, stop the progression of the fibrotic process, and to prevent recurrence.

A variety of medical therapies, including glucocorticoids, immunosuppressants, and tamoxifene, used alone or in combination, are available for treatment. The optimal strategy for disease recurrence is unclear. We describe a case of recurrent idiopathic RF successfully treated with anti-CD20 monoclonal antibody Rituximab.

**Methods:** A 44 year old man was admitted to our unit in 01/2008 for obstructive acute renal failure. Abdominal CT showed a RF encasing left kidney (unfunctiong at nuclear imaging), aorta and right ureter. A ureteral stent was positioned in right ureter resolving hydronephrosis with normalization of renal function. Diagnosis of RF was made by laparoscopic biopsy. Since 06/2008 to 06/2009 he was treated with prednisone alone (initial dose 1 mg/Kg/day reducing to 5 mg/day) with partial response (less but still present fibrosis around right ureter) at abdominal CT and positron emission tomography (PET/CT). Since 06/2010 to 10/2011 we added full dose of methotexate (15 mg/week) without response. Since 10/2011 to 01/2013 treatment was shifted to tamoxifen 10 mg bid plus prednisone 5 mg/day without response again. During this period creatinine was in normal range and ureteral stent was changed every six months. In 01/2013 (with PET/CT positive) we treated with a course of Rituximab (375 mg/mq every week for four doses). In 05/2013 PET/CT was negative and ureteral stent was removed.

**Conclusions:** RF is a rare condition usually responsive to steroid treatment but some patient may be steroid-refractory; other immunosuppressants are not of proven superiority and their effectiveness in unknown. Because B cells infiltrate lesions anti-CD20 antibody may be a therapeutical option: our patient affected by RF non responsive to steroids and second and third line therapy showed a complete response with rituximab.

**PUB331**

**Effect or Side Effect** Maria Saleem Khan, Rakesh Kilari. *Medicine, Loyola Univ Medical Center, Chicago, IL.*

**Background:** Atypical hemolytic-uremic syndrome(aHUS) is a rare and life threatening complement mediated disorder characterized by nonimmune hemolytic anemia, thrombocytopenia and renal impairment. In late 2011, eculizumab, a monoclonal anti-C5 antibody was approved by the FDA for aHUS. We describe a case of aHUS treated with eculizumab, but this could not be continued due to side effects.

**Methods:** A 51year old female with history of HTN presented with minimal urine output for 2 days. She also had several episodes of vomiting and diarrhea which had resolved few days prior to presentation. Her physical exam was unremarkable. Serum creatinine was 8.6 mg/dl. FeNa 3.9%, FeUrea 36.8%. Random prot/Cr ratio was 1.1 g/g. LDH was 2140 and haptoglobin <15. Her initial hemoglobin was 11.8g/dl, but was down trending, and was 7.3g/dl on hospital day 3. DAT-Coombs test was negative. Initial Platelet count was 60,000/UL. She was noted to have significant number of schistocytes on peripheral smear and concern was raised for hemolytic uremic syndrome (HUS). There was no improvement in renal function or Urine output with IV fluids. Renal biopsy confirmed thrombotic microangiopathic changes, with some features of acute tubular necrosis as well. Stool was negative for shigatoxin/O157:H7 genotype. ADAMTS13 activity was within normal limits. Pt was initiated on dialysis and plasmapheresis, with some improvement in urine output, stabilization of hemoglobin and resolution of thrombocytopenia. Several weeks after discharge, renal function improved, but she continued to have modest evidence of hemolysis, and was started on eculizumab, with positive response, but had to be stopped after few months, due to liver enzyme abnormalities, weight gain and fatigue.

**Conclusions:** The high morbidity and mortality of aHUS indicates a severe and unmet medical need. Eculizumab which is the only treatment to offer a highly specific complement-targeted therapeutic option for patients with aHUS has revolutionized the treatment approach. However, treatment had to be stopped in our patient due to intolerance. Although this novel drug has shown early promising results, not every patient may be able to be tolerate it. More research is needed to help develop additional treatment options for aHUS.

**PUB332**

**Tenofovir Induced Acute Kidney Injury in a Patient with Nephrotic-Range Proteinuria** Omid Bakhtar, Nduka-obi Ossai, Machaiah M. Madhrira. *Dept of Nephrology, Univ of Arizona, Tucson, AZ.*

**Background:** Tenofovir induced acute kidney injury has been reported, in association with proximal tubular dysfunction, osteomalacia, and non-nephrotic proteinuria. Commonly seen risk factors include preexisting renal insufficiency, older age, and concomitant use of protease inhibitors. However, we report a case of tenofovir induced nephrotoxicity presenting with nephrotic-range proteinuria that successfully resolved after discontinuation of the offending drug.

**Methods:** A 46-year-old white male with HIV diagnosed in 2002 (CD4 1297 and undetectable viral load) currently on Atripla with Stage 2/3 CKD due to chronic NSAIDS presents for evaluation of an increase in creatinine from 1.2mg/dL to 1.6mg/dL in a 3 month period. On physical examination, BP is 111/77, mucous membranes moist and no peripheral edema. Laboratory results were significant for creatinine of 1.6mg/dL, eGFR 57, urine sodium < 20, albumin/creatinine 841mg/g, and protein to creatinine ratio of 3.09 g/g. Urinalysis showed glucosuria with normal serum glucose of 102 and urine sediment demonstrated granular casts 4/lpf, tubular epithelial cells, oval fat bodies, and no dysmorphic RBCs. SPEP, UPEP, C3/4, ANCA, RF, antiGBMAb, ANA, antidsDNAAb, RPR, and hepatitis profile werenegative. A high fractional excretion of phosphate and uric acid, hypophosphatemia, hypouricosemia, and aminoacidouria were also demonstrated. He was subsequently scheduled for a renal biopsy, which demonstrated ATN possibly secondary to tenofovir exposure. After withdrawal of tenofovir, albumin/creatinine decreased to 126 mg/g and protein to creatinine ratio decreased to 0.5 g/g, serum creatinine was 0.8mg/dL and eGFR >60.

**Conclusions:** This case provides organization of evidence of a rare case of tenofovir induced nephrotoxicity presenting with nephrotic-range proteinuria. In the light of this case, it is important to consider this unique presentation.

**PUB333**

**Warfarin-Induced Calciphylaxis** Chadi Saifan, Elie El-Charabaty, Chetana Rondla, Ninad D. Parekh, Suzanne E. El Sayegh. *Staten Island Univ Hospital.*

**Background:** Calciphylaxis has been a challenging complication of ESRD with unknown underlying mechanism. Several risk factors were identified such as hyperphosphatemia, hypercalemia, hyperparthyoidism, low serum albumin levels, history of warfarin therapy.

**Methods:** A 56 y/o female with DMII, morbid obesity (BMI =48kg/m$^2$), DVT and PE on warfarin for 3 years, chronic kidney disease stage IV and peripheral vascular disease presented with s/p fall and worsening AKI (baseline creatinine 2.42). The patient had drop in hemoglobin, and warfarin was held for 4 days for suspicion of blood loss, and then restarted on day 6 (INR=1.6) after placement of Ash Catheter and institution of dialysis. She developed a right foot blister on day 7 and bilateral thighs blisters on day 10.

Labs were Ca 7.4 mg/dL-Albumin 2.9 g/dL, IP 10.3 mg/dL, creatinine 7.68 mg/dL BUN 98 mg/dL. The skin became mottled and the lesions had worsened progressively over 3 days to necrotic eschar. Extensive workup for vasculitis was negative. Patient had a right lower extremity eschar lesion of 75 x 20 cm, and a left lower extremity 75x20 cm and abdominal lesion of 10x5x5. Patient was taken in charge by the burn specialist, underwent skin debridement and wound care but failed all resuscitation efforts on d 42. Skin biopsy specimen showed a portion of skin and subcutaenous tissue with diffuse necrosis. Multiple small arteries showing calcification of the tunica media. This pattern is strongly suggestive of calciphylaxis.

**Conclusions:** We hypothesise that the reintroduction of warfarin in patients with ESRD induces an imbalance favoring calcification in the vessels in a previously sensitized conditions, which set our patient up for a catastrophic acceleration of vascular calcification. Understanding the pathophysiology of this process will certainly enhance our treatment approach and reduce the morbidity and mortality of this devastating condition.

## PUB334

**Acute Kidney Injury with the Histologic Diagnosis of Osmotic Nephrosis without an Identifiable Cause** Jun Sohn,[1] Ashok P. Chaudhari,[1] Jinil Yoo.[2] *[1]Nephrology, Metropolitan Hospital, New York, NY; [2]Nephrology, Montefiore Medical Center - Wakefield Campus, Bronx, NY.*

**Background:** Osmotic nephrosis is a histologic pattern of acute tubular injury, characterized by marked vacuolization and swelling of renal tubular cells, mostly related to IV infusion of non-metabolizable macromolecules such as hydroxyethyl starch or IV immunoglobulin. We present a case of acute kidney injury (AKI) with the histologic diagnosis of osmotic nephrosis without an identifiable cause.

**Methods:** A 74 year old man with type 2 DM and hypertension was admitted with pneumonia, and treated initially with IV ceftriaxone and oral doxycycline, then IV ampicillin/sulbactam. During the 10-day's hospitalization, he did not receive other IV medications, IV colloids, or IV contrast, and was discharged with serum creatinine (Cr) 1.2 mg/dL. 4 days later, he was readmitted because of oliguric AKI (Cr 9 mg/dL). He denied taking any unusual foods, solutions, or medicines except his regular glipizide, metformin, and lisinopril. Physical examinations on admission revealed BP 125/65 mmHg, no edema. UA was positive for trace protein, RBC 2~4/HPF, and coarse granular casts. Serologic studies and kidney sonogram were not remarkable. The kidney biopsy revealed prominent swelling and vacuolization of proximal tubular cells without any remarkable glomerular changes, imparting "osmotic nephrosis". Cr plateaued to 11.2mg/dL, then started to improve only with gentle IV hydration to 1.7mg/dL on discharge.

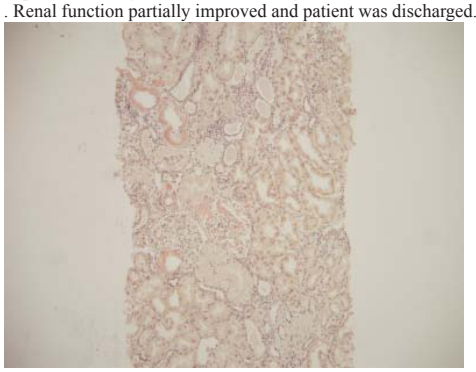
**Conclusions:** Our patient developed oliguric AKI with histologic features of osmotic nephrosis just after being discharged from the hospital, without receiving any known non-metabolizable macromolecules or substances. Histologic "look alikes" to osmotic nephrosis have been described in calcineurin-inhibitor toxicity, foam cells in lipid storage, hypokalemia, ischemic tubular injury, or ethylene glycol intoxication. However the histologic findings of our patient conformed to the description of a classical osmotic nephrosis, but without an identifiable case.

## PUB335

**Muckle-Wells Syndrome and Secondary Amyloidosis (AA) with Nephropathy** Tariq Javed, Shirisha Bodana, Catherine G. Staffeld-Coit, Abdul Moiz. *Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

**Background:** Incidence of AA amyloidosis in Muckle-Wells syndrome is 25 percent. Muckle-Wells syndrome consists of periodic fever, urticaria, arthralgia and deafness. Muckle-Wells syndrome is transmitted by an autosomal dominant trait. In clinical practice, renal failure due to amyloidosis and Muckle-Wells syndrome is rare and should be considered as differential diagnosis in difficult cases of renal failure.

**Methods:** A 75 years old white male with PMH of Arthritis, Skin rash presented to ER with nausea, vomiting and abdominal pain for 3 weeks. Review of system is positive for joint pain, skin rash from childhood, and hearing loss for couple of years. Family history is positive for same symptoms of arthritis and skin rash in a daughter and a son. Physical exam shows normal vital signs, short stature, hearing loss, left wrist swelling and tenderness and diffuse skin rash. Initial labaroratory work up shows CBC with white blood cells 10.18, hemoglobin 10.6, platelets 298, chemistry shows sodium 142, k 4.8, Cl 111, bicarb 20, BUN 44, creatinine 2.8, calcium 8.8, albumin 1.7. Creatinine on 2/26/2012 was 0.9 and on 7/26/12 was 2.9. Urine collection for 24 hours showed proteinuria with 6.3 gm per day. Renal ultrasound was unremarkable. Renal biopsy showed findings AA amyloidosis with mild chronicity. Rheumatological work up was negative. He was clinically diagnosed with Muckle-Wells syndrome because of episodic skin rash, arthralgias and generalized pain, fatigue, intermittent fever, late-onset sensorineural hearing loss. Genetics Consult was requested, they agreed with clinical diagnosis and they recommended NLRP3 gene testing . Renal function partially improved and patient was discharged.



**Conclusions:** Renal failure due to amyloidosis secondary to Muckle-Wells syndrome is rare and should be considered as differential diagnosis in difficult cases of renal failure.

## PUB336

**Transient False Positive Hepatitis B Surface Antigenemia following Hepatitis B Vaccine (Recombinant) Administration** Timothy A. Williams,[1] Cynthia F. Frazier,[2] Daniel F. Balkovetz.[1,2,3] *[1]Medicine and Nephrology, Univ of Alabama at Birmingham, Birmingham, AL; [2]Dialysis, Birmingham VA Medical Center, Birmingham, AL; [3]Medicine and Nephrology, Birmingham VA Medical Center and Univ of Alabama at Birmingham, Birmingham, AL.*

**Background:** Hepatitis B vaccination is mandatory for all hepatitis B surface antigen (HBsAg)-negative patients on hemodialysis.

**Methods:** A case of transient HBsAg positivity was detected in a previously HBsAg negative hemodialysis patient 2 days after the administration of recombinant hepatitis B vaccine (Engerix-Bä). The patient was placed on hemodialysis isolation while further confirmatory testing was conducted. The hemodialysis unit's infection control practices were reviewed and the patient and family members were interviewed for possible exposure and risk factors. The initial positive HBsAg test result caused concern and anxiety for the patient, family, and staff. Confirmatory testing including a repeat HBsAg and hepatitis viral DNA was negative and indicated the earlier HBsAg result was false positive. A review of the literature found case reports in 1996 indicating transient HBsAg positivity (lasting less than 21 days) following administration of the hepatitis B vaccine. The University of Iowa also reported three cases of false positive HBsAg tests due to recent hepatitis B vaccine administration. The possibility of false positive HBsAg testing following administration of the hepatitis B vaccine is not mentioned in the vaccine package insert. Further review found evidence to support the practice that HBsAg should not be tested within ~30 days of administration of the hepatitis B vaccine.

**Conclusions:** This case is presented to increase awareness of this phenomenon to health care providers. To prevent this phenomenon, HBsAg testing should be deferred until approximately 30 days after administration of the recombinant hepatitis B vaccine.

*Funding:* Veterans Affairs Support

## PUB337

**A Grave Case of Acute Weakness: Thyrotoxic Hypokalemic Periodic Paralysis** Mamta Shah, Rahul Mutneja. *Internal Medicine, Univ of Connecticut, Farmington, CT.*

**Background:** Thyrotoxic hypokalemic periodic paralysis (THPP) is a rare complication of thyrotoxicosis. Usually associated with Grave's disease, it can also be seen in other forms of thyrotoxicosis like toxic nodular goiter, drug induced, use of thyroxine containing weight loss supplements and thyroiditis. Common in males (male to female ratio of 20:1), the typical presentation includes recurrent episodes of paresis, in the presence of low potassium levels usually precipitated by heavy meals, stress or strenuous exercise. Patients may also present with life threatening arrthymias secondary to hypokalemia.

**Methods:** A 31 year old Hispanic male with no significant past medical history presented with acute onset bilateral lower extremity weakness. He was unable to get out of bed and had no sensation in his legs. Patient gave history of strenuous exercise and lower extremity cramps the day prior. In the emergency room, patient was anxious, tachycardic and exam was significant for 2/5 strength in both lower extremities proximally and 4/5 distally, 1+ reflexes and inability to walk. He was found to have potassium of 1.7mEq/L. EKG showed sinus tachycardia. He was given 80 mEq's of potassium with subsequent improvement of symptoms. Further work up showed TSH of 0.04Uu/ml, free T4 of 4.54pg/ml, free T3 of 10.2pg/ml. Thyroglobulin antibody was negative. A thyroid uptake scan showed increased uptake of 54% and findings consistent with Grave's disease. Patient was managed with propranolol and propylthiouracil and he returned to full strength in 48 hours. He subsequently underwent radioactive iodine ablation, following which he was discharged to home with follow up.

**Conclusions:** THPP is an important differential of acute weakness and should be kept in mind for all patients presenting with a similar picture. Recognition of this is important since treatment is easy and provides quick and early relief of symptoms. Almost all patients show response to potassium replacement and management of thyrotoxicosis with non selective beta blockers like propranolol and anti thyroid agents. Definitive treatment in the form of radioactive iodine or thyroidectomy should be considered especially in cases refractory to medical management.

## PUB338

**Successful Treatment of Telaprevir in Saudi Patient with Hepatitis C on Hemodialysis** Mamdouh Abdulghafour Nada. *Nephrology-Hepatology, Prince Sultan Military Medical City, Riydh, Saudi Arabia.*

**Background:** Telaprevir is a hepatitis C vInterferon remains contraindicated post-renal transplant; therefore, it is recommended to treat HCV infection in patients with concomitant kidney disease prior to kidney transplantationirus protease inhibitor that is both a substrate and an inhibitor of CYP3A.

**Methods:** Our patient is a 44 year old male Saudi with ESRD Secondary to Chronic Pyelonephritis on Hemodialysis since 1990. Status post living non-related kidney transplant in India which survived for 4 years. Another attempt for a transplant was a cadaveric renal transplant which was removed 2 weeks after transplantation due to perinephric hematoma and renal vein thrombosis. The patient had previously received treatment for the hepatitis by taking PEG-IFN as a single treatment, but failed to respond. Another attempt to cure him was done by administering a dual medication of PEG-IF with Ribavirin. According to the kidney biopsy, the patient was considered to have grade 2 chronic hepatitis stage 2 associated with HCV. Abdominal ultrasound was unremarkable for the liver. Hepatitis C virus PCR (HCV viral load) was 197,731 IU/ml, genotype 1A. The patient had a

compensated liver function with normal liver enzymes. So the patient was considered to be a non - responder with a non - cirrhotic liver genotype 1. Therefore the team decided that this patient fulfilled the criteria to start the triple medication for 12 weeks as Telaprevir 750 mg every 8 hrs in combination with PEG-IFN alpha 130 mcg once weekly plus Ribavirin 200 mg three times per week. Then we administered dual medication for 36 weeks as PEG-IFN alpha plus Ribavirin.

**Results:** After 12 weeks of triple combination therapy, the patient was considered a responder (he achieved undetectable HCV RNA at weeks 4 and 12) and the treatment still ongoing.

**Conclusions:** The team concluded that triple therapy with a first generation protease inhibitor could be the new standard for the treatment of HCV patients with ESRD on hemodialysis. To confirm our findings, this study must be performed on a larger scale to clarify the efficacy of this therapy.

## PUB339

**Tendon Rupture and Calcification: Consequence of Tertiary Hyperparathyroidism in CKD 5** Ankur Sharma, Andrew I. Chin, Shubha Ananthakrishnan. *Dept of Internal Medicine, Nephrology Div, Univ of California, Davis, Sacramento, CA.*

**Background:** Tendon ruptures usually occur in athletic patients aged below 40 years, much more following sport injuries. Several systemic diseases predispose patients to spontaneous tendon rupture and calcification such as CKD5d, hyperparathyroidism, diabetes, rheumatoid arthritis, and SLE. Spontaneous rupture of quadriceps or patellar tendons represents a rare entity.

**Methods:** We present 2 cases of CKD5 patients with complications from renal osteodystrophy. Case 1, is a 26 year old man with CKD5resumed to be secondary to neonatal injury who started Peritoneal dialysis at age 8, eventually transplanted from a living donor. He lost the allograft due to medication noncompliance and started hemodialysis at age 21. He developed progressive pain in his ankles and difficulty in ambulation. A CT scan revealed heavily calcified achilles tendon bilaterally. He had high PTH (peak 1593pg/ml) for 5 years. The patient underwent an elective tendon transfer procedure bilaterally with successful outcome. Case2 is a 27 year old man with CKD5 presumed due to congenital renal malformation who received a pre-emptive transplant from a living donor at 6 years. He lost the allograft due to medication noncompliance at age 23 and was started on PD. He has high PTH for 6 years (peaked at 1688pg/ml). He presented to the hospital with bilateral knee pain which began suddenly after he tried to sit up and heard a loud "pop" and was unable to bear weight. MRI showed near complete tear of the quadriceps tendons bilaterally which was repaired and he subsequently underwent elective parathyroidectomy 4 weeks later.

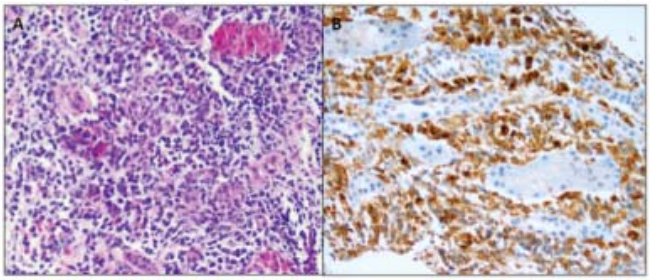
**Conclusions:** In absence of trauma, generally an underlying condition leads to abnormal tendons that rupture under normal stress. Risk factors include Diabetes, hyperparathyroidism, chronic renal failure, obesity, SLE, steroid use and gout. Medline review by Mrugeshlumar of 66 patients showed that younger patients were most likely to have CKD5 (43%) and hyperparathyroidism. In the review, only the duration CKD and duration of dialysis was related with spontaneous rupture. Both of our patients had CKD for over 15 years with dialysis for more than 4 years.

## PUB340

**Primary Renal Manifestation of Acute Myeloid Leukemia: A Case Report** Sana Waheed,[1] Duvuru Geetha,[1] Naima Carter-Monroe,[2] Lois J. Arend,[2] Satish Shanbhag.[1] *[1]Dept of Medicine, Johns Hopkins Univ, Baltimore, MD; [2]Dept of Pathology, Johns Hopkins Univ, Baltimore, MD.*

**Background:** Kidneys can be a site of extra medullary involvement in leukemias, typically occurring late in the disease course. We describe a case of acute myeloid leukemia (AML) with renal involvement as a presenting feature.

**Methods:** 62-year-old female with history of Diabetes Mellitus, hypertension and breast cancer s/p mastectomy had new onset anemia, thrombocytopenia and acute renal failure. She had recently taken ibuprofen and doubled her dose of losartan. Her physical exam was notable for a fine maculopapular rash over bilateral knees. Labs were significant for sodium 134 mEq/L, potassium 4.8 mEq/L, BUN 46mg/dL, serum creatinine 3.6mg/dL (baseline 0.9mg/dl),hemoglobin 7.7g/dL,platelets 81000/mm$^3$ and LDH 1234 IU/L. Proteinuria (2.53 g/g of creatinine) was present on urinalysis without hematuria or pyuria.Renal ultrasound showed echogenic 13 cm kidneys bilaterally. Renal biopsy revealed extensive interstitial infiltration by atypical myelocytic cells in a background of severe acute tubular injury.



After a dry tap on a bone marrow biopsy, a core specimen showed focal involvement by similar atypical myeloid cells and patient was started on chemotherapy for AML. Her kidney function improved to baseline without needing renal replacement therapy.

**Conclusions:** Renal involvement including dense infiltration of kidneys (often bilateral involving both cortex and medulla) is seen in up to 34% of patients diagnosed with AML, acute lymphocytic leukemia and non-Hodgkin's lymphoma. Most cases are seen in patients after a diagnosis of AML has been confirmed in contrast to our case where dense infiltration of the kidneys with myeloid blasts was noted first leading to bone marrow biopsy revealing focal bone marrow involvement.

## PUB341

**A Case of IgA1-κ Monoclonal Immunoglobulin Deposition Disease in Alcoholic Liver Cirrhosis** Naoko Nakaosa, Akira Fukui, Nobuo Tsuboi, Kentaro Koike, Yoichi Miyazaki, Makoto Ogura, Tetsuya Kawamura, Takashi Yokoo. *Div of Kidney and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** Hepatic glomerulosclerosis, also termed hepatic IgA nephropathy, typically presents with chronic mild alterations in glomeruli. A novel form of proliferative glomerulonephritis related to glomerular deposition of monoclonal IgG mimicking immune-complex glomerulonephritis, termed proliferative glomerulonephritis with monoclonal IgG deposits (PGNMID), is recently described.

**Methods:** The patient was a 60-year-old male with a medical history of alcoholic liver cirrhosis since he was 50 years old. He had an episode of hepatic encephalopathy 4 years before admission, when his serum creatinine (Cr) level was within normal range. On admission, the patient showed leg edema and his serum Cr level was 1.69mg/dl. He presented nephrotic syndrome with urinary protein excretion of 4.7g/day and serum albumin level of 2.3mg/dl, and the urinalysis showed microscopic hematuria. Serum IgA level was 507mg/dl, and serum complement levels were normal. Serum anti-neutrophil cytoplasmic antibodies, anti-nuclear antibodies, cryoglobulins, and hepatitis virus B and C were all negative. Serum immunoelectrophoresis showed no evident monoclonal protein. Renal biopsy showed diffuse mesangial proliferation together with doubling of the glomerular basement membrane. Cellular crescents were also observed in about 20% of the glomeruli. Immunofluorescence (IF) showed granular deposition of IgA and C3 along the glomerular capillary walls. IF findings of IgA subtypes and light chains showed only positive for IgA1 and κ. Granular electron dense deposits were observed in the subendothelial areas. These findings led us to the diagnosis of monoclonal IgA1-κ deposition disease.

**Conclusions:** The clinicopathological features of our case are compatible with those of PGNMID. In this case, monoclonal IgA1-κ deposits may be involved in the formation of acute glomerular lesions which is atypical in hepatic glomerulosclerosis. Lastly, our case suggests an importance of IF assays for immunoglobulin subtypes and light chains in the differential diagnosis of glomerular immunoglobulin deposition diseases.

## PUB342

**Nontuberculous Mycobacterial Exit-Site Infection in Patients on Peritoneal Dialysis: Report of Three Cases** Kana Asari, Nanae Matsuo, Masatsugu Nakao, Yudo Tanno, Izumi Yamamoto, Ichiro Ohkido, Keitaro Yokoyama, Tatsuo Hosoya, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Japan.*

**Background:** Nontuberculous mycobacteria (NTM) are an uncommon cause of peritoneal dialysis(PD)-associated infections. A standard diagnostic procedure and treatment regimen for NTM infection have not yet been established. We report here three different cases of NTM exit-site infections (ESI) in PD patients.

**Methods:** [Case 1] A 42-year-old female on PD due to IgA nephropathy, presented with refractory ESI extend beyond the external cuff. The catheter was removed and the new one was placed at the opposite site simultaneously. Nine days after the operation, she presented peritonitis. The catheter was removed immediately. From the catheter culture at the time of operation, the acid-fast bacillus smear was positive, and *M. abscessus* was identified. She was treated with Imipenem/Cilastatin(IPM/CS), Amikacin(AMK) and Clarithromycin(CAM), and her condition impoved rapidly. [Case 2] A 75-year-old male on PD due to nephrosclerosis, presented with refractory tunnel infection beyond the external cuff. The exit-site culture grew a NTM, identified as *M.abscessus*. The catheter was removed, and he temporarily swiched to hemodialysis. He continued undergoing IPM/CS, AMK, CAM therapy and cleansing open wound therapy. After we confirmed that the wound culture was negative for 4 weeks after the PD catheter removal, the catheter was replaced again. He remains on PD with no evidence of tunnel infection or peritonitis. [Case 3] A 70-year-old male on PD due to nephrosclerosis, developed tunnel infection due to NTM, which did not extend beyond the external cuff. Partial catheter reimplantation was perfomed and no relapse have been observed.

**Conclusions:** Each of the 3 cases that we present here had different process of treatment. These cases are highly suggestive to consider timing of surgical treatment and what surgery is appropriate for each patient. Based on our experience and other cases reported previously, we discuss appropriate diagnosis and treatment strategies for the management of PD-associated NTM infections.

## PUB343

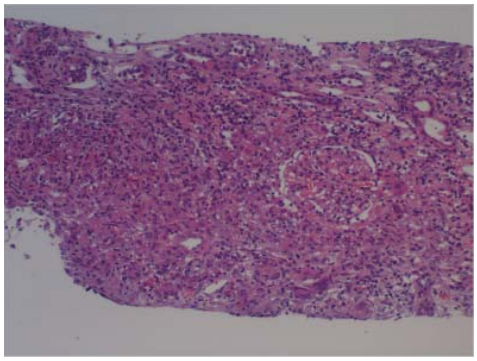
**Sarcoidosis Manifesting as Acute Kidney Injury** Mandeep Singh, Roberto L. Collazo, Sreevalli Pariti. *Methodist Dallas Medical Center.*

**Background:** Granulomatous interstitial nephritis is a rare manifestation of Sarcoidosis. We report a case of Sarcoidsis presenting as acute kidney injury.

**Methods:** A 26 y/o male with past medical history of pancytopenia and hepatosplenomegaly was admitted for evaluation of acute kidney injury.On initial

evaluation he had sub-nephrotic range proteinuria.Worsening of his renal function prompted kidney biopsy which showed granulomatous interstitial nephritis with focal acute tubular injury,classic noncaseating granulomas.Patient was started on pulse dose steroids with dramatic improvement in his renal function.ACE levels were normal,CT scan of chest did not reveal any hilar adenopathy. This case was a rare presentation of Sarcoidosis manifestion as acute kidney injury in the absence of overt systemic sarcoidosis,normal levels of ACE and dramatic response to steroid therapy.

**Conclusions:**



## PUB344

**Emphysematous Pyelonephritis after Plasmapheresis in a Renal Transplant Patient** Rapeepat Lekkham, Rasib Raja. *Medicine, Albert Einstein Medical Center, Philadelphia, PA.*

**Background:** Emphysematous pyelonephritis(EPN) is a rare but devastating complication after renal transplantation. It carries the risk of graft loss and is associated with a high mortality. The majority of cases reported thus far have undergone graft nephrectomy. Here we present a case of EPN in a renal allograft after plasmapheresis for recurrent FSGS that was successfully treated conservatively.

**Methods:** A 49-year-old women received a second living-related renal allograft from her son in April 2009. Her first transplanted kidney from deceased donor in 2002 failed from acute rejection and required allograft nephrectomy. Her native kidney disease was FSGS. 3 weeks prior to the admission, she developed acute generalized edema with nephrotic range proteinuria with allograft dysfunction. Plasmapheresis was initiated after her allograft biopsy confirmed diagnosis of recurrent FSGS. After the 9th sessions, she developed fever, tachycardia, leukocytosis and thrombocytopenia. CT scan of the abdomen revealed focal medial enlargement of the transplant kidney, with a moderate sized area of gas-filled collection in the parenchymal with small subcapsular gas. The possible emergent need for transplant nephrectomy was discussed, but she decided to preserve the graft with medical management. Urgent intervention with percutaneous abscess drainage and empiric broad-spectrum antibiotic coverage with IV aztreonam and tobramycin (changed to ciprofloxacin later on) helped stabilize the patient's condition. Mycophenolate mofetil and tacrolimus were held except for low dose prednisone. The urine culture, fluid from the drain and blood culture all grew Klebsiella pneumoniae. The drain was removed on day 23rd, the antibiotic was continued for total of 14days. Repeat U/S 1 month later showed normal renal allograft parenchyma and collecting system, her allograft function was back to her baseline as well.

**Conclusions:** Plasmapheresis in renal transplant patient may increase risk of EPN. However, timely diagnosis and early conservative intervention with aggressive intravenous antibiotics and percutaneous drainage will help in preservation of renal allograft and may be able to avoid graft nephrectomy like in our patient.

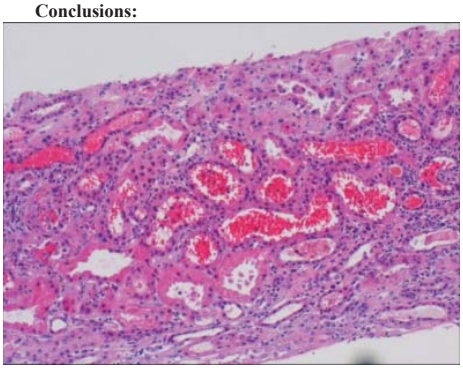
## PUB345

**A Rare Case of Anti GBM Disease in Alpha 1 Antitrypsin Deficiency** Mandeep Singh,[1] Roberto L. Collazo,[2] Sreevalli Pariti.[3] *[1]Nephrology, Methodist Dallas Medical Center, Dallas, TX; [2]Nephrology, Methodist Dallas Medical Center, Dallas, TX; [3]Nephrology, Methodist Dallas Medical Center, Dallas, TX.*

**Background:** We report a rare case of Anti GBM disease manifesting as acute kidney injury in a patient with history of liver cirrhosis secondary to alpha 1 antitrypsin deficiency.

**Methods:** A 61 y/o female with past medical history of liver cirrhosis due to alpha 1 antitrypsin deficiency admitted to the hospital for acute kidney injury with elevated BUN and ceatinine found on outpatient labs.Patient had significant eosinophiluria and peripheral eosinophilia on admission.Her worsening renal function prompted kidney biopsy which showed acute interstitisl nephritis,tubular luminal hemorrhage with glomerular capillary linear IgG deposition.Patient started on i.v steroids for acute interstistisl nephritis but her renal function kept deteriorating and further investigations showed extremely high anti GBM antibodies levels.This was a rare case of non crescentic anti GBM disease in a patient with alpha 1 antitrypsin deficiency.

**Conclusions:**



## PUB346

**Nephritic Syndrome due to Mixed Cryoglobulinemia Non Hepatitis C-Related: Report of 3 Cases** Carla Queiroz Neves, Alline S. A. Oliveira, Camila Barbosa L. Oliveira, Luis H.B.C. Sette, Gisele Vajgel Fernandes, Maria Alina G.M. Cavalcante, Lucila Maria Valente. *Serviço de Nefrologia, Universidade Federal de Pernambuco, Recife, Pernambuco, Brazil.*

**Background:** Mixed Cryoglobulinemia is a rare cause of glomerular disease and Membranoproliferative Glomerulonephritis (MPGN) is the most frequent histological finding. The association with hepatitis C (HCV) infection is approximately 90-100% of the patients.

**Methods:** We retrospectively analyzed 3 patients with Nephritic Syndrome (NS), positive serum cryoglobulins, negative serology and viral load by polymerase chain reaction (PCR) for HCV, between 2011 and 2013. Epidemiology, clinical manifestations and outcomes are described in table 1.

| | Patient 1 | Patient 2 | Patient 3 |
|---|---|---|---|
| Age | 36 | 64 | 47 |
| Sex | female | female | male |
| Nephrotic syndrome | yes | no | yes |
| Hematuria | yes | yes | yes |
| Proteinuria (g/day) | 4.0 | 0.8 | 9.8 |
| Serum Creatinine (mg/dL) | 0.6 | 1.1 | 0.8 |
| C3 (90-180) (mg/dL) | 81 | 66 | 108 |
| C4 (10-40) (mg/dL) | 0 | 3 | 1 |
| FAN | neg | 1:320 | neg |
| ANTI-HCV (ELISA) | neg | neg | neg |
| PCR HCV-RNA | neg | neg | neg |
| HBV (ELISA) | neg | neg | neg |
| HIV (ELISA) | neg | neg | neg |
| Serum cryoglobulins | pos | pos | pos |
| Malignancy | mantle cell lymphoma | no | no |
| Renal Biopsy | MPGN | MPGN | no |
| Steroids | yes | yes | yes |
| Cyclophosphamide | yes | yes | yes |
| Riruximab | yes | yes | no |
| Plasmapheresis | yes | yes | yes |
| Follow-up time (months) | 20 | 17 | 10 |
| Dialysis | yes | yes | yes |
| Time to start dialysis (months) | 5 | 11 | 2 |
| Outcome | death | death | ESRD |

All patients underwent metilprednisolone pulse, followed by prednisone 1mg/kg and cyclophosphamide (CYC) pulse and plasmapheresis. Two patients underwent rituximab therapy, one due to lymphoma treatment and the other to CYC toxicity.

**Conclusions:** We described 3 cases of mixed cryoglobulinemia non-HCV related associated with NS. Prognosis was unfavorable and all patients required dialysis. According to literature, non-infectious cryoglobulinemia with renal involvement carries a poor prognosis despite treatment instituted as shown in this series of cases.

## PUB347

**Atypical Presentation and Evolution of a Single Case of Goodpasture Syndrome** Tiago Assis Pereira, Jorge Dickson, Jose Diogo Barata. *Nephrology Dept, Hospital Santa Cruz, Lisbon, Portugal.*

**Background:** Goodpasture Syndrome (GPS) is a clinical syndrome characterized by rapidly progressive glomerulonephritis and hemorrhagic pulmonary involvement. There is clinical consensus for aggressive treatment with cyclophosphamide (CF), high dose corticosteroids and coadjuvant plasmapheresis in most cases. Other immunosuppressive agents have been used occasionally, in specific or refractory cases.

**Methods:** We report a 25-year-old white man, smoker, who presented with macroscopic haematuria and haemoptysis. On admission, nephrotic syndrome was diagnosed and further investigation was initiated. The investigation came up positive only for the presence of anti-glomerular basement membrane (GBM) antibodies and renal biopsy was compatible with anti-GBM disease. Accordingly, CF, corticotherapy and plasmapheresis was initiated, with partial recovery and negativation of anti-GBM antibodies. Patient was discharged on oral prednisone and CF therapy. One week later, a relapse of macroscopic haematuria, nephrotic range proteinuria and pulmonary radiologic findings; the laboratory workout unveiled for the first time disturbed renal function. Facing a very early clinical relapse under aggressive

imunosupression, the initial diagnosis was challenged and laboratorial and histological study was repeated: there was a re-positivation of anti-GBM antibodies and crescentic glomerular findings on biopsy. The initial diagnosis was reaffirmed, plasmapheresis was resumed and Mofetil Mycophenolate (MMF) was replaced for CF, with good clinical and laboratorial response. MMF was maintained for 2 years and then weaned. With 8 years of follow-up, the patient has remained asymptomatic, renal function and nephrotic syndrome fully recovered.

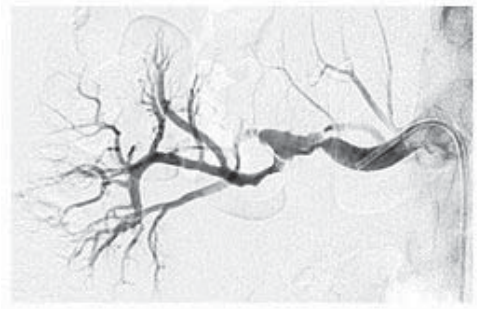
**Conclusions:** This case of GPS is atypical both for its nephrotic presentation and successful response to MMF, after relapse under CF. To the best of our knowledge, only two cases of successful therapy with MMF after failure of CF were reported. Based on our findings, GPS should be considered in the differential diagnosis of nephrotic syndrome with pulmonary involvement and additional study is needed to validate MMF as a therapeutic option.

## PUB348

**Delayed Intervention in Acute Renovascular Thromboembolic Disease Could Salvage Renal Function** Suyash Sharma, Hemant J. Mehta, Anup Chaudhari. *Nephrology, Lilavati Hospital, Mumbai, Maharashtra, India.*

**Background:** An acute renal arterial occlusion can happen due to in-situ thrombus or embolism. Unless immediately treated, it can lead to renal infarction. We are presenting a case where there was a delay in diagnosis, still renal function could be salvaged partially with prompt intervention.

**Methods:** 40/M, Non-smoker on routine health check up 7 years ago has BP of 130/94 mm Hg and S. Creatinine 1.3mg/dl. Presented to a gastroenterologist after 15 days with pain in right upper abdomen. S. Bilirubin: 1.8, direct 1.0mg/dl; all other laboratory investigations and USG abdomen were normal. Since the severe pain persisted after 1 week, CT abdomen with CT abdominal angiography was done, which showed right renal infarction and raised possibility of right renovascular cause. The patient was referred to our hospital. BP on admission 170/130 mm/Hg and except for mild tenderness over right lumbar area, no other clinical signs present. DSA showed right renal artery dissection, thrombus and right renal lower pole infarction.



The question was: Will an intervention be able to salvage the right renal function after 1 week? Right renal angioplasty with stenting was performed, the BP stabilized. One week later (and until now), right kidney GFR remains at 26ml/min on DTPA renogram and S. Creatinine value normal. BP is well controlled.

**Conclusions:** There is a dilemma about the outcome of interventions when the acute thromboembolic events of renal artery are diagnosed late. We have presented a case where, in spite of a delay of 1 week from the onset of symptoms to diagnosis and endovascular intervention, right kidney function could be salvaged partially. This case report should encourage clinicians to enforce immediate radiological intervention, especially in the patient at risk. Even if diagnostic procedures are delayed, radiological intervention should be taken into account.

## PUB349

**New Genetic Variant of ADPKD-2** Tetiana Litvinchuk, Tetyana L. Vasylyeva. *Pediatrics, TTUHSC, Amarillo, TX.*

**Background:** ADPKD is an autosomal dominant renal cyst disorder due to mutations in genes coding for polycystin1(PKD1, on ch 16p13.3) and polycystin 2 (PKD2, on ch 4q13-23), and PKD3 gene (gene unmapped).It is also associated with TSC2/PKD1 contiguous gene syndrome. ADPKD is usually inherited but new mutations without a family history occur in 10% of the cases.

**Methods:** A 17 y.o. boy was followed since he was a 13 y.o. for bilateral cystic kidney disease, hypertension and obesity. The diagnosis was an accidental finding during abdominal CT at age 13 to rule out appendicitis Labs: BUN-14, Cr-0.77, electrolytes-within normal limits. Ultrasonogram: The right kidney measures 11.3x5.2cm. The left kidney 11.2x5.2cm. There is a cluster of cysts about the upper pole of the right kidney measuring 2.4x1.9x3.4cm and identified cysts of the right kidney measuring 1.9x1.6x1.7cm and 1.7x1.2x2.3cm ,and of the left kidney measuring 1.7x1.4x2.0cm. No hydronephrosis and a good corticomedullary differentiation. Impression: Bilateral renal cysts. Because of parental history of bilateral renal cysts, PKD1 and PKD2, genetic testing was ordered.

**Results:** PKD2 variant 1:3 bp deletion of TGT was found; nucleotide position: 1602_1604; codon position: 512-513; mRNA reading frame maintained. ADPKD2 disease is often present later in life. A variety of genetic defects have been described including frameshift, deletion, and missense mutations in patients with ADPKD. Most families have an abnormality on chromosome 16 in the PKD1 locus that is tightly linked to the alpha-globin gene locus (85-90% of cases).Most of the remaining patients have a defect in the PKD2 locus on chromosome 4. (10% of cases). PKD1 and PKD2 encode proteins called polycystin-1 and polycystin-2. Mutated proteins are involved in cell differentiation, polarization, proliferation and membrane transport.This is a case of new genetic mutation, which probably causes a development of ADPKD2 in this patient during a childhood.

**Conclusions:** A smaller number of patients have a defect in the PKD2 locus on chromosome 4 (resulting in PKD2 disease) and a few families have an undefined defect. There are not known published cases on this genetic variant of ADPKD2 cystic kidney disease. In this case the disease is present unusually early in life.

## PUB350

**A Case of Cardiac Tamponade and Proteinuria: Is There an Etiological Relationship?** Vasanthi Balaraman, Shyam Ravisankar, Robert D. Zenenberg. *Dept of Medicine, Saint Barnabas Medical Center, Livingston, NJ.*

**Background:** Cardiac tamponade, as a cause of proteinuria has not been described in the literature. We demonstrate a temporal relationship between the onset of proteinuria with cardiac tamponade and its resolution subsequent to pericardial window on two occasions in the same patient.

**Methods:** A 75 year old lady with pancreatic adenocarcinoma was admitted for acute kidney injury and proteinuria. Physical examination was unremarkable.Laboratory data showed serum creatinine of 2.33 mg/dl (baseline creatinine 0.75-1.20 mg/dl) and proteinuria of 300 mg/dl on urinalysis. The spot urine protein to creatinine ratio was 3 gram/g creatinine. On day 3, she developed shortness of breath and palpitations. Echocardiogram showed a large pericardial effusion with early cardiac tamponade. Pericardial window was performed and 500cc of clear fluid was drained. Cytology revealed adenocarcinoma. Serial measurements of her spot urine protein to creatinine ratio decreased from 4.39 to 3.6 to 2.3 to 1.66 g/g creatinine subsequently. Four months after discharge, she was admitted with shortness of breath and was diagnosed with cardiac tamponade. She had proteinuria of 100 mg/dl on dipstick. Her proteinuria completely resolved after the pericardial window.

**Conclusions:** In acute febrile illnesses and subsequent to vigorous exercise, one can see proteinuria related to hemodynamic stress. In Orthostatic proteinuria, Cardiorenal syndrome and Nutcracker phenomenon (left renal vein traverses under the superior mesenteric artery and becomes trapped between aorta and superior mesenteric artery), there is increased efferent glomerular vasoconstriction, increased glomerular back pressure with increased angiotensin II release and resultant proteinuria. Our case of cardiac tamponade can be categorized within a subset of "Type I" cardio-renal syndrome. Glomerular capillary hemodynamic changes due to renal venous back-pressure and elevated AT-II levels may influence glomerular permselectivity to macromolecules and can evoke proteinuria. The relationship between proteinuria and cardiac tamponade has not been specifically studied to our knowledge and warrants further research.

## PUB351

**Type B Lactic Acidosis in Multiple Myeloma** Luis Daniel Torres, Sreevalli Pariti. *Nephrology Dept, Methodist Dallas Medical Center, Dallas, TX.*

**Background:** Type B lactic acidosis is a rare manifestation related to underlying diseases, errors in metabolism, medications, intoxication and rarely in some hematologic malignancies and solid tumors. Only 3 cases of Type B lactic acidosis in multiple myeloma have been reported worldwide, and of those 3, only 2 reported in the U.S.

**Methods:** 62 year old female who was admitted due to back pain, weakness and difficulty breathing. Upon admission she was found to be volume depleted, with acute kidney injury, severe hypercalcemia and high anion gap metabolic acidosis and pancytopenia. Treatment was initiated with aggressive volume expansion and broad spectrum antibiotic. Once her volume status improved and no evidence of infection, lactic acid levels remained high. Bone marrow biopsy showed atypical plasmacytosis consistent with multiple myeloma. During her stay,her blood pressure remained normal and responded well to volume expansion with excellent urinary output. No evidence of tissue hypoperfusion was ever showed.She was treated aggressively for her hypercalcemia as well. Days later, once her serum creatinine improved to baseline, chemotherapy was started with bortezomib,dexamethasone and cyclophosphamide. On top of that, zoledronic acid and thiamine was added. It wasn't until chemotherapy started that her lactic acid levels decreased slowly in the next 3 days from 12.4mmol/L to 4.2mmol/L.

**Conclusions:** This case illustrates how the high lactic acid levels were not associated with any episode of tissue hypoperfusion or hypotension, and it was more related to high cell turnover seen in severe hematologic malignancies such as leukemias,high grade lymphomas and rarely in multiple myeloma. Our case was unique because our patient followed all her laboratory findings typical of multiple myeloma except the high lactic acid resistant to volume expansion, antibiotics and good renal perfusion.it wasn't until chemotherapy was started when levels dropped progressively, making this, type B lactic acidosis related to multiple myeloma.

## PUB352

**Markedly Nephrotic Rapidly Progressive Glomerulonephritis** Lisa Aimee Hechanova. *Nephrology, Loma Linda Univ Medical Center, Loma Linda, CA.*

**Background:** Seronegative pauci-immune glomerulonephritis is much more common than traditionally thought, with an incidence of about 30%, instead of the previously thought 10-15%. Seronegative pauci-immune glomerulonephritis has a much more aggressive presentation and worse prognosis than seropositive pauci-immune glomerulonephritis, and thus is essential to diagnose and treat early. Herein is presented a severe case of seronegative pauci-immune glomerulonephritis.

**Methods:** A 79-year-old black male with longstanding HTN, DM2, CKD stage 3 presented with several weeks fatigue, malaise, decreased appetite, unintentional 10lbs weight loss, worsened SOB. On review of his prior labs, his creatinine worsened from his baseline of 2.0mg/dL to 4.2mg/dL over a ten month span, then rapidly progressed from 4.2mg/dL to 14.3mg/dL over a one month span. He was found to have iron deficiency anemia with hemoglobin 7.1. Spot urine protein/creatinine ratio 35.5g/g, SPEP negative, UPEP unable to be obtained due to progression to anuria, immunofixation electrophoresis was negative, skeletal survey with no focal lytic or blastic bony lesions. Anti-GBM negative, cANCA/pANCA negative, hepatitis panel negative, compliment normal. Renal ultrasound showed 11cm kidneys. Renal biopsy showed acute crescentic GN, moderate active and chronic tubulointerstitial nephritis, mild to moderate interstitial fibrosis and tubular atrophy. Immunoflorescence was negative, and electron microscopy did not show any electron dense deposits.

**Conclusions:** Seronegative pauci-immune GN is much more common than previously thought, with an incidence of about 30%. Age of onset is generally younger: 39.7 +/- 17yrs vs 57.6 +/- 14yrs with seropositive pauci-immune GN. Only 20% will have constitutional symptoms vs 67% with seropositive pauci-immune GN. Renal failure is more dramatic, and patients generally have a worse renal survival rate. Proteinuria is also more severe with average urinary protein excretion is 5.5g/24hrs in seronegative pauci-immune GN vs 2.2g/24hrs in seropositive pauci-immune GN. Thus it is imperative that one be aware of the high proportion of pauci-immune glomerulonephritis which can be seronegative, and be very aggressive about diagnosis and treatment.

## PUB353

**Hyponatremia Associated with Unilateral Hand Weakness and Numbness** Fazel Dinary, Buthayna Dinary, Merugu Srinivas, Keyvan Ravakhah. *Internal Medicine/Nephrology, St. Vincent Medical Center, Cleveland, OH.*

**Background:** The key clinical feature in this case is making the diagnosis of apical lung cancer (Pancoast tumor) in a patient with brachial plexopathy and to recognize the association between SIADH as a paraneoplastic syndrome and non-small cell lung cancer (NSCLC).

**Methods:** A 62 year old mechanist male presented with 3 months h/o worsening right hand numbness and weakness with difficulty operating machinery at work. He reported anorexia, unintentional weight loss of about 20 lbs over 3 months and mild chronic cough with no fever, night sweats, hemoptysis or dyspnea. He denied neck pain, headaches or dizziness. His vitals were normal with BMI of 17. His grip strength in right hand was 4/5 with atrophy of the interossei muscles). Sensation to pinprick was reduced along the right C7, C8 and T1 dermatomes. Initial LABS was normal except serum sodium of 121mmol/L. R. shoulder and chest x-ray showed R. apical pleural based density suggestive of a soft tissue mass lesion. CT scan and MRI of the chest showed large R. apical superior sulcus pulmonary mass (Pancoast tumor) with extensive spread to proximal R. first and second ribs, R. brachial plexus nerve roots. Histopathology showed a poorly differentiated NSCLC . Tumor was staged IV (T3N2M1a). Workup for hyponatremia showed serum osmolality of 254 mOsmol/kg, urine osmolality of 451 mOmol/kg, and urinary sodium of 69mmol/L. TSH, LFT and cosyntropin stimulation test were all normal. Results were consistent with SIADH. His initial treatment consisted of pain control and fluid restriction. At 4 months follow up, the hyponatremia resolved and reported partial improvement in his right hand weakness.

**Conclusions:** Tumor-associated SIADH in majority of the cases is caused by small cell lung cancer (SCLC). NSCLC is shown to be responsible for a small proportion with few cases reported in the literature. The optimal therapy for SIADH is to treat the underlying malignant disease which may improve this paraneoplastic condition. Although SIADH is rare in NSCLC, careful history and early workup for hyponatremia in patient with weight loss and brachial plexopathy helps early detection and prevent progression of cancer.

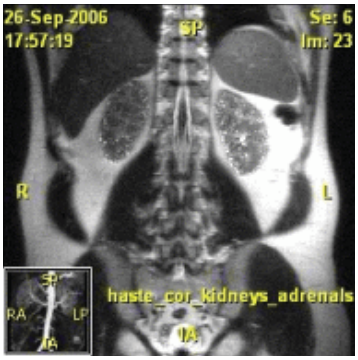
## PUB354

**Lithium Nephropathy Presenting in CKD, DI, and Bilateral Cystic Kidney Disease** Sami Safadi, Vicente E. Torres. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

**Background:** Lithium is used for the treatment of bipolar disorder. A frequent side effect is renal toxicity. The major biochemical action of lithium is inhibition of glycogen synthase kinase-3, an enzyme that has an important role in the regulation of vasopressin action in the renal collecting ducts.

Lithium nephrotoxicity can be divided into three main categories: nephrogenic diabetes insipidus, acute intoxication, and CKD.

**Methods:** A 56 y/o male with a past medical history significant for bipolar disorder, hypertension, and obstructive sleep apnea presented to our clinic for a second opinion regarding chronic kidney disease, and bilateral cysts on his kidneys. He was diagnosed with CKD several years ago when a routine laboratory workup revealed a serum creatinine of 1.7 mg/dl. He also had a sub-nephrotic range proteinuria around 1.5 gm/day. The patient had bipolar disorder and received lithium for 20 years. The dose was adjusted based on his blood levels. His lithium was stopped 16 ago. Exam: The patient was afebrile; his blood pressure was 133/85. He looked comfortable, and his examination was unremarkable. Laboratories: He had an elevated serum creatinine of 2.6 mg/dL with an estimated GFR of 26 ml/min. His serum sodium was 146 mmol/L. His urine osmolarity was low indicating the presence of diabetes insipidus. He has a nephrotic range proteinuria. Imaging: MRI done several years ago showed a diffusely abnormal appearance of the kidneys with numerous tiny cysts throughout both kidneys. The cysts were less than 5 mm in size and more pronounced in the periphery of the kidneys near the corticomedullary junctions.



**Conclusions:** Nephrogenic DI is the most common adverse effect of lithium. The concentrating defect and natriuretic effect develop within weeks of lithium initiation. After years of lithium exposure, full-blown nephropathy can develop, characterized by decreased GFR and CKD.

## PUB355

**Familial Hyperkalemia** R.R. Malchira,[1] A.C. Ortiz-Guerrero,[1] S. Sarani,[1] P.T.T. Pham,[2] P.C. Pham.[1] *[1]Nephrology, Olive View MC; [2]Kidney & Pancreas Transplant, UCLA, LA, CA.*

**Background:** We present a case of hyperkalemia of undiagnosed etiology requiring multiple unwarranted admissions prior to his presentation to our institution.

**Methods:** A 22 year old man was referred for an incidental serum potassium (K) of 7.7 mmol/L. He denied musculoskeletal symptoms, palpitations, high K intake, medication use, strenuous activity, or constipation. Family history: hyperkalemia in maternal grandmother, great-aunt, and uncle. Evaluation: Serum Na 137 mmol/L, K 6.8 mmol/L (non-hemolyzed), Cl 110 mmol/L, bicarbonate 23 mg/dL, creatinine 0.93 mg/dL, glucose 108 mg/dL. EKG: no peaked T waves. Physical exam: afebrile, blood pressure 124/66 mmHg, heart rate 80 bpm. Well-nourished and developed, comfortable, moist oral mucosa. Heart, lungs, abdomen, extremities were unremarkable. Familial hyperkalemia due to K leakage from red blood cells with cooling to or below room temperature was ruled out (serial K measurements with blood cooling). Subsequent evaluation: urine transtubular potassium gradient: 3.3, random urine K concentrations of 17.8 mmol/L and 5.5 mmol/L with corresponding serum K of 5.7 and 5.6 mmol/L respectively on 2 different days. Blood gas consistent with non-gap metabolic acidosis. Hyperkalemia was suspected to be due to reduced renal secretion. Possible causes: inhibition or reduced function/expression of the Na epithelial channel (ENaC), hypoaldosteronism or pseudohypoaldosteronism, reduced ROMK activity and/or expression, or urinary stasis. Investigation for medication induced inhibition of ENaC, aldosterone, and ROMK was negative. Kidney, bladder ultrasound: no obstruction or retention. Plasma renin activity: 0.35 ng/mL/h (range 0.25-5.82), aldosterone: 7 ng/dL. Both were considered low in the presence of hyperkalemia. Relative hyporenin hypoaldosteronism was entertained. Patient responded minimally to a trial of fludrocortisone and high salt intake (K 5.7-5.8 mmol/L), but markedly to hydrochlorothiazide (K 4.7 mmol/L).

**Conclusions:** Our evaluation suggested Gordon's syndrome, likely due to WNK1 or WNK4 mutations. A systematic approach to the evaluation of hyperkalemia can lead to the correct diagnosis and treatment, hence avoidance of unnecessary hospitalizations.

## PUB356

**Spontaneous Clearance of Hepatitis B Surface Antigenemia in a Chronic Hemodialysis Patient** Chinmay P. Patel,[1] Divya Monga,[1] Mohini Alexander,[1] John D. Wagner,[1] Joseph Mattana.[2] *[1]Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY; [2]Nephrology, Winthrop Univ Hospital, Mineola, NY.*

**Background:** Hepatitis B virus (HBV) infection is a substantial global health problem. For a variety of reasons, patients with end stage renal disease (ESRD) on hemodialysis (HD) are at increased risk of acquiring HBV. Because of cellular immunity disturbances, clearance of HBsAg is an unusual event in a HD patient with chronic HBV infection. We report a patient who was HBsAg positive for 9 years and then spontaneously seroconverted and offer a hypothesis for its occurrence.

**Methods:** A 62-year-old woman with ESRD from diabetic nephropathy was started on HD and found to be HBsAg positive. Her anti-HBs Ab was negative and liver enzymes were in the normal range. She underwent arterio-venous graft (AVG) placement and developed multiple episodes of thrombosis requiring revisions. Two years after starting dialysis she developed staphylococcal bacteremia due to infection of the AVG site. She received antibiotic therapy and underwent partial excision of the AVG. Cultures from the excised AVG revealed Staphylococcus aureus and Pseudomonas aeruginosa. Patient subsequently developed multiple episodes of AVG infection requiring aggressive antibiotic therapy. After approximately 10 years of starting HD, her HBsAg testing came back negative for the first time. Her anti-HBc was positive, anti-HBs was negative, HBeAg was negative, anti-HBe was positive, HBV DNA PCR was <60 IU/mL and anti-HCV was negative. Two years later her anti-HBs titer became positive at >100 and after 4 years her HBsAg has continued to remain negative.

**Conclusions:** In our patient we hypothesize that the AV graft infection may have provided a strong stimulus to her immune system. This may have resulted in substantial amounts of TNF-alpha secretion which reduced Treg-mediated suppression of the anti-HBV response, thus helping her clear the chronic HBV infection. A better understanding of the mechanism by which this occurs might help develop therapeutic approaches to help HBsAg positive HD patients clear this infection.

## PUB357

### Transplant Renal Artery Stenosis Causing Hypertension and Acute Renal Failure Without Biopsy Evidence of Acute Tubular Necrosis

Talal K. Mahmood, Iasmina Craici, Kenneth E. Kokko, Steven Wagner. *Internal Medicine Nephrology, Univ of Mississippi Medical Center, Jackson, MS.*

**Background:** Transplant renal artery stenosis (TRAS) is a potentially treatable and reversible cause of post-transplant hypertension and allograft dysfunction. It generally occurs 3 months to 2 years post-transplant, and its prevalence varies from 1-23% depending on the diagnostic criteria and technique used. Renal hypoperfusion & renin-angiotensin system activation lead to ischemia & fluid retention.

**Methods:** A 50-year-old African American male with ESRD secondary to hypertension and type II diabetes underwent deceased donor ECD kidney transplant. Post-operative course was complicated by delayed graft function before achieving a nadir creatinine of 2.3. He was admitted 4 months post-transplant with hypertensive emergency, volume overload & acute kidney injury (BUN 55, Creatinine 3.7). He was also noted to have pancytopenia (WBC 3.8, Hb 8.4, PLT 75). Transplant renal ultrasound showed turbulent flow at the anastomosis. Allograft biopsy showed evidence of atypical thrombotic microangiopathy, including amorphous material in the glomerular capillaries, without significant evidence of acute tubular necrosis. He failed therapy with plasma exchange and was noted to have continued worsening of renal function with progressive oliguria. Dialysis was initiated secondary to hyperkalemia & volume overload. Repeat allograft biopsy showed no significant abnormality, and previously noted amorphous material in the glomerular capillaries was no longer present. Repeat ultrasound again showed turbulent flow in the region of anastomosis concerning for kinking. He underwent renal artery angiogram, angioplasty, and stent placement. Urine output increased immediately after the procedure and renal function started to improve without the need for further dialysis. Nine months after transplant, his creatinine is 1.85 and hypertension is well controlled with clonidine, metoprolol, and nifedipine.

**Conclusions:** This case illustrates that TRAS can cause severe allograft dysfunction requiring dialysis without biopsy evidence of acute tubular necrosis, and that timely intervention can lead to complete recovery of renal function.

## PUB358

### Renal Failure in an Adult Niemann-Pick Disease Type E

Cailian Cheng, Zhenda Zheng, Chenggang Shi, Xun Liu, Wenbo Zhao, Tan-qi Lou. *Dept of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China.*

**Background:** Niemann-Pick (NP) disease is an autosomal recessive lipid-storage disorder. At least five forms (types A to E) of NP disease have been identified. However, NP disease type E is uncommon and seldom reported.

**Methods:** A 43-year-old woman was admitted to our hospital complaining of abdominal distension, weakness, and anorexiawith a weight loss of 5 kg in a month. Laboratory findings were: hemoglobin level was 9.5 g/dl. All autoimmunity markers were negative. HIV and hepatitis B and C serologies were negative. Alanine transaminase and aspartate aminotransferase were normal.Laboratory tests confirmed glomerulopathy with renal failure, with serum creatinin 3.7 mg/dl, serum albumin 31 g/L, proteinuria 2.5 g/24 h, and hematuria 20000 RBC/min.Abdominal ultrasonography showed parenchyma of the liver and renal cortex showed diffuse increased echogenicity with the paraumbilical vein open and large amounts of ascites. Microscopic study of a kidney biopsy identified widespread cytoplasmic vacuolation of endothelial and visceral epithelial cells in the glomerulus. Widespread vacuolar degeneration, focal dissolve and desquamation in the proximal convoluted tubule, protein casts, and interstitial diffused foam cells were observed, but chronic changes such as interstitial fibrosis or tubular atrophy were absent. Inflammatory cell infiltration was not seen. Electron microscopy showed massive lipidic deposits in endothelial cells and podocytes. Liver biopsy showed widespread foam cells.Bone marrow examination identified the presence of NP cells. Acid sphingomyelinase activity was normal in leukocytes and chitotriosidase activity was moderately elevated at 768.7 µmol/L/h. Albumin, erythropoietin,and vitamins were administered. Abdominocentesis and aspirated ascites were performed to alleviate abdominal distention. With these treatments, the patient achieved clinical improvement of symptoms. In follow-up visits, symptoms did not rapidly progress.

## PUB359

### Mesangial IgA Deposition in Tip Lesion Focal Segmental Glomerulosclerosis

Ingrid Calliste, Liliana E. Rios Rojas, Shayan Shirazian, Joseph Mattana, James Drakakis. *Dept of Medicine, Winthrop Univ Hospital, Mineola, NY.*

**Background:** IgA Nephropathy is the most common cause of glomerulonephritis worldwide, with hypertension, hematuria, minimal proteinuria, and elevated serum creatinine as some of the presenting features. More rarely, mesangial deposition of IgA has been described as being concurrent with the glomerular lesion of minimal change disease (MCD). We describe a case of nephrotic syndrome, where the incidental dual glomerulopathy consisted of mild mesangial IgA nephropathy and the tip lesion variant of focal segmental glomerulosclerosis (FSGS), an entity which closely approximates MCD.

**Methods:** A 53 year old male presented to the emergency department with the complaint of abrupt onset lower extremity swelling. In addition to elevated blood pressure, he was found to have a serum albumin of 2.7g/dL and a normal serum creatinine. Urinalysis showed 4+ protein, 2+ blood and 4 red blood cells oer high powered field. He admitted to occasional nonsteroidal anti-inflammatory drug use as a fairly long-standing practice. Loop diuretic and angiotensin converting enyzme inhibitor therapy were initiated. Given the clinical and laboratory findings, percutaneous renal biopsy was undertaken. Histological analysis showed the glomerular tip lesion variant of FSGS and mesangial hypercellualrity with dominant staining for IgA.

**Conclusions:** Prior literature has described the concurrence of MCD and mild mesangial IgA nephropathy. This case illustrates a more overlap, in which the nephrotic entity is not MCD, but rather the closely related tip lesion variant of FSGS. The course of these nephrotic lesions is typically favorable, being exquisitely steroid responsive with low risk of progressive renal failure. Whether the concurrent expression of mesangial IgA deposition is purely coincidental, or instead is a manifestation of a mechanistic relationship between these disorders, remains to be determined.

## PUB360

### Hyponatremia due to the Syndrome of Inappropriate Antidiuretic Hormone (SIADH) following Administration of Intrathecal Methotrexate (IT MTX)

Fernanda Payan Schober, Gerald A. Hladik. *Nephrology, Univ of North Carolina, Chapel Hill, NC.*

**Background:** IT MTX has been routinely used in treatment of primary central nervous system (CNS) lymphoma, leptomeningeal metastatic disease, and as CNS prophylaxis in patients with non-CNS lymphoma. This case illustrates a possible link between IT MTX and SIADH.

**Methods:** A 50 year old man with diffuse large B-Cell lymphoma with CNS involvement was treated with IT MTX and Rituximab. He completed 2 of 6 cycles without complications and MRI of the brain showed response to treatment with decreased size and near resolution of CNS lesions. During the third cycle of therapy he was noted to develop acute hyponatremia. Serum sodium was 135mEq/L on admission. IT MTX was administered on day 4, which was followed by a fall in serum sodium from 133 mEq/L on day 5 to 120mEq/L on day 6. Notably, he had been receiving intravenous sodium bicarbonate to decrease the risk of MTX nephrotoxicity. He endorsed nausea, but had no other complaints. On physical examination he was alert and oriented. Blood pressure was 129/87 without postural changes. There was no edema and remainder of the examination was normal. Additional laboratory studies revealed serum osmolality 262mOsm/kg, serum creatinine 0.63mg/dL, urine sodium 127mEq/L and urine osmolality 459mOsm/kg. Serum thyroid-stimulating hormone and cortisol levels were normal. The findings were felt to be most consistent with SIADH. Intravenous sodium bicarbonate was discontinued. He was placed on a 1L fluid restriction and furosemide 20mg daily was started. Over the next 2 days the serum sodium improved to 124 mEq/L and nausea resolved. Two days later, serum sodium was 129mEq/L.

**Conclusions:** The time-related onset of SIADH following administration of IT MTX in this patient supports IT MTX as a possible cause of this syndrome. The diagnosis of lymphoma-related SIADH is less likely given the near resolution of CNS lesions on MRI, absence of hyponatremia on admission, and onset of hyponatremia following chemotherapy administration. Close monitoring of the serum sodium level in patients receiving IT MTX is therefore warranted, particularly when administered in conjunction with intravenous hydration.

## PUB361

### Coexisitng Acute Interstitial Nephritis and Atheroembolic Renal Disease

Nima Rabbani, Omid Bakhtar, Machaiah M. Madhrira. *Dept of Nephrology, Univ of Arizona, Tucson, AZ.*

**Background:** Acute interstitial nephritis is characterized by an inflammatory process induced by drugs, infections, or a systemic disease. The syndrome is important, in part, because it can cause a decline in creatinine clearance. However, we report a unique case of concomitant acute interstitial nephritis and atheroembolic renal disease.

**Methods:** A 63 year old male with a past medical history of ckd 3 with a baseline creatinine of 1.1-1.2mg/dl, hypertension, COPD, CAD with CABG was admitted with shortness of breath. He was diagnosed with CHF exacerbation, pneumonia and a left foot ulcer. He was prescribed antibiotics during his hospital course and discharged with a creatinine of 1.2 mg/dl. He was then readmitted at an outside facility with chest pain and had a cardiac catheterization with an unknown creatinine at discharge. He was subsequently readmitted for a worsening left ankle ulcer and was diagnosed with osteomyelitis. His creatinine was 3.5 mg/dl during that hospital stay and his AKI was determined to be due to nsaid use and was recommended supportive care. The patient was then started on iv antibiotics for 8 weeks (cefuroxime) and discharged home.

**Results:** On a subsequent follow up in the clinic, his BP was 118/64, mucous membranes moist and no peripheral edema was present. The rest of his physical exam was unremarkable. Laboratory results were significant for creatinine of 4.8mg/dL and a protein to creatinine ratio of 1.2 g/g. ANA, spep/upep, hepatitis panel, C3, C4, and ANCA levels were negative. An increased absolute eosinophilic count of 1.75% was demonstrated. Renal US showed no hydronephrosis with right kidney measured 10.4 cm and left kidney 12.1 cm. Renal biopsy was pursued which subsequently demonstrated changes consistent with acute interstitial

nephritis and atheroembolic renal disease. The patient's renal function progressed to a creatinine of 5.3 mg/dl in which renal function stabilized to 2.0-2.7 mg/dl with egfr ~35 ml/min after a two year therapy of steroids.

**Conclusions:** This case provides corroboration of evidence of a presentation of acute interstitial nephritis and atheroembolic renal disease.

## PUB362

**Long Term Follow Up of Proteinuria Associated with Vascular Endothelial Growth Factor Receptor (VEGF-R) Inhibition** Advayanand Shirsalkar, Anuradha Wadhwa. *Loyola Univ Medical Center.*

**Background:** High incidence of proteinuria and hypertension with VEGF-R inhibitors is well known but data regarding long-term follow up and optimal management of these side effects is lacking. Development of proteinuria can result in discontinuation or alteration of therapy, limiting treatment options for patients with malignancy. We describe long term follow up of a challenging case treated with VEGF-R inhibitors presenting with proteinuria and difficult to control hypertension.

**Methods:** A 48 year-old man with right nephrectomy for renal cell carcinoma was found to have metastatic disease to brain and lungs during routine follow up. Over a course of 4 years, patient was treated with multiple chemotherapeutic agents (including VEGF-R inhibitors- sunitinib, sorafenib, pazopanib) due to disease progression and/or limiting side effects. Prior to this therapy, the patient had no protein on urine dipstick. This increased to 1+ to 2+ protein soon after treatment with sunitinib was initiated and persisted when therapy was changed to sorafenib. Patient was then switched to pazopanib and proteinuria increased to 3+ on dipstick and 9 g on 24 hour urine collection. Given disease progression while on pazopanib and development of nephrotic syndrome, decision was made to stop the agent. Proteinuria decreased to 2 g/g within 4 weeks of discontinuing pazopanib. Patient was subsequently treated with sunitinib followed by axitinib. After complete cessation of VEGF-R inhibitor therapy in January 2013, proteinuria persisted but remained stable. Patient required close renal follow up for management of difficult to control blood pressure (2 additional antihypertensive agents required).

**Conclusions:** This challenging case with persistent proteinuria and difficult to control hypertension was successfully managed with a multidisciplinary team approach. Data regarding long term follow up and management of proteinuria and hypertension in patients treated with VEGF-R inhibitors is lacking. Reporting of this data with a larger series of patients ought to be made so that nephrologists may make evidence-based recommendations on managing these patients.

## PUB363

**Nodular Glomerulosclerosis of Diabetic Nephropathy Superimposed with Crescentic Glomerulonephritis** Kathleen Joy Paredes Garcia, Kristin Mercado Luzentales, Beatrice P. Concepcion. *Section of Nephrology, Philippine General Hospital, Manila, Philippines.*

**Background:** Diabetic nephropathy is a clinical diagnosis in a patient with long standing history of diabetes presenting with proteinuria, ultrasound findings ruling out other cause of renal insufficiency, signs of other end organ damage, and progressive decline in GFR at an average rate of 4ml/min annually. Deviation from the usual clinical picture should prompt a search for alternative diagnoses.

**Methods:** 34 year old male, diabetic for 5 years, poorly controlled with, nephropathy and retinopathy, presented with sudden onset of anuria, rapid decline in estimated GFR, and normal systemic findings apart from hypertensive urgency. Urinalysis showed active urinary sediments (pyuria, hematuria, WBC, coarse granular and waxy casts) and nephrotic range proteinuria. Impression was ARF from RPGN, Chronic Kidney disease secondary to diabetic kidney disease with chronic glomerulonephritis. HBsAg, anti-HCV, pANCA, cANCA and anti-nuclear antibody test were negative. Complement factor C3 was low. He underwent hemodialysis, methylprednisolone pulse therapy and kidney biopsy. Renal function failed to improve after treatment. Renal biopsy showed crescentic glomerulonephritis with 12% cellular crescents; diabetic nephropathy, nodular glomerulosclerosis; moderate interstitial fibrosis and tubular atrophy with 88% global sclerosis and 12% segmental sclerosis; arteriosclerosis and hyaline arteriolosclerosis. Immunofluorescence showed negative immunoglobulin staining, consistent with pauci-immune GN.

**Conclusions:** Studies show that among biopsied diabetic patients, the most common glomerular diseases superimposed with diabetic glomerulosclerosis (DGS) are membranous GN, IgA nephropathy, and post-infectious GN. Acute renal failure (ARF) from rapidly progressive glomerulonephritis (RPGN) on top of DGS is rare and occurs among older patients. Progressive decline in kidney function is almost inevitable in DM nephropathy. Physicians should have a high index of suspicion in looking for alternative causes of renal deterioration in this population.

## PUB364

**A Case Report of Aplastic Anemia Developed in a Peritoneal Dialysis Patient due to Lupus Nephritis** Hae Min Lee, Yong Kyun Kim, Euy Jin Choi, Ho Cheol Song. *Div of Nephrology, Dept of Internal Medicine, Bucheon St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea, Republic of Korea.*

**Background:** Aplastic anemia (AA) is often accompanied with systemic lupus erythematosus (SLE). Extrarenal manifestations of lupus nephritis became gradual complete or partial resolution after development of end-stage renal disease. We describe a rare case report of severe AA developed in a peritoneal dialysis patient due to lupus nephritis who was treated successfully with cyclophosphamide and steroid.

**Methods:** A 26-year-old woman who has maintained continuous ambulatory peritoneal dialysis since 2 years ago visited our outpatient clinic because of general weakness. She was diagnosed with SLE and lupus nephritis before 5 years then got treatment with cyclophosphamide and rituximab. Her vital sign was stable at the time of visiting. Her hemoglobin level and platelet count declined from 11.6 to 7.5 g/dL and from 1.3 x $10^{11}$ to 1.6 x $10^{10}$ /L within 5 weeks. Her absolute neutrophil count decreased from 3.87 x $10^{9}$ to 1.89 x $10^{9}$ /L 2 days after hospitalization. Bone marrow revealed less than 5% of cellularity and all the erythroid and granulocytic precursors and megakaryocytes are markedly decreased in number. She was diagnosed with severe AA. Her serum anti-DNA antibody level fell from > 50 at the diagnosis of SLE to 23.27 IU/mL. After diagnosis with AA, she had gotten treatment with 5 times of cyclophosphamide and 1 time of steroid pulse. During the course of treatment with maintenance low dose prednisolone, her white blood cell and platelet counts have been normal and hemoglobin level was maintained between 9.5 and 11.5 g/dL with erythropoiesis stimulating agent (ESA).

**Conclusions:** Although severe AA is rarely developed in patient with ESRD due to lupus nephritis whose lupus activity fell over 50 %, the patient successfully treated with formal immunosuppressive therapy of AA with cyclophosphamide. We do not hesitate to evaluate bone marrow study if anemia is acutely aggravated or poorly responded to ESA with or without decrement of other cellular linage in ESRD patients due to lupus nephritis even though their lupus activity is low.

## PUB365

**Treatment of Calcific Uremic Arteriolopathy in Peritoneal Dialysis Patient** Neelima Chilukuri.[1,2] *[1]Nephrology, Metropolitan Hospital Center, New York, NY; [2]Nephrology, SUNY Downstate Medical Center, New York, NY.*

**Background:** Calcific Uremic Arteriolopathy ( Calciphylaxis) is medial calcification of arterioles leading to ischemia and subcutaneous necrosis commonly seen in ESRD patients on chronic dialysis, and there are no controlled studies that compare its treatment modalities.

**Methods:** We are presenting a rare case of calciphylaxis in a caucasian female who is 50 years old and was started on peritoneal dialysis recently, she has past medical history of Hypertension, ESRD secondary to Post streptococcal Glomerulonephritis. She presented with painful nodules on her lower extremities, even before she was started on peritoneal dialysis, one of the lesions which ulcerated was biopsied and was confirmed to be calciphylaxis, her labs around the time of diagnosis calcium was 10.5, phosphorus was above 9.0, PTH was above 3000, BUN 92, Cr 6.08. She was dialysed adequately by PD, she was given sevelamer as phosphate binder, was treated with cinacalcet for secondary hyperparathyroidism, she was told to avoid all calcium supplements, her calcium levels came down to 9.5, phosphorus to 5.5 and PTH to 1318, her ulcer on her lower extremity was aggressively treated with local wound care to avoid superinfection, her lesions gradually started healing , we did not give sodium thiosulphate since patient was on peritoneal dialysis.

**Conclusions:** There are no studies that would compare different treatment strategies for calciphylaxis, except for few case reports, where sodium thiosulphate was used successfully in hemodialysis patients after each dialysis, which acts as chelator and antioxidant along with decreasing calcium phosphate product less than 55 and treating secondary hyperparathyroidism, in our patient we could not use sodium thiosulphate , if given oral its not very effective, if given intraperitoneal has risk of chemical peritonitis as reported in one case report, and if given Intravenous will be dialysed by PD and would not be effective. Its still a question whether and how to use sodium thiosulphate in PD patients.

## PUB366

**Successful Treatment with Tocilizumab in a Case of Lupus Nephritis Complicated with Nuropsychiatric Complications** Oonishi Takahiro. *Nephrology, Ise Red Cross Hospital.*

**Background:** Neuropsychiatric complications of SLE (NPSLE) have been reported to occur in 14-75% of SLE patients at any time during in disease course. The features of this condition may include seizures, stroke, depression, psychosis and cognitive disorders. Neuropsychiatric complications are associated with increased morbidity and mortality of SLE patients. In NPSLE immunoregulatory cytokines ,such IL-6, IL-10,

IFN,IL-1 and TNF-α were extensively examined. On the other hand TCZ was reported could effectively block IL-6 in patients with SLE.(Gabor G. Illei1, Arthritis Rheumatism 2010) To assess that TCZ might be a therapeutic option for SLE, especially in case complicated with NPSLE.

**Methods:** Case report 45-year-old woman with nephrotic syndrome was diagnosed lupus nephritis in January 2012. Pathological examination of a renal biopsy specimen revealed membranous lupus nephritis (Class V). After renal biopsy she had seizure with consciousness loss. Her cerebrospinal fluid (CSF) displayed a leukocyte count of 9/μl ,a sugar level 40 mg/dl, a protein level of 60mg/dl, serum anti Sm antibody 83.8 positive anti-ribosomal P was positive. MRI detected abnormal signal in ponse and basal ganglia. She was diagnosed LN with NPSLE. Remission induced by treatment with high dose of prednisolone and cyclophosphamide was followed by relapse within 1 year. Although her condition was resistant to immunosuppressive drugs, her symptoms inflammatory response and quality of life measures were successfully improved by tocilizumab, a humanized anti-interleukin-6 receptor antibody. IL-6 is expressed in a wide variety of cell lineages, including monocyte/macrophages, T cell, fibroblasts, and endothelial cells, in response to diverse stimuli. Although a significant role for IL-6 in CNS during NPSLE is not clearly elucidated, elevated IL-6 in the CNS could be relevant in active NPSLE. TCZ may be a therapeutic option for SLE, especially in case complicated with NPSLE.

## PUB367

**Long-Term Intravenous Vancomycin Hydrochloride Induced Erythema** Eleni Chelioti,[1] Maria Sotiraki,[1] Alexia Papalexandrou,[1] Evangelia Gkalitsiou,[1] Evdokia Efthimiou,[1] Kassiani Manoloudaki,[2] Maria Tsilivigou.[1] *[1]Dept of Nephrologr, General Hospital of Piraeus, Athens, Greece; [2]Dept of Pathology, General Hospital of Piraeous, Athens, Greece.*

**Background:** Erythema on face and on upper body (red neck or red man syndrome), with hypotension and flushing is reported as an adverse reaction on intravenous (iv) Vancomycin Hydrocloride(VAN-HCL) in >10% of cases. Erythema is a rare hypersensitivity infusion-related reaction to VAN-HCL. It is often associated with rapid infusion of the first dose and 94% of patients are undergoing treatment less than a month. We report a case of generalized erythema due to iv VAN-HCL.

**Methods:** A 72 years-old man with a history of chronic kidney disease and long-term indwelling urinary catheter due to prostatic hypertrophy presented in a uremic state that necessitated urgent initiation of dialysis treatment. After few hemodialysis his renal function was improved. The patient experienced fever and presented recurrent urinary infections due to Enterococcus falcium, Acinetobacter baumani and Enterobacter aerogenes. Also,the patient presented bloodstream infections by methicillin-resistant Staphylococcus epidermidis, haemolyticus and capitis and treated by iv VAN-HCL. His clinical condition remained critical and in more than a month of continuous iv VAN-HCL, a symmetric generalized, total body, erythematous rash appeared with prominent scaling and desquamation. Skin swabs were taken of the erosions and a skin biopsy was performed. Skin biopsy was consistent with a diagnosis of drug-vancomycin-reaction dermatitis. Stopped using VAN-HCL and started corticosteroids, resulted to amelioration of his clinical status. Unfortunately, our patient became septicemic and died on month after onset.

**Conclusions:** Long term iv use of VAN-HCL is associated with erythema in only 5% of cases. Erythema can be generalized with scaling, affecting greater than 90% of the total body surface area. It appears in less than a month treatment on i.v. VAN-HCL, most commonly in male patients, of a mean age of 60+. Our patients had many predisposing factors for the development of erythema. Since today 114 people have erythema when taking i.v. VAN-HCL and only 4 cases have reported on 2012.

## PUB368

**Belatacept for Kidney Transplant Recipients with Baseline Low Blood Pressure: A New Indication?** Swati Mehta, John R. Lee, Thangamani Muthukumar, Manikkam Suthanthiran. *Nephrology and Hypertension, New York Presbyterian Hospital- Weill Cornell.*

**Background:** Calcineurin inhibitors(CNI) are the mainstay of immunosuppressive medications in transplantation. Unfortunately, acute tubular injury secondary to their vasoconstrictive properties is a common phenomenon.This may be particularly severe in kidney transplant recipients with low blood pressures, an identified risk factor for primary non-function (Webber et al.Transplantation 2005;93:54-60). Belatacept (CTLA-4-Ig fusion protein) is being evaluated as a CNI sparing agent in kidney transplant recipients. We report a case of a kidney transplant recipient with acute tubular injury attributed to tacrolimus that improved remarkably after replacing tacrolimus with belatacept.

**Methods:** A 64yr old male with ESRD secondary to presumed iatrogenic phosphate nephropathy received a living unrelated renal transplantation. He had been on home hemodialysis for two years with systolic blood pressures (SBP) in the 90-mmHg range. A pretransplant donor CDC crossmatch and DSAscreen with HLA single antigen beads were negative. Initial immunosuppression consisted of thymoglobulin induction and maintenance therapy with tacrolimus and mycophenolate mofetil. Following uneventful kidney transplantation, creatinine (Cr) decreased from 5.7 to 1.7 mg/dl on post op day (POD)#2. His course was complicated by hypotension, not responding to IV saline. Tacrolimus was initiated on POD#2 and reached a level of 14 ng/mL on POD#4. His Cr rose from 1.7 to 3.2 mg/dl on POD#6. Renal ultrasound was negative and biopsy revealed widespread tubular vacuolization consistent with CNI toxicity. Tacrolimus was discontinued and he was switched to belatacept. Patient continued on mycophenolic acid and started on tapering prednisone. Patient's Cr peaked at 4.2mg/dl on POD#8 but decreased to 1.7mg/dl by POD#14. His most recent Cr at 5-month follow up was 1.6mg/dl.

**Conclusions:** Belatacept was utilized as a salvage therapy to prevent further CNI-associated acute tubular injury. Belatacept conversion may be a novel approach for kidney transplant recipients with low mean arterial blood pressures and particularly sensitive to CNI-associated vasoconstriction and consequent renal injury.

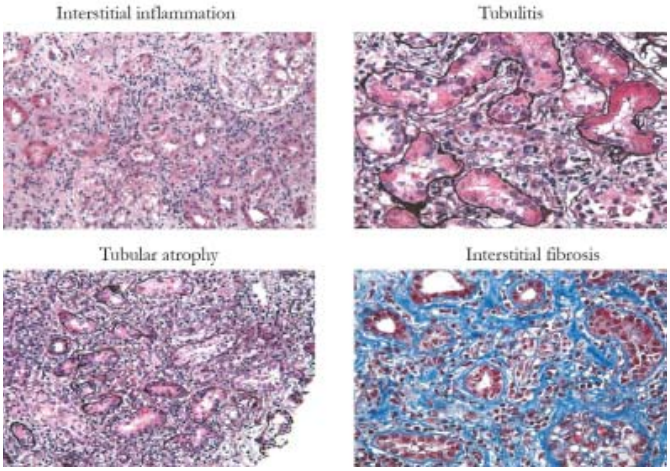
## PUB369

**Omeprazole-Induced Acute Tubulo-Interstitial Nephritis** Rakesh Malhotra,[1] Srujana Polsani,[2] Anjali Acharya,[2] Zaher Hamadeh.[2] *[1]UMDNJ; [2]Jacobi Medical Center.*

**Background:** Proton pump inhibitors (PPIs) are widely prescribed to treat acid-related gastrointestinal disorders. We report a case of reversible acute renal failure due to acute tubulointerstitial nephritis (AIN), confirmed by histology of a renal biopsy, associated with taking omeprazole.

**Methods:** A 70-year-old female presented with complain of generalized weakness and abdominal pain for last 2 months. She had a past medical history for HTN, diabetes, and CKD (baseline sCr 1.6 mg/dL). Physical examination revealed pale conjunctivae. There was no pedal edema, skin rash, petechiae or purpura. Lab results showed elevated BUN of 53 mg/dL and sCR of 2.4 mg/dl. Her Hb was 11g/dL. Urinalysis revealed proteinuria and eosinophiluria. Complements were normal. Serological markers for Hep B, Hep C, and HIV were negative, and no cryoglobulins were detected. Renal ultrasonography was normal. Patient was started on IV fluids however her sCr kept worsening with peak sCr of 4.1 mg/dL. Nephrology consult was obtained and kidney biopsy performed. Biopsy results showed interstitial inflammation with active tubulitis and acute tubal injury. Biopsy also showed chronic features including interstitial fibrosis and tubular atrophy. Overall, findings were consistent with severe interstitial nephritis. The patient had initiated treatment with omeprazole 3 months prior to admission. Omeprazole was discontinued in view of the diagnosis of AIN. Patient was started on oral prednisone for 6-8 weeks with further tapering. The patient sCr gradually improved with subsequently serum creatinine concentration leveled off at 1.2 mg/dl.

**Conclusions:** The pathogenesis of omeprazole-associated AIN is unclear and may be related to the involvement of both humoral and cellular immune mechanisms. Physicians should be aware of this disorder. Accurate and timely diagnosis and withdrawal of the offending drug can prevent potentially life-threatening renal failure.

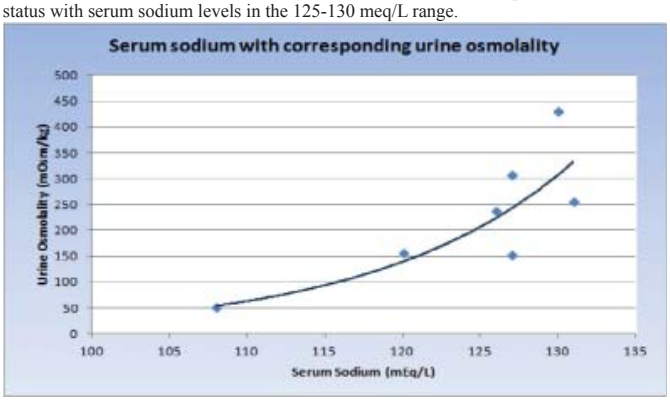


## PUB370

**A Case of Hyponatremia Secondary to Reset Osmostat** Rushi K. Nayak. *Dept of Nephrology, St. Luke's-Roosevelt Hospital Center, New York, NY.*

**Background:** The syndrome of inappropriate anti-diuretic hormone (SIADH), and its reset osmostat variant, result in impaired water metabolism and hyponatremia. Alternatively, the ADH response is maintained in psychogenic polydipsia, in which a massive water ingestion overwhelms the kidney's diluting abilities, resulting in water retention. Here we present a case of hyponatremia related to reset osmostat, unmasked by psychogenic polydipsia.

**Methods:** A 62 y/o male with history of schizophrenia, non-compliant with antipsychotics, presented with altered mental status for 3 days. In addition to poor memory and inability to care for himself, he was also noted to be drinking large quantities of water. He was admitted 2 months prior for acute confusion with severe hyponatremia secondary to massive water ingestion. On initial evaluation, patient was awake but disoriented, afebrile, and hemodynamically stable. Laboratory evaluation was significant for serum Na 120 meq/L, serum osmolarity 250 mOsm/kg, BUN 11, and Cr 1.2. Thyroid and cortisol studies were unremarkable. Urine osm was found to be 157, with UNa of 18. Review of labs from prior admission revealed serum Na of 107meq/L with a corresponding Uosm of 54 mosm/kg. During current admission, patient was treated with water restriction; serial measurements of serum Na and urine osm are shown. Patient had improvement in mental status with serum sodium levels in the 125-130 meq/L range.



**Conclusions:** Reset osmostat is a variant of the SIADH marked by disordered ADH regulation. ADH levels can be maximally suppressed at a basal hyponatremic state, but rise quickly with serum sodium long before the hyponatremia is corrected. As shown in Figure 1, this patient demonstrated an ability to maximally dilute the urine when his serum sodium reaches a value of 107 meq/L, but ADH levels quickly rise as serum sodium levels approach 120 meq/L. The end result is a persistent hyponatremic state.

**PUB371**

**An Overlooked Entity: Warfarin Related Nephropathy – A Case Report** Manjunath Kottalgi, Pragnesh J. Patel, Amber S. Podoll, Kevin W. Finkel. *Internal Medicine, Renal Disease and Hypertension, Univ of Texas Medical School, Houston, TX.*

**Background:** Warfarin has long been used as the oral anticoagulant of choice for treatment, primary and secondary prophylaxis in patients with various pro-thrombotic states that can lead to thromboembolic events. Several adverse effects of warfarin overdose on renal function have been described in the recent literature including glomerular hemorrhage, acute tubular injury with occlusive red blood cell casts[3] and interstitial nephritis[2,8]. Hematuria in patients on warfarin therapy has been described as early as in 1964 by Reilly et al. The incidence, population at risk and outcomes has been described recently by Brodsky et al in a prospective study[3]. Warfarin-related nephropathy has been an overlooked entity; but it can have a significant impact on morbidity and mortality, more so in patients with chronic kidney disease[3].

**Methods:** A 68 year old female was recently started on warfarin anticoagulation for an acute pulmonary embolism one week prior to presentation. On readmission, she complained of fatigue, tremors of hands, decreasing urine output and dysuria. She denied any fever, chills, nausea, vomiting, abdominal pain, hematuria, prior history of renal disease or use of NSAIDS. She was initially hypoglycemic. She had an acute rise in her serum creatinine from 0.8 mg/dl to 8.0 mg/dl along with a correlated rise in INR from 1.11 to 5.67 over 9 days. She was oliguric at presentation with urine output of 20ml/hr. Urine analysis showed 6 rbcs/hpf, 42 wbcs/hpf, moderate blood, mild proteinuria. Urine culture was negative. Biopsy was deferred due to coagulopathy. Subsequently along with correction of INR with vitamin K, her renal functions improved over the course of 7 days to a creatinine of 1.7mg/dl and eGFR of 31ml/min/1.73m2 at discharge. She never required renal replacement therapy.

**Conclusions:** Considering the large population on warfarin therapy clinicians should have a heightened awareness of this entity. This calls for a larger prospective study to identify at risk populations, guidelines to monitor renal functions while being treated with warfarin, precautions and therapies to minimize the risk of warfarin- related nephropathy.

**PUB372**

**Crescentic IgA Nephropathy (IgAN) in the Renal Allograft: A Case Report** Shashikant Patel, Samir Parikh, Jon R. Von Visger. *Dept of Nephrology, The Ohio State Univ Medical Center, Columbus, OH.*

**Background:** Aggressive IgAN is rare in the renal allograft. We report a case of recurrent IgAN that manifested as a necrotizing and crescentic glomerulonephritis (GN).

**Methods:** 31 year old male received deceased donor renal transplant (Tx) after developing ESRD due to IgAN. Induction therapy included ATG, steroids (5 days) and sirolimus. Nine months after Tx he developed acute cellular and antibody mediated rejection with mild IgA staining which improved with steroids. Graft function again worsened and repeat biopsy showed crescentic GN but no IgA. Therapy was started but due to worsening disease a 3rd biopsy was done and showed crescentic IgAN. Graft function returned to baseline after treatment with oral cyclophosphamide and steroids.

**Conclusions:** We report a case of crescentic IgAN in a renal allograft successfully treated with oral cyclophosphamide. Crescentic IgAN in the renal allograft is rare. Reports from our institution suggest steroid free regimen and sirolimus may increase risk. Treatment with cyclophosphamide appears to be effective with response similar to native IgAN. Crescentic IgAN is a devastating manifestation that can cause graft failure. Early recognition and aggressive treatment provides the best chance for graft survival.

**PUB373**

**BK Nephropathy or Rejection** Sarah Khan, Bhupinder Sangha, Scott McRight, Neeraj Singh, Adrian P. Sequeira. *LSU Health Sciences Centre, Shreveport, LA.*

**Background:** BK virus nephropathy may mimic acute cellular rejection histologically. We present a kidney transplant recipient with worsening renal function 2 years post-transplant. Her kidney biopsy showed lymphocytic cellular infiltrate, with weakly positive BK stain and a negative plasma BK virus PCR, presenting a diagnostic dilemma.

**Methods:** A 53 year old female with a deceased donor kidney transplant presented with slowly rising serum creatinine. She was on tacrolimus 2mg twice daily, mycophenolate mofetil 360 mg twice daily and prednisone 2.5 mg daily for maintenance. Her baseline serum creatinine was 1.5 mg/dl, had slowly risen to 2.3 mg/dl over 6 months. She was treated for biopsy proven BK nephropathy 15 months earlier, with plasma BK virus at 135,000 copies/ml. Her immunosuppression was reduced and serum creatinine returned to baseline with resolved viremia. On current admission, plasma BK virus PCR was undetectable (<5000 copies/ml, Mayo Clinic Laboratories). Kidney biopsy showed intense lymphocytic cellular infiltrate, no viral cytopathic changes and weakly positive BK stain. Donor specific antibodies was negative. Banff 1B acute cellular rejection was diagnosed; managed with IV steroids. Serum creatinine improved to 1.7 mg/dl at 2 weeks, but again worsened to 3.0 mg/dl a month later. Repeat biopsy showed persistent cellular infiltrate, and a stronger BK virus stain than previous. Plasma BK virus PCR was positive at 18,200 copies/ml. Diagnosis of BK nephropathy was made and immunosuppression was reduced with improvement in both serum creatinine and BK viremia.

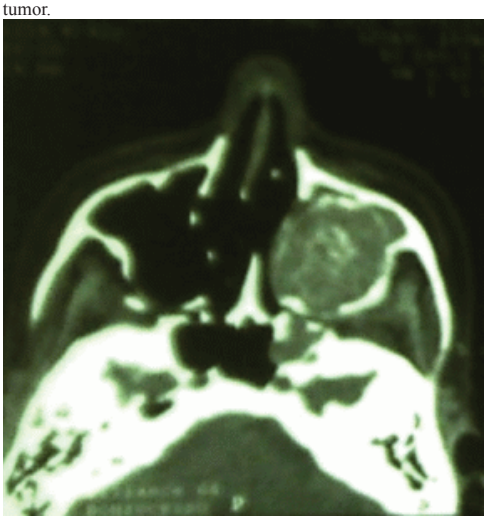
**Conclusions:** This case underlines the difficulty differentiating BK nephropathy from acute rejection, specially in absence of BK viremia, cytopathic changes; and weakly positive stain. Negative plasma BK virus PCR is reported to have a 100% negative predictive value for ruling out BK nephropathy. Our case highlights that BK nephropathy may occur at serum BK virus levels below the threshold levels reported by some laboratories. It is unclear whether our patient had a genotype variant causing falsely low BK virus PCR. Finally, if weak staining for BK virus has the same significance as intense staining, and whether some genotype variants may cause a weak BK virus staining is unclear.

**PUB374**

**Multiple Brown Tumors as a Complication of Hyperparathyroidism in a Patient with Chronic Kidney Disease** Guilherme Fonseca Mendes, Talita Mourao Chaves Corrica, Talita Cardoso Proenca, Tatiana Santos, Maria izabel Neves de Holanda Barbosa, Luiz Fernando Christiani. *Nephrology, Hospital Federal de Bonsucesso, Rio de Janeiro, Brazil.*

**Background:** Brown tumors are benign lesions with mass effect and intense osteoclastic activity caused by primary or secondary hyperparathyroidism. It is observed in 1.5-13% of secondary hyperparathyroidism.This should be managed with active Vitamin D and calcimimetics to avoid serious complications.

**Methods:** We report a case of a 42yo african-american female patient referred to our department for evaluation of hyperparathyroidism and chronic kidney disease managed by hemodialysis for 12 years. She was using calcitriol 3mcg 3x/week and Calcium 2g/day. Due to history of multiple kidney stones leading to left side nephrectomy, we considered the diagnosis of primary hyperparathyroidism. The physical exam was relevant for several deformities, especially left eye proptosis, chest enlargement and phalanx resorption. On chest x-ray was seen multiple masses close to chest wall; the skull, chest and spine CT performed showed multiple inflating lesions in ribs, severe spinal compression and orbital tumor.



The 99TC parathyroid scintigraphy evidentiate two hypercaptating areas, suggesting hyperplasia. Laboratory workup was relevant for: PTHi: 1771 pg/mL; ALP: 1318 U/L; P: 4,6 mg/dL; Ca: 8,8 mg/dL. She underwent total parathyroidectomy with subcutaneous implant, improving significantly her quality of life and laboratory findings. The brown tumors still, but are being followed with CT and had no reduction in 4 months.

**Conclusions:** Several complications may be associated with hyperparathyroidism. In this patient, the lack of an early diagnosis and the development of chronic kidney disease contributed to this level of deformity. Thus, hyperparathyroidism, either primary or secondary, must be controlled aggressively to avoid this level of complication.

**PUB375**

**Posterior Reversible Encephalopathy Syndrome in an Adult Patient with Thrombotic Microangiopathy and Diffuse Alveolar Hemorrhage** Zhongguang Yang, John Doran, Titilayo O. Ilori. *Nephrology, Emory Univ School of Medicine, Atlanta, GA.*

**Background:** Posterior reversible encephalopathy syndrome (PRES) is a neurologic condition characterized by headache, altered consciousness, seizures, and cortical visual loss with typical MRI features.Its pathogenesis is unclear. Renal failure and hypertension

are known risk factors. Limited PRES cases associated with immunosuppressive drugs including cyclophosphamide (CYC) and steroids were reported. We present an interesting case of biopsy-proven thrombotic microangiopathy (TMA) who developed PRES.

**Methods:** A 29 year old male with ESRD and biopsy proven TMA presented developed diffuse alveolar hemorrhage. The etiology of alveolar hemorrhage was unclear. He was stared on plasmapharesis followed by high dose prednisone and IV CYC monthly. Patient was admitted with hypertensive emergency with pulmonary edema. He received 2nd dose of CYC 20 days before admission. Before hemodialysis started, he suddenly developed altered consciousness, headache, and seizure lasting 2 minutes together with visual loss. Head CT demonstrated hypodense foci in bilateral posterior occipital lobes. CT angiogram of head and neck failed show blood vessel abnormalities. Brain MRI revealed T2- and fluid-attenuated inversion recovery (FLAIR)-weighted hyperdense lesions in bilateral parieto-occipital lobes. EEG showed mild generalized slowing of the background without focal features. PRES was diagnosed and treated with hemodialysis and aggressive antihypertensive therapy as well as keppra.

**Conclusions:** PRES is a rare finding in patients with glomerulonephritis and more commonly seen in lupus. It has also been reported in few cases of atypical HUS and thrombotic thrombocytopenic purpura. We believe our patient may have atypical HUS secondary to mutations in the complement pathway, genetic testing was not done. CYC, steroids and uncontrolled hypertension might also be causative factors for PRES. CYC may cause water toxicity; corticosteroids may lead to hypertension and fluid overload. Early recognition and intervention with aggressive antihypertensive therapy and hemodialysis will improve outcome and avoid permanent brain injury and sequela.

## PUB376

**Disseminated Primary Varicella Infection in Adult Renal Transplant Patient** Ramandeep S. Banga, Maria Aurora C. Posadas, Dannah Wray, Titte Srinivas. *MUSC.*

**Background:** Immunosuppressed patients are susceptible to disseminated varicella (VZV) due to impaired cell-mediated immunity. We present a case of primary varicella in an adult patient with kidney transplant.

**Methods:** A 37 year old African-American male who received a cadaveric renal transplant 3 years ago presented with rash. His maintenance immunosuppression included tacrolimus, mycophenolate mofetil (MMF), and prednisone. He denied any history of recent travel or VZV in the past. His nephew was recently diagnosed with VZV. The patient presented with diffuse vesiculo-papular rash spreading from his scalp, face, arms, trunk, and groin over a period of three days. He had no rashes on his hands and feet. Direct fluorescence antibody testing performed on the serous fluid from his vesicle was positive for VZV. His VZV IgM was high (5.47) while IgG was negative. His VZV PCR was 173,000 copies/ml. HSV, HIV, hepatitis B, and hepatitis C serologies were all negative. The patient's MMF was held. He was treated with Acyclovir 10mg/kg IV q8 hours for 7 days. Soon after starting treatment, the patients vesiculo-papular rashes evolved into crusting lesions.

**Conclusions:** Since the introduction of Varicella vaccine in 1995, only approximately 2-4% of adult solid organ transplant (SOT) recipients are seronegative for VZV and therefore susceptible to primary varicella infection. Currently, there are no guidelines for using varicella vaccine in patients with end-stage renal disease. Early diagnosis and aggressive treatment with acyclovir effectively alters the clinical course and could be life saving. Varicella vaccination has been shown to reduce morbidity in VZV seronegative recipients and should be considered in ESRD patients anticipating kidney transplant. VZV seronegative transplant patients should also be counseled on precautions to take to reduce the risk of disease transmission from recently vaccinated or infected contacts.

## PUB377

**Subclinical Transient Immune-Complex Mediated Glomerulonephritis in Living Donor Kidney** Manpreet Singh, Jean M. Francis, Sandeep Ghai. *Renal Section, Boston Univ School of Medicine, Boston, MA.*

**Background:** Kidney transplantation is the best available therapy for patients with end stage renal disease (ESRD) with live kidney donation having better long-term outcomes. Selection criteria for live donors should be very strict to prevent any long-term complications after kidney donation. We report a case of young living donor with transient immune complex (IC) mediated glomerulonephritis(GN) noted as an incidental finding on zero time allograft biopsy. We emphasize the importance of a systematic approach to donor evaluation.

**Methods:** A 31 year old female donated a kidney to her father who has ERSD from diabetic nephropathy. She has a history of well controlled skin psoriasis . She was deemed a good candidate byrheumatology with a negative workup. Her workup was completely normal, importantly she had two normal UA without proteinuria and hematuria and two 24-urine collections with normal creatinine clearance and normal proteinuria. Her physical Exam was unremarkable. A zero time biopsy was performed per our protocol which showed diffuse mild glomerular hypoperfusion without an active inflammatory process, There was mild chronic changes and a focal finding of IC deposits predominantly distributed in the mesangium with immune-fluorescence positive for C3, IgM, trace IgA and IgG. A repeat biopsy of the graft was done 3 months after transplant, which showed persistence of the immune deposits. Both donor and recipient remain totally asymptomatic.

**Conclusions:** Despite the extensive workup performed in our patient to rule out the possibility of any potential kidney disease, her glomerular lesion remained silent and subclinical. Our patient likely had a transient IC mediated (GN) in the setting of a skin infection prior to kidney donation. Her skin infection was successfully treated, and she continues to do well without any serologic evidence of any disease process, and her kidney function remains normal without proteinuria and hematuria. This case underlies that a complete and thorough evaluation remains a difficult process. A systematic approach should be used on a case by case basis and follow up of all donors should be regimented.

## PUB378

**Overlapping Syndrome of ANCA Vasculitis and Lupus Nephritis** Noemie C. Juaire, Paramita Mukherjee. *Div of Nephrology, Univ of Washington, Seattle, WA.*

**Background:** ANCA associated vasculitis is rarely seen to occur simultaneously with lupus nephritis (LN). We present a case of an elderly man with no prior history of kidney disease, who presented with general malaise and acute kidney injury and was found to have lupus nephritis and ANCA related vasculitis concurrently.

**Methods:** 73 year old Caucasian man with known hypertension presented to his primary care doctor with anorexia, nausea and vomiting over 2 weeks and 30 pound weight loss over last 1 year. He had no prior history of kidney disease. Physical exam was remarkable only for a blood pressure of 143/83. Initial workup showed blood urea nitrogen of 118mg/dL and creatinine of 10.9mg/dL. His creatinine 1 year back was normal. Urine analysis was notable for 3+ blood and 3+ protein. Numerous monomorphic red blood cells (RBC) and few dysmorphic RBC were seen on urine sediment. Urine protein to creatinine ratio was 1.5 grams/gram, C3 was low at 75mg/dL, C4 was normal, cryoglobulins, hepatitis and human immunodeficiency virus serologies were negative. Autoimmune workup revealed p-ANCA positive at 1:320 and myeloperoxidase autoantibodies at >100. Interestingly, anti-dsDNA , anti-cardiolipin IgM and IgG were significantly elevated at 45 IU/mL, 87.3 U/mL and 101.7 U/mL respectively. On hospital day 3, he was started on dialysis. Renal biopsy done on hospital day 6 showed findings consistent with concurrent LN and ANCA vasculitis. Subsequently, he was started on plasmapheresis, cyclophosphamide and pulse dose steroids. He had partial renal recovery and both plasmapheresis and dialysis were stopped after 2 weeks.

**Conclusions:** Although, cases of concurrent LN and ANCA related vasculitis reported in the literature is very low, their association occurs more frequently than just the coincidental occurrence of unrelated diseases. Both these diseases are mediated by a T helper1 immune mechanism suggesting a possible pathogenic link. Therefore, it is important to consider both ANCA vasculitis and LN in patients with high suspicion of glomerulonephritis associated with renal failure.

## PUB379

**The Chronic Kidney Disease Water Intake Trial: Results from a Pilot Study** William F. Clark, Jessica M. Sontrop, Shih-Han S. Huang, Louise M. Moist, Andrew A. House, Matthew A. Weir, Amit X. Garg. *Nephrology, London Health Sciences Centre, Canada.*

**Background:** Evidence from animal and human studies suggests a beneficial effect of increased water intake on kidney function. Prior to conducting a large trial on the effect of increased water intake on kidney function in chronic kidney disease (CKD) patients, we conducted a pilot trial to examine the safety and feasibility of increasing water intake in CKD patients.

**Methods:** In this randomized pilot trial, 29 adults with stage 3 CKD were randomly assigned, in a 2:1 ratio, to a hydration intervention (n=18) or control group (n=11) (Canada, 2012-2013). Participants in the hydration group were instructed to drink 1.0 to 1.5 L water per day for 6 weeks (in addition to usual consumed beverages), depending on sex and weight. Patients in the control group were instructed to maintain their current fluid intake. Participants collected 24-hr urine samples at baseline, 2- and 6-weeks after randomization.

**Results:** Participants were an average of 61 years (SD 14), 63% male, and 81% Caucasian; 54% had diabetes and 86% had hypertension. Average eGFR at baseline was 40 ml/min/1.73m$^2$(SD 11 ml/min/1.73m$^2$); the median albumin to creatinine ratio was 19 mg/mmol (IQR: 6-74 mg/mmol). Between baseline and 6-weeks, 24-hour urine volume increased by 0.7 L/d in the hydration group and decreased by 0.3 L/d in the control group (between-group difference in change 0.9 L/d; p=0.002) (**Figure 1**). Average plasma sodium was 138 mmol/L in both groups at 6 weeks and remained above 130 mmol/L for all patients at all time points. No changes in electrolytes, osmolality, or eGFR were observed. Health-related quality of life remained similar between groups. No serious adverse events were reported nor observed.

**Conclusions:** Patients with stage 3 CKD can safely and successfully increase daily water intake up to 1.5 L/day in addition to usual daily fluid intake.

**PUB380**

**Uric Acid Lowering in Metabolic Syndrome Patients Utilizing a Phytochemical Approach** Günter Siegel,[1,2] Janine Berkholz,[1] Karl Winkler,[3] Eugeny Ermilov.[1] *[1]CharitéCrossOver, Charité - Univ Clinic Berlin, Berlin, Germany; [2]Biomedical Center, Univ of Uppsala, Uppsala, Sweden; [3]Institute of Clinical Chemistry, Univ Clinic Freiburg, Freiburg, Germany.*

**Background:** As a rule, hyperuricaemia leaves to think of gout, renal insufficiency and/or especially metabolic syndrome (MetS). We sought to determine whether uric acid (URAC) could be lowered in MetS patients by a phytochemical approach. In a 2-month clinical pilot study with Ginkgo biloba (EGb761, 2×120 mg/d) on 11 MetS patients, a novel biomarker spectrum made point-of-care theranostics feasible.

**Methods:** Photometric methods, ELISAs, EIAs, ellipsometry.

**Results:** The ratio oxLDL/LDL was reduced by 21.0% (p<0.002), 8-iso-PGF$_{2\alpha}$ 39.8% (p<0.002), MPO 29.6% (p<0.0137), IL-6 12.9% (p<0.0407), hs-CRP 39.3% (p<0.0049), Lp(a) 26.3% (p<0.001), MMP-9 32.9% (p<0.042), insulin 9.4% (p<0.042), HOMA-IR 14.0% (p<0.0244), nanoplaque formation 14.3% (p<0.0077), nanoplaque size 23.4% (p<0.0004), whereas SOD was augmented 17.7% (p<0.0095), GPx 11.6% (p<0.001), cAMP 43.5% (p<0.001), and cGMP 32.9% (p<0.001). Since none of the patients had a manifest kidney disease, we evaluated URAC. Fasting morning URAC was reduced by 10.6% (p<0.0033) from 315.7 to 285.2 µmol/L (p<0.0046). Because ginkgo is not an ASS- and allopurinol-like agent, we looked out for a mechanistic explanation. URAC was directly correlated to SOD,GPx,MPO,Lp(a),IL-6,hs-CRP,TGFβ$_1$,insulin,HOMA-IR,VLDL,AST,ALP, and inversely to nanoplaque formation k$_{Ca2-3/Lp}$,ALT,GGT,CREA. Thus, changes in cytokine pattern and beneficial effects on oxidative stress parameters could unravel diminution of URAC.

**Conclusions:** Ginkgo had beneficial effects on a multitude of inflammatory, oxidative stress, diabetic and arteriosclerotic biomarkers. URAC reached reference values in all patients. Thus, ginkgo may be used as complementary drug in the treatment of MetS and gout patients.

| Biomarker | ΔURAC [µmol/L] | |

**PUB381**

**Supplemental Knowledge of an Elevated Creatinine** James Francis Dylewski,[1] Christopher Neil Marshall,[1] Robert Pursell.[2] *[1]Internal Medicine, St. Luke's Univ Hospital and Health Network, Bethlehem, PA; [2]Nephrology, St. Luke's Univ Hospital and Health Network, Bethlehem, PA.*

**Background:** Serum creatinine (Cr) is conventionally used as a surrogate marker to estimate glomerular filtration rate and therefore kidney function. There are many causes for an elevated Cr, but the majority are due to decreased creatinine elimination resulting from kidney injury. However, this is not the only cause.

**Methods:** A 27-year-old Caucasian male presented for evaluation of flank pain of several days duration. It was found that his Cr was 5.4 mg/dl and BUN 34. The patient denied any urinary symptoms & denied taking any medications including NSAIDs or anabolic steroids. He did, however, relate he was taking arginine & creatine supplements for athletic enhancement. His urinalysis was bland in dip & microscopic examination. His CPK was 184 U/L & tests including CBC, ASO titer, C3, C4, CH50, ANA, HIV antibody, & hepatitis panel were all normal. Additionally, urine drug screen, eosinophils, & myoglobin were also normal. A retroperitoneal ultrasound showed normal sized kidneys without hydronephrosis, calculi, or masses. CT of the abdomen did not demonstrate any abnormalities. The patient was given intravenous fluids & monitored closely. With discontinuation of the arginine & creatine supplements, his Cr fell significantly to 1.3 mg/dL, which was felt to be his baseline.

**Conclusions:** Creatine is an endogenous nitrogen based organic acid that is synthesized from arginine & serves as an energy source for skeletal muscles, particularly when phosphorylated. In muscle cells, creatine & creatine phosphate are converted to creatinine as part of degradation. Creatine monohydrate is a common supplement used by athletes and is readily oxidized to creatine in the body. Consequently, with large exogenous intake of creatine & arginine, Cr could be elevated. This is a case of a patient who chronically ingested arginine & creatine that developed what appeared to be acute kidney injury from these substances. The supplements were stopped & his Cr improved accordingly. Review of the literature yielded a few cases of similar occurrences with the use of creatine supplements.

**PUB382**

**L-Arginine or L-Citrulline Supplementation Does Not Protect Diabetic Renal Injury** Alaa S. Awad,[1] Hanning You,[1] Ting Gao,[1] Timothy K. Cooper,[2] Sidney M. Morris.[3] *[1]Medicine, Penn State Univ College of Medicine, Hershey, PA; [2]Comparative Medicine, Penn State Univ College of Medicine, Hershey, PA; [3]Microbiology and Molecular Genetics, Univ of Pittsburgh, Pittsburgh, PA.*

**Background:** Our recent publication showed that pharmacological blockade of arginases confers kidney protection in diabetic nephropathy via a nitric oxide synthase 3 (NOS3)-dependent mechanism. Arginases compete with NOS for the common substrate L-arginine. L-arginine or L-citrulline supplementation showed beneficial effect in patients with hypertension, angina and erectile dysfunction by improving endothelial function with enhanced NO synthesis. Therefore, we hypothesized that L-arginine or L-citrulline supplementation would prevent or reduce diabetic renal complication.

**Methods:** DBA mice injected with multiple low doses of vehicle or streptozotocin (STZ; 50 mg/kg ip for 5 days) were provided drinking water (DW) supplemented with L-arginine, L-citrulline, isonitrogenous nonessential amino acid control or no amino acids (DW control) for 9 weeks.

**Results:** Diabetic mice with DW control showed significant increases in urine albumin excretion ($p<0.05$), albumin/creatinine ratio ($p<0.05$), kidney weight/body weight ratio ($p<0.05$), plasma creatinine ($p<0.05$), blood urea nitrogen ($p<0.05$), glomerular histopathological changes ($p<0.001$), and kidney macrophage recruitment ($p<0.001$) compared to normal mice after 9 weeks of diabetes. Isonitrogenous amino acid supplementation in diabetic mice was similar to DW control diabetic mice. Interestingly, neither L-arginine nor L-citrulline supplementation in diabetic mice affected any of these renal parameters despite increasing kidney arginine levels (6- and 8-fold; respectively).

**Conclusions:** These findings indicate that chronic L-arginase or L-citrulline supplementation does not prevent or reduce diabetic renal injury.

## PUB383

**The Influence of Age on the Changes in Reduced Glutathione (GSH) Levels in Mitochondria from Rat Kidney Cortex and Medulla following Dietary Supplementation with N-Acetylcysteine (NAC)** Marianna J. Zamlauski-Tucker, Bingwei Ye. *Physiology & Health Science, Ball State Univ, Muncie, IN.*

**Background:** Dietary supplementation is beneficial since it increases the level of GSH, the principal antioxidant inside cells, and protects cells against oxidative injury. A previous study reported that mitochondrial GSH levels in kidneys from young rats did not change with dietary supplementation. The present study investigated whether rat age influenced the effect of supplementation with NAC on mitochondrial and cytosolic GSH levels in the kidney.

**Methods:** Young Experimental (i.e., 3 months of age) and Old Experimental (i.e., 22 months of age) female Lewis rats were given NAC (200 mg/Kg body wt) via intraperitoneal injection for one week. Age-matched Control rats were not given any supplementation. At the end of the treatment period, the kidneys were harvested and separated into cortical and medullary sections. The sections were further separated into cytosolic and mitochondrial fractions by differential centrifugation. GSH levels in the fractions were measured using a spectrophotometric assay. There were 6 to 8 rats in each group and statistical comparisions between similar aged rats were done using a Student's t test.

**Results:** There were significant increases in mitochondrial and cytosolic GSH levels in kidney cortex and medulla from both Young and Old rats.

| | | Young | | Old | |
|---|---|---|---|---|---|
| | | Control | Experimental | Control | Experimental |
| Cytosol | | | | | |
| umol/g kid wet wt | Cortex | 5.5 ± 0.4 | 7.7 ± 0.6* | 5.6 ± 0.6 | 11.4 ± 0.4* |
| | Medulla | 3.1 ± 0.2 | 9.2 ± 0.2* | 3.2 ± 0.6 | 7.9 ± 0.4* |
| | | | | | |
| Mitochondria | | | | | |
| nmol/ g kid wet wt | Cortex | 100 ± 6 | 133 ± 6* | 128 ± 23 | 198 ± 13* |
| | Medulla | 94 ± 7 | 130 ± 8* | 124 ± 23 | 240 ± 12* |

All date expressed as X + SEM. * significantly different from age-matched Contol.

**Conclusions:** Rat age does not influence the increase in either mitochondrial or cytosolic GSH levels observed in rat kidneys following exogenous dietary supplementation with NAC.

## PUB384

**Health Literacy and Serum Albumin in Veterans on Chronic Hemodialysis** Anil Ramesh, Michael J. Fischer, Anuradha Wadhwa, Elisa J. Gordon. *Nephrology, Hines VA Medical Center, Hines, IL.*

**Background:** Adults with end-stage kidney disease (ESKD) suffer many metabolic complications. Controlling albumin and serum potassium requires dietary control and understanding of dietary counseling. Inadequate health literacy (HL) could impair the ability of patients to understand and follow simple instructions related to dietary health. However, little is known about whether health literacy contributes to patients' ability to maintain nutrition/electrolyte balance.

**Methods:** We conducted a cross-sectional study involving semi-structured interviews with Veterans with ESKD requiring chronic hemodialysis at one VA outpatient dialysis unit between 2011-2013. HL was assessed by the Short Form Test of Functional Health Literacy Assessment (S-TOFHLA), and inadequate/marginal HL was defined by a score of < 67. Adequate HL was assessed by a score of > 68. Serum laboratory values including albumin, potassium and sodium were obtained from the electronic Health Record (EHR) at time of interview. T- Test was used to assess association between laboratory values and HL.

**Results:** Among 43 patients (88% participation rate), 19 (44%) had inadequate/marginal HL. Serum albumin mean concentration was 3.70 (standard deviation 0.41). Patients with adequate HL had serum albumin concentrations of 3.81 (standard deviation 0.43) compared with 3.56 (standard deviation 0.33) in patients with marginal/low HL ($p=0.044$). Potassium and sodium were not significantly related to HL ($p>0.05$).

**Conclusions:** Low health literacy is associated with lower serum albumin levels, suggesting that health literacy may impact nutritional status in patients with ESKD. Nutrition counseling should be provided to accommodate ESKD patients of all literacy levels.

## PUB385

**Effect of Intradialytic Parenteral Nutrition (IDPN) on Nutrition Status in Hemodialysis Patients** Zvi Barnea, Sara Blumberg Benyamini, Relu Cernes, Biro Alexander, Ze'ev Katzir. *Nephrology, Wolfson Medical Center, Holon, Israel.*

**Background:** Malnutrition is common in hemodialysis patients and is associated with an increase in morbidity and mortality. Intradialytic parenteral nutrition (IDPN) has been proposed to improve nutritional status and outcome in malnourished patients. The aim of this study was to evaluate the effect of IDPN in patients suffering from nutrition deterioration.

**Methods:** We have evaluated nutrition monthly score, based on six biochemical parameters (albumin, creatinine, urea, cholesterol, Kt/V, C-Reactive Protein) and weight change (paper in preparation) in 28 malnourished hemodialysis patients. We calculated the slope of three subsequent monthly scores prior to beginning of IDPN treatment and three months following beginning of treatment. We used paired t test to compare score, slope, and each of the score components before and after three months of IDPN treatment.

**Results:** In 28 HD patients, three months following beginning of treatment, IDPN treatment has stopped nutritional deterioration: Average nutrition score was significantly improved. Slope values of three subsequent monthly scores turned positive compared to a negative slope before treatment. IDPN treatment induced a significant increase in albumin, urea and post dialytic weight. Creatinine, cholesterol, CRP, Kt/V were not significantly changed.

| Nutrition parameters | Average value three months before IDPN | Average value three months after IDPN | P value |
|---|---|---|---|
| Nutrition score | 67 (7.77) | 70 (8.37) | 0.0426 |
| Slope | -5.14 (1.03) | 1.73 (0.83) | <0.0001 |
| Albumin (mg/dL) | 3.13 (0.49) | 3.25 (0.4) | 0.0454 |
| Creatinine (mg/dL) | 5.71 (1.29) | 5.94 (1.24) | 0.156 |
| Urea (mg/dL) | 91.24 (28.4) | 106.0 (26.88) | 0.0023 |
| Cholesterol (mg/dL) | 135.9 (34.17) | 138.2 (5.85) | 0.247 |
| Percent post dialysis weight change | -0.3 (0.1) | 0.4 (0.02) | 0.038 |
| Kt/V | 1.32 (0.3) | 1.29 (0.6) | 0.15 |

**Conclusions:** IDPN treatment improved nutrition parameters, score and slope of nutrition status, and stopped nutritional deterioration in HD patients.

## PUB386

**Effect of an Increased Water Intake in DNA Adducts Formation and Urinary Mutagenicity in Smokers: A Randomised Controlled Trial** Inmaculada Buendia Jimenez,[1] Pascaline Richardot,[1] Pascaline P.P. Picard,[1] Glenn Talaska,[2] Michel De Meo,[3] Gerard Friedlander.[4] *[1]Danone Research, Palaiseau, France; [2]Dept of Environmental Health, Univ of Cincinnati, Cincinnati, OH; [3]Laboratoire Mutagenèse Environnementale, Univ de la Méditerranée and IMBE, Marseille, France; [4]Institute for European Expertise in Physiology, Paris, France.*

**Background:** The association between fluid intake and bladder cancer risk remains controversial since epidemiological studies has produced mixed results. To date, very little is known about to which extent the amount of water intake influences the action of excreted toxics upon the urinary system. We performed a proof of concept trial to investigate the effect of water intake on mutagenesis in smokers, a high risk population for bladder cancer.

**Methods:** Monocentric randomized controlled trial. Inclusion criteria: Male subjects aged 20-45 y/o, smokers (at least 15 cigarettes per day) and small drinkers (≤1 L of fluid/day; ≤500 mL of water/day; urinary 24-hour urinary volume 700 mOsmol/kg). Exclusion criteria: History of diseases which could affect the results of the study or under treatment which could modify measurements of the study. Primary outcome: 4-ABP DNA adducts formation in exfoliated bladder cells in 24-hour urine collection. Secondary outcome: urinary mutagenicity in 24-hour urine. Study design: Subjects were allocated in two groups: Test group: Subjects had to consume 1.5 L daily of the study product (EVIAN®) on top of their usual water intake for 50 days. Control group: Subjects had to continue their usual lifestyle habits.

**Results:** 65 subjects were randomized. Mean age was 30 y/o and mean cigarettes per day was 20. A slight decrease in adducts formation was observed between baseline and last visit but no statistically significant difference was demonstrated between the groups.

Conversely, urinary mutagenicity significantly decreased.

**Conclusions:** Our study shows that increasing water intake decreases urinary mutagenicity. However, it is not confirmed by urinary adducts formation. Further research with a larger sample size or longer intervention period would be necessary to address the impact of water intake on this parameter.

## PUB387

**Providing Snacks during Dialysis Treatment Contributes to an Adequate Protein-Energy Intake in Hemodialysis Patients** Geertrude I. Struijk-wielinga,[1] Floor Neelemaat,[1] Peter Jm Weijs,[1] Pieter M. Ter Wee.[2] *[1]Nutrition & Dietetics, Internal Medicine, VU Univ Medical Centre, Amsterdam, Netherlands; [2]Dept of Nephrology, VU Univ Medical Centre, Amsterdam, Netherlands.*

**Background:** Protein-energy wasting (PEW) is a strong predictor of mortality in hemodialysis patients. Although PEW is also caused by non nutritional conditions, nutritional support targeting adequate protein intake has been shown to improve PEW and

patient outcome. Previously we found that our patients, consuming an in-center meal and snack during dialysis treatment were still short of 15 grams of protein and 240 kcal per day. Aim: to investigate a 6 week intervention of a snack with education focused on adequate protein-energy intake particularly on dialysis days.

**Methods:** Hemodialysis patients in a university hospital, dialysed three times per week, were offered a choice out of 7 different snacks (±15 g protein, 240 kcal). Indirect calorimetry and physical activity level were measured to provide daily energy needs. 24 hour dietary recall was completed for 2 dialysis days both at baseline (t0) and after 6 weeks (t6).

**Results:** 28 patients (15 men), age 57±12 year (mean ± SD), BMI 24±4 kg/m$^2$were enrolled. At t0 protein intake was 78% of estimated requirements (65±25 g/d, p<0.01), and increased to 100% (85±29, p<0.002) at t6. At t0 energy intake was 84% of energy requirements (1693±535 kcal/d, p<0.007) and increased to 99% (1989±606, p<0.033) at t6. At t0 8 patients out of 25 (32%) achieved their protein goal, at t6 13 patients (57%) (p<0.003).

**Conclusions:** Protein and energy intake of hemodialysis patients on dialysis days is insufficient and can be improved by providing a snack (±15 g protein, 240 kcal) and education during dialysis treatment.

## PUB388

### Validation of Objective Malnutrition Inflammation Scores in Pediatric and Adolescent Cohort on Chronic Maintenance Dialysis

Franca M. Iorember, Oluwatoyin F. Bamgbola. *Pediatrics, LSU Health Science Center, New Orleans, LA.*

**Background:** Altered body composition and uremic milieu often confound accuracy of single-item diagnostic tools [including anthropometry]. In addition, shared pathophysiologic process makes it impractical to dissociate burden of nutritional deficiency and pro-oxidative inflammation in dialysis patients. Hence, composite score of malnutrition-inflammation morbidity [MIM] has been validated in adult dialysis patients. However, despite greater burden of chronic uremia, similar tools are not widely available for pediatric use. Objective: To assess the validity of composite scoring of clinical indices of malnutrition-inflammation morbidity in a pediatric dialysis cohort.

**Methods:** We derived composite scores [OMI] from quantitative indices of renal pathology, nutrition, dialysis adequacy, protein catabolism, and dialysis modality. We avoided items that required [cognitive] subjective responses in the questionnaire. We assessed reliability by a test-retest method and measured validity by examining predictive relationship of the indices with serum c-reactive protein [CRP] in a multiple regression analysis.

**Results:** Twenty patients on chronic dialysis with a mean age of 12.8 years were enrolled. Eight subjects with elevated CRP [> 0.3 mg/dl] had higher scores for MIM. Patients on hemodialysis [HD] had greater OMI score than those on peritoneal dialysis [PD]. Test-retest score showed high degree of reliability [typical error 0.07; r = 0.95]. Diagnostic indices of MIM were predictive of elevated serum CRP in a regression analysis [$R^2$ = 0.9, F = 4.3, p = 0.03]. Sensitivity of OMI score was 62.5%, specificity 83%, accuracy 75% and precision was 71%.

**Conclusions:** Anthropometric and laboratory indices of nutritional status are often confounded by proximate events [e.g. inflammation, fluid retention] in dialysis patients. Composite scoring system may be more accurate and cost effective. Unlike Subjective Global Assessment instrument in adults, we attempted to improve accuracy and enhance universal applicability by avoiding cognitive input [subjective responses] from patients. Large scale population studies are needed to optimize clinical effectiveness and refinement of the diagnostic tools.

## PUB389

### Effect of Appetite and Body Mass Index on Energy Intake in Chronic Kidney Disease Stage 3 and 4 Patients

Anita Saxena,[1] Amit Gupta,[1] Raj K. Sharma,[1] Reena Choudhary.[1] *[1]Nephrology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, UP, India; [2]Nephrology, Madras Medical Mission, Chennai, TN, India; [3]Inst#1; [4]Inst#1.*

**Background:** Assessment of nutritional status in chronic kidney disease requires multiple markers.

Objective: To assess effect of appetite on nutritional status of predialysis patients on first visit to nephrology center.

**Methods:** Three day dietary intake of 141 stage 3 and 4 CKD patients was recorded. Appetite was classified as normal, average, poor and anorexic. Body mass index was classified as normal, underweight, severely, underweight and overweight.

**Results:** Serum albumin was 2.9± 0.9 g/dL; protein 5.7 ±1.40; and proteinuria 3.5 ±1.4g. Of 140 patients, 52.8% had normal BMI, 15% were underweight, 5.71% were severely underweight and 27.1% overweight. BMI correlated (p .000) with energy, protein, carbohydrate, creatinine, serum protein, proteinuria and SGA scores. There was difference in dietary intake in BMI groups in weight (p .000), appetite (.004), energy (.004) and carbohydrate (.003). Dietary intake was: energy 18.8±8.9 kcal/kg; protein 0.7±.33 g/kg , fat 0.34±.4g/kg and carbohydrate 3.0±1.4/kg. Based on BMI classification, energy intake was: normal 18.8 ±9.0, underweight 19.3±10.0, severely underweight 16.3±11.1, overweight 19.0±7.8kcal/kg. Protein intake was: normal 0.73 ±.34; underweight 0.81±0.4, severely underweight 0.67±.44, overweight 0.63±.20 g/kg.

Appetite correlated (p .000) with weight, BMI, dietary energy, protein, fat , serum albumin and creatinine. Based on appetite groups energy intake was: normal 29.9±4.6; average 20.4±.4, poor 18.2±5.8 and anorexic 10.1±5.5 kcal/kg and protein intake was: normal 1.0±.3; average 0.75±.2; poor 0.68±.2 and anorexic 0.43±.2.

**Conclusions:** 47.2% patients were underweight. Energy intake was low. Protein intake was as required for prediialysis patients. Serum albumin and serum protein were low. Loss of appetite, low energy intake and presence of proteinuria may have a synergistic effect and cause malnutrition in CKD stage 3 and 4 patients. Inadequate energy intake, poor appetite, body mass index and low serum albumin and protein are markers of malnutrition in predialysis population.

## PUB390

### Is Free Testosterone Concentration a Prognostic Factor of Survival in Chronic Renal Failure?

Stanislaw Niemczyk,[1] Katarzyna Szamotulska,[2] Longin Niemczyk,[3] Malgorzata Gomolka.[1] *[1]Military Institute of Medicine; [2]National Research Institute of Mother and Child; [3]Medical Univ of Warsaw.*

**Background:** Persons with chronic kidney disease (CKD) experience low quality of life and increased cardiovascular mortality. Understanding the reasons of poor outcomes in renal failure seems to be an important challenge.

Aims. 1) evaluation of total (T) and free testosterone (fT) concentrations in pre-dialysis patients and patients treated with different methods of dialysis 2) assessment of relationship of T and fT concentration with biochemical parameters, which are sensitive to renal failure 3) evaluation of prognostic importance of T and fT levels in predicting long-term survival of CKD patients.

**Methods:** Four groups of men were examined: 14 hemodialysed (HD), 13 on peritoneal dialysis (PD), 9 pre-dialysis and 8 healthy aged 56±17, 53±15, 68±12, 43±10 years respectively. The concentrations of T, SHBG, TBG, prealbumin, albumin, CRP, Hb and gasometry were measured. FT was estimated from formula.

**Results:** T concentration [ng/ml] was 3.98±1.76 in HD, 5.46±1.95 in PD, 4.02±1.26 in pre-dialysis and 6.40±2.43 in healthy subjects (p=0.035) , fT [ng/ml] 0.065±0.025, 0.091±0.041, 0.060±0.014, 0.104±0.043, respectively (p=0.004). T and fT were negatively correlated with age in all studied groups. There was also observed a negative significant association between T concentration and body mass index (p=0.013) , a negative marginally significant association between T concentration and HCO3 concentration (p=0.085), and a negative significant association between fT concentration and HCO3 concentration (p=0.006). Within six years from the baseline, there were 5 deaths in HD, 1 in PD and 3 in pre-dialysis. In univariate analysis, both age (p=0.002) and fT (p=0.001) were related to survival probability. However, when both variables were entered into the model only fT was marginally significant (p=0.094).

**Conclusions:** The concentration of free testosterone was lower in hemodialysis and pre-dialysis patients than in healthy subjects. Free testosterone is related to metabolic acidosis and in chronic renal failure may prognose long-term survival better than age.

## PUB391

### Olive Oil in the Treatment of Constipation of Patients on Hemodialysis

Christiane Ishikawa Ramos, Aline Fátima Andrade De Lima, Daniela Gimenes Grilli, Giovana Sertori, Maria A. Kamimura, Lilian Cuppari. *Nutrition Program, Div of Nephrology, Federal Univ of São Paulo, São Paulo, Brazil.*

**Background:** Constipation is a common gastrointestinal symptom in patients with chronic kidney disease (CKD), especially those on hemodialysis (HD). Although effective and safe treatment for constipation has not been established, mineral oil is commonly used due to its laxative effect. Edible oils, such as olive oil, could also be an alternative for the management of constipation of these patients. Therefore we aimed to investigate the effect of olive oil in comparison to mineral oil on constipation of patients with CKD on HD.

**Methods:** This was a double-blind randomized controlled trial conducted for 4 weeks (wk4). Constipation was diagnosed by the Roma III criterion.Thirty-one patients (16M, 52.1±11.0 years) diagnosed as constipated were randomized to mineral oil (MG; n=16) or olive oil (OG; n=15) groups. The initial dose of each oil was 4ml/day and was adjusted as needed.

**Results:** There was no difference in total oil used between the groups during the follow-up (MG=143.5 ± 51.5 ml, OG=148.5 ± 42.7 m, p=0.67). As shown in the table, the decrease in the frequency of the symptoms of constipation, evaluated by Roma III criterion, was similar between mineral oil and olive oil groups.

| | Mineral% | | Olive% | |
|---|---|---|---|---|
| | baseline | wk4 | baseline | wk4 |
| < 3 evacuations/week | 50.0 | 6.3* | 40.0 | 13.3* |
| Straining on defecation | 68.8 | 18.8* | 60.0 | 20.0* |
| Lumpy or hard stools | 75.0 | 18.8* | 86.7 | 26.7 |
| Incomplete evacuation | 87.5 | 18.8 | 100.0 | 26.7 |
| Anorectal obstruction | 68.8 | 25.0 | 73.3 | 6.7* |
| Manual maneuvers | 12.5 | 0.0* | 13.3 | 0.0* |
| Abdominal pain | 56.3 | 18.8* | 26.7 | 6.7* |
| *p<0.05; baseline vs wk4. | | | | |

At the end of follow-up in 57% and 60% of the patients of mineral oil and olive oil groups, respectively, constipation was resolved (p=0.83).

**Conclusions:** Olive oil seems to be an effective and health alternative in the treatment of the constipation of HD patients.

**Investigation of ANCA Induced Activation of Human Neutrophils Using High Content Analysis** Alice M. Coughlan,[1] Vincent P. O'Reilly,[1] Anthony Mitchell Davies,[2] Julie M. Williams,[3] Mark Alan Little.[1] *[1]Trinity Health Kidney Centre, Trinity College Dublin, Ireland; [2]The Irish National Center for High Content Screening and Analysis, Trinity College Dublin, Ireland; [3]School of Immunity and Infection, Univ of Birmingham, United Kingdom.*

**Background:** ANCA vasculitis is associated with the presence of autoantibodies that are capable of stimulating neutrophils in vivo. There is marked variability in stimulatory capacity both between donors and IgG preparations. However, this phenomenon is difficult to study due to inter-assay variability.

**Methods:** To overcome this variability in ANCA induced neutrophil activation we used high content analysis (HCA) to screen IgG from vasculitis patients and controls for their ability to activate healthy donor neutrophils. Neutrophils from up to 8 donors were stimulated with a panel of protein-G purified IgG in 384 well plates. Activation was accessed by measuring actin rearrangement (phalloidin stain) and superoxide production (Dihydrorhodamine 123) by automated fluorescence microscopy using an InCell Analyser 1000™.

**Results:** We were able to simultaneously assess the stimulatory potential of IgG from 22 patients or controls against neutrophils from 8 healthy donors. Neutrophil responses to ANCA varied greatly. Some donor neutrophils were poor responders to all ANCA preparations. Furthermore, ANCA preparations that did activate neutrophils, did so in a donor dependent manner. The DHR assay produced a more robust and reproducible signal than the phalloidin stain.

**Conclusions:** Using robotic fluid handlers and the InCell Analyser™ to miniaturise and automate ANCA neutrophil assays allowed us to overcome the inter-assay variability observed when neutrophil donors are assessed on different days and facilitated testing of a large number of IgG preparations simultaneously.

**Effection of IL-17 on the Proliferation and IgA1 Underglycosylation of B Cells** Junming Fan,[1,2] Jiaru Lin,[2] Fugang Li,[2] Li Liu.[2] *[1]Dept of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China; [2]Div of Nephrology, Dept of Internal Chinese Medicine, Luzhou Medical College, Luzhou, Sichuan, China.*

**Background:** IL-17, a Th17 cell-derived proinflammatory molecule, has been found to play an important role in the pathogenesis of autoimmune diseases. IL-17 may be associate with IgA nephropathy (IgAN). Wherefor it has been not known whether IL-17 exerts a direct effect on B Lymphocytes in IgA nephropathy. This study was to investigate the effection ofIL-17 on the proliferation and underglycosylation of IgA1 in a B Lymphocytes line.

**Methods:** DAKIKI, was cultured and stimulated by IL-17. For dose-dependent test, cell was cultured for 48h with different doses (5ng/ml, 10ng/ml, 20ng/ml, 40ng/ml, 80ng/ml, 160ng/ml, 320ng/ml) of IL-17. For time-dependent test, cell was cultured for 24, 48 and 72h. The cell proliferation was examined by CCK-8 assay. The IgA1 concentration and galactosylation in supernatant tested by ELISA and HAA lectin *binding assay*.

**Results:** 1.The result of CCK-8 showed that the proliferation of DAKIKI cells in group with 10ng/ml,20ng/ml,40ng/ml concentration were statistical significance obviously increased ($P<0.05$) compared with medium group. 2. The ELISA showed that the DAKIKI cells could secreted more IgA1 than control after induceded by IL-17. The levels of IgA1 secreted by DAKIKI cells in IL-17 incubation were gradually increased with the dose- and time-dependent. 3. The HAA lectin showed that, the glycosylation of IgA1 were decreased with dose- and time-dependent manner after 48 hours incubation with IL-17.

**Conclusions:** IL-17 could induced the B cell proliferation, IgA1 secretion and IgA1 underglycosylationin in DAKIKI cells with a dose-dependent and time-dependent manner. The results suggested that the possible mechanism IL-17 participation the pathogenesis of IgA nephropathy was associated with B lymphocyte secreting much IgA1 and underglycosylation of IgA1.

**CD19_CD5_ B Cells in Primary Nephropathy** Hilmi Umut Unal,[1] Ali Kilinc,[2] Mahmut Ilker Yilmaz.[3] *[1]Nephrology, Gulhane Military Medical School, Ankara, Etlik, Turkey; [2]Internal Medicine, Gulhane Military Medical School, Ankara, Etlik, Turkey; [3]Nephrology, Gulhane Military Medical School, Ankara, Etlik, Turkey.*

**Background:** In developing countries, IgA nephropathy is the most common cause of the primary glomerulonephritis. As can be seen at any age, it most frequently occurs between the ages of 20 and 30. The etiology of this disease is unknown. Focal segmental glomerulosclerosis (FSGS) has become an important lesion found to underlie the nephrotic syndrome in adults . Primary FSGS is one of the causes of idiopathic nephrotic syndrome that may be etiologically related to but more severe than minimal change disease.CD19CD5 B cells are important producers of IgA and contribute to several autoimmune diseases, they may play an important role in IgA nephropathy.In this study, peripheral Lymphocyte subgroups CD-5-19 with primary glomerulonephritis (IgA ve primary FSGS) evaluated the relationship between response to treatment and don't response to treatment.

**Methods:** In the 6-month follow-up responses to the treatment of patients which as a result of renal bx FSGS (primary) or IgA reported that CD5- CD19 values evaluated retrospectively. Lymphocyte subgroups were measured by flow cytometry in 31 patients. The results of the patients between two groups who do not respond and respond to treatment were compared.A complete response is a reduction in proteinuria to <200 to 300 mg/day. A partial response in patients presenting with nephrotic range proteinuria is a reduction of ≥50 percent, and to less than 3.5 g/day.

**Results:** There was no significant difference between the lymphocyte sub-groups in two groups.

**Conclusions:** In humans, elevated numbers of CD19CD5 B cells have been reported in patients with Sjogren syndrome and rheumatoid arthritis. CD19CD5 B cells are the main IgA producers in mucosal tissues. As few as 5% of the circulating B cells are CD5 B cells in normal adults. Further researches need doing on use of flow cytometry results for the activity of the disease and disease in response to treatment.

**PUB395**

**The Involvement of Histone Acetylation in Kidney Injury of Dahl Salt-Sensitive Rats** Kumiko Io,[1] Tomoya Nishino,[1] Shinichi Abe,[1] Yoko Obata,[1] Takehiko Koji,[2] Shigeru Kohno.[1] *[1]Second Dept of Internal Medicine, Nagasaki Univ School of Medicine, Nagasaki City, Nagasaki Prefecture, Japan; [2]Dept of Histology and Cell Biology, Nagasaki Univ School of Medicine, Nagasaki City, Nagasaki Prefecture, Japan.*

**Background:** Renal sclerosis is caused by arteriosclerosis associated with long-term hypertension. Although epigenetics, which is an acquired regulation of gene expression, has recently been reported to be related to the progression of hypertension, it is unclear whether epigenetics is associated with the progression of renal sclerosis. Therefore, we investigated the relationship between epignetics, especially histone acetylation, and renal sclerosis.

**Methods:** 6 week-old male Dahl salt-sensitive (DS) rats were used as models of renal sclerosis. Rats were divided into 3 groups: (i) rats fed normal salt diet defined as NS group, (ii) rats fed high salt diet defined as HS group, (iii) HS group administered curcumin, a histone acetyltransferase inhibitor, daily defined as HS+C group. After 6 week from the start of salt load, the kidneys of these rats were dissected out. Morphologic changes were assessed by Masson's Trichrome staining. ED-1 which is a marker of macrophage, Monocyte Chemotactic Protein-1 (MCP-1) and histone acetylation were assessed by immunohistochemistry or by Western blotting.

**Results:** Compared with NS group, HS and HS+C groups showed a significant increase of systolic blood pressure from the 2 weeks of salt load. Serum creatinine increased markedly in HS group at the 6 week, while the increase of serum creatinine was suppressed in HS+C group. In HS group, interstitial fibrosis and glomerular sclerosis were observed and the numbers of ED-1 or MCP-1 positive cells were increased significantly more than those in NS group at the 6 week. On the other hand, HS+C group showed the inhibition of these inflammation and fibrosis. Histone acetylation was more increased in HS group than that in NS group, whereas the administration of curcumin decreased histone acetylation in the kidney.

**Conclusions:** Our results suggested that histone acetylation was involved in progression of hypertensive kidney injury in DS rats.

**PUB396**

**The Effects of AST-120 Treatment on Uremia-Induced Disruption of Colonic Epithelial Tight Junctions and the Associated Systemic Inflammation** Hoang Anh Nguyen,[1] Jun Yuan,[2] Nosratola D. Vaziri.[2] *[1]UCI Dept of Internal Medicine; [2]UCI Div of Nephrology & Hypertension.*

**Background:** The primary functions of the intestinal mucosa are absorption of nutrients, secretion of waste products, and serving as a barrier to prevent absorption of waste products and entry of luminal microorganisms and their harmful by-products in the host's internal milieu. This study was designed to test the hypothesis that oral administration of the activated charcoal (AST-120) may attenuate uremia-induced depletion of the intestinal tight junction key protein constituents ZO1, occludin, and claudin-1 via absorption of ammonia and its subsequent conversion to the highly caustic ammonium hydroxide.

**Methods:** Male Sprague-Dawley rats were randomized into control (CTL), experimental (CRF), and AST-120 treatment groups for two weeks. The CTL group consumed regular diet. Two CRF groups were rendered uremic by addition of 0.7% adenine to their food, and one of these CRF groups was exposed to AST-120 for two weeks. Then, they were euthanized and the colons were harvested and processed for the expression of the key constituents of the tight junctional proteins using Western blot analysis and immunohistological staining.

**Results:** The Western blot revealed that the CRF group showed a significantly marked reduction in protein expressions of ZO1 ($p < 0.001$), occludin ($p < 0.01$), and claudin-1 ($p < 0.01$) compared to the CTL group. However, activated charcoal (CRF + AST) treatment group showed significant increase in protein expression only for ZO1 ($p < 0.05$). Immunohistological staining indicated that the colonic tissues have increased wall thickness and accumulation of mononuclear leukocytes in the lamina propria and microvilli in the CRF animals. With AST-120 treatment, the inflammatory markers in the colonic tissues decreased compared to the CRF group.

**Conclusions:** Uremia results in depletion of the key protein constituents of the colonic tight junction leading to impairing intestinal barrier function and contributing to the systemic inflammation. Activated charcoal was effective in attenuating uremia-induced depletion of colonic epithelial tight junction and the associated systemic oxidative stress and inflammation.

## PUB397

**Isolation of MicroRNA from the Proximal Tubules of Archival Renal Biopsies Utilising Laser Capture Microdissection**

Geraint James Rees Dingley,[1,2] Juan Mason,[1] Sara Kathryn Campbell,[1,2] Paul Steven Bass,[3] Jane Elizabeth Collins.[2] *[1]Wessex Renal and Transplant Service, Portsmouth Hospitals NHS Trust, United Kingdom; [2]Clinical Experimental Sciences, Univ of Southampton, United Kingdom; [3]Dept of Cellular Pathology, Royal Free Hospital, London, United Kingdom.*

**Background:** MicroRNAs are short noncoding RNAs that play important roles in regulating mammalian gene expression by inducing posttranscriptional gene repression by blocking protein translation or mRNA degradation. Altered regulation of miRNAs are implicated in mechanisms of tubulointerstitial fibrosis in renal disease and are differentially expressed in different cell populations within the kidney. To understand the role of microRNAs in the kidney it is desirable to quantify microRNA expression from individual cell types.

Due to the serious risk of bleeding associated with renal biopsy, it is not ethically advisable to take additional biopsies for research. The archive of paraffin-embedded biopsy specimens therefore offers an invaluable source of diseased human tissue for molecular interrogation. Laser Capture Micro dissection (LCM) provides a method to isolate miRNAs from specific cell types within biopsies.

**Methods:** Serial sections were cut through renal biopsy and normal kidney blocks which had been fixed in formalin and embedded in paraffin-wax for a similar period of time. Sections were stained with lectins to accurately identify the proximal tubules prior to LCM. RNA was extracted from the samples using a commercially available kit which was modified to optimise RNA yields. MicroRNA expression was quantified with RT-PCR.

**Results:** In proximal tubules of patients with moderate to severe diabetic nephropathy, miRNAs 192 and 194 were consistently downregulated at a statistically significant level compared with morphologically normal proximal tubules from healthy tissue. Three other microRNAs were also differentially expressed at statistically significant levels.

**Conclusions:** This result is consistent with published data using in situ hybridisation and demonstrates that LCM of archival biopsy samples is a reliable and powerful quantitative tool in the study of cell specific microRNAs in healthy and diseased tissues.

## PUB398

**Bone-Derived Mesenchymal Stromal Cells from HIV Transgenic Mice Exhibit Altered Proliferation, Differentiation Capacity and Paracrine Functions along with Impaired Therapeutic Potential in Kidney Injury**

Kang Cheng, Xiqian Lan, Partab Rai, Andrei Plagov, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical Center, Great Neck, NY.*

**Background:** Mesenchymal stem cells (MSCs) secrete paracrine factors that could be cytoprotective and serve roles in immunoregulation during tissue injury. Although MSCs express HIV receptors, and co-receptors, and are susceptible to HIV infection, whether HIV-1 may affect biological properties of MSCs is not clear. We hypothesize that MSCs derived from Tg26 mice will have compromised paracrine function. To test our hypotheis, we evaluated cellular proliferation, differentiation and paracrine functions of MSCs isolated from compact bones of healthy control mice and HIV-1 transgenic (Tg26) mice.

**Methods:** MSCs were isolated from compact bones of control and HIV transgenic (Tg26) mice and their properties were characterized (Exp Mole Pathol, 2013). Control or HIV-MSCs were administered 24 hours prior to administration of cisplatin (12 mg/Kg, intraperitoneal) in mice (6 mice in each group). Total RNA was extracted from HIV-MScs and probed for HIV genes. The ability of control and HIV- MSCs to protect against cisplatin toxicity was also studied in cultured renal tubular cells.

**Results:** We successfully isolated MSCs from healthy mice and Tg26 HIV-1 transgenic mice and found the latter expressed viral Nef, Vpu, NL4-3 and Vif genes. The proliferation and differentiation of Tg26 HIV-1 MSCs was inferior to MSCs from healthy mice. Moreover, transplantation of Tg26 HIV-1 MSCs less effectively improved outcomes compared with healthy MSCs in mice with acute kidney injury. Also, Tg26 HIV-1 MSCs secreted multiple cytokines, but at significantly lower levels than healthy MSCs, which resulted in failure of conditioned medium from these MSCs to protect cultured renal tubular cells from cisplatin toxicity.

**Conclusions:** HIV-1 had adverse biological effects on MSCs extending to their proliferation, differentiation, function, and therapeutic potential. These findings will help in advancing mechanistical insight in renal injury and repair in the setting of HIV-1 infection.

**Milk Fat Globule-Epidermal Growth Factor-8 Modulates Tissue Fibrosis and Renal Damage in Ureteral Obstruction**

Jean-Francois Cailhier, Marie-joelle Brissette. *Medicine, Institut du Cancer de Montreal, CRCHUM, Montreal, Canada.*

**Background:** Renal diseases are characterized by tubulointerstitial fibrosis due to the loss of renal parenchymal cells. In the early phases of inflammation, macrophages kill renal parenchymal cells leading to renal fibrosis. Mediators released by the apoptotic renal resident cells play a crucial role in the modification of the renal microenvironment. We recently demonstrated that milk fat globule-epidermal growth factor E8 (MFG-E8) was released by apoptotic epithelial and endothelial cells, resulting in a reduced pro-inflammatory cytokine production by macrophages. Therefore, we propose to study the role of MFG-E8 on the modulation tissue damage and the inflammatory response in unilateral ureteral obstruction (UUO).

**Methods:** C57BL/6 WT or MFG-E8 KO mice underwent unilateral ureteral ligation for 3, 7 and 14 days to evaluate tissue damage and macrophage phenotype. MFG-E8 (30μg/kg) was administered intra-peritoneally 1 day before and every 3 days subsequently. Kidneys were harvested and stained with Sirius Red (collagen fibers) and with aSMA (myofibroblasts) to evaluate fibrosis. We also used PAS to evaluate tissue damage. F4/80 and iNOS staining were used to assess macrophage phenotype.

**Results:** MFG-E8 administration reduced kidney damage and fibrosis compared to control, moreover, its absence in MFG-E8 KO mice was associated with a worse outcome. Furthermore, the presence of MFG-E8 was associated a decreased number of pro-inflammatory M1 macrophages.

**Conclusions:** This suggests that MFG-E8 (prior to any MFG-E8 release by apoptotic cells) can attenuate tissue damage induced by UUO through modulation of the inflammatory response.

## PUB400

**Hydrochlorothiazide Is Superior to Furosemide as a Renoprotective and Antiproliferative Add-On to Losartan in the Remnant Kidney Model**

Simone C.A. Arias, Renata A. Souza, Claudia R. Sena, Camilla Fanelli, Denise M.A.C. Malheiros, Clarice K. Fujihara, Roberto Zatz. *Univ of Sao Paulo, Brazil.*

**Background:** We showed previously that a losartan+hydrochlorothiazide (L+H) association arrests renal injury in the remnant kidney model (Nx) even when started after renal injury is already established. Here we investigated whether this is due solely to a diuretic effect.

**Methods:** Munich-Wistar rats (n=61) underwent Nx. One month later, tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/d), glomerulosclerosis index (GSI), % glomerular collagen-1 (%COLL), %interstitial (INT) α-smooth muscle actin (%SMA), INT PCNA (PCNA, cells/mm$^2$), and glomerular volume ($V_G$, x $10^6$ μm$^3$) were evaluated in 17 rats ($\mathbf{Nx_{pre}}$). The remaining rats were divided in: **Nx** (untreated); $\mathbf{Nx_{LH}}$ (L, 50 mg/Kg/d + H, 6 mg/Kg/d); and $\mathbf{Nx_{LF}}$ (L + Furosemide (F), 20 mg/Kg/d, the highest nontoxic F dose), and followed for 7 months, when all measurements were repeated.

**Results:**

| | TCP | ALB | GSI | %COLL | %SMA | PCNA | $V_G$ |
|---|---|---|---|---|---|---|---|
| $Nx_{pre}$ | 198±5 | 91±7 | 16±3 | 12±2 | 4±1 | 145±17 | 0.7±0.1 |
| Nx | 200±14 | 203±26[a] | 327±38[a] | 24±3[a] | 9±1[a] | 163±21 | 1.4±0.1[a] |
| $Nx_{LH}$ | 145±6[ab] | 26±4[ab] | 15±5[b] | 10±2[b] | 3±1[b] | 34±3[ab] | 1.3±0.5[a] |
| $Nx_{LF}$ | 167±6[abc] | 90±18[bc] | 40±13[abc] | 19±3[c] | 5±1[bc] | 86±10[abc] | 1.6±0.1[ac] |

Mean ± SE, [a, b, c] $p<0.05$ vs. $Nx_{Pre}$, Nx, and $Nx_{LH}$, respectively

Survival was 35% in Nx, 100% in $Nx_{LH}$ and 82% in $Nx_{LF}$. L+H arrested GS, SMA and COLL, and reversed TCP, ALB, and interstitial PCNA. Likewise, L+F partially reversed hypertension and exerted a renoprotective effect, which nevertheless was always less pronounced than with L+H. In addition, glomerular volume was increased in L+F compared with L+H.

**Conclusions:** The striking renoprotection afforded by L+H treatment in the Nx model is at least in part associated with effects unrelated to its diuretic action, such as limited glomerular hypertrophy, regression of interstitial proliferation and arrested inflammation. Thiazide add-on can exert superior renoprotection even in advanced chronic kidney disease.

**Early Glomerular Crescents Consist of the Accumulation of Podocytes That Undergo Detachment from the GBM**

Wilhelm Kriz,[1] Isao Shirato.[2] *[1]Anatomy and Embryology, Medical Faculty Mannheim, Univ of Heidelberg, Mannheim, Germany; [2]Internal Medicine, Nephrology, Juntendo Univ, School of Medicine, Tokyo, Japan.*

**Background:** Cellular crescents are a prominent feature encountered in many glomerular diseases. The pathogenesis is poorly understood. Frequently, the hypothesis is favored that breaks in the GBM allow the leakage of plasma and cells triggering cell proliferation in Bowman's space (Ryu et al 2012, J Pathol 228: 482 i.a.). Focal ruptures of the GBM in crescents have been shown but evidence that such gaps precede and represent the cause of crescent formation is lacking. Since many years we have known that podocytes are shedded from the GBM and excreted as viable cells with the urine in patients with kidney diseases (Hara et al. 1998, Am J Nephrol 18: 35; Vogelmann et al. 2003, Am J Physiol Renal Physiol 285: F40 i.a.)Meanwhile, the detachment of podocytes from the GBM has been documented by TEM as a gradual process of viable cells (Kriz et al. 2013, Am J Physiol Renal Physiol 304: F333). We pursued the idea that detaching podocytes accumulate in Bowman's space forming clusters corresponding to a cellular crescent.

**Methods:** We studied the process of podocyte detachment in several models of glomerular diseases (including growth stimulation by FGF2, Masugi GN, PAN nephrosis) by LM in 1mm serial sections and TEM.

**Results:** We found that the process of podocyte disconnection from the GBM is extremely gradual comprising hundreds of individual steps. Portions of a certain podocyte may be found to be fully disconnected, others were seen in intermediate stages, still others had close contact to the GBM. Prolongation of this process was achieved by podocytes that established new contacts to adjacent podocytes, which were still connected to the GBM.

In addition, contacts to parietal cells were regularly seen. These manoeuvres prevented detached podocytes from being spoiled into the urine and led to their accumulation in Bowman's space.

**Conclusions:** Cellular crescents consist of detaching and detached podocytes linked to each other as well as to the tuft and Bowman's capsule.

**Influence of Klotho in Cognitive Deficit Linked to Chronic Kidney Disease (CKD) on Animal Model of CKD (5/6 Nephrectomy)** Sabrina Degaspari,[1] Carmen B. Tzanno-martins,[2] Clarice K. Fujihara,[3] Roberto Zatz,[3] Tania Araujo Viel,[4] Ana Elisa Bohmer,[1] Cristoforo Scavone,[1] Elisa M. Kawamoto.[1,5] *[1]Dept of Pharmacology, Univ of São Paulo - USP, Brazil; [2]CINE, São Paulo, Brazil; [3]Faculdade de Medicina, USP, Brazil; [4]School of Arts, Sciences and Humanities, USP, Brazil; [5]Laboratory of Neurosciences, NIH.*

**Background:** CKD is believed to have a negative impact on cognitive function. Recent studies have reported changes in serum klotho with aging, and levels of this protein are strongly influenced by renal function. Also, it may be involved in the cognitive impairment (CI) found in CKD. The aim of the present study is to evaluate the correlation between CI and levels of Klotho in serum and hippocampus and frontal cortex in 5/6 nephrectomized rats (Nx).

**Methods:** Forty Munich-Wistar rats underwent 5/6 nephrectomy (Sham rats were used as control groups). After 30 days of surgery, all animals were evaluated using different behavior tests (Fear Conditional Test and New Object Recognition Test) during five months. Nx animals which had only 25% or less of the markers of Sham group in the behavior tests were included in the CI group (Nx-CI). At the end of this period, blood and brain samples were collected. All samples were used to analyze Klotho levels by ELISA test.

**Results:** After Nx surgery, rats showed higher levels of creatinine (1.13±0.05) compared to Sham group (0.65±0.05), we found an increase of glomerulosclerosis in Nx group (9.96±1.9) than in Sham rats (0.92±0.9), and an important interstitial expansion in Nx group (6.64±0.8) comparing with Sham rats (0.04±0.01). Forty six percent of Nx rats (Nx-CI) showed impaired memory retention (novel object recognition test and contextual fear conditioning). After 4 months from Nx, we observed that serum Klotho was lower in Nx-CI than in Sham and Nx rats. Our data also show a decreased in frontal cortex Klotho in Nx-CI group comparing with Sham and Nx rats, however, hippocampus Klotho levels showed no difference between groups.

**Conclusions:** Together, the present data suggest that changes in Klotho signaling plays a key role in the development of cognitive changes associated with chronic renal failure.

**Iron Reduction Suppresses Renal Tubulointerstitial Fibrosis in Mice with Unilateral Ureteral Obstruction** Iori Ozono,[2] Yasumasa Ikeda,[1] Shoji Kagami,[3] Toshiaki Tamaki.[1] *[1]Pharmacology, Institute of Health Biosciences, The Univ of Tokushima Graduate School, Tokushima, Japan; [2]Student Laboratory, Tokushima Univ, Tokushima; [3]Pediatrics, Institute of Health Biosciences, The Univ of Tokushima Graduate School, Tokushima.*

**Background:** Renal fibrosis plays an important role in onset and progression of chronic renal diseases. We have clarified that iron is involved in the pathological conditions on obesity, atherosclerosis and diabetic nephropathy. Although several underlying mechanisms of renal fibrosis have been shown, the role of iron in the process of renal fibrosis remains unclear.

**Methods:** o investigate iron role in renal fibrosis, we employed mice with unilateral ureter obstruction (UUO) and mice with sham operation as control. Mice with UUO were divided into 2 groups, treatment with deferoxamine (DFO), an iron chelator, or vehicle.

**Results:** At 1 week after surgery, renal interstitial fibrosis, as same as increased mRNA expression of collagens, were increased in mice with UUO and these changes were suppressed by DFO treatment. UUO-induced macrophage infiltration was reduced in UUO mice with DFO. UUO-induced expression of inflammatory cytokines and extracellular matrixes were ameliorated with iron reduction. Iron chelation inhibited the activated signaling of transforming growth factor-ß1-Smad3 pathway in mice with UUO operation. UUO-induced renal superoxide production and $p22^{phox}$ expression was attenuated by DFO treatment. Additionally, renal expressions of interleukin-1ß and NOD-like receptor, pyrin domain containing 3 were induced in mice with UUO, these changes were ameliorated by DFO treatment. In renal iron transporters, protein expressions of ferroportin and ferritins were upregulated, and transferrin receptor-1 and divalent metal transporter-1 were down-regulated in mice with UUO compared to sham operated mice although no difference of renal iron content was seen between mice with sham and mice with UUO.

**Conclusions:** These results have suggested iron is involved in the progression of renal tubulointerstitial fibrosis through oxidative stress and inflammatory changes, therefore the iron reduction potentiates to be a new therapeutic approach for renal fibrosis.

**PUB405**

**Sphingosine-1-Phosphate Receptor 1 and 3 Are Pivotal Mediators of Renal Fibrosis** Shunji Shiohira, Takumi Yoshida, Hidekazu Sugiura, Miki Nishida, Kosaku Nitta, Ken Tsuchiya. *Dept of Medicine Four, Tokyo Women's Medical Univ, Shinjuku, Tokyo, Japan.*

**Background:** Sphingosine-1-phosphate (S1P) has been suggested to be involved in the mechanism of renal fibrosis that functions through Sphingosine-1-phosphate receptor (S1PR) signaling pathways. Five subtypes of S1PRs have been identified. There have been reports of fibrosis and S1P in each cell in each organ, and differences in the effects of S1PRs have been reported in each organ. To get more insight into roles for S1P and receptor subtype effects *in vitro*, we performed siRNAs knockdown of receptor subtypes (1 and 3) and S1PR1 agonist and S1PR3 antagonist.

**Methods:** Normal rat kidney interstitial fibroblast (NRK-49F) cells were stimulated with exogenous S1P. Then the morphological changes of the NRK-49F cells after stimulation by S1P were examined. The growth and migration of cultured cells was quantified by using CL-Quant software to analyze time-lapse images in a Nikon BioStation CT. The real-time images of cell migration were monitored for 2 days. And the expressions (mRNA/Western blotting) of a-SMA, E-cadherin, collagen type 1 (COL1), collagen type 4 (COL4), TIMP1 and PAI1 were examined. To specify the kidney specific signal pathway, siRNAs targeted to S1P receptor subtypes (1 and 3) were generated. And also NRK-49F cells were stimulated with S1P after the addition of S1PR1 agonist and S1PR3 antagonist were evaluated.

**Results:** S1P stimulated fibrosis of NRK-49F cells in a dose- and time-dependent manner as previously observed, and induced morphological changes of NRK-49F cells. Migration of NRK49F cells was accelerated and increased a-SMA, COL1, COL4, TIMP1, and PAI1 and decreased E-cadherin expression levels were observed in the S1P-stimulated cells. S1PR3 siRNA transfection to NRK-49F cells attenuated S1P-induced cell growth, cell migration, and the expression of fibrotic markers. And also in the presence of S1PR1 agonist and S1PR3 antagonist, fibrosis and migration induced by S1P were suppressed.

**Conclusions:** These results suggest that S1P signaling mediated by S1PR1 and S1PR3 results in renal fibrosis.

**Medullary Fibrosis Assessment in Human Renal Biopsies: Correlation with Cortical Fibrosis** Alton Brad Farris,[1] Diane H. Lawson,[1] Cynthia Na Cohen,[1] Seymour Rosen.[2] *[1]Emory Univ; [2]Harvard Univ/Beth Israel Deaconess Medical Center.*

**Background:** Renal tubulointerstitial injury evaluation is important in both native and transplant kidneys; however, past studies have primarily focused on the renal cortex. To study medullary fibrotic injury, interstitial fibrosis (IF) was quantitated in both the renal cortex.

**Methods:** Native renal biopsies (n=37), included in the study if they contained medullary tissue, were scanned into digital whole slide images (WSIs); and IF was quantitated on trichrome stains and collagen III (CIII) immunohistochemistry using a positive pixel count algorithm. The algorithm was also used to quantitate the % composed of BM material on a PAS stain. IF was also measured by subtracting the PAS BM% from the trichrome (Trichrome%–PAS%, referred to as T–P) in order to account for BM material also detected on trichrome staining. Pathologist visual assessment of %IF was also obtained.

**Results:** IF showed a wide range by the different measurement modalities (e.g., 20-61% for all tissue by trichrome IF%). Image analysis of trichrome and T-P WSIs correlated for all anatomic compartments (r=0.66–0.98, p all <0.0001). Visual measures also showed a wide range, from 15-90% for all tissue and a significant correlation with all of the trichrome and T-P measures. CIII showed a range of 9.5-47% for all tissue and correlated between compartments (r=0.74, p=0.0001 for all tissue vs. cortex, r=0.89, P<0.0001 for all tissue vs. medulla, and r=0.71, P=0.0003 for cortex vs. medulla); however, CIII did not show a significant relationship with any of the other IF measures.

**Conclusions:** Trichrome and T-P WSI analysis correlated between the cortex, medulla, and entire tissue, and with visual assessment. In this study, CIII deposition correlated between compartments but not with other IF measures, suggesting the importance of additional components in extracellular matrix composition. Overall, medullary measurements may show utility in larger studies prospectively correlating medullary IF with renal function in both human and animal models; and medullary measurements could prove useful in drug studies, clinical trials, and evaluation of biopsies containing only medulla.

**Chronic Nicotine Attenuates Pro-Fibrotic Signal-Dependent Induction of HO-1: Its Role in Exacerbation of Renal Fibrosis** Istvan Arany, Dustin Reed, Robert Kampen, Luis A. Juncos. *Univ of Mississippi Medical Center.*

**Background:** There is a strong epidemiological association between smoking and risk of development and accelerated progression of chronic kidney diseases (CKD). Since plasma levels of TGFβ1 –a known mediator of renal fibrosis- are elevated in smokers, smoking may contribute to progression of CKD by augmenting tubulointerstitial fibrosis. On the other hand, HO-1 is an important factor that controls pro-fibrotic signaling. Here, we tested the hypothesis whether chronic nicotine (Ch-NIC) exposure exacerbates renal fibrosis by mitigating anti-fibrotic effects of HO-1.

**Methods:** A mouse model of unilateral ureteral obstruction (UUO) was employed to assess effect of chronic NIC exposure on interstitial fibrosis as well as expression of HO-1 and mediators of fibrosis (TGFβ1, IL-6) in the obstructed kidneys of mice exposed or not

to Ch-NIC. Contralateral kidneys served as controls. In vitro, the impact of chronic NIC on TGFβ1-mediated activation of HO-1 and alpha-smooth muscle actin (αSMA: a marker of fibroblast activation) promoters were studied in renal interstitial fibroblasts (NRK49F).

**Results:** UUO significantly increased tubulointerstitial fibrosis (αSMA expression and Masson trichrome staining), expression of TGFβ1, IL-6 and HO-1 in the obstructed kidneys. Ch-NIC exposure augmented fibrosis and expression of IL-6 but not TGFβ1 while decreased HO-1. In vitro, chronic NIC or IL-6 augmented TGFβ1-mediated activation of the αSMA but attenuated the HO-1 promoter. Activation of endogenous HO-1 by cobalt protoporphyrin (CoPP) or exogenous overexpression of HO-1 greatly diminished promoter activity of αSMA.

**Conclusions:** Our results suggest that chronic NIC augments promoter activity of the αSMA gene through IL-6-dependent suppression of HO-1 induction. Further studies are on the way to determine whether this effect is associated with suppression of the antioxidant response element or other cis-acting element of the HO-1 promoter. Manipulation of those pathways may present therapeutic means to ameliorate adverse effects of chronic NIC/smoking on renal interstitial fibrosis.

## PUB408

**Synergistic Interplay of the Canonical Wnt and TGFβ Pathways Induces Fibrosis** Omar H. Maarouf,[1] Derek Paul DiRocco,[1] Deepika Rangarajan,[2] Benjamin D. Humphreys.[1] *[1]Medicine/Renal, Brigham and Women's Hospital, Boston, MA; [2]Biotechnology, SRM Univ, Chennai, India.*

**Background:** Fibrosis is the morphologic hallmark of CKD and is characterized by exaggerated accumulation of collagen and emergence of myofibroblasts. Both the TGFβ and canonical Wnt signaling pathways are activated during kidney fibrosis, but whether these pathways interact during myofibroblast activation is unknown. We hypothesize that these pathways synergize, through β-catenin activation, to drive fibrotic gene expression in myofibroblasts.

**Methods:** We used two cell culture myofibroblast models: immortalized NRK49F cells and primary human dermal fibroblasts. The Wnt pathway was modulated pharmacologically, and the ability of TGFβ alone or with β-catenin stabilization to drive a luciferase-based β-catenin activity reporter (BAR) was assessed. Levels of activated myofibroblast transcripts, like fibronectin and αSMA, were also measured.

**Results:** TGFβ independently induced β-catenin activation in both NRK-49F cells and primary human dermal fibroblasts. Blocking β-catenin activation with XAV939, a tankyrase inhibitor which induces β-catenin degradation, repressed TGFβ-induced myofibroblast gene expression (fibronectin and αSMA). Stimulation of the Wnt pathway with the GSK3β inhibitor CHIR99021 induced fibronectin production. Combining TGFβ and CHIR99021 at sub-threshold doses led to an increase in the fibrotic phenotype by inducing fibronectin production and αSMA expression. Using the BAR system, sub-threshold doses of TGFβ and CHIR99021 were synergistic in inducing β-catenin pathway activation in a dose- and time-dependent fashion.

**Conclusions:** In fibroblast cell lines, the TGFβ and canonical Wnt pathways synergize to induce β-catenin activity, fibronectin expression and αSMA expression. Future efforts will focus on understanding whether β-catenin is required for myofibroblast gene expression induced by TGFβ, either alone or in combination with Wnt ligands.

## PUB409

**Is Galectin-3 Responsible for Microvascular Dysfunction in Uremia?** Andrew Duncan Stewart Findlay, Steven Michael Harwood, Julius Edward Kieswich, Magdi Yaqoob. *Translational Medicine and Theraputics, William Harvey Research, London, United Kingdom.*

**Background:** Microvascular dysfunction is universal in uraemia and contributes to cardiovascular mortality. The aetiology of uremic microvascular dysfunction remains elusive. We investigated microvascular dysfunction in experimental chronic uraemia by intravital microscopy (IVM) of leucocyte endothelial interactions in cremasteric postcapillary venules. We aimed to establish if the pro-adherent leucocyte cell surface protein Galectin-3 – (which is elevated in uremic leucocytes) would augment the interaction.

**Methods:** Wild Type (WT) C57Bl mice subject to 4 weeks 0.25%Adenine diet (AD n=8) or Sham Diet (SD n=6) underwent cremasteric IVM. Leucocyte rolling velocity, adhesion and transmigration were assessed. Galectin-3 Knockout (G3KO) mice were then subjected to 4 weeks AD (n=5) vs 4 weeks SD (n=3) and had Cremasteric IVM performed.

**Results:** WT AD fed mice had significantly more cell adhesion vs WT SD (p=0.008), Cell rolling velocity and emigration were not significantly altered. In Galectin-3 KO on AD the cell adhesion was reduced to equivalent WT and G3KO SD levels. Interestingly the G3KO on AD had a milder uraemic phenotype than WT on AD with significantly higher body weights and lower plasma creatinine.

**Conclusions:** Leucocyte adhesion on post capillary venules is increased in experimental uremia which is either directly or indirectly regulated by Galectin-3 interactions. The aetiology of AD induced chronic kidney disease is initially by Adenine deposition in renal tubules but also of secondary macrophage infiltration and tubulointerstitial fibrosis. A reduction in the uremic phenotype is likely to be due to a reduction in macrophage infiltration as Galectin-3 is a chemoattractant for monocytes and activates macrophages towards a pro-fibrogenic M2 phenotype.

## PUB410

**Pressure Promotes Fibrotic Responses in Renal Tubular Cells through miR-328-Mediated CD44 Up-Regulation** Tso Hsiao Chen, Cheng-hsien Chen. *Internal Medicine, Taipei Medical Univ-Wan Fang Medical Center, Taipei, Taiwan.*

**Background:** Pressure force is an important mechanism contributing to the induction and progression of tubulointerstitial fibrogenesis in ureteric obstruction.

**Methods:** In this study, we set up an in vitro pressure culture system, and investigated microRNA expression alterations correlate with pressure treatment in rat renal tubular cells (NRK-52E). When NRK-52E cells were cultured in the pressure culture system, 60 mmHg of pressure induced the expression of connective tissue growth factor (CTGF), transforming growth factor (TGF)-β, and fibronectin.

**Results:** MicroRNA array assays showed that pressure reduced miR-328 at the initial stage of pressurization. The expression level of miR-328 in pressurized cells significantly decreased within 2 h, recovered at 4 h, and increased at 8 h. Potential target of miR-328 has been reported to be human CD44. We identified a potential target sequence of miR-328 in rat CD44 3'-UTR as proven by 3'-UTR analysis. Protein analysis demonstrated that expression of CD44 was up-regulated at the initial stage of pressurization. CD44 siRNA transfection significantly reduced pressure-induced fibronectin in NRK-52E cells. However, CTGF expression was not influenced by CD44 siRNA transfection. In normal cells, pressure reduced E-cadherin, an important EMT marker, at 4 and 8 h. CD44 siRNA transfection induced E-cadherin in pressurized cells at 4 and 8 h. In UUO animal model, we also found CD44 increased in renal tubular cells in slight dilated tubules.

**Conclusions:** Our results suggest that miR-328-mediated CD44 up-regulation play an important role in pressure-induced fibrotic responses in renal tubular cells.

## PUB411

**Responses of Human Podocytec Grown on Different Cellular Matrices** Tarunkumar H. Madne, Mysore Keshavmurthy Phanish, Mark Edward Dockrell. *SWT Institute for Renal Research, London, United Kingdom.*

**Background:** Cell phenotype and survival is strongly regulated by interaction with the extracellular matrix proteins, particularly those of a basement membrane. The glomerular basement membrane (GBM) is dynamic structure made up of protein secreted by endothelial cells and podocytes. In renal disease there are changes to the quantity and quality of GBM proteins contributing to the progression of disease such as fibrosis. We previously described TGFβ1-induced EDA+Fn expression in human podocytes. In this study we investigate response of podocyte culture grown on GBM proteins such as collagen IV and cellular and plasma fibronectin.

We aim to investigate the role of different matrices on podocyte phenotype and responses to TGFβ1.

**Methods:** Human podocyte were grown dishes coated with different matrices; collagen IV (Col IV), cellular fibronectin containing the EDA Exon (EDA+ Fn), plasma fibronectin, which lacks the EDA Exon, (EDA –Fn). Expression of EDA+Fn, synaptopodin and alpha-SMA was assessed by RT-PCR and Q-PCR in the presence and absence of TGFβ1 (2.5ng/ml).

**Results:** Marked changes in podocyte morphology were observed by light microscopy in cells grown on the different matrices. A decrease of ~40% in synaptopodin expression was observed in cells grown on cellular Fn. The expression alpha-SMA mRNA did not significantly change at this time point. Investigating the effects of different cellular matrix protein on TGFβ-mediated responses demonstrated that the TGFβ1-mediated increase in expression of EDA+Fn was completely abolished in cells grown on collagen IV. The effect of TGFβ on synaptopodin was also greatly affected by the growth surface, with opposite effects seen on collagen as compared to fibronectin. Activation of receptor Smads is unaffected by different matrices.

**Conclusions:** Alteration of the constituents of the GBM is likely to significantly alter podocyte phenotype and cellular responses to growth factors involved in podocytopathies, such as TGFβ.

## PUB412

**Upregulation of Protein Phosphatase 2A Activity by Nitration in Endothelial Cells Is Associated with Renal Fibrosis** Min Han, Yuanjun Deng, Ping Liu, Gang Xu. *Tongji Hospital, Tongji Medical College, Huazhong Univ of Science and Technology.*

**Background:** Previous studies show that endothelial cells may acquire smooth muscle–like phenotype and contribute to extracellular matrix deposition in renal fibrosis. The underlying mechanism, however, remains elusive.Here,we hypothesize that a protein post-transcriptional modification of PP2A may have profound effects on the process of extracellular matrix deposition resulted from endothelial cells.

**Methods:** The expression of VE-cadherin and α-SMA were detected by using western blot, immunofluorescence and flow cytometry 72h after human umbilical vein endothelial cell (HUVEC) were treated with TGF-β1. PP2Ac (PP2A catalytic subunit) nitration was determined by Immunoprecipitation (IP) after TGF-β1 stimulation. Further, we used tandem mass spectrometry to map the nitration sites of PP2Ac treated with Peroxinitrite (a nitric oxide with superoxide- product) in vitro. Site-specific liquid chromatography-mass spectrometry quantitative analyses were designed to specifically determine the order of the nitration sites.

**Results:** After the stimulation of TGF-β1, certain subsets of endothelial cells lose endothelial characteristics and transformed into smooth muscle-like cells characterized by loss of endothelial marker VE-cadherin, and gain mesenchymal markerα-SMA. TGF-β1 stimulation upregulated PP2A activity companied with increased PP2Ac nitration. Tandem mass spectrometry identified that of the fifteen tyrosine residues in PP2Ac, Tyr-284, Tyr-218, Tyr-265, and Tyr-267, Tyr-127 and Tyr-130 were nitrated. Site-specific liquid chromatography-mass spectrometry quantitative analyses demonstrated that the favored modification site following exposure to peroxynitrite is Tyr-284. And these profibrotic effects were significantly attenuated by adding okadaic acid and NADPH oxidase inhibitor apocynin.

**Conclusions:** Nitric oxide with superoxide pathway can regulate PP2A modification under oxidative stress conditions, which modulate TGF-β1 induced phenotype change mechanisms involved in profibrotic effects. This can augment extracellular matrix deposition and fibrosis linked to renal fibrosis.

## PUB413

**Effects of Membrane Cholesterol Content and the Anionic Amphipath Trinitrophenol on Mechanical Activation of TRPC6 Channels in Podocytes**

Stuart E. Dryer,[1,2] Cory Wilson,[1] Marc Thomas Anderson.[1] *[1]Biology and Biochemistry, Univ of Houston, Houston, TX; [2]Nephrology, Baylor College of Medicine, Houston, TX.*

**Background:** We have previously shown that TRPC6 channels can be activated by mechanical stimuli in cultured podocytes and in podocytes in isolated glomerulus preparations. Mechanical activation of TRPC6 in podocytes persists after inhibition of phospholipases or G proteins. Knockdown of the podocin increased TRPC6 activation by mechanical stimuli, but suppressed activation by diacylglycerol analogs[1].

**Methods:** Whole-cell recordings from mouse podocyte cell lines and filipin staining of membrane cholesterol.

**Results:** Filipin staining showed that cholesterol occurred in distinct patches, often arranged in an elliptical pattern on the surface of immortalized mouse podocytes. This same spatial pattern of filipin staining persisted in podocin knockdown cells[1], but filipin staining was eliminated after 18-24 hr treatment with 10 mM methyl-β-cyclodextrin (MBCD). MBCD treatment caused a marked increase in hypoosomotic stretch-activation of TRPC6 in podocytes. Conversely, it is possible to increase membrane cholesterol content by pre-equilibrating MBCD with cholesterol in a 20:1 molar ratio. A 24-hr exposure to this reagent caused nearly complete inhibition of hypoosmotic stretch-activation of TRPC6. Exposure to 10 mM MBCD for just 20 min caused a marked increase in stretch-activation of TRPC6. It is possible that this brief treatment with MBCD selectively depletes cholesterol from the outer leaflet resulting in microfolding of the membrane. A similar effect was evoked by treating cells for 20 min with the anionic amphipath trinitrophenol (200 μM), which is known to cause crenelation of the plasma membrane[2].

**Conclusions:** These data suggest that cholesterol content regulates membrane mechanical properties in podocytes and the transmission of force to TRPC6 channel complexes. This is consistent with our observation that podocin interactions suppress mechanical activation of TRPC6 channels in podocytes[1].

**Mechanistic Studies of a Chinese Herbal Medicine Prescription for Treatment of IgA Nephropathy**

Zhi Qiang Huang,[1] Yiping Chen,[2] Nicolas Maillard,[1] Stacy D. Hall,[1] Bruce A. Julian,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Medicine, Longhua Hospital Affliated to Shanghai Univ of Traditional Chinese Medicine, Shanghai, China.*

**Background:** Immune complexes (IC) consisting of galactose-deficient IgA1 (Gd-IgA1) and anti-Gd-IgA1 IgG induce protein-kinase signaling, including PDGF pathway, and proliferation in human mesangial cells (MC). Thus, blocking IC-mediated activation of MC is of therapeutic significance. Chinese herbal medicine prescription LH-1 improves hematuria and proteinuria in IgA nephropathy (IgAN) patients, but the mechanism is unknown. In this study, we assessed the effects of LH-1 on proliferation and signaling in MC induced by IC or PDGF.

**Methods:** Powder of LH-1 water extract was reconstituted in water before use. Cultured, quiescent MC were incubated with *in vitro*-formed IC or with PDGF (10 ng/ml) for 24 hr in the presence or absence of LH-1. Proliferation of MC was assessed by $^{3}$H-thymidine uptake. Cells were also stimulated with IC or PDGF for 15 min with or without LH-1 and cell signaling was analyzed using SDS-PAGE/Western blotting with phospho-Tyr-antibody or phospho-ERK1/2 and total ERK1/2 antibodies. Quiescent MC, without treatment or treated with only LH-1, were used as control.

**Results:** IC induced MC proliferation and LH-1 blocked this stimulatory effect in a dose-dependent manner. Phosphorylation of multiple Tyr-containing proteins, including ERK1/2, was enhanced by IC. LH-1 inhibited activation of Tyr-phosphorylation in a dose-dependent manner. PDGF increased MC proliferation and enhanced Tyr-phosphorylation, including ERK1/2. LH-1 blocked these stimulatory effects of PDGF as well. LH-1 treatment did not affect quiescent MC at the concentrations ≤400 μg/ml.

**Conclusions:** LH-1 inhibited MC proliferation and the enhanced Tyr-phosphorylation induced by IC or PDGF. Thus, LH-1 may contain potent Tyr-kinase inhibitor(s) that may provide compounds for development of disease-specific treatment of IgAN.

**Transcriptome Based Analysis of Nephrotic Syndrome for Therapeutic Target Identification**

Sebastian Martini,[1] J. B. Hodgin,[2] Viji Nair,[1] Wenjun Ju,[1] Celine C. Berthier,[1] Ann Randolph,[1] Clemens D. Cohen,[3] Matthias Kretzler.[1] *[1]Nephrology, Univ of Michigan; [2]Pathology, Univ of Michigan; [3]Nephrology, Univ of Zurich.*

**Background:** Focal Segmental Glomerulosclerosis (FSGS), Membranous Nephropathy (MN), or Minimal-change Disease (MCD) share ultra-structural and functional glomerular alterations. We have generated comprehensive glomerular gene expression profiles to define regulatory networks of the glomerular filter. These signatures can be mined for patterns of known drug targets.

We hypothesized that:

1.Gene expression signatures in FSGS, MN, and MCD reflect specific disease-relevant mechanisms.

2.Transcripts that are differentially expressed in all three diseases allow for detailed description of common molecular mechanisms of filtration barrier dysfunction.

3.A Connectivity Map (CMaP) analysis of the shared transcriptome can identify transcriptional networks to be targeted by established therapeutic compounds.

**Methods:** Fifty nine glomerular gene expression profiles of NS patients from the ERCB were compared to 31 controls. Enriched pathways were defined among differentially expressed genes individually for each disease and for the shared transcriptome. Potential drug candidates capable of either enhancing or reversing the transcriptional changes seen among genes of the shared transcriptome were identified using Connectivity Map.

**Results:** Pathway analysis highlighted novel and known pathways for each disease, i.e.: Lymphocyte/interferon-related pathways for FSGS; NFkappaB-signaling pathway for MCD as well as antigen presentation pathways/PLA2R1 for MN. CMaP identified drugs with nephrotoxic properties that recapitulated the transcriptional changes seen in NS disease in in vitro systems, while compounds with known beneficial effects on renal function (i.e. PI3K-inhibitor LY294002 in model systems) reversed these transcriptional changes *in vitro*.

**Conclusions:** Our studies have catalogued transcriptional changes and identified known and novel pathways that may play a role in the pathogenesis of nephrotic syndrome diseases. The cross-sectional analysis of these diseases also allowed for screening of therapeutic and toxicological profiles of candidate drugs in NS.

## PUB416

**IgA and Immune Complex Profile of an IgA-Dominant Post-Infectious Secondary Glomerulonephritis**

Eric L. Wallace,[1] Nicolas Maillard,[3] Hiroyuki Ueda,[3] Stacy D. Hall,[3] Huma Fatima,[2] Jan Novak,[3] Bruce A. Julian.[1] *[1]Div of Nephrology, UAB, Birmingham, AL; [2]Dept of Pathology, UAB, Birmingham, AL; [3]Dept of Microbiology, UAB, Birmingham, AL.*

**Background:** A 67-year old woman, baseline creatinine 1.0 mg/dL, developed a gallbladder-fossa infection after gallbladder resection for adenocarcinoma. Admission creatinine was 1.9 mg/dL with a bland urinary sediment. The infection cleared with antibiotics, and creatinine improved to 1.3 mg/dL at discharge. She was readmitted with acute renal failure, nephritic urinary sediment, 3.3 g/g proteinuria, leg edema, and hypertension. She had diarrhea later attributed to *Clostridium difficile*-induced colitis. Due to a rapidly rising creatinine, renal biopsy was performed. Light microscopy showed marked mesangial and endocapillary hypercellularity; immunofluorescence microscopy showed dominant IgA staining with less staining for IgG in the mesangium and capillary loops; electron microscopy showed large subendothelial and mesangial deposits consistent with immune deposits of a post-infectious glomerulonephritis (PIGN). She became dialysis dependent. Because the pathogenesis of IgA-dominant PIGN is unknown, we undertook additional laboratory studies.

**Methods:** Serum levels of IgA and galactose-deficient IgA1 were measured by ELISA. Western blot after SDS-PAGE separation of serum IgA under non-reducing conditions determined the ratio of monomeric and polymeric IgA. Serum (native or IgA- or IgG-depleted) was fractionated by size-exclusion chromatography, and fractions were added to cultures of human mesangial cells and proliferation assessed by thymidine incorporation. Fractions were assessed by ELISA for IgA and IgG profiles.

**Results:** Serum level of total IgA was markedly elevated, with normal polymeric-to-monomeric ratio of IgA. Total serum level of galactose-deficient IgA1 was elevated. Large-molecular-mass circulating immune complexes containing IgA and IgG stimulated proliferation of mesangial cells.

**Conclusions:** For this patient with IgA nephropathy associated with colitis due to *Clostridium difficile*, an increased serum level of galactose-deficient IgA1 likely led to formation of circulating nephritogenic IgA-IgG immune complexes.

*Funding:* NIDDK Support

## PUB417

**Evaluation of Disease State of 200 Patients with Various Glomerulonephritis by Claudin1, CD68 Positive Cells and the mRNA Levels of M1 and M2 Macrophages in Urine** Kojiro Yamamoto,[1] Takashi Oda,[1] Takahiro Uchida,[1] Atsushi Watanabe,[1] Hanako Takechi,[1] Naoki Oshima,[1] Yutaka Sakurai,[2] Hiroo Kumagai.[1] *[1]Nephrology, National Defense Medical Collage, Tokorozawa, Saitama, Japan; [2]Preventive Medicine and Public Health, National Defense Medical Collage, Tokorozawa, Saitama, Japan.*

**Background:** Urine test is non-invasive and can reflect more general condition of the whole kidney than findings of renal biopsy.

**Methods:** We collected morning urine samples from 200 patients for kidney biopsy from 2008 to 2011. Logistic regression analysis was performed with the finding of renal biopsy as dependent variable (0 = normal; 1 = crescent existed) and with claudin1and CD68 positive cell count as predictor variables. And the relations of claudin1 and CD68 positive cell count in urinary sediment with urinary protein or red blood cell were examined. Secondly, we evaluated phenotypes of the macrophage in urinary sediment. The relationship between relative levels of target mRNAs and the histological changes such as crescent formation (CF) (exist or none) or global sclerosis rate was evaluated.

**Results:** Logistic analysis of claudin1 and CD68 positive cell count with the presence of CF revealed ROC curve with the area under the curve (AUC) of 0.60 and 0.70, respectively, both of which were statistically significant. There was significant positive trend between the claudin1 positive cell count and the urinary protein, but no trend was found between the CD68 positive cell count and the urinary protein. Both claudin1 and CD68 positive cell count showed significant positive correlation with the urinary red blood cell. The relative mRNA levels of the M2 makers (CD163, CD204, CD206, IL-10) were significantly higher in patients with than without CF. On the other hand, the relative mRNA levels of M1 markers (iNOS, IL-6) were similar in both patients with and without CF.

**Conclusions:** These data suggest that the claudin1, CD68 positive cell count and quantification of the mRNA of the M2 markers of urinary sediment are useful for the evaluation of the state of the glomerular disease and that claudin1 reflects parietal epithelial damage not only by glomerular inflammation but also by urinary protein.

## PUB418

**Pentraxin 3 Expression in Renal Tissue of HIV Positive and HIV Negative Patients with Glomerular Diseases** Manuela Nebuloni,[1] Angelita Ferri,[2] Antonella Tosoni,[2] Pietro Zerbi,[1] Irina Edu,[2] Giovanni Belgiojoso.[2] *[1]Pathology Unit, DIBIC, Univ Milan, Milan, Italy; [2]Path. Unit, L.Sacco Hospital.*

**Background:** Pentraxin 3 (PTX3) is involved in inflammation and regulation of innate immunity. It has been detected in renal tissue of patients with glomerulonephritis (GNs), suggesting a possible role in glomerular and tubular injury. On the other side, HIV infection *per se* is a causative agent/eventual cofactor for GNs.

Aim of the study is to evaluate the additional role of HIV infection in PTX3 expression as a modulatory factor in tissue injury in different GNs.

**Methods:** Renal biopsies from 35 HIV + and 46 HIV - patients (pts) with various types of GNs were tested for PTX3 by immunohistochemistry. Immunostaining distribution and intensity were considered. Immune complex related GNs (IC) and non immune complex GNs (NIC), in HIV+ and HIV- groups were compared. The Mann Whitney U test was employed for statistical analysis of results.

| Diagnosis | HIV+ | HIV- |
|---|---|---|
| IgA Nephropathy* | 4 | 8 |
| Lupus-like GN* | 4 | - |
| Lupus GN* | - | 6 |
| Membranoproliferative GN* | 4 | 7 |
| Membranous GN* | 4 | 9 |
| Diabetic nephropathy | 4 | 4 |
| Minimal changes | 2 | 2 |
| Focal Segmental Glomerulosclerosis | 12 | 11 |

distribution of cases in single Gns. *: IC group.

**Results:** PTX3 immunostaining was localized in the interstitium and in the cytoplasm of some endothelial cells and macrophages. IC vs NIC GNs, irrespective of HIV infection: no statistical difference. IC GNs and NIC GNs, HIV- pts: no statistical difference. IC vs NIC GNs, HIV+ pts: p=0.02. PTX3 expression in IC GNs higher than in NIC GNS. IC GNS, HIV+ pts, vs IC GNs, HIV- pts: p=0.04. PTX3 expression in HIV+ pts higher than in HIV- pts.

**Conclusions:** HIV infection within IC GNs group enhances PTX3 expression in glomerular diseases. Moreover, the presence of IC *per se* is an increasing factor for PTX3 expression among HIV+ pts. Our results suggest that PTX3 can modulate tissue injury in glomerular diseases but its exact role is unclear.

## PUB419

**Clinicopathological Spectrum of Kidney Diseases in Patients Treated with Vascular Endothelial Growth Factor Inhibitor for Cancer Therapy** Joichi Usui,[1,2] Ilya Glezerman,[3] Chandra B. Chandran,[4] Steven Salvatore,[1] Carlos D. Flombaum,[3] Surya V. Seshan.[1] *[1]Dept of Pathology, Weill Cornell Medical College, Cornell Univ, New York, NY; [2]Univ of Tsukuba, Japan; [3]Renal Service, Dept of Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY; [4]Nephrology Div, Dept of Medicine, St. Joseph's Regional Medical Center, Paterson, NJ.*

**Background:** Recently, cancer therapies have been supplemented by vascular endothelial growth factor(VEGF) inhibitors as anti-angiogenic agents. The present work discloses the spectrum of pathological features in VEGF inhibitor-associated kidney disease.

**Methods:** Clinicopathological findings of kidney disease were retrospectively studied in 5 cancer patients treated with VEGF inhibitors.

**Results:** Four cases received bevacizumab(anti-VEGF-A) and one was given sorafenib(tyrosine kinase inhibitor affecting VEGFR2), with chemotherapeutic agents. All patients presented with acute kidney injury(serum Cr 1.6-6mg/dl), hypertension and/or proteinuria(none to 2.6g/day). All kidney biopsies showed endothelial injury of varying severity, including 2 with typical active features of thrombotic microangiopathy(TMA). Evidence of chronic endothelial injury and vascular sclerosis were also observed. Furthermore, acute tubular injury with focal necrosis was seen in all cases. While administration of VEGF inhibitor was discontinued in 4 cases, it was resumed for 5 more doses, following steroid therapy in 1 case. Cessation of VEGF inhibitor was successful in reversing anemia and led to improvement of hypertension and proteinuria in 4 of the 5 cases. One case with active and severe TMA progressed to ESRD, but renal function of other 4 cases improved(final serum Cr 0.5-1.6mg/dl).

**Conclusions:** A range of renal pathologic lesions secondary to endothelial injury are noted often accompanied by acute tubular damage following anti-VEGF therapy, the most severe being TMA. While most of the clinical manifestations are reversible with discontinuation of therapy, the role of other nephrotoxic chemotherapeutic agents in enhancing renal injury and other host factors with possible poor outcome should be considered.

## PUB420

**Analysis of AKT/mTOR Signaling Pathway in the Renal Biopsy Tissue of Patients with Glomerulonephropathy by Luminex xMAP Technology** Hong Liu, Lujun Xu, Xiang Zhou, Fu-You Liu. *Dept of Nephrology, The Second Xiangya Hospital of Central South Univ, Changsha, Hunan, China.*

**Background:** To investigate role of AKT-mTOR signaling in the pathogenesis of glomerulonephropathy by the xMAP technology.

**Methods:** Kidney tissues were obtained from 25 patients who were diagnosed as IgA nephropathy, idiopathic membranous nephropathy , idiopathic FSGS or minor lesions nephropathy. The activation of AKT-mTOR signaling was determinied by the xMAP technology. The correlation between AKT-mTOR and the clinical indicators was analyzed.

**Results:** 1. Compared with minor lesions nephropathy group, the level of hematuria of the IgAN group was higher(P=0.03). The level of pAKT, pGSK3?,pmTOR of the kidney tissue of the IgAN group was increased , and the level of pPTEN of the kidney tissue of was decreased than the minor lesions nephropathy group( P=0.003). Hematuria was positively correlated to pAKT, pGSK3?,pmTOR , and negatively correlated to pPTEN. 2. Compared with minor lesions nephropathy group, the level of cholestasis, triglycerides,proteinuria and hematuria of the idiopathic membranous nephropathy group was higher(P=0.04). The level of pAKT, pmTOR,pp70s6K of the kidney tissue of the idiopathic membranous nephropathy group was increased than the minor lesions nephropathy group( P=0.04). Cholestasis, triglycerides, proteinuria and hematuria were positively correlated to pAKT, pmTOR and pp70s6K. 3. Compared with minor lesions nephropathy group, the level of systolic pressure,mean arterial pressure ,proteinuria and hematuria of the of idiopathic FSGS group was higher(P=0.004,0.036,0.004, 0.006). The level of pAKT of the kidney tissue of the idiopathic FSGS group was increased and pPTEN was decreased than the minor lesions nephropathy group( P=0.04). Systolic pressure,mean arterial pressure, proteinuria and hematuria were positively correlated to pAKT ,and systolic pressure ,mean arterial pressure and proteinuria were negatively correlated to pPTEN.

**Conclusions:** We find that Akt-mTOR pathway might play a role in the pathogenesis of IgAN,IMN and iFSGS. Our research indicated the potential for the application of luminex xMAP technology to explore more signaling pathways related to chronic kidney disease.

## PUB421

**Henoch-SchÖlein Purpura Nephritis and IgA Nephropathy in Children: A Comparison Pathological Features Using "Oxford Classification of IgA Nephropathy" and Clinical Correlation** Xu Zeng,[1] Murty Adabala,[2] David G. Bostwick,[1] Deloar Hossain,[1] Tej K. Mattoo.[2] *[1]Nephrocor, Bostwick Laboratories, Orlando, FL; [2]Pediatric Nephrology, Children Hospital of Michigan, Detroit, MI.*

**Background:** Henoch-SchÖlein purpura nephritis (HSPN) and IgA nephropathy (IgAN) are common in children with overlapping clinical, genetic and immunological features. Both entities are characterized by IgA deposits in glomeruli. However, a systemic approach to compare both diseases is lacking. The objective of this study was to assess the benefit of applying the newly described Oxford classification of IgA nephropathy", to distinguishing these two entities.

**Methods: R**enal biopsies in Children's Hospital of Michigan during 2004-2010 with HSPN and IgAN were reviewed. The MEST scheme of "Oxford classification of IgA nephropathy" was applied to measure mesangial cellularity, endocapillary proliferation, segmental glomerulosclerosis and tubular atrophy/interstitial fibrosis. Active glomerular lesions, i.e. the highest number of mesangial cells, percentage of glomeruli with endocapillary proliferation, cellular crescent and segmental necrosis were measured. Hypertension, protein/creatinine ratio, hematuria and estimate glomerular filtration rate were compared. Student t-test (P<0.05 is considered to be statistical significance).

**Results:** A total of 23 HSPN (F:M=12:11) and 26 IgAN (F:M=11:15) were included. The HSPN patients were younger than those with IgAN (7.8 3.3 vs 12.4 3.2, year-old, p<0.05). Patients with HSPN had more mesangial cells (11 3.2 vs 8.3 2.4), higher percentages of glomeruli with endocapillary proliferation (14.9 2.2 vs 4.9 8.2), cellular crescents (10.4 1.2 vs 4.3 2.8) and segmental necroses (6.6 1.3 vs 0.7 1.1, all P<0.05). There was no significant difference between HSPN and IgAN in MEST scheme (P>0.05). There is higher, but not significant difference in protein/creatinine ratio between HSPN and IgAN.

**Conclusions:** HSPN has more extensive mesangial/endocapillary proliferation and higher percentage of glomeruli with cellular crescents and segmental necrosis, thus more severe glomerular damage. These findings further characterize pediatric HSPN and will benefit to the clinical management.

## PUB422

### Histologic and Clinical Progression of ANCA Associated Glomerulonephritis

Naima Carter-Monroe, Lois J. Arend, S. Bagnasco, Lorraine C. Racusen, Duvuru Geetha. *Johns Hopkins School of Medicine.*

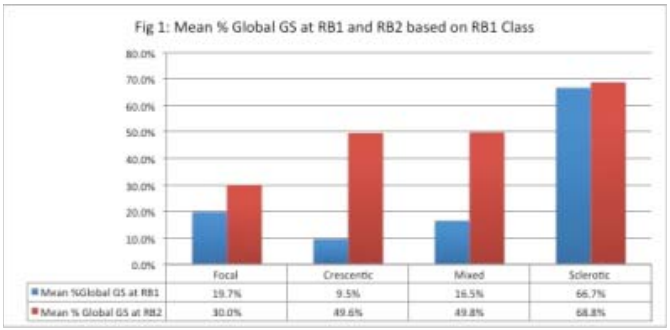
**Background:** Histologic correlates with outcomes in ANCA associated glomerulonephritis (ANCA-GN) based on IWGRP class are limited to findings on initial biopsy. Analysis of evolution of these changes over time would lead to better understanding of salvageable lesions.

**Methods:** Cases of ANCA-GN diagnosed from 1996 to 2009 with at least one follow up biopsy were identified. Clinical data at the time of initial (RB1) and follow up (RB2) biopsy were collected. Biopsies were categorized as Focal, Crescentic, Mixed, or Sclerotic (IWGRP classification for AAV-GN) based on original pathology reports.

**Results:** Eighteen patients (mean age: 57 years, 50% males, 83% Caucasian, 50%p-ANCA, 33% c-ANCA) had RB2 at a mean of 47 months after RB1. RB2 was performed for suspected relapse (n=13), persistent hematuria (n=3) and CKD (n=2). Most cases were classified on RB1 as Focal (n=7) or Mixed (n=7), and showed mixed progression, with 3 Focal cases unchanged and 2 becoming Sclerotic; equal Mixed cases were classified as Focal or Sclerotic on RB2 (n=3 each). Among 7 patients who reached ESRD at a mean of 24 months post RB2, 5 patients progressed to Sclerotic and 2 were classified as Focal. (Table 1). Although Crescentic cases demonstrated the lowest mean % global glomerulosclerosis (GS) at RB1, they showed greater progression to GS at RB2 when compared to Focal cases (Fig. 1).

Table 1:RB1 and RB2 Class with Progression to ESRD

| RB1 Class (n) | RB2 Class | ESRD (n) |
|---|---|---|
| Focal (7) | Absent | 0 |
| | Focal | 2 |
| | Mixed | 0 |
| | Sclerotic | 1 |
| Crescentic (3) | Focal | 0 |
| | Sclerotic | 2 |
| Mixed (7) | Focal | 1 |
| | Crescentic | 0 |
| | Sclerotic | 1 |
| Sclerotic (1) | Sclerotic | 1 |



**Conclusions:** All classes at initial biopsy showed progression to ESRD. The IWGRP class changes seen in follow up biopsy suggests that some active lesions revert to normal phenotype with therapy while others progress to a chronic pattern.

## PUB423

### The Anti-Aging Gene Klotho Represents a Potential Predictive Marker of Metastasis in Renal Cell Carcinoma (RCC)

Margherita Gigante,[1] Paola Pontrelli,[1] Giuseppe Stefano Netti,[2] C. Divella,[1] Cesira Cafiero,[1] Matteo Accetturo,[1] Simona Simone,[1] G. Grandaliano,[2] Loreto Gesualdo,[1] E. Ranieri,[2] G. Stallone.[2] *[1]DETO, Univ of Bari, Italy; [2]Med and Surg Sciences Dept, Univ of Foggia, Italy.*

**Background:** The identification of new therapeutic and prognostic biomarkers for clear cell renal cell carcinoma (ccRCC) is needed since most patients appear in advanced stages of disease at diagnosis. The renoprotective antiaging gene Klotho works as a tumor suppressor in different human cancers. Aim of our study was to evaluate Klotho expression in tissue and serum of RCC pts and correlate it with disease progression.

**Methods:** We used a genome wide screening of the human exons expressed in 11 ccRCC vs paired adjacent non-tumoral tissue by microarray. Klotho expression in tumor tissue of primitive and metastatic RCC pts, was studied using quantitative RT-PCR and immunohistochemistry and the soluble serum levels were titrated in 35 primary RCC, 25 metatatic RCC and 15 healthy donors, by sandwich ELISA. Comparisons of variables among different groups were performed by Student's t-test and Mann-Whitney U-test. Frequencies were compared by chi-squared test. Kaplan–Meier estimates were used to generate overall patient survival curves and differences were assessed by log-rank test.

**Results:** Ingenuity pathway analysis revealed a set of genes modulated in ccRCC (FDR<5% and f.c.≥2), associated with inflammatory response, cancer and renal disorders. Among them, Klotho was strongly down-regulated in all ccRCC (f.c.:-41,9, p=0.0007) respect to paired normal renal tissue (NT). Both at gene and protein level, Klotho significantly decreased in RCC vs NT and the down-regulation was more evident in metastatic RCC than primitive RCC. This trend was also observed in serum samples, where circulating Klotho significantly decreased in RCC when compared with healthy donors and it was dramatically decreased in metastatic RCC than primitive RCC sera (p<0.001). Lower serum levels of KLOTHO protein at RCC onset are related to worse clinical presentation and outcome.

**Conclusions:** The decrease of Klotho correlates with the progression of RCC and suggest a key role of Klotho in the onset of cancer metastasis.

## PUB424

### Proteomic Profile of Retained Proteins from Hemodiafiltration with On-Line Endogenous Reinfusion (HFR) Cartridge

Mauro Atti,[1] Marialuisa Caiazzo,[1] Giuseppe Palladino,[1] Aurora Cuoghi,[3] Elisa Bellei,[3] Emanuela Monari,[3] Stefania Bergamini,[3] Aldo Tomasi,[3] Francesco Bruni.[2] *[1]Scientific Affairs, Bellco S.r.l., Mirandola, Modena, Italy; [2]Nephrology and Dialysis, Civil Hospital Madonna del Soccorso, San Benedetto del Tronto, Ascoli Piceno, Italy; [3]Dept of Diagnostic, Clinical and Public Health Medicine, Univ of Modena and Reggio Emilia, Modena, Italy.*

**Background:** Hemodiafiltration with on-line endogenous reinfusion (HFR) is a dialytic method, which combines the processes of diffusion, convection and adsorption. The performance of this system is linked to the optimal combination of the membrane permeability and cartridge resin bed.

Lupus nephritis (LN) remains one of the most severe manifestation of systemic lupus erythematous (LES), associated with considerable morbidity and mortality.

In this preliminary study, ESI-QTOF Mass Spectrometer was used for protein identification of ultrafiltrate (UF) and for the protein captured by resin bed, obtained from one dialysedpatient with LN.

**Methods:** Plasma, UF (pre and post cartdrige) of one patient with LN treated with HFR, were collected at the 15 min and at 235 min of the dyalitic session. The cartridge utilized during treatment, containing styrenic resin, was opened and the proteins kept by the resin were eluted by incubation O/N with 60% ACN and 1%TFA. Samples was desalted and separated by SDS-page, interesting band was picked and "in-gel" triptic digested before ESI-QTOF analysis.

**Results:** ESI-QTOF analysis of eluted protein resulted in the identification of several biomarker of kidney injury in LN, such as Retinol binding protein 4, Neutrophil gelatinase-associated lipocain, and Cystatin-C (and TRFE, A1AG1, PTGDS, TTHY). Moreover we identify several fragment of Immunoglobulin, that are implicated in the etiopathogenesis of LES.

**Conclusions:** The results of this study demonstrate that, styrenic resin retain several proteins implicated in the Lupus nephritis pathogenesis the corresponding bands in the UF disappear confirming the remotion of this proteins from the cartridge.

## PUB425

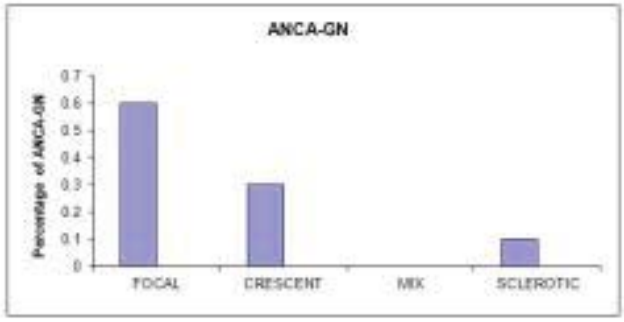
### Pediatric Anti-Neutrophil Cytoplasmic Antibody (ANCA)-Associated Glomerulonephritis (ANCA-GN) Is Predominately Focal

Xu Zeng, Guillermo A. Herrera, Deloar Hossain, David G. Bostwick. *Nephrocor, Bostwick Laboratories, Orlando, FL.*

**Background:** ANCA-GN is the most common cause of rapidly progressive GN and diagnosis is made mainly by renal biopsy. The majority of cases of ANCA-GN occur in adult patients. The recent published "histopathologic classification of ANCA-GN" divides ANCA-GN into four categories, including focal, crescentic, mixed, and sclerotic, corresponding to the order of severity of renal impairment. Most of adult patients belong to the crescentic group, which has highly active renal disease and severely reduced renal function. Less is known about pediatric ANCA-GN.

**Methods:** Renal biopsies with the diagnosis of ANCA-GN in children were reviewed. Based on the predominance of normal glomeruli, cellular crescents, and globally sclerotic glomeruli, each ANCA-GN case was categorized as mentioned above. The percentage of each group was recorded. In addition, the activity index, the percent of cellular crescent and segmental necrosis, as well as background renal function, global sclerotic glomeruli and tubular atrophy/interstitial fibrosis, were also recorded.

**Results:** A total of 10 ANCA-GNs (F:M=1:1) were diagnosed in children adolescents (age 12.8 ±3.0). The majority were focal (6/10, 60%); four (30%) were crescentic, 1 was sclerotic (1/10, 10%) and none was mixed. The average percentage of crescents, necrosis, global sclerotic and tubular atrophy/interstitial fibrosis was 29.3%, 17.3%, 11.9% and 15, respectively.



**Conclusions:** Our findings indicate that pediatric ANCA-GN is predominately focal and has a relatively favorable outcome with mild activity including a small percentage of cellular crescents and segmental necrosis. Renal function at the time of biopsy was relatively good with a low number of globally sclerotic glomeruli and low tubular atrophy and interstitial fibrosis.

## PUB426

**Result of the Online Registry for Early Detection and Care of Lupus Nephritis and Other Glomerular Diseases in the Colombian Caribbean Region** Gustavo Jose Aroca Martinez,[1,2,3,4] Andres A. Cadena,[1,2,4] Raul Garcia,[1,3] Antonio Iglesias,[4,5] Eder Augusto Hernandez Ruiz,[3] Erick Estrada.[2] *[1]Nefrologia, Clinica de la Costa, Barranquilla, Atlantico, Colombia; [2]Medicina, Universidad Simon Bolivar, Barranquilla, Atlantico, Colombia; [3]Medicina Interna, Universidad del Norte, Barranquilla, Atlantico, Colombia; [4]Nefrologia, Nefrologos del Caribe, Barranquilla, Atlantico, Colombia; [5]Reumatologia, Universidad Nacional, Bogota, Cundinamarca, Colombia.*

**Background:** The registry of the Latin American Society of Nephrology reports that 19,3% of cases of chronic kidney disease(CKD) in the region are due to Lupus Nephritis(LN) and Primary Glomerulonephritis(PGN). In the Colombian Caribbean region, there is a paucity of epidemiological data and many patients develop CKD secondary to delays in diagnosis and treatments. The purpose of this project is to create an online database that allows physicians to access in a opportune manner all the information of patients who are being actively worked up for LN and other PGN.

**Methods:** The NEFRORED database (href="http://www.nefrored.org/) was created to access the information of patients being worked up for PGN and LN. The information include demographics, clinical, laboratory findings and renal pathology results.

**Results:** Currently the network covers 7 states in the northern side of Colombia. Collection of data started on January 2008 and continues to May 2013, 616 biopsies were included; 40.7 % of the biopsies were reported as LN and the 59.2% to PGN. 83% of the patients are mestizo and 81% are female. 65% of the biopsies with LN had an activity index between 1 and 8 and 33% between 9 and 17. In PGN the most common diagnosis were IgA GN(24.2%), Membranous GN(21.6%), Mesangial Proliferative GN(14.7%), Membranoproliferative GN(11.5%), Focal Segmental GN(9%), Minimal Change GN(4.3%), Rapidly Progressive GN(4.3%) and others(11.7%).

**Conclusions:** The online Registry for Early detection and care of LN and other GN diseases in the Colombian Caribbean Region improves communication between all the physicians treating patients with complex kidney diseases, the information stored in the database is an important tool to establish the prevalence, geographical distribution and to facilitate the management of patients with glomerular diseases.

## PUB427

**Clinico-Pathological Features and Outcomes of Not Otherwise Specified (NOS) Variant in Focal Segmental Glomerulosclerosis (FSGS) Compared with NOS Variant in IgA Nephropathy (IgaN)** Lectícia Jorge, Lilian P.F. Carmo, Aline Lázara Resende, Elerson Costalonga, Leonardo Abreu Testagrossa, Denise M.A.C. Malheiros, Cristiane Bitencourt Dias, Rui Toledo Barros, Viktoria Woronik. *Nephrology, Univ of São Paulo, Brazil.*

**Background:** Columbia Classification(CC) of FSGS discloses five variants with different progression rate to CKD and NOS variant is the most common form in primary FSGS. Columbia criteria can be applied to IgAN although not usual. It is largely unknown if one histological phenotype (NOS)expressed in two different glomerular diseases(FSGS and IgAN) affects clinical disease expression and outcomes.The aim of our study was to compare clinical profile and outcomes of ours NOS FSGS patients with NOS IgAN.

**Methods:** A retrospective analysis was carried out on all patients with biopsy-proven IgAN(n=165) or primary FSGS(n=80) between 1999-09. Biopsies were reviewed and classified according to CC, NOS subtypes was selected for analysis. Twenty-one patients with NOS FSGS and 25 patients with NOS IgA met inclusion criteria of age>18 years, biopsies containing at least 8 glomeruli and follow up longer than 1 year. The endpoint was defined as a variation of glomerular filtration rate(GFR) per year(ΔGFR/y), calculated as the difference between final and initial eGFR adjusted by follow-up time for each patient.

**Results:** The data are shown in Table 1.

| N | NOS FSGS(21) | NOS IgAN(23) |
|---|---|---|
| AGE(y) | 33±18 | 38±15 |
| Female | 13(62%) | 15(60%) |
| eGFRi(ml/min) | 58±29 | 43±27 |
| Proteinuriai(g/day)* | 11±5.1 | 2.5±1.5 |
| Hematuria* | 6(28%) | 21(84%) |
| Vascular Lesions* | 4(21%) | 17(65%) |
| Follow up*(m) | 53±41 | 87±34 |
| eGFRend(ml/min)* | 55±35 | 34±29 |
| ΔeGFR/year(ml/min) | -4.2±22 | -3.6±10 |
| ESRD | 3(14%) | 9(36%) |

Results are shown as mean±SD or n(%) *p<0.05

**Conclusions:** This study showed that NOS FSGS and NOS IgAN were different regarding clinical presentation. The NOS FSGS group are more nephrotic and less hematuria and vascular lesions. However the rate of progression to chronic kidney disease did not differ between the two groups, as shown in the data of ΔeGFR/y.

## PUB428

**Clinical Course and Long-Term Follow-Up of 50 Patients with Idiopathic Membranous Nephropathy: Retrospective Cohort** Camila Barbosa L. Oliveira, Alline S. A. Oliveira, Luis H.B.C. Sette, Carla Queiroz Neves, Clarissa Jacob Barros Carvalho, Gisele Vajgel Fernandes, Maria Alina G.M. Cavalcante, Lucila Maria Valente. *Nefrologia, Universidade Federal de Pernambuco, Recife, Pernambuco, Brazil.*

**Background:** Natural course of idiopathic membranous nephropathy (IMN) is variable, and data related to prognosis were performed 2 or 3 decades ago, when antiproteinuric and immunosuppressive therapies were less well established and efficient than in present times. The aim of this study is to evaluate the clinical course and long-term prognosis of patients with IMN.

**Methods:** We conducted a retrospective cohort of adult patients with IMN and nephrotic syndrome between 1997 and 2012. Complete remission (CR) and partial remission (PR) were evaluated. Time to doubling creatinine (Cr), Cr clearance (Cl) < 30 ml/min/1.73m$^2$ and renal replacement therapy (RRT) were also analyzed. Patients were evaluated until RRT, last clinical visit or lost of follow up.

**Results:** Demographic data, clinical and prognostic characteristics are shown in Table 1.

| **Baseline characteristics** | **N = 50** |
|---|---|
| Mean age, years | 42.4 ± 16.6 |
| Male gender, n (%) | 31 (62) |
| SCr, mg/dL | 1.1 ± 0.5 |
| CrCl, ml/min/1.73m$^2$ | 72.2 ± 20.7 |
| Serum albumine, mg/dL | 2.0 ± 0.81 |
| Proteinuria, g/day | 7.6 ± 4.6 |
| Hypertension, n (%) | 33 (66) |
| ACEI/ARB, n (%) | 46 (92) |
| Cyclosporine, n (%) | 33 (66) |
| Follow-up, months | 55.1 ± 41.9 |
| **Outcomes** | |
| Any PR, n (%) | 21 (42) |
| Any CR, n (%) | 15 (30) |
| Relapse, n (%) | 14 (28) |
| Doubling creatinne, n (%) | 14 (28) |
| CrCl < 30 ml/min/1,73m$^2$ | 17 (34) |
| RRT, n (%) | 5 (10) |

Developing any remission was associated with a reduced risk of doubling Cr (OR 0.24, p=0.041), CrCl < 30ml/min/1,73m$^2$ (OR 0.05, p<0.001) and requirement for RRT (OR 0.07, p=0.018). Suffering a relapse after remission was not significantly associated with an increased risk of doubling Cr (p=0.495), CrCl < 30 ml/min/1,73m$^2$ (p=0.327) or RRT (p=0.523).

**Conclusions:** We found that most of the patients developed PR or CR during follow-up and achieving remission was the most significant factor associated with a reduced risk of RRT.

## PUB429

**Tacrolimus/Rituximab: A Promising Combination for Corticoresistant Idiopathic Nephrotic Syndrome in Adults** Michelle Elias, Charlene Levi, Sophie Chauvet, Elsa Guiard, Claire Trivin, Christian Jacquot, Eric Thervet, Alexandre Karras. *Nephrology, Hopital Europeen Georges Pompidou, Paris.*

**Background:** Resistance to corticosteroids is difficult to overcome when treating idiopathic nephrotic syndrome (INS), namely minimal change disease (MCD) and focal and segmental glomerulosclerosis (FSGS). Rituximab and calcineurin-inhibitors are efficient drugs for the treatment of steroid-dependent or frequently relapsing INS. However, there

is a lack of data on the effect of these treatments on corticoresistant (CR)-INS. This pilot study was conducted in order to test the efficacy of the tacrolimus/rituximab association in adults with CR-INS.

**Methods:** A total of 7 patients with CR INS (3 MCD, 4 FSGS) were enrolled in this study: 4 were corticoresistant from the beginning, 3 had developed resistance after a INS relapse. All patients had been unsuccessfully treated with 1mg/Kg/day of corticoids for an average of 16 weeks prior to the introduction of the immunosuppressive regimen. Our protocol treatment combined tacrolimus (target levels 4 to 8 ng/ml) and 4 weekly injections of rituximab (375mg/m2/wk). Complete remission (CR) was defined by an albuminemia above 30g/L and proteinuria below 0,05g/mmol of creatininuria. Patients were considered in partial remission (PR) if albuminemia was above 25g/L and proteinuria below 0,25g/mmol of creatininuria.

**Results:** After a mean follow up of 22 weeks, 4 patients showed CR and 3 were in PR, allowing a rapid tapering of corticosteroids. No significant side effects were observed, such as serious infectious disease or acute deterioration of renal function. Only 1 relapse was noted and was concomitant with a rise in the CD19+ B-cell levels.

| | Before RTX | At 6 months |
|---|---|---|
| Serum creatinin (µmol/l) | 104 (34-260) | 89.3 (76-126) |
| Serum Albumin (g/l) | 18.6 (4-32) | 36.6 (28-47) |
| Proteinuria (g/mmolCreat) | 0.858 (0.535-1.200) | 0.08 (0-0.200) |
| Steroids (mg/day) | 65.7 (20-80) | 8.9 (7.5-10) |

**Conclusions:** The Tacrolimus/Rituximab combination seems to be an efficient strategy for the treatment of patients with corticoresitant INS. Nevertheless, further controlled studies are necessary to confirm our preliminary data.

## PUB430

**Assessment of Predictive Factors for Resistance to Tonsillectomy and Steroid Pulse Therapy in Patients with IgA Nephropathy** Hiroaki Kikuchi, Hiroyuki Tanaka, Teiichi Tamura. *Dept of Nephrology, Yokosuka Kyosai Hospital, Kanagwa, Japan.*

**Background:** Tonsillectomy plus steroid pulse (TSP) therapy has been proposed as an effective method for obtaining clinical remission (CR), defined as negative proteinuria, in IgA nephropathy (IgAN) patients. However, it remains a challenge to predict outcomes for IgAN patients receiving TSP therapy. The purpose of this study was to identify the clinical and histological factors which affect obtaining of CR in IgAN patients treated by TSP therapy.

**Methods:** We retrospectively investigated 48 IgAN patients who were followed up for more than 18 months after TSP therapy between 2005 and 2012. Patients were divided into two groups according to whether CR was obtained (CR, n=28) or not (non-CR, n=20) 12 months after TSP therapy. The base line clinical characteristics and histological findings were compared between two groups.

**Results:** Univariate analysis revealed that there was a significant difference between non-CR and CR subgroups in amount of proteinuria (1.54±1.19 versus 0.94±0.89 g/day, p=0.04), male to female ratio (13/7 versus 8/20, p=0.01) and presence of chronic lesions including global sclerosis, segmental sclerosis and fibrous crescent (p=0.01). A multivariable logistic analysis demonstrated that resistance to TSP therapy depends on age at onset (p=0.03), presence of severe proteinuria (>0.5g/day) (p=0.01) and sex (p=0.01). Presence of chronic lesions was not significant in a multivariable analysis.

**Conclusions:** Older age, male and severe proteinuria were identified as predictive factors for resistance to TSP therapy in patient with IgAN. IgAN patients with these factors may require adjunctive therapy otherwise obtaining CR 12 months after TSP therapy.

## PUB431

**Successful Use of ACTHAR in Patient with Nephrotic Syndrome and Oral Steroid Intolerance** E.J. Barney,[1] E. McCann,[1] S. Sarani,[1] C.S. Huang,[1] P.C. Pham.[1] *[1]Nephrology and Hypertension, Olive View MC; [2]Kidney and Pancreas Transplant, UCLA, Los Angeles, CA.*

**Background:** ACTHAR gel (repository corticotropin injection) has been reported to successfully treat various resistant nephrotic syndromes including idiopathic membranous glomerulonephropathy (MGN), focal segmental glomerulosclerosis (FSGS), and IgA nephropathy (IgAN).

**Methods:** We report a case of nephrotic syndrome where patient successfully responded to ACTHAR gel after developing severe depression with oral prednisone. A 66 year old Filipino lady with a solitary left kidney due to donor right nephrectomy over 20 years prior, hypertension, dyslipidemia, and fully treated papillary thyroid carcinoma (currently cancer free), who presents with increasing urine protein to creatinine ratio (UPCR) of 4.9 g/g creatinine. HIV, RPR, hepatitis B and C screen, C3, C4, CH50, ANA, ANCA, and serum and urine protein electrophoresis and immunofixation were negative. Routine malignancy screen appropriate for age and LDH were negative. As patient only has a single kidney, no biopsy was performed. She was treated empirically with oral prednisone at 60 mg daily for the presumed top three differential diagnoses of FSGS, IgAN, or MGN (based on clinical history) after risks and benefits were fully explained. At 1- and 2- month-follow-up, her proteinuria decreased to 1.8 g/g Cr. Unfortunately, patient reported intolerable severe depression including crying spells, feeling of doom alternating with anxiety, and easy bruising, and self-discontinued the prednisone. Her proteinuria increased back up to 5.2 g/g Cr in the subsequent 5 months. After a full discussion with patient, she agreed to undergo a trial therapy with ACTHAR gel at 80 units/mL subcutaneously twice weekly in addition to losartan and simvastatin. Follow-up at 2- and 4 months revealed a gradual fall in UPCR to 1.5 and 0.95 g/g Cr, respectively. Patient reports feeling well without any mood altering or easy bruising effects.

**Conclusions:** ACTHAR gel may be considered in patients with nephrotic syndromes who cannot tolerate severe mood altering and easy bruising side effects of oral prednisone, but whose kidney disease is steroid-responsive.

## PUB432

**Clinicopathological Characteristics of Japanese Patients with ANCA-Positive Microscopic Polyangiitis with Relapse and Infection** Kiyoki Kitagawa,[1] Shinji Kitajima,[2] Tadashi Toyama,[2] Yasunori Iwata,[2] Norihiko Sakai,[2] Kengo Furuichi,[2] Takashi Wada.[2] *[1]Div of Internal Medicine, Kanazawa Medical Center, Kanazawa, Ishikawa, Japan; [2]Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.*

**Background:** Relapse and infection are key prognostic factor for ANCA-positive microscopic polyangiitis (mPA). We examined clinicopathological characteristics in mPA patients with relapse and infection.

**Methods:** A total of 46 patients who were diagnosed as mPA with crescentic glomerulonephritis and achieved remission from 2002 to 2012 was examined in this study. Follow-up period was from initial treatment to relapse / infection or March 31, 2013 (mean period 1152 days).

**Results:** Ten patients (22%) were relapsed and 16 patients (35%) developed infection during the follow-up period (Relapse group: mean age 63.6±10.6, female 8, male 2. Non-relapse group: mean age 67.0±9.3, female 16, male 20. Infectious group: mean age 69.1±7.4, female 10, male 6. Non-infectious group: mean age 65.6±10.6, female 14, male 16). The levels of vasculitis damage index (VDI) at remission were higher in relapse group than non-relapse group (Relapse group 6 (5-6) (median and IQ ranges (25th and 75th percentiles)), non-relapse group 2 (2-4), p<0.01). Cyclophosphamide (CY) therapy for remission induction was frequently used in infectious group (Infection group 43%, non-infection group 17%, p<0.05). In the analysis using the Cox regression model, the levels of VDI were related to relapse (HR 3.32, 95% CI 1.23-8.93, p<0.05), and the use of CY was related to infection (HR 4.07, 95% CI 1.32-12.5, p<0.05). Neither clinical findings (urinalysis, serum creatinine, CRP, ANCA level, and dose of prednisolone) nor pathological findings (% of crescentic formation and the intensity of interstitial fibrosis) at initial treatment had statistical difference between each group.

**Conclusions:** In conclusion, the levels of VDI at remission were related to relapse, and the use of CY therapy was related to infection in patients with mPA.

## PUB433

**Renal Survival in Anti-Glomerular Basement Membrane Antibody Disease** Jason M. Kidd, Patrick H. Nachman. *UNC Kidney Center, UNC Hospitals, Chapel Hill, NC.*

**Background:** Anti-Glomerular basement membrane antibody (anti-GBM) disease presents with renal failure and is often accompanied by pulmonary hemorrhage. We studied our inception cohort to compare our patient population and outcomes to those that have been previously reported as a method of quality assurance.

**Methods:** Inception cohort study of 25 patients with diagnosis of anti-GBM disease based on renal biopsy. Age, sex, race, smoking history, serum creatinine on admission, need for dialysis during first admission, presence of pulmonary hemorrhage, ANCA positivity, renal biopsy results and renal survival were recorded.

**Results:** 25 patients were studied. Median age was 47 years (interquartile range (IQR): 24.5, 62) 44% were female, 90% Caucasian (based on available data), 48% had a history of tobacco use. Median serum creatinine on admission was 6.5 mg/dl, median estimated GFR by MDRD equation was 8 ml/min/1.73m^2 (IQR: 5,16) and 36.8% were ANCA positive. 44% of patients had pulmonary hemorrhage. 76% needed hemodialysis during their initial presentation. 96% of patients received glucocorticoids, 88% received plasmapheresis with a median of 6 treatments and 80% received cyclophosphamide. All patients who had 100% crescents on renal biopsy became dialysis dependent. All patients survived to hospital discharge. 87% (20/23) had reached end stage kidney disease (on dialysis or had received transplant) at last follow up.

**Conclusions:** Patients with anti-GBM disease frequently present with very severe renal failure, either due to the fulminant nature of the disease, or to delay in diagnosis. Our retrospective study confirms the previously reported poor renal outcomes of patients with anti-GBM and severe renal failure (Cr > 5.7mg/dL )(1). Our current therapy appears effective at preventing death from pulmonary hemorrhage, but is insufficient in reversing renal failure. Early diagnosis and perhaps more intensive therapy are needed to improve renal recovery.

## PUB434

**Clinical Outcome of ANCA-Related Nephritis: Single Center Experience** Arzu Velioglu,[1] Serdar Osman Nalcaci,[1] Gurdal Birdal,[1] Derya Oztas,[1] Izzet Hakki Arikan,[1] Mehmet Koc,[1] Haner Direskeneli,[2] Serhan Tuglular,[1] Cetin Ozener.[1] *[1]Nephrology, Marmara Univ School of Medicine, Istanbul, Turkey; [2]Rheumatology, Marmara Univ School of Medicine, Istanbul, Turkey.*

**Background:** Standard therapeutic regimens for ANCA-related glomerulonephritis have not been established. Treatment usually planned individually depending on disease status. In patients required hemodialysis at the beginning, response to treatment may vary

according to the intensity of the treatment. In this retrospective study, we reviewed the clinical course, treatment and outcome of patients with ANCA-related glomerulonephritis.

**Methods:** We evaluated 28 patients with ANCA-related glomerulonephritis (mean age: 54.8±13.8 years, F/M: 9/19). Clinical characteristics and outcomes of patients were investigated.

**Results:** Wegener's Granulomatosis in 14 patients, microscopic polyangiitis in 14 patients had been diagnosed. Baseline creatinine level was 3.8±3.5 mg/dl. 21 patients (75%) had active urinary sediment. 15 patients (53%) were needed hemodialysis at the beginning. Crescentic glomerulonephritis was found in 21 patients. All patients received steroid treatment. 23 patients were received intravenous cyclophosphamide. 13 patients also underwent plasmapheresis. The mean follow-up time was 40.7±44.8 months. End-stage renal disease (ESRD) developed in 6 (21%) patients. 5 patients (17%) died due to infectious complications (pneumonia in 4, cytomegalovirus disease in 1). ESRD and death were significantly higher in patient required hemodialysis compared to the patients did not required hemodialysis (6/15 vs. 0/13, p=0.013; 5/15 vs. 0/13, p=0.031). There was no need for hemodialysis after plasmapheresis in 9 of 15 patients required hemodialysis. After the treatment, mean creatinine level was stabilized at 2.4±2.2 mg/dl.

**Conclusions:** Initial hemodialysis requirement is the most important factor for ESRD development and death in ANCA-related glomerulonephritis. Plasmapheresis in addition to steroid and cyclophosphamide improves the renal outcome in these patients. However, infectious complications, especially in terms of pneumonia, should be closely followed.

## PUB435

**Clinical Factors Affecting Cardio-Ankle Vascular Index (CAVI) in Patients with IgA Nephropathy of Low CAVI Values** Hideo Okonogi, Keita Hirano, Akihiro Shimizu, Nobuo Tsuboi, Yoichi Miyazaki, Makoto Ogura, Tetsuya Kawamura, Takashi Yokoo. *Div of Kidney and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** Cardio-ankle vascular index (CAVI) is commonly used as a non-invasive indicator of arterial stiffness. In general, CAVI of 9 or more is considered significant for assessment of atherosclerosis. In our previous study concerning IgA nephropathy (IgAN), hyaline change of afferent arterioles (HAA), which is one of the factors predicting adverse outcome, significantly correlated with CAVI, and the threshold of CAVI for diagnosis of the presence of HAA was 7.55 by receiver-operating characteristic analysis. Therefore, we examined the clinical parameters affecting CAVI in patients with IgAN of low CAVI values, i.e. those without marked atherosclerosis.

**Methods:** Thirty-three IgAN patients with CAVI of 8.5 or less at the time of renal biopsy were included. The relationship between CAVI and clinical findings including serum levels of inflammatory parameters were analyzed.

**Results:** CAVI significantly correlated with systolic blood pressure (BP) ($r=0.407$, $p<0.05$). Moreover, when patients were categorized into two groups by the CAVI=7.55, CAVI significantly correlated with lower estimated glomerular filtration rate (eGFR) (44 vs 67 ml/min/1.73m$^2$, $p<0.05$), higher uric acid (UA) (7.5 vs 6.2 mg/dl, $p<0.05$), and higher lipoprotein(a) (LP(a)) (39 vs 14 mg/dl, $p<0.05$). However, CAVI did not correlate with proteinuria, HbA1c, LDL-C, non HDL-C, remnant-like particle cholesterol, high-sensitivity C-reactive protein, D-dimer, and thrombomodulin, while these parameters correlated with CAVI in previous studies including patients with higher CAVI values.

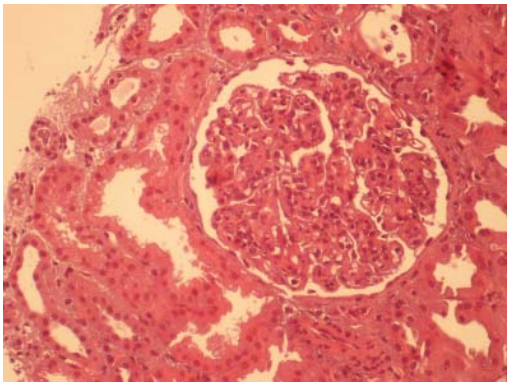
**Conclusions:** These results indicate that systolic BP, UA and Lp(a) correlate with CAVI in patients with IgAN of low CAVI values and, therefore, these clinical factors may be involved in formation of HAA in IgAN.

## PUB436

**Acute Kidney Injury and Diuretic-Resistant Anasarca in a Case of Idiopathic Membranous Glomerulonephritis** Claudio Angelini, Albania Calvetta, David Cucchiari, Manuel Alfredo Podesta', Elisa Merizzoli, Salvatore Badalamenti. *Humanitas Clinical and Research Center, Italy.*

**Background:** Membranous glomerulonephritis (MGN) is the most common cause of nephrotic syndrome in adult patients. Acute kidney injury (AKI) in this setting is a rare occurrence, usually related to complications of nephrotic syndrome (renal veins thrombosis), drugs toxicity (NSAIDs), or ensues on the basis of a superimposed immunologic process (anti-GBM, crescentic GN).

**Methods:** A 51 years-old woman presented to our unit with anasarca, developed in the previous two weeks. Laboratory tests revealed normal renal function (creatinine 0.7 mg/dL), nephrotic-range proteinuria (44 g/day) and macrohematuria. A renal biopsy was performed, showing diffuse thickening of capillary loops with focal endocapillary proliferation, focal tubular atrophy and interstitial fibrosis, but no signs of extracapillary proliferation.



Immunofluorescence showed parietal deposits of IgG and C3, confirming MGN diagnosis. An autoimmune panel and HBV/HCV screening tested negative. These findings and anti-PLA2R negativity raised the likelihood of paraneoplastic MGN: an accurate screening for malignancies was carried out, but resulted negative. Intravenous methylprednisolone (IVM) boluses were administered. During hospitalization, the patient developed AKI (creatinine up to 4.4 mg/dL), requiring hemodialysis.

**Conclusions:** AKI may have been caused by interstitial edema and tubular cells swelling, which have been described in some pediatric cases of AKI in minimal change disease. This hypothesis could not be confirmed by histology because these changes most likely occurred only after the biopsy was performed. Owing to the low gastrointestinal absorption rate, due to mucosal edema, IVM administration was maintained for the first month of therapy. Complete recovery from AKI was obtained, and proteinuria dropped to 22 g/day.

## PUB437

**Comparative Study between Primary and Secondary Focal Segmental Glomerulosclerosis** Vijay Sundaram Thanaraj, Muhammad Nauman Hashmi, Arvind Ponnusamy, Ajay Prabhakar Dhaygude. *Deaprtment of Renal Medicine, Lancashire Teaching Hospital, Preston, Lancashire, United Kingdom.*

**Background:** Focal Segmental Glomerulosclerosis (FSGS) is a common histological diagnosis encompassing variety of clinical presentations. Main types include primary and secondary. Immunohistochemistry shows IgM and C3 deposition in primary FSGS which are typically absent in secondary FSGS. Full-blown nephrotic presentation (proteinuria, oedema, hyperlipidaemia, and hypoalbuminaemia) is rare in secondary FSGS and main stay of treatment is rennin angiotensin aldosterone system (RAAS) blockade. While Nephrotic syndrome is common in primary FSGS and relentless progression to end stage renal disease (ESRD) is common though immunosuppression has been used with success for treatment. Although both primary and secondary FSGS are common, published data lacks comparative studies. In this study we compared degree of proteinuria, serum albumin, response to RAAS blockade, incidence of thrombo-embolism and ESRD.

**Methods:** This is a retrospective review of 51 patients with biopsy proven FSGS diagnosed between 1997 – 2008. Data regarding demographics, laboratory parameters, treatment details, incidence of thrombo-embolism and patient outcomes were collected.

**Results:** Average age at presentation was 50.33 ± 10.26 years and 54% were male. The follow up period was 2678.30 ±1627.6 days.

RAAS blockade therapy was initiated in 90% of secondary FSGS and in 76.19% of primary FSGS. Differences in the clinical features, laboratory parameters and outcomes are presented in Table 1.

| Parametres | Primary FSGS | Secondary FSGS | P value (paired t test) |
|---|---|---|---|
| Baseline Creatinine (umol/L) | 203.9±198.3 | 165.4 ±83.42 | P < 0.0001 |
| Baseline Proteinuria (grams/24hrs) | 7.07±5.5 | 2.5±1.5 | P < 0.0001 |
| Baseline Albumin (g/L) | 31.87±8.91 | 41±2.8 | P < 0.0001 |
| Pedal Oedema | 64% | 40% | |
| Incidence of VTE | 7.14% | 0% | |
| Progression to ESRD | 40.5% | 20% | |

**Conclusions:** 1] Classical nephrotic presentation was more common in Primary FSGS;
2] Response to RAAS blockade was superior in Secondary FSGS
3] Thrombo-embolism was absent in Secondary FSGS.

**Limitations:**
1] Relatively small sample size;
2] Retrospective study.

## PUB438

**Proteinuria in Severe Lupus Nephritis Correlates with Diffuse Foot Process Effacement** Preeti Gurnani,[1] David J. Cimbaluk,[2] Edmund J. Lewis,[1] William Whittier.[1] [1]*Nephrology, Rush Univ Medical Center, Chicago, IL;* [2]*Pathology, Rush Univ Medical Center, Chicago, IL.*

**Background:** Among the lesions of lupus nephritis, membranous glomerulonephritis (GN), mesangial GN, and minimal change glomerulopathy have all been reported to occur in patients with nephrotic range proteinuria associated with diffuse foot process effacement (FPE). This podocytopathy has not been described in other forms of lupus nephritis. The purpose of this study was to determine if any histopathologic characteristics correlate with nephrotic range proteinuria in severe lupus nephritis.

**Methods:** We conducted a retrospective clinicopathologic study of patients with lupus nephritis (N=265) at Rush University Medical Center. Mesangial and Membranous lupus GN were excluded. In patients with severe lupus nephritis (defined as ≥ 50% active segmental lesions, ISN/RPS Class III, IVs; and diffuse global lesions, ISN/RPS IVg) (N=63), demographic and clinical data were recorded and analyzed. Light, fluorescence (IF), and electron microscopy (EM) was used to detail the histologic characteristics and degree of FPE.

**Results:** Twenty-six patients (41%) had nephrotic range proteinuria (>3 grams proteinuria/gram creatinine [g/g]) and thirty-seven (59%) demonstrated subnephrotic range proteinuria (≤3g/g). Proteinuria was greater in the nephrotic patients (6.3±4.4 g/g compared to 1.3±0.9 g/g, p<0.001). There was a greater degree of FPE seen in the nephrotic compared to subnephrotic patients (foot process width [FPW], 1991±1655 nanometers (nm) compared to 939±467 nm, p<0.001). There was a positive correlation between FPE and proteinuria, r=0.694, p<0.0001. In ISN/RPS Lupus Class III and IVs, the proteinuria was less compared to Class IVg (2.5±3.0 g/g compared to 5.5±5.0 g/g, p=0.004). FPW in biopsies with Class III and IVs was also less (Class III, 1105± 712 nm compared to Class IV, 1991±1840 nm, p=0.008).

**Conclusions:** In severe lupus nephritis, a distinguishing morphologic feature in patients with nephrotic range proteinuria is diffuse foot process effacement. Given a lack of difference in other histologic characteristics, nephrotic range proteinuria in severe lupus nephritis may be a manifestation of concomitant podocytopathy.

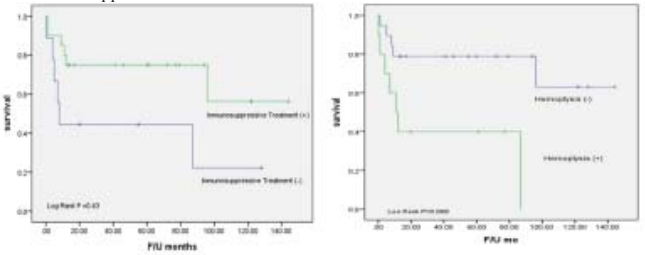
## PUB439

**Clinical Features and Outcome in Patients with ANCA-Associated Vasculitis (AAV) with Renal Involvement in Korea: An 12 Year Retrospective Single Center Study** Hyun Chul Chung, Jong Soo Lee, Jongha Park. *Univ of Ulsan College of Medicine, Ulsan Univ Hospital, Ulsan, Korea.*

**Background:** Granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) are major causes of rapid progressive glomerulonephritis. But they are not common in Korea, therefore little is known about their clinical features and outcome.

**Methods:** We respectively investigated 29 Korean patients with renal involvement in relation to AAV during 2001-2012.

**Results:** This study comprises 2 GPA, 22 MPA or 5 Renal limited vasculitis(RLV) patiensts (mean age 61.22±13.67 years), follow up for a median of 41 mo(0.1 – 144). ANCA was detected by ELISA in 28 (96.6%) of patient, of whom 23 had MPO-ANCA, 3 had PR3-ANCA, 2 had both, and one patient had negative. BVAS and lung involvement at diagnosis were 17.1±6.4 and 55.2%. Four patients(13.8%) were diagnosed after maintenance dialysis more than one month. Other twelve patients (41.4%) required dialysis at initial admission period, and 7 patients among them treated with immunosuppressive drug. 4 patients were able to be taken off dialysis during treatment. Twenty patients treated with prednisolone, cyclophosphamide and/or plasmapheresis, and nine patients received supportive care and/or hemodialysis. During follow up period, 17 relapses in 11 patients were recorded. Eleven patients (37.9%) resulted in death and other ten patients (34.5%) developed end-stage renal disease during their disease course. Mortality was associated with presence of hemoptysis, and immunosuppressive treatment.



**Conclusions:** Immunosuppressive treatment decreased the risk of mortality (RR, 0.38; CI, 0.11 to 1.33) and hemoptysis increased the risk of mortality (RR, 6.05; CI, 1.06 to 34.42) in Korean AAV patients.

## PUB440

**High Prevalence of Thyroid Diseases in Patients with Glomerulonephritis** Mohammad Kazem Fallahzadeh,[1,2] Sedighe Jafarian,[1] Ali Zamani,[1] Joan Blondin,[2] Mohammad Mahdi Sagheb.[1] *[1]Nephrology Research Center, Shiraz Univ of Medical Sciences, Shiraz, Islamic Republic of Iran; [2]Dept of Medicine, LSUHSC, Shreveport, LA.*

**Background:** There are few reports on the association of thyroid diseases with different types of glomerulonephritis (GN). However, this association has not been evaluated in a systematic study so far. The aim of this study was to evaluate the prevalence of thyroid diseases in patients with different types of GN.

**Methods:** All patients who had renal biopsy at our center in 2012 and were diagnosed with primary GN were invited to participate in this case-control study. All cases of secondary GN were excluded. A similar number of age and sex matched subjects from general population were enrolled as controls. Thyroid function test was done for all consenting cases and controls.

**Results:** Of all invited patients with primary GN, 98 (male/female: 46/52; mean age: 38.4±11.9 years) were enrolled as cases; 98 subjects (male/female: 46/52; mean age: 38.7±11.7 years) from general population were enrolled as controls. Cases and controls were similar in terms of age and sex (p=0.83 and p=1.0, respectively). Of 98 controls, 86 were euthyroid, 8 were hypothyroid and 4 had subclinical hypothyroidism. The prevalence of different types of GN and different types of thyroid diseases in cases are listed in the following table:

| | Euthyroidism | Hypo-thyroidism | Subclinical Hypothyroidism | Subclinical Hyperthyroidism | Hyper-thyroidism |
|---|---|---|---|---|---|
| Membranous GN (n=39) | 21 | 8 | 10 | 0 | 0 |
| Mesangioproliferative GN (n=22) | 17 | 3 | 1 | 1 | 0 |
| Focal Segmental Glomerulosclerosis (n=18) | 13 | 3 | 1 | 1 | 0 |
| Membranoproliferative GN (n=13) | 7 | 2 | 3 | 0 | 1 |
| Minimal Change Disease (n=5) | 2 | 1 | 1 | 0 | 1 |
| IgA Nephropathy (n=1) | 0 | 0 | 1 | 0 | 0 |
| Total | 60 | 17 | 17 | 2 | 2 |

The total prevalence of thyroid diseases was significantly higher in patients with GN compared with controls (39% vs 12%, p<0.001). Moreover, thyroid diseases were more common in some types of GN like minimal change disease (60%), membranous GN (46%) and membranoproliferative GN (46%).

**Conclusions:** Compared with general population, thyroid diseases are more common in patients with GN, particularly in some types like minimal change disease, membranous GN and membranoproliferative GN.

## PUB441

**Patient Satisfaction after Electronic Health Record Implementation in a Nephrology Outpatient Setting** Tarik Noureldeen, Neeharika Muddana, Annie Culver, Swati Arora, Kalathil K. Sureshkumar, Richard J. Marcus, Barbara A. Clark. *Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.*

**Background:** Electronic health records (EHR) are currently being implemented throughout the nation. The goal is to improve the quality of health care by providing efficient care, reduce medical errors and increase overall patient's satisfaction.

**Methods:** We conducted anonymous cross-sectional patient surveys from Nov 2011 to Dec 2012 during 3 phases of EHR implementation (pre, start and post-EHR). Surveys were done in the domains of satisfaction, care, distraction, waiting time and visit length. The primary objective was to assess patient's satisfaction with physician's visit with respect to EHR implementation.

**Results:** A total of 187 surveys were obtained. Visit satisfaction decreased (P=0.02), exam room wait time increased (P=0.009), and visit length increased (P=0.03) after EHR implementation along with a trend towards perception of improved care as shown in the table.

| | Pre-EHR (n=52) | Start-EHR (n=41) | Post-EHR (n=94) | p value |
|---|---|---|---|---|
| | | | | |
| Visit Satisfaction (-2 to 2) | 1.9±0.6 | 1.7±0.4 | 1.6±0.7 | 0.02 |
| Improve Care (-2 to 2) | 0.4±1.2 | 0.8±1.1 | 0.8±1.1 | 0.12 |
| MD Distraction (-2 to 2) | –1.6±0.9 | –1.4±1.0 | –1.5±0.9 | 0.39 |
| Waiting Room Wait (min) | 8±7 | 11±12 | 9±10 | 0.40 |
| Exam Room Wait (min) | 9±6 | 12±9 | 15±15 | 0.009 |
| Visit Length (min) | 33±19 | 37±17 | 42±19 | 0.03 |
| MD Charting (min) | 10±10 | 13±13 | 14±12 | 0.21 |

**Conclusions:** After implementation of EHR in our nephrology outpatient clinic, patient's wait time in the exam room and length of visit increased significantly. We believe this could be related to the learning curve phenomenon regarding EHR use among staff. Overall patient satisfaction with the visit decreased as result. We plan to repeat the survey after EHR has been implemented for a year to get past the learning curve. Despite these observations, it is encouraging to note a trend towards improved patient perception regarding overall care.

## PUB442

**Utility of CD4+ T Lymphocyte Counts to Determine Need for PJP Prophylaxis in ANCA Vasculitis** William Franklin Pendergraft,[1,2,3] Andrew P. Murphy,[3] Karen A. Laliberte,[3] John Niles.[2,3] *[1]Joint Nephrology Fellowship Program, Massachusetts General Hospital (MGH) and Brigham and Women's Hospital, Boston, MA; [2]Div of Nephrology, MGH, Boston, MA; [3]Vasculitis and Glomerulonephritis Clinic, MGH, Boston, MA.*

**Background:** Our group currently manages over 400 patients with anti-neutrophil cytoplasmic autoantibody (ANCA) vasculitis, the majority of which were exposed previously to numerous immunosuppressants and currently receive rituximab every four to six months to maintain durable remission. Prophylactic antibiosis is employed universally in these patients to prevent *Pneumocystis jirovecii* pneumonia (PJP). It is unclear if PJP prophylaxis is needed once patients are transitioned to rituximab alone, and also if CD4+ T cell counts can be used to guide the use of prophylaxis. We sought to investigate the levels of CD4+ T cells in our cohort.

**Methods:** We reviewed absolute CD3+CD4+ T cell counts in patients with ANCA vasculitis in our cohort who were undergoing rituximab-induced continuous B cell depletion. Additional standard clinical and serologic parameters were measured and compared.

**Results:** 215 patients treated by our group from April 2006 through June 2013 underwent continuous CD20-positive B cell depletion with rituximab. None of these patients developed PJP. Furthermore, there has not been a case of PJP in an ANCA vasculitis patient in the past fifteen years in our center. CD3+CD4+ T cell counts were measured in 59 ANCA vasculitis patients (64% (n=38) MPO-ANCA, 56% (n=33) women). Nine of these patients

were not receiving rituximab. B cells were undetectable in the rituximab group. Median absolute CD3+CD4+ count was 461 cells/mm$^3$ (S.D. 284, normal range 348-1456 cells/mm$^3$). Four patients had CD3+CD4+ T cell counts < 200 cells/mm$^3$.

**Conclusions:** CD3+CD4+ T cells were within normal limits in the majority of patients tested despite a history of prior cytotoxic therapy. These preliminary results suggest that cessation of PJP prophylaxis in patients receiving RTX monotherapy could be considered.

## PUB443

**Pneumococcal Sepsis in Patients with Systemic Lupus Erythematosus**

Tingting Li, Anitha Vijayan. *Renal Div, Washington Univ, St. Louis, MO.*

**Background:** Severe infections caused by *Streptococcus pneumoniae* are an important cause of morbidity and mortality in pts with systemic lupus erythematosus (SLE). Immunosuppressive therapy (IS), functional asplenia, hypocomplementemia, defective opsonization and phagocytosis, impaired humoral and cellular immunity, and nephritis may contribute to increased susceptibility and severity of pneumococcal infections in this pt population. We aim to describe pt characteristics, clinical presentation and outcome of SLE pts with pneumococcal sepsis (PS).

**Methods:** After retrospectively identifying all cases of PS in SLE pts over a 13-year period at a single center using ICD-9 codes, we conducted a thorough chart review.

**Results:** Thirteen cases were identified in 11 pts between 2000 and 2013. One was male, 7 AA, 4 white, aged 19-60. Ten cases had active SLE, of which 7 had nephritis. Complement levels were low in 8 cases and not available in 3. IgG level was measured in 6 pts and was low in 1. Six pts were on steroids (10-60 mg/d) on presentation with 2 taking concurrent mycophenolate. One pt was on leflunomide. The rest were not on IS. Three cases had prior splenectomy. The rest had normal-sized spleen on imaging. Blood smear examination in 2 pts did not suggest functional asplenia. Three of 4 cases who had prior Pneumovax® were vaccinated >5 years prior to presentation. All cases of PS were confirmed with positive cultures (12/13 in blood and 1/13 in pericardial fluid). Twelve required ICU stay and 9 had septic shock. Sources of PS included tubo-ovarian abscess (1), pneumonia/empyema (3), pericarditis (1), meningitis (2), endocarditis (2), cellulitis (2), septic arthritis (2). Infection source was not identified in 2 cases. Two pts had recurrent PS, 5 and 12 years after the initial episode. 10/11 pts survived.

**Conclusions:** Pts with SLE are susceptible to PS, even during periods of lupus inactivity or in the absence of IS therapy, implicating the role of immune dysfunction in SLE. Physicians should have heightened awareness for PS in this pt population. Pneumovax® should be recommended for all SLE pts and repeat vaccination should be given after 5 years. Per recent CDC recommendation, vaccination with Prevnar 13® should also be a consideration.

## PUB444

**Analyses of Renal Dysfunction and Hyperuricemia in Patients with Chronic Hepatitis C Receiving Telaprevir-Based Triple Therapy**

Satoru Ogahara,[1] Kenji Ito,[1] Yasuhiro Abe,[1] Maho Watanabe,[1] Takao Saito,[2] Hitoshi Nakashima.[1] *[1]Div of Nephrology and Rheumatology, Internal Medicine, Fukuoka Univ School of Medicine, Fukuoka, Japan; [2]General Medical Research Center, Fukuoka Univ School of Medicine, Fukuoka, Japan.*

**Background:** Telaprevir (TVR) are available in combination with peginterferon and ribavirin for the treatment of chronic hepatitis C. It was reported that TVR caused a limited case of transient and reversible increase in serum uric acid (UA) and decrease in eGFR in patients who were enrolled in phase 3 trial. Recently, reports of severe renal dysfunction and hyperuricemia were increasing in post-marketing surveillance. We evaluated the association between the background and adverse effects especially, renal dysfunction and hyperuricemia in patients treated by telaprevir-based triple therapy (TT).

**Methods:** Fifty seven patients were administrated TVR. We measured the change of eGFR and serum UA, the percent of fractional excretion of UA (FEua), %recovery of eGFR and other laboratory findings.

**Results:** All patients decreased eGFR after TT including subclinical states. The decrease change rate of eGFR was divided into quartiles (Q1: 70-48%, Q2: 47-39, Q3: 38-32, Q4: 31-12.There were no association between quartiles of the change of eGFR and background of patients on administration (age, sex, eGFR, hemoglobin, albumin, UA). Compared with Q1, which had a 77% recovery of eGFR, there were lower in Q3 (91%, $p<0.01$) and Q4 (99%, $p<0.01$). Compared with Q1, which had a 93% increased change of UA, there were higher in Q3 (60%, $p=0.024$) and Q4 (60%, $p=0.027$). A mean FEua had 3.95±1.55% after TT. There were no association between FEua and quartiles of change of eGFR. Yet one case of patients had a renal hypouricemia (UA:0.4mg/dl), eGFR was decreased as well as other patients.

**Conclusions:** Renal dysfunction and hyperuricemia frequently occur after TT. The stronger a patient occurs renal dysfunction, the longer a patient has a time of renal recovery. Hyperuricemia appears to be the cause of lower UA excretion. Renal dysfunction is independent of hyperuricemia. It should be noted that eGFR is frequently measured after TT. We need to try uricosuric drug such as benzbromarone.

## PUB445

**Use of Monitoring Equipment and Fluoroscopy in the Insertion of Haemodialysis Permanent Catheter Essential or Ancillary – A Four Year Prospective Comparative Study**

Ebadur Rahman, Naveed Aslam, Nader Mohamed Omran, Seddeg Younis, Ahmed Soliman, Raees Farhan Mushtaq, Dujanah Hassan Mousa. *Nephrology, PSMMC.*

**Background:** Monitoring equipments are used during the insertion of central lines and permanent catheters in hospital settings however, in proficient hands these equipments might not be essential. Hence a comparative study was done in Riyadh Military Hospital.

**Methods:** 388 consecutive patients were included in the study from June 2009 to June 2013. The Hemodialysis permanent catheter insertion was done by two groups: Nephrologists without monitoring equipment or fluoroscopy and vascular surgeons with monitoring equipment and fluoroscopy. Blood pressure, pulse and ECG were monitored by the monitoring equipment. The overall immediate complications and failure rates between the two groups were analyzed by SAS Software version 9.2. The unstable patients (with hypotension, with pacemaker or arrhythmia) were not included.

**Results:** The median age of the study group was 59 years and 52% patients were male. 51% of the cases were done by nephrologists. Overall complications and failure rates were less than 1% in both the groups. Minor complications like Hematoma exit site oozing were also less than 1% in both groups. There were no fatal complications in either of the groups. Each group had one major complication ( pneumothorax) which did not require any intervention. Statistical analysis was not significant regarding complications and failure rates between the two groups.

**Conclusions:** Monitoring equipments are used universally for catheter insertion but did not show to improve procedure related morbidity in stable patients.

## PUB446

**Successful Reduction in Interdialytic Weight Gain Using Decreased Sodium Dialysate Concentration**

Madhavi Katikaneni, Carol J. Blanchard, Roger F. Carbajal Mendoza, Donald I. Baumstein, Ashok P. Chaudhari. *Nephrology, Metropolitan Hospital, New York, NY.*

**Background:** Excess Interdialytic weight gain (IDWG) is associated with increased morbidity and mortality in hemodialysis patients. As a quality improvement project in a outpatient hemodialysis unit we sought to reduce IDWG by lowering dialysate sodium after first trying patient counseling. Aim was to decrease the IDWG by 1lb in patients with IDWG>6lb in 3 months time.

**Methods:** 14 out of total 19 patients on the first 2 shifts of Monday Wednesday Friday group had greater than 6lb of IDWG on Monday after the 3 day interdialytic interval. Of those 14 patients 8 are male and 6 are female with age range 38 to 73 yrs and average dialysis vintage of 3.7yrs. 86% have diabetes, 100% have hypertension, and 78% have heart failure. 9 are Hispanic, 4 African American and 1 Korean. Average number of antihypertensive medications is 3. For 2 months patients were counseled by staff using various methods. 5 out of 14 (36%) patients achieved the goal of decreasing IDWG with counseling alone. Subsequently in 8 out of 14 patients dialysate sodium was reduced to 138 meq/L from 140meq/L. One patient was excluded due to hypotension at baseline.

**Results:** In 1st and 3rd week 5 out of 8 (62%) of them reached the target. In 2nd and 4th week 4 out of 8 (50%) of them reached the target. No hypotensive episodes were noted. Antihypertensives were unchanged. In 36% of patients goal of lower IDWG was achieved by counseling. In those who did not improve with counseling at least 50% of those patients achieved the goal by reducing dialysate sodium. Taken together in 9 out 14 (64%) achieved reduction in IDWG with our intervention.

| | Number of patients | Average IDWG(lbs) for 14pts |
|---|---|---|
| Initial | 14 | 7.9 |
| After counseling phase | 9 | 7.48 |
| After counseling plus sodium 138meq/L dialysate | 5 | 6.78 |

Table 1. Patients with excess IDWG

**Conclusions:** There is no established standard of acceptable IDWG but excess weight gain leads to more fluid removal increasing the complications. In our study we found that decreasing dialysate sodium increases goal of lesser IDWG beyond that obtained through patient education and staff support.

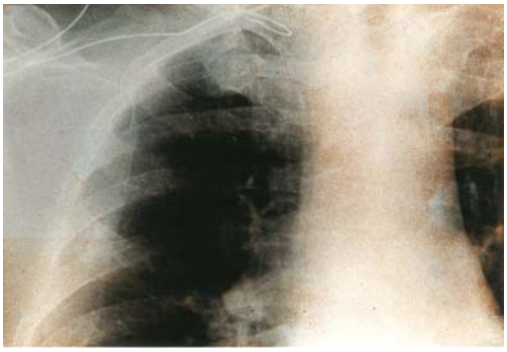
## PUB447

**Knot a Routine Central Line: Case Report of a Tangled Guidewire**

Sunny Kar, Pran M. Kar. *Pran M Kar MD PA, Orlando, FL.*

**Background:** Central venous catheter placement is a common procedure. Complications resulting from line placement are not uncommon. This is a case report of a knotted guidewire.

**Methods:** The patient is a 74 year old male with a history of end status renal disease (ESRD) who presented to the ER with a clotted graft in his left arm. His lab work revealed a potassium level of 6.1 mEq/L, last hemodialysis was 48 hours prior. A decision to insert a catheter for emergency dialysis was made. Due to failed attempts to cannulate his internal jugular, a subclavian catheter placement was planned. Complications including, but not limited to, bleeding, infection, pneumothorax, and death were explained to the patient and an informed consent was obtained. Using the Seldinger technique the subclavian vein was cannulated. The guidewire was inserted through the introducer and a slight resistance was felt after 13 cm of insertion. The introducer was then withdrawn and replaced with a dilator. Retraction of the guide was met with significant resistance. An X-ray revealed a tangled wire.



The guidewire was extracted in the operating room using a larger bore dilator.

**Conclusions:** Compilation rate for all lines is as high as 19%, and range from cardiac conduction abnormalities to embolization of a broken wire. Guidewire tangling is an unusual complication, marked by resistance during wire advancement. It is proposed that use of excess force can worsen the knots or kinks that may have formed. Caution should be extended to dilator insertion to avoid agitation of the guide. It is proposed that to reduce potential complications, guidewires should not be advanced beyond 18 cm. We caution that the guidewire be neither retracted nor advanced with force if any resistance is encountered during placement. Instead, use of a larger bore dilator should be encouraged to recover damaged guidewires. We propose that standard consents be modified to include guidewire related morbidity.

## PUB448

### Can Renal Artery Revascularisation Be Performed Safely as a Day-Case Procedure?

Richard W. Corbett, Alok Singh Chauhan, Peter Hill. *Imperial College Renal and Transplant Centre, Hammersmith Hospital, London, United Kingdom.*

**Background:** Percutaneous renal artery revascularisation continues to have a role in the treatment of both native and transplant renal artery disease. Given the complications associated with this intervention, patients have traditionally been observed for 24 hours prior to discharge. This study was designed to assess whether an early discharge after 6 hours of observation could be performed without an impact on the incidence of significant complications.

**Methods:** All individuals undergoing out-patient percutaneous renal artery revascularisation within our centre were retrospectively identified over two periods of four months, the initial period with patients observed for at least 24 hours and the subsequent second period with these procedures performed as a day-case. Blood pressure, serum creatinine and haemoglobin results were obtained for all patients both prior to and at an interval of five to ten days following the procedure. Requirements for readmission or re-intervention were also examined.

**Results:** 32 interventions (12 transplant, 20 native) were performed in the initial period and 23 interventions (8 transplant and 15 native) during the day-case four months. In the latter group three individuals were admitted for overnight observation while one individual required admission for treatment of pulmonary oedema that developed directly following angiography. In neither group was there a requirement for re-admission, re-intervention nor was there identified pseudo-aneurysm formation or symptomatic hypotension. In the initial group Δ sCr (change in serum creatinine at time of clinic follow-up from pre-procedure) [mean ± sd] was 3.3 ± 16.7 μmol/l compared to 10.4 ± 23.1 μmol/l in the day-case group (p = 0.06). Equally, no difference in change of haemoglobin or systolic blood pressure was seen between the groups.

**Conclusions:** In this small study no differences in complications could be demonstrated between individuals discharged at six hours as compared to 24 hours following percutaneous intervention to either native or transplant renal arteries. Though limited by small numbers this study would support a move to performing these procedures as a day-case.

## PUB449

### Pharmacokinetic Study of Cefazolin in Short-Daily Hemodialysis

Katie Palmer,[1] Sarbjit Vanita Jassal,[1] Robert M. Richardson,[1] Marisa Battistella.[1,3] *[1]Univ Health Network, Toronto, Canada; [2]Univ of Toronto, Toronto, Canada.*

**Background:** A number of centres across Canada offer short-daily hemodialysis (SDHD) treatments. Dialysis sessions are on average two hours in duration performed six times per week. As with intermittent hemodialysis, infections requiring treatment with cefazolin are common. To date, cefazolin pharmacokinetics have not been described in patients undergoing SDHD. The primary objective of this study was to investigate the effect of SDHD on the pharmacokinetics of cefazolin.

**Methods:** Prospective, observational, single-centred study. Five non-infected adults undergoing SDHD were enrolled. Participants received a 1 g intravenous infusion of cefazolin after SDHD on study day one, and a second dose after SDHD on day two. To determine the concentration of cefazolin, six blood samples were drawn at 0, 1, 2, 2.3, 4, and 24 hours after initiation of dialysis on day two, and two dialysate samples were drawn at 1 and 2 hours after initiation of dialysis on day two. Samples were analyzed using high-performance liquid chromatography (HPLC) and pharmacokinetic parameters were determined.

**Results:** Median off-dialysis clearance was 3.6 mL/min (IQR: 2.6-4.8 mL/min) and median on-dialysis clearance was 41.9 mL/min (IQR: 37.7-87.3 mL/min). Median off-dialysis half-life was 25.8 hours (IQR: 22.7-27.3 hr) as compared to a median on-dialysis half-life of 1.6 hours (IQR: 1.6-2.2 hr). The percent removal of cefazolin during dialysis varied between patients, ranging from 34.2 to 93.3 % with a median of 56.2% (IQR: 34.2-56.2%).

**Conclusions:** Estimated cefazolin dialysis clearance is higher than previous estimates with thrice weekly regimens. Current dosing recommendations appear to achieve serum drug concentrations that meet existing standards for microbiological eradication. Further study is warranted in a larger cohort of patients.

## PUB450

### Biopsy-Derived Immortalized Human Proximal Tubule Cells: A New Model to Study the Role of Pharmacogenetics in CNI-Associated Nephrotoxicity

Noel Knops,[1,4] Dirk R. Kuypers,[2] Rosalinde Masereeuw,[3] Elena N. Levtchenko.[1,4] *[1]Pediatric Nephrology, UZ Leuven, Leuven, Belgium; [2]Nephrology, UZ Leuven, Belgium; [3]Pharmacology and Toxicology, Radboud Univ, Nijmegen, Netherlands; [4]Labarotory for Pediatrics, Dept of Development & Regeneration, KU Leuven, Leuven, Belgium.*

**Background:** Calcineurin inhibitors (CNI) constitute the basis of most immunosuppressive regimes in transplantation, but are associated with the development of histological lesions leading to kidney failure. CNI's are metabolized by CYP3A and excreted by Pgp (*MDR1*), primarily in the gut and liver but also in renal proximal tubule cells (PTC). Clinical studies demonstrated a relation between common variants of *CYP3A5*/*MDR1* genes and CNI-associated nephrotoxicity (CNIT). The mechanism is unknown. Here we established a model of human PTC that can be used to study the pathogenesis of CNIT.

**Methods:** A method was developed to culture cells from a protocol biopsy in renal allograft recipients. Primary cells were transfected with SV40T and hTERT virus for conditional immortalization and differentiation. Subclones were selected based upon specific PTC markers (AQP1 and CD13) using Western Blot (WB) and FACS. Light and scanning electron microscopy were performed to detect PTC morphology. PCR and sequencing was used to assess genotype, next to quantative RT-PCR and WB. CYP3A5 activity was assessed by midazolam(MDZ) hydroxylation using LC-MS and Pgp activity by calcein accumulation.

**Results:** From 27 out of 38 biopsies cell lines were generated. Based upon genotype, 10 subclones with PTC biomarkers, cobblestone appearance and brush border microvilli were selected. CYP3A5 and Pgp mRNA and protein expression was confirmed. *CYP3A5*1*carriers had increased 1OH/4OH MDZ formation v (0,83 vs 0,41; p<0,05). Pgp activity was confirmed by 138% (95% CI: 113-163) calcein accumulation, but not related to *MDR1 3435C>T* genotype.

**Conclusions:** PTC cell lines can be generated from a kidney biopsy and demonstrate functional expression of genes involved in CNI metabolism after immortalization. Differences in protein function were detected for *CYP3A5* but not *MDR1* genotypes. This in vitro model can be used to study the role of pharmacogenetic variation in CNIT.

## PUB451

### Significance of Serum Cholesterol Concentration for the Cyclosporine Treatment of Idiopathic Membranous Nephropathy with Steroid Resistant Neprhotic Syndrome

Takao Saito,[1] Yoshie Sasatomi,[2] Satoru Ogahara,[2] Maho Watanabe,[2] Hitoshi Nakashima.[2] *[1]General Medical Research Center, Fukuoka Univ School of Medicine, Fukuoka, Japan; [2]Div of Nephrology and Rheumatology, Fukuoka Univ School of Medicine, Fukuoka, Japan.*

**Background:** For the treatment of idiopathic membranous nephropathy (IMN) with steroid resistant nephrotic synodrome (SRNS), the combination of prednisolone (PSL) and cyclosporine (CYA) is one of the important tools, and therapeutic drug monitoring (TDM) of CYA is useful for predicting the effect. Based on data of receiver operating characteristic (ROC) curves, we proposed 600 ng/mL for the therapeutic target point of C2 (ASN 2009). However, this propose was criticized, because CYA may be influenced by various factors in the nephrotic condition. Now we compare C2 with several factors statistically and consider TDM of CYA again.

**Methods:** Thirty-seven IMN patients with SRNS were treated with PSL+CyA for 48 weeks. PSL was initially prescribed at 40mg/day and tapered. CyA was given at 3mg/kg BW/day. Biochemical data in sera and 24 hours urine protein (UP) were assayed repeatedly. The remission status of nephrotic syndrome were indicated by UP. C2 was monitored more than 4 times and the average was calculated. Significance of these factors for complete remission (CR) and influence of laboratory data on C2 were analyzed by logistic and multiple regression models, respectively. A ROC curve of each factor was drawn for CR.

**Results:** C2 was significantly related to CR (p=0.010) and was not influenced by any laboratory data. Although the cut-off point of C2 for CR (614.5 mg/dL) was determined from area under the curve of ROC (AUC/ROC) (0.731, 95%CI 0.557-0.905, p=0.022), but not so reliable for clinical use because of low likelihood ratio 3.2. When the subjects were limited to patients with TC<340mg/dL (N=25), however, AUC/ROC was increased into 0.868 (I 0.712-1.000, p=0.003) and likelihood ratio 7.3 was enough practically.

**Conclusions:** It is known that pharmacokinetics of CYA is affected by the plasma lipid concetration. Our study suggests that TDM of CYA is more available for the treatment when CYA is administered in the comparatively low level of serum cholesterol.

## PUB452

**Uremic Serum Inhibits the Function of Multiple Human Drug Transporters**

Catherine K. Yeung,[1,2] Danny D. Shen,[1,3] Kenneth E. Thummel,[3] Jane J. Huang,[4] Jonathan Himmelfarb.[2] *[1]Dept of Pharmacy, Univ of Washington, Seattle, WA; [2]Kidney Research Institute, Univ of Washington, Seattle, WA; [3]Dept of Pharmaceutics, Univ of Washington, Seattle, WA; [4]Optivia Biotechnology Inc., Menlo Park, CA.*

**Background:** In vivo pharmacokinetic studies suggest that uremia alters drug transport and metabolism; however the underlying molecular mechanisms remain poorly defined, especially in human subjects. The purpose of the study was to determine whether human uremic whole serum and serum ultrafiltrate inhibit the transport of substrate by P-gp, BCRP, OAT1, OAT3, OCT2, OATP1B1 or OATP1B3 transporter proteins.

**Methods:** For this study, MDCK-II cells expressing human solute carrier transporters OAT1, OAT3, OCT2, OATP1B1, OATP1B3, or ATP-binding cassette transporter MDR1 and Caco-2 cells expressing the ATP-binding cassette transporter BCRP were utilized. Probe substrates for each transporter were OCT2: [$^{14}$C]-metformin, OAT1: [$^{3}$H]-p-aminohippurate, OAT3: [$^{3}$H]-estrone-3-sulfate, OATP1B1: [$^{3}$H]-estradiol-17β-D-glucuronide, OATP1B3: [$^{3}$H]-CCK-8, BCRP: [$^{3}$H]-genistein, and P-gp: [$^{3}$H]-digoxin. Appropriate positive controls for inhibition were included with each set of incubations. Pooled uremic whole serum and serum ultrafiltrate were evaluated at a concentration of 10% in standard incubation medium.

**Results:** Changes in transport of probe substrates were observed between control serum and uremic serum for OATP1B1, OAT1, and P-glycoprotein. This difference was attenuated by removal of protein bound uremic constituents. No change was observed between control serum and uremic serum (whole/ultrafiltrate) for transporters OAT1B3, OAT3, OCT2, or BCRP.

**Conclusions:** We have shown that uremic toxins can alter the in vitro activity of multiple specific drug transporters and that the changes in activity are due mostly to protein bound constituents. These alterations in transporter activity may explain some of the pharmacokinetic variability observed in subjects with CKD and uremia.

## PUB453

**Dialysis Adequacy Measures and Dialytic Removal of Levofloxacin and Gentamicin**

Brian S. Decker,[1] Mary Chambers,[1] Kevin M. Sowinski.[2] *[1]Indiana Univ School of Medicine; [2]Purdue Univ School of Pharmacy.*

**Background:** Short-daily hemodialysis (SDHD) is emerging as an alternative to conventional, thrice-weekly hemodialysis due to its putative physiological benefits. However, there is a paucity of data regarding the appropriate dosing of medications in patients receiving SDHD and the ability of dialysis adequacy measures to predict drug removal.The purpose of this study was to investigate the ability of urea to predict levofloxacin and gentamicin removal in SDHD.

**Methods:** Six non-infected anuric adults treated with SDHD were studied. Following the completion of a subject's first SDHD, levofloxacin IV 250 mg and gentamicin 2 mg/Kg were administered. Blood samples for the determination of levofloxacin, gentamicin and urea were obtained before and during the next intradialytic period and for 4 hours after the dialysis session. Blood samples were processed and the serum stored at -80$^{0}$C until analysis. Levofloxacin concentrations were determined by microbiologic assay and urea and gentamicin concentrations by standard clinical methods. Regression analysis was utilized to investigate the relationship between urea removal and drug removal. The study was approved by the IUPUI IRB and all subjects gave written informed consent prior to study.

**Results:** Five men and one woman were studied. All subjects received SDHD with a new CT dialyzer (Exeltra 150, Baxter Healthcare, Inc.). SDHD dialysis operating characteristics were: dialysis time: 2.5 (2-2.5 hours) and Qb: 500 (450-500) mL/min. Mean urea and drug removal are shown in the table below (SD: standard deviation; RR: reduction ratio; e: equilibrated; sp: single pool). There was no statistically significant relationship between levofloxacin or gentamicin reduction ratios and measures of dialysis adequacy.

| | Urea RR | spKt/V | eKt/V | Levofloxacin RR | Levofloxacin eRR | Gentamicin RR | Gentamicin eRR |
|---|---|---|---|---|---|---|---|
| Mean | 0.412 | 0.611 | 0.518 | 0.605 | 0.460 | 0.656 | 0.503 |
| SD | 0.025 | 0.049 | 0.034 | 0.103 | 0.295 | 0.086 | 0.022 |

**Conclusions:** Dialysis adequacy measures do not predict dialytic removal of levofloxacin or gentamicin.

## PUB454

**Effect of Hemodialysis on Phenytoin**

Robert Zoël Bell,[1] Sarah Bezzaoucha,[1] Jean-Philippe Lafrance,[1] Louis-Philippe Laurin,[2] Michel Vallee,[1] Vincent Pichette.[1] *[1]Nephrology, Hopital Maisonneuve-Rosemont, Montreal, Canada; [2]UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC.*

**Background:** Phenytoin is one of the main drugs used in patients undergoing dialysis as treatment of various types of epileptic seizures. Several studies have revealed that the binding of phenytoin to albumin is dramatically decreased in patients with chronic kidney disease. This phenomenon could lead to increased free plasma levels and toxicity. However, no study has yet evaluated the effects of dialysis on phenytoin-protein binding and plasma concentrations.

**Methods:** The plasma protein binding of phenytoin was evaluated in 10 hemodialysis-patients on phenytoin maintenance therapy. Total and free phenytoin serum concentrations were collected before and after hemodialysis sessions. All the patients were dialyzed 4 hours 3 times a week with high-flux polysulfon filters.

**Results:** In all the patients, the unbound phenytoin fractions, calculated from total and free phenytoin plasma concentrations, were significantly decreased in postdialysis serum compared to predialysis serum in all patients, with a mean value of 25 ± 0.04 % and 14 ± 0.03, respectively ( n=10, p <0.001). The mean free phenytoin predialysis concentration decreased from 6.86 ± 3.14 µmol/L to 3.90 ± 2.03 µmol/L post-dialysis (n=10, p <0.001), while the mean concentration of total phenytoin did not vary.

**Conclusions:** Our results clearly demonstrate that a dialysis session has a major impact on binding parameters that may decrease the anticonvulsant effect of phenytoin after dialysis sessions. Knowledge of these pharmacokinetics effects should be considered in the management of hemodialysis patients in order to achieve higher desired plasma free phenytoin concentrations and prevent seizures that may be associated with subtherapeutic levels.

## PUB455

**Racial Differences in the Risk of Tenofovir Related Nephrotoxicity**

Srujana Polsani,[1] Sumit Mohan,[2] Jyotsana Thakkar,[1] Ali G. Gharavi,[2] Anjali Acharya.[1] *[1]Nephrology, Jacobi Medical Center, Bronx, NY; [2]Nephrology, Columbia Univ, New York, NY.*

**Background:** Tenofovir is an effective first line agent in the treatment of human immunodeficiency virus (HIV) infection. Although Tenofovir is thought to have a low overall toxicity profile, numerous case reports and studies in literature have shown that it can cause proximal tubular injury and Fanconi syndrome. There is limited information looking at its effect on phosphate wasting.

**Methods:** We reviewed charts for a 101 HIV patients (44% male, 45% Black, average age 46 with a deviation of 12 years) receiving care at the outpatient HIV clinic at Jacobi Medical Center. Our cohort includes 85 pts who received tenofovir for an average of 4.4±3 years.

**Results:** Exposure to tenofovir resulted in overt hypophosphatemia in only 4% of patients – all of them were females with somewhat longer exposure to tenofovir (5.8±3.5 vs 4.3±3.1 yrs, p=ns) who were also receiving other HAART agents. Patients exposed to tenofovir had a small but significant drop in the serum phosphate (3.5±0.6 vs 3.3±0.5, p=0.01) which on subgroup analysis appeared to remain significant only among non-Black patients (3.40.6 vs 3.2±0.5, p=0.03) but not among Black pts (3.5±0.6 vs 3.3±0.6, p=0.23).

**Conclusions:** Our results suggest possible racial pharmacokinetic differences, which may be protective. Blacks appear to be less prone to developing tenofovir related nephrotoxicity as evidenced by hypophosphatemia. Hypophosphatemia is likely related to increased urinary phosphate. This subtle change appears to be an early change that precedes the development of glycosuria. These findings are being confirmed in a larger cohort.

## PUB456

**Therapeutic Effect and Safety of Ginseng in Chronic Cyclosporine Treatment**

Kyoung Chan Doh,[1] Long Jin,[1] Shang Guo Piao,[1] Jian Jin,[1] Seong Beom Heo,[1] Sun Woo Lim,[1] Byung Ha Chung,[1,2] Chul Woo Yang.[1,2,3] *[1]CRCID & Transplant Research Center, The Catholic Univ of Korea, Republic of Korea; [2]Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

**Background:** Ginseng is a popular traditional herbal medicine and has been used since ancient times. However, the study associated with ginseng effect on CsA treatment has not yet been performed. Therefore, we investigated the following issues;First,whether ginseng treatment influence immune response. Second,whether ginseng protect CsA-induced renal and pancreatic injury. Third,whether ginseng leads to unwanted drugs interactions.

**Methods:** We evaluated population of Th1,Th2,Th17and Treg in treatment ofCsA and ginseng in mouse splenocyte. Allogenic Tcell proliferation was also performed byMLR assay. Next, mice were treated with CsA(30 mg/kg) and ginseng(0.2,0.4g/kg) for4 weeks. Then, we measured renal function,histopathology,IPGTT,serum insulin,islet size, and oxidative stress marker(8-OHdG) in serum and urine. To confirm pharmacological interaction between CsA and ginseng, we measured CsA level usingLC-MS/MS in whole blood, and tissues.

**Results:** Cotreatment of ginseng with CsA decreased the population of Th17 and Th1. But, the population of IL-4 and Treg was increased by addition of ginseng. MLR results showed ginseng treatment decreased T cell proliferation in dose dependent manner. Four weeks of CsA treatment caused renal dysfunction,typical interstitial fibrosis,high level of blood glucose level,low level of insulin,and reduction of isle size. However, addition of ginseng on CsA recovered above parameters compared with CsA alone. These changes were accompanied by decreased the level of 8-OHdG. There was no difference in the CsA level between CsA alone and CsA+ginseng treated group in bloodand tissues.

**Conclusions:** Cotreatment of ginseng with CsA suppressed pathogenic Tcell proliferation and elicited immune tolerance. Chronically, addition of ginseng has protective effect in CsA-induced renal and pancreatic injury via decreasing oxidative stress without drug interactions. Our results provide good evidence that supplement of ginseng has significant effectiveness and safety in transplant patient receiving CsA.

## PUB457

**Effects of Omega-3 Polyunsaturated Fatty Acid on Renal Function and Proteinuria in Kidney Transplant Recipients** Tariq Shah,[1,2,3,4] Don Vu,[1,2,3] Robert Naraghi,[1,2] Elizabeth Cadag,[2] Caron Hutchinson,[3] David I. Min.[2] *[1]Transplant Research Institute; [2]Saint Vincent Medical Center; [3]Western Univ of Health Sciences; [4]Univ of Southern California.*

**Background:** Omega-3 polyunsaturated fatty acid (O-3PUFA, fish oil) may slow the progression of kidney disease and reduce proteinuria in kidney transplant recipients (KTR). However, evidence from clinical trials is inconsistent. The aim of this study is to assess the effects of O-3PUFA therapy on renal function and proteinuria in KTR.

**Methods:** 137 allograft recipients who received O-3PUFA therapy between 2009 and 2012 at Saint Vincent Medical Center (SVMC) were studied in a retrospective study design. EGFR measured by the Cockcroft-Galt method and daily proteinuria calculated by the random urine protein/creatinine ratio were collected at various time intervals for each participant for 1 year. Statistical analysis was done using a paired t-test for changes in eGFR and proteinuria from baseline, and a p-value <0.05 was of statistical significance.

**Results:** O-3PUFA therapy started an average 6.8 months post- transplantation with a mean daily dose of 3.0±1.4 g/day. The mean eGFR ml/min (±SD)at baseline, 1, 3, 6, 9 and 12 months during O-3PUFA therapy were 51.8 ±22.6, 55.8±19.8, 57.9±19.7, 57.1±18.5, 55.8±19.5 and 56.4±20.1*, respectively (all p<0.05 except for *). Daily mean urine protein excretion g/day (±SD) were 2.60 ±4.28, 1.76 ±2.77, 1.68 ±2.92, 1.74 ±3.28, 1.11 ±2.13 and 1.07±2.02 at baseline, 1, 3, 6, 9 and 12 months, respectively (all p>0.05). Any significant side effects from O-3PUFA were not observed during study period.

**Conclusions:** In our study, O-3PUFA therapy significantly improves renal function measured by eGFR at one month, of which effects last up to 9 months. However, O-3PUFA therapy did not affect proteinuria in KTR at any time during therapy. Well-designed, prospective, randomized, controlled clinical trials are needed to further examine the potential benefits of O-3PUFA in kidney transplant recipients.

## PUB458

**Outcomes of Kidney Transplantation with the Use of Reduced-Dose Rabbit Antithymocyte Globulin Induction and Steroid Avoidance Maintenance Immunosuppression: A Single Center Experience** Sunn Sunn H. Thaw,[1] Nyan Pyae,[1] Susan Puumala,[2] Adit S. Mahale.[3] *[1]Dept of Internal Medicine, Univ of North Dakota, Fargo, ND; [2]Center for Health Outcomes and Prevention Research, Sanford Research, Sioux Falls, SD; [3]Dept of Nephrology, Sanford Health, Fargo, ND.*

**Background:** Induction and maintenance immunosuppression regimens in renal transplantation are largely variable. We analyzed the outcomes of kidney transplant recipients who had reduced-dose rabbit antithymocyte globulin (rATG) for induction and steroid-free maintenance immunosuppression in our center.

**Methods:** A group of 108 kidney transplant patients treated at our institution scheduled to receive reduced-dose rATG as induction therapy and treated with a steroid-free maintenance therapy were analyzed for graft and overall survival using the Kaplan-Meier method. We also explored prognostic indicators within this group to assess differences in graft and overall survival through a Cox regression model.

**Results:** Both graft and overall survival were favorable with one-year survival estimates of 100% and 98% respectively. No differences were found for either graft or overall survival for donor type, human leucocyte antigen (HLA) mismatch score, peak panel reactive antibody (PRA) > 50, or body mass index. A significant difference was found by racial groups, with Native Americans having lower graft survival (hazard ratio [HR], 27.61; p=0.001) compared to Caucasians, but no difference was found between these two groups for overall survival (HR, 1.05; p=0.98). Age at the time of transplant was associated with overall survival (HR, 1.14; p=0.05), but not with graft survival (HR, 0.99; p=0.66). Prevalence of diabetes and peak PRA levels >50 were significantly different between Native Americans and Caucasians (81.8% vs. 24.7%, p <0.001) and (45.5% vs. 11.8%, p=0.01) respectively.

**Conclusions:** Native American kidney transplant patients had lower graft survival compared to Caucasian patients with the use of reduced-dose rATG induction and steroid-free maintenance immunosuppression based on our observation. Higher prevalence of diabetes and higher peak PRA levels could contribute to this disparity in the Native American recipients.

## PUB459

**Acute Graft Pyelonephritis in Renal Transplant Recipients: Risk Factors, Graft Outcome and Association with Acute Rejection** Prem P. Varma,[1] Ashok Kumar Hooda,[1] Sonia Badwal.[2] *[1]Dept of Nephrology, Army Hospital (Research & Referral), New Delhi, Delhi, India; [2]Dept of Nephrology, Army Hospital (Research & Referral), New Delhi, Delhi, India; [3]Dept of Pathology, AFMC, Pune, Maharashtra, India.*

**Background:** Urinary tract infection is a common infection in the renal transplant recipients. However the risk factors and long term outcome of acute graft pyelonephritis (AGPN) remain unclear. Aim- To study the impact of graft pyelonephritis on graft outcome.

**Methods:** In this prospective study from 2002-2011, all transplant recipients were followed for development of UTI. Graft PN was diagnosed if patient had fever, graft tenderness, leucocytosis, pyuria, bacteruria, + Graft dysfunction. The risk factors for AGPN were analysed and impact of AGPN on graft outcome was studied.

**Results:** Of the 556 transplant recipients, 32 patients were diagnosed to have acute graft pyelonephritis. 30/32 patients had graft dysfunction and after 2 weeks of parenteral antibiotics, 26 of them with persisting graft dysfunction underwent biopsies. 7/26 patients revealed evidence of concomitant acute rejection. Anti-rejection therapy did not alter the course of these patients (p< 0.05). Both early as well as late AGPN had poor outcomes with late AGPN being worse off (p=0.02 , p< 0.01 respectively). Despite 4-6 weeks of antibiotics followed by prophylaxis, 75% of patients relapsed requiring repeat courses of antibiotics. The statistically significant risk factors identified in this study were HCV infection and pre-transplant history of UTI (p=0.01 & p=0.01 respectively). In a pilot study of controls, a 70% incidence of post-transplant vesicoureteric reflux (VUR) was demonstrable on MCU (18/26); however, VUR didn't predict AGPN in them (p=0.84). The effect of net immunosuppression in the causation of AGPN was highlighted by the lower incidence demonstrated in the latter half (10% vs 2%) by lowering the doses of steroids and calcineurin inhibitors (p<0.05) .

**Conclusions:** Both early and late graft pyelonephritis especially if associated with graft dysfunction has poor outcome.

## PUB460

**An Environmental Scan of Kidney Transplant Referral Practices in Georgia, North Carolina and South Carolina Dialysis Units** Teri Browne,[1] M. Ahinee Amamoo,[2] Rachel E. Patzer,[3] Leighann Sauls,[2] Jenna Krisher,[2] Stephen O. Pastan.[3] *[1]College of Social Work, Univ of South Carolina, Columbia, SC; [2]Southeastern Kidney Council, Raleigh, NC; [3]Emory Transplant Center, Emory Univ School of Medicine, Atlanta, GA.*

**Background:** The Southeastern United States has the lowest kidney transplant (KTx) rates in the country. To most effectively promote more kidney transplant referrals among dialysis units in the area, the Southeastern KTx Coalition conducted an environmental scan to determine existing dialysis provider beliefs, attitudes and practices related to KTx in their unit.

**Methods:** Every dialysis unit in GA, NC & SC (n=586) was invited to participate in a survey about facility practices in helping dialysis patients get a Ktx. 51% (n=297) of facilities completed the survey. Data were analyzed with descriptive statistics and bivariate and multivariate analyses.

**Results:** The majority of surveys were completed by nurse managers (48%) or social workers (25%). 90% of respondents reported that they were comfortable discussing KTx with their patients, and over 80% have a protocol in place for KTx education. Only 19% of respondents report that 50% or more of patients are interested in KTx as a treatment option, and 87% of respondents report that < 50% of their patients have success in navigating the pathway to KTx. Respondents identified the following barriers to patients receiving a KTx: Lack of patient education materials (34%), unclear KTx center requirements (22%), insufficient patient social support (61%), patient transportation (74%) and patient financial status (89%).

**Conclusions:** This is the first study in the Southeastern United States to survey dialysis units to determine the dialysis facility-level barriers and attitudes about KTx. Results suggest that dialysis professionals are equipped to explore KTx with patients (in that they feel comfortable doing so and have a process in place); however, patient and organizational- level barriers still exist that impede Ktx parity in this region. This study can help inform future research and program development to improve dialysis patient outcomes related to Ktx.

## PUB461

**Factors Associated with Preemptive Referral for Kidney Transplant Evaluation** Mohua Basu, Brendan P. Lovasik, Justin D. Schrager, Nancy G. Kutner, Rachel E. Patzer. *Emory Univ School of Medicine.*

**Background:** While kidney transplantation (KTx) prior to initiation of dialysis is the optimal treatment for end-stage renal disease (ESRD), racial and socioeconomic disparities exist in access to preemptive KTx. Little is known about factors associated with referral for KTx evaluation prior to initiation of dialysis, or preemptive referral.

**Methods:** We examined factors associated with preemptive referral in patients with no previous transplant referred to a Southeastern KTx center for KTx evaluation from 2005-2010. KTx center referral data were linked to United States Renal Data System baseline and follow-up data through September 2011. Multivariable logistic regression was used to examine the association between patient factors and preemptive referral.

**Results:** Of 4,914 referred patients, 934 (19%) were preemptively referred. In models adjusted for patient demographic, clinical, and socioeconomic factors, white (vs. Black) patients, patients who received pre-ESRD nephrology care, and patients with private (vs. public) insurance had a greater odds of preemptive referral (Table). Female sex, glomerulonephritis as cause of ESRD, erythropoietin use, and higher albumin and hemoglobin levels were also significantly associated with access to preemptive referral (Table).

**Table: Factors Significantly Associated with Preemptive Referral (Adjusted Model)**

| | OR (95% CI) | P-Value |
|---|---|---|
| Female (vs. Male) Sex | 1.20 (1.0-1.4) | 0.0333 |
| White (vs. Black) Race | 2.27 (1.6-2.5) | <.0001 |
| ESRD Etiology: Glomerulonephritis (vs. Diabetes) | 1.39 (1.1-1.8) | 0.0192 |
| Pre-ESRD Nephrology Care | 5.75 (4.6-7.1) | <.0001 |
| Erythropoietin Use | 1.25 (1.1-1.5) | 0.0135 |
| Low Albumin (<3.5 mg/dL) | 0.52 (0.4-0.6) | <.0001 |
| Low Hemoglobin (<10 mg/dL) | 0.83 (0.7-1.0) | .0370 |
| Private (vs. Public) Insurance | 2.68 (2.3-3.2) | <.0001 |

**Conclusions:** Minority race, pre-ESRD nephrology care, private insurance, and other patient factors play a role in preemptive referral for KTx. Interventions to increase preemptive referral may reduce racial and socioeconomic disparities in KTx.

## PUB462

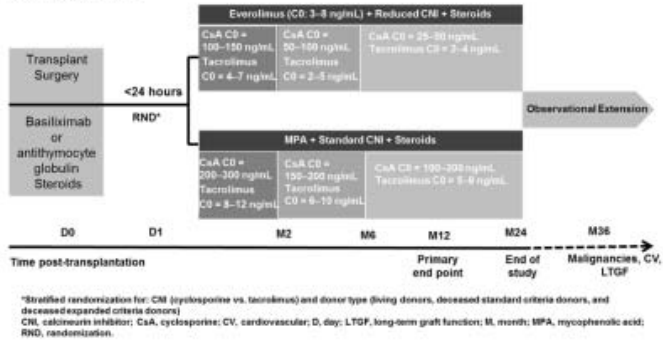
**The TRANSFORM Trial Design: A Large Randomized, Multicenter, Open-Label Study of Everolimus with Reduced Calcineurin Inhibitors in *De Novo* Renal Transplantation** Titte Srinivas, Julio Pascual, Steven J. Chadban, Franco Citterio, Mitchell L. Henry, Christophe M. Legendre, Federico Oppenheimer, Helio Tedesco Silva, F. Vincenti, Yoshihiko Watarai, J. M. Hexham, Peter Bernhardt, Martin G. Zeier. *For TRANSFORM Study.*

**Background:** Immunosuppressive regimens allowing both freedom from rejection and reduction calcineurin inhibitors (CNI) exposure and their associated nephrotoxicity remain an unmet need in kidney transplantation (KTx). Here, we present a phase IV study, TRANSFORM, designed to evaluate the efficacy and safety of everolimus (EVR) plus reduced CNI exposure in comparison to mycophenolic acid (MPA) plus standard CNI exposure in de novo KTx recipients (KTxR).

**Methods:** TRANSFORM, a 24-month (mo), multicenter, open-label study will be conducted across 200 centers worldwide. Approximately >2000 KTxR will be randomized (1:1) to receive either EVR (C0, 3–8 ng/mL) with reduced CNI exposure or MPA with standard CNI exposure, all with basiliximab or antithymocyte globulin induction and steroids (Figure 1).The primary endpoint will be the composite of (i) treated biopsy-proven acute rejection (tBPAR) rate or (ii) proportion of KTxR with estimated glomerular filtration rate <50 mL/min/1.73m$^2$ (eGFR;MDRD4) at mo 12 post-Tx. The key secondary endpoint is composite efficacy failure rate (tBPAR, graft loss, or death) at mo 12 post-Tx. These endpoints will be also analyzed at mo 24. Patients completing 24 mo of treatment will be eligible to participate in an observational extension study for a further 36 mo with outcomes analyzed up to 5 years including eGFR, patient and graft survival, and incident cardiovascular disease, malignancy, and infection.

**Results:**

Figure 1: Study Design



*Stratified randomization for: CNI (cyclosporine vs. tacrolimus) and donor type (living donors, deceased standard criteria donors, and deceased expanded criteria donors)
CNI, calcineurin inhibitor; CsA, cyclosporine; CV, cardiovascular; D, day; LTGF, long-term graft function; M, month; MPA, mycophenolic acid; RND, randomization.

**Conclusions:** TRANSFORM will be the largest clinical trial in KTx and is designed to demonstrate the short- and long-term benefits of de novo CNI-minimization with an EVR-based regimen.

## PUB463

**A Patient-Centered Approach to Exploring Kidney Transplant Promotion in the Southeastern United States** Teri Browne,[1] M. Ahinee Amamoo,[2] Rachel E. Patzer,[3] Jenna Krisher,[2] Henry Well,[4] Stephen O. Pastan.[3] *[1]College of Social Work, Univ of South Carolina, Columbia, SC; [2]Southeastern Kidney Council, Raleigh, NC; [3]Emory Transplant Center, Emory Univ School of Medicine, Atlanta, GA; [4]National Kidney Foundation of GA, NC & SC, Columbia, SC.*

**Background:** Disparities in access to kidney transplantation is a significant problem in the United States, and even worse in the Southeastern region. To determine perceived barriers and facilitators to kidney transplant in the Southeastern United States (and thereby respond to patient needs in program planning), we conducted three patient focus groups in Georgia, North Carolina and South Carolina.

**Methods:** We conducted three focus groups of kidney disease patients in GA, NC & SC. Forty participants were recruited from attendees at a kidney patient educational event hosted by the National Kidney Foundation. An interview guide was used by the group facilitators to explore patient interest and personal experience related to kidney transplantation. A constant comparative method was used to identify themes that emerged from a line-by-line review of the focus group transcripts.

**Results:** Of the 40 participants, 14 (48.3%) were male, 25 (87%) were African American, and the majority (46%) were on dialysis for more than two years. Participants described five main barriers to getting a kidney transplant: financial, medical, informational, attitudinal, and the composition and behaviors of the dialysis team, medical providers, and others in their social networks. They identified finances, younger age, information, attitudes and beliefs, and helpful medical professionals and others as facilitators for getting a kidney transplant.

**Conclusions:** This study is the first of its kind to explore the barriers and facilitators of getting a kidney transplant in the area of the United States with the greatest kidney transplant disparity. The study findings provide the basis for the development of targeted interventions that can improve kidney transplant parity in a way that is patient-centered.

*Funding:* NIDDK Support, Other NIH Support - NIMHD

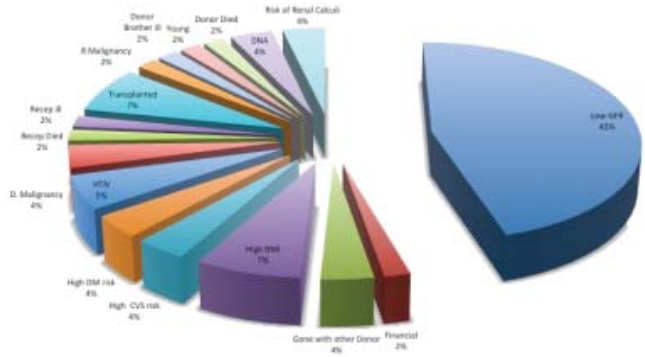
## PUB464

**Live Donor Evaluation, Why Do Potential Donors Not Proceed?** Maharajan Raman, Rachel Middleton, Grahame N. Wood. *Renal Medicine, Salford Royal Foundation NHS Trust, United Kingdom.*

**Background:** Live donation represents 38% of Kidney transplants in the United Kingdom. Live donation has become a treatment of choice. Donor welfare is paramount. Vigilant donor care and management is essential to inspire public confidence. We evaluated the reasons for unsuitability and outcomes following live donor assessment.

**Methods:** Retrospectively analysis of 109 donors who were referred to the consultant led live donor clinic following initial assessment in the Nurse lead clinic between the year 2009 and 2011. 49 of these donors (45%) were found to be unsuitable for donation. Evaluated donor demographics, relationship to recipient, past medical history, reasons for unsuitability, recipient eGFR and change in modality during this period.

**Results:** The average donor age was observed to be 47 years and majority of them were Caucasians (91%). Hypertension (19%) was the commonest past medical history followed by mental health issues (11%)and high cholesterol (10%). 31% of the recipients were in the pre-dialysis group and 69% were on RRT. The average eGFR among the pre-dialysis group was observed to be 12ml/min. 6% changed modality form pre-dialysis to requiring RRT during the assessment period. The chart below shows the various reasons for unsuitability.



Following the assessment of these unsuitable donors 8% were placed in the CKD register, 4% were referred to the Geneticist and 2% of the donors were either referred to Cardiologist, Gastroenterologist, Gynecologist or Psychologist due to abnormal findings discovered during the live donor assessment period.

**Conclusions:** In our cohort of donors we found low isotopic GFR to be the commonest reason for unsuitability followed by high BMI and hypertension. Hence isotopic GFR can be used as an effective screening and a cost saving tool. Incidental findings discovered among the unsuitable donors during this assessment period were appropriately managed.

## PUB465

**Patient Navigation to Increase Kidney Transplant Evaluation Completion in High-Risk Patients** Mohua Basu, Rachel Koval, Jennie P. Perryman, Kevin M. Clark, Dawn L. Fletcher, Perry Dykes, Lisa Petgrave-nelson, Rachel E. Patzer. *Emory Transplant Center.*

**Background:** Racial and socioeconomic disparities exist in the rate of kidney transplant (KTx) evaluation completion among referred patients. An ongoing pilot study will assess the effectiveness of a patient navigation (PN) intervention to increase the KTx evaluation completion rate and to decrease the time from KTx evaluation to candidacy decision in high-risk patients at a Southeastern KTx center.

**Methods:** We created a risk assessment tool that uses patient demographic and clinical factors to estimate probability of waitlisting for patients referred for KTx evaluation based on center-level and national surveillance follow-up data. Patients with <40% probability of waitlisting were classified as high-risk and randomly assigned to receive PN or standard of care during KTx evaluation. Kaplan-Meier methods and Cox models will be used to assess the KTx evaluation completion rate and time from evaluation to candidacy decision for patients receiving PN compared to standard of care.

**Results:** Since initiation of the study in January 2013, 213 (34%) patients referred for KTx evaluation were classified as high-risk. Currently 50 high-risk patients have been assigned to receive PN and 47 the standard of care. Characteristics of referred patients appear below (Table).

**Table: Patient Characteristics by Risk Group**

| | Total N=635 | High Risk N=213 (33.5%) | Low Risk N=422 (66.5%) |
|---|---|---|---|
| **African American** | 68.7% | 79.3% | 63.4% |
| **Less than High School Education** | 14.7% | 35.2% | 4.5% |
| **Private Insurance** | 47.7% | 9.4% | 67.1% |
| **Married** | 50.1% | 26.1% | 62.1% |
| **Non-English Speaker** | 2.5% | 7.6% | 0% |
| **Mean BMI** | 29.9± 7.3 | 31.9 ± 8.2 | 29.0 ± 6.6 |

**Conclusions:** Preliminary data support the feasibility of identifying high-risk patients and intervening with PN. The effectiveness of PN to increase the KTx evaluation completion rate and reduce disparities in KTx access will be evaluated upon study completion. Results will inform decisions about implementation of a long-term PN program in the KTx center.

## PUB466

**Tacrolimus Dose and Trough Blood Levels in a U.S. Kidney Transplant Population** Brett Pinsky,[1] Mary Helen Tran,[2] Aylin A. Riedel.[1] *[1]OptumInsight, Eden Prairie, MN; [2]Novartis Pharmaceuticals Corp, East Hanover, NJ.*

**Background:** The goal of this study was to examine tacrolimus (TAC) dose over time and by TAC trough levels in kidney transplant (KTX) patients.

**Methods:** A retrospective analysis of transplanted kidney and a prescription claim for TAC (tacrolimus) between 01Jan2004 and 31Aug2011 was conducted using a large US healthcare claims database. The date of the first TAC claim was defined as the index date. All patients were required to have continuous enrollment for 1 year prior (pre-index) and a minimum of 6 months following (post-index). Evidence of KTX was defined in the pre-index period as at least one claim with a diagnosis or procedure code for KTX. Incident cases were defined as having evidence of transplant surgery during the pre-index period; all other cases were defined as prevalent. Patients had ≥1 lab result measuring TAC trough level in the post-index period. Average TAC trough levels were examined from index date in three month intervals through the first year. The average daily dose of TAC was examined during the same intervals and in relation to trough level.

**Results:** Study sample included 531 incident and 336 prevalent KTX patients with a TAC trough result. Depending on time frame, 96% to 73% of patients had a TAC fill in the same time period as an available TAC trough result. Over the first year the percentage of patients with TAC levels ≥7.5 ng/ml decreased from 46% to 41%. In the prevalent group, the percentage of patients with TAC levels ≥7.5 ng/ml is 40%. Table 1 examines the shift in the population's TAC trough levels over time and the relationship between dose and TAC trough level.

Table 1. Tacrolimus Trough Level and Dose over time

| | Tacrolimus Trough Level | | | | |
|---|---|---|---|---|---|
| | 0 – 4.799 ng/mL | 4.8 – 6.199 ng/mL | 6.2 – 7.499 ng/mL | 7.5 – 9.399 ng/mL | 9.4 – 20 ng/mL |
| *Incident Transplant* | | | | | |
| **3 Months (N)** | **92 (18%)** | **92 (18%)** | **94 (18%)** | **91 (18%)** | **145 (28%)** |

| TAC daily dose (mg) | 5.86 | 5.99 | 6.34 | 6.95 | 6.27 |
| *Prevalent Transplants* | | | | | |
| **Over 12 Months* (N)** | **209 (18%)** | **260 (23%)** | **206 (18%)** | **248 (22%)** | **229 (20%)** |
| TAC daily dose (mg) | 5.06 | 5.50 | 6.12 | 5.94 | 5.78 |

*In the prevalent transplant cohort, TAC blood levels and TAC daily dose were all calculated at 3, 6, 9 and 12 months following the index date to identify a temporal relationship. The time periods were combined and classified as over 12 months since the timing in the prevalent cohort is happenstance.

**Conclusions:** TAC dose and trough level appear to change over time as evidenced by decreasing dosage and levels. A significant number of patients remain at a TAC lever >7.5 ng/ml or higher. This suggests that TAC management is not routinely occurring.

## PUB467

**Epidemiology of Infections Requiring Hospitalisation during Long Term Follow-Up in Kidney-Transplant Patients** Laure Champion,[1] Christel Renoux,[2] Christine Randoux,[1] Caroline Du Halgouet,[1] Latifa Azeroual,[1] Denis Glotz,[3] Francois Vrtovsnik,[1] Eric Daugas.[1] *[1]Nephrology, Bichat Hospital, Paris, France; [2]McGill Univ, Montreal, Canada; [3]Kidney Transplantation, Saint Louis Hospital, Paris, France.*

**Background:** Are there more infections requiring hospitalisation (IRH) following renal transplantation nowadays than previously reported?

**Methods:** We performed a retrospective cohort study of 314 consecutive renal transplant recipients from 1999 to 2012. We stratified the cohort further by date of the renal transplantation (P1:1999-2003: n=61; P2:2004-2007: n=89; P3:2008-2012: n=164). Data regarding the IRH, including bacterial, viral, parasite and fungal infections, were collected. The main objectives of the study were to estimate the incidence rate of IRH (events/100 patients year), the median time to the first IRH in the 3 time periods (P1 being the reference period) and the risk factors of IRH using survival analysis.

**Results:** The patients who underwent a transplant during P3 were older, had more cardiovascular risks factors, higher title of pre-transplant antibodies, and received an RATG induction therapy more often. At 3 and 5 years, the graft and patient survival rates were 95%-89% and 95%-89% respectively, with a growing incidence of acute rejection from P1 to P3 (1.69; 5. 62; 6. 83). Overall, 172 (54. 8%) patients developed at least one IRH in a total of 381 during a median follow-up of 4.18 years. The median time for the occurrence of the first IRH was shorter for most recent transplant recipients: P1 : 9.53 years (IC-95% : 3.40 to non estimable) ; P2 : 2.83 years (1.30-4.55) ; P3 : 1.74 years (0.95-3.88) ($p<0.05$). Incidence rate of IRH adjusted for sex and age (3.38; 9.1; 14.03), opportunist infection (0.90; 5.04; 8.48), late infection (8.3; 22.16; 36.05) and death rate increased over time ($p<0.001$ for all). In a multivariate Cox regression analysis, the potential risk factors for IRH were age, time under dialysis before transplant, induction by RATG, corticoid use, and a transplant after 2004.

**Conclusions:** The incidence rate of IRH increases over time.This higher incidence might be related to different patient profiles and immunosuppressive protocols including RATG.

## PUB468

**Why Do Patients Forget to Take Their Immunosuppression Medications and Can a Smartphone App Help?** Ajay K. Israni,[1] Brian J. Kasel,[2] Winston Anderson Wildebush,[2] Bertram L. Kasiske,[1] Chihhung Jason Wang.[3] *[1]Medicine, Hennepin County Medical Center (HCMC), Univ of Minneosta (UMN), Minneapolis, MN; [2]Minneapolis Medical Research Foundation (MMRF), Minneapolis, MN; [3]Stanford Univ, Stanford, CA.*

**Background:** Kidney transplant recipients must adhere to their immunosuppressive medication regimen. However non-adherence remains a major problem post-transplantation.

**Methods:** We performed a qualitative study that included home or work place visits and interviews with kidney transplant recipients from a single urban, transplant center. The goal was to determine how patients remembered to take their medications, and to assess patients' perception and beliefs about adherence to immunosuppressive medications and barriers to medication adherence. Patients also reviewed screen shots of a prototype app to be used in smartphones. All transcripts were transcribed and coded for qualitative data analysis.

**Results:** We conducted home or work place visits with sixteen patients; an average of 3 visits were conducted per patient. The visits showed that most patients have incorporated medication use into their daily lives. However any minor deviation from daily routines results in non-adherence. The qualitative surveys revealed that transplant recipients understood the importance of taking their immunosuppressive medications and described various factors that motivated them to take their medications. However, patients reported barriers to adherence such as: forgetting to take or renew medications, procrastination, being short on money, having depression, distractions, or change in daily routine, forgetting medications while away from home, alcohol use and falling asleep before taking evening dose. All patients were interested in using the app. However, they reported potential barriers to using the app such as: cell phone being turned off or not with the patient, ignoring reminders from the app, app reminders becoming too annoying and app is inflexible about timing of reminders.

**Conclusions:** Although kidney transplant recipients understood the importance of medication adherence, there were significant barriers to maintaining adherence. Patients also reported interest in using a smartphone app.

## PUB469

**Clinical Epidemiology of Resistant Hypertension in Renal Transplant Patients** Francesca Mallamaci, Vincenzo Panuccio, Rocco Tripepi, Giovanna Parlongo, Maria Carmela Versace, Raffaele Politi, Carmine Zoccali. *CNR-IBIM, Clin Epid and Physiopath of Renal Diseases and Hypert., Reggio Calabria, Italy.*

**Background:** Only scattered information exists on treatment-resistant hypertension (RH) in transplant pts and the issue has never been assessed according to rigorous ABPM criteria.

**Methods:** We assessed the problem in unselected series of 219 renal transplant pts followed up according to recommendations by the Am Soc of Transplantation (AST, JASN 11: S1–S86, 2000) and in two well matched groups of stage 2-5 CKD patients. We applied the stringent diagnostic criterion for RH by NICE (Mean daytime BP>135/85 mmHg despite treatment with 3 drugs) and the standard JNC-VII criterion for RH.

**Results:** The prevalence of RH (NICE criteria) was substantially less in renal transplant pts (5 patient/219, i.e. 2.3%) than in the first CKD group (8.7%, $p=0.03$). Coherently with this finding, comparison of the transplant pts group with the second CKD group by the JNC VII criterion (Transplant Pts 1.1% vs CKD-B 11.9%, $p<0.001$) confimed a substantially lower prevalence of RH in transplant pts. Further analyses in a sub-group (n= 165) of CKD pts strictly matched to renal transplant pts for the GFR again showed a substantially lower prevalence of RH in renal transplant pts (1.1% vs 7.9% in CKD pts $p=0.002$). The prevalence of RH across these groups went along with the number of visits (12 visits/year in transplant pts vs 1- 2 visits/year in the two CKD pts groups).The low prevalence of RH in transplant patients went along with a lower frequency ($P<0.001$) of uncontrolled hypertension in this population.

**Conclusions:** Notwithstanding the use of pro-hypertensive drugs lik calcineurin inhibitors and the surge obesity after renal transplantation, the prevalence of RH is remarkably lower in renal transplant pts than in well matched CKD pts. Such a low prevalence goes along with the intense follow-up (number of visits) after renal transplantation. Effective hypertension control can be achieved in a substantial number of renal transplant pts underscoring the relevance of intensified follow up on BP control in this population.

**PUB470**

**Lower Incidence of Post-Transplant Diabetes Mellitus after Kidney Transplantation with Redused Tacrolimus Levels and Angiotensin Receptor Blockers** Mediha Boran,[1] Mertay Boran,[2] Ertay Boran,[3] Faruk Gonenc.[4] *[1]Dept of Nephrology, Hemodialysis and Transplantation, Turkiye Higher Education Hospital, Ankara, Turkey; [2]Clinic of Thoracic Surgery, Cankiri State Hospital, Cankiri, Turkey; [3]Dept of Anesthesiology and Reanimation, Izmir Ataturk Education and Research Hospital, Izmir, Turkey; [4]Dept of Urology, Turkiye Higher Education Hospital, Ankara, Turkey.*

**Background:** Post-transplant diabetes mellitus (PTDM) is an undesirable consequence of transplantation, affecting approximately 12-54% of renal transplant recipients. The objectives of the present study were to assess the incidence of PTDM and the factors that were associated with the development of this complication in kidney transplant recipients maintained on reduced tacrolimus (TAC) based immunosuppressive regimen and angiotensin receptor blockers (ARB) therapy.

**Methods:** The study was a retrospective analysis of a prospectively maintained database that compared clinical outcomes of 137 kidney allograft recipients transplanted in a single center from 2004 to 2011 receiving reduced TAC, mycophenolate mofetil (MMF) and minimal prednisone and ARB. In an attempt to detect risk factors predisposing to PTDM, data were compared between 12 recipients with PTDM and 125 recipients without PTDM.

**Results:** In this study, we selected consecutive 137 kidney transplant recipients receiving TAC, MMF and steroid. PTDM occurred in 12 of the recipients (9.6%) 30 days after transplantation. A multivariate analysis including variables which have significant effect on PTDM risk in univariate analysis revealed that recipients who were overweight (>65kg) (p=0.004) and have target TAC trough levels (p=0.005) have significant risk of PTDM.

**Conclusions:** In our study, kidney transplant recipients with reduced dose of TAC and steroid and adittional ARB therapy showed low incidence of PTDM. . The incidence of PTDM was associated with the doses of immunosuppression and overweight of the kidney transplant recipients. These findings demonstrated that PTDM is more consistent with an insulin resistance than with an insulin- deficient state. PTDM was not representing a risk for poor graft and recipient outcomes.

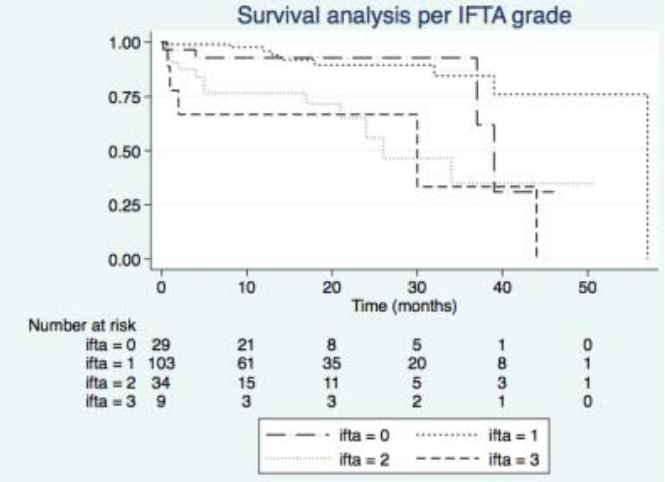
**PUB471**

**Interstitial Fibrosis and Tubular Atrophy as a Predictor of Median Renal Allograft Survival** Ana Paula Rossi,[1] Maxwell Yisheng Li,[2] Mahendra Mangray,[1] Douglas M. Dressel,[3] John P. Vella.[1] *[1]Div of Nephrology and Transplantation, Maine Medical Center, Portland; [2]Dept of Medicine, Medstar Georgetown Univ Hospital, Washington, DC; [3]Dept of Pathology, Spectrum Medical Group, ME.*

**Background:** Many patients with failing grafts start dialysis without adequate access and experience high morbidity and mortality. Better allograft prognostic tools may allow improved preparation for ESRD.

**Methods:** Retrospective review of 175 kidney transplant recipients undergoing for cause graft biopsies. IFTA was graded according to the Banff criteria. Main outcome was graft loss. Kaplan Meier curves and Cox proportional hazards model were used for analyzing graft survival.

**Results:** Mean follow up time was 16 ±13 months. Thirty patients (17%) lost their grafts. Mean graft age was 47 ±51 vs 25 ±48 months for lost vs functioning grafts (p0.02). Subjects with graft loss were younger (41 ±16 vs 48 ±14 years, p0.03), had a higher creatinine ([Cr] 3.3 ±2.1 vs. 2.3 ±1.3 mg/dL, p0.002) and IFTA grade (p<0.001), and were more likely to have antibody mediated rejection (34.8 vs 15.4%, p0.03) than subjects with no graft loss. There were no differences in immunosuppressives, antihypertensives or history of prior rejection. Median graft survival was 39, 57, 26 and 30 months for IFTA grade 0, I, II, and III respectively (p<0.0001). On univariate analysis, higher IFTA score (HR 0.52, p0.3; HR 2.66, p0.09; and HR 4.09, p0.04 for IFTA grade I, II and III respectively, IFTA=0 as reference), graft age (HR 1.01, p0.06) and higher Cr (HR 1.17, p0.01) were associated with a greater risk of graft loss. After adjusting for age, gender, donor type, graft age, Cr, concurrent rejection and IFTA grade, only Cr (p0.03) conferred greater risk of graft loss.



**Conclusions:** Median graft survival from biopsy is significantly shorter for grafts with IFTA grade II or higher compared to lower degrees of fibrosis.

**PUB472**

**What Factors Influence Renal Transplant Wait List Status** Mary McCarthy, Sarah Margaret Moran, William D. Plant. *Nephrology, Cork Univ Hospital, Ireland.*

**Background:** Renal transplantation (RTX) is the optimum form of renal replacement therapy (RRT) for End Stage Kidney Disease (ESKD) patients. Not all patients are suitable for listing; a variety of processes are necessary for patients to transition onto the wait-list; the reasons why a patient is not listed at a particular time point may vary; standardisation of processes may streamline future wait-listing strategies.

**Methods:** A cross-sectional single-centre study was performed. Departmental ESKD Registry identified all patients treated by any form of long-term dialysis on 31/12/12. Low clearance patients and patients with failing RTX were not included. Transplant wait-list status, transplant history, age, gender, ESKD vintage, modality of RRT, and reasons for current status were established by electronic and paper record review, supplemented by supervising Consultant interviews.

**Results:** 167 patients were identified. Mean age was 61 (range 26-90, median 62) years. Mean ESKD duration was 58 (range 0–386, median 36) months. 22 (13%) had had previous transplants. 134(80%) were undergoing centre haemodialysis, 6(4%) home haemodialysis, and 27(16%) home peritoneal dialysis.

| | N | % |
|---|---|---|
| On RTX List (Active/Suspended) | 50 (47/3) | 30% (28%/2%) |
| Working Up for RTX List (Ongoing / Ongoing – previous medical barrier improved/Suspended - medical barrier) | 43 (19/6/18) | 26% (11%/4%/11%) |
| Unwilling to consent to RTX despite offer to workup | 14 | 8% |
| Advised that permanent medical barrier to joining RTX List exists | 58 | 35% |
| Unclear as to RTX List status | 2 | 1% |

Table 1 indicates the point prevalence on the RTX wait-list on 31/12/12. For those working up for addition to the list, transient medical barriers were important factors leading to delays in completing wait-listing. Patients availing of Home Therapies (58%) were more likely to be RTX wait-listed than those on Centre-based Therapies (23%).

**Conclusions:** A definitive conclusion to RTX wait-listing processes had been attained for 73% of patients. A highly variable matrix of reasons for non-conclusion in the 26% still undergoing workup was identified on Consultant interview – these processes may benefit from structured and prioritised attention.

**PUB473**

**Clinical Usefulness of AKIN Criteria in Deceased Donor Kidney Transplantation** Myung Hyun Lee, Jong Hoon Lee, Keun Suk Yang, Yul Hee Cho, Ji Hyun Yu, Seun Deuk Hwang, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, Seoul, Republic of Korea.*

**Background:** In this study, we analyzed the renal graft function and graft survival after Kidney transplantation (KT) from deceased donors with acute kidney injury (AKI) defined using AKIN (Acute Kidney Injury Network) criteria.

**Methods:** We analyzed 157 deceased donor kidney grafts transplanted at our institution between September 1996 and December 2012. Donors were divided into non-AKI (n=112) and AKI groups(n=45) according to the AKIN classification. Out of 45 AKI donors, 35 donors(22%) were included in stage 1, 9(6%) in stage 2 and 1(0.6%) in stage 3 categories. We compared the incidence of delayed graft function(DGF), the change of allograft function assessed by MDRD-eGFR until 1 year from KT and graft failure between AKI and non-AKI groups.

**Results:** The proportion of deceased donors with diabetes, hypertension and old age (>50 years) did not differ between AKI and non-AKI groups. The development of DGF was significantly higher in the AKI group than in the non-AKI group recipients (12.3% vs 8.3%, p<0.05). Independent predictors of DGF were AKI defined by AKIN criteria(OR 4.94, p=0.001) and PRA(panel reactive antibody) percentage(OR 1.01, p=0.009) in multivariate

analysis. Allograft function until 6 months from KT showed significantly deteriorated pattern in AKI group compared to non-AKI group as well (9.12±5.69 vs 19.37±15.61, 43.74±24.83 vs 58.65±26.73, 53.29±32.3 vs 61.34±20.81, 54.97±18.72 vs 61.26±18.05, 56.39±19.09 vs 62.09±18.18, p<0.05; MDRD-eGFR on 3 day, 2weak, 1month, 3months and 6months in AKI and non-AKI group, respectively). However, allograft function at 12 months from KT did not differ between two groups(58.92±20.63 vs 63.07±23.57, p>0.05; MDRD-eGFR in AKI and non-AKI group, respectively). Graft failure also did not differ between two groups (2% vs 7.4%, p >0.05, AKI and non-AKI group, respectively).

**Conclusions:** In conclusion, definition of AKI according to AKIN criteria in deceased donor is useful to predict the development of DGF and the change of allograft function after KT.

## PUB474

### Immunosuppressive Regimen Adjustment Has No Effect on Serum Cystatin C Concentration in Patients with Severe Pulmonary Infection after Renal Transplantation

Fei Liu. *Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

**Background:** Assesment of renal function is of vital importance for patients with renal transplants. Cystatin C has the characteristics of an ideal marker to assess renal function.

**Methods:** A descriptive, analytical and prospective study was conducted between January 1st,2010 and January 31th, 2013 on 27 renal transplant recipients with severe pulmonary infection.

**Results:** Immunosuppressive drugs was abolished in 11cases of them and the methylprednisolone 40 mg only used by intravenous drips once a day. The forbidden course of immunosuppression was 7 to 20 days. The dose of immunosuppressive drugs was decreased in 13cases of them. No patients had rejection during the forbidden or reduced course of immunosuppression. The serum cystatin C concentration of 27 patients were 2.02±0.99 mg/L before adjustment and 2.21±1.12 mg/L after adjustment. There was no statistically significant difference between before and after adjustment of immunosuppressive regimen for serum cystatin C concentration (P=0.053).

**Conclusions:** Our results showed no significant difference for serum cystatin C was obtained between before and after adjustment of immunosuppressive regimen. Adjustment of immunosuppressive regimen was effective and safe for patients with severe infection after renal transplantation. Serum cystatin C may be considered as a sensitive predictive parameter of kidney function in renal transplant recipients with infection.

## PUB475

### Improvement in Renal Function in High Immunologic Risk Kidney Transplant Recipients Switched from Tacrolimus to Belatacept

Gaurav Gupta,[1] Stacey Posner,[2] Dhiren Kumar,[1] Qing Ren,[1] Marc P. Posner,[2] Amit Sharma,[2] Anne L. King.[1] *[1]Nephrology, Virginia Commonwealth Univ, Richmond, VA; [2]Transplant Surgery, Virginia Commonwealth Univ, Richmond, VA.*

**Background:** Belatacept might be an alternative to Calcineurin Inhibitors (CNI) to avoid short and long-term nephrotoxicity. Prior data on low immunologic risk de-novo kidney transplant recipients (KTx) switched from a CNI to belatacept demonstrated improved renal function. There is no literature on the use of belatacept for sensitized patients or regrafts.

**Methods:** All patients were confirmed to be EBV seropositive. Tacrolimus (tac) was tapered and belatacept initiated based upon prior published protocol (Grinyo et al., Transpl Int. 2012 Oct;25). Mycophenolate mofetil dose was increased to a dose of 2-2.5g/d to minimize risk of rejection.

**Results:** Five patients, of whom 60% (3/5) were African-American, were switched from tac to belatacept and followed for a median of 4.8 mths (range=3-7 mths). Clinical features are listed below:

| Pt N0. | cPRA (%) | Regraft (Y/N) | Index Biopsy | Time Post-KTx (mths) | Peak SCr(mg/dL) | Current SCr (mg/dL) |
|---|---|---|---|---|---|---|
| 1 | 23 | N | IFTA Gd II + isometric vacuolization | 2.2 | 3.3 | 1.5 |
| 2 | 0 | N | IFTA Gd III | 3.0 | 2.7 | 2.1 |
| 3 | 99 | Y | IFTA Gd II + isometric vacuolization | 8.7 | 1.9 | 1.6 |
| 4 | 97 | Y | IFTA Gd II | 25.7 | 3.0 | 1.5 |
| 5 | 0 | N | IFTA Gd III | 4.0 | 3.2 | 1.8 |

IFTA Gd: Interstitial fibrosis and tubular atrophy Grade (per Banff criteria)

Renal function improved significantly ($p$=0.02) from a mean serum creatinine (SCr)of 2.8±0.6mg/dL prior to the switch to a mean SCr of 1.7±0.2mg/dL at most recent follow-up. No rejection episodes were diagnosed. One patient had an infectious complication (CMV re-activation).

**Conclusions:** In this preliminary report we show a significant improvement in renal function in five patients, the majority of whom were high immunologic risk, when switched from tac to belatacept. Improved renal function was noted even in patients with chronic allograft fibrosis without evidence of acute CNI toxicity. Further follow-up and protocol biopsies are needed to ensure safety and wider applicability of this approach.

## PUB476

### Metformin Use in Kidney Transplant Recipients in the United States

Ajay K. Israni,[1,2] Sally K. Gustafson,[1] Jon J. Snyder,[1] Bertram L. Kasiske.[1,2] *[1]Scientific Registry of Transplant Recipients, Minneapolis, MN; [2]Medicine, Hennepin County Medical Center (HCMC), Univ of Minnesota (UMN).*

**Background:** Metformin is contraindicated in patients with "renal dysfunction (e.g., as suggested by serum creatinine levels ≥1.5 mg/dL [males], ≥1.4 mg/dL [females] or abnormal creatinine clearance)" (US Food and Drug Administration) due to the risk of lactic acidosis. The prevalence of metformin use in kidney transplant recipients (KTX) in the US is not known.

**Methods:** We linked Scientific Registry of Transplant Recipient data for all incident KTX occurring between 2001 and 2012 with pharmacy claims from a database constructed by IMS Health. We then excluded records that were inconsistent between the two databases based on gender, date of birth or state of residence; and required at least one pharmacy claim post-transplant. The final dataset included 123,533 KTX, which represented 82.1% of the initial match and 63.9% of all incident KTX recipients.

**Results:** There were 4,291 KTX (3.5% of final dataset) with at least one claim for metformin post-transplant and the number of claims for metformin ranged from 1 to 111 per KTX. Over 50% of these KTX had 5 or more claims. The first claim for Metformin was at a mean of 1116 ± 950 days post-transplant and the creatinine level prior to this first claim was 1.45 mg/dl ± 1.22 (Interquartile range, IQR 1-1.5). Characteristics of KTX on metformin versus the remaining 119,242 not on metformin are shown in Table.

**Baseline characteristics of kidney transplant recipients on metformin versus those not on metformin**

| Characteristics | On Metformin, n (%) | Not on Metformin, n (%) | p-value |
|---|---|---|---|
| Age in years | | | |
| 18 to 34 | 262 (6%) | 13,851 (12%) | <0.001 |
| 35 to 49 | 1225 (29%) | 36,763 (31%) | |
| 50 to 64 | 2142 (50%) | 49,993 (42%) | |
| 65 + | 662 (15%) | 18,635 (16%) | |
| | | | |
| Gender: Female | 1,990 (46%) | 46,620 (39%) | <0.001 |
| | | | |
| Mean Creatinine at discharge in mg/dl ± S.D. | 2.4 ± 2.12 | 2.8 ± 2.5 | <0.001 |

**Conclusions:** Metformin has been used in 3.5% of KTX. The KTX on metformin had a lower creatinine than those not on metformin. The KTX on metformin will be compared for morbidity and mortality with diabetic KTX not on metformin.

## PUB477

### Kidney Transplant in Patients with History of Cardiac Surgery

Salvador Roberto Lopez, Pamela Vázquez, Francisco E. Rodríguez Castellanos. *Nephrology, Instituto Nacional de Cardiologia, Mexico DF, Mexico.*

**Background:** The survival of patients who undergo kidney transplant (KT) has improved considerably over the past three decades, death with a functioning kidney is a major reason for graft loss. Few published studies address renal graft and patient survival in patients with a history of cardiac surgery (HCS), which is important due to pretransplant cardiac disease (CD) is a major risk factor for developing post transplant CD.

**Methods:** Between 1995-2012, 600 KT were performed in our center including 7 cases with HCS We compared those patients with 21 patients without HCS We recorded renal function parameters at baseline (at discharge of KT), 6 and 12 months of follow up. In patients with HCS we analyzed echocardiogram parameters before and 1 year after KT.

**Results:** The age was significantly higher in HCS group. In HCS group the principal etiology of ESRD was diabetes (57.1%) Concerning cardiac surgery procedures, most patients (57.1%) underwent CABG and the rest of the group (42.9%) required valve replacement including one case with three cardiac valve replacement. All patients underwent first KT. The median time between cardiac surgery and KT was 8 months (25-75th IQR: 7-20). At 12 months of follow up serum creatinine were no significantly different between groups (1.4±0.12 vs.1.5±0.4 mg/dl in HCS and no-HCS group respectively). One-year patient and graft survival in both groups was 100%. In HCS group the ejection fraction increased after KT (45.3±13.5 vs. 51.3±18.5%, p=NS, before and one year after KT respectively).

**Conclusions:** In dialysis patients, the estimated survival after CRV is 40-54% and after CABG is 56% at 2-year. Debska reported a one year survival of 93% in 16 dialysis patients who had HCS and underwent KT. We found one-year graft and patient survival of 100% which is better compared with others reports. At one year of follow up we observed improvement of ejection fraction, no significant maybe due to sample size. Kidney allograft function was similar between groups at the end of follow up, thus it seems probable that patients with HCS have a favorable long term prognosis. We consider that KT is a safe procedure in patients with HCS, therefore such patients could be included in KT programs.

## PUB478

### Early Changes in Plasma Creatinine Predicts One Year Graft Function following Kidney Transplantation

Nicoline Valentina Krogstrup,[1] Bo M. Bibby,[2] Camilla Aulbjerg,[1] Bente Jespersen,[1] Henrik Birn.[1] *[1]Dept of Renal Medicine, Aarhus Univ Hospital, Denmark; [2]Dept of Biostatistics, Aarhus Univ, Denmark.*

**Background:** Much research aims to improve long term kidney graft function. Post transplant dialysis due to delayed graft function is associated with poorer long term graft survival. Little is known about the long term importance of initial graft recovery in patients

not requiring dialysis. This study evaluates the association between the velocity of initial kidney graft recovery estimated by the change in plasma creatinine (p-creatinine) and graft function after one year.

**Methods:** A single center, observational, cohorte study including 100 kidney transplants followed for one year at Aarhus University Hospital. P-creatinine was registered immediate before transplantation, daily the first seven days post transplant and finally after one year along with relevant patient characteristics. Patients with no improvement in graft function or requiring dialysis within the first week of transplantation were excluded. A total of 80 patients remained in the analysis. Time to a 50% drop in p-creatinine after transplantation was calculated based on either an exponential or logistic decrease of p-creatinine over time, depending on which model fitted the single patient data better. A multiple linear regression model was used to analyse the association between the time to a 50% drop in p-creatinine and p-creatinine after one year.

**Results:** The time to a 50% drop in p-creatinine correlated positively with p-creatinine at one year ($r$=0.31, beta=0.148, p=0.0052). The correlation persisted when corrected for donor type and recipient age, initial p-creatinine level, sex, number of rejections and use of calcineurin inhibitors (p=0.0468).

**Conclusions:** The initial change in p-creatinine is independently associated with one year kidney graft function indicating 1) that non dialysis dependent differences in early graft function may be important for long term outcome and 2) that this may be used as surrogate marker in studies aimed at enhancing long term outcome by improvement of early graft function.

## PUB479

### Basal Creatinine as Predictor of Graft Dysfunction a Postransplant Year

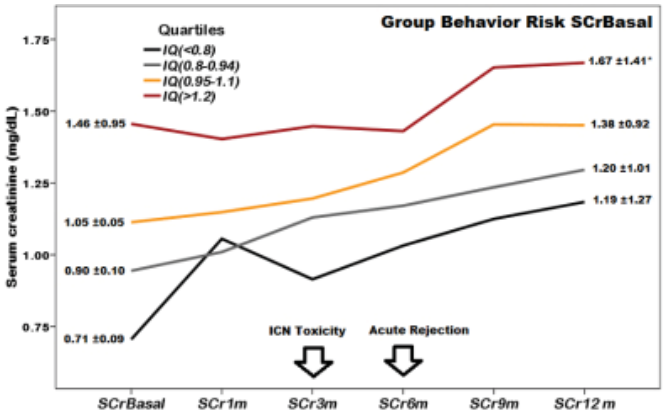
Gerardo Gilberto Azúa Díaz, Benjamin Gomez-Navarro, Enrique Rojas-Campos, Alfonso M. Cueto-Manzano. *Nefrologia, IMSS, Guadalajara, Jalisco, Mexico.*

**Background:** In renal transplant (RT) an increase of serum creatinine (SCr) ≥1.5mg/dl at 1yr of RT predict graft loss at 3yrs in almost 20%. The objective was to establish whether the creatinine at discharge postsurgical unit (SCrbasal) could predict the presence of graft dysfunction (GD) at 1yr post-RT in a Mexican population.

**Methods:** This is a retrospective cohort study performed between January 2009-June 2011 in 561 RT receptors; GD was defined as SCr ≥1.5mg/dl at 1yr.

**Results:** 71% were male receptors, living related donor in 92%, negative crossmath 16.34%. Patients were divided according to SCrbasal values in quartiles. Risk SCrbasal was defined as that with a value >1.2mg/dl because showed a value of SCr of 1.67mg/dl at 1yr post-RT. Changes in SCr and comparison between quartiles variables are show in table and figure (*p<0.005, **p<0.001).

| Variables:(n) | IQ(<0.8)(139) | IQ(0.8-0.94)(78) | IQ(0.95-1.1)(165) | IQ(>1.2)(179) |
|---|---|---|---|---|
| Receptor Age(yr) | 25.5±10.8 | 32.5±15.5 | 26.1±10.5 | 28±10.7 |
| GD Immediately after RT(%) | 1 | 8 | 10 | 14* |
| Time Dialysis(m) | 28.5±26.9 | 25.3±22.4 | 24.9±22.0 | 25±25.4 |
| HLA Antigens Matched(n) | 3.3±1.7 | 3.1±1.7 | 3.6±1.5 | 3.2±1.5 |
| MMF-TAC-PDN(%) | 83 | 87 | 87 | 87 |
| Basiliximab Induction(%) | 56 | 58 | 60 | 62 |
| Acute Rejection (AR)(%) | 25 | 22 | 34 | 42* |
| ICN Toxicity(%) | 48 | 35 | 54 | 51* |
| SCrBasal | 0.71±0.09 | 0.90±0.10 | 1.05±0.05 | 1.46±0.95** |
| SCr 6m | 1.03±0.83 | 1.07±0.29 | 1.26±0.52 | 1.42±0.47** |
| SCr 12m | 1.19±1.27 | 1.20±1.01 | 1.38±0.92 | 1.67±1.41* |



**Conclusions:** In receptors RT, SCrBasal concentration >1.2mg/dl, predicts GD at 1yr-RT ($X^2$62.4, p<0.0001) with a relative risk (RR) of 4.47 (IC95% 2.9-6.8). The factors involved were 1) GD immediately after RT (RR 28.27, IC95% 10.1-82.9) and 2) Gender male (RR 2.52, IC95% 1.6-4.0). This group had a higher number of events of ICN toxicity and AR in the first yr-RT.

## PUB480

### Late Onset De Novo Thrombotic Microangiopathy after Solid Organ Transplant

Mohamad Alhosaini, Krishna Pothugunta, Susan H. Hou, Kavitha Vellanki. *Div of Nephrology and Hypertension, Loyola Univ Medical Center, Maywood, IL.*

**Background:** De novo thrombotic micoangiopathy (TMA) is a well-described complication with calcineurin inhibitors (CNI) and mammalian target of rapamycin inhibitors (mTORI). The vast majority of the reported cases occurred within the first year post solid organ transplant. Here we report our center's experience with late onset TMA.

**Methods:** Since March 2010, we had 4 patients with solid organ transplant develop late onset de novo TMA. The patient characteristics are as shown in Table 1.

| patient | age/sex | type of transplant | etiology | transplant date | baseline immunosuppression | baseline cr (mg/dl) |
|---|---|---|---|---|---|---|
| 1 | 32 male | lung | Cystic fibrosis | 5/2009 | tacrolimus, sirolimus | 2.2 |
| 2 | 49 female | kidney | lupus | 7/2003 | tacrolimus, prednisone | 4.2 |
| 3 | 42 male | kdiney | Alport | 4/2001 | tacrolimus, mycophenolate mofetil, prednisone | 3.9 |
| 4 | 48 female | heart | dilated cardiomyopathy | 12/2010 | tacrolimus, sirolimus, mycophenolate sodium | 2.0 |

**Results:** The mean and the median times of developing TMA were: 82 and 80.5 months respectively post transplant. All patients had acute renal failure, hemolytic anemia, thrombocytopenia and schistocytes. Important characteristics and outcomes are summarized in Figure 1.

| Patient | Time to diagnosis (month) | Tacrolimus level (ng/ml) | Cr at presentation (mg/dl) | Plasmapheresis | Renal outcome | Alternative immunosuppression |
|---|---|---|---|---|---|---|
| 1 | 46 | 41.5 | 7 | Yes | HD for 3 months then recovery | Cyclosporine/mycophenolate mofetil |
| 2 | 115 | 2.4 | 9.7 | No | Permanent HD | Mycophenolate sodium/prednisone |
| 3 | 140 | 7 | 9.2 | No | Permanent HD | Cyclosporine/mycophenolate sodium/prednisone |
| 4 | 27 | 8.5 | 4.1 | No | Recovery | Sirolimus/mycophenolate sodium/ Prednisone |

**Conclusions:** Late onset TMA should be considered in the differential diagnosis of acute kidney injury in solid organ transplant patients on CNI or mTORI therapy for immunosuppression after solid organ transplant.

## PUB481

### Indian Transplantation of Human Organs Act (THOA) and Rules: Practical Problems

Bharat V. Shah. *Nephrology, Global Hospital, Mumbai, Maharashtra, India.*

**Background:** Transplantation of Human Organs Act (THOA) was passed to regularize organ transplant and prevent commercial dealing in transplant. While this has been achieved to a great extent, it has made living donor transplant very difficult and deceased donor transplant has not picked up. The aim of this study is to highlight with examples the problems faced in transplantation due to THOA and rules.

**Methods:** A detailed study of THOA and rules and their amendments has been made (http://www.orbo.org.in/Doc/Ann%204%20THOA%20ACT%202011.pdf). Further, check-list of documents to be submitted as per Directorate of Health Services, is studied. The problems are divided into those pertaining to regulation of professionals and institutions and those pertaining to patients to obtain approval of Authorization committee.

**Results:** Problems for professionals and institutions: 1. If a professional registered at 1 center wishes to perform transplants at another center, he/she again has to apply from that center – a process which takes months. 2. An institution is recognized for transplant for 5 years. For renewal, If the inspection is delayed by the committee, beyond expiry date, transplants cannot be performed at that center until inspection and renewal of recognition.

Problems for patients: 1. For LDT, a) Police verification report of recipient's and donor's address and criminal records report of unrelated and out of state transplants. This is necessary even if a passport is provided as proof of residence. b) If patient or donor or both are not domicile of the state, NOC of concerned state authorization committee to be obtained. c) The Authorization committee often questions medical evaluation of the transplant team.

2. For DDT the act requires removal of organ to be done in a recognized center. As per this act, if a family wishes to donate organs, if the deceased person is not in a center recognized for transplant, he/she has to be moved to a recognized center.

**Conclusions:** The Indian Transplant Act has resulted in severe hardships to many patients with end stage organ disease. In many cases it has lead to substantial delay and increase in avoidable expense, morbidity and mortality.

## PUB482

### Comparing 10 Year Renal Function Outcomes in Patients with Live Donor and Deceased Donor Liver Transplant: A Single Center Retrospective Study

Shaifali Sandal, Sandesh Parajuli, Anirban Bose. *Nephrology, Univ of Rochester, Rochester, NY.*

**Background:** Incidence of chronic kidney disease is approximately 25% by 10 years after an orthotopic liver transplantation (OLT). Long term survival of patients undergoing living donor liver transplant (LDLT) compared to those undergoing deceased donor liver transplant (DDLT) have yielded mixed results and no literature exists comparing the long

term renal outcomes in this patient population. LDLT have become rare at our institution. The purpose of this study is to compare long term renal outcomes in patients who underwent LDLT and DDLT.

**Methods:** A retrospective analysis of patient who received an OLT in years 2000 and 2001 was conducted. Data was obtained from databases UNOS, EPIC and OTTR.

**Results:** A total of 220 OLT were performed in the years 2000 and 2001, of which 82 were LDLT and 137 were DDLT. 1 combined liver and kidney transplant was excluded. Overall patient survival was: 87.7% at 6 months (87.8% for LDLT and 87.6% for DDLT), 84.5% at 1 year (84.1% for LDLT and 84.7% for DDLT), 69.9% at 5 years (74.4% for LDLT and 67.1% for DDLT) and 53% at 10 years (57.3% for LDLT and 50.3% for DDLT). Graft survival was: 80.8% at 6 months (80.5% for LDLT and 81% for DDLT), 76.2% at 1 year (75.6% for LDLT and 76.6% for DDLT), 61.6% at 5 years (63.4% for LDLT and 60.6% for DDLT) and 47.5% at 10 years (47.6% for LDLT and 47.4% for DDLT). 9.1% patients needed some form of RRT prior to the transplant and 25.1% in the immediate post transplant period. Our preliminary data suggest no significant difference in the average GFR of patients who received LDLT versus DDLT at 6 months, 1 year, 5 years and 10 years. We await more robust statistical analysis of this data.

**Conclusions:** Preliminary data shows that patients who receive LDLT and DDLT may have similar 10 year renal function outcomes.

## PUB483

### The Effect of Weight Loss Surgery before Kidney Transplant on Recipient Outcomes

Julie Ann T. Linatoc, Haidr Sabah Agha, Qing Ren. *Virginia Commonwealth Univ.*

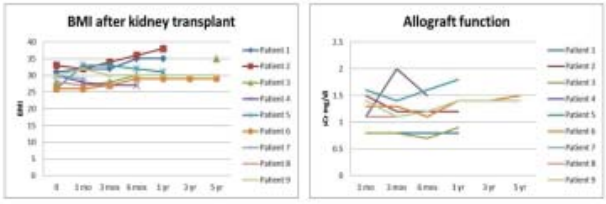
**Background:** Obese patients with a body mass index (BMI) greater than 35 are often denied for kidney transplantation. Obesity is associated with poor graft and patient survival and higher risk of wound infection. Weight loss surgery before kidney transplant may be a solution in this clinical scenario.

**Methods:** We retrospectively studied patients from January 2004 to June 2013 who underwent weight loss surgery, either laparoscopic gastric banding (LGB) or Roux-en-Y gastric bypass (GBP) prior to kidney transplant.

**Results:** Our series included 9 patients. Eight of 9 patients had a BMI below 30 at the time of kidney transplant and maintained BMI less than 35 post-transplant. Waiting time for 4 deceased donor (DD) kidney transplants was between 2 to 11 months. Only 1 of 5 recipients who were not diabetic prior to transplant developed new onset diabetes mellitus. All patients have excellent allograft kidney function with no wound infection or cardiovascular complications.

| Patient | Age (yrs)/ Sex | Weight loss surgery type | Donor Type | Waiting time (mos) | Wound infection | CV events | NODAT |
|---|---|---|---|---|---|---|---|
| 1 | 48/F | LGB | LD | 6 | no | no | N/A |
| 2 | 52/M | LGB | LD | 3 | no | no | N/A |
| 3 | 42/F | LGB | LD | 3 | no | no | no |
| 4 | 63/F | GBP | LD | 10 | no | no | no |
| 5 | 37/M | LGB | DD | 7 | no | no | no |
| 6 | 36/F | GBP | LD | 3 | no | no | N/A |
| 7 | 57/M | LGB | DD | 3 | no | no | N/A |
| 8 | 46/M | GBP | DD | 11 | no | no | yes |
| 9 | 57/F | GBP | DD | 2 | no | no | no |

LD, living donor; CV, cardiovascular; NODAT, new onset diabetes mellitus after transplant; N/A, not applicable, patient was diabetic prior to transplant



**Conclusions:** Weight loss surgery before kidney transplant could be used effectively to control obesity and allow these obese renal failure patients to have the opportunity of successful kidney transplantation with excellent outcomes.

## PUB484

### Perceived Bias in the Kidney Allocation System Predicts Mortality among Black Hemodialysis Patients

Avrum Gillespie,[1] Vladimir Ouzienko,[2] Jeanne Dreier,[1] Heather Hammer,[3] Teri Browne,[4] Zoran Obradovic.[2] *[1]Nephrology, Hypertension, and Kidney Transplantation, Temple Univ School of Medicine, Philadelphia, PA; [2]Center for Data Analytics and Biomedical Informatics, Temple Univ, Philadelphia, PA; [3]Abt SRBI, Silver Springs, MD; [4]College of Social Work, Univ of South Carolina, SC.*

**Background:** Perceived racism has been associated with disparities in renal transplantation and poorer health outcomes for African American hemodialysis patients. This study aimed to determine if perception of the kidney transplant allocation system as racially biased predicts mortality independent of biomarker data in a cohort of urban, African American hemodialysis patients.

**Methods:** In this study of the 101 end-stage renal disease (ESRD) patients who self-identified as black or African American in a hemodialysis clinic survey, perceived racism and other subjective variables were measured with the Dialysis Patient Transplant Questionnaire (DPTQ) and merged with prospective biomarker and mortality data. The predictive association with mortality was measured using chi-square, Fisher's exact test, and multivariate logistic regression.

**Results:** Twenty-two patients (21.8%) died during the study period. Fisher's exact tests showed that patients who thought the kidney transplant allocation system was definitely or mostly biased against blacks were 2.49 times more likely to die compared to those less certain (P=0.001). Serum albumin was also associated with mortality, however, in general, patients that percieved racism were more likely to die independent of their biomarkers.

**Conclusions:** This is the first study to validate the link between perceived racism in the kidney allocation system among African American hemodialysis patients.

## PUB485

### Effect of mTOR Inhibitors in Patients with Severe Posttransplantation Encapsulating Peritoneal Sclerosis

Edin Colic,[1] Claus Bistrup,[1] Helle C. Thiesson,[1] Niels Marcussen,[2] Martin Tepel.[1] *[1]Nephrology, Odense Univ Hospital, Odense, Denmark; [2]Pathology, Odense Univ Hospital, Odense, Denmark.*

**Background:** Posttransplantation encapsulating peritoneal sclerosis is a live threatening complication seen in patients after kidney transplantation who had previously been treated with peritoneal dialysis. In the present study we investigated the effects of mTOR inhibitors on outcome in patients with severe posttransplantation encapsulating peritoneal sclerosis.

**Methods:** Using the transplantation registry of the Odense University Hospital of Southern Denmark, we identified all patients with kidney transplantation between 2006 and 2012. The risks of encapsulating peritoneal sclerosis as diagnosed by radiological or histological signs and need for laparotomic or laparoscopic interventions were estimated. In addition, the effects of treatment with mTOR inhibitors during follow up were evaluated. Major outcome measures were patients' survival, graft survival, number of acute rejections and relapse of encapsulating peritoneal sclerosis.

**Results:** A total of 341 transplanted patients were evaluated. Five (4 female and 1 male) out of 94 patients with previous peritoneal dialysis (5.3 percent) developed posttransplantation encapsulating peritoneal sclerosis. Median age was 54 years (range, 46-59). Median duration of peritoneal dialysis was 63 months (range, 36-107). Median time for development of encapsulating peritoneal sclerosis after transplantation was 13 months (range, 1-38). 1 patient was shifted to rapamycine, whereas 4 patients were shifted to everolimus. During a median follow up period of 21 months, 2 patients developed a relapse of encapsulating peritoneal sclerosis necessitating additional surgical interventions. Graft loss was observed in 2 other patients. There were no acute rejections. All 5 patients are still alive.

**Conclusions:** This retrospective observational study in patients with severe posttransplantation encapsulating peritoneal sclerosis with need of surgical intervention shows that shifting from calcineurin inhibitors to mTOR inhibitors did not ameliorate ongoing fibrosis. However, altered speed of progression can not be excluded.

## PUB486

### Assessing the Quality of Deceased Donor Kidneys by Simple and More Accurate Prognostic Factors

Ana Pinho,[1] Inês Castro Ferreira,[2] Isabel Tavares,[2] Susana Moreira Norton.[2] *[1]Nephrology, Faro Hospital, Faro, Portugal; [2]Nephrology, São Jão Hospital, Oporto, Portugal.*

**Background:** Since the increasing use of lesser quality kidneys, both survival benefit and a quality of life advantage of kidney transplantation over dialysis is know a difficult question of patients to their transplant team. In order to clarify, several Donor Risk Indexes (KDRI)were derived from many potential donor factors that need to be validated. The aim of this study was to determine which donor factors predict poorer transplant outcome.

**Methods:** Data from transplant registry on 273 adult recipients of adult deceased donor kidney transplants, performed consecutively between 2009 and 2012 were analyzed. Donor factors potentially influencing transplant outcome were investigated using Cox regression, adjusting for significant recipient and transplant factors.

**Results:** Donor hypertension was the most significant factor predicting poor transplant outcome (hazard ratio [HR] 4.96; 95% confidence interval [CI] 1.81 to 13.55)*).* The cause of death by cerebrovascular accident (HR 3.85; 95% CI 1.49 to 9.92) and Donor age (HR for a 10-yr increase 1.44; 95% CI 1.1 to 1.78*)* were also associated with increased risk with poorer outcomes up to 4 years posttransplant. Other donor factors including diabetes history, longer hospital stay before death, use of adrenaline, previous infection and terminal creatinine were not significant.

**Conclusions:** This finding corroborates the relevance of donor risk factors, such as age, cause of death and hypertension; that may be of value for researchers and clinicians in provide a clinically useful tool that help with organ allocation and informed consent.

## PUB487

**Complications Associated with Failed Pediatric Renal Allograft**
Murty Adabala,[1] Tej K. Mattoo,[1] Gaurav Kapur,[1] Rossana Baracco,[1] Amrish Jain.[1] *[1]Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI; [2]Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI; [3]Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI; [4]Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI; [5]Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI.*

**Background:** NAPRTCS data reports 18-30% graft loss in the 1st 5 years post transplant. The failed graft in adult is associated with increased morbidity and mortality. However, there is paucity of pediatric reports on complications associated with failed renal allograft and their outcome.

**Methods:** Retrospectively reviewed medical records of patients with failed renal transplant over last 10 years (2001-2011). For study purpose, graft intolerance was defined by presence of chronic inflammatory state, pain at the graft site or hematuria.

**Results:** 11 grafts were lost in 10 patients( 50% male, 60% African American). Obstructive uropathy and FSGS accounted for 30% each for the primary renal disease. Mean age at transplant was 9.6y. Graft intolerance was noted in 9/11 (81%) grafts leading to nephrectomy in 8/11 (72%). The most common indication for the transplant nephrectomy was recurrent abdominal pain with hematuria.

| Variables Patients | Age at transplant (years) | Time to dialysis | Graft intolerance | Nephrectomy | Indication for nephrectomy |
|---|---|---|---|---|---|
| 1 | 10.1 | 5y | Y | Y | Persistent Systemic Inflammation |
| 2 | 10 | 5y | Y | Y | AP+H |
| 3 | 11.7 | 1 day | Y | Y | Surgical |
| 4 | 14.5 | 1.4y | Y | Y | AP+H |
| 5 | 11 | 2.3y | Y | Y | AP+H |
| 6 | 6.1 | 2.5y | Y | Y | AP+H |
| 7 | 9.3 | 2.6y | Y | N | |
| 8 | 8.8 | 1 day | Y | Y | Hyper acute Rejection |
| 9a | 6.7 | 1 day | Y | Y | Hyper acute Rejection |
| 9b | 11.11 | 5.7y | N | N | |
| 10 | 6.7 | 2.1y | N | N | |

Y = Yes, N = No

**Conclusions:** The complications associated with failed renal graft are common and a high percentage of our patients required allograft nephrectomy. More studies are needed to further define the complications of failed renal allograft and the indications for elective transplant nephrectomy in such patients.

## PUB488

**Effect of Valganciclovir Prophylaxis on Cytomegalovirus Disease in Kidney Transplant Recipients**
Gopal Basu, Golla Sudhakar, Riyaz A. Asad, Anna T. Valson, Anjali Mohapatra, Suceena Alexander, Shibu Jacob, Vinoi George David, Santosh Varughese, Chakko Korula Jacob, Veerasamy Tamilarasi. *Nephrology, Christian Medical College, Vellore, India.*

**Background:** Valganciclvoir (ValG) prophylaxis modifies the cytomegalovirus (CMV) disease pattern in kidney transplant recipients (KTRs). We aimed to study the efficacy of ValG prophylaxis in preventing CMV disease, the difference in CMV disease pattern and the effect of CMV disease and ValG on transplant survival.

**Methods:** All KTRs who underwent transplantation at Christian Medical College, Vellore between Jan 2006 to Dec 2011 were studied. KTRs from 2007 were offered ValG prophylaxis for first 3 months. The outcomes studied were CMV disease, transplant survival, pattern of CMV Disease and coincident Infections. Analysis was performed using standard statistical methods.

**Results:** Of the 470 KTRs studied (mean age =36.5±12.1 years; M:F = 3.3:1), 9.6% received deceased donor grafts, Basiliximab induction in 62.7% with prednisolone + Tacrolimus + Mycophenolate in 81.6% and ValG prophylaxis (3 months) in 62.4%. The overall incidence of CMV disease was 14.9 % . ValG prophylaxis effectively reduced CMV disease (10.9% vs. 21.5%; p<0.01; NNT=10), delaying its onset (median time of 11.9 vs 3.7 months) and reduced the degree of viremia. However,ValG prophylaxis was not associated with any difference in tissue invasive disease, recurrence or CMV associated mortality. There was however, a reduction in coincident infections such as Post transplant TB, varicella zoster virus and Hepatitis C virus infections as well as mortality. Graft survival was better in ValG group (p <0.01) despite no difference in rejection rates, probably associated with effective immunosuppression as well as control of the indirect effects of CMV. Within the ValG group also, CMV disease was significantly and independently associated with co-incident infection and mortality indicating a generalised immunosuppressed state.

**Conclusions:** ValG prophylaxis reduces incidence of CMV disease by 50%, delays its onset, decreases viremia and is associated with better graft and patient survival probably by controlling both the direct and indirect effects of CMV in KTRs.

## PUB489

**Combination Therapy of Leflunomide and Ciprofloxacin for Treatment of (Suspected) Polyomavirus BK-Associated Nephropathy in Kidney Transplant Recipient Lacking Graft Biopsy (Single Center Experience)**
Seddeg Younis, Dujanah Hassan Mousa, Ebadur Rahman, Naveed Aslam, Raees Farhan Mushtaq, Mamdouh Abdulghafour Nada, Nader Mohamed Omran, Ahmed Soliman. *Prince Sultan Military Medical City, Riyadh, Saudi Arabia.*

**Background:** Polyoma Virus type BK Nephropathy (BKVN) occurs in 1-10% of Renal Transplant Recipients. Progression to Graft Failure in the First year is up to 70%. Immunosuppression Reduction (ISR) is the Treatment of BKVN. Diagnosis of BKVN is Based on BKV Replication in Blood and Histological Evidence of BKV Involvement. In this Prospective Study, we Reported 7 Patients with Graft dysfunction and Significantly High BK Viral Load, declined to do Graft Biopsy, were treated Blindly as BKVN, with addition of Leflunomide & Ciprofloxacine to Improve Graft Survival.

**Methods:** Blood BKV Quantitative Polymerase Chain Reaction (PCR) and Graft Biopsy for all Patients with Unexplained Graft dysfunction. Between Jan 2011 to May 2012. Seven Patients Presented with Slowly Rising Creatinine and high BKV Viral Load, refused to do Graft Biopsy. The Median Ceartinine at Baseline was 121µmol/l (68-174), and the Median Peak Viral Load was $7X10^5$copies/ml ($1.2X10^4$-$3X10^6$). They were treated with ISR and Combination of Leflunomide and Ciprofloxacine. Leflunomide Loading dose was 40mg daily for One Week, Lowered to 20mg Until Complete Viral Clearance or Progressive Reduction in Viral Load, then Continued at 10mg. Ciprofloxacine, 500mg twice daily for 6 Week. The treatment Monitored by Serial Measurement of LFT, FBC, Serum Creatinine, and BKV PCR. Graft Function and Viral Clearance were Followed.

**Results:** After 22 months (19-22) follow up, Median creatinine was 152µml/l (84-273). Creatinine was Stable in 3/7 (42.9%) and deteriorated in 4/7(57.1%), but there was no Graft Loss on follow up. Complete viral clearance Occurred in 2/7, and Significant Reduction in 5/7(p<0.0001). There were no Serious Adverse effects.

**Conclusions:** Despite Good Response to Treatment of (Suspected) BKVN with ISR and Combination Therapy of Low Dose Leflunomide and Ciprofloxacine the Decline in Graft is not Determined, this Highlights the Importance of Graft Biopsy in the Diagnosis of BKVN and Alternative Etiology.

*Funding:* Government Support - Non-U.S.

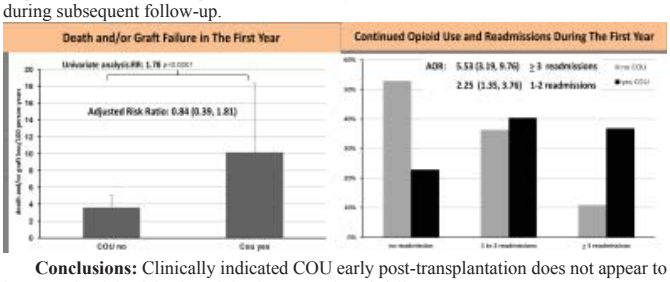
## PUB490

**Chronic Opioid Use, Pain and Outcomes of Kidney Transplantation**
Satyarth Kulshrestha,[1] Fidel Barrantes,[2] Milagros D. Samaniego-Picota,[1] Fu L. Luan.[1] *[1]Div of Nephrology, Univ of Michigan, Ann Arbor, MI; [2]Nephrology, Presbyterian Kidney Transplant Center, Albuquerque, NM.*

**Background:** Chronic opioid usage (COU) is relatively common among patients with end stage renal disease qualified for kidney transplantation. The prevalence of continued COU after kidney transplantation and its impact on transplant outcomes remains unknown.

**Methods:** We conducted a retrospective single center study to describe the prevalence of COU during the first year after transplantation, to identify the predictors of COU and to determine the effect of COU on patient and kidney transplant survival.

**Results:** Among 1045 kidney transplant patients, 114 (10.8%) had COU during the first year. The most common cause of pain was surgery-related (39.9%) and the most commonly prescribed opioid analgesic was hydrocodone (59.2%). A history of COU prior to transplantation was the strongest predictor of COU in the first year post-transplantation. Compared to patients without COU, COU patients had 2 to 5 folds higher risk of hospital readmission during the first year (AOR 2.25, 95% CI 1.35, 3.76, p=0.002 for 1 or 2 readmissions, and AOR 5.52, 95% CI 3.13, 9.76, p<0.0001 for >3 readmissions, respectively), but similar patient and kidney graft survival, both within the first year and during subsequent follow-up.



**Conclusions:** Clinically indicated COU early post-transplantation does not appear to increase the risk of death and death censored graft failure.

## PUB491

**Comparison of Cadaveric Kidney Transplantation from In-Center and External Hospital Donors**
Ajin Cho, Hye Ryoun Jang, Jung Eun Lee, Wooseong Huh, Yoon-Goo Kim, Ha Young Oh, Dae Joong Kim. *Internal Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea.*

**Background:** Renal transplantation is the best treatment modality for end-stage renal disease. We investigated the effects of cadaver donor sources, inside vs. outside of transplantation center, on renal allograft and patient survival.

**Methods:** We retrospectively analyzed 190 cadaver kidney transplants carried out in our center from January 2000 to December 2009, 136 cadaver harvested in our transplant center and 54 harvested in external hospital. All patients received induction therapy and standard triple immunosuppressive protocols with cyclosporine or taclorimus (FK506), mycophenolate-mofetil, and prednisone. Variables on this study were donor and recipient age, sex, body mass index (BMI), presence of diabetes mellitus, HLA mismatching, dialysis duration, cold ischemic time, donor from external hospital, acute rejection episodes, delayed graft function (DGF) and panel reactive antibody (PRA) > 30%. Graft and patient survival were assessed with the Kaplan-Meier method and the significance of possible variables with the Cox proportional hazard model.

**Results:** Donor and recipient ages, recipient BMI, duration of dialysis, presence of DGF and PRA >30% were not significantly different. Cold ischemic time was shorter in recipients of cadaver from our center, 288 min, than external hospital, 388 min (P<0.001). Twenty recipients lost their grafts (14 cadaver from external hospital and 6 cadaver from our center). Graft survival at 1, 3, and 5 years were 99.2%, 97.3%, and 95.5% for our center donor while 98.1%, 88.9%, and 86.2% for external hospital donor transplants (P=0.01). Total of 8 patients died. (2 from external hospital and 6 from our center ). No difference in patient survival rates was found. Acute rejection episodes (hazard ratio [HR] =13.8; P<0.001) and location of harvest (HR =7.0; P=0.02) were independent associating factors for graft failure.

**Conclusions:** Graft survival rate of cadaveric transplants from external hospital donor was lower than that from donor harvested in our center. Acute rejection episodes and location of harvest were significant factors on graft survival.

## PUB492

### Adult Kidney Transplantation with Allografts from Pediatric Cardiac Death Donors in China – A Single-Center Experience

Ying Xu, Jianghua Chen. *The Kidney Disease Center, The Firtst Affiliated Hospital, College of Medcine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

**Background:** Current transplant experience with cardiac death donors (DCD) organs has focused on the adult donor population, little is known about the outcome of pediatric donor used in adult recipients. The abstract is aimed to report clinical outcomes of kidney transplantation from pediatric DCD in China, and to investigate its feasibility to expand the organ donor pool.

**Methods:** We retrospectively reviewed the clinical data of 45 DCD kidneys from 27 donors from 1st January 2012 to 30th November 2012 in our center. Recipients were followed for patient and graft survival.

**Results:** There were seven pediatric DCD donors (age < or = 18) and twenty adult DCD donors (age > 18 years). All the eleven recipients who received the pediatric donors were adults. The age of the pediatric DCD donors ranged from 31 months to 17 years old (31 months, 50 months, 12 years, 13 years, 14 years, 15 years and 16 years respectively). The average weight of the donated kidneys was 126 grams (ranged from 46 to 160 grams). The incidence of delayed graft function was 18.2% (2/11); these two recipients received the kidneys from the youngest donor (31 months, 46 grams), their allograft function recovered to normal range within 3 months post-transplant. The function of the allograft from the 50 months-old donor recovered with a slow rate to the normal range. All other recipients survived with good allograft function.

**Conclusions:** Although kidney transplantations from younger pediatric DCD donors showed a higher rate of DGF with a longer duration of graft recovery, we achieved favorable short-term clinical outcome in terms of graft survival and function. Donation after pediatric cardiac death could expand the organ donor pool in China.

## PUB493

### The Effect of Kidney Transplantation on Left Ventricular Function and Valvular Regurgitation in End Stage Renal Disease Patients

Prabhakar Doddi,[1] Harbir Singh Kohli,[1] Ajay Bahl.[2] *[1]Nephrology, PGIMER, Chandigarh, India; [2]Cardiology, PGIMER, Chandigarh, India.*

**Background:** Most patients with chronic kidney disease suffer frequently from cardiac abnormalities including valvular disorders and left ventricular(LV) systolic and diastolic dysfunction. At present, little information is available regarding the effect of kidney transplantation on LV function and valvular regurgitation in End Stage Renal Disease (ESRD) patients.

**Methods:** This is a prospective study in which 250 patients with ESRD on maintenance hemodialysis were enrolled between July 2010 to June 2011 and 30 patients were studied who subsequently underwent kidney transplantation. Base line LV function and valvular abnormalities were evaluated by using conventional echocardiography 4 weeks before kidney transplantation and same was repeated at 12 weeks after transplantation.

**Results:** In this study we found that 4 weeks prior to renal transplant, out of 30 patients, 15(50%) had low ejection fraction (EF), 13(43.3%) patients had moderate and 1(3.3%) patient had severe mitral regurgitation (MR). There were 13 (43.3%) patients with moderate tricuspid regurgitation (TR) and 2(6.7%) with severe TR. Twelve weeks post transplantation it was observed that there was significant improvement in EF(p<0.001) and valvular regurgitation(P<0.001 for MR and 0.001 for TR). Of 13 patients with moderate MR, 6 improved to mild MR and in rest 7 MR disappeared. One patient with severe MR had complete disappearance of MR after transplantation. Of 13 patients with moderate TR, 8 improved to mild, in 4 TR disappeared and one patient it persisted. Out of 2 patients with severe TR, one improved to mild and in other TR disappeared. Of 15 patients with low EF, 14 improved.

**Conclusions:** In this study we found that there was significant improvement in LVEF and valvular regurgitation after kidney transplantation and it implies that poor LV function and valvular regurgitation should not be contraindications for kidney transplantation.

## PUB494

### Impact of the Declaration of Istanbul on the Dynamics of Renal Transplantations in Oman

Nabil Mohsin, Ehab Mohamed Hassan, Emily Militsala, Issa A.L. Salmi. *Nephrology, Royal Hospital, Muscat, Oman.*

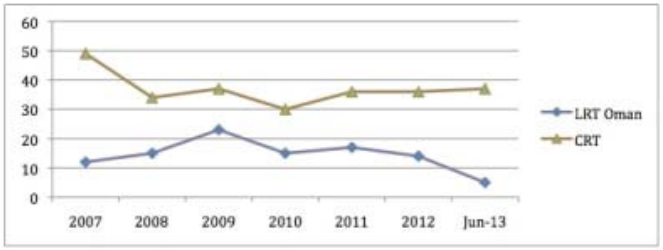
**Background:** Organ shortage is a universal thorny issue. Living related transplantations (LRT) are offered free of charge for all citizens. Law bans commercial transplants. Commercial renal transplants (CRT) are still practiced in some low-income countries. The declaration of Istanbul (DoI) formulated in April 2008 constitutes the global framework for transplantation practice rejects and combats this practice. We analyzed the impact of the DoI on LRT and CRT dynamics in Oman.

**Methods:** Registry data analysis for the period 2007 till June 2013 of local LRT and CRT. The chi-square proportion test was applied to look for significance before (year 2007) and after the DoI (2008-june 2013). We used Stata12.1,Tx, USA.

**Results:** Dynamics of Living related (LRT) and Commercial (CRT) transplants in Oman before and after DoI are shown on the table below:

| | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 06/2013 |
|---|---|---|---|---|---|---|---|
| LRT | 12 | 15 | 23 | 15 | 17 | 14 | 5 |
| CRT | 49 | 34 | 37 | 30 | 36 | 36 | 37 |
| LRT/CRT (p-value) | 0.24* | 0.24/0.44 (0.06) | 0.24/0.62 **(<0.001)** | 0.24/0.50 **(0.02)** | 0.24/0.47 **(0.03)** | 0.24/0.39 (0.15) | 0.24/0.14 (0.2) |

In 2007 the proportion of LRT to CRT was 24%. The proportion increased significantly to reach a peak of 62% in 2009. Also, CRT from Pakistan decreased from 84% in 2007 to 38% and 51% in 2008 and 2009 respectively. Painfully, Commercialism resurged, grows and affects negatively the local program.



**Conclusions:** Oman enjoyed a significant positive impact of the DoI till 2011. However, the effect seems to lessen due to the resurgence of commercial transplants. Mechanisms of resurgence should be analyzed meticulously. Concomitantly, an active deceased donor program and further development of the living donor program to ensure self-sufficiency would be effective means to deter this phenomenon and reinforce the Declaration.

## PUB495

### Long-Term Effects of Renal Transplantation on Cardiac Autonomic Dysfunction

Eduardo Cruz,[1] Fadi Tohme,[1] Roberto S. Kalil,[1] Harald M. Stauss.[2] *[1]Medicine/Nephrology, Univ of Iowa; [2]Exercise Physiology, Univ of Iowa.*

**Background:** It has been suggested that uremic autonomic neuropathy in patients with end-stage renal disease (ESRD) contributes to cardiac autonomic dysfunction that has been associated with increased cardiovascular morbidity and mortality. With this regard, it has been demonstrated that reduced low frequency to high frequency (LF/HF) ratio of heart rate variability (HRV) is associated with a higher probability of cardiovascular disease events in patients with chronic kidney disease (Chandra P. et al., 2011). We hypothesized that renal transplantation (RTX) in patients with ESRD will improves autonomic dysfunction (indicated by an increase in the LF/HF ratio of HRV) and, thus, reduces the probability of cardiovascular disease events.

**Methods:** To test this hypothesis, we studied cardiac autonomic function by frequency domain HRV analysis (power spectral analysis) in patients with ESRD before and 3 months, 12 months, and 36 months following renal transplantation.

**Results:** 28 patients were studied. Mean age was 51.6 ±17.4 years with 20 males. Mean eGFR was 56.4 ±17.9. Low frequency to high frequency ratio of HRV increased from 1.1±0.6 before RTX to 1.9±0.5 at 3 months and 3.2±0.7 at 1 year after RTX (P=0.07 vs. before RTX). However, 3 years after renal transplant, the LF/HF ratio of HRV was no longer significantly elevated compared to before RTX (1.7±0.4).

**Conclusions:** Our results indicate that renal transplantation improves cardiac autonomic function only temporarily (for less than 3 years). Other factors than improved cardiac autonomic function appear to contribute to the beneficial long-term effects of RTX on the reduction in cardiovascular events. Further larger, prospective studies are needed to examine the impact of cardiac autonomic dysfunction on long-term outcomes of kidney transplantation.

**PUB496**

**10-Year Survival of Kidney Graft: Analysis of Predictive Factors** Francesca K. Martino,[1] Daniela Dissegna,[1] Tefanos Chiaramonte,[1] Claudio Ronco.[1,2] *[1]Nephrology, San Bortolo Hospital, Vicenza, Italy; [2]IRRIV, Vicenza, Italy.*

**Background:** The quality of graft plays an important role in the outcome of kidney transplant (KT). On the other hand, the possible complications following KT could impact on the kidney function in the long-term. This study investigates specific influence of pre-implantation and after-implantation features in the prediction of KT survival in the short and long period.

**Methods:** We performed a retrospective study on 72 patients, who received renal graft from January 2000 to December 2002. For all patients the following parameters were obtained: pre-implantation kidney biopsy with Karpinski score, duration of cold ischemia, donor's age, requirement of dialysis treatment after the KT, presence of early rejection in the first 6 months after KT, creatinine level after 1 week, 1 month, 1 year, and 10 years from KT and survival of KT. Kaplan-Meier methods was used for survival analysis. Logistic regression model was employed to evaluate the variable related with delayed allograft function. Cox regression models addressed the time to graft survival. All reported p-values were two sided, and statistical significance was set at $p < 0.05$. All statistical tests were performed with SPSS version 17.

**Results:** The median age of donor was 47 years (IQR 32-56). Delayed graft function and early reject occurred in 20.8% and 15.3% of case, respectively. The median biopsy score was 2 (IQR 1-3). Karpinski score and duration of cold ischemia were predictors of dialysis need (OR 2.5, p=0.014 and OR 0.035, p=0.03, respectively). The median follow-up duration was 120 month (IQR 38.75-120). Five and 10-year survival free from graft failure estimates were 83.7% and 78.6%, respectively. In the long-term, the survival of KT was predicted only by dialysis need after KT (HR 3.84 p=0.016), level of creatinine in the first month (HR 1.91 p<0.001) and presence of early rejection (HR 4.012 p 0.02). Conversely, Karpinski score was not predictive(HR 0.88, p=0.539).

**Conclusions:** The clinical features such as delayed graft function and early reject seem to have an important influence on long-term graft survival.

**PUB497**

**Mineral Bone Density and Cardiovascular Survival in Kidney Transplant Patients** Francesca K. Martino,[1] Daniela Dissegna,[1] Tefanos Chiaramonte,[1] Claudio Ronco.[1,2] *[1]San Bortolo Hospital, Vicenza, Italy; [2]IRRIV, Vicenza, Italy.*

**Background:** Previous studies demonstrated an association between low bone mineral density (BMD) and increased risk of death both in men and women. In kidney transplantation (KT) there is a different profile of risk to develop osteoporosis. Moreover, vascular calcification and arterial stiffness are inversely correlated with BMD and are independent predictors of cardiovascular mortality. The aim of the present study was to examine the pattern of cardiovascular mortality risk related with BMD in kidney recipients.

**Methods:** We studied the relationship between BMD and cardiovascular death among 123 patients undergoing KT from 1990 to 1999 who had DXA during the same period at all the following skeletal site: hip, spine and middle arm. Baseline data included general information about the patient and specifically about KT such as immunosuppressive therapy, level of creatinine, level of PTH life, age, presence of comorbidity, and BMD measured using DXA. Cox regression models addressed the time to patient survival. All reported p-values were two sided, and statistical significance was set at $p < 0.05$. All statistical tests were performed with SPSS version 17.

**Results:** Patients were followed for a median period of 15 years (IQR 9,5-15). During follow-up, 42 (34.1%) patients died, 17 (13.8%) due to cardiovascular disease. The median value of BMD at hip, spine, and middle arm were 0.74 (IQR 0.67-0.85), 0.89 (IQR 0.8-0.99), and 0.71 (IQR 0.65-0.8), respectively. BMD level at hip site was associated with increased mortality (OR 0.036 p=0.038), while BMD at spine and at middle arm were not predictors of cardiovascular mortality (OR 0.096 p=0.068 and OR 0.447 p=0.689, respectively).

**Conclusions:** Low BMD at hip is associated with a substantial excess risk of cardiovascular death compared to low BMD at spine and middle arm.

**PUB498**

**Patient Factors Contribute to Compliance for Renal Transplant Recipient Evaluation** Asha M. Alex, Mohini Alexander, Meredith Akerman, Eric Siskind, Poornima Ramadas, Prathik Krishnan, Prejith P. Rajendran, Qazi Nuaman Masood, Kellie R. Calderon, Ernesto P. Molmenti, Madhu C. Bhaskaran. *Kidney Transplant Center, North Shore LIJ Health System, Manhasset, NY.*

**Background:** This study sought to examine the different factors that may prevent patients from completing their workup for receiving a renal transplant.

**Methods:** We retrospectively reviewed 170 patients who did not complete their pretransplant evaluation. Records of patients, who were either on dialysis or had less than 20 ml/min creatinine clearance (pre-emptive transplantation), were reviewed to identify a variety of factors which may have influenced the likelihood of completing their workup.

**Results:** 56% of pre-emptive patients completed their work up, while 36% of dialysis patients completed their work up. The data revealed that the factors contributing towards patients completing their workup included intrinsic motivation (4 times more likely), lack of specific medical co morbidities ( 3 times more likely), and patients not on dialysis (2 times more likely). Among the patients on dialysis, the factors which contributed towards them completing their work up included intrinsic motivation (5 times more likely), absence of cardiovascular complications (4 times more likely). When comparing patients on dialysis to patients not on dialysis, there was a significant difference between the two groups' in terms of distance from their respective homes to the transplant center, their level of education, and presence of specific medical co-morbidities.

**Conclusions:** We believe that through targeted interventions such as timely referral, providing appropriate educational resources and development of adequate support systems, all patients with advanced CKD, including those on dialysis, can be motivated to complete their pre-transplant workup.

**PUB499**

**Early Belatacept Conversion for Slow Renal Allograft Function** David Wojciechowski, Sindhu Chandran, F. Vincenti. *Medicine-Nephrology, UCSF, San Francisco, CA.*

**Background:** Slow renal allograft function (SGF), which we define as the need for HD or a Cr >2 mg/dL >14 days post-transplant, has a negative impact on long-term graft outcome. Tacrolimus is postulated to prolong SGF. We investigated belatacept conversion from tacrolimus as a novel treatment strategy for SGF.

**Methods:** Retrospective single center analysis of the first 8 patients converted to belatacept for SGF (Group 1) compared to a historical control group of 16 SGF patients remaining on tacrolimus (Group 2) matched for the following variables: type of kidney transplant, cause of ESRD, and CIT. Primary outcome: eGFR at 6 months; secondary outcomes: rates of rejection and infection.

**Results:** Table: Baseline demographic and transplant characteristics.

| | Group 1 (8) | Group 2 (16) | P Value |
|---|---|---|---|
| **Race, n** | | | 0.19 |
| White | 1 | 7 | |
| African-American | 4 | 3 | |
| Asian | 3 | 6 | |
| **Male, n** | 5 | 14 | 0.29 |
| **Age, years (SD)** | 56.4 (14.8) | 57 (13.2) | 0.92 |
| **Donor type, n** | | | 0.24 |
| Standard | 5 | 13 | |
| ECD/DCD | 3 | 3 | |
| **ESRD cause, n** | | | 1.0 |
| DM | 1 | 2 | |
| HTN | 1 | 2 | |
| GN | 3 | 6 | |
| Other | 3 | 6 | |
| **cPRA, mean (SD)** | 26.8 (31.7) | 7.7 (22) | 0.1 |
| **CIT, hours (SD)** | 10.6 (4) | 10.3 (4) | 0.86 |
| **Induction agent, n** | | | 0.67 |
| rATG | 6 | 10 | |
| Basiliximab | 2 | 6 | |
| **Steroid maintenance, n** | 8 | 16 | |
| **Tacrolimus mean POD initiation (SD)** | 2.3 (1.4) | 2.8 (2) | 0.53 |
| **Tacrolimus mean trough (SD)** | | | |
| Week 2 | 9.9 (4.2) | 6.8 (2.2) | 0.03 |
| Week 4 | 7.7 (1.6) | 9.2 (3.3) | 0.24 |
| Month 3 | | 8.9 (2.4) | |
| Month 6 | | 7.2 (1.3) | |

Mean POD of conversion was 46.6 (range: 21-74). Mean number of HD treatments (SD) for Groups 1 and 2 was 8.4 (8.3) and 6.6 (6.5), respectively (P = 0.57). Mean eGFR mL/min/1.73m$^2$ (SD) for Groups 1 and 2 were 54.3 (35.4) and 45 (21.7; P = 0.43) at 3-months and 56.1 (28) and 46.8 (21.6; P = 0.38) at 6-months post-transplant, respectively. No clinical rejection occurred, however subclinical rejection occurred in 3 patients in Group 1 (all type 1a) and 1 patient in Group 2 (type 2a), all diagnosed on a 6-month post-transplant surveillance biopsy. Similar rates of CMV and BK viremia, and UTIs occurred between the groups.

**Conclusions:** Belatacept conversion for SGF is a novel strategy that resulted in numerically higher eGFR 6 months post-transplant compared to a historical control group. Expansion of this cohort with longer follow-up is necessary to further define efficacy and safety.

**Early Identification of Skin Cancer in Renal Transplant Recipients through a Nurse-Led Skin Surveillance Service** Donald Choi,[2] Rosa M. Montero,[1] Christopher Harland,[1] Mona Wahba.[1] *[1]Epsom & St. Helier Univ Hospitals NHS Trust, London, United Kingdom; [2]St. George's Univ of London, London, United Kingdom.*

**Background:** Non-melanoma skin cancer (NMSC), has become one of the major causes of morbidity and mortality in renal transplant recipients (RTRs), with a 20 fold increase of NMSC rates in RTRs. Previous studies predominantly address the incidence of these cancers in white populations while little is available to compare ethnically diverse populations such as that found in London. This study was to determine the incidence of skin lesions occurring in RTRs and the impacts of skin surveillance screening clinics.

**Methods:** 152 RTRs were seen in our renal and transplant unit nurse-led skin screening clinic between September 2010 and November 2011, 27 were excluded (16 did not attend, 5 declined, 3 reviewed elsewhere, 1 death, 1 notes were unavailable). A total of 125 RTRs were reviewed for diagnosis of de novo skin lesions in consultant/nurse led clinics. Diagnoses of de novo skin lesions, demographics and clinical data were collected retrospectively from patients' notes.

**Results:** Male to female ratio 2:1, mean age 53.4yrs. 65% White, 17.6% Asian, 15.2% Black and 1.6% not stated. NMSC were found in 13 patients (12 basal cell carcinoma, 1 squamous cell carcinoma), no melanoma was found. There were 17 pre-malignant lesions

(PMLs) in 15 RTRs (11 actinic keratosis, 5 Bowen's disease, 1 lentigo maligna). Total NMSC in this cohort was 10.4% with total PML of 12%. The incidence of NMSC in this cohort was 6.8%, and PMLs of 9%. Both NMSC and PML occurred in less than 5 years and more than 10 years post 1st renal transplant.

**Conclusions:** The incidence of NMSC and PMLs in this cohort supports the need for skin surveillance screening in RTRs. It also indicates both NMSC and PML are present in RTRs within 5 years of transplant and would support early screening post transplant. Long term follow up should also be considered in view of NMSC and PML detected at more than 10 year post transplantation.This nurse-ledservice with early detection and relatively simple and inexpensive treatments represents a cost effective way of post-operative skin management for RTRs and warrants further economic investigation.

**PUB501**

**New Onset Diabetes after Transplantation Has No Impact on Clinical Outcomes – A Retrospective Single Center Study** Raja Mohammed Kaja Kamal, Rosa M. Montero, Khandaker Jubair Islam, Simona Petkovic-miletic, Mona Wahba. *Epsom & St. Helier Univ Hospitals NHS Trust.*

**Background:** New Onset Diabetes After Transplantation(NODAT) is a complication following renal transplantation(RT) that has been reported to lead to reduced graft function and increased morbidity and mortality. Single centre study looking at the occurrence of NODAT and its effects on overall transplant function.

**Methods:** Retrospective study collecting data on 250 transplant patients from 2007-2012 at a single centre. PreRT oral glucose tolerance test (OGTT), were recorded. NODAT was diagnosed if random blood glucose was >11.1mmol/L.

**Results:** 19/250(7.6%) developed NODAT.15 White, 3 Asian, 1 Black. 14 male:5 female. The median age at time of NODAT diagnosis was 56.6 years with a median time of developing NODAT 3.7months post RT. 5/19(26.3%) had an impaired preRT oral glucose tolerance test(OGTT). The eGFR at 1, 2 and 3 years was not affected by NODAT and was comparable with those that did not develop NODAT. Median HbA1c at time of diagnosis was 52mmol/mol that increased to 58.5 by 1 year($p>0.05$). The median weight at time of diagnosis was 75.7kg. Weight did not correlate with OGTT or HbA1c in the follow up period. Median UPCR at the time of diagnosis of NODAT was 40.4mg/mmol and stabilised at 1 year post RT. 14/19(73.7%) patients were on immunosuppressive regimens with prednisolone(P) at time of diagnosis with NODAT.14/160(8.8%) RT on P based regimens developed NODAT whereas 5/90(5.6%) on P free regimen developed NODAT($p=0.08$). Treatment with Insulin or oral hypoglycaemics had no effect on eGFR as good HbA1C levels were achieved. A decrease in UPCR was seen in those with insulin treatment that was independent to eGFR. PreRT dialysis modality showed no predisposition to the development of NODAT. NODAT had no effect on renal or patient survival at 1, 2 and 3 years post RT.

**Conclusions:** Our data suggests that in our predominantly white population NODAT has no influence on clinical outcome. P based regimen does not appear to increase the risk of developing NODAT. Optimal control of diabetes and proteinuria following NODAT appears important for good clinical outcome, this needs to be confirmed in a study with a longer follow up period.

**PUB502**

**Hypercalcaemia Post Renal Transplantation Does Not Affect Renal Transplant Function: A Retrospective Single Centre Study** Khandaker Jubair Islam, Rosa M. Montero, Raja Mohammed Kaja Kamal, Simona Petkovic-miletic, Mona Wahba. *Epsom & St. Helier Univ Hospitals NHS Trust.*

**Background:** Hypercalcaemia post renal transplantation (RT) has been previously described as a consequence of hyperparathyroidism. Previous studies have reported a loss of eGFR with hypercalcaemia post RT.

**Aim:** This retrospective study determined the natural history of hypercalcaemia and the effect of cinacalcet post RT.

**Methods:** 210 patients' notes were reviewed between 2007-2012. Corrected calcium (Ca), parathyroid hormone (PTH), phosphate (P) levels were collected over time together with their eGFR. Hypercalcaemia was defined as corrected calcium >2.60mmol/L at 1 month post RT.

**Results:** 13/210 (6.2%) developed hypercalcaemia by 1 month post RT, 1/13 was hypercalcaemic pre-transplant. 10 White, 2 Asian and 1 not stated. 7 male; 6 female. No significant difference in eGFR between normocalcaemic and hypercalcaemic patients 1, 2 and 3 years post RT. A decrease in PTH was seen in the hypercalcaemic patients following RT though they continued to have raised PTH irrespective of their high Ca levels. 6/13 were started on Cinacalcet for treatment of hypercalcaemia, 4 of these had parathyroid adenomas. Cinacalcet improved eGFR and reduced PTH in these patients. There was a sharp decline in P at 3 months that was maintained over the 3 years. A decline in eGFR was seen in 1 cinacalcet treated patient whose hypercalcaemia continued. 6/210 (2.9%) were hypercalcaemic pre-RT with only 1 of these continuing to be hypercalcaemic 1 month post RT.

**Conclusions:** PreRT hypercalcaemia does not predict post RT Ca levels. High Ca levels at 1 month post RT are maintained at 1 year with no effect on eGFR. eGFR is unaffected by hypercalcaemia up to 3 years later. Treatment with Cinacalcet suggests a beneficial effect on eGFR whilst reducing PTH. This cohort had small numbers on this treatment and further studies are needed to confirm these initial findings. The effects of maintained hypercalcaemia on cardiac function, vascular calcification and bone status have not been addressed in this study and may warrant investigation to its possible implication.

**PUB503**

**A Comparison of the Effects of Hypercalcaemia Post Renal Transplantation in Live and Deceased Donor Transplants; a Retrospective Single Centre Study** Rosa M. Montero, Khandaker Jubair Islam, Raja Mohammed Kaja Kamal, Simona Petkovic-miletic, Mona Wahba. *Epsom & St. Helier Univ Hospitals NHS Trust.*

**Background:** Hypercalcaemia post renal transplantation(RT) has previously been described. It is unclear whether this differs in those with live donor(LD) or deceased donor(DCD) transplants.

**Aim:** A retrospective study to determine whether the natural history of hypercalcaemia differs in LD or DCD RT.

**Methods:** 210 patients' notes were reviewed between 2007-2012. Corrected calcium(Ca), parathyroid hormone(PTH), phosphate(P) levels were collected over time, with their eGFR. Immunosuppression regimen was recorded. Hypercalcaemia was defined as corrected calcium >2.60mmol/L at 1 month post RT.

**Results:** 13/210(6.2%) developed hypercalcaemia by 1 month post RT, 6 were LD and 7 DCD. Live: 3 male; 3 female, 4 white, 1 Asian 1 not stated. Median age 52 years. 3/6 adenomas, 2 haemodialysis(HD), 4 peritoneal dialysis(PD) preRT. 1/6 was hypercalcaemic preRT Median Ca 2.66(2.61-2.92). 3 had raised PTH preRT with 3 on cinacalcet and no vitamin D. 2 were given cinacalcet post RT. eGFR at 1 year was not significantly different from eGFR post 1 month RT. DCD: 4 male;3 female, 6 White, 1 Asian. Median 65 years old. 2/7 had adenomas, 1 a parathyroidectomy. 4 were on HD, 3 PD preRT. No DCD were hypercalcaemic preRT Median Ca 2.74(2.68-2.94). All had raised PTH preRT with 2 on cinacalcet and 3 on vitamin D. 2 were given cinacalcet post RT. Those whose eGFRs were seen to improve had lower Ca levels at 3 year follow up compared with post 1 month calcium. eGFR did not correlate with corrected calcium post RT. There was no significant difference in eGFR or Ca between groups. Both groups had a decrease in PTH and P levels by 3 months that was sustained to 3 years.

**Conclusions:** LD that were hypercalcaemic post RT had a higher number of parathyroid adenomas. DCD had a higher proportion of patients with hypercalcaemia preRT that continued compared with LD. Hypercalcaemia appeared to decrease over time. DCD had less adenomas with hypercalcaemia occurring post RT. We would recommend surveillance for parathyroid adenomas in those found to be hypercalcaemic post LD RT with close follow up to those hypercalcaemic preRT undergoing DCD.

**PUB504**

**Outcomes of Non Compliance with Immunosuppression after Renal Transplantation: Comparison between High and Low Immune Risk Patients** Ernesto P. Molmenti, Jasmeet Kaur, Eric Siskind, Antonette S. Flecha, Kellie R. Calderon, Ankita Sagar, Mohini Alexander, Asha M. Alex, Madhu C. Bhaskaran. *Kidney Transplant Center, North Shore LIJ Health System, Manhasset, NY.*

**Background:** Late acute rejection is a challenge faced by transplant nephrologists & non compliance is a leading factor for rejection. Ensuring compliance reduces the risk of non compliance related late acute rejection (NCR) in transplant recipients & improves allograft outcome.

**Methods:** Review of case records revealed first episode NCR in 19 recipients. High immunological risk factors (HIR) evaluated include 3 out of 6 HLA mismatches; prior failed transplants; antibody mediated rejection; HO desensitization, prior rejection , preexisting allograft dysfunction and appropriateness of therapy instituted. Outcome of treatment were - recovery of function or need for RRT (dialysis or transplant).

**Results:** 8 patients were female and 11 male, age 31 to 65, ABO compatible. Two had prior episodes of acute rejections. Eight recipients had no HIR factors prior to the episode of NCR. In HIR group, 81% NCR lead to renal replacement therapy (RRT). On the other hand only 12% required RRT in the low risk group (*$p<0.005$).

| | High Immune Risk=11 | Low Immune Risk=8 |
|---|---|---|
| Recovered | 2 | 7 |
| Not Recovered | 9 | 1 |

**Conclusions:** At least 1 HIR factor leads to high need for RRT after NCR in our limited data series. Low risk group did not need RRT despite NCR in 88% of cases. In our limited analysis HIR appeared to be a significant predictor of irreversible NCR. Noncompliance related late acute rejection may be a preventable cause of end stage renal disease in HIR recipients. Targeted intervention in this subgroup may offer significant benefit to allograft survival.

**Duration and Magnitude of BK Viremia Post Renal Transplant and Its Impact on Allograft Function** Asha M. Alex, Mohini Alexander, Madhu C. Bhaskaran, Ernesto P. Molmenti, Eric Siskind. *Nephrology, North Shore Univ Hospital, Great Neck, NY.*

**Background:** With the use of induction therapy and potent immunosuppressive regimens, BK virus has become an important cause of allograft dysfunction in kidney transplant recipients. Prospective monitoring for BK viremia is now a routine practice in post transplant follow-up. Significance of duration and magnitude of BK viremia, and its influence on allograft function is unclear. The aim of the study was to evaluate the impact of duration and magnitude of BK viremia on allograft function in kidney transplant recipients.

**Methods:** We retrospectively reviewed blood BK PCR for recipients 48 months post-transplant. For the purpose of this study, we classified BK viremia according to viral copies as follows: Low grade transient (<5000 lasting less than 3 months); Low grade persistent (<5000 lasting more than 3 months); High grade transient (>5000 lasting less than 3 months); High grade persistent (>5000 viral copies lasting more than 3 months).

**Results:** Records of 78 transplant recipients were reviewed. 13% demonstrated BK viremia. Of these, 20% showed evidence of allograft dysfunction, while 80% did not. Of the total sample, 3% showed allograft dysfunction attributable to BK virus nephropathy (BKVN) on biopsy, and these patients belonged to the high-grade persistent group. Patients with BKVN are almost always found to have BK viremia. Our analysis of a limited sample revealed that a persistent high-grade viremia is probably more likely to be associated with BKVN, unlike transient BK viremia detected on prospective monitoring without allograft dysfunction. The impact of low-grade persistent viremia remains to be determined.

| | Patients with BK viremia (%) | Total Patients (%) |
|---|---|---|
| Low grade transient | 30 | 3.84 |
| Low grade persistent | 0 | 0 |
| High grade transient | 40 | 5.12 |
| High grade persistent | 20 | 2.56 |

**Conclusions:** High-grade persistent BK viremia post transplant with allograft dysfunction is most likely suggestive of BKVN. Transient BK viremia without allograft dysfunction may be less likely to be associated with BKVN.

## HI-OR01

**Acute Kidney Injury from Off-Pump or On-Pump Coronary Bypass Grafting and Kidney Function One Year Later** Amit X. Garg,[1] Philip J. Devereaux,[2] Salim Yusuf,[2] Meaghan S. Cuerden,[1] Chirag R. Parikh,[3] Steven G. Coca,[3] Michael Walsh,[2] Richard J Cook,[3] Richard P. Whitlock,[2] Richard J Novick,[3] Yongning Ou,[2] Xiangbin Pan,[3] Sirish Parvathaneni,[3] Andre Lamy.[2] *[1]London Kidney Clinical Research Unit, London, ON, Canada; [2]Population Health Research Institute, Hamilton, ON, Canada; [3]On Behalf of the CORONARY Investigators.*

**Background:** Most acute kidney injury (AKI) observed in hospital is defined by sudden mild or moderate increases in serum creatinine which may persist for several days. It is unknown whether an intervention which reduces the risk of such AKI better preserves long term kidney function.

**Methods:** Within the CORONARY trial we assessed kidney function in 2932 patients (from 63 sites, 16 countries) who were randomly assigned to coronary-artery bypass grafting (CABG) either with a beating-heart technique (off-pump) or with cardiopulmonary bypass (on-pump) [CORONARY kidney protocol published BMJ Open 2012; 2:e001080]. The primary outcomes were AKI within 30 days of surgery (□ 50% increase in serum creatinine from pre-randomization value) and loss of kidney function at one year (□ 20% loss in estimated glomerular filtration rate from pre-randomization value).

**Results:** Off-pump (n=1472) vs. on-pump (n=1460) CABG reduced the risk of AKI (17.5% vs. 20.8%, relative risk 0.83 (95% confidence interval [CI] 0.72 to 0.95); p=0.01); however, there was no significant difference between the two groups in the loss of kidney function at one year (17.0% vs. 15.3%, relative risk 1.09 (95% CI 0.93 to 1.28); p=0.29). Results were consistent with multiple alternate continuous and categorical definitions of AKI or kidney function loss.

**Conclusions:** The use of off-pump vs. on-pump CABG reduced the risk of post-operative AKI with no significant difference in kidney function between the two groups at one year. The findings emphasize that an intervention which reduces the risk of mild AKI may not necessarily improve long term kidney function.

## HI-OR02

**The Effect of Bardoxolone Methyl in Patients with Type 2 Diabetes Mellitus and Stage 4 Chronic Kidney Disease** Glenn M. Chertow,[1] Tadao Akizawa,[2] Paul Audhya,[3] George L. Bakris,[4] Melanie Chin,[3] Heidi Christ-schmidt,[5] Angie Goldsberry,[3] Hiddo Jan Lambers Heerspink,[6] Mark T. Houser,[7] Melissa Krauth,[3] John J. Mcmurray,[8] Colin John Meyer,[3] Hans-Henrik Parving,[9] Giuseppe Remuzzi,[10] Robert D. Toto,[11] Nosratola D. Vaziri,[12] Christoph Wanner,[13] Janet Wittes,[5] Danielle Wrolstad,[5] Dick de Zeeuw.[6] *[1]Stanford U.; [2]Showa U.; [3]Reata; [4]U. Chicago; [5]Statistics Collaborative; [6]U. Groningen; [7]AbbVie; [8]U. Glasgow; [9]U. Copenhagen; [10]IRCCS - Mario Negri; [11]U. TX SW Med Ctr; [12]U. CA; [13]U. Würzburg.*

**Background:** Although inhibitors of the renin-angiotensin-aldosterone system can slow the progression of diabetic kidney disease, residual risk is high. Whether antioxidant-inflammation modulators further reduce this risk is unknown.

**Methods:** We randomized 2185 patients with type 2 diabetes mellitus (T2DM) and CKD stage 4 (estimated glomerular filtration rate (eGFR) 15 to <30 mL/min/1.73m$^2$) to bardoxolone methyl 20 mg daily or placebo. The primary composite outcome was end-stage renal disease (ESRD) or cardiovascular death.

**Results:** The Sponsor and Steering Committee terminated the trial as recommended by the Independent Data Monitoring Committee; median follow-up was 9 months. Sixty-nine of 1088 (6.3%) patients randomized to bardoxolone methyl and 69 of 1097 (6.3%) patients randomized to placebo experienced a primary composite outcome (hazard ratio 0.98, 95% confidence interval (95% CI) 0.70 to 1.37, p=0.92). In the bardoxolone methyl group, 43 patients developed ESRD and 27 experienced cardiovascular death; in the placebo group, 51 patients developed ESRD and 19 experienced cardiovascular death. Ninety-six patients were hospitalized with or died from heart failure in the bardoxolone methyl group compared with 55 in the placebo group (hazard ratio 1.83, 95% CI 1.32 to 2.55, p<0.001). Estimated GFR (6.4 mL/min/1.73m$^2$, 95% CI 5.9 to 6.9 mL/min/1.73m$^2$), blood pressure and albuminuria increased significantly and body weight decreased significantly in the bardoxolone methyl group relative to placebo.

**Conclusions:** In patients with T2DM and stage 4 CKD, bardoxolone methyl did not reduce the risk of ESRD or cardiovascular death. More frequent cardiovascular events prompted termination of the trial.

## HI-OR03

**Combined Angiotensin Inhibition for Treatment of Diabetic Nephropathy: VA Nephron D** Linda F. Fried,[1] Nicholas Emanuele,[2] Jane Hongyuan Zhang,[3] Mary Brophy,[4] Todd Conner,[5] William Duckworth,[6] David J. Leehey,[2] Peter A. McCullough,[7] Theresa Z. O'Connor,[3] Paul M. Palevsky,[1] Robert F. Reilly,[8] Stephen L. Seliger,[9] Stuart Warren,[5] Suzanne Watnick,[10] Peter Peduzzi,[3] Peter Guarino.[3] *[1]VA Pittsburgh HCS, Pittsburgh, PA; [2]Hines VA, Hines, IL; [3]Cooperative Studies Program Coordinating Center, VA Connecticut HCS, West Haven, CT; [4]VA Boston HCS, Boston, MA; [5]VA Cooperative Studies Program Research Pharmacy, Albuquerque, NM; [6]Carl T. Hayden VA Medical Center, Phoenix, AZ; [7]St John Providence Health System, Novi, MI; [8]VA North Texas HCS, Dallas, TX; [9]VA Maryland HCS, Baltimore, MD; [10]Portland VA Medical System, Portland, OR.*

**Background:** Combination therapy with angiotensin converting enzyme inhibitors (ACEI) and angiotensin receptor blockers (ARB) decreases proteinuria; however its safety and impact on progression of kidney disease is uncertain.

**Methods:** Patients with type 2 diabetes, urine albumin excretion □300 mg/g creatinine and estimated glomerular filtration rate (eGFR) 30-89.9 ml/min/1.73m$^2$ were treated with losartan 100 mg/day and then randomized to lisinopril (10 to 40 mg/day) or placebo. The primary endpoint was the composite of change in eGFR (decline of □30 ml/min/1.73m$^2$ if initial eGFR □60 or □50% decline if initial eGFR <60 ml/min/1.73m$^2$), end-stage renal disease (ESRD), or death. Change in eGFR or ESRD was a secondary renal endpoint. Safety outcomes included mortality, hyperkalemia, and acute kidney injury.

**Results:** The study was stopped early for safety concerns. Among 1448 randomized patients with a median follow-up of 2.2 years, there were 152 primary endpoints in the monotherapy arm and 132 in the combination arm [HR 0.88 (95% CI 0.70 to 1.12), p=0.30]. A trend towards benefit in renal endpoint [HR 0.78 (0.58 to 1.05), p=0.10] decreased with time (non-proportionality p-value = 0.02). There was no benefit on mortality [HR 1.04 (0.73 to 1.49), p= 0.75] nor cardiovascular events. Combination therapy increased the risk of hyperkalemia [6.3 vs. 2.6 per 100 person years, p< 0.001] and acute kidney injury [12.2 vs. 6.7 per 100 person years, p<0.001].

**Conclusions:** Combination ACEI and ARB therapy is associated with an increased risk of adverse events in patients with diabetic nephropathy.

*Funding:* Veterans Administration Support, Pharmaceutical Company Support - Merck (study drug donation)

## HI-OR04

**Hypertension in Hemodialysis Patients Treated with Atenolol or Lisinopril (HDPAL): A Randomized Controlled Trial** Rajiv Agarwal,[1,2] Arjun D. Sinha,[1,2] Maria K Pappas,[1,2] Terri N Abraham,[1,2] Getachew G. Tegegne.[1,2] *[1]Medicine, Indiana University, Indianapolis, IN; [2]Medicine, VAMC, Indianapolis, IN.*

**Background:** To evaluate the comparative safety and efficacy of an ACE inhibitor-based to a β-blocker-based antihypertensive treatment, we conducted a randomized, open-label, parallel-group, single-center trial.

**Methods:** Subjects on maintenance hemodialysis with echocardiographic left-ventricular hypertrophy and hypertension confirmed by interdialytic 44-hour ambulatory blood pressure (BP) monitoring were randomized to lisinopril (LIS) (n=100) or atenolol (ATL) (n=100) each administered 3 times weekly after dialysis. Home BP was controlled to <140/90 mmHg. The primary outcome was the change in left ventricular mass index (LVMI) from baseline to 12 months.

**Results:** Average age was 52.7 y, 33% were women, and 85% black. At baseline, 44h ambulatory BP was 151.5/87.1 mmHg in the ATL group. BP was similar in the LIS group, improved over time in both groups, and no statistical difference between drugs was noted. An independent data safety monitoring board recommended termination of the study when a clear signal for cardiovascular safety emerged. Serious cardiovascular events in the ATL group occurred in 14 subjects who had 18 events (22.2/100 patient-years (PY)) and in the LIS group in 26 subjects who had 40 events (54/100 PY; incidence rate ratio (IRR) 2.29 (95% CI 1.28-4.24, p=0.003). Combined serious adverse event of myocardial infarction, stroke, hospitalization for heart failure or cardiovascular death in the ATL group occurred in 10 subjects who had 11 events (13.5/100 PY) and in the LIS group in 17 subjects who had 23 events (31.0/100 PY; IRR 2.29 (p=0.021). Hospitalizations for heart failure were worse in LIS group (IRR 3.13, p=0.021). All-cause hospitalizations in the ATL group occurred in 37 subjects who had 73 hospitalizations (89.9/100 PY) and in the LIS group in 59 subjects who had 107 hospitalizations (144.3/100 PY; IRR 1.61 (95% CI 1.18 -2.19, p=0.002). LVMI improved with time; no difference between drugs was noted.

**Conclusions:** Atenolol-based antihypertensive therapy may be superior to lisinopril-based therapy in preventing cardiovascular morbidity and all-cause hospitalizations.

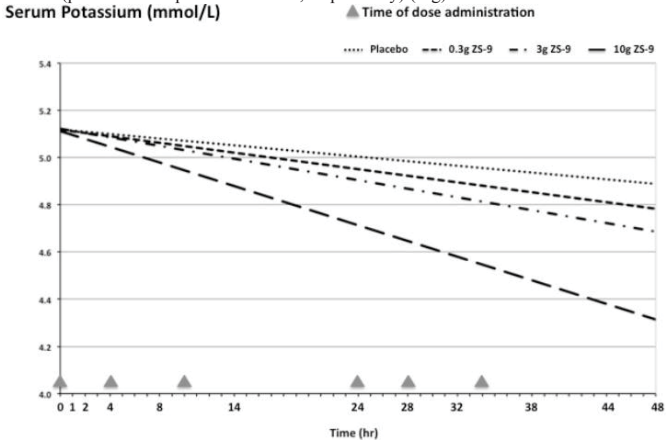
## HI-OR05

**Safety and Efficacy of ZS 9, a Novel Selective Cation Trap, for Treatment of Hyperkalemia in CKD Patients** Stephen R. Ash,[1] Bhupinder Singh,[2] Philip T. Lavin,[3] Fiona Stavros,[4] Henrik S. Rasmussen.[4] *[1]Indiana University, Lafayette, IN; [2]Southwest Clinical Research Institute, Tempe, AZ; [3]Boston Biostatistics Research Foundation, Framingham, MA; [4]ZS Pharma Inc., Fort Worth, TX.*

**Background:** Hyperkalemia is associated with significant mortality and limits use of cardio- and reno-protective RAASi, yet no reliably safe and effective treatment for this condition exits. ZS-9 is a selective cation exchanger designed to preferentially entrap excess potassium. A Phase 2 randomized, double-blind PBO-controlled trial (RCT) assessed ZS-9's safety and efficacy in CKD pts. with mild-to-moderate hyperkalemia.

**Methods:** Eligible pts. (N=90) with eGFR 30-60 mL/min/1.73 $m^2$ and serum potassium [s-$K^+$] 5-6 mmol/L on normal diets were randomized 2:1 to ZS-9 (0.3g [n=12], 3g [n=24], and 10g [n=24]) or PBO (n=30), given TID orally on an in-patient basis with regular meals. The primary efficacy endpoint was the rate of s-$K^+$ decrease over the first 48 hr, using longitudinal modeling to achieve a best fit to the data.

**Results:** ZS-9 was well tolerated and no serious AEs were reported; no patients withdrew. Only one ZS-9 AE (mild constipation, 3g) was considered at least possibly drug related. No significant hypokalemia, hypomagnesemia, or hypocalcemia was observed. At baseline, mean s-$K^+$ was 5.1 mmol/L across groups. ZS-9 demonstrated significant dose-dependent reductions in s-$K^+$; the primary efficacy endpoint was met in the 10g and 3g cohorts ($p<0.0001$ and $p=0.048$ vs PBO, respectively) (Fig).



Serum $K^+$ decreased 1 hr after the first dose of ZS-9 10g ($p=0.022$ vs PBO), and maximal mean reduction from baseline was 0.92 mmol/L after 38 hr ($p<0.001$ vs PBO), without affecting serum or urinary sodium.

**Conclusions:** In CKD patients with hyperkalemia, ZS-9 was safe and well tolerated and led to a rapid and sustained s-$K^+$ reduction. Consequently, ZS-9 is being evaluated in a large Phase 3 RCT.

## HI-OR06

**Treatment of Lupus Nephritis with Abatacept Plus Low-Dose Pulse Cyclophosphamide: The Results of the ACCESS Trial** Brad H. Rovin,[1] The Access Trial Investigators.[2] *[1]Internal Medicine, Ohio State University Wexner Medical Center, Columbus, OH; [2]The Immune Tolerance Network.*

**Background:** CTLA4Ig (abatacept, ABA) plus intravenous cyclophosphamide (IVC) act synergistically to treat murine lupus nephritis (LN). The ACCESS trial tested low-dose (i.e. Euro-lupus) IVC ± ABA in human LN to determine if complete renal response (CRR) rate could be improved with ABA, and if CRR in ABA-treated patients could be maintained without maintenance immunosuppression (IS).

**Methods:** ACCESS enrolled patients with Class III or IV (±V) LN and a urine protein to creatinine ratio (UPCR) >1. All patients were given a steroid taper and IVC (500 mg q 2 weeks X6) followed by azathioprine (AZA, 2mg/kg/d). Patients were randomized to placebo (n=68) or ABA (n=66) at weeks 0, 2, 4 and then monthly. The primary outcome was CRR at week 24, defined as UPCR <0.5, serum creatinine normal or within 25% of baseline, and prednisone □10mg/d. At week 24 AZA was stopped in ABA patients who had CRR, but continued in controls who had CRR. This group was followed to week 52.

**Results:** The ACCESS cohort was 39% African American (AA), 40% Hispanic/Mestizo, and 19% European American. Control and ABA patients were well-matched for baseline clinical characteristics. At week 24 CRR occurred in 33% ABA and 31% of control, and CRR+PRR was 59% in both arms. CRR occurred in 33% of AA ABA patients and 16% of AA control patients (p=NS). There were no statistically significant differences between study arms in anti-dsDNA or complement levels, frequency of serious or infectious adverse events, or withdrawals. Among complete responders at week 24, 50% (11/22) and 62% (13/21) of ABA and control patients respectively, still met CRR criteria at week 52 (p=NS).

**Conclusions:** ABA+IVC did not improve CRR over IVC alone. There was no difference in the number of ABA and control patients who maintained CRR to 1 year despite discontinuation of maintenance IS in the ABA group and continued AZA in the control group, suggesting ABA-treated patients may not need maintenance IS. ACCESS also showed, for the first time, that low-dose IVC may have applicability in racially and ethnically diverse LN patients. The CRR of >30% at 24 weeks is higher than any recent LN trial.

*Funding:* Other NIH Support - Immune Tolerance Network

## HI-OR07

***APOL1* Risk Variants, Race, and Progression of Chronic Kidney Disease** Afshin Parsa,[1] Wen Hong Linda Kao,[2] the AASK and CRIC Collaborative Research Groups.[1,2] *[1]Nephrology, University of Maryland School of Medicine; [2]Epidemiology, Johns Hopkins Bloomberg School of Public Health.*

**Background:** African Americans (AAs) are at substantially increased risk for end-stage renal disease (ESRD) compared to European Americans (EAs).

**Methods:** We examined the effects of *APOL1* variants on chronic kidney disease (CKD) progression separately in the African American Study of Kidney Disease and Hypertension (AASK) and the Chronic Renal Insufficiency Cohort Study (CRIC). AASK enrolled 693 AAs with CKD attributed to hypertension. CRIC enrolled EAs and AAs with CKD (n=2955, 46% with diabetes). *APOL1* risk group was defined by two copies of the high-risk *APOL1* variants. In AASK, primary outcomes were ESRD and a composite of ESRD or doubling of serum creatinine. In CRIC, primary outcomes were the slope in estimated glomerular filtration rate (eGFR) and the composite of ESRD or halving of eGFR from baseline.

**Results:** In AASK, the primary outcome occurred in 58% of participants in the *APOL1* risk group and 37% in the *APOL1* non-risk group [adjusted hazard ratio (HR)=1.88,P<0.001]. There was no interaction between *APOL1* status and trial interventions (3 drugs and 2 BP targets) or baseline proteinuria.

In CRIC, the adjusted rate of decline in eGFR was greater among AAs in the *APOL1* risk group than EAs in participants with diabetes (-1.32 ml/min/1.73$m^2$/year, P<0.001) and participants without diabetes (-1.11 ml/min/1.73$m^2$/year, P<0.001). The rate of decline in eGFR was similar among AAs in the *APOL1* non-risk group and EAs. Among participants with diabetes, the HR of a renal event was 1.95 (95% CI: 1.39-2.73) in AAs in the *APOL1* risk group and 1.40 (95% CI: 1.10-1.78) in AAs in the non-risk group, each compared to EAs. Corresponding HRs among participants without diabetes were 2.68 (95% CI: 1.78-4.05) and 1.57 (95% CI: 1.11-2.21).

**Conclusions:** *APOL1* renal risk variants increase CKD progression in AAs, even in the setting of well-controlled BP. These variants explain, in part, the markedly increased risk of ESRD in AAs compared to EAs, regardless of diabetes status. In the context of prior studies, our results suggest that *APOL1* risk variants increase CKD progression in AAs, irrespective of CKD etiology.

*Funding:* NIDDK Support

## SA-PO1076

**A Randomized Clinical Trial to Evaluate the Efficacy of Cinacalcet to Correct Hypercalcemia in Renal Transplant Recipients with Autonomous Hyperparathyroidism** Pieter Evenepoel,[1] Kerry Cooper,[2] Hallvard Holdaas,[3] Piergiorgio Messa,[4] Georges J. Mourad,[5] Klaus Olgaard,[6] Boleslaw Rutkowski,[7] Heidi M. Schaefer,[8] Hongjie Deng,[2] Jose-Vicente Torregrosa,[9] Rudolf P. Wuthrich,[10] Susan V. Yue.[2] *[1]U Ziekenhuizen, Belgium; [2]Amgen, USA; [3]Oslo U Hospital, Norway; [4]Fondazione Ca' Granda IRCCS Policlinico, Italy; [5]U of Montpellier Hopital Lapeyronie, France; [6]U of Copenhagen, Denmark; [7]Medical U of Gdansk, Poland; [8]Vanderbilt U Medical Center; [9]U of Barcelona, Spain; [10]U Hospital Zurich, Switzerland.*

**Background:** Autonomous hyperparathyroidism (HPT) after kidney transplantation (KTx) is associated with elevations of serum calcium (Ca) and reductions in serum phosphorus (P). Cinacalcet (Cin) has been shown to reduce Ca and increase P levels in several open-label, single arm studies.

**Methods:** 114 KTx recipients (□18 years) with autonomous HPT were randomized 1:1 to receive Cin (n=57):placebo (n=57) to evaluate the primary endpoint: correction of hypercalcemia (Ca < 10.2 mg/dL); secondary endpoints: to assess the percent change in bone mineral density (BMD) at the femoral neck and the change in serum P levels. Randomization was stratified by baseline corrected total serum Ca levels: □11.2 mg/dL (2.80 mmol/L; n=45) and >11.2 mg/dL (n=69). Efficacy assessment for Ca, parathyroid hormone and P occurred between wks 21 and 26 and wk 52 for BMD.

**Results:** Demographic distribution was similar across groups: 55% male, 82% white, with median (min, max) age of 53 (24, 76) years. The proportion of subjects achieving the primary endpoint was 78.9% and 3.5% for the Cin and placebo groups (p <0.001). BMD mean (SD) percent change from baseline to wk 52 was 2.16 (7.74)% and 0.73 (4.40)% for the Cin and placebo groups, respectively (n.s.). There was a nominally significant difference ($p<0.001$) for the observed increase in P from baseline to efficacy assessment in the Cin vs the placebo group. No new safety risks were identified.

**Conclusions:** This is the largest randomized trial with Cin in KTx subjects. Data support the efficacy of cinacalcet for the treatment of hypercalcemia in KTx subjects with autonomous HPT.

*Funding:* Pharmaceutical Company Support - Amgen Inc.

## SA-PO1077

**18 Month Results from a Randomised Trial of Mycophenolate Mofetil versus Cyclophosphamide for Remission Induction of Severe ANCA-Associated Vasculitis: MYCYC** Rachel B. Jones,[1] Lorraine Harper,[2] Michael Walsh,[3] David R.W. Jayne.[1] *[1]Addenbrooke's Hospital; [2]University of Birmingham; [3]McMaster University.*

**Background:** Mycophenolate mofetil (MMF) is a potential alternative to cyclophosphamide (CYC) for remission induction of ANCA-associated vasculitis (AAV). We present the 18 month data of an international randomised, controlled trial comparing MMF to CYC as initial therapy in severe AAV.

**Underline represents presenting author/disclosure.**

**Methods:** Patients with newly diagnosed severe AAV were randomised to receive 3 to 6 months of induction with MMF 2-3 g/day (n=70) or 6-10 pulses of IV CYC 15 mg/kg (n=70). Both groups received the same tapering prednisolone regimen and azathioprine therapy after remission induction. The primary outcome was remission at 6 months defined as no disease activity for □4 weeks without excess prednisolone. We considered MMF non-inferior to IV CYC if the lower bound of the 90% confidence interval (CI) for remission was no more the 12% lower for MMF.

**Results:** The groups were similar at baseline. The primary endpoint occurred in 51 (73%) MMF vs 52 (74%) CYC (risk difference -1%, 90% CI -14 to 11%; p=0.08 for non-inferiority). The secondary remission endpoint occurred in 63/70(90%) MMF vs 56/70 (80%) CYC (risk difference 10%, 90% CI 0 to 20%; p<0.001 for non-inferiority). Although, cumulative prednisolone dosing at 6 months did not differ (p>0.9), there was slightly more noncompliance at low doses in the MMF group. At 18 months, 21 patients (35%) in the MMF group and 12 (22%) in the CYC group relapsed (risk ratio 1.57, 95% CI 0.87 to 2.94; p=0.12). Other key secondary outcomes did not differ significantly between groups: estimated glomerular filtration rate (mean difference 2.6 ml/min, 95% CI -7.6 to 12.9; p=0.62), serious adverse events (risk ratio 1.25, 95% CI 0.86 to 1.81; p=0.23), serious infections (risk ratio 1.5, 95% CI 0.78 to 2.88; p=0.22) or deaths (risk ratio 1.25, 95% CI 0.35 to 4.46; p=0.73).

**Conclusions:** Although remission induction rates were similar, we did not demonstrate non-inferiority of MMF vs IV CYC and MMF was not substantially safer. MMF may offer an alternative to cyclophosphamide in select patients but requires particular attention to disease activity and glucocorticoid dosing.

*Funding:* Pharmaceutical Company Support - Roche

## SA-PO1078

**Continuous, Maintenance Iron Therapy Using Soluble Ferric Pyrophosphate Citrate Chelate (SFP, Triferic™) Infusion via Hemodialysate in CKD-HD: Phase III CRUISE Studies**

Steven Fishbane,[3] Ajay K. Singh,[2] Raymond D. Pratt,[1] Vivian H. Lin,[1] Carrie D. Guss,[1] Ajay Gupta.[1] *[1]R&D, Rockwell Medical, Wixom, MI; [2]Nephrology, Brigham and Women's Hospital, Boston, MA; [3]Nephrology, North Shore - Long Island Jewish Health System, Inc., Manhasset, NY.*

**Background:** SFP (Triferic™), a novel, unique, carbohydrate-free, complex iron salt delivered via hemodialysate donates iron rapidly and directly to apotransferrin, bypassing the RE system. The safety and efficacy of this novel dialysate delivery method for maintaining iron balance in adult, CKD-HD, was examined in two identical RCTs.

**Methods:** Iron replete HD patients were randomized to either placebo (standard iron-free dialysate) or dialysate containing SFP at 2 μM (110 μg iron/L), with every hemodialysis for up to 48 weeks while ESA dose changes and IV/oral iron were prohibited. Subjects meeting pre-specified criteria for a change in anemia management were advanced to SFP-only extension stage.

**Results:** The safety profile and tolerability of SFP were similar to placebo with no anaphylactoid reactions in over 20,000 administrations. AE and SAE were similar and there was no increase in intradialytic hypotension, CV events or infections. No deaths were attributed to SFP.

The primary endpoint was mean change in Hgb from baseline to the end of treatment (last 1/6th of randomized phase), analyzed using ANCOVA with baseline Hgb as covariate. Hgb was maintained with SFP, while placebo demonstrated a statistically significant decline.

| | CRUISE-1 | | CRUISE 2 | |
|---|---|---|---|---|
| | SFP N=148 | Placebo N=151 | SFP N=142 | SFP N=144 |
| Baseline Hgb g/dL | 10.96 | 10.90 | 10.96 | 10.93 |
| LS Mean Change from Baseline g/dL (SE) | 0.06 (0.115) | -0.30 (0.114) | -0.05 (0.108) | -0.40 (0.109) |
| Difference from Placebo LS Mean g/dL (SE) | 0.36 (0.14) | | 0.36 (0.14) | |
| 95% CI | 0.08, 0.63 | | 0.08, 0.63 | |
| P-value | **0.011** | | **0.011** | |

SFP reliably delivered iron which was rapidly cleared and maintained reticulocyte Hgb and ferritin while placebo experienced significant declines.

**Conclusions:** In HD patients, the novel iron salt-SFP infused by hemodialysis for up to 48 weeks is well tolerated with a safety profile similar to placebo. SFP is effective in maintaining hemoglobin by preventing iron deficiency without inducing iron overload.

## SA-PO1079

**FIND-CKD: A 56-Week Randomized Trial of Intravenous Ferric Carboxymaltose versus Oral Iron in Anemic Patients with Chronic Kidney Disease and Iron Deficiency**

Iain C. Macdougall,[1] Andreas H. Bock,[2] Fernando Carrera,[2] Kai-Uwe Eckardt,[2] Carlo A. Gaillard,[2] David B. Van Wyck,[2] Bernard Roubert,[3] Jacqueline G. Nolen,[3] Simon D. Roger.[2] *[1]King's College Hospital, London, United Kingdom; [2]On behalf of the FIND-CKD Study Investigators; [3]Vifor Pharma, Switzerland.*

**Background:** The optimal iron regimen in non-dialysis CKD (ND-CKD) is unknown.

**Methods:** FIND-CKD was a 56-week, open-label, multicenter, prospective, randomized study of 626 anemic patients with ND-CKD and iron deficiency not receiving an erythropoiesis-stimulating agent (ESA). Patients were randomized (1:1:2) to ferric carboxymaltose (FCM) targeting a higher (400–600μg/L) or lower (100–200μg/L) ferritin level, or oral iron. The primary endpoint was time to initiation of other anemia management (ESA, other iron therapy, or blood transfusion) or hemoglobin (Hb) trigger of 2 consecutive values <10g/dL during weeks 8–52.

**Results:** Time to initiation of other anemia management or Hb trigger was significantly longer with FCM targeting a higher ferritin level vs oral iron (mean [SE] 313 [8] days vs 287 [8] days [p=0.035]; hazard ratio 0.67; 95% CI 0.46, 0.98) but not vs FCM targeting a lower ferritin level. The increase in mean Hb from baseline to month 12 was greater with high ferritin FCM vs oral iron (p=0.014). Hb increased by □1g/dL in more patients with high ferritin FCM (56.9%) vs low ferritin FCM (34.2%, p<0.001) or oral iron (32.1%, p<0.001). High ferritin FCM was associated with a significantly greater increase in ferritin than oral iron, and a similar increase in transferrin saturation. Change in eGFR was minimal and similar in each group. No renal, cardiovascular, or infectious toxicity was observed. Rates of adverse events, serious adverse events, and deaths were comparable between groups. Intolerance led to study discontinuation in 0.7% of high ferritin FCM, 1.3% of low ferritin FCM and 7.5% oral iron patients (p=0.002 vs high ferritin FCM).

**Conclusions:** IV FCM targeting a ferritin range of 400–600μg/L significantly delayed the requirement for ESA therapy or other anemia therapy compared to oral iron in anemic patients with ND-CKD and iron deficiency. High target FCM led to a greater Hb increase than oral iron, maintained Hb, and was well tolerated.

## SA-PO1080

**Increased Duration and Dose of Prednisolone (PSL) Treatment Does Not Reduce Relapses in Childhood Nephrotic Syndrome**

Norishige Yoshikawa,[1] Koichi Nakanishi,[1] Mari Saito Oba,[2] Mayumi Sako,[3] Yasuo Ohashi,[4] Kazumoto Iijima.[5] *[1]Wakayama Medical Univ., Japan; [2]Yokohama City Univ.; [3]National Center for Child Health and Development; [4]Univ. of Tokyo; [5]Kobe Univ.*

**Background:** Although prolonged initial steroid treatment has been reported to decrease the risks of relapse in pediatric patients with steroid-sensitive nephrotic syndrome (SSNS), the initial treatment approach varies considerably. A Cochrane review concluded that although treating patients for up to 7 month(m)s appears more effective than 2 m-therapy in achieving sustained remissions, additional well designed and adequately powered randomized clinical trials are required.

**Methods:** We evaluated the hypothesis that prolonging a 2-m initial PSL therapy to 6 ms using an increasing cumulative dose would not reduce the incidence of frequently relapsing (FR) NS. We conducted a multicenter, randomized, open-label non-inferiority trial at 91 hospitals in Japan and compared a 2-m initial PSL treatment (cumulative dose 2240 mg/m$^2$) with a 6-m treatment (3885 mg/m$^2$). The primary endpoint was time to FRNS. A prespecified non-inferiority margin was hazard ratio (HR) of 1.3 and significant level was one-sided 5%. We randomly assigned 255 children with an initial episode of SSNS either 2-m treatment(n=128) or 6-m treatment (n=127).The trial medication consisted of initial PSL treatment and relapse PSL treatment as specified in the protocol. Enrolled patients received this for a total of 24 ms.

**Results:** The FRNS-free rates at 24 ms were 56.2% (95% confidence interval [CI], 47.0-64.4%) in the 2-m treatment group and 50.8% (95% CI, 41.4-59.4%) in the 6-m treatment group. The HR was 0.86 (90% CI, 0.64-1.16) and met the non-inferior margin (p = 0.011). There was no significant difference in the number of relapses during the 24-m intervention period (1.25 vs. 1.30/person-years; relapse rate ratio 0.94, 95% CI 0.71-1.22, p = 0.649). The incidence of central obesity in the 6-m treatment group was higher than in the 2-m treatment group (p = 0.03).

**Conclusions:** This trial shows that extending initial PSL treatment from 2 to 6 ms with an increasing dose does not reduce the incidence of FRNS.

*Funding:* Government Support - Non-U.S.

## SA-PO1081

**The Antialbuminuric Effects of an Aldosterone Blocker in Hypertensive Patients with Albuminuria: A Double-Blinded, Randomized, Placebo-Controlled (EVALUATE) Trial**

Toshiro Fujita,[1] Shunya Uchida,[2] George Seki,[3] Shinya Kaname.[4] *[1]Department of Epigenetics, RCAST, University of Tokyo, Tokyo, Japan; [2]Department of Nephrology, Teikyo University, Tokyo, Japan; [3]Department of Nephrology & Endocrinology, University of Tokyo, Tokyo, Japan; [4]Department of Nephrology, Kyorin University, Tokyo, Japan.*

**Background:** Results of many animal studies but a few human studies suggest that mineralocorticoid receptor (MR) blockades can inhibit albuminuria and renal damage in chronic kidney disease (CDK) patients. The aim of this trial was to evaluate the potential renoprotective capacity of the MR blockade in non-diabetic patients with hypertension and proteinuria who were already receiving the angiotensin receptor blockers (ARB) or angiotensin-converting enzyme inhibitors (ACE-I) and optimal treatment for hypertension.

**Methods:** We evaluated the antialbuminuric effect of the MR blockade by adding treatment of low dose (50 mg/day) of eplerenone to optimal antihypertensive therapy including in non-diabetic hypertensive CKD patients who had blood pressure [BP] of 130-180/80-100 mmHg and albuminuria (urinary albumin/creatinine [Cr] ratio: 30-600 mg/g). The patients had estimated glomerular filtration rate □50 mL/min/1.73m$^2$. We enrolled 314 patients in this multicenter, double-blinded, randomized, placebo-controlled trial (UMIN#000001803). The primary outcome was a percent reduction in urinary albumin/Cr, as measured in an early-morning sample, at 12 months.

**Results:** Treatment with 50 mg of eplerenone, as compared with placebo, reduced the mean urinary albumin/Cr (-17.8±99.5 [mean±SD] % vs. 8.7±109.4%, P<0.05). A small, but significant (both, p<0.05), difference in systolic and diastolic BP was seen between the treatment groups by the end of the study period: 138.7±11.16 to 126.8±11.52 mmHg in the eplerenone group and 138.7±12.58 to 129.4±12.87 mmHg in the placebo group. Serum potassium was similar between the two groups (4.32±0.40 vs. 4.17±0.50 mEq/L, NS), and total numbers of adverse events were also similar in the groups.

**Underline represents presenting author/disclosure.**

**Conclusions:** Low dose of eplerenone may have renoprotective effects in non-diabetic patients with hypertension and nephropathy who are receiving ARB or ACE-I.

*Funding:* Pharmaceutical Company Support - Pfizer

## SA-PO1082

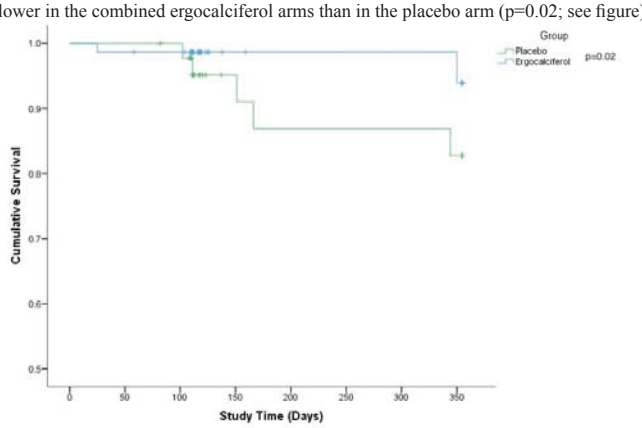
**The DIVINE Trial: Dialysis Infection and Vitamin D in New England**

Ishir Bhan, Dorothy A Dobens, Caitlin A. Trottier, Julia Beth Wenger, Hector Tamez, Joseph James Deferio, Kathryn J. Lucchesi, Ravi I. Thadhani. *Division of Nephrology, Massachusetts General Hospital, Boston, MA.*

**Background:** The role of nutritional vitamin D in ESRD remains uncertain. We performed a randomized, double-blind placebo-controlled trial to assess the safety and efficacy of ergocalciferol in chronic hemodialysis patients.

**Methods:** We randomized 105 incident dialysis patients with 25(OH)D levels □ 32 ng/mL from 32 centers in the northeast US to ergocalciferol 50,000 IU weekly (n=36), monthly (n=33), or placebo (n=36) for a 12 week treatment period. Follow-up was at 20 weeks and one year. The primary outcome was 25(OH)D levels at 12 weeks. Secondary outcomes included markers of mineral metabolism, hospitalizations, and one year mortality.

**Results:** Baseline features and active vitamin D use were similar across the groups. Most subjects were white (62.9%) and male (78.1%). The mean age was 57 ± 17 years. Mean 25(OH)D levels at 12 weeks were significantly higher than placebo (27.3 ng/mL ± 2.3) in the weekly (49.8 ng/mL ± 2.3; p<0.001) and monthly (38.3 ng/mL ± 2.4; p=0.001) treatment arms. 25(OH)D sufficiency (>32 ng/mL) was achieved in 90.9%, 64.5%, and 35.3% of patients receiving weekly ergocalciferol, monthly, and placebo, respectively. There were no differences between groups in serum calcium, phosphorus, or PTH. Overall hospitalizations (p=0.64), hospitalizations for infection (p=0.32) and cardiovascular hospitalizations (p=0.47) did not differ between groups. All-cause mortality at one year was significantly lower in the combined ergocalciferol arms than in the placebo arm (p=0.02; see figure).



**Conclusions:** Ergocalciferol can safely and effectively increase 25(OH)D levels in incident dialysis patients. Preliminary analysis suggests a lower one-year mortality rate among ergocalciferol-treated patients compared with placebo.

Clinicaltrials.gov NCT99782099, Funded by NIDDK R01DK09143.

## SA-PO1083

**Prospective Randomized Controlled Trial of Individualized Dialysate Cooling to Provide Brain and Cardiac Protection in Haemodialysis Patients**

Chris W. McIntyre, Mohamed Tarek Eldehni, Aghogho Odudu. *Division of Medical Sciences and Graduate Entry Medicine, School of Medicine, University of Nottingham, Derby, United Kingdom.*

**Background:** Conventional haemodialysis (HD) results in significant circulatory stress producing recurrent and cumulative ischaemic injury to the heart and brain. Cool dialysate temperature (DT) is safe, well tolerated and acutely protects against HD induced cardiac stunning. This study aimed to evaluate the use of DT (with conventional thrice-weekly HD) to provide neuro and cardio-protection.

**Methods:** 49 incident HD patients were randomized (1:1) to receive either conventional HD or DT (-0.5°C below tympanic temperature). Study duration was 12 months. Patients underwent cardiac MR and Diffusion Tensor MR Imaging of the brain to assess white matter (WM) ultrastructural injury (with neurocognitive testing) at baseline and 12 months.

**Results:** At baseline, HD patients exhibited significant diffuse WM damage, well correlated with degree of neurocognitive impairment. DT resulted in significantly better haemodynamic response to HD, c.f. control treatment. Voxel based tract base spatial statistics (TBSS) analysis demonstrated progression of diffuse sub-acute changes in the brain WM (higher fractional anisotropy (FA) and lower diffusivity values p<0.05) -exclusively in the control group. DT provided protection against further brain injury. Axial diffusivity (AD) and radial diffusivity (RD) were computed separately from the eigenvalues of the diffusion tensor. The prospective changes were exclusively in radial diffusivity, a pattern pathognomonic of ischaemic injury. There was also evidence of cardio-protection, with DT being associated with a preserved pattern of segmental function and significant effects on changes in left ventricular mass (Control-LVMI increased by 3 ±14g/m$^2$, DT-reduced by 6 ±11 g/m$^2$, P=0.04).

**Conclusions:** HD results in functionally significant brain and cardiac injury. Dialysate cooling is well tolerated and effectively abrogates these effects. This intervention can be delivered without additional cost and is universally applicable. This study justifies further larger scale testing of dialysis based interventions (directed at iatrogenic HD induced organ injury).

*Funding:* Government Support - Non-U.S.

## SA-PO1084

**A Randomized Controlled Multicenter Trial of a Heparin-Grafted Polyacrylonitrile Membrane for No-Heparin Hemodialysis versus Standard-of-Care: Results of the HepZero Study**

Maurice Laville,[1] Marc Dorval,[2] Joan Fort,[3] Renaud Fay,[5] Frederique Moureau,[4] Nathalie Loughraieb,[4] Patrick Rossignol.[5] *[1]Nephrology Department, Lyon-Sud Hospital Centre, Lyon University, Lyon, France; [2]Dr-Georges-L.-Dumont University Hospital Centre, Moncton, Nouveau-Brunswick, Canada; [3]Nephrology Department, University Hospital Vall d'Hebron, Autonomous University of Barcelona, Spain; [4]Gambro-Hospal, Meyzieu, France; [5]Nancy-University Hospital, Lorraine University & ALTIR, Nancy, France.*

**Background:** Heparin is used in most patients on maintenance hemodialysis (MHD), but no-heparin HD (NH-HD) is occasionally needed to decrease bleeding risk. A new dialyzer, (Evodial®, Gambro-Hospal, Meyzieu, France) contains a heparin-grafted polyacrylonitrile membrane (HGPM) and may allow safe and efficient NH-HD.

**Methods:** The HepZero study NCT01318486 is the first large randomized controlled trial comparing no-heparin strategies. This multicenter international open-label trial was designed to demonstrate non inferiority (ultimately superiority if demonstrated) in two parallel groups comprising 251 MHD patients requiring NH-HD. Patients were randomly allocated for up to three NH-HD sessions, to be treated with either HGPM, or standard-of-care (Controls) including regular saline flushes or on-line predilution. The first NH-HD session was considered successful when there was neither complete occlusion of air traps or dialyzer; nor additional saline flushes, changes of dialyzer or bloodlines, or premature termination.

**Results:** It is found that current standard-of-care results in high failure rates (50%). Success rate in the HGPM arm was higher than in Controls (68.5% vs. 50.4 %, p = 0.003), consistent for all standard-of-care modalities. Absolute HGPM vs Controls arms difference was 18.2%, with a lower bound of the one-tailed 95% confidence interval (O-T, 95% CI) equal to + 10%. Hypothesis of the non-inferiority at 15%-level was accepted, although superiority at the 15%-level was not reached.

**Conclusions:** Hence, HGPM achieves 18% higher successful anticoagulation-free HD session compared to both saline flushes and on-line pre-dilution, and is shown to be firmly non-inferior to standard-of-care.

## SA-PO1085

**A Two-Part Trial of Patiromer for the Treatment of Hyperkalemia in Chronic Kidney Disease Subjects on Renin Angiotensin Aldosterone System Inhibition**

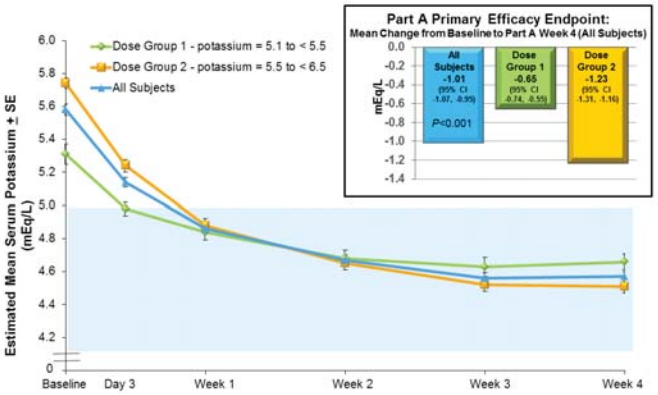
Matthew R. Weir,[1] George L. Bakris,[2] Martha Mayo,[3] Yuri Stasiv,[3] Heidi Christ-Schmidt,[4] Janet Wittes,[4] Lance Berman.[3] *[1]University of Maryland; [2]University of Chicago Medicine; [3]Relypsa; [4]Statistics Collaborative.*

**Background:** Hyperkalemia (HK) affects patients with chronic kidney disease (CKD), especially when treated with renin angiotensin aldosterone system inhibitors (RAASi). Patiromer (RLY5016), a novel ion exchange polymer with good gastrointestinal tolerability, lowered serum potassium ($K^+$) with daily administration in clinical trials. This multicenter international study in 243 hyperkalemic subjects with an eGFR 15 to < 60 mL/min/1.73m$^2$ with/without diabetes and on RAASi medication, was a two-part Phase 3 study: Part A, the 4-week single-blind treatment study, assessed patiromer for the treatment of HK; Part B, the 8-week placebo-controlled randomized withdrawal study, assessed whether chronic treatment with patiromer prevented recurrent HK.

**Methods:** Two subgroups were defined by screening serum $K^+$: 5.1 to < 5.5 (n=92) and 5.5 to < 6.5 mEq/L (n=151). The Part A primary outcome was change in serum $K^+$ from Part A Baseline to Part A Week 4 (all subjects). The Part B primary outcome was the between group difference in the change in serum $K^+$ from Part B Baseline to Part B Week 4. Secondary outcomes included the proportion of subjects with a serum $K^+$ in the target range at Part A Week 4 and the proportion of subjects with recurrent HK in Part B. An additional outcome was the proportion of subjects with modified RAASi treatment due to recurring HK.

**Results:**

**Underline represents presenting author/disclosure.**



*Final presentation will include population characteristics; Part B endpoints and safety data.

The proportion of subjects with a serum $K^+$ in the target range (3.8 to < 5.1 mEq/L) at Part A Week 4 was 76% (95% CI 70, 81).

**Conclusions:** Results from Part A demonstrate the efficacy of patiromer in treating HK.

*Funding:* Pharmaceutical Company Support - Relypsa, Inc.

## SA-O1086

**Effects of Atorvastatin on Renal Function in Patients with Dyslipidemia and Chronic Kidney Disease: ASsessment of Clinical Usefulness in CKD Patients with Atorvastatin (ASUCA) Trial** Genjiro Kimura,[1] Kenji Ueshima,[2] Masato Kasahara,[2] Sachiko Tanaka,[2] Shinji Yasuno,[2] Akira Fujimoto,[2] Tosiya Sato,[3] Shinji Kosugi,[4] Kazuwa Nakao.[5] *[1]Asahi Rosai Hospital, Owariasahi, Japan; [2]Department of EBM Research, Institute of Advancement of Clinical and Translational Science, Kyoto University Hospital, Kyoto, Japan; [3]Department of Biostatistics, Kyoto University School of Public Health, Kyoto, Japan; [4]Department of Medical Ethics/Medical Genetics, Kyoto University School of Public Health, Kyoto, Japan; [5]Medical Innovation Center, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

**Background:** The effects of a strong statin, atorvastatin, on renal function was examined in patients with dyslipidemia and CKD.

**Methods:** The ASUCA trial was a prospective, multi-center, open-labeled, randomized study to compare the reno-protective effects between lipid-lowering agents other than statins (control group, Group C) and atorvastatin (atorvastatin group, Group A) under diet therapy in 349 patients with dyslipidemia (LDL-C □ 100 mg/dL in subjects taking lipid-lowering agents other than statins or □ 140 mg/dL) and CKD (eGFR < 60 mL/min/1.73m$^2$). Target of LDL-C was less than 100 mg/dL. The primary endpoint was the change in eGFR after 2 years of treatment.

**Results:** The patients were randomly assigned to either Group C or A, and the FAS population consisted of 166 patients in Group C and 168 patients in Group A (mean age: 63.1 vs 63.2 y.o.; mean LDL-C: 145.9 vs 142.2 mg/dL; median urinary albumin/creatinine ratio: 29.1 vs 24.9 mg/gCr, respectively). LDL-C was significantly reduced in Group A compared with Group C. Changes in mean eGFR were -2.6 mL/min/1.73m$^2$ (from 54.4 to 51.9) in Group C and -2.3 mL/min/1.73m$^2$ (from 56.2 to 53.9) in Group A, showing no difference between the two groups (P=0.85). Similarly, the changes in albuminuria were not different.

**Conclusions:** The ASUCA trial indicates no significant difference between atorvastatin and non-statin in the effect on renal function after 2 years of treatment in patients with dyslipidemia and CKD.

*Funding:* Pharmaceutical Company Support - The ASUCA trial was funded by EBM Research Center, Kyoto University Graduate School of Medicine with an unrestricted grant from Pfizer Co., LTD.

## SA-PO1087

**A Randomised, Placebo-Controlled Trial of Oxpentifylline on Erythropoiesis Stimulating Agent Resistance in Anemic Patients with Chronic Kidney Disease: The HERO Trial** Sunil V. Badve.[1,2] *[1]Nephrology, Princess Alexandra Hospital, Brisbane, QLD, Australia; [2]The Australasian Kidney Trials Network, Brisbane, QLD, Australia.*

**Background:** Erythropoiesis stimulating agent (ESA)-resistant anemia is common in chronic kidney disease (CKD) and associated with increased risks of hospitalization, cardiovascular events and mortality. Oxpentifylline shows promise as a treatment for ESA-resistant anemia but has not been rigorously evaluated.

**Methods:** In this multi-centre, prospective, double-blind, randomised, placebo-controlled trial, adult patients with stage 4 or 5 CKD, and ESA-resistant anemia (defined as hemoglobin [Hb] concentration □120 g/L and ESA resistance index [ERI] □1.0 IU/kg/week/g Hb for erythropoietin-treated patients and □0.005 mg/kg/week/g Hb for darbepoeitin-treated patients), were randomized to oxpentifylline (400 mg daily; N=26) or matching placebo (control N=27) for 4 months. The primary outcome was ERI. Secondary outcomes were Hb concentration, ESA dosage, iron stores, blood transfusion requirement, adverse events, costs and quality of life.

**Results:** ERI was not significantly different between the two groups, although the mean value was 15% lower in oxpentifylline-treated patients (adjusted mean difference -0.39 IU/kg/g, 95% CI -0.89 to 0.10, p=0.12). Hb concentrations were significantly increased in the oxpentifylline group (mean difference 7.6 g/L, 95% CI 1.7 to 13.5, p=0.01), despite no significant change in ESA dosage (-20.8 IU/kg/week, 95% CI -67.2 to 25.7, p=0.37). No interaction was observed for treatment group by C-reactive protein sub-group. No differences were observed between the two groups with respect to blood transfusion requirements or adverse events.

**Conclusions:** Oxpentifylline did not significantly modify ESA resistance, but did safely increase Hb concentration without a change in ESA dosage. Oxpentifylline offers a method by which Hb concentration can be increased in ESA-resistant anaemia without needing to increase ESA dose.

*Funding:* Pharmaceutical Company Support - Roche Foundation for Anaemia Research (RoFAR), Amgen, Janssen-Cilag, Government Support - Non-U.S.

## SA-PO1089

**Risk and Severity of Hyperkalemia with Combined Angiotensin Antagonism in Diabetic Nephropathy – The VA-NEPHROND Study** Stephen L. Seliger,[1] Jane Hongyuan Zhang,[4] Nicholas Emanuele,[3] Paul M. Palevsky,[2] Linda F. Fried.[2] *[1]Medicine, Baltimore VA, Baltimore, MD; [2]Medicine, Pittsburgh VA, Pittsburgh, MD; [3]Medicine, Hines VA, Hines, IL; [4]Coordinating Ctr, VA Co-Operative Studies, West Haven, CT.*

**Background:** Greater angiotensin antagonism may increase the risk of hyperkalemia in renal disease. Few studies have compared the risk and severity of hyperkalemia with dual-angiotensin antagonism in diabetic nephropathy patients.

**Methods:** We performed a secondary analysis of the VA-NEPHROND study, a randomized clinical trial comparing losartan monotherapy to losartan + lisinopril combination therapy in patients with type 2 diabetes, overt albuminuria, and stage 2-3 CKD. Hyperkalemia was a pre-specified safety outcome defined as a potassium>6 mEq/L or requiring emergency care or dialysis. Cox survival regression was used to identify factors predictive of hyperkalemia, and to test for interaction between treatment group and clinical factors. Severity and management of hyperkalemia was compared between the groups.

**Results:** Among 1448 participants, there were 104 with hyperkalemic events over a median 2.2 years. Those randomized to losartan+lisinopril had a 177% greater risk of hyperkalemia (HR=2.77, 95%CI=1.79, 4.28). This excess risk from combination therapy was not modified by race, baseline potassium, heart failure, use of diuretics, albuminuria, eGFR, use of insulin, or HbA1C (p>0.2 for all tests of interaction). Among all participants, other factors associated with hyperkalemia were initial eGFR (per mL/min/1.73m$^2$: HR=0.97, p<.001) and initial potassium concentration (per 1-mEq/L increment, HR=3.78, p<.001). Among hyperkalemic cases, the losartan + lisinopril group had higher peak potassium (6.60±0.50 vs. 6.33±0.56 mEq/L, p=0.017), were more likely to be referred for emergency care (69% vs. 50%, p=.057), to be treated with IV calcium (25% vs. 9.4%, p=.07) and insulin (34.7% vs. 15.6% p=.047), and to have study medications permanently discontinued (40.4% vs. 18.8%, p=.033).

**Conclusions:** Dual angiotensin antagonism in overt diabetic nephropathy markedly increases both the risk and severity of hyperkalemia, and this excess risk is similar regardless of renal function, co-morbdiity, initial potassium and concurrent diuretic use.

*Funding:* Veterans Administration Support

## SA-PO1090

**A Comparison of Short-Term Exposure of Once-Daily Extended Release Tacrolimus (Advagraf®) and Twice-Daily Tacrolimus (Prograf®) on 24 Hour Renal Hemodynamics and Function in Healthy Volunteers** David Cherney, Jeffrey S. Zaltzman. *University of Toronto.*

**Background:** Calcineurin inhibitor (CNI) nephrotoxicity remains an ongoing concern in organ transplant recipients, however the pathophysiology of this nephrotoxicity is unclear. Previous studies have demonstrated that after administration of Neoral® there is a strong correlation between $C_{max}$ and decreases in renal perfusion and GFR, possibly contributing to long-term nephrotoxicity. This response is attenuated with both tacrolimus formulations, the twice-daily Prograf®(P) and the once daily Advagraf®(A), the latter demonstrating similar $AUC_{24}$, but a different PK profile, with a lower $C_{max}$ and no second peak.

**Methods:** Healthy, normotensive, adult male volunteers (n=19) were randomized to receive once daily A and twice daily P in a prospective, randomized, open label, cross over design. Baseline and drug studies included 24 hr effective renal plasma flow (ERPF), and 24 hr GFR by PAH and inulin clearances. Renal blood flow (RBF), filtration fraction (FF) and renal vascular resistance (RVR) were then calculated and all measurements were repeated over a number of time points throughout the 24 hour period. Tacrolimus dosing was initiated at 0.15 mg/kg/d with TDMs titrated to [$C_0$] of 8-12 ng/ml. All studies were repeated on day 10 and 20 of A/P or P/A.

**Underline represents presenting author/disclosure.**

**Results:** Despite similar CNI exposure, RBF remained higher in the Advagraf versus the Prograf phase of the trial (p=0.037, Table 1).

| | Baseline | Prograf | Advagraf |
|---|---|---|---|
| [Co]ng/ml | - | 11.3±1.8 | 10.9±2.2 |
| AUC (24 hour*mg/ml/1.73m2) | - | 385±79 | 410±66 |
| ERPF (24 hour*ml/min/1.73m2) | 14468±1648 | 14544±2125 | 15761±2985* |
| RBF (24 hour*ml/min/1.73m2) | 24834±3037 | 24306±2987 | 26506±4703** |
| GFR (24 hour*ml/min/1.73m2) | 2625±202 | 2598±217 | 2751±327 |
| FF (24 hour) | 4.4±0.4 | 4.4±0.7 | 4.3±0.8 |
| RVR (24 hour*mmHg/L/min/1.73m2) | 2.03±0.33 | 2.11±0.41 | 1.96±0.46 |

* p=0.046, **p=0.037 for advagraf vs prograf

**Conclusions:** Renal hemodynamic effects characteristic of CNI are attenuated with Advagraf® compared to Prograf®, which may correlate with the differing PK profile of these CNIs. Possible explanations for apparent improvements over baseline are being investigated.

*Funding:* Pharmaceutical Company Support - Astellas

## SA-PO1091

**Changes in Cardiac Structure and Function after Revascularization versus Medical Therapy for Renal Artery Stenosis: The ASTRAL Heart Echocardiography Sub-Study** Darren Green,[1] Natalie Ives,[2] Kelly Handley,[2] Philip A. Kalra.[1] *[1]Salford Royal Hospital, United Kingdom; [2]University of Birmingham, United Kingdom.*

**Background:** The ASTRAL trial showed no difference in clinical outcomes between medical therapy and revascularization for atherosclerotic renal vascular disease (ARVD). Here we report a sub-study using echocardiography to assess differences in cardiac structure and function at 12 months.

**Methods:** ASTRAL patients from 7 participating centres underwent echocardiography at baseline and 12 months after randomization. Changes (mean ± standard deviation) in left ventricular ejection fraction (LVEF), left ventricular mass (LVM), left atrial diameter (LAD), aortic root diameter (AoRD), E:A and E deceleration time (EDT) were compared between study arms.

**Results:** 92 patients were included (50 medical vs 42 revascularization). There were no statistical differences in baseline co-morbidities and clinical characteristics between the groups (mean age 71 vs 70 years, eGFR 43 vs 45mL/min, systolic blood pressure 152 vs 146 mmHg, number of antihypertensives 3.0 vs 2.9) except that more medical patients were on a statin (93% versus 76%, p=0.03).

Echocardiography showed no statistical difference between arms in any echocardiographic parameter at baseline (LVEF medical 54±11% vs revasc 54±9%, LVM 203±37g vs 202±34g, LAD 3.8±0.5cm vs 3.9±0.5cm). Change in LVEF at 12 months was greater in medical patients: ΔLVEF medical 0.8±8.7% vs revasc -2.8±6.8% (p=0.049). In a multivariate model including age, blood pressure, renal function, degree of stenosis, beta blockade and ACE-inhibitor use this was no longer significant. There were no significant differences between arms for: ΔLVM -2.9±33.1 vs -1.7±38.9g, ΔLAD 0.1±0.4 vs 0.01±0.5cm, ΔAoRD 0.002±0.3 vs 0.1±0.3cm, ΔE:A 0.0±0.6 vs 0.03±0.7, ΔEDT -1.1±55.5 vs -9.0±70.2ms.

**Conclusions:** This sub-study did not show any significant differences in cardiac structure and function accompanying renal revascularization in ASTRAL. Limitations include sample size, relative insensitivity of echocardiography, as well as clinical heterogeneity of the patient population as described in the main study.

This abstract is presented by the authors on behalf of the ASTRAL Heart Collaborators.

## SA-PO1092

**Four-Week Safety, Efficacy and Pharmacodynamic Study of Hypoxia-Inducible Factor (HIF)-Prolyl Hydroxylase Inhibitor GSK1278863 in Anemic Hemodialysis Subjects Switching from Recombinant Human Erythropoietin** Amy M. Meadowcroft, Louis Holdstock, Rayma Maier, Delyth Jones, Brendan Johnson, Alexander Ralph Cobitz, John J. Lepore. *GlaxoSmithKline, Research Triangle Park, NC.*

**Background:** Hypoxia inducible factor (HIF)-prolyl hydroxylase inhibitors (PHIs), such as GSK1278863, are an emerging class of oral agents for treatment of chronic kidney disease (CKD) anemia. PHIs inhibit HIF-prolyl hydroxylases, resulting in accumulation of HIFα transcription factor, thus stimulating pathways activated during hypoxia, including erythropoiesis and iron mobilization.

**Methods:** This 4-week, randomized, blinded (with respect to GSK1278863 dose), active-controlled study examined the relationship between GSK1278863 dose and hemoglobin (Hgb) level in 83 hemodialysis-dependent (HDD) subjects with anemia of CKD previously receiving a stable dose of recombinant human erythropoietin (rhEPO). Effects of GSK1278863 on circulating levels of erythropoietin (EPO) and vascular endothelial growth factor (VEGF) were also explored. Subjects with a stable baseline Hgb of 9.5-12.0g/dL were randomized to stop rhEPO and receive once daily 0.5, 2 or 5mg GSK1278863 or to continue on rhEPO.

**Results:** Baseline Hgb (overall mean 10.8g/dL) was similar across treatment groups. Switching from rhEPO to 5 mg GSK1278863 had a similar effect on Hgb as continuing rhEPO, maintaining stable Hgb over 4 weeks (mean change from baseline at Week 4: 5mg: -0.08g/dL; rhEPO: -0.25g/dL), whereas switching to 0.5 or 2 mg GSK1278863 resulted in a decline in Hgb (0.5mg: -1.06g/dL; 2mg: -0.93g/dL). The maximum observed circulating EPO levels with GSK1278863 were markedly lower than those in the rhEPO group (0.5mg: 13.9U/L, 2mg: 12.7U/L; 5mg: 24.7U/L; rhEPO: 424.9U/L). No significant change in VEGF was observed in any group. GSK1278863 was safe and well tolerated.

**Conclusions:** These data inform the Hgb dose-response relationship of GSK1278863 in anemic HDD subjects after being switched from a stable dose of rhEPO and demonstrate that GSK1278863 can maintain Hgb with minimal effects on EPO levels and without significantly elevating VEGF.

## SA-PO1093

**Randomized Controlled Trial on the Effects of a Six-Month Intradialytic Physical ACTIvity Program and Adequate NUTritional Support on Protein-Energy Wasting, Physical Functioning and Quality of Life in Chronic Hemodialysis Patients ACTINUT** Dan Hristea,[1] Anne Paris,[1] Justine Magnard,[2] Thibault Deschamps.[2] *[1]Dialysis, ECHO, Nantes, France; [2]STAPS, Nantes, France.*

**Background:** The aim of this randomized controlled trial was to investigate the effects of a six-month intra-dialytic physical ACTIvity program and adequate NUTritional support on protein-energy wasting (PEW), physical functioning and quality of life in chronic hemodialysis patients.

**Methods:** 210 patients of 2 dialysis units in Nantes, France were screened for the presence of PEW according to criteria of the ISRNM. 20 Patients were randomized in an exercise and nutrition group (Ex +N) or nutrition only group (N). In both groups the prescription of nutritional supplements (oral or IV) were adapted according to the dietary record in order to attain goals set by the European guidelines for nutrition in terms of protein and energy intake. In addition in EX+N group patients a 6-months progressive submaximal intra-dialytic cycling exercise program was conducted. Primary outcome was to compare the number of patients having reached remission of PEW in N+EX vs. N group at 6 months.

**Results:** 20 patients (11 men) were randomized. Mean age was 70. 9 years (range 52 – 89) in Ex+ N and 63.6 (50-92) in N group.

Preliminary results at 2 months:

No serious adverse effects occurred. No significant effect on nutritional (albumin, prealbumin) or anthropometric parameters (lean body mass measured by bioimpedance spectroscopy, body mass index) could be observed in the two groups. Performance in the six-minute walk test increased in N+EX group from (217 ± 102.92 *vs* 257.75 ± 83.37 meters; p=0.04) and tended to decrease in N group. Moreover a significant increase of the Physical (PCS)(+26.27% ; p=0.005) and Mental (+ 22.64% ) Component Scale of the SF-36 was observed in N+EX patients while N patients had a significant decrease of PCS (-18.14% ; p=0.01).

**Conclusions:** Combining intradialytic exercise and nutritional support is safe and increases significantly physical performances and quality of life in malnourished frail dialysis patients. The successful completion of this current trial may give precious clues about the potential of exercise in the treatment of PEW.

## SA-PO1094

**The Pharmacokinetics of Laquinimod and Mycophenolate Mofetil during Treatment of Active Lupus Nephritis** David R.W. Jayne,[1] Gerald B. Appel,[2] Daniel Tak Mao Chan,[3] Dorit Mimrod,[4] Ofer Spiegelstein,[4] Hadas Barkay,[4] Roberta Weiss,[5] David Wofsy.[6] *[1]Addenbrooke's Hospital, London, United Kingdom; [2]Columbia University, New York, New York; [3]University of Hong Kong, Hong Kong; [4]Teva Pharmaceuticals, Netanya, Israel; [5]Teva Pharmaceuticals, Frazer, PA; [6]University of California at San Francisco, San Francisco, CA.*

**Background:** A recently completed phase 2a trial evaluated the safety, tolerability & clinical effect of two doses of laquinimod (LAQ, 0.5mg and 1.0mg) vs. placebo in patients with active Lupus Nephritis (LN) receiving mycophenolate mofetil (MMF) and corticosteroids. Although the trial was not powered to conclusively assess efficacy, percent change from baseline to week 24 suggest possible improvement in eGFR (placebo vs. 0.5mg vs. 1mg LAQ: 12.1±20.2 vs. 18.0±30.7 vs. 24.3±28.8), and 24-h UPCR (-23.1±74.7 vs. -49.0±62.1 vs. -46.7±37.0, respectively). There was no difference between treatment groups in frequency of AEs or SAEs. Here, we describe analyses between renal function and the PK of LAQ in patients with active LN and the influence of LAQ on the PK of MMF.

**Methods:** Patients with active LN were randomized to 24 wk treatment with LAQ 0.5mg/day (n=16), LAQ 1mg/day (n=15), or placebo (n=15). Plasma levels of LAQ and MPA (mycophenolic acid) were obtained at week 4.

**Results:** LAQ exposure in LN patients was similar to previously observed values in multiple sclerosis patients. No meaningful change of LAQ PK parameters (Cmax, Cmin, $AUC_{0-24}$) was seen across renal function categories (6 patients normal renal function; 9 mild renal insufficiency, 9 moderate, and 5 severe). Plasma MPA exposure (mean±SD of Cmax [μg/mL], Cmin [μg/mL], and $AUC_{0-12}$ [h*μg/mL]) was similar in placebo (12.5±5.4, 2.50±2.5, 38.6±19.3) and LAQ-treated patients at doses of 0.5mg (12.9±6.7, 3.24±5.2, 36.7±15.7) and 1.0mg (13.0±9.5, 2.67±2.0, 42.7±19.6), respectively.

**Conclusions:** Laquinimod pharmacokinetics was not affected by renal insufficiency nor altered by the co-administration of MMF. MMF pharmacokinetics was unchanged in the presence of LAQ, suggesting that LAQ can be safely given with MMF and corticosteroids for treating patients with active LN without requiring dose modification.

## Universal Prophylaxis for Cytomegalovirus in Pediatric Kidney Transplantation in Developing Country: Medellin, Colombia

Liliana Rubio, Jorge Henao, Joaquin Rodelo Ceballos. *Pediatric Nephrology, Hospital Universitario San Vicente Fundacion, Medellin, Antioquia, Colombia.*

**Background:** Cytomegalovirus affects more than 50% of transplant recipients, is one of most common complications, including infection with opportunistic pathogens and allograft rejection.

Objetive determine the effectiveness of prophylaxis with ganciclovir and valganciclovir for 3 months in pediatric kidney transplantation in one year of follow-up because data in pediatrics are limited.

**Methods:** This prospective cohort study included 34 kidney transplant, between December 2005 and April 2013. 82,4% and 100% respectively, received iv ganciclovir, 10mg/kg/day, dose 166 mg/day during 9,5 days followed by valganciclovir, using the following formula: (mg) = 7 x body surface area ($m^2$) x creatinine clearance (mL/min per 1, 73 $m^2$) the dose was 462mg day for 99 days, adjusted for renal function.

**Results:** (71%) were males, median age was 8 years and 97% were the cadaveric origin. Most kidney transplant recipients received induction therapy with thymoglobulin (n=27) other induction therapy included basiliximab (n=7). Maintenance immunosuppression consisted of tacrolimus, prednisone plus mycophenolate; Regarding CMV antibody status, 25 patients (73,5%) were D+/R+, 4(11,7%) were D-/R+, and 5 (14,8%) were D+/R-).5,8 % patients with serology D+/R- had CMV disease and 5,8% with serology D-/R+ had CMV disease for an incidence of 11,76 % and the late- onset CMV disease was 8%, The bivariate analysis showed that the highest risk group for CMV disease was D+ R-.(p=0.05).

| Variable | | Disease n (%) | No Disease n (%) | Chi squared | Significance |
|---|---|---|---|---|---|
| IgG Donante CMV | positive | 2 (50%) | 28 93,3 % | 6,38 | 0.05 |
| | negative | 2 (50%) | 2 6,7 % | | |
| IgG receptor CMV | positiva | 2 (50%) | 27 90 % | 4,5 | 0.09 |
| | negativa | 2 (50%) | 3 10 % | | |
| Dose timoglobulin | | 2,67 DS(0,57) | 3,40 DS(0,9) | 1,34 | 0.19 |

There was no mortality or graft loss secundary to infection, either resistance and difference in creatinine in the 1 year.

**Conclusions:** The main preventive strategy against CMV in pediatric renal transplantation is the universal prophylaxis and extension to 200 days is a benefit to prevent late onset CMV disease.

## Acute Kidney Injury (AKI) Associated with Combined Angiotensin Antagonism in Patients with Diabetic Nephropathy – A Secondary Analysis of the VA NEPHRON-D Study

Paul M. Palevsky,[1] Jane Hongyuan Zhang,[2] Stephen L. Seliger,[3] Nicholas Emanuele,[4] Linda F. Fried.[1] *[1]VA Pittsburgh HCS, Pittsburgh, PA; [2]CSP Coordinating Center, VA Connecticut HCS, West Haven, CT; [3]VA Maryland HCS, Baltimore, MD; [4]Hines VAMC, Hines, IL.*

**Background:** Dual blockade of the renin-angiotensin system (RAS) is associated with an increased risk of acute kidney injury (AKI); however the etiology, severity and outcome of AKI have not been carefully evaluated.

**Methods:** We performed a secondary analysis of the VA NEPHRON-D study, a RCT comparing losartan monotherapy (MT) to losartan/lisinopril combination therapy (CT) in patients with type 2 diabetes, overt albuminuria, and stage 2-3 CKD. Data were collected on etiology, severity and outcomes of episodes of AKI. Cox regression was used to identify predictive factors and test interactions with treatment group.

**Results:** 295 episodes of AKI occurred in 210 of 1448 (14.1%) study participants; 105 in 80 MT patients (6.7 events/100 person-years) and 190 in 130 CT patients (12.2 events/100 person-years; p<0.001). The maximal serum creatinine was <2x baseline in 54.4% of episodes in MT and 57.6% of episodes in CT (p=0.18); 12 episodes required dialysis in MT and 17 in CT. AKI was attributed to prerenal azotemia in 73.1% and 76.3%, respectively, and to ATN in 24.0% and 24.7% of episodes, respectively, in MT and CT. Predictors of AKI included albuminuria >1 g/g creatinine, lower baseline eGFR, and treatment group. Recovery of kidney function was similar in both arms, although mortality after AKI was higher in MT patients (15.0% vs. 4.7%; p=0.009). Patients who developed AKI were more likely to progress to the primary study endpoint of death, ESRD or CKD progression (HR: 1.78; 95% CI: 1.34-2.36; p<0.001). Among patients with AKI, the hazard for the endpoint was lower with CT than MT (HR: 0.60; 95% CI: 0.37-0.98; p=0.04).

**Conclusions:** Dual blockade of the RAS increases the risk but not the severity of AKI in patients with overt diabetic nephropathy as compared to monotherapy. Although the hazard for death, ESRD or CKD progression was higher in patients on monotherapy who developed AKI, the higher frequency of AKI in the combination therapy arm may have attenuated its potential benefit on progression of CKD.
