**Results:** GSK3β physically interacted with microtubule associated proteins tau and CRMP2 in podocytes *in vivo* and *in vitro*. Of note, both tau and CRMP2 possess multiple GSK3β phosphorylation consensus motifs, denoting a GSK3β directed phosphorylation and activity control. Ectopic expression of a constitutively active mutant of GSK3β induced hyperphosphorylation of tau and CRMP2, concomitant with microtubule depolymerization, cell body shrinkage and shortening of podocyte projections, reminiscent of the effect of adriamycin injury, which amplified GSK3β activity. Conversely, overexpression of a kinase dead mutant of GSK3β suppressed phosphorylation of tau and CRMP2, accompanied with enhanced microtubule polymerization, cell body extension and thickening and lengthening of podocyte processes. Lithium, a selective inhibitor of GSK3β, abrogated adrimycin-induced hyperphosphorylation of tau and CRMP2, improved microtubule stability and normalized podocyte shape. In adriamycin injured mice, delayed lithium therapy prominently attenuated proteinuria and glomerulosclerosis, associated with thickening and elongation of podocyte primary processes but no podocyte replenishment. Mechanistically, lithium inhibited GSK3β activity in injured glomeruli and abrogated adriamycin induced hyperphosphorylation of tau and CRMP2 in podocytes.

**Conclusions:** Therapeutic targeting of GSK3β improves podocyte microtubule integrity, reinforces the compensatory adaptation to podocyte loss and attenuates proteinuria and glomerulosclerosis.

### Podocytes Exhibit a Specialized Protein Quality Control Employing Derlin-2

Guohui Ren, Mehmet M. Altintas, Jochen Reiser. *Dept of Medicine, Rush Univ Medical Center, Chicago, IL.*

**Background:** Protein quality control in endoplasmic reticulum (ER) may be particularly important for podocytes, highly differentiated cells, upon ER stress induction caused by substances passing the filtration barrier. Derlin-2, a target of the inositol-requiring enzyme 1 (IRE1) branch of unfolded protein response (UPR), is a key player in protein quality control.

**Methods:** Derlin-2 floxed mice were crossed with Podocin-Cre mice to generate podocyte-specific Derlin-2 knockout mice; Podocin-Cre$^-$ littermates were served as controls. Adriamycin (ADR, 20 mg/kg body wt) was injected via tail vein. Lentivirus containing a shRNA targeting Derlin-2 gene was transduced to cultured conditionally immortalized mouse podocytes. A virus containing a scrambled shRNA construct served as a control. Lentiviral transduced, differentiated podocytes were treated with ADR (0.1 μg/ml).

**Results:** Derlin-2 is expressed in podocytes in vivo and in vitro. Podocyte-specific Derlin-2 knockout mice developed significant albuminuria, peak at Day 21 (4836.9±2055.0 vs. 49.3±28.5 mg/g creatinine in control mice) after ADR administration, and foot process effacement.

Cultured podocytes with lentiviral knock down of Derlin-2 were indistinguishable from control cells in cell morphology and survival, however, were highly sensitized to ADR. Derlin-2 knockdown podocytes were increasingly retracted and detached after ADR treatment for 24 hours, and at day 5 only 61.4±6.4% cells were alive compared with control cells ($P<0.001$). After 24-72 hours of exposure to ADR, the expression of ER stress sensors (IRE1, GRP 94) was upregulated by 28~201%, while podocyte markers including synaptopodin, nephrin and CD2AP were downregulated by 21~72% in Derlin-2 knockdown podocytes compared to control cells.

**Conclusions:** Derlin-2 is expressed in podocytes. Derlin-2 is required in maintaining resistance of mouse podocytes to ER stress inducers such as ADR, and is hypothesized to provide essential protection to podocytes under stress by regulating UPR.

### SMPDL3b Expression Determines Differential suPAR-Mediated Podocyte Injury in FSGS and DKD

Tae-Hyun Yoo,[1,2] Johanna Guzman,[1] Alla Mitrofanova,[1] Changli Wei,[3] Rodrigo Villarreal,[1] Christopher E. Pedigo,[1] Mayrin Correa-medina,[1] Christian Faul,[1] Jochen Reiser,[3] George William Burke,[1] Matthias Kretzler,[4] Markku Lehto,[5] Per-Henrik Groop,[6] Sandra M. Merscher-Gomez,[1] Alessia Fornoni.[1] *[1]Univ of Miami; [2]Yonsei Univ College of Medicine; [3]Rush Univ; [4]Univ of Michigan; [5]Helsinki Univ Central Hospital.*

**Background:** Podocyte injury is an important feature of diabetic kidney disease(DKD) and focal segmental glomerulosclerosis(FSGS). Increased soluble urokinase receptor(suPAR), lipid-dependent podocyte αvβ3 integrin activation, and decreased glomerular sphingomyelinphosphodiesterase like 3b(SMPDL3b)/acid sphingomyelinase(ASMase) occur in patients with recurrent FSGS.

**Methods:** We hypothesized that both increased suPAR and decreased SMPDL3b are necessary to cause podocyte injury in FSGS, and we aimed to determine if suPAR and SMPDL3b are similarly modulated in DKD.

**Results:** Our data indicate that serum suPAR levels are equally elevated in two cohorts of primary FSGS and DKD. However, while SMPDL3b expression was down-regulated in glomeruli from patients with FSGS and in FSGS sera treated human podocytes, the opposite was found for DKD. Treatment of human podocytes with FSGS sera resulted in suPAR-mediated β3 integrin activation,which was prevented by overexpression of SMPDL3b. On the contrary, treatment of human podocytes with DKD sera did not result in suPAR-mediated β3 integrin activation but caused podocyte apoptosis, which was prevented by SMPDL3b knockdown. To elucidate the role of SMPDL3b expression in β3 integrin activation, we performed competitive co-immunoprecipitation experiments. We were able to show that SMPDL3b interacts with suPAR/UPAR and prevents suPAR/β3 integrin interaction and activation. Furthermore, suPAR treatment increased cell migration and Rac 1 activity in SMPDL3b knockdown cells, but it increased apoptosis and RhoA activity in SMPDL3b overexpressing podocytes. Consistent with these in vitro data, the use of an ASMase inhibitor reduced proteinuria in diabetic animals but worsened proteinuria in animal models of FSGS.

**Conclusions:** In conclusion, the degree of SMPDL3b expression determines differential suPAR-mediated podocyte injury in FSGS and DKD.

## FR-PO886

### Serum Albumin and Associated Factors Induce Inflammatory and Stress Responses in Podocytes and Glomeruli

Shipra Agrawal,[1] Adam J. Guess,[1] Melinda A. Chanley,[1] Rainer Benndorf,[1,2] William E. Smoyer.[1,2] *[1]Center for Clinical & Translational Research, The Research Institute at Nationwide Childrens Hospital; [2]Dept of Pediatrics College of Medicine, The Ohio State Univ.*

**Background:** Albuminuria is both a hallmark and a risk factor for progressive glomerular disease and leads to increased podocyte exposure to serum albumin (SA). We hypothesized that increased SA exposure induces podocyte pro-inflammatory and stress responses with potential pathogenic roles in progressive glomerular injury.

**Methods:** Male Wistar rats received low endotoxin BSA (5 mg/g IP) daily for 5 days and proteinuria and glomerular mRNA analyzed. Also, mRNA and protein were analyzed from mouse podocytes exposed to 40 mg/ml BSA, human SA (HSA), recombinant HSA (rHSA), charcoal-treated SA and SA preparations specifically devoid of globulins, endotoxins, glycoproteins or fatty acids. Podocytes and alveolar macrophages were also treated with 1 μg/ml LPS.

**Results:** BSA-injected rats developed marked albuminuria and enhanced glomerular gene expression of COX-2, MCP-1, CXCL1 and HSP25. In podocytes, physiological BSA levels induced B7-1 and HSP70i, as well as COX-2, MCP-1, CXCL1 and HSP25. No induction of ICAM-1, MIP-2, TNFα or CXCL5 was seen in podocytes or glomeruli upon SA-overload. LPS treatment of podocytes elicited a broad pro-inflammatory response, but did not induce COX-2, MIP-2 or TNF-a, despite strongly inducing COX-2, MCP-1 and TNF-a in macrophages. COX-2, which renders podocytes susceptible to further injury, was markedly induced (~30 fold) by SA in podocytes. While BSA, HSA and globulin-, endotoxin- and glycoprotein-free SA preparations all strongly induced COX-2, rHSA, charcoal-treated SA and fatty acid-free SA only moderately induced COX-2, indicating that SA-associated factors contributed partially to COX-2 induction.

**Conclusions:** Induction of proteinuria in SA-overload rats and SA exposure of podocytes are both associated with induction of COX-2 and pro-inflammatory and stress response genes. This response appears due in part to SA-associated factors such as fatty acids that may be removable by charcoal treatment, suggesting this as a novel potential treatment to reduce progressive glomerular injury.

## FR-PO887

**Exploring the Role of Annexin A2 in the Glomerulus** Biao Li,[1] Tuncer Onay,[2] Chengjin Li,[3] Susan E. Quaggin.[4] *[1]Dept of Nephrology, Feinberg Cardiovascular Research Institute, Chicago, IL; [2]Dept of Nephrology, Feinberg Cardiovascular Research Institute, Chicago, IL; [3]Dept of Nephrology, Feinberg Cardiovascular Research Institute, Chicago, IL; [4]Dept of Nephrology, Feinberg Cardiovascular Research Institute, Chicago, IL.*

**Background:** Anxa2 (Annexin A2) is a phospholipid binding protein, which participates in a number of critical cellular processes that include specific binding to plasminogen, formation of filopodia and lamellipodia through interaction with F-actin, and acting as a capping protein for actin. Our previous studies identified Anxa2 to be involved in podocyte attachment and foot process (FP) formation triggered by soluble Flt1 (sFlt1) binding to the podocyte surface. We hypothesize that Anxa2 cooperates with sFlt1 to guide cytoskeletal changes in podocyte FP formation and maintenance.

**Methods:** We generated an Anxa2 floxed mouse line and used it to develop whole body and podocyte specific knockout (KO) mice. The stability of the FP cytoskeleton was tested by protamine sulphate perfusion of KO and WT mice followed by heparin recovery. In vitro, cell cycle and motility of human podocytes was examined, following knockdown (KD) of Anxa2 by siRNA.

**Results:** Histologic analysis did not demonstrate any major differences between Anxa2 global or podocyte -KO and control kidneys at 4 weeks of age; however, diffuse fibrin deposition was observed in glomerular capillaries of KO kidneys. Following perfusion with protamine sulphate, KO mice showed a trend towards protection. In vitro, KD of Anxa2 in human podocytes resulted in a dramatic increase in podocyte cell size, development of cytosolic stress fibers, and formation of focal adhesions. Furthermore, Anxa2 KD podocytes demonstrated a marked decrease in proliferation (Day 5, 1.33±0.12 X $10^5$ vs 2.53±0.29 X$10^5$, p=0.029). Cell cycle was arrested at G1 determined by FACS (0.7921±0.047 vs 0.7097±0.048, p=0.001). Cell motility was also decreased.

**Conclusions:** Loss of Anxa2 appears to confer stability to podocyte FPs when acutely challenged. Further studies are ongoing to determine how Anxa2 regulates podocyte adhesion, FP formation and function.

## FR-PO888

**Mutual Antagonism of WT1 and β-Catenin Dictates Podocyte Health and Disease** Li Li Zhou,[1] Roderick J. Tan,[2] Dong Zhou,[1] Youhua Liu.[1] *[1]Dept of Pathology, Univ of PIttsburgh, Pittsburgh, PA; [2]Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

**Background:** Activation of β-catenin, the principal mediator of canonical Wnt signaling, plays a critical role in mediating podocyte dedifferentiation and dysfunction in the evolution of proteinuric kidney diseases. However, the mechanism by which β-catenin induces podocyte injury remains poorly understood. Here, we demonstrate that β-catenin directly antagonizes Wilms tumor 1 (WT1), a key transcription factor exclusively expressed in podocytes and required for the maintenance of podocyte differentiation and glomerular filtration barrier function.

**Methods:** BALB/c mice and cultured podocytes were used. Expression of various genes was analyzed by qRT-PCR, Western blot and immunostaining, respectively.

**Results:** In BALB/c mice injected with adriamycin, WT1 protein was gradually lost in glomerular podocytes at 1, 3 and 5 weeks. Interestingly, loss of WT1 was apparently not due to podocyte depletion in this model, as other podocyte-specific markers including synaptopodin and α-actinin-4 were preserved. Loss of WT1 was closely associated with up-regulation of β-cateninn in podocytes, which was accompanied by loss of nephrin and acquisition of Snail1, PAI-1, Fsp1 and MMP-7. In vitro, over-expression of β-catenin suppressed WT1-mediated podocalyxin expression. Conversely, over-expression of WT1 in podocytes inhibited β-catenin-mediated Snail1 and PAI-1 expression, suggesting that WT1 and β-catenin mutually antagonize each other. We found that β-catenin induced WT1 protein degradation through the ubiquitin-proteasomal pathway, and incubation with MG-132 preserved WT1. In vivo, either inhibition of β-catenin signaling by small molecule inhibitor ICG-001 or administration of Wnt antagonist Klotho restored WT1 protein and attenuated podocyte injury and proteinuria in adriamycin nephropathy.

**Conclusions:** These findings suggest that β-catenin signaling targets WT1 degradation, leading to podocyte dedifferentiation and dysfunction. Our results also indicate that WT1 and β-catenin play an opposing role in podocyte biology and their ratio dictates podocyte health and disease in vivo.

## FR-PO889

**CLIC5A Deficiency Accentuates Glomerular Damage in DOCA/Salt Hypertensive Mice** Mahtab Tavasoli, Laiji Li, Lin-fu Zhu, Benjamin Alexander Adam, Barbara J. Ballermann. *Medicine, Univ of Alberta, Edmonton, Canada.*

**Background:** Glomerular capillary (GC) hypertension is a risk factor for glomerular injury, including diabetic nephropathy. Podocytes extend inter-digitating actin-based foot processes around the exterior of glomerular capillaries, buttressing the vessel wall against the prevailing high intra-capillary pressure. CLIC5A is highly and uniquely expressed at the apical plasma membrane (PM) of podocyte foot processes, where it is part of the Ezrin-NHERF2 complex that links podocalyxin to cortical actin, and deletion of CLIC5A in mice leads to ezrin dephosphorylation and disorganization of podocyte foot processes (*Am.J.Physiol 298:F1492, 2010*). This study explored the hypothesis that lack of CLIC5A is detrimental to glomerular integrity under conditions of increased mechanical strain.

**Methods:** Hypertension was induced in wild-type (WT) and CLIC5A deficient ($CLIC5A^{-/-}$) mice using subcutaneous slow-release deoxycorticosterone (DOCA) pellets and 1% saline drinking water (DOCA/Salt), starting 14 days after uninephrectomy (UNX). Control mice were subjected to UNX only. 20 days after initiation of DOCA/Salt treatment, blood pressure, urinary albumin (Albumin:Creatinine ratio; ACR) were determined, and kidney histology was evaluated in a blinded fashion. Data are presented as the mean ± SD.

**Results:** Compared to UNX alone, systolic blood pressure increased to a similar degree in DOCA/Salt treated WT (119±6 vs. 98.9±8 mmHg; p<0.001) and $CLIC5A^{-/-}$ (121±11.5 vs. 97±8 mmHg; p<0.001) mice. All DOCA/Salt treated mice developed a hypokalemic metabolic alkalosis. In WT and $CLIC5A^{-/-}$ mice urine albumin excretion was unaffected by UNX alone. DOCA/Salt induced albuminuria in WT and $CLICA^{-/-}$ mice. The urine albumin excretion rate was significantly higher in $CLIC5A^{-/-}$ compared to WT mice (ACR mg/g: 1,720±960 vs. 780±235; p < 0.05). Histological analysis revealed microaneurysms in a much larger proportion of glomeruli from $CLIC5^{-/-}$ mice than in WT mice (57±17.9% vs. 31±17.1%; p<0.05).

**Conclusions:** These findings suggest that CLIC5A serves to stabilize the extracapillary podocyte buttress that protects against the deleterious effects of glomerular capillary hypertension in mice.

## FR-PO890

**Lysosomal Processing of Albumin in Podocytes** John M. Carson,[1] Kayo Okamura,[1] Hidefumi Wakashiu,[2] Evgenia Dobrinskikh,[1] Jeffrey B. Kopp,[2] Judith Blaine.[1] *[1]Univ of Colorado Denver, Aurora, CO; [2]NIDDK, NIH, Bethesda, MD.*

**Background:** Albuminuria is a strong, independent predictor of CKD progression. The effect of albuminuria on podocytes is unknown. In collapsing FSGS, where albumin vacuoles in podocytes are a prominent feature, podocyte loss and glomerulosclerosis occur rapidly. In minimal change disease, albumin accumulation in podocytes is nominal and decline in renal function is gradual. We hypothesize that podocyte processing of albumin, via the lysosome, may be an important determinant of podocyte injury and loss.

**Methods:** Human urine derived podocyte-like epithelial cells (HUPEC) were used for all *in vitro* experiments. Albumin uptake was quantified by Western blot after loading HUPECs with FITC-albumin. Co-localization of albumin with lysosomes was determined by confocal microscopy. Albumin degradation was measured by quantifying FITC-albumin abundance in HUPEC lysates by Western blot. Degradation experiments were repeated in HUPECs treated with chloroquine, a lysosome inhibitor, or MG-132, a proteasome inhibitor. Lysosome activity was measured by fluorescence recovery after photobleaching. Cytokine production was measured by ELISA. Cell death was determined by Trypan blue staining. *In vivo*, staining with albumin and LAMP-1, a lysosome marker, was performed on tissue from a Denys-Drash mouse model of albuminuria.

**Results:** HUPECs endocytosed albumin which co-localized with LAMP-1. Chloroquine, but not MG-132, inhibited albumin degradation in HUPECs, indicating degradation occurs in lysosomes. Cathepsin B activity significantly decreased in HUPECs treated with albumin (12.5% of activity in controls) and chloroquine (12.8%) alone, and declined further when treated with albumin plus chloroquine combined (8.2%). Cytokine production and cell death were significantly increased in HUPECs treated with albumin and chloroquine alone, and these effects were potentiated by treatment with albumin plus chloroquine. Compared to wild-type mice, glomerular staining of albumin and LAMP-1 was increased in Denys-Drash mice and was most prominent in podocytes.

**Conclusions:** These data suggest lysosome dysfunction may contribute to podocyte injury and glomerulosclerosis in albuminuric diseases.

## FR-PO891

**Molecular Characterization of Podocyte-Endothelial Cell Signaling Crosstalk Identifies New Endothelial Cell Targets for Prevention of Glomerular Diseases** Ilse S. Daehn,[1] Gabriella Casalena,[1] Liping Yu,[1] Kerstin Ebefors,[2] Detlef O. Schlondorff,[1] Borje Haraldsson,[2] Erwin P. Bottinger.[1] *[1]Dept of Medicine - Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Molecular and Clinical Medicine - Nephrology, Institute of Medicine, Univ of Gothenburg, Gothenburg, Sweden.*

**Background:** Focal segmental glomerular sclerosis (FSGS) is characterized by progressive loss of glomerular function with proteinuria due to podocyte injury and depletion, collapse and sclerosis of glomerular capillary segments. We have previously shown that podocyte-specific TGFβ signaling in mice (PodTbrI mice) induces endothelin-1(Edn1)-mediated mitochondrial oxidative stress and dysfunction selectively in adjacent endothelial cells via Ednar activation, which precedes subsequent podocyte loss and proteinuria [Daehn et al., ASN 2011]. We have further characterized endothelial-podocyte crosstalk and confirmed the involvement of Edn1-Ednra in other models of podocyte injury.

**Results:** In the podocyte injury models: podocyte-specific dicerKO and Adriamycin-induced glomerulosclerosis we confirmed activation of TGFβ signaling in podocytes associated with mitochondrial oxidative stress and increased Ednra specifically in glomerular endothelial cells. Adriamycin treatment rapidly induced Edn1 release by podocytes, there was loss of Isolectin B4 staining associated with apoptosis and loss of fenestrae by glomerular endothelial cells. Endothelial injury provoked podocyte apoptosis and proteinuria. Selective Ednra blockade or mitochondrial-targeted ROS scavenging prevented endothelial damage and subsequent podocyte loss, albuminuria and glomerulosclerosis. Ednra knockdown in mGEC prevented mtDNA damage and mitochondrial dysfunction mediated by conditioned media with increased Edn1 from PodTbr1 podocytes. Edn1 knockdown in PodTbr1 podocytes prevented mGEC dysfunction and subsequent podocyte apoptosis in co-cultures.

**Conclusions:** Podocyte injury induces Edn1 as an essential mediator of endothelial mitochondrial stress and dysfunction that underlies proteinuric podocyte-initiated segmental glomerulosclerosis. Prevention of endothelial damage may be considered a new therapeutic approach for FSGS.

*Funding:* NIDDK Support

## FR-PO892

**$PLA_2R$ Tightly Associates with Integrin $\alpha_3\beta_1$ in the Podocyte Membrane: A New Insight into IMN Pathogenesis** Quansheng Zhu, Liyo Kao. *Medicine, Univ of California, Los Angeles, Los Angeles, CA.*

**Background:** $PLA_2R$ has been firmly established to serve as the major antigen on the podocyte surface targeted by circulating autoimmune antibodies in patients with idiopathic membranous nephropathy (IMN), however, the pathobiology of how the antibodies binding to the extracellular domain of $PLA_2R$ then cause IMN remains largely unclear. Other than serving as a scavenger receptor for inactivation and removal of the secreted phospholipase $A_2$, $PLA_2R$ was found to carry signaling functions that triggers cellular responses with an undefined mechanism. Integrin $\alpha_3\beta_1$ is a membrane adhesion receptor that is highly expressed on the basal surface of podocytes along the glomerular basement membrane (GBM), where it is critically involved in GBM matrix arrangement and podocyte intracellular cytoskeleton organization. We hypothesize that $PLA_2R$ may interact with integrin $\alpha_3\beta_1$ in the human podocytes and that autoimmune antibodies binding to $PLA_2R$ perturbs the downstream signaling pathways of both $PLA_2R$ and integrin $\alpha_3\beta_1$ resulting in thickened GBM and altered podocytes cytoskeleton organization in IMN.

**Methods:** In the present study, we tested $PLA_2R$ and integrin $\alpha_3\beta_1$ interaction in the differentiated human podocytes, the human kidney cortex and HEK 293 cells co-expressing $PLA_2R$ and integrin $\alpha_3\beta_1$ by using immunocytochemistry, co-immunoprecipitation and biochemical analysis.

**Results:** We discovered that two populations of $PLA_2R$ exist in the human podocytes: one co-localizes with integrin $\alpha_3\beta_1$ in both of the endoplasmic reticulum and the plasma membranes, and the other is free. Immunoprecipitation study using an anti-integrin $\alpha_3\beta_1$ antibody revealed that $PLA_2R$ associates with integrin $\alpha_3\beta_1$ not only in the differentiated human podocytes, but also in the human kidney cortex and the HEK 293 cells co-expressing $PLA_2R$ and integrin $\alpha_3\beta_1$ heterologously. Further analysis showed this interaction occurs in the extracellular domains between the two receptors.

**Conclusions:** Our findings demonstrated for the first time that $PLA_2R$ associates tightly with integrin $\alpha_3\beta_1$ on the podocyte surface, which may provide new insights into the pathogenic mechanism of IMN mediated by auto-immune antibodies binding to $PLA_2R$.

*Funding:* Private Foundation Support

## FR-PO893

**Glepp1 Deficency Promotes GBM Humps** Eva Koenigshausen,[1] Laura Lennartz,[1] Ivo Quack,[1] Thorsten Wiech,[2] Lars C. Rump,[1] Lorenz Sellin.[1] *[1]Nephrology, Heinrich Heine Univ, Duesseldorf, Germany; [2]Pathology, Univ Hospital Eppendorf, Hamburg, Germany.*

**Background:** Proteinuria is one of the symptoms of inherited and acquired glomerular kidney diseases. Proteinuria evolves out of the damage of the glomerular filter. One major components of the glomerular slit diaphram is nephrin, which is phosphorylated by src kinases. A loss of nephrin out of the glomerular silt, for example by endocytosis, results in proteinuria. GLEPP1 is a receptor tyrosine phosphatase in the podocyte foot process. Mutations in the GLEPP1 gene were shown to be associated with FSGS in childhhood. The precise function of GLEPP1 is not fully understood.

**Methods:** Perfused kidneys from mice were fixed in 4% paraformaldehyde or in RNA stabilization reagent. For light microscopy kidneys were embedded in paraffin for further PAS staining, or were embedded in Epon and processed for electron microscopy. RNA was isolated and qPCR for Col4 alpha1 and alpha2 was performed. Mouse urine was analyzed for albuminuria by Coomassie stain and by ELISA. Urine creatinine was measured via an ELISA kit.

**Results:** In PAS stained sections of Glepp1 deficient glomeruli in aged mice an elevated count for PAS positive thickening of the GBM is seen. In TEM sections of glomeruli the GBM of Glepp1 deficient mice presents significantly more GBM humps than the age machted wilde type control. These GBM changes in the absence of Glepp1 is observed in two Independent genetic backgrounds (129P3, Balb/c). qPCR of renal RNA shows an increased signal for type IV collagen alpha1 and alpha2 in Glepp1 deficient mice. Interestingly, the aged Glepp1 deficient mice of both strains present proteinuria.

**Conclusions:** Glepp1 deficiency mediates GBM humps. These GBM humps seem to be formed by type IV collagen alpha1 and alpha2. It can be speculated that Glepp1 deficiency switches the type IV collagen expression von alpha 3,4,5 to alpha 1 and 2. Functionally, the Glepp1 deficient aged mice with increased numbers of GBM humps present proteinuria. These findings stress the protective and beneficial role of Glepp1 in podocytes.

## FR-PO894

**Patterns of Circulating Autoantibodies in Patients with Lupus Nephritis** Dawn J. Caster,[1] Daniel J. Birmingham,[2] Ami S. Joglekar,[1] Jon B. Klein,[1,3] John Barker Harley,[4] Erik Korte,[1] Brad H. Rovin,[2] Kenneth R. McLeish,[1,3] David W. Powell.[1] *[1]Medicine, Univ of Louisville, Louisville, KY; [2]Medicine, The Ohio State Univ, Columbus, OH; [3]VAMC, Louisville, KY; [4]Pediatrics, Cincinnati Children's Hospital, Cincinnati, OH.*

**Background:** Lupus nephritis (LN) occurs in at least 50% of SLE patients, but the nephritigenic autoantibodies responsible have yet to be identified. Recently, an autoantibody to the M-type phospholipase $A_2$ receptor on podocytes was identified as causing primary membranous nephropathy using immunoblot analysis of patient sera. This study used sera from SLE patients with and without LN to test the hypothesis that patients with different classes of LN express unique patterns of autoantibodies against native glomerular proteins.

**Methods:** Human glomerular extracts were IgG depleted and separated by SDS-PAGE and immunoblotted with 1:200 dilution of sera from 16 Class V LN patients, 10 Class III/IV LN patients, 10 SLE patients without nephritis, and 5 normal controls (NC).

**Results:** A reactive band between 43-46 kDa was present in 14/16 patients with class V LN and 9/10 patients with class III/IV LN, but was seen in only 1/10 SLE patients without nephritis and 2/5 NC. A reactive band between 36-40 kDa was present in 11/16 patients with class V LN, 3/10 patients with class III/IV LN, 2/10 SLE patients without nephritis, and 1/5 NC. A reactive band between 23-28 kDa was present in 10/16 patients with class V LN, 8/10 patients with class III/IV LN, 4/10 SLE patients without nephritis, and 2/5 NC. A reactive band between 98-105 kDa was present in the majority of subjects in all groups, including NC. Using LC-MS/MS we identified 14 membrane-associated podocyte proteins, including AAMP and NCEH1 in the 43-46 kDA molecular weight range and ANXA2 in the 36-40 kDa range.

**Conclusions:** We conclude that LN patients express unique patterns of autoantibodies against native glomerular proteins that will allow identification of the targets of nephritigenic autoantibodies that cause various forms of LN.

*Funding:* Other NIH Support - NIAID; NIAMS

## FR-PO895

**Neph1 Signaling, a Novel Therapeutic Target for Protection of Podocytes against Glomerular Injury** Deepak Nihalani, Ehtesham Arif, Babita Kumari, Lawrence B. Holzman. *Medicine, Univ of Pennsylvania, Philadelphia, PA.*

**Background:** Podocytes are specialized epithelial cells that are critical components of the glomerular filtration barrier and their dysfunction leads to proteinuria and renal failure. Thus preserving podocyte function in the event of a glomerular injury is therapeutically significant.

**Methods:** We used zebrafish as an in vivo model and poocyte cell culture as an in vitro model to demonstrate that inhibiting Neph1 signaling prevents podocyte from glomerular injury.

**Results:** In this study, we show that inhibiting the intracellular signaling of Neph1 by transducing the cytoplasmic domain of Neph1 (Neph1CD) in cultured podocytes protects podocytes from PAN induced injury. In addition to inhibiting the PAN induced Neph1 phosphorylation, the Neph1CD transduced cells were resistant to PAN induced cytoskeletal damage. In an in vivo assay using zebrafish model system, we demonstrated that transduction of Neph1CD in zebrafish prevented them from PAN induced injury. Further biochemical analysis using subfractionation of the transduced and control podocyte cells showed that unlike the control cells Neph1 was retained in the lipid raft fractions in the transduced cells following treatment with PAN. In accordance, the immunofluorescence analysis suggested that Neph1CD transduced cells had increased ability to retain endogenous Neph1 at the membrane in response to PAN induced injury. Consistent with these observations, maintaining high levels of Neph1 at the membrane using a podocyte cell line overexpressing chimeric Neph1 had a similar protective effect from PAN induced injury with increased propensity to maintain tight junctions in podocytes. The albumin filtration assay further suggested that these cells were resistant to PAN induced albumin leakage.

**Conclusions:** Collectively, these results identify Neph1 signaling as a novel therapeutic target for the prevention of podocyte damage that is commonly observed in various glomerular diseases.

## FR-PO896

**Involvement of Planar Cell Polarity Pathway in Glomerular Development and Function** Brittany L. Rocque, Elena Torban. *Depts of Physiology and Medicine, McGill Univ, Montreal, Canada.*

**Background:** The Planar Cell Polarity (PCP) signaling pathway is crucial for tissue morphogenesis. Vangl2 protein is central in the PCP pathway: its loss is embryonic lethal causing neural tube defects in mice and humans. In the kidney, PCP signaling is thought to be important for the organization of glomerular epithelial cells, podocytes, along the glomerular basement membrane. Podocyte cell protrusions, foot processes (FP), are critical for kidney filtration functions; loss of FP architecture results in proteinuria and, in severe cases, focal segmental glomerulosclerosis. In our previous studies, we demonstrated an effect of PCP pathway on podocyte shape, actin rearrangement and cell motility (Babayeva, 2011, AJP). We, therefore, hypothesized that the PCP pathway is involved in glomerualar development and function.

**Methods:** Mouse embryonic kidneys were used to examine Vangl2 expression in developing glomeruli. Kidneys from *Looptail* (Vangl2) embryos and from newly generated conditional podocyte-specific Vangl2 knockout mice (Vangl2 cKO) were analyzed by histological and immunofluorescent methods. In Vangl2 cKO, ELISA was used to measure urine albumin/creatinine ratio.

**Results:** Vangl2 is dynamically expressed in developing glomeruli: in podocyte precursors, Vangl2 is expressed at the plasma membrane; as podocytes mature, it migrates to the basal side of cells where FPs extend. In mature glomeruli, Vangl2 levels are decreased. Quantification of glomeruli at various developmental stages in *Looptail* mutants vs wildtype embryos revealed a significant developmental delay in glomerular maturation in *Looptail* embryos suggesting that Vangl2 may be required for podocyte function. To examine whether loss of Vangl2 affects glomerular functions in adult animals, we created conditional podocyte-specific Vangl2 cKO mice. At 12 months, Vangl2 cKO animals do not exhibit proteinuria or signs of altered kidney morphology. An effect of podocyte injury in Vangl2 cKO vs. control mice is being currently analyzed.

**Conclusions:** During development, loss of PCP gene Vangl2 significantly affects glomerular maturation. However, it appears that Vangl2 is dispensable for the functions and maintenance of podocytes in adult mice.

**Thioredoxin-Interacting Protein Mediates hHcys-Induced NLRP3 Inflammasome Activation in Glomerular Sclerosis** Justine M. Abais,[1] Min Xia,[1] Krishna M. Boini,[1] Todd W. Gehr,[2] Pin-lan Li.[1] *[1]Pharmacology & Toxicology, Virginia Commonwealth Univ, Richmond, VA; [2]Internal Medicine, Virginia Commonwealth Univ, Richmond, VA.*

**Background:** Our studies have demonstrated that NADPH oxidase-derived reactive oxygen species activates NLRP3 inflammasomes causing hyperhomocysteinemia (hHcys)-induced podocyte and glomerular injury, but the mechanism regarding how the inflammasome senses changes in oxidative stress is still unknown. Thioredoxin-interacting protein (TXNIP) inhibits the antioxidant thioredoxin (TRX) and has been shown to dissociate from TRX, bind to inflammasome protein NLRP3, and stimulate formation of the inflammasome complex. The current study explored whether TXNIP mediates hHcys-induced NLRP3 inflammasome activation *in vivo*.

**Methods:** Adult, C57BL/6J male mice were fed a folate-free diet for 4 weeks to induce hHcys. TXNIP was inhibited by verapamil (1 mg/mL, drinking water) or by local kidney microbubble-ultrasound TXNIP shRNA transfection. *In vivo* inflammasome formation and activation was assessed by confocal microscopy, coimmunoprecipitation, and measurement of caspase-1 activity and IL-1β production. Glomerular morphology and function was determined by Periodic acid-Schiff (PAS) staining and measurement of urinary protein and albumin.

**Results:** Evidenced by immunofluorescence and coimmunoprecipitation studies, mice with hHcys had significantly increased inflammasome formation and TXNIP binding to NLRP3, which were not observed in TXNIP shRNA-transfected mice or those receiving verapamil. Importantly, hHcys increased caspase-1 activity 1.5-fold and IL-1β production 2.0-fold, signifying increased inflammasome activation, which was substantially blocked after TXNIP inhibition. *In vivo* TXNIP blockade demonstrated glomerular protective effects shown by normalized expression of podocyte markers podocin and desmin, reduced proteinuria and albuminuria, and preserved glomerular morphology through reduced mesangial cell expansion, fibrosis, and capillary collapse.

**Conclusions:** These results show that TXNIP binding to NLRP3 is a key signaling mechanism necessary for hHcys-induced NLRP3 inflammasome formation and activation, and subsequent glomerular injury.

## FR-PO898

**Dynamin Oligomerization Regulates Actin and Represents a Novel Therapeutic Target in Proteinuric Kidney Diseases** Mario Schiffer,[1,3] Changkyu Gu,[2] Beina Teng,[1] Nils Hanke,[1,3] Hermann G. Haller,[1,3] Sanja Sever.[2] *[1]Nephrology, Hannover Medical School, Hannover, Germany; [2]Medicine, Harvard Medical School, Charlestown; [3]Mount Desert Island Biolab, Salsbury Cove.*

**Background:** Misregulation of the actin cytoskeleton in podocytes represents a common pathway in the pathogenesis of proteinuric diseases in general and FSGS in particular. We previously showed that the GTPase dynamin maintains the actin cytoskeleton in podocytes by displacing the actin capping protein gelsolin from barbed ends and that dynamin downregulation underlies proteinuria.

**Methods:** We used in vitro and in vivo approaches to show that the small molecule Bis-T-23 promotes dynamin's natural propensity to oligomerize into higher order assemblies. Bis-T-23 is used in different rodent models of proteinuria and in different zebrafishmodels with gene knockdowns of known genes affecting the actin cytoskeletton of podocytes.

**Results:** We found that Bis-T-23 stimulates the actin polymerization in podocytes independently of RhoA, Rac1, and Cdc42 signaling pathways. Administration of Bis-T-23 in diverse animal models of kidney disease reverses foot process effacement, ameliorates proteinuria, attenuates glomerular scarring, and increases survival through an effect on actin dynamics.

**Conclusions:** Our results establish the dynamin oligomerization cycle as an important *in vitro* and *n vivo* regulator of actin and a therapeutic target in genetic or acquired proteinuric kidney diseases.

## FR-PO899

**Activation of XBP1 following Endoplasmic Reticulum Stress Is Essential for Podocyte Function in the Kidney** Hossam Hassan,[1] Xuefei Tian,[2] Shuta Ishibe.[2] *[1]Pediatrics, Yale Univ School of Medicine, New Haven, CT; [2]Internal Medicine, Yale Univ School of Medicine, New Haven, CT; [3]Internal Medicine, Yale Univ School of Medicine, New Haven, CT.*

**Background:** Protein misfolding in the endoplasmic reticulum (ER) leads to ER stress. To handle misfolded proteins, the ER has in place quality control mechanisms, including the unfolded protein response and ER-associated degradation (ERAD). Induction of ER stress in glomerular cells has been described in experimental models of membranous nephropathy and membranoproliferative glomerulonephritis but the physiologic relevance remains unknown. We have identified that loss of Sec63, an ER transport protein, in podocytes results in the activation of the unfolded protein response protein, IRE1α-XBP.

**Methods:** Wild type and podocyte specific SEC63 / XBP1 double knock out (DKO) mice were analyzed to determine the role of SEC63 /XBP1 in vivo and primary podocytes were isolated for in-vitro studies.

**Results:** Loss of Sec63 or XBP1 alone in podocytes did not elicit an overt phenotype. However, the loss of Sec63 and XBP1 specifically in podocytes demonstrated severe albuminuria, which began at 2-3 months of age and continued to progress when compared to wild type(84.59±3.78 vs. 66.23±2.3), 2 month (470.37±70.15vs. 79.96±2.45), 6 month (622.21±45.27 vs.71.39±1.80), 1 year (1988.79±224.98 vs.74.22±5.54). Histological examination of the podocyte specific *Sec63/XBP1 DKO* mice kidney cortex demonstrated mesangial matrix accumulation in the glomeruli, dilated tubules with proteinaceous casts, and interstitial fibrosis. Ultrastructural analysis demonstrated severe foot process effacement with a thickened glomerular basement membrane.

**Conclusions:** Our results emphasize that the loss of Sec63 in podocyte induces ER stress and activates the unfolded protein response arm, IRE1a-XBP1. Inability to respond to the ER stress in this arm, by concomitant genetic inactivation of XBP1 appears fundamentally required for the maintenance of the kidney glomerular filtration barrier.

## FR-PO900

**SIRT1 Maintains Podocyte Homeostasis via Regulation of Actin Fiber Formation** Shuta Motonishi,[1] Reiko Inagi,[1] Takehiko Wada,[1] Takamoto Ohse,[1] Akira Shimizu,[2] Masaomi Nangaku.[1] *[1]Div of Nephrology and Endocrinology, The Univ of Tokyo School of Medicine, Tokyo, Japan; [2]Dept of Pathology, Nippon Medical School, Tokyo, Japan.*

**Background:** Recent studies highlighted the renoprotective effect of SIRT1, a deacetylase that contributes to cellular regulation. However, its molecular mechanism in podocytes is still unclear. The actin cytoskeleton plays a critical role in supporting the structure and function of podocytes. We thus investigated the effect of SIRT1 on the maintenance of actin fiber in podocytes.

**Methods:** We made podocyte specific SIRT1 knockout ($SIRT1^{-/-}$) mice by crossing $SIRT1^{flox/flox}$ mice with podocin-Cre mice. Then, we induced glomerular damage by injection of sheep anti-GBM antibody in $SIRT1^{-/-}$ or wild-type mice. Measurement of urinary albumin/creatinine ratio (U-alb/cre), blood urea nitrogen (BUN), and histological analyses by PAS staining and electron microscopy were performed. In in vitro study using conditionally immortalized murine podocytes, we assessed the structural or functional changes in podocytes treated with SIRT1 inhibitor, by phalloidin staining, scratch assay, and Western blotting (WB) for actin fiber-related proteins.

**Results:** Seven days after the disease induction, both U-alb/cre and BUN in $SIRT1^{-/-}$ mice were significantly higher than those in wild-type mice (93.5±73.9 vs. 28.3±20.5 mg/mg, 26.9±3.7 vs. 22.3±3.2 mg/dl, respectively, $P<0.05$) and glomerular injury, such as crescent formation, was significantly increased in $SIRT1^{-/-}$ mice. By electron microscopy, we found that foot process effacement and actin fiber derangement were markedly exacerbated in $SIRT1^{-/-}$ mice compared with wild-type mice. Similarly, mild actin fiber derangement in $H_2O_2$-treated cultured podocytes became prominent when the cells were pretreated with SIRT1 inhibitor. Cellular motility was also reduced by SIRT1 inhibition. In WB analysis, the level of acetylated cortactin, which decays actin fiber formation, was increased in SIRT1 inhibitor-treated cells.

**Conclusions:** SIRT1 maintains podocyte homeostasis and prevents glomerular injury by deacetylated cortactin and the subsequent actin fiber formation.

## FR-PO901

**Functional Role of Sirt1 in Kidney Podocytes** Peter Y. Chuang,[1] Yan Dai,[2] Leyi Gu,[3] John C. He.[1,4] *[1]Medicine, Div of Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Medicine, Div of Nephrology, Shanghai First Affiliated Hospital, Shanghai, China; [3]Renal Div and Molecular Cell Laboratory for Kidney Disease, Renji Hospital, Shanghai Jiatong Univ School of Medicine, Shanghai, China; [4]Renal Div, James J Peters Veterans Affairs Medical Center, Bronx, NY.*

**Background:** The silent mating type information regulation 2 homolog (SIRT) 1 gene encodes for a $NAD^+$-dependent lysine deacetylase. *SIRT1* is expressed in kidney podocytes, but Sirt1's function in the podocyte has not been examined in detail.

**Methods:** *Sirt1* knockout mice exhibit developmental defects in multiple organs and a shorten lifespan, which hinder the examination of *Sirt1* in adult mice and could potentially confound the interpretation of *Sirt1* function. To study *Sirt1* function in podocytes we created two lines of mice with doxycyline (DOX)-inducible and reversible knockdown of

*Sirt1* by adapting a novel *in vivo* RNA interference (RNAi) model. *Sirt1* protein and mRNA levels were assessed by western blotting and quantitative realtime PCR. Urinary protein excretion was quantified by urinary albumin to creatinine ratio and SDS gel electrophoresis followed by Coomasie Blue staining. Serum creatinine was measured by HPLC. PAS-stained kidney sections and transmission electron microscopy were used to assess renal histology and podocyte morphology.

**Results:** We achieved temporal and spatial control over *Sirt1* expression in kidney podocytes and tubular cells.We confirmed that up to ~80% reduction of Sirt1 in podocytes is dispensable for normal kidney function. Mice with global *Sirt1* knockdown developed more proteinuria compared to those without *Sirt1* knockdown when both were injected with Adriamycin (ADR). Furthermore, ADR-treated mice with podocyte-specific *Sirt1* knockdown developed more severe glomerulosclerosis, podocyte foot process effacement and proteinuria, which were partially reversed upon reversal of *Sirt1* knockdown, whereas mice with tubular-specific *Sirt1* knockdown were not susceptible to ADR-induced nephropathy.

**Conclusions:** Podocyte Sirt1 serves a protective role in ADR-induced nephropathy.

## FR-PO902

### PPARγ in Podocytes Promotes Resistance to Crescentic Glomerulonephritis

Carole Hénique-Gréciet,[1,2] Guillaume Bollee,[1,2] Marine Milon,[1,2] Pierre-Louis F. Tharaux.[1,2] *[1]Paris Cardiovascular Research Centre - PARCC, INSERM, Paris, France; [2]Univ Paris Descartes, Sorbonne Paris Cité, Paris, France.*

**Background:** The nuclear receptor peroxisome proliferator-activated receptor gamma (PPARγ) agonists have beneficial effects on renal structure and function in models of diabetes and chronic kidney diseases. In this study, we have explored the involvement of PPARγ in crescentic rapidly progressive glomerulonephritis (RPGN).

**Methods:** RPGN was induced by injection of anti–glomerular basement membrane antiserum (nephrotoxic serum, NTS).

**Results:** Gain-of-function approach: Pioglitazone, a PPARγ agonist, limited renal injury in RPGN. Pioglitazone ameliorated podocyte damage and reduced proteinuria. Pioglitazone administration was effective when performed from the first day of NTS injection or when started in a delayed manner (4 days after NTS injection). Loss-of-function approach: We generated mice with specific deletion of PPARγ alleles in podocytes (Pod-PPARγ mice). Pod-PPARγ mice developed more severe glomerular injury and RPGN upon NTS administration. Pod-PPARγ mice displayed a 2-fold increase in Albuminuria to Creatinuria ratio at day 10 (2843 +/- 329 vs. 1664 +/- 207 g/mol, $p<0.001$) than wild-type mice and higher crescent incidence (35.6 +/- 5.4 vs. 15.6 +/- 3.7 %, $p<0.01$). Accordingly, PPARγ deletion in podocytes promoted worsening of blood urea nitrogen levels (119.9 +/- 11.6 vs. 56.7 +/- 9.0 mg/dl, $p<0.001$). Such aggravation was not due to an effect on proliferation and migration of primary podocytes.

**Conclusions:** In conclusion, PPARγ activity is an essential pathway protecting podocyte phenotype and the glomerular architecture during experimental RPGN. PPARγ is involved in mitochondrial biogenesis and function. Moreover, it is known that mitochondria are the main site of reactive oxygen species production. In cells exposed to oxidative stress, NRF2 activity is increased, further driving the transcriptional activation of genes whose expression is essential to control cellular redox homeostasis. Thus, we have also further explored the role of oxidative stress via NRF2 anti-oxidant pathway in this model.

## FR-PO903

### Angiotensin II and Diacylglycerol Cause Activation of Stat-3 in Podocytes through a Pathway That Includes TRPC6 Channels, Calcineurin, and CaM Kinase

Stuart E. Dryer,[1,2] Mousa Abkhezr.[1] *[1]Dept of Biology and Biochemistry, Univ of Houston, Houston, TX; [2]Div of Nephrology, Baylor College of Medicine, Houston, TX.*

**Background:** Previous studies have shown that the transcription factor signal transducer and activator of transcription-3 (Stat-3) plays a role in progression of glomerular diseases, especially in HIV nephropathy[1,2].

**Methods:** Immunoblot analysis of Stat-3 tyrosine phosphorylation and confocal microscopy in mouse podocyte cell lines.

**Results:** Application of 100 nM angiotensin II (Ang II) for 15 min-1 hr caused a marked increase in the phosphorylation of Stat-3 on tyrosine Y705. A similar effect was seen after treatment with 100 μM of the diacylglycerol analog 1-oleoyl-2-acetyl-sn-glycerol (OAG). In confocal microscopy, we observed that both treatments led to accumulation of Stat-3 in the cell nucleus. Stat-3 phosphorylation and nuclear localization were reduced by pretreatment with the pan-TRP channel inhibitor SKF-96365, and by siRNA knockdown of TRPC6, which also reduced basal phosphorylation of Stat-3. The effects of OAG persisted in cells treated with the PKC inhibitor chelerythrine. We used several agents to examine pathways downstream of TRPC6 that could lead to Stat-3. We observed that Ang II-evoked phosphorylation of Stat-3 was blocked by pretreatment with the CaM Kinase inhibitor KN-93, by the calcineurin inhibitor cyclosporine-A, and by the JAK inhibitor AG-490.

**Conclusions:** Stat-3 is a downstream effector of TRPC6 signaling, but Ang II may activate more than one cascade leading to tyrosine phosphorylation of this transcription factor. It remains to be determined if calcineurin, CaM kinase and JAK comprise parallel pathways feeding into Stat-3.

## FR-PO904

### Large-Scale Analysis of the Glomerular Phosphoproteome Reveals Novel Regulatory Mechanisms at the Kidney Filtration Barrier

Markus M. Rinschen,[1] Tim König,[2] Trairak Pisitkun,[3] Henning Hagmann,[1] Stuart E. Dryer,[4] Paul T. Brinkkoetter,[1] Thomas Benzing.[1] *[1]Dept II of Internal Medicine and Center for Molecular Medicine, Univ of Cologne, Cologne, Germany; [2]Institute for Genetics, Univ of Cologne, Cologne, Germany; [3]Univ of Aarhus, Aarhus, Denmark; [4]Biology and Biochemistry, Univ of Houston, Houston, TX.*

**Background:** Diseases of the kidney filtration barrier are a leading cause of endstage renal failure. Most disorders affect the podocytes, polarized cells that are connected by a unique cell junctional complex, the slit diaphragm. Podocytes require tightly controlled signaling to maintain their integrity, viability and function.

**Methods:** We use state-of-the-art tandem mass spectrometry to provide an atlas of *in vivo* phosphorylated, glomerulus-expressed proteins including podocyte-specific gene products.

**Results:** We discovered 2,449 phosphorylated proteins corresponding to 4,079 identified high-confident phosphorylated residues. We performed a systematic bioinformatics analysis of this dataset, revealing distinct phosphorylation motifs and roles for tyrosin-phosphorylation sites. Among the 146 phosphorylation sites found on proteins abundantly expressed in podocytes, synaptopodin was a dominant phosphoprotein with 18 identified proline-directed phosphorylation sites. Several sites resided close to homologous human residues known to be mutated in human genetic forms of proteinuria. One such site discovered on the slit diaphragm protein podocin, threonine-234 (T234), is a potential aPKC site. Using extensive molecular dynamics simulations and biochemistry, we show that phosphorylation critically regulates podocin dimer formation and multimerization and that this represents a general principle for the assembly of the large family of PHB-domain containing proteins.

**Conclusions:** We show that integration of phosphoproteomics with genetic, biochemical and structural data allows a powerful approach to understand regulatory processes at the slit diaphragm and its alterations in health and disease.

## FR-PO905

### Self-Regulation of HO-1 in GEC

Maria Detsika,[1] Pu Duann,[2] Elias A. Lianos.[2] *[1]Medicine, National and Kapodistrian Univ of Athens, Greece; [2]Div of Nephrology, Univ of Medicine and Dentistry of New Jersey.*

**Background:** Athough Heme oxygenase (HO)-1 is renoprotective, glomerular epithelial cells (GEC) have a limited ability to upregulate HO-1 as shown in HO-1 inducing forms of GEC injury. This raises the question of whether HO-1 induction in GEC is subject to tight regulation and was addressed in normal rat glomeruli.

**Methods:** Glomeruli were isolated from male, wild type (WT), Sprague-Dawley rats (SD), hmox1$^{+/-}$ SD, hmox1$^{-/-}$ SD, and SD with (GEC)-targeted HO-1 overexpression (GEC$^{HO-1}$). hmox1$^{+/-}$ and hmox1$^{-/-}$ SD were obtained using Zinc Finger Nuclease (ZFN) technology designed to generate a 10-bp deletion in a specific HO-1 sequence within Exon 3. GEC$^{HO-1}$ SD were obtained by Sleeping Beauty Transposon mediated transgenesis using a nephrin promoter. Glomeruli from WT, hmox1$^{+/-}$, hmox1$^{-/-}$ and GEC$^{HO-1}$ SD were treated with defined Heme concentrations for 18 h. Glomerular HO-1 protein and mRNA levels were assessed by western blotting and Real-time PCR amplification.

**Results:** A 60-70% reduction in constitutive HO-1 levels and complete HO-1 absence was observed in hmox1+/- and hmox1-/- glomeruli, respectively. In WT glomeruli, low Heme (6-200 mM) concentrations increased HO-1 synthesis (mRNA and protein) in a dose dependent manner. At higher Heme concentrations (400 mM), HO-1 synthesis (mRNA and protein) was reduced to constitutive levels while at 800 mM there was an even higher reduction to sub-constitutive levels. In hmox1$^{+/-}$ glomeruli, Heme (400 mM) failed to reduce HO-1 synthesis. In GEC$^{HO-1}$ glomeruli, there was a shift of the inhibitory effect of Heme on HO-1 synthesis to lower Heme concentrations (200 mM) capable of inducing HO-1 in WT glomeruli. This effect was mimicked in WT glomeruli co-incubated with Heme and MG132, (proteasome inhibitor) at concentrations that increased endogenous HO-1 levels.

**Conclusions:** Heme-mediated HO-1 synthesis in GEC is negatively regulated by HO-1 protein levels achieved, pointing towards a negative feed-back regulatory mechanism. This may serve as a HO-1 switch-off mechanism, upon injury-mediated HO-1 induction, preventing HO-1 from reaching potentially cytotoxic levels.

## FR-PO906

### Podocytes Lacking Cell Surface Heparan Sulfate Show Enhanced Production/Shedding of Nephrin Positive Microparticles/Exosomes

Kevin J. McCarthy, Deborah J. McCarthy. *Pathology, LSU Health Sciences Center-Shreveport, Shreveport, LA.*

**Background:** Several recent reports have shown that one cell surface proteoglycan family, syndecans (SDCs), play a key role in the regulation of exosome production/release. Since heparan sulfate (HS) is found covalently attached to SDCs and mediate SDC interactions and clustering at the cell surface, we hypothesized that loss of HS from SDC core proteins on podocyte (podo) pedicels would affect the production of podo urinary exosomes.

**Methods:** Mutant mice having podo lacking the ability to assemble heparan sulfate (HS) on SDC proteins were previously described (PEXTKO mice, Kid Int 74:289-299). Kidneys from wild type (WT), unilateral nephrectomized (UNX) WT, PEXTKO, and PEXTKO UNX

mice were processed for frozen sections and transmission electron microscopy (TEM). Sections were immunostained for SDC-4, SDC-1, ALIX (exosome marker),nephrin (also found in urinary exosomes), and synaptopodin.

**Results:** Podo in PEXTKO mice showed mislocalization of SDC core proteins from the pedicel basal surface. A disruption in synaptopodin staining pattern was seen in PEXTKO podocytes compared to WT. TEM micrographs showed the presence of microvilli on the apical surfaces of podo, the greatest number seen in PEXTKO and PEXTKO UNX podo. Coincident with the former observation, glomerular nephrin immunoreactivity showed a gradation of intensity, with PEXTKO UNX>PEXTKO>WT UNX>WT. Immunostaining for ALIX showed a pattern of intensity gradation similar to nephrin. Nephrin positive immunoreactivity, having the appearance of small particles, was also seen within the cytoplasm of proximal tubule cells (PTC). Double-label immunostaining of PTC for nephrin and ALIX showed little overlap between the two populations of particles. The number of nephrin positive particles/tubule profile was determined to be PEXTKO UNX>PEXTKO>WT UNX>WT.

**Conclusions:** We believe that SDC HS plays an integral role in regulating the genesis/release of microparticles/exosomes from podo. The microparticles/exosomes fall into two populations, ALIX or nephrin positive. This may result from differences in the mechanism of their genesis and may deliver different types of cargo to PTE cells.

*Funding:* NIDDK Support

## FR-PO907

**Morphological Change of Podocytes 1 Hour after Exposure to Serum of Recipients with Recurrence of Focal Segmental Glomerulosclerosis after Kidney Transplantation**

Kiyonobu Ishizuka,[1] Yutaka Harita,[2] Haruko Tsurumi,[2] Tatsuo Asano,[1] Kei Nishiyama,[1] Noriko Sugawara,[1] Hiroko Chikamoto,[1] Yuko Akioka,[1] Yutaka Yamaguchi,[3] Motoshi Hattori.[1] *[1]Dept of Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan; [2]Dept of Pediatrics, Graduate School of Medicine, Univ of Tokyo, Tokyo, Japan; [3]Yamaguchi's Pathology Laboratory, Matsudo, Chiba, Japan.*

**Background:** The pathogenesis of recurrent FSGS after renal transplantation remains unclear. To clarify the sequential events in the glomeruli after exposure of FSGS plasma in situ, we analyzed the morphological and molecular change of podocytes in transplanted kidney.

**Methods:** Five sets of renal graft specimens were studied in three time frames, before reperfusion (0 hour), one hour after reperfusion, and several days after reperfusion. FSGS recurred in three of all five cases after transplant, with massive proteinuria within 72 hours from reperfusion. We analyzed the degree of foot process (FP) effacement, intracellular localization of various functional proteins of podocytes by confocal microscopy, and podocyte number in glomeruli through these periods of time.

**Results:** Within one hour after reperfusion, FP effacement was observed only in all the post-transplant recurrent cases. Staining pattern of Neph1, SIRP alpha, Zo-1, Podocalyxin, Ezrin, Synaptopodin, Vimentin, and Myo1E did not change in any specimens of all cases. However, in all the recurrent cases, staining pattern of Nephrin and Podocin altered from linear pattern to granular pattern in cytoplasm as early as one hour after reperfusion. These cytoplasmic Podocin and Nephrin were partially localized in Golgi apparatus, but not in ER. Coarse granular staining of CD2AP, which is distinct from that of Nephrin or Podocin, was also observed in 1 hour and later specimen only in recurrent cases.Podocyte number did not change during the study period.

**Conclusions:** Exposure to recurrent FSGS sera for one hour results in dissociation and partial translocation of slit diaphragm component to cytoplasm and simultaneous FP effacement. These hyperacute changes which precede proteinuria represent fundamental mechanism which underlie the pathogenesis of FSGS, and may hold predictive value in FSGS recurrurence.

## FR-PO908

**Aristolochic Acid Causes Albuminuria by Promoting Mitochondrial DNA Damage and Dysfunction in Podocyte**

Yang Zhou, Xueqin Bian, Chunsun Dai, Junwei Yang. *Center of Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

**Background:** Aristolochic acid nephropathy (AAN), initially found in patients intaking slimming herbs containing aristolochic acid, was previously considered as a progressive renal interstitial fibrosis and urothelial malignancy. However, the presence of albuminuria in some patients with AAN suggests that aristolochic acid may also damage the glomerular filtration barrier.

**Methods:** In this study, mice AAN model was generated by daily administration of aristolochic acid I sodium salt (AA) intraperitoneally at a dose of 10mg/kg body weight for 3 days. Mice were killed 3 or 7 days later with their urine and kidney harvested for further examination. Cultured mice podocytes were incubated with AA at a dose of 10μmol/L for various time periods. Mitochondria were isolated and mitochondrial DNA (mtDNA) damage was evaluated by single cell gel electrophoresis assay (comet assay). Q-PCR assay was used to quantify the copy number of mtDNA. Western blot analysis was applied to examine the expression level of mitochondrial protein. Mitochondrial function was determined by ATP content, oxygen consumption rate, membrane potential and reactive oxygen species.

**Results:** All of the mice developed heavy albuminuria at day 3 and 7 after AA administration. In the mice received AA, morphologic change of glomeruli was minor under light microscopy but podocyte foot-process effacement was evident under electron microscopy. In mitochondria from isolated glomeruli, prominent mtDNA damage was accompanied with marked decrease of mtDNA copy number and mtDNA-encoded mitochondrial protein expression. Similar to those in vivo results, AA treatment could impair the filtration barrier function of cultured podocytes. AA promoted mtDNA damage, decreased mtDNA copy number and mitochondrial protein expression in podocytes. In addition, AA treatment could also decrease ATP content, oxygen consumption rate and mitochondrial membrane potential as well as increase cellular reactive oxygen species in cultured podocytes.

**Conclusions:** Aristolochic acid can induce podocyte damage and dysfunction, which may be mediated by promoting mitochondrial DNA damage and dysfunction in podocytes.

## FR-PO909

**Assessment of Glomerular Changes in a Passive Mouse Model of IgA Nephropathy**

Lea Novak,[1] Zina Moldoveanu,[1] Zhi Qiang Huang,[1] Colleen J. Winstead,[1] Stacy D. Hall,[1] Rhubell T. Brown,[1] Bruce A. Julian,[1] Casey T. Weaver,[1] Jiri F. Mestecky,[1] Hitoshi Suzuki,[2] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Juntendo Univ, Tokyo, Japan.*

**Background:** IgA nephropathy (IgAN) is an autoimmune glomerulonephritis wherein immune complexes (IC) composed of galactose-deficient IgA1 (Gd-IgA1) and anti-glycan autoantibodies deposit in the glomeruli. We developed an animal model by using *in vitro*-formed IC from human Gd-IgA1 myeloma protein and recombinant Gd-IgA1-specific IgG for induction of IgAN-like disease in mice. The purpose of this study was to quantify mesangial proliferation in this model of IgAN.

**Methods:** Severe-combined-immunodeficiency (SCID) mice were repeatedly injected every other day (total 3 injections) with Gd-IgA1-IgG IC (IC-group) or with Gd-IgA1 only (control group). Kidneys from IC-group mice were removed 1, 4, 7, and 14 days after the last IC administration and from the control group mice 1 day after the last Gd-IgA1 administration. Kidneys were fixed in formalin, processed, and embedded in paraffin. Tissue sections, 5 μm thick, were stained with periodic-acid Schiff. Using IP Lab software, multiple glomeruli for each animal were examined and average cellularity per unit of glomerular area was calculated.

**Results:** Mesangial cellularity in the control group was 34.6±1.1 x $10^5$ nuclei per $\mu m^2$ with normal histology at 1 day after the last injection of Gd-IgA1. In the IC-group, significantly increased cellularity of mesangial cells was observed at 1, 4, and 7 days after the last injection: 42.6±1.6, 39.9±0.7 and 42.8±1.8 x $10^5$ nuclei per $\mu m^2$, respectively. At 14 days after the last injection, glomerular cellularity declined to baseline, 38±1.3 x $10^5$ nuclei per $\mu m^2$. The glomerular changes were consistent with those of human IgAN as they included glomerular hypercellularity and mesangial matrix expansion.

**Conclusions:** Our passive mouse model of IgAN confirms the importance of circulating Gd-IgA1-IgG IC in the pathogenesis IgAN and induction of histopathologic changes typical of human IgAN. Morphometric evaluation of the glomerular cellularity is an objective method for assessment of pathological changes in this model.

## FR-PO910

**Global Analysis of Glucocorticoid Action in Human Podocytes**

James McCaffrey,[1,2] Hellyeh Hamidi,[1] Nicholas J. Webb,[2] David W. Ray,[1] Rachel Lennon.[1,2] *[1]Institute of Human Development, Univ of Manchester, United Kingdom; [2]Dept of Nephrology, Royal Manchester Children's Hospital, United Kingdom.*

**Background:** Children presenting with nephrotic syndrome (NS) typically receive an empiric course of glucocorticoid (Gc) therapy. Glucocorticoids activate ligand-dependent transcription factors. Those who do not respond to Gc treatment are at high risk of developing end stage renal disease. The clinically-relevant, podocyte-specific mechanisms of action of glucocorticoids in NS have not been determined. Elucidating relevant pathways will guide novel therapeutic targeting. We undertook a global analysis of Gc-regulated genes in human podocytes to generate hypotheses for Gc mechanisms of action.

**Methods:** The transcriptional profile of prednisolone-treated and prednisolone-naïve wild type human podocytes were compared using the Affymetrix U133 Plus 2.0 Array. Comparing whole genome expression data from the two cell groups allowed the creation of a list of Gc-regulated transcripts. This list underwent enrichment analysis for gene ontology terms with two independent software packages, and further experimental validation with live cell imaging and immunofluorescence.

**Results:** 606 Gc-regulated transcripts were identified (fold change with treatment ±1.5, q value ≤0.05). Enriched gene ontology terms included those associated with regulation of apoptosis, cell signalling and cell motility. Live cell imaging analysis showed that Gc exposure significantly reduced podocyte motility (0.0034 μm/sec in untreated cells Vs. 0.0025 μm/sec in treated cells, p-value <0.0001), and altered sub-cellular localisation of synaptopodin, which has already been implicated in both regulation of podocyte motility and recovery of the filtration barrier from proteinuria-inducing agents.

**Conclusions:** Whole genome transcriptional profiling of human podocytes allowed identification of Gc-regulated transcripts. Selected follow-up validation demonstrated that glucocorticoids affect podocyte motility in vitro, and alter the localisation of synaptopodin, a key regulator of cytoskeletal dynamics. These findings may relate to the therapeutic effect of glucocorticoids in NS.

**Localization of SGLT2 in Bowman's Capsule of Mouse Kidney** Niloofar M. Tabatabai,[1] Paula North,[2] Kevin R. Regner,[1] Suresh Kumar,[2] Christine Duris,[2] Amy B. Blodgett.[1] *[1]Medicine, Medical College of Wisconsin; [2]Pathology, Medical College of Wisconsin.*

**Background:** SGLT2 is a sodium-dependent glucose transporter. Genetic mutations in human and gene knock out studies in mouse have shown that SGLT2 is responsible for most of the glucose reabsorbed from the renal glomerular filtrate. Treatment of diabetic patients with inhibitors of SGLT2 increases the urinary excretion of glucose and lowers the serum concentration of glucose. It is known that SGLT2 is expressed in early proximal tubule. In this study, we re-examined SGLT2 localization by immunohistological analyses on kidneys from wild-type mice using our custom SGLT2 antibody.

**Methods:** Male C57BL/6 mice at 4, 12, and 22 weeks of age were used. Western blot was performed with SGLT2 antibody (0.77 µg/ml) on proteins from whole kidney lysate (25 µg) or cortical brush border membrane (BB) (2 µg), and detection was carried out by chemiluminescence. For immunohistology, formalin-fixed paraffin-embedded tissues were sectioned (4 µm) and stained with SGLT2 (1 µg/ml) or nephrin antibody, and staining was detected with horseradish peroxidase chromogen method (IHC). Slides were counterstained with hematoxylin and then scanned to make digital images. Fluorescence detection (IF) of SGLT2 and nephrin staining was done with using Cy3 and Alexa-647 coupled secondary antibodies, respectively, and nuclei were stained with 4',6-Diamidino-2-Phenylindole. Fluorescence imaging was done with a Zeiss confocal microscope. SGLT2-stained glomeruli were counted in IHC slides and expressed as percent total glomeruli.

**Results:** In Western blot, SGLT2 antibody hybridized to a ~60 kDa protein in whole kidney lysate and in brush border membrane. As expected, SGLT2 antibody stained cortical region and apical side of the proximal tubule cells in kidneys from three age groups. SGLT2 staining was also observed in Bowman's capsule, and IF double staining showed that it was not co-localized with nephrin. SGLT2-positive glomeruli were 14%, 67%, and 87% in tissue sections from 4, 12, and 22 week old mice, respectively.

**Conclusions:** Our results suggest that SGLT2 is expressed in glomerular parietal epithelial cells and that this expression may be regulated by age.

**Shiga Toxin 1 Induces ICAM-1 Protein Expression in Human Glomerular Microvascular Endothelial Cells** Elena Volokhina,[1] Thea J. Van der Velden,[1] Dineke Westra,[1] Nicole Van De Kar.[1] *[1]Dept of Pediatric Nephrology, Radboud Univ Nijmegen Medical Centre (RUNMC), Nijmegen, Netherlands; [2]Dept of Laboratory Medicine, Radboud Univ Nijmegen Medical Centre (RUNMC), Nijmegen, Netherlands; [3]Dept of Pediatrics, Univ Hospitals Leuven, Leuven, Belgium.*

**Background:** Hemolytic uremic syndrome (HUS) is often preceded by infection with Shiga toxin (Stx) producing *Escherichia coli* (*STEC*). The exact mechanism of how Stx exposure causes HUS is still poorly understood. Intercellular Adhesion Molecule 1 (ICAM-1) is an adhesive molecule, which is important in Stx-mediated endothelial inflammation. In this work we studied Stx1 effect on ICAM-1 protein expression.

**Methods:** HUVEC and human glomerular microvascular endothelial cells (GMVEC) from three donors were treated for 6, 12, 24 and 48 hours with 0, 0.1, and 1.0 nM of Stx1 with or without prestimulation with TNFα. The culture supernatant and cells were collected for ELISA and qPCR analyses to assess the expression of ICAM-1 on protein and mRNA levels.

**Results:** Stx1 upregulated levels of soluble ICAM-1 in culture supernatant of GMVEC when cells were preincubated with TNFα in time- and dose-dependent manner for up to 20 times ($p<0.001$). This upregulation on the protein level was consistent with enhanced ICAM-1 mRNA expression. No effect of Stx1 on HUVEC was observed. Incubation with TNFα only enhanced release of soluble ICAM-1 in both cell lines for up to 10 fold ($p<0.001$).

**Conclusions:** Our results indicate that increased expression of ICAM-1 protein in GMVEC is directly triggered by Stx1. This feature might contribute to pathophysiology of *STEC*-HUS.

**A Common ß3 Integrin Polymorphism L33P Renders Enhanced Reactivity to Soluble Urokinase Receptor: Relevance to Focal Segmental Glomerulosclerosis** Changli Wei, Jing Li, Jochen Reiser. *Dept of Internal Medicine, Rush Univ Medical Center, Chicago, IL.*

**Background:** Our recent findings suggest soluble urokinase receptor (suPAR) as a circulating focal segmental glomerulosclerosis (FSGS) factor. Induction of suPAR activates podocyte □vß3 integrin both *in vivo* and *in vitro*, thus contributing to the development of proteinuria and an FSGS-like nephropathy. ß3 integrin activity is enhanced in platelets with the ß3 integrin genetic polymorphism L33P ($PI^{A2}$). We tested several well defined cohorts of native and transplant FSGS patients and found the prevalence of L33P to be around 20%. Thus we hypothesized that L33P renders enhanced reactivity to suPAR, so that comparably lower or normal suPAR levels might already cause increased ß3 integrin activity in podocytes and glomerular kidney disease.

**Methods:** ß3 integrin mutation L33P was generated by QuickChange site-mutagenesis and cloned into Lentiviral system. Fully differentiated cultured human podocytes were infected with lentivirus expressing either L33P, or wild type ß3 integrin or same amount of control virus. 48 h after infection, cells were treated with different amount of recombinant suPAR protein or saline. 24 h later, the cells were harvested to look at ß3 integrin activity.

**Results:** Compared to human podocytes infected with mock virus, cells received ß3 integrin showed significant higher baseline ß3 integrin activity, with highest signal observed in $PI^{A2}$-ß3 integrin infected cells. Simultaneous suPAR treatment even at low level further enhanced ß3 integrin activity and the highest ß3 integrin activation signal was again found in podocytes infected with $PI^{A2}$-ß3 integrin.

**Conclusions:** In summary, ß3 integrin genetic polymorphism $PI^{A2}$ allows for enhanced ß3 integrin activity in human podocytes (lowered activation threshold), and generates increased sensitivity to suPAR. While *in vivo* work is warranted, these data suggest that ß3 integrin polymorphism $PI^{A2}$ may play a role in FSGS where serum suPAR level is not significantly increased.

**VEGF165b Protects against Increases in Glomerular Water Permeability in the Pod-DTR Model of Glomerular Disease** Megan Stevens, Andy Salmon, David O. Bates, Steve Harper, Sebastian Oltean. *Physiology and Pharmacology, Univ of Bristol, Bristol, United Kingdom.*

**Background:** The pod-DTR transgenic mouse model (podocin promoter – diphteria toxin receptor) is an inducible model of glomerular disease triggered by podocyte injury after treatment with diphtheria toxin (DT). The vascular endothelial growth factor splice isoform $VEGF_{165}b$ has been shown to decrease glomerular water permeability ($L_pA/V_i$) in kidneys of transgenic mice over-expressing $VEGF_{165}b$ under a nephrin promoter (neph-$VEGF_{165}b$). This study investigates whether $VEGF_{165}b$ over-expression can rescue the glomerular injury phenotype of the pod-DTR model.

**Methods:** WT, Pod-DTR and double-transgenics (Pod-DTR x neph- $VEGF_{165}b$) mice were given a single dose of DT (1, 5 or 100ng/g body weight). Urinary albumin creatinine ratio (uACR) was measured from urine collected post toxin administration on days 3, 5, 7, 10 and 14. Glomerular $L_pA/V_i$ was measured on day 14. Nephrin immunofluorescence was used as an indicator of podocyte number in WT and pod-DTR mice 14 days after toxin induction.

**Results:** Proteinuria is seen in pod-DTR mice 5 days after 1ng/g DT administration ($n=5$, $p<0.05$) and albuminuria is seen in pod-DTR mice 5 days after 100ng/g DT administration ($n=4$, $p<0.05$) in comparison with WT controls. This normalized by day 14 at both doses. Glomerular $L_pA/V_i$ is significantly increased in pod-DTR mice treated with 1 and 5ng/g DT compared to WT DT-treated controls ($n=5$, $p<0.05$). When pod-DTR x neph-$VEGF_{165}b$ mice were treated with the same doses, $L_pA/V_i$ was significantly lowered ($n=5$, $p<0.05$). There is a reduction in nephrin staining in pod-DTR mice treated with 1ng/g DT, as well as an increase in glomerular area ($n=3$, $p<0.05$) in comparison to WT mice.

**Conclusions:** An increase in glomerular permeability to water is observed in pod-DTR transgenic mice after 1 or 5 ng/g DT administration. This is rescued by over-expression of $VEGF_{165}b$ in podocytes, suggesting a protective role in this model of glomerular injury.

**High Content Screening for the Discovery of Podocyte Targeted Therapeutics** Tristan Hays, Mehmet M. Altintas, Mohd Hafeez Faridi, Jochen Reiser, Vineet Gupta. *Dept of Internal Medicine, Rush Univ Medical Center, Chicago, IL.*

**Background:** Podocyte dysfunction and loss are commonly associated with proteinuric kidney diseases and adversely effect glomerular filtration. Currently, a majority of therapeutics approved for proteinuric kidney diseases focus on improving systemic hemodynamics and metabolite levels but do not directly address harmful changes seen in podocytes. Therefore, new therapeutics to prevent podocyte dysfunction in glomerular diseases are urgently needed. However, current methods are inadequate for podocyte targeted drug discovery. Here we describe a high content approach for the discovery of novel podocyte targeted therapeutics.

**Methods:** Automated high-throughput imaging and analysis was used as an unbiased approach to quantitate phenotypic changes of podocytes. Conditionally immortalized podocytes were treated with increasing doses of the podocyte damaging agent puromycin aminonucleoside to mimic in vivo podocyte damage. Cells were stained for the nucleus, cytoplasm, F-actin, and focal adhesions to visualize podocyte changes. Cells were then linearly classified using parameters based on cell morphology and the actin cytoskeleton to separate damaged and healthy cell populations. These populations were then compared to generate a percent healthy statistic per well.

**Results:** Our assay showed quantitative, dose-dependent changes in podocyte health upon treatment with damaging agents, without loss of cell viability. Our assay was also reproducible and robust, with a Z-prime factor > 0.5, which makes it suitable for high-throughput screening. Treatment with known podocyte protective agents showed a dose-dependent protection of podocytes from damage in this assay. This approach was then used to screen an FDA approved compound library for the identification of novel podocyte protective drugs.

**Conclusions:** We have developed a novel, high-throughput assay for unbiased scoring of changes in podocyte health in vitro. Application of our assay resulted in identification of novel podocyte protective agents as potential therapeutics for the treatment of proteinuric kidney diseases.

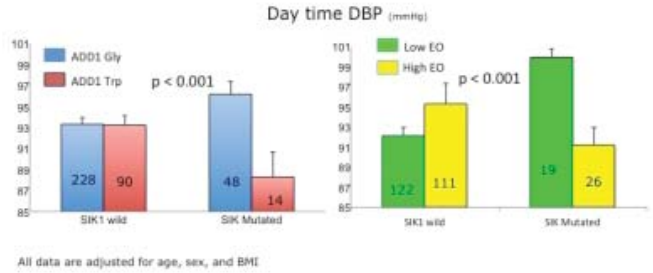
**FR-PO916**

**SIK1 Localizes in Glomerular Podocytes Affecting ADD1 and Endogenous Ouabain Control of Blood Pressure** Mara Ferrandi,[1] Isabella Molinari,[1] Marco Simonini,[1] Simona Delli Carpini,[1] Gianpaolo Zerbini,[1] Chiara Lanzani,[1] Lino Merlino,[1] John Hamlyn,[2] Paolo Manunta.[1] *[1]San Raffaele Scientific Institute, Milan, Italy; [2]Univ of Maryland, Baltimore.*

**Background:** Many genetic alterations of renal ion transport predispose to Na accumulation and may progress to hypertension and organ complications. In the kidneys, the active tubular transport of Na is driven by the Na-K ATPase (NK). ADD1 polymorphisms and increased levels of endogenous ouabain (EO) activate NK and lead to hypertension. ADD1 mutations and high EO, via downregulation of glomerular podocyte nephrin, are implicated in AKI. As the salt-inducible kinase 1 (SIK1) targets the renal NK and is activated by mutant ADD1 in proximal tubular cells, it is of potential relevance to hypertension development.

**Methods:** We investigated the influence of SIK1on the association between BP levels and ADD1 variant, EO levels in 372 naive hypertensive patients and studied the localisation of SIK1in renal glomeruli.

**Results:** In the presence of the wild-type SIK1 no difference of Diastolic BP was observed among patients carrying the wild-type or the mutant ADD1 (93±1.2 mmHg). In contrast patients with high EO (>200 pM) had increased DBP (97.5±1.1 mmHg) vs those with low EO (92.5±0.8 mmHg). However, in the presence of the mutant SIK1 variants, patients carrying the mutant ADD1 or elevated EO showed a reduced DBP vs those with the wild-type ADD1, or low EO, respectively as shown in figure 1.



SIK1 colocalized with nephrin in human glomerular podocytes and SIK1 and nephrin protein expression were highly correlated (r=0.78, p<0.001).

**Conclusions:** The present findings show that SIK1 polymorphism modulate BP control together with ADD1 and EO possibly by modulation of the tubular NK activity. Direct relationship between SIK1 and nephrin expression suggests that SIK1 may be also involved in podocyte damage and kidney injury.

**Angiotensin II Induces Podocyte Apoptosis by the Modulation of CD2AP: Role of ROS, AMPK, and PI3-K** Tae-Sun Ha. *Pediatrics, Chungbuk National Univ, Cheongju, Korea.*

**Background:** Angiotensin II (Ang II) induces dysfunction of glomerular podocytes, which play a crucial role in establishing glomerular filtration barrier permselectivity, thereafter, proteinuria. The glomerular slit diaphragm (SD), a slit between interdigitating foot processes of podocytes, serves as a size-selective barrier and is linked to the actin-based cytoskeleton by adaptor proteins, including CD2-associated protein (CD2AP). Therefore, damages to CD2AP affect not only function of the slit diaphragm, but also directly disrupt the podocyte cytoskeleton, leading to pathological changes inducing proteinuria. In addition, CD2AP can facilitate the nephrin-induced phosphoinositide 3-kinase (PI3-K)/Akt signaling, which protects podocytes form apoptosis. We investigated the changes of CD2AP and podocyte apoptosis by Ang II, a major vascular injury inducer.

**Methods:** Mouse podocytes were incubated in media containing various concentrations of Ang II and signal-related agents. The changes of CD2AP were observed by confocal imaging and Western blotting and podocyte apoptosis by TUNEL assay according to the presence of Ang II.

**Results:** CD2AP were located diffusely but predominantly in peripheral cytoplasm and co-localized with nephrin. However, Ang II decreased CD2AP stainings diffusely and induced spatial separation from concentrated nephrin, similar to those of compound C-treated condition. AICAR and metformin, AMPK activators, ameliorated the abnormal distributional changes of CD2AP. In Western blot analysis, Ang II notably reduced CD2AP in time- and concentration-dependent manners, which were recovered significantly by AMPK activators and Ang II type 1 receptor antagonist, losartan. Ang II increases the intracellular ROS level of podocytes via Nox4 activation and also increased apoptosis in time- and concentration-dependent manners in TUNEL assay, which were also recovered significantly by LY294002, a PI3-K inhibitor.

**Conclusions:** We suggest that Ang II induces the relocalization and reduction of CD2AP protein in podocytes via AT1R, which would cause podocyte apoptosis by the oxidative stress and the suppression of AMPK and PI3-K signalings.

**JAK/STAT-Associated Inflammatory Markers and the Benefits of JAK/STAT Signaling Inhibition in Peritoneal Dialysis** Tiane Dai,[1] Ying Wang,[1] Cynthia C. Nast,[2] Janine A. La Page,[1] Sharon G. Adler.[1] *[1]Nephrology, LABiomed at Harbor-UCLA, Torrance, CA; [2]Pathology, Cedars-Sinai Medical Center, Los Angeles, CA.*

**Background:** Peritoneal barrier (Pbarrier) pathology limits long-term peritoneal dialysis (PD). Inflammation induces Pbarrier failure. JAK/STAT signaling is implicated;direct evidence is sparse.

**Methods:** Mesothelial cells were cultured in heat-sterilized, filter-sterilized, or filter-sterilized peritoneal dialysis fluid (PDF) with glucose degradation products (GDP) added with or without the pan-JAK inhibitor (JAKi) pyridone (P6). Phospho-JAK1/ 2, STAT1/ 3, periostin, and cleaved caspase-3 (CC-3) were measured by immunoblotting, and CC-3 by immunohistochemistry (IH). Ex vivo, JAK-activators IL6 and IL15 were measured by electrochemiluminescence (ECL, Meso Scale Discovery, Gaithersburg, MD) and proteins with STAT binding sites in or near their promoter regions (IL6, MCP-1, and periostin) were measured by ECL, ELISA, and/or immunoblot in 20 peritoneal dialysis effluent (PDE) samples from 8 new (N) and 7 long-term (LT) PD patients. PDE cell pellet total and phospho-JAK1/2 were measured in 4 N and 4 LT patients. In vivo, PD was performed in rats with saline (PDC, N=3), 4.25% dextrose PDF (PDF4.25%, N=3), or PDF4.25%+5mg/kg JAK1/2i (N=4) x10 days. Pbarrier was stained with trichrome & anti-phospho-JAK1 ab.

**Results:** In vitro, all PDFs induced phospho-STAT1/3 and CC-3. P6 attenuated STAT1/3 phosphorylation, periostin secretion, and CC-3 activation. Ex vivo, cell pellet JAK was phosphorylated in LT but not N patients. In PDE, the STAT-regulated proteins MCP-1, IL-6, and periostin (normalized to CA125) were higher in LT vs N patients. In rats, PDF4.25%, but not saline, activated JAK, and induced mesothelial cell hyperplasia, inflammation, and fibrosis. JAK1/2i abrogated these changes.

**Conclusions:** JAK/STAT signaling directly mediates Pbarrier pathology, which is attenuated by JAK1/2i. Therapy to preserve residual renal function is implemented in PD. Fewer therapeutic strategies target Pbarrier function preservation. Studies coupling inflammatory biomarkers with Pbarrier function may provide support for testing JAK/STATi to address this unmet clinical need.

**FR-PO919**

**Effect of Adipose Tissue-Derived Mesenchymal Stem Cells in Peritoneal Fibrosis** Amanda Pires, Filipe M. Silva, Irene L. Noronha. *Nephrology, Univ Sao Paulo, Brazil.*

**Background:** Adipose tissue-derived mesenchymal stem cells (ADMSC) display immunomodulatory effects and may represent a strategy to block peritoneal fibrosis (PF), a serious complication of long term peritoneal dialysis. The aim of the study was to analyze the effect of ADMSC in an experimental model of PF developed in uremic rats.

**Methods:** CKD was induced in Wistar rats with a 0.75% adenine-containing diet, during 30 days. PF was induced with intraperitoneal injections of chlorhexidine gluconate. ADMSC were injected IV at days 15 and 21. Rats were divided into 5 groups (n=10/group): **Control,** normal rats; **CKD,** rats receiving adenine diet; **PF,** rats receiving chlorhexidine gluconate to induce PF; **CKD+PF**, CKD rats with PF; **CKD+PF+ADMSC**, CKD rats with PF treated with ADMSC. Peritoneal membrane thickness was measured by masson thrichrome. Macrophages (MØ), T-cells and α-smooth muscle actin (α-SMA) were analyzed by immunohistochemistry, and cytokine expression was analyzed by qPCR at day 30.

**Results:** Infusion of ADMSC significantly reduced the peritoneal membrane thickness, α-SMA expression, MØ and T-cell infiltration, and mRNA cytokine expression in the peritoneal membrane.

**Effect of DNA Demethylation in Experimental Encapsulating Peritoneal Sclerosis** Sun-Hee Park, Hye-Myung Ryu, Eun-Joo Oh, Sehyun Oh, Ji-Sun Ahn, Soon Youn Choi, Ji-Young Choi, Jang-Hee Cho, Chan-Duck Kim, Yong-Lim Kim. *Div of Nephrology and Dept of Internal Medicine, Kyungpook National Univ Hospital, Daegu, Republic of Korea.*

**Background:** Encapsulating peritoneal sclerosis (EPS) is characterized by progressive inflammation and excessive fibrosis of peritoneum in patients on peritoneal dialysis, and eventually leads to constriction of viscera and bowel obstruction in the later stages. This study aims to evaluate the therapeutic effect of DNA demethylation in experimental EPS.

**Methods:** Experimental EPS was induced by intraperitoneal injection of 0.1% chlorhexidine gluconate (CG) and 15% ethanol to non-uremic male SD rats (n= 19) which were divided into 3 groups: control group (C, n=5) with normal saline injection, EPS group (CG, n=7) with CG injection for 4 weeks and treatment group (CGA, n=7) with 5'-azacytidine injection for the last 2 weeks during CG injection. Morphometric analysis of peritoneum was performed with immunohistochemical staining for type 1 collagen and α-SMA. The expression of TGF-β, fibroblast-specific protein (FSP)-1 and DNA methyltransferase (DNMT)-1 were analyzed by western blot. Methylation specific PCR for Ras GTPase activating-like protein 1 (RASAL1) was performed with measurement of RASAL1 protein expression.

**Results:** The thickness of parietal peritoneum and the number of vessels in omental tissue were significantly decreased in CGA group compared to CG group. The expression of type 1 collagen, α-SMA, TGF-β and FSP-1 were significantly attenuated in CGA group compared to CG group. DNMT1 was significantly increased in CG group, whereas it was reduced in CGA group. Hypermethylation of RASAL1 was associated with decreased expression of RASAL1 protein in CG group, whereas it was reversed in CGA group.

**Conclusions:** DNA demethylation by 5'-azacytidine treatment improved pathologic changes of peritoneum in experimental EPS and it was associated with reversal of increased expression of DNMT1 and hypermethylation of RASAL1.

**FR-PO921**

**Statin Inhibits Peritoneal Dialysis-Related Epithelial-Mesenchymal Transition** Hye-Young Kang,[1] Hyung Jung Oh,[2] Seung Hyeok Han,[2] Shin-Wook Kang.[1,2] *[1]BK21; [2]Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea.*

**Background:** Small GTPases are demonstrated to be activated through the mevalonate pathway and to be involved in epithelial-mesenchymal transition(EMT). However, little is known about the effect of statins, which inhibit isoprenylation, on peritoneal dialysis(PD)-related EMT.

**Methods:** In vitro, human peritoneal mesothelial cells(HPMCs) were exposed to normal glucose(NG,5.6mM), NG+mannitol, or high glucose(HG,100mM) with or without simvastatin(SV,1μM). In addition, isoprenoid product(GGPP,5μM)-induced EMT and HG-induced small GTPases were evaluated. In vivo, PD catheters were inserted into 32 Sprague-Dawley rats, and saline(C,n=16) or 4.25% PD fluid(PDF,n=16) was infused for 4 wks. 8 rats from each group were treated with 5mg/kg/day of SV intraperitoneally. EMT markers in HPMCs and peritoneum were evaluated by Western blot analysis, and immunofluorescence or immunohistochemical staining.

**Results:** Compared to NG group, E-cadherin expression was significantly decreased, while α-SMA, snail, and fibronectin expression were significantly increased in HPMCs exposed to HG, and these changes were significantly abrogated by SV($p<0.05$). In addition, cobblestone-like appearance of HPMCs was converted into a fibroblast-like morphology after HG treatment, which was reversed by SV. Similar changes of EMT in HPMCs were also induced by GGPP($p<0.05$). HG significantly increased the expression of RhoA and Rac1 in the membrane fractions of cultured HPMCs, and these increases were ameliorated by SV($p<0.05$). Moreover, HG-induced EMT was attenuated by RhoA or Rac1 inhibitor($p<0.05$). Compared to C rats, the thickness of the mesothelial layer and the intensity of Masson's trichrome staining in the peritoneum were significantly greater in the PDF group($p<0.05$). Furthermore, E-cadherin expression in the peritoneum was significantly decreased, whereas α-SMA, snail, and fibronectin expression were significantly increased in PDF rats, and these changes were significantly abrogated by SV($p<0.05$).

**Conclusions:** PD-related EMT was significantly inhibited by statin treatment, suggesting that PD-related EMT was mediated by the activation of small GTPases through the mevalonate pathway.

**FR-PO922**

**The Predictive Value of Matrix Metalloproteinase-2 and Plasminogen Activator Inhibitor-1 in Peritoneal Dialysis Patients Who Develop Encapsulating Peritoneal Sclerosis** Deirisa Lopes Barreto, Dirk Gijsbert Struijk, Raymond T. Krediet. *Internal Medicine, Div of Nephrology, Academic Medical Center, Univ of Amsterdam, Amsterdam, Netherlands.*

**Background:** Encapsulating peritoneal sclerosis (EPS) is the most severe morphological complication that may occur in 3% of peritoneal dialysis (PD) patients. Recently the use of effluent matrix metalloproteinase-2 (MMP-2) and plasminogen activator inhibitor-1 (PAI-1) as potential biomarkers of peritoneal fibrosis has been demonstrated during longitudinal follow-up of incident PD patients. This study focuses on effluent MMP-2 and PAI-1 as early markers in the preceding years of patients who develop EPS.

**Methods:** In this nested case-control study, patients who developed EPS were compared to controls with a PD duration of at least 57months. Levels of effluent MMP-2 and PAI-1 were determined by an ELISA and appearance rates (AR) were calculated. The time courses of AR MMP-2 and PAI-1 were studied by means of a linear repeated-measures model in the years prior to the diagnosis of EPS adjusted for age. Furthermore, time-specific ROC analyses were executed to assess the predictive value of the markers in the years prior to diagnosis of EPS.

**Results:** In total 11 patients developed EPS and 34 controls were assembled. No difference in the time course of AR MMP-2 was present between controls and EPS patients. In contrast, higher AR of PAI-1 were found in EPS patients as compared to the controls ($p=0.002$). The time-specific ROC analyses indicated a discriminative ability for PAI-1 ($AUC=0.78$, $p=0.01$), whereas this was absent for AR of MMP-2.

**Conclusions:** It is unlikely that MMP-2 can be used as a biomarker of EPS as no distinction between patients who develop EPS and controls can be made. The time course confirms a persistent contribution of effluent MMP-2 in peritoneal tissue remodeling. Throughout, elevated levels of AR PAI-1 are present in patients who develop EPS, pointing to progressive peritoneal fibrosis and sclerosis. AR PAI-1 has a fair discriminative capacity from 3 years prior to EPS diagnosis. Therefore, PAI-1 can possibly be used to monitor peritoneal fibrosis and serve as biomarker of EPS.

**FR-PO923**

**Over-Expression of E-cadherin Attenuated Epithelial-Mesenchymal-Transition Induced by TGF-β in Human Peritoneal Mesothelial Cells** Hao Zhang, Ke Zhang, Liu Yan, Bin Yi. *Nephrology, The Third Xiangya Hospital, Changsha, Hunan, China.*

**Background:** Uptodate the investigation shows that E-cadherin(ECAD) might not only the effector but also regulator in Epithelial mesenchymal transition(EMT). We aimed to over express the ECAD with plasmid transfection into human peritoneal mesothelial cell lines (HMrSV5) and to investigate the effects of ECAD over-expression on the epithelial-mesenchymal transition HMrSV5 cells.

**Methods:** 1. Using E. coli DH5α to amplify the ECAD cDNA plasmid and blank plasmid, the plasmid was identified by enzyme digestion and RT-PCR; 2. HMrSV5 cells were divided into 3 groups: control group, ECAD group (transfected with ECAD plasmid) and blank plasmid group (transfected with blank plasmid). The transfection efficiency was detected by Flow cytometry. The level of ECAD mRNA and protein in 12h, 24h, 36h, 48h and 72h were detected by RT PCR and western blot; 3. HMrSV5 cells were divided into groups: normal group, TGF-beta group and E-cadherin +TGF-beta group (transfected with E-cadherin and then treated by TGF-beta with 12h, 24h, 36h and 48h, respectively). The level of E-cadherin mRNA was detected by RT PCR. The level of α-SMA and Vimentin protein were detected by western Blot. Immunofluorescence was used to detect the ECAD and α-SMA protein level.

**Results:** 1. The recombinant plasmids are verified by sequencing analysis, with the sequence identified in gene bank.

2. The transfection efficiency with ECAD transfection was peaked on 36h(74.12%). Level of ECAD mRNA is increased with ECAD transfection after 12h ($p<0.05$), and peaked on 36h ($p<0.01$).

3. In TGF-β group, the protein level of α-SMA and Vimentin are increased by TGF-β in a time-dependent manner ($p<0.01$, compared with control group), and ECAD mRNA level is decreased ($p<0.01$, compared with control group). Otherwise, the effect is attenuated in ECAD +TGF-beta group ($p<0.01$, compared with TGF-β group).

**Conclusions:** 1. ECAD cDNA plasmid transfection does over express ECAD in HMrSV5 cells; 2. Over-expression ECAD with ECAD cDNA plasmid can attenuate the EMT induced by TGF-β in HMrSV5cells.

**FR-PO924**

**Paricalcitol Ameliorate Epithelial to Mesenchymal Transition of Peritoneal Mesothelial Cells** Seokhui Kang,[1] Tae woo Kim,[2] Kyu-hyang Cho,[1] Jong-Won Park,[1] Kyung woo Yoon,[1] Jun-Young Do.[1] *[1]Internal Medicine, Yeungnam Univ Hospital, Daegu, Republic of Korea; [2]Internal Medicine, Soonchunhyang Univ Gumi Hospital, Gumi, Republic of Korea.*

**Background:** Paricalcitol plays an important role not only in the establishment and maintenance of calcium metabolism but also in direct effects on renal and/or extra-renal tissues. The aim of this study is to evaluate the effect of paricalcitol on epithelial to mesenchymal transition (EMT) of peritoneal mesothelial cells.

**Methods:** The effects of paricalcitol on EMT in both human peritoneal mesothelial cells (HPMCs) and peritoneal membranes were evaluated. HPMCs were incubated with TGF-β and/or paricalcitol. EMT was assessed with α-smooth muscle actin (α-SMA) and E-cadherin. Furthermore, 36 male Sprague-Dawley rats were equally divided into three groups: C (control), PD (peritoneal dialysis), and PD + Pari (peritoneal dialysis and paricalcitol). Peritoneal dialysis were given twice daily for 8 weeks. The morphometric analyses performed on the peritoneal membranes of tissue specimens obtained at the end of the study.

**Results:** In vitro, exposure of HPMCs to TGF-β resulted in an increase of the expression of mesenchymal markers such as α-SMA and was associated with a decrease in the expression of epithelial markers, E-cadherin. Treatment of HPMCs with paricalcitol showed an amelioration of TGF-β induced changes in markers of EMT. In addition, paricalcitol decreased the expression of phosphorylated-Smad2/3 and increased the expression of Smad4. The cobblestone-like appearance of HPMCs were converted to a fibroblast-like morphology after treatment with TGF–β. Treatment with paricalcitol blocked this morphologic transformation. In vivo, Trichrome-stained parietal peritoneum

of abdominal wall showed a marked increase in submesothelial matrix in PD group, which is ameliorated by paricalcitol (7.42 ± 1.35 μm in C group, 49.26 ± 7.89 μm in PD group, and 22.04 ± 3.64 μm in PD + Pari group).

**Conclusions:** Our results suggest that paricalcitol has a protective effect on EMT in peritoneal mesothelial cells. It was mediated by TGF-β/Smad pathway.

## FR-PO925

**Impact of Alanyl-Glutamine on Peritoneal Health – Results from the Clinical Phase I/II of PD-protec™** Klaus Kratochwill,[1] Michael Boehm,[1] Rebecca Herzog,[2] Katharina Gruber,[1] Anton Lichtenauer,[2] Lilian Kuster,[2] Andreas Gleiss,[1] Christoph Aufricht,[1] Andreas Vychytil.[1] *[1]Medical Univ of Vienna, Austria; [2]Zytoprotec GmbH, Austria.*

**Background:** Peritoneal dialysis fluids (PDF) impair peritoneal health via their bio-incompatible composition, resulting in clinical complications such as deterioration of membrane function and infections. Supplementation of parenteral nutrition with alanyl-glutamine dipeptide has been shown to improve clinical outcome e.g. in critically ill patients.

**Methods:** In a phase I/II trial (EudraCT 2010-022804-29) at the Medical University of Vienna 20 stable patients (6 with a history of prior peritonitis) on PD underwent a single 4 h dwell of standard PDF (Dianeal® PD4 3.86%, Baxter) or PD-protec™ (Dianeal® with 8 mM alanyl-glutamine (Dipeptiven®, Fresenius-Kabi)) in an open label, randomized, two-period, cross-over design. Following a peritoneal equilibration test (PET) PD effluent was tested for oxidative stress, sterile inflammation and reduced immunocompetence.

**Results:** Safety of PD-protec™ was demonstrated by stable laboratory and clinical data and by absence of any drug-related adverse event. PD-protec™ also demonstrated efficacy in the sub-group of 'peritonitis positive' patients with attenuated peritoneal levels of advanced oxidized protein products (AOPP) and significantly reduced interleukin 8 (IL-8). In addition, highly sensitive fluorescent cyanine dyes and 2D-DIGE were used to quantify the oxidative stress proteome of cell pellets from PD effluents (5 μg) yielding 2D gels containing more than 1300 spots. *Ex-vivo* assay exposure of PBMC to PD effluent from the PD-protec™ group significantly improved LPS-induced cytokine release, associated with significantly increased intracellular glutamine levels.

**Conclusions:** The obtained data clearly show the potential of PD-protec™ for improving peritoneal health by counteracting PD related pathomechanisms at least in the clinically highly relevant risk population that has previously suffered from peritonitis. These results will form the basis for a trial investigating the effects of more extended treatment in a larger number of PD patients.

## FR-PO926

**The Peritoneal Endothelial Glycocalyx in Uremic Rats – The Effect of Dialysis Solutions and Relationships with Peritoneal Transport** Carmen A. Vlahu,[1] Dirk Gijsbert Struijk,[1,2] Raymond T. Krediet.[1] *[1]Dept of Nephrology, Academic Medical Center, Amsterdam, Netherlands; [2]Dianet Foundation, Utrecht, Netherlands.*

**Background:** Continuous peritoneal dialysis (PD) leads to continuous exposure of the peritoneal membrane to high concentrations of glucose and its degradation products, causing inflammation and angiogenesis, which may all alter the endothelial glycocalyx. We investigated the changes in peritoneal endothelial glycocalyx induced by chronic kidney failure (CKF) and by long-term PD, using a conventional or a 'biocompatible' dialysis solution. These changes were related to peritoneal transport and morphological alterations of the peritoneal membrane.

**Methods:** Forty-four Wistar rats were divided in 4groups: normal kidney function (NKF), CKF, CKF exposed to Dianeal 4.25% (CKDD), or Physioneal 3.86% (CKDP). CKF was induced by 70% nephrectomy. At 16 weeks, the rats underwent Sidestream Darkfield (SDF) imaging of the peritoneal blood vessels. The status of endothelial glycocalyx was assessed by measuring the perfused boundary region (PBR) near the vessel wall. A standard peritoneal permeability test adapted for the rat and light microscopy were performed.

**Results:**

| | NKF | CKF | CKDD | CKDP |
|---|---|---|---|---|
| Renal creat cl (ml/min) | 4.3±0.7 | 1.8±0.5* | 2.3±0.5* | 1.8±0.6* |
| D/P creat | 0.4±0.06 | 0.5±0.03 | 0.6±0.08* | 0.6±0.05* |
| Glucose abs (%) | 62.2±8.6 | 61.8±1.5 | 69.9±1.4 | 66.7±3.3 |
| Fibrosis score | 0(0-1) | 2(0-3)* | 5(4-8)* | 4(3-6)* |
| Vessel density | 8.6±1.9 | 13.1± 4.9* | 30.4±5.4* | 18.9±5.2* |
| PBR(μm) | 2.2±0.2 | 2.1±0.4 | 2.1±0.2 | 2.1±0.1 |

*p<0.05 versus NKF.

**Conclusions:** Although we could reproduce the functional and morphological peritoneal abnormalities we described previously, this was not associated with a difference in the state of the endothelial glycocalyx as measured by SDF imaging, between the groups. Also no relationship with parameters of light microscopy and peritoneal transport could be established. This suggests that the damage induced by dialysis solutions is independent of the endothelial damage from the circulation.

## FR-PO927

**Systemic Microvascular Endothelial Glycocalyx and Peritoneal Transport in Peritoneal Dialysis Patients** Carmen A. Vlahu,[1] Dirk Gijsbert Struijk,[1,2] Hans Vink,[3] Raymond T. Krediet.[1] *[1]Dept of Nephrology, Academic Medical Center, Amsterdam, Netherlands; [2]Dianet Foundation, Utrecht, Netherlands; [3]Cardiovascular Research Institute Maastricht, Netherlands.*

**Background:** During peritoneal dialysis (PD), the capillary wall, coated at the luminal side by the endothelial glycocalyx, represents the main transport barrier between blood and the peritoneal cavity, and could thereby influence peritoneal transport. However, the magnitude of peritoneal solute transport is also dependent on the number of perfused peritoneal capillaries. In this study we investigated the relationship between the systemic endothelial glycocalyx and parameters of peritoneal transport in PD patients.

**Methods:** Investigations were performed in 17 stable PD patients. We performed Sidestream Darkfield imaging of the sublingual blood vessels. The state of the endothelial glycocalyx was assessed by measuring the red blood cells column width (RBCW) and the perfused boundary region (PBR) near the vessel wall. All patients underwent a Standard Peritoneal permeability Analysis.

**Results:** PBR and RBCW were 3.6±0.4μm and 10.2±0.6μm. Fast transport status was defined as the presence of two of the following parameters: glucose absorption >75%, MTACcreatinine>13 ml/min, MTACurate>11 ml/min. In the patients with a non fast transport status, PBR positively correlated with net ultrafiltration ($p<0.01$, $r=0.6$) and negatively correlated with MTACcreatinine ($p=0.04$, $r=-0.4$) MTACurea ($p=0.02$, $r=-0.5$) and MTACurate ($p=0.02$, $r=-0.5$), glucose absorption ($p<0.01$, $r=-0.7$). Such relationships were absent in those with a fast transport status.

**Conclusions:** The negative correlation between the state of the systemic endothelial glycocalyx and the transport of small solutes, suggests that a thicker permeable fase of the glycocalyx delays the access of small solutes from blood to the small inter-endothelial pores, probably by decreasing their diffusion velocity. The above mentioned correlation was absent in patients with fast transport status, suggesting that in this group, the increase in the number of perfused vessels, probably induced by locally produced substances, leading to an increased number of functional small pores, prevails.

## FR-PO928

**High Glucose Promotes TGF-β1 Production by Inducing FOS Expression in Human Peritoneal Mesothelial Cells** Shigehiro Doi,[1] Ayumu Nakashima,[2] Takao Masaki.[3] *[1]Blood Purification, Hiroshima Univ Hospital, Hiroshima, Japan; [2]Regeneration and Medicine, Hiroshima Univ Hospital, Hiroshima, Japan; [3]Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.*

**Background:** Peritoneal fibrosis is a serious complication of peritoneal dialysis (PD). A high concentration of glucose in PD fluid is a major factor in the development and pathology of peritoneal fibrosis. Although it is known that high glucose induces production of transforming growth factor-beta1 (TGF-β1), the mechanism remains elusive. The aim of this study was to determine the gene(s) involved in high glucose-induced TGF-β1 production in human peritoneal mesothelial cells (HPMCs).

**Methods:** Microarray analysis was performed following 3-hour preincubation of HPMCs in 4% glucose medium. Amang of the up-regulated genes, the transcriptional genes were selected by Gene Ontology analysis for biological processes, including regulation of transcription and DNA-dependent. In the selected genes, mRNA amplication were confirmed. Effects of the small interfering RNA (siRNA) treatments of the increased genes on the up-regulation of TGF-β1 mRNA were assessed by Real time PCR. Finally, enzyme-linked immunosorbent assays (ELISA) was performed to determine the gene(s) that contributes to production of TGF-β1 protein in the medium.

**Results:** Microarray analysis revealed that the expression of 51 genes increased by more than 3-fold. By Gene Ontology analysis, 13 were selected for further study. Real time PCR confirmed mRNA amplification for 9/13 genes. Furthermore, the high glucose-induced up-regulation of TGF-β1 mRNA was attenuated by the siRNA of 4 genes: MDS1 and EVI1 complex locus (MECOM), FBJ murine osteosarcoma viral oncogene homolog B (FOSB), FBJ murine osteosarcoma viral oncogene homolog (FOS) and activating transcription factor 3 (ATF3). ELISA showed that siRNA treatment of FOS, but not MECOM, FOSB or ATF3, suppressed the increase of TGF-β1 protein in the medium.

**Conclusions:** FOS is a downstream effector of high glucose stimulation in HPMCs that contributes to TGF-β1 production, and suggest that blocking FOS expression may be a therapeutic target for peritoneal fibrosis.

*Funding:* Private Foundation Support

## FR-PO929

**Peritoneal Fibrosis: A Study Comparing Histological Assessment with Abdominal Wall UltraSonography** Alferso C. Abrahams,[1] Amelie Dendooven,[2] Jan Willem Van der Veer,[1] Gerard Stapper,[3] Paul Berger,[4] Tri Q. Nguyen,[2] Marianne C. Verhaar,[1] Walther H. Boer.[1] *[1]Nephrology; [2]Pathology; [3]Radiology; [4]Surgery, UMC, Utrecht, Netherlands.*

**Background:** Long-term peritoneal dialysis (PD) causes peritoneal thickening (fibrosis). Longitudinal measurements of the thickness of the peritoneum could be useful to screen PD patients for evolving encapsulating peritoneal sclerosis. Abdominal wall ultrasonography (US) has been used to measure peritoneal thickness. However, no studies have directly related measurement of the peritoneal thickness by US with histologic examination of peritoneal biopsies. We hypothesized that US provides a reliable non-invasive method to measure peritoneal thickness.

**Methods:** We obtained biopsies of the parietal peritoneum of 50 patients during kidney transplantation: 5 uremic patients, 13 HD patients, and 32 PD patients with different vintage (<2yrs n=10; 2-4yrs n=14; >4yrs n=8). The extent of peritoneal fibrosis was determined by measuring the thickness of the submesothelial compact zone on H&E-stained formalin-fixed tissue sections. In 32 of these patients the parietal peritoneum was examined by US using a high resolution 2D real-time scanner with a linear 17 mHz probe.

**Results:** No agreement between the methods was observed when the difference between the paired measurements was plotted against the mean value (bias=257μm, 95% limit of agreement 4.6-511μm) with US measuring higher results compared to biopsy assessments (371±95μm vs 113±62μm, p<0.0001). Increased peritoneal thickness as assessed in biopsies was observed in patients who had undergone PD for >4yrs (160±102μm) compared to uremic patients (94±41μm, β=83μm, p=0.011) and patients who had undergone PD for <2yrs (94±41μm, β=83μm, p=0.008). US showed no differences in thickness between groups.

**Conclusions:** This is the first study that directly compares measurements of peritoneal thickness by US to microscopic examination. We observed no agreement between the methods. This may be due to the possibility that US measurements include other components of the parietal peritoneum than the submesothelial compact zone. Prospective longitudinal studies are needed to determine whether US can be used for routine assessment of PD treatment.

## FR-PO930

**Suppressive Effects of Intraperitoneal L-carnitine on Peritoneal Fibrosis Caused by Chronic Dialysate Exposure in Rats** Yoshihiro Matsumoto, Yasushi Shimada, Youichi Nojima. *Dept of Nephrology, Shizuoka City Hospital, Japan.*

**Background:** Conventional glucose-containing peritoneal dialysates are reportedly not biocompatible and may be associated with the development of peritoneal sclerosis. L-carnitine is a natural substance (molecular weight, 161 Da) that plays a critical role in fatty acid oxidation and metabolic homeostasis. In the present study, we aimed to evaluate the beneficial effects of L-carnitine on peritoneal fibrosis that develops due to chronic exposure to conventional glucose-containing dialysates.

**Methods:** We prepared dialysis fluids containing 188 mM glucose (GluPD) as well as dialysis fluids containing 169 mM glucose and 19 mM L-carnitine (10% of glucose replaced with L-carnitine to a concentration of 0.3% L-carnitine; CarPD). Sprague-Dawley rats (n = 7 for each treatment) were intraperitoneally administered GluPD or CarPD twice a day for 6 days per week. After 13 weeks, we histologically examined the parietal peritoneum of the rats and measured peritoneal thickness. Mesothelial cells on the liver surface were enumerated using imprint technique, and the numbers of mesothelial cells were compared between the treatment groups.

**Results:** The peritoneal thickness in rats treated with GluPD and CarPD was significantly greater than that in non-treated rats. The thickening of the peritoneum in rats treated with CarPD was significantly suppressed by 50–70% compared to that in rats treated with GluPD. However, the number of mesothelial cells on the liver surface was greater in rats treated with GluPD and CarPD as compared to that in non-treated rats; the difference in this value between rats treated with GluPD and CarPD was not significant.

**Conclusions:** Considering the suppression of peritoneal thickening in rats treated with CarPD, the use of the L-carnitine-containing dialysates might be effective in improving or preventing peritoneal sclerosis in dialysis patients.

## FR-PO931

**Expression of microRNA-200c and Its Role in the Process of High Glucose Induced EMT in Human Peritoneal Meosthelial Cells** Hong Liu, Xiang Zhou, Youming Peng, Fu-You Liu. *Dept of Nephrology, The Second Xiangya Hospital of Central South Univ, Changsha, Hunan, China.*

**Background:** To investigate the effect of miRNA-200c in the process of high glucose induced EMT and ECM accumulation in HMrSV5 cell lines.

**Methods:** HMrSV5 cells were exposed to 60mM D-glucose.The expressions of E-cadherin, vimentin ,FN and COL-1 were examined by realtime PCR and western blo, meanwhile realtime PCR for miRNA-200c.Furthermore HMrSV5 cells were transfected with miRNA-200c mimic or miRNA mimics negative control before exposing to 60mM D-glucose.Then the expressions of E-cadherin, col-1, vimentin and FN were detected by immunofluorescence, realtime PCR and western blot.

**Results:** Stimulation of HMrSV5 cells with high gluose resulted in a significant decrease of E-cadherin and increase of vimentin, COL-1 and FN, all in time-dependent manner. High glouse also repressed miRNA-200c.Compared to high glouse group, overexpression of miRNA-200c in HMrSV5 cells upregulated the mRNA and protein expression of E-cadherin, and downregulated the mRNA and protein expression of vimentin,COL-1 and FN.However, miRNA mimics negative control had no significant effect on the expression of E-cadherin, vimentin ,COL-1and FN.

**Conclusions:** Our data suggest that microRNA-200c plays a significant role in the progression of high glucose induced peritoneal fibrosis.

## FR-PO932

**Interferon-Gamma Alters Mesothelial Cell Response to Transforming Growth Factor Beta-1, Promoting Peritoneal Fibrosis** Donald Fraser,[1] Tanya Jayne Bodenham,[1] Timothy Bowen,[1] Nicholas Topley.[2] *[1]Insitute of Molecular and Experimental Medicine, Cardiff Univ, Cardiff, Wales, United Kingdom; [2]Institute of Infection, Immunity and Biochemistry, Cardiff Univ, Cardiff, Wales, United Kingdom.*

**Background:** Peritonitis infections are a serious complication for patients receiving peritoneal dialysis (PD) leading to progressive fibrosis of the peritoneal membrane, one of the major reasons for treatment failure in PD patients. TGF-β1 is a key regulator of tissue repair and the fibrotic process and the interaction between TGF-β1 and pro-inflammatory signalling may affect how cells respond to this cytokine either by repair and resolution, or by fibrosis and disease.

**Methods:** In vivo and in vitro systems have been used to characterise the interplay between TGF-β1 signalling and Signal Transducer and Activator of Transcription (STAT) activation by Interleukin 6 (IL6) and Interferon gamma (IFN-y). The in vivo system consists of a murine model of inflammation driven fibrosis, where mice are injected with repeated inflammatory stimulation resulting in scarring of the peritoneum. The in vitro system comprises culture of primary human peritoneal mesothelial cells (HPMC) in the presence of TGF-β1 +/- IFN-y.

**Results:** Stimulation of HPMC with TGF-β1 results in induction of matrix metalloproteinase 3 (MMP3) at the mRNA and protein level, which is specifically inhibited in the presence of IFN-y. IFN-y did not alter other TGF-β1 responses. Increased matrix production has been shown in the in vivo system thus supporting the in vitro findings. Chemical inhibition of mitogen activated kinase pathway (MAPK) through blockade of ERK 1/2 and p38 signalling prevented the TGF-β1 dependent induction of MMP3. This induction was also blocked via inhibition of SMAD 3 phosphorylation, thus suggesting that MMP3 induction via TGF-β1 requires both SMAD dependent and SMAD independent signalling pathways.

**Conclusions:** Within HPMC, IFN-y appears to promote fibrosis by favouring matrix accumulation over remodelling through specific inhibition of MMP3. Current investigations are directed at the mechanism by which IFN-y regulates MMP3 expression.

## FR-PO933

**Heme Oxygenase-1 Attenuates Lipopolysaccharide (LPS)-Induced TLR4 and Proinflammatory Signaling in Human Peritoneal Mesothelial Cells (HPMCs)** Jongho Shin, Jeongho Kim, Jinuk Jeong, Kitae Bang. *Nephrology, Eulji Univ Hospital, Dae-jeon, Republic of Korea.*

**Background:** Bacterial peritonitis is a major complication of PD and a leading cause of technique failure. Recognition of bacterial pathogens by the peritoneum is mediated in part by toll-like receptors. Heme oxygenase-1 gene expression by LPS in macrophages is not only induced via a TLR-4-dependent mechanism, but also increased HO-1 activity has also been shown to have inhibitory effects on intracellular signaling, that is initiated by TLR-4 activation. This regulatory interplay between TLR-4 and HO-1 appears to form a negative feedback loop which might inhibit excessive activation of macrophage by LPS. However, The regulatory effects of HO-1 overexpression on LPS-induced inflammation, which plays a leading cause of technique failure, are unknown in HPMCs, yet. So, the objectives of this study are examine the effects of overexpression of human HO-1 on LPS-induced inflammation in HPMCs.

**Methods:** We treated HPMCs with LPS(1μmol/l) and HO-1 inducer(hemin,10μmol/l). To further investigate the pure effect of HO-1 on LPS-induced inflammation, Gene transfer of recombinant Adenovirus-harboring human HO-1 to HPMCs was done. The involvement of MAP kinase family and nuclear factor(NF)-κB in these processes was also studied.

**Results:** HPMCs constitutively expressed TLR4 and HO-1. LPS increased the expression of TLR4 and HO-1. A prominent induction of IL-8 was detected after LPS stimulation. Treatment of HPMCs with HO-1 inducer, hemin showed a amelioration of LPS- induced changes in expression of TLR4 and IL-8 with increase of expression of HO-1. Human HO-1 gene transfection resulted in a significant increase in HO-1 expression and ameliorated LPS- induced changes. NF-κB expression was also detected but ERK and JNK were not detected in our study like other previous reports.

**Conclusions:** Our study suggest that HO-1 pathway is involved in LPS-induced TLR4 responsiveness and HO-1 may regulate LPS-induced inflammation in HPMCs. This study has implications for improving treatment of infection in PD patients and is the first to show the beneficial effect of HO-1 on attenuating LPS-induced inflammation in HPMCs.

## FR-PO934

**Competing Risks of Encapsulating Peritoneal Sclerosis: Results from PD-CRAFT** Mark Lambie,[1] David W. Johnson,[2] Simon J. Davies.[1] *[1]Health Services Research Unit, Keele Univ, Stoke on Trent, United Kingdom; [2]Queensland Univ, Brisbane, Australia.*

**Background:** Encapsulating peritoneal sclerosis (EPS) is an uncommon complication of peritoneal dialysis (PD), where the risk increases significantly with increasing time on therapy. We hypothesised that, at the start of PD, risk factors for death would decrease the risk of developing EPS as death will act as a competing risk for EPS.

**Methods:** We combined 3 large datasets (AnzData, Global Fluid Study, Scottish Renal Registry(SRR)) with complete data on EPS occurrence and the denominator population. All incident patients aged ≥15 years were included and a competing risks survival analysis used with outcomes of censored, EPS (prior to death) or death and robust standard errors.

Comorbidity data was classified by either primary renal diagnosis (low comorbidity = glomerulonephritis, polycystic kidney disease, chronic pyelonephritis, high comorbidity = other) and diabetic status (all 3 datasets) or by Stoke comorbidity score (AnzData and Global).

**Results:** There were 112 cases of EPS out of 17,912 patients. The cumulative incidence at 10 years varied from 0.04 in AnzData, to 0.25 in SRR. Competing risks models showed age (SHR 0.79 per decade, 95% CI 0.5-0.83) and high comorbidity renal disease (SHR 0.54, 95% CI 0.41-0.73) decreased the risk of EPS which Cox models failed to demonstrate. The SRR had a SHR of 5.62 (95% CI 5.28-6.21) relative to AnzData but this was not through a decreased mortality (HR for mortality in SRR vs AnzData in adjusted Cox model 1.14, 95% CI 1.05-1.42) or through longer periods of PD (median months on PD, SRR 22.6, AnzData 21.1, p=0.2). The Global dataset had an intermediate risk (SHR relative to AnzData 2.11, 95% CI 1.78-2.49) but the numbers were small so no further analysis was performed on this.

**Conclusions:** For patients commencing PD, factors that increase the risk of death decrease the risk of developing EPS. Competing risks regression is an appropriate model for analysis of dialysis outcomes. The Scottish Renal Registry has a significantly higher rate of EPS than found in AnzData, possibly due to ascertainment bias or genetic factors.

*Funding:* Pharmaceutical Company Support - Baxter

## FR-PO935

**Peritoneal Membranes Are More Inflamed in Patients with Subsequent Encapsulating Peritoneal Sclerosis: Results from the GLOBAL Fluid Study**

Mark Lambie,[1] Nicholas Topley,[2] Simon J. Davies.[1] *[1]Health Services Research Unit, Keele Univ, Stoke on Trent, United Kingdom; [2]Cardiff Univ School of Medicine, Cardiff, United Kingdom.*

**Background:** Risk factors for Encapsulating Peritoneal Sclerosis (EPS), a serious, uncommon complication of Peritoneal Dialysis (PD), include a fast peritoneal solute transport rate (PSTR) and a fast PSTR is associated with increased peritoneal inflammation. Whether inflammation is present in patients with subsequent EPS is not known.

**Methods:** We performed a nested case control study on UK patients from a multi-centre, international, cohort study (the GLOBAL Fluid Study). All definite cases of EPS (n=11) were matched on centre, age and duration of completed PD with 3 controls each. All 4-hour dialysate effluent and plasma samples from cases and controls collected by repeated sampling during routine peritoneal equilibration tests prior to PD cessation were assayed by electrochemiluminescence for IL-6, IFN-γ, TNF-α and IL-1β. Analysis was by multilevel modelling of log-transformed cytokine levels accounting for clustering by person (level 2) and case-control strata (level 3) with EPS and time till PD end as predictors. A skewed distribution of IL-1β necessitated a logistic model.

**Results:** Dialysate IL-6 (β=0.78 of one $\log_{10}$ order of cytokine concentrations, 95%CI 0.13, 1.44, p=0.02), IFN-γ (β=0.63, 95%CI 0.02, 1.24, p=0.04) and TNF-α (β=0.67, 95%CI 0.30, 1.03, p<0.001) were all significantly higher in cases with subsequent EPS. Dialysate IL-1β was not significantly different, possibly due to loss of statistical power through conversion to a binary variable. Plasma IL-6 (β=0.31, 95%CI -0.01, 0.63, p=0.06) tended to run slightly higher, whereas plasma IFN-γ was significantly lower in EPS patients (β=-0.51, 95%CI -0.81, -0.22, p=0.001) and there was no difference in plasma TNF-α. Dialysate and plasma IL-6 rose significantly towards the end of PD, while plasma IFN-γ fell.

**Conclusions:** Peritoneal membranes are more inflamed in PD patients who subsequently develop EPS.

## FR-PO936

**Detection of Pericytes in a Peritoneal Dialysis Rat Model and Its Functional Study**

Nan Chen, Hong Fu Yan, Jingyuan Xie. *Dept of Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ, School of Medicine, Shanghai, Shanghai, China.*

**Background:** Angiogenesis and vascular remodeling of peritoneum are associated closely with ultrafiltration failure(UF) in peritoneal dialysis (PD) patients. Pericytes may relate to angiogenesis and contribute to UF. Although it is still unavailable, the detection of angiogenesis may helpful to the early diagnosis of UF. The purpose of this study is to determine the existence of pericytes and to develop an approach to measure the peritoneum vessels and neovascularization (NV).

**Methods:** 48 SD rats were divided into 7 groups; Dialysate (100 ml/kg/d ) was injected into peritoneal cavity through the PD catheters. Rats in Group N (n=6) were subjected to sham operation; Group U (n=6) which were conducted 5/6 nephrectomy; Rats in Group PD1 (N=6), Group PD2(N=6) and Group PD3(N=6) were injected by 1.5% , 2.5%, 4.25% PD fluid for one month 12w after the 5/6 nephrectomy; Group PD4 used 4.25% PD fluid injection for two months 12w after the 5/6 nephrectomy; Rats in Group N+P (n=6) were performed 4.25% PD fluid injection for one month.

**Results:** We detected pericytes in normal peritoneum, the markers of pericyte were various in different part of peritoneum, in the superficial part, marked by CD248/PDGF-ß, while Desmin/PDGF-ß was detected in deep peritoneum. However, during PD process, the DESMIN marker appears in the superficial part. We found obvious NV in the peritoneum, the degree was obviously associated with the glucose concentration. Spatial distribution of NV present obvious lateral and vertical inhomogeneity. By electron microscopy, we observed two manners of angiogenesis: sprout new blood vessels and the angiogenesis of endothelial like tumor cells. The concentrations of VEGF secreted by the pericyte and VEGF-R 2 secreted by the endothelial cells were both rised, associated with the glucose concentration and the PD duration.

**Conclusions:** We found the pericytes are exist in the peritoneum of PD rat and the surface markers of pericyte changes to match the pathophysiological circumstance. The function of pericytes is related to angiogenesis of peritoneum and has potential values in early prediction of the development of UF.

## FR-PO937

**Tissue Advance Glycation End Products Deposits Are Reduced in Peritoneal Dialysis Patients Treated with Biocompatible Peritoneal Fluids**

Arkom Nongnuch,[1,2] Stanley Fan,[3] Andrew Davenport.[2] *[1]Renal Unit, Dept of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand; [2]Centre for Nephrology, Royal Free Hospital, Univ College London, London, United Kingdom; [3]Dept of Nephrology, Barts & the London National Health Service Trust, Royal London Hospital, London, United Kingdom.*

**Background:** Advance Glycation End Products (AGEs) are a novel biomarker for cardiovascular disease (CVD) and may be absorbed during the intraperitoneal dwell in peritoneal dialysis patients. The amount of AGEs present in standard acidic lactate PD fluids is greater than those found in neutral PD fluid. The objective of this study was to compare skin autofluorescence as a measurement of AGEs between standard and bicarbonate base PD fluid.

**Methods:** We measured tissue AGEs using skin autofluorescence (sAF) (DiagnOptics, Groningen, Netherland) on 145 peritoneal dialysis patients, 78 on standard PD solution and 61 on neutral PD solution.

**Results:** The results are shown in the table.

| Parameters | Standard Solution | Neutral solution | P value |
|---|---|---|---|
| Skin autofluorescence, AU (mean ± SD) | 3.15±1.23 | 3.08±0.9 | NS |
| Age, years (mean ± SD) | 63±16 | 57±16 | 0.03 |
| Hypertension (%) | 55(70) | 33 (54) | 0.04 |
| Diabetes (%) | 30 (38) | 24 (39) | NS |
| Smoking (%) | 42 (53) | 24 (39) | NS |
| History of CVD | 19 (24) | 12 (20) | NS |
| History of PVD | 5 (6) | 4 (6) | NS |
| Dialysis Vintage, median (range), years | 10 (1-156) | 23 (2-82) | 0.004 |
| Urine volume, (median, range), ml | 944 (0-3042) | 850 (0-3324) | NS |
| B2 microglobulin, (median, range), mg/dL | 15.7 (5.2-50.5) | 23.4 (7.8-59.5) | 0.018 |
| Total Kt/V (mean ± SD) | 2.41±1.01 | 2.3±0.83 | NS |

After correcting for multiple statistical analyses, those patients treated with "biocompatible" peritoneal dialysis fluids had similar sAF results despite a longer dialysis vintage and exposure to peritoneal dialysis fluids, and a greater B2 microglobulin, a marker of inflammation and residual renal function.

**Conclusions:** The more biocompatible neutral pH peritoneal dialysis solutions may have beneficial effect on reducing tissue AGE accumulating in PD patients. Further prospective studies are warranted to confirm these encouraging findings.

## FR-PO938

**IL6 and Peritoneal Dialysis Adequancy**

Sabrina Milan Manani, Grazia Maria Virzì, Alessandra Brocca, Giacomo Mason, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco. *Nephrology Dep-IRRIV, Italy.*

**Background:** Inflammation is a predictor of all-cause mortality in the general population and in CKD patients. In these patients several factors can contribute to inflammation. Furthermore, in peritoneal dialysis (PD) patients, many systemic and local inflammatory mediators have been associated with membrane failure and increased mortality risk. Inflammation often coexists with malnutrition and there is a relationship between nutritional indices, as serum Albumin (Alb), and mortality. C-Reactive Protein (CRP) is an index of inflammatory activity. IL6 is a proinflammatory cytokine and modulates inflammation. The aim of the study was to investigate the systemic inflammatory biomarkers and assess their relationship with PD adequacy.

**Methods:** Serum levels of Alb, CRP and IL6 were measured in 46 PD patients (31CAPD/15APD). We evaluated IL6 concentration by ELISA. We used weekly $Kt/V_{urea}$ and Creatinine Clearance (wCc) as estimates of PD adequacy. PD patients were divided into 2 groups based on $Kt/V_{urea}$ value: 1.7 was the cut-off value as recommended by K/DOKI guidelines. Statistical analysis was performed by STATA Software. A p<.01 was considered statistically significant.

**Results:** The median values of Alb, CPR and IL6 showed no significant differences between CAPD and APD. IL6 levels showed a positive correlation with CPR (p<.001). IL6 correlated negatively with Alb (p=.01). PD patients with Kt/V <1.7 had significantly higher IL6 compared to PD patients with Kt/V>1.7 (median 62; IQR 33-162 vs 12; IQR 8-59 ng/ml, p=.015).

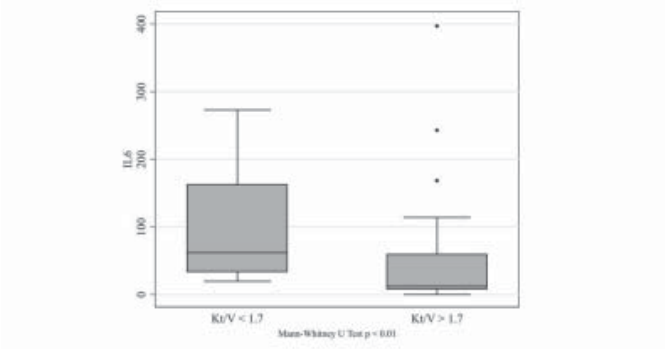

Figure1: PD patients with Kt/V <1.7 had significantly higher IL6 compared to PD patients with Kt/V>1.7 (median 62pg/mL; IQR 33-162 *vs* 12; IQR 8-59 pg/ml)

No statistically significant relationship between IL6 and the wCc was observed, but a positive trend was evident.

**Conclusions:** In conclusion, this study suggested that a low grade of IL6, as a marker of inflammation state, may be considered an index of PD adequacy. It is necessary to increase the sample size of PD subjects enrolled to validate our hypothesis.

## FR-PO939

**The Effect of Bicarbonate Containing Peritoneal Dialysis Solution on Epithelial-to Mesenchymal Transition in Omentum-Derived Mesothelial Cells** Kyu-hyang Cho,[1] Jun-Young Do,[1] Seokhui Kang,[1] Jong-Won Park,[1] Kyung woo Yoon,[1] Tae woo Kim.[2] *[1]Dept of Internal Medicine, Yeungnam Univ Hospital, Daegu, Republic of Korea; [2]Dept of Internal Medicine, Soonchunhyang Univ Gumi Hospital, Gumi, Republic of Korea.*

**Background:** The purpose of this study is to investigate the effect of bicarbonate containing PD (peritoneal dialysis) solution on EMT (epithelial-to mesenchymal transition) in omentum-derived mesothelial cells.

**Methods:** Omentum-derived mesothelial cells from 20 nonuremic patients undergoing abdominal surgery were incubated with lactate-buffered standard PD solutions (L group; Dianeal® and Stay-safe®), bicarbonate/lactate buffered PD solutions (LB group; Physioneal® and Balance®) or bicarbonate buffered PD solution (B group; BicaVera®) diluted 1:1 with culture medium. E-cadherin was measured as standard mesothelial marker by quantitative RT-PCR (real time-polymerase chain reaction) analysis. Snail and alpha-SMA (alpha-smooth muscle actin) were also measured as fibroblast marker by quantitative RT-PCR analysis. The number of CD54 (cluster of differentiation 54) positive cells (indicative mesothelial cells) was counted among confluent omentum-derived mesothelial cells by FACS (fluorescence-activated cell sorter).

**Results:** There were no significant differences in level of E-cadherin, snail and alpha-SMA among three groups.The number of CD54 positive cells among confluent omentum-derived mesothelial cells was B group, BL group and L group in order but the difference did not reach the statistical significance.

**Conclusions:** Bicarbonate containing PD solution groups showed a trend of higher number of CD54 positive cells among confluent omentum-derived mesothelial cells in vitro but without significant statistical differences in this study. We need further studies to clarify the impact of bicarbonate containing peritoneal dialysis solution on EMT in mesothelial cells.

## FR-PO940

**Hepatocyte Growth Factor Signalizes Ultrafiltration Failure in Peritoneal Dialysis Patients** Ana Paula Bernardo,[1,2] Olivia Santos,[1] Maria João Carvalho,[1] António Manuel Nunes Cabrita,[1] Anabela Rodrigues.[1,2] *[1]Nephrology, CHP, Porto, Portugal; [2]UMIB/ICBAS/Porto Univ.*

**Background:** Ultrafiltration failure (UFF) is a leading cause of peritoneal dialysis (PD) drop-out. Increased submesothelial fibrosis is a key process linked with such complication. Hepatocyte growth factor (HGF) ameliorates peritoneal fibrosis both in animal models and in-vitro studies, but no study explored dialysate HGF concentration in PD patients with UFF. Our aim was to assess the relation of dialysate HGF concentration with the UF profile, free water transport quantification (FWT), and small-solute transport ($MTAC_{creatinine}$) in a group of prevalent PD patients.

**Methods:** We performed a 4-hour, 3.86% glucose PET with additional measurement of UF at 60 minutes in 68 PD patients (age 50±14 years, 52% male, on PD for 19±23 months). We calculated Dialysate (D)/Plasma (P) ratio of creatinine, $MTAC_{creatinine,}$ FWT and small-pore ultrafiltration. We measured HGF and CA125 in the effluent.

**Results:** Effluent HGF strongly correlated with UF measured in a 4h, 3.86% glucose PET (r=-0,80, p=0,009), with FWT (r=-0,69, p=0,04) and with $MTAC_{creatinine}$ (r=0,75, p=0,02). Patients with UFF had higher dialysate HGF concentration and HGF/CA125 ratio than patients without UFF (103 pg/mL vs 77 pg/mL, p=0,018 and 6,2 pg/U vs 4,6 pg/U, p= 0,68, respectively). Moreover, patients with severe UFF forms, namely with FWT compromise, had higher dialysate HGF concentration compared with patients with UFF but no FWT compromise (104 pg/mL vs 88 pg/mL, p=0.08). FWT≤45% without UFF was documented in some patients: these also had a higher effluent HGF concentration, but a significantly lower HGF/CA125 ratio compared with those with preserved FWT (3,6 pg/U vs 5,1 pg/U, p=0,014).

**Conclusions:** Our study establishes that dialysate HGF concentration is significantly higher among patients with UFF, specially, if FWT is compromised. This increase possibly signalizes an ongoing counteracting process facing peritoneal membrane deterioration.

## FR-PO941

**Glucose Degradation Product Methylglyoxal Induces Immature Angiogenesis and Peritoneal Dysfunction in Peritoneal Membrane in Patients Undergoing Peritoneal Dialysis** Toshiaki Nakano,[1] Tohru Mizumasa,[2] Hisako Yoshida,[1] Masahiro Eriguchi,[1] Masatomo Taniguchi,[1] Kosuke Masutani,[1] Hideki N. Hirakata,[2] Kazuhiko Tsuruya,[1] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [2]First Dept of Internal Medicine, Fukuoka Red Cross Hospital, Fukuoka, Japan.*

**Background:** Angiogenesis in peritoneal membrane has been recognized to induce ultrafiltration failure and possibly lead to encapsulated peritoneal sclerosis in patients on CAPD. We investigated whether glucose degradation product methylglyoxal (MGO) is associated with angiogenesis in peritoneal membrane and induce a disturbance of angiogenesis in vitro.

**Methods:** Peritoneum obtained when CAPD catheters were removed from 61 CAPD patients was analyzed. Peritoneum was immunohistochemically stained with anti-CD34 (for endothelial cells), anti-αSMA (for pericytes) and anti-MGO antibodies. We evaluated the associations between the number of capillary vessels, peritoneal function (D/PCr) and the degree of MGO deposition. In addition, we measured the levels of VEGF and PDGF-BB mRNA in culture endothelial cells (human umbilical vein endothelial cells) and culture smooth muscle cells (human aortic smooth muscle cells) after the administration of MGO 50μM in vitro.

**Results:** We defined CD34-positive and αSMA-negative vessels as capillary vessels in peritoneal membrane using serial sections. The number of capillary vessels was associated significantly with the value of D/PCr and the degree of MGO depositions (both P<0.01). In vitro, the expression of PDGF-BB mRNA and protein in culture endothelial cells significantly decreased after the administration of MGO, though the expression of VEGF mRNA increased (both P<0.01). The expression of PDGF-Rβ mRNA in culture smooth muscle cells did not change after the administration of MGO, though the expression of VEGF mRNA increased (P<0.01).

**Conclusions:** Glucose degradation product MGO enhanced the production of VEGF and suppressed the production of PDGF-BB, suggesting it may lead to a disturbance of angiogenesis in peritoneal membrane. The accumulation of MGO in peritoneum may cause immature angiogenesis and peritoneal dysfunction.

## FR-PO942

**Fetuin Calciprotein Particles May Be Formed in Peritoneal Dialysis Fluid and May Contribute to Peritoneal Inflammation** Edward Robert Smith,[1] Stephen G. Holt.[3] *[1]Dept Renal Medicine, Eastern Health Clinical School, Monash Univ, Melbourne, VIC, Australia; [2]Eastern Health Intergrated Renal Services, Monash Univ, Melbourne, VIC, Australia; [3]Royal Melbourne Hospital, Melbourne Univ, Melbourne, VIC, Australia.*

**Background:** Fetuin-A (Fet-A) is a protein synthesised in the liver circulating at high concentrations. Fet-A forms high molecular weight complexes with calcium phosphate nanocrystals called calciprotein particles (CPP). CPP are detectable in the serum of patients with chronic kidney disease and/or inflammation, but not normal controls. CPP may be cleared by macrophages uptake via scavenger receptor-A, but in doing so cause inflammatory cytokine and oxidant species generation. CPP have been reported in the PD fluid of patients with calcific peritonitis. Since free FetA has a similar molecular weight to albumin and CPP are too big to pass through large peritoneal membrane pores, we tested the hypothesis that CPP might be formed in situ in peritoneal fluid (PDF).

**Methods:** We measured Free FetA, CPP and albumin in spent dialysate and in the serum of 20 patients undergoing PD without obvious complication.

**Results:** Mean (SD) total Fet-A concentration was 187 (30) and 88 (46) mg/L in serum and PDF respectively. The mean (SD) CPP-associated Fet-A concentration was significantly higher in serum than in PDF [45 (13) vs. 24 (16) mg/L, P=0.012]. The proportion of Fet-A present as CPP was not significantly different to serum [24 (7) vs. 23 (6) %, P>0.1]. Mean (SD) albumin concentrations in serum and PDF were markedly different [31 (4) vs.1.2 (0.6) g/L P<0.0001]. Thus, the ratio of Fet-A to albumin was significantly higher in PDF fluid than in serum [81(44) vs 5(1) mg/g, P<0.0001]. PDF CPP Fet-A concentration was significantly correlated with phosphate (r=0.54, P=0.001), total protein (r=0.48, P=0.031) and 8-iso-PGF2α (r=0.48, P=0.032), but not with calcium (P=0.37) or albumin concentrations (P=0.40).

**Conclusions:** CPP formation may occur within the peritoneal cavity. CPP may interact with peritoneal macrophages and contribute to inflammation and oxidant stress.

## FR-PO943

**The Mutual Relationship between Peritonitis and Peritoneal Transport** Sadie Van Esch, Anouk Van diepen, Raymond T. Krediet, Dirk Gijsbert Struijk. *Nephrology, Academic Medical Centre, Amsterdam, Netherlands.*

**Background:** Preservation of the peritoneal membrane is required to achieve long-term PD. We investigated the effect of multiple peritonitis episodes on peritoneal transport.

**Methods:** We prospectively collected transport parameters from 709 incident adult PD patients treated between 1990 and 2010. Strict inclusion criteria were used to select patients: follow-up of at least 3 years with the availability of a standard peritoneal permeability analysis (SPA) in the first year after start of PD and a SPA after the third year of PD, without peritonitis preceding the first SPA. Patients either had to remain peritonitis-free (group 0, n=30) or experienced ≥3 peritonitis episodes (group ≥3, n=16) during follow-up.

**Results:** At baseline the groups were similar with regard to the transport of low molecular weight solutes and fluid. However, group ≥3 had lower peritoneal protein clearances and a higher restriction coefficient compared to group 0. This resulted in lower dialysate concentrations in group ≥3 vs group 0: albumin: 222 mg/L vs 416 mg/L, $p<0.01$, IgG: 36 mg/L vs 69 mg/L, $p<0.01$, $\alpha$2-macroglobulin: 2 mg/L vs 4 mg/L, $p<0.01$. Plasma concentrations were not different. After 3 years, group ≥3 showed a significant increase in the mass transfer area coefficient (MTAC) of creatinine and glucose absorption (GA) with a concomitant decrease in transcapillary ultrafiltration (TCUF) compared with group 0 (MTACcreat: p=0.03, GA: p=0.04, TCUF: p=0.03). No changes in free water transport were found.

**Conclusions:** Slow initial peritoneal transport rates of serum proteins result in lower dialysate concentrations, and likely a lower opsonic activity, which is a risk factor for peritonitis. This disappears during follow-up. Patients with frequent episodes of peritonitis show an increase in the transport of low-molecular weight solutes and a concomitant decrease of ultrafiltration, but no changes in free water transport; this was not found in long-term peritonitis-free PD patients. These findings suggest that frequent peritonitis leads to the development of an increase of the effective vascular peritoneal surface area without the structural membrane alterations that may develop after long-term PD.

## FR-PO944

**Characteristics and Outcomes of Fungal Peritonitis in a Modern North American Cohort** Annie-Claire Nadeau-Fredette, Joanne M. Bargman. *Div of Nephrology, Dept of Medicine, Toronto General Hospital - Univ Health Network, Univ of Toronto, Toronto, Canada.*

**Background:** Peritonitis remains a common complication of peritoneal dialysis (PD). Although representing only 1-12% of overall peritonitis in dialysis patients, fungal peritonitis (FP) is associated with serious complications, including technique failure (15-85%) and death (5-55%). Only scarce data has been published regarding FP outcomes in modern cohorts in North America. In this study, we aim to evaluate rates, characteristics and outcomes of FP in a major North American PD center.

**Methods:** We conducted a retrospective cohort study including all fungal peritonitis among peritoneal dialysis patients followed in a large PD center between January 2000 and February 2013. Our pre-specified end-points included rates of FP, characteristics, outcomes and determinants of death.

**Results:** Thirty-six episodes of FP were identified during the follow-up period (one episode per 671 patient-months), representing 4.5% of the total peritonitis events. Patients' mean age and peritoneal dialysis vintage were 61.3 ± 15.5 and 2.9 (1.5-4.8) years, respectively. Of the 36 episodes of FP, seven (19%) resulted in death and 17 (47%) led to technique failure with permanent transfer to hemodialysis. Surprisingly, PD was eventually resumed in 33% of cases with a median delay of 15 weeks (interquartile range 8-23) between FP and catheter reinsertion. In a univariable analysis, a higher Charlson comorbidity index (Odds ratio [OR] 3.25 per unit increase, 95% confidence interval [CI] 1.23-8.58) and PD fluid white blood cell (WBC) count greater than 3000/ $mm^3$ at presentation (OR 6.56, 95%CI 1.05-40.95) predicted death.

**Conclusions:** While fungal peritonitis is still associated with a high frequency of death and technique failure, one-third of our patients eventually returned to PD. Patients with a high burden of comorbidity and presenting with markedly elevated PD effluent WBC count appear at higher risk of death. We postulate that the high mortality associated with FP is partially related to the severity of comorbidity among patients with FP, rather than the infection per se. Importantly, PD can be resumed in a significant proportion of cases.

## FR-PO945

**Glucose-Based Peritoneal Dialysis Fluids Inhibit Complement-Mediated Host Defenses against *Staphylococcus aureus*** Parvathi S. Kumar,[1] Clifford T. Mauriello,[1] Pamela S. Hair,[3] Reem Raafat,[2] Kenji M. Cunnion.[1] *[1]Dept of Pediatrics, Eastern Virginia Medical Center/ Children's Hospital of the Kings Daughters, Norfolk, VA; [2]Dept of Pediatrics, Children's Hospital of the Kings Daughters, Norfolk, VA; [3]Dept of Pediatrics, Eastern Virginia Medical Center, Norfolk, VA.*

**Background:** Staphylococcus aureus peritonitis is a serious complication of Peritoneal Dialysis (CPD).Complement-mediated effectors of innate host defense are essential for optimal opsonophagocytosis of S.aureus.Hyperglycemic conditions impair optimal C3-mediated opsonization of S.aureus in vitro and in vivo.Since most peritoneal dialysis(PD) fluids are glucose-based,we hypothesized that glucose-based(GB)PD fluids likely inhibit S.aureus-induced complement host defenses compared to amino acid or dextran based PD fluids.

**Methods:** Commercial glucose-based(Dianeal) or dextran-based(Extraneal) PD fluids were purchased.Amino acid-based(Nutrineal) PD fluid was donated by Baxter International. Control PD fluid, excluding glucose,was generated with the same electrolyte composition as Dianeal. Dianeal supplemented with amino acids was also used.Human serum and $10^9$CFU *S.aureus* was incubated in each PD fluid for 1hour at 37°C.The samples were sedimented and the supernatant was assayed for C5a and C3a by ELISA and quantitative Western blot, respectively. Pelleted *S.aureus* was stripped off of covalently-bound C3-fragments and assayed by ELISA and Western blot.

**Results:** GB PD fluids inhibited *S.aureus*-initiated generation of complement anaphylatoxins C3a and C5a.GB PD fluids inhibited C3-fragment(C3b/iC3b) opsonization of *S.aureus* compared to non-glucose containing PD fluids.

**Conclusions:** *S.aureus* activation of complement was severely inhibited by GB PD fluids compared with amino acid or dextran-based PD fluids. Generation of analyphylatoxins critical for neutrophil recruitment and activation was inhibited. Opsonization of *S. aureus* with complement C3b/iC3b,vital for efficient phagocytosis, was also inhibited. The results suggest that GB PD fluids may inhibit critical complement-mediated host defenses increasing the risk of *S.aureus* peritonitis. Non glucose based PD fluids might reduce risk of infections.

## FR-PO946

**Calprotectin: A Novel Diagnostic and Prognostic Marker in PD-Related Peritonitis?** Francesco Iannuzzella,[1] Mattia Corradini,[1] Maria Parmeggiani,[2] Lucia Belloni,[2] Alfredo Stefani,[1] Sonia Pasquali.[1] *[1]Nephrology and Dialysis Unit, Arcispedale Santa Maria Nuova, Reggio Emilia, Italy; [2]Laboratory and Molecular Biology Unit, Arcispedale Santa Maria Nuova, Reggio Emilia, Italy.*

**Background:** The diagnosis of PD related peritonitis is relatively easy, but clinicians have limited tools to determine which patients will progress to more severe forms of infection. Calprotectin is a novel inflammatory biomarker widely used in the diagnosis of inflammatory bowel disease. The aim of this study was to assess the utility of peritoneal fluid calprotectin as a novel diagnostic and prognostic marker in PD-related peritonitis.

**Methods:** A total of 44 consecutive peritoneal fluid samples from 11 patients were collected at the peritonitis onset and on days 3, 7 and 30. All samples were examined for cell count, bedside culture and calprotectin concentration. Moreover we evaluated C reactive protein and blood leucocytes on the same days of PD effluent collection.

**Results:** We investigated 48 patients: 28 men, 61±18 yrs, 24.3% diabetic, mean PD vintage 30±16 months. During the follow-up, peritonitis was diagnosed in 11 patients (8 men, 59±16 yrs). The PD effluent culture was positive in 9 patients. The mean calprotectin concentration was 263.7±81.4 on day 0 and 35.7±66.8 on day 3. Calprotectin was undetectable in PD samples in 6 patients on day 3 and in 9 patients on day 7, and in all patients on day 30. The only 2 patients with persistence of calprotectin on day 7 were those who presented with a worse clinical course, a long in-hospital stay and who underwent peritonitis recurrence after treatment suspension. In all patients, both PD white cells count and calprotectin levels decreased significantly after the start of treatment ($p<0.001$). At the time of peritonitis onset, calprotectin concentration correlated well with both the neuthrophil count in the PD effluent ($r=0.68$) and in the circulation ($r=0.62$).

**Conclusions:** Calprotectin was detected in PD fluids of all patients at the peritonitis onset and then slowly disappeared within 7 days. Persistence of calprotectin on day 7 or its reappearance after a previous disappearance should be regarded as a risk factor for a worse clinical course.

## FR-PO947

**Eosinophilic Peritonitis: Possible Association with Laparoscopic Peritoneal Dialysis Catheter Insertion** Yuko Akioka, Tatsuo Asano, Kei Nishiyama, Noriko Sugawara, Kiyonobu Ishizuka, Masataka Hisano, Hiroko Chikamoto, Motoshi Hattori. *Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

**Background:** The methods for peritoneal dialysis (PD) catheter insertion include the open technique and the laparoscopic technique. A major advantage of laparoscopy is the complete visualization of the peritoneal cavity with diagnosis of some potential problems such as inguinal hernias, which can be repaired at the same time. However, the specific complications of the laparoscopic insertion were not sufficiently reported. The purpose of this study was to examine the association of eosinophilic peritonitis with laparoscopic insertion.

**Methods:** We examined 14 pediatric PD patients who underwent laparoscopic catheter insertion. Age-matched 12 patients who underwent open insertion were also examined. The cell counts of the peritoneal fluid were routinely studied during the post-operative period. Eosinophilic peritonitis was defined as showing >100 leukocytes/$mm^3$ effluent, of which >10% was eosinophils in the differential cell count.

**Results:** The incidence of eosinophilic peritonitis in the laparoscopic group was significantly higher than that of open group (64.3% vs. 16.7%, $p<0.01$). Eosinophilic peritonitis developed asymptomatically at 2.4±2.0 days, and resolved spontaneously in 14.0±7.6 days after laparoscopic insertion. The peak count of leukocytes was 798.0±748.6 cells/$mm^3$ (ranging from 275 to 2100) with a mean eosinophil percentage of 72.0±20.5. In patients with laparoscopic insertion, there were no differences in the duration of pneumoperitoneum, serum IgE level, eosinophilia in peripheral blood, and the presence of allergic diseases or immunosuppressive therapy between those with or without eosinophilic peritonitis.

**Conclusions:** Although the larger numbers of study will be needed, this study suggests the possible association of eosinophilic peritonitis with laparoscopic PD catheter insertion.

**FR-PO948**

**Predictors and Clinical Course of Culture-Negative Peritonitis in Peritoneal Dialysis Patients: Experience of a Center** Daniela Lopes, Clara Santos, Ana Marta Gomes. *Serviço Nefrologia, CHVNG/E, VNGaia, Portugal.*

**Background:** Peritonitis is the main infectious complication related to peritoneal dialysis (PD) and is a major reason for hospitalization and technique failure. Up to 20% of cases are culture-negative peritonitis (CNP). The aim of the study is to examine the frequency, predictors and clinical outcome of CNP in PD patients.

**Methods:** Retrospective cohort study of all episodes of PD-related peritonitis between 1998 and 2012. To determine the predictors and clinical outcome were compared 2 groups: positive-culture or CNP. Predictors:socio-demographic and clinical variables. Outcome analysis: resolution, hospitalization, catheter removal and hemodialysis transfer. Tests were conducted multilevel logistic regression to estimate the associations between the variables in analysis. The significance level for the models were determined as $P < 0.05$.

**Results:** We studied 163 episodes of peritonitis in 67 patients with a mean age of 55 ± 11 years, 70.5% male, yielding an overall rate of 0.59episodes/patient.year. There was 40 episodes (24.5%) of CNP. When comparing the 2 groups there were no differences regarding age, gender, etiology of kidney disease and major co-morbidities between the groups. A history of previous antibiotic treatment (past 30 days) was significantly more common with CNP than culture-positive (42.5% vs 7.3%, $p < 0.05$). The reasons for the administration of antibiotics were: infection of the outlet orifice (2 cases), peritonitis (1 case) and other medical reasons (14 cases). No association was found between the need for hospitalization ($p = 0.33$), cure ($p = 0.46$) and transfer technique ($p = 0.95$) with CNP. There was no association between previous antibiotic treatment and clinical outcome ($p = 0.88$).

**Conclusions:** In our study a history of previous antibiotic treatment was an important risk factor, this can be due to the fact that antibiotic can promote the change of the local flora and cause peritonitis with fastidious microorganisms or impairing the ability of cultures to detect the infectious organism.Thus, most cases of CNP may be explained by recent antibiotic treatment but there is no differences in clinical outcome between groups.

**FR-PO949**

**Global Pediatric Perspective on Peritonitis: A Report from the IPPN** Vimal Chadha,[1] Anja Christine Sander,[2] Franz S. Schaefer,[2] Bradley A. Warady.[1] *[1]Children's Mercy Hospital and Clinics; [2]Univ of Heidelberg.*

**Background:** Peritonitis remains a frequent complication of peritoneal dialysis (PD) and is the most common reason for technique failure. Our previous published registry experience revealed world-wide variation in causative organisms. To build upon that experience, the International Pediatric PD Network (IPPN) has collected data pertaining to peritonitis and other PD related issues in children receiving PD since 2007.

**Methods:** Data on children receiving maintenance PD, enrolled in the IPPN on-line registry was analyzed for this report.

**Results:** To date, 1991 children receiving PD have been enrolled in the registry from 95 centers in 35 countries. One-third of the patients receiving PD have experienced > 1 episodes of peritonitis with an overall annualized rate of 0.47 ± 0.29. 42% of the episodes were caused by Gm pos organisms, 19% by Gm neg organisms, 2.6% by fungus and 33% were culture neg. Staphylococcal and enterococcal infections were more common in Europe, whereas MRSA and pseudomonas episodes were more common in Latin American countries. Latin America and Turkey had the highest rate of culture neg results. Exit-site/tunnel infections (8%) and touch contamination (7%) were the most common identifiable sources of infection. Of 508 episodes of exit-site infection, 20% were associated with peritonitis. Presence of ostomy (RR 1.28), hypoalbuminemia (< 3.0 g/dL) (RR 1.34) and Staph aureus carrier state (RR 1.27) were all significant risk factors for occurrence of peritonitis. Dialysis modality, catheter configuration, number of cuffs, or exit-site orientation had no impact on the peritonitis rate. Relapse of peritonitis occurred in 60 patients; 73% of these occurred due to Gm pos organisms and 70% followed intermittent antibiotic therapy. There were 32 episodes of fungal peritonitis; 59% were preceded by bacterial peritonitis.

**Conclusions:** Despite published guidelines on the prevention of infection, peritonitis continues to complicate PD in a substantial percentage of pediatric patients. Efforts to further decrease the rate of infection and enhance treatment should focus on eliminating modifiable risk factors and improving culture techniques worldwide.

**FR-PO950**

**Astragalus Membranaceus Based Chinese Medicine Formula Might Better Preserve Residual Renal Function in Patients Undergoing Continuous Ambulatory Peritoneal Dialysis** Sing-Leung Lui, Terence Yip, Wai Kei Lo. *Medicine, Tung Wah Hospital, Hong Kong SAR, China.*

**Background:** Astragalus membranaceus is a Traditional Chinese Medicine which has been shown to possess renal protective effects in animal studies. The aim of this study was to examine the effect of Astragalus membranaceus based Chinese Medicine formula on preservation of residual renal function (RRF) and daily urine volume in patients newly started on continuous ambulatory peritoneal dialysis (CAPD).

**Methods:** The RRF and daily urine volume of 8 CAPD patients who have been receiving Astragalus membranaceus based Chinese Medicine formula (CM Group) and 16 Controls matched for age, sex, diabetes status and duration of CAPD (Control Group) were compared at the commencement of CAPD and after 2 years of CAPD.

**Results:** The mean age of the patients in the CM and Control Groups was 66.3±11.6 and 64.0±11.6 years respectively (p=0.659). Half of the patients in both Groups were diabetic. The RRF and daily urine volume of the CM and Control Groups were similar at baseline (3.52±2.0 ml/min/1.73m$^2$ vs. 4.19±1.8 ml/min/1.73m$^2$, p=0.412 and 883±342 ml vs. 838±347 ml, p=0.452 respectively). After 2 years of CAPD, patients in the CM Group had significantly higher RRF (2.92±1.43 ml/min/1.73m$^2$ vs. 1.36±1.54 ml/min/1.73m$^2$, p=0.026) and daily urine volume (769±576 ml vs. 238±268 ml, p=0.005) than the Controls. Their rate of decline of RRF and daily urine volume were significantly lower than those of the Controls (-0.30±0.40ml/min/1.73m$^2$/year vs. -1.42±0.30ml/min/1.73m$^2$/year, p=0.004 and -56.9±108.5 ml/day/year vs. -299.8±59.7ml/day/year, p=0.007 respectively). A significantly higher proportion of the Controls had developed anuria (daily urine <100ml) after 2 years of CAPD (56.3% vs. 0%, p=0.009). KT/V values and D/P Cr ratio at 4 hours of the two Groups at baseline and after 2 years of CAPD were similar. The two Groups did not differ in their diuretic and ACEI/ARB usage.

**Conclusions:** The use of Astragalus membranaceus based Chinese Medicine formula might be beneficial in preserving RRF in CAPD patients during the first 2 years of dialysis. Further prospective randomized control trials are warranted to confirm these preliminary observations.

**Evaluation of Protein Energy Wasting and Inflammation on Continuous Ambulatory Peritoneal Dialysis Patients and Its Correlation** Sham Sunder, Venkataramanan K, Himanshu Verma, Satyanand Sathi, Rajesh Padmalatha Jayaraman, Prabhu K, Anurag Gupta. *Nephrology, PGIMER & Dr. Ram Manohar Lohia Hospital, New Delhi, India.*

**Background:** Protein energy wasting and heightened inflammation are highly prevalent and is a strong risk factor for morbidity and Mortality in CAPD patients. Evaluation of malnutrition, prevalence of inflammation as well as inter-relationship between various nutritional indices and inflammation has not been studied in much detail.

**Methods:** 63 CAPD patients (M=28, F=35) were assessed for their nutritional status and inflammation. Nutritional status was assessed by dietary diary, Anthropometry, Subjective global assessment, multi- frequency BIA and serology . Inflammation was assessed by High-sensitivity C - reactive and Interleukin-6. Diagnosis of malnutrition was made. Correlation between inflammation and various other nutritional assessment indices were analyzed.

**Results:** Mean age of the patients was 57.6 ± 11.6 years. The average calorie and protein intake / Kg/ day were 25.5±4.6 Kcal and 0.81±0.2 gm resp. The mean and standard deviation of BMI(23.7±5),MAC(26.3±4.5)Cm,TST(1.624±0.4)Cm MAMC(25.6±4.5),cMA MA(45.7±19.7), were respectively .The mean values of S.protein, S.Albumin S.Pre-albumin. S.Transferrin, S.Cholesterol, S. Triglyceride, hs-CRP and IL-6 were 5.9 gm/dl, 3.0 gm/dl, and 21.11 mg/dl, 130.6 mg/dl, 155.9 mg/dl, 136.1 mg/dl, and 8.8±7.6 mg/l and 8.4±12.2 pg/dl respectively. Based on SGA, 17.4%; 54%;28.6% ; S.albumin 21%; 62%:17%: BMI 52%; 37%; 11% of CAPD patients had normal, moderate, severe malnutrition status resp. Based on hs-CRP and IL-6, 70 % and 71.8% of CAPD patients were high inflammation resp. hsCRP co-relates negatively ($p<0.05$) with S. Albumin, S.pre-albumin and S.transferrin: IL-6 co-relates negatively ($p<0.05$) with protein /kg/day, MAC, MAMA, S.albumin, S. cholesterol and S.transferrin.

**Conclusions:** Protein energy wasting (80-85%) by various methods and inflammation (70%) was very highly prevalent . Inflammatory markers shown significant negative correlation with Anthropometry and serological markers.Inflammatory markers should be included in the regular assessment of CAPD patients, for the better management of protein energy wasting.

**FR-PO952**

**Peritoneal Permeability Is Not Associated with Patient Survival** Hironori Nakamura,[1] Makoto Higuchi.[2] *[1]Dept of Nephrology, Shinonoi General Hospital, Nagano, Japan; [2]Dept of Nephrology, Shinsyu Univ, Matsumoto, Japan.*

**Background:** Several studies have suggested a relationship between high peritoneal transport and adverse outcomes in patients with peritoneal dialysis (PD). However, there have been no adequate studies comparing the outcomes of high and low peritoneal permeabilitis.

**Methods:** we investigated longitudinal changes in peritoneal permeability and patient survival, including transfer to hemodialysis after a dropout of peritoneal dialysis therapy, related to differences between PET categories at baseline. We performed a retrospective, single-hospital study of patients with PD treated from 1998 to 2009. Based on baseline dialysate-to-plasma creatinine (D/P Cr), the 76 patients were divided into two categories: L-LA (D/P Cr, <0.65) and HA-H (D/P Cr, ≥0.65). Patient demographics and clinical features were compared. The changes in D/P Cr, ultrafiltration, Kt/V, dialysate glucose load, total protein loss, and urine volume were followed for 5 years. The overall mortality rate was evaluated using the Kaplan–Meier method.

**Results:** 1) A comparison with baseline showed no significant differences between the L-LA and HA-H groups: age (57 vs. 61years), gender (64 vs. 77% male), diabetes (38 vs. 31%), APD (54 vs. 60%), icodextrin (9 vs. 26%), serum albumin (3.5 vs. 3.4 g/dL), and serum creatinine (9.1 vs. 7.9 mg/dL). 2) The D/P Cr value increased to 0.63 and 0.68 at years 2 and 3 from 0.51 in the L-LA group and decreased to 0.65 and 0.68 at years 2 and 3, respectively from 0.79 in the HA-H group. In the HA-H group, ultrafiltration increased to 521 mL at year 3 from 215 mL at baseline. No significant changes were observed in total Kt/V, dialysate glucose load or total protein loss between the two groups over the 5-year period. 3) There were no significant differences in mean PD duration (53 vs. 51 months) or mean survival time from PD initiation (71 vs. 62 months) in the L-LA vs. HA-H groups, respectively. Kaplan–Meier curves showed no survival differences between groups (log-rank test; $p = 0.362$).

**Conclusions:** Both high and low peritoneal permeabilities at baseline were rated as regression to average status in years 2 and 3, but not were associated with overall patient survival.

## FR-PO953

**Free Water Transport (FWT) and Sodium Sieving in Different Clinical Settings** Javier De Arteaga,[1] Fabian Ledesma,[1] Bengt Rippe.[2] *[1]Nephrology, Hospital Privado, Catholic Univ, Córdoba, Argentina; [2]Nephrology, Lund Univ, Sweden.*

**Background:** Peritoneal sodium sieving(Ss), an indirect measure of FWT, is mainly the consequence of aquaporin function. A high transport state and/or a plasma/ dialysate Na gradient >5 mmol/lt, may influence this sieving effect with sodium diffusion from plasma. A diffusion correction may apply for assessing FWT. Upregulated peritoneal aquaporins increasing FWT is possible and described in the postransplant state, due mostly to steroids (NDT2011vol 26). Ascitic pts on PD have a high UF and fast transport **Objective:** evaluate Ss and FWT in our pts in different clinical settings.

**Methods:** Minipets (lamilia) done yearly and in any altered clinical circumstances: ie: UFF. Patients are all consecutive chronic PD from 2007 to end 2012. N = 53 pts.

**Results:** Solute transport, FWT and Na dip

| | controls | cirrhotics | Postransplant | P | P | P |
|---|---|---|---|---|---|---|
| N | A: 44 | B: 5 | C: 4 | A/B | B/C | A/C |
| D/P Cr 60m | 0.48 ± 0.12 | 0.61 ± 0.06 | 0.44 ± 0.02 | **0.03** | **0.001** | 0.52 |
| P Na | 139.6 ± 3.9 | 141,2 ± 2,9 | 139.2 ± 1.5 | 0,38 | 0.26 | 0,85 |
| D/P Na 3m | 0,94 ± 0,02 | 0,94 ± 0,04 | 0.94 ± 0.004 | 0,69 | 0.88 | 0,51 |
| D/P Na 60m | 0,88 ± 0,03 | 0,92 ± 0,02 | 0.82 ± 0.01 | **0,004** | **0.0002** | **0,0004** |
| Na Dial 3m | 130,3 ± 2,7 | 132,8 ± 4,76 | 131.1 ± 0.9 | 0,07 | 0.52 | 0,53 |
| Na Dial 60m | 122,4 ± 4,2 | 129,8 ± 2,9 | 114.2 ± 2.2 | **0,0004** | **0.0001** | **0.0004** |
| DIP Na | 7,9 ± 3,7 | 3,0 ± 3,8 | 17.0 ± 1.6 | **0,007** | **0.0001** | **0.0001** |
| % FWT | 43,4 ± 19,7 | 15,6 ± 6,5 | 68.5 ± 19.2 | **0.006** | **0.0006** | **0.01** |
| UF60m ml | 445,7 ± 171,4 | 636 ± 132,2 | 245 ± 94.3 | **0,02** | **0.001** | **0.02** |

**Conclusions:** As compared to controls, Ss is blunted in cirrhotic pts and enhanced in the postransplant state. The cause of this in the former, we don't know, but we can hypothesize that it could be due to ascitic fluid generated "per se", a high Na P/D gradient and transport state. In the latter, an upregulation of aquaporins for steroid use is the most probable case. UF and NAR is significantly higher in cirrhotics.

## FR-PO954

**Leptin Impact in Peritonitis Events of a Peritoneal Dialysis Population** Silvia Coelho,[1] Ana Paula Bernardo,[2] Maria João Carvalho,[2] Olivia Santos,[2] Guilherme Rocha,[2] António Manuel Nunes Cabrita,[2] Anabela Rodrigues.[2] *[1]Nephrology, Hospital Fernando Fonseca, Lisboa, Portugal; [2]Nephrology, CHP Hospital Santo António, Porto, Portugal.*

**Background:** Leptin is a key link between nutritional status and immunity function. Hypoleptinemic states have been associated with increased risk of infection. In peritoneal dialysis-PD this link has not yet been studied.

We aimed to explore the clinical association between leptin levels and peritonitis events.

**Methods:** A cross sectional measurement of leptin was performed in a prevalent PD population. Peritonitis episodes occurring one year before and two years after were documented. Corporal composition was evaluated with BCM®.

**Results:** Patients (n=66) had a mean age of 50.3 years (SD 14.3), 48.5% female, 56.2% were on APD and 44% used icodextrin. Total kt/v was 2.2 (1.8-2.9) and renal kt/v 0.9 (0.4-1.3). Nutrionally, they had a mean body mass index-BMI of 25.2 (SD 4.4), normalized protein catabolic rate-nPCR 0.8 (SD 0.6) and serum albumin-sAlb 3.8 (SD 0.4). Peritonitis was observed in 36.4% with a median of 2 (1.0-2.75) episodes/patient during the study period.

Patients with peritonitis were predominantly women (p=0.006) and older (p=0.034) but did not differ in respect to BMI, LBM, FBM, nPCR and sAlb levels (p>0.05). Leptin and IL6 levels were similar in patients with or without peritonitis, p=0.178 and p=0.805, respectively.

Considering the median value of leptin in our population (17.3ng/ml), patients were divided in high leptin (HL) and low leptin (LL) groups. The HL had higher BMI (27.3 vs 23.4) and FBM (14.0 vs 8.5), lower LBM (12.5 vs 14.3) and lower nPCR (0.7 vs 0.9), all p<0.05. There were no statistical differences (p>0.05) between the HL and LL groups with respect to the presence or number of peritonitis episodes, recruited leucocytes in the peritoneal effluent or the level of IL6.

**Conclusions:** Hyperleptinemia was associated with obesity but not with systemic inflammation. On the other hand, hypoleptinemia in the absence of other signs of undernutrition, was not associated with peritonitis events or outcome. The link between leptin and immunity in PD deserves further investigation.

## FR-PO955

**Comparison of Small Solute Transport between Two Different Peritoneal Equilibration Tests** Suchai Sritippayawan, Kanjana Tianprasertkij, Thatsaphan Srithongkul, Nipa Aiyasanon, Sukit Raksasuk. *Renal Unit, Internal Medicine, Siriraj Hospital, Mahidol Univ, Bangkok, Thailand.*

**Background:** Measurement of small solute transport have been developed and modified to obtain more information of solute and fluid kinetics in peritoneal dialysis(PD). However, the dialysate to plasma creatinine ratio at 4 hours(D/PCr4hr) of the original standard peritoneal equilibration test(PET) has still been used in clinical practice. The aim of this study is to compare the D/PCr4hr between the standard PET and the new modified PET with temporary drainage.

**Methods:** Two PETs(2.5%Dextrose(D)PET and 4.25%D PET with temporary full drainage at 1 hr) were performed consecutively in 59 stable chronic PD patients(sample size was calculated from a pilot study of 10 patients). The D/PCr4hr at the end of 4 hr was measured and dialysate Cr was corrected for the glucose concentration. Small solute transport was classified as fast, average and slow by the D/PCr4hr of >0.81, 0.81-0.50 and <0.50 respectively. Intra-class correlation coefficients was used to assess the agreement of D/PCr4hr and weighted kappa was used to evaluate the agreement of transport categories between the 2 PETs.

**Results:** The mean age of the patients was 68 years and median time of PD duration was 11.4 months. Intra-class correlation of D/PCr4hr between the 2 PETs was 0.73(CI 0.58-0.83,p<0.001). The agreement of peritoneal transport categories among the 2 PETs was moderate(weighted kappa=0.46,p<0.001). Most agreement(88.5%) were found in average group. The D/PCr4hr of standard PET tended to be higher in fast transporter but lower in slow transporter than D/PCr4hr of modified PET with temporary drainage.

**Conclusions:** The D/PCr4hr of the modified PET with temporary drainage well correlated with the standard PET in average transporter but may overestimated and underestimated in slow transporter and fast transporter, respectively in PD patients.

## FR-PO956

**Clinical Investigation of Relationship between Peritoneal Dialysis Effluent Cytokine Profiles and Peritoneal Solute Transport Rate** Guochun Chen, Feng Wen, Hong Liu, Xiang Zhou, Jing Liu, Fu-You Liu. *Dept of Nephrology, The Second Xiangya Hospital of Central South Univ, Changsha, Hunan, China.*

**Background:** Fast peritoneal solute transport rate (PSTR) is reportedly correlated with high mortality in peritoneal dialysis(PD) patients. The immune dysfunction provoked by incompatible solutions may contribute to variability of PSTR in peritoneal cavity.

**Methods:** This study was to apply the Luminex IMax technology to detect the cytokine profiles in overnight dwelled PD effluent of stable continuous ambulatory peritoneal dialysis(CAPD) patients, including inflammatory cytokines(IL-6, MCP-1, TNFα, IL-17A, IL-17F, IL-21, IL-22, IL-23), angiogenic factor (VEGF), pro-EMT/fibrosis factor(TGF-β1). The clinical data were analyzed from 30 CAPD patients in the Second Xiangya Hospital from September 2012 to February 2013.

**Results:** According to the peritoneal transport characteristics, all patients were divided into low and low-average transport (L/A) (D/P Cr <0.64) group, high and high average transport (H/A) (D/P Cr ≥0.65) group, respectively.Dialysate IL-6,MCP-1 ,TNFα, VEGF,and TGF-β1 level were above the detected limit.Dialysate IL-17A, IL-17F, IL-21, IL-22, IL-23 could not be detected. Dialysate IL-6 in H/A group were higher than L/A group(P<0.05). Among PDE inflammatory profiles, IL-6 levels (r = 0.656, P<0.001), MCP-1 level (r=0.620, P<0.001) was significantly associated with D/P Cr ;Dialysate VEGF(r=0.425, P=0.019) and TGF-β1(r=0.425, P=0.019) were also correlated with D/P Cr. Among systemic markers, serum albumin but not CRP showed a negative correlation with D/P Cr (r=-0.369, P=0.045). Multivariate regression analysis showed that D/P Cr was independently correlated with dialysate IL-6. Besides, dialysate IL-6, MCP-1, VEGF and TGF-β1 correlated with each other.TGF-β1 was negtively correlated with eGFR(r=-0.370, P=0.048), and for these patients whose eGFR≥2ml/min/1.73m$^2$, TGF-β1 level is much lower than the rest(P=0.018).

**Conclusions:** Our study indicated that these dialysate cytokines contributing to chronic inflammation, angiogenesis and fibrosis maybe contribute to high PSTR in stable CAPD.

## FR-PO957

**Decreased Circulating Klotho Levels Is Associated with Oxidative Stress in Patients on Peritoneal Dialysis** Ji Sun Paeng,[1] Hye-Young Kang,[1] Hyung Jung Oh,[2] Sung Jin Moon,[3] Tae-Hyun Yoo,[1,2] Shin-Wook Kang,[1,2] Seung Hyeok Han.[2] *[1]Brain Korea 21; [2]Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul; [3]College of Medicine, Kwandong Univ, Gyeonggi-do, Korea.*

**Background:** Klotho is known as an anti-aging gene, which is predominantly expressed in the distal convoluted tubules of the kidney. Previous studies have shown that circulating klotho levels are decreased in experimental kidney disease models and that klotho exerts anti-oxidative and anti-inflammatory effects. Meanwhile, patients with end-stage renal disease (ESRD) are particularly characterized by increased inflammation and oxidative stress. However, little is known about the relationship between these features and klotho in these patients.

**Methods:** We conducted a cross-sectional single-center study in 78 ESRD patients on peritoneal dialysis (PD). Serum concentrations of klotho, interleukin-6 (IL-6), and 8-isoprostane were measured by enzyme-linked immunosorbent assay. To identify independent factors associated with klotho, Spearman's correlation coefficients were determined between co-variates andmultiple linear regression analyses were conducted.

**Results:** When patients were classified according to the median value of serum klotho (329.6 pg/ml), serum 8-isoprostane and IL-6 levels were significantly higher in the 'high' klotho group compared to patients with 'low' klotho. In correlation analyses, log 8-isoprostane ($\gamma$=-0.310, P=0.006) and log IL-6 ($\gamma$=-0.343, P=0.002) were inversely correlated with log klotho. After adjustment for age, gender, MAP, log iPTH, and log IL-6, log 8-isoprostane was independently associated with log klotho ($\beta$=-0.158, P=0.040). In contrast, the significant relationship between klotho and IL-6 disappeared in an adjusted model.

**Conclusions:** Circulating klotho concentrations were significantly associated with 8-isoprostane levels in ESRD patients on PD, suggesting a potential link between klotho deficiency and enhanced oxidative stress in these patients. Further studies with a large number of patients are required to confirm the relationship between klotho, oxidative stress, and inflammation in ESRD patients.

## FR-PO958

**Peritoneal Protein Clearance Rather Than Faster Transport Status Determines Outcomes in Peritoneal Dialysis Patients** Gayathri K. Rajakaruna, Ben Caplin, Andrew Davenport. *UCL Centre for Nephrology, Royal Free Hospital, London, United Kingdom.*

**Background:** Fast peritoneal transport status was shown to be associated with increased mortality risk for peritoneal dialysis (PD) patients. However fast transport could either be due to increased peritoneal capillary surface area or increased permeability. Peritoneal protein clearance (PPC) has been proposed to differentiate increased permeability from increased capillary surface area.

**Methods:** Patients underwent bioimpedance measurements of extracellular water (ECW) and total body water (TBW) attending for their first peritoneal transport assessment. We also measured PPC in PD patients and grouped them into high (top quartile) or low PPC groups and followed patient outcomes.

**Results:** 300 patients, median age 57.0 (44-66) years, 47.7% male, 29.0% diabetic and 56.3% Caucasoid were studied. Mean PPC 87.7±2.8 ml/day. During a median follow up of 62 (29.3-86) months 24% died, with a median duration of peritoneal dialysis of 28 (15.3-50) months, 37.3% transplanted and 30.3% transferring to haemodialysis. Overall mortality was greater for those in the high PPC group (log rank test p=0.01). On Cox proportional hazards modeling the high PPC group was associated with an increased risk of death (hazard ratio HR 1.81, p=0.018), as was age (HR 1.04, p=0.000), increased ECW/TBW (HR 2.43, p=0.04) and Davies co-morbidity score (HR 1.55, p=0.01) independent of serum albumin and C-reactive protein.

**Conclusions:** We found an independent association between a high PPC and mortality. Mortality risk was also increased with age, co morbidity and ECW/TBW. Peritoneal protein clearance may be a surrogate for capillary permeability, and can be relatively easily measured, and as such could be used to identify patients at risk of increased mortality to allow future interventional trials.

## FR-PO959

**Protein Binding of P Cresol Sulphate and Indoxyl Sulphate in Peritoneal Dialysis Effluent** John F. Collins,[1] David B. Lee,[2] Martin Roberts.[2] *[1]Renal Medicine, Auckland City Hospital, Auckland, New Zealand; [2]VAGLA Healthcare System, David Geffen School of Medicine, UCLA, Los Angeles, CA.*

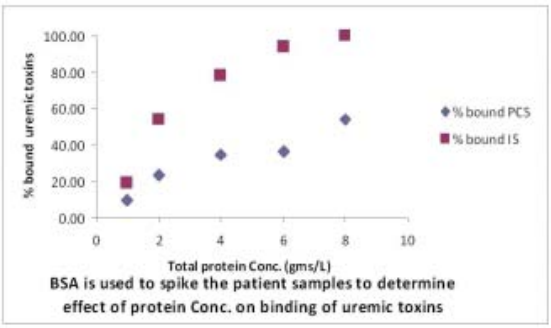
**Background:** The small MW highly protein-bound solutes P Cresol Sulphate (PCS) and Indoxyl Sulphate (IS) are recognized uremic toxins. Hemodialysis removes a tiny fraction of the total toxins as a consequence of high plasma protein binding (> 90%). In The PD-based Automated Wearable Artificial Kidney (AWAK) peritoneal proteins are not discarded but are continuously regenerated and re-turned to the patient Thus, the protein-content of the dialysate is anticipated to rise to levels higher than those seen in conventional PD effluent (PDE). Potentially the removal of protein bound toxins could be enhanced. However there is no data on PDE protein binding of PCS and IS.

**Methods:** 24 hour PDE was collected from 10 patients on CAPD/APD and total, free and protein-bound PCS/IS were measured with an HPLC method. One 24 hour PDE was spiked with BSA at concentrations ranging from 1gm/L-8gms/L to mimic the anticipated effect of increasing protein concentrations achieved with AWAK.

**Results:** The mean +/-SD concentration of total PCS in PDE was 1.73 +/-1.32 mg/L ( range 0.57-4.48 mgs/L) in 6 samples(below detectable range of 0.47 mgs/L in 4 samples). Mean protein-binding of PCS was 34 +/-29%.

The mean concentration of total IS in PDE was 1.03 +/-0.68 mg/L ( range 0.37-2.74 mgs/L) in 10 samples. Mean protein-binding of IS was 32 +/-19%.

The mean protein concentration in PDE was 0.825 gms/L (range 0.73-2.88 gms/L).



**Conclusions:** We have shown that the protein binding of PCS and IS in PDE were 34% and 32% respectively - levels substantially lower than those reported in plasma. However when the PD protein concentrations were artificially raised to mimic those aniticipated with the use of AWAK, binding was enhanced substantially for both PCS and IS. Clinical use of the AWAK may result in improved removal of these toxins.

## FR-PO960

**Inflammatory Markers among Diabetic Women with End-Stage Renal Disease: A Role in Higher Cardiovascular Mortality?** Sudha P. Chennasamudram,[1] Essam N. Nakhla,[2] Tarek H. Naguib,[2] Tetyana L. Vasylyeva.[1] *[1]Pediatrics, TTUHSC; [2]Internal Medicine, TTUHSC, Amarillo, TX.*

**Background:** Cardiovascular disease (CVD) mortality is higher for diabetic women, women under 65 years of age, and those under 70 years with end-stage renal disease (ESRD) than for comparable men. CVD also worsens mortality of persons with diabetes mellitus (DM) among ESRD population. Due to the implication of interleukin 1 beta (IL-1β) and endothelin 1 (ET-1) in CVD, we hypothesized that sex differences relative to the proinflammatory and endothelial markers may exist and play a role in the higher CVD mortality of women in this population. The study objective is to investigate whether endothelial function (EF) and proinflammatory markers vary by sex among persons younger than 65 years with DM and ESRD.

**Methods:** This is a post-hoc analysis of 15 subjects (average age of 54±9 years, 8 females), on peritoneal dialysis (PD), from an earlier study done for phosphate binder comparison. We evaluated EF by reactive hyperemia index (RHI). We measured serum levels of EF biomarkers: ET-1, plasminogen activator inhibitor 1 (PAI-1), soluble vascular adhesion molecule 1 (sVCAM) and soluble intercellular adhesion molecule 1 (sICAM); and proinflammatory markers: interleukin 6 (IL-6), IL-1β, tumor necrosis factor alpha (TNF-α) and C- reactive protein (CRP). Wilcoxon test was performed for all the study parameters.

**Results:** Proinflammatory markers in males vs females were: TNF-α was 49.4±7.6 vs 36.8±3.0 pg/mL (P=0.054), IL-6 was 11.6±1.1 vs 14.0±2.1 pg/mL (P=0.158), IL-1β was 2.1±0.07 vs 2.8±0.3 pg/mL (P=0.028), CRP 25.8±9.7 vs 34.7±5.6 ng/mL (P=0.251). RHI was not significantly different between sexes. For serum markers of EF, see Table 1.

| Markers (ng/mL) | Males | Females | P Value |
|---|---|---|---|
| PAI-1 | 2.47±0.28 | 2.99±0.37 | 0.157 |
| ET-1 | 1.98±0.21 | 2.38±0.44 | **0.035** |
| sICAM | 51.14±8.2 | 35.87±4.9 | 0.327 |
| sVCAM | 53.37±18.22 | 101.06±27.26 | 0.190 |

**Conclusions:** Diabetic women aged under 65 years on PD due to ESRD have higher levels of IL-1β and ET-1, than comparable men. These markers may have a role in the higher CVD mortality in women of this population.

*Funding:* Private Foundation Support

## FR-PO961

**Competing Risk Analysis of First Peritonitis for Technique Failure and Death in Peritoneal Dialysis** Jinn-Yang Chen. *Div of Nephrology, Taipei Veterans General Hospital.*

**Background:** Competing risk outcomes may be encountered in peritoneal dialysis (PD) treatment. Identifying the differential effects of risk factors on different outcomes may improve initial assessment and treatment of PD patients.

**Methods:** Records for patients aged 20 years and older, started dialysis therapy between January 2006 and December 2009, and had received peritoneal dialysis as their initial dialysis modality (modality used on 90th day after initiating dialysis) were reviewed for our study. Cause-specific hazard and subdistribution hazard models were performed. Technique failure and death during PD were defined as censoring events or competing events for each other. Demographics, comorbidities and first peritonitis episode as a time-dependent covariate were included in the model.

**Results:** Among 4553 incident PD patients, 665 (14.6%) patients experienced technique failure and 632 (13.9%) patients died during PD. Patients who experienced technique failure had higher peritonitis rate (0.68 episode/patient-year). Patients who died during PD were older (67.7 ± 13.1 years) and had higher prevalence of comorbidities. Using the subdistribution model, male sex (HR: 1.42; 95% CI: 1.21-1.66), diabetes (HR: 1.6; 95% CI: 1.34-1.91) and the first peritonitis episode (HR: 1.76; 95% CI: 1.5-2.06) increased the risks of technique failure. By contrast, age, diabetes, CHF, CVA/TIA, GI bleeding, liver disease and cancer significantly increased risks for death during PD. The first peritonitis episode was associated with death during PD in the cause-specific model (HR: 2.44; 95% CI: 2.06-2.88), but the risk became insignificant in the subdistribution model. Time-varying risk of technique failure after the first peritonitis was highest during the first 49 days (HR: 5.01, 95% CI: 3.93-6.39) and patients remained at increased risk of technique failure for another 6 months after the episode.

**Conclusions:** After the first PD peritonitis, the risk for technique failure was higher than that for death. Patients of advanced age or multiple comorbidities had higher risks of death than technique failure. Male diabetic PD patients need the most aggressive care for peritonitis prevention.

## FR-PO962

**Vascular Calcification Is Associated with Lower Weekly Phosphate Clearance in Peritoneal Dialysis** Juan Carlos Ramirez-Sandoval, I.E. Casanova, Jorge A. Villar-Tapia, Ricardo Correa-Rotter. *Dept Nephrology and Mineral Metabolism, National Medical Science and Nutrition Institute Salvador Zubirán, Mexico City, DF, Mexico.*

**Background:** Vascular calcification contributes to increase cardiovascular risk in patients on dialysis and is commonly associated with hyperphosphatemia. Lower phosphate clearance in hemodialysis might be associated with vascular calcification yet there is no data on phosphate clearance and its relation to vascular calcification in patients in peritoneal dialysis (PD).The aim of this study was to evaluate the association between phosphate removal in patients treated with PD and vascular calcification assessed by radiographic studies (KDIGO guidelines).

**Methods:** We included 47 patients >18 years with at least 6 months on PD and stable clinical course for at least 2 mo. We measured 2 vascular calcification scores: based on radiographic films (hands and pelvis or lateral abdominal). Phosphate was measured in 24-hour dialysate. In patients with residual renal function (RRF), phosphate was determined in 24-hour urine collection. Weekly total phosphate clearance was calculated (L/week). Other collected variables: age, time on dialysis, diabetes, body mass index (BMI, kg/m$^2$), RRF (mL/day), and serum lipids, phosphorus, calcium, iPTH, and alkaline phosphatase.

**Results:** Forty-seven patients aged 38 ± 12.5 y (range 18-66) were included, 29 female (62%). Negative correlations were observed between vascular calcification scores and weekly total phosphate clearance (hands and pelvis: r=-0.36, p<0.001 and abdominal lateral column r=-0.33, p<0.001). Relevant correlations were observed between vascular calcification scores and age (r=0.54, p<0.001), time on dialysis (r=0.36, p<0.01), BMI (r=0.30, p <0.04) and RRF (r=-0.26, p<0.04). Serum phosphorus, calcium, iPTH were not associated with vascular calcification. In a multiple regression analysis, weekly total phosphate clearance (p<0.01), age (p<0.001), and RRF(p<0.03) remained independently associated with vascular calcification scores.

**Conclusions:** Lower weekly total phosphate clearance is associated with increased vascular calcification and may be useful as a prognostic marker and treatment objective in patients on PD.

## FR-PO963

**An Easy Way to Estimate Total Kt/V in Patients on Peritoneal Dialysis between Mandatory Routine Measurements** Fernando Sales, Rosilene M. Elias, Adriano Sanjuan, Benedito J. Pereira, Manuel C. Castro, Hugo Abensur. *Div of Nephrology, Univ of Sao Paulo, School of Medicine, Sao Paulo, Brazil.*

**Background:** For patients on peritoneal dialysis (PD), all guidelines recommend measurements of dialysis dose by calculating renal Kt/V every 2 months and peritoneal Kt/V every 4 months, in order to achieve a total Kt/V minimal of 1.7/week. However, patients can lose their residual renal function between these intervals, while the physicians are blinded to the offered dialysis dose. In this meantime an estimated Kt/V is welcome. The purpose of our study was to compare measured total Kt/V (mKt/V) with estimated Kt/V (eKt/V) based on equations.

**Methods:** From May 2006 to August 2012, 21 patients on chronic PD (age 51.5 ± 18.3 years, male sex 51%) were included in this study. To estimate renal Kt/V, we assumed urea U/P ratio as 4. To estimate peritoneal Kt/V, we assumed urea D/P ratio as 0.9 and 0.5 for CAPD and NIPD, respectively. For CCPD, we assumed urea D/P as 0.5 during night time and 1 during day time.

**Results:** Table 1 shows values as mean ± SD, as well as Pearson correlation between measured and estimated Kt/V. ROC determined that total eKt/V can predict a total mKt/V of 1.7 with sensibility of 89% and specificity of 86% (AUC= 0.872; p=0.002).

| | ***Measured*** | ***Estimated*** | *Correlation* |
|---|---|---|---|
| **Renal Kt/V (n=110)** | 0.92 ± 0.43 | 1.01 ± 0.53 | r=0.683; p<0.0001 |
| **Peritoneal Kt/V (n=51)** | 1.27 ± 0.41 | 1.08 ± 0.32 | r=0.751; p<0.0001 |
| **Total Kt/V (n=51)** | 2.19 ± 0.48 | 2.00 ± 0.43 | r=0.828; p<0.0001 |

**Conclusions:** Our data showed how to estimate PD Kt/V. We are not proposing a replacement of the well validated method to calculate Kt/V. However, as a simple tool, this estimation might help to adjust the dialysis dose in the intervals we do not have measured Kt/V.

## FR-PO964

**Comparison of Various Antiseptics Impact on Torque Required for Transfer Set Disconnection and Implications for Safety** Catherine Firanek, Ira D. Davis, James A. Sloand, Dorota Wolpiuk, Audrey M. Hutchcraft, Mary E. Gellens. *Medical Affairs, Baxter Healthcare Corporation, Deerfield, IL.*

**Background:** To evaluate the security of the attachment of the Peritoneal Dialysis (PD) transfer set (TS) to the Baxter (B) titanium catheter adapter (TCA) following the submerged contact of the TCA threads using 5 antiseptics and measuring removal torque (T).

**Methods:** The Baxter TCA was soaked separately in Amuchina, Octenisept, Braunol Povidone Iodine 10%, Chlorhexamed Forte 0.2% and Purdue 10% Povidone Iodine (PI) before connectingtothe B-TS with a clockwise torque range of 2.5-3.0 inch-lbs. A test without antiseptic application (dry) was used as a control. One lot of TCAs was used and 28 units tested in each of the five antiseptic groups. Counter-clockwise torque off assessment of the security of the connection was evaluated with a hand torque gauge at a connection time of 24 hrs prior to disconnection. Connection integrity was also measured using the tensile pull test, leak test, vacuum test and torque test.

**Results:** Connection integrity was measured. All antiseptic-containing and dry connections sustained a 0.2 in-lbf force for 10 seconds and endured a pull force of 7lbf. No leaks were found with the leak and vacuum tests.The removal torque (in-lbf) *mean* resultsare as follows:

| **Antiseptic** | **Mean Removal Torque (in-lbf) ± Standard Deviation (SD)** |
|---|---|
| Dry (no antiseptic) | 1.79 (±0.25) |
| Purdue PI 10% | 4.08 (±1.24) |
| Amuchina | 2.89 (±0.62) |
| Octenisept | 2.13 (±0.73) |
| Braunol PI 10% | 2.36 (±0.83) |
| Chlorhexamed | 1.59 (±0.50) |

**Conclusions:** Our data suggests that the use of Purdue 10% PI at the connection site is associated with a tighter TCA-TS connection compared to four other antiseptics and compared with a dry connection. Enhanced tightness of the TCA-TS connection would be expected to reduce the probability of a partial or complete TCA-TS disconnection and the possibility of peritonitis.

*Funding:* Pharmaceutical Company Support - Baxter Healthcare Corporation

## FR-PO965

**Greater Omentum Folding in Open Surgical Placement of PD Catheters: A Randomized Controlled Study and Systemic Review** Guochun Chen, Hong Liu, Linshan Zhou, Puzhang Wang, Youming Peng, Fu-You Liu. *Dept of Nephrology, The Second Xiangya Hospital of Central South Univ, Changsha, Hunan, China.*

**Background:** Mechanical catheter dysfunction caused by omentum entrapment remains a major complication of PD therapy. The purpose of this study was to determine the outcomes of omentum folding at the time of primary open catheter insertion.

**Methods:** From March 2008 to December 2012, total 67 PD subjects were enrolled in the study and randomly assigned to receive either Regular Open Insertion (ROI group, n=33) or Open Insertion with Omentum Folding (OIOF group, n=34). The primary outcome was defined as PD catheter tip migration with dysfunction. A systematic review was performed to analyze the outcomes of omentum management in PD catheter implantation, based on published data from 1990 to 2013.

**Results:** There was no statistical difference of baseline patient characteristics between ROI and OIOF groups. 9 (27.3%) patients in the ROI group presented with the catheter malposition in the late stage (>60 days) of the study, significantly higher than 2 (5.9%) of the OIOF group (P=0.049). Significant differences of catheter survival rate between 2 groups were observed in the late stage (P=0.030) and the full time of the study (P=0.028). A higher incidence of irreversible catheter dysfunction was shown in the ROI group (15.2%), whereas none occurred in OIOF group (P=0.031). No statistical difference was determined in other catheter-related complications or patient survival rate. There were no statistical differences of peritoneal transport characteristics or dialysis adequacy between 2 groups upon evaluation of 3-, 6- and 12-month. Systemic review of current publications suggested that PD catheter placement with omentum managements could lead to less irreversible catheter dysfunction and improved outcome of catheter survival.

**Conclusions:** Our data suggest that ometum folding at the initial time of open catheter placement can significantly reduce the risk of catheter tip migration with dysfunction and improve the outcome of PD technique.

## FR-PO966

**Which Fluid Space Is Affected by Ultrafiltration?** Mihaly B. Tapolyai,[1,3] Maria Faludi,[1] Tibor Fulop,[2] Klara Berta.[1] *[1]Fresenius Medical Care, Semmelweis Univ, Budapest, Hungary; [2]Medicine, Div of Nephrology, Univ of Mississippi, Jackson, MS; [3]Medicine, Div of Nephrology, WJB Dorn VA Medical Center, Columbia, SC.*

**Background:** Ultrafiltration (UF) is a common and everyday procedure performed with almost all dialysis session. During UF several liters of fluid are removed, however, what proportion of this fluid is removed from which fluid space could not be easily and clinically measured until now; we designed this study to evaluate the fluid spaces most affected by UF.

**Methods:** This is a prospective cohort study of 40 prevalent chronic dialysis (HD) patients in receiving thrice weekly hemodiafiltration. We measured the patients' fluid spaces using a whole body bioimpedence apparatus to evaluate the changes of fluid spaces right from the beginning of the HD session and immediately after. We recorded the fluid spaces, UF volumes, and blood pressures.

**Results:** 40 prevalent HD patients (mean age: 60 ±52 year; 15 male; 11 diabetic; mean weight: 71.03 ±15.48 kg had bioimpedence (BCM, Fresenius) measurements before and after HD. On the average 2.38 ±0.98 L of UF was achieved (measured overload: 2.35±1.44L). The Extracellular Volume decreased from 16.84 ±3.52 to 14.89 ±3.06 Liters (p: <<0.0001); Intracellular Volume from 16.88 ±4.40 to 16.55 ±4.48 Liters (p: 0.45); the Volume of Distribution of Urea from 31.38 ±7.28 to 30.70 ±7.32 Liters (p: 0.45) and the degree of volume overload from 13.60 ±7.30 to 3.83 ±8.32 % (p: <<0.0001) of the extracellular space. The Mean Arterial Pressures also decreased from 122.95 ±19.02 to 108.50 ±13.91 mmHg (p: <<0.0001).

**Conclusions:** We conclude that UF almost exclusively reaches the extracellular fluid space and the fluid in the intracellular fluid space is not significant affected when fluid spaces are measured immediately after a 4 hour dialysis session.

## FR-PO967

**Dialysability and Safety of Gadoterate Meglumine (Dotarem®) in Hemodialysis Patients** Eric E. Gheuens,[1] Ronald Daelemans,[1] Sofie Mesens.[2] *[1]Dept Nephrology-Hypertension, Ziekenhuis Netwerk Antwerpen, Antwerpen, Belgium; [2]Clinical Pharmacology Unit, SGS, Antwerpen, Belgium.*

**Background:** To evaluate the dialysability and safety of gadoterate meglumine (a macrocyclic gadolinium based contrast agent) in hemodialysis patients.

**Methods:** Phase I, monocentric, non-comparative, non-randomized, open-label clinical trial, including 10 patients, requiring hemodialysis 3 times a week for 4 hours. Gadoterate was injected intravenously (0.1 mmol/kg). The primary evaluation criterion was the decrease in serum gadoterate concentration (SGC) after each hemodialysis session. To calculate the dialysability, blood samples were drawn simultaneously from the inflow and outflow lines of the circuit during the first hemodialysis session, and from the vascular access just before and after each of the 3 hemodialysis sessions. These started 1 to 2 hours, 2 days and 4 days, following the gadoterate injection. The total SGC was measured by inductively coupled plasma mass spectrometry. The secondary evaluation criteria were the clinical safety (vital signs, injection site tolerance) and laboratory assessments which were evaluated during a 4-day follow-up after gadoterate injection. Adverse events (AEs) and serious AEs were evaluated after 3 weeks, 3 months and 1 year.

**Results:** All 10 subjects were Caucasian, 50.0% were female. Median age was 64.0 (31-79) years. Median weight was 70.6 (61-116) kg. During the first hemodialysis, the mean gadolinium clearance (mL/min) was 224.6 at 0.5h and 225.9 at 1.5h and the SGC decreased over time by 88% to 93% and 97% at 0.5h, 1.5h, and 4h after start of dialysis. After the third hemodialysis session the SGC dropped by 99.7% compared to the pre-dialysis value of the first session. No Aes related to gadoterate were reported. No Aes occurred at the injection site during the observation period. There were no clinically relevant changes in mean laboratory values and vital signs. No cases of Nephrogenic Systemic Fibrosis have been reported so far.

**Conclusions:** This is the first study to document the excellent dialysability of gadoterate (recently FDA approved). After 3 hemodialysis sessions the serum concentration dropped by 99.7%. Furthermore we confirm the safety in hemodialysis patients.

## FR-PO968

**Dialysis Hypotension: A Role for Inadequate Arginine Vasopressin Release? A Systematic Literature Review** Esmee M. Ettema,[1] Debbie Zittema,[1] Johanna J. Kuipers,[2] Ron T. Gansevoort,[1] Paul E. de Jong,[1] Ralf Westerhuis,[2] Casper F.M. Franssen.[1] *[1]Nephrology, UMC Groningen, Groningen, Netherlands; [2]Nephrology, Dialyse Centrum Groningen, Groningen, Netherlands.*

**Background:** Intradialytic hypotension (IDH) is one of the most common complications of hemodialysis (HD) treatment. Some studies have suggested that inadequate AVP secretion could play an important role in the pathogenesis of IDH. However, AVP levels during HD and its relation to IDH has never been systematically studied.

**Methods:** We performed searches on PubMed and Embase (1970-2013, search terms "hemodialysis" and "vasopressin"). Eligible were studies reporting on AVP levels during standard HD or other dialysis techniques. Observational studies reporting on AVP levels pre- and post-HD were additionally included in a meta-analysis.

**Results:** Thirty-seven studies, including 681 patients, were finally included in the systematic literature review of which 26 studies, including 496 patients, were eligible for meta-analysis. The main findings are that pre-treatment AVP levels were more than twice as high in dialysis patients compared with healthy controls (6.4±3.5 vs. 2.5±1.3 pg/ml) and that plasma AVP levels showed little or no increase during standard HD (7.0±4.9 vs. 8.8±9.3 pre- vs. post-HD, p=NS). Significant heterogeneity was found between studies. Meta-regression analysis revealed no significant associations between the change in AVP and age, gender, treatment duration, dialysate sodium, change in blood pressure or plasma osmolality. Studies on other dialysis techniques showed mixed results with regard to the plasma AVP level course. Seven studies addressed the relation between IDH and AVP levels and showed inconsistent results with some studies reporting a rise in plasma AVP during IDH whereas others found no difference in the AVP response between patients with and without IDH.

**Conclusions:** Plasma AVP levels are higher in HD patients compared with healthy controls, but show little or no increase during standard HD. The lack of a rise in AVP levels during HD may therefore be pathophysiologically involved in the onset of IDH.

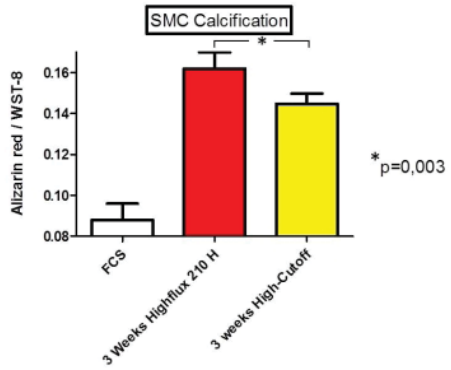
## FR-PO969

**Hemodialysis with High-Cutoff Membranes Reduces In Vitro Calcification of Human Vascular Smooth Muscle Cells** Daniel Zickler,[1] Achim Joerres,[1] Nahid Hakiy,[1] Markus Storr,[3] Roman Fiedler,[2] Matthias Girndt,[2] Ralf Schindler.[1] *[1]Nephrology, Charité Univ Medicine Berlin, Berlin, Germany; [2]Nephrology, Martin-Luther-Universität Halle-Wittenberg, Halle, Germany; [3]Gambro Dialysatoren GmbH, Germany.*

**Background:** Vascular calcification and subsequent cardiovascular events are a major problem in chronic hemodialysis patients. One possible cause is increased chronic microinflammation related to insufficient elimination of proinflammatory mediators. A newly developed, highly permeable High-cutoff (HCO) membrane allows elimination of proteins with a molecular size of up to 45 kd.

**Methods:** In a randomized controlled trial 40 chronic hemodialysis patients were dialysed with HCO or regular Highflux membranes for three weeks following a cross-over-design. Weekly serum samples were drawn before dialysis. Afterwards, vascular smooth muscle cells were incubated with calcification media and these serum probes (10%). After ten days calcification was measured using alizarin red staining and set in relation to the number of proliferating cells using WST-8.

**Results:** After ten days of incubation, SMCs incubated with serum obtained after 3 weeks dialysis with HCO showed significantly reduced calcification compared to SMC incubated with serum during Highflux dialysis ( 0,1448±0,0052 vs. 0,1618 ±0,008, p=0,003). SMCs incubated with FCS showed a very low degree of calcification. (0,09 ± 0,007).



**Conclusions:** Calcification of SMC in vitro is lower using serum during dialysis with HCO compared to serum during Highflux dialysis. This effect may be caused by improved elimination of pro-calcifying mediators with HCO membranes.

*Funding:* Pharmaceutical Company Support - Gambro Dialysatoren GmbH, Government Support - Non-U.S.

## FR-PO970

**The Impact of Low Triiodothyronine Levels on Mortality Is Mediated by Malnutrition and Cardiac Dysfunction in Incident Hemodialysis Patients** Hyang Mo Koo,[1] Fa Mee Doh,[1] Ji Sun Paeng,[2] Hyung Jung Oh,[1] Tae-Hyun Yoo,[1,2] Shin-Wook Kang.[1,2] *[1]Dept of Internal Medicine, Yonsei Univ College of Medicine; [2]Severance Biomedical Science Institute, Brain Korea 21, Yonsei Univ, Seoul, Korea.*

**Background:** Accumulating evidence has indicated that a reduced triiodothyronine (T3) level in prevalent hemodialysis (HD) patients is a prognostic factor for adverse clinical outcome. However, little is known about the association between low T3 and mortality in end-stage renal disease (ESRD) patients starting HD and whether the impact of T3 on mortality is mediated by malnutrition, inflammation, or cardiac dysfunction in these patients.

**Methods:** A prospective cohort of 471 incident HD patients from 36 dialysis centers of the Clinical Research Center for ESRD in Korea was selected for this study. Based on the median value of T3, patients were divided into 'higher' and 'lower' groups. All-cause and cardiovascular (CV) mortality rates were compared between the two groups. The independent prognostic values of T3 levels for all-cause and CV mortality were also determined.

**Results:** Compared to the 'higher' T3 group, albumin, total cholesterol, triglyceride, lean body mass (LBM-Cr), and normalized protein catabolic rate (nPCR) were significantly lower in the 'lower' T3 group. The 'lower' T3 group also had higher left ventricular mass

index (LVMI) and lower LV ejection fraction (LVEF). All-cause (113.4 vs. 18.2 events/1000 patient-years, P < 0.001) and CV mortality rates (49.8 vs. 9.1 events/1000 patient-years, P = 0.001) were significantly higher in the 'lower' T3 group compared to the 'higher' T3 group. Kaplan-Meier analysis also showed significantly worse cumulative survival rates in the 'lower' T3 group (P < 0.001). In Cox regression analysis, low T3 was a significant independent predictor of all-cause mortality, even after adjusting for traditional risk factors (HR, 3.76; P = 0.021). However, this impact was attenuated when LBM-Cr, nPCR, LVMI, or LVEF was incorporated into the successive Cox model.

**Conclusions:** Low T3 was a significant independent risk factor for all-cause mortality in incident HD patients, which was partly attributed to malnutrition and cardiac dysfunction.

## FR-PO971

**Prominent Accumulation in Hemodialysis Patients of Solutes Normally Cleared by Tubular Secretion** Tammy L. Sirich,[1] Natalie Plummer,[1] Thomas H. Hostetter,[2] Timothy W. Meyer.[1] *[1]Medicine, Stanford Univ; [2]Medicine, Case Western Reserve Univ.*

**Background:** The native kidney clears many solutes efficiently by secretion while hemodialysis clears solutes by passive diffusion. We tested whether concentrations of solutes which the kidney clears by secretion therefore rise to high levels in dialysis patients.

**Methods:** We compared the plasma concentrations and clearances of solutes normally cleared by secretion - p-cresol sulfate (PCS), indoxyl sulfate (IS), and hippurate (HIPP) - with those of urea in patients maintained on hemodialysis (HD; n=9) and in normal subjects (Nl; n=8). Values were expressed in terms of the free, unbound solute concentrations as these are the levels to which body tissues are exposed.

**Results:** Results showed (mean±sd; [a], p<0.05 dialytic versus native kidney clearance; [b], p<0.05 secreted solutes vs urea):

| Solute | $k_{Nl}$ (ml/min) | $k_{HD}$ (ml/min) | $k_{HD}/k_{Nl}$ | HD/Nl |
|---|---|---|---|---|
| Urea | 70 ± 18 | 292 ± 52 [a] | 4.2 | 4 |
| PCS | 1319 ± 597 [b] | 517 ± 68 [a,b] | 0.39 | 45 |
| IS | 2776 ± 1190 [b] | 583 ± 94 [a,b] | 0.21 | 79 |
| HIPP | 1758 ± 629 [b] | 287 ± 39 [a] | 0.16 | 89 |

Urea undergoes partial tubular reabsorption and its native kidney clearance $k_{Nl}$ is lower than its dialytic clearance $k_{HD}$. Thus even with intermittent treatment the ratio of the average pretreatment urea concentration in dialysis patients to the average concentration in normal subjects (HD/Nl) was only 4. The native kidney obtains much higher clearances for PCS, IS, and HIPP by tubular secretion and values for the ratio of the dialytic clearance to the native kidney clearance, $k_{HD}/k_{Nl}$, for these solutes were thus much lower. Their pretreatment plasma concentrations relative to the concentrations in normal subjects were correspondingly much higher than those of urea. Mathematical modeling showed that the elevation of HD/Nl is explained by the ratio $k_{HD}/k_{Nl}$ and the concentration reduction ratio during intermittent treatment.

**Conclusions:** These results show that plasma concentrations of solutes normally cleared by tubular secretion remain very high in hemodialysis patients. Adoption of urea as our index solute for dialysis efficacy has had the unintended effect of concealing how poorly conventional treatment replaces the native kidney's secretory function.

## FR-PO972

**Dialysate Containing Nitric Oxide Suppresses Blood Coagulation during Hemodialysis in a Rat Hemodialysis Model** Shunichiro Urabe,[1] Yuki Kariya,[2] Kenichi Kokubo,[1,2] Hiroshi Tsukao,[1,3] Hirosuke Kobayashi.[1,2] *[1]Kitasato Univ Graduate School of Medical Science, Sagamihara, Kanagawa, Japan; [2]Kitasato Univ School of Allied Health Sciences, Sagamihara, Kanagawa, Japan; [3]Tokyo Univ of Technology School of Health Sciences, Tokyo, Japan.*

**Background:** In blood vessels, nitric oxide (NO) generated by NO synthase on endothelial cells suppresses the aggregation and activation of platelets. Therefore, the biocompatibility of dialysis membranes could likely be improved using an NO-containing dialysate capable of delivering NO to blood through the membrane. The present study examined whether an NO-containing dialysate suppressed blood coagulation during hemodialysis without any effects on blood pressure in a rat hemodialysis model.

**Methods:** Hemodialysis was performed using 10-12-week-old male rats (Sprague Dawley) for 4 h. Blood was removed from the carotid artery of a rat, forced to flow through a miniaturized dialyzer (membrane area: 100 $cm^2$) made of polysulfone using a peristaltic pump, and returned to the tail vein. NO was added using gas exchange membranes (membrane area: 56 $cm^2$) placed just before the dialysate inlet of the dialyzer. Heparin was injected once before dialysis. Pentobarbital was continuously injected to anesthetize the rats. The arterial-side and venous-side blood pressures in the blood circuit were measured. All coagulation events were recorded.

**Results:** The arterial-side blood pressures during hemodialysis were stable and similar between the control (without NO) and NO-addition groups, indicating that NO did not affect the blood pressure during hemodialysis. However, the venous-side pressures in the control group were unstable and in some cases had increased at 150 to 240 min after the start of dialysis, whereas the pressures in the NO-addition group were stable throughout hemodialysis. Coagulation events (such as blood clotting in the cannula or blood circuit) or an increase in the venous-side pressure occurred in the control group (3/5 cases) but not in the NO-addition group (0/5 cases).

**Conclusions:** The addition of NO to the dialysate suppressed blood coagulation during hemodialysis in a rat model without having any effect on the blood pressure during hemodialysis.

*Funding:* Government Support - Non-U.S.

## FR-PO973

**Vascular Refilling Is Independent of Fluid Overload in Hemodialysis Patients** Mauro Pietribiasi,[1] Krassimir Katzarski,[2,3] Magda Galach,[1] Joanna Stachowska-Pietka,[1] Daniel Schneditz,[4] Bengt Lindholm,[2] Jacek Waniewski.[1] *[1]Institute of Biocybernetics and Biomedical Engineering, Warsaw, Poland; [2]Baxter Novum and Renal Medicine, Karolinska Institutet, Stockholm, Sweden; [3]Diaverum, Stockholm, Sweden; [4]Institute of Physiology, Medical Univ of Graz, Graz, Austria.*

**Background:** Fluid removal by ultrafiltration during a hemodialysis (HD) session is balanced by vascular refilling from the interstitium, driven by the increase in plasma oncotic pressure ($\pi p$). Inadequate refilling rate (Qr) is suspected to contribute to hypotensive crises. The refilling process was quantified by the *refilling coefficient (Kr)* expressing Qr driven by a unit increase in $\pi p$. We calculated Kr for two groups of HD patients differing by pre-treatment fluid status and session time, but similar in ultrafiltration rate (Qu).

**Methods:** Nine stable patients underwent two HD sessions: short session of 3.5 h (SH, after 2 day break) and long session of 4.5 h (LH, after 3 day break). Relative blood volume changes were measured online with Gambro AK 200 Ultra HD machine module, and solute concentrations were measured before and after HD, and regularly during the session. The volume of body fluid compartments was measured by bioimpedance analysis.

**Results:** Patients were more hydrated before LH session: initial body weight, total body water (31.7±5 l for SH vs. 32.5±5 l for LH) and extracellular water (16.6±2 l for SH vs. 17±2 l for LH) were higher. $\pi p$ was similar for both sessions. Qr was higher for LH. Kr decreased with dialysis time, but showed no statistically significant difference between sessions both at the beginning and at the end of HD (Kr at 1h: 268±127 ml/h/mmHg for SH and 396±198 ml/h/mmHg for LH, NS). The final, stable value of Kr was reached at similar times (3 h) and was similar for both sessions (137±55 ml/h/mmHg for SH and 166±94 ml/h/mmHg for LH).

**Conclusions:** Patients undergoing LH, despite being more volume expanded, did not have higher initial Kr, even with higher initial Qr. Final Kr values stabilized on similar levels at similar times, notwithstanding differences in initial fluid status or Qr in the two groups, suggesting that Kr is relatively insensitive to the initial fluid status of the patient.

## FR-PO974

**Prevalence and Risk Factors of MRSA Infections and Effect of Program for MRSA Eradication in ESRD Patients on Hemodialysis: Single Center Study** Young-Il Jo,[1] Jung-Hwan Park,[1] Jong-Ho Lee,[1] Eun Hye Seo,[1] Jeong-hwa Choi,[2] Hyun-kyun Ki.[2] *[1]Div of Nephrology, Konkuk Univ School of Medicine, Seoul, Republic of Korea; [2]Dept of Infectious Disease, Konkuk Univ Medical Center, Seoul.*

**Background:** Hemodialysis (HD) patients with meticillin-resistant Staphylococcus aureus (MRSA) infections face high morbidity and mortality. This study was designed to estimate the prevalence of MRSA nasal carriage, to define the risk factors of MRSA nasal carriage, and to investigate the effect of anti-infective program on the prevalence of MRSA nasal carriage among HD patients.

**Methods:** A total of 126 HD patients without signs of overt clinical infection (M:F 59:67, duration of dialysis 48.9±47.8 months) were enrolled in 2011. Nasal carriers for MRSA received standardized mupirocin therapy. Anti-infective program including education and hand washing has been taken place for all patients. All patients were followed up for elimination and infections for 1 year.

**Results:** The prevalence of nasal carriage for MRSA was 16.4% including 4.0% for the outpatients and 69.6% for inpatients. In the univariate analysis, a statistically significant difference was found for the number and duration of hospitalization, duration of dialysis, history of antibiotics use, history of central catheterization and history of urinary indwelling catheterization between the carriage of MRSA. In the multivariate analysis, duration of hospitalization (p=0.029, Exp(B) 1.027, 95% confidence interval 1.003-1.053) and length of stay in ICU (p=0.044, Exp(B) 1.508, 95% confidence interval 1.012-2.247) were independently associated with MRSA carriage . After anti-infective program for 1-year, the prevalence of nasal carriage for MRSA was 4.5%. Mupirocin eliminated MRSA in 75.0% (3/4) of patients. The 5.1% (4/77) patients without nasal carriage for MRSA showed nasal colonization of MRSA in follow-up screening in 2012.

**Conclusions:** Compared with previous reports, the prevalence of MRSA nasal carriage in outpatient was markedly lower. However, the prevalence in inpatients was high, and the long duration of hospitalization and ICU care was risk factor of nasal carriage for MRSA. Anti-infective program appears to be an effective preventive strategy.

## FR-PO975

**Free P-Cresol Sulfate Is Associated with Septicemia in Hemodialysis Patients** Tanushree Banerjee,[1] Timothy W. Meyer,[2] Tariq Shafi,[3] Michal L. Melamed,[4] Thomas H. Hostetter,[5] Yang Liu,[3] Neil R. Powe.[1] *[1]Univ of California, San Francisco; [2]Stanford Univ; [3]Johns Hopkins Univ; [4]Albert Einstein College of Medicine; [5]Case Western Reserve Univ.*

**Background:** The uremic syndrome is attributed to progressive retention of compounds which, under normal conditions, are excreted by the healthy kidneys. P-cresol sulfate (PCS), a prototype protein-bound uremic retention solute, has been shown to exert toxic effects in *vitro*. Recent studies have identified relations between increased levels of PCS and adverse clinical outcomes in hemodialysis (HD) patients. We explored the relationship between free PCS with septicemia in HD patients.

**Methods:** In a U.S. cohort of 294 incident HD patients enrolled in 1995-1998 and followed for an average of 3.4 years, we measured free PCS using mass spectroscopy. We linked USRDS Medicare billing records to ascertain septicemia over follow-up. We used Poisson regression to calculate incidence rate ratios (IRRs) for septicemia.

**Results:** Mean age was 57 years, 59% White and 44% female. The incidence of septicemia per 1000 patient-years was 43 in the lowest tertile, 87 in the middle tertile and 120 in the highest tertile of free PCS level. Unadjusted analysis showed a 68% higher risk of septicemia in the middle and 89% in the highest tertiles of PCS levels when compared with the lowest tertile (p=0.07, 0.002, respectively). After adjustment for age, sex, race, body mass index, comorbid disease, albumin, creatinine, Kt/V, and residual kidney function; those with levels in the middle tertile had 5% higher risk of septicemia [IRR (95% CI) =1.05 (0.65-1.69)] and those with highest tertiles had a 31% higher risk of septicemia [IRR (95% CI) = 1.31 (0.83-2.07)] when compared with the lowest tertile of PCS levels.

**Conclusions:** These results suggest an association between higher levels of free PCS and septicemia in HD patients. Better methods of dialysis should be developed to evaluate the utility of removing PCS and its effect on the outcome.

## FR-PO976

**Will Haemodialysis Patients Previously Immunized with a Hepatitis B Vaccine Respond to a Booster Dose Using a Different Product? Single Centre Experience on 115 Patients** Rosa M. Montero, Raja Mohammed Kaja Kamal, Khandaker Jubair Islam, Maggi Steele, David Makanjuola. *Epsom & St. Helier Univ Hospitals NHS Trust.*

**Background:** Maintaining immunity to hepatitis B in the haemodialysis (HD) population is important in order to reduce the chances of patients contracting this infection. Little evidence is available to determine whether those vaccinated with a particular type of hepatitis B vaccine will continue to maintain immunity if given a booster with a different type of hepatitis B vaccine.

**Aim:** To determine the effectiveness of a single booster dose of the recombinant Hep B DNA vaccine, Fendrix in a cohort of HD patients previously immunised with HBVaxPro.

**Methods:** All patients with established immune response to HBVaxPro had annual hepatitis B surface antibody titres measured. A titre< 10mIU/ml required a booster. All patients from October 2010- May 2013 were given booster doses using Fendrix. Data were collected through computerised systems. Davies co-morbidity scores were calculated for all patients to determine whether this affected response rates.

**Results:** 115 HD patients required boosters over this period. 62 male, 44 female. Median age 71.9 years with a median time of 2228 days on HD. 106 (92.9%) responded to a booster. The majority were Caucasian and 34% had type 2 diabetes. The non-responders had similar Davies co-morbidity score to the responders. 9 that showed no response went on to have a course of Fendrix; of these 100% responded to a full course.

**Conclusions:** Those with previous immunity to HBVaxPro showed a good response to a booster dose of Fendrix. Those that did not respond to a single booster went onto develop full immunity following a full course. Gender, age, median length on HD, type 2 diabetes or Davis co-morbidity score were not independent predictors of response. Our data show that in patients who previously responded to vaccination with the Hep B vaccine, this immunity is likely to be maintained despite changing to a different Hep B vaccine.

## FR-PO977

**Does It Matter which Type of Hepatitis B Vaccine Is Given to Haemodialysis Patients?** Rosa M. Montero, Khandaker Jubair Islam, Raja Mohammed Kaja kamal, Maggi Steele, David Makanjuola. *Epsom & St. Helier Univ Hospitals NHS Trust.*

**Background:** Maintaining immunity to hepatitis B in the haemodialysis (HD) population is important in order to reduce the chances of patients contracting this infection. We are not aware of any reports of the efficacy of switching to a different vaccine in HD patients when immunity has already been established with a different product.

**Aim:** To compare the response (R) and Non response (NR) between Hep B vaccine naive HD patients vaccinated with Fendrix compared with a historical cohort who had HBVaxPro.

**Methods:** A single centre retrospective study. Data were collected on all patients from October 2010 until May 2013. Fendrix was administered at 0, 1, 2 and 6 months. Patients with post-vaccination titres >10mIU/ml were classified as R, those with titres <10mIU/ml received a second course. Those that did not respond following 2 courses were classified as NR. Comparison was made with a historical cohort vaccinated with HBVaxPro from 1999-September 2010. The HBVaxPro course consisted of vaccinations given at 0, 1 and 6 months.

**Results:** 432 patients (3 were excluded for missing data) were in the historical cohort. 353/429 (82.3%) were immune following a single course with HBVaxPro. 212 male; 144 female, median age 66.8 years with median length of HD days 1690. 72 (17.7%) were given a second course and only 4 (0.9%) were NR. NRs had median age of 80.7 years with median length of 1544 days on HD. In contrast, the Fendrix cohort was 428 patients. 363 (84.8%) were immunised after. 258 male; 105 female with median age 70.8 years. 65 (15.2%) had a second course, of which 9 had no response (2.1% of the total cohort). The median age of NRs was 74.3 years and median time on HD was 1004 days. There were no significant correlations between response rates and ethinicity, diabetes, or the Davies co-morbidity scores in either group.

**Conclusions:** Response rates were similar between the two vaccines in our HD population. NR rates were slightly higher with Fendrix but this did not reach statistical significance. There was a trend towards non-response to the vaccines with male gender and increasing age. Overall, we found that both vaccines provided good levels of immunity.

## FR-PO978

**Discrepancy between Serological and Virological Analysis of Viral Hepatitis in Hemodialysis Patients** Jer-Ming Chang.[1,2,3] *[1]Dept of Internal Medicine, Kaohsiung Municipal Hsaio-Kang Hospital, Kaohsiung, Taiwan; [2]Div of Nephrology, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; [3]Falculty of Renal Care, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

**Background:** The aim is to reveal the discrepancy between serological and virological analysis of viral hepatitis in hemodialysis (HD) patients, and review the suggestion of dedicated HD bed and machine.

**Methods:** 1681 HD patients (for at least six months) from 15 institutes were recruited. Hepatitis B surface antigen (HBsAg) and antibody to hepatitis C virus (anti-HCV) were detected by a chemiluminescent microparticle immunoassay. HBV DNA was quantitatively measured with COBAS® AmpliPrep/COBAS® TaqMan® HBV test v2.0 (Roche Molecular System) kit. HCV RNA was measured by reverse transcription-polymerase chain reaction with Abbott RealTime™ HCV kit. HBsAg and anti-HCV were examined for every patient. HBV DNA was detected in HBsAg (+) samples and HCV RNA in anti-HCV (+) samples. HBVDNA/HCVRNA detection was done in a subset of HBsAg(-)/anti-HCV(-) patients.

**Results:** 230 (13.7%) patients are HBsAg (+) and 190 (17.3%) patients are anti-HCV (+).We are unable to detect HBV DNA in 97 of 230 (42.2%) HBsAg (+) patients, and HCV RNA cannot be found in 76 of 290 (26.2%) anti-HCV (+) patients. In 167 HBsAg (-) patients, only one shows a trace amount of HBV DNA (repeated examination showed negative result). None of 151 anti-HCV (-) patients shows detectable HCV RNA. Liver enzyme levels are significantly higher in patients with either positive serological or positive virological tests then those with negative tests.

**Conclusions:** Serological tests over-estimates the virological evidence. False positive rate for HBV is 42.2%, and for HCV is 26.2%. This study cannot provide sensitivity or specificity. But, at least in a subset of patients, false negative rate for hepatitis (negative HBsAg/anti-HCV but positive DNA/RNA) approaches zero. The annual sero-conversion rate (from negative to positive) of viral hepatitis has been very low in Taiwan (0.25% for HBV, 0.72% for HCV). Our findings might challenge the current suggestion of dedicated machine/bed and the diagnosis of viral hepatitis based solely on the serological examination.

## FR-PO979

**Engaging Patients in the Consumer Assessment of Heathcare Providers and Systems 2012 Survey: Social Workers as Care Advocates** Deborah A. Benner, Duane V. Dunn, Shelley Murphy, Paul Asper, Andrew Lee, Andrew Barba. *DaVita HealthCare Partners, Denver, CO.*

**Background:** In 2012, the Centers for Medicare and Medicaid Services (CMS) required dialysis providers to administer the 58-question Consumer Assessment of Healthcare Providers and Systems (CAHPS) patient-experience survey to chronic in-center hemodialysis (ICH) patients (pts). Providers were directed to use a third-party vendor, applying the survey via mail or phone, but were permitted to operationalize survey administration as best suited to each provider. The administration of such an industry-wide tool had never been tested, nor were response rates easily predictable for such a tool.

**Methods:** DaVita HealthCare Partners and a vendor administered the ICH CAHPS survey between Sep-Nov 2012. Dialysis center staff received pre-education about the survey process. Social Workers and care givers provided education to each ICH patient, encouraging participation. The vendor mailed a prenotification letter then survey to patient addresses. Nonresponders received a postcard then second survey via mail. Continuing nonresponders were contacted by phone. From center-specific results, improvement plans were generated, and pts received education about center results and planned improvements.

**Results:** From 113,583 administered surveys, 52,410 (46.1%) were completed (39.0% mail, 7.2% phone), achieving an overall response rate of 46.9%. Response rate by geographic region ranged from 45%-50% with the highest rate in the Midwest. Reasons for nonresponse included no response to phone messages (14.1%), refusals (9.0%), no response (5.8%), language barriers (2.3%), callbacks (2.3%), and partial responses (0.9%). Some pts died during the survey period. Low responses came from homeless and nursing home pts. Center staff reported problems with health literacy and pts reading skills.

**Conclusions:** Intense patient advocacy by social workers resulted in high participation of pts dialyzed in DaVita HealthCare Partners centers. Achieving greater participation will require developing more effective approaches to specific patient groups. Utility of the survey would be enhanced by including home modalities and addressing challenges in health literacy.

## FR-PO980

**Removing the Two Day Gap in Three Times a Week Hemodialysis: A Cost Effectiveness Model** James Fotheringham,[1] Damian G. Fogarty,[2] Meguid El Nahas,[3] Michael J. Campbell,[1] John W. Stevens,[1] Andrew C. Rawdin.[1] *[1]School of Health and Related Research, Univ of Sheffield, Sheffield, United Kingdom; [2]The UK Renal Registry, Bristol, United Kingdom; [3]Global Kidney Academy, Sheffield, United Kingdom.*

**Background:** Excess admission and mortality rates exist after the 2 day gap in 3 times a week hemodialysis (HD). Existing comparative observational studies greatly increase HD frequency or are confounded by indication. The cost and potential impact of alternate day HD have not been evaluated.

**Methods:** Incident renal replacement therapy patients starting between 2002 and 2006 in England with available data until 2009 from the UK Renal Registry were analysed. Hospitalisation data was used to identify HD attendance patterns, comorbidity, admissions and associated cost. The model factored the cost of an additional HD session per fortnight, and a saving and survival benefit with the reduction in excess hospitalisation and mortality rates over the 2 day gap to that of the rest of the week. Estimated survival was calculated using a Weibull parametric model. Quality of life for patients on HD and time hospitalized were obtained from existing literature.

**Results:** 5790 patients were analysed. Compared to the rest of the week excess emergency admissions (2.29 vs 1.36 per patient year, P<0.001) and mortality (21.3 vs 15.7 deaths per 100 patient years, P<0.001) were identified after the 2 day gap, with greater differences for heart failure patients. For all patients mean survival was predicted at 7.7 years. Additional HD sessions cost $34,328 USD, generated a hospitalization cost saving of $2,411 and accrued 0.40 quality adjusted life years (QALYs). The cost per QALY was $79,067. For heart failure patients surviving a mean of 4.4 years, additional HD cost $20,722, saved $1,768 in hospitalisations and accrued 0.26 QALYs. The cost per QALY was $73,539. If survival and hospitalisation advantages were increased from approximately 10% to 16% the cost per QALY was $49,496 in all patients.

**Conclusions:** Alternate day dialysis would not be deemed cost effective based on a reduction in admissions and mortality after the two day gap to the rest of the week, but may be cost effective with a more global reduction in rates.

## FR-PO981

**Association of Initial Twice-Weekly Hemodialysis Treatment with Preservation of Residual Kidney Function in ESRD Patients** Minmin Zhang,[1] Mengjing Wang,[1] Haiming Li,[1] Ping Yu,[1] Jing Chen,[1] Kamyar Kalantar-Zadeh.[2] *[1]Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China; [2]Nephrology & Hypertension, Univ of California Irvine Medical Center, Orange, CA.*

**Background:** The relationship between hemodialysis(HD) and residual kidney function(RKF) has not been well examined. We hypothesized that twice-weekly HD during the first several months of HD maintains RKF longer.

**Methods:** A historical cohort study was performed in 85maintenance HD patients to compare RKF loss and clinical outcomes, in which 30 patients on twice-weekly HD for more than 6 months initially, the other 55 patients starting and maintaining thrice-weekly HD. Then, a subcohort study was implemented in 48 incident HD patients whose residual GFR was examined serially, to assess the potential predictors of the decline of RKF.

**Results:** The main cohort study showed that the HD adequacy and the clinic outcomes were same in 85 patients receiving HD treatment for more than 5 years. However, the rate of RKF loss(defined as urine volume <200 ml/day) was significantly lower in twice-weekly group(60%) compared to thrice-weekly(82%), especially during the first year of HD initiation(10% versus 40%, p=0.03). In the subcohort study, the residual GFR of 48 patients, treated with 2.69±0.43 times per week HD for 10.27±3.53 months, declined from baseline 6.95±2.66 to 2.12±1.97 ml/min/1.73m$^2$ and 40% of patients lost their RKF over an average period of 7.6±4.5 months of HD initiation. Multivariate logistical regression analysis showed that odds ratio of RKF loss for each additional HD treatment per week was 7.2 in HD patients.

| Factor | Univariate | | | Multivariate | | |
|---|---|---|---|---|---|---|
| | OR | 95%CI | *P* | OR | 95%CI | *P* |
| Sex(male to female) | 0.34 | 0.10-1.16 | 0.09 | 0.08 | 0.01-0.64 | 0.018 |
| HD frequency(time/week) | 3.38 | 0.83-13.75 | 0.09 | 7.20 | 1.10-47.09 | 0.039 |
| Urea reduction ratio(%) | 0.94 | 0.87-1.02 | 0.15 | 0.85 | 0.72-0.998 | 0.047 |
| Intradialytic hypotension episode(each episode) | 2.04 | 0.92-4.54 | 0.08 | 2.51 | 1.06-5.95 | 0.036 |

**Conclusions:** Initial twice-weekly HD during the first year of dialysis therapy appears associated with better RKF preservation.

*Funding:* Government Support - Non-U.S.

## FR-PO982

**The Returns of the MACs: A Natural Experiment Relating More Than Thrice Weekly Home Hemodialysis and Patient Outcomes** Richard Hirth, Adam S. Wilk, Wei Zhang, John R.C. Wheeler, Tammie A. Nahra, Kathryn Sleeman, Joseph M. Messana. *Univ of Michigan, Ann Arbor.*

**Background:** Fiscal intermediaries (FIs) and Medicare Administrative Contractors (MACs) that pay Medicare claims can authorize payment for >3 weekly treatments. In prior work we show FIs/MACs may contribute significantly to variation in HHD practice and a HHD patient's expected treatment frequency may be a function of the FI/MAC that processes the facility's claims. The plausibly random exposure of similar patients to different HHD treatment frequencies across FIs/MACs offers a natural experiment for assessing differences in patient (pt) outcomes due to more and less frequent HHD: we look at measures of inpatient days and drug costs per outpatient month.

**Methods:** We identified all Medicare HHD patients in 2009-12 by FI/MAC, and as average monthly HHD pt treatments (adjusted for inpatient days to reflect HHD treatments per outpatient month), average counts of inpatient days, and average amounts paid for erythropoietin-stimulating agents (ESAs) and other ESRD-related drugs per patient-month by FI/MAC.We used regression models to define the association between HHD pt treatments per month and individual FIs/MACs active by year, adjusting for pt age, race, BMI, and 23 Medicare claims-derived comorbidities. We plotted average predicted HHD treatments against each outcome measure by FI/MAC by year.

**Results:** Evidence suggests that higher HHD treatment frequency is associated with fewer inpatient days (slope=-0.27, p<.0001) and lower non-ESA drug costs per month, such as for iron (slope=-5.1, p<.0001) and vitamin D (slope=-2.9, p<.0001) was found. (Effects for ESA costs are not significant).

**Conclusions:** These cost savings offset only a fraction of the increased spending on extra HHD sessions. We find similar results in two-stage least squares analyses of effects of increased HHD treatment frequency on pt outcomes, instrumenting for HHD treatment frequency with average HHD authorizations by FI/MAC. While increased HHD treatment frequency may improve some pt outcomes, effects on other important outcomes like survival and quality of life remain to be examined.

*Funding:* Other U.S. Government Support

## FR-PO983

**Characteristics of Patients Receiving Twice Weekly Hemodialysis** Menaka Sarav, Neenoo Khosla. *Dept of Nephrology and Hypertension, NorthShore Univ HealthSystem, Evanston, IL.*

**Background:** In developing countries, large numbers of patients with ESRD receive hemodialysis (HD) less than three times a week. In the United States, this practice is uncommon. However, patients who are elderly and have residual renal function (RRF) may do well with twice weekly dialysis. We evaluated characteristics of incident HD patients at 4 dialysis units who receive twice weekly HD and compared this group's hospital rate to the United States Renal Data System (USRDS) rate.

**Methods:** All patients receiving HD, more than 3 months, twice weekly were included. Demographics, pre-dialysis and recent lab and clinical status were evaluated.

**Results:** Eighteen patients out of a total of 283 patients were included. Data evaluated is presented in the table below.

| **Demographics** | **Data** |
|---|---|
| Total HD patients | 283 |
| Total 2x week HD patients | 18 (6.3% of the total) |
| Average age | 75 +/- 15 years |
| Male | 80% |
| Caucasian | 55% |
| African American | 20% |
| Diabetics | 30% |
| Pre-CKD care with nephrologist | 70% |
| Pre-ESRD BUN | 71 +/- 27 mg/dl |
| Pre-ESRD Cr | 5.2 +/- 2 mg/dl |
| Uremia as indication for start of HD | 70% |
| Vintage | 2.9 +/- 2.2 years |
| Access at start of HD- catheter | 70% |
| Current BUN | 61 +/- 17 mg/dl |
| Current Cr | 6.7 +/- 3 mg/dl |
| URR (Urea reduction ratio) | 71.9 +/- 5 |
| Current albumin | 3.68 +/- 0.5 gm/dl |
| Average weight | 70 +/- 14 kg |
| IDW (Inter-dialytic weight gain) | 1.5 +/- 0.8 kg |
| Hospital days / pt year | 2.27 |

Patients have been maintained on twice weekly HD for an average of 2.9 years +/- 2.2 years. The majority of patients were non- diabetic males and Caucasians aged 75+/-15. Seventy percent were seen in a dedicated CKD clinic prior to HD. Uremia was the main indication for initiation. The average inter-dialytic weight gain was low (1.5 +/-0.8 kg) suggesting preserved RRF. The serum albumin was maintained at an average of 3.68 +/-0.5 mg/dl. The hospital rate was lower at only 2.27 days / patient year when compared to the USRDS rate of 12 days / patient year.

**Conclusions:** Patients can be maintained for extended periods of time on twice weekly HD with a low rate of hospitalization and preserved volume and nutritional status. Further studies comparing outcomes to patients on thrice weekly dialysis are needed.

## FR-PO984

**Outcomes of Patients with End-Stage Renal Disease Undergoing Twice-Weekly and Thrice-Weekly Hemodialysis** Thanachai Panaput, Dhavee Sirivongs, Bandit Thinkhamrop, Cholatip Pongsakul, Sirirat Ruengjui, Surapong Narenpitak, Pisith Intarawongchot, Laksamon Praderm, Sajja Tatiyanupanwong, Chavasak Kanokkanapong, Pakorn Tungkasereerak, Thatsalang Keonounma, Amarit Suwattanasin. *The Hemodialysis Study Group (HENNET), Thailand.*

**Background:** Most ESRD patients in a resource-limited setting were treated with twice-weekly haemodialysis (HD). We aimed to analyze outcomes between patients on twice HD per week (2-HD/wk) and thrice HD per week (3-HD/wk).

**Methods:** A prospective multi-center cohort study was conducted in 11 HD centers. The participants aged of 18 to 80 years, undertaken twice-weekly or thrice-weekly HD for at least 3 months were recruited. Baseline characteristics were recorded at recruitment. Outcomes including death and first hospitalization were observed. Kaplan-Meier method and cox regression analysis was computed.

**Results:** A total of 673 participants, 504 in 2-HD/wk and 169 in 3-HD/wk group were recruited. They were male in 59% with mean age of 56 years and 39.8% were DM. Median follow up time was 13.7 months. During the total follow-up time, 9,254 patient-months,45 patients died, 33 in 2-HD/wk group (6.5%), and 12 in 3-HD/wk group (7.1%). The one year survival probability of 2-HD/wk group, 0.94 (95% confidence interval (CI); 0.92 to 0.96) was comparable to that of 3-HD/wk group, 0.94 (95% CI; 0.89 to 0.96), hazard ratio = 0.99, 95% CI; 0.5 to 2.0, p = 0.99.

**Figure 1.** Kaplan Meier survival estimate among patients treated with twice-weekly and thrice-weekly HD.

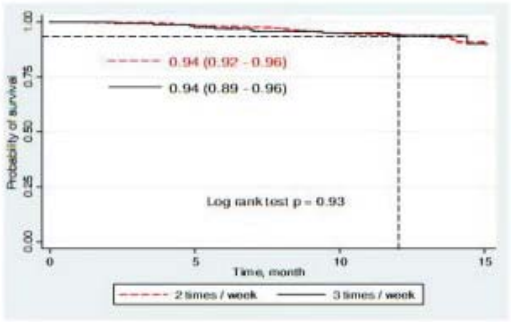

**Figure 2.** Kaplan-Meier survival curves of first hospitalization among patients treated with twice-weekly and thrice-weekly HD.

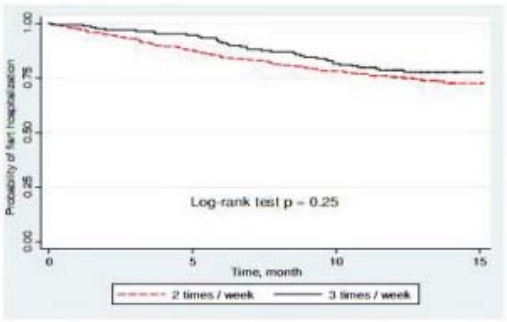

There was no significant difference in incidence of first admission between 2-HD/wk (24.2 / 100 patient-years) and 3-HD/wk group (19.7 / 100 patient-years), log rank test p-value = 0.25.

**Conclusions:** Participants who were treated with 2-HD/wk had a similar one year survival rate but tended to associate with higher incidence of hospitalization when compared to those with 3-HD/wk. Twice-weekly HD is an alternative treatment scheme in resource-limited settings.

## FR-PO985

**Challenges Recruiting to a Study Investigating Extended Treatment Time on Haemodialysis Outcomes** Seema Singh, Albert J. Power, Charles D. Pusey, Neill D. Duncan, Edwina A. Brown. *Imperial College Renal & Transplant Center, United Kingdom.*

**Background:** Outcomes on conventional haemodialysis (HD) remain suboptimal with observational data suggesting better survival with extended treatment times (TT). In the absence of prior trial data we studied the effect of extended TT on HD outcomes.

**Methods:** Randomised cross-over study of in-centre HD patients with TT of either 6 hrs or 4 hrs for a period of 24 wks with a 4wk washout period between the two arms (NCT01721421). Assessments of nutritional status (malnutrition inflammation score, bioimpedance analysis, hand grip), inflammation and atherosclerosis (hs-CRP, MCP-1, BNP) are made before and after each treatment phase. Time to recovery is assessed and quality of life domains (KDQoL).

**Results:** In total 634/725 (87%) patients screened met inclusion criteria 23 of these consented to date (21 male, mean age 58.7±12.9yrs), a recruitment rate of 4%. Reasons cited by patients for refusing consent include inability to sit for long periods and commitments as carers to partners & family and anxiety that the shorter control TT (for those whose pre study TT>4) may be detrimental. 60% of nursing staff questioned felt extended TT was beneficial with 36% reporting it well tolerated. Nonetheless just 38% would recommend extended TT to patients with 66% stating it affected service provision.

**Conclusions:** Enrolled patients tolerate extended treatment times well but there is a significant impact on in-centre HD provision. Staff attitudes may impact on enrolment in similar trials and must be addressed. Extended TT maybe more pragmatic in domiciliary or nocturnal HD services.

*Funding:* Government Support - Non-U.S.

## FR-PO986

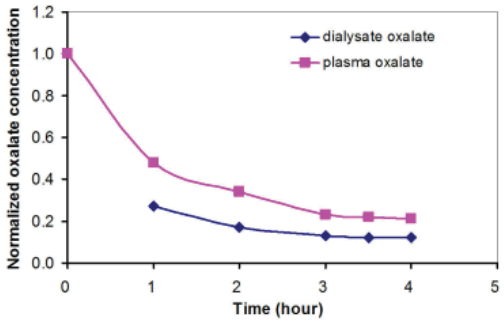
**Oxalate Quantification in Hemodialysate to Assess Dialysis Adequacy for Primary Hyperoxaluria** Xiaojing Tang, Nick Voskoboev, Stacie L. Wannarka, Julie B. Olson, Dawn S. Milliner, John C. Lieske. *Mayo Clinic, Rochester, MN.*

**Background:** Aggressive hemodialysis (HD) is required to prevent systemic oxalosis in primary hyperoxaluria (PH) patients with renal failure, and the required amount of HD increases as residual renal function declines. Due to extravascular oxalate deposition, plasma oxalate (Pox) does not reflect systemic oxalate loads. This study validated a method to accurately measure oxalate removal via HD.

**Methods:** 14 stable PH1 patients treated with HD by physicians in the Rare Kidney Stone Consortium were included. A high flux dialyzer (Polyflux Revaclear) was used 3-4 h per session. Dialysate (Dox) and Pox were measured hourly via enzymatic oxalate oxidase. Oxalate production was estimated from historical Uox measured when GFR was > 50 mL/min/1.73m$^2$. HD regimens were adjusted according to historical Uox, amount of oxalate removal at HD, residual Uox, and predialysis Pox.

**Results:** Mean reduction in Pox was 79±7% (Figure), with a mean pre and post dialysis Pox of 68.9±37.5 μM/L and 13.0±5.8 μM/L. 12 patients had urine output at the time of study with an average Uox of 1.1±0.8 mM/24h. Based upon HD oxalate removal and Uox clearance, 7 patients required HD 6 times a week, 2 patients 5 times a week, and 5 patients 3 times a week. Combined renal and HD oxalate clearance was 16.8±7.6 mM/wk, which exceeded endogenous oxalate production (13.4±3.9mM/wk). 8 patients received a kidney or combined liver-kidney transplant after a mean period of 4 mos on HD. The final pre-dialysis Pox before transplantation was significantly lower than the initial pre-dialysis Pox before individualizing HD (45.4±23.1 vs 78.8±38.0 μM/L, P=0.002).

**Oxalate kinetics on Hemodialysis averaged from 14 patients.**



**Conclusions:** In conclusion, a method to measure Dox was validated that can be used to individualize the HD prescription of PH patients to prevent systemic oxalosis, and to reduce the risk of oxalate nephropathy in the transplanted kidney.

*Funding:* NIDDK Support, Other NIH Support - National Center For Advancing Translational Sciences (NCATS)

## FR-PO987

**Calcium Equivalent Citrate Dialysis** Jan P. Sternby, Anders Nilsson, Gunilla Grundstrom, Maria Alquist. *Research Dept, Gambro.*

**Background:** Citrate has in recent years been introduced as a more physiological alternative to acetate in bicarbonate hemodialysis. Citrate entering the blood complex binds calcium (Ca). Some protein bound Ca is then released to maintain the equilibrium between protein bound and free ionized Ca. Both free and citrate bound Ca can pass the dialysis membrane which increases the Ca transport from the blood. We developed an algorithm to calculate the mass balance of Ca transfer over the membrane. The objective was to establish which Ca concentration in a citrate containing dialysis fluid gives the same total Ca mass transfer as a citrate-free dialysis fluid. The same was also done for magnesium (Mg).

**Methods:** The mass transfer area coefficients for ions and complexes were assumed proportional to their diffusive mobility. The electrical membrane potential was considered by requiring electroneutrality. As transfer of complexes across the membrane affects concentration gradients for both complexes and individual ions, we included in the calculations the (pH dependent) binding of ions like hydrogen, Ca and Mg to albumin and of Ca and Mg to bicarbonate and citrate. The dialyzer was considered being composed of serial subsegments. For each segment the transport of each solute and complex were calculated separately. With the given inlet concentrations for each solute the outlet concentrations for a dialyzer segment were calculated from the transports. From total outlet concentrations new distributions between free concentrations and complexes were calculated and used as input to the next subsegment. Parameters used: Plasma concentration of total Ca 2.2-2.4 mM (mmol/l), plasma citrate 0.1-0.3 mM, blood flow rate 200-400 ml/min, dialysis fluid flow rate 500 and 800 ml/min, urea KoA 700 and 1000 ml/min, Ca concentrations in dialysis fluid without citrate 1.0, 1.25, 1.5 and 1.75 mM, and citrate levels in the dialysis fluid 0.25 – 2 mM.

**Results:** In all cases the need for extra Ca and Mg in the dialysis fluid increases almost linearly with the citrate level. Each mM of citrate requires 0.15 mM additional Ca to maintain the same Ca mass balance.

**Conclusions:** Calcium equivalent citrate dialysis requires 0.15 mM more calcium in the dialysis fluid for each mM of citrate.

**FR-PO988**

**Extracorporeal Phosphate Removal with a Packed Bed Adsorber**

Shada M. Salem,[1] Rebecca J. Desch,[1] Vadim Guliants,[1] Stephen W. Thiel,[1] Heather Duncan,[2] Kotagal Shashi Kant.[2] *[1]Biochemical, Chemical and Environmental Engineering, Univ of Cincinnati, Cincinnati, OH; [2]Internal Medicine, Univ of Cincinnati College of Medicine, Cincinnati, OH.*

**Background:** Phosphate (PO4) continues to be a complex and vexing problem for dialysis patients. PO4 dialysance with conventional dialysis is suboptimal largely because of the multicompartment distribution of phosphate. Oral PO4 binder effectivenss is limited by cost, efficacy, and adherence. Our approach incorporates a packed bed for PO4 adsorption into the dialysis circuit to remove excess PO4 during hemodialysis. This will address the multicompartment nature of PO4 distribution and increase total PO4 removal.

**Methods:** The efficacy of adsorbents incorporating aluminum, lanthanum, and zirconium were evaluated with batch adsorption (0-40 mg/dL PO4), kinetic studies (10 mg/dL PO4), and column studies (50 mg/dL) in water at pH 8.2 and 37°C.

**Results:** PO4 adsorption to resin-based adsorbents was slow. Lanthanum-activated carbon and aluminum oxide showed relatively rapid adsorption with a PO4 capacity of 30 mg/g adsorbent at a PO4 concentration of 5 mg/dL. PO4 adsorption kinetics were often not first order, showing rapid initial uptake followed by slower equilibration after 30 min. Type I adsorption isotherms demonstrated strongly favorable adsorption at low PO4 concentrations. The interference of key blood components, including salts and proteins, was tested for the adsorption of 20 mg/dL PO4. Most components enhanced or slightly reduced PO4 loadings; however, bovine serum albumin (BSA) reduced PO4 capacity significantly. Column tests showed significant phosphate removal but more rapid PO4 breakthrough and lower adsorbent utilization than expected.

PO4 desorption using potential regenerants was measured. Concentrated acid or base effectively desorbed PO4 but damaged the adsorbents.

**Conclusions:** Lanthanum activated carbon and aluminum oxide show promise as selective, high-capacity, low-cost materials for extracorporeal phosphate removal in dialysis. Key issues moving forward are increasing the capacity of the adsorbent materials and improved column design to capitalize on the inherent equilibrium and kinetic properties of these materials.

**FR-PO989**

**Biofeedback Controlled Haemodialysis Increases Ionic Mass Removal**

Isabelle Kazes,[1] Coralie Barbe,[2] Khaled Gaha,[1] Herve Maheut,[1] Philippe Rieu.[1] *[1]Nephrology Dept, Univ Hospital, Reims, France; [2]Clinical Research Unit, CHU, Reims, France.*

**Background:** The Hemocontrol® system controls **blood volume changes** by acting on the actual ultrafiltration rate and the actual dialysate conductivity during the whole dialysis session. It has been shown that biofeedback haemodialysis can improve intradialytic hypotension.

We have studied the effect of Hemocontrol® (HC) on ionic mass balance, weight loss and dialysis quality parameters, compared to standard haemodialysis (HD).

**Methods:** Between 2007 and 2011, part of chronic dialysis patients at the University Hospital of Reims (France) were dialysed using both HD and HC haemodialysis. One or the other mode of dialysis was used with each patient in an occasional manner, only depending on organizational obligations. 35 439 dialysis sessions were analyzed. In total 2101 pairs, concerning 155 patients (i.e. 4202 sessions) were matched on 6 different criteria: the patient him/herself (the patient being his own control), the dialysis membrane, the blood pump speed (±15ml/min), patient weight before dialysis (± 100 gr), prescribed dialysate conductivity and the period (±6 months). The two groups HC and HD were compared using conditional logistic regression.

**Results:** With the same duration of dialysis sessions in the two groups (3:56±0:14 [3:00; 4:59]h:min for HC and 3:57±0:14 [3:00; 4:59]h:min for HD), we observed in the **HC group:** a **higher depurated volume** Kt (measured by ionic dialysance: 43.38±5.35 [30.0; 65.5]L *vs* 42.95±5.33 [30.0; 62.4]L; p<0.0001), and Kt/V (measured by ionic dialysance: 1,25±0,22 [0.58; 2.01] *vs* 1,24±0,21 [0.60; 2.08]; p<0.0001), a **significant increase** of **total fluid removal** (2.71±0.83 [0.47; 5.47]L *vs* 2,47±0,69 [0.50; 5.0]L; p<0.0001) and **ionic mass balance** (391.34±169 [-299; 953]mmol *vs* 286,13±116 [-91; 709]mmol; p<0,0001). No difference was observed on plasma conductivity at the end of treatment . Dry weight was obtained more often in the HC group (80,4% *vs* 78,1%; p=0,048).

**Conclusions:** This study shows that the **Hemocontrol®** System makes it possible to reach target dialysis dose with higher extraction of salt (105 mmol on average). 1/3 of this is linked to higher fluid removal (240 mL on average).

**FR-PO990**

**Individualized Dialysate Bicarbonate Concentration in Hemodialysis Patients**

Rapeepat Lekkham, Rasib Raja. *Nephrology, Einstein Medical Center, Philadelphia, PA.*

**Background:** Metabolic alkalosis is associated with adverse outcomes in hemodialysis patients. Prescription of high dialysate bicarbonate concentration was common in the United States but the optimal concentration remains uncertain. We studied the different variables among patients treated with different dialysate bicarbonate concentrations to find the optimal dialysate bicarbonate.

**Methods:** We conducted a retrospective data analysis on 90 patients who received HD 3 times a week from a single dialysis unit. Total study duration was 6 months. Data was collected retrospectively for first 3 months, when we were using 38 mEq/L bicarbonate dialysate concentration with acetate 8 mEq/L. Then we individualized the bicarbonate concentration to maintain the serum pre-dialysis bicarbonate 22±2 mEq/L and collected data for the following 3 months.We compared the different variables in the both study groups.

**Results:** The mean serum pre-dialysis bicarbonate before and after individualized bicarbonate bath was 25.44±2.09 mEq/L and 22.82±2.36mEq/L respectively (P <0.001). After individualizing dialysate, 67.8% of patients required 35mEq/L, 14.4%>35mEq/L and 17.8 %< 35mEq/L of bicarbonate concentration. Most patients before individualized dialysate had high serum pre-dialysis bicarbonate ( >25meq/L in 65.6% and >29meq/L in 5.6%). After individualizing, serum pre-dialysis bicarbonate was >25meq/L in only 8.8% and >29meq/L in 1%. There was no statistically significant difference in the other variables like Kt/V, Albumin, phosphate, iPTH, ESA, sensipar, and vitamin D requirements in both groups. In subgroup analysis, there was no statistically significant difference in those variables in patients who required dialysate bicarbonate concentration 35 mEq/L, less than 35 mEq/L or more than 35 mEq/L.

**Conclusions:** Our data suggests that there is no standard dialysate bicarbonate bath in hemodialysis patients. We need to individualize the dialysate bicarbonate concentration to maintain serum pre-dialysis bicarbonate 22±2 mEq/L. Monthly serum pre-dialysis bicarbonate was the only laboratory parameter which influence the choice of dialysate bicarbonate concentration.

**FR-PO991**

**Removal of Protein-Bound, Hydrophobic Uremic Toxins by a Combined Fractionated Plasma Separation and Adsorption Technique**

Falko Boehringer,[1] Markus Toelle,[1] Markus Van der Giet,[1] Sonja Steppan,[2] Vera Jankowski,[1] Joachim Jankowski.[1] *[1]Med. Klinik IV, Charite, Berlin, Germany; [2]Fresenius Medical Care, Germany.*

**Background:** Patients with chronic kidney disease show an increased cardiovascular mortality and morbidity due to several conservative risk factors and uremic retention solutes toxicity. Protein-bound uremic toxins, such as phenylacetic acid, indoxyl sulfate and p-cresylsulfate contribute substantially to the progression of chronic kidney disease and cardiovascular disease. However, based on their protein-binding these hydrophobic uremic toxins are poorly cleared during conventional dialysis and thus accumulate in CKD-5D-patients.Therefore, we investigated whether hydrophobic and cationic adsorbers are more effective for removal of protein-bound, hydrophobic uremic toxins than conventional high-flux hemodialyzer.

**Methods:** Five CKD-5D patients were treated using the fractionated plasma separation, adsorption and dialysis system (FPAD) for 5 h; for anticoagulation. A control group of five CKD patients was treated with conventional high-flux hemodialysis. Plasma concentration of phenylacetic acid, indoxyl sulfate and p-cresylsulfate were quantified at different time points and different sites, using gradient ion-pair reversed phase chromatography.

**Results:** The removal rates of FPAD treatment in comparison to conventional high-flux hemodialysis were increased by 130 % for phenylacetic acid, 187 % for indoxyl sulfate and 127 % for p-cresol.The plasma concentration of phenylacetic acid, indoxyl sulfate and p-cresylsulfate decreased by 1.15±0.17 mmol $L^{-1}$, 0.21 ± 0.05 mmol $L^{-1}$ and 0.24 ± 0.06 mmol $L^{-1}$ using the FPAD and 0.75 ± 0.40 mmol $L^{-1}$, 0.09 ± 0.04 mmol $L^{-1}$ and 0.23 ± 0.11 mmol $L^{-1}$ using conventional high-flux hemodialysis (p<0.05).

**Conclusions:** Due to the high impact of protein-bound, hydrophobic uremic toxins on progression of CKD and CVD in CKD-5D patients, the use of an adsorber in combination with dialysis membranes may be a new therapeutic option to increase the removal rate of these uremic toxins. However, larger, long-term prospective clinical trials are needed to demonstrate the impact on clinical outcome.

**FR-PO992**

**Elimination of the Middle Size Molecules by the FXCorDiax 60 in Relation to the FX 60-Dialyzer**

Francisco Maduell,[1] Paul Wieneke,[2] Marta Arias,[1] Manel Vera,[1] Josep M. Campistol.[1] *[1]Nephrology and Renal Transplantation, Hospital Clinic Barcelona, Spain; [2]Fresenius Medical Care Deutschland GmbH, Germany.*

**Background:** The incorporation of nano-controlled spinning technology in the design of dialyzers allowed to create a new generation of dialyzers with the goal of moving the sieving coefficient curve to the right and increase the steepness in order to get an optimal cut-off point. Theaim of this study was to compare two 1.4$m^2$ polysulfone dialyzers, current and new generation with respect to the efficiency in the elimination of a broader spectrum of uremic toxins.

**Methods:** In an open, randomized, cross-over, monocentric, controlled, prospective clinical study 30 hemodialysis patients were treated by post-dilution on-line hemodiafiltration once with the FX 60 or FX CorDiax60 dialyzer type. The remaining dialysis parameters did not vary: dialysis time 292±17 minutes, blood flow 408±32 ml/min and dialysate flow 500 ml/min. Intraindividually the removal ratio (RR) of urea, phosphate, $ß_2$-microglobulin ($ß_2$-m), myoglobin, prolactin, $a_1$-microglobulin, $a_1$-acid glycoprotein, albumin and total protein was compared.

**Results:** A significantly higher RR of myoglobin (75.2 ± 11 vs 58.6 ± 12, p<0.001), BUN (86.2 ± 4 vs 84.9 ± 5, p<0.015), $ß_2$-m (84.7 ± 4 vs 81.3 ± 5, p<0.001), Prolactin (73.0 ± 10 vs 56.9 ± 13, p<0.001) and $a_1$-microglobulin 20.9 ± 18 vs 13.6 ± 12.5, p<0.001) was detected for FX CorDiax 60 in comparison to FX 60. There were no significant differences inthe RR for phosphate, $a_1$-acid glycoprotein, albumin and total protein. On the dialysate side, a significantly increased eliminated mass was observed for myoglobin (1.83 ± 0.9 vs 1.51 ± 0.8 mg, p<0.002), $ß_2$-m (0.26 ± 0.09 vs 0.24 ± 0.09 g, p<0.001), prolactin (0.17 ± 0.13 vs 0.14 ± 0.08 mg, p<0.02) and albumin (4.25 ± 3.5 vs 3.01 ± 2.4 g, p<0.03), respectively.

**Conclusions:** In this study it could be shown that treating patients with FX CorDiax 60 dialyzers instead of FX 60 results in significantly increased reduction ratios of middle sized molecules without clinically relevant changes in albumin loss. This change could represent an improvement in the removal capacity that could be transferred to potential clinical benefits.

## FR-PO993

**Intra-Dialyzer Oxidative Stress (OS) Is Ameliorated by Molecular Hydrogen-Enriched Hemodialysis (HD) Solution ($H_2$-HD)** Wan-jun Zhu,[1,2] Hiroyuki Terawaki,[1] Masaaki Nakayama,[1,2] Yasuhito Takahashi,[1] Shigeru Kabayama,[2] Kaoru Sakurai,[1] Sadayoshi Ito.[2] *[1]Dialysis Center, Fukushima Medical Univ, Fukushima, Japan; [2]Center for Advanced and Integrated Renal Science, Graduate School of Medicine, Tohoku Univ, Sendai, Japan.*

**Background:** OS is the leading cause of HD patients' mortality. HD exacerbates OS via removing antioxidants and excess oxidative burst of neutrophils in the dialyzer. We recently revealed that $H_2$ could act as an anti-OS mediator using $H_2$-HD in the clinical setting. This study aimed to clarify $H_2$-HD's possible anti-OS effect during HD session.

**Methods:** A HD cross-over study was performed using standard solution (S-HD) and $H_2$-HD in the mid-week (n=8, 4 hours each). Blood samples of inlet and outlet were obtained from the dialyzer at the start and end. The redox state of human serum albumin (HSA) were examined as an OS marker; non-oxidized human mercapto-albumin (HMA), reversibly-oxidized human non-mercaptoalbumin-1 (HNA-1) and irreversibly-oxidized form (HNA-2) by HPLC.

**Results:** $H_2$ level of $H_2$-HD in blood and solution were 50 times of S-HD. In $H_2$-HD, f(HMA) increased and f(HNA-1) decreased significantly ($p<0.05$, start of HD, respectively), furthermore, f(HNA-1) decreased significantly ($p<0.05$, end of HD), while no changes in S-HD, suggesting $H_2$-HD's anti-OS effect.

| The albumin redox of each serum | | | | | |
|---|---|---|---|---|---|
| | S-HD | | | H2-HD | |
| | | f (HMA) % | f (HNA-1) % | f (HMA) % | f (HNA-1) % |
| Pre | | | | | |
| | Inlet | 62.2±14.6 | 34.2±14.0 | 60.5±13.3 | 35.6±12.5 |
| | Outlet | 62.9±13.2 | 33.4±13.0 | 63.3±13.8* | 32.8±13.0* |
| Post | | | | | |
| | Inlet | 77.1±9.5 | 20.0±9.0 | 74.5±10.8 | 22.7±10.5 |
| | Outlet | 76.1±9.6 | 21.2±11.0 | 75.9±11.0 | 20.9±9.5¶ |

*; P < 0.05 vs. Pre-Inlet, ¶; P < 0.05 vs. Post-Inlet, f;fraction

**Conclusions:** $H_2$-HD could suppress intra-dialyzer OS induced by HD session.

## FR-PO994

**Different Impact of Membrane Flux on Mortality between Incident and Prevalent Hemodialysis Patients** Yong Kyun Kim,[1] Hyung Wook Kim,[1] Su Hyun Kim,[2] Su Jin Choi,[1] Young ok Kim,[1] Ho Cheol Song,[1] Yong-Lim Kim,[3] Yon Su Kim,[4] Shin-Wook Kang,[5] Chul Woo Yang.[1] *[1]Dept of Internal Medicine, College of Medicine The Catholic Univ of Korea, Seoul, Korea; [2]Dept of Internal Medicine, College of Medicine Chung-Ang Univ, Seoul, Korea; [3]Dept of Internal Medicine, School of Medicine Kyungpook National Univ, Daegu, Korea; [4]Dept of Internal Medicine, College of Medicine Seoul National Univ, Seoul, Korea; [5]Dept of Internal Medicine, College of Medicine Yonsei Univ, Seoul, Korea.*

**Background:** The effect of flux membrane on mortality has been controversial. Previous study reported that the effect of high-flux dialysis on mortality may vary depending on the duration of dialysis. We evaluated the effects of dialyzer membrane flux on mortality in incident hemodialysis (HD) patients and prevalent HD patients.

**Methods:** In this prospective observational study, 817 incident and 1,353 prevalent patients with HD were included. In incident HD patients, 589 patients were dialyzed using low-flux dialysis membrane and 228 were dialyzed using high-flux dialysis membrane. In prevalent HD patients, 801 patients were dialyzed using low-flux dialysis membrane and 552 patients were dialyzed using high-flux dialysis membrane. All-cause mortality was primary outcome.

**Results:** After a median 20 months of follow-up, mortality was not significantly different between the high-flux group and low-flux group in incident HD patients (HR 1.45, 95% CI, 0.86-2.58, P = 0.155). In prevalent HD patients, HD using high-flux dialysis membrane was associated with decreased mortality compared to HD using low-flux dialysis membrane in univariate (HR 0.43, 95% CI, 0.25-0.74, P = 0.002), multivariate (HR 0.40, 95% CI, 0.21-0.77, P = 0.006) or propensity score-matched (HR 0.35, 95% CI, 0.18-0.67, P < 0.001) analyses.

**Conclusions:** Our data showed that HD using high-flux dialysis membrane had survival benefit in prevalent HD patients, but not in incident HD patients. These findings suggest that the effect of flux membrane on mortality may be different between incident and prevalent HD patients and high-flux dialysis might be recommended for the prevalent patients with HD treatment.

*Funding:* Government Support - Non-U.S.

## FR-PO995

**Correlation of Ionic Dialysance Kt/V with Urea-Based Kt/V Is Better in Men Than in Women for All Estimations of V** Tuan A. Nguyen, Vincent Paracuelles, Niti Madan, Andrew I. Chin. *Div of Nephrology, Univ of California, Davis School of Medicine, Sacramento, CA.*

**Background:** Use of ionic dialysance (ID) based measures of Kt/V in HD patients requires input of an estimated urea distribution volume (V). We examined gender-stratified correlation of ID Kt/V, using various calculations of V, against traditional urea-based Kt/V.

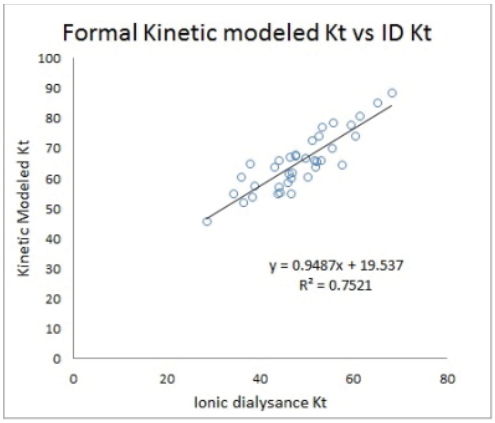
**Methods:** This was a retrospective review of CKD 5 on HD patients who had ID Kt/V measures with simultaneous pre and post HD BUN levels done. We compared ID Kt/V, using an array of calculations for V, against urea-based Kt/V by the Daugirdas equation.

**Results:** Anthropometric V methods and correlation of ID Kt/V to urea-based Kt/V are shown in the table.

| Method of calculated V | Correlation of ID Kt/V with Daugirdas Kt/V ($R^2$ value)* | | |
|---|---|---|---|
| | All subjects | Men | Women |
| | *n=68* | *n=31* | *n=37* |
| Watson | 0.43 | 0.63 | 0.29 |
| Surface Area Normalized Watson | 0.41 | 0.59 | 0.31 |
| Chertow | 0.43 | 0.68 | 0.25 |
| HEMO | 0.42 | 0.64 | 0.27 |
| Lee | 0.45 | 0.72 | 0.27 |

**all correlations statistically significant p<0.01*

There was a consistent underestimation of Kt/V by ID. While statistically significant in both genders, the correlation of ID Kt/V with Daugirdas Kt/V was much lower in women than men, regardless of V estimation method. We found a reasonable correlation between kinetically modeled Kt and ID Kt (n=38, Figure), though consistent undervaluation by ID was noted.



**Conclusions:** The usefulness of ID Kt/V as a tool depends on its correlation to established clinical measures. ID Kt/V does not account for ultrafiltration which may, in part, account for the lower values. Using all methods of estimating V, the correlation of ID Kt/V with urea based Kt/V was worse in women than in men. Given the reasonable correlation between modeled Kt and ID Kt, the problem resides in the calculation of V, especially in women.

*Funding:* Clinical Revenue Support

## FR-PO996

**No Discrepancy between Relative Plasma Volume Change and Absolute Plasma Volume during Ultrafiltration and Hemodialysis** Werner Ribitsch,[1] Gernot Schilcher,[1] Joerg H. Horina,[1] Vanessa Stadlbauer,[3] Alexander R. Rosenkranz,[1] Daniel Schneditz.[2] *[1]Clinical Div of Nephrology, Medical Univ of Graz (MUG), Austria; [2]Institute of Physiology, MUG; [3]Div of Gastroenterology and Hepatology, MUG.*

**Background:** One explanation for the poor prediction of intradialytic adverse events by excessive hemoconcentration measured by on-line techniques is assumed to reside with a systematic underestimation of the true blood volume drop induced by ultrafiltration (UF). The purpose of this study was to compare relative plasma volume changes calculated from on-line data with absolute plasma volumes determined in chronic and stable hemodialysis (HD) patients.

**Methods:** Intradialytic plasma volume (Vp) was determined in hourly intervals at 4 time points (t=1, 2, 3, 4) by indocyanine-green (ICG) dilution (modified from Mitra et al., JASN 2003). Hematocrit (H) as well as ICG concentrations were continuously measured by optical technique (CritLine, Fresenius Medical Care, USA).

**Results:** Twelve patients (6 female, 69.8±14.8 kg) were studied twice, the mean UF volume was 1.82±0.7 L. H significantly increased from 35.3±2.8% at t=1 to 37.1±3.1% at t=4 ($p<0.001$), corresponding to a drop of relative plasma volume ($\Delta Vp,H$) to 92.5%. Mean absolute plasma volume (Vp) was reproducibly measured as 3.48±0.21 L and slightly different between time points (p = 0.123). The plasma volume dropped to 94.2% of the initial value ($\Delta Vp$) and was not different from $\Delta Vp,H$ determined from on-line measurements.

| t | H | Vp | ΔVp,H | ΔVp |
|---|---|---|---|---|
| | % | L | % | % |
| 1 | 35.3±2.77 | 3.6±1.03 | 100 | 100 |
| 2 | 35.8±2.9 | 3.5±1.05 | 97.8±2.7 | 97.7±9.7 |
| 3 | 36.5±2.8 | 3.5±1.10 | 94.9±3.9 | 97.6±9.6 |
| 4 | 37.1±3.1 | 3.4±1.02 | 92.5±4.5 | 94.2±9.2 |
| | p < 0.001 | p = 0.123 | p < 0.001 | p = 0.123 |

**Conclusions:** These results indicate that on-line hemoconcentration captures the true plasma volume changes during HD in patients with moderate UF volumes. Failure of on-line H monitoring to predict intradialytic morbid events is therefore unlikely to depend on systematic overestimation of intravascular volume.

## FR-PO997

**Determinants of Aortic Stiffness by Cardiovascular Magnetic Resonance in Patients New to Haemodialysis** Aghogho Odudu,[1,2] Mohamed Tarek Eldehni,[1,2] Mark A. Horsfield,[3] Gerry P. McCann,[3] Chris W. McIntyre.[1,2] *[1]Div of Medical Sciences, Univ of Nottingham; [2]Dept of Renal Medicine, Royal Derby Hospital; [3]NIHR Cardiovascular Biomedical Research Unit, Leicester, United Kingdom.*

**Background:** Aortic stiffness is a novel cardiovascular risk factor in HD patients. Prior prevalent studies estimated stiffness by pulse wave velocity (PWV) with external devices. These are limited by inaccuracy of aortic length & determinants are unclear. Cardiac Magnetic Resonance (CMR) can accurately measure cardiac structure & function & directly measure aortic distensibility (AD) & PWV. We aimed to investigate the determinants of directly-measured AD by CMR & the utility of MR-determined PWV (MR-PWV) in a cohort of patients within 6 months of commencing HD.

**Methods:** 30 HD patients with 19 age & sex-matched controls (NC, n=19) were studied. AD and MR-PWV were determined from velocity-encoded imaging of the aortic arch using standard techniques. Carotid-femoral PWV was measured with an external oscillometric device (Ex-PWV). Skin autofluorescence (SAF), a marker of advanced-glycation end-products, high-sensitivity troponin-T & NT-Pro-BNP were measured in the HD cohort.

**Results:** Mean±IQR of data are presented. AD was reduced in HD compared to NCs, despite similar blood pressure & Ex-PWV (2.0±1.8mmHg-1×10-3 vs 4.0±4.8mmHg-1×10-3, p<0.001). Univariate analysis showed significant inverse correlations of AD to age (r=-0.67, P<0.001), MR-PWV (r=-0.72, p<0.001), Ex-PWV (r=-0.41 p=0.005) & left ventricular mass(r=-0.34, p=0.016). AD was positively correlated to ejection fraction (r=0.43, p=0.002) & strain (r=0.33, p=0.02). In HD patients, AD was inversely correlated to high sensitivity troponin-T(r=-0.53, p=0.014) & SAF (r=-0.57, p=0.013). There was no relation to anthropometric measures, NT-Pro-BNP or Calcium-Phosphate product. Multiple regression analysis identified MR-PWV & age as the strongest independent determinants of AD (adjusted $R^2$=0.70 p<0.001).

**Conclusions:** In a cohort of incident HD patients, age & PWV by CMR were independent determinants of directly-measured aortic stiffness. Long-term follow-up will investigate aortic stiffness as an independent risk factor for HD-associated cardiomyopathy.

## FR-PO998

**Overhydration Index Measured with BCM Is Correlated with Mean Arterial Pressure in Dialysis Patients** Eun Kyoung Lee,[1] Ji Eun Lee,[1] So Mi Kim,[2] Hyun woo Kim.[2] *[1]Dankook Univ Hospital; [2]Jeju National Univ Hospital.*

**Background:** It is important to maintain euvolemia to prevent further cardiovascular events and to reduce mortality in dialysis patients.

But in daily practice fluid status is assessed by using clinical methods such as body weight, clinical sign (blood pressure, edema, dyspnea), laboratory data (hemoconcentration or hemodilution) or chest X-ray because there is rare objective method to assess fluid status.

We evaluated fluid status in dialysis patients using the portable whole-body multifrequency BIA device, Body Composition Monitor BCM (Fresenius Medical Care, Germany).

**Methods:** We measured the body composition in 48 dialysis patients (M:F=29:19, age 52±12.6, CAPD:HD=32:16, DM:HTN:CGN:etc=19:14:12:3) from Dankook University Hospital using the BCM. We compared the overhydration index (OH) which was measured by BCM with blood pressure and cardiothoracic ratio (CTR).

**Results:** Mean overhydration index was 3.8±2.9 Liter and mean value of systolic blood pressure (SBP), diastolic blood pressure (DBP), mean arterial blood pressure (MAP) and CTR were 147±22 mmHg, 82±12 mmHg, 104±14mmHg and 0.54±0.08, respectively.

Correlation coefficient between overhydration index and SBP was 0.608 (p=0.001). It was 0.494 (p=0.08) with MAP but there was no significant correlation between overhydration index with DBP(r=0.343, p=0.109).

**Conclusions:** Overhydration index which was measured by BCM could be used as a relatively objective guide to decide ultrafiltration volume in dialysis patients.

## FR-PO999

**Plasma Sodium Levels and Cardiovascular Stability in Hemodyalisis Patients** Eduardo Baamonde,[1] Elvira Bosch,[1] German Perez Suarez,[1] Cesar Garcia-canton,[2] Mar Lago alonso,[2] Dolores Checa.[2] *[1]Nephrology, AVERICUM, Telde, Las Palmas, Spain; [2]Nephrology, Hospital Insular de Gran Canaria, Las Palmas de Gran Canaria, Las Palmas, Spain.*

**Background:** A relationship between pre-hemodialysis (HD) plasma sodium and mortality has been described. Lower sodium levels are associated with higher mortality.We analyze the relationship between pre-HD plasma sodium levels and intra-HD hemodynamic stability in a group of patients on standard HD and constant dialysate sodium.

**Methods:** Retrospective analysis of 231 prevalent patients in HD classified into three groups (**G**) according to their pre-HD sodium levels corrected for glucose (cNa): **G0**: cNa < 137 mEq/L (n=59); **G1**: cNa:137 to 139.9 mEq/L (n=126); **G2**: cNa > 140 mEq/L (n=46). Patients were followed up for two years. Mean blood pressure (MBP), inter-dialysis weigth gain (HDWG), ultrafiltration rate (UF), dry weight (DW) and dialysis hypotension (DH) was calculated in every single session. Laboratory tests, HD adequacy and antihypertensive treatment (AT) were analyzed.

**Results:**

| | G0 | G1 | G2 | p-value |
|---|---|---|---|---|
| **Average cNa mEq/L** | 135.4±1.45 | 138.5±0.78 | 140.95±0.91 | 0.000 |
| **Age (years)** | 61.73±15.2 | 60.44±13.84 | 63.39±12.08 | ns |
| **DM(%)** | 62.7 | 50.8 | 52.2 | ns |
| **DW(kg)** | 71.01±17.11 | 77.23±15.33 | 80.28±15.8 | 0.008 |
| **HDWG %** | 2.95±0.72 | 2.76±0.75 | 2.34±0.76 | 0.000 |
| **UF rate (ml/Kg/h)** | 8.13±2.18 | 7.38±2.03 | 6.33±1.76 | 0.000 |
| **% DH** | 17.33±15.56 | 11.46±13.25 | 11.76±13.7 | 0.024 |
| **Albumin (gr/dl)** | 3.57±0.29 | 3.72±0.25 | 3.71±0.25 | 0.00 |

cNa level was negatively correlated with UF rate (r: 0.325; p:0.000), percent weight gain (r: 0.279; p: 0.000) and % DH: (r: 0.146; p: 0.027).

**Conclusions:** Pre-dialysis plasma sodium was inversely related with cardiovascular stability. Patients with lower sodium levels showed higher tendency to hypotension may be related with higher inter-dialysis gain and UF rates.

## FR-PO1000

**Hemoglobin Levels, Cardiovascular and All Cause Hospitalization Rates, and Mortality in Pediatric Chronic Hemodialysis Patients** Blanche M. Chavers,[1,2] Julia T. Molony,[2] Craig Solid,[2] Michelle N. Rheault,[1] Thomas Nevins,[1] Charles A. Herzog.[2,3] *[1]Univ of MN, Pediatrics, Minneapolis, MN; [2]U.S. Renal Data System/CVSSC; [3]Univ of MN, Medicine.*

**Background:** Our objective was to describe the association of pt hemoglobin (Hgb) levels with risk of all cause and cardiovascular disease (CVD) hospitalization and mortality in pediatric chronic hemodialysis pts.

**Methods:** Pediatric pts (ages <18) from the CMS ESRD Clinical Performance Measures (CPM) project, from 2000 to 2008, were merged to the USRDS database. Prior Hgb and Epogen (EPO) use were determined from CPM data, and beginning annually on Jan. 1st, pts were followed for up to 1 yr and censored at the first date of death, lost to follow-up, or Dec. 31st. Outcomes included mortality and hospitalizations (all cause and CVD). We calculated the rates of outcome events per time at risk and stratified by pt Hgb levels.

**Results:** Pts with an average Hgb<10g/dL prior to follow-up had the highest unadjusted 1-year rates of mortality and all cause hospitalization (5.85 and 278.89, respectively, per 100 pt yrs), and both rates declined with increasing entry period Hgb levels. In contrast, the unadjusted rates of CVD hospitalizations were relatively constant across Hgb groups except for pts with Hgb>13g/dL who had the lowest rate. EPO use also differed by Hgb level with the lowest Hgb group having the fewest EPO users [at least 2 out of 3 months (Oct-Dec) with an EPO prescription] and the highest average dose per prescription.

| Hgb Group | N patients | EPO users (%) | Avg. prescribed EPO (units/wk.) | 1-year unadjusted rates per 100 pt yrs | | |
|---|---|---|---|---|---|---|
| | | | | mortality | hospitalizations (all cause) | hospitalizations (CVD) |
| Hb<10 | 461 | 76.85 | 20,418 | 5.85 | 278.89 | 41.42 |
| 10≤Hb<11 | 432 | 86.30 | 16,992 | 4.52 | 236.24 | 39.45 |
| 11≤Hb<12 | 798 | 92.67 | 12,727 | 3.19 | 203.40 | 38.41 |
| 12≤Hb<13 | 682 | 92.94 | 13,922 | 1.63 | 196.63 | 41.11 |
| Hb>=13 | 323 | 86.56 | 13,789 | 2.82 | 162.95 | 33.84 |

**Conclusions:** There is an association between a pt's Hgb levels and their risks of hospitalizations and mortality in the year following Hgb measure. Future analyses will adjust for pt characteristics and clinical profile.

## FR-PO1001

**Association between Blood Pressure Levels and Adverse Clinical Outcomes in Korean Incident Hemodialysis Patients** Fa Mee Doh,[1] Hyang Mo Koo,[1] Hyung Jung Oh,[1] Tae-Hyun Yoo,[1,2] Shin-Wook Kang.[1,2,3] *[1]Dept of Internal Medicine, College of Medicine; [2]Brain Korea 21, Yonsei Univ, Seoul, Korea; [3]On behalf of the Clinical Research Center for ESRD Investigators.*

**Background:** BP control is an important issue in ESRD patients on HD. In general, it is recommended that target pre- and post-dialysis BP should be <140/90 mmHg and <130/80 mmHg, respectively. However, there is much controversy about the optimal BP in these patients.

**Methods:** A prospective cohort of 807 incident HD patients from 36 dialysis centers of the CRC for ESRD in Korea was included in this study. Time-averaged BPs were expressed as means of each BP measured at 6-mo intervals. The impact of BP levels on a composite of all-cause mortality or cardiovascular (CV) events was clarified by multivariate Cox regression analysis.

**Results:** The mean time-averaged BPs were as follows: pre- and post-dialysis SBP, 146±19 mmHg and 143±18 mmHg; and pre-and post-dialysis DBP, 77±12 mmHg and 77±12 mmHg. During a mean follow-up duration of 20.5 mo, 65 patients died and 49 CV events occurred. Compared to patients with pre-dialysis SBP of 140-149 mmHg, HRs for the composite outcome were 2.16 (p=0.044), 1.90 (p=0.073), 2.28 (p=0.021), and 2.42 (p=0.010) in the pre-dialysis SBP groups of <130, 130-139, 150-159, and ≥160 mmHg, respectively, after adjustment for potential confounders. Similar relationship was also observed across post-dialysis SBP categories, where post-dialysis SBP ≥150 mmHg was associated with a significantly higher risk for the composite outcome. In terms of DBP, HRs for the composite outcome in the pre-dialysis DBP groups of <60, 60-69, 80-89, and ≥90 mmHg were 0.56 (p=0.171), 0.50 (p=0.011), 0.87 (p=0.596), and 2.55 (p=0.024), respectively, when compared to patients with pre-dialysis DBP of 70-79 mmHg. Similarly, post-dialysis DBP ≥90 mmHg exhibited a significantly higher risk for the composite outcome.

**Conclusions:** Pre-dialysis SBP of 140-149 mmHg and post-dialysis SBP of 130-149 mmHg were revealed to be the optimal BP levels associated with a favorable clinical outcome in incident HD patients. In addition, maintaining pre- and post-dialysis DBP <90 mmHg may provide a more beneficial effect in these patients.

## FR-PO1002

**Outcome of ESRD Patients Three Months after Initiation of Hemodialysis at a Tertiary Care Hospital of a Developing Country** Syed Rizwan Bokhari,[1] Hafiz I. Ahmad,[1] Shoaib Islam,[1] Nouman Hameed,[1] Khalid Tahir,[1] Arif Asif.[2] *[1]Dept of Nephrology, Allama Iqbal Medical College, Lahore, Punjab, Pakistan; [2]Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.*

**Background:** Patients with advanced CKD 5 mostly present to tertiary care hospitals with uremic complications and dialysis treatment is initiated to ameliorate acute symptoms. After a few inpatient dialysis sessions,due to paucity of dialysis services and lack of financial resources, they are unable to continue treatment or if they continue, the treatment is less than optimal. The fate of these patients is generally unknown.

**Methods:** 123 consecutive patients admitted with advanced CKD 5 (11-2012 - 03-2013) were included in this prospective study. Patients were interviewed according to a standardized questionnaire and were followed on monthly basis via telephone for a period of three months after initiation of dialysis. Eighteen patients died during hospital stay due to inter-current illnesses and 13 patients were lost to follow-up and as such were excluded from study.

**Results:** Ninety two patients completed three month follow up, of which 54(58%) were males with mean age of 38±5 years. Forty five (49%) patients were alive at the end of 3 months. Of these, only 4(4%) patients were getting thrice weekly dialysis. Thirty two (35%) were getting twice and 5 (5%) patients were getting once weekly hemodialysis. Four (4%) patients were not getting any dialysis. Forty seven (51%) patients died during follow up. Of these, 20 (21%), 38 (41%) and 47 (51%) had expired within one, two and three months of the initiation of Hemodialysis.

**Conclusions:** Majority of ESRD patients who had initiated hemodialysis due to acute uremic manifestations in a tertiary care hospital died within 3 months and those who had survived were receiving sub optimal treatment. This is an alarming situation that needs major efforts to improve pre ESRD care, timely initiation of dialysis and more resource allocation for provision of optimal dialysis services.

## FR-PO1003

**Prevalence and Management of the Dialysis Disequilibrium Syndrome: A Survey of U.S. Nephrologists** Rajeev Raghavan, Charles G. Minard, Flordeliza Lilagan. *Medicine, Baylor College of Medicine, Houston, TX.*

**Background:** The dialysis disequilibrium syndrome (DDS) presents as neurological symptoms that develop during or immediately following dialysis. Recommendations to reduce its incidence include a 50% reduction in blood flow rate and treatment time, intravenous mannitol, and repeating dialysis on two consecutive days. Despite widespread acceptance, these interventions have never been proven to reduce the incidence of DDS and are associated with substantial expense and time. This cost may be as high as $3000 extra per patient. In our institution, patients who rely on emergent dialysis seldom receive preventative measures, and we observe very few cases of the DDS. The purpose of our study was to ascertain the prevalence of DDS and assess how U.S. nephrologists manage at-risk patients.

**Methods:** Survey recipients were selected from a national sample of practicing nephrologists listed in a database licensee company for the AMA. The 18-question survey was electronically mailed to 5537 nephrologists, ages 28-80 years old, and took approximately 10 minutes to complete.

**Results:** Two hundred fifty-two (252) nephrologists responded (4.5%). Over 50% of the sample had encountered at least one case of the DDS within the past year. The number of years of experience as an attending nephrologist was not significantly associated with or predictive of using interventions to prevent/treat the DDS. However, nephrologists with less than 10 years experience had 3.9 times higher odds of using osmotically active agents (e.g. mannitol) than those practicing with >25 years experience (95% CI: 1.3, 12.0). The less seasoned nephrologist and nephrologists' practicing in the South were three times more likely to send at-risk patients to a more closely monitored setting (e.g. hospital) for dialysis (95% CI: 1.2, 4.2; 1.5, 5.4, respectively).

**Conclusions:** The dialysis disequilibruim syndrome remains highly prevalent throughout the U.S. and choice of interventions used to mitigate its occurence vary among US nephrologists, by age and practice location. This lack of concordance questions whether time-consuming and costly interventions, such as hospitalization, should be used for patients at-risk for the DDS.

## FR-PO1004

**Global Pediatric Hemodialysis Dialysis Experience: The PICCOLO MONDO Cohort** Maria E. Ferris,[1] Keisha L. Gibson,[1] Debbie S. Gipson,[2] Brett W. Plattner,[3] Peter Kotanko,[3] Daniele Marcelli,[4] Mondo Consortium,[5] Len A. Usvyat.[5] *[1]Medicine and Pediatrics, Univ of North Carolina, Chapel Hill, NC; [2]Pediatrics, Univ of Michigan, Ann Arbor, MI; [3]The Renal Research Institute, New York, NY; [4]Fresenius Medical Care, Bad Homburg, Germany; [5]MONDO Consortium, New York.*

**Background:** Pediatric hemodialysis (HD) patients worldwide have not been characterized. We describe the Global **PICCOLO MONDO (P**ediatric **I**nvestigation and **C**lose **C**ollaboration to examine **O**ngoing **L**ife **O**utcomes in the **MON**itoring **D**ialysis **O**utcomes) Cohort.

**Methods:** The MONDO consortium consists of HD data from US Renal Research Institute clinics; dialysis facilities of Fresenius Medical Care in Europe, Asia Pacific, Latin America; KfH (Germany); Imperial College (UK), Hadassah Medical Center (Israel); and University of Maastricht (The Netherlands) (Usvyat, Blood Purif 2013) with 62, 345 incident patients from 1,052 units in 26 countries. The **PICCOLO MONDO Cohort** includes incident 1 to 18 year old patients between 2000 and 2012.

**Results:** Analysis of 494 patients (0.8% of the population), revealed that 17 patients were from the Asia Pacific (41% males, mean age 13.35); 43 from the USA (49% males, mean age 15.13); 87 from Europe (64% males, mean age 15.91); and 347 from Latin America (52% males, mean age 14.3). The Asia Pacific units reported the youngest incident patients (mean age 10.83) and diabetes in 18%, whereas the Europeans had the oldest patients (mean age 15.35). The use of HD catheters is greatest in the Americas (75%), followed by Europe (52%) while Asia Pacific had 0%. The USA cohort had the greatest prevalence of hypertension (58%) and cardiovascular comorbidities (58%), followed by the European cohort (26 & 18% respectively).

**Conclusions:** The **PICCOLO MONDO Cohort** provides an opportunity to compare pediatric hemodialysis populations and outcomes at an international level. The prevalence of diabetes in the Asia Pacific units is unexpectedly high and requires additional investigation. The units in the Americas have the greatest use of HD catheters and the USA has the greatest prevalence of cardiovascular disease.

## FR-PO1005

**US Dialysis Facilities Target Hemoglobin (Hb) outside of Guidelines and Conduct Frequent Hb Measures and ESA Titrations Despite Lack of Belief in Effectiveness of These Anemia Practices** Alex Yang, Jennifer Vavrinchik. *NCS Research.*

**Background:** With the recent implementation of the CMS ESRD bundle, an updated FDA label for ESAs, and shifting QIP measures, changes in the approaches to anemia management have implications to the quality of care and management of patients on dialysis. Szczech et al (2012) demonstrated a lack of association between more frequent Hb measures and decreased Hb excursions and between more frequent ESA titrations and decreased Hb excursions. In this study, we evaluated current anemia management practices.

**Methods:** In this study, >2000 nephrology professionals were screened against inclusion criteria: US nephrology professional, dialysis practice setting, >1 yr of nephrology experience, and consent. 367 eligible study candidates were invited with eventual 175 study participants (48%). Hb targets, Hb threshold for ESA holds, and frequency of Hb measures and ESA titrations were evaluated. Analyses presented here were conducted across all study participants with no excluded data for any reason.

**Results:** 30% of study participant facilities use a Hb <10g/dL as lower range for target Hb, and 36% use a Hb >11g/dL as upper range for target Hb. 22% hold ESA dose at Hb of 11g/dL or less. 88% make ESA dose adjustments on average once a month or more frequently for each dialysis patient. Respectively, 14% and 15% of study participants believe that more frequent Hb measures and more frequent ESA titrations reduce Hb excursions.

**Conclusions:** Many US dialysis facilities seem to have Hb targets outside of the recommended ranges. Despite guidance to not make frequent ESA dose adjustments, nearly all facilities report frequent Hb testing and frequent ESA dose adjustment. Furthermore, nearly all participants do not believe these frequent Hb measurements and ESA dose titrations reduce Hb excursions, the purported reason to measure Hb and titrate an ESA. These apparent disconnects may represent the struggle between clinical beliefs, regulatory guidance, reimbursement constraints, and corporate directives.

**FR-PO1006**

**Early versus Late Initiation of Dialysis on Clinical Outcomes of Quality of Life and Survival: A Propensity-Matched Analysis** Jeonghwan Lee,[1,6] Jung-woo Noh,[2,6] Yong-Lim Kim,[3,6] Yon Su Kim,[4,6] Chun Soo Lim,[5,6] Jung Pyo Lee.[5,6] *[1]Dept of Internal Medicine, Hallym Univ Hangang Sacred Heart Hospital, Seoul, Korea; [2]Dept of Internal Medicine, Hallym Univ Gangnam Sacred Heart Hospital, Seoul, Korea; [3]Dept of Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Korea; [4]Dept of Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [5]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea; [6]CRC ESRD Investigators Group.*

**Background:** There is controversy on the adequate timing of the initiation of renal replacement therapy for the patients with end-stage renal disease.

**Methods:** We enrolled a total of 1779 adult patients who start dialysis from 2007 to2012 in a multi-center, prospective cohort of the Clinical Research Center for End Stage Renal Disease in Korea. All patients were interviewed and answered the questionnaire about Karnofsky performance score (KPS), Beck depression inventory (BDI), and kidney disease quality of life (KDQOL). Patients were classified, according to the mean values of estimated glomerular filtration rate (GFR) which is 7.372 ml/min/1.73 $m^2$, as early start group or late start group when GFR was above or below the mean values at the time of dialysis start.

**Results:** Before propensity-score matching, early start group showed poor score of KDQOL (56.8 ± 13.4 vs. 61.7 ± 14.6, P < 0.001), KPS (75.5 ± 15.4 vs. 78.8 ± 14.9, P = 0.002), and survival (P = 0.002). 1554 patients were eligible for matching and 395 patients were selected in each group. KPS (76.1 ± 15.0 vs. 78.6 ± 14.5, P = 0.086), BDI (16.4 ± 10.4 vs. 15.3 ± 10.4, P = 0.290), and KDQOL (57.8 ± 15.0 vs. 60.1 ± 14.5, P = 0.113) were similar between early start group and late start group. Overall survival was not different between groups (P = 0.259). In the subgroup analysis of patients with age above 65 years old, KPS (72.7 ± 15.2 vs. 73.2 ± 14.9, P = 0.869), BDI (16.8 ± 9.3 vs. 18.1 ± 11.0, P = 0.467), KDQOL (55.3 ± 12.4 vs. 54.6 ± 15.0, P = 0.791), and survival (P = 0.845) was comparable between groups.

**Conclusions:** Early initiation of dialysis was not associated with poor survival or quality of life even in the old age group.

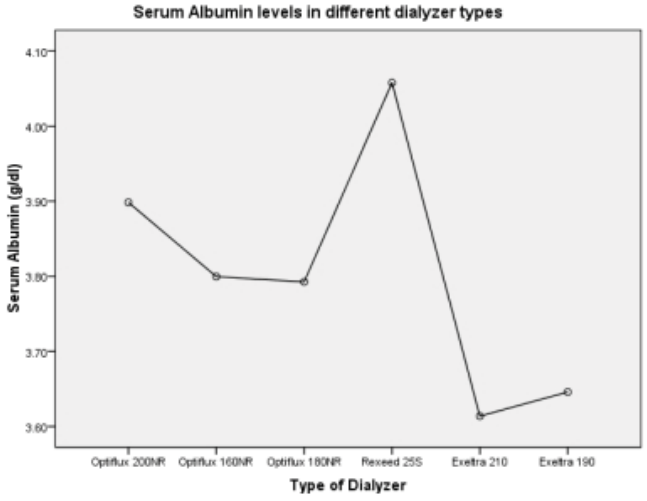
**FR-PO1007**

**Impact of Dialyzer on Serum Albumin Levels in End Stage Renal Disease Undergoing Chronic Hemodialysis** Alla Goldberg,[1] Hafiz Hussain,[2] Aruna Ray,[1] Farhanah Yousaf,[1] Bruce S. Spinowitz,[1] Chaim Charytan.[1] *[1]New York Hospital Queens, Flushing, NY; [2]Lutheran Medical Center, Brooklyn, NY.*

**Background:** Serum albumin level is an important predictor of morbidity and mortality in end stage renal disease. However, very little is known about impact of different dialyzers on filtration of albumin molecules which may affect serum albumin. The purpose of our study was to evaluate the effect of different dialyzers on serum albumin levels.

**Methods:** Patients undergoing chronic hemodialysis at a single dialysis unit between January 1st to December 31st 2012 were included in present study. Patients who were hospitalized during year 2012 were excluded from current analysis. Medical records and lab values were reviewed. Patients were divided into 6 groups based on dialyzer; Optiflux 200NR, Optiflux 160NR, Optiflux 180NR, Rexeed 25S, Exeltra 210, and Exeltra 190. Univariate analysis of variance was used to analyze the data.

**Results:** 179 patients met the inclusion criteria with 46 % females. Mean age of patients was 67 years. Mean serum albumin was found to be statistically significant different ($p<0.05$) except Optiflux 160NR versus Optiflux 180NR and Exeltra 210 versus Exeltra 190. Age, gender, and cholesterol levels were independent predictors of serum albumin levels. However, serum albumin levels in different dialyzer groups were still significantly different even after controlling for age, gender, and cholesterol.



**Conclusions:** Our study suggests that the choice of dialyzer may affect serum albumin levels in end stage renal disease. Dialyzer may be selected based on patients serum albumin levels and malnourished patients may benefit from specific dialyzers such as Rexeed 25S. Further studies are warranted to confirm these results.

**FR-PO1008**

**Correlation between Dt/V Derived from Ionic Dialysance and the Kt/V of Urea Using Daugirdas Formula in African-American Hemodialysis Patients** Wihib A. Gebregeorgis, Nishi Pradhan, Stephen D. Migdal, Lakshminarayanan Nandagopal, Reddy Singasani, Tehmina Mushtaq, Yahya M. Osman Malik. *Internal Medicine, Div of Nephrology, Wayne State Univ/Detroit Medical Center, Detroit, MI.*

**Background:** Dt/V obtained by using ionic dialysance (D) as a surrogate for urea clearance has been suggested as an adjunct measure of hemodialysis adequacy & has been shown to have variable correlation with the Kt/V of urea. We investigated the correlation between Dt/V & Kt/V of urea in African American HD patients & evaluated the impact of body size & ultrafiltration (UF) volume on the correlation.

**Methods:** A prospective single center observational study was conducted over a period of 3 months in 81 African-American HD patients. Each patient had 1-3 sessions of HD during which simultaneous evaluations of online Dt/V & spKt/V-urea were made. SpKt/V-urea was estimated using the second generation Daugirdas formula. The 'D' was evaluated using conductivity probes at the dialysate inlet & outlet and 'V' was estimated using the Watson's formula. Patients were categorized into three groups based on their body size & UF volume. The correlation between Dt/V & Kt/V was evaluated for the entire cohort & each pre-specified subgroup.

**Results:** A total of 81 patients had 186 HD sessions. The mean Kt/V was greater than the mean Dt/V (1.72 vs 1.50). There was an overall moderate correlation between Dt/V & Kt/V with an r2 of 0.602. The correlation was stronger in the medium BMI group compared to those in the lower & higher cohorts (r2 of 0.604, 0.653, 0.545 for those with BMI < 25, 25-30 & > 30kg/m2 respectively). The same trend was seen with the 3 weight subgroups. The correlation between Dt/V & Kt/V had inverse relationship to the UF volume; the lower the UF volume, the better the correlation between Dt/V & Kt/V (r2 of 0.698, 0.621 & 0.558 for those with UF volume of < 1.5, 1.5-3.0 & > 3 L respectively). 99.3% of the patients with Dt/V > 1.3 also had Kt/V > 1.3.

**Conclusions:** There is a moderate degree of correlation between Dt/V & Kt/V in African American chronic HD patients. Body size & UF volume affect the correlation between Dt/V & Kt/V. A Dt/V of > 1.3 strongly predicts adequate dialysis as defined by Kt/V of > 1.3.

**FR-PO1009**

**Association of Smoking Status with Cotinine Concentration Identified via Metabolic Profiling in Plasma Samples from Hemodialysis Patients** Quinlyn A. Soltow,[1] Dean P. Jones,[2] Rebecca H. Zhang,[1] Douglas I. Walker,[2] Nancy G. Kutner.[1] *[1]USRDS Rehabilitation/QoL Special Studies Ctr, Emory Univ, Atlanta, GA; [2]Medicine, Clinical Biomarkers Laboratory, Emory Univ, Atlanta, GA.*

**Background:** Smoking is associated with increased morbidity and mortality risks in chronic hemodialysis (HD) patients, but the evidence for higher incidence of cardiovascular events in smokers vs. nonsmokers is inconsistent (Liebman et al. 2011; McCausland et al. 2012). Patient reports suggest that smoking prevalence is higher than that identified in provider-generated data such as CMS Form 2728 (Longenecker et al. 2000), but the true prevalence in this population is difficult to determine. Using an objective biomarker of nicotine exposure, cotinine, in plasma samples from a subset of patients participating in a USRDS HD cohort study, we sought to validate patient-reported active cigarette smoking.

**Methods:** A multi-center cohort of over 750 prevalent HD patients was enrolled 2009-2011 in the ACTIVE/ADIPOSE study conducted jointly by the Rehabilitation/QoL and Nutrition USRDS Special Studies Centers. In a subset of 114 patients (113 African-American, 1 white) enrolled in Atlanta, GA, plasma samples were obtained at 6-month intervals over a 2-year period. Cotinine levels were measured using reverse phase chromatography-LTQ-Velos Orbitrap mass spectrometry-based metabolic profiling. Cotinine concentrations were confirmed by MS/MS using an authentic standard. Values exceeding 10 ng/ml indicate at least light active smoking.

**Results:** 27.5% of patients in the analysis subset reported current smoking, and cotinine values were consistent with these reports. An additional 11.0% of the subset had cotinine values consistent with active smoking but did not report being smokers; the ages of these patients ranged from 36 to 74, and two-thirds were male.

**Conclusions:** The contribution of smoking to outcomes such as hospitalization and mortality may be underestimated due to misclassification bias from underreported smoking. Metabolic profiling offers a window on the true prevalence of smoking exposure among patients undergoing HD, which may be relevant for the issue of ascertaining cardiovascular risk associated with active smoking.

**FR-PO1010**

**Comparison Study on Optimal Timing of Hemoperfusion Combined with Maintenance Hemodialysis** Chen Yu. *Dept of Nephrology, Tongji Hospital, Shanghai, China.*

**Background:** Hemodialysis (HD) combined with hemoperfusion (HP) was superior to HD in regularly eliminating middle and large molecule uremic toxins accumulated in the body. According to the different combining time of HD with HP, there were two types: Early type (HP was operated in the first two hours of HD) and Late type (HP was operated in the last two hours of HD). The purpose of this study is to compare the eliminating efficiency between these two types.

**Methods:** Twenty HD patients(4 hours each time, 3 times each week for more than 3 months treatment)were enrolled. All patients were alternately given Early type and Late type of HD + HP. Serum concentration of creatinine (sCr), BUN, immunoreactive parathyroid hormone (iPTH), ß (2) microglobulin (ß (2)-MG), interleukin-1, interleukin-6 (IL-6) and tumor necrosis factor-α (TNF-α) were determined before and after each treatment. Adverse events (low blood pressure, blood coagulation and so on) were observed.

**Results:** 1) Serum concentrations of all above mentioned were significantly declined after each type of treatment ($p<0.01$). 2) The eliminating efficiency of serum iPTH, ß (2)-MG , TNF-α, IL-1 and IL-6 was better in the Late type of HD+HP ($p<0.05$). 3) There were no significant differences of the eliminating efficiency of Scr,BUN between the two types of HD+HP. 4) There was no significant difference in the incidence of adverse events (low blood pressure, blood coagulation and so on) between these two types.

**Conclusions:** Both two types of HD+HP are efficient in eliminating uremic toxins for MHD patient. Comparatively, the Late type of HD+HP ((HP was operated in the last two hours of HD) has a better efficiency on elimination of middle and large molecule uremic toxins, like iPTH, ß (2)-MG, IL-1, IL-6 and TNF-α. However, there were no significant differences on elimination of small molecules, like sCr and BUN, between these two type of treatment. There was no significant difference of incidence of adverse events in the two types of HD+HP.

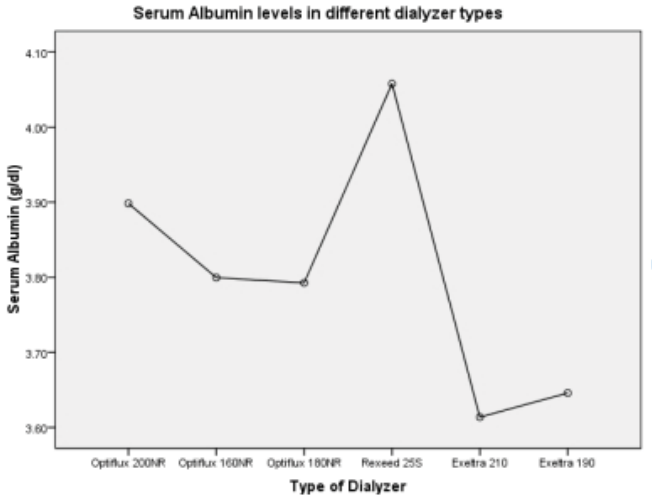
**FR-PO1011**

**Markers of Financial Efficiency and Patient Quality Outcomes Are Interrelated in Dialysis Clinic Operations** Len A. Usvyat, John Long, Norma J. Ofsthun, Franklin W. Maddux. *FMCNA, Waltham, MA.*

**Background:** Dialysis providers face an increased pressure to reduce cost while trying to provide highest quality service to its patients. With ESRD Seamless Care Organizations (ESCO) and other commercial integrated care arrangements, this pressure is even further accentuated whereby dialysis providers want to provide best care possible in the most efficient manner. We aim to understand whether patient quality measures are related to dialysis clinic financial and operational efficiency measures.

**Methods:** We used data from 1700 FMCNA dialysis clinics. For calendar year 2012, we computed measures of financial and operational efficiency: employee retention ratio (max of 100%) and EBIT per treatment as well as measures of quality such as percent of patients with albumin >4.0 g/dL and standardized mortality ratio (SMR). We divided measures of financial efficiency into quartiles and computed mean quality related measures in those groups. Comparisons between quartiles are performed by using independent t-tests.

**Results:** We found that clinics with higher employee retention ratios had lower SMR (ns) and higher percent of patients with albumin ≥4.0 (ns). Further, clinics with higher EBIT per treatment also had lower SMR ($p<0.05$) and higher percent of patients with albumin ≥4.0 ($p<0.05$).



**Conclusions:** This analysis suggests that dialysis operational efficiency is tied to patient outcomes: clinics with higher employee retention ratios and highest EBIT/treatment also have the lowest SMR and highest albumin levels. While these relationships are not always significant in this analysis, they are performed on a clinic-wide basis with much variability in other clinic related characteristics, but highlight the positive association between quality outcomes and financial performance.

**FR-PO1012**

**Dialysis Modality Decision Making** Suma Prakash,[1,2] Steven A. Lewis,[1,2] Anna McGrail,[1] Jesse D. Schold,[3] Mary Ellen Lawless,[1,2] Ashwini R. Sehgal,[1,2] Adam T. Perzynski.[1,2] *[1]MetroHealth Medical Center, Cleveland, OH; [2]Case Western Reserve Univ, Cleveland, OH; [3]Cleveland Clinic Foundation, OH.*

**Background:** Preparing patients for dialysis is part of patient centered care for late stage chronic kidney disease. Stage of change (SoC) algorithms can be useful tools to assess patient's readiness to make decisions and take health care actions. SoC algorithms classify patient readiness as pre-contemplation, contemplation (thinking SoC) preparation and action (acting SoC). The aims of this study were: 1) to develop a SoC tool for dialysis modality decision making, 2) determine associations between SoC and dialysis modality decision making and 3) determine additional factors associated with SoC and dialysis modality decision making.

**Methods:** Cross-sectional, observational study of adult patients with eGFR≤20 mL/min/1.73m$^2$. Qualitative interviews were conducted to support development and refinement of the survey. Survey responses were compared by SoC and by whether a dialysis decision was made using Fisher exact tests (dichotomous variables) and Wilcoxon's two sample tests (continuous measures).

**Results:** 49 patients are enrolled. 69%-female, 38%-White, 60%-Black, 92%-high school graduates and 82% had annual income<$25,000. 10% were in pre-contemplation, 55%-contemplation, 8%-preparation and 27%-action. 63% made a dialysis modality decision. Thinking versus acting SoC patients were less likely to have made modality decisions (50% vs. 88%, $p=0.01$). More patients made modality decisions with higher knowledge scores (1.4-decided vs. 0.2-undecided) and with physicians explaining modality options (41% vs. 74%) (both $p<0.05$). Modality decision barriers included: feeling home dialysis too difficult, others' opinions, body image with peritoneal dialysis catheter, fears about dialysis and feeling overwhelmed (all $p<0.05$). Composite barrier score was higher in the thinking compared to acting SoC (means of 1.1 vs. 0.7) ($p=0.01$).

**Conclusions:** Modality decision making is associated with SoC. Findings from this measurement development study suggest that helping patients overcome self-identified barriers may allow them to feel ready and make dialysis modality decisions.

**FR-PO1013**

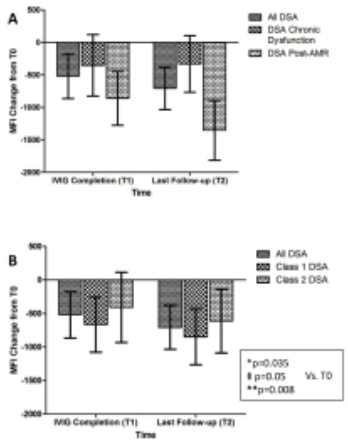
**Post-Transplant High Dose Intravenous Immunoglobulin (IVIG) for De Novo Donor Specific Antibodies in Kidney Transplant Recipients with Graft Dysfunction** James E. Cooper, Jane Gralla, Alexander C. Wiseman. *Kidney Transplant Center, Univ of Colorado, Denver, Aurora, CO.*

**Background:** Post-kidney transplant donor specific antibodies (DSA) are important contributors to graft loss and no effective therapeutic options exist. In the largest reported series of post-transplant DSA IVIG treatment to date, we describe outcomes in patients with de novo DSA and graft damage treated with a long-term high dose IVIG protocol.

**Methods:** Retrospective analysis of 28 kidney transplant recipients with DSA and graft damage in the form of either a recent prior acute antibody-mediated rejection (AMR) episode (n=8, group 1) or chronic graft dysfunction (n=20, group 2) prescribed a standard regimen of high dose (5 gm/kg) IVIG dosed over 6 months at our center**.**

**Results:** Mean fluorescence intensity (MFI) of 70 total DSA decreased by 520 at the end of treatment (T1, $p=0.14$) and by 708 at last follow up (T2, $p=0.035$) compared to treatment initiation (T0) MFI. The most robust treatment effect was seen in group 1 DSA (-1354 at T2 vs. T0, $p=0.008$) (figure 1a) and in class I DSA (-849 at T2 vs. T0, $p=0.05$) (figure 1b). Group 1, class I DSA underwent the largest MFI reduction (-1636 at T2 vs. T0, $p=0.01$). Antibody clearance, defined as MFI falling below 500, occurred in 68% of class I DSA vs. 16 % of class II ($p<0.001$) and in 63% group 1 vs. 24% of group 2 DSA ($p<0.001$). Graft function stabilized in group 1 patients but continued to decline in those in group 2.

Figure 1



**Conclusions:** High dose IVIG resulted in modest DSA MFI reductions in patients with previous graft damage, while graft function either stabilized or continued to decline despite treatment. The most robust MFI effect was seen in Class I DSA in patients with recent acute AMR. This already-at-risk cohort may benefit from IVIG therapy in order to reduce the degree of future chronic DSA-mediated graft damage.

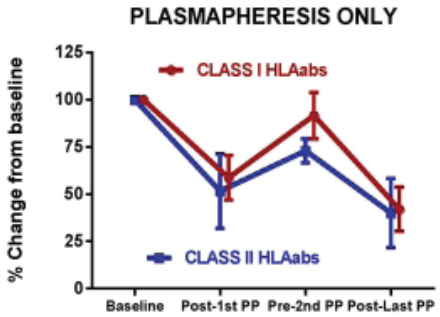
**FR-PO1014**

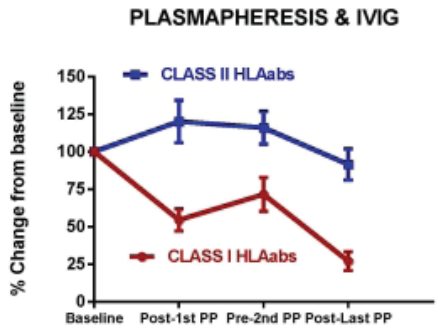
**Plasmapheresis Effect on the HLA-Antibodies in Kidney Transplantation and Desensitization** Lluvia A. Marino-vazquez,[1,2] Araminta Guichard,[1] Anh Nguyen,[2] Josefina Alberú,[1] Luis E. Morales-Buenrostro.[1] *[1]Nephrology and Transplant, INCMNSZ, Mexico, DF, Mexico; [2]Terasaki Foundation Laboratory, Los Angeles, CA.*

**Background:** Anti-HLA donor-specific antibodies (DSA) increase the risk of graft loss. Protocols for elimination/inhibition of these are heterogeneous. The cornerstone and oldest maneuvers to eliminate them is plasmapheresis (PP) with/without IVIG, but there is little information about the percentage removal of DSA with each session of PP. This report examine the behavior of DSA under PP treatment.

**Methods:** We included 33 kidney transplant recipients with humoral rejection and 4 patients who received PP for desensitization (Aug/11-Jul/13); divided in two groups: 1) Patients treated with PP (n=8) and 2) Patients treated with PP+IVIG (n=29). Sera samples were taken at baseline, after 1st PP, before 2nd PP, and after the last PP. HLA-DSA level were determined by Luminex single antigen bead assay (One Lambda, Canoga Park, CA). All samples were tested at the same time.

**Results:** Mean age was 34.39 ± 8.97 years; 64.1% were males. The 82.1% of patients received a living donor graft and the most common cause of CKD was unknown. For Group 1: 8 patients developed DSA Class I, decreasing to 42% and 6 Class II decreasing to 44%. In Group 2: 19 had Class I, decreasing to 27% and 25 Class II decreasing only to 91%. The figures depict the behavior of DSA.





**Conclusions:** PP was effective to remove DSA. We were able to identify an expected rebound after PP, due to exchange of DSA from interstitial fluid to plasma. The final reduction of DSA was similar in both groups, except for Class II when IVIG was used, maybe due to luminex measure issue. It is well known the possible interference of IVIG on DSA measure, but in this study it was only evident for Class II DSA. Each center must to compare different treatment schemes to define the best cost-benefit option for eliminate the HLA-DSA.

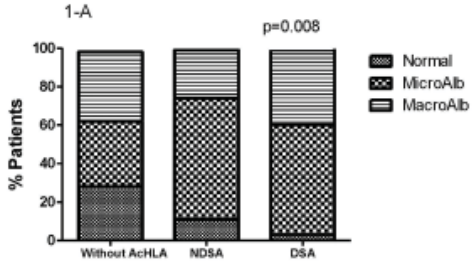
**FR-PO1015**

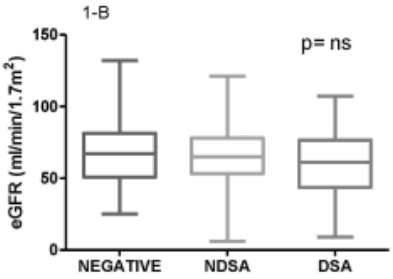
**HLA Antibodies and Albuminuria Precede Decline in Glomerular Filtration Rate Post-Transplantation** Lluvia A. Marino-vazquez,[1,2] Erick Hernández,[1] Araminta Guichard,[1] Norma O. Uribe-uribe,[1] Nubia Banuelos,[2] Josefina Alberú,[1] Luis E. Morales-Buenrostro.[1] *[1]Nephrology, Transplant and Pathology, INCMNSZ, Mexico, DF, Mexico; [2]Terasaki Foundation Laboratory, Los Angeles, CA.*

**Background:** HLA antibodies have been shown to be a predictive marker of long-term graft loss mainly due to endothelial damage. Albuminuria, a recognized marker of glomerular injury, is also considered a risk factor for graft failure. This report examine the association between post-transplant HLA antibodies and the key markers of renal injury: albuminuria and glomerular filtration rate (eGFR).

**Methods:** We included 266 renal transplant recipients, transplanted between 1984 and 2012, and at least one-year follow-up. HLA antibodies were determined by Luminex single antigen bead assay (One Lambda, Canoga Park, CA). Albuminuria was determined using turbidometry measured in urine collected over a 24 hr period. The result was normalized to the creatinine content in the same sample (albuminuria/creatinuria index). eGFR was calculated from serum creatinine values using MDRD equation.

**Results:** Of the 266 patients, 33.5% developed donor-specific HLA antibodies (DSA), and 45.1% had non donor-specific HLA antibodies (NDSA). 35 of the DSA patients had HLA Class I antibodies, while 64 had HLA Class II DSA. Patients with DSA had significantly higher albuminuria compared to patients with no antibodies (p=0.008). Interestingly, NDSA also showed higher proteinuria than the negative group. There was no significant difference between eGFR among the antibody and control groups at this point of follow-up.





**Conclusions:** Albuminuria is highly associated with the presence of HLA-DSA, and mildly correlated with NDSA. The fact that DSA and albuminuria were detected while eGFR remained at normal range, suggests that antibodies and albuminuria are earlier markers of graft injury than eGFR or serum creatinine.

*Funding:* Government Support - Non-U.S.

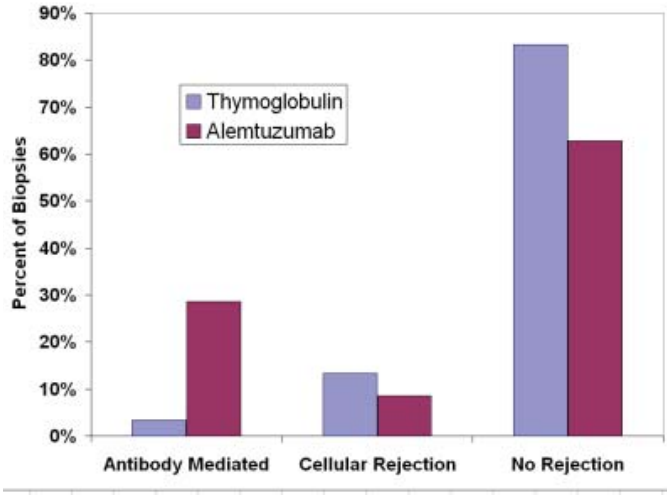
**FR-PO1016**

**Incidence of Antibody Mediated Rejection with Alemtuzumab Induction in Kidney Transplantation** Zurab Albekioni, Neeharika Muddana, Tarik Noureldeen, Leonardo P. Machado, Richard J. Marcus, Sabiha M. Hussain, Kalathil K. Sureshkumar. *Div of Nephrology, Allegheny General Hospital, Pittsburgh, PA.*

**Background:** Induction with lymphocyte-depleting antibodies is commonly used in kidney transplantation to prevent rejection. Little is known about the rate of antibody mediated rejection (AMR) with alemtuzumab(ALE) vs. rabbit-antithymocyte globulin (r-ATG) induction.

**Methods:** We conducted a retrospective cohort study of patients who underwent kidney transplants between Jan 2009 and Nov 2011. Patients were divided into 2 groups based on the induction received (ALE versus r-ATG). Primary end-points of the study were rates of AMR and acute cellular rejection (ACR) within 12 months of transplantation. Diagnostic criteria for AMR included peritubular capillary C4d deposition along with either histological changes on allograft biopsy or a positive donor specific antibody titer.

**Results:** Among 108 patients, 40 received r-ATG and 68 ALE induction. There were 30 allograft biopsies done in r-ATG and 35 in ALE groups. A significantly higher AMR (15% VS. 2%, P=0.008) but similar ACR (5% vs. 6%, p=0.69) rates were observed in ALE vs. r-ATG groups respectively. There were no differences in the incidence of delayed graft function (9% vs. 18%, p=0.30), as well as one year serum creatinine (1.7mg/dl vs. 1.8mg/dl, p=0.63), graft (91.1±3.5% vs.94.5%±3.8%, p=0.48) and patient (93.8±3.0% vs.92.7%±5.0%, p=0.92) survival rates.



**Conclusions:** A higher rate of AMR observed in the ALE group did not translate into adverse short term graft and patient outcomes. Increased AMR incidence associated with ALE induction could be related to lesser suppression of humoral immune response when compared to r-ATG. Similar rates of ACR between the groups imply adequate suppression of T cell mediated immunity by ALE. Long-term impact of these observations is less clear.

## FR-PO1017

### Rituximab with Prophylactic Intravenous Immunoglobulin Lowers Antibody Mediated Rejection in Flow Crossmatch Positive Kidney Transplant Recipients

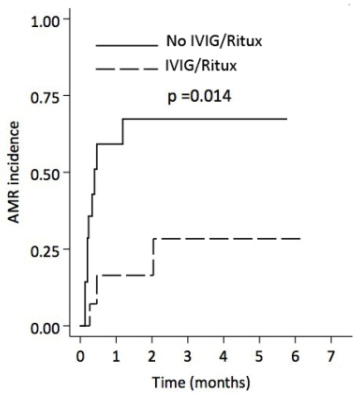
Shefali Patel,[1] Russell J. Crew,[2] Sumit Mohan,[2] Lloyd Ratner.[1] *[1]Surgery, Columbia Univ; [2]Nephrology, Columbia Univ.*

**Background:** Successful kidney transplantation in sensitized patients remains a challenge with high rates of antibody mediated rejection (AMR).

**Methods:** Our protocol for live donor kidney transplantatation with a flow positive crossmatch is pre- and post-transplant plasmapheresis (PP) with IL2 receptor antagonist induction, IV methylprednisolone tapered to prednisone 20 mg on postop day 4, with tacrolimus/mycophenolate maintenance therapy. To reduce AMR rates, in 2008, we added intraoperative Rituximab (375 mg/m$^2$) and intravenous immunoglobulin (IVIG) 2gm/Kg in divided doses at months 0, 2, 4, 6. This study compares the 17 patients (grp 1) who received this AMR prophylaxis to a historical cohort of 14 pts (grp 2) that received the original regimen. Kidney biopsies were done at weeks 1, 2, 4, 12, 26, 52, then yearly.

**Results:** There were no significant differences between groups in terms of age (46.4±12.5 vs 45±9.8 yrs, *p=0.92*), gender (females 53% vs 79%, *p=0.26*), or prior transplant (76% vs 38%, *p=0.06*). Overall biopsy proven rejection rates were similar (82 v 86%, p=0.99). However, in the Rituximab/IVIG arm, rates of AMR were lowered significantly (see figure, Log Rank = 12, *p= 0.015*), cases of concomitant ACR and AMR (0% vs 36%, *p=0.012*) were eliminated, and likely contributed to a small improvement in rejections with a complete response to therapy (85% vs 58%, *p=0.2*). Creatinine at one year was lower in grp 1, but not significantly different (1.5±0.6 vs 1.8±0.6 mg/dL, *p*=0.2). There were no significant differences in hospitalizations for infectious complication (4 vs 6) or rates of BK virus nephropathy (2 vs 0).

**Conclusions:** The addition of IVIG and Rituximab post-transplant appears to lower rates of AMR in patients receiving live donor positive flow crossmatch kidneys and should be considered in all such patients.



## FR-PO1018

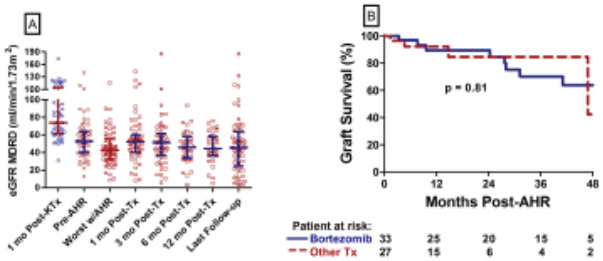
### Adding Bortezomib or Rituximab to PP Does Not Offer Advantage in the Treatment of Acute Humoral Rejection. A Single Center Experience in Mexico

Luis E. Morales-Buenrostro, Lluvia A. Marino-vazquez, Araminta Guichard, Cristhian R. Arias-delgadillo, Norma O. Uribe-uribe, Josefina Alberú. *Nephrology, Transplantation & Pathology, National Institute of Medical Sciences and Nutrition SZ, Mexico City, DF, Mexico.*

**Background:** Treatment for acute humoral rejection (AHR) has been an adaptation of the desensitization schemes. Includes removal of circulating HLA-antibodies (HLAabs) by plasmapheresis (PP), neutralization of HLAabs with IVIG, rituximab (RTX), and Bortezomib (Borte) intended to decrease HLAabs-producing plasma cells derived from B-cells, as well as use of rATG looking to control the cellular component (or interaction between T- and B-cells). This study compare different treatment protocols in order to guide future decisions.

**Methods:** Between May/08 and Apr/13, we prospectively recruited all 60 patients who had AHR. The histological description was made according to modified Banff 97 classification. DS-HLAabs were determined by Luminex single antigen bead assay (One Lambda). Kaplan-Meier survival curve with Log Rank test were used for compare graft survival.

**Results:** We included 60 KTR. Mean age 33.2±11.9; male gender 70%; first transplant 85%; living donor 76.7%; induction therapy 56.7%; maintenance triple therapy with CI 89.9%. The most used treatment schemes were PP+IVIG+RTX(36.7%), PP+IVIG+RTX+BORTE(35%), PF+IVIG+BORTE(6.7%), others (21.6%). A 41.7% received more than one treatment (2-7). A 95% of the patients used PP, and 55% received Borte. There were not differences in graft survival when Borte, RTX, or IVIG were added to PP. Also, receive more than one treatment cycle, or the time after KT did not showed difference. The figure shows the eGFR behavior, and graft survival according to Borte use.



**Conclusions:** At 4 years of follow-up, an important global graft survival reduction after AHR was found (55%) despite treatment. Adding Borte, RTX, or IVIG to PP did not showed any advantage.

*Funding:* Government Support - Non-U.S.

## FR-PO1019

### Five-Year Patient and Graft Survival in Desensitized Patients with Positive Complement-Dependent Cytotoxicity Crossmatch Is Similar to Unsensitized Patients

Kassem Safa,[1] Jude A. Yagan,[2] Helen Mah,[3] Jamil R. Azzi,[1] Edgar L. Milford,[3] Anil K. Chandraker,[1] Leonardo V. Riella.[1] *[1]Renal Div/Transplantation Research Center, Brigham and Women's Hospital, Boston, MA; [2]International Society of Nephrology; [3]Tissue Typing Laboratory, Brigham and Women's Hospital, Boston, MA.*

**Background:** More than 30% of potential kidney transplant recipients have pre-existing anti-HLA antibodies. Desensitization has been widely used and is accepted as an important strategy for overcoming this barrier. However, limited data is available regarding long-term outcomes, in particular for the highest risk group with a positive complement-dependent cytotoxicity crossmatch (CDC-XM) prior to desensitization.

**Methods:** Between 2002 and 2010, 39 patients underwent living-kidney transplantation across a positive CDC-XM against their donors at our center. The desensitization protocol involved pre-transplant immunosuppression, plasmapheresis, low-dose intravenous immunoglobulin ± rituximab. Measured outcomes included patient and graft survival, renal function and rates of rejection, infection and malignancy.

**Results:** The mean and median follow up was 5.2 years. Patient survival was 95% at 1 year, 95% at 3 years and 86% at 5 years. Graft survival was 87% at 1 year, 79% at 3 years and 72% at 5 years. Death-censored graft survival was 94% at 1 year, 88% at 3 years and 84% at 5 years. Chronic antibody-mediated rejection (AMR) caused 4 out of 6 graft failures; 24 subjects (61%) developed acute AMR with the majority occurring in the first month after transplan; one patient lost their graft due to hyperacute rejection. Chronic rejection/transplant glomerulopathy developed in 15 patients (38.5%). Acute cellular rejection occurred in 9 patients (24%). Infectious complications included pneumonia (17%), BK nephropathy (10%), and CMV disease (5%). 10% of patients developed skin cancer; there were no cases of lymphoproliferative disorder.

**Conclusions:** Desensitization in living-donor kidney transplantation results in acceptable 5-year patient and graft survival, despite high acute rejection rates. This approach represents a reasonable strategy for sensitized patients with no access to other alternatives such as paired kidney donation.

**FR-PO1020**

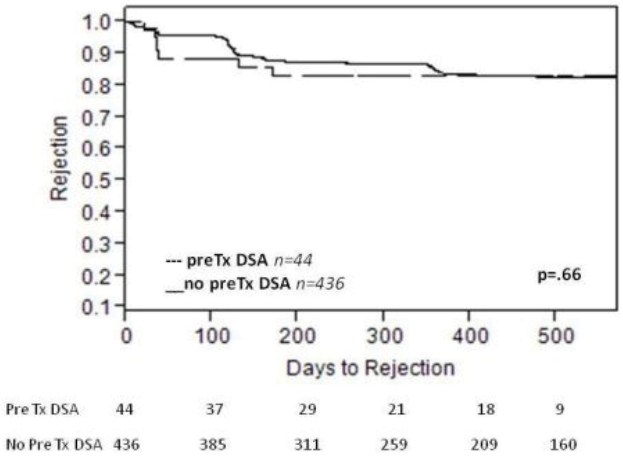
**Donor Specific Antibodies at Time of Transplant with a Negative or Weakly Positive Crossmatch Have Little Impact on Post Kidney Transplant Outcomes** Hasan Khamash, Kunam Sudhakar Reddy, Ala Nijim, Harini A. Chakkera, Janna Huskey, Raymond L. Heilman. *Mayo Clinic - Arizona.*

**Background:** We wanted to retrospectively study the impact of pretransplant donor specific antibodies DSAs on kidney allograft rejection and graft survival.

**Methods:** We included all recipients of kidneys from July 2010 to January 2013 excluding multiorgans. HLA and crossmatch (CXM) data was reviewed including the presence of DSAs at time transplant. A DSA was considered if the MFI >1000. HLA Luminex testing and protocol biopsies were obtained at 4 months and 1 year in addition to indication biopsies. Follow up data was available till May 2013. We also included transplants with weakly positive CXM in the analysis.

**Results:** 44/506 recipients identified to have at least one DSA at transplant, 26 recipient with no available pretransplant HLA data and 436 with no DSAs. The group with DSAs were more likely to have a kidney from a deceased donor, receive rATG for induction and be on steroid maintenance. Also more likely to have a previous transplant and a higher PRA. There was no difference in rejection or graft failure. AMR was increased in the DSA group but not significant.

| | Pre-Tx DSA n=44 | No DSA n=436 | p |
|---|---|---|---|
| Deceased Donor | 31(70%) | 219(50%) | .01 |
| Retransplant | 12(27%) | 38(9%) | <.01 |
| PRA (mean) | 39% | 10% | <.01 |
| Positive crossmatch | 5(11%) | 37(8%) | NS |
| rATG induction | 41(93%) | 119(27%) | <.01 |
| Steroid Maintenance | 43(98%) | 199(46%) | <.01 |
| 1 year GFR | 59±21 | 62±20 | NS |
| Antibody mediated rejection | 3(7%) | 12(3%) | NS |
| Graft failure | 2(5%) | 13(3%) | NS |



The DSAs were class I in 14/44, class II in 33/44 with a median MFI 1650. 11/44 had a DSA with and MFI>3000. By 4 month post transplant 18/40 had no DSA.

**Conclusions:** Employing rATG induction and steroid maintenance, recipients with pretransplant DSAs and negative/weakly positive CXM can be safely and successfully transplanted with at least similar short term outcomes compared to recipient with no DSAs.

**FR-PO1021**

**Bacterial and Fungal Infections Do Not Increase Sensitization in Kidney Transplant Recipients** Maria Ajaimy, Enver Akalin. *Kidney Transplant, Montefiore-Einstein Kidney Transplant Center, Bronx, NY.*

**Background:** Infections might increase sensitization in kidney transplant recipients due to interaction between innate and adaptive immunity or decreased immunosuppression during infection.

**Methods:** Patients transplanted between March 2009-2012 were included. Anti-HLA antibody testing using Luminex SAG was performed at 3, 12 months, and annually after transplantation. Increased sensitization was defined as increased panel reactive antibody and/or mean fluorescence intensity values of donor-specific anti-HLA antibodies (DSA) or development of new DSAs.

**Results:** Of the 267 patients studied, 64 (24%) demonstrated increased sensitization during a median follow-up of 25 months (3-48) after transplantation. 68 patients (26%) developed infection; 39 urinary tract, 13 pneumonia, 8 sepsis and 9 other infections. The risk factors for increased sensitization after transplantation were summarized in Table. The only statistically significant factor for increased sensitization was history of rejection prior to or within 2 months after Luminex. There was no association with the other factors studied including infection.

**Conclusions:** Acute rejection but not infection is associated with development of increased sensitization after kidney transplantation in our cohort of patients.

| Characteristic (%)or mean standard deviation | No increased sensitization N=203 | Increased sensitization N=64 | P-value |
|---|---|---|---|
| Infection prior to or within 2 months after sensitization date | 22.6 | 28.1 | 0.22 |
| Infection prior to sensitization date | 20.2 | 20.3 | 0.99 |
| Graft rejection prior to or within 2 months after sensitization date | 4.9 | 15.6 | 0.005 |
| Blood transfusion given prior to sensitization date | 37.0 | 31.0 | 0.41 |
| Mean, Age | 52.4+12.1 | 49.4+13.0 | 0.09 |
| Race, African-American | 34.5 | 25.0 | 0.16 |
| Gender, female | 40.9 | 53.1 | 0.09 |
| History of previous transplant | 14.9 | 12.5 | 0.64 |
| Donor type,( Deceased-donor) | 64.0 | 64.1 | 0.99 |
| Pretransplant class 1 PRA>79% | 11.6 | 19.2 | 0.17 |
| Pretransplant class 2 PRA >79% | 10.4 | 14.8 | 0.33 |
| Pretransplant DSA present | 16.8 | 26.6 | 0.08 |
| Induction with basiliximab | 39.1 | 35.9 | 0.61 |

**Safety of Transplanting Patients with Pre-Transplant Donor-Specific (DSA) Anti-HLA Antibodies without Pre-Transplant Desensitization Therapy** Maria Ajaimy, Kwaku Marfo, Adriana Colovai, Enver Akalin. *Kidney Transplantation, Montefiore-Einstein Center for Transplantation, Bronx, NY.*

**Background:** Patients with strong DSAs develop higher rates of acute and chronic antibody-mediated rejection (AMR) despite pretransplant desensitization treatment. We created a pre-transplant immunologic risk assessment protocol based on mean fluorescence intensity (MFI) of DSAs and channel shift of values of flow-cytometry cross-match.

**Methods:** Patients with DSA MFI values between 1,000-5,000 and flow-cytometry T or B cross-match channel shift values of 50-150 and 100-250, respectively were accepted for transplantation. All patients with DSA received anti-thymocyte globulin (total 6 g) and IVIG (2 g/kg) induction treatment.

**Results:** Between May 2009 and December 2012, 66 kidney transplant recipients with a mean number of DSAs (1.63 ± 0.82), MFI (2904 ± 2776), Flow T (136 ± 50), and B cell channel shift (162 ± 60) were compared to 308 patients without DSAs (Table). During a median 2.3 years follow-up, there was no difference in terms of patient and graft survival and graft function between 2 groups. Acute rejection was only observed in 8% of the DSA+ patients. Total of 73 DSAs were lost, and mean number of DSAs (0.54 ± 0.79) and MFI (2077 ± 3483) values significantly decreased posttransplant.

**Conclusions:** Successful kidney transplantation with a low acute rejection rate could be achieved in DSA+ patients with an immunologic risk assessment based on MFI and flow channel shift values and without pretransplant desensitization therapy.

| | DSA(N=66) | No-DSA(n=308) | P-value |

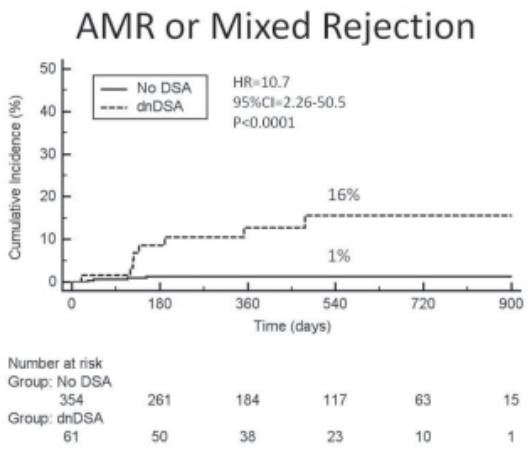
**Early De Novo Donor Specific Antibodies (dnDSA) after Kidney Transplantation: Impact on Rejection and Histology Findings** Raymond L. Heilman, Ala Nijim, Yvonne M. Desmarteau, Hasan Khamash, Marcelo Pando, Harini A. Chakkera, Janna Huskey, Riccardo Valdez, Kunam Sudhakar Reddy. *Mayo Clinic, Phoenix, AZ.*

**Background:** Our aim was to study (1) the frequency of dnDSA during the first year post-transplant and (2) the impact of dnDSA on protocol biopsy findings and rejection.

**Methods:** All patients receiving a solitary kidney transplant between 7/2010 and 1/2013 were included. Luminex Single Antigen Bead (SAB) assay was performed at 1, 4 and 12 months post-transplant. Only DSA's with MFI≥1000 were included. The cohort was grouped by the presence of a dnDSA at any time point during the first 12 months. Protocol kidney biopsy (Bx) was done at 12 months.

**Results:** 506 patients were transplanted during the study period. Exclusions: 51 with pre-transplant DSA, 26 without pre transplant testing, 9 with early non-immune related graft loss. 415 of the remaining 420 patients had at least one Luminex SAB assay during the first 12 months. 61 (15%) had dnDSA: 24 (6%) class I, 44 (11%) class II, 7 (2%) both. The dnDSA group was younger (50.4±13.5 vs. 55.4±13.1 yrs, p=0.007). Otherwise baseline patient characteristics were similar: female 39%, Black race 7%, deceased donor 50%, previous transplant 9%, 9% had pre transplant PRA>50%, and mean HLA mismatch 3.7±1.7. The control group was more likely to receive induction with a non depleting agent (18% vs. 3%, p=0.003). eGFR at 1 year was not different. The dnDSA group had more glomerulitis, tubulitis, interstitial inflammation and ptc>0 on the 1 yr Bx. Banff cg and C4d staining were not different. There was more antibody mediated rejection (AMR) in the dnDSA group.



**Conclusions:** The incidence of dnDSA during the first post-transplant year was 15%. Patients with dnDSA are more likely to have AMR and have changes on 1 year Bx compatible with endothelial injury. Further study of the impact of dnDSA on graft survival is needed.

## FR-PO1024

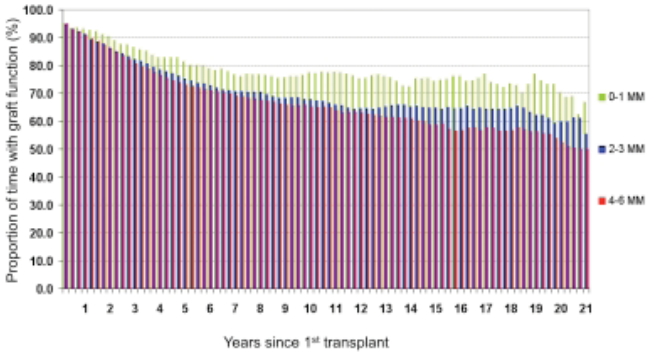
**Impact of HLA Mismatch at First Kidney Transplant on Lifetime with Graft Function in Young Recipients** Bethany J. Foster,[1] Xun Zhang,[1] Mourad Dahhou,[1] Robert Platt.[2] *[1]Pediatrics, McGill Univ, Montreal, Canada; [2]Epidemiology and Biostatistics, McGill Univ, Montreal, Canada.*

**Background:** Concerns have been raised that poor matching at 1st transplant may lead to greater sensitization and difficulty finding an acceptable donor for a 2nd transplant should the 1st transplant fail. We compared proportion of total lifetime with graft function after first transplant, and waiting times for a 2nd transplant between individuals with different levels of HLA mismatch (MM) at 1st transplant.

**Methods:** We studied patients recorded in the USRDS (1988-2009) who received a 1st DD transplant at ≤21 years old (n=8433), and the subgroup who were listed for a 2nd DD transplant following 1st graft failure (n=2498). We used logistic regression, with generalized estimating equations (GEE), to estimate the association between HLA ABDR MM at 1st transplant and proportion of total observed lifetime with graft function, and Cox models to compare the waiting times for a 2nd transplant between patients with different levels of HLA MM at the 1st transplant. All models were adjusted for sex, race, recipient age, socioeconomic status, transplant era, donor source, duration of dialysis before transplant, blood group, panel reactive antibody, and an index of HLA matchability (based on HLA profile compared with the donor pool).

**Results:** Compared with recipients of 2-3 MM 1st grafts, 4-6 MM graft recipients spent 15% [95%CI 13%, 18%] less of their time with a functioning graft after the 1st transplant (p<0.0001), and were significantly less likely to receive a 2nd transplant after listing (HR 0.87 [95% CI 0.78, 0.98]).

Figure 1



**Conclusions:** The benefits of better HLA matching at first transplant on lifetime with graft function are relatively small, and may be overshadowed by longer waits for a first graft if HLA matching were to be emphasized in allocation.

*Funding:* Government Support - Non-U.S.

## FR-PO1025

**Impact of Transplant Nephrectomy on HLA-Sensitization and Re-Transplantation** Saad Ajmal,[1] George P. Bayliss,[2] Jason T. Machan,[3] Claire Kassakian,[2] Paul E. Morrissey.[1] *[1]Surgery, Alpert Medical School, Providence, RI; [2]Medicine, Alpert Medical School, Providence, RI; [3]Biostatistics, Alpert Medical School, Providence, RI.*

**Background:** The management of a failed renal allograft is controversial. Transplant nephrectomy can lead to anti-HLA antibody formation (allo-sensitization). We evaluated the effect of transplant nephrectomy on allo-sensitization and the rate of subsequent transplantation.

**Methods:** We conducted a retrospective review of data from prospectively collected institutional and UNOS databases of kidney transplant recipients from 1997-2012 at a single academic transplant unit: some 933 renal transplants were performed out of which 183 failed (19.6%). Patients with failed transplants were divided into two groups: transplant nephrectomy for-cause (TN=53/172) and those who retained allograft (RA=119/172). Panel Reactive Antibody (PRA) values of patients who were re-listed, the main outcome measure, were collected at selected time points after graft failure.

**Results:** Age at transplantation, race, gender, living vs. deceased transplant, etiology of ESRD and time to graft failure were similar in both groups. No differences in co-morbidities were observed except for more patients with diabetes mellitus in the RA group (47.4% vs. 26.4%; p= 0.0097). TN group demonstrated a significant increase in PRA values immediately following TN (30.5 % vs. 43.8 %; p= 0.027). Patients with a failed allograft did not have significant change in PRA values (p= 0.67) over 1 year post-failure. 5/28 (17%) patients in TN group became highly sensitized (PRA>60) compared to 3/52 (5.7%) in RA group (p=0.08). Re-transplantation rates were similar at 4 years from graft failure in both groups (TN= 9/53, RA= 20/119; p=0.30). There was no statistically significant survival advantage offered by transplant nephectomy; but peri-operative morbity was high, and there were two deaths within 30 days of nephrectomy.

**Conclusions:** Although a mild increase in PRA was observed immediately following transplant nephrectomy, TN does not decrease the opportunity for re-transplantation. TN should only be performed for cause.

*Funding:* Clinical Revenue Support

## FR-PO1026

**Duration of HLA Antibody Elevation following a Transfusion Event in Patients awaiting Kidney Transplantation** Mary S. Leffell,[1] Deborah Kim,[2] Jeffrey Petersen,[3] John M. Hart,[1] Renato Vega,[1] Brian D. Bradbury,[2] Andrea A. Zachary.[1] *[1]Johns Hopkins Univ Immunogenetics Laboratory, Johns Hopkins Univ School of Medicine, Baltimore, MD; [2]Center for Observational Research, Amgen, Thousand Oaks, CA; [3]Clinical Development, Amgen, Thousand Oaks, CA.*

**Background:** HLA sensitization remains a major barrier to successful kidney transplantation. This study examines the association of transfusions with the occurrence, strength, specificity and duration of HLA antibody formation using highly sensitive/specific methods for testing HLA antibody.

**Methods:** We linked USRDS data with HLA antibody (Ab) data obtained from a pooled antigen assay comprised of HLA class I only and class II only antigens on the Luminex® platform for patients (pts) on dialysis awaiting primary kidney transplant at Johns Hopkins Transplant Center. We individually matched pts who had a transfusion event between 2 Ab measurements with ≤4 non-transfused pts on 6 demographic characteristics. We compared changes in adjusted, normalized values between treatment groups. Among pts with an increase in HLA antibodies following a transfusion, we examined changes in HLA class I and II Ab levels for up to 1 year using generalized estimating equations.

**Results:** We identified 89 transfused and 251 matched non-transfused pts. A greater proportion of pts experienced changes in adjusted values ≥25 for class I and ≥30 for class II antigens for transfused (20.4%) than non-transfused pts (2.4 %) (OR 9.6, 95% CI: 3.0-30.7). Following transfusion, Ab levels declined gradually over the following year (Fig 1).

**Conclusions:** Significant increases in HLA Ab strength and specificity can occur following a red blood cell transfusion and may persist for up to 1 year.

## FR-PO1027

**Some Renal Transplants Diagnosed as Glomerulonephritis Probably Have Antibody-Mediated Rejection** Andre Barreto Pereira,[1,3] Jessica Chang,[1] Konrad S. Famulski,[1] Philip F. Halloran.[1,2] *[1]Alberta Transplant Applied Genomics Centre, Edmonton, Canada; [2]Dept of Medicine, Div of Nephrology and Transplant Immunology, Univ of Alberta, Edmonton, Canada; [3]Dept of Nephrology, Santa Casa de Misericordia de Belo Horizonte, Belo Horizonte, Minas Gerais, Brazil.*

**Background:** In renal transplants recurrent and de novo glomerulonephritis (GN) is common, but distinguishing GN from antibody-mediated rejection (ABMR) is difficult. We hypothesized that a recently developed test for ABMR would reveal that some GN causing failure in renal transplants is actually ABMR.

**Methods:** From a prospective study of transplant indication biopsies taken >1year post transplant, we selected assessed 64 diagnosed as GN and assessed their microarray ABMR score (S) and conventional features (C).The underlying renal disease was identified as biopsy-proven GN in 24/64 (38%).

**Results:** 9/64 (16%) of transplants diagnosed as GN had positive ABMR scores (Table 1). In microarray analysis, S+ biopsies were later and had higher expression of DSA associated (DSAST), IFNG-induced (GRIT), and NK cell (NK) transcripts, typical of ABMR, and had higher AKI scores, than S-. S+ biopsies also had higher histologic cg and ci scores, and a higher frequency of failures than the 55 S- biopsies (Table 1). However, the TCMR scores were not different.

**Conclusions:** 16% of transplants diagnosed as GN in late biopsies have positive ABMR scores. These have an increased frequency of molecular features of ABMR, glomerular double contours and glomerulitis, and increased risk of graft failure. With treatment options emerging for ABMR, microarray diagnosis may aid in correctly distinguishing ABMR from GN.

Table 1 - GN in late combined biopsies (1 random biopsy per patient)

| GN variables | ABMR score<0.2(Failures) | ABMR score>0.2(Failures) | p value |
|---|---|---|---|
| n | 55(10) | 9(5) | 0.042 |
| DSA | 9(2) | 2(2) | 0.20 |
| Time post transplant (days) | 2740±2148 | 5068±2477 | 0.0017 |
| cg (glomerular double contours) | 0.35±0.70 | 1.37±1.06 | 0.002 |
| g (glomerulitis) | 0.22±0.60 | 0.62±1.06 | 0.12 |
| ptc (peritubular capillaritis) | 0.06±0.31 | 0.12±0.35 | 0.34 |
| mm (mesangial matrix increase) | 1.32±0.91 | 1.62±1.18 | 0.40 |
| ci (interstital fibrosis) | 1.15±0.81 | 2.37±0.74 | 0.0008 |
| ABMR score | 0.06±0.05 | 0.43±0.16 | 1.84e-06 |
| TCMR score | 0.007±0.029 | 0.0004± 0.0007 | 0.37 |
| AKI score (IRRAT) | 0.38±0.77 | 1.19±0.65 | 0.003 |
| DSA associated transcripts (DSAST) | 0.21±0.33 | 0.63±0.27 | 0.0008 |
| IFNG-induced transcripts (GRIT) | 0.44±0.40 | 0.80±0.27 | 0.012 |
| NK transcripts | 0.64±0.55 | 1.33±0.55 | 0.002 |

## FR-PO1028

**The Role of Medication Nonadherence in the Generation of De Novo Donor Specific Antibodies** Julia W. Tzeng,[1] Robert B. Ettenger,[1] Elaine F. Reed,[1] David W. Gjertson,[1] Ting-yan Chan,[1] Dechu P. Puliyanda,[2] Eileen W. Tsai.[1] *[1]Pediatrics, Mattel Children's Hospital UCLA, LA, CA; [2]Pediatrics, Cedars-Sinai Medical Center, LA, CA.*

**Background:** Medication nonadherence (MNA) has been associated with development of de novo donor specific antibodies (DSA) and rejection (rej) in kidney transplant (Tx) patients (pts). However, these studies linking MNA and DSA were limited, since the technique of identifying MNA was not rigorously defined. We recently showed that the percent coefficient of variation (CV%) of tacrolimus (TAC) is significantly associated with MNA and rej. Since DSA worsens Tx outcome and predicts antibody mediated rejection (ABMR), we sought to establish a precise relationship between DSA and MNA determined by pt self-report and CV% of TAC.

**Methods:** We studied 125 pediatric pts txed from Jan 2005 to Dec 2011. Pts were induced with anti-CD 25 antibody or anti-thymocyte globulin and maintained on TAC and anti-metabolite ± steroids. Biopsies and DSA were done per protocol and for clinical suspicion of rej and MNA. Rej was classified by Banff 09. DSA, using Luminex single antigen beads, were identified when mean fluorescent intensity >1000. MNA was determined by pt self-report using a standardized interview and by CV% of TAC (standard deviation divided by mean multiplied by 100%).

**Results:** Nonadherent pts defined by self-report were at higher risk of developing DSA (p <0.001, Fig 1a). Pts with DSA had a higher median CV% (p=0.002, Fig 1b). ROC analysis showed that CV% cut-off point of 42% was associated with an increased risk of developing DSA (AUC=0.71). We found an association between MNA as defined by either pt self-report or CV% and ABMR (p<0.001 and p=0.02, respectively).

Figure 1a: DSA is associated with MNA by pt self-report

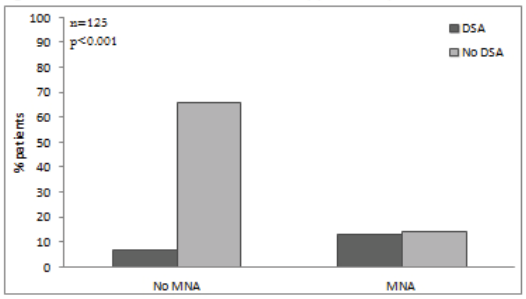

Figure 1b: DSA is associated with CV%

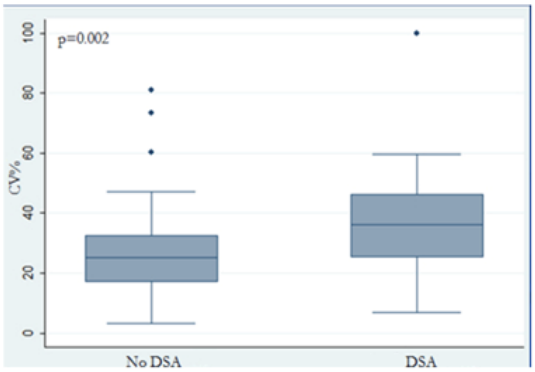

**Conclusions:** Rigorously defined MNA, DSA, and ABMR are conclusively associated. Thus, DSA can potentially be used as a novel marker to monitor MNA.

## FR-PO1029

**Is There an Increased Risk of Posttransplant De Novo Donor-Specific HLA Antibodies in Calcineurin-Inhibitor Sparing Immunosuppression?** Claudia Sommerer,[1] Christian Morath,[1] Matthias Schaier,[1] Petra Gombos,[2] Caner Süsal,[2] Martin G. Zeier.[1] *[1]Nephrology, Univ, Heidelberg, Germany; [2]Immunology, Univ, Heidelberg, Germany.*

**Background:** The important role of humoral immunity in the pathogenesis of chronic allograft nephropathy has prompted research assessing the role of anti-HLA antibody (Ab) monitoring to predict allograft outcome. Data on the prevalence of donorspecific antibodies (DSA) depending on the immunosuppressive regimen are limited.

**Methods:** We evaluated 106 immunologically low risk renal allograft recipients for de novo Ab occurrence. DSA were assessed by Luminex technology (One Lambda; Canoga Park, CA, USA). Initial immunosuppression consisted of basiliximab as induction therapy, CsA, MPA and steroids.

**Results:** Altogether, sera of 106 immunologically low-risk patients were included in the present analysis. At month 3 after transplantation, 86 patient were eligible for randomization either to continue standard immunosuppression (S: CsA+MPA, n=28) or to be converted to a CNI-free regimen with the mTOR inhibitor everolimus (CNI-free: EVE+MPA, n=29) or to a CNI-low regimen (CNI-low: CsA+EVE, n=29). At 4-year follow up, 17/79 patients (22%) had developed de novo DSA with 4/24 (17%), 5/28 (18%) and 8/27 (30%) in the standard, CNI-free and CNI-low group, respectively (n.s.). DQ de novo DSA was much more likely to appear compared with other loci antibodies. Patients with DR mismatch had an increased risk for developing of de novo DSA. In the follow-up period, four patients developed active C4d+ antibody-mediated rejection (AMR) (2 CNI-low, 2 CNI-free). In all four patients classical de novo DSA directed to HLA-A, -B or –DR antigens were observed and all patients demonstrated low CsA and/or EVE trough levels.

**Conclusions:** In summary, in the 4-year follow-up period, de novo DSA occurred in 22% of the patients. Incidence of de novo DSA was higher in the CNI-low group without reaching statistical significance. Most of the DSA were directed to the HLA-antigen DQ. DR HLA mismatch and low immunosuppressive exposure were identified as risk factors for development of de novo DSA. AMR was only detected in patients demonstrating de novo DSA directed to "classical" HLA-antigen A, B or DR.

**FR-PO1030**

**Impact of Donor-Specific Antibodies and Biopsies of the Grafts on the Therapy of Pancreas-Kidney Transplantation Patients**
Luis Eduardo Becker,[1] Sebastian Schäfer,[1] Ruediger Waldherr,[2] Martin G. Zeier,[1] Caner Süsal,[3] Christian Morath.[1] *[1]Nephrology, Univ of Heidelberg, Germany; [2]Pathology, Univ of Heidelberg, Germany; [3]Immunology, Univ of Heidelberg, Germany.*

**Background:** While the role of donor specific antibodies (DSA) in simultaneous pancreas kidney transplantation (SPKT) is still unclear, the histological evaluation of the pancreas allograft remains essential to judge immunological processes in the graft. Because of the growing clinical significance of DSA in the kidney-alone transplant setting, we performed a critical retrospective analysis of the indications and the further therapeutic consequences of these diagnostic tools on SPKT patients from our program.

**Methods:** All 17 cadaveric SPKT (from a total of 29) patients who underwent one or more biopsies of the pancreas allograft between Oct 2009 and Jan 2012 at our facility were included in the analysis. A total of 51 percutaneous biopsies (22 of the pancreas, 29 of the kidney) was performed in a median follow-up of 24 months. Analysis of DSA IgG against HLA antigens occurred prior to transplantation and by the time of the pancreas or kidney allograft biopsies.

**Results:** Adequate samples according to Banff were obtained in 15 of 22 procedures (68%). Successful pancreas biopsy led to a significant change in the immunosuppressive therapy in eleven episodes (73%) and justified the employment of antibody directed therapy in six (40%). In the remaining six patients, the therapy was oriented by the result of a concomitant kidney biopsy or the presence of DSA; antibody directed therapy was employed in one patient. Nine patients (60%) had at least one DSA positivity, eight of them with concomitant pancreas or kidney allograft rejection (88%), three with c4d positivity (33%). Six patients had negative DSA, four of them (67%) having sings of rejection in the kidney or pancreas histology, but none with antibody mediated rejection (AMR).

**Conclusions:** Even with the employment of Luminex tests in the routine and a possible association of DSA and the presence of AMR in our patient collective, the result of pancreas histology remained pivotal for the employment of a targeted, often more aggressive immunosuppression.

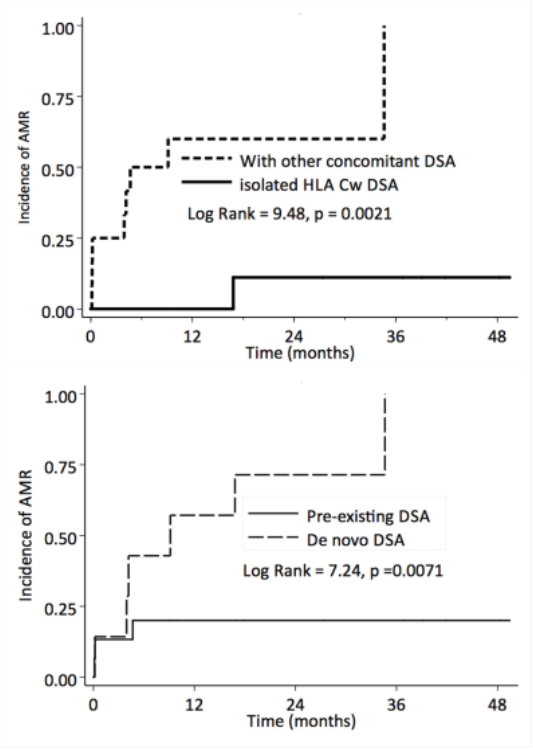
**FR-PO1031**

**Antibody Mediated Kidney Rejection Associated with HLA-Cw Specific Alloantibodies**
Ziad S. Zaky, Demetra Tsapepas, Elena Rodica Vasilescu, Geoffrey K. Dube, Russell J. Crew, Lloyd Ratner, David J. Cohen, Sumit Mohan. *Columbia Univ Medical Center.*

**Background:** It is unclear whether donor-specific antibodies (DSA) directed against HLA-Cw increase risk for antibody-mediated rejection (AMR) after kidney transplant.

**Methods:** Since 2008, kidney transplant recipients (KTR) at Columbia University Medical Center are screened for DSA against HLA-Cw pretransplant and at the time of graft dysfunction. We identified 84 KTR with Cw alloantibodies including 22 KTR with HLA-Cw DSA, either in isolation (45.5%) or combined with other class I or class II DSA (54.5%).

**Results:** Our cohort was 68.2% male, with a median age of 56.7yrs (IQR 46.5–67.6 yrs); the majority (68.2%) had no previous organ transplant. Nine KTR had an AMR (3 with pre-existing Cw DSA vs 6 with *de novo* Cw DSA, *p=0.007*). KTR with isolated Cw DSA were less likely to experience AMR (10% vs 66.7%, *p=0.03* and OR=0.56, *p=0.02*) and have a longer time to AMR (*p=0.002*) despite similar MFI (Cw DSA MFI median 1600 vs 3600, *p=0.08*) to patients with additional DSA. No KTR with isolated pre-existing Cw DSA (n=9) experienced AMR while 50% (3/6) with other pre-existing DSA had AMR (*p=0.04*). Seven KTR developed *de novo* Cw DSA at a median of 126 days (IQR 53-909 days) post transplant but only 1 developed Cw DSA in isolation; 85.7% (6/7) had AMR. KTR with *de novo* Cw DSA had significantly shorter time to rejection than pts with pre-existing Cw DSA at transplant (*p=0.007*) despite similar MFI (median 2000 vs 2200, *p=0.32*). After adjustment for the presence of other HLA DSA, KTR with *de novo* Cw DSA were still more likely to develop AMR than those with pre-existing Cw DSA.



**Conclusions:** Our results suggest a lower incidence of AMR among KTR with isolated pre-existing HLA-Cw DSA compared to KTR who have multiple DSA. However, *de novo* HLA-Cw DSA even in isolation is associated with a higher risk of AMR than preformed HLA-Cw DSA.

**FR-PO1032**

**Significance of Donor Specific Anti-HLA Antibodies Identified Using Recombinant HLA Coated Single Antigen Beads in Kidney Graft Recipients with a Negative Donor Flow Cytometry Crossmatch**
Darshana Dadhania, Dinesh Kannabhiran, John R. Lee, Jun B. Lee, Thangamani Muthukumar, Manikkam Suthanthiran. *Nephrology, Weill Cornell Medical Center, New York, NY.*

**Background:** Flow cytometry crossmatch (FCXM) and recombinant HLA coated single antigen bead assay (SAB assay) are highly sensitive assays for detection of donor specific antibodies (DSA). Many transplant centers consider a positive FCXM as a contraindication to kidney transplantation. We investigated the clinical significance of DSA using SAB assay, in the context of negative FCXM.

**Methods:** We evaluated 204 patients who underwent prospective FCXM and SAB testing prior to kidney transplantation. Sera were profiled using LabScreen SAB assay & DSA with mean fluorescence (MFI) value >1000 MFI were scored as positive. Donor FCXM was scored as positive when the mean channel displacement was >40 for donor T cells and/or >150 for donor B cells.

**Results:** Of the 204 renal transplant recipients tested, 43 had a positive FCXM with donor T and/or B cells. In the remaining 161 recipients with a negative FCXM result, 50 were positive for DSA. Seven of 50 patients with the positive DSA by SAB assay experienced AMR and four experienced graft loss. In a multivariable logistic regression analysis, DSA detected by SAB assay in patients with a negative flow cross match result was an independent risk factor for AMR. Risk of graft loss was also increased (OR=4, 0.9, 17; P=0.07).

| Multivariable Analysis | Risk of AMR Odds Ratio (95% CI) | P value |
|---|---|---|
| DSA | 11.7 (1.3, 106) | 0.03 |
| DGF | 6.2 (0.9, 43) | 0.06 |
| Class I Mismatch | 1.76 (0.69, 4.5) | 0.23 |
| Class II Mismatch | 0.86 (0.44, 1.7) | 0.66 |

**Conclusions:** Donor specific antibodies, not detected by flow cytometry but identifiable by SAB assay, is associated with an increased risk of antibody mediated rejection and with a trend toward increased graft loss in kidney graft recipients. Standardized screening of sera using SAB assay, in addition to identification of patients at risk for AMR, offers opportunities for personalized immunosuppressive therapy in kidney graft recipients.

*Funding:* Clinical Revenue Support

**FR-PO1033**

**Lower Rejection Rates with Class 1 versus Class 2 Donor Specific Antibodies in Sensitized Kidney Transplant Recipients** Russell J. Crew,[1] Shefali Patel,[2] Sumit Mohan,[1] Joan Kelly,[2] Mary Jane Samuels,[2] Lloyd Ratner.[2] *[1]Div of Nephrology, Columbia Univ; [2]Surgery, Columbia Univ.*

**Background:** Renal transplant recipients with donor specific antibodies (DSA) have high rejection rates. Determination of which class of DSA are associated with worse outcomes will aid in donor selection and paired kidney exchange participation.

**Methods:** Since 2004, we have performed 57 live donor positive cytotoxic or flow crossmatch (+XM) renal transplants. All patients received pre- and post- transplant plasmapheresis(PP) with intravenous immunoglobulin (IVIG) replacement (100mg/kg) for a minimum of 2 treatments and until CDC crossmatch was negative. Induction therapy varied with time but included either an IL-2 receptor blocker or Thymoglobulin® with or without intra-operative Rituximab. Maintenance therapy is tacrolimus and mycophenolate. All patients received IV methylprednisolone with taper to prednisone 20 mg daily by post-operative day 4. Protocol biopsies are done at 1, 2, 4, 13, 26 and 52 weeks; then annually.

**Results:** Of the 57 patients, 40 had results of DSA measurement by single antigen beads available. Among the 18 patients with cytoxic +XM, rejections rates were high regardless of DSA type (Class 1- 9/9, class 2- 3/4, class 1&2- 5/5). Analysis was then restricted to the 22 patients with only flow +XM. Patients with class 2 and class 1&2 antibodies behaved similarly and were grouped together for analysis. There were significant differences in outcomes between patients with class 1 compared to those with only class 2 or both class 1 and 2 DSA.

| FLOW CROSSMATCH RECIPIENTS ONLY | | | |
|---|---|---|---|
| | Class 1 DSA (n=5) | Class 2 and 1&2 DSA (n=17) | p value |
| Age (yrs) | 54.9±9 | 45±10 | 0.12 |
| Women | 4/5 | 8/17 | 0.32 |
| Prior txp | 2/5 | 12/17 | 0.3 |
| Creatinine 1 yr (mg/dL) | 1.26±0.47 | 1.77±0.74 | 0.28 |
| Recent creatinine (mg/dL) | 1.16±0.26 | 2.07±1.48 | 0.19 |
| Overall rejection | 2/5 | 16/17 | 0.02 |
| First rejection type | | | |
| AMR | 0/5 | 5/17 | 0.29 |
| ACR | 2/5 | 8/17 | 1.0 |
| Combined AMR/ACR | 0/5 | 3/17 | 1.0 |
| Recurrent rejection | 0/2 | 7/16 | 0.49 |

**Conclusions:** Among sensitized patients, those with only flow +XM donor specific antibodies restricted to class 1 MHC have fewer rejections and less recurrent rejections than those with class 2 or class 1 and 2 antibodies.

**FR-PO1034**

**Elevated Urinary CCL2: Cr at 6 Months Is Associated with the Development of Renal Allograft Interstitial Fibrosis and Inflammation at 24 Months** Julie Ho,[1] Chris J. Wiebe,[1] Ian W. Gibson,[2] Ang Gao,[1] Claudio Rigatto,[1] Martin Karpinski,[1] Leroy J. Storsley,[1] Peter W. Nickerson,[1] David N. Rush.[1] *[1]Internal Medicine, Section of Nephrology, Univ of Manitoba, Winnipeg, Canada; [2]Pathology, Univ of Manitoba, Winnipeg, Canada.*

**Background:** We have previously demonstrated that 6 month urinary CCL2: Cr is an independent predictor of interstitial fibrosis and tubular atrophy on 24 month biopsy and subsequent death-censored graft loss. Patients with graft loss frequently have a combination of graft interstitial fibrosis plus inflammation (GIF & "i", i>0 & ci>0). The goal of this study was to determine if 6 month urinary CCL2: Cr is an independent predictor for the development of GIF &"i".

**Methods:** The patients were from a prospective, multi-centre adult renal transplant study (n=111) that had 6 month urines and 24 month protocol biopsies. CCL2 was measured with ELISA, corrected for urinary creatinine. Renal histopathology was reported using the Banff schema. Stepwise logistic regression was performed with the potential covariates: 6 month urinary CCL2: Cr, donor age >50 years, delayed graft function, living vs. deceased donor, ACEi/ARB exposure, PRA and HLA match.

**Results:** Six-month urinary CCL2: Cr was significantly higher in GIF & "i" [26.8 ± 17 ng/mmol, p=0.003, n=28] and transplant glomerulopathy patients [36.3 ± 36 ng/mmol, p=0.004, n=15] compared to normal histology [15.4 ± 10ng/mmol, n=30] at 24 months. By multivariate analysis, 6 month urinary CCL2: Cr was an independent predictor for developing GIF & "i" at 24 months [OR 1.04, 95% CI 1.013-1.082, p=0.01]. Finally, 6-month urinary CCL2: Cr had an AUC 0.695 [95% CI 0.571-0.819], with a sensitivity/specificity of 0.71/0.62 at a cut-off value of 15ng/mmol for identifying 24 month GIF & "i".

**Conclusions:** This study demonstrates that 6-month urinary CCL2: Cr is an independent predictor for developing 24 month GIF & "i". Urinary CCL2: Cr may be used to stratify patients at risk for GIF & "i", who may require more intensive post-transplant surveillance and avoidance of drug minimization/withdrawal protocols. Finally urinary CCL2: Cr may help identify patients for novel interventional trials targeting GIF & "i".

**FR-PO1035**

**Protocol Biopsy at 0, 14 and 90 Days to Identify Renal Allograft Dysfunction – Single Center Study** Muhammad Rafiqul Alam, Md. Morshed Ul Islam, Asia Khanam, Syed fazlul Islam. *Dept of Nephrology, Bangabandhu Sheikh Mujib Medical Univ, Dhaka, Bangladesh.*

**Background:** To identify histological changes of renal allograft by protocol biopsy for detection of early graft dysfunction.

**Methods:** Thirty five kidney transplant recipients were included in this study over a period of two years in the Department of Nephrology, BSMMU, Dhaka. All received cyclosporine based immunosuppressive treatment. Serum creatinine was done daily for first 14 days and then weekly for three months. Cyclosporine blood ($C_2$) level was done 7th and 14th POD and monthly for three months. Protocol transplant kidney biopsy was done at day 0, day 14 and day 90. For histopathology haemotoxilyne and eosin (H&E) and periodic acid Schiff (PAS) stain was done.

**Results:** Over 35 recipients 23(66%) show normal graft function and 12(34%) showed early graft dysfunction. Among 35 biopsies, per operative 26 showed normal histology (no sclerotic glomeruli), 6 showed 10% sclerotic glomeruli and 3 showed 16% sclerotic glomeruli. Protocol biopsy at 14th post operative day showed 57.1% (n=20) normal histology 14.3% (n=5) had clinical rejection (elevated serum creatinine along with histological features of rejections). 14.3% (n=5) had sub clinical rejection (normal serum creatinine with histological features of rejections), cyclosporine toxicity 5.7% (n=2), ATN 5.7% (n=2) and 2.9% (n=1) had recurrent GN. Rejection episodes are further categorized by Banff-97 classification. Banff grade I (20%) (n=1) grade II (60%) (n=3) and grade III (20%) (n=1) were found in clinical rejection group and Banff grade I (80%) (n=4) and grade II (20%) (n=1) in sub clinical rejection group.

**Conclusions:** Adequate histological evaluation is helpful for detection of clinical and subclinical rejection. So routine allograft biopsy should be practiced in different transplant center of Bangladesh.

**FR-PO1036**

**Complications Associated with Renal Graft Biopsy in Transplant Patients** Claudia Grisel Tapia Canelas, Rosa Del Carmen Zometa Estrada, Carlos Jimenez, Rafael Selgas. *Nephrology, Hospital Universitario La Paz, Madrid, Spain.*

**Background:** Percutaneous biopsy of renal grafts is a diagnostic method for the assessment, management and clinical monitoring of renal transplant, so it is necessary to know its complications. There are few data in the literature regarding complications from biopsies in renal grafts.

**Methods:** We performed a retrospective observational study, including data from 256 patients who underwent renal graft biopsies from January 2000 to September 2012. Major complications were defined as: anemia requiring blood transfusion, intraparenchymal arteriovenous fistula or arterial bleeding requiring embolization, nephrectomy, other surgery and exitus. And as minor complications: anemia without blood transfusion, intraparenchymal arteriovenous fistula without embolization, hematomas or perirenal collections, hematuria and fever. Kidney biopsies were performed with ultrasound guidance and automatic devices.

**Results:** We performed 390 kidney graft biopsies. Total complications in renal graft biopsies were 49, which corresponds to an overall rate of 12.6%, of which 22 were major complications (5.6%) and 27 minor complications (6.9%). Among the 22 biopsies with major complications, 12 presented anemia which required blood transfusions (3.1%), 6 embolizations, of which one was for arterial bleeding and 5 were for intrarenal fistulas (1.5%), 1 trasplantectomy secondary to important bleeding for laceration of the renal lower pole post-graft biopsy (0.3%), 1 required surgery for perirenal hematoma evacuation (0.3%) and two finally died (0.5 %). Among the other 27 biopsies with minor complications, 12 were perirenal collections (3.1%), 9 were arteriovenous fistula not requiring embolization (2.3%), 3 haematuria (0.8%), 2 presented anemia who did not require blood transfusion (0.5%) and 1 episode of fever (0.3%). The success rate of tissue obtained for histopathological study was 97.9%.

**Conclusions:** The rate of complications related to renal graft biopsy observed in our center are similar to those described for native kidneys, and therefore we believe it remains a safe and effective technique, and an important diagnostic tool in transplant patients.

**FR-PO1037**

**Banff Lesion Scores in Renal Allogarft Biopsies Correlate with Graft Function and Survival** Ramandeep S. Banga,[1] David J. Taber,[1] Sally Self,[1] Stuart M. Flechner,[2] Nicole A. Pilch,[1] Emilio D. Poggio,[2] Kenneth Chavin,[1] Prabhakar Baliga,[1] Titte Srinivas.[1] *[1]MUSC; [2]Cleveland Clinic.*

**Background:** The renal allograft biopsy is pivotal in establishing causes of graft dysfunction. Banff lesion scores (BLS) may allow the capture of the balance between acute and chronic pathologic lesions in the allograft and help refine both diganosis and prognosis. However, data on the correlation between individual Banff lesion scores with clinical outcomes are sparse.

**Methods:** We examined the relationship between BLS and graft outcomes in a retrospective review of 84 biopsies (all for cause, 1st biopsies) performed between 2008 & '11 The primary outcome measures were serum creatinine absolute values and changes from baseline, at biopsy and up to 2 years post-biopsy. Secondary outcomes were graft loss or death. We examined the association between BLS and outcomes in multivariate models.

**Results:** Of all the BLS, only "cg" and "t" scores were independently associated with creatinine trajectory, even after controlling for baseline clinical and demographic data in a multiple linear regression model (Table 1). The "ci" score was the only BLS independently

associate with graft loss in a multivariate logistic regression model (Table 2). Patients with moderate to severe t-scores had an improvement in renal function that was transient compared to those with mild t-scores (Figure 1).

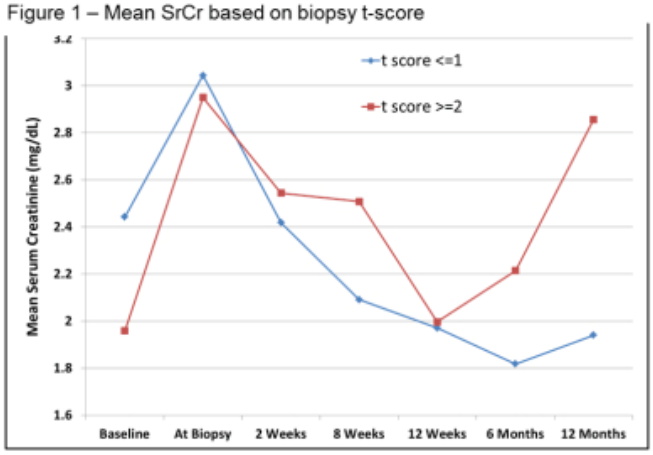
**Table 1 - Linear Regression Model for Proportion of Final SrCr to Baseline SrCr**

| Covariate | Reference Value | Beta Coefficient | p-Value |
|---|---|---|---|
| CG score | 0 | 0.231 | 0.033 |
| T score | 0 | 0.320 | 0.006 |
| Male Gender | Female | 0.248 | 0.021 |
| Age at Transplant | 15 | -0.212 | 0.053 |
| Pulse Dose Steroids for Biopsy Treatment | No Treatment | -0.187 | 0.102 |

**Table 2 - Binary Logistic Regression for Graft Loss**

| Covariate | Reference Value | Hazard-Ratio | p-Value |
|---|---|---|---|
| CI score | 0 | 2.65 | 0.020 |
| Male Gender | Female | 2.89 | 0.069 |
| African-American | Non-AA | 2.21 | 0.192 |
| Age at Transplant | 15 | 0.96 | 0.061 |
| Pulse Dose Steroids for Biopsy Treatment | No Treatment | 0.43 | 0.206 |
| SrCr at time of biopsy | 1.0 | 1.29 | 0.073 |

Figure 1 – Mean SrCr based on biopsy t-score



**Conclusions:** Biopsy derived indices provide valuable short and long-term prognostic information. The "t" score likely reflects reversible short term injury and the "cg" score likely informs short term creatinine trajectory. Post-biopsy creatinine improvement was not sustained with higher "t" scores. The "ci" score informs prognosis regarding long term graft survival. The balance between acute and chronic lesion scores determines the magnitude and sustainability of functional improvement after treatment of allograft rejection.

## FR-PO1038

**Revisiting the Natural History of IF/TA in Renal Transplantation Based on Protocol Graft Biopsies** Ken Sakai,[1] Tatsuru Matsukiyo,[1] Kiyoto Koibuchi,[1] Hiroki Hase,[3] Sonoo Mizuiri.[2] *[1]Nephrology, Toho Univ, Tokyo, Japan; [2]Nephrology, Harada Hospital, Hiroshima, Japan; [3]Nephrology, Toho Univ Ohashi Hospital, Tokyo, Japan.*

**Background:** The landmark study by Nankivell et al.in 2003, suggested two distinct phases of injury involved in IF/TA: an early tubulo-interstitial damage from allograft rejection and, beyond 1 year, an interstitial injury interpreted as secondary CsA toxicity. According to the improvement of current immunosuppression, we re-examined the natural history of IF/TA in this era.

**Methods:** 1hour, 1year, 3year and 5year protocol biopsy was performed after kidney transplant (KTx) for all recipients in this institution. From 2000 to 2003, 56 recipients underwent protocol biopsies up to 5 years after KTx. They took protocol biopsy completely and analyzed in this retrospective study. Anti CD25 antibody was used as an initial immunosuppressant for all recipients. Biopsy tissue was evaluated by Banff classification 1997. Newly appearance of Ah (arteriolar hyalinosis) score was defined as CNI toxicity.

**Results:** In this group (21% for ABO incompatible KTx, 7% for secondary KTx, 26 cases using ciclosporin and other for tacrolimus, mean age 32.8±18.4yrs, donor 52.1±12.6yrs), Cv score remained constant (0.25±0.59, 0.22±0.48, 0.09±0.39, 0.16±0.25 at 1hour, 1y, 3y, 5y respectively=NS) and Ah also remained constant (0, 0.08±0.28, 0.31±0.54, 0.17±0.31 at 1hour, 1y, 3y, 5y respectively, P=NS), while Ci and Ct (IF/TA) increased significantly (Ci:0.1±0.2 to 0.86±0.8, p=0.007, Ct:0.125±0.3 to 0.95±0.61, p=0.005) during 5 years. Inflammation score (i and t) also elevated followed by IF/TA (i: 0.35±0.73 to 0.83±0.68, p=0.005, t: 0.45±0.74 to 0.76±0.81, p=NS) during 5 years. Serum creatinine (mg/dl) remained stable during 5 years (1.04±0.33 to 1.18±0.52, P=NS).

**Conclusions:** Contemporary use of CNI with CD25 antibody significantly stabilized CNI toxicity defined as newly appearance of Ah. Interstitial inflammation and tubulitis resulted in increasing IF/TA not caused by CNI toxicity in this era. Such graft damage have an identifiable cause that is not idiopathic IF/TA or CNI toxicity and that alloimmunity remains the most common mechanism.

## FR-PO1039

**Molecular Acute Kidney Injury Score in Deceased Donor Kidney Predicts Post-Transplant Function of Both Kidneys** Konrad S. Famulski,[1] Chatchai Kreepala,[2] Declan De freitas,[3] Philip F. Halloran.[1] *[1]Univ of Alberta, Edmonton, Canada; [2]Srinakarinwirot Univ, Nakornayok, Thailand; [3]Beaumont Hospital, Dublin, Ireland.*

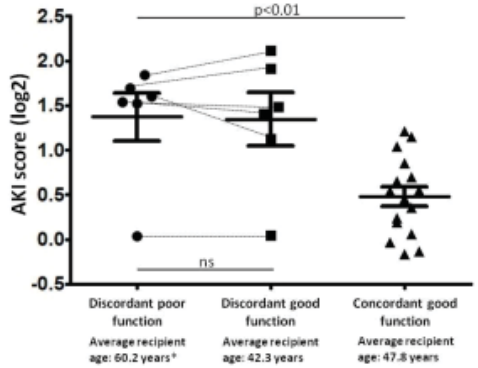
**Background:** Shortage of deceased donor (DD) kidneys for transplantation prompts clinicians to use more old and injured kidneys. Molecular acute kidney injury (AKI) score in DD kidneys can be measured by expression of injury-repair transcripts and at transplantation predicts impaired early function. We hypothesized that AKI score in each kidney predicts future function (Cr at day 7) of the mate kidney.

**Methods:** We analyzed microarray data, histology and clinical data of 15 kidney pairs from brain dead DD.

**Results:** The AKI score was highly similar within pairs r=0.95, while histology score (Remuzzi) was much more variable r=0.65. AKI score correlated with the future function of the opposite kidney,but histology did not.

| | Correlation with function | | | |
|---|---|---|---|---|
| Molecular assessment | same kidney | opposite kidney | Fold increase in DD vs LD | Correlation between pre and post-implant biopsies |
| CDH6 | 0.35 | 0.43 | 2.2 | 0.95 |
| OLFM4 | 0.40 | 0.44 | 3.4 | 0.75 |
| MEGF11 | 0.51 | 0.42 | 2.1 | 0.89 |
| OSMR | 0.42 | 0.37 | 2.7 | 0.79 |
| NNMT | 0.38 | 0.37 | 3.3 | 0.54 |
| AKI score | 0.51 | 0.47 | 2.7 | 0.92 |

AKI score reflected the effect of brain death, it was higher in DD compared to living donors (LD). In pairs with discordant outcomes - one recipient with poor, another with good function, AKI score was high in both kidneys.



Thus the discordant kidneys were more injured and actual function was influenced by other factors e.g. recipient age. AKI score was similar in pre- and 1h post implant biopsies, indicating that it is established before kidney removal.

**Conclusions:** Thus the molecular measurements in either kidney can be used in the future to predict function of both and may prove useful in organ utilization decisions.

## FR-PO1040

**Glomerular Abnormalities in Cirrhotic Patients: Immune Mediated?** Anjali Gupta, Aws Aljanabi, James M. Pullman, Paul Joseph Gaglio, Enver Akalin, Graciela De boccardo. *Montefiore Medical Center.*

**Background:** We previously demonstrated universal glomerular abnormalities in kidney biopsies after orthotopic liver transplantation (OLT). We hypothesize that these changes exist prior to OLT and may play a role in the development of renal failure after OLT. We investigate the mechanism of kidney disease in patients listed for OLT by microarrays.

**Methods:** The clinical and pathological data of 25 cirrhotic patients listed for OLT who underwent kidney biopsy was analyzed. Gene expression profile of biopsies (n=8) was studied by Affymetrix HuGene 1.0 ST expression assay and compared with pre implantation living donor biopsies (n=9).

**Results:** Etiology of liver disease was hepatitis C (72%) and alcoholic hepatitis (24 %). Mean MELD, serum creatinine, GFR and proteinuria were 17+ 6, 1.8 ±0.7 mg/dl, 42±13 ml/min and 0.85±0.7 gm/day, respectively. Low complement was seen in 70%. Glomerular abnormality was seen in 92% of the biopsies, most commonly increase in mesangial matrix (88%) and focal interstitial inflammation (88%). 5 patients had nodular glomerulosclerosis (3 had DM), 2 FSGS and 1 MPGN. Immunofluorescence staining showed mesangial, capillary wall or tubular basement-membrane deposition of IgM, IgG and complement deposition in 83% and IgA in 78% of the biopsies. Electron microscope showed effacement of podocytes (93%) and duplication (35%) and widening of glomerular basement membranes (GBM) (45%). Gene expression profiles by Gene Ontology revealed significant up-regulation of

genes implicated in immune response, including T-cell, leucocyte and platelet activation and differentiation. Pathogenesis-based transcripts revealed significantly increased expression of cytotoxic T-cell, macrophage, B-cell, natural killer cell, and endothelial cell associated transcripts, indicating an ongoing inflammatory immune response.

**Conclusions:** Our study demonstrates universal presence of glomerular abnormalities in biopsies of cirrhotic patients. Majority had increase in mesangial matrix, podocyte effacement, and widening and duplication of GBM. Increased gene expression profiles related to immune activity indicates immune-mediated mechanisms in development of kidney disease.

## FR-PO1041

**Increased Rejection-Associated Gene Transcripts in Biopsies of DSA+ Patients without Histopathologic Findings of Rejection** Nicole A. Hayde, Yi Bao, James M. Pullman, Michelle L. Lubetzky, Graciela De boccardo, Enver Akalin. *Montefiore/Einstein Transplant Center, Bronx, NY.*

**Background:** The presence of donor specific antibodies (DSA) without allograft injury questions whether accommodation or other preventative mechanisms exist or if this is a state of pre-rejection. A set of genes was shown to be upregulated in the blood of tolerant patients by microarrays. We investigated the gene expression of kidney and whole blood samples of DSA+ patients with antibody-mediated rejection (AMR) and without rejection, including the tolerance genes.

**Methods:** DSA were measured by Luminex. The biopsy and whole blood samples of 28 DSA+/AMR+, 14 DSA+/AMR- and 20 DSA negative patients with normal histopathology (control) were analyzed by Affymetrix HuGene 1.0 ST expression arrays.

**Results:** Both DSA+/AMR+ and DSA+/AMR- biopsies showed increased cytotoxic T (CAT), constitutive macrophage (CMAT), natural killer cell (NKAT), and endothelial cell associated (ENDAT) pathogenesis based transcripts, and donor specific antibody selective transcripts seen in AMR (DSAST) compared to DSA- biopsies.

However, there were no significant differences in the whole blood gene expression profiles of DSA+/AMR- and DSA- patients. DSA+/AMR+ patients had increased CAT, CMAT and interferon-γ and rejection induced transcripts (GRIT) in their blood. There was also no difference in expression of tolerance-associated genes in whole blood and biopsy samples of DSA+/AMR- compared to DSA-.

**Table 1: Pathogenesis Based Transcript Comparisons**

| | BIOPSY | | BLOOD | |
|---|---|---|---|---|
| PBT | DSA+/AMR+ to DSA- | DSA+/AMR- to DSA- | DSA+/AMR+ to DSA- | DSA+/AMR- to DSA- |
| GRIT | **0.004** | 0.05 | 0.05 | 0.22 |
| CAT | **0.001** | **0.03** | **0.007** | 0.17 |
| BAT | 0.05 | **0.03** | 0.38 | 0.11 |
| CMAT | **0.02** | **0.03** | **0.03** | 0.17 |
| NKAT | **0.03** | **0.02** | 0.23 | 0.48 |
| ENDAT | **0.03** | **0.04** | 0.45 | 0.45 |
| DSAST | **0.003** | **0.02** | 0.52 | 0.91 |

GRIT: IFN-Gamma and rejection induced transcripts, CAT: Cytotoxic T cell associated transcripts, BAT: B cell associated transcripts, CMAT: Quantitative constitutive macrophage-associated transcripts NKAT: Natural killer cell-associated transcripts ENDAT: Endothelial cell associated transcripts, DSAST: Transcripts differentially expressed between rejection-classified biopsies from DSA+ patients compared to DSA negative patients

**Table 2: Tolerance Genes**

| TLR5 | 0.16 | 0.12 | 0.18 | 0.17 |

Values showed are log2 fold change. * denotes adjusted p-value <0.05.
**TNFAIP3:** Tumor necrosis factor, alpha-induced protein 3, **BCL2:** B-cell CLL/lymphoma 2, nuclear gene encoding mitochondrial protein, transcript variant alpha, **BCL2L1:** BCL2-like 1, nuclear gene encoding mitochondrial protein, transcript variant 1, **CD79b:** Molecule, immunoglobulin-associated beta, transcript variant 1, **FCRL1:** Fc receptor-like 1, transcript variant 1, **HMOX1:** Heme oxygenase (decycling) 1, **HS3ST1:** Heparan sulfate (glucosamine) 3-O-sulfotransferase 1, **MS4A1:** Membrane-spanning 4-domains, subfamily A, member 1, transcript variant 1, **PNOC:** Prepronociceptin, **SH2D1BL:** SH2 domain containing 1B, **SLC8A1:** Solute carrier family 8 (sodium/calcium exchanger), member 1, transcript variant A, **STAP1:** Signal transducing adaptor family member 1, **TCL1A:** T-cell leukemia/lymphoma 1A, transcript variant 1, **TLR5:** Toll-like receptor 5

In contrast, TNFAIP3, BCL2 were upregulated in biopsy and blood samples of DSA+/AMR+ patients. CD79B, FCRL1, MS4A1 and SH2D1B were upregulated in DSA+/AMR+ biopsies.

**Conclusions:** DSA+ patients without rejection showed increased immune activity in their allografts but not in their blood indicating an ongoing local alloimmune response but not accommodation/ignorance.

## FR-PO1042

**Uncontrolled Complement after Renal Transplantation and C5b9 Deposits on Graft Predict Graft Outcome in Adult Renal Transplant with C3 Glomerulopathy** Moglie Le Quintrec,[1] Marion Rabant,[2] Maria Chiara Marinozzi,[3] Frank Bridoux,[4] Michel Delahousse,[1] Christophe M. Legendre,[5] Veronique Fremeaux-bacchi.[6] *[1]Nephrology and Renal Transplantation, Hopital Foch, Suresnes, France; [2]Anatomopathologie, Hopital Necker, Paris, France; [3]Inserm UMR 872, Cordeliers Research Center, Paris, France; [4]Nephrology and Renal Transplantation, CHU de Poitiers, Poitiers, France; [5]Nephrology and Renal Transplantation, Necker Hospital, Paris, France; [6]Laboratoire d'Immunologie, Hôpital Européen Georges Pompidou, Paris, France.*

**Background:** C3 glomerulopathy (C3G) is a severe disease strongly associated with abnormal control of complement alternative pathway activation. Few data are available on recurrence risk and graft outcome.

**Methods:** We studied 47 patients with DDD (n=15), GNC3 (17) and MPGN type I (n=15) who received renal transplantation. Plasma C3 and sMAC were performed by Elisa, C3 and C5b9 staining by immunochemistry.

**Results:** Graft survival was 98% and 77% at one and five years respectively. 48% of patient (23/47) had a clinical graft recurrence biopsy proven; 60% (14/23) of them occurred in the first year after transplantation. The recurrence occurred in 33% (5/15), 47% (8/17) and 60% (9/15) of patients with DDD, GNC3 and MPGN type I respectively. At five years, 54% of graft lost was due to recurrence (n=6/11). Before transplantation, a low C3, positive C3 Nef were documented in 63 % of patients. After renal transplantation, a low C3, positive C3 Nef and high sMAC were present in 20% (7/34), 33%(11/33) and 37%(6/14) of patient respectively. Only 34%(7/17) of patients with low C3 before transplantation had a recurrence. At time of recurrence, 60%(11/18) of patients had a low C3 or/and high sMAC and 8% (2/24) if no reccurence occured . All patients who lost graft before 5 years due to recurrence had C3 low and/or sMAC high. All patients with recurrence had positive C3 staining, C5b9 staining (6/34) was positive only in lost graft due to early recurrence from patients who.

**Conclusions:** Uncontrolled pathways activation and C5b9 deposits were associated with severe recurrence and poor graft outcome.

## FR-PO1043

**Clinicopathological Correlation of Transplant-Associated Thrombotic Microangiopathy** Miriam Berry,[1] Victoria Bardsley,[2] Meryl Helen Griffiths,[2] Nicholas Torpey,[1] Verena Broecker.[2] *[1]Transplant Unit, Addenbrooke's Hospital, Cambridge, United Kingdom; [2]Dept of Histopathology, Addenbrooke's Hospital, Cambridge, United Kingdom.*

**Background:** Transplant associated thrombotic microangiopathy (TA-TMA) is found in 1% of renal transplant biopsies. Clinicopathological correlation is required to identify the cause. However there are often discrepancies between the histological, clinical and serological results at the time of diagnosis. This uncertainty has significant therapeutic implications.

**Methods:** We retrospectively re-evaluated 69 renal transplant biopsies from 16 patients with TA-TMA over 5 years, identified by a database search. Biopsies were graded according to Banff criteria. Clinical parameters were collected and correlated with histology.

**Results:** TA-TMA was diagnosed at median 0.6 months (range 1 week to 3 years) post transplant. Donor specific antibodies (DSA) were present in 50%.

Histological diagnoses were: rejection with a humoral component (microcirculation injury) (n=9); consistent with CNI toxicity (n=6): pure cellular rejection (Banff II) (n=1). Overall the prevalence of endothelialitis (v-lesion) was high (n=9). 2/6 patients with probable CNI toxicity had DSA at the time of TMA. In 6/9 cases showing rejection with a humoral component, TMA preceded the presence of microcirculation injury. This prodrome of microthrombi with subsequent development of rejection could not be attributed to reduced immunosuppression.

4 patients lost their graft and 1 died with a functioning graft. There was no significant reduction in eGFR from baseline (45 vs 47 ml/min) in the remaining grafts.

**Conclusions:** We identified a complex overlap between microcirculation injury, DSA and endothelialitis. The absence of microcirculation injury at the time of biopsy did not exclude a humoral process as the potential cause of TMA. The high prevalence of endothelialitis suggests an endothelial insult which may be triggered by DSA in some cases, however TMA may arise in the absence of humoral pathology. The outcome was bimodal, ie graft loss or recovery to baseline renal function. TA-TMA is a histological finding rather than a diagnosis; it may be an early sign of humoral pathology and should prompt serological investigations.

## FR-PO1044

**Web-Based Virtual Microscopy to Validate Histologic Classification Schemes of Renal Diseases: Are We There Yet?** A. Gasim,[1] Harsharan Kaur Singh,[1] Surya V. Seshan,[2] Jennifer Melton,[1] Volker Nickeleit.[1] *[1]Div of Nephropathology, Univ of North Carolina, Chapel Hill, NC; [2]Pathology, Weill Cornell Medical Center, New York, NY.*

**Background:** Attempts are made to stage polyomavirus nephropathy (PVN) (A: early disease; B: florid; C: sclerosed). During the validation phase of the proposed PVN classification scheme, web-based recruitment of pathologists world-wide and virtual slide microscopy was used for interobserver reproducibility studies. How good are the results?

**Methods:** A) Web-based study on 19 PVN biopsies. 110 pathologists from 6 continents participated and used virtual microscopy to stage PVN. Four web-based mandatory study modules were designed: 1) introduction to PVN, 2) demographic data collection, 3) training module on PVN staging, 4) test set with 19 PVN cases. B) Conventional approach with exchange of glass slides on 190 cases: PVN disease staging on conventional glass slides from 9 centers was conducted. Outside results were compared to central review UNC data that served as "gold standard diagnoses" in both study groups.

**Results:** Evaluation of conventional glass slides versus web-based virtual microscopy generated similar scoring results. Only 2 significant differences were noted estimating mild degrees of intra renal polyomavirus load levels and mild degrees (ci-1) of Banff fibrosis scores. These differences do not appear to play a major role in a validation study. In the web-based study group (A) results did not significantly differ among demographic groups or according to the level of expertise in pathology.

| Diagnosis | Web-Based Study with Virtual Slides (Study Group A) Agreement Rate: Outside Pathologist versus UNC Central Review | Conventional Study with Glass Slides (Study Group B) Agreement Rate: Outside Pathologist versus UNC Central Review | p-value |
|---|---|---|---|
| PVN Stage A | 84% | 94% | ns |
| PVN Stage B | 63% | 63% | ns |
| PVN Stage C | 80% | 71% | ns |
| **PV Intrarenal Load Level** | | | |
| 1 | 79% | 84% | ns |
| 2 | 59% | 73% | **p=0.01** |
| 3 | 70% | 66% | ns |
| **BANFF Fibrosis ci-score** | | | |
| 0 | 55% | 48% | ns |
| 1 | 43% | 58% | **p=0.04** |
| 2 | 53% | 62% | ns |
| 3 | 89% | 45% | na |

**Conclusions:** Web-based virtual microscopy is well suited for validation studies of histologic classification systems of renal diseases. Yes, we are there, and things will likely improve further!

## FR-PO1045

### miRNA and mRNA Regulation in Donor and Follow-Up Kidney Biopsies Diagnosed with Acute Rejection and Acute Renal Failure

Julia Wilflingseder,[1,2] Alexander Kainz,[1,2] Judith Sunzenauer,[1,2] Eva Toronyi,[3] Robert M. Langer,[3] Rainer Oberbauer.[1,2] *[1]Nephrology, Medical Univ of Vienna, Austria; [2]Nephrology, KH der Elisabethinen, Linz, Austria; [3]Transplantation and Surgery, Semmelweis Univ Budapest, Hungary.*

**Background:** We previously showed that miRNAs are involved in the regulation of post-transplant events such as biopsy confirmed acute rejection (BCAR) and acute renal transplant failure (ARF). However, only few studies examined the concomitant regulation of miRNAs and mRNAs in the same biopsy samples.

**Methods:** We prospectively collected zero-hour and follow-up kidney biopsies of renal allograft recipients. Of these 242 donor kidney biopsies, we identified ten biopsy sample pairs of each clinical condition (1) BCAR (2) ARF, and (3) management biopsies without pathology within ten days after TX and subjected to miRNA and mRNA genome wide analyses. ARF was defined as acute tubular necrosis. An integrative bioinformatics approach was chosen to combine differentially regulated miRNA and miRNA targets before and after transplantation. miRNA target prediction was verified by correlation analysis and experimental data. Target genes were further evaluated based on their functional annotation.

**Results:** Preliminary results show that allografts with acute renal failure exhibit a distinct molecular pattern compare to acute rejection and management biopsies on the mRNA and miRNA levels. T-cell and B-cell activation (p=0.002 and p=0.03, respectively) in the zero-hour biopsies, Integrin signalling pathway (p=0.008) in the follow-up biopsies and p53 pathway (p=0.02) and Ras pathway (p=0.04) in the development are significantly enriched pathways associated with ARF. A detailed analysis of the miRNAs and target genes will be presented at the meeting.

**Conclusions:** Based on these data we identified miRNAs as major molecular regulators of post-transplant events. miRNA-182 is mainly involved in the development of ARF and miRNA-155 was identified as a classifier of BCAR. These two miRNAs will be further investigated as potential therapeutic and/or prophylactic targets towards the prevention of ARF and BCAR.

*Funding:* Government Support - Non-U.S.

## FR-PO1046

### Spleen Tyrosine Kinase (SYK) Expression in Renal Allograft Rejection

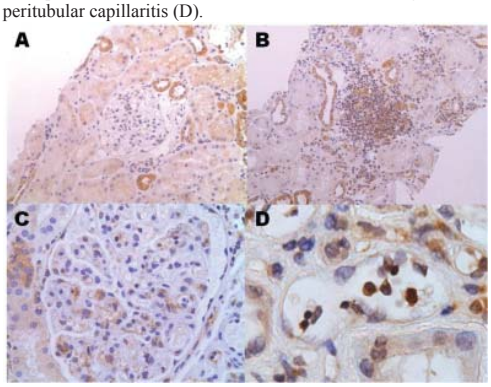
Stephen Paul McAdoo, Gurjeet Bhangal, Jennifer Smith, David Taube, Charles D. Pusey, Frederick W.K. Tam, H. Terence Cook. *Imperial College London.*

**Background:** Rejection is a leading cause of renal allograft failure. Spleen tyrosine kinase (SYK) has in important role in BCR and FcR immunoreceptor signalling, and may therefore represent a treatment target in rejection. In work previously reported by our group, SYK inhibition has shown efficacy in a rat model of renal allograft rejection. SYK expression, however, in experimental and clinical renal tissue has not been characterised.

**Methods:** We conducted immunohistochemical analysis for total and phosphorylated SYK in experimental renal allograft rejection (Brown Norway to Lewis rats) and in clinical renal allograft biopsies: normal surveillance biopsies, n=3; acute cellular rejection (ACR), 4; antibody-mediated rejection (AMR), 12.

**Results: Experimental Samples**: Normal rat tissue was positive for total SYK in distal tubules only. Rejecting kidney tissue showed positive staining for both total SYK and phophorylated SYK, localised to cellular infiltrates in the interstitium.

**Clinical Samples:** Staining for total SYK in normal surveillance biopsies (Fig A) was positive in distal tubules only, similar to that seen in normal rat tissue. Tubular infiltrates in ACR were positive for T-SYK in 4/4 patients (B). In AMR (total n=12), total SYK positive cells were identified in 5/10 cases with glomerulitis (C) and 7/10 cases of peritubular capillaritis (D).



**Conclusions:** We believe this is the first report that SYK is expressed in various types of renal allograft rejection in patients, and localises to pathological lesions (tubulitis, glomerulitis, peritubular capillaritis). SYK is also expressed and activated (i.e. phosphorylated) in a rat model of renal allograft rejection that responds to SYK inhibitor treatment. We therefore believe that clinical studies targeting SYK in allograft rejection are warranted.

## FR-PO1047

### Decreased Expression of Mitochondrial Energy Generation and Antioxidant Response Genes in One Year Protocol Biopsies Is Associated with Poor Allograft Outcome

Diana Zepeda-Orozco,[1] Richard H. Scheuermann.[2] *[1]Pediatrics, Univ of Iowa Carver College of Medicine, Iowa City, IA; [2]Informatics, J. Craig Venter Institude, San Diego, CA.*

**Background:** Progression of chronic histological damage associated with subclinical inflammation are factors associated with poor allograft survival. The role of non-immunological pathways in the activation of this chronic injury-repair response have not been assessed.

**Methods:** To identify non-immunological genes and pathways that might influence long-term allograft outcome, we analyzed a public microarray dataset that included low risk kidney transplant recipients without rejection episodes who underwent a 1-year protocol biopsy. Three patient/sample groups were defined based on their histological findings: normal histology (n=25), interstitial fibrosis alone (IF; n=24), and interstitial fibrosis with inflammation (IF+I; n=16). IF+I was associated with lower death-censored graft survival and lower renal function compared to the IF and normal histology groups. We performed data normalization, data filtering, and statistical testing with ANOVA on the gene expression microarray data to discover differentially-expressed genes across the sample groups.

**Results:** Clustering and gene ontology (GO) enrichment analysis identified significant co-clustering of genes with similar functional properties. The analysis showed downregulation of *mitochondrion* (p=6.52E-17) and mitochondrial part (p=1.75E-11) genes in the IF+I group compared to the other two groups, including genes involved in *generation of precursor metabolites and energy*, and *response to oxidative stress*, as the most significant biological processes.

**Conclusions:** Allografts with histological evidence of inflammation and interstitial fibrosis are associated with lower graft survival and poor renal function. Through gene expression analysis, we have found evidence that inadequate mitochondria function, and an inappropriate antioxidant response may be important non-immune factors involved in chronic allograft injury that could serve as novel targets for therapeutic intervention.

## FR-PO1048

### IgA Nephropathy Recurrence after Transplantation: Altered IgA Glycosylation and Its CD89 Receptor as Biomarkers of the Disease and Effectiveness of Steroid Pulse Therapy for Recurrence

Laureline Berthelot,[1] Thomas Robert,[2] Thierry Tabary,[2] Vincent Vuiblet,[2] Moustapha Dramé,[2] Philippe Rieu,[2] Renato C. Monteiro,[1] Fatouma Toure,[2] Olivier Toupance.[2] *[1]INSERM U699, INSERM, Paris, France; [2]CHU Reims, CHU, Reims, France.*

**Background:** IgA nephropathy (IgAN) is a leading cause of end-stage renal disease and kidney transplantation. However, recurrence of the disease is frequent after transplantation. We investigated the efficacy of steroid treatment and predictive value of three markers for IgAN recurrence: galactose deficient (Gd) IgA1, IgG anti-IgA autoantibodies and IgA-soluble (s) CD89 complexes.

**Methods:** Kidney transplanted recipients treated with IV pulse steroids therapy for IgAN recurrence (R group, n=11) were compared to those without recurrence (NR group, n=13). Gd-IgA1 and IgA complexes containing IgG and sCD89 levels were determined in serum collected before and after transplantation.

**Results:** Proteinuria was markedly reduced by steroids treatment in R group ($p< 0.001$). Before transplantation, serum levels of Gd-IgA1 were significantly higher in R group compared to NR group or healthy controls ($p< 0.01$). Serum IgA-IgG complexes were also elevated in R group ($p< 0.001$). Both groups had enhanced values of IgA-sCD89 complexes compared to healthy controls, but values were lower in R group compared to NR ($p<0.01$). The receiver-operating-characteristic (ROC) curve showed predictive power of each biomarker for IgAN recurrence ($p=0.003$; $p=0.0002$; $p=0.001$). In the R group, diseaserecurrence was associated with decreased serum Gd-IgA1 and IgA-IgG complexes while IgA-sCD89 complexes were significantly increased. Treatment with steroids restored levels of all 3 markers back to pre-transplantation level.

**Conclusions:** Pulse IV steroid therapy was an efficient and safe option for treatment of IgAN recurrence. Gd-IgA1 and IgA complexes containing IgG or sCD89 were found as biomarkers of the disease recurrence.

## FR-PO1049

**Prognosis of Transplant Glomerulopathy with Complete versus Incomplete Criteria for Chronic Active Antibody-Mediated Rejection** Julie Lesage, Real Noel, Jean-guy Lachance, Isabelle Lapointe, Eric Wagner, Olivier Desy, Isabelle Houde, Sacha A. De Serres. *Renal Div, CHUQ L'Hotel-Dieu de Quebec, Univ Laval, Quebec, Canada.*

**Background:** Transplant glomerulopathy (TG) is currently included in the Banff classification as a criterion in the diagnosis of chronic active antibody-mediated rejection (CAABMR), with C4d, antidonor antibodies (DSA) and other lesions of chronic tissue injury. However, TG often present without complete criteria for CAABMR, making the pathological results difficult to translate clinically. Here we studied the prognosis of a large cohort of TG patients in relation with C4d and DSA.

**Methods:** 106 consecutive recipients with TG diagnosed between 1998 and 2012 were compared to controls matched 1:1 on age, donor type and year of transplant from a single-center cohort. We studied the association between a composite endpoint of death-censored graft failure or doubling of serum creatinine (Scr) and the presence of TG with incomplete or complete criteria for CAABMR. We used Cox models adjusted for SCr, recipient gender and donor characteristics.

**Results:** Median time post transplant was 108mo. Compared to controls, patients with TG had a higher Scr ($1.3\pm0.1$ vs. $2.1\pm0.1$) and a higher HLA-DR mismatch ($0.5\pm0.1$ vs. $0.7\pm0.1$; both $p<0.01$). 61 patients with TG (58%) vs. 6 controls (6%) reached the endpoint ($p<0.001$). The proportion of patients with isolated TG (DSA-C4d-), TG but incomplete CAABMR (DSA- and/or C4d-), and CAABMR (DSA+C4d+) were 59, 33 and 8% respectively, whereas their adjusted HR for the endpoint were 7.0, 9.7, and 18.5 (all $p<0.01$). TG score (cg) was also associated with the endpoint (HR 1.8, 95% CI 1.4-3.4, $p=0.01$; adjusted for the above and C4d, DSA, i and t scores). A higher proportion of patients with TG had their maintenance immunosuppression reduced or withdrawn (13 vs. 30%, $p<0.01$), mostly CNIs (8 vs. 20%, $p=0.01$).

**Conclusions:** The prognosis of TG with incomplete criteria for CAABMR, which represents a majority of cases, is dismal, however it is not considered in the current Banff nomenclature. These results are particularly important, because they provide a rationale to include these patients in coming trials studying ABMR.

## FR-PO1050

**Clinical Phenotypes of Chronic Antibody-Mediated Rejection after Kidney Transplantation** Sunhwa Lee, Ran-hui Cha, Jung Pyo Lee, Dong Ki Kim, Yon Su Kim, Hajeong Lee. *Dept of Internal Medicine, Seoul National Univ Hospital.*

**Background:** Chronic antibody-mediated rejection (CAMR) is a significant challenge for long-term graft survival over the last decade. The prognosis of CAMR is poor, but the clinical and immunological phenotype of CAMR remains unclear.

**Methods:** From 2005 to 2012, 915 kidney transplantations were performed at Seoul National University Hospital. Among them, twenty-six (2.8%) patients were diagnosed as CAMR according to Banff '05 criteria. We reviewed the clinical and immunological findings at the time of transplantation and diagnosis of CAMR. In addition, the responses to the anti-rejection therapy were classified according to the change of serum creatinine level, donor specific antibody (DSA) titer, and proteinuria amount.

**Results:** The increases of serum creatinine, DSA titer, and proteinuria were the main indications for the allograft biopsy. The median time to the development of CAMR after kidney transplantation was $8.8 \pm 5.8$ years. The mean number of human leukocyte antigen (HLA) mismatch was $2.5 \pm 1.5$. Twenty-six patients showed a progressive decline of estimated GFR of 1.6 ml/min/1.73m$^2$ over 6 months using simple regression analysis. Nine patients were non-responders, 6 patients were stable disease, and 8 patients were responders, respectively. Seven patients had reached to end stage renal disease in 24 months after biopsy. The time interval from transplantation to CAMR diagnosis was longer in patients who showed poor response. In addition, histological analysis revealed that the grade of interstitial fibrosis and tubular atrophy (IFTA) ($P = 0.04$) and vascular fibrointimal thickening score ($P = 0.03$) were lower in recipients who showed better response to anti-rejection therapy. The MFI of DSA did not predict the effect of anti-rejection therapy.

**Conclusions:** This retrospective observation revealed the basic characteristics of CAMR after kidney transplantation although it was a single center experience. For the better long-term graft survival, prognostic indicators for the specific treatment and surrogate markers for disease progression should be developed in near future utilizing multi-center registration.

## FR-PO1051

**Incidence and Clinical Course of Antibody-Mediated Rejection in Kidney Allografts Associated with Non-HLA-Antibodies Targeting Angiotensin Type 1 Receptor** Gaurav Gupta,[1] Julie Ann T. Linatoc,[1] David Donghyung Lee,[2] Marc P. Posner,[2] Qing Ren,[1] Anne L. King.[1] *[1]Nephrology, Virginia Commonwealth Univ, Richmond, VA; [2]Transplant Surgery, Virginia Commonwealth Univ, Richmond, VA.*

**Background:** Non-human leukocyte antigen (HLA) non-complement-fixing autoantibodies reacting to endothelial artery-specific antigens like the angiotensin II type 1 receptor (AT1R-AA)have been linked to antibody-mediated rejection (AbMR) and malignant hypertension in kidney allograft recipients. There is very little data about the incidence, clinical course or therapy of rejection associated with the AT1R-AA.

**Methods:** AbMR was diagnosed based upon the Banff criteria including peritubular capillaritis, glomerulitis, arteritis, and/or positive c4d staining. Eight consecutive KTx patients with 9 episodes of AbMR and no detectible anti-HLA alloantibodies at the time of rejection were retrospectively screened for the presence of AT1R-AA. A commercial ELISA assay was used for detection of antibodies. A result of >17U/ml was considered positive based upon prior published data.

**Results:** Four of nine (44%) episodes of AbMR were associated with a positive AT1R-AA. None of the patients had malignant HTN. All four episodes were treated with pulse steroids and six sessions of plasmapheresis and low-dose CMVIg (150mg/kg/session). All patients had a response to therapy with a decline in mean serum creatinine from 3.6mg/dL to 1.6mg/dL at a median follow-up of 3 months. Table 1 shows the trend in AT1R-AA titer.

| Patient Number | AT1R-AA titer at diagnosis (U/ml) | AT1R-AA titer at end of therapy (U/ml) |
|---|---|---|
| 1 | 30 | 10 |
| 2 | 75 | 14 |
| 3 (1st episode) | 28 | 18 |
| 3 (2nd episode) | 24 | 9 |

Patient 3 who had recurrent AbMR had a positive AT1-R-AA titer at the end of therapy for his first episode. He was started on losartan after his second episode and has now remained rejection free.

**Conclusions:** Kidney transplant patients with biopsy findings concerning for AbMR and undetectible HLA alloantibodies should be screened for anti-AT1R-AA. An excellent response with plasmapheresis was noted though AbMR recurred in one patient. The addition of angiotensin receptor blocker therapy might be helpful to prevent further episodes.

## FR-PO1052

**Peripheral Blood Mononuclear Cells (PBMCs) Phosphoproteome Analysis to Investigate Antibody-Mediated Chronic Rejection (AMCR)** Maria Teresa Rocchetti,[2] G. Stallone,[2] Paola Pontrelli,[1] F. Rascio,[1] Marco Fiorentino,[1] Anna Zito,[1] Giuseppe Castellano,[2] Loreto Gesualdo,[1] G. Grandaliano.[2] *[1]Dept Emergency and Organ Transplantation, Univ of Bari, Bari, Italy; [2]Dept of Medical and Surgical Sciences, Univ of Foggia, Foggia, Italy.*

**Background:** AMCR represents one of the main causes of kidney transplant failure. Specific markers for an early diagnosis of AMCR are currently missing. In the attempt to identify potential diagnostic markers and to elucidate the signaling pathways involved in AMCR pathogenesis, we analyzed the PBMCs phosphoproteome profile to identify cellular signaling networks differentially activated in AMCR patients.

**Methods:** PBMCs were harvested from 6 biopsy-proven AMCR according to Banff 2009 consensus, 7 renal transplant recipients with normal graft function and histology (tx-CTRL), and 6 healthy subjects (CTRL). Phosphoproteins were isolated by precipitation with lanthanum ions, separated by 2-D gel electrophoresis and stained by Sypro Red. Image Master Software was used to standardize the PBMCs phosphoproteome map and to list the differentially expressed protein spots among the 3 groups. MALDI-TOF-MS/MS analysis was used to identify the phosphoproteins.

**Results:** 2-D gel electrophoresis of PBMC detected $554\pm68$ (mean±SD) protein spots (CV=26%) differentially expressed in CTRL, $418\pm119$ protein spots (CV=35%) in AMCR and $475\pm75$ protein spots (CV=20%) in tx-CTRL. We recognized, by densitometric analysis, a protein signature of 10 protein spots, corresponding to 4 proteins, which discriminated AMCR patients from CTRL and tx-CTRL and 4 protein spots whose density was increased in all transplant recipients compared to CTRL. Finally, 5 protein spots, corresponding to 2 proteins, distinguished tx-CTRL from AMCR and CTRL.

**Conclusions:** Our preliminary results suggest that PBMC phosphoproteome might help to distinguish biopsy-proven AMCR patients from healthy subjects and stable renal transplant recipients. In addition, the differentially phosphorylated protein spots may indicate potential therapeutic targets for AMCR.

*Funding:* Government Support - Non-U.S.

## FR-PO1053

**Medical Complication after Acute Humoral Rejection Treatment** Araminta Guichard, Lluvia A. Marino-vazquez, Cristhian R. Arias-delgadillo, Norma O. Uribe-uribe, Josefina Alberú, Luis E. Morales-Buenrostro. *Nephrology, Pathology, and Transplantation, National Institute of Medical Sciences and Nutrition SZ, Mexico City, DF, Mexico.*

**Background:** Treatment for acute humoral rejection (AHR) includes removal of circulating HLA-antibodies (HLAabs) by plasmapheresis (PP), neutralization of HLAabs with IVIG, rituximab (RTX), and Bortezomib (Borte) intended to decrease HLAabs-producing plasma cells derived from B-cells, as well as use of rATG looking to control the

cellular component (or interaction between T- and B-cells). Some of them potentially could increased the complication rates. This study compare the rate of complications between different treatment protocols.

**Methods:** Between May/08 and Apr/13, we prospectively recruited all 60 patients who had AHR. Each event was handled as a separate treatment with a total of 97 treatments cycles in 60 patients. The histological description was made according to modified Banff 97 classification. DS-HLAabs were determined by Luminex single antigen bead assay (One Lambda).

**Results:** We included 60 KTR. Mean age 33.2±11.9; male gender 70%; first transplant 85%; living donor 76.7%; induction therapy 56.7%; maintenance triple therapy with CI 89.9%. The most used treatment schemes were PP+IVIG+RTX(36.7%), PP+IVIG+RTX+BORTE(35%), PF+IVIG+BORTE(6.7%), others (21.6%). A 41.7% received more than one treatment (2-7). A 95% of the patients used PP, and 55% received Borte. There were not differences in graft survival when Borte, RTX, or IVIG were added to PP. Also, receive more than one treatment cycle, or the time after KT did not showed difference. There was 30 complication in 26 treatments. The most frequent complication were infections (11 events), hematologyc (10 events), neuropathy (4 events), metabolic (2 events), and other (3 events). There was no relationship between type of treatment and kind of complications.

**Conclusions:** Most of the complications were like we expected. Only few of them were severe. Intensification of treatment after AHR is safe.

*Funding:* Government Support - Non-U.S.

## FR-PO1054

**ABO Antibody Removal of Plasmapheresis (PP) with Intravenous Immunoglobulin (IVIG) before ABO-Incompatible (ABOI) Kidney Transplantation: Single Center Experience**

Jeongmyung Ahn,[1] Dong Ryeol Lee,[1] Byung Chang Kim.[2] *[1]Medicine, Maryknoll General Hospital, Busan Catholic Univ, Busan, Republic of Korea; [2]Laboratory, Medicine, Maryknoll General Hospital, Busan Catholic Univ, Busan, Republic of Korea.*

**Background:** ABOI kidney transplantation is an inevitable option to overcome serious organ shortage. There are few data on success rates of ABO antibody removal or relating to patients in who antibody removal fails. The purpose of this study was to evaluate the likelihood of achieving transplantation depending on ABO antibody titers.

**Methods:** 55 patients were enrolled between 2007-2012. We perform ABOI kidney transplantation using anti-CD20 antibody, tacrolimus and PP with IVIG. The median antibody titer was 1:64 (Range 8-4096). Transplantation was preceded when the ABO titer reached ≤ 1:8. To determine the likelihood of achieving transplantation, the number of PP required to proceed transplantation and baseline ABO titer were analyzed.

**Results:** All 55 patients(100%) successfully completed transplantation after 5.75±4.3 PP with IVIG. Three patients did not reach target ABO titer and their achieved ABO titers at the time of transplantation were 1:16. (Initial ABO titers were 1:256 in one patient, 1:2048 in one patient, and 1:1024 in one patient). The median follow-up duration was 18.1 month (Range 0.9-71.8). The mean age was 45.8±9.9 year and 65.6% were female. The median ABO titer was 2 (Range 1-16) at the time of transplantation, 4(Range 1-64) at 1month posttransplantation and 4 (Range 4-128) at the last follow-up, respectively. The number of PP to reach an ABO titer of ≤ 1:8 was significantly correlated with baseline ABO IgG titers ($r^2$=0.829, P < 0.001).

**Conclusions:** All 55 patients successfully preformed ABOI kidney transplantation without failure to achieve transplantation. Three patients even failed to reach target titer at the time of transplantation, however, all of them were successfully transplanted. Though optimal ABO titer at the time of transplantation remains debatable, we carefully need to tailor our protocol with target ABO titer of greater than or equal to1:16 at the time of transplantation to expand kidney donor pool.

## FR-PO1055

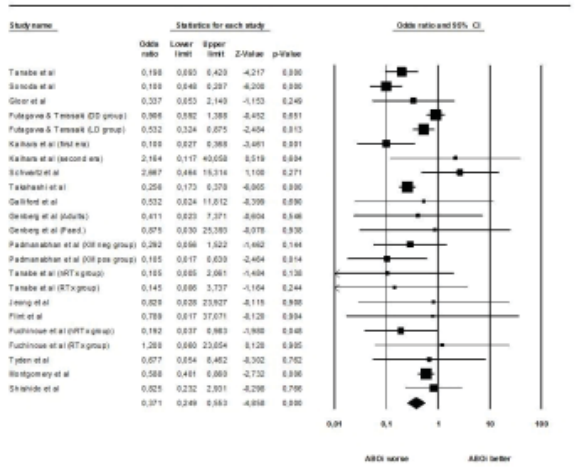
**Graft Survival after ABO Incompatible Renal Transplantation–A Metaanalysis of Available Evidence**

Bernhard M.W. Schmidt,[1] Anette Melk,[2] Daniel Kayser.[1] *[1]Dept of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Dept of Pediatric Nephrology, Hannover Medical School, Hannover, Germany.*

**Background:** ABO incompatible (ABOi) renal transplantation (rTx) is increasingly used to overcome the organ shortage. Smaller studies evaluating the outcome of ABOi rTx showed no difference in outcome compared to controls, but may have been underpowered. Our aim was to provide a broader data pool by meta-analyzing the available studies.

**Methods:** We identified studies by searching Medline and the Cochrane library. Additional studies were identified by review of cited literature. Primary efficacy endpoint was probability of 1-year-graft survival. Random effects model was used. Subgroup analysis was performed for studies using rituximab or not, meta-regression analysis was used to evaluate the impact of continuous variables.

**Results:**



From 536 articles 17 reports including 23 patient groups with ABOi rTx could be used for data retrieval. Analysis of all 23 patient groups revealed significantly worse 1-year-graft survival in recipients of an ABOi graft (OR 0.37, 95% CI 0.25-0.56, p<0.001) than in controls. The studies showed relevant heterogeneity ($I^2$=62.3, Q test p<0.001). In studies using rituximab 1-year-graft survival was also worse in ABOi rTx (OR 0.34, 95% CI 0.16-0.77, p=0.01). Within these studies we detected no heterogeneity ($I^2$=0, Q test p=.89). However, we detected signs of publication bias suggesting that studies showing worse outcome of ABOi rTx have not been published.

**Conclusions:** Metaanalysis of the available evidence showed worse 1-year-graft survival for recipients of an ABOi graft. This information should be acknowledged when informing patients about an ABOi rTx. However, we should also acknowledge that in real life the right comparator is not ABO compatible living related donorship (as used in most studies) but waiting for a deceased donation for several years.

## FR-PO1056

**Immunochemical Characterizaion of Light Chains in Posttransplant IgA Nephropathy**

Yasuhiro Otsuka, Asami Takeda, Shinichi Sueta, Keiji Horike, Daijo Inaguma, Yoshihiko Watarai, Kunio Morozumi. *Kidney Center, Nagoya Daini Red Cross Hospital, Nagoya, Aichi, Japan.*

**Background:** IgA nephropathy (IgAN) is a clinically and histologically diverse glomerular disease characterized by mesangial IgA deposits. The nature of the light chains in immunofluorescence (IF) studies in IgAN remains obscure, although there are a few reports that lambda light chains were found predominantly in the mesangial deposits in IgAN. In particular in posttransplant IgAN, some cases display poor prognosis, some cases can be diagnosed only by IgA deposits in the mesangial area, and the nature of the light chains is unknown.

**Methods:** In order to examine the immunochemical characterization of light chains in posttransplant IgAN, direct IF studies using polyclonal rabbit anti-human kappa and lambda light chains were performed from consecutive 30 native renal biopsies of IgAN (native IgAN) and 18 cases of posttransplant IgAN, excluding Henoch-Schönlein Purpura.

**Results:** The age at the biopsy of native IgAN and posttransplant IgAN were 28.0±21.3 and 35.9±12.2, respectively. Posttransplant IgAN were diagnosed from 3 weeks to 15 years after transplantation. In native IgAN, both kappa and lambda light chains were detected in 28 of 30 cases, and 11 of 28 were strongly positive for lambda light chains. 2 of 30 native IgAN were negative for kappa and lambda light chains. In posttransplant IgAN, both kappa and lambda light chains were detected in 11 of 18 cases, and 8 of 11 were strongly positive for lambda light chains. 7 of 18 posttransplant IgAN were negative for kappa and lambda light chains. The percentage of both kappa and lambda light chains negative cases were significantly higher in posttransplant IgAN (p=0.0091, Fisher's exact test).

**Conclusions:** The nature of the light chains in posttransplant IgAN is not the same as the one in native IgAN. Our results suggest that the mechanism responsible for the development of IgAN is different from native IgAN and posttransplant IgAN.

## FR-PO1057

**Decreased Total Interstitial Inflammation with Higher Mycophenolate Mofetil Dose after Kidney Transplantation**

Karlo K. Mihovilovic,[1] Petar Senjug,[2] Bojana Maksimovic,[1] Danica Galessic Ljubanovic,[2] Renata Zunec,[3] Biserka Palfi,[3] Mladen Knotek.[1] *[1]Clinical Hospital Merkur, Zagreb, Croatia; [2]Clinical Hospital Dubrava, Zagreb, Croatia; [3]Clinical Hospital Zagreb, Zagreb, Croatia.*

**Background:** We have recently found that higher average mycophenolate mofetil (MMF) dose during first posttransplant year was associated with decreased progression of interstitial fibrosis and tubular atrophy during first posttransplant year in kidney transplant recipients. In the present study we sought to evaluate effect of MMF dose on total interstitial inflammationscore at one year.

**Methods:** This is a single-center retrospective study in which 67 kidney, or kidney-pancreas recipients with 12 month protocol biopsy were included.Patients with recurrence of glomerulonephritis and with BKV nephropathy were excluded from the analysis. Immunosuppression consisted of anti-IL2 induction, with tacrolimus or cyclosporine and MMF ± steroid maintenance.During 2007-2010 MMF was dosed in our center according to C0 monitoring, which led to its dose dispersion (1000-4000 mg/day). Total interstitial inflammation (ti score) and interstitial fibrosis (ci score) were determined according to Banff classification. Creatinine clearence (eClcr) was estimated by the Cockroft-Gault formula.

**Results:** Recipients, were 44.75 ± 12.34 y/o, 65 percent of them were male. There were 20 living donor transplantations. At 12 months postttransplant mean MMF dose was 2205 ± 627 mg/d, eClcr 62.1 ± 16.4 ml/min, ci score 0.87 ± 0.78 and ti score 0.72 ± 0.88. Average MMF dose during first posttransplant year was 2238 ± 571 mg. There was positive correlation between 12 months ci and ti score (r=0.716, p<0.001). Both, ci (r=-0.401, p<0.001) and ti score (r=-0.319, p=0.01) were negatively correlated with MMF dose at 12 months.Similarly, there was a negative correlation of average MMF dose over first posttransplant year with ci (r=-0.337, p<0.01) and ti score (r=-0.250, p<0.05). MPA concentration (C0) at either 12 months, or 1 year average, as well as respective tacrolimus concentrations did not correlate with 12 month ci or ct scores.

**Conclusions:** Higher MMF dose during first year posttransplant may be associated with better kidney allograft histology and less inflammation.

## FR-PO1058

**Basliximab versus Low Doses of Thymoglobulin as Induction Therapies in Kidney Transplant Recipients** Daniel Perez-Vega,[1] Benjamin Gomez-Navarro,[1] Enrique Rojas-Campos.[2] *[1]Dept of Nephrology and Organ Transplant Unit, Hospital de Especialidades, CMNO, IMSS, Guadalajara, Jalisco, Mexico; [2]Medical Research Unit in Renal Diseases, Hospital de Especialidades, CMNO, IMSS, Guadalajara, Jalisco, Mexico.*

**Background:** Induction therapies such as Basiliximab (BSX) and Thymoglobulin (rATG) are associated with lower incidence of acute rejection in kidney transplant recipients (KR) but there is still conflicting data regarding the outcomes of these agents specially comparing low dose schemes of rATG versus an Interleukin 2 receptor antagonist.

**Methods:** The aim of the study is to show the incidence of acute rejection (AR), adverse effects and the graft survival at 12 months with the use of two different induction therapies in a cohort of 225 KR that were prospectively analyzedin 2 groups according to the induction agent: group 1 with 125 KR that received BSX ( 20mg in day 0 and day 4), group 2 with 100 KR that received rATG in a low dose scheme ( 0.6 to 1.2mg/kg in days 0 through 3). The primary end point was the incidence of biopsy proven rejection and graft survival. The secondary end points were renal function, adverse effects and infections.

**Results:** In the BSX group we found a significantly higher incidence of biopsy proven rejection at 12 months after transplant ( 23 % vs 10% in group of rATG) . No difference was found between groups in graft survival, adverse effects, infections and global survival as seen in Table 1.

**Conclusions:** In our population induction therapy with rATG at low doses was associated with a lower incidence of acute rejection compared with BSX in kidney transplant recipients but with a similar incidence of infections, graft loss and global survival.

**Table 1. 12 month outcomes according to induction agent.**

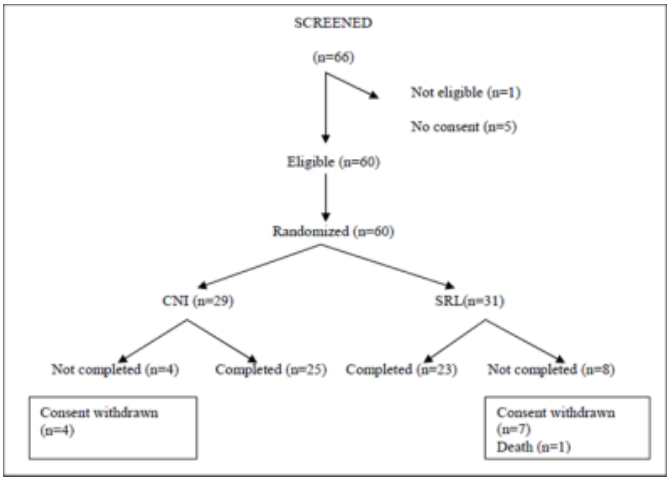
| Variable | All (n=225) | Basiliximab (n=125) | Thymoglobulin ( n=100) |
|---|---|---|---|
| Biopsy proven rejection n (%) | 39 (17) | 29 (23)** | 10 (10)** |
| Antibody treated rejection n (%) | 22 (10) | 16 (13) | 6(6) |
| Infections n (%) | 127 (56) | 72(57.6) | 55 ( 55) |
| Urinary tract infections n ( %) | 109 (48) | 56(45) | 43( 43) |
| Cytomegalovirus n (%) | 6( 2.5) | 4(3) | 2(2) |
| BK Virus n (%) | 3(1.3) | 2(1.5) | 1(1) |
| Death n (%) | 11 (5) | 4 (3) | 7 (7) |
| Graft loss n (%) | 9(4) | 5 (4) | 4(4) |
| Serum Creatinine (mg/dl) | 1.35±0.55 | 1.41±0.43 | 1.27±0.32 |
| ** p=<0.05 | | | |

## FR-PO1059

**Deferred Pre-Emptive Switch from Calcineurin Inhibitor to Sirolimus Leads to Improvement in GFR and Expansion of T Regulatory Cell Population** Dinesh Bansal,[1] Vivekanand Jha,[1] Vinay Sakhuja,[1] Mukut Minz,[2] Ashok Kumar Yadav.[1] *[1]Nephrology, PGIMER, Chandigarh, India; [2]Transplant Surgery, PGIMER, Chandigarh, India.*

**Background:** Measures to prevent chronic calcineurin inhibitor (CNI) toxicity have included limiting exposure by switching to sirolimus (SRL). SRL may favorably influence T regulatory cell (Treg) population. This randomized controlled trial compares the effect of switching from CNI to SRL on GFR and Treg frequency.

**Methods:** In this prospective open label randomized trial, primary living donor kidney transplant recipients on CNI-based immunosuppression were randomized to continue CNI or switched to SRL 2 months after surgery; 29 were randomized to receive CNI and 31 to SRL.



All patients received MMF and steroids. The main outcome parameter was eGFR at 180 days by CKD EPI equation. Treg population was estimated by flow cytometry.

**Results:** Baseline characteristics in the two groups were similar. Forty-eight patients completed the trial. At six months, patients in SRL group had significantly higher eGFR as compared to CNI group (96.00 ± 13.75 vs 81.80 ± 22.38mL/min, p = 0.012). Patients on SRL had a mean 13 mL/min gain of eGFR at the end of six months. Patients in SRL group showed significant increase in Treg population at 30 days, which persisted till day 180. There was no difference in the adverse events in terms of number of acute rejection episodes, death, infections, proteinuria, lipid profile, blood pressure control and hematological parameters between the two groups. Four patients taking SRL developed enthesitis. No patient left the study or switched treatment because of adverse event.

**Conclusions:** A deferred pre-emptive switch over from CNI to SRL safely improves renal function and Treg population at 6 months in living donor kidney transplant recipients.

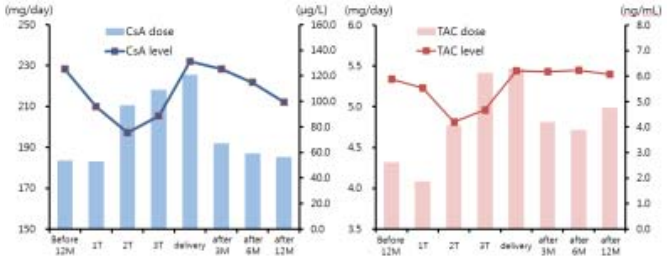
## FR-PO1060

**Tacrolimus also Needs to Be Increased during Pregnancy for Transplant Recipients** Hyosang Kim,[1] Jong Cheol Jeong,[2] Jaeseok Yang,[2] Wonseok Yang,[1] Curie Ahn,[2] Duck Jong Han,[3] Su-Kil Park.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea; [2]Transplantation Center, Seoul National Univ Hospital, Seoul, Republic of Korea; [3]Dept of Surgery, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea.*

**Background:** To investigate the effects of pregnancy to renal function of women with allograft kidney and the relationship between immunosuppressant dose and blood drug level during pregnancy and postpartum.

**Methods:** The study population consisted of 75 women with 88 deliveries after kidney transplantation at Asan Medical Center and Seoul National University Hospital from 1991 to 2012.

**Results:** The mean age at the time of transplantation and delivery were 26.7±4.2 and 31.7±3.6 years old, respectively. Significant serum creatinine elevation, defined as more than 0.5 mg/dL, was found in 8 (9.1%) deliveries. In other 80 (90.9%) deliveries which maintained relatively stable creatinine levels, mean serum creatinine was slightly reduced by 0.14 mg/dL on average during gestation and returned to pre-pregnant level after delivery. As for calcineurin inhibitor (CNI), tacrolimus was used in 28 (31.8%) deliveries and cyclosporine in other cases. Neither gestational period and body weight at birth was different in both CNI groups, and the changing pattern of serum creatinine during pregnancy was similar to each other. Figure shows blood CNI levels and their doses at each time point. Other immunosuppressant doses, azathioprine and steroid, were not changed during pregnancy.



**Conclusions:** In most women with allograft kidney, renal function was slightly improved during pregnancy and returned to previous level after delivery. To maintain therapeutic blood level, about 20~25% dose elevation of tacrolimus and cyclosporine should be considered.

**FR-PO1061**

**Intensified Dosing of Mycophenolate in African American Renal Transplant Recipients Does Not Reduce Rejection or Graft Loss**
Jillian Leigh Descourouez,[1] David Hager,[1] Glen E. Leverson,[2] Arjang Djamali,[2] Luis A. Fernandez.[2] *[1]Pharmacy, Univ of Wisconsin Hospital and Clinics, Madison, WI; [2]Surgery, Univ of Wisconsin Hospital and Clinics, Madison, WI.*

**Background:** Intensified mycophenolate dosing strategies have been proposed in African American (AA) renal transplant recipients to reduce rates of acute rejection, graft loss and to improve survival. This study evaluated the efficacy of intensified dosing of mycophenolate in a cohort of AA renal transplant recipients.

**Methods:** Adult AA renal allograft recipients (n=247) transplanted between 1/1/2002 - 12/31/2011 were divided as follows; group A (n=128) had a dose reduction in mycophenolate mofetil (MMF) to <3 g/day or mycophenolate sodium (MPS) to <2160 mg/day within 3 months post-transplant; group B (n=119) remained on ≥MMF 3 g/day or ≥MPS 2160 mg/day at 3 months post-transplant. The primary outcome was a composite of suspected rejection or treatment failure. Secondary endpoints included patient (PS) and graft survival (GS); death censored graft survival; graft function as measured by estimated glomerular filtration rate (eGFR) at 1 month, 6 months, 1, 3 and 5 years; and overall infection.

**Results:** Baseline characteristics did not vary between groups except the number of primary renal allografts was greater in group B (88.2% vs. 76.6%, p=0.03). A MMF or MPS dose reduction by 3 months post-transplant occurred in 51.8% of patients (n=128). No difference was observed for the primary end point (group A: n=59, group B: n=51, p=0.38). PS and death-censored GS at 1, 3 and 5 years were not different (97, 88, and 82% PS, and 94, 85 and 75% GS respectively for group A, and 100, 92.7 and 91% PS and 95, 76.8 and 71% GS for group B). eGFR did not differ at 1 month, 6 months, 1, 3, or 5 years (p=0.43, 0.70, 0.98, 1.00, and 1.00 eGFR). Rates of rejection or infection at 1, 3 and 5 years were not significantly different between groups (p=0.86 and p=0.24).

**Conclusions:** African American renal transplant recipients remaining on intensified dosing of mycophenolate at 3 months post-transplant did not have improved efficacy or an increased risk of infectious complications. These results do not support the use of MMF > 2000 mg/day or MPS >1440 mg/day.

**FR-PO1062**

**Effect of Basiliximab Induction Therapy in Living Donor Renal Transplantation**
Flávia Oliveira, Irene L. Noronha. *Nephrology, Univ of Sao Paulo, Brazil.*

**Background:** The beneficial effects of induction therapy with basiliximab in kidney transplantation with deceased donors has been extensively confirmed, but limited data are available for transplantation with living donors. The aim of this study was to analyze the impact of basiliximab in patients with HLA-haploidentical living donor kidney transplantation compared with no induction.

**Methods:** Primary kidney transplantation (n=74) receiving calcineurin inhibitor+mycophenolate+steroids were divided into 2 groups: basiliximab (n=34) and no induction (n=40). The primary endpoint was the occurrence of biopsy proven acute rejection (BPAR) at 1 year post-transplantation (post-Tx). Secondary endpoints included patient and graft survival at the 1st and 5th year, renal function and adverse events at 1 year pos-Tx.

**Results:** The incidence of BPAR was significantly lower in the basiliximab group (2 cases Banff II) compared with the no induction group (4 cases Banff I, 3 cases Banff II, and 1 antibody-mediated). The incidence of CMV infection and cancer was not diferent between the groups. The results are shown in table 1.

| | Basiliximab | No Induction |
|---|---|---|
| **Receptor's age** | 34.8±13.4 | 39.3±14.5 |
| **Gender (male)** | 19/34 **(55.9%)** | 25/40 **(62.5%)** |
| **Race (caucasian)** | 24/34 **(70.6%)** | 29/40 **(72.5%)** |
| **Time on dialysis** (months) | 16 (10.2-33.5) | 16 (9-24.7) |
| **Donor's age** | 43.3±10 | 42.6±11.3 |
| **BPAR 1 year** | 2/33 **(6.1%)** | 9/37 **(24.3%)*** |
| **Time to BPAR** (days) | 39±35.3 | 24±45.7 |
| **Patient survival** | | |
| 1 year | 97% | 94.6% |
| 5 years | 94.1% | 92.5% |
| **Graft survival** | | |
| 1 year | 94.1% | 87.5% |
| 5 years | 82.4% | 82.5% |
| **Serum creatinine (mg/dL)** | 1.5±0.6 | 1.9±0.7* |
| 6 months | 1.4±0.4 | 1.5±0.6 |
| 12 months | 1.4±0.5 | 1.4±0.5 |
| **CMV infection** | 6/32 **(18.8%)** | 9/36 **(25%)** |
| **Cancer** | 1/32 **(3.1%)** | 2/35 **(5.7%)** |

*p<0,05.

**Conclusions:** Induction therapy with basiliximab in living donor renal transplantation was associated with lower rate of BPAR, without increasing adverse effects.

**FR-PO1063**

**Predictors of Diabetes after Kidney Transplant**
Maria P. Martinez Cantarin,[1] Scott W. Keith,[2] Bonita E. Falkner.[1] *[1]Medicine-Nephrology, Thomas Jefferson Univ Hospital, Philadelphia, PA; [2]Pharmacology, Thomas Jefferson Univ, Philadelphia, PA.*

**Background:** New Onset Diabetes After Kidney Transplantation (NODAT) is a highly prevalent complication after solid organ transplantation and is associated with worse transplant outcomes including graft loss and patient death. The aim of this study was to determine if an inflammatory phenotype is associated with development of diabetes post-transplantation.

**Methods:** End stage kidney disease participants that did not have diabetes were recruited from Thomas Jefferson University Transplant program before kidney transplantation. Participant's plasma was obtained pre-kidney transplantation and three to six months post-transplantation. Inflammatory and anti-inflammatory cytokines including IL-8, IL-6, TNF alpha, CRP, MCP-1, total adiponectin and high molecular weight (HMW) adiponectin were assayed by ELISA. Participants were followed prospectively for 1 year and monitored for development of NODAT. Unadjusted comparisons of the distributions of variables between study groups were made by the Kruskal-Wallis test or the Fisher's exact test. Logistic regression was used to determine a model of the risk of NODAT.

**Results:** Of the 32 participants enrolled in the study, 11 developed NODAT using ADA criteria. Participants that develop NODAT had the same median age, BMI and proportion of male/females than participants that did not develop NODAT. Transplant participants that develop NODAT had lower total adiponectin, lower HMW to total adiponectin ratio and higher TNF alpha levels pre-transplant. After transplant, inflammatory cytokines and adiponectin decreased in both groups but transplant patients that developed NODAT maintained higher IL-6, IL-8 and CRP and lower HMW to adiponectin ratio. The odds of NODAT were significantly increased by almost 5-fold for each half-unit increase in log TNF-$\alpha$ (OR = 4.90, p = 0.04) pretransplant after adjusting for age in years (OR = 1.10, p = 0.07).

**Conclusions:** Our data suggest that a phenotype of increased inflammation with lower adiponectin levels pre-transplant could be associated with the development of diabetes after kidney transplant and that TNF alpha may be a predictor of NODAT.

**Low Vitamin D and Adverse Allograft Outcomes in Kidney Transplant Recipients**
Yoshitsugu Obi,[1] Takayuki Hamano,[2] Naotsugu Ichimaru,[3] Kodo Tomida,[4] Naohiko Fujii,[5] Isao Matsui,[1] Hiromi Rakugi,[1] Shiro Takahara,[3] Yoshitaka Isaka,[1] Yoshiharu Tsubakihara.[2] *[1]Dept of Geriatric Medicine & Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Dept of Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [3]Dept of Advanced Technology for Transplantation, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [4]Dept of Kidney Disease and Hypertension, Osaka General Medical Center, Osaka, Japan; [5]Dept of Internal Medicine, Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Hyogo, Japan.*

**Background:** Vitamin D, which is often deficient in kidney transplant (KTx) recipients, has potential immunomodulatory effects.

**Methods:** In a prospective cohort of 264 ambulatory KTx recipients, we measured the baseline 25-hydroxyvitamin D (25D) levels and examined its association with (i) annual decline in estimated glomerular filtration rate (eGFR); (ii) the composite event of a 50% increase in serum creatinine, end-stage renal disease, or death; and (iii) rejection episodes, with intravenous methylprednisolone ≥250 mg (IV-MP) as the index.

**Results:** Multivariate cubic spline analysis showed that the serum 25D levels had an almost linear relationship with annual eGFR decline. With vitamin D sufficiency (≥20 ng/mL) as the reference, inadequacy (≥12 and <20 ng/mL) and deficiency (<12 ng/mL) showed a significant dose-dependent associations with a higher risk of the composite event and IV-MP in the multivariate Cox regression analyses. These findings were confirmed in the propensity-matched cohort independent of 30 potential confounders. Further, time after KTx was a significant effect modifier for the association of serum 25D levels with annual eGFR change and IV-MP. Stratified analyses showed pronounced relationships in patients with <10 years since KTx (1.04 [95% CI, 0.26–1.83] mL/min/1.73 m$^2$ per 10 ng/mL of serum 25D levels in the analysis for annual eGFR decline), but no significant associations in patients with ≥10 years since KTx.

**Conclusions:** Low vitamin D predicts adverse allograft outcomes, and vitamin D supplementation early after KTx may improve patient outcome.

**FR-PO1065**

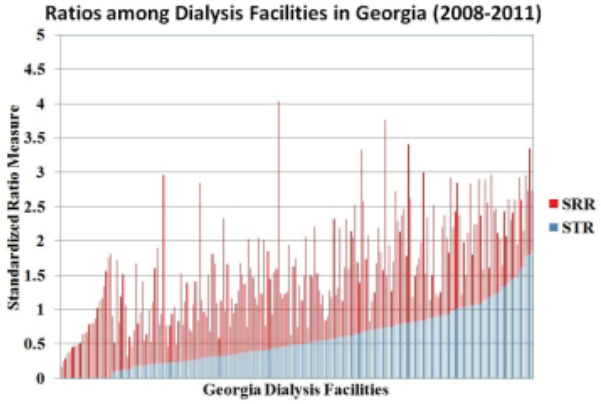
**Correlation of Kidney Transplant Referral with Transplant Rates at the Dialysis Facility Level**
Rachel E. Patzer,[1] M. Ahinee Amamoo,[2] Jenna Krisher,[2] Laura L. Mulloy,[3] Carlos F. Zayas,[4] Stephen O. Pastan.[1] *[1]Emory Transplant Center, Atlanta, GA; [2]Southeastern Kidney Council, Raleigh, NC; [3]Georgia Regents, Augusta, GA; [4]Piedmont Transplant Institute, Atlanta, GA.*

**Background:** Variability in dialysis facility-level kidney transplant (KTx) rates have been reported, but little is known about whether KTx referral rates vary by facilities and the extent to which referral rates are correlated with transplant rates.

**Methods:** Through the Southeastern KTx Coalition of End Stage Renal Disease Network 6, we collected data on all patient referrals to the 3 adult Ktx centers in Georgia (GA) from 2008-2011 and calculated crude referral rates and standardized referral ratios (SRR) -- the number of observed divided by the number of expected KTx referrals -- for each GA dialysis facility using a 2-stage Cox model. Pearson correlation coefficients (r) were calculated to examine correlations between referral and transplant rates, and the SRR and the standardized transplant ratio (STR).

**Results:** 276 dialysis facilities referred 7,180 ESRD patients for transplant in GA from 2008-2011. The median age was 52 years (IQR: 41, 61), 56.6% were male, and 68.5% were African American. The median annual KTx referral rate at the dialysis facility level was 16.6% (IQR: 9.7%, 22.2%) over 4 years. We found a weak correlation between the SRR and STR (r=0.16, p=0.0175).

**Figure. Standardized Referral Ratios and Standardized Transplant Ratios among Dialysis Facilities in Georgia (2008-2011)**



There was a moderate correlation between crude referral and transplant rates (r = 0.25, p<0.0001) that was higher among facilities with 25+ patients (r=0.33, p<0.0001).

**Conclusions:** Crude referral rates and SRR are correlated with KTx rates. Quality improvement interventions targeting facilities with lower than expected KTx referrals may improve patient access to KTx. SRR may be used to help launch a surveillance system throughout ESRD Network 6 to regularly measure KTx referral.

## FR-PO1066

**Renin Gene Mutation Causing Anemia and Kidney Injury in Childhood**

Faris Q. Hashim,[1] Anthony J. Bleyer,[2] Stanislav Kmoch,[3] Richard E. Neiberger.[1]
*[1]Pediatric Nephrology, Univ of Florida, Gainesville, FL; [2]Internal Medicine-Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; [3]Institute of Inherited Metabolic Disorders, Charles Univ, Prague, Czech Republic.*

**Background:** *REN* mutations produce rare but treatable conditions. There have been only five reported cases of mutations in the *REN* gene encoding renin causing chronic kidney disease (CKD) [1, 2]. Here we report a new family with this condition.

**Methods:** A 5 year old girl presented for evaluation of a hemoglobin of 8.8 g/d and a serum creatinine (Cr) level of 0.5 mg/dl (eGFR 86 ml/min/1.73m$^2$). The patient's mother had undergone a kidney biopsy showing medullary cystic kidney disease. On physical examination, blood pressure was 87/36, height 101 cm (10$^{th}$ percentile) and weight 14.3 kg (3rd percentile). Her examination was unremarkable. Urinalysis was normal. The serum uric acid (SUA) was 9.2 mg/dl (normal for age <6 mg/dl) with a 24 h urate excretion of 125 mg/day (normal <175mg/day) and fractional urate excretion 6.5 %(normal 18±5 %). Serum K was mildly elevated 5.1 meq/l. SUA increased to 11 mg/dl despite strict diet control. A renal ultrasound showed normal size kidneys. A mutational analysis of the *REN* gene revealed an L16R mutation. The patient was started on allopurinol 5 mg/kg bid which decreased her UAC to 7.4 mg/dl. The mother developed acute kidney injury at 17 years after running in a race. A kidney biopsy revealed medullary cystic kidney disease. She had minimal proteinuria and a SUA concentration of 11 mg/dl. Her eGFR was 38ml/min (Cr 2 mg/dl) at age 32 years.

**Conclusions:** This child presented with a classic case of a REN mutation, anemia, mild hyperkalemia, mild hypotension, and CKD. The acute kidney injury that occurred in her mother has also been noted to occur in patients with this condition. Recognition of REN Gene Mutation allows prompt intervention to treat anemia, hyperkalemia, hyperuricemia, and avoid acute kidney injury.

## FR-PO1067

**Implications of an Unusual Diagnosis: Uromodulin-Associated Kidney Disease**

Jonathan A. Bolanos,[1] Anthony J. Bleyer,[2] Christina M. Yuan,[1] John Stephen Thurlow.[1] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Wake Forest Univ School of Medicine, Winston Salem, NC.*

**Background:** Uromodulin-Associated Kidney Disease (UAKD), synonymous with medullary cystic kidney disease type 2 and familial juvenile hyperuricemic nephropathy, is a rare autosomal dominant interstitial kidney disease caused by mutations in the *UMOD* gene encoding uromodulin (Tam-Horsfall protein). These mutations result in defective assembly and subsequent accumulation of mutated uromodulin in tubular cells, leading to cell atrophy and death.

**Methods:** A 35 y/o white male presented for transplant evaluation. He had suffered from slowly progressive chronic kidney disease (CKD) for over a decade and had a 4 year history of recurrent gout. His father and paternal uncle had gout in their 30s, followed years later by ESRD attributed to glomerulonephritis. His paternal grandfather died in his 30s from an uncertain cause. Urinalysis was bland with no proteinuria or hematuria, and renal imaging was unremarkable. Mutational analysis of exons 4 and 5 of the *UMOD* gene (Athena Diagnostics) by PCR amplification identified a missense mutation resulting in a substitution of tyrosine for cysteine at codon 148, a common mutation associated with UAKD. Due to this finding, family members were contacted, and three living family members have since been diagnosed and others are undergoing evaluation.

**Conclusions:** The diagnosis of UAKD requires a careful family history in patients with a bland urine sediment, gout, and slowly progressive kidney disease. Correct diagnosis of an individual often leads to diagnosis for many family members. As in the current case, *UMOD* analysis can then be performed in potential living-related kidney donors to improve safety and quality of donation. Genetic counseling, gout treatment, and CKD management, including renal transplant evaluation, are the cornerstones of therapy for UAKD. *The views expressed are those of the authors and do not necessarily reflect the official policy or position of the Department of the Army, the Department of the Navy, the Department of Defense, nor the US Government.*

## FR-PO1068

**Tri-Allelic Inheritance of NPHS1 Gene in Infantile-Onset Steroid-Resistant Nephrotic Syndrome**

Yusuke Kumagai,[1] Hiroaki Ueda,[1] Koichi Nakanishi,[2] Norishige Yoshikawa,[2] Ryota Kurayama,[3] Kunimasa Yan,[3] Akira Ashida,[4] Daisuke Yamamoto,[5] Michio Nagata,[6] Rika Fujimaru.[1] *[1]Pediatrics, Osaka City General Hospital, Osaka, Japan; [2]Pediatrics, Wakayama Medical Univ, Wakayama, Japan; [3]Pediatrics, Kyorin Univ School of Medicine, Tokyo, Japan; [4]Pediatrics, Osaka Medical College, Osaka, Japan; [5]Biomedical Computation Center, Osaka Medical College, Osaka, Japan; [6]Kidney and Vascular Pathology, Graduate School of Comprehensive Human Sciences, Univ of Tsukuba, Ibaraki, Japan.*

**Background:** Recently, NPHS1 mutations have been identified as a cause of steroid-resistant nephrotic syndrome (SRNS) in all age groups and milder courses of the diseases. We report a case of infantile-onset SRNS associated with a severe mutation and two mild variants, which resulted in the tri-allelic hit of the NPHS1 gene.

**Methods:** A girl was diagnosed with SRNS at 9 months of age. A renal biopsy showed glomerular hypertrophy and severe interstitial fibrosis without focal glomerulosclerosis. Electron microscopy revealed effacement and fusion of podocyte foot processes. In immunohistochemistry, the expression of nephrin protein had partially decreased, while podocin was found along the glomerular capillary wall. Genetic analysis of the NPHS1 gene revealed three different amino-acid changes. One was a novel stop codon (p.E189X), and the others (p.P206T and p.R800C) had previously been reported on either missense variants or polymorphisms. No mutation of NPHS2 was detected. Mutation screening of non-consanguineous healthy parents revealed that the E189X and R800C were paternal origin and that the P206T was maternal which was predicted to a disease-causing mutation. Based on our molecular model analysis, the R800C substitution also could be classified as a mild missense variant, probably leading to conformational changes in nephrin structure. After a year of follow-up, she had a mild clinical course because of the disappearance of edema but persistent proteinuria with administration of an angiotensin receptor blocker.

**Conclusions:** The tri-allelic inheritance of the *NPHS1* gene observed in the present case might be responsible for atypical and milder form of SRNS.

## FR-PO1069

**Very Early Onset of Alport Syndrome in a Two Year Old Lithuanian Boy with Additional Polymorphisms in Nephrin- and Podocin-Genes**

Jenny Kruegel,[1] Matthias Kettwig,[2] Hermann-Josef Groene,[3] Mato P. Nagel,[4] Hildegard F. Zappel,[2] Oliver Gross.[1] *[1]Nephrology & Rheumatology, Univ Medicine Goettingen, Goettingen, Germany; [2]Pediatrics, Univ Medicine Goettingen, Goettingen, Germany; [3]Cellular & Molecular Pathology, German Cancer Research Center, Heidelberg, Germany; [4]Nephrology & Metabolic Disorders, Molecular Diagnostics, Weißwasser, Germany.*

**Background:** Some patients with familial benign hematuria develop early onset of renal failure despite a "benign" heterozygous mutation in type IV collagen genes (COL4A3/4/5). According to our hypothesis, polymorphisms in other genes of the glomerular filtration barrier can aggravate the clinical course of glomerular diseases such as Alport syndrome.

**Methods:** A two year old boy with macrohematuria and 1.2 g/gCrea proteinuria was referred to our clinic for further evaluation. His non-consanguineous parents originate from Lithuania and had no history of renal diseases. Renal biopsy revealed ultrastructural changes typical for Alport syndrome. However, referred to the patient's age, an unusual severe splitting and thickening of the glomerular basement membrane (GBM) with prominent focal segmental glomerular sclerosis was found. Additional defects in podocyte-genes were suspected. The diagnosis of X-chromosomal Alport syndrome was confirmed by sequencing. Direct sequencing of Nphs1 (Nephrin) and Nphs2 (Podocin) resulted in additional Nphs1- and Nphs2-polymorphisms. Interestingly, the COL4A5 mutation and Nphs2 polymorphism were de novo in the boy, with a heterozygous Nphs1 polymorphism in the mother. Ramipril therapy was started and proteinuria gradually dropped within 12 months below 0.5g/gCrea.

**Conclusions:** In conclusion, Podocin-polymorphisms can aggravate heterozygous COL4 mutations – as described previously in patients with familial benign hematuria. In our patient, polymorphisms of Nephrin and Podocin might exacerbate Alport-pathogenesis. This points towards a possible synergistic role of genes coding for GBM- and slit diaphragm-proteins in the pathogenesis of glomerular kidney diseases. The podocyte-interaction between GBM and slit diaphragm is currently investigated by our group using a $COL4A3^{+/-}$// $Nphs2^{+/R140Q}$ mouse model.

## FR-PO1070

**Diagnostic Difficulty in Alport Syndrome** Jennifer H. Adam,[1] Katrina M. Wood,[1] John Andrew Sayer.[1,2] *[1]Dept of Renal Medicine, Freeman Hospital, Newcastle upon Tyne, Tyne and Wear, United Kingdom; [2]Institute of Genetic Medicine, Newcastle Univ, Newcastle upon Tyne, Tyne and Wear, United Kingdom.*

**Background:** Alport syndrome is an inherited disease that causes progressive glomerular damage, often in association with sensorineural hearing loss. The histological diagnosis of Alport syndrome can present a challenge as features on light microscopy can be non-specific and ultrastructural lesions may not be apparent until later in life.

**Methods: Family 1** A 26 year old man presented with hypertension, haematuria, proteinuria and sensorineural deafness. His renal biopsy revealed light microscopy features consistent with FSGS. Electron microscopy (EM) revealed pathognomonic splitting of the glomerular basement membrane suggesting Alport syndrome. His mother had undergone a renal transplant eleven years previously. A review of her native renal biopsy revealed mesangial proliferative changes on light microscopy. There were no glomeruli in EM or IMF specimens. These mesangial changes on light microscopy had, over time, been mistranslated into a label of MCGN. Genetic testing confirmed that both mother and son had a mutation in the *COL4A5* gene causing X-linked Alport syndrome. The proband developed progressive CKD. Had his mother's initial diagnosis been accurate, his renal biopsy could have been avoided. **Family 2** A 47 year old woman presented with haematuria, proteinuria and abnormal renal function. Her renal biopsy showed mild mesangial proliferative changes. EM of glomeruli was not available. She also had high frequency hearing loss and a family history of renal disease. Genetic analysis confirmed that the proband and two of her daughters with microscopic haematuria were heterozygous for a pathogenic mutation in *COL4A3* gene consistent with autosomal dominant Alport syndrome.

**Conclusions:** These cases demonstrate that a diagnosis of Alport syndrome can elude nephrologists in patients with non-specific histological changes on light microscopy, particularly when EM is not available. It also highlights the important role of molecular genetics in confirming a diagnosis of Alport syndrome. We stress the importance of eliciting a family history of renal and extra-renal disease in all patients.

## FR-PO1071

**Early Bilateral Nephrectomy as Rescue Therapy for Autosomal Recessive Polycystic Kidney Disease with Progressive Massive Nephromegaly in Early Infancy** Tamara Mallett, Emma O'Hagan, Karl McKeever. *Dept of Paediatric Nephrology, Royal Belfast Hospital for Sick Children, Belfast, Co Antrim, United Kingdom.*

**Background:** The management of neonatal Autosomal Recessive Polycystic Kidney Disease (ARPKD) complicated by severe pulmonary insufficiency presents complex clinical challenges. Where massive nephromegaly exists, early bilateral nephrectomy, supportive peritoneal dialysis (PD) and early aggressive nutrition can improve survival. Consensus is lacking on the optimal timing and indeed role of nephrectomy, with decision-making driven by the patient's clinical condition and expertise of centre. We report an infant with ARPKD requiring PD and survival at 9 months following early bilateral nephrectomy.

**Methods:** A male infant diagnosed antenatally with ARPKD and third trimester olioghydramnios, was born at term with pulmonary insufficiency requiring high-pressure ventilation. He had massive bilateral nephromegaly with renal insufficiency and hypertension. A PD catheter was inserted on day 15 and dialysis commenced in view of progressive renal impairment, oliguria and respiratory failure. Unilateral nephrectomy was performed at 8 weeks of age in view of progressive massive nephromegaly, high-frequency oscillatory ventilator-dependence and failure to tolerate enteral nutrition. Recovery was complicated by respiratory compromise secondary to increasing nephromegaly. Contralateral nephrectomy was performed 11 days later allowing withdrawal of ventilatory support and establishment of enteral nutrition and PD. The infant is now 9 months old on nocturnal PD, complicated by a solitary episode of bacterial peritonitis. He has no respiratory support and growth is optimised by nasogastric feeding. Development is moderately delayed and there is evidence of early hepatic involvement.

**Conclusions:** Early bilateral nephrectomy should be considered as a potential rescue therapy for infants with ARPKD where progressive massive nephromegaly results in ventilator-dependent pulmonary insufficiency and failure to establish enteral nutrition.

## FR-PO1072

**Longterm Survival in an Anephric Twin** James G. Atherton,[1] Sabahat Afshan,[1] Margaret Colleen Hastings,[1,2] Bettina H. Ault.[1] *[1]Pediatric Nephrology, Univ of Tennessee Health Science Center, Memphis, TN; [2]Nephrology, Univ of Tennessee Health Science Center, Memphis, TN.*

**Background:** Bilateral renal agenesis occurs in 1 in 4,000 neonates. Live births occur but mortality from pulmonary hypoplasia usually ensues soon after birth. In monoamniotic monochorionic twins, an "experiment of nature" may arise: a twin with normal kidneys provides amniotic fluid neccessary for lung development of a twin with renal agenesis. Heretofore such infants have survived no more than 2 months. We describe an infant who has survived past 1 year of life and is near transplant.

**Methods:** Monochorionic monoamniotic twins of gestational age 34.2 wks and prenatally known congenital abnormalities were born to a 31 year old G3P5 female. Twin A had bilateral renal agenesis, hemivertebrae, 2-vessel unbilical cord, ambiguous genitalia, and imperforate anus. Twin B had omphalocele, bladder exstrophy, patent ductus ateriosis, and ambiguous genitalia. Both twins had normal lungs at birth. Both were karyotype 46 XX with normal chromosomal microarray. Twin B died on day of life (DOL) 95 from respiratory failure. Twin A started peritoneal dialysis on DOL 13. She had bacterial peritonitis three times in her first 12 months. She had complications similar to other infants with end stage renal disease: hypertension, electrolyte abnormalities, anemia, and secondary hyperparathyroidism. Her development has been near normal: at 6 months old corrected age, her gross motor skills were at a 5 month level, social at 6-9 months, and language at 3 to 6 months.

**Conclusions:** To our knowledge, our patient is the longest surviving child with bilateral renal agenesis. She has grown and developed well on peritoneal dialysis. A literature search showed 6 cases of a live born twin with bilateral renal agenesis and healthy lungs; all of these died before 2 months of age, most near the time of birth. Despite setbacks including peritonitis and secondary hyperparathryoidism, her development has been excellent and she continues advancing toward transplant.

## FR-PO1073

**Ferumoxytyl as an Alternative to Gadolinium Based Contrast Agents in a Pediatric Chronic Kidney Disease Patient** Anjali B. Nayak,[1] Aarti Luhar,[2] Mark Hanudel,[1] Theodore R. Hall,[2] Joshua Zaritsky.[1] *[1]Pediatric Nephrology, UCLA, Los Angeles, CA; [2]Dept of Radiology, UCLA, Los Angeles, CA.*

**Background:** Gadolinium based contrast agent (GBCA) exposure in ESRD patients is associated with the development of a potentially fatal disorder, Nephrogenic Systemic Fibrosis (NSF). Although contrast enhanced computed tomography(CT) is an alternative it carries the risk of radiation exposure and further reduction of residual renal function Therefore we sought to assess the efficacy of ferumoxytyl, a parenteral iron supplement that contains superparamagnetic iron oxide, as an alternative contrast agent.

**Methods:** We describe the case of a 5 year old, 13 kg female ESRD patient in whom we were unable to place vascular access despite multiple surgical attempts. Previous Doppler ultrasound imaging was inconclusive. Ferumoxytyl (4mg/kg, IV) was administered for a magnetic resonance venogram (MRV) using a Siemens scanner at 3T according to standard department protocol.The patient tolerated the procedure without difficulty. Resulting image quality was comparable to GBCA enhanced MRV studies and was notable for multiple vascular occlusions explaining the previous failures to obtain vascular access.

**Conclusions:** Given the serious safety concerns associated with GBCA, ferumoxytyl is an excellent alternative contrast agent in pediatric ESRD patients who need detailed vascular mapping via MRV. Future studies are needed in order to further evaluate safety and efficacy in this patient population and to asses whether ferumoxytyl can be used as a contrast agent for other MRI studies.

**FR-PO1074**

**ABO Incompatible Renal Transplantation Can Improve HLA Matching in Children** Anjali B. Nayak,[1] Robert B. Ettenger,[1] Gerald S. Lipshutz,[3] Eileen W. Tsai.[1] *[1]Pediatric Nephrology, Mattel Children's Hospital, UCLA, Los Angeles, CA; [2]Pediatric Radiology, UCLA, Los Angeles, CA; [3]Dept of Surgery, UCLA, Los Angeles, CA.*

**Background:** It is important for pediatric (Ped) patients (pt) to get expedited kidney (Kid) transplants (Tx) to resolve uremic symptoms and grow. Also,due to long projected life-years, it is optimal for them to get well-matched Tx to minimize the chances of long-term sensitization. Such sensitization has been reported to make second Txs difficult in these pts. In North America ped kid Tx is largely dependent upon the use of deceased donor organs making it challenging to identify timely well matched Txs. One solution is to utilize ABO incompatible (ABOi) Tx and, if necessary, paired donation.

**Methods:** In the past year, we adopted this approach for 3 pts. (age 2 -13 yrs) who got transplanted across the ABO barrier with Txs well matched for HLA A, B, DR and DQ.

Table 1. Donor and Patient HLA Typing

| | HLA | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | A | | B | | DR | | DQ | |
| Patient 1 | 2 | 3 | 13 | 35 | 7 | 13 | 2 | 6 |
| Donor 1 | 2 | 3 | 13 | 65 | 7 | 13 | 2 | 6 |
| Patient 2 | 2 | 4 | 18 | 41 | 11 | 13 | 7 | 6 |
| Donor 2 | 24 | 26 | 13 | 41 | 7 | 13 | 2 | 6 |
| Patient 3 | 11 | 29 | 27 | 44 | 7 | 15 | 2 | 6 |
| Donor 3 | 1 | 11 | 7 | 27 | 15 | 15 | 6 | 6 |

Pts received pre-Tx immunomodulation(anti-CD20 antibody, intravenous immunoglobulin, and plasmapheresis) until an acceptable isoagglutinin(IG) titer <1:8 was reached at Tx. IG titers were monitored, and postoperative plasmapheresis was initiated if titers increased. We utilized standard immunosuppression with anti thymocyte globulin induction, prednisone, MMF, and tacrolimus. All grafts functioned well 3-12 mos post-Tx, without development of DSAs. Particularly notable was a 13 yo male with > 90% CPRA due to a previous failed transplant, and had been waiting on the deceased donor list for 2 years. He received an ABOi paired exchange Tx donor with 5/6 HLA match; the Tx has an eGFR of >90ml/min/1.73 m2 at 1 yr post Tx. Both pt and renal allograft survival to date is 100%.

**Conclusions:** These results highlight the safety and efficacy of ABOi Tx in Ped Kid Txs. Combining the paired exchange program with ABOi Tx can improve HLA matching, minimize wait times, and enhance allograft survival.

**FR-PO1075**

**Perinephric Fluid Collection in a Girl with Dandy Walker Malformation: Mystery Revealed** David M. Shafran,[1] Rupesh Raina,[1] Katherine MacRae Dell,[1] Jonathan Ross.[2] *[1]Dept of Pediatrics, Nephrology, Univ Hospitals, Rainbow Babies and Children's Hospital, Cleveland, OH; [2]Dept of Pediatric Surgery, Univ Hospitals, Rainbow Babies and Children's Hospital, Cleveland, OH.*

**Background:** Renal lymphangiectasia, a developmental malformation of the renal lymphatics, is a rarely reported clinical entity. Hematuria, flank pain and abdominal pain are usually the presenting symptoms.It is described in the limited literature as "self-resolving".

**Methods:** 11year old girl with a distant history of Dandy Walker malformation and placement of a VP shunt at birth presented with a one week history of increasing abdominal distension and discomfort. Physical examination was remarkable for mild hypertension and a markedly distended abdomen. A shunt series was normal and an abdominal CT demonstrated large bilateral perinephric fluid collections. The diagnosis of renal lymphangiectasia was suspected (and other diagnoses, such as lymphoma were excluded) when with needle aspiration of fluid from the perinephric collections demonstrated no cells, isotonic fluid and absence of chyle, all consistent with renal lymph. Percutaneous drains were placed into the perinephric spaces. Drain output increased steadily to approximately 3 liters from each side, requiring continuous intravenous fluids to prevent volume depletion. Furosemide, HCTZ,lisinopril, octreotide , and sclerosing agents (doxycycline and bleomycin) were all unsuccessfull to dicrease the lymphatic output. The patient developed several drain infections requiring multiple courses of intravenous and oral antibiotics. Two months later, a left renal capsulectomy was performed followed by a right capsulectomy with transaction of the lymphatics approximately 4 months after initial presentation. Lymphatic output gradually decreased permitting the removal of both drains.

**Conclusions:** Renal lymphangectasia is a rare, poorly understood condition, which typically resolves without intervention. Several medical treatments, including those used in our patient, have been described in case reports in the literature. However, none were successful in this case. Whether surgical intervention resulted in resolution or was coincidental is unknown.

**FR-PO1076**

**Successful Treatment for Short Stature in a Pubertal Kidney Transplant Recipient Using a Combination of Gonadotropin Releasing Hormone Agonist and Growth Hormone** Hideki Matsumura,[1] Akihiko Shirasu,[1] Hyogo Nkakura,[1] Akira Ashida,[1] Motoshi Hattori,[2] Hiroshi Tamai.[1] *[1]Pediatrics, Osaka Medical College, Takatsuki, Osaka, Japan; [2]Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

**Background:** Despite various developments in the management of children with CKD, including the use of recombinant human growth hormone (rhGH), achieving an adequate final body height remains a challenge for such children, especially around the time of puberty. Here, we report a pubertal kidney transplant recipient with short stature who was treated with a combination of gonadotropin releasing hormone analog (GnRHa) and rhGH.

**Methods:** We treated an 18-year-old girl with ESRD due to Senior-Loken syndrome. Peritoneal dialysis had been started at the age of 8 years. Her height standard deviation score (SDS) had deteriorated, becoming -3.5 at the age of 12 years 5 months, and we started rhGH therapy. Although her height velocity improved from 0.5 cm/year to 6 cm/year within one year after starting rhGH therapy, her height SDS did not improve. At the start of rhGH therapy, the patient has been at Tanner stage II; therefore we decided to add GnRHa therapy in order to prolong the pre-pubertal growth phase and obtain catch-up growth. At the age of 13 years 9 months, 4 months after initiation of the combined therapy, the patient underwent living-donor kidney transplantation. Immunosuppressive agents included cyclosporine, mycophenolate mofetil, and methylprednisolone. The methylprednisolone was reduced quickly to 0.3 mg/kg/day at 4 weeks after transplantation, and to 4 mg on alternate days from 4 months. At the age of 15 years 8 months, her height SDS had improved to -2.3, and we terminated the GnRHa therapy. At the age of 16 years 6 months, the patient had her first menstrual period, and as her height SDS had reached -2.1, we completed the rhGH therapy. Finally, by the age of 18 years, her height SDS had improved to -1.8. Since then, her transplanted kidney function has been stable and her menstruation cycles have been regular.

**Conclusions:** Combination therapy with rhGH and GnRHa may be safe and effective option for the treatment of short stature in pubertal kidney transplant recipients.

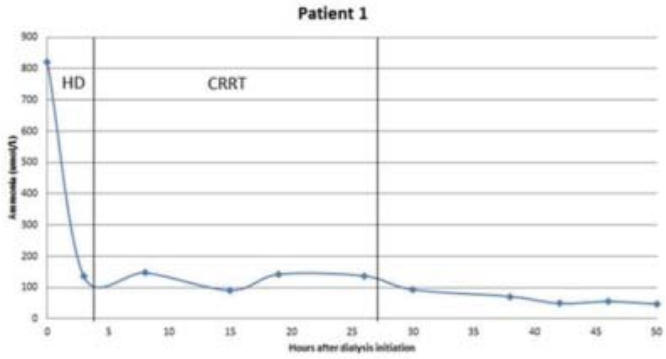
**FR-PO1077**

**A Novel Biphasic Dialytic Strategy for the Treatment of Neonatal Hyperammonemia** Mark Hanudel, Sonal Avasare, Eileen W. Tsai, Joshua Zaritsky. *Dept of Pediatrics, UCLA, Los Angeles, CA.*

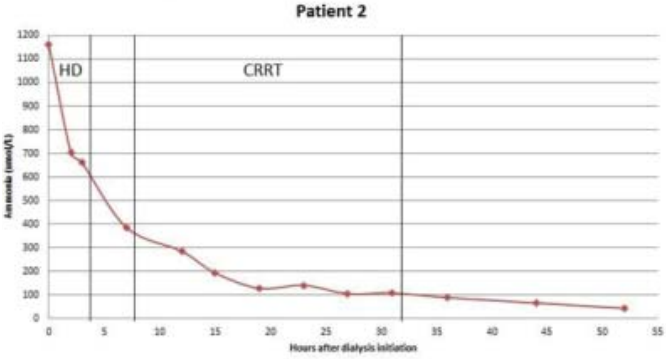
**Background:** Neonates with inborn errors of metabolism often develop hyperammonemia which, if not corrected quickly, may result in poor neurologic outcomes. As pharmacologic therapy cannot rapidly lower ammonia levels, dialysis is frequently required. Both intermittent hemodialysis (IHD) and standard-dose continuous renal replacement therapy (CRRT) are effective; however, IHD may be followed by post-dialytic ammonia rebound, and standard-dose CRRT may not effect a rapid enough decrease in ammonia levels.

**Methods:** We present two cases of IEM-associated neonatal hyperammonemia. The first patient, eventually diagnosed with citrullinemia, presented with lethargy on the fourth day of life. The second patient, eventually diagnosed with methylmalonic acidemia, presented with poor feeding and abnormal newborn screening results on the fourth day of life. Both patients were found to be hyperammonemic (peak ammonia levels 841 umol/L and 1830 umol/L, respectively). For both patients, we employed a biphasic dialytic treatment strategy, initially using dialysis parameters closer to those of IHD (blood flow rate 20-30 mL/min and dialysate flow rate 5000 mL/hr) to rapidly decrease ammonia levels to <400 umol/L, then transitioning to treatment parameters closer to those of standard CRRT (blood flow rate 30 mL/min and dialysate flow rate 500 mL/hr, approximately 4000 mL/hr/1.73m$^2$) to maintain ammonia levels <200 umol/L without rebound.

**Conclusions:** These cases provide an example of a novel biphasic dialytic treatment strategy for neonatal hyperammonemia, effecting rapid ammonia reduction without rebound, employing a seamless transition between two dialytic modalities without equipment changes.



HD: Qb 30 mL/min, Qd 5000 mL/hr; CRRT: Qb 30 mL/min, Qd 500 mL/hr



HD: Qb 20 mL/min, Qd 5000 mL/hr; CRRT: Qb 30 mL/min, Qd 500 mL/hr

**FR-PO1078**

**What Looks like Fabry Disease, May Not Be Fabry!** Reem Daloul, Francis Dumler, Ping L. Zhang. *William Beaumont Hospital, Royal Oak, MI.*

**Background:** Fabry disease is a rare x-linked lysosomal storage disorder caused by deficiency of lysosomal hydrolase alpha-galactosidase A (alpha-Gal A). This results in the accumulation of globotriaosylceramide within the lysosomes of different cell types with eventual organ dysfunction. Renal involvement is characterized by proteinuria and progressive renal failure.

**Methods:** We report a 38 year old previously healthy African American male who presented with intermittent gross hematuria. The patient was otherwise asymptomatic. Family history was strongly positive for chronic kidney disease in both parents, sister, maternal and paternal grandmothers. Urinalysis showed +3 blood, 8 RBCs, 4 WBCs and no protein. Creatinine and eGFR were 1.02 mg/dL and 99 mL/min/1.73m2. Urine protein/creatinine ratio was 0.1. Abdominal CT, renal ultrasound, and cystoscopy were all normal. Renal biopsy showed slight glomerular congestion with occasional foamy cells along the glomerular capillary wall and no proliferation, necrosis, or glomerular sclerosis. CD68 and lysozyme stained sections revealed granular aggregates in the podocytes. Electron microscopy disclosed normal basal membrane thickness without splitting or immune complex deposition and preserved foot processes. Circular and laminated materials were identified in the cytoplasm of the podocytes. These structures correlated with the CD68 positive aggregates identified by light microscopy. The pathological findings are characteristics of Fabry disease. The patient denied any history of neuropathic limb pain, cerebrovascular accidents, heart disease, or skin rash suggestive of telangiectasias or angiokeratomas. Echocardiogram showed normal ventricular wall thickness and valves. Leukocyte Alpha-Gal A was found to be within normal limits.

**Conclusions:** The sensitivity and specificity of the leukocytes alpha-Gal A assay in males approaches 100%. Normal values in our patient excludes the diagnosis of Fabry disease, particularly in the presence of a negative history and a normal physical examination. It raises the possibility of another rare lysosomal disorder being responsible for this patient's renal involvement. A question that we will turn to genetic testing for further answers.

**FR-PO1079**

**Acute Kidney Injury with Hydronephrosis, Eosinophilc Tubolinterstitial Nephritis and Extracapsular Perirenal Eosinophil Infiltrates. A Rare Presentation of Idiopathic Hypereosinophilic Syndrome** Marat Abdullin,[1] Kiran M. Goli,[1] Jonathan Freeman,[2] Syed S. Ali,[1] Jonathan Bayuk,[1] Benjamin J. Freda.[1] *[1]Medicine, Baystate Medical Center; [2]Pathology, Baystate Medical Center.*

**Background:** We describe a patient with Acute Kidney Injury (AKI), hydronephrosis and eosinophilia. To our knowledge, this is the first reported case of Idiopathic Hypereosinophilic Syndrome (IHES) with renal involvement characterized by both obstruction and renal parenchymal injury.

**Methods:** A 55-year-old male presented with 6 months of malaise, night sweats and weight loss. He had bilateral cervical and axillary lymphadenopathy. His white blood cell count (WBC) was 5600/mm$^3$, with an absolute eosinophil count (AEC) of 2000 cells/mm$^3$. The serum creatinine was 1.9 mg/dL and the urinalysis showed 1+ albuminuria, without WBC or red blood cells. A CT scan revealed multiple enlarged mesenteric and retroperitoneal lymph nodes. There was diffuse enlargement of both kidneys with bilateral hydronephrosis and perinephric inflammatory changes. There was thickening of both renal pelvises and proximal ureters with involvement of the periureteral fat. A kidney biopsy showed chronic and active tubulointerstitial nephritis with eosinophils and involvement of the outer renal cortex and extrarenal fibroadipose tissue. The glomeruli were normal. Bone marrow biopsy was normocellular with eosinophilia. Immunophenotyping did not show a B-cell clone or aberrant T-cell population. There was no evidence of eosinophilic leukemia. He was diagnosed with IHES and treated with 40 mg prednisone daily. His symptoms resolved in 1 week. After 3 weeks, his AEC was 0 cells/mm$^3$ and the creatinine decreased to 1.2 mg/dL. Six months later, a renal ultrasound revealed mild residual dilatation of the right kidney collecting system, and complete resolution of the left-sided hydronephrosis.

**Conclusions:** IHES should be considered in patients presenting with AKI and unexplained eosinophilia. Renal involvement is rarely described in IHES. Our case highlights a novel renal manifestation of IHES: obstructive AKI due to perirenal and periureteral eosinophilic infiltration and lymphadenopathy. The obstruction and AKI resolved with prednisone.

**FR-PO1080**

**Case Report: Positive Immunoreactivity for Serum Amyloid A Protein in a Case of Leukocyte Cell-Derived Chemotaxin 2-Type Associated Renal Amyloidosis Confirmed by Tandem Mass Spectrometry** Vanessa Moreno, William F. Glass. *Pathology and Laboratory Medicine, The Univ of Texas - Health Science Center at Houston, Houston, TX.*

**Background:** Leukocyte cell-derived chemotaxin 2 (LECT2) has been recently identified as an amyloidogenic protein affecting the kidney with extensive mesangial, interstitial and vascular involvement by congophilic deposits "non-reactive" for conventional amyloid immunostaining. This amyloid subtype may be identified using an anti-LECT2 antibody or by liquid chromatography tandem mass spectrometry (LC MS/MS).

**Methods:** A 61 year-old Hispanic male undergoing hemodialysis for chronic kidney disease of unknown etiology was referred for evaluation. Kidney biopsy showed extensive mesangial expansion, and diffuse interstitial and vascular involvement by congophilic deposits with typical ultrastructural features of amyloid. Immunofluorescence stains against IgA, IgG, IgM, C3, C1q, fibrinogen, albumin, and κ/λ light-chains were negative. Immunohistochemistry for serum amyloid A (SAA) protein was interpreted as positive and AA-type amyloidosis diagnosed. One year later, the case was reviewed for pre-transplant evaluation, and AA-IHC reinterpreted as positive but less so than AA amyloid control tissue. LC MS/MS was ordered to confirm the nature of the amyloid protein; however, the results demonstrated a peptide profile consistent with LECT2-type amyloid.

**Conclusions:** We present a case of LECT2-type-associated renal amyloidosis with partial immunoreactivity for AA-type amyloid. Immunohistochemistry is the usual method used for typing renal amyloid in more than 90% of cases. In the last decade, at least 12 cases of LECT2-type renal amyloidosis have been reported and described as negative for κ/λ light-chains, AA protein, fibrinogen and transthyretin. However, our experience in this case raises concern that in some cases, LECT2-type renal amyloid may react with partial positivity with antibody to SAA protein. Confirmation by LC MS/MS is crucial in such cases for accurate diagnosis.

**FR-PO1081**

**Karyomegalic Interstitial Nephritis: An Unusual Cause of Progressive Chronic Kidney Disease** Victoria Brocklebank,[1] Alison Brown,[1] John Andrew Sayer.[1,2] *[1]Renal Services Centre, Freeman Hospital, Newcastle upon Tyne, Tyne and Wear, United Kingdom; [2]Institute of Genetic Medicine, International Centre For Life, Newcastle Univ, Newcastle upon Tyne, Tyne and Wear, United Kingdom.*

**Background:** In many patients with progressive chronic kidney disease (CKD) the aetiology is not identified. Karyomegalic Interstitial Nephritis (KIN) may cause insidious CKD. KIN was first described in 1974 and since then only twelve families with KIN have been reported[1], thus it remains rare or under-diagnosed. KIN is characterised by chronic tubulointerstitial nephritis with large abnormal hyperchromatic nuclei. In 2012, recessive mutations in *FAN1* were identified as the cause of KIN[1]. *FAN1*, encoding Fanconi anemia–associated nuclease 1, is involved in DNA damage repair[1].

**Methods:** A 40 year old woman was referred to the nephrology clinic with progressive CKD (eGFR 34ml/min/1.73m$^2$). She was normotensive with negative urinalysis, and immunological tests were negative except for a weakly positive ANA. Renal ultrasound showed slightly small kidneys and cortical thinning. Renal biopsy was performed and histopathological analysis demonstrated characteristic features of KIN. We undertook a molecular genetic analysis of the *FAN1* gene and identified a homozygous missense mutation, affecting a highly conserved residue and predicted to be pathogenic.

**Conclusions:** This patient developed progressive CKD in the absence of the usual risk factors, thus an interstitial nephritis was suspected. Following a renal biopsy, a histological and molecular genetic diagnosis were obtained. These allow some insight into her disease pathogenesis, provide prognostic information, and allows genetic screening of other family members. We speculate that other cases labelled as progressive CKD of unknown aetiology may have underlying genetic abnormalities. KIN secondary to *FAN1* mutations remains rare but because *FAN1* is involved in DNA damage repair, mutations in this gene links the accumulation of DNA damage with the slow and late onset of KIN and the associated CKD.

## FR-PO1082

**Using Fresh Frozen Plasma with Therapeutic Plasma Exchange in a Patient with Acquired C1 Esterase Iinhibitor Deficiency Without Triggering Angioedema** Sajan K. Eapen, Andre A. Kaplan, Wilner Samson. *Nephrology, Univ of Connecticut Health Center.*

**Background:** Acquired C1 esterase inhibitor deficiency (acquired angioedema [AAE]) is a rare syndrome affecting the skin, gastrointestinal (GI) and respiratory tracts. The syndrome's acquired form appears after 40 years of age and is associated with lymphoproliferative B cell disorders. In acute attacks, lack of C1 esterase leads to uninhibited bradykinin generation, causing angioedema presenting as cutaneous swelling, severe GI symptoms (colic, nausea, and vomiting) and severe laryngeal edema. The acute attack is unaffected by conventional treatments for *allergic* angioedema (steroids, epinephrine). First line pharmacologic therapies are seldom readily available. Plasma, with natural C1 esterase inhibitor, has been used for acute attacks but there are concerns that plasma could potentially trigger or worsen angioedema through bradykinin substrate replenishment. We present a case of a patient with AAE who developed thrombotic thrombocytopenic purpura (TTP), successfully treated with a series of therapeutic plasma exchange (TPE) using fresh frozen plasma (FFP).

**Methods:** A 39 year old female with B cell lymphoproliferative disease and AAE had malaise and headache with a platelet count of 20,000 k/μl, LDH 701 U/L, reticulocyte count 2.7%, haptoglobin <15 mg/dl and 10 -15 schistocytes per high power field. TTP was suspected as the underlying disease process and emergent TPE was ordered. Aware of a potentially fatal reaction with plasma use, Ecallantide (kallikrein inhibitor) , a first line therapy for AAE angioedema, was secured but not administered and TPE was performed. The patient underwent 6 treatments with a total of 18 liters of FFP. The patient tolerated therapy without angioedema.

**Conclusions:** First line therapies for AAE are not often readily available. Prematta et al (Ann Allergy Asthma Immunol. 2007; 98:383.) have described therapeutic use of FFP for management of acute AAE without incident. This is the first report of TPE using such a large volume of FFP (18 liters) in a patient with AAE and TTP, further substantiating that FFP is tolerated and potentially favorable for AAE in settings where its use is necessitated.

## FR-PO1083

**A Case of Nephritic-Nephrotic Syndrome in a Man with NF** Suzanne Boyle, Rebecca Kurnik Seshasai, Iram Aqeel, Michael Chaknos, Sidney M. Kobrin. *Renal, Hypertension, and Electrolyte Div, Hospital of the Univ of Pennsylvania, Philadelphia, PA.*

**Background:** This is a patient with nephritic-nephrotic syndrome with biopsy-proven MPGN secondary to IgG lambda monoclonal gammopathy (MG) and type I cryoglobulinemia. Bone marrow biopsy confirmed a diagnosis of malignant lymphoplasmacytic lymphoma.

**Methods:** A 26 year-old man with a history of NF type I, hypertension, and possible Noonan's Syndrome (NS) with pulmonic valve disease presented with a rising creatinine (Cr) over the course of 6 months (baseline 1.0 mg/dl). Physical examination: BP 150/70 mm Hg and anasarca. No lymphadenopathy, rash, fever, or arthritis. Lab values: Cr 3.5 mg/dl, BUN 48 mg/dl, urine protein:Cr 5.0, serum albumin 2.4 g/dl, low C3 of 52 mg/dl , normal C4 of 20 mg/dl, negative anti-nuclear antibody. Hepatitis serologies and HIV unremarkable. Urinalysis: 5-10 white cells/high-powered field (HPF), 50-100 red cells per HPF with dysmorphic features, no cellular casts. Kidney biopsy: MPGN pattern on light microscopy. Immunofluorescence demonstrated 3+ C3 and IgG with a lambda-light chain restriction. Electron microscopy revealed subendothelial deposits, pseudomthrombi, and diffuse foot process effacement. Serum and urine protein electrophoresis showed hypogammaglobulinemia with an IgG lambda band on immunofixation. Cryoglobulin screen positive for monoclonal IgG. Bone marrow biopsy: expanded lymphoid aggregate (15 to 25% of cellularity) and a lambda-biased plasma cell population (5 to 10% of cellularity). Flow cytometry negative. A diagnosis of malignant lymphoplasmacytic lymphoma was made.

**Conclusions:** Monoclonal gammopathy of renal significance (MGRS) is an increasingly recognized entity in immunoglobulin complex-mediated MPGN. We describe a case in a patient with a history of NF type I and possible NS. Both of these autosomal-dominant genetic disorders involve loss-of-function mutations in a common pathway which regulates cellular proliferation. Disruption of this pathway predisposes these patients to various malignancies. The above presentation underscores the importance of maintaining a high index of suspicion for MGRS in young patients with these disorders who present with glomerular disease.

## FR-PO1084

**Complete Remission of Nephrotic Syndrome and Acute Kidney Injury in Crescentic IgA Nephropathy: Role of Mycophenolate Sodium** Ezra Israel, Hitesh H. Shah, Louis R. Spiegel, Kenar D. Jhaveri. *Medicine, Hofstra Northshore-LIJ School of Medicine, Great Neck, NY.*

**Background:** Optimal therapy and prognosis of crescentic IgA nephropathy (C-IgAN) is not known. Reported treatment options for C-IgAN include: combination of corticosteroids and cyclophosphamide for six months. Role of mycophenolate sodium in C-IgAN is unknown. We report a case of C-IgAN that was successfully treated with combination immunosuppressive therapy with follow-up.

**Methods:** Case report: A 54 year old man presents with acute kidney injury (serum creatinine: 3.8mg/dl), microscopic hematuria and massive proteinuria (18 grams/day). Kidney biopsy revealed C-IgAN. The patient was initially started on IV pulse corticosteroids for 3 days followed oral corticosteroids and monthly IV cyclophosphamide for six months. Serum creatinine subsequently improved to 2.2 mg/dl. In addition, pt. was initiated on angiotensin receptor blocker. After 6 months of above therapy, 24 hour urine protein decreased to 2 grams and serum creatinine improved to 1.6mg/dl. Patient was subsequently started on mycophenolate sodium 360 mg twice daily for six additional months as maintenance therapy and oral steroids were slowly tapered off. At follow-up after 2.5 years of initial presentation, patient maintains normal renal function and has no proteinuria.

**Conclusions:** C-IgAN has poor renal prognosis without therapy. A combination of corticosteroid and cyclophosphamide-based induction therapy followed by mycophenolate-based maintenance therapy resulted in complete remission of nephrotic syndrome and acute kidney injury in our patient. Our patient continues to be in complete clinical remission with normal renal function, 1.5 years after completing immunosuppressive therapy. Based on our experience, one can consider mycophenolate sodium for maintenance therapy in C-IgAN.

## FR-PO1085

**Early Ultrafiltration Failure in a Patient with Familial FSGS Secondary to a Mutation in α-Actinin 4: A Postulated Extrarenal Manifestation of Hereditary Focal Sclerosis** Yael Einbinder,[1] Joanne M. Bargman.[2] *[1]Nephrology and Hypertension, Meir Medical Center, Kfar Saba, Center, Israel; [2]Nephrology, Toronto General Hospital, Toronto, Canada.*

**Background:** One variant of hereditary focal segmental glomerulosclerosis has been linked to a mutation in alpha-actinin 4. Alpha actinins are present in epithelial podocytes and endothelial cells and are highly conserved, cross-linking proteins that function in the connection between the actin filaments in the cytoskeleton and the transmembrane anchoring proteins such as cadherin and integrin (cell to cell and cell to matrix adhesion molecules). Previous studies have demonstrated that alpha actinins play a role in maintaining and enhancing the endothelial cell barrier.

**Methods:** We present a 48 year old female with this mutation who progressed to end stage kidney disease requiring dialysis. She also had a diagnosis of papillary thyroid carcinoma, history of midline laparotomy due to major motor vehicle accident and Cesarean section. An uneventful PD catheter insertion was done by advanced laparoscopy. Her continuous ambulatory peritoneal dialysis (CAPD) prescription was three daily exchanges of 1.5 liters, 2 with 2.5% dextrose and one exchange with icodextrin. Absence of ultrafiltration was noted during training. Results of the peritoneal equilibration test (PET) have demonstrated calculated D/P ratio for creatinine and urea was 0.95 and 1.04 respectively, suggesting an extremely high small solute transport rate. Ultrafiltration failure was the result of rapid dissipation of the osmotic gradient across the membrane. The patient eventually became persistently volume overloaded and was transitioned to hemodialysis.

**Conclusions:** In the peritoneal membrane, the endothelial cells of the perfusing capillaries are believed to be the most important structure determining transmembrane transport. We postulate that the mutant alpha actinin 4 altered intercellular anchorage, leading to an increase in endothelial permeability and rapid dissipation of the glucose osmotic gradient. This abnormality would be the first described extra-renal manifestation of the AD mutation of alpha-actinin 4.

## FR-PO1086

**An Unusual Association of Autosomal Dominant Polycystic Kidney Disease with Secondary Focal Segmental Glomerulosclerosis** Olga Kuchmak,[1] William L. Clapp,[2] I. David Weiner.[3] *[1]Div of Nephrology, Hypertension and Transplantation, Univ of Florida, Gainesville, FL; [2]Dept of Pathology, Univ of Florida, Gainesville, FL; [3]Div of Nephrology, Hypertension and Transplantation, Univ of Florida, Gainesville, FL.*

**Background:** In patients with autosomal dominant polycystic kidney disease (ADPKD), urinary protein excretion usually less than 1 g/24 hours. Nephrotic range proteinuria, with or without an accompanying decline in renal function, is unusual and should warrant renal biopsy to exclude coexisting glomerular disease.

**Methods:** A 39-year-old WM with a history of ADPKD diagnosed 5 years ago was referred to our clinic for further evaluation of nephrotic range proteinuria. The laboratory evaluation revealed serum creatinine 3.8 mg/dl, BUN 39 mg/dl, eGFR 18mL/min, albumin 4.3 g/dl, hemoglobin 14.8 g/dl, random UPCr 5.2 g. Based on the records his baseline Cr was 2.-2.7 mg/dl. On exam the patient was found to have elevated BP at 149/96 mmHg. Otherwise physical exam was unremarkable. To establish the etiology of this rare presentation we elected to proceed with renal biopsy. In addition to moderate to severe arterial and arteriolar nephrosclerosis, the renal biopsy also revealed presence of segmental sclerosis and hyalinosis. An additional glomerulus showed global sclerosis with prominent

hyperplastic cells present within Bowman's Space. Electron microscopy demonstrated definite segmental sclerosis with ultrastructural analysis confirming the segmental sclerosis with collapsed glomerular capillary loops accompanied by hyalinosis in the subendothelial regions. There was also fairly prominent podocyte foot process effacement present. No definitive electron dense "immune-type" deposits were identified.

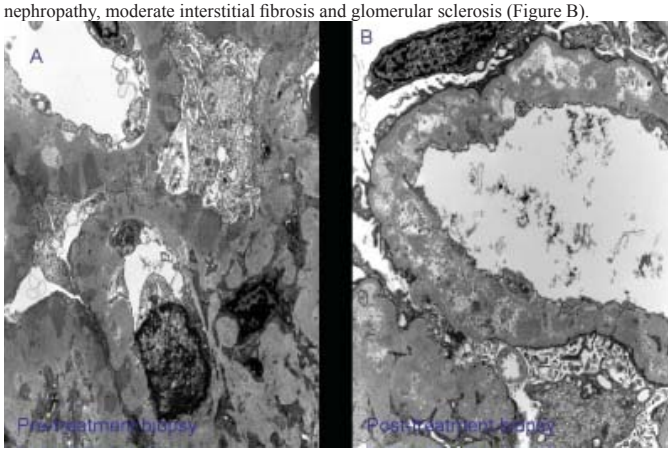
**Conclusions:** We report a rare case of FSGS in patient with ADPKD. Our case emphasizes the importance of renal biopsy in patients with ADPKD with nephrotic-range proteinuria which can provide further guidance in terms of the prognosis and treatment options.

## FR-PO1087

**A Novel Approach to Treating Membranous Nephropathy Secondary to Chronic Lymphocytic Leukemia** David Levy,[1] Wajid M. Choudhry.[2] *[1]Dept of Internal Medicine, Unity Health System, Rochester, NY; [2]Dept of Nephrology, Univ of Rochester Medical Center, Rochester, NY.*

**Background:** Although uncommon, there have been several case reports of biopsy proven membranous nephropathy (MN) caused by chronic lymphocytic leukemia (CLL). Many of these reports have demonstrated clinical improvement following CLL treatment with combination chemotherapy. However, few if any reports have shown biopsy proven disease regression following Rituximab monotherapy.

**Methods:** 62 year old male with a past medical history of diabetes, hypertension, proteinuria (2.6 grams/day) and CLL (not on treatment). Presented with worsening renal function (serum Cr increased from 0.6 mg/dl to 2 mg/dl) and increasing proteinuria (6.3 grams/day). A kidney biopsy was performed which showed lymphoid aggregates predominantly CD20. PLA2 receptor antibodies where negative and the staining pattern was consistent with secondary membranous nephropathy (Figure A). Due to worsening renal function he was initially started on Pentostatin, Cyclophosphamide, and Rituximab. Therapy was discontinued after two cycles since his serum creatinine had increased (3.88 mg/dl). Six months later treatment was restarted with Rituximab dosed at 3.75grams/$m^2$ weekly. After four cycles of treatment his kidney function gradually improved (serum Cr 2.66) and his proteinuria returned to baseline (1.7 grams/day). A repeat kidney biopsy showed clearance of intramembranous deposits consistent with resolution of membranous nephropathy, moderate interstitial fibrosis and glomerular sclerosis (Figure B).



**Conclusions:** To our knowledge we are presenting the first documented case of CLL induced membranous nephropathy with clinical and biopsy proven resolution after Rituximab treatment. This case demonstrates the potential clinical utility of Rituximab as monotherapy for CLL induced membranous nephropathy.

## FR-PO1088

**Use of Adrenocorticotropic Hormone in Managing Proteinuria and Hypoalbuminemia Associated with Focal Segmental Glomerulosclerosis Leading to End Stage Renal Disease** Pallavi D. Shirsat, Sabeen Y. Habib. *Dept of Pediatrics, LSU Health Shreveport, Shreveport, LA.*

**Background:** 14 year old African American female with history of End stage renal disease (ESRD) secondary to Focal Segmental Glomerulosclerosis (FSGS), persisted to have proteinuria and hypoalbuminemia. She was tried on RAAS blockade with no resolution. In order to improve her albumin in preparation for transplant, we tried treatment with ACTH gel (Acthar: a repository corticotrophin injection) to improve her baseline albumin of 0.5 g/dl.

**Methods:** Patient received Acthar 80 units subcutaneously twice a week x 6 months. She was followed closely at the dialysis unit. Then she was weaned off over the next one month.

**Results:** Patient responded to ACTH gel and showed significant improvement in her serum albumin level. Serum albumin improved from 0.5 g/dl at the beginning of treatment to 3.7 g/dl over a period of 6 months. She did not have any significant adverse effects except for cushingoid facies. She is now off Acthar with sustained normal albumin level.

**Conclusions:** ACTH therapy has shown to benefit patients with Idiopathic Membranous Nephropathy in a study conducted in Europe by Ponticelli et al and few observational retrospective studies conducted in the United States. Based on the encouraging results, we decided to use it in our ESRD patient, who has biopsy proven FSGS with proteinuria resistant to conventional treatment with corticosteroids and tacrolimus. After starting ACTH therapy, patient showed significant improvement in her serum albumin level; without having any serious adverse effects. The mechanism of action of ACTH remains unclear at this time; the proposed theories are it may work at the melanocortin receptor in podocytes to reduce proteinuria, or by stimulating endogenous cortisol secretion. ACTH therapy may be a promising treatment for patients with nephrotic syndrome resistant to conventional therapies like corticosteroids and immune suppression. Results available from the limited studies using ACTH therapy are encouraging. Further studies in this area using large sample size and long term follow up are warranted.

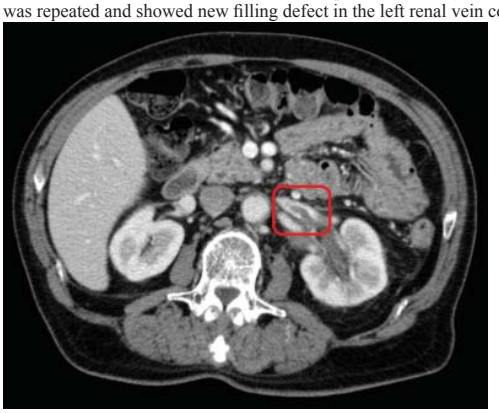
## FR-PO1089

**Unusual Cause of Renal Vein Thrombosis** Mohammad Sharif,[1] Navin Jaipaul,[2] Seyed-ali Sadjadi.[2] *[1]Nephrology, Loma Linda Univ Medical Center, Loma Linda, CA; [2]Nephrology, Veterans Affairs Loma Linda Healthcare System, Loma Linda, CA.*

**Background:** Renal vein thrombosis (RVT) has numerous etiologies; such as, nephrotic syndrome, malignancy, hypercoagulable state, oral contraceptive pills use, steroids therapy, trauma, and kidney transplant. We present a case of an elderly gentleman who developed RVT after laser lithotripsy for obstructive nephrolithiasis.

**Methods:** A 76-year-old male, known to have hypertension, coronary artery disease, stroke and dyslipidemia presented with left flank pain, hematuria and left renal angle tenderness, was found to have left ureteric stone with hydronephrosis which was diagnosed by abdomen computed tomography (CT) scan. He underwent left ureteroscopic laser lithotripsy with stent placement. Pain and acute kidney injury improved and he was discharged home. A few days later, he pulled the string of the stent and he was able to remove it. Then two days after, he started to complain of left flank pain. Laboratory evaluation showed Creatinine decreased compared to discharge value. Abdominal CT scan was repeated and showed new filling defect in the left renal vein consistent with RVT.



He was started on anticoagulation. Extensive work up showed no evidence of glomerular disease, malignancy or thrombophilia. At 3-month follow up, the pain had subsided and a repeat CT scan showed resolution of the thrombosis.

**Conclusions:** Laser lithotripsy is not a recognized etiology for RVT. In this case, common causes were ruled out and the proximity of the procedure to his presentation made RVT likely induced by laser lithotripsy, which could be explained by edema and pressure induced by instrumentation of the ureter or by pressure induced when he self-retracted the stent or combination of both. This case could be an eye opener for unknown etiology of RVT or possibly underdiagnosed etiology of flank pain post laser lithotripsy.

## FR-PO1090

**Novel Mutations in CLDN16 Gene in a Belgian Patient with Hypomagnesemia, Hypercalciuria and Nephrocalcinosis** Pauline Erpicum,[1] Laurent E. Weekers,[1] Emilie Castermans,[2] Vincent Bours,[2] Jean-marie H. Krzesinski,[1] Francois Jouret.[1] *[1]Nephrology, ULg CHU, Liege; [2]Genetics, ULg CHU, Liege.*

**Background:** Hypomagnesemia, hypercalciuria and nephrocalcinosis (HHN) is a rare autosomal recessive tubular disorder characterized by urinary losses of $Mg^{2+}$ and $Ca^{2+}$. HHN leads to end-stage renal disease (ESRD) in early adulthood. HHN is genetically heterogeneous, with mutations in *CLDN16* or *CLDN19* genes.

**Methods:** At the age of 19, our patient presented with a loss of consciousness secondary to dehydration. His medical history included dehydration at birth, arrhythmia and polyuria/polydipsia with nycturia. His father and uncle had kidney stones. Physical examination was unremarkable. Blood parameters: creatinine [17.5mg/l], ionized $Ca^{2+}$ [1.12mM], $Mg^{2+}$ [0.61mM], uric acid [87mg/l], PTH [167pg/ml]. Urine analyses: increased fasting $Ca^{2+}$/creat. ratio (0.21), proteinuria (1.3 g/g creat.), hypocitraturia. Uroscan evidenced bilateral medullary calcinosis. Oral $Ca^{2+}$-loading test induced an appropriate inhibition of PTH secretion. Kidney biopsy showed tubular atrophy with von kossa-positive deposits, as well as glomerular segmental and focal hyalinosis. Genetic analyses identified 2 novel mutations in the *CLDN16* gene: c.340C>T (p.R114*) and c.427+5G>A. Treatment included ACE inhibitors and thiazides, as well allopurinol, statins and $Mg^{2+}$-citrate. Proteinuria got normalized in contrast to serum $Mg^{2+}$ levels. Five years later, the patient reached ESRD requiring kidney transplantation (KTx) from a deceased donor. Immunosuppression included FK506, MMF and methylprednisolone. Serum $Mg^{2+}$ levels remained low at 7 months post KTx.

**Conclusions:** The pathogenesis of ESRD in HHN remains debated. *CLDN16* genotype predicts renal decline. Our patient met the criteria for accelerated loss of renal function, with dehydration at birth and GFR decline estimated at 8.2 ml/min per 1.73$m^2$/year. The

apparent compound heterozygosity includes one nonsense mutation truncating the protein in the first extracellular domain and one intronic mutation of a highly conserved nucleotide close to exon 2 donor splice site. Their impact on claudin 16 expression, function and distribution remains to be determined.

*Funding:* Clinical Revenue Support

**FR-PO1091**

**Renal Cell Carcinoma Associated with Xp 11.2 Translocation in Autosomal Dominant Polycystic Kidney Disease** Hyuk Huh,[1] Hayne C. Park,[1] Yongjin Yi,[1] Miyeun Han,[1] Young-Hwan Hwang,[2] Curie Ahn.[1] *[1]Dept of Internal Medicine, Seoul National Univ Hospital; [2]Dept of Internal Medicine, Eulji General Hospital.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common hereditary cystic disease. The prevalence of renal cell carcinoma (RCC) has been reported to be higher in ADPKD patients with advanced renal failure. Xp11.2 translocation RCC is related to translocation of several genes involving the transcription factor E3 (TFE3) gene. Xp11.2 translocation RCC have an aggressive clinical course with tendency to spread to perirenal lymph nodes in adults. This is the first case report of Xp11.2 translocation RCC in an ADPKD patient.

**Results:** A 38-year-old woman was diagnosed of ADPKD in 1996. She had multiple cysts in kidney and liver. 10 x 11cm sized cystic lesion with inner septation and well-enhancing solid portion was incidentally detected in her right kidney upper pole on 2004. The cystic mass was followed up by biennial abdominal CT or ultrasonography and found to be stable without change in morphology or size until January 2011. Then, the size of cystic mass began to increase from 10 x 11 to 10 x 12 cm, and lymph node enlargement was newly found in the retrocaval and aortocaval areas. Cyst aspiration and cytologic examination did not show malignant cells. After 6 months, the size of cystic mass further increased to 10.7 x 12.7cm. In October 2011, we decided to perform diagnostic and therapeutic right radical nephrectomy. Microscopic examination of the right kidney revealed RCC containing clear cell components with strong TFE3 expression. The FISH confirmed the diagnosis of Xp 11.2 translocation by showing break-apart signal in TFE3 gene. Shortly after the diagnosis, multiple metastatic lesions were detected in lung and she has been treated by systemic chemotherapy.

**Conclusions:** In general, Xp 11.2 translocation RCC is reported to appear in the childhood and shows female preponderance. It accounts for approximately 5% to 20% of RCCs in pediatric patients, but is much less common in adults RCCs (1.6%-5%). This case suggests that Xp 11.2 translocation RCC change the clinical manifestation of renal mass dynamically in ADPKD patients.

**FR-PO1092**

**Ezetimibe, Hyperoxaluria and Nephrolithiasis** Ivan E. Porter, William E. Haley. *Nephrology/Hypertension, Mayo Clinic, Jacksonville, FL.*

**Background:** Excessive urinary excretion of oxalate can manifest as recurrent urolithiasis, nephrocalcinosis and progression to ESRD. This is described in primary hyperoxaluria and also with use of the lipase inhibitor orlistat. I present two cases of hyperoxaluria associated with the use of ezetimibe, a selective cholesterol absorption inhibitor.

**Methods:** Case1: 74-year-old Caucasian female was evaluated for renal insufficiency. She had no history of kidney stones, but hyperlipidemia, intolerant of statins, treated with ezetimibe starting about 10 years prior. Her urinalysis was unremarkable and 24 hr urine showed supersaturation of calcium oxalate and U oxalate of 0.47 mmol/spec. Renal US showed a 6mm nonobstructing stone in the right lower pole. Following discontinuation of ezetimibe, 24 hr urine testing showed reduction of U oxalate. Case2: 53-year-old male presented with a history of nephrolithiasis since age 18. He had passed about 50 stones in his lifetime prior to a subacute kidney injury requiring a kidney biopsy revealing calcium oxalate crystals in tubules and intratubular deposition consistent with hyperoxaluria and oxalosis. Genetic testing confirmed primary hyperoxaluria type 1 with mutations in both AGXT and GRHPR. His history of hyperlipidemia was controlled with Vytorin 10/20 for many years. Vytorin was discontinued with subjective decrease in urinary tract symptoms and passage of stones.

**Conclusions:** These cases raise the possibility of a role of ezetimibe in hyperoxaluria and calcium oxalate stone formation. Previous studies suggest that the use of lipase inhibitors is associated with an increase in urinary oxalate along with a decrease in urine calcium and urine magnesium. Fat and bile acids react with calcium in the gut preventing binding with free oxalate, raising intestinal oxalate and thus urinary excretion of oxalate and a predisposition to calcium oxalate stones. This same association has not been described with the selective cholesterol absorption inhibitor ezetimibe. Based on the mechanism of action of ezetimibe and the findings of a relationship between stone formation and the use of orlistat, ezetimibe use should be considered in the evaluation and management of patients with nephrolithiasis.

**FR-PO1093**

**Use of Cinacalcet for Treatment of Hypercalcemia of Malignancy Refractory to Conventional Therapies** Sean R. Campbell,[1] Carlos D. Flombaum,[2] Ilya Glezerman.[2] *[1]Dept of Nephrology and Hypertension, Weill Cornell Medical College, New York, NY; [2]Renal Div, Memorial Sloan-Kettering Cancer Center, New York, NY.*

**Background:** Hypercalcemia of malignancy (HCM) occurs either due to tumor bone invasion causing increased osteoclastic activity or in humoral HCM due to tumor secreted parathyroid hormone related peptide (PTHrP) direct effect on the bone. Initial treatment of hypercalcemia is intravenous (IV) hydration, IV bisphosphonates and, recently, denosumab. Cinacalcet is a calcimimetic agent that binds tissue calcium sensing receptor (CaSR). It has been used to treat hyperparathyroidism and parathyroid carcinoma. We present a case of a patient with HCM, which was resistant to standard therapy but responded to cinacalcet.

**Methods:** The patient was a 66 years old male with history of metastatic renal cell carcinoma. He had developed hypercalcemia with serum Ca (sCa) of 11.4 (8.5-10.5) mg/dl and was started on bisphosphonates and hydration. CT scan of the pelvis was significant for iliac lytic lesions, PTH was 10 (12-88) pg/dl and PTHrP 114 (14-27) pg/dl. Due to ongoing hypercalcemia two doses of denosumab (120mg) were given with no response. After 4 months of worsening hypercalcemia patient was hospitalized with sCa level of 14.2 mg/dl. He was started on cinacalcet 30mg daily and at discharge sCa was 11.0 mg/dl. One week later sCa was 11.4 mg/dl and cinacalcet was increased to 60 mg daily. Ten weeks after initiation of cinacalcet sCa was 10.1 mg/dl and PTHrP level was 159 pg/ml.

**Conclusions:** CaSR is expressed in many tissues including bone, intestine, renal tubules and in malignant tissue secreting PTHrP. Cinacalcet may act by binding CaSR and lowering PTHrP level, increasing calciuria, decreasing intestinal calcium absorption and decreasing calcium efflux from bone. Recently cinacalcet was used in a patient with non small cell lung cancer and humoral HCM resulting in lowering of SCa and PTHrP levels. In our patient the PTHrP levels did not decrease and cinacalcet therapeutic effect was likely mediated via its effect on non-malignant tissues. Cinacalcet is a well-tolerated drug with a low side effect profile which warrants further investigation as treatment of HCM.

**FR-PO1094**

**Hypercalcemia Induced by Ectopic Overproduction of Calcitriol in a Hemodialysis Patient with Rosai-Dorfman Disease** Mai Uemura,[1] Shunsuke Yamada,[1,2] Masanori Tokumoto,[2] Kazuhiko Tsuruya,[1] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Div of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan.*

**Background:** Hypercalcemia is usually associated with the excessive use of Ca-containing Pi-binders or VDRA in dialysis patients. Extra-renal overproduction of calcitriol occasionally leads to hypercalcemia. We report the case of a hemodialysis patient with Rosai-Dorfman disease, who developed hypercalcemia as a result of the ectopic overproduction of calcitriol.

**Methods:** A 65-year-old male receiving hemodialysis for 33 years was admitted because of declining consciousness and fever. His laboratory data showed an increase in his corrected serum Ca (12.8 mg/dL) and CRP levels, while his serum PTH and PTHrP levels were normal. His serum calcitriol level (26 pg/mL) was much higher than the average value in hemodialysis patients. Computed tomography showed enlargement of the systemic lymph nodes. A lymph node biopsy showed massive proliferation of histiocytes with the phagocytosis of intact blood cells (emperipolesis) in the dilated sinuses. The final diagnosis was “Rosai-Dorfman disease”. Interestingly, an immunohistochemical analysis of the affected lymph nodes disclosed many histiocytes (Rosai-Dorfman cells) positive for 1α-hydroxylase, provided evidence for the extra-renal overproduction of calcitriol. Oral prednisolone therapy attenuated inflammation and decreased the serum calcitriol level (9 pg/mL), followed by the normalization of hypercalcemia (8.6 mg/dL) and consciousness, and also a remission of the lymph node swelling.

**Conclusions:** Rosai-Dorfman disease is a benign lymphadenopathy characterized by the massive proliferation of histiocytes with emperipolesis in the dilated sinuses of lymph nodes (Rosai J et al. Arch Pathol 1969). The etiology is unknown, but an association with immunological disorders and the effectiveness of corticosteroid therapy are assumed. Hypercalcemia induced by Rosai-Dorfman disease has been rarely reported. This case is worth reporting, because we have demonstrated that the ectopic overproduction of calcitriol in the lymph node led to hypercalcemia.

**FR-PO1095**

**Proteomics in Guaifenesin Induced Nephrolithiasis: A Pseudomatrix Stone** Faheemuddin A. Ahmed,[1,2] Ann M. Kolbach,[2] Samuel R. Cohen,[2] Neil S. Mandel,[1,2] Jeffrey Wesson.[1,2] *[1]Medical College of Wisconsin, Milwaukee; [2]Zablocki VA Medical Center, Milwaukee, WI.*

**Background:** A number of drugs, including Guaifenesin, have been reported to cause kidney stones, but there are no proteomic reports on these stones. We present a case that was referred for evaluation of matrix stones, which turned out to be a guaifenesin-related kidney stone with a matrix-like component.

**Methods:** A 30 year-old Caucasian woman with no medical history presented at age 27 with renal colic and was found to have acute kidney injury. Work-up revealed bilateral nephrolithiasis with hydronephrosis and had subsequent stent placement. Urine sediment analysis was reported as 100% mucin and no other known stone material. Her symptoms resolved and creatinine returned to baseline. Her medications included potassium citrate

and allopurinol. Her OTC medications included mucinex and claritin for allergy symptoms. The patient was referred to our clinic and enrolled in our IRB approved study. Laboratory evaluation showed normal blood tests. Her urorisk panel revealed low urine volume, low citrate, high sodium, high oxalate, high uric acid and pH 5.5. The patient experienced bilateral flank pain similar to prior episodes and collected a urine sample that showed three discrete phases: urine, mucus strand and sediment. Microscopy of the urine sediment showed spherical, birefringent crystals. FTIR analysis of the sediment revealed 40% guaifenesin and 60% protein. The sediment was fractionated into the drug and protein isolate using ultrafiltration. Standard gel electrophoresis performed on the urine proteins as compared to the sediment proteins revealed increased concentrations of Tamm Horsfall glycoprotein, transferrin and osteopontin and decreased concentrations of albumin and zinc alpha 2 glycoprotein. These findings were further confirmed with mass spectroscopy.

**Conclusions:** Drug-induced kidney stones can mimic matrix stones and can be misdiagnosed with insufficient or inaccurate stone analysis. The guaifenesin associated proteome was found to be different from that reported in the literature for both calcium and matrix stones.

## FR-PO1096

### Calciphylaxis Presenting as Progressive Gangrene of the Digits and Penis

Vasil Peev, Sharad Virmani, Ali Nayer. *Div of Nephrology and Hypertension, Univ of Miami, Miami, FL.*

**Background:** Calciphylaxis, known as calcific uremic arteriolopathy, is characterized by slowly progressive necrosis of skin and subcutaneous tissue secondary to calcification and thrombosis of small- and medium-sized arteries. It manifests most commonly in Middle-aged individuals with renal disease involving their abdomen, legs, and breasts. The digits and penis are rarely affected.

**Methods:** A 49-year-old man presented with gangrene of the fingers and penis. Past medical history included diabetes mellitus, hypertension, dyslipidemia, coronary artery disease, peripheral vascular disease, and end-stage renal disease on hemodialysis for 5 years. Physical examination revealed dry gangrene of the fingers (A, B), penis, and scrotum. Dusky red discoloration of right lateral great toe was also noted (C). Serum concentration of albumin was 1.7 g/dL, calcium 7.7 mg/dL, phosphorus 5.0 mg/dL, and parathyroid hormone 162 pg/mL. Laboratory tests revealed no cryoglobulins, cold agglutinins, cryofibrinogen, lupus anticoagulant or Prothrombin G20210A mutation. Antibodies directed against cardiolipin, beta2 glycoprotein I, myeloperoxidase, proteinase 3, platelet factor 4, nuclear antigens, hepatitis B and C were negative. Serum concentrations of antithrombin, protein S, protein C and complement C3 and C4 were normal. Gangrene of the affected areas worsened (D-F) during work-up. Radiographs of hands and feet revealed vascular calcification (G-J). Skin biopsy revealed calcified subcutaneous small blood vessels consistent with calciphylaxis (Von Kossa stain) (K). Microthrombi were noted in subcutaneous small blood vessels (L, M).

**Conclusions:** This case illustrates a striking presentation of a rare and life-threatening disorder. Similarly presenting conditions like antiphospholipid syndrome, cryoglobulinemia, Waldenstrom's macroglobulinemia, thrombophilia, and scleroderma were excluded.

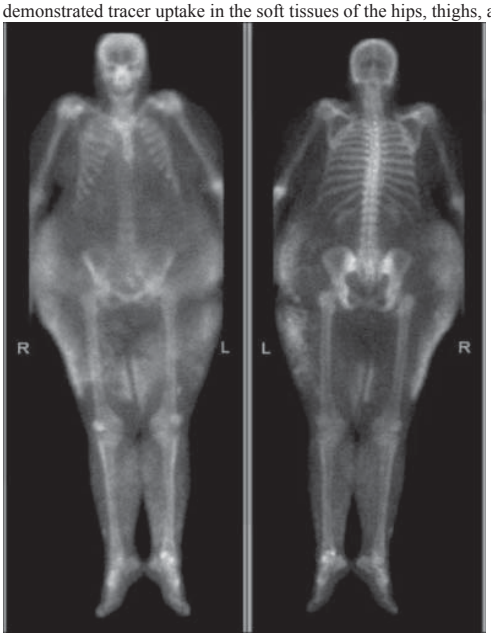
## FR-PO1097

### Calciphylaxis Presenting as Myopathy

Eric S. Kerns, Jose F. Rueda. *Div of Nephrology and Hypertension, Dept of Medicine, Oregon Health and Science Univ, Portland, OR.*

**Background:** Calciphylaxis typically presents with necrotic, painful skin ulcers. We describe the case of a woman who developed severe bilateral leg pain in the absence of visible lesions. Technetium-labeled bone scintigraphy was used to make the diagnosis.

**Methods:** A 63 year old woman with a history of obesity, diabetes, pulmonary embolism on coumadin, and end-stage renal disease (ESRD) due to lupus nephritis was admitted with leg pain. On exam, there were subcutaneous nodules along the thighs without overlying skin changes. Serum calcium was 12.6 mg/dl (normal <10.2), phosphorus was 6.0 mg/dl (normal <4.7), and calcium-phosphate product was 75.6. Erythrocyte sedimentation rate was >120 mm/hr (normal <30). A nerve conduction study showed myopathy. A bone scan demonstrated tracer uptake in the soft tissues of the hips, thighs, and calves.



The diagnosis of calciphylaxis was confirmed with a biopsy of the thigh showing medial calcification in small blood vessels.

**Conclusions:** Calciphylaxis is a disease caused by arteriolar calcification leading to tissue ischemia and necrosis. The mortality rate approaches 50% at one year. Most patients with calciphylaxis have ESRD or kidney transplant. Additional risk factors include hyperparathyroidism, an elevated calcium-phosphate product, female sex, diabetes, obesity, warfarin use, and chronic inflammation. Classic skin lesions are livedo reticularis and necrotic ulcers, though skeletal muscle myopathy has been described in the absence of cutaneous findings. Imaging modalities that aid in the diagnosis are mammography and bone scintigraphy. Catching the diagnosis at an early stage, prior to skin ulceration, confers a greater chance of treatment response. Thus, in patients with ESRD, calciphylaxis should be considered in the differential diagnosis for myopathy, and a reasonable non-invasive diagnostic modality is bone scintigraphy.

## FR-PO1098

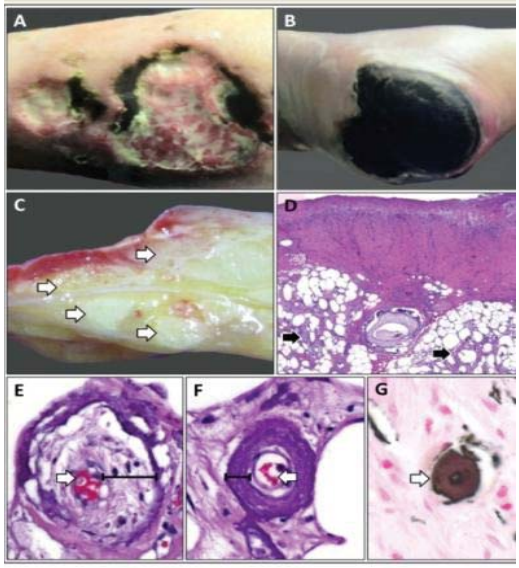
### Pre-Uremic Calciphylaxis

Sharad Virmani, Loay H. Salman, Ali Nayer. *Div of Nephrology and Hypertension, Univ of Miami Miller School of Medicine, Miami, FL.*

**Background:** Calciphylaxis, also known as calcific uremic arteriolopathy, is a life-threatening disorder characterized by calcification and thrombosis of small- and medium-sized arteries resulting in ischemic necrosis of skin and subcutaneous tissue. The pathogenesis is incompletely understood. Primarily diagnosed in dialysis patients, calciphylaxis is rarely diagnosed in patients with CKD in the pre-uremic phase.

**Methods:** A 72-year-old obese Caucasian woman with CKD presented with worsening left lower leg pain and purplish skin discoloration with ulcerations on the heel and dorsal foot.Past medical history was significant for long-standing diabetes mellitus, hypertension, peripheral vascular disease, secondary hyperparathyroidism, and deep vein thrombosis. Physical exam revealed a 10-cm calf ulcer and a violaceous eschar of the heel (Figure1). Significant tenderness to palpation was present in the left upper thigh, calf and foot. Serum creatinine was 3.1mg/dl, calcium of 7.9mg/dl,phosphorous of 6.6mg/dl, and albumin of 1.7g/dl.Angiography revealed occluded left superficial femoral artery,popliteal artery and distal tibial artery.A left below-the-knee amputation was performed.Gross examination revealed calciphylaxis within adipose tissue and severe calcific atherosclerosis (Figure1). Histologic examination disclosed calciphylaxis among large and small vasculature with Van Kossa staining.

FIGURE



**Conclusions:** We highlight calciphylaxis in a patient with chronic kidney disease before starting dialysis. When affecting distal limbs, calciphylaxis can clinically resemble atherosclerotic peripheral vascular disease. This case also emphasizes that calciphylaxis and peripheral vascular disease share many risk factors and can coexist in the same patient. This case increases the awareness to a disorder that could be disguised as peripheral vascular disease.

## FR-PO1099

**Successful Treatment of Recurrent Calciphylaxis Using Sodium Thiosulfate in a Patient with Normal Renal Function** Ankur Sharma, Burl R. Don. *Div of Nephrology, Univ of California, Davis, Sacramento, CA.*

**Background:** Calciphylaxis (CPX), also known as calcific uremic arteriolopathy, is a clinical condition of accelerated dermal arterial medial calcification resulting in severe cutaneous ulcerations and eshcar formation. It is seen generally in patients with advanced chronic kidney disease (CKD) and carries a poor prognosis. Sodium thiosulfate (STS) has been used with varying degress of success in the treatment of CPX in patients with CKD, but its use for patients with recurrent CPX and normal renal function has not been described.

**Methods:** A 53 year old woman with alcoholic liver disease and normal renal function was admitted to the hospital with preliminary diagnosis of severe bilateral lower extremity cellulitis refractory to outpatient antibiotics and cutaneous thigh ulcers. She underwent debridement of the non healing ulcers and a subsequent skin biopsy noted vascular calcification consistent with CPX. The patient had normal creatinine, calcium, phosphorus, parathyroid hormone, 25-OH and 1,25-OH vitamin D blood levels. Treatment with IV STS, 25 g thrice weekly was intiated and after two months of therapy, there was dramatic improvement of the ulcers and reduction of the cutaneous inflammation. The STS was discontinued, but after one month. She had a relapse with recurrent violaceous inflammation with the development of plaque-like nodular densities and early ulceration in her thighs. Additional lab work noted normal FGF-23, complement, PTH related peptide, protein S, protein C blood levels and a negative rheumatologic panel. STS was restarted and she had marked improvement in her cutaneous lesions within 1 month.

**Conclusions:** CPX in the setting of normal renal function is unusual and has been described in association with primary hyperparathyrodism, chronic liver disease, Crohn's disease, warfarin use, systemic steroids and malignancy. The use of STS in the treatment of CPX and normal renal function has been noted, but there are no randomized trials assessing its efficacy. This case establishes that STS is effective therapy for CPX inasmuch as discontinuation of STS resulted in relapse and retreatment resulted in remission. STS is an effective therapy for recurrent CPX.

## FR-PO1100

**Secondary Hyperparathyroidism in Association with Combined Use of Proton Pump Inhibitors and Intravenous Magnesium** Sami Safadi, Qi Qian. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

**Background:** The interplay between magnesium and calcium is complex and crucially influences calcium homeostasis. We describe a unique case of secondary hyperparathyroidism associated with combined use of PPI and IV magnesium.

**Methods:** 49-year old woman with ulcerative colitis that required total colectomy and ileostomy was diagnosed with severe magnesium deficiency. Her initial magnesium level was near 0 mg/dL. Oral magnesium was started, but due to intolerance, it was switched to IV magnesium sulfate. The dose was titrated up to 4 grams of magnesium sulfate twice weekly. This was continued for almost a year, but her blood magnesium level remained low between 1.0 to 1.2 mg/dL. She remained quite weak and unable to work. The patient was then referred to our clinic. Her examination revealed a magnesium IV pump imbedded subcutaneously in the mid-abdomen, and a colostomy bag in the right lower quadrant. Labs revealed a creatinine of 0.7 mg/dL (ref. 0.6-1.1), Calcium of 10.7 mg/dL (ref. 8.9-10.1), and magnesium of 1.5 mg/dL (ref. 1.7-2.3). PTH was 105 pg/ml (ref. 15-65). A parathyroid scan showed two foci of increased sestamibi radiotracer uptake suspicious for adenomas. Her urine calcium excretion was normal. The patient's IV magnesium was stopped, and she was converted to an oral magnesium regimen. Oral PPI was discontinued as it likely had interfered with magnesium absorption from the GI tract. Her magnesium normalized to 1.7-2.0 mg/dL. Her PTH normalized as well (as per her local MD records) and a repeat scan one year later showed stable appearance.

**Conclusions:** We present here an unusual case of severe hypomagnesemia that's likely caused by oral PPI intake, and secondary hyperparathyroidism likely triggered by repeat IV magnesium. We hypothesize that severe hypomagnesemia diminishes PTH secretion. However, episodic IV magnesium infusions release the block on PTH secretion. Repeated parathyroid stimulation by high magnesium levels results in secondary hyperparathyroidism. This case cautions us to avoid using chronic IV magnesium as a treatment for total body magnesium depletion as it would not restore magnesium homeostasis, and can induce abnormalities in the PTH-Ca axis.

## FR-PO1101

**Normocalcemic Hyperparathyroidism Presenting with Multiple Brown Tumors Mimicking Malignancy in a Kidney Transplant Recipient** Shuang Ying Bao,[1] Alan Mark Weinstein,[1] Sheron Latcha,[1,2] Ilya Glezerman.[1,2] *[1]Dept of Nephrology and Hypertension, Weil Cornell Medical College, New York, NY; [2]Dept of Nephrology, Memorial Sloan-Kettering Cancer Center, New York, NY.*

**Background:** Although secondary hyperparathyroidism is common in dialysis patients, it resolves after renal transplantation in parallel with improvement in renal function. Some patients develop tertiary hyperparathyroidism and hypercalcemia which persists even after the transplantation. We present a case of normocalcemic hyperparathyroidism in a transplant patient.

**Methods:** Case Description: 36 years old female patient with history of renal transplant in 2005 presented with left arm pain. Plain X-ray showed 7 cm area of lytic bone lesion. PET scan showed multiple bone lesions involving cervical and lumbar spine, humerus, femoral neck, iliac and clavicle bone. Patient underwent fixation of the left humerus and right hip hemiarthroplasty. Bone biopsy showed giant cell rich lesion consistent with brown tumor. Parathyroid hormone (PTH) was 1947 pg/ml (12-88), serum creatinine 1.3 mg/dl (0.6-1.3), ionized calcium 4.7 mg/dl (4.8-5.3), Phos 2.9 mg/dl (2.4-4.7). Review of labs showed that patient's calcium and phosphate levels have been normal since the transplantation. No data prior to the transplantation was available for review. Thyroid ultrasound and parathyroid nuclear scan revealed possible left parathyroid adenoma.

**Conclusions:** Brown tumor is a rare manifestation of tertiary hyperparathyroidism in kidney transplant recipients and is associated with hypercalcemia. Our case shows that the calcium level may be normal in that setting. It is prudent to obtain baseline PTH level in all transplant patients to screen for hyperparathyroidism.

## FR-PO1102

**Brown Tumor: A Serious Complication of an Old Disease** Rodrigo Amblard Wanderley, Márcia Avelino, Jose Edevanilson Gueiros, Ana Paula Gueiros. *Nephrology Div, IMIP, Recife, Pernambuco, Brazil.*

**Background:** Brown Tumor (BT) is a serious consequence of secondary hyperparathyroidism (SHPT). The majority of cases report the maxilla and mandible as the main sites of occurrence. Symptoms result from considerable dimensions of the tumor and its localization. When BT involves the face and has progressive growth, it may cause severe deformities, discomfort, and alteration of the masticatory apparatus.

**Methods:** The objective of this study was to describe the case of a patient with BT in the face provoked by severe SHPT. Case: Patient of 32 years, male and on hemodialysis for 10 years. He has developed in six months a tumor located in the fast growing region of the face, affecting the palate. The lesion expanded so severely that destroyed the entire base of the nose, prevented the closure of the mouth and dramatically reduced the space between the palate and tongue. As a result, the patient presented with difficulty breathing and swallowing and also reported intense and generalized bone pain, muscle weakness, loss of height, and weight loss. Patient reported unsuccessful attempts SHPT treatment with calcitriol and sevelamer. Laboratory tests evidenced iPTH 2527pg/mL, calcium 8.1 mg/dL, phosphorus 4.0 mg/dL, alkaline phosphatase 2024 IU/L, 25OH vitamin D 58.9 pg/mL and hemoglobin 5.2 g%. The CT scan demonstrated change in bone volume and texture, highlighting a greater impairment of mandible and maxillary bones, identifying numerous erosions linear aspect, characterized as an aspect known as uremic bone leonine facies. On June 12, 2012, patient underwent parathyroidectomy (PTX) with full self-implantation. Improvement of bone pain, in addition to decreased tumor mass in the face, allowing him to better breathing and swallowing. One year after PTX, patients had weight gain of 13 pounds and his iPTH was 81pgmL.

**Conclusions:** BT represent a serious presentation of cystic fibrosis osteitis caused by SHPT. Although benign, can grow aggressively, causing destructive lesions and morbidity. Surgical PTX is the most adequate therapeutic approach in patients with unsatisfactory response to medical treatment.

## FR-PO1103

**Multiple Bone Lesions in Cinacalcet Era. A Case Report** Natacha Rodrigues,[1] Estela Nogueira,[1] Maria Alice Gonçalves Fortes,[1] Tiago Rodrigues,[3] Antonio Gomes da Costa,[1] Andre L. Weigert,[2] Sofia C.A. Jorge.[1] *[1]Nephrology, CHLN, Portugal; [2]Nephrology, CHLO, Portugal; [3]Radiology, CHLN, Portugal.*

**Background:** Chronic Kidney Disease (CKD) commonly evolves with disturbances in mineral and bone metabolism, currently defined as Chronic Kidney Disease - mineral and bone disorder (CKD-MBD). Although, management strategies have changed and progressed along the years, our knowledge is still sparse and consensus in treatment has not been achieved. Severe complications of high turnover bone disease have been significantly reduced after the emergence of calcimimetic agents. Nevertheless, sporadic cases of brown tumors in patients with controlled hyperparathyroidism have been reported in the literature. They result from increased osteoclast activity and if left untread can have disastrous consequences.

**Methods:** The authors describe a case of a 42-years-old female, undergoing hemodialysis in the last 13 years, that developed a scull lesion that was submitted to surgery and several weeks later was admitted in the hospital with severe low back pain with radiation to the left limb. CT scan revealed several lytic lesions in the jaw, dorsal vertebrae, right acetabulum, pubis and ilium (with extraosseous component of 7,5 cm) and full body X ray demonstrated lesions in the right metacarpal bones.

A biopsy of the iliac bone was compatible with brown tumor. Retrospectively, PTH levels in the last 6 months were 300 to 600 ng/l, under treatment with vitamin D analogs and cinacalcet.The gravity of this case, with multiple bone lesions, severe pain and possible neurologic impairment lead to the decision to parathyroidectomy. Following the intervention, bone pain disappeared and the lesions regressed.

**Conclusions:** This case enphasizes the importance of considering brown tumors when approaching a CKD patient with bone lesions even if PTH levels appear fairly controlled. Treatment generally requires parathyroidectomy.

## FR-PO1104

**The Formation Process of "White Kidney" in a Patient with Late Onset Primary Hyperoxaluria Type I** Emiko Kono, Junichiro J. Kazama, Michihiro Hosojima, Ichiei Narita. *Clinical Nephrology and Rheumatology, Niigata Univ, Niigata, Japan.*

**Background:** Primary hyperoxaluria type I (PHO-I) is a peroxisome disease in which glyoxlate metabolism is congenitally impaired. A characteristic whole kidney calcification called "white kidney" is seen in its advanced stage, while its formation process remains obscure.

**Methods:** A 62-year-old man with no particular personal or family medical histories visited Niigata University Medical and Dental Hospital complaining of fatigue. Although he had received regular medical check up every year, kidney dysfunction was not detected. Fever persisted for 1 week, and thereafter his appetite decreased for 2 months untill his visit. His serum urea nitrogen level was 52 mg/dl and the creatinine level was 7.39 mg/dl. The first abdominal computed tomography displayed a thin faint calcified lesion at the cortico-medullary border of bilateral swollen kidneys. Biopsied kidney tissue demonstrated scattered intratubular crystal depositions around the cortico-medullary border. Both the serine/pyruvate aminotransferase and the serine/glyoxylate aminotransferase activities in his biopsied liver samples were below detectable levels. He was initiated into a maintenance hemodialysis therapy. The second abdominal CT was performed 4 months later. The thickness and intensity of the cortico-medullary border calcification increased, and the 3-dimensional image reconstruction revealed the extension of the calcified lesion to renal columns. The third abdominal CT scan was performed 1 year later. Bilateral whole kidney cortex was calcified, which showed a typical "white kidney" appearance. A 3-dimensional image revealed that neither renal papillae nor renal pelvises were calcified even at this disease stage.

**Conclusions:** Most cases of late onset PHO-I have clinical episodes that would cause acute kidney injury before its onset. The cortico-medullary border is the most sensitive area to acute kidney injury related ischemia. We concluded that calcium oxalate crystals are initially deposited in the damaged tubular lumen, then calcified deposits extend into the upstream direction, and finally form white kidney.

## FR-PO1105

**Peritoneal Dialysis Peritonitis Associated with Beta Cap Adapters: Quality Improvement Project** Pavan Devulapally, Sudhir R. Thaduri, Dumitru Rotaru. *Dept of Nephrology, Univ Arakansas for Medical Sciences, Little Rock.*

**Background:** Puncture holes and catheter disconnection of the PD catheter is an uncommon occurrence.

**Methods:** Between Dec 2012 and Apr 2013 we identified 7 patients in our Davita PD clinic with puncture holes at the junction of PD catheter and the proximal end of the Beta cap adapter. 1 patient also had an episode of disconnection of the transfer set from the distal end of the adapter. As a consequence PD peritonitis occurred in 2 patients associated with puncture hole events and in the patient with the disconnection. 2 patients needed hospitalization and 1 attended the ER.One of the catheters was removed due to relapsed PD peritonitis.

| Patient | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
|---|---|---|---|---|---|---|---|
| Puncture hole | Dec 1 | Feb 1 | Feb 19 | Mar 19 | Mar 20 | Mar 22 | Apr 19 |
| Disconnection | | | Mar 20 | | | | |
| Peritonitis | MSSE Dec2<br>MRSE Dec 28 | | Pepto streptococcus | MSSE | | | |
| Catheter removed | Yes | | | | | | |
| Hospitalised | Yes | | ER visit | | | Yes | |

All events were seen in 35 DaVita PD clinic patients using the beta cap adapters. No events were found in our 27 VA PD clinic patients where the titanium adapters are used.

**Results:** A similar experience with catheter holes associated with beta cap adapters was reported in 2012. These authors felt that these events were related to a recent change in the design of the proximal end of adapter from a rounded edge to a sharper edge. We also found an FDA class II recall in 2011 and an ECRI alert in 2012 both reporting a reduction in thread engagement which may lead to a risk of separation of transfer set from the distal end of the adapters.

**Conclusions:** We undertook a QI project with goals to decrease the risk of PD peritonitis, improve quality of patient care in our clinic and increase the awareness of this complication. We reported our findings to the UHC Patient Safety Net, DaVita Dialysis management, company representative and at our QA Faculty Meeting. Based on the experience with the titanium adapter in our VA PD clinic and also from previous literature reports we decided to use the titanium adapters for all new and existing PD catheters in our clinic.

## FR-PO1106

**Continuous Renal Replacement Therapy (CRRT) in Times of Calcium Shortage, Do We Have Options?** Nitin Relia, Yusra R. Cheema, Rupal Mehta, Cybele Ghossein. *Div of Nephrology and Hypertension, Northwestern Univ, Chicago, IL.*

**Background:** The use of citrate as regional anticoagulation in patients on continuous renal replacement therapy (CRRT) requires IV calcium to maintain therapeutic systemic ionized calcium levels. The shortage of IV calcium has limited the use of citrate. We present a case of a patient on CRRT managed with the use of citrate and only commercially available calcium containing replacement solution.

**Methods:** The patient is an 80 year old male admitted to the Surgical Intensive Care Unit for repair of a leaking abdominal aortic aneurysm. Postoperatively, he developed Acute Kidney Injury (AKI) necessitating CRRT. Continuous Veno Venous Hemofiltration (CVVH) was initiated on Prismaflex machine using a HF 1400 filter but was limited by multiple clotting episodes. Citrate, in the form of Acid Citrate Dextrose (ACD), was initiated as an anticoagulant at a rate of 300 ml/hr pre-filter and rates adjusted in units of 10 ml/hr to target circuit ionized calcium of 0.25-0.35 mmol/L. The blood flow rate was set at 200 ml/hr and post-filter replacement solution containing 3.5 mEq/L of calcium chloride was started at a rate of 2L/hr giving a total of 3.5 mmol of calcium/hr.

Figure 1

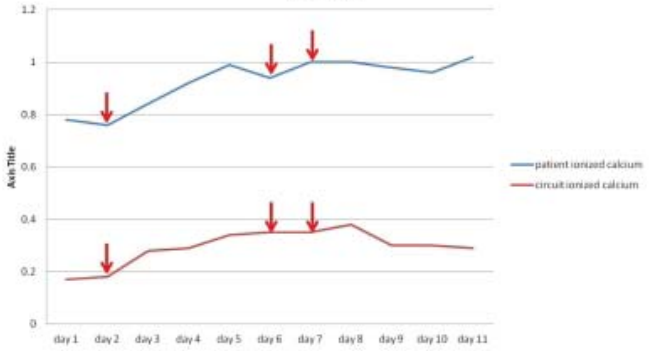


Figure 1 shows the trends of ionized calcium of the patient and circuit over the next 11 days. The post filter replacement fluid was adjusted/increased at marked time points (arrows in figure 1) to achieve near therapeutic serum ionized calcium levels (0.9-1.0 mmol/L). CVVH was able to run for next 11 days without further episodes of clotting.

**Conclusions:** We present a protocol for the use of citrate for anti coagulation in CRRT without the need of separate IV calcium drip but with the use of calcium containing replacement fluid.

**FR-PO1107**

**Peritoneal Fibrosis Caused by Short-Term Peritoneal Dialysis** Leslie J. Padrnos,[1] Nirav Patel,[1] Maxwell L. Smith,[2] Leslie F. Thomas.[3] *[1]Internal Medicine Residency, Mayo Clinic Arizona, Phoenix, AZ; [2]Div of Laboratory Medicine & Pathology, Mayo Clinic Arizona, Scottsdale, AZ; [3]Div of Nephrology & Hypertension, Mayo Clinic Arizona, Phoenix, AZ.*

**Background:** Complex changes to the peritoneum have been described in patients treated with peritoneal dialysis (PD). A rare complication of PD is encapsulating peritoneal sclerosis (EPS), which may lead to bowel obstruction due to a progressive fibrosis of peritoneal tissue. Previously described cases of EPS typically occurred after years of treatment with PD.

**Methods:** A 40-year-old woman with a three month history of PD use was hospitalized with a one month history of progressive anorexia, nausea, vomiting, and epigastric pain. The patient was found to have resolving esophagitis on endoscopy and discharged. She was hospitalized one month later with a similar presentation and PD was stopped. Six months later, she was hospitalized with severe malnutrition. She demonstrated ascites which eventually was attributed to her severe hypoproteinemia. Tube feeds were attempted, but they were not tolerated. A small bowl follow-thru was normal. Trials of anti-emetics and pro-kinetics were unsuccessful. After 30 days of multiple studies and therapeutic interventions, an exploratory laparoscopy was performed. The appearance of the organs and peritoneum was normal. Peritoneal biopsy showed marked fibrohistiocytic thickening with scattered hemosiderin laden macrophages and reactive mesothelial cells. IgG4 staining was negative. Overall, the histologic changes were strikingly similar to those found in EPS. The patient was treated with prednisone 50 mg daily for 12 weeks and tapered off over the next 12 weeks with a prolonged improvement in symptoms.

**Conclusions:** Symptomatic peritoneal fibrosis is typically associated with PD after several years of therapy. We now demonstrate similar changes in a patient who received PD for four months. Glucocorticoid therapy led to a swift resolution of her symptoms, which had previously been resistant to multiple other treatments.

**FR-PO1108**

**Initiation of Peritoneal Dialysis in a Patient with Liver Disease and Refractory Ascites** Satyam Arora, Oleg Grapp, Alden Michael Doyle. *Dept of Medicine, Div of Nephrology, Drexel Univ College of Medicine, Philadelphia, PA.*

**Background:** Patients with end-stage liver disease (ESLD) complicated by refractory ascites often have concomitant ESKD. The dialysis modality of choice has been difficult to determine for these patients. Hemodialysis is more commonly employed but is challenging because of intradialytic hypotension that limits ultrafiltration, a difficult to assess dry weight because of fluctuating amounts of ascites, and the requirement for a salt restrictive diet in a population of patients who are often nutritionally compromised. PD can be advantageous in this situation because of slow continuous UF and direct removal of ascitic fluid. There are several non-randomized case-control studies showing similar outcomes in patients receiving HD vs. PD but despite these, there remains reluctance to recommend PD because of fears about infection.

**Methods:** We report a 55 year old male with a past medical history of hepatitis C cirrhosis s/p an orthotopic liver transplant in 2005 with recurrent HCV and allograft cirrhosis, Stage V CKD secondary to HRS, CMML, and HTN. Patient was suffering from refractory ascites being managed with intensive diuretics combined with weekly paracentesis requiring pre-procedure platelet transfusions. Dialysis was recommended when the patient developed signs of uremia and became 20 lbs over his dry weight despite diuretics and salt restriction. A PD catheter was inserted laparoscopically without complications. Over the following 4 months, the patient has not had peritonitis, no episodes of bleeding, and required no additional platelet transfusions. He has been able to maintain his dry weight without a salt restrictive diet or paracentesis and has not been hospitalized. His RR KT/V was 1.76 and KT/V PD was 0.91 with a total KT/V of 2.67. He required a total of 20 L, 1.5% 6 L bags with 2 L prime, and 3 exchanges nightly on a cycler.

**Conclusions:** Our case highlights a successful outcome of initiating PD in a patient with ESLD-associated ascites and concomitant ESKD. We suggest that PD is not only safe but offers marked advantages for the patient's wellbeing when compared with the use of HD in this challenging population of patients.

**FR-PO1109**

**Hemodialysis in a Patient with Eisenmenger's Syndrome** Akinwande A. Akinfolarin,[1] Anitra W. Romfh,[2] Dirk M. Hentschel,[1] Finnian R. McCausland.[1] *[1]Renal Div, Brigham & Women's Hospital; [2]Dept of Cardiology, Children's Hospital, Boston.*

**Background:** Adults with cyanotic congenital heart disease (CCHD) present a unique set of challenges for hemodialysis. We present a patient with unrepaired patent ductus arteriosus (PDA), hypoplastic right lung and resultant Eisenmenger's syndrome referred for dialysis initiation.

**Methods:** A 49yo woman with CCHD and Eisenmenger's syndrome experienced progressive proteinuric kidney disease, presumed secondary to chronic glomerulosclerosis. Her baseline $O_2$ saturations displayed differential cyanosis, with upper extremities in the low 90's and lower extremities in the 70-80's. A left radial-cephalic autogenous access was created nine months prior without change in symptoms. Significant laboratory values included a creatinine of 4.7 mg/dL, albumin of 2.3 g/dL and hemoglobin of 23.4 g/dL. At the end of her first session (Qb 200mL/min, Qd 300mL/min, F160 membrane, no UF) she experienced increasing dyspnea and a decline in upper extremity $O_2$ sats, requiring initiation of non-invasive support. These changes were felt to be due to a hemodialysis-induced decline in systemic vascular resistance, resulting in increased right-to-left shunting and decline in systemic oxygenation. Her subsequent treatments were notable for high trans-membrane pressures, thought to be related to hyperviscosity. She clotted several filters and thus auto-phlebotomized to a hemoglobin of 20.1 g/dL. These concerns necessitated manipulations in the dialysis prescription: 1) saline infusion pre-filter with UF post-filter in an effort to dilute blood and prevent clotting; 2) slower titration in Qb, Qd and session length; 3) heparin to minimize filter clotting; 4) close attention to hemoglobin goals (iron repletion as needed; avoidance of EPO where possible; but higher target hemoglobin in setting of chronic erythrocytosis).

**Conclusions:** Hemodialysis in patients with CCHD presents several challenges. Close attention must be paid to volume status, hemodynamics, target hemoglobin, residual renal function and nutritional status. In our case we successfully manipulated the hemodialysis prescription to minimize hemodynamic perturbations and clotting.

**FR-PO1110**

**Treatment of Life Threatening Hyperkalemia with Peritoneal Dialysis. A Slower but Effective Option** D.A. Roseman, Jasvinder S. Bhatia. *Renal Section, Boston Univ Medical Center, Boston, MA.*

**Background:** Life threatening hyperkalemia is an uncommon scenario in maintenance peritoneal dialysis (PD) and because potassium clearance rates are significantly lower in PD compared to hemodialysis (HD), its use for this condition is generally discouraged. There is limited data regarding the use of PD for patients at imminent risk of death due to hyperkalemia.

**Methods:** A 48 year old man with history of hypertension, anuria and ESRD on automated peritoneal dialysis for five years presented directly to the emergency department (ED) with two days of weakness and non-productive cough after returning from a two week Caribbean vacation. The patient had discontinued dialysis for one week prior to presentation due to a perceived lack of sterility in the PD unit and fear of infection. On presentation, the patient was conversant, hypertensive, tachycardic, and hypoxic. His respiratory rate progressively increased with associated lethargy requiring non-invasive mechanical ventilation. An EKG showed sinus tachycardia with loss of p-waves and early peaked T-waves that quickly deteriorated into a wide complex tachycardia. Laboratory values showed Na 140 mmol/L, K 8.1 mmol/L, Cl 103 mmol/L, CO2 13.2 mmol/L, BUN 179 mg/dL, and creatinine 31.86 mg/dL. The patient was given calcium gluconate, insulin, dextrose, sodium bicarbonate, and albuterol. A manual PD exchange was initiated in the ED and the patient was transferred to the intensive care unit where he subsequently underwent manual 2 liter exchanges every 2 hours. After 10 hours serum potassium decreased to 6.6 mmol/L and by 16 hours was 5.4 mmol/L with no concerning events on telemetry. Exchanges were then extended to every 4 hours. The patient was discharged 3 days after admission with complete resolution of hyperkalemia.

**Conclusions:** This case illustrates that PD, when combined with standard medical therapy, can be an effective treatment modality for life-threatening hyperkalemia if initiated quickly by experienced staff. The slower potassium clearance rates of PD compared to HD should not limit its consideration. This may be particularly relevant for patients with indwelling PD catheters and centers with limited or delayed resources.

**FR-PO1111**

**Severe Mycobacterium Fortuitum Infection due to Inappropriate Exit-Site Care by Using Mountain Spring Water in a Patient Undergoing Continuous Ambulatory Peritoneal Dialysis** Yasuhiro Yoshimura,[1] Yoshikazu Miyasato,[2] Masataka Adachi,[2] Yasuyuki Fujie,[2] Naoki Shiraishi,[2] Kenichiro Kitamura.[2] *[1]Dept of Nephrology, Arao Municipal Hospital, Arao, Japan; [2]Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.*

**Background:** Exit-site infections are common complications among peritoneal dialysis (PD) patients. Nontuberculous mycobacterium (NTM) species which are usually derived from environmental sources account for less than 1% of exit-site infections. These organisms are more resistant to the antimicrobial agents that are typically used as an initial therapy for the exit-site infections and they often cause the loss of PD catheter and the interruption of PD. Here, we report a case of severe Mycobacterium fortuitum exit-site infection due to the inappropriate exit-site care by using mountain spring water.

**Methods:** A 54-year-old woman with end-stage kidney disease due to IgA nephropathy had been treated with continuous ambulatory peritoneal dialysis (CAPD) for 3 years when she presented with purulent discharge from the exit-site. Although we introduced the standard exit-site care procedure by using normal saline as a cleaning solution, she had been using mountain spring water for 1 year. M.fortuitum grew on the culture of the purulent discharge. Acid-fast staining of the mountain spring water revealed acid-fast bacilli (Gaffky 2) and M.fortuitum was confirmed by the sequencing of 16S rRNA. Then, she was treated with oral levofloxacin and clarithromycin. However, since the exit-site infection was not improved during the 6 weeks course of therapy, her PD catheter was removed and her dialysis modality was switched to hemodialysis.

**Conclusions:** Diagnosis of NTM species should be considered in PD patients with exit-site infections that are refractory to initial antimicrobial therapy. To our knowledge, this is the first report demonstrating that mountain spring water was responsible for the source of M.fortuitum exit-site infection. Routine evaluation and repeated education of the exit-site care would have prevented the M.fortuitum exit-site infection and the additional catheter surgery.

**FR-PO1112**

**A Case Report of *Staphylococcus aureus* Non-Valvular Endocarditis in a Chronic Hemodialysis Patient** Jennifer C. Rodrigues,[1] Paul E. Barre,[1] Richard Fraser,[2] Ahsan Alam.[1] *[1]Div of Nephrology, McGill Univ, Montreal, Canada; [2]Pathology, McGill Univ, Montreal, Canada.*

**Background:** Staphylococcus aureus bacteremia is a common infectious complication of central venous catheter (CVC) access. Non-valvular endocarditis occurs infrequently and may be an under recognized issue in hemodialysis. Here we present a case of right papillary muscle endocarditis diagnosed at autopsy in a hemodialysis patient treated for S. aureus sepsis.

**Methods:** A 54-year-old man was on chronic hemodialysis via a tunneled CVC. His ESRD was from reflux nephropathy and he had a failed kidney transplant. He was also known for congestive heart failure, chronic obstructive pulmonary disease, and bilateral below knee amputations secondary to thromboangiitis obliterans. He presented with progressive dyspnea, cough, nausea, vomiting, and diarrhea. He presented with a fever of 101.3ºF, bibasilar crackles, and an elevated jugular venous pressure. He did not have any stigmata of endocarditis. His CVC had been changed three months prior. His chest x-ray showed mild pulmonary edema, and thus was treated with moxifloxacin, inhaled bronchodilators, intravenous steroids, and additional dialysis treatments. Due to a lack of improvement within 48 hours, broad-spectrum antibiotics (piperacillin-tazobactam and vancomycin) were initiated. Blood cultures returned positive for S. aureus in four of four bottles. The patient subsequently deteriorated and died 2 days later with multi-organ failure secondary to sepsis. An echocardiogram was not performed; however, post mortem demonstrated endocarditis (gram positive cocci) localized to a right ventricular papillary muscle. There was no involvement of the heart valves and, although the CVC was thrombosed, there was no evidence of infection.

**Conclusions:** Non-valvular endocarditis is a rare diagnosis. It has been shown in patients with congenital heart defects, hypertrophic cardiomyopathy, and associated with implantable cardiac defibrillators. This is, to our knowledge, the first report in a hemodialysis patient. Non-valvular endocarditis should be considered in a hemodialysis patient with unexplained sepsis, particularly when a CVC is present.

**FR-PO1113**

**Prolonged Systemic Anticoagulation following Heparin Locking of Tunneled Hemodialysis Catheters** Liliana E. Rios Rojas, Ingrid Calliste, Nobuyuki (Bill) Miyawaki, Shayan Shirazian, Joseph Mattana. *Medicine, Winthrop Univ Hospital, Mineola, NY.*

**Background:** Tunneled hemodialysis catheters (THDCs) continue to be used for hemodialysis (HD). There have been several reports of prolonged activated partial thromboplastin times (aPTTs) following HD in which heparin (H) locking of the THDC is carried out. What has been less well recognized is the danger of prolonged anticoagulation many hours after HD is completed. Here we describe three illustrative cases in which HD patients were found to have markedly prolonged aPTTs hours after THDC H locking was performed.

**Methods:** The first patient was a 68 year old man who underwent THDC locking with a 5,000 U/mL H solution into each lumen. He presented to the emergency department (ED) 8.5 h later with bleeding at the THDC site. His aPTT (repeated) was >200 sec and progressively normalized over the next 24h. The second patient was an 84 year old woman who underwent identical THDC locking with H. She presented to the ED 6 h later after a fall and had an aPTT of >200 sec which normalized over the next 24h. The third patient was a 78 year old woman who underwent HD with one needle placed into an underdeveloped AVF and with one lumen of her THDC used to complete the blood circuit. The THDC was locked with H as above. The patient was seen later in the ED with persistent bleeding from the AVF needle puncture site. Five hours later an aPTT was found to be >200 sec. As in the first two patients the aPTT also progressively normalized. In all cases the H lock volume administered was based on the volume printed on the THDC by the manufacturer. The H locking solution was subsequently decreased to 1,000 U/mL and no further bleeding episodes occurred.

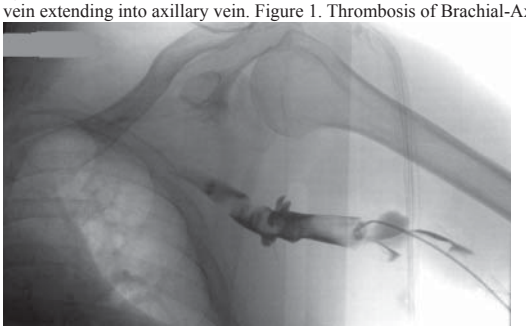
**Conclusions:** HD patients who undergo H locking may be fully anticoagulated hours after HD is completed and this may be due to ongoing diffusion of H from the THDC lumens. Among the many hazards this creates is the risk for bleeding in invasive procedures, a risk which may be unknown to the physician performing the procedure. Greater awareness of this danger might lead to strategies to help prevent the development of hemorrhagic events and enhance the safety of procedures in these patients.

**FR-PO1114**

**Fatal Pulmory Embolism after Hemodialysis Vascular Access Declotting** Maryam Sharif-Hassanabadi, Seyed-ali Sadjadi. *Nephrology, Jerry L Pettis VA Medical Center, Loma Linda, CA.*

**Background:** Thrombosis and failure to maturation are the common causes of vascular access failure. Thrombosis usually occurs because of anatomical problems of the access, trauma or sometimes infection. It can be treated by declotting that is usually uneventful. Herein we present a case of access thrombectomy that was complicated by pulmonary embolism(PE).

**Methods:** 59 years old male with history of diabetes, Hypertension, coronary artery disease, hyperlipidemia, hepatitis C and end stage renal disease on hemodialysis for 5 years presented with a clotted left upper extremity arteriovenous graft(AVG). He had multiple dialysis access placements; the most recent a brachial-axillary graft fistula created 2 years ago and clotted 3 times since its creation. Ultrasound confirmed thrombosis in the outflow vein extending into axillary vein. Figure 1. Thrombosis of Brachial-Axillary AVG.



Mechanical thrombectomy was performed by an experienced interventional radiologist who had performed all previous successful thrombectomies. With Heparin injection, balloon angioplasty was performed and rotational thrombectomy device was used. During the same session a tight arterial narrowing was also treated with balloon angioplasty. Shortly after flow restoration, the patient complained of chest pain, developed dyspnea and hypoxemia that deteriorated rapidly culminating in. Resuscitation was unsuccessful and he expired. Postmortem examination showed extensive PE.

**Conclusions:** Access thrombosis is frequently associated with subclinical PE that is usually inconsequential but occasionally it may be fatal. In cases of access clotting with extension to the central vein, it is advisable to forego the existing access and use a central vein catheter or a new access to dialyze the patient.

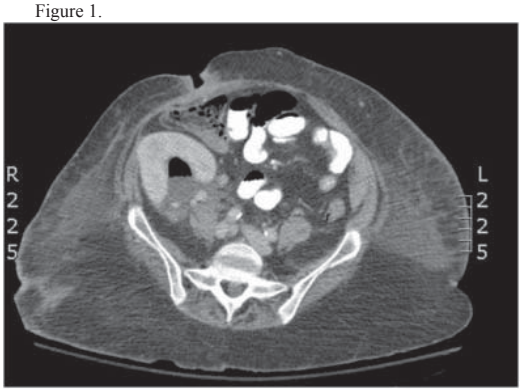
**FR-PO1115**

**Transplant Nephrectomy due to Persistent Bacteremia** Maryam Sharif- Hassanabadi, Alfred C. Cottrell. *Nephrology, Loma Linda Univ Medical Center, Loma Linda, CA.*

**Background:** Bacteremia after kidney transplant is a significant cause of morbidity and mortality. Here we report a complicated case of early post-transplant infection.

**Methods:** A 57 years old female with history of diabetes, hypertension, breast cancer and end stage renal disease on hemodialysis for 11 years was admitted for deceased donor renal transplant. She received Cefazolin as surgical prophylaxis. During the surgery, urinary bladder was found to be small with friable mucosa, making implantation of ureter difficult with ureteral stent placed. On post-op day 3 she developed fever and all cultures grew multidrug resistant Enterobacter Aerogenes(sensitive to Imipenem). Despite Meropenem, she developed necrotizing fasciitis of the right flank, for which she required agressive tissue debridement and a wound vac. Wound, urine and blood cultures grew the same organism. 3 weeks after transplant she was discharged with excellent graft function and apparent resolution of infection. 12 weeks after transplant she was readmitted with fever and persistent bacteremia with the same organism and sensitivities. Abdominal CT angiogram revealed infected pseudoaneurysm of the transplant renal artery anastomosis (Figure 1).

Figure 1.



The fully functional kidney was removed to allow vascular repair of the large mycotic aneurysm as there was no safe way to salvage the transplant organ. The likely initial source of infection was the friable bladder colonized with organisms resistant to Cefazolin. Early bacteremia at the time of transplant, failure of initial antibiotics to cover the organism and immunosuppression led to the aneurysm.

**Conclusions:** Anuric patients can have low level bladder infections and may harbor organisms with multidrug resistance. In certain instances intraoperative flushing of the bladder with extended spectrum antibiotics or perioperative use of a broad spectrum antibiotic to cover resistant bacteria may be prudent.

## FR-PO1116

**Acute Right Sided Heart Failure as a Complication of AVG Creation in a Dialysis Patient** Mohsen M. Elramah, Ahmed I. Al-Absi, Sarguni Singh, Micah R. Chan. *Nephrology Div, Univ of Wisconsin, Madison, WI.*

**Background:** Heart failure is an important source of mortality in dialysis patients. Predisposing factors that might contribute to pump failure in dialysis patients include high output hemodynamics due to dialysis access including arteriovenous fistulae (AVF) and grafts (AVG). In this case report, we describe a dialysis patient presenting with right sided heart failure and high output cardiac failure precipitated by AVG creation.

**Methods:** Case Description: A 68 year old male dialysis patient with history of hypertension, cardiomyopathy and orthotropic heart transplant presented with new onset hypotension and tachycardia. Few days prior to presentation, he had a new axillary artery to axillary vein AVG creation. Physical examination revealed a blood pressure of 66/40 and a regular pulse rate of 140/minute. Initial work up showed a severely concentric left sided heart with an estimated ejection fraction of 80%. His right ventricular chambers were hypertrophied with severely reduced systolic function . Other diagnostic tests were unremarkable. Trans-sonic flow of the AVG revealed a flow rate of 2.4 L/minute. The patient's hemodynamics improved significantly with bedside manual occlusion of his AVG. AVG fistulogram and ligation of the AVG was done by Interventional Nephrology team. The patient's hemodynamic profile improved significantly and he was discharged with normal vital signs.

**Conclusions:** To our knowledge, this is the first reported case of high cardiac output failure in a patient with AVG with axillary-axillary anastomosis. The exact prevalence of high output failure in dialysis population is unknown; however several factors are associated with an increased risk of fistula-induced high-output cardiacfailure. These include location of the dialysis access (proximalmore than distal), male sex, high blood flow through the fistula. Our patient was considered to be at high risk given his comorbid conditions. This case illustrates the importance of weighing risk factors (particularly proximal location of AV access) when considering placement of AVF/AVG in dialysis patients.

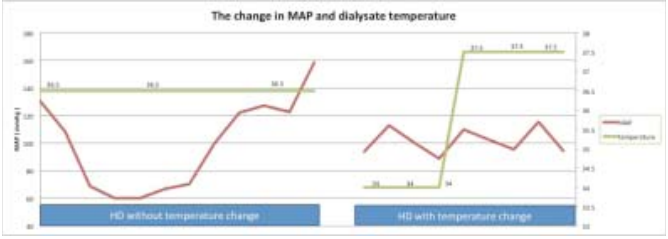
## FR-PO1117

**Dialysate Temperature Adjustment as an Effective Treatment for Baroreflex Failure Syndrome in Hemodialysis Patient** Natsumi Tanabe, Koki Takane, Yudo Tanno, Keitaro Yokoyama, Izumi Yamamoto, Ichiro Ohkido, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan.*

**Background:** Baroreflex failure syndrome is a rare disorder which causes labile blood pressure, headache, flushing, diaphoresis and emotional lability. It is caused by history of trauma or radiotherapy around neck, bilateral carotid-body tumor or section of glossopharyngeal nerve. We experienced a case of hemodialysis patient who had difficulty in controlling blood pressure during hemodialysis because of his baroreflex failure syndrome.

**Methods:** We report a case of a 68-year-old CKD5 patient who had difficulties of hemodialysis treatment because of severe fluctuations in blood pressure with hypertensive attacks or hypotensive episodes which caused him a severe discomfort. His dialysis treatment was started in 2010 and since that time baroreflex failure syndrome has been suspected because of his clinical manifestations and history of radiotherapy around his neck for his cancer of tongue in 1994. Baroreflex failure syndrome is diagnosed by cold stressor test. So we found from the mouse experimental vagotomy model of baroreflex failure syndrome, cold stimulation of mouse tail caused signinficant elevation of blood pressure.From this experimental finding of mouse model, we changed the patients dialysate temperature between 34-38° according to his change in blood pressure through 80-240 mmHg. From this attempt, his blood pressure was successfully controlled between 100-180 mmHg and he was able to continue hemodialysis without any discomfort.

**Conclusions:** In our case, environmental stimulation such as temperature change modified the patients fluctuating blood pressure. Change of dialysate temperature could be an option for controlling the unstable blood pressure due to baroreflex failure syndrome.



## FR-PO1118

**A Rare Case of Upper Gastrointestinal Bleeding in a Hemodialysis Patient** Deepak K. Nandikanti, Saba Farooq, Elvira Gosmanova. *Nephrology, Univ of Tennessee Health Science Center, Memphis, TN.*

**Background:** Upper esophageal varices (UEV), a rare cause of upper gastrointestinal bleeding (UGIB), typically occur with superior vena cava (SVC) obstruction. Here we describe a hemodialysis (HD) patient with UEV resulting from right innominate vein (RIV) occlusion with a patent SVC, complicated by UGIB.

**Methods:** 31-year old male with ESRD on HD via right (R) brachiobasilic AV fistula (AVF) presented with hematemesis and tarry stools for 2 days. He also reported progressive worsening of R upper extremity (RUE), neck and facial swelling. Prior to AVF placement in 2011, he had bilateral internal jugular (IJ) tunneled catheters, but no arm swelling. On exam, BP was 128/80 mmHg. Facial swelling, nasal congestion, and a hoarse voice were present. RUE had pitting edema. AVF had a normal thrill. Multiple collateral veins were noted on R side of the neck and upper chest. His hemoglobin was 9.1g/dL (2 weeks prior it was 11.6g/dL) and stool hemoccult positive. EGD showed downhill UEV but no active bleeding. CT chest showed severe RIV stenosis with extensive R chest wall collaterals, bilateral IJ narrowing but no evidence of intrathoracic masses. SVC appeared patent. RUE venogram confirmed the severe RIV occlusion that was not amenable to recanalization. Facial and arm swelling, nasal congestion and mild stridor were concerning for SVC-like syndrome, related to RIV obstruction in combination with RUE AVF. The blood coming from AVF was likely overwhelming venous return from the RUE and the head, causing blood shunting into right thyroid vein that in turn, led to the development of UEV and UGIB. Since RIV could not be recanalized, the AVF was ligated and the patient was switched to peritoneal dialysis. Complete resolution of stridor, facial, and RUE swelling occurred within 10 day of AVF ligation. No further episodes of UGIB were noted.

**Conclusions:** Development of arm and facial swelling after AVF construction warrants evaluation for central vein stenosis, which untreated can lead to development of UEV. UEV are usually asymptomatic, but can lead to life threatening UGIB. Repair of the stenosis or AVF ligation leads to resolution of both SVC syndrome and UEV.

## FR-PO1119

**Pulmonary Nocardiosis and Pneumocystis Jiroveci Pneumonia: Dual Opportunistic Lung Infection in a Kidney Transplant Recipient** Ekamol Tantisattamo, Ashtar Chami, Stephen O. Pastan. *Renal Div, Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA.*

**Background:** Pulmonary infections are a common complication after kidney transplantation. We report a case of a kidney transplant recipient who presented with a mixed pulmonary infection with both *Nocardia pseudobrasiliensis* and *Pneumocystis jiroveci*.

**Methods: Case Description:** A 60-year-old man with history of ESRD received a deceased donor renal transplant and was treated with tacrolimus, mycophenolate mofetil and prednisone. He presented 1 year post transplantation with a six week history of fever, night sweats and a 14 kg weight loss. For three weeks he complained of dyspnea and fatigue. Serum creatinine was elevated to 3 mg/dL from a baseline of 2.4 mg/dL. Chest x-ray was unremarkable; however, a chest CT scan revealed a 2.8x2.6 cm right lower lobe mass. Initially, he was empirically treated for a fungal infection with amphotericin B and posaconazole. He underwent bronchoscopy with transpbronchial biopsies, but pathology revealed no evidence of malignancy and tissue culture was negative for bacteria and legionella. Acid fast bacilli and fungal smear were also negative. As he continued having fevers and hypoxemia, video-assisted thoracic surgery (VATS) with biopsy was performed and frozen section revealed evidence of granulomatous disease. Gram stain suggested *Nocardia spp.* and trimethoprim/sulfamethoxazole was started. Finally, tissue culture grew *Nocardia pseudobrasiliensis* and pathology revealed *Pneumocystis jiroveci* by GMS stain. He responded well to treatment with trimethoprim/sulfamethoxazole. Tacrolimus and mycophenolate mofetil doses were reduced during the hospitalization, and renal function returned to his baseline.

**Conclusions:** Bacterial infection is the most common cause of pneumonia in kidney transplant recipients, although opportunistic infections are also commonly seen. Immunocompromised patients are also at risk for infection with multiple organisms. Early use of invasive diagnostic measures, such as bronchoscopy or VATS, should be pursued for patients who present with nonspecific symptoms and who do not respond to initial empiric treatment.

## FR-PO1120

**Eculizumab in the Treatment of De Novo Post-Transplant Thrombotic Microangiopathy** Federico Calaf, Juan M. Gonzalez, Wadi N. Suki. *Dept of Internal Medicine, The Methodist Hospital, Houston, TX.*

**Background:** Eculizumab is an anti C5 monoclonal antibody currently approved for the treatment of Paroxysmal Nocturnal Hemoglobinuria and atypical Hemolytic Uremic Syndrome. Experimental data suggests complement activation is involved in Anti Phospholipid Syndrome (APS) pathogenesis, yet the mechanism remains unclear. We added eculizumab as a salvage therapy for treatment of acute de novo allograft thrombotic microangiopathy. Our case suggests that activation of the complement cascade plays a crucial role in graft thrombosis, even though currently there is no complement target therapy approved for APS.

**Methods:** A 42 y/o Caucasian male with history of End Stage Renal disease secondary to Anti Phospholipid Syndrome (APS) and SLE nephritis on hemodialysis for 10 months underwent living related donor renal transplantation. The patient had slow graft function post operatively requiring no dialysis. His immune suppression regimen consisted of

antithymocyte globulin, solumedrol, and mycophenolate. Due to the lack of improvement in renal function, a renal allograft percutaneous biopsy was performed three days post operatively. The biopsy showed thrombotic microangiopathy with disseminated glomerular thrombosis, focal vascular thrombosis and endothelial injury. The c4d stainings were negative. No signs of hemolytic anemia or thrombocytopenia were evident and haptoglobin remained normal. Laboratory data showed a weakly positive antinuclear antibody, elevated anticardiolipin antibodies and undetectable double stranded DNA. C3 and C4 complement levels were low, but had been within normal levels prior to surgery. An ADAMS 13 activity level was unremarkable. On post-operative day 4, eculizumab 900mg IV-weekly infusion was added to his immune suppression regimen. After three weeks, eculizumab was increased to 1200mgIV every other week for five additional doses. The serum creatinine improved from 6.7mg/dL before eculizumab to 3.4mg/dL at the end of the treatment. A repeat kidney biopsy showed tubular atrophy and interstitial fibrosis but no features of acute thrombotic microangiopathy. Seven months after his last eculizumab treatment his serum creatinine is 2.5mg/dl.

## FR-PO1121

**Eculizumab for Treatment of Acute Antibody Mediated Rejection** Manmeet Brar, Youshay Humayun, Iasmina Craici, Kenneth E. Kokko, Steven Wagner. *Internal Medicine Nephrology, Univ of Mississippi Medical Center, Jackson, MS.*

**Background:** Antibody mediated rejection (AMR) complicates about 5% of all kidney transplants. AMR is relatively refractory to treatment and leads to reduced graft survival. Current therapy is often insufficient. Here we present a patient who was successfully treated for AMR with Eculizumab, an inhibitor of the terminal complement cascade.

**Methods:** A 24 year old male with a failed living related donor kidney transplant 6 years ago received a deceased donor SCD transplant with thymoglobulin induction. Pre-transplant PRA was 16% class I and 70% class II, with negative flow and CDC crossmatches. He was discharged on post-operative day 4 with prograf, cellcept, and a prednisone taper; creatinine at discharge was 1.6. He was readmitted after one week with anuria and a creatinine of 5.1. Allograft biopsy showed diffuse 3+ C4d staining and diffuse peritubular capillaritis with luminal neutrophils, consistent with Banff grade II acute antibody mediated rejection (AMR). Donor specific antibodies were detected to A29 (1:16), B45 (1:16), DR4 (1:64), and DR15 (1:64). In addition to solu-medrol, two sessions of plasma exchange, and 4 doses of Bortezomib (1.3 mg/m2), he received a single 900 mg dose of Eculizumab. Urine output returned within 12 hours of Eculizumab infusion, and he was discharged with a creatinine of 2.2. Class I donor specific antibody (DSA) titers fell to 1:4 by 2 weeks post treatment, but class II titers remained unchanged at 1:64. Renal function continues to improve, with a creatinine of 1.15 about 6 months after treatment. To date, there have been no infectious or surgical complications.

**Conclusions:** AMR is often difficult to treat and is associated with a poor prognosis. Therapy with IV immunoglobulin, bortezomib, and plasma exchange is often inadequate. Eculuzimab, a humanized antibody specific for the C5 component of the complement cascade, has been shown to be effective for prevention of antibody mediated rejection in positive crossmatch transplant. Its usefulness in the treatment of AMR remains to be determined. Our case illustrates that Eculizumab may be a useful adjunct to standard therapy in the treatment of acute AMR.

## FR-PO1122

**Alemtuzumab for the Treatment of Acute Humoral Renal Allograft Rejection** Mohit Agarwal, Iasmina Craici, Kenneth E. Kokko, Steven Wagner. *Internal Medicine Nephrology, Univ of Mississippi Medical Center, Jackson, MS.*

**Background:** Alemtuzumab is a recombinant DNA-derived humanized, rat immunoglobulin G1 (IgG1) monoclonal antibody directed against CD52, a cell surface glycoprotein expressed at high levels by T and B lymphocytes. It was originally approved as Campath® in 2001 for B-cell chronic lymphocytic leukemia (B-CLL) but was subsequently withdrawn in 2012 in preparation for relaunch as Lemtrada® for the management of Multiple Sclerosis. It has also found use in kidney transplantation and is increasingly being utilized for induction therapy and for the management of acute cellular rejection (ACR). We report the 1st case series of its use in the management of acute humoral rejection (AHR).

**Methods:** We retrospectively evaluated the efficacy of Alemtuzumab in three patients with biopsy confirmed acute humoral rejection of renal allografts. Two patients also had prominent acute cellular rejection. All patients were on triple maintenance immunosuppression with prednisone, tacrolimus and mycophenolate and were treated with Alemtuzumab 30 mg IV in conjunction with three day course of high dose IV methylprednisolone. All patients exhibited depletion of peripheral lymphocytes. Of the two patients with mixed cellular and humoral rejections, one patient (Grade AHR:II, ACR:IA) had a drop in serum creatinine (sCr) from 3.3 to 1.8 in two weeks and the other patient (Grade AHR:II, ACR:IIA) had a sudden rise in sCr from 2.1 to 2.4 next day followed by a progressive fall to 1.8 over the next week. The third patient had predominantly humoral rejection (Grade AHR:II, ACR:Questionable) with coexisting transplant glomerulitis and chronic transplant glomerulopathy. She exhibited minimal initial response followed by a progressive sustained rise in sCr from 1.8 to 4.8. A repeat biopsy three and half month later again revealed the above, though, this time accompanied by calcineurin inhibitor acute tubular toxicity.

**Conclusions:** Alemtuzumab destroys mature lymphocytes expressing CD52. Our experience suggests that it can be a viable treatment option in the management of acute humoral rejection (AHR) of renal allografts.

## FR-PO1123

**Sirolimus-Induced Diffuse Alveolar Hemorrhage in a Kidney Transplant Recipient** Manpreet Singh, Sandeep Ghai, Moshe Shashar, Steven C. Borkan, Jean M. Francis. *Renal Section, Boston Univ School of Medicine, Boston, MA.*

**Background:** Sirolimus, a mammalian target of rapamycin inhibitor, is commonly used in solid organ transplant recipients. Diffuse alveolar hemorrhage related to sirolimus has been reported in 9 cases in the literature. The case herein describes an additional kidney transplant recipient who developed diffuse alveolar hemorrhage while on sirolimus.

**Methods:** The patient is a 45 year-old Ethiopian female with a past medical history significant for end stage renal disease secondary to uncontrolled hypertension and treated latent tuberculosis. She underwent a cadaveric renal transplant 10 months prior to her admission to our hospital. She received tacrolimus, prednisone and mycophenolate mofetil acid for maintenance immunosuppression. 9 months after kidney transplantation, sirolimus was substituted for tacrolimus due to calcineurin inhibitors toxicity. 4 weeks after the switch, she presented to our hospital with productive cough, fever and hemoptysis. Although clinically stable on admission, 24 hours later, the patient acutely decompensated and required ventilator support. Computed Tomography of her thorax demonstrated bilateral multilobular infiltrates. Bronchoscopy confirmed the presence of diffuse alveolar hemorrhage. Extensive workup was negative for infectious, autoimmune or neoplastic processes. Sirolimus induced diffuse alveolar hemorrhage was the likely etiology. Sirolimus was discontinued on admission and high-dose steroids were administered. The patient developed severe kidney graft failure secondary to acute tubular necrosis that was confirmed by allograft biopsy. She improved clinically on high dose steroids and was successfully weaned off the ventilator, but continued to require dialysis after discharge.

**Conclusions:** We describe a case of sirolimus induced diffuse alveolar hemorrhage in a kidney transplant recipient. Extensive workup to rule out other etiologies, early withdrawal of sirolimus and high dose steroids seem to be effective in the treatment of this near fatal complication. This case substantiates the need for close monitoring of pulmonary symptoms while taking Sirolimus.

## FR-PO1124

**Back to Square One: Graft Irradiation for the Treatment of Kidney Transplant Rejection** Paramveer Singh Saluja, Marwan M. Abu Minshar, Ann Kathleen N. Gamilla-Crudo, Pradeep V. Kadambi. *Internal Medicine, UTMB, Glaveston, TX.*

**Background:** Kidney transplant is the preferred option to treat end stage kidney disease (ESKD). Allograft rejection continues to be a major cause of transplant failure in spite of ongoing advancement in immunosuppression (IS). We are presenting a case series of patients who underwent local graft irradiation (RT) for acute allograft rejection refractory to conventional therapies.

**Methods:** A 40 year old male with ESKD due to Membranous Nephropathy received a kidney transplant in 2005. His clinical course within the first year was complicated by 2 episodes of acute cellular rejection (ACR) that led to loss of allograft function, necessitating nephrectomy. He received a second kidney transplant in 2009 with a baseline creatinine of 1.9 mg/dl. Three years after transplant, he developed ACR (Banff 2b) and humoral rejection, and was treated with IVIG, anti-thymocyte globulin (ATG), and steroids. His allograft function continued to worsen (peak creatinine of 4.6 mg/dl) and repeat biopsy 3 weeks later showed persistent Banff 2b ACR. Since he had refractory rejection, he was treated with 4 doses of RT combined with IS. Over 1 month following treatment, his creatinine improved to 1.9 mg/dl. A 50 year old male with ESKD due to DM type 1 received a SPK transplant (CMV D+/R-) in 2012 with new creatinine level of 1.2 mg/dl. Six months after his transplant, he developed CMV Viremia due to non-adherence to valganciclovir. His IS was reduced and valganciclovir was reinitiated. Subsequently, his creatinine rose to 5.0 mg/dl and allograft biopsy revealed ACR (Banff 2b) and humoral rejection. He was treated with IVIG, plasmapheresis, ATG and steroids. His allograft function continued to worsen (peak creatinine level of 6.9 mg/dl) and repeat biopsy 2 weeks later showed persistent ACR (Banff 1b). Further augmentation of IS was not possible because of concomitant CMV infection hence, 5 doses of RT were given and creatinine improved to 2.5 mg/dl.

**Conclusions:** Based on our experience and available literature, patients who have acute rejection refractory to IS or those who have concomitant infection, local radiation of the allograft would be a viable adjunct to the overall management.

## FR-PO1125

**Pulmonary Phaeohyphomycosis Caused by Phaeoacremonium and Dactylaria Constricta in a Renal Transplant Recipient: Successful Treatment with Posaconazole** Saivaralaxmi Monaganti, Carlos Q. Santos, Daniel C. Brennan. *Internal Medicine, Washington Univ School of Medicine, St. Louis, MO.*

**Background:** Phaeoacremonium and Dactylaria are dematiaceous fungi. Over 70 genera and 150 species cause human and animal disease. They are widely distributed in soil, wood and decomposing plant debris and characterized by melanin or melanin-like pigments in their cell wall. Phaeohyphomycosis is a collective term for cutaneous, subcutaneous and systemic disease caused by dematiaceous fungi. It is most frequently an opportunistic infection in immunosuppressed patients, and has been rarely reported to affect organ transplant recipients. The overall mortality rate with skin, soft-tissue or joint infections is 7% and 57% with systemic disease. To our knowledge, this is the first case of pulmonary infection by multiple dematiaceous fungi and only the third reported case of lung infection caused by Phaeoacremonium.

**Methods:** A 49 year old white female, 6 years post-renal transplantation, presented to the transplant clinic with a history of worsening dyspnea, cough and fatigue over 6 months after failure to respond to several courses of antibiotics prescribed by her primary physician. Physical exam was unremarkable. CT of the chest revealed nodular opacities in the right upper lobe. Culture of a fine needle aspiration yielded Phaeoacremonium species. Culture of BAL yielded Dactylaria constricta and a few Mycobacterium avium-intracellulare. The patient was started on posaconazole 200 mg PO QID and her tacrolimus dose was reduced. A repeat CT after 1 month showed improvement. Posaconazole was changed to 400 mg PO BID for 4 months with complete resolution.

**Conclusions:** There is no standard antifungal regimen for Dactylaria or Phaeoacremonium reported in the literature. Posaconazole is the most recently approved triazole with an extended spectrum of activity. Posaconazole was chosen over other azoles because it is well tolerated, has a favorable side effect profile, and low potential of drug interactions with only a moderate interaction with tacrolimus compared to other azoles. Our patient responded well to treatment with no relapse of symptoms during 2.5 years of follow up.

*Funding:* NIDDK Support, Clinical Revenue Support

## FR-PO1126

**The Story of Having Subclavian Venous Catheter and the AV Fistula on Same Side** Mohd. Majid Mohd. Ayyub Momin, Anup Chaudhari, Hemant J. Mehta, Zaheer Amin Virani, Suyash Sharma. *Nephrology, Lilavati Hospital, Mumbai, Maharashtra, India.*

**Background:** The use of subclavian veins (SCV) as hemodialysis vascular access is not recommended. Patients who had SCV catheter in the past can present with a problem years later.

**Methods:** This is the story of a 33 years old man who was initiated on hemodialysis (HD) in the year 2000 through right internal jugular vein (IJV) non-cuffed catheter, for his ESRD due to CTID. Soon, he had left wrist native AV fistula (AVF) and the right IJV catheter was removed after 4 weeks. The left AVF had spontaneous closure after 3 months following an episode of post HD hypotension. He had right SCV non-cuffed HD catheter as right IJV could not be cannulated. He agreed for a second AVF at right wrist, 8 months later. This fistula matured well and his right SCV catheter was removed after 9 months. In 2005, he developed right upper limb (UL) swelling and was diagnosed to have right SCV stenosis. He underwent right SC venoplasty with stenting and the AVF worked well till 2009, when he underwent cadaver renal transplantation. The AVF was not used since 2009. He developed swelling of right UL over past 1 year.

He was detected to have fracture of right SCV stent with obstruction. He underwent stent plasty with new covered stent in the SCV. 1 month later, his swelling disappeared, and his right wrist AVF was surgically ligated. Hand returned to near normal shape.

**Conclusions:** SCV HD catheters are associated with high risk of central venous stenosis and hence it is recommended not to use SCV for HD catheters. This patient had a SCV in the era when such recommendation did not exist. Also, stenting of central vein stenosis is not preferred at present. This patient had a stent in the right SCV at a time when it was the usual practice. The stent fractured and led to severe venous congestion of right UL which could have resulted in the loss of right UL.

## FR-PO1127

**De Novo Renal Cell Carcinoma in Renal Graft 22 Years following Cadaveric Transplantation with Atypical Presentation of Refractory Metabolic Acidosis** Zaid Brifkani,[1] Kavita Pal,[2] Raafat Farag Makary,[3] Andreea Poenariu.[1] *[1]Div of Nephrology and Hypertension, Dept of Medicine, Univ of Florida, Jacksonville, Jacksonville, FL; [2]Dept of Medicine, Univ of Florida, Jacksonville, Jacksonville, FL; [3]Pathology and Laboratory Medicine, Univ of Florida, Jacksonville, Jacksonville, FL; [4]Div of Nephrology and Hypertension, Dept of Medicine, Univ of Florida, Jacksonville, Jacksonville, FL.*

**Background:** Post-Transplant graft Renal Cell Carcinoma (RCC) has rarely been reported. The longest post-transplant time at the diagnosis of graft RCC reported has been 13 years.

**Methods:** We present the case of a fifty-two year old African American female who received a cadaveric right kidney transplantation in 1990 secondary to End State Renal Disease (ESRD) from Systemic Lupus Erythematosus (SLE). She had stable chronic allograft dysfunction and was being maintained on Cyclosporine, Mycophenolate Mofetil , in addition to Prednisone. Regular follow up revealed no complaints of gross hematuria or flank pain. Ultrasonography, performed due to refractory metabolic acidosis, revealed a 4.5 cm heterogenous hypoechoic lesion within the midportion of the transplanted allograft with increased vascularity. MRI confirmed the presence of a higly suspicious mass for renal cell carcinoma with no distant metastases. A renal allograft biopsy revealed renal cell carcinoma (RCC), conventional clear cell type. The patient subsequently underwent successful Radical Transplant Nephrectomy and was placed on Hemodialysis.

**Conclusions:** This case demonstrates a rare presentation of allograft RCC 22 years following transplantation with refractory metabolic acidosis. It also highlights the importance of regular close follow up with ultrasonography and the need for more clear guidelines for post-transplant ultrasonographic follow up, especially in cases of long post-transplant period.

## FR-PO1128

**Polyomavirus-Associated Nephropathy: Not Just BK-Virus** Sandra Barrow, Juan M. Gonzalez, Wadi N. Suki. *Internal Medicine/ Nephrology, Methodist Hospital, Houston, TX.*

**Background:** Over the past decade, polyomavirus associated nephropathy (PVAN) emerged as a major cause of allograft dysfunction and graft loss. The vast majority of PVAN is associated with BK virus infection but this case illustrates that other polyomaviridae need to be considered in the differential diagnosis.

**Methods:** A 61 year old man with end stage renal disease received a living nonrelated donor kidney transplant in 2004. He had stable renal allograft function with serum creatinine ranging from 1.9- 2.5 mg/dl. He received maintenance immunosuppressive therapy with prednisone, mycophenolate mofetil and tacrolimus. Eight years after transplantation, his serum creatinine increased to 3.5 mg/dl. Kidney biopsy was performed. Light microscopy revealed several foci of tubular lymphocytic infiltration along with viral nuclear changes. Calbiochem® Anti-SV40 T Antigen stain was strongly positive suggesting a diagnosis of BK virus-associated nephropathy. Surprisingly, BK viral loads measured by PCR assay in the blood and urine remained undetectable. However, a positive Anti-SV40 T Antigen stain may also represent the presence of other human polyomaviruses. Therefore, urinary and serologic samples were analyzed for JC virus (JCV) and PCR assays revealed markedly elevated urinary levels as well as JCV viremia. A diagnosis of JC virus associated nephropathy was established and reduction of immunosuppression was initiated. Additionally, the patient received intravenous immunoglobulin every two weeks. Treatment is currently in progress and creatinine levels have remained stable.

**Conclusions:** BKV, JCV and the monkey virus SV40 belong to the family of polyomaviridae. They share 69-75% of their DNA sequences and immunohistochemical staining using Calbiochem® Anti-SV40 T Antigen does not distinguish between them. JCV associated nephropathy is an exceptionally rare cause of PVAN. Therapy primarily targets a reduction of immunosuppression but successful treatment with immunoglobulins, cidofovir and leflunomide have been reported. Since timely treatment of PVAN is crucial it is important to recognize that a positive Anti-SV40 T Antigen stain in the absence of BKV viremia may represent JCV associated nephropathy.

## FR-PO1129

**Intrarenal Urothelial Carcinoma Staining Positive for BKV Years after Resolution of BKV Nephropathy** Patricia M. Myers-Gurevitch, Darshana Dadhania, Steven Salvatore, Jun B. Lee, Surya V. Seshan. *Nephrology and Hypertension, New York Presbyterian Hospital - Weill Cornell, New York, NY.*

**Background:** Reactivation of BKV is common in renal allograft recipients, placing them at risk for nephropathy and graft loss. Recent literature suggests BKV infection may be associated with certain malignancies. We report a case of intra-graft malignant urothelial carcinoma (UC) associated with positive staining for BKV presenting years after resolution of BK viremia/nephropathy.

**Methods:** A 53 year old sensitized woman received a living unrelated renal transplant following pre-transplant immunomodulation for a positive donor flow cytometry crossmatch. Post-transplant, baseline creatinine (crt) was 1.5mg/dL. 8 months later, her crt rose to 2.2 mg/dL in the setting of high BK viremia. Renal allograft biopsy was positive for BKV associated nephropathy. Immunosuppression was reduced, and repeat was negative for BKV. 7 months later BK viremia cleared and crt normalized. 5 years post-transplant, the patient still free of BK viremia, developed de novo DSA to DR53. Immunosuppression was intensified. 7 years post-transplant, the patient was admitted for gastrointestinal symptoms and rising crt. She underwent a repeat renal biopsy which revealed intratubular UC in situ associated with positive BKV and p53 stain. The benign tubules were negative for BKV. Subsequent transplant nephrectomy revealed microinvasive high grade UC, extensively involving renal tubules, with multifocal lymphatic invasion.

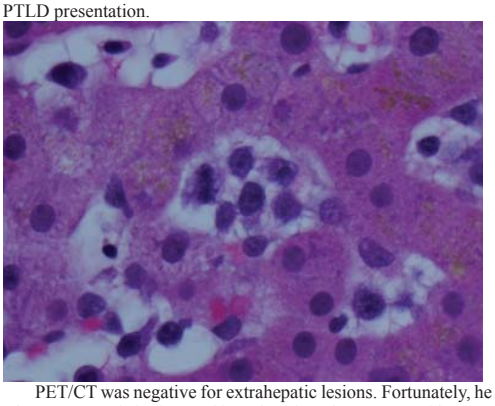
**Conclusions:** Immunosuppression places transplant recipients at higher risk for malignancy. The incidence of UC in this population is low (2%). Most UC arises in the native bladder or ureter, and is very rarely restricted to the allograft. Although there is a known association with BK virus infection and urothelial malignancy, intrarenal UC staining positive for BKV has not been reported. The positive BKV stain within the tumor nuclei may signify incorporation of BKV DNA transcripts into the genome of neoplastic cells. With negative C4d staining and no evidence of antibody mediated rejection, the rising DSA could be an indirect sign of local immune activation to control tumor growth.

## FR-PO1130

**Fever of Unknown Origin in a Renal Transplant Patient** Karl Pembaur, Grant Springman, Joseph Kremer, Blake Nestok. *The Christ Hospital, Cincinnati, OH.*

**Background:** PTLD is a complication following organ transplantation that occurs in 1-2% of patients. Current research has concluded that the degree of immunosuppression along with positive EBV serotype leads to triggering of monoclonal activation of B cells resulting in lymphoma.

**Methods:** A 72 year-old white male was 17 years post living related renal transplantation for Focal Segmental Glomerulosclerosis who presented with 3 weeks of fevers, night sweats, diarrhea, and 15lb weight loss. He had been adherent to immunosuppressive therapy with stable renal function. Review of systems was negative except for persistent dry cough. Vital signs and physical examination were within normal limits. Admission lab results demonstrated elevated bilirubin, alkaline phosphatase, and liver transaminases with stable creatinine. Ultrasound of the RUQ was obtained and revealed calcified hepatic granulomas. Autoimmune biomarkers and infectious serologies were negative. CT of the Chest/Abdomen/Pelvis was negative. A bone marrow biopsy was negative for malignant cells. Due to the persistent elevated liver profile and symptoms a liver biopsy was performed. Histopathology revealed a rare extranodal, EBV negative, large B cell lymphoma as his PTLD presentation.



PET/CT was negative for extrahepatic lesions. Fortunately, he responded to six cycles of R-CHOP and six doses of intrathecal methotrexate and is currently in remission.

**Conclusions:** Despite most PTLD arising within the first year post-operatively, multiple studies demonstrated a bimodal distribution, with a late-onset presentation occurring 5+ years later. Additionally, when comparing early versus late onset PTLD, late-onset PTLD seems to be less associated with seropositive EBV status and more likely to be extranodal than early-onset PTLD. In our case report, the patient presented 17 years post transplant with extranodal PTLD in the liver only and a seronegative EBV status.

## FR-PO1131

**Emphysematous Pyelonephritis in a Renal Allograft** Kashif J. Piracha, Edward P. Nord, Nand K. Wadhwa. *Nephrology & Hypertension, Stony Brook Medicine, Stony Brook, NY.*

**Background:** Emphysematous pyelonephritis (EPN) is a fulminant necrotizing bacterial infection of the kidney caused by gas-forming organisms, which requires prompt evaluation and treatment because of high mortality.

**Methods:** A 58 year old man with ESRD due to diabetic nephropathy received a deceased donor renal allograft in 2007, and presented with a one week history of nausea, vomiting and right lower quadrant abdominal pain. Physical examination revealed a temperature of 37.2°C, BP of 139/69 mmHg and HR of 121 beats/min. His abdominal examination revealed right lower quadrant tenderness over the allograft. Urinalysis was positive for leukocyte esterase and >182 WBC/hpf. He received empiric piperacillin/tazobactam on admission. Over the next 24 hours, the patient developed septic shock with acute respiratory failure requiring intubation and norepinephrine. His urine and blood cultures grew klebsiella pneumoniae. A noncontrast CT scan of the abdomen and pelvis showed heterogeneous gas containing collection in the allograft. Transplant kidney nephrectomy was performed. The gross pathology revealed an acutely inflamed, friable, necrotic, gas filled kidney with extensive hemorrhage with yellow exudates. Microscopic examination revealed acute severe pyelonephritis with abscesses. He postoperatively completed two weeks of antibiotic therapy and was discharged home in stable condition.

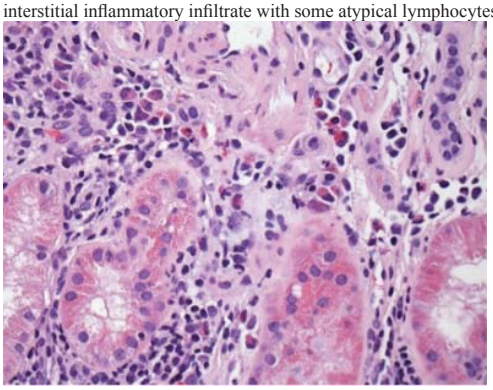
**Conclusions:** EPN is an acute, severe, necrotizing bacterial or fungal infection of the renal parenchyma, collecting system or perinephric tissue. The grade of severity of EPN guides therapy and Al-Geizawi et al have classified EPN of the renal allograft into 3 stages that is determined by the extent of gas collection. Our patient with multi-organ failure and uncontrolled sepsis not responding to medical management falls into the severest category (stage 3) of his classification. Our patient underwent emergent nephrectomy and rapidly improved thereafter. Recognition of the severity of EPN guides therapy.

## FR-PO1132

**Fever and Pancytopenia in Kidney Transplant Recipient-Malignancy Is Always a Possibility** Jie Cui, Francesca Cardarelli, Vanesa Bijol, Martina M. McGrath. *Nephrology Dept, Brigham and Women's Hospital, Boston, MA.*

**Background:** Single or multi-lineage cytopenia is very common in renal transplant patients. While infection and immunosuppression are the most common causes of pancytopenia in transplant recipients, it is crucial to maintain a high suspicion of other relevant etiologies including thrombotic microangiopathy, graft-versus-host disease, autoimmunity and malignancy.

**Methods:** A 33-year-old male with a history of ESRD due to primary FSGS, living unrelated kidney transplant (CMV+/CMV-) 9 years previously, maintained on rapamune and cellcept, presented with a 2-week history of fever and left buccal ulceration. Clinical exam was remarkable for temperature 102F and 1cm induration on the left buccal mucosa. His labs showed creatinine was up to 4.8 mg/dl from baseline 2.4mg/dl, urine protein/creatinine was 1.2, WBC count 2.06/mm$^3$ with 12% neutrophils, Hg 7.8 g/dl, HCT 24% and platelet 54,000/mm$^3$. He was treated with broad-spectrum antimicrobial and anti-viral medications. However, extensive infectious work up including HSV, EBV, CMV, parvovirus, HIV, blood culture and urine culture were negative and he remained intermittently febrile. His AKI failed to resolve with volume resuscitation and subsequent renal biopsy showed marked interstitial inflammatory infiltrate with some atypical lymphocytes.



Bone marrow biopsy showed 25% blasts and flow cytometry was consistent with acute myeloid leukemia. Cytogenetics demonstrated no clonal abnormalities. He was treated with cytarabine and daunorubicin. Bone marrow biopsy on day 29 post chemotherapy showed <5% blasts.

**Conclusions:** Hematological malignancy should be suspected in transplant recipients presenting with pancytopenia, especially in those with long term exposure to immunosuppressive medications. Hematological malignancy is also a rare cause of inflammatory infiltration in a transplanted kidney.

## FR-PO1133

**Recurrent Idiopathic Nodular Glomerulosclerosis after Kidney Transplantation** Mamoun Elsir Bashir,[1] Irfan Warraich,[2] Melvin E. Laski.[1] *[1]Internal Medicine, Texas Tech Univ Health Sciences Center, Lubbock, TX; [2]Pathology, Texas Tech Univ Health Sciences Center, Lubbock, TX.*

**Background:** Idiopathic nodular glomerulosclerosis is a rare condition that closely resembles diabetic nodular glomerulosclerosis but occurs in non-diabetic individuals. It differs from the nodular glomerulosclerosis that develops in fibrillary diseases and membranoproliferative glomerulonephritis by the absence of fibrils or tubular structures on electron microscopy and negative immunofluorescence respectively. The cause of idiopathic glomerulosclerosis remains unknown but it has been associated with tobacco use in some studies.

**Methods:** Patient is 64 year old non-diabetic, non-smoking Caucasian male with history of well controlled hypertension who developed end stage renal disease secondary to idiopathic nodular glomerulosclerosis diagnosed by renal biopsy. The biopsy tissue revealed typical nodular glomerulosclerosis and was negative for amyloid material, and negative for fibrils or other deposits on electron microscopy. The patient underwent deceased donor kidney transplant and did well in regard to his renal transplant with creatinine between 1.0 and 1.1mg/dl and no significant proteinuria. Three years later worsening allograft renal function (creatinine 1.6 mg/dl) and progressive proteinuria (up to 4 gm/d) were noted. Subsequent transplant biopsy diagnosed recurrent idiopathic nodular glomerulosclerosis, and also was negative for amyloid or other fibrillar structures. There was no sign of humoral or cell mediated rejection. The patient remained non-diabetic throughout the pre- and post-transplant course.

**Results:** .

**Conclusions:** The pathology seen in the transplant biopsy duplicated the findings of the native disease in this patient. The disease recurred approximately three years after transplant, which is much more rapid than expected in the case of recurrent diabetic nodular glomerulosclerosis. We believe this to be the first case of recurrent idiopathic glomerulosclerosis post-kidney transplantation. It establishes that the condition can redevelop and that the lag time for recurrence may be shorter than that seen with diabetic nodular glomerulosclerosis.

## FR-PO1134

**Iron Metabolism and Rapamycin (Sirolimus)-Induced Microcytic Anemia in Renal Transplant Patients** Shivani Upadhyay, Joshua Zaritsky, Tomas Ganz. *UCLA.*

**Background:** Sirolimus is a macrocyclic antibiotic, which binds to the FK binding protein and modulates the activity of mTOR (mammalian target of rapamycin). This drug is widely used for preventing rejection of solid organ transplants and graft vs host disease following bone marrow transplantation. A unique feature of sirolimus is that it also induces profound microcytosis, which is poorly understood. Previous studies in renal transplant patients have demonstrated that oral iron supplementation in patients who received sirolimus did not improve their microcytic anemia. However, anemia improved once patients discontinued sirolimus.

**Methods:** First a retrospective chart review of pediatric renal transplant patients was done to determine the prevalence and characteristics of sirolimus-induced anemia. Then a prospective study was designed to evaluate functional iron deficiency in pediatric

and adult patients with solid organ transplants treated with sirolimus. The study design includes evaluation of serum iron, total iron binding capacity, serum hepcidin, ferritin, mean corpuscular hemoglobin concentration, reticulocyte count,hemoglobin content and CRP prior to initiation of sirolimus therapy and at four time points post initiation of therapy.

**Results:** The retrospective chart review of 21 renal transplant patients (10 pediatric, 11 adult) was completed. The hemoglobin and MCV were compared one month prior to the of start of sirolimus and 6 months after. MCV was decreased in sirolimus-treated patients compared to baseline (0.0001, paired t-test). We currently have enrolled 5 pediatric patients in the prospective study showing microcytosis and iron deficiency after the start of sirolimus. The hepcidin appropriately responded to iron deficiency showing decreasing levels from baseline to 2 months after the start of sirolimus. However, they continue to remain iron deficient. Ferritin also is low in these patients.

**Conclusions:** Hepcidin does have appropriate response to iron deficiency in patients on sirolimus. Therefore, sirolimus must work downstream of the hepcidin pathway. There is evidence to suggest that sirolimus does affect the iron pathway, however, it is not through hepcidin.

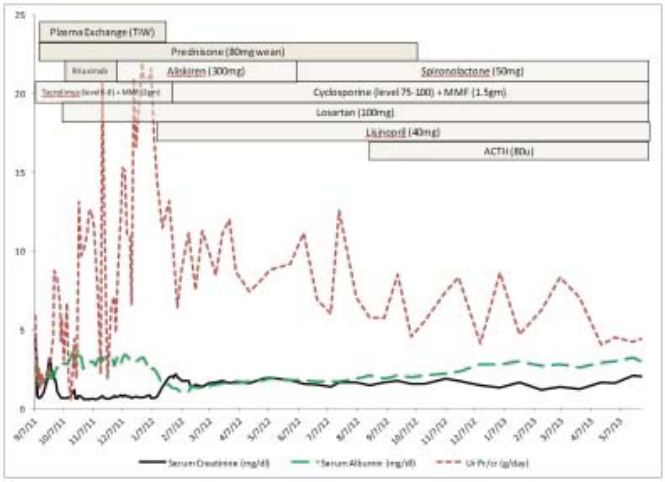
## FR-PO1135

### Treatment of Post-Transplant Immunosuppression Resistant Focal Segmental Glomerulosclerosis with Adrenocorticotropic Gel

Patrick P. McHugh, Muhammad Ahmad Mujtaba, Tim E. Taber, Muhammad S. Yaqub, Asif A. Sharfuddin. *Nephrology/Transplant, Medicine, Indiana Univ, Indianapolis, IN.*

**Background:** Post-transplant recurrence of focal segmental glomerulosclerosis (FSGS) is associated with poor outcomes and early graft failure. Adrenocorticotropic Hormone (ACTH) has shown efficacy in some cases of native kidney nephrotic syndrome including FSGS. Its actions include reducing oxidative stress and diminishing podocyte apoptosis and podocyte loss through binding to melanocortin receptors. We report a case of immunosuppression resistant FSGS after transplant treated with ACTH with resultant decrease in proteinuria.

**Methods:** A 60-year-old white female with a history of FSGS since 2003 (chronic kidney disease stage 5) underwent pre-dialysis living related kidney transplant. She was induced with Thymoglobulin®, early corticosteroid (4-day) withdrawal, and was maintained on tacrolimus and mycophenolate mofetil. Her serum creatinine (Cr) at postoperative (POD) 7 was 0.9mg/dL. On POD11 she was readmitted with Cr of 3.1mg/dL and worsening proteinuria. Biopsy showed no evidence of rejection and negative immunofluorescence staining, but electron microscopy showed widespread podocyte effacement consistent with recurrent FSGS. Plasma exchange and high dose steroids were given. Conventional antiproteinuric treatments included ACEi/ARB and statin, plus those shown below.



Nephrotic syndrome persisted, so ACTH was initiated at 10 months post-transplant. Subsequently she demonstrated continued partial remission of proteinuria, sustained rise in serum albumin, and stable graft function.

**Conclusions:** To our knowledge this is the first case of post-transplant recurrent FSGS where ACTH has been used. Our case suggests there may be an additional effect of ACTH in immunosuppression resistant FSGS patients, to durably reduce proteinuria and preserve graft function.

## FR-PO1136

### A Rare Case of Bovine Ketoacidosis in a Lactating Woman

Rekha Durairaj,[1] Viswanathan S. Iyer,[1] Pramil Cheriyath.[1] *[1]Internal Medicine, Pinnacle Health Harrisburg Hospital, Harrisburg, PA; [2]Nephrology, Pinnacle Health Harrisburg Hospital, Harrisburg, PA; [3]Internal Medicine, Pinnacle Health Harrisburg Hospital, Harrisburg, PA.*

**Background:** Lactation ketoacidosis, first described by Stinson in 1929, is a common disorder among cows. The basis is an imbalance between energy demands of milk production and the energy generating capacity of the animal. We report a rare case of bovine ketoacidosis in a lactating woman secondary to stress from influenza.

**Methods:** A 33 year old. 5 month postpartum woman presented to the emergency room with flu-like symptoms for 3 days. Patient also reported decrease in appetite with poor intake for 5 days. Patient stated that she has been actively breast feeding since delivery. She denied any alcohol or illicit substance use. Initial vital signs were unremarkable except for hypotension, which responded to fluid administration. Initial labs included: sodium 137, potassium 4.7, chloride 108, bicarbonate 11, BUN 12, creatinine 0.6, glucose 80 and anion gap was 18. Serum lactate was within normal limits. Serum acetone was 2+ with serum osmolar gap of 12. Arterial blood gas analysis at the time of presentation showed pH 7.23, PCO2 22.6, PO2 135 and HCO3 12.7. CBC was unremarkable except for WBC at 1.9K/µl. Urinalysis showed specific gravity of 1.020, 3+ acetone and no active sediments. A comprehensive drug screen was negative including salicylates and acetaminophen. Chest radiograph, blood and urine cultures were within normal limits. Patient tested positive for influenza B. Patient was volume resuscitated, given dextrose infusion and started on tamiflu. With cessation of lactation and high caloric intake, patient's symptoms rapidly improved.

**Conclusions:** The patient who was apparently doing well developed an increased anion gap metabolic acidosis secondary to physiological stress of lactation ketoacidosis. The purpose of this case report is to bring awareness among clinicians about lactation ketoacidosis in patients with similar presentation with stressors such as infection. This will aid in expediting treatment and improving the high mortality and morbidity associated with lactation ketoacidosis.

## FR-PO1137

### Pregnancy or Uremia? – A Case of Pregnancy Symptoms Mimicking Uremia in a Woman with Advanced Chronic Kidney Disease (CKD)

Anil Regmi,[1] Antonios Tzamaloukas,[2] David Buchwald,[1] Amarpreet S. Sandhu.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Univ of New Mexico Health Science Center, Albuquerque, NM; [2]Div of Nephrology, Dept of Internal Medicine, VA Hospital Albuquerque, Albuquerque, NM.*

**Background:** Pregnancy is rare in women undergoing renal replacement therapy (RRT) and may lead to maternal and fetal complications. Due to negligible rates of conception, early pregnancy symptoms can be confused with uremic symptoms in patients with CKD stage V. We present a case that illustrates the diagnostic and management challenges created by pregnancy in women on peritoneal dialysis (PD).

**Methods:** A 25-year-old-woman with CKD stage V (CrCl < 15 ml/min) due to autosomal dominant polycystic kidney disease developed nausea, vomiting, and anorexia. A PD catheter was placed for presumed uremic symptoms. Two weeks after placement of the PD catheter, she presented with persistent nausea, vomiting, and abdominal cramps. CT showed ascending colitis, scattered free intra-abdominal fluid, polycystic kidneys, and no mention of uterus. She was diagnosed with gastroenteritis. Serum β-HCG, obtained 2 weeks later due to persistent symptoms, was positive. US revealed a 20-week pregnancy. At 24 weeks of gestation, PD prescription was changed. Fill volume was decreased to 1.5 L and exchanges increased to 5 cycles. Dialysis adequacy was maintained with Kt/V urea of> 3.5/week and BUN< 50 mg/dl throughout the pregnancy. She received increased doses of iron and epoetin. Labor was induced after she developed abdominal discomfort during infusion of the dialysate at 38 weeks. She delivered a healthy baby boy. During labor PD was continued with a decreased fill volume dwell time. Regular PD prescription was resumed 12 hours after delivery.

**Conclusions:** A combination of low expectation of pregnancy as well as gastrointestinal symptoms resulted in a delayed diagnosis of pregnancy in this case. The CT scan did not show the pregnancy, probably because of the early stage. Coordinated care between a nephrologist, obstetrician, and nutritionist is essential for better outcomes. Women on PD require special care towards the end of pregnancy.

## FR-PO1138

### Pauci Immune ANCA Associated Vasculitis De Novo in Pregnancy

Hasan Riaz,[1] Quarrat-Ul-Ain Shamim,[1] Raafat Farag Makary,[2] Leighton R. James,[1] Andreea Poenariu.[1] *[1]Dept of Medicine, Div of Nephrology, Univ of Florida College of Medicine, Jacksonville, FL; [2]Dept of Pathology, Univ of Florida College of Medicine, Jacksonville, FL.*

**Background:** Antineutrophil cytoplasmic antibody (ANCA) - associated vasculitis (AAV) is infrequently seen in women of childbearing age. Pregnancies occurring in active disease have a documented unfavorable outcome for both the mother and the child. There is a dearth of literature on the de novo occurrence of AAV in pregnancy and on the best approach to management.

**Methods:** We present a case of a young woman who was admitted to hospital with hyperemesis gravidarum, volume depletion and acute kidney injury (plasma creatinine 4.46 mg/dL). Urinalysis demonstrated hematuria, pyuria and urine sedimentation showed leukocytes, erythrocytes and no casts. Despite adequate volume repletion, the patient became increasing oliguric with further deterioration in renal functional parameters. Serologic testing revealed elevated c-ANCA titer and kidney biopsy was consistent with pauci-immune crescentic glomerulonephritis. Despite steroids, intravenous immunoglobulin (x5 at 400mg/kg) and plasma exchange (1.5 plasma volumes every other day for 7 days) the patient required hemodialysis. Following pregnancy termination, intravenous cyclophosphamide therapy (1mg/m$^2$ once a month) was initiated. After two months, renal function recovered and hemodialysis was discontinued. She continues on tapering prednisone and monthly cyclophosphamide (1 mg/m$^2$) without relapse.

**Conclusions:** This case highlights the challenges related to management of pregnant patients with new onset Pauci-immune ANCA positive, rapidly progressive glomerulonephritis (ANCA-RPGN). Given limited guidelines, management of affected individuals requires mutli-disciplinary teams that have developed skills in managing pregnant patients with rare autoimmune disorders.

**FR-PO1139**

**De Novo Collapsing Glomerulopathy Associated with Pregnancy** Ederson Vidal Moura,[1] Carla Queiroz Neves,[1] Alline S. A. Oliveira,[1] Camila Barbosa L. Oliveira,[1] Luis H.B.C. Sette,[1] Gisele Vajgel Fernandes,[1] Filipe Carrilho,[1] Lucila Maria Valente.[1] *[1]Nefrologia, Universidade Federal de Pernambuco, Recife, Pernambuco, Brazil; [2]Nefrologia, UFPE, Recife, Pernambuco, Brazil.*

**Background:** Collapsing glomerulopathy (CG) was initialy described as idiopatic or related to HIV. Currently is associated to other clinical conditions such as: autoimmune diseases, drugs, infections and trombotic microangiopathy. In renal allografts, CG may be recurrent or rarely *de novo*.

**Methods:** A 39 years old female patient diagnosed with SLE in 1993 developed ESRD. She underwent hemodialysis for 7 years and kidney transplant (deceased donor) in 2001. During follow-up serum creatinine (Scr) levels remained around 1.0 mg/dL. She had IgG + for CMV and HTLV since pre-transplant period, without clinical evidence of infection. Immunosuppressive drugs were prednisone, FK and azathioprin. In march 2013, during the 27th week of pregnancy, she developed proteinuria (3.19 g/24 h), edema, dyslipidemia, hypertension and worsening SCr, whithout symptoms of lupus flare or increased FK levels. Pregnancy was interrupted and blood pressure levels improved, but both renal function (SCr 2.3) and proteinuria (11.4 g/24 h) worsened. Renal biopsy, performed a month after pregnancy interruption, revealing: 9 glomeruli, 4 presenting with collapse of glomerular capillary surrounded by hypertrophic podocytes consistent with CG. Moderate chronic transplant nephropathy and arteriolar hyaline deposits were also found. Immunofluorescence revealed traces of IgM in glomeruli. During follow-up the patient showed stabilization of renal function (SCr: 2.0), lower proteinuria (2.3 g/24 h) and a proper blood pressure control.

**Conclusions:** CG is associated with multiple trigger factors includding hemodynamic disturbance and endothelial lesion. In this case repport, no other factor such as: HTLV, CMV or Parvovirus B19 activity were found in histologic and sorologic investigation. Histological findings were absent for endotheliosis, however the biopsy was performed lately enough for regression of the lesions. The association with pregnancy was performed since it was the most obvious precipitating factor for the onset of nephrotic syndrome and renal allograft dysfunction.

**FR-PO1140**

**Post-Partum Hypopituitarism Presenting with Symptomatic Hyponatremia** Richa A. Pandey, Quynh N. Lam, Didier Portilla. *Div of Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

**Background:** Post partum anterior pituitary insufficiency from pituitary necrosis is rare and can manifest as SIADH causing hyponatremia.

**Methods:** 29 year old Egyptian lady presented with acute onset dizzines 7 days post-vaginal delivery of a term pregnancy, complicated by profuse vaginal bleeding, hypotension and severe anemia which responded to PRBC transfusion. She subsequently developed severe headache, salt craving and inability to lactate. She was normotensive on admission, laboratory work up revealed serum sodium and potassium (mEq/L) to be 117 and 3.5 with normal renal function. Serum and urine osmolalities (mOsm/kg) were 249 and 506, urine sodium of 191 mEq/L. Given her history of severe post partum hemorrhage Sheehan's syndrome was considered. Brain MRI revealed enlarged pituitary with features concerning for recent hemorrhage. Serum hormone panel showed partial hypopituitarism : random PM cortisol of 1 ng/dL (2-16), ACTH 6 pg/ml (6-58), TSH 0.54 uIu/mL (0.34-5.60), Free T4 0.57 ng/dL (0.58-1.68), FSH 0.59 mIU/mL, LH 0.20 mIU/mL, Prolactin 14 ng/mL. Hyponatremia was thought to be multifactorial including, hypocortisolism, hypothyroidism vs SIADH. For the first 12 hours serum sodium levels did not respond to 3% Saline and stress dose steroids. She was given a dose of conivaptan leading to a rapid rise in serum sodium from 118 to 132 mEq/lt requiring the use of hypotonic solutions, and one dose of desmopressin to dampen the rise. At this point all fluid replacement was held. The patient was discharged home on oral hormone replacements and serum sodium 10 days after discharge was 139 mEq/L.

**Conclusions:** Our patient did not have all the clinical features of post partum panhypopituitarism, however, the diagnosis of SIADH is likely based on laboratory data sugesting inappropiate excess of ADH. This case further confirms a previous report of the presence of SIADH causing hyponatremia during the early phase of post-partum hypopituitarism.

**FR-PO1141**

**Hypertension and Hypokalemia during Pregnancy with Complete Aldosterone Suppression** Louis R. Spiegel, Anna Mathew, Alessandro Bellucci. *Div of Kidney Diseases & Hypertension, Hofstra North Shore - LIJ School of Medicine, Great Neck, NY.*

**Background:** Common causes of hypertension during pregnancy include pre-existing hypertension, gestational hypertension, and pre eclampsia. If hypokalemia and metabolic alkalosis are present then disorders of the renin-angiotensin-aldosterone system must be considered. We present a case of a woman with hypertension and hypokalemia during the third trimester of her first pregnancy, likely due to a rare gain-of-function mutation of the mineralocorticoid receptor.

**Methods:** A 21 year old female with no prior medical history was admitted to the hospital from her obstetrician's office at 32 weeks of gestation with hypertension to 170/100. Upon admission serum potassium was 2.2 mEq/L and serum bicarbonate was 27mEq/L. She denied history of hypertension, or intake of licorice. Workup for secondary hypertension, including 24 hour urine for cortisol and catecholamines, plasma metanephrines and serum TSH, was negative. Transtubular potassium gradient (TTKG) was elevated indicating renal potassium wasting. She had no edema and 24 hour urine protein was 180 mg/day. Plasma renin activity was 0.97 ng/mL/hr and plasma aldosterone was suppressed to <1 ng/dL. Frequent intravenous and oral potassium supplementation normalized the serum potassium. Adequate blood pressure control was obtained via up-titration of oral labetalol.

**Conclusions:** We present a unique case of de novo onset hypertension and hypokalemia during the third trimester of pregnancy. Suppressed levels of aldosterone and elevated TTKG are most consistent with a rare gain-of-function mutation of the mineralocorticoid receptor (Geller's syndrome), causing progesterone to act as an agonist. High levels of progesterone result in hypertension during the second or third trimester. Follow-up genetic testing for this autosomal dominant point mutation of the mineralocorticoid receptor will be conducted to confirm the diagnosis.

**FR-PO1142**

**Syphilis in a Patient with Recently Acquired HIV-Infection: A Reversible Cause of Nephrotic Syndrome** Oleh M. Akchurin, Aracelis D. Fernandez, Linda Wesp, Daniel Schwartz, James M. Pullman, Frederick J. Kaskel, Amy L. Skversky. *Montefiore Medical Center.*

**Background:** Secondary syphilis is a rare but described cause of nephrotic syndrome (NS), usually with a good prognosis. Much less is known about NS in patients with syphilis and HIV co-infection.

**Methods:** A 20 year-old Hispanic male presented with pitting edema, 7 kg weight gain, macular rash to the face, trunk and extremities, and exudative tonsillitis. Patient has a history of HSP and penicillin allergy. Two months prior, patient had negative syphilis test, normal serum chemistries, creatinine and albumin. Family history: grandmother had ESRD secondary to SLE-nephritis. Social history: patient is sexually active with men, and reported negative HIV test 4 months prior. Laboratory evaluation confirmed the diagnosis of NS (urine protein-to-creatinine ratio 7.1, serum albumin 1.5 g/dL), and AKI (peak serum creatinine 1.5 mg/dL). His C3/C4 complement levels were normal, ANA, ASLO, and streptozyme were negative. A throat swab was positive for group A *streptococcus*. Urine DNA-probe test for gonorrhea and Chlamydia was negative. HIV-1 Western blot was positive and viral load was 113,011 copies/ml. Syphilis serology was positive and RPR was 1:256. Kidney biopsy showed no glomerular, tubulointerstitial or vascular abnormalities on light microscopy. Immunofluorescence revealed 2+ IgG, trace IgM, 1+ IgA, trace C3, 1+ C1q, 1+ Kappa and Lambda light chains in granular pattern. Electron microscopy showed scattered subendothelial, mesangial, and subepithelial electron dense deposits and subtotal foot processes effacement. Treatment of syphilis with Doxycycline resulted in resolution of the NS and normalization of kidney function within 2 weeks. Subsequently, treatment for HIV was initiated. Urinalysis remained protein-free and kidney function was normal 6 months later.

**Conclusions:** To our knowledge, this is the first report with the availability of renal histology describing syphilis as a reversible cause of the NS in an adolescent patient with HIV-infection. The pathology showed IgG/IgA immune complex disease as the probable cause, likely related to IgA, membranous or post infectious glomerulopathy.

## SA-PO001

**Design of a Bioartificial Renal Cell System (BRECS) for Mass Production**
H.D. Humes,[1,2] C. Pino,[1] T. DeLandsheer,[1] A. Westover,[1] D. Buffington.[1]
*[1]Innovative BioTherapies; [2]Univ of Michigan.*

**Background:** The bioartificial renal epithelial cell system (BRECS), is a cell-based device to treat acute kidney injury. This technology is based on a Phase I/II clinically proven cell-therapy approach, previously demonstrated by our group: renal assist device (RAD). To enable widespread implementation of cell therapy, the BRECS was designed to be cryopreserved as a complete device, cryostored, cryoshipped to an end-use site, thawed as a complete device, and employed in a therapeutic extracorporeal hemofiltration circuit. This strategy overcomes the storage and distribution issues that have been previous barriers to cell therapy.

**Methods:** Following computer aided design (CAD) to simulate flow through the device, prototype BRECS were produced by stereolithography (SLA-BRECS) and tested to determine the design to be mass-produced by injection molding (IM-BRECS). Cell viability and functionality were assessed by lactate production, oxygen consumption rate (OCR) and glutathione metabolism during perfusion culture. Impact of cryopreservation on SLA-BRECS and IM-BRECS were assessed by metabolic function after thaw, and viability stains upon study termination.

**Results:** The SLA-BRECS design with the best cell performance was chosen to be mass-produced by injection molding. The resulting IM-BRECS design was palm-size, had a fill volume of ~10 mL, and exhibited near plug-flow conditions without major stagnation points or areas of recirculation. This design was capable of supporting ~1 x $10^8$ cells, with a mean OCR of ~200 nmol/min, lactate production of ~700 µmol/day, and glutathione degradation of ~800 nmol/hr over extended culture periods up to 2 months. ZO-1 (epithelial tight junctions), AT-1 (central cilia) and brush border enzymes were evident in cell populations, demonstrating renal cell specific phenotypes. Cell viability was well retained throughout developed cryopreservation and thaw procedures.

**Conclusions:** IM-BRECS can be mass-produced for potential use in AKI and related indications which have been preliminarily assessed in pre-clinical large animal models. This innovative, tissue engineered device overcomes many of the hurdles to clinical implementation of cell therapy.

*Funding:* NIDDK Support, Other U.S. Government Support

## SA-PO002

**Comparison of Kidney Injury between Two Stage Revision Arthroplasty with Antibiotic Loaded Spacers and Other Revision Orthopaedic Procedures**
Anshul Bhalla,[1] Madhumathi Rao.[2] *[1]Dept of Medicine, Tufts Medical Center, Boston, MA; [2]Div of Nephrology, Tufts Medical Center, Boston, MA.*

**Background:** Two-stage revision arthroplasty using antibiotic loaded spacers (ALS) is the standard of care for prosthetic joint infections (PJI). Although systemic toxicity is believed to be rare, acute kidney injury (AKI) has been reported. We examined the attributable risk (AR) for AKI from arthroplasty with spacers, compared with other revision orthopedic procedures.

**Methods:** Between August 2007 and December 2012 we identified all patients who underwent two-stage revision arthroplasty using antibiotic loaded spacers (Group 1, N=75), revision surgeries with prophylactic antibiotic in cement (Group 2, N=33) and revision surgeries with no antibiotic in cement (Group 3, N=80) at a single Referral Center. Tobramycin and vancomycin were uniformly used in the cement. We compared the incidence of AKI (by AKIN and RIFLE definitions) and examined risk factor relationships across the three groups.

**Results:** Table 1 shows the incidence of AKI across the three groups and was significantly higher among Group 1 patients. The AR for AKI was 15.4% (95% CI 3% to 28%) for spacers compared to revision arthroplasty without antibiotic cement. Other risk factors for AKI included baseline CKD (p=0.05), cardiovascular disease (p = 0.03), hypertension (p<0.01), use of NSAIDS (p=0.02), intra operative hypotension and/or use of pressors (p<0.01) and need for transfusion (p<0.01).

| | Group 1, N=75 | Group 2, N=33 | Group 3, N=80 | P-value |
|---|---|---|---|---|
| Age (years) | 63.2 (SD 12.9) | 64.6 (SD 10.5) | 66.4 (SD 13.8) | 0.3 |
| Female (%) | 46.7% | 78.8% | 62.5% | <0.01 |
| Incidence of AKI | 26.7% | 15.2% | 11.3% | 0.04 |

**Conclusions:** AKI is significantly associated with two stage arthroplasty with antibiotic loaded spacers for PJI compared to other revisions and is accentuated by comorbidities and intra-operative complications. A better understanding of the risk benefit ratio of this procedure is needed.

## SA-PO003

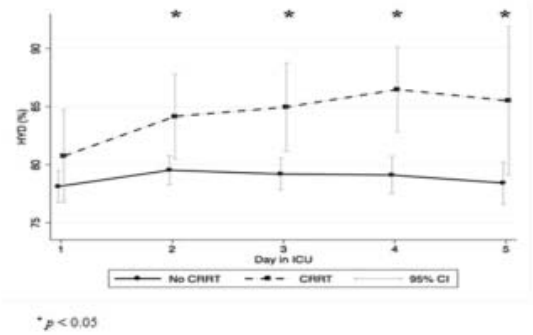
**Prospective Hydration Status Evaluation by Bioelectric Impedance Analysis in Patients Admitted to ICU**
Flavio Basso, Giacomo Mason, Sonya Day, Alessandra Brendolan, Claudio Ronco. *International Renal Research Institute of Vicenza, Vicenza, Italy.*

**Background:** Fluid imbalance is an important risk factor for morbidity and mortality in ICU, whether or not they require CRRT. The aim of the study is the prospective evaluation of hydration status, measured by Bioelectric Impedance Analysis(BIVA), in patients at the admission to the ICU and in following days.

**Methods:** This is a prospective cohort study in critically ill patients, observed daily, for a period of 72 to 120 hrs from admission. Patients were considered normohydrated if BIVA was between 72.7% and 74.3% of body water, fluid overloaded if BIVA>74.3% and dehydrated if BIVA<72.7%.

**Results:** 280 BIVA measurements were taken in 64 pts. 14 subjects were started on CRRT during ICU stay. More than 70% of pts were admitted to the ICU in a hyperhydration state, and remained overhydrated during the observation period. Pts who underwent CRRT showed significant increase in hydration during ICU stay (p<0.05). While no difference in hydration at admission was seen between CRRT and non-CRRT pts (Fig. 1), the former show a higher hydration status in the remaining 4 days of observation (p<0.05).

Fig. 1: Median Cummulative Hydration Status during the 5 days observational period for subjects receiving or not receiving CRRT



*$p < 0.05$

Univariate logistic regression shows a significant correlation between ICU mortality and maximum hydration(p<0.05) and mean hydration(p<0.05), respectively. Even in a bivariate analysis with both hydration and severity of prognosis, hydration remains significant regardless of which of the 3 ICU scoring systems (APACHE II,SAPS II,SOFA) is used to stratify the model(p<0.05).

**Conclusions:** Fluid overload is a frequent condition in critically ill patients. Hyperhydration persists during ICU stay, independently from the need of CRRT. Both mean hydration and maximum hydration reached represent a significant risk factor for mortality in the ICU. These findings suggest the need to develop adequate protocols to monitor hydration status in ICU patients.

## SA-PO004

**Early Goal-Directed Therapy in the Management of Type 1 Hepatorenal Syndrome: A Combined Retrospective and Pilot Study**
Zhiwei Zhang,[1] Geetha S. Maddukuri.[2] *[1]Nephrology, VA Loma Linda Healthcare System and Loma Linda Univ, Yorba Linda, CA; [2]Nephrology, St. Louis Univ, St. Louis, MO.*

**Background:** Appreciation of the central role for arterial vasodilatation in the pathogenesis of hepatorenal syndrome (HRS) has led to routine use of vasoconstrictors in combination with albumin as a medical therapy for HRS. Various vasoconstrictors have been explored but the optimal approach for such therapies has not yet been established. The aim of current study was to examine the role of early goal-directed therapy (EGDT) in the management of type 1 HRS, a condition associated with very poor prognosis.

**Methods:** A total of 59 patients with type 1 HRS who received a combination therapy of vasoconstrictors and albumin were enrolled into a retrospective cohort study. Subjects having a sustained increase of more than 10 mmHg in mean arterial pressure (MAP) by day 3 after initiation of therapy were categorized as EGDT and the rest as controls. In addition, five patients were enrolled into a prospective pilot study in which a titration protocol of vasoconstrictors was utilized to achieve EGDT.

**Results:** Patients in the EGDT group achieved significantly higher incidence of treatment success or total response, less requirement of dialysis and more incidence of liver transplantation. More importantly, EGDT is associated with better short-term and long-term overall survival as well as transplant-free survival. The effectiveness of such an approach was further confirmed in the pilot study.

**Conclusions:** Management of HRS with EGDT is associated with favorable clinical outcomes. Targeting an early and sustained increase in MAP is clinically feasible and physiologically sound, although the optimal target has yet to be determined by prospective studies.

*Funding:* Veterans Affairs Support

## SA-PO005

**Body Composition Monitor in Contrast-Induced AKI: A New Tool for an Old Enemy**
Paolo Lentini,[1] Luca Zanoli,[2] Stefania Rastelli,[2] Massimo de Cal,[1] Anna Basso,[1] Andrea Contestabile,[1] Valentina Pellanda,[1] Roberto Dell'Aquila.[1] *[1]Nephrology, San Bassiano Hospital, Bassano del Grappa (VI), Italy; [2]Internal Medicine, Catania.*

**Background:** Most radiological procedures require administration of contrast media. Contrast-induced acute kidney injury (CI-AKI) is the third cause of hospital acquired AKI. Extracellular volume expansion reduced contrast-induced tubulo-toxic effects.We aimed to test if control of hydration by bioimpedance is useful to reduce incidence of CI-AKI.

**Methods:** 50 patients undergoing contrast medium infusion of 100-150 ml of iopamidol for abdominal or thoracic computer tomography were enrolled and randomly assigned to receive standard CI-AKI protocol prevention or Bioimpedance-based hydration protocol. Standard CI-AKI protocol consisted in administration,1day before and 1day after the administration of contrast media,at least 1 ml/kg/h of saline solution,1 mg/kg/h of sodium

bicarbonate and N-acetyl-cysteine twice a day.In the bioimpedance-based protocol,a mild over-hydration (within +1 and +3)was obtained the day of the procedure and the next 3 days with the infusion of saline solution plus 1 mg/kg/h of sodium bicarbonate and N-acetyl-cysteine twice a day.Bioimpedance was performed daily with Body Composition Monitor(BCM -Fresenius Medical Care®)to evaluate the hydration status.Laboratory and clinical examination were performed daily after the procedure for 3 days.CI-AKI was defined as a rise in sCr of 0.5 mg/dl 48hrs after a radiological procedure.

**Results:** 49 patients were enrolled(63±14yrs;GFR64±31ml/min/1.73m2):29 patients were included in the bioimpedance-based protocol harm and 20 patients in standard protocol harm.For a comparable age,sCr and GFR at baseline,incidence of AKI was significantly lower in bioimpedance-based than in standard protocol(14%vs40%,respectively;P=0.04 ).In multivariate analysis adjusted for age,the bioimpedance-based protocol(OR0.17 if performed;95%CI 0.03-0.99;P<0.05)and high baseline GFR(OR0.92 for 1 ml/min/1.73m2 increase;95%CI0.87-0.98;P=0.005)reduced the risk of CI-AKI.

**Conclusions:** The bioimpedance-based control of hydration is useful to reduce CI-AKI incidence in patients undergoing abdominal or thoracic computer tomography.

## SA-PO006

**Acute Creatinine Improvement after CT with and without Intravenous Iodinated Contrast Use** Masahiko Nagahama,[1] Goki Eriguchi,[2] Keita Hirano,[1] Fumika Taki,[1] Takuya Fujimaru,[1] Kenichiro Koitabashi,[1] Kumiko Shimasaki,[1] Yasuhiro Komatsu.[1] *[1]Nephrology, St. Luke's International Hospital, Tokyo, Japan; [2]Biostatistics, Kurume Univ Graduate School of Medicine, Fukuoka, Japan.*

**Background:** Administration of intravenous (IV) iodinated contrast medium has been associated with acute kidney injury (AKI), known as contrast induced nephropathy (CIN). Of interest, there are some subjects whose serum creatinine (sCr) is decreased and kidney function seems to be improved after contrast use. We have termed this condition "Acute Creatinine Improvement (ACI)". The purpose of this study was to clarify the incidence and prognosis of "ACI" as well as CIN in patients undergoing CT with and without IV contrast.

**Methods:** sCr was evaluated for 7039 patients who had had, either enhanced CT (Exposure, n=3671) or unenhanced CT (Comparison, n=3368), at St. Luke's international hospital in Tokyo between 2003 and 2010. CIN is defined as a 0.5 mg/dL increase in sCr or a 25% or greater decrease in eGFR within 7 days after CT, while "ACI" is defined as a 0.5 mg/dL decrease in sCr or a 25% or greater increase in eGFR as opposed to CIN. The survival rate was compared in "ACI" and Non-"ACI "subjects as well as CIN and Non-CIN subjects using Kaplan-Meier curves.

**Results:** In exposure group, 7.2% of patients developed CIN and 7.9% of patients developed "ACI", while in comparison group, 14% of patients developed "ACI". The prognosis of patients with CIN was significantly worse than that without CIN (P<0.0001 by log-rank). Although the prognosis of patients with "ACI" and Non-"ACI" in exposure group were not significantly different (P=0.32 by log-rank), the prognosis of patients with "ACI" was significantly worse than that without "ACI" in comparison group (P<0.0001 by log-rank).

**Conclusions:** We identified a high incidence of "ACI" in both exposure group and comparison group. Remarkably, development of "ACI" has poor impact on prognosis as CIN does. This suggests that any fluctuation of sCr, either rise or fall, in one week period is related to worse prognosis.

## SA-PO007

**Hydration prior to CT-Pulmonary Angiography Is Not Required for Prevention of Contrast Induced-Acute Kidney Injury: The Randomized Nefros Trial** Judith Kooiman,[1] Yvo W.J. Sijpkens,[2] Marjolyn Van Buren,[3] Aart J. Molen, Van der,[1] Nicolas Jm Aarts,[2] Cornelis J. Van Rooden,[3] Suzanne Cannegieter,[1] Hein Putter,[1] Ton J. Rabelink,[1] Menno V. Huisman.[1] *[1]Leiden Univ Medical Center; [2]Bronovo Hospital; [3]Haga Teaching Hospital; [4]Medical Center Haaglanden.*

**Background:** Hydration to prevent contrast induced-acute kidney injury (CI-AKI) results in a diagnostic delay when performing CT-pulmonary angiography (CTPA) in patients presenting with clinically suspected acute pulmonary embolism (PE). The aim of our study was to analyze whether withholding hydration is non-inferior to one hour 250ml 1.4% sodium bicarbonate (Na-bic) hydration prior to intravenous contrast administration for CTPA in patients with a GFR<60 ml/min.

**Methods:** Primary outcome of this randomized trial was the increase in serum creatinine 48-96 hours post CT. Secondary outcomes were the incidence of CI-AKI (increase in serum creatinine >25%/>0.5mg/dl), recovery of renal function, and the need for dialysis. Withholding hydration was considered non-inferior if the mean relative serum creatinine increase was at most 15% higher compared with Na-bic.

**Results:** From 2009-2013, 135 patients with clinically suspected PE undergoing CTPA (mean age 70.4years range 69, mean GFR 41.9 range 51) were randomized. Mean relative serum creatinine increase for no hydration was -3.3%(SD20.5) and -3.0%(SD17.2) for Na-bic (mean difference -0.4%,95%CI-7.0 to 6.3, P non-inferiority<0.001). CI-AKI occurred in 9(7.0%) patients; 4(6.5%) did not receive hydration, 5(7.5%) were treated with Na-bic (p=0.82). Two patients with CI-AKI in the no hydration arm died of causes other than renal failure and one CI-AKI patient in the Na-bic arm started pre-planned dialysis within two months post CTPA. Renal function recovered in all other CI-AKI patients within two months.

**Conclusions:** Withholding hydration was non-inferior to Na-bic hydration prior to CT-PA, with a similar risk of CI-AKI in both groups. Therefore, our study results demonstrate that preventive hydration can be safely withheld in daily practice of chronic kidney disease patients undergoing acute CTPA for symptomatic PE.

## SA-PO008

**Evalution of the Risk Factors for Contrast Induced Nephropathy in Hypertensive Patients with Normal Renal Function** Osman Z. Sahin,[1] Fatih Sumer,[2] Mehmet Bostan,[3] Teslime Ayaz,[2] Yavuz Ugurlu.[3] *[1]Nephrology, Recep Tayyip Erdogan Univ Faculty of Medicine, Rize, Turkey; [2]Internal Medicine, Recep Tayyip Erdogan Univ Faculty of Medicine, Rize, Turkey; [3]Cardiology, Recep Tayyip Erdogan Univ Faculty of Medicine, Rize, Turkey.*

**Background:** Coronary angiography which requires intravascular administration of iodinated contrast media (CM) is a leading cause of contrast induced nephropathy (CIN). The aim of this study was to assess the risk factors on the development of CIN in hypertensive patients who have normal renal function undergoing coronary angiography.

**Methods:** This retrospective study included all consecutive patients who underwent elective coronary angiography at our center between September 2011 and May 2012. Coronary angiography was performed 254 hypertensive patients. Before the procedure, IV saline infusion and N-acetylcysteine were given to the all patients. ACE-I or ARB was discontinued 2 days before the procedure.CIN was defined as >0.5 mg/dL increase or >25% rise in serum creatinine (SCr) concentration within 48 hours of contrast exposure compared to baseline.

**Results:** The study population consisted of 254 patients, aged 19-84 years (mean: 57.67 ± 9.7) and 57% of them were male. 29.1% of the patients had type 2 diabetes. CIN occurred in 7% of the patients. Clinical data of the patients are presented in table 1.

| | Patients with CIN (n=18) | Patients without CIN (n=236) | *p* |
|---|---|---|---|
| **Age (years)** | 61.33±9.71 | 57.39±9.72 | 0.098 |
| **Gender (% male)** | 72.2% | 56.8% | 0.201 |
| **Fasting plasma glucose (mg/dl)** | 95.61±9.96 | 116.80±40.85 | **0.029** |
| **Proteinuria (mg/day)** | 0.282±0.127 | 0.205±0.020 | 0.344 |
| **Presence of type 2 diabetes (%)** | 16.7% | 30.1% | 0.227 |
| **Contrast volume (ml)** | 138.05±50.96 | 133.26±61.151 | 0.748 |
| **Uric acid (mg/dl)** | 6.22±1.16 | 5.52±1.45 | **0.048** |

**Conclusions:** Hyperuricemia can be a predictor of contrast induced nephropathy in hypertensive patients with normal renal function.

## SA-PO009

**Sodium Bicarbonate, N-Acetylcysteine, Both, or Saline Alone for Prevention of Contrast-Induced Nephropathy: A Network Meta-Analysis** Seth Wright, Katherine H. Michener, Amy Earley, Raveendhara R. Bannuru, Katrin Uhlig. *Tufts Medical Center, Boston, MA.*

**Background:** Trials have shown inconsistent results on whether contrast-induced nephropathy (CIN) can be prevented by giving IV sodium bicarbonate (Bic) instead of IV saline or by adding oral N-acetylcysteine (NAC) to IV saline. Furthermore, it is uncertain which intervention is superior or whether they should be combined.

**Methods:** We conducted a systematic review in MEDLINE and the Cochrane Central Register of Controlled Trials (1995-4/2013) of trials using these interventions and reporting outcomes of CIN (based on creatinine rise ≥25% or 0.5 mg/dL) or dialysis for a network meta-analysis. Analysis was by a Bayesian random effects multiple treatment comparison model with non-informative priors, using Markov Chain Monte Carlo implement through OpenBUGS software.

**Results:** 38 studies (n=6466) provided data on CIN. Mean patient age ranged from 59-78 years. Most patients had CKD stage 3 (range 1-4) and received intra-arterial contrast (predominantly for coronary angiography). The Figure shows the odds ratios for CIN for the different comparisons by network meta-analysis. There was consistency between direct and indirect effect estimates. For the dialysis outcome, odds ratios showed the same order but with wide, non-statistically significant credibility intervals due to fewer events and comparisons (12 studies, 2587 patients).

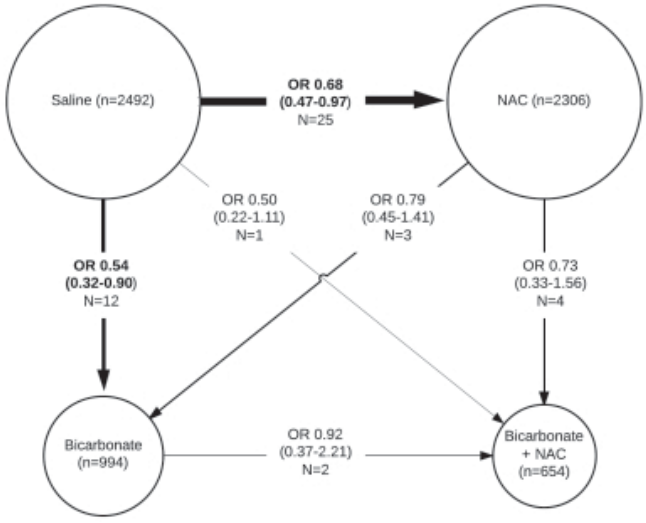

*Figure:* Odds ratios for CIN (with 95% credibility interval). Arrow tail = reference intervention. Circle size reflects the n of subjects; line width reflects the N of direct comparisons.

**Conclusions:** By network meta-analysis, Bic and NAC are both superior to saline with a 46% and 32% reduction in odds of CIN, respectively. Bic or NAC should be given rather than saline alone. These data also suggest combination therapy may have additional benefit.

## SA-PO010

**Risk Factors and Renal Outcomes for Cisplatin Nephrotoxicity** Zeenat Yousuf Bhat, Kevin B. Ginsburg, Milani Sivagnanam, Pravit Cadnapaphornchai, Mona D. Doshi. *Internal Medicine, Wayne State Univ, Detroit, MI.*

**Background:** Nephrotoxicity is a well-known complication of Cisplatin-based chemotherapy. Our goal was to determine the risk factors for development of Cisplatin nephrotoxicity (CN) and to assess renal function at 12 months thereafter, in the current era of aggressive hydration and careful patient selection.

**Methods:** We identified 131 patients who received 317 cycles of high-dose Cisplatin for treatment of head and neck cancer. All patients were hydrated per protocol and none had baseline glomerular filtration rate via CKD-EPI (GFR) < 60mL/min/1.732m$^2$. The patients were grouped based on development of acute kidney injury (AKI) and graded for levels of injury, per RIFLE criteria. Patients with AKI were screened for the absence of nephrotoxin use and a temporal decline in serum potassium and magnesium levels to labeled as CN.

**Results:** Of the 131 patients included in the study, 77 (58.7%) developed CN -25 (33%) grade 1, 40 (52%) grade 2, and 12(15%) grade 3 level of injury. Their potassium and magnesium levels negatively correlated with level of injury (p<0.05). In the univariate analysis, African Americans (AA), males, smokers, and hypertensives were more likely to develop CN (p<0.05). In the multivariate analysis, AA race and history of hypertension remained to be significant risk factors for CN, OR 6.5 (95% CI 2.1 to 19.9) and 3.2 (95% CI 1.1 to 9.6) respectively, and having a PEG tube was protective, OR 0.25 (0.09 to 0.7). Table 1 shows the GFR at 12 month after therapy was lower than baseline in patients with CN.

| | GFR, mL/min/1.732m$^2$ | | | |
|---|---|---|---|---|
| | Baseline | During Treatment | 1-month follow-up | 12-month follow-up† |
| No AKI | 110±16 | 94±21 | 109±19 | 107±22 |
| AKI, grade 1 | 109±20 | 66±22 | 94±28 | 92±30* |
| AKI, grade 2 | 114±20 | 51±17 | 84±31 | 89±30* |
| AKI, grade 3 | 125±18 | 25±10 | 68±30 | 80±30* |

†versus baseline

*p<0.05

**Conclusions:** CN remains a common complication resulting in irreversible loss of GFR. PEG tube placement may be beneficial in patients with head and neck cancer receiving Cisplatin to maintain their volume status.

## SA-PO011

**Is It Safe to Use IV Ketorolac in Hospitalized Patients?** Joseph E. Chan, Debra J. Hain, Rute C. Paixao, Dianne T. Sandy, Fei Wang, Mauro Braun. *Dept of Nephrology and Hypertension, Cleveland Clinic Florida, Weston, FL.*

**Background:** Ketorolac has been known to cause acute kidney injury (AKI) but current data suggests that it is safe for those who have low risk for renal dysfunction. In our facility, there have been cases of AKI in patients treated with Ketorolac but the incidence is not known. This study describes the prescribing habits of Ketorolac in our facility and determines the incidence of AKI while on this therapy.

**Methods:** Electronic medical records of hospitalized patients who received Ketorolac were reviewed during a 3 month period. AKI was defined as an increase of serum creatinine of 0.3 mg/dl or greater and a decrease in eGFR to less than 60 ml/min while on treatment with Ketorolac. Treatment duration is defined as the time of initial administration up to the third day from the last dose of Ketorolac.

**Results:** A total of 633 medical records were reviewed and 341 patients met the inclusion criteria. The mean age was 45.7 years and 65% were females. The most common diagnosis for prescribing Ketorolac was Osteoarthrosis. The conventional prescribed dose was 30 mg IV every 6 hours. AKI developed in 6.4% of patients. In patients with AKI, 68% were 65 years or older, 68% had hypertension, 41% were diabetic, 40% were concomitantly receiving either an ACE-i or an ARB and 40% were also being given diuretics. The mean pre dose creatinine was 1.09 mg/dl and mean post dose creatinine was 1.72 mg/dl. During the time of AKI, 72% still received Ketorolac.

**Conclusions:** AKI occurs more commonly than previously anticipated in Ketorolac treated patients even at average doses. Hypertension and diabetes are the two most common comorbidities in patients who developed AKI. Those who are older than 65 years old may be at higher risk. Concomitant use of drugs that affect renal function, such as ACE-i, ARBs and diuretics, may also increase the risk of AKI. Ketorolac prescribing in the acute care hospital should consider individual comorbdities, and use of other drugs that can increase AKI. Awareness of current renal function through diligent review of daily labs may help prevent administration of Ketorolac in those with already impaired renal function.

## SA-PO012

**Creatinine Production Is Reduced in Acute Kidney Injury Patients with Sepsis** Rolando Claure-Del Granado,[1] Josee Bouchard,[2] Glenn M. Chertow,[3] Jonathan Himmelfarb,[4] T. Alp Ikizler,[5] Ravindra L. Mehta.[6] *[1]School of Medicine, IIBISMED, Universidad Mayor de San Simon, Bolivia; [2]Univ of Montreal, Canada; [3]Stanford School of Medicine; [4]Kidney Research Institute, Univ of Washington; [5]Vanderbilt Univ Medical Center; [6]Univ of California San Diego.*

**Background:** Diagnosis and staging of acute kidney injury (AKI) uses the serum creatinine concentration (sCr). In a previous animal model of AKI, Doi et al. have shown that sepsis dramatically decreases sCr and creatinine production. This phenomenon would limit early detection of AKI. We evaluated the effect of sepsis on sCr, creatinine production (Pc'), and creatinine degradation (Dc') in patients with AKI. We hypothesized that sepsis will reduce creatinine production and sCr.

**Methods:** We analyzed data from 234 critically ill non-dialyzed patients with AKI from five centers included in the PICARD study. Creatinine production was calculated using Cockcroft-Gault formula and using the Moran et al. formula (Kidney Int 1985, 27:928-937), which adjusts sCr for fluid balance. Creatinine degradation was computed using the Mitch et al. equation (Clin Sci 58:327-335, 1980) and adjusted for fluid balance.

**Results:** Of the 234 patients, 139 were septic (59%). Non-adjusted and adjusted sCr levels were lower in patients with sepsis (non-adjusted sCr median 2.0 mg/dL IQR [1.5 – 2.8] vs. 2.5 mg/dL IQR [1.8 – 3.5] and adjusted sCr 2.0 mg/dL IQR [1.4 – 2.7] vs 2.4 mg/dL IQR [1.8 – 3.6]; p <0.001). Pc' was significantly lower in septic than in non-septic (1,211 mg/day IQR [934 – 1,472] vs. 1,278 mg/day IQR [1,017 – 1,538] mg/day; p < 0.001); and after adjusting Pc' for fluid balance (1,092 mg/day IQR [828 – 1,295] vs. 1,124 mg/day IQR [892 – 1,344]; p < 0.001). Dc' was also significantly lower in septic than in non-septic patients.

**Conclusions:** Sepsis reduces creatinine production and reduces serum creatinine in critically ill patients with AKI thereby blunting the expected increases of serum creatinine. These observations could confound the early diagnosis of AKI. Sepsis also affects creatinine degradation.

*Funding:* NIDDK Support

## SA-PO013

**Remote Ischaemic Preconditioning Does Not Prevent Kidney Injury after Cardiac Surgery in Patients with Chronic Kidney Disease** Sean Gallagher,[1] Dan A. Jones,[1] Steven Michael Harwood,[3] Rakesh Uppal,[1] Magdi Yaqoob.[2] *[1]Cardiology, Barts Health NHS Trust, London, United Kingdom; [2]Nephrology, Barts Health NHS Trust, London, United Kingdom; [3]William Harvey Research Institute, Queen Mary Univ, London, United Kingdom.*

**Background:** Perioperative complications of cardiac surgery including myocardial infarction and acute kidney injury (AKI) are associated with substantial morbidity and mortality. We assessed the impact of remote ischaemic preconditioning (RIPC) upon these complications in patients with chronic kidney disease (CKD).

**Methods:** 86 patients with CKD (defined as eGFR < 60mL/min) undergoing coronary surgery were randomized 1:1 to standard care with (n=43) or without (n=43) RIPC. RIPC consisted of three 5-minutes cycles of forearm ischaemia and reperfusion. Primary end point was development of AKI defined as a 0.3 mg/dL increase in serum creatinine within 48 hours of surgery. Secondary end points included a comparison of biomarkers of renal injury (serum cystatin C (CyC), serum and urinary neutrophil gelatinase associated lipocalin (NGAL)) and a comparison of myocardial enzyme release (defined by 72 hour troponin T area under the curve (72 hrs AUC cTnT)).

**Results:** Clinical and operative characteristics were similar between RIPC and control groups. 27.9% (24/86) of the study cohort developed AKI following surgery. The incidence of AKI was similar in both groups (RIPC 27.9% (12/43) vs control 27.9% (12/43); p=1.0). There was no difference in biomarkers of renal injury or myocardial enzyme release between the groups following surgery.

**Conclusions:** RIPC using forearm ischaemia confers no meaningful additional renal or myocardial protection in patients with CKD undergoing cardiac surgery.

**SA-PO014**

**Effect of Hospital Volume on Acute Kidney Injury in Percutaneous Nephrolithotomy Admissions** Ankit Sakhuja,[1] Manoj Monga,[2] Juan C. Calle.[1] *[1]Nephrology, Cleveland Clinic, Cleveland, OH; [2]Urology, Cleveland Clinic, Cleveland, OH.*

**Background:** Acute Kidney Injury (AKI) is an important cause of morbidity and mortality in hospitalized patients. In general, procedural volume has been shown to be associated with worse outcomes. However, not much is known about AKI in hospitalized patients undergoing Percutaneous Nephrolithotomy (PCNL). We, therefore, designed this study to look at the frequency and effect of hospital volume on AKI in hospitalized patients undergoing PCNL.

**Methods:** We designed a retrospective cohort study using Nationwide Inpatient Sample database, which is the largest all-payer inpatient care database in US and contains a 20% stratified sample of US community hospitals. Patients aged ≥18 years undergoing PCNL in year 2010 were identified using ICD-9-CM codes. AKI was identified using ICD-9-CM codes 584.X. End Stage Renal Disease Patients were excluded. Chi square test was used to compare categorical variables. Hospital procedure volume for the year studied was generated and divided into low volume (<50), medium volume (50-100), high volume (>100) hospitals. A multivariable logistic regression was used to assess the effect of hospital volume on AKI.

**Results:** Of estimated 46,899 (95% CI: 42,710-51,088) PCNL admissions in the year 2010, 34.1% (16,010) had AKI. Patients with AKI tended to be more often older males, African Americans and on Medicare. They also more often had chronic kidney disease (CKD), Urinary Tract Infection (UTI) and hydronephrosis with UTI. Patients with AKI also seemed to be admitted more often to lower volume hospitals (57.0.% vs 66.3% of those with no AKI; p<0.001). On multivariable regression, in comparison to low volume hospitals, admission to high volume hospitals was associated with decreased odds of AKI (OR 0.59; 95% CI 0.44-0.81). The protective effect of high volume hospitals was persistent even after excluding those with primary diagnosis of hydronephrosis (OR 0.58; 95% CI 0.42-0.80).

**Conclusions:** AKI seems to occur over a third of hospitalized patients undergoing PCNL. Hospital volume of PCNL is an predictor of AKI with a protective effect of high volume hospitals.

**SA-PO015**

**The Economic Impact of Acute Kidney Injury in England** Marion Kerr,[1] Michael Bedford,[2] Beverley Matthews,[3] Donal O'Donoghue.[4] *[1]Insight Health Economics; [2]East Kent Hospitals Univ NHS Foundation Trust; [3]NHS Kidney Care; [4]Salford Royal NHS Foundation Trust.*

**Background:** Acute kidney injury (AKI) is one of the most serious and common complications affecting hospital inpatients. We estimate the prevalence of AKI in hospital inpatients in England, and the impact on mortality, length of stay and National Health Service (NHS) costs.

**Methods:** National data (Hospital Episode Statistics, HES) were examined to identify all recorded cases of AKI among adult inpatients in English hospitals in 2010-11. The findings were compared with data from East Kent Hospitals, where AKI was identified from laboratory records and classified using AKIN criteria, with the lowest serum creatinine recorded in the 12 months before admission used to estimate baseline. Multivariate regressions were used to estimate the impact of AKI on mortality and length of hospital stay. Unit costs were derived from national tariffs and NHS Reference Costs.

**Results:** AKI was recorded in 2.43% of hospital admissions in HES, and in 13.22% of admissions at East Kent (laboratory-identified and age- and gender-adjusted to match the HES population). The odds ratio for in-hospital mortality associated with AKI was 10.52 (95% confidence interval 9.93-11.16) in HES data and 5.38 (4.42-6.54) in East Kent data. AKI diagnosis was associated with a length of stay 2.59 (2.56-2.62) times as high as that for admissions without AKI in HES data and 1.63 (1.58-1.69) times as high in East Kent data. The annual cost of AKI-related care recorded in HES is estimated at £337 million. Based on the higher prevalence estimated from East Kent data, the annual cost of AKI-related inpatient care is estimated at £942 million, 5% of inpatient spending in England.

**Conclusions:** AKI prevalence in inpatients may be considerably higher than previously thought, and up to four fifths of cases may not be captured in routine hospital data. AKI is associated with large numbers of in-hospital deaths and with high NHS costs. Comparison of HES and East Kent data suggests that most of the cases recorded in HES may be relatively severe AKI (AKIN 2-3). These estimates do not include AKI in the non-hospitalised population.

**SA-PO016**

**Minocycline to Prevent Kidney Injury after Cardiac Surgery: A Randomized Double-Blinded Placebo-Controlled Pilot Study** Ladan Golestaneh,[1] Ziyad Al-Aly,[2] Michael I. Rauchman,[2] Kevin J. Martin,[3] Allon N. Friedman,[4] Pierre C. Dagher,[4] Tarek M. El-Achkar.[4] *[1]Montefiore Medical Center, Bronx, NY; [2]St. Louis VA Medical Center, St. Louis, MO; [3]St. Louis Univ, St. Louis, MO; [4]Indiana Univ, Indianapolis, IN.*

**Background:** Acute Kidney Injury (AKI) after cardiac bypass surgery (CABG) is a grave complication associated with significant morbidity and mortality. Minocycline therapy attenuates kidney injury in animal models of AKI but effects in humans are unclear.

**Methods: Study Design:** Randomized, double-blinded, placebo-controlled, multi-center study. **Setting & Participants:** We screened high risk patients who were scheduled to undergo CABG in 2 medical centers between Jan 2008 and June 2011. 40 patients were randomized and 19 patients in each group completed the study. **Intervention:** Minocycline prophylaxis given twice daily, at least for four doses prior to CABG to prevent AKI. **Outcome**: Primary outcome defined as AKI (0.3 mg/dl increase in Creatinine (Cr)) within 5 days after surgery. **Measurement:** Daily serum Cr for 5 days, various hemodynamic measures and length of stay (LOS).

**Results:** The two groups had similar baseline and intra-operative characteristics. The primary outcome occurred in 52.6% of patients in the minocycline group compared to 36.8% of patients in the placebo group (p= 0.51). Peak Cr was 1.6±0.7 vs. 1.5±0.7mg/dl (p=0.45) in the minocycline and placebo groups, respectively. Death at 30 days occurred in 0% vs. 10.5% in the minocycline and placebo groups, respectively (p=0.48). There were no differences in post-operative LOS, and cardiovascular events between the two groups, though there was a trend towards lower diastolic pulmonary artery pressure (16.8±4.7vs. 20.7±6.6 mmHg (p=0.059) and central venous pressure (11.8±4.3 vs. 14.6±5.6mmHg (p=0.13) in the minocycline group compared to placebo on the first day after surgery. In univariate analysis, obesity, peripheral vascular disease, duration of surgery and intraoperative hypotension were all significantly associated with developing AKI.

**Conclusions:** Minocycline did not reduce the risk of AKI in patients undergoing CABG. The potential effects of minocycline on pulmonary and cardiac compliance warrant a larger trial.

**SA-PO017**

**The Mechanism Underlying Nesiritide's Renal Protective Effects in Cardiac Surgery** Thomas M. Beaver,[1] Jessica A. Cobb,[1] Debra Robertson,[1] Maria Cecilia Lopez,[3] Henry V. Baker,[3] Lyle L. Moldawer,[1] Tomas D. Martin,[1] Philip J. Hess,[1] A. Ahsan Ejaz.[2] *[1]Surgery, Univ of Florida, Gainesville, FL; [2]Medicine, Univ of Florida, Gainesville, FL; [3]Molecular Genetics & Microbiology, Univ of Florida, Gainesville, FL.*

**Background:** Acute Kidney Injury (AKI) following cardiac surgery continues to be a problem; however, studies have demonstrated natriuretic peptides have renal protective effects. This study examined the protective mechanism of nesiritide, a human recombinant brain natriuretic peptide.

**Methods:** 29 cardiac surgery patients at risk for AKI were randomized to 48 hrs of nesiritide (0.01 mcg/kg/min) or placebo starting prior to surgery. AKI was based on KDIGO urine output criteria (<0.5mL/kg/hr over 6 hrs) and the biomarkers urineNGAL and urine IL-18. Serum pro-inflammatory cytokines and endothelin-1 were evaluated up to 24 hrs post cardiopulmonary bypass (CPB). In addition, microarrays of RNA from circulating neutrophils were examined. Statistical analyses were done with Mann-Whitney U and Fisher's exact tests.

**Results:** There was a trend towards decreased AKI based on urine output (57% of nesiritide group had AKI vs. 80% of placebo) and urineNGAL and IL-18 levels. Proteomic analysis found nesiritide had a mild anti-inflammatory effect (IL-6 and IL-10 levels decreased in the first hr after CPB). There was also a trend of lower endothelin-1 levels. Comparison of microarray expression patterns in patients with AKI vs. no AKI showed no significant difference. Table1: () denotes time post CPB in hrs. Values expressed as mean±SEM; NGAL in ng/mL; all others in pg/mL.

| | Nesiritide | Placebo | p-value |
|---|---|---|---|
| IL-6 (1) | 39.84±5.81 | 84.54±15.88 | 0.010 |
| IL-10 (0) | 1548.71±388.34 | 2399.49±327.25 | 0.021 |
| Endothelin-1 (4) | 2.674±0.207 | 3.567±0.429 | 0.163 |
| NGAL (2) | 230.27±71.49 | 554.39±263.31 | 0.253 |
| IL-18 (6) | 29.93±4.77 | 254.49±118.36 | 0.091 |

**Conclusions:** Nesiritide patients showed trends towards less AKI by biomarkers and greater urine ouput. A short-term anti-inflammatory effect and a trend of lower endothelin levels may explain nesiritide's renal protective effect.

**SA-PO018**

**Clinical Acquired Resistance to Cisplatin-Induced Acute Kidney Injury in Cancer Patients** Naoko Tsuji,[1] Hideo Yasuda,[1] Takayuki Tsuji,[1] Naro Ohashi,[1] Akihiko Kato,[1] Yoshihide Fujigaki.[2] *[1]1st Dept of Medicine, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Dept of Medicine, Teikyo Univ, Tokyo, Japan.*

**Background:** Animals that are recovering from cisplatin-induced acute kidney injury (AKI) are known to be resistant to kidney injury by repeated administration of cisplatin. This phenomenon, which is so-called acquired resistance, has not been reported in a clinical setting. We pick upped cancer patients who had cisplatin-induced AKI and investigated subsequent chemotherapy and kidney injury.

**Methods:** 54 cancer patients to which cisplatin were given in otorhinolaryngology/head and neck surgery and gastroenterology units of Hamamatsu University School Hospital from January 2007 to December 2011 were consecutively enrolled. We retrospectively investigated their clinical background and outcome. AKI was diagnosed by the criteria of Kidney Diseases: Improving Global Outcomes.

**Results:** 26 of 54 patients developed AKI after administration of cisplatin. Among 26 patients affected by cisplatin-induced AKI, cisplatin was administrated to 13 patients repeatedly in the following cycles. In the following cycles, only 3 patients (23.1%) developed AKI and but 10 patients (76.9%) did not. In 10 patients who did not repeat AKI in following cispaltin administrations, blood pressure, dosage of cisplatin, baseline serum creatinine, urine specific gravity, hydration volume, use of diuretics and blockades of renin-angiotensin systems, and other nephrotoxic agents such as non-steroidal anti-inflammatory drugs were not significantly different between the chemotherapeutic cycles with AKI and subsequent cycles without AKI. These suggested the first increases in serum creatinine were

caused by intrinsic kidney damage but not pre-renal hypovolemia. In 3 patients repeating AKI induced by cisplatin, the intervals of chemotherapeutic cycles tended to be longer than in acquired resistant patients (89.3±54.4 days vs 34.3±4.9 days).

**Conclusions:** Less incidence of AKI caused by repeated administrations of cisplatin after recovering from cisplatin-induced AKI suggested that the resistance to AKI has been acquired in the cancer patients.

## SA-PO019

**High Performance Information Search Filters for Acute Kidney Injury Content in PubMed, Ovid Medline, and Embase** Ainslie M. Hildebrand,[1] Arthur Iansavichus,[2] Nancy L. Wilczynski,[3] Amit X. Garg.[1,2,3] *[1]Div of Nephrology, Western Univ, London, Canada; [2]Kidney Clinical Research Unit, London Health Sciences Centre, London, Canada; [3]Dept of Epidemiology and Biostatistics, McMaster Univ, Hamilton, Canada.*

**Background:** We frequently fail to identify relevant articles when we search the large bibliographic databases PubMed, Ovid Medline or Embase.

**Methods:** We used computer automation to create information search filters to better identify articles relevant to acute kidney injury in these databases. We first manually reviewed a sample of 22,992 full text articles and used reference criteria to determine if each article contained acute kidney injury content or not. In the development phase (two thirds of the sample) we developed and tested the performance of over 1.6 million unique filters. Filters with high sensitivity and high specificity for the identification of acute kidney injury articles were then retested in the validation phase (remaining third of the sample).

**Results:** We succeeded in developing and validating high-performance acute kidney injury search filters for each bibliographic database with sensitivities and specificities in excess of 90%. Filters optimized for sensitivity reached at least 97.2% sensitivity and filters optimized for specificity reached at least 99.4% specificity. The filters were complex; for example one PubMed filter included over 140 terms used in combination, including 'acute kidney injury', 'tubular necrosis', 'azotemia', and 'ischemic injury'. In proof of concept searches physicians found more articles relevant to topics in acute kidney injury with the use of the filters.

**Conclusions:** These high performance information filters are now available online and can be used to better identify acute kidney injury content in large bibliographic databases.

## SA-PO020

**Sepsis Six Bundle of Care May Reduce the Incidence of Severe Acute Kidney Injury in Hospital** Edward Stern, Kelly Wright, Ben Caplin, Dorothea Nitsch, Nick R. Murch, Steve Shaw, Chris Laing. *Royal Free Hospital, London, United Kingdom.*

**Background:** Systemic sepsis is estimated to be a contributory cause in 47% of episodes of in-hospital acute kidney injury (AKI). There is limited evidence for interventions to reduce the incidence of sepsis-associated AKI. The Sepsis Six bundle uses fixed physiological cutoffs (triggers) on the bedside observation chart to identify patients at risk of severe sepsis. The bundle specifies six mandatory interventions (oxygen, fluid balance chart, arterial blood gas, intravenous fluid, blood cultures, antibiotics) to be performed within one hour of trigger. We investigated whether compliance with this bundle of care was associated with improved acute renal outcome.

**Methods:** We collected data on 415 consecutive patients who triggered for Sepsis Six shortly after introduction of the bundle to the Royal Free Hospital in London. We compared baseline with peak creatinine up to 10 days post-trigger to classify renal outcome using KDIGO delta creatinine criteria. We compared AKI outcomes between patients with complete and incomplete implementation of the Sepsis Six bundle.

**Results:**

| (number in group) | No AKI | AKI 1 | AKI 2 | AKI 3 | Total |
|---|---|---|---|---|---|
| 6 interventions | 140 | 22 | 23 | 11 | 196 |
| 0-5 interventions | 141 | 25 | 14 | 39 | 219 |
| Total | 281 | 47 | 37 | 50 | 415 |

We calculated relative risk ratio (RRR) for developing each stage of AKI (versus no AKI) with all six interventions completed and corrected for the presence of hypotension when triggering: AKI 1 RRR=0.9 (95% CI 0.5-1.7, p=0.73); AKI 2 RRR=1.5 (95% CI 0.8-3.1, p=0.24); AKI 3 RRR=0.3 (95% CI 0.1-0.6, p<0.01).

**Conclusions:** Sepsis Six triggers (simple bedside observations) identified a cohort with a high incidence of AKI (32%). Full compliance with the Sepsis Six bundle was associated with a 70% reduction in the risk of developing AKI 3, compared with incomplete compliance. A non-significant rise in the incidence of AKI 2 suggests potentially severe renal injury may have been converted to moderate injury by good compliance with the bundle. These data support the hypothesis that a simple, protocolised intervention, performed early in the course of sepsis, could protect against severe AKI.

## SA-PO021

**Does a Care Bundle Improve Management of Acute Kidney Injury? Results from Completed Audit Cycle** Jennifer R. Joslin, Daniel Zubli, Nathan Gauge, Hannah R. Wilson, Anna Buckingham, Tracy Ellimah, Cornelia Junghans Minton, Charlotte Masterton-smith, Sabrina Rossi, Joanna Sutherby, Katherine E.S. Warren, Mark Andrew Yates, Taryn Pile, Maria Ostermann. *Guy's and St. Thomas NHS Foundation Trust, London, United Kingdom.*

**Background:** An audit in 2011 showed poor recognition and management of patients with acute kidney injury (AKI) in level 1 inpatients (poster presentations, ASN 2011). In response, an AKI 'care bundle' was developed, in conjunction with the London AKI network, and AKI education among doctors and nurses was increased. This project completes the audit cycle.

**Methods:** The same methods were used as in the audit in 2011. During a 7 day period in April 2013, electronic patient records of all level 1 medical and surgical patients in a London teaching hospital were screened. Medical notes of patients with AKI as defined by the KDIGO criteria were reviewed by doctors independent from the treating team to assess compliance with recommended management. Patients receiving palliative care were excluded. Data were compared with results from 2011.

**Results:** 99 patients had AKI in the 2011 audit period and 95 in 2013. Mean ages were 73 and 69 years, respectively. Data of 244 AKI inpatient hospital days was available in 2011, and 250 for 2013.

| | 2011 AKI patient-days (%) | 2013 AKI patient-days (%) | p-value |
|---|---|---|---|
| AKI recognised by managing team | 59 | 74 | <0.001 |
| Documented AKI management plan if AKI recognised | 82 | 85 | 0.47 |
| Clinical assessment of fluid status | 37 | 66 | <0.001 |
| Complete fluid balance chart | 32 | 40 | 0.04 |
| iv fluids given if vulnerable to hypovolaemia | 82 | 75 | 0.2 |
| Contrast prophylaxis given if indicated | 44 | 56 | 0.5 |
| Timely antibiotics given if septic | 82 | 69 | 0.22 |
| Nephrotoxic drugs discontinued if appropriate | 31 | 76 | <0.001 |

There was also better recognition of AKI by the managing team on the 1st day of AKI (50% in 2011 vs 70% in 2013, p=0.015).

**Conclusions:** Implementation of an AKI bundle, together with enhanced education improves recognition of AKI and some aspects of care. However, more work is needed to understand the factors which limit recognition and good medical care.

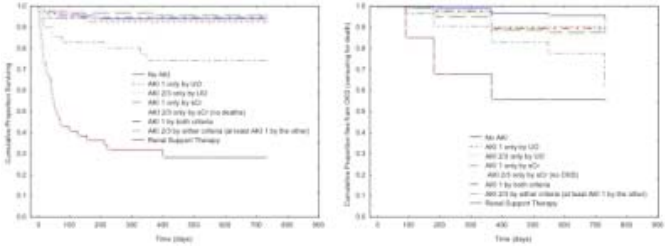
## SA-PO022

**Differential Prognosis after Cardiac Surgery-Associated Acute Kidney Injury According to Creatinine or Urine Output Criteria** Maribel Merino, Cesar Flores-Gama, Armando Vazquez-Rangel. *Nephrology, Instituto Nacional de Cardiologia, Ignacio Chavez, Mexico, Mexico.*

**Background:** Cardiac surgery-associated acute kidney injury (CS-AKI) results in increased morbidity and mortality. We analyzed short and midterm mortality and progression to chronic kidney disease (CKD) according to the criteria, either by serum creatinine (sCr) or by urine output (UO).

**Methods:** Retrospective analysis of adult patients who underwent cardiac surgery between March 2010 and June 2012 was made. CS-AKI was defined within 7 days according to KDIGO criteria. Progression to CKD was defined as having beyond 3 months an estimated glomerular filtration rate (eGFR) by CKD-EPI <60 ml/min/1.73 $m^2$ and a reduction from baseline eGFR of at least 15 ml/min/1.73 $m^2$. Kaplan-Meier curves were constructed for outcomes.

**Results:** A total of 794 patients were included, 56.9% were men, mean age was 53.5±15.8 years and baseline eGFR of 87.3±21.7ml/min/1.73 $m^2$ Any CS-AKI occurred in 494 (62.2%) patients, 103 (20.8%) had isolated UO criteria, 222 (44.9%) had isolated sCr criteria, and 113 (22.9%) had combined criteria, all of them without renal support therapy (RST). Just 56 patients required RST. With a median follow-up time of 365 days, 78 (9.8%) died and 52 (6.5%) progressed to CKD (censoring for death). In survival analysis, patients with AKI stage 1 by any or both criteria, patients with stage 2/3 but only by one of the criteria and not requiring RST, did not show significant difference in mortality and progression to CKD from patients without AKI. In contrast, AKI stage 2/3 with both AKI criteria or patients requiring RST, had a significant increase in mortality and progression to CKD.



**Conclusions:** CS-AKI contributes to a different short and midterm prognosis according to specific fulfilled criteria. Patients with stage 2/3 but only by one of the criteria showed a similar prognosis to those without AKI.

## SA-PO023

**Diverse Hemostasis Results in Cancer Patients with Acute Kidney Injury (AKI) Evaluated by Standard Coagulation Methods or Thromboelastography**

James Hung,[1] Tania Rubia Flores Rocha,[2] Elbio Antonio D'amico,[2] Luis Yu.[1]
*[1]ICESP, Universidade de Sao Paulo; [2]Universidade de Sao Paulo.*

**Background:** Routine tests, such as prothrombin time (PT), activated partial thromboplastin time (aPTT) and thrombin time (TT) are frequently ordered to assess clotting function but they might be inadequate. Thus, we compared the results of conventional tests with thromboelastography (TEG), which assesses clot formation in whole blood, including plasma and cellular components, in cancer patients with AKI.

**Methods:** We prospectively analysed patients admitted to the ICU of a Cancer University Hospital with sepsis. Renal dysfunction was classified according to the AKIN criteria. Besides standard coagulation tests (PT, aPTT and TT), TEG was used to evaluate the entire process of hemostasis.

**Results:** We included 103 patients: mean age 61±15y, 57% male, 85% solid tumors, 15% hematological tumors, 67% on vasopressors, 68% developed AKI (AKIN 1 - 19 patients, AKIN 2 - 20 patients, AKIN 3 - 31 patients).

| | Without AKI# | AKIN 1 | AKIN 2 | AKIN 3 | p |
|---|---|---|---|---|---|
| creatinine (mg/dl) | 0.8 | 1.29 | 1.4 | 2.59 | <0.05, # vs AKIN 2 and 3 |
| urea (mg/dl) | 44 | 66 | 87 | 142 | <0.05, # vs AKIN 2 and 3 |
| calcium (mg/dl) | 4.6 | 4.7 | 4.5 | 4.6 | 0.72 |
| hemoglobin | 8.7 | 9.8 | 8.5 | 9.7 | <0.05, AKIN 2 vs AKIN 3 |
| platelets ($10^3$/mm$^3$) | 184 | 214 | 236 | 160 | 0.56 |
| PT | 1.12 | 1.28 | 1.41 | 1.55 | <0.05, # vs AKIN 2 and 3 |
| aPTT | 0.99 | 1.02 | 1.14 | 1.15 | <0.05, # vs AKIN 2 and 3 |
| TT | 1.06 | 1.11 | 1.14 | 1.31 | <0.05, # vs AKIN 3 |
| **TEG** | | | | | |
| R | 8.5 | 8.9 | 8.4 | 10.6 | 0.08 |
| K | 2.4 | 2.6 | 2.8 | 3.2 | <0.05, # vs AKIN 3 |
| angle | 56.7 | 52.6 | 55.1 | 44.2 | <0.05, # vs AKIN 3 |
| MA | 64 | 60 | 64 | 58 | 0.53 |
| CI (coagulation index) | 1.6 | 1.4 | 1.8 | 0.7 | 0.52 |

**Conclusions:** Severe AKI caused impaired coagulation in cancer patients as evaluated by standard assays of hemostasis, suggesting a bleeding risk in this situation. In contrast, a normal result was shown in the same cancer patients using TEG. Thus, diverse hemostasis status was demonstrated in AKI cancer patients that may lead to distinct diagnostic and therapeutic maneuvers.

*Funding:* Government Support - Non-U.S.

## SA-PO024

**Acute Kidney Injury (AKI) Is Associated with Bronchopulmonary Dysplasia (BPD) in Very Low Birth Weight (VLBW) Infants**

Neha Patil, Rajesh Koralkar, Susan Keeling, Namasivayam Ambalavanan, David J. Askenazi. *Pediatrics, Univ of Alabama at Birmingham, Birmingham, AL.*

**Background:** Lung dysfunction has been linked with AKI in animal models and is thought to contribute to poor outcomes in critically ill children and adults with lung injury. Chronic lung injury is very common in neonates; yet the association between AKI and lung outcomes has not been explored.

**Objective:** To evaluate association between AKI and BPD in VLBW infants.

**Methods:** Between February 2012 to February 2013, 91 VLBW Infants (birth weight <=1200 gm. or gestational age <31 weeks) had serum creatinine (SCr) values prospectively collected on days 1, 2, 3, 4, and 14; and combined with clinically measured SCr to determine AKI status according to KDIGO; whereby AKI was defined if SCr ≥ 0.3 mg/dl or ≥ 150-200% from lowest previous value. Difference in the changes of SCr between day 4 and 14 were assessed between respiratory support categories using repeated measures ANOVA controlling for potential confounders.

**Results:** The incidence of AKI over first two weeks of life was (27/87) 31%. AKI infants were more likely to receive ventilator support at day 28 compared to those without AKI (p< 0.05). Changes in SCr from day 4 to 14 were different among respiratory support categories at day 7, 14, 21 and 28 (p value <0.01). When controlling for potential confounders individually, this association was significant for birth weight, surfactant, gender and race (p value <0.05), however; with combination of them and addition of gestational age this independent association was no longer present.

| Respiratory Support Day 28 | AKI Day 3 | | AKI Day 7 | | AKI Day 15 | |
|---|---|---|---|---|---|---|
| | No (66) | Yes (15) | No (60) | Yes (21) | No (57) | Yes (24) |
| **Room air /Oxygen Dome** | 48 (74%) | 7 (47%) | 46 (77%) | 9 (43%) | 45 (79%) | 10 (42%) |
| **NC / CPAP** | 9 (13%) | 2 (13%) | 8 (13%) | 3 (14%) | 8 (14%) | 3 (12%) |
| **Mechanical Ventilation** | 9 (13%) | 6 (40%) | 6 (10%) | 9 (43%) | 4 (7%) | 11 (46%) |
| **P value** | 0.05 | | 0.002 | | 0.0001 | |

**Conclusions:** In VLBW infants, AKI is strongly association with receipt of respiratory support. Whether AKI truly contributes to BPD in these infants is yet to be determined.

## SA-PO025

**Lysozyme-Induced Acute Tubular Injury: An Under-Recognized Cause of Acute Renal Failure**

Larry N. Cossey, Christopher Patrick Larsen. *Nephropath, Little Rock, AR.*

**Background:** Increased serum lysozyme has been reported in association with many diseases, however only rare case reports have shown lysozyme-induced tubular injury leading to acute renal failure. This report attempts to more fully describe the clinical and laboratory findings associated with this disease.

**Methods:** Two patients with lysozyme-induced acute renal failure were identified from our database in the past year. Routine light, immunofluorescence, and electron microscopy were performed. In addition, immunoperoxidase staining for lysozyme and laser microdissection of cortical tubules coupled with mass spectrometry were performed on both patients and two controls.

**Results:** The patients are 77 and 80 year-old males with acute-on-chronic renal failure and non-nephrotic range proteinuria. Both patients had bland urine sediment and no hematuria. Serum creatinine at time of biopsy was 2.0 and 2.1 mg/dl, respectively. Serum lysozyme level was available in one patient and was >12x reference range. Chronic myelomonocytic leukemia and myelodysplastic syndrome were present, respectively. By light microscopy diffuse acute tubular injury with epithelial thinning and loss of brush boarder was seen. Proximal tubules had brightly eosinophilic cytoplasm with round, slightly refractile (non-polarizable) protein droplets. Congo red stained positive within this material in the proximal tubules with no birefringence on polarization. Staining for lysozyme showed intense positivity within the proximal tubules and interstitium with mild tubular staining identified in proteinuric controls. Laser microdissection of cortical tubulointerstitium followed by mass spectrometry showed lysozyme as the most abundant protein in patients but not controls.

**Conclusions:** Lysozyme-induced acute renal injury is likely an under-reported cause of acute renal injury with this study confirming that the eosinophilic substance within the proximal tubules of these patients is lysozyme. By histology, we describe a unique constellation of findings including intensely eosinophilic protein droplets in proximal tubules with nonspecific staining for Congo red. Additionally, increased tubulointerstitial lysozyme staining can aid in diagnosis.

## SA-PO026

**Effects of *Schizolobium Parayba* Extract on Experimental Bothrops Venom-Induced Acute Kidney Injury**

Monique Silva Martinez,[1] Miriam Mendes,[2] Maria H.M. Shimizu,[1] Veridiana Avilla,[2] Isac De Castro,[1] Sebastiao R. Ferreira-Filho,[2] Denise M.A.C. Malheiros,[1] Luis Yu,[1] Emmanuel A. Burdmann.[1] *[1]Univ of Sao Paulo Medical School; [2]Uberlandia Federal Univ.*

**Background:** Venom-induced acute kidney injury (AKI) is a frequent complication of *Bothrops* snakebite, carrying relevant morbidity and mortality. The aim of this study was to assess the effects of *Schizolobium parayba* (SP) extract, a natural medicine with confirmed anti-phospholipase A2 effects in an experimental model of *Bothrops jararaca* venom (BV)-induced AKI.

**Methods:** Groups of 8-10 rats were assessed 20 min after injection of saline (VH), SP 2 mg/kg, BV 0.25 mg/kg and BV plus SP. The following parameters were analyzed: glomerular filtration rate (GFR, ml/min/100g, inulin clearance), renal blood flow (RBF, ml/min, Doppler), blood pressure (BP, mmHg, intra-arterial transducer), renal vascular resistance (RVR, mmHg/ml/min/, formula), urinary osmolality (UO, mOsm/kg, freezing point), urinary NGAL (NGAL, µG, ELISA), lactic dehydrogenase (LDH, IU/L, kinetic method), fibrinogen (F, mg/dl, Klauss modified) and blinded renal histology. Results (mean±SE) are shown below (*p<0.05 vs. control).

**Results:**

| | VH | SP | BV | BV+SP |
|---|---|---|---|---|
| GFR | 0.87±0.04 | 0.63±0.04* | 0.47±0.05* | 0.52±0.07* |
| RBF | 6.3±0.2 | 6.2±0.2 | 3.0±0.2* | 3.6±0.3* |
| BP | 134±4 | 132±4 | 127±7 | 120±4 |
| RVR | 20±1 | 21±1 | 39±7* | 34±3* |
| UO | 1305±113 | 1275±117 | 569±48* | 669±54* |
| NGAL | 11.8±2.3 | 11.3±1.5 | 23.8±4.5* | 18.4±2.3 |
| LDH | 107±38 | 267±156 | 2883±589* | 2946±912* |
| F | 164±12 | 144±19 | 60±5* | 60±1 |

BV caused acute tubular necrosis, which was not prevented by SP.

**Conclusions:** SP administered simultaneously with BV, in an approximate 10:1 concentration, was not able to prevent BV-induced AKI, hemolysis and fibrinogen consumption. SP alone caused GFR decrease.

## SA-PO027

**IgA Nephropathy with ANCA Seropositivity: A Case Series**

Angela K. Muriithi,[1] Lynn D. Cornell,[2] Fernando C. Fervenza,[1] Mary E. Fidler,[2] Sanjeev Sethi,[2] Samih H. Nasr.[2] *[1]Divs of Nephrology, Mayo Clinic; [2]Anatomic Pathology, Mayo Clinic, Rochester, MN.*

**Background:** Anti-neutrophil cytoplasmic antibodies (ANCA) are typically associated with pauci-immune necrotizing and crescentic glomerulonephritis (GN). There have been rare reports and small case series of ANCA positivity in patients with crescentic IgA nephropathy (IgAN). It is unclear if ANCA positivity in IgAN correlates with prognosis or the presence of crescents.

**Methods:** We report the clinical and pathologic findings of 18 patients with IgAN and concomitant ANCA positivity.

**Results:** We identified 13 men and 5 women from 1993 to 2012 among 425 patients with biopsy-proven IgAN who had ANCA positivity by ELISA (4%). Mean age was 50 years. 15 had myeloperoxidase (MPO), 1 proteinase-3 (PR3) and 2 both.

8 patients (47%) presented with proteinuria/microhematuria, 4 (24%) with rapidly progressive GN (RPGN), 4 (24%) with chronic kidney disease and 1 patient with acute kidney injury. All 18 had proteinuria (mean 3.4 g/24h), and 15/17 (88%) microhematuria. 2/17 (12%) had pulmonary involvement and 5/17 (29%) skin lesions. Mean serum creatinine was 2 mg/dl.

Histologically, 6 (35.3%) had crescents involving a mean of 35% glomeruli (range 10-59). 4 (24%) had glomerular necrosis; none had arteritis. All patients had IgA dominant mesangial staining on immunofluorescence. Mesangial deposits were seen in all 15 cases studied ultrastructurally.

Follow-up was available for 15 patients; 2 received ACE inhibition and/or fish oil only and 11 immunosuppressive therapy: cyclophosphamide/steroids then mycophenolate/azathioprine (n=6), mycophenolate/steroids (n=3), steroids only (n=2). Of the 6 with crescentic IgAN, 3 had RPGN and 4 received cyclophosphamide-based therapy. At a mean follow-up of 46 months, 2 died of unrelated causes, 4 progressed to ESRD (all 4 had RPGN, 3 with crescentic IgAN), and 9 had stabilized or improved their kidney function.

**Conclusions:** ANCA positivity is rare in patients with IgAN. Contrary to previous reports, we found that ANCA was associated with RPGN in only a quarter of IgAN patients and with crescentic disease in only a third. The outcome in crescentic IgAN patients with ANCA appears to reflect that of crescentic IgAN who present with RPGN.

## SA-PO028

**The Incidence, Etiology, and Outcome of Acute Kidney Injury in Patients with Liver Abscess** Seong Eun Yun, Dong Jun Park, Se-Ho Chang, Hyun Seop Cho, Yeojin Kang, Eunjin Bae. *Div of Nephrology, Dept of Internal Medicine, Gyeongsang National Univ Hospital, JinJu, Republic of Korea.*

**Background:** Acute kidney injury (AKI) can occur in various infectious conditions. Liver abscess is relatively rare disease leading to severe complications. Study about AKI in patients with liver abscess is rare.

**Methods:** We retrospectively reviewed the medical records of 404 patients who were diagnosed as liver abscess from January, 2000 to March, 2013.

**Results:** Male to female ratio was 61:39 and the mean age was 62.9 ± 13.1 years old. AKI occurred in 137 patients (34%). As per RIFLE classification, renal injury was in risk (35.8%), injury (47.4%), and failure (16.5%). One hundred fourteen patients (83.2%) initially had AKI on admission whereas others progressed to AKI during hospitalization. Fifty six (41%) patients had pre-renal azotemia whereas 19 patients (14%) were compatible with radio-contrast induced nephropathy. AKI occurred frequently in men and patients with liver cirrhosis (P<0.001 and P=0.005). Lower serum albumin and higher AST and ALT level were shown in patients with AKI, compared to patients with non-AKI. Isolation of organisms from blood culture and liver abscess aspirates were more frequent in AKI patients (P<0.001 and P=0.007). Hospitalization period was also longer in AKI patients (P<0.001). Existence of septic shock was positively correlated with occurrence of AKI (P=0.002). Twenty patients (5.0%) had chronic kidney disease (CKD). AKI was significantly more frequent in patients with CKD (P=0.04). Mortality had no difference between AKI and non-AKI. However, higher mortality was presented in CKD patients accompanied by AKI (P<0.001). Hemodialysis was done in three patients with AKI; two patients who had initially normal renal function completely recovered whereas one CKD patient progressed to ESRD requiring maintenance hemodialysis.

**Conclusions:** AKI is relatively common in patients with liver abscess although most are recovered completely. However, patients with previous renal impairment may have poorer prognosis if they are accompanied by AKI. Physician should make an effort to prevent, detect, and manage AKI early in patients with liver abscess.

## SA-PO029

**Clinical Characteristics of Acute Kidney Injury in Patients with Scrub Typhus – RIFLE Criteria Validation** In O. Sun, Kwang Young Lee. *Div Nephrology, Dept of Internal Medicine, Presbyterian Medical Center, Jeonju, Korea.*

**Background:** The aim of this study is to investigate the incidence and clinical characteristics of acute kidney injury (AKI) based on RIFLE criteria in scrub typhus.

**Methods:** From 2010 to 2012, 238 patients were diagnosed as scrub typhus. Of these, we included 223 patients who were followed up until renal recovery or for at least 3 months, and evaluated the incidence, clinical characteristics and severity of AKI based on RIFLE classification.

**Results:** Of 223 patients, 47 (21%) had scrub typhus-associated AKI. The incidence of AKI was 21.1%; of which, 10.7%, 9.4% and 1% were the Risk, Injury and Failure classes, respectively. In comparison with patients in non-AKI group, the patients in AKI group were older (70 ± 9 vs 61 ± 14 year, P=0.01) and had more comorbidities such as hypertension, diabetes and chronic kidney disease (77% vs 22%, P=0.01). The patients in AKI group had worse renal function than that of Non-AKI group at admission (37 ± 15 vs 82 ± 19ml/min/1.73m$^2$, P=0.01). Forty-five had AKI prior to admission, whereas 3 patients experienced AKI during their hospitalization.By multivariative logistic regression analysis, age and comorbidity were significant predictors of AKI. All patients recovered baseline renal function without renal replacement therapy following antibiotics such as doxycycline and supportive care.

**Conclusions:** The incidence of AKI in patient with scrub typhus is 21%. Age and co-morbidity are significant predictors of AKI in scrub typhus. In case of scrub typhus-associated AKI, anti-rickettsia agent and supportive care is very important.

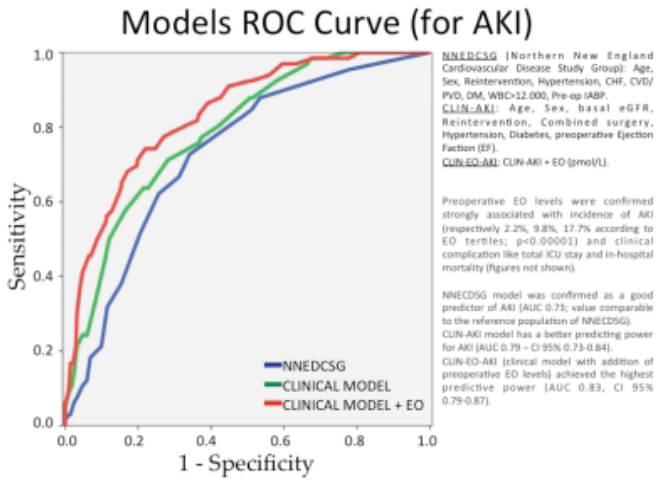
## SA-PO030

**A New Clinical Model for Postoperative AKI: Role of Endogenous Ouabain** Marco Simonini,[1] Nunzia Casamassima,[1] Chiara Lanzani,[1] Elena Bignami,[1] Elena Frati,[1] Roberta Meroni,[1] Elisabetta Messaggio,[1] John Hamlyn,[2] Paolo Manunta.[1] *[1]San Raffaele Scientific Institute, Milan, Italy; [2]Univ of Maryland, Baltimore.*

**Background:** AKI is a frequent complication of cardiosurgery. A lot of models predicting AKI have been proposed, but only few focused on milder AKI not requiring dialysis (AKI-ND), which is very common and contributes to several in-hospital outcomes. Endogenous Ouabain (EO) is an adrenal stress hormone with hemodynamic and renal effects. Recently it has been reported that higher pre-operative EO levels are associated with a worse renal outcome after surgery. Our aim is to develop a new risk model of AKI-ND using clinical aspects and EO as biomarker.

**Methods:** AKI according to AKIN was studied. We built predictive risk model (CLIN-AKI) considering clinical variables (see figure 1 for details). A further risk score (CLIN-EO-AKI) was developed adding preoperative EO values to the CLIN-AKI score. NNECDSG model, the only preoperative model for AKI-ND reviewed, was used for comparison.

**Results:** All models were tested on 802 patients admitted for elective cardiac surgery. 79 patients developed AKI (9.9%). NNECDSG model was confirmed as a good predictor of AKI (AUC 0.73, value comparable to the reference population). CLIN-AKI model has a better predicting power for AKI per se (AUC 0.79). Adding the preoperative EO level to the clinical model AUC increased to 0.83 (CI 95% 0.79-0.87). Inclusion of EO improved the risk prediction over the clinical models alone (ΔAUC respectively +0.06, p<0.03 and +0.1, p<0.01).



**Conclusions:** We developed a powerful and accurate risk model based on eight simple preoperative variables. This model was greatly improved by the addition of EO level as marker of kidney and vascular subclinical damage. Both these models are straightforward, useful and readily applicable at the bedside.

## SA-PO031

**Acute Kidney Injury from Calcium Channel Blocker-Clarithromycin Drug Interactions** Amit X. Garg,[1,2,3] Sonja Gandhi,[1,2] Jamie L. Fleet,[2] David G. Bailey,[2] Eric McArthur,[3] Ron Wald,[4] Faisal Rehman.[2] *[1]Western Univ; [2]London Health Sciences Centre; [3]Institute for Clinical Evaluative Sciences; [4]Univ of Toronto.*

**Background:** Calcium channel blockers are metabolized by the cytochrome P450 3A4 (CYP3A4) enzyme. Blood concentrations of calcium channel blockers can rise to harmful levels when this enzyme is inhibited. Clarithromycin is an inhibitor of CYP3A4 while azithromycin is not, making comparisons of the two co-prescriptions useful to understand the potential consequences of this drug-drug interaction.

**Methods:** We conducted a population-based retrospective cohort study of older adults (mean 76 years) who were newly co-prescribed clarithromycin (n=96,226) or azithromycin (n = 94,083) while taking a calcium channel blocker (amlodipine, felodipine, nifedipine, diltiazem, or verapamil) in Ontario, Canada from 2003 to 2012. The primary outcome was hospitalization with acute kidney injury and two secondary outcomes were hospitalization with hypotension and all-cause mortality. All outcomes were assessed within 30 days of a new co-prescription. Risks were expressed in both absolute and relative terms.

**Results:** Amlodipine was the most commonly prescribed calcium channel blocker (>50% of patients). Co-prescription with clarithromycin *vs.* azithromycin was associated with an increased risk of hospitalization with acute kidney injury [absolute risk increase 0.22% (95% confidence interval (CI) 0.16 to 0.27); relative risk (RR) 1.98 (95% CI 1.68 to 2.34)]. In subgroup analysis, this risk was highest with nifedipine [RR 5.33 (95% CI 3.39 to 8.38)]. Co-prescription with clarithromycin *vs.* azithromycin was also associated with an increased risk of hospitalization with hypotension [absolute risk increase 0.04% (95% CI 0.02 to 0.07); RR 1.60 (95% CI 1.18 to 2.16)] and all-cause mortality [absolute risk increase 0.43% (95% CI 0.35 to 0.51); RR 1.74 (95% CI 1.57 to 1.93)]. The primary associations proved robust in multiple additional analyses.

**Conclusions:** In older adults taking a calcium channel blocker, co-prescription of clarithromycin increases the risk of adverse events. Better prescribing to avoid CYP3A4 drug interactions with calcium channel blockers is warranted.

*Funding:* Government Support - Non-U.S.

## SA-PO032

**Bioelectrical Impedance as Prognostic Predictor in Acute Kidney Injury. Importance of Na/K Ratio, Total Water Corporal Volume and Its Distribution. Risk Stratification** Francisco Javier Lavilla, Jose Maria Mora Gutierrez, Nuria Garcia-Fernandez, Paloma L. Martin Moreno, Carmen Calderon Gonzalez, Diana Lopez Espinosa, Pedro Errasti. *Nephrology, Univ CLinic of Navarra, Pamplona, Navarra, Spain.*

**Background:** Evaluate prognostic implication of bioimpedance (BIA) in acute kidney injury (AKI). Importance of bioelectrical parameters, total body water and its distribution.

**Methods:** In 133 patients ( 64 years, EE: 1.57; 76 males) with AKI and bioimpedance analysis. We evaluated bioelectrical (phase angle -PA- and Na/K exchange ratio -Na/K-) and volemic parameters (liters -L-) (total body water -TBW-, extracellular water -ECW-, intracellular water -ICW- and ECW/ICW ratio), and relationship with prognostic index (Individual Severity Index -ISI– and Multi-Organ Failure Index –MOFI –), C reactive protein (CRP), prealbumin (PRALB) and natriuretic (BNP). Statistical analysis with SPSS 15.0.

**Results:** The PA, Na/K and ECW/ICW were associated with prognostic index, chronic health status, inflammatory status and protein metabolism.

| | ISI | MOFI | CRP | ALB | PRALB | KAR |
|---|---|---|---|---|---|---|
| PA<br>p | -0.295<br>0.039 | -0.235<br>0.018 | -0.300<br>0.003 | 0.324<br>0.007 | 0,440<br>0,005 | 0,443<br>0,000 |
| Na/K<br>p | 0.235<br>0.016 | 0.316<br>0.003 | 0.221<br>0.046 | -0.020<br>0.886 | -0,518<br>0,002 | -0,327<br>0,002 |
| ECW/ICW<br>p | 0.232<br>0.009 | 0.234<br>0.008 | 0.331<br>0.005 | | -0.433<br>0.002 | 0.281<br>0.015 |

PA: Phase angle. Na/K: Na/K exchange. ECW/ICW: extracelular/intracelular water ratio. ISI: Individual Severity Index. MOFI: Multi-Organ Failure Index. CRP: C-reactive protein PRALB: Prealbumin. BNP: Blood natriuretic peptide.

The NA/K was independently associated with death risk (p = 0.022 OR 5.05, 95% CI: 1.251-23.7), area under the curve of 0.714 p = 0.036 and cutoff of 1.1, sensitivity (0.889) and specificity (0.759). Mortality analysis showed differences in ECW/ICW, with greater values in deceased patients (1.5 EE EE 0.07 vs 1.97 0.20, p = 0.027).

**Conclusions:** The electrical bioimpedance analysis can be used as a prognostic parameter in patients with AKI. Na/K ratio may assess the risk of death, mainly with values greater than 1.1. The volume distribution is mostly related with prognosis, especially with extracellular-intracellular shift.

## SA-PO033

**Acute Kidney Injury in Pediatric Patients after Cardiac Surgery: Risk Factors and Prognosis** Maria Goretti M.G. Penido,[1] Nilzete Liberato Bresolin,[2] Vanessa Oliveira Duarte,[3] Andreia Elisa Baldissera,[3] Aline Patrícia Alves Pereira Bianchini.[4] *[1]Pediatric Nephrology Unit, Federal Univ of Minas Gerais, Belo Horizonte, MG, Brazil; [2]Joana de Gusmão Infant Hospital, Federal Univ of Santa Catarina, Florianopolis, SC, Brazil; [3]Dr J Amarante Faria Infant Hospital, Florianopolis, SC, Brazil; [4]Syrian Lebanese Social Responsibility Institute, Sao Paulo, SP, Brazil.*

**Background:** Studies on acute kidney injury (AKI) after cardiac surgery in children using the pediatric pRIFLE criteria are rare. The aims of this study were to analyze the prevalence of AKI, the association with cardiopulmonary bypass (CPB), with clinical variables and the prognosis after cardiac surgery in children admitted to a pediatric intensive care unit (ICU). The pRIFLE and the RACHS-1 score were analyzed as a prognostic tool.

**Methods:** This retrospective case-control study consisted of 160 children who underwent cardiac surgery. They were divided in G1 (without AKI, 75 patients) and G2 (with AKI, 85 patients) and classified according to the pRIFLE criteria. Data included: age, gender, weight, height, RACHS-1, prior renal function, use of mechanical ventilation, vasoactive drugs, need for dialysis, CPB time, length of stay (LOS) and outcome (discharge or death). Poisson multivariate analysis was used to estimate the associated factors.

**Results:** Eighty-five patients (53%) developed AKI. Association with the following parameters were observed: 69% had higher prevalence after the use of nephrotoxic drugs (p=0.008), 55% after surgeries with CPB (p=0.038). There was an inverse correlation between length/heigth and AKI (p<0.001). LOS in the ICU (p<0.001), CPB time (p<0.001) and mortality (p=0.006) were significantly higher in G2, as severity increased progressively among subgroups of G2 (p<0.001). Mortality was higher in patients with higher RACHS-1 scores (p<0.001). The cutoff time of CPB for risk of AKI was 70 minutes.

**Conclusions:** AKI was frequent and its incidence was higher in those with CPB-time ≥70 min. pRIFLE criteria were useful to define AKI and were also prognostic predictor. Mortality and LOS in the ICU were higher in G2. Use of nephrotoxic drugs, age, length/height, weight, and CPB were independent risk factors for AKI.

## SA-PO034

**Association between Low High-Density Lipoprotein Cholesterol Level and Increased Risk of Contrast Nephropathy in Non-Diabetic Patients with Myocardial Infarction** Hyung Wook Kim, Hoon Suk Park, Kyungyoon Chang. *Internal Medicine, St. Vincent's Hospital, The Catholic Univ of Korea, Suwon, Gyeonggi-do, Korea.*

**Background:** Hypercholesterolemia is a well-known risk factor for cardiovascular disease (CVD), and HDL cholesterol reportedly has a protective effect against CVD. However, whether hypercholesterolemia or hyperlipidemia is a risk factor for contrast induced acute kidney injury (CI-AKI) is not established. We performed this study to find the relationship between cholesterol levels and CI-AKI.

**Methods:** This study included 289 non-diabetic patients with myocardial infarction (MI) undergoing percutaneous coronary intervention.Demographic data and clinical findings were compared between patients with and without CI-AKI. Logistic regression analysis was performed to identify independent risk factors. We also compared clinical courses between the 2 groups.

**Results:** HDL cholesterol level (odds ratio [OR] 0.82, 95% confidence interval [CI]: 0.72–0.94; p = 0.003) was an independent risk factor for CI-AKI in multivariable logistic regression analysis, besides MDRD eGFR (OR 0.86, 95% CI: 0.79–0.95; p = 0.002) and troponin T level (OR 1.50, 95% CI: 1.13–1.99; p = 0.005). The group with CI-AKI had a longer hospital stay (10.2 ± 6.5 days vs. 6.6 ± 4.6 days, p = 0.047), increased in-hospital death (50% vs. 2.9%, p < 0.001), and poorer patient survival (p <0.001) than the group without CI-AKI.

**Conclusions:** Low HDL cholesterol level is associated with an increased risk of CI-AKI in non-diabetic MI patients. More intensive strategies should be implemented for preventing CI-AKI in patients with low HDL cholesterol levels, and HDL cholesterol can be a new target in CI-AKI prevention.

## SA-PO035

**Renal Blood Flow Characterization in Critically Ill Patients with and without Acute Kidney Injury** Htay Htay, Manish Kaushik, Han Khim Tan. *Renal Medicine, Singapore General Hospital, Singapore.*

**Background:** Although the clinical manifestations of acute kidney injury (AKI) are well-known, much less is known about the changes in renal perfusion in this setting. The study focussed on critically ill patients with severe AKI.

**Methods:** This was an observational cohort study of 16 critically ill patients from medical intensive care unit: 10 patients with AKI requiring continuous renal replacement therapy (CRRT) (AKI group) and 6 patients with normal renal function (non-AKI group). Bedside trans-abdominal Doppler ultrasound interrogation of the renal arterial and aortic circulation was performed by cardiovascular technicians upon successful informed consent taking. The indices measured were abdominal aortic blood flow, renal artery blood flow and resistive indices (RI). The machine algorithm converted blood flow velocities into blood flow rates (mL/min).

**Results:** The median age in years of patients in AKI and non-AKI group were 57 (interquartile range 49-74) and 72 (49-75); p=0.36, respectively. The male to female ratio was 8:2 in AKI group and 5:1 for non-AKI group. The median hospital admission creatinine (umol/L) were 236 (102-391) for the AKI group and for the non-AKI group, 69 (54-81); p=0.02.

Comparing AKI versus non-AKI groups respectively, the median abdominal aorta flows (mL/min) were 3117 (Interquartile range 2743-3506) versus 3119 (2348-5440, p=0.875, the median renal arterial blood flows (mL/min) 440 (307-570) versus 735 (529-940), p=0.02; and, the median resistivity indices 0.83 (0.82-0.86) versus 0.75 (0.72-0.8), p=0.02.

**Conclusions:** Reduction in renal arterial blood flow during severe AKI in critically ill patients was associated with a significant rise in resistivity index (RI) but comparable aortic blood flows in both AKI and non AKI patients. The pathophysiologic significance of these findings needs further elucidation.

## SA-PO036

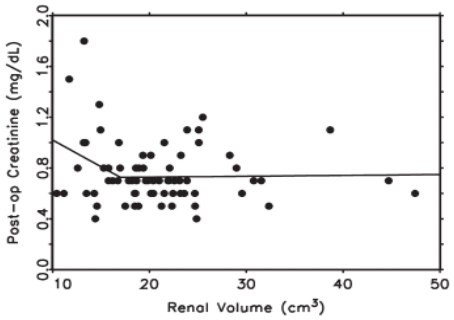
**Preoperative Renal Volume Predicts Peak Creatinine after Congenital Heart Surgery in Neonates** J. Bryan Carmody,[1] Michael D. Seckeler,[4] Cortney Ballengee,[5] Mark Conaway,[2] Kaimal A. Jayakumar,[3] Jennifer Richardson Charlton.[1] *[1]Div of Pediatric Nephrology, Univ of Virginia, Charlottesville, VA; [2]Dept of Biostatistics and Epidemiology, Univ of Virginia, Charlottesville, VA; [3]Div of Pediatric Cardiology, Levine Children's Hospital, Charlotte, NC; [4]Div of Pediatric Cardiology, Univ of Arizona, Tucson, AZ; [5]Dept of Pediatrics, Univ of Virginia, Charlottesville, VA.*

**Background:** Acute kidney injury (AKI) is common in neonates following surgery for congenital heart disease. We sought to determine whether neonates with smaller preoperative renal volume were more likely to develop postoperative AKI.

**Methods:** We reviewed 72 neonates who underwent congenital heart surgery at our center for any lesion other than patent ductus arteriosus from 2007-2011. Renal volume was calculated by ultrasound using the prolate ellipsoid formula. The presence and severity of postoperative AKI was determined both by measuring the peak serum creatinine in the first 7 days postoperatively and by using the Acute Kidney Injury Network (AKIN) scoring system.

**Results:** Using a linear change point model, a threshold renal volume of 17 $cm^3$ was identified. Below this threshold, there was an inverse linear relationship between renal volume and peak postoperative creatinine for all patients ($p = 0.036$) and the subgroup with

a single morphologic right ventricle ($p = 0.046$). There was a non-significant trend toward more AKI using the AKIN criteria in all neonates with renal volume ≤ 17 cm$^3$ ($p = 0.11$) and in the subgroup with a single morphologic right ventricle ($p = 0.17$).



**Conclusions:** Preoperative renal volume ≤17 cm$^3$ is associated with a higher peak postoperative creatinine and potentially greater risk for postoperative AKI for neonates undergoing congenital heart surgery. Infants with a single right ventricle may be at higher risk.

## SA-PO037

### Clinical Outcome of Patients on Combined ECMO and CRRT

Bijin Thajudeen, Mahmoud Kamel, Machaiah M. Madhrira, Amy Nicole Sussman. *Nephrology, Univ of Arizona, Tucson, AZ.*

**Background:** Extracorporeal membrane oxygenation (ECMO) is a supportive therapy, which provides cardiopulmonary and end-organ support in critically ill patients when other measures fail. Acute kidney injury in patients on ECMO is multifactorial. CRRT is a beneficial and efficient method of treatment in these patients. Since there is only limited outcome data on adult patients needing combined ECMO and CRRT, we looked at clinical characteristics of these patients and the factors determining mortality.

**Methods:** We did a retrospective observational chart review study of 40 consecutive patients above the age of 18, over a period of five years who received combined ECMO and CRRT. Outcomes measured included mortality and renal function at 30 days post initiation of combined ECMO and CRRT.

**Results:** Mean age of the cohort was 47 years. The most common indication for initiation of CRRT was maintenance of fluid balance in the presence or absence of acute kidney injury. 82.5 %( 33/40) of the patients died at 30 days post initiation of combined ECMO and CRRT. Mortality was found to be higher in patients above the age of 50 years compared to patients below the age of 50 years( P value=0.033). Renal function at the time of initiation, total fluid balance, serum albumin concentration and cardiac function at time of initiation of combined ECMO and CRRT did not predict mortality. Among the 7 (17.5 %) survivors, 5 patients required on going renal replacement therapy at 30 days( one required CRRT, four required intermittent hemodialysis). Two patients had complete recovery of their renal function.

**Conclusions:** Maintenance of fluid balance seems to be the most common indication for initiation of CRRT in adult patients on ECMO. Mortality is very high in adult patients receiving combined CRRT and ECMO. Age is an important predictor of mortality in these patients.

## SA-PO038

### Thrombotic Microangiopathy and Acute Renal Failure Associated with Intravenous Abuse of Opana ER: Report of Three Cases

Josephine M. Ambruzs,[1] Christopher Patrick Larsen.[1,2] *[1]Nephropath, Little Rock, AR; [2]Dept of Pathology, UAMS, Little Rock, AR.*

**Background:** There has been recent report and warning of a thrombotic thrombocytopenic purpura (TTP)-like illness associated with intravenous abuse of a prescription narcotic intended for oral use. Opana ER is an extended-release opioid agonist, oxymorphone hydrochloride, which has undergone a tamper-resistant reformulation. However, instances of melting and dissolving tablets with subsequent injection continue to occur.

**Methods:** We report the clinical and renal biopsy findings in three cases of acute renal failure associated with intravenous abuse of reformulated Opana ER.

**Results:** All cases involved young Caucasian adults including two males and one female. The clinical presentation was that of hemolytic anemia and acute renal failure. Two cases had concomitant accelerated hypertension. The hemoglobin on presentation ranged from 8.7-12.5 g/dL and there was an elevated lactate dehydrogenase and decreased haptoglobin in all cases. The serum creatinine ranged from 3.7-15.1 mg/dL. All cases reported a drug abuse history to include recent intravenous injection of reformulated Opana ER. On renal biopsy, the predominant finding was thrombotic microangiopathy consisting primarily of severe arterial mucoid intimal edema. Glomeruli showed ischemic corrugation of the basement membranes and segmental duplication as well as mesangiolysis. All cases required hemodialysis and two also underwent therapeutic plasma exchange. Renal outcomes included continued hemodialysis in one and persistent renal dysfunction in another after one month and three months follow-up respectively.

**Conclusions:** We report the first renal biopsy case series of thrombotic microangiopathy associated with the intravenous abuse of reformulated Opana ER. All of the cases were young adults presenting with hemolytic anemia and acute renal failure. Treatment involved hemodialysis as well as therapeutic plasma exchange. Early follow-up suggests renal outcome is poor. The specific component or components of reformulated Opana ER responsible for endothelial injury remains to be elucidated.

## SA-PO039

### Eculizimab Therapy for Gemcitabine Induced Hemolytic Uremic Syndrome

Ashok K. Ananthasayanan,[1] Pradeep Arora,[1,2] Rajiv Ranjan,[1,2] James W. Lohr.[1,2] *[1]Medicine, SUNY at Buffalo, Buffalo, NY; [2]Medicine, VAMC, Buffalo, NY.*

**Background:** Atypical hemolytic uremic syndrome (aHUS) is a rare but serious complication associated with gemcitabine therapy. We identified 4 cases of gemcitabine -induced aHUS over a 2 month period in patients being treated for lung cancer and biliary cancer.

**Results:** Three patients had kidney biopsies due to the atypical presentation of HUS (no schistocytes), confirming the diagnosis of aHUS. After stopping gemcitabine, all patients were initially or subsequently treated with eculizimab, a recombinant humanized monoclonal antibody that binds to terminal complement C5 protein. Treatment with eculizimab resulted in stopping hemolysis and improvement in renal function in all 4 patients. Details are shown in the table.

| | Case 1 | Case 2 | Case 3 | Case 4 |
|---|---|---|---|---|
| Age/Gender | 75/male | 70/male | 73/female | 69/female |
| Clinical Presentation | Hypertensive urgency,subacute renal failure | Subacute renal failure | Subacute renal failure | Acute renal failure |
| Schistocytes | No | No | No | Yes |
| Haptoglobin (mg/dl) | <10 | <10 | <10 | <10 |
| ADAMTS-13 | 74% | 79% | 83% | >95% |
| Kidney biopsy | Yes | Yes | Yes | No |
| Peak serum creatinine (mg/dl) | 2.6 | 2.8 | 4.3 | 2.8 |
| Time after stopping gemcitabine and start of eculizimab | 4 weeks | 3 weeks | 5 weeks | 3 weeks |
| Post-treatment haptoglobin (mg/dl) | 42 | 50 | 45 | 50 |
| Follow up creatinine | 2.0 | 1.4 | 3.4 | 1.2 |
| Outcome | improved | improved | died of cancer | improved |
| | | | | |

**Conclusions:** Gemcitabine induced aHUS is a rare but serious entity that has significant morbidity and mortality that requires early recognition and intervention. In view of the fact that we identified 4 cases over a 2 month period, we would recommend that patients being treated with gemcitabine be monitored for the development of HUS by serial serum haptoglobin levels on a regular basis. Eculizumab appears to be a well-tolerated, safe and effective treatment for gemcitabine-induced HUS.

## SA-PO040

### Women Are Prone to Develop a More Severe Course of Shiga Mediated HUS

Leyla Ramazan,[1] Jan Beneke,[1] Jan T. Kielstein,[1] Ulrich Kunzendorf,[3] Hermann G. Haller,[1] Rolf A. Stahl,[2] Jan Menne.[1] *[1]Medical School Hannover, Germany; [2]Univ Medical Center Hamburg-Eppendorf, Germany; [3]Univ Hospital Schleswig-Holstein, Kiel, Germany; [4]Klinikum Region Hannover, Germany.*

**Background:** In the 2011 German EHEC O104:H4 outbreak a high number of EHEC-HUS patients (68%) were women even so they represented only 58% of all EHEC cases. We analyzed in this study if gender did influence the clinical course of the disease.

**Methods:** 612 adult EHEC-HUS patients treated during German 2011 outbreak in 45 hospitals are included. Patients suffering from EHEC-associated enterocolitis without HUS were excluded. We prospectively and retrospectively collected demographic, clinical, and laboratory data on a standardized case-history form.

**Results:** 443 (72.4%) of patients were female and 169 (27.6%) male. The median age was comparable (45 vs. 43; n.s.). 50% of patients were admitted until day 3 of diarrhea. On admission the baseline laboratory values (LDH and platelets) were not different between m and f. Hemoglobin (Hb) was slightly lower and the eGFR was 51.2 vs. 68.5. ml/min. More women (62.5% versus 47.9%; p<0.001) required dialysis and time on dialysis was longer (median 10 vs. 8 days; n.s.). Furthermore, >100 days after the start of the disease 17.8% vs. 10.4% had still an eGFR <60 ml/min. Additionally, more women required intensive care treatment (60.3% vs. 45%, p<0.001). The ventilation rate was higher (25.3% vs. 17.8%, p=0.054) and the mortality was increased (3.6% vs. 0.6%; p=0.04). More women than men required intestinal surgery (2.9% vs. 1.2%, n.s.). The frequency of blood transfusions was higher in women (70.4% vs. 53.3%; p<0.001) and the median blood units given were 4 vs. 2 (p=0.002). Hospitalization was also longer in women compared to men (median 22 vs. 18 days, p=0.007). Surprisingly neurological symptoms (55.5% vs. 52.7%) and seizures (17.2% vs. 22.5%) were not significantly different. In both groups 85% of patients were treated with plasma exchange.

**Conclusions:** Women are more susceptible to develop severe clinical symptoms of HUS. The causes of these findings are unclear. Further investigations are required.

**SA-PO041**

***E. coli* O104:H4 Induced HUS-Outbreak in Germany 2011: Symptoms and Clinical Course** Jan Menne,[1] Jan Beneke,[1] Leyla Ramazan,[1] Ulrich Kunzendorf,[3] Jan T. Kielstein,[1] Hermann G. Haller,[1] Rolf A. Stahl.[2] *[1]Medical School Hannover; [2]Univ Eppendaorf Hamburg; [3]UNiversity Schleswih-Holstein Kiel.*

**Background:** Consumption of sprouts contaminated with the Shiga-toxin 2 producing E.coli (STEC) O104:H4 resulted in the largest reported outbreak ofhemolytic-uremic syndrome (HUS).

**Methods:** For the present analysis, we collected demographic, clinical, and complete laboratory data of 658 EHEC-HUS patients (80% of total affected patients).

**Results:** The disease consists of four phases. The **incubation phase** from sprout consumption to the start of diarrhea lasted 7.4±3.3 days. The **gastrointestinal (GI) phase** started with the onset of GI symptoms (day 0 of the disease). Diarrhea was documented in 97.3%. During the early phase of the disease nausea and vomiting was common. 2.3% of the patients required intestinal surgery.

During the **HUS phase** between day 5-15, 50-60% of patients developed peripheral edema (often marked) and >50% also pleural effusion and/or ascites. During this phase of the disease 362 patients (55%) were treated on intensive care units and 22.6% of the patients required ventilation. Importantly, most patients (53.5%) developed neurological symptoms usually between day 10 and 14. 18.4% of patients had seizures and some patients had severe neurological problems without renal impairment.

The **recovery phase** was characterized by fatigue and weakness which started after day 5 and persisted in most patients for several months. Additionally some patients had symptoms comparable to a post-traumatic stress syndrome with night mares and anxiety for many weeks/months. Neurological symptoms disappeared; however, some mild residual symptoms were present. 6 (0.9%) remained permanently on dialysis (4 younger than 30 years) and in 15% an eGFR <60 ml/min persisted.18 (2.7%) of the patients died due to the following three main causes: 1. infection, 2. patient's refusal of advanced live support, or 3. interventional complications.

**Conclusions:** Shiga-toxin HUS is a severe and life-threatening disease. A high percentage of patients need dialysis and ventilation. Most patients were severely affected and require a long rehabilitation and eventually life long follow up.

*Funding:* Clinical Revenue Support

**SA-PO042**

**Sceleroderma Renal Crisis versus Atypical Hemolytic Uremic Syndrome** Ganesh Kambhampati,[1] A. Ahsan Ejaz.[2] *[1]Nephrology, Baypines VA Medical Center; [2]Nephrology, Univ of Florida.*

**Background:** We report a case of successful treatment of aHUS associated with scleroderma with the novel terminal complement inhibitor humanized monoclonal antibody eculizumab.

**Methods:** 62 year old WM with +SCl-70Ab/-ACA scleroderma presented with recent onset nausea, abd pain, SOB, weakness, uncontrolled BP (150-170mmHg) for the previous 2 months. PMH was significant for COPD, esophageal strictures, gastric antral vascular ectasia, Raynauds with digital ulcers and sclerodactyly, CVA with residual aphasia and absence of scleroderma crisis. PE revealed systolic murmur, bibasilar crackles and LE edema. Labs were as follows: BUN 29mg/dL, SCreat 1.55mg/dL (90 days earlier was 0.7mg/dL), Hgb 13g/dL, HCT 40.3%, Plt $61x10^3/mm^3$ (previously $190x10^3/mm^3$), LDH 414U/L, haptoglobin <15mg/dL, D-dimer 441mg/l, UA prot 100mg/dL, WBC 1/hpf, RBC 0/hpf, casts 0/hpf. An Echo performed demonstrated mod LVH, severe TR, severe RAE, LVEF 70-75%, mod RV dilatation, pulm HTN, and eRVSP 97.7 mmHg. Based on clinical and laboratory findings sceleroderma renal crisis (SRC) was one of the DDxs. Peripheral blood smear showed schistocytes suggestive of microangiopathic hemolytic anemia and thrombocytopenia. DDx now also included TMA (TTP/HUS) vs. SRC. ADAMTS13 Level was ordered and sent before planned initiation of plasmapheresis.

**Results:** Treatment initiated with ACE-inhibitor captopril (6.25-12.5mg mg PO q8hr) with no improvement in clinical condition. Patient received 5 sessions of plasmapheresis (TPE) and labs remained as follows: Plt $143x10^3/mm^3$, BUN 23mg/dL, SCreat 2.57mg/dL and elevated LDH 313U/L. ADAMTS13 activity was reported as 55%. Presumed diagnosis of atypical HUS was given. Due to persistent renal failure, thrombocytopenia and elevated LDH after treatment with plasma exchange, Eculizumab (Soliris) was empirically administered. TPE was discontinued, labs improved after three doses of Eculizumab to BUN 45 mg/dL, SCreat 1.90mg/dL, Hgb 12g/dL, Hct 38%, Plt $171x10^3/mm^3$ and LDH 212 U/L.Patient did not require renal replacement therapy.

**Conclusions:** Eculizumab successfully treated a patient with presumed diagnosis of aHUS associated with scleroderma and prevented need for renal replacement therapy, TPE and progression to severe renal failure.

**SA-PO043**

**Thrombotic Microangiopathy Associated with Hemolytic Uremic Syndrome: A Single Center 10 Year Experience** Prabesh Bajracharya,[1] Rossana Baracco,[2] Amrish Jain,[3] Tej K. Mattoo,[4] Gaurav Kapur.[5] *[1]Pediatric Nephrology and Hypertension, Children's Hospital of Michigan, Detroit, MI; [2]Pediatric Nephrology and Hypertension, Children's Hospital of Michigan, Detroit, MI; [3]Pediatric Nephrology and Hypertension, Children's Hospital of Michigan, Detroit, MI; [4]Pediatric Nephrology and Hypertension, Children's Hospital of Michigan, Detroit, MI; [5]Pediatric Nephrology and Hypertension, Children's Hospital of Michigan, Detroit, MI.*

**Background:** Microangiopathic hemolytic anemia with renal failure characterizes HUS. Atypical HUS (aHUS) linked to mutations in alternate complement pathway is less common. The aim of this retrospective study was to evaluate the clinical course of patients with aHUS seen in a tertiary center over a 10 year period.

**Methods:** A retrospective chart review (2003-2012) of patients aged 1 to 18yrs admitted with a diagnosis of HUS. Patients with no history of bloody diarrhea & absence of infection with Shigella, and Ecoli O157;H7 were grouped as aHUS.

**Results:** In aHUS group; 1 patient had C3 mutation & 1 had negative evaluation for known genetic mutations. In others (n=9) genetic evaluation was not done based on normal C3 & resolution of renal failure & hematological abnormalities. Clinical profile of patients with aHUS was similar to typical HUS group.

| | Typical HUS(N=32) | aHUS(N=11) |
|---|---|---|
| Median Age(Range) | 3(1.1-15) | 1.5(1-15) |
| Male/Female | 15/17 | 7/4 |
| At presentation<br>Mean Hb<br>Mean Platelet count<br>Mean GFR | <br>8.4±1.9<br>61±33<br>17±13 | <br>8.5±2.2<br>84±58<br>23±15 |
| % of patients with neurological symptoms(n) | 6.2(2) | 9.1(1) |
| % of patients requiring dialysis(n) | 62.5(20/32) | 36.6(4/11) |
| Median Duration of dialysis(range) | 11(4-120) | 9(9-11)one chronic PD |
| % of patients treated with plasma infusion(n) | 9.4(3) | 27.3(3) |

One patient with stable renal function is receiving Eculizumab infusion.

**Conclusions:** aHUS is a heterogenous disorder associated. Genetic defects associated with complement pathway abnormalities are rare & Eculizumab is indicated in these patients.

**SA-PO044**

**Complement Activation and Plasmatic Membrane Attack Complex in Acute Kidney Injury of Different Etiologies** Eva Rodriguez, Marta Riera, Judit Rigol, Clara Barrios, Maria Jose Soler, Carlos Enrique Arias, Julio Pascual. *Nephrology, Parc de Salut Mar-IMIM, Barcelona, Spain.*

**Background:** Final component of complement pathway, membrane attack complex (MAC), has been demonstrated to be involved in models of ischemia-reperfusion. After injury, complement pathway is activated leading to the production of MAC and proinflammatory cytokines. The aim of this study is to establish if complement pathway is activated in different patterns of Acute Kidney Injury (AKI).

**Methods:** Prospective cohort study 133 patients with different conditions known to be at high risk of AKI. Overall, 53% had AKI and 47% normal kidney function. Plasma-EDTA sample was collected, four groups were classified according to the main risk factor for developing AKI: 1) septic model, patients admitted in intensive care unit with the diagnosis of sepsis (n=26, 50% AKI), 2) ischemia-reperfusion model, kidney transplant patients (n=46, 54% AKI), 3) nephrotoxic model, patients under colistin treatment (n=37, 48% AKI) and 4) multifactorial AKI (n=24, 62% AKI). Samples were tested for IL-6 and MAC using ELISA kit.

**Results:** AKI patients were classified according ADQI as Risk (n=14, 19,7%), Injury (n=12, 16,9%), Failure (n=25, 35,2%) and Loss (n=20, 28,2%). Among the 71 AKI patients, 23 (32,5%) needed renal replacement therapy. Eleven AKI patients died;31 survivors recovered full renal function, whereas 29 patients did not recover o recovered partially. Plasmatic MAC level was statistically different in patients with AKI as compared to normal renal function controls, regardless of the etiology of AKI (501±247 vs 388±150 mAU/mL, $p$=0.015). In AKI-patients, plasmatic MAC levels >460 mAU/mL were related with the probablility of not recovering renal function but no reached statistic significance whereas plasmatic MAC levels >460 mAU/mL were related with the need of renal replacement therapy (p=0,03). Plasmatic IL-6 levels were significant higher in a AKI patients compared to normal kidney function (10,47±2,8 vs 7,37±3,0 pg/mL, $p$=0,02).

**Conclusions:** Our data show that in AKI, regardless etiology, the complement system is activated, leading to an increase in MAC and pro-inflammatory cytokine stimulation (IL-6). High MAC levels are related to AKI severity.

**SA-PO045**

**Genetic Polymorphisms of Heme-Oxygenase 1 May Impact on Acute Kidney Injury, Bronchopulmonary Dysplasia and Mortality in Very Low Birth Weight (VLBW) Infants** David J. Askenazi, Brian Halloran, Neha Patil, Rajesh Koralkar, Namasivayam Ambalavanan. *Pediatrics, Univ of Alabama at Birmingham, Birmingham, AL.*

**Background:** The enzyme Heme Oxygenase 1 (HO1) catalyzes the rate-limiting step in heme degradation, producing biliverdin, iron and carbon monoxide. These products have anti-inflammatory and anti-oxidant properties which protect against AKI in several animal models. Genetic polymorphisms of HO-1 are associated with poor clinical outcomes in several critically ill cohorts.

**Methods:** Between Feb 2012 and Feb 2013, 91 VLBW Infants (birth weight ≤1200 gm. or gestational age ≤31 weeks) were prospectively followed. Serum creatinine (SCr) values on first two weeks of life were used to determine AKI status according to KDIGO; whereby AKI was defined if SCr ≥ 0.3 mg/dl or ≥ 150-200% from lowest previous value. Brochopulmonary dysplasia (BPD) was defined if an infant was receiving oxygen at 28 days of life. DNA was collected (Genotek Oragene) isolated (Qiagen Gentra Puregene) and the promoter region of HO-1 was sequenced (Qiagen Type-It Mutation Detect PCR Kit. The number of GT(n) repeats were counted for each infants' alleles and classified as short (≤ 27) or long (> 27). The –413 snp allele (A v T) was documented for each allele.

**Results:** AKI occurred in 27/87 (31%); mortality occurred in 9/87 (10.3%) and 36/78 (46.1%) survivors had BPD. The average number of GT repeats were not different by AKI or BPD category but those who died trended to have higher average GT repeats (27.7 +/- 1.12 vs. 25.7 +/- 0.4; p< 0.09). Categories of allele length (SS vs. SL vs. LL) did not differ by survival, AKI or BPD. A vs. T at –413 tended towards differences for AKI (p< 0.09), BPD (p< 0.08) and survival (p< 0.2), and was significant for the composite of BPD, AKI or mortality.

| -413 | No AKI, BPD or Death | Yes AKI, BPD or Death | P value |
|---|---|---|---|
| AA | 10 (29%) | 12 (24%) | < 0.05 |
| AT | 11 (31%) | 28 (56%) | |
| TT | 14 (40%) | 10 (20%) | |

**Conclusions:** In this small pilot study of VLBW infants, the number of tandem GT(n) repeats did not appear to predict AKI, BPD or mortality. However, a single polymorphism at position – 413 before the HO-1 promoter may predict clinical outcomes.

**SA-PO046**

**Levamisole-Associated Glomerulonephritis in a Habitual Cocaine User** Jonathan Scott Kurche,[1] Julie M. Simpson,[1] Shalini Tayal,[1,2] Jie Tang.[1,2] *[1]Univ of Colorado Denver, Aurora, CO; [2]Denver Health Medical Center, Denver.*

**Background:** Use of levamisole as a cutting agent for cocaine has resulted in increasing incidence of cutaneous vasculitis and agranulocytosis among abusers. Transient autoantibodies, including perinuclear antineutrophil cytoplasmic antibodies (p-ANCA) are often present, and could lead to renal pathology. Levamisole has only been loosely associated with glomerular disease and the renal implications of levamisole-associated vasculitis are unknown.

**Methods:** We describe a 49-year-old female habitual cocaine user with a history of cocaine-associated cutaneous vasculitis characterized by a high p-ANCA titer, who developed acute renal failure with new nephrotic-range proteinuria. Urine sediment deonstrated dysmorphic erythrocytes, consistent with rapidly-progressing glomerulonephritis (RPGN) in the setting of recent cocaine use and laboratory-demonstrated levamisole exposure. Renal biopsy demonstrated crescentic glomerulonephritis (GN) involving more than 50% of glomeruli, as well as membranous nephropathy (MN) with immune complex deposition in the mesangium and subepithelium (figure). She developed granulocytopenia and signs of cutaneous vasculitis (figure). She was treated with IV steroids and cyclophosphamide and had significant improvement in her creatinine clearance and resolution of her skin rash.

**Conclusions:** We believe this to be the first description of biopsy-proven RPGN in the setting of levamisole exposure. This case demonstrates progression of disease in a patient with previously diagnosed cocaine-associated vasculitis, the presence of both GN and MN on biopsy, and the potential link of levamisole to MN. Levamisole is chemically similar to a class of characterized Toll-like receptor (TLR) agonists; we hypothesize that the variable presentation of this disease may be related to pleiotropic effects of TLR agonists on the immune system.

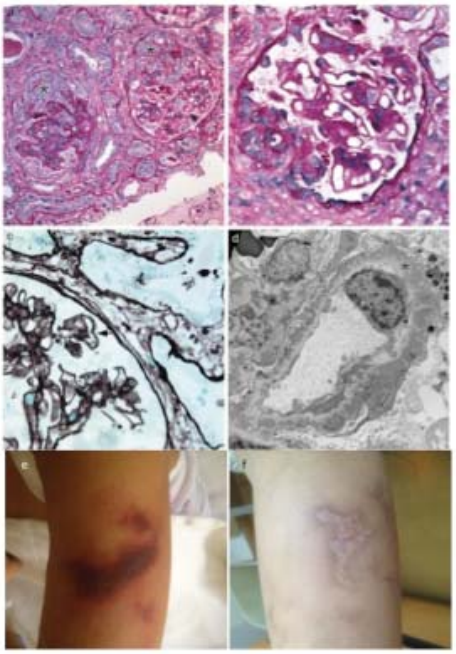

**Figure:** Spectrum of levamisole-associated injury in our patient. (a) Of 58 glomeruli, 10 (17%) were globally sclerosed, 27 (46.5%) demonstrated active crescents (21 complete cellular, 6 partially cellular), and 6 inactive crescents (10%, 2 fibrocellular, 4 fibrous), amounting to 43 of 58 (74%) of total glomeruli (PAS stain). Marked tubular injury was apparent, along with mild interstitial fibrosis (25%). Vessels were remarkable for thickened walls and tortuous appearance, but there was no definitive evidence of vasculitis. (b, c) Thickened basement membranes (b, PAS stain) with "spike & dome pattern" (c, arrow, silver stain). (d) Electron microscopy revealed sub-epithelial electron-dense immune complex deposits (single asterisk) and mesangial immune-complex deposits (double asterisks). Rare subendothelial deposits and extensive foot-process effacement were noted. No tuboreticular inclusions were present within endothelial cells. (e,f) Spectrum of both pristine (e) and mature (f) cutaneous upper extremity lesions in a patient with a history of cocaine-associated vasculitis. Lesion (e) developed in the absence of trauma on day 4 of hospitalization, lesion (f) was present at admission and, per patient report, previously appeared as lesion (e).

**Synthetic Cannabinoids Triggered Thrombotic Microangiopathy Leading to Acute Kidney Injury** Jagadish B. Khanagavi,[1] Savneek S. Chugh,[2] Prajakta M. Phatak,[1] Randy A. Goldberg,[1] Praveen N. Chander.[3] *[1]Internal Medicine, New York Medical College(NYMC), Valhalla, NY; [2]Internal Medicine, Div of Nephrology, NYMC, Valhalla, NY; [3]Pathology, NYMC, Valhalla, NY.*

**Background:** Synthetic cannabinoids (SCs) like SPICE are psychoactive compounds marketed as bath salts, incense products and smoked as drugs of abuse. A few cases of acute kidney injury (AKI) attributed to it have been reported but the underlying pathophysiology is unknown. We report the first biopsy proven case of SCs-induced thrombotic microangiopathy (TMA) leading to AKI.

**Methods:** A 20-year-old man with no prior medical history presented with seizures, nausea, vomiting but no diarrhea. Blood Pressure was 176/88 mmHg and heart rate 104/minute. Physical exam was otherwise unremarkable. Lab data showed anemia, thrombocytopenia, elevated serum creatinine (SCr) (3.6 mg/dl) and LDH levels, low haptoglobin and schistocytes confirming thrombotic microangiopathic hemolysis. ADAMTS13 and Complement levels were normal. Urinalysis showed specific gravity of 1.018, 3+ protein, 5-10 WBCs and 5-10 RBCs per high-power field and occasional muddy brown and RBC casts. Urine toxicology revealed tetrahydrocannbinol. ANA, ANCA, anti-GBM antibodies, hepatitis screens, and HIV antibody screen were negative. Renal ultrasound was unremarkable. A diagnosis of atypical hemolytic uremic syndrome was made and plasmapharesis initiated. Patient showed clinical improvement but SCr remained elevated necessitating hemodialysis (HD). Patient later admitted to daily use of marijuana and SPICE over few months. Serum toxicology showed two SCs: SPICE (CP 47,497) and Hebrew University (HU)–320. Renal biopsy showed thrombotic vasculopathic lesions affecting glomeruli as well and acute tubular necrosis possibly due to vasculopathy. Three months later he remains on HD but is now non-oliguric.

**Conclusions:** We believe AKI associated with SCs in some cases is secondary to TMA possibly due to drug induced endothelial damage. Strong clinical suspicion and systematic analysis for such agents is required to promptly diagnose cases of unexplained AKI with TMA in young and otherwise healthy patients.

## SA-PO048

**Carbonyl Stress Induced Protein Modification – A New Link in Pathogenesis of Malarial Acute Kidney Injury** Pinaki Mukhopadhyay,[1] Debarati Mukherjee,[1] Raghwendra Mishra,[1] Monoj Kar,[1] Piyali Banerjee,[2] Gautam Mukherjee.[3] *[1]Nephrology, NRS Medical College, Kolkata, India; [2]Biochemistry, NRS Medical College, Kolkata, India; [3]Medicine, Bagnan Rural Hospital, Howrah, India; [4]Gynae & Obstetrics, North Bengal Medical College, Siliguri, India.*

**Background:** 1.To find out the incidence and degree of parasitism of falciparum malaria mediated acute kidney injury (FMAKI) and their outcome.

2. To measure the carbonyl and oxidative stress of FMAKI patients and correlation with outcome.

**Methods:** In all P.F malaria cases AKI was diagnosed by RIFLE criteria. Demographical, clinical and biochemical parameter were analyzed and they are followed from hospitalization to discharge/death . Oxidative and carbonyl stress markers [Advanced oxidation protein product (AOPP), Advanced Glycation End product (AGE), Pentosidine, Dityrosine, Thioberbituric acid reactive substance (TBARS) and Methyl glyoxal (MG)] were measured consecutively in 15 patient according to standard protocol. All data were analysed in appropriate statistical tool.

**Results:** Among 174 pts 50 (28.7%) had AKI (FMAKI).M: F was 2.6:1.About 45 had very low GFR (10.65 ±3.07ml/min).Among 50 cases of FMAKI 42% had parasite density <5%, 26% had 5-10% and 32% had >10%. Out of 29 cases of severe AKI 9 patients had parasite density<5% and 20 had >5%. Dialysis was required in 62%.Total 13 patients died of them majority belong oliguric severe AKI.There is positive correlation between parasite density, renal failure and surrogate outcome. The Oxidative stress indexes (OSI) of FMAKI patients were 1.89 times higher than normal control. The TBARS, MG level were 6.49 and 5.56 times higher indicating a significant carbonyl stress in these patients. AOPP level the marker of protein modification was also 2.33 times higher than normal control indicating that proteins are highly insulted in FMAKI. Areas under the curves for AOPP and MG were (0.735, p= 0.001),(0.691, p= 0.005) respectively. Mortality and need for dialysis was high in these patients.

**Conclusions:** 1. Parasitic index is independent surrogate predictor of FMAKI.

2. The carbonyl stress marker(MG) along with oxidative stress(AOPP) are significantly raised and possibly linked to the final kidney injury.

## SA-PO049

**ANCA-Associated Pauci-Immune Glomerulonephritis Presenting as Cryptogenic Organizing Pneumonia** Manish K. Saha,[1] Tarek Hamieh,[1] Vishal Sagar.[2] *[1]Medicine, Regions Hospital, St. Paul, MN; [2]Nephrology, Regions Hospital, St. Paul, MN.*

**Background:** Cryptogenic Organizing pneumonia (COP), formerly bronchiolitis obliterans-organizing pneumonia is usually idiopathic but has been associated with connective tissue disorder, infections and drug toxicity. Association of ANCA-related renal vasculitis with COP is rare.

**Methods:** A 68 year old male with history of type 2 diabetes mellitus presented with six weeks of fever, profuse night sweats and a nonproductive cough. His vital signs were normal. Physical exam revealed basilar crackles at bases. White blood cell count of 11.5k/ul, hemoglobin 6.8 g/dl, creatinine 1.53 mg/dl with eGFR 55.7 ml/min/1.73m². His baseline creatinine was 1.15mg/dl. Urinalysis showed 8 rbc/hpf with 30 mg/dl proteinuria and no casts/crystals. Total protein creatinine ratio was 0.5. CRP was 26.1 mg/dl .CT chest showed patchy infiltrate in left upper lobe and prominent bilateral interstitial infiltrate . Bronchoalveolar lavage was non-dagnostic. Cultures were negative .He underwent left lung biopsy which was suggestive of organizing pneumonia .There were no granulomas, or evidence of vasculitits. ANA was positive with MPO ANCA (myeloperoxidase–antineutrophilic cytoplasmic antibodies) >100 with normal proteinase-3. Viral hepatitis serology was negative. With active urine sediment and worsening renal function, kidney biopsy was performed. Pathology revealed pauci-immune type of focal segmental cresentric glomerulonephritis with no immunoreactivity and electron microscopy was normal. With the diagnosis of organizing pneumonia and ANCA positive pauci-immune glomerulonephritis, he was given a pulse dose methylprednisolone and started on Rituximab for four weeks. After completion of Rituximab and Prednisone taper, his creatinine was 1.26 mg/dl and ANCA was <6. Urinanalysis was bland. A repeat CT chest suggested improvement in patchy interstitial infiltrate .

**Conclusions:** In the appropriate clinical setting, even with minimal active sediment and mild renal insufficiency , the association of ANCA-related renal vasculitis and organizing pneumonia should be considered for timely evaluation and treatment to prevent progression of acute kidney injury.

## SA-PO050

**Midkine–A Novel and Early Biomarker of CI-AKI in Patients Undergoing Percutaneous Coronary Interventions-PCI** Jolanta Malyszko,[1] Jacek S. Malyszko,[1] Hanna Gajewska,[2] Ewa Koc-Zorawska,[1] Slawomir Dobrzycki.[2] *[1]Nephrology, Med. Univ, Bialystok, Poland; [2]Invasive Cardiology, Med Univ, Bialystok, Poland.*

**Background:** Midkine, a cytokine, expressed mainly in proximal tubular epithelial cells and is induced by oxidative stress. We tested the hypothesis whether midkine could represent an early biomarker of contrast-induced AKI in 89 patients with normal serum creatinine undergoing PCI.

**Methods:** Midkine, serum and urinary NGAL, cystatin C were evaluated before, and after 2, 4, 8, 24 and 48 hours after PCI using commercially available kits. Serum creatinine was assessed before, 24 and 48 hours after PCI.

**Results:** We found a significant rise in serum midkine as early as after 2 hours ($p<0.001$) when compared to the baseline values. It was also significantly higher 4 and 8 hours after PCI, then returned to the baseline values after 24 hours and started to decrease after 48 hours. Serum NGAL increased after 2, 4 and 8 hours, and in urinary NGAL after 4,8 and 24 hours after PCI. We found a significant rise in serum NGAL after 2, 4 and 8 hours, and in urinary NGAL after 4, 8&24 hours after PCI.Serum cystatin C increased significantly 8 hours, reaching peak 24 hours after PCI and then decreased after 48 hours. When contrast nephropathy was defined as an increase in serum creatinine by >25% of the baseline level 48 hours after PCI, the prevalence of CIN was 10%. Patients with CIN received significantly more contrast agent ($p<0.01$), but duration of PCI was similar.

Midkine were significantly higher 2, 4 and 8 hours after PCI in patients with CIN, while NGAL levels were significantly higher in patients with CIN starting 2 hours after PCI (serum NGAL) or 4 hours (urinary NGAL). Cystatin C were higher only 8&24 hours after PCI in patients with CIN.

**Conclusions:** Since the "window of opportunity" is narrow in CI-AKI and time is limited to introduce proper treatment after initiating insult, particularly when patients are discharged within 24 hours after the procedure, midkine needs to be investigated as a potential early marker for renal ischemia and/or nephrotoxicity. Inhibition of midkine can prevent the migration of inflammatory cells to the injured epithelial layer, reducing the severity of renal damage.

*Funding:* Government Support - Non-U.S.

## SA-PO051

**Distinct Populations of Label Retaining Cells (LRCs) Incorporate into Epithelia Post-Ischemia Reperfusion Injury (IRI) in Different Compartments of the Nephron** Sunil Rangarajan,[1] Paul W. Sanders,[1,2] Lisa M. Curtis.[1,2] *[1]Medicine, Univ of Alabama at Birmingham, Birmingham, AL; [2]Veterans Affairs Medical Center, Birmingham, AL.*

**Background:** Mechanisms underlying epithelial repair post-IRI are incompletely understood. One possible mechanism that has been explored is the contribution from LRCs residing in the kidney. LRCs represent a group of "stem-like" slow cycling cells that have been conventionally labeled using thymidine analogs. Labeling paradigms of LRCs were different in each of the previous studies that have described contradicting characteristics. Here, we have examined the dynamics of the differing populations of LRCs post-IRI.

**Methods:** Thymidine analogs, Chlorine-labeled deoxyuridine & Iodine-labeled deoxyuridine, distinguished by antibody staining, were administered at different postnatal times to the same mouse. This labeling allows for evaluation under identical conditions. At 12 weeks postnatal, these labeled mice were subjected to unilateral nephrectomy & contralateral IRI for 30 minutes. Nephrectomized kidneys obtained at surgery (internal control) & ischemic kidneys harvested 12, 24, 48, & 72 hours after IRI were analyzed for the dynamics of LRCs in specific compartments of the nephron.

**Results:** Majority of the neonatal LRCs resided within the epithelial structures in cortical & medullary regions. Nearly 1/3$^{rd}$ were outside the epithelia in the papilla. Adult LRCs were very few & were predominantly in the cortex. A large proportion of adult LRCs were outside the epithelia. Both LRCs increased 12 hours post-IRI & subsequently declined to levels at or below baseline. Most prominent dynamics of neonatal LRCs were seen in the collecting ducts while that of adult LRCs were seen in proximal tubules.

**Conclusions:** Different paradigms for labeling LRCs in the kidney result in identification of different populations of cells & each population exhibits compartment specific changes post-IRI. Consequently, they may contribute different functions during the post-IRI repair. Further characterization of these LRCs is required to understand their dynamics post-IRI along with the signaling processes involved, which might provide insight into possible therapeutic interventions.

*Funding:* Veterans Affairs Support

## SA-PO052

**Glucagon-Like Peptide-1 Attenuates Cisplatin-Induced Renal Injury: A Gut-Kidney Connection in Acute Kidney Injury** Daisuke Katagiri,[1] Yoshifumi Hamasaki,[1] Kent Doi,[1,2] Koji Okamoto,[1] Kousuke Negishi,[1] Masaomi Nangaku,[1] Eisei Noiri.[1] *[1]Dept of Nephrology and Endocrinology, Univ Hospital, Univ of Tokyo, Tokyo, Japan; [2]Dept of Emergency and Critical Care Medicine, Univ Hospital, Univ of Tokyo, Tokyo, Japan.*

**Background:** Accumulating evidence of the beyond-glucose lowering effect by glucagon-like peptide-1 (GLP-1) has been reported in the context of remote organ connections. This study investigated whether GLP-1 treatment using an inhibitor of dipeptidyl peptidase-4 (DPP-4), alogliptin (AG) and a GLP-1 receptor (GLP-1R) agonist, exendin-4 (Ex-4) attenuate cisplatin-induced AKI (CP-AKI).

**Methods:** C57Bl/6 mice were orally given 10 mg/kg of AG or vehicle once daily from 7 days before and to 96 hr after 15 mg/kg CP intraperitoneal injection. The apoptosis in tubular epithelial cells evaluated using immunoassay for ssDNA and cleaved caspase-3. The balance between pro-apoptotic (Bax and Bim) and anti-apoptotic (Bcl-2 and Bcl-xL) mechanism were evaluated by Quantitative real-time PCR. In another set of experiments Ex-4 was given once a day from 7 days before to 96 hr after CP injection. To demonstrate that GLP-1R–mediated pathway contributes to renal protection by AG, we also conducted an experiment using in vivo small interfering RNA (siRNA) against GLP-1R.

**Results:** Injection of CP to mice increased BUN and serum creatinine, and caused a remarkable renal pathological injury including tubular necrosis. AG treatment significantly reduced these renal injury induced by CP. The mRNA expression ratios of pro-apoptotic/

anti-apoptotic in the AG treated mice were significantly lower than those of the untreated mice. Blood GLP-1 showed significantly higher in the AG-treated mice, whereas other DPP-4 substrates (SDF-1, NPY) increased with the decline of renal function in the untreated mice and decreased according to AG treatment. Ex-4 also attenuated CP-AKI. Suppressing GLP-1R expression in the kidney by using siRNA injection reversed the protection of AG against CP-AKI.

**Conclusions:** These data suggest that a gut-released hormone GLP-1 would ameliorate CP-AKI via anti-apoptotic effects and this gut-kidney axis could be anticipated as a new drug target in AKI.

## SA-PO053

### Acute Kidney Injury in Mice Induces Specific Changes in Gut Microbiota

Daniel A. Peterson,[1] Yu Chen,[2,3] Sanjeev Noel,[2] Samatha Bandapalle,[2] Maria Noel Martina Lingua,[1] James Robert White,[4] Abdel Hamad,[1] Hamid Rabb.[2] *[1]Dept of Pathology, Johns Hopkins Univ, Baltimore, MD; [2]Dept of Medicine, Johns Hopkins Univ, Baltimore, MD; [3]Dept of Medicine, Nanjing Medical Univ, Nanjing, Jiangsu, China; [4]Independent.*

**Background:** Acute kidney injury (AKI) leads to distant organ effects. Crosstalk between organs may worsen or attenuate AKI. Prior work in germ-free mice demonstrated a direct effect of intestinal microbiota on experimental AKI (Jang & Rabb, *Am J Physiol* 2009). Thus current study examines how AKI modulates the bacterial composition of the gut microbiota by pyrosequencing. To identify changes specific to AKI we employed two different models of AKI, ischemia reperfusion injury (IRI) and nephrotoxic (cisplatin-CPN).

**Methods:** IRI was induced by bilateral clamping of the renal pedicles in C57Bl/6 mice for 30 minutes, or chemical AKI induced by CPN injection. Sham operated groups were also studied. To assess the microbiota, DNA was extracted from the fecal pellets (n=4-5 per group), before and day 3 intervention, and subjected to DNA extraction and PCR amplification of the 16S rRNA V3-V5 gene region using the 357F/926R primer set, amplicons were sequenced in multiplex using the Roche/454 platform. The sequences were clustered into 95% operational taxonomic units (OTUs) and taxonomic analysis performed by RDP classifier (rdp.cme.msu.edu).

**Results:** We observed a dramatic change in the gut microbiota that appears specific to AKI. There were key differences between IRI vs CPN-induced AKI effect on gut. The relative abundance of the taxonomic class Erysipelolotrichi, was expanded in AKI mice, IRI (21.3%, sem-2.6%, p =0.02) and in the CPN (3.5%, sem-1.2%, p=0.01). The level in the Sham group (0.4%) was similar to the average of the pretreated mice, (0.35%). This dramatic expansion (~11-65 folds) was compensated by a decrease in primarily the class Bacilli, but also other taxonomic classes.

**Conclusions:** The impact of both ischemic and nephrotoxic AKI on gut microbiota is profound, with key similarities and differences between IRI and CPN. Future studies are warranted to examine the microbiota as a target to improve our understanding and outcomes during AKI.

## SA-PO054

### C5aR Deficiency and C5aR Blockade Protect Mice from Acute Pyelonephritis

Ke Li,[1,2] Naheed Chowdary,[2] Steven H. Sacks,[2] Wuding Zhou.[2] *[1]Core Research Laboratory, The Second Affiliated Hospital, Xi'an Jiaotong Univ; [2]MRC Centre for Transplantation, King's College London.*

**Background:** UTIs are mainly caused by uropathogenic *E. coli* (UPEC), and infections can progress from the bladder to the kidneys. Recent studies have suggested that complement (C) activation is actually harmful instead of beneficial for the host. However, the underlying mechanism remains to be established. It is unknown if the pro-inflammatory actions of C and specifically that mediated by C5aR signal represent an important pathogenic factor in UTIs.

**Methods:** We employed a well-established mouse model of ascending UTI leading to kidney infection and used C5aR-/- mice or C5aR antagonist to assess whether the severity of pyelonephritis is dependent on C5aR signaling. Using bone marrow chimeras between wild type (WT) and C5aR-/- mice, we evaluated the relative contribution of C5aR signaling on renal parenchymal cells and the infiltrating cells.

**Results:** We found that deficiency of C5aR or blocking C5aR significantly protected mice from kidney infection at 72h after bladder inoculation of E. coli. Compared with wild type (WT) mice, C5aR-/- mice exhibited a lower rate of kidney infection (31% vs 79%, n = 29), reduced bacterial load in the kidney and tissue damage, however, leucocytes accumulation was similar in both groups. C5aR antagonist treated mice also protected from the kidney infection with a similar protection level as that observed in C5aR-/- mice. Chimera studies showed that the absence of C5aR on renal or circulating cells attenuated kidney infection, suggesting that C5aR on both renal and circulating cells contribute to the infection. In vitro, C5a stimulation significantly increased TNF-α, IL-6 and KC production by macrophages and REC, while impaired neutrophil functions (bacteria uptake, reactive oxygen species activity), in the presence of LPS or uropathogenic E coli.

**Conclusions:** Our results demonstrate a pathogenic role for C5aR in pyelonephritis, implicating therapeutic potential of blocking C5aR in human UTI. it also suggest a mechanism by which activation of C5aR cross-talk with TLR4 exaggerates local inflammation, but impairs neutrophil bactericidal function, thus promoting kidney infection.

## SA-PO055

### The α-Intercalated Cell Detects Urinary Pathogenic *Escherichia coli* and Defends the Urinary Tract by Synchronized Secretion of NGAL and $H^+$

Neal A. Paragas,[1] Ritwij Kulkarni,[1] Catherine Forster,[1] Max Werth,[1] Kai M. Schmidt-Ott,[3] Thomas L. Nickolas,[1] Jonathan M. Barasch.[1] *[1]Medicine, Columbia Univ, New York; [2]Pediatrics, Columbia Univ, New York; [3]MDC, Berlin.*

**Background:** The intercalated (IC) cells of the collecting duct cells are responsible for acid base homeostasis with excretion of H+ by the alpha-IC and the excretion of bicarbonate by the beta-IC. We found a novel function of the A-IC, that it responds to Gram-negative urinary pathogenic *E. coli* (UPEC) in both cystitis and pyelonephritis urinary tract infections (UTI) with the graded expression of H+ and NGAL.

**Methods:** (1) Developed a conditional allele of NGAL. (2) Developed a bioluminescent pathogenic bacteria. (3) Knocked out intercalated cells lineage.

**Results:** A reanalysis of our multi-center ER study (n=1635) demonstrated that healthy patients with different severities of Gram-negative (but not Gram-positive) UTIs had significantly increased, dose-dependent expression of urinary NGAL which was reversible with antibiotics. Consistently, uNGAL levels and H+ secretion mirrored the intensity and timing of urinary CFUs (uCFUs) in mice. Sibling matched NGAL deleted mice took significantly longer to clear the infection and conversely, NGAL significantly inhibited UPEC growth in urine cultures by reversibly depleting bacterial iron. To visualize the UTI process, we developed a NGAL reporter mouse (NGAL-Luc2) and a reporter bacteria (UPEC-lux). Bladder inoculation of UPEC-lux induced NGAL-Luc2, Ngal RNA, and NGAL protein distantly in kidneys in a TLR4 dependent fashion. NGAL was predominately expressed by A-IC which directly bound the fluorescent UPECs. These data were reproduced in explanted medullary epithelia co-cultured with UPECs.

**Conclusions:** We show that A-IC are not only regulators of metabolic acids but immune defense cells with both sensing and effector functions. NGAL was necessary and sufficient for bacteriostasis; NGAL was co-regulated with the acidification of the urine. These findings provide an explanation for the intensive expression of kidney NGAL in septic and aseptic diseases: the kidney defends the urinary system via exocrine delivery of NGAL.

### Kidneys Recovering from Ischemia/Reperfusion Injury Modulate Specific Cytokine Responses to Subsequent Polymicrobial Sepsis in Mice

Takayuki Tsuji,[1] Ana C. Souza,[2] Xuzhen Hu,[2] Peter S.T. Yuen,[2] Robert A. Star.[2] *[1]1st Dept of Medicine, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan; [2]NIDDK, Bethesda, MD.*

**Background:** Sepsis frequently develops post-AKI and portends a poor prognosis. We previously showed that sepsis, induced 48 hr after partial recovery from AKI, had worse renal function and survival vs sepsis alone, despite less liver, muscle, spleen damage, and systemic cytokine response (HMGB1, IL-6, IL-10). Thus, partial recovery from AKI unexpectedly dissociated renal and systemic effects of sepsis. To test how recovering kidneys might affect cytokines, we removed the kidneys 0 hr post-CLP (48hrs post-I/R), then measured serum cytokines.

**Methods:** We performed sham I/R surgery or 40' bilateral ischemia/reperfusion (I/R) in male C57BL/6 mice. 48 hr later we induced polymicrobial sepsis by cecal ligation and puncture (CLP), then bilateral nephrectomy (Nx) or sham Nx. We measured outcomes pre-CLP (48 hr post-I/R) or 24 hr post-CLP.

**Results:** Bilateral nephrectomy at the time of CLP did not alter HMGB1 response after sham-I/R→CLP or I/R→CLP. However, IL-10 was significantly increased after Nx (vs sham Nx) after both sham-I/R→CLP and I/R→CLP. Strikingly, Nx increased IL-6 levels (vs sham Nx) in I/R→CLP but not sham I/R→CLP.

| | without bilateral nephrectomy | with bilateral nephrectomy |
|---|---|---|
| | sham→sham, I/R→sham, sham→CLP, I/R→CLP | sham→sham, I/R→sham, sham→CLP, I/R→CLP |
| HMGB-1 (ng/ml) | 2.7±0.9, 0.7±0.4, 70.2±15.1, 25.8±7.3 | 5.6±1.6, 4.9±2.6, 99.2±17.8, 39.1±4.6 |
| IL-6 (pg/ml) | 27±13, 67±8, 380,000±100,000, 64,700±35,000 | 84±7, 66.8±16.3, 443,000±89,500, 334,000±75,500 |
| IL-10 (pg/ml) | 33±18, 46±24, 20,600±1,020, 3,980±992 | 304±40, 258±41, 111,000±11,600, 58,900±18,500 |

**Conclusions:** After partial recovery from AKI, HMGB1, IL-6, and IL-10 had diminished responses to sepsis. Kidney removal did not affect the reduction of HMGB1, reversed the reduction in IL-6, and derepressed IL-10. Thus, the post-AKI kidneys selectively alter circulating cytokines, suggesting a complex interplay between systemic responses to infection and kidneys.

### Krüppel-Like Factor 4 in Endothelial Cells Protects Mice from Renal Ischemia-Reperfusion Injury

Tadashi Yoshida, Maho Yamashita, Matsuhiko Hayashi. *Apheresis and Dialysis Center, School of Medicine, Keio Univ, Tokyo, Japan.*

**Background:** Krüppel-like factor 4 (Klf4) is a zinc-finger transcription factor involved in cellular differentiation and proliferation in multiple cell types. For example, results of our previous studies showed that deletion of the Klf4 gene in mice delayed down-regulation of smooth muscle differentiation markers, but accelerated neointimal formation following carotid injury. We demonstrated that enhanced neointimal formation in Klf4-deficient mice was caused by reduced induction of p21, a cell-cycle inhibitor, in smooth muscle cells following injury. Klf4 has also been shown to be expressed in aortic endothelial cells (ECs),

where it plays anti-inflammatory and anti-thrombotic roles. However, the role of Klf4 in the kidney remains unknown. The aims of the present studies were to determine the expression of Klf4 in the kidney, and examine if Klf4 plays a role in renal ischemia-reperfusion injury.

**Methods:** Klf4 expression in the kidney was determined by immunohistochemistry. Role of Klf4 in renal ischemia-reperfusion injury was investigated in EC-specific Klf4 knockout mice, which were generated by breeding Tie2-Cre transgenic mice and Klf4 floxed mice.

**Results:** Results showed that Klf4 was expressed in ECs in the kidney of control mice, but not of EC-specific Klf4 knockout mice. Following renal ischemia-reperfusion injury, EC-specific Klf4 knockout mice exhibited significantly enhanced acute tubular necrosis, enhanced expression of pro-inflammatory molecules such as Vcam-1, and highly elevated serum levels of urea nitrogen, as compared to control mice. Results in human umbilical vein endothelial cells showed that Klf4 inhibited cytokine-induced expression of Vcam-1 by binding to p65, an active component of NF-kB.

**Conclusions:** Results suggest that Klf4 in ECs plays a protective role in renal ischemia-reperfusion injury.

## SA-PO058

**Low Energy Extracorporeal Shock Wave (SW) Ameliorates Renal Tubular Injury in a Rodent Acute Kidney Injury (AKI) Model** Mai Yoshida,[1] Takashi Nakamichi,[1] Takefumi Mori,[1] Kenta Ito,[2] Hiroaki Shimokawa,[2] Sadayoshi Ito.[1] *[1]Div of Nephrology, Endocrinology, and Vascular Medicine, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan; [2]Dept of Cardiovascular Medicine, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan.*

**Background:** SW therapy recovers ventricular function in ischemic cardiomyopathy, which is associated with upregulation of angiogenic factors such as vascular endothelial growth factor (VEGF) and nitric oxide (NO) expression. Recently, SW has been clinically available to patients with angina pectoris. VEGF and NO are known to play important roles in AKI. The aim of our study is to investigate whether SW ameliorates AKI in a rodent model.

**Methods:** Renal ischemia reperfusion (I/R) surgery was performed for left kidney in male 8-week-old Sprague-Dawley rats. The operated rats were divided into the following 2 groups: SW-treated group (SW, n=11) and no SW-treated control group (CON, n=11). Both kidneys of only SW group were treated with SW (200 shocks/day for each kidney, 0.09 $mJ/mm^2$) just after I/R operation, day1 and day2. The rats of both groups were sacrificed immediately after the last SW treatment. Then, plasma, urine and both kidneys were collected to determine plasma creatinine concentration, urinary NO, renal VEGF mRNA expression, and histological changes of the kidneys.

**Results:** On day2, the left kidney weight was decreased in SW (SW 0.45±0.02 vs. CON 0.52±0.02 g/100 g body weight, $P<0.05$) and plasma creatinine of SW was significantly lower than CON (SW 0.32±0.03 vs. CON 0.43±0.03 mg/dl, $P<0.05$). A light microscopy revealed that tubular injury scores in the outer medulla of SW were significantly lower than CON (SW 1.6±0.2 vs. CON 2.0±0.1, $P<0.05$) on day2. Urinary $NO_2$ and $NO_3$, products of NO, of SW were significantly higher than CON (SW 0.06±0.014 vs. CON 0.051±0.013 mol/day, $P<0.05$). Realtime-PCR analysis demonstrated a significant upregulation of right renal VEGF mRNA expression of SW on day2 (SW 1.29±0.1 vs. CON 0.97±0.1 VEGF/GAPDH).

**Conclusions:** SW improved renal tubular injury and its function, in which angiogenic factors might play roles. SW may be an effective and non-invasive treatment for ischemic AKI.

## SA-PO059

**The Renoprotective Effect of Acute, but Not Delayed, Ischemic Preconditioning Depends on Tubular Cell Autophagy** Man Jiang Livingston,[1,2] Zheng Dong.[1,2] *[1]Dept of Cellular Biology and Anatomy, Georgia Regents Univ; [2]Charlie Norwood VA Medical Center.*

**Background:** Ischemic preconditioning (IPC) is an important mechanism of tissue protective in which application of one or more brief episodes of ischemia-reperfusion results in tolerance to subsequent ischemic injury. IPC is potentially useful for clinical applications in diseases including heart and kidney failure. The mechanism of IPC is very complex and remains poorly understood. Autophagy is induced in tubular cells during renal ischemia-reperfusion and protects against acute kidney injury (AKI). However, it is unknown whether autophagy contributes to the renoprotective effect of IPC.

**Methods:** This study examined the role of tubular cell autophagy in the effect of kidney IPC using both pharmacological and genetic approaches. IPC was induced in C57 mice by a non-lethal bilateral renal ischemia of 15 minutes. After either an hour (acute IPC) or 4 days (delayed IPC) of reperfusion, the mice were subjected to bilateral renal ischemia of 27 minutes followed by reperfusion. Renal function, histology and tubular cell death were monitored.

**Results:** Both acute and delayed IPC suppressed the renal function loss and tissue damage induced by subsequent severe ischemic AKI. While delayed IPC suppressed both tubular cell necrosis and apoptosis, acute IPC mainly inhibited tubular apoptosis. Autophagy was induced in kidneys to a comparable extent by both types of IPC, as indicated by LC3-II accumulation and P62 degradation. Pharmacological inhibition of autophagy by 3-methyladenine or chloroquine abrogated the renoprotective effect of acute IPC, but not that of delayed IPC. The renoprotective effect of acute IPC was abolished in proximal tubule-specific Atg7 knockout mice, whereas the effect of delayed IPC was preserved in this autophagy–defective model. Preconditioning treatment of C57 mice with Tat-beclin1 activated autophagy in kidneys and afforded significant renoprotection against ischemic AKI.

**Conclusions:** Together, these results suggest that tubular cell autophagy is indispensable for renoprotection by acute, but not delayed, IPC. Pharmacological up-regulation of autophagy may be an effective approach for prevention and treatment of AKI.

## SA-PO060

**Mir-421 Regulates ATM after Acute Kidney Injury** Florian E. Toegel, Steven Leal-Ekman, Linshan Zhou, Joseph V. Bonventre. *Renal Div, Brigham and Women's Hospital, Boston, MA.*

**Background:** Fibrosis after AKI is an important contributor to CKD. Cell cycle arrest after AKI mediates maladaptive injury repair and induces a profibrotic phenotype. Ataxia Telangiectasia Mutated (ATM) is activated after AKI. ATM mediates cell cycle arrest causing up-regulation of profibrotic genes. MicroRNA-421 has been shown to down-regulate ATM expression.

**Methods:** Mir-421 levels were quantified by RTq-PCR. We knocked down Mir-421 expression with antimirs and enhanced expression by using mimics for *in vitro* studies.

**Results:** Mir-421 was down-regulated by ~80% in the injured kidney on day 5 after severe unilateral ischemia/reperfusion (28 min clamping) compared to the non-injured kidney. Bilateral ischemic injury (31 min clamping) caused mir-421 down-regulation on day 7, 12 and 14 post-injury by 44%, 74% and 74%, respectively. Mir-421 down-regulation correlated with increased ATM staining by immunofluorescence. Studies in vitro further defined the relationship between mir-421 and ATM. HK2 cells were transfected with antimirs or mimics and exposed to aristolochic acid (AA), which induces ATM. Mir-421 mimic significantly decreased the amount of p-ATM positive cells after AA exposure whereas antimir increased the p-ATM positive cells. Similar results were obtained when the mimic or antimir was applied after exposure to AA, suggesting a potential therapeutic use after the injury has occurred. Mir-421 mimic significantly decreased cell cycle arrest in HK2 cells after exposure to AA (G2/M 36.78 % control vs 16.44 % mimic). MTT assays showed no change in cell proliferation rate between cells treated with antimir or mimic compared to lipofectamine-treated controls. Antimir or mimic transfection did not change the time to closure of a wounded (scratch assay) monolayer indicating that mir-421 does not affect cell migration.

**Conclusions:** Down-regulation of mir-421 after ischemic AKI results in elevated ATM levels in vivo, and facilitates G2/M arrest after AA exposure in vitro. Mimics of mir-421, applied after injury, may represent a potential therapeutic approach to decrease maladaptive repair associated with AKI.

*Funding:* NIDDK Support

## SA-PO061

**Induction of Hypoxia-Inducible Factor Up-Regulates microRNA miR-21 in Renal Ischemia/Reperfusion** Xialian Xu,[1] Xiaoyan Jiao,[1] Yi Fang,[1] Mingyu Liang,[2] Xiaoqiang Ding.[1] *[1]Nephrology, Fudan Univ Zhongshan Hospital, Shanghai, China; [2]Physiology, Medical College of Wisconsin, Milwaukee, WI.*

**Background:** Hypoxia-inducible factor (HIF) is an important transcriptional regulator in cellular response to hypoxia. We have found that microRNA miR-21 protects mouse kidneys from ischemia/reperfusion injury and HIF mediates hypoxia-induced up-regulation of miR-21 in human renal epithelial cells. In present study, we examined the role of HIF induction in the regulation of miR-21 expression in C57BL/6N mice.

**Methods:** Mice received intraperitoneal injection of saline or cobalt chloride ($CoCl_2$), a classical inducer of HIF activation. 30min bilateral renal ischemia and 24h reperfusion was induced in mice after two injections. Renal injury and miR-21 abundance were analyzed.

**Results:** Compared with the sham group, elevation of Scr (2.49±0.88 vs 0.53±0.05 mg/dl, $P< 0.01$, n=6/group) and morphological injury were induced in the I/R group. Pretreatment with $CoCl_2$ afforded striking functional improvement (Scr: 0.71±0.11 vs 2.49±0.88 mg/dl, $P<0.01$, n=6/group) associated with amelioration of tubulointerstital damage. In the kidneys of mice treated with $CoCl_2$, protein levels of HIF-1α were up-regulated significantly. Ischemia/reperfusion induced up-regulation of miR-21 expression in the kidney. Renal abundance of miR-21 was increased in the $CoCl_2$ + I/R group by 236% ± 54% compared to the saline + I/R group ($p<0.05$, n=6/group).

**Conclusions:** These data, together with our previous findings, suggest HIF activation might mediate up-regulation of miR-21 in the kidney. miR-21 may be invovled in the mechanism of HIF-conferred renal protection against ischemic injury.

*Funding:* Government Support - Non-U.S.

## SA-PO062

**Induction of Mir-489 during Renal Ischemia-Reperfusion Protects against Acute Kidney Injury** Qingqing Wei,[1] Yong Liu,[2] Pengyuan Liu,[2] Mingyu Liang,[2] Zheng Dong.[1,3] *[1]Dept of Cellular Biology and Anatomy, Medical College of Georgia, Georgia Regents Univ, Augusta, GA; [2]Dept of Physiology, Medical College of Wisconsin, Milwaukee, WI; [3]Charlie Norwood VA Medical Center, Augusta, GA.*

**Background:** MicroRNAs have been implicated in acute kidney injury (AKI). While some microRNAs contribute to cell injury/death and tissue damage in AKI, others may protect kidney cells and tissues. By microarray analysis, we profiled microRNA expression during renal ischemia-reperfusion in mice and identified over a dozen of microRNAs showing significant changes. Among them, mir-489 was significantly induced both in vivo in ischemically injured kidney tissue and in vitro in hypoxia-treated renal proximal tubular cells (RPTCs).

**Methods:** Mir-489 induction during hypoxia was attenuated in HIF-1a knockdown cells, indicating that the induction is HIF-1 dependent. Consistently, proximal tubule-specific HIF-1a knockout mice showed lower mir-489 induction duringrenal ischemia-reperfusion than wild type. Functionally, transfection of anti-mir-489 in RPTCs increased apoptosis following ATP-depletion, suggesting a protective role of mir-489. Deep sequencing (RNA-Seq) was further conducted to identify the target genes of mir-489.

**Results:** Agonaute-2-bound RNAs in the presence or absence of mir-489 were immunoprecipitated, sequenced and compared. The analysis identified several classes of mir-489 targets, including the genes involved in cell stress response, wound-healing, cell communication, and cell differentiation.

**Conclusions:** Together, the results suggest that mir-489 is induced during renal ischemia-reperfusion to target some of the key pathways to protect kidney cells and tissues from AKI.

## SA-PO063

**Urinary MicroRNAs as Biomarkers for Drug-Induced Nephrotoxicity** Oana M. Nicoara,[1] Krithika Ramachandran,[2] Daniel J. Antoine,[3] Vishal S. Vaidya.[2] *[1]Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Medicine, Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [3]Molecular and Clinical Pharmacology, MRC Centre for Drug Safety Science, Univ of Liverpool, Liverpool, United Kingdom.*

**Background:** Kidneys are vulnerable to injury due to their high filtration capacity and metabolic activity. Most drugs are eliminated by the kidney, thus causing drug-induced nephrotoxicity (DIN), that accounts for ~25% of the episodes of acute kidney injury (AKI). Traditional markers of AKI suffer from limitations of sensitivity, specificity, and timeliness of diagnosis. MicroRNAs (miRNAs) are a family of short, non-coding RNAs that stably exist in various body fluids and have emerged as potential biomarkers. Previously we performed an entire miRNome screen of the human urine and identified miR-21, miR-200c and miR-423 to be sensitive indicators of AKI in the hospital setting. The aim of our current study was to investigate if urinary miR-21, miR-200c and miR-423 could differentiate patients with acetaminophen (APAP)-overdose kidney injury from those without AKI.

**Methods:** Urine samples were obtained from APAP-overdose patients and healthy controls. The experiment was performed using a 384-well custom plate from Qiagen that contained specific probes for the 3 candidate miRNAs and miR-489 (previously identified as an invariant miRNA). A real time PCR analysis was performed using the ABI-7900HT instrument.

**Results:** The 3 candidate miRNAs were able to successfully distinguish the APAP overdose patients (n=70) from healthy controls (n=65). It was also found that these 3 miRNAs were significantly different between patients with APAP-induced kidney injury (n=43) and patients with APAP-overdose but no kidney injury (n=27): miR-21 (p=0.01), miR-200c (p=0.003) and miR-423 (p=0.003).

**Conclusions:** We report 3 urinary miRNAs as potential biomarkers of DIN. Further evaluation of these candidate miRNAs for sensitivity, specificity and early diagnostic abilities in an expanded longitudinal cohort of patients with APAP-overdose with or without AKI will help in establishing the value of these urinary miRNAs as non-invasive biomarkers for DIN.

## SA-PO064

**A Critical Role of Class I Histone Deacetylasesin in Mediating Renal Tubular Cell Regeneration and the Recovery of Renal Function after Acute Kidney Injury** Shougang Zhuang. *Dept of Medicine, Rhode Island Hospital, Alpert Medical School of Brown Univ, Providence, RI.*

**Background:** Class I histone deacetylases (HDACs) are critically involved in the regulation of gene transcription, cell proliferation and renal development.

**Methods:** In this study, we tested the hypothesis that class I HDACs mediate renal regeneration and renal function recovery after acute kidney injury (AKI) in murine models of rhabdomyolysis or folic acid induced AKI.

**Results:** Intramuscular injection of glycerol to induce rhabdomyolysis or peritoneal injection of folic acid resulted in tubular damage and a rise in serum creatinine. Inhibition of class I HDACs with MS-275, a selective class I HDAC inhibitor, induced hyperacetylation of histone H3, and potentiated these responses. MS-275 administration also significantly enhanced rhabdomyolysis and folic acid-induced expression of NGAL and Kim-1, activation of caspase-3 and apoptosis of renal tubular cells. Conversely, this agent reduced renal expression of Pax2, vimentin and proliferating cell nuclear antigen in injured kidneys. In response to rhabdomyolysis and folic acid, multiple signaling molecules, including epidermal growth factor receptor (EGFR), AKT, signal transducer and activator of transcription-3(STAT3), and NF-kappa Bp65 were phosphorylated; two chemokines, MCP1 and RANTES, were also highly expressed in the kidney. Interestingly, MS-275 treatment suppressed phosphoryation of EGFR, AKT and STAT3, but enhanced NF-kappa Bp65 phosphorylation and MCP1 and RANTES expression.

**Conclusions:** Taken together, these data suggest that class I HDACs play a critical role in mediating renal tubular cell survival and regeneration after acute injury and EGFR and NF-kappB are downstream effectors of class I HDACs.

*Funding:* NIDDK Support, Government Support - Non-U.S.

## SA-PO065

**Isoform-Specific Increases in Histone Deacetylase (HDAC) Activity Contribute to the Progression of Renal Fibrosis** Scott R. Manson, Paul F. Austin. *Dept of Surgery, Washington Univ, Saint Louis, MO.*

**Background:** Histone deacetyalases (HDACs) are among the most widely expressed and important regulators of gene transciption. While the 10 HDAC isoforms function by similar biochemical mechanisms, they elicit disparate biological responses dependent upon their target genes. In this study, we examine the role of individual HDAC isoforms during the progression of renal injury along with their potential therapeutic importance.

**Methods:** Renal injury was modeled in mice by acute ischemia-reperfusion (IR) and chronic unilateral ureteral obstruction (UUO). The effects of HDAC inhibition were determined by treatment with the broad spectrum inhibitor Trichostatin A (TSA) and the isoform-specific inhibitors MS-275 (HDAC1-3), MC1568 (HDAC4, 5, 7, 9), CAY10603 (HDAC6, 10), PCI34051 (HDAC8).

**Results:** Each of the 10 HDAC isoforms demonstrate cell type-specific localization in the normal kidney. UUO leads to a 52.0% increase in total HDAC activity along with a 41.9% decrease in Histone H3 acetylation. This coincides with a dramatic increase in the expression of Class IIA HDAC proteins (HDAC4, 5, 7, 9), including an 11.3-fold increase in HDAC7 and a 6.7-fold increase in HDAC9 that localizes primarily to the proximal tubular epithelium. Additionally, infiltrating pro-fibrotic pericytes exhibit high levels of HDAC8 expression. Broad spectrum inhibition of HDAC activity with TSA results in a 31.1% decrease in renal fibrosis and a 43.4% decrease in the loss of renal architecture following UUO. While treatment with each of the isoform-specific HDAC inhibitors resulted in varying levels of renal protection, these compounds appeared to function by different mechanisms. [All results $p < 0.05$].

**Conclusions:** Increased HDAC activity contributes to the progression of renal fibrosis following both acute and chronic renal injury. This is primarily the result of an upregulation in the expression of Class IIA HDAC proteins. While broad-spectrum HDAC inhibition has significant renal protective effects, isoform-specific HDAC inhibition may provide a means of targeting specific cell populations and pathologic mechanisms during the progression of renal injury.

## SA-PO066

**Vitamin D Deficiency-Induced Inhibition of p21 Upregulation in Ischemic Acute Kidney Injury: Negative Effects** Ana C. de Bragança, Rildo A. Volpini, Janaina Garcia Gonçalves, Daniele Canale, Maria H.M. Shimizu, Rosa M.A. Moyses, Antonio C. Seguro, Lucia Andrade. *Nephrology, Univ of Sao Paulo, Brazil.*

**Background:** Vitamin D deficiency (VDD) is a major predictor of mortality in critically ill patients. Coordinated cell cycle inhibition via increased expression of the cyclin-dependent kinase inhibitor p21 is necessary for optimum recovery from ischemia/reperfusion-induced acute kidney injury (IR-AKI). Because p21, a genomic target of 25-hydroxyvitamin D [25(OH)D], acts via vitamin D receptors (VDRs), VDD-induced inhibition of p21 upregulation could aggravate IR-AKI.

**Methods:** Wistar rats were fed 25(OH)D-depleted or normal diets for 30 days. We studied four groups: control (C), VDD, IR (both renal arteries clamped for 45 min on day 28) and VDD+IR. At 48 h after IR, we measured inulin clearance (Cin); serum 25(OH) D and PTH; and fractional interstitial area (FIA). Immunohistochemistry (for PCNA and ED1) and immunoblotting (for protein expression of p21 and VDRs) were performed in kidney tissue. Morphological kidney damage was scored from 0 to 4. Data are mean±SEM.

**Results:**

| | Cin (ml/min/100g) | p21 (%) | VDR (%) | PCNA+ cells | ED1+ cells | FIA (%) | Damage (score) |
|---|---|---|---|---|---|---|---|
| C (n=7) | 0.93±0.05 | 99±6.0 | 99.5±0.5 | 0.21±0.06 | 2.35±0.12 | 11.32±1.01 | 0.06±0.01 |
| VDD (n=8) | 0.76±0.03[a] | 100±27 | 57.5±8.5[a] | 1.2±0.14 | 5.8±0.73[a] | 14.04±1.02[a] | 0.1±0.01 |
| IR (n=7) | 0.43±0.04[a,b] | 290±4.8[a,b] | 198.5±0.7[a,b] | 29.41±5.12[a,b] | 9.98±0.68[a,b] | 16.70±0.7[a,b] | 1.44±0.12[a,b] |
| VDD+IR (n=8) | 0.29±0.03[a,b,c] | 182±29[a,b,c] | 172.7±10.9[a,b,c] | 33.17±5.88[a,b] | 10.38±0.75[a,b] | 19±0.49[a,b] | 1.72±0.09[a,b,c] |

[a]p<0.05 vs. C; [b]p<0.05 vs. VDD; [c]p<0.05 vs. IR

25(OH)D was decreased in VDD and VDD+IR; PTH was increased in VDD, IR and VDD+IR. Fractional excretions (Ca and P) were higher in VDD+IR than in VDD.

**Conclusions:** In this IR-AKI model, VDD-induced inhibition of p21 upregulation was associated with greater severity of morphological and functional kidney damage. VDD promotes renal interstitial expansion and inflammatory cell infiltration.

**Chronic Nicotine Exposure Reverses Stimulatory Effect of ERK on Acute Renal Ischemia/Reperfusion-Dependent Induction of Heme Oxygenase-1** Istvan Arany, Dustin Reed, Robert Kampen, Luis A. Juncos. *Univ of Mississippi Medical Center.*

**Background:** Chronic nicotine (Ch-NIC) exposure exacerbates acute ischemia/reperfusion-mediated oxidative stress and renal injury (IR-AKI) in the mouse. Extracellular signaling regulated kinase (ERK)-dependent activation of heme oxygenase-1 (HO-1) is considered a major mediator of survival during IR-AKI. Hence, we determined whether Ch-NIC affects activation of those signaling pathways.

**Methods:** In vivo: Some mice were exposed to chronic NIC or vehicle (4 weeks) and subjected to 18-minutes of bilateral warm renal ischemia or sham operation followed by 1, 6 and 24 hours of reperfusion. In vitro: Cultured renal proximal tubule cells (LLC-

PK1) were treated with 200 μM NIC for 24 hours after which cell injury was induced by 400 μM $H_2O_2$. Extent of phosphorylation (U0126), duration of activation (via EGF or constitutively active MEK) or subcellular localization of activated ERK (cytoplasmic or nuclear constitutively active ERKs) was manipulated. Activation of the HO-1 promoter and the antioxidant response element (ARE) was determined in reporter luciferase assays.

**Results:** Ch-NIC attenuated IR-AKI-mediated induction of HO-1 while augmented phosphorylation, duration of phosphorylation and nuclear localization of the phosphorylated ERK (pERK) in the kidney. In vitro, $H_2O_2$-mediated activation of the HO-1 promoter was dependent on pERK-mediated activation of the ARE. Ch-NIC mitigated this induction of the HO-1 promoter through pERK-dependent attenuation of the ARE. Transient activation (by EGF) or cytoplasmic overexpression of an activated ERK construct augmented $H_2O_2$-dependent activation of the ARE while sustained activation (by constitutive MEK) or nuclear overexpression of an activated ERK construct mitigated it.

**Conclusions:** The activated ERK elicits opposing effects in induction of the HO-1 promoter: under oxidative stress ERK activation is transient and cytoplasmic that induces the ARE. In contrast, upon exposure to Ch-NIC the activated ERK is sustained and nuclear, which mitigates oxidative stress-dependent induction of the ARE. These results may offer therapeutic means to ameliorate adverse effects of Ch-NIC.

## SA-PO068

**The Role of Nicotinic Acetylcholine Receptor in Adverse Effects of Chronic Nicotine Exposure on Renal Acute Ischemic Injury** Istvan Arany, Dustin Reed, Robert Kampen, Luis A. Juncos. *Univ of Mississippi Medical Center.*

**Background:** Earlier we reported that chronic nicotine (Ch-NIC) exposure exacerbates acute renal ischemic injury (IR-AKI) in mice. NIC –a major component of cigarette smoke- is an agonist of the α7-nicotinic-acetylcholine receptor (α7nAChR). While acute activation of the α7nAChR is connected to anti-inflammatory signaling, its desensitization via Ch-NIC may activate signaling pathways that support inflammation and injury. In this work we tested the hypothesis that Ch-NIC exerts its adverse effects on IR-AKI through α7nAChR.

**Methods:** IR-AKI was established in wild type or α7nAChR knockout mice that were subjected or not to chronic NIC. 24 hours post-reperfusion, oxidative stress, renal dysfunction, injury and markers of survival/death signaling and inflammation were determined. In vitro, renal proximal tubule cells (LLC-PK1) were treated with 200 μM NIC for 24 hours followed by treatment with 400 μM $H_2O_2$. α7nAChR was inhibited by the antagonist α-bungarotoxin (αBTX); ROS production, mitochondrial depolarization, cell injury as well as activity of the MCP-1 gene were determined.

**Results:** IR-AKI-mediated renal dysfunction (plasma creatinine), injury (renal KIM-1), inflammation (MCP-1) and oxidative stress (MDA and nitrotyrosine expression) was attenuated in α7nAchR k.o. mice compared to their wild type counterparts. In vitro, αBTX attenuated NIC+$H_2O_2$-mediated production of ROS, mitochondrial depolarization and injury as well as activation of the MCP-1 promoter.

**Conclusions:** Our results suggest that the α7nAChR plays a pivotal role in transducing injury signals in the presence of Ch-NIC. Thus, manipulation of the receptor activity may offer therapeutic means to ameliorate adverse effects of chronic NIC/smoking.

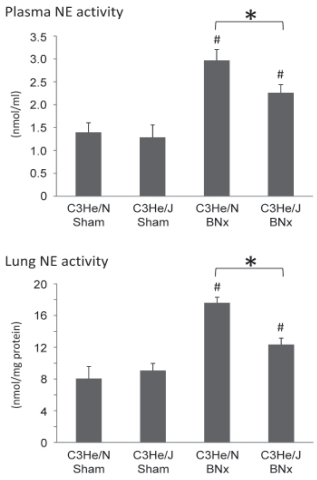
## SA-PO069

**High-Mobility Group Protein B-1–Toll-Like Receptor 4 Pathway in Acute Lung Injury Induced by Bilateral Nephrectomy** Kent Doi,[1] Tomoko Ishizu,[2] Yoshifumi Hamasaki,[2] Tetsushi Yamashita,[2] Masaomi Nangaku,[2] Naoki Yahagi,[1] Eisei Noiri.[2] *[1]Emergency and Critical Care Medicine, The Univ of Tokyo, Tokyo, Japan; [2]Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan.*

**Background:** Acute lung injury (ALI) and acute kidney injury (AKI) are severe complications in critically ill patients. These two organ dysfunctions synergistically increase mortality in intensive care units. Organ cross-talk between the kidney and the lung has been suggested recently as amplifying each organ injury. This study was conducted to identify a possible mechanism of AKI-induced ALI using a mouse bilateral nephrectomy (BNx) model.

**Methods:** Bilateral nephrectomy was conducted with TLR4-mutant C3H/HeJ and their TLR4 wild-type control strain C3H/HeN mice. Neutrophil infiltration, neutrophil elastase (NE) activity and cytokine expression (IL-6, KC, TNF-α) in the lung were examined. Plasma HMGB1 concentration was measured by ELISA. Anti-HMGB1 neutralizing antibody treatment and *s*plenocyte transfer from C3He/N to C3H/HeJ mice were conducted to demonstrate the contribution of HMGB1–TLR4 pathway to lung injury.

**Results:** TLR4-mutant C3He/J mice were resistant to lung injury including neutrophil infiltration and increased NE activity caused by BNx. Injection of splenocytes isolated from C3He/N mice to C3He/J mice reversed the suppression of NE activity in C3He/J mice. Blood concentrations of HMGB1 in C3He/J and C3He/N mice were increased significantly by BNx. Blockade of HMGB1 by neutralizing antibody reduced lung injury not in TLR4-mutant C3He/J but in TLR4-wild type C3He/N mice.



**Conclusions:** The obtained data suggest that enhanced HMGB-1–TLR4 pathway contributes to lung injury induced by BNx. Targeting the HMGB-1–TLR4 pathway will enable development of a new therapeutic strategy to improve the outcome of severely ill patients with ALI and AKI.

## SA-PO070

**BMP and NF-κB Signaling Interaction in Acute Kidney Injury** Emilia Vigolo,[1] Lajos Marko,[2] Giulietta Roel,[1] Dominik Müller,[2] Ruth Schmidt-Ullrich,[1] Kai M. Schmidt-Ott.[3] *[1]Max Delbrueck Center for Molecular Medicine, Berlin, Germany; [2]Experimental and Clinical Research Center, Charité - Universitätsmedizin, Berlin, Germany; [3]Dept of Nephrology, Charité - Universitätsmedizin, Berlin, Germany.*

**Background:** Renal ischemia reperfusion injury (IRI) is a major cause of AKI. Both bone morphogenic protein (BMP) and nuclear factor-κB (NF-κB) signaling have been implicated in the pathogenesis of AKI. However, the precise timing of their activity and interconnection remain unknown. We hypothesized that BMP and NF-κB signaling interact to modulate the pathogenesis of AKI.

**Methods:** We induced IRI by clamping the renal pedicle for 25 minutes in NF-κB specific reporter (*κ-luc*) mice and Emx1-Cre;IκBαΔN$^{flox}$ (*Emx1-ΔN*) mice, in which NF-κB activity is specifically suppressed in renal tubules. We analyzed serum creatinine, renal neutrophil gelatinase-associated lipocalin (NGAL) mRNA expression, and histological damage scores. BMP signaling activation was detected by pSmad1/5/8 immunostaining.

**Results:** *κ-luc* mice displayed a gradual increase of NF-κB activity with a significant peak after 3 days following IRI, whereas tubular canonical BMP signaling was simultaneously down-regulated as verified by pSmad1/5/8 staining. To address the specific function of NF-κB in tubular cells, we generated the *Emx1-ΔN* mice. The mRNA expression of the NF-κB target genes IkBa, IL6, ICAM1 and VCAM1 was up-regulated in control, but not in *Emx1-ΔN* ischemic kidneys. 24 hours after IRI, *Emx1-ΔN* mice displayed reduced tubular injury, serum creatinine and NGAL expression compared to control littermates. Additionally, extracellular matrix expansion, inflammatory cell infiltration and CTGF expression were strongly reduced in the postischemic *Emx1-ΔN* mice compared to littermate controls. Conversely, tubular pSMAD1/5/8 was increased in postischemic *Emx1-ΔN* kidneys suggesting that NF-κB signaling suppresses the intrinsic tubular BMP activity.

**Conclusions:** These data provide initial evidence of a cross-talk between NF-κB and canonical BMP signaling in the postischemic kidney. Importantly, NF-κB-mediated repression of BMP signaling may participate in the maladaptive aggravation of tubular injury and perturbed regeneration following renal ischemia.

## SA-PO071

**The Effects of Aging on the Development of Renal Ischemia-Reperfusion Injury** Eun Hee Koo, Hye Ryoun Jang, Jung Eun Lee, Dae Joong Kim, Yoon-Goo Kim, Ha Young Oh, Wooseong Huh. *Dept of Medicine, Div of Nephrology, Samsung Medical Center, Seoul, Korea.*

**Background:** Ischemia-reperfusion injury (IRI) is the leading cause of ischemic acute kidney injury in both native and transplanted kidneys. IRI is known to increase acute rejection and have deleterious effect on long term outcome of allografts. Previous studies have reported that the elderly are more prone to ischemic acute kidney injury. In this study, we investigated how aging affects the development of renal IRI.

**Methods:** Both renal pedicles were clamped for 25 minutes on 9-week (9W, n=15), 6-month (6M, n=15), and 12-month-old (12M, n=11) male C57BL/6 mice. Renal function changes were evaluated with serum creatinine and cystatin C for 48 hours. Tubular injury, infiltration of CD 45 positive leukocytes, and cytokine expression on post-ischemic kidneys were analyzed.

**Results:** There was no difference in serum creatinine among groups, although serum cystatin C level was higher in 12M mice compared with 9W and 6M mice. Both 6M and 12M mice showed higher proportion of damaged tubules in the cortex than 9W mice, but medullary tubular damage was comparable. There was no difference in the infiltration of leukocytes into the post-ischemic kidney. Interleukin (IL)-6 expression was higher in 6M and 12M mice than 9W mice. The expression of interferon-γ was comparable. Both IL-4 and IL-10 were comparable among groups on baseline and day 2 after IRI. Vascular endothelial growth factor (VEGF) was lower in 6M and 12M mice at baseline. VEGF significantly decreased in all groups after IRI, and was much lower in 6M and 12M mice compared with 9W mice on day 2 following IRI.

**Conclusions:** Older mice showed more severe cortical tubular injury compared to young mice. Pronounced increase of IL-6 and decrease of VEGF on the post-ischemic kidneys in older mice seem to be the cause. However, pathologic changes did not correlate with age or changes in renal function.

## SA-PO072

**In Vivo Hydrogen Sulfide Measurements during Renal Ischemia Reperfusion** Bernardo Lopez, Cayetano Perez, Moises Hernandez, Francisco J. Fenoy, Miguel G. Salom, Francisca Rodriguez. *Physiology, School of Medicine at Universidad de Murcia, Campus de Espinardo, Murcia, Spain.*

**Background:** Hydrogen sulfide ($H_2S$) has recently been classified as a member of the gasotransmitter family. The enzymes involved in its production are mainly cystathionine β–synthase (CBS) and cystathionine γ–lyase (CSE) that generate $H_2S$ from L-Cysteine (L-Cys). Recent studies highlight $H_2S$ protective effects on renal ischemia-reperfusion injury (IRI), a major cause of acute renal failure and renal transplant dysfunction. The aim of this study was to determine the real-time cortical levels of the gaseous signaling molecule $H_2S$ during a renal IRI.

**Methods:** Anesthetized SD rats underwent 45/60 min of warm ischemia/reperfusion during intrarenal infusion of saline (IRI, n=8), 80 nmol/Kg/min NaHS (IRI+$H_2S$, n=6), 80 µmol/Kg/min L-Cys (IRI+L-Cys, n=4) or 2 µmol/Kg/min propargylglycine (PPG, a CSE inhibitor) + 0.5 µmol/Kg/min amino-oxyacetic acid [(AOAA, a CBS inhibitor), IRI+Inh, n=5]. Cortical $H_2S$ concentration was measured electrochemically; renal blood flow (RBF), and glomerular filtration rate (GFR) were also assessed. In other rats set, GFR was measured 24 h after ischemia in nonischemic, and in ischemic rats kidneys i.v. given (in mg/Kg) either saline (IRI, n=6), 1 NaHS (IRI+H2S, n=10), 50 L-Cys (IRI+L-Cys, n=8), or 40 PPG+3 AOAA (IRI+Inh, n=5).

**Results:** Renal ischemia increased cortical $H_2S$ levels, which dropped to preischemic values on reperfusion. Ischemic $H_2S$ increase was significantly blunted in the IRI+Inh rats group. NaHS, L-Cys, or PPG+AOAA infusion did not alter RBF and GFR basal values; RBF, but not GFR, came back to preischemic values on reperfusion. $H_2S$ donor, L-Cys, or PPG+AOAA had no effect on GFR (1154.6±177.1 µl/min/g) in nonischemized kidneys. 24 h after ischemia, GFR decreased in ischemized kidneys of IRI (226.7±75.8) and IRI+Inh (153.2±67.1) rats. The GFR fall was significantly improved in the ischemized kidneys of rats pretreated with NaHS (579.8±131.1) or L-Cys (698.2±155.3).

**Conclusions:** Renal ischemia produces a rise in endogenous renal cortical $H_2S$ levels, but only a pretreatment with an exogenous $H_2S$ source seems to contribute to the significant amelioration of the renal failure observed 24 h after reperfusion.

*Funding:* Government Support - Non-U.S.

## SA-PO073

**Urinary Excretion of Nidogen-1 by Meprin A during Acute Kidney Injury** Christian Herzog,[1] Randy S. Haun,[2,3] Gur P. Kaushal.[1,3] *[1]Medicine, UAMS, Little Rock, AR; [2]Pharmaceutical Sciences, UAMS, Little Rock, AR; [3]CAVHS, Little Rock, AR.*

**Background:** Nidogen-1 is an important component of the extracellular matrix (ECM) located at the basement membrane of tubular epithelial cells (RTEC) in the kidney. In a mouse model of acute kidney injury (AKI), nidogen-1 fragments appear in the urine long before the rise of the diagnostic markers BUN and serum creatinine, whereas these fragments are absent in normal urine. Actinonin, a potent inhibitor of meprin A (a metalloproteinase highly enriched in the brush border membrane (BBM) of RTEC) reduces the excretion of these fragments. Previous studies of our group have shown that meprin A (tetramer of α and β subunits) can degrade nidogen-1 in vitro. As several deleterious effects of AKI have been attributed to proteolysis by meprin A, its role in the excretion of nidogen-1 fragments was investigated.

**Methods:** Urinary excretion of nidogen-1 fragments was monitored by western blot (WB) in male C57Bl/6n mice as well as in knockout (KO) mouse models of meprin α and β after induction of AKI by cisplatin ± actinonin. Degradation of nidogen-1 was monitored in kidney homogenates by WB. Kidney distribution of meprins and nidogen-1 during AKI was visualized by immuno-fluorescence.

**Results:** Nidogen-1 fragments appear in the urine 12h after cisplatin-injection, long before the rise of BUN and serum creatinine levels and this excretion is markedly reduced by the meprin inhibitor actinonin. Meprin β KO-mice (characterized by the complete loss of membrane bound meprin A) show an even stronger reduction in urinary excretion of nidogen-1 fragments, whereas meprin α KO mice do not. Mice subjected to AKI show altered localization of meprin A from the BBM towards the cytosol and the basolateral membrane suggesting close contact with components of the ECM such as nidogen-1.

**Conclusions:** Meprin A, and particularly its β subunit, seem to be responsible for the proteolytic cleavage of nidogen-1 in the early stages of cisplatin-induced AKI long before the rise in BUN and serum creatinine levels. As meprin A changes its localization during AKI and targets molecules of the ECM, it becomes a valuable target for pharmaceutical intervention.

## SA-PO074

**Therapeutic Manipulation of the Angiopoietin/Tie2 Pathway in Septic Acute Kidney Injury** Thomas Stiehl,[1] Kristina Thamm,[1] Hermann G. Haller,[1] Ansgar Santel,[2] Sascha David.[1] *[1]Nephrology, Medical School Hannover, Hannover, Germany; [2]Silence Therapeutics AG, Berlin, Germany.*

**Background:** Intensive basic research into sepsis and associated acute kidney injury (AKI) has yielded numerous putative molecular targets, but many have not translated into successful therapies. We have shown that Angiopoietin-2 (Angpt-2), a partial antagonist of the endothelium-stabilizing receptor Tie-2 secreted by endothelium, contributes to septic AKI and adverse outcomes in this disease. Here we report translational data modulating the Angpt/Tie2 pathway as a potential therapeutic strategy in murine experimental sepsis.

**Methods:** Endothelial Angpt-2 transcription was reduced via an Angpt-2 specific lipophilic in vivo siRNA approach in male C57Bl6 mice. Experimental polymicrobial sepsis was induced by cecal ligation and puncture (CLP). In this model we analysed the 1) renal expression of endothelial adhesion molecules (VCAM-1, ICAM-1) via qPCR and immunofluorescence (IF) staining, 2) infiltration of inflammatory cells (IF Gr-1), 3) organfunction, 4) pulmonary vascular leakage (Evans blue permeability assay) 5) severity of illness (activity score), and 6) mortality.

**Results:** Validation of the Angpt-2 siRNA showed a 45.5 ± 5.4 % reduction of Angpt-2 mRNA septic mice (p=0.01). We found a significant reduction in renal ICAM-1 and VCAM-1 expression in Verum treated septic animals, an observation that was associated with less organ infiltration of inflammatory cells (*Gr*-1 pos cells per high power field: Verum 19.3 ± 7.6 vs. Placebo: 36.5 ± 12.7 p<0.0001) and better organ function (*creatinin:* Verum 47.8 ± 8.4 vs. Placebo 66.2 ± 15.7 umol/l; *urea:* Verum 20.6 ± 13.4 vs. 41.2 ± 7.7 umol/l, p=0.008). Renal histological damage as visualized by brush border staining (lectin phythemaglutinin) was ameliorated (p=0.008). Moreover, Angpt-2 siRNA improved vascular severity of illness (p=0.01), reduced vascular leakage (p=0.008) as well as overall survival (after 72 hrs: Verum 50% vs. Placebo 0%, p=0.0002).

**Conclusions:** The Tie2 antagonist Angpt-2 might represent a novel promising target against sepsis and associated AKI. A specific lipophilic siRNA approach could be a clinically relevant way of application to reduce pathological Angpt-2 transcription.

*Funding:* Pharmaceutical Company Support - Silence Therapeutics

## SA-PO075

**Expression of DJ-1 in Renal Ischemia Reperfusion Injury** Guanhui Wu,[1] Kim-Chong Yong,[1] Yeong-Hau Howard Lien,[2,3] Li-Wen Lai.[1] *[1]Chemistry and Biochemistry, Univ of Arizona, Tucson, AZ; [2]Medicine, Univ of Arizona, Tucson, AZ; [3]AKDHC, Tucson, AZ.*

**Background:** DJ-1 (PARK7) is a ubiquitous cytoprotector against oxidative stress and cell death, acting as ROS scavenger, molecular chaperon, and regulator of other antioxidant genes. DJ-1 mutation causes autosomal recessive Parkinson disease and its role as a neural protector has been under intensive investigation. However, the protective role of DJ-1 in the kidney is largely unknown. Since oxidative stress is the major pathogenesis of renal ischemia/reperfusion injury (IRI), we measured the DJ-1 protein and mRNA level in the kidney.

**Methods:** Male NIH Swiss mice were subjected to 30 min of bilateral clamping of renal pedicles, followed by reperfusion for 1, 4, 8, 16, or 24 h. The total protein and mRNA were isolated and analyzed using Western Blotting and quantitative RT-PCR, respectively.

**Results:** The immunoblotting results showed a 50% reduction of renal DJ-1 protein level at 1 h after reperfusion in comparison to the control but the DJ-1 protein was restored back to the baseline level at 8, 16, and 24 h after reperfusion. In contrast, the qRT-PCR showed that renal DJ-1 mRNA abundance was slightly increased (130% of baseline level) at 1 h and 4 h, while it was dramatically increased to 260% at 8 h and remained elevated (150% of baseline level) after 16 and 24 h.

**Conclusions:** Upon oxidative stress, DJ-1 has been shown to undergo irreversible oxidative modification, leading to its inactivation and rapid degradation. Collectively, the transient decrease and reverse of DJ-1 protein level in combination of upregulation of DJ-1 mRNA abundance suggest that 1) DJ-1 is highly regulated at both protein and mRNA levels during renal IRI; 2) IRI causes oxidative modification and degradation of DJ-1 protein which is restored by the feedback upregulation of DJ-1 mRNA synthesis; 3) DJ-1 may serve as a potential drug target in the prevention/treatment of AKI.

*Funding:* NIDDK Support

## SA-PO076

**Sildenafil (SIL) Protects against Acute Kidney Injury (AKI)-Induced Cardiac Dysfunction via Direct Effects on Myocardial Cells** Andrea P. Soljancic,[1] Damian G. Romero,[2] Istvan Arany,[3] Rodrigo Maranon,[4] Kiran B. Chandrashekar,[1] Ruisheng Liu,[4] Luis A. Juncos.[1] *[1]Medicine-Nephrology, Univ of Miss Med Center; [2]Biochemistry, Univ of Miss Med Center; [3]Pediatrics, Univ of Miss Med Center; [4]Physiology, Univ of Miss Med Center.*

**Background:** AKI causes cardiac dysfunction. We reported that Sil protects against AKI and its associated cardiac inflammation. However, we did not discern if this beneficial cardiac effect was due to the less severe AKI or its direct cytoprotective effect (via heme

oxygenase-1; HO-1) in myocardial tissue. Therefore, we tested if Sil not only augments AKI-induced cardiac HO-1 (despite the less severe renal injury) in vivo, but also whether this augmentation was due to a direct effect on myocardial cells in vitro.

**Methods:** *In Vivo Studies*: SD rats treated with vehicle or Sil were subjected to 40 mins of bilateral renal ischemia-reperfusion (I/R). Blood and tissue were collected at 72 h. In Vitro Studies: H9c2 cells (embryo cardiomyoblasts) treated with vehicle or Sil (10 uM) were exposed for 24 h to rat serum collected 48 h post either 40 min of I/R-AKI or a sham surgery.

**Results:**

| In vivo | BUN mg/dl | Urine NGAL UI/ml | TNFα pg/ug | Cytochrome C ng/ug | HO-1 ng/ug |
|---|---|---|---|---|---|
| Sham | 21±2 | 700 ± 182 | 0.3±0.1 | 2±0.1 | 0.1±0.01 |
| Sham-Sil | 17±2 | 694 ± 92 | 0.3±0.1 | 1±0.1* | 0.1±0.01* |
| I/R-AKI | 76±3* | 3401 ± 139* | 4±0.2* | 10±0.6* | 0.7±0.03* |
| I/R-AKI-Sil | 41±3# | 2381 ± 62 # | 2±0.1# | 7±0.4# | 0.9±0.04# |
| **In vitro** | **TNFα (pg/ml)** | **Cytochrome C (ng/ml)** | **HO-1 (ng/ml)** | | |
| FBS | 3±0.5 | 6±0.1 | 6±0.1 | | |
| FBS-Sil | 3±1 | 6±0.1 | 16±0.4 δ | | |
| Sham | 4±0.5 | 6±0.6 | 7±0.1 | | |
| Sham-Sil | 3±0.3 | 6±0.3 | 17±0.2 λ | | |
| I/R-AKI | 255±6 λ | 97±6 λ | 24±0.3 λ | | |
| I/R-AKI-Sil | 74±2 ξ | 22±1 ξ | 38±0.3 ξ | | |

Data: Mean ± SEM. p<0.05: * vs Sham, # vs I/R-AKI, δ vs FBS, λ vs Sham, ξ vs I/R-AKI. FBS: Fetal Bovine Serum.

**Conclusions:** Sil directly enhances I/R-induced increases in HO-1 in myocardial cells, and blunts I/R-AKI-induced cardiac inflammation and apoptosis, suggesting that Sil-induced HO-1 in the heart may contribute to its protective effect during AKI.

*Funding:* Other NIH Support - NIH DK073401.

## SA-PO077

**Common Genetic Variation and Risk for Acute Kidney Injury in Trauma-Related Critical Illness** Paramita Mukherjee, Grant O'Keefe, Amber Burt, Jonathan Himmelfarb, Mark M. Wurfel. *Kidney Research Institute, Univ of Washington, Seattle, WA.*

**Background:** Acute kidney injury (AKI) is seen in 5-20% of critically ill patients. Better molecular and genetic markers are needed to assess individual risk for AKI. Our objective was to identify common genetic variants in the form of single nucleotide polymorphisms (SNPs) that influence susceptibility to AKI after major trauma by using a genome-wide association study (GWAS).

**Methods:** We used the Illumina Human610 Quad Beadchip to genotype 975 subjects from a cohort of Caucasian patients (age > 18) enrolled from the trauma ICU at Harborview Medical Center between 2003-2005 and followed for development of AKI. AKI was defined using a modified Acute Kidney Injury Network (AKIN) based on difference between the highest and lowest creatinine during the first 4 days of ICU admission and were coded as a 3-level ordinal outcome variable: stages 0, 1, 2 and 3 combined. We used logistic regression, assuming additive genetic effects (adjusting for age and sex) to identify SNPs associated with AKIN stage.

**Results:** The 975 subjects genotyped had a mean age of 45 years, were 74.2% male, and included 7% with chronic kidney disease. Injury was quite severe for most subjects as evidenced by a mean trauma related injury severity score (TRISS) of 33.7. Stage 1 and combined stage 2+3 AKI occurred in 52.8% and 5.9% of subjects respectively and was not correlated with the TRISS. Although, no associations achieved genome-wide significance, the top two SNP identified were in *CACNA2D4* encoding a voltage-dependent calcium channel and *ATP2C2* encoding a secretory $Ca^{2+}$ ATPase responsible for calcium uptake, with $p=2.1 \times 10^{-6}$ and $p=2.8 \times 10^{-5}$ respectively. We also identified 50 SNPs with $p < 1 \times 10^{-4}$ that fell within genes related to polycystic kidney disease , cell cycle and T cell regulation.

**Conclusions:** Common genetic variation in *CACNA2D4* and *ATP2C2* demonstrate moderate associations with risk for AKI after major trauma. Given that studies in rodent models of acute kidney injury have shown that increases in cytosolic calcium levels are associated with renal epithelial cell injury, these results warrant validation.

## SA-PO078

**Impact of P-Glycoprotein Induction on Colistin-Induced Nephrotoxicity in Cultured Human Proximal Tubular Cells** Hyo-Wook Gil,[1] Soon Hyo Kwon.[2] *[1]Dept of Internal Medicine, Soonchunhyang Univ Cheonan Hospital, Cheonan, Chungnam, Korea; [2]Dept of Internal Medicine, Soonchunhyang Univ Seoul Hospital, Seoul, Korea.*

**Background:** Intravenous colistin is used to treat resistant infections caused by gram-negative organisms and is associated with nephrotoxicity. The pathogenesis of colistin-associated nephropathy has not been clarified and no effective therapeutic or prophylactic agent is available. This study aimed to examine the mechanisms underlying colistin-induced nephrotoxicity and to determine if P-glycoprotein (P-gp) induction can prevent nephrotoxicity.

**Methods:** We examined the cytotoxicity of colistin in cultured human proximal tubular cells (HK-2) by MTT assay and LDH assay. To evaluate colistin-based induction of reactive oxygen species (ROS), ROS were measured using DCF-DA. To investigate colistin-induced apoptosis, a TUNEL assay was conducted, and caspase 3/7 activity was evaluated. Autophagy was assessed by measuring the levels of LC3. To evaluate whether P-gp was involved in the efflux of colistin in HK2 cell lines, P-gp expression and cell toxicity were determined in cells treated with colistin with and without dexamethasone (i.e., P-gp inducer) and verapamil (i.e., selective P-gp inhibitor) by real-time PCR and MTT assays.

**Results:** Colistin showed cell toxicity in dose- and time-dependent patterns in the HK2 cell lines. Colistin induced ROS in a dose-dependent manner in the DCF-DA assay. Caspase 3/7 activity increased in a dose-dependent pattern at 6 h (25, 50, and 100 μg/mL) and was inhibited by N-acetylcysteine. Apoptosis was confirmed by TUNEL assay at 6 h (50.00 μg/mL). The ratio of LC3II to LC3Iincreased at 2 h. Colistin itself suppressed P-gp expression. P-gp expression and activity in the colistin-treated HK2 cell line were enhanced by treatment with dexamethasone, whereas colistin-induced cytotoxicity decreased. In addition, the induced P-gp transporter was shown to improve the efflux effect in colistin-treated HK2 cell lines, as shown by the Calcein-AM fluorescence accumulation assay.

**Conclusions:** P-gp is involved with colistin efflux in HK2 cell lines. This study suggests a protective effect of P-gp induction against colistin-induced nephrotoxicity.

## SA-PO079

**Ablation of C/EBP Homologous Protein (CHOP) Protects Ischemia/Reperfusion-Induced Acute Kidney Injury** Chiung-ying Huang,[2] Bo-lin Chen,[1] Ching-chin Yang,[1] Cheng-tien Wu,[1] Shing-Hwa Liu,[1] Chih-Kang Chiang.[1,2,3] *[1]Institute of Toxicology, National Taiwan Univ, Taipei, Taiwan; [2]Dept of Internal Medicine, National Taiwan Univ, Taipei, Taiwan; [3]Dept of Integrated Diagnostics & Therapeutics, National Taiwan Univ Hospital, Taipei, Taiwan.*

**Background:** Renal ischemia-reperfusion (IR) yields high rates of acute kidney injury (AKI), but its potential mechanism remains poorly understood. Endoplasmic reticulum (ER) stress has been shown involved in the pathogenesis of AKI. This study investigated whether C/EBP Homologous Protein (*chop*), an important ER stress-related transcriptional factor, mediated IR-induced AKI.

**Methods:** Wild type and *chop*-knockout mice received bilateral renal arteries clamped by non-traumatic clamps for 15 min on the heat plate, followed by reperfusion. Renal pathology, renal functional assay, and ER-related signals were evaluated after reperfusion at the series time points. We also arranged bone marrow transplantation to clarify the influences of *chop* ablation in native immunity in AKI.

**Results:** *chop* deficiency retarded renal injury after IR-induced AKI. Both renal proximal tubule damage and collagen deposition were attenuated in *chop* deficiency mice. Furthermore, *chop* deficiency could decrease IR-induced caspase-3 cleavage and activity. Lipid peroxidation was enhanced after 24 h of IR, but it reversed by CHOP deficiency mice kidney. In addition to in vivo study, we evaluated the effects of reactive oxygen species in the *chop* knockdown renal tubule cells. *chop*-silenced tubule cells were treated by anaerobic/reperfusion condition and $H_2O_2$, and shown more resistant to apoptosis. In spite of lesser leavage of caspase-3 in *chop*-silenced tubular cells, mitochondria-related apoptosis signals, including Bax and Bcl-2, were not influenced by $H_2O_2$ and *chop* siRNA treatment. Finally, *chop* deficiency blocked NFκB activation and COX-2 expression, which suggested *chop*-related signals contributed to the oxidative stress-mediated inflammation responses.

**Conclusions:** To the best of our knowledge, this is first report demonstrated that *chop* deficiency attenuated IR-related AKI by modulating apoptotic, inflammatory and oxidative responses.

**NRF2 Activators as Potential Modulators of Injury in Human Kidney Cells** Melanie S. Joy,[1] Amanda Atilano,[1] Xia Wen,[2] Lauren Aleksunes.[2] *[1]Univ of Colorado; [2]Rutgers Univ.*

**Background:** Cisplatin is a chemotherapeutic drug that is known to cause proximal tubule injury. We have demonstrated that the transcription factor nuclear factor e2-like 2 (NRF2, NFE2L2) protects against cisplatin-induced nephrotoxicity in rodents. The purpose of the current investigation was to study the ability of three NRF2 activators, oleanolic acid, sulforaphane, and oltipraz, to protect against the cytotoxicity of cisplatin and to regulate known NRF2 transcriptional pathways in human kidney cells.

**Methods:** Human renal proximal tubule epithelial cells (RPTEC) and HEK293 cell lines were exposed to cisplatin at 0-100 μM and cell viability measured by the MTT assay.Cells were treated with NRF2 activators (5 μM) either pre- or post- exposure (2 hrs) to cisplatin. Cells were harvested, total RNA isolated, and RT-PCR performed to quantify changes in expression of NRF2 itself and prototypical target genes GCLC and NQO1 in RPTECs.

**Results:** Pre-treatment of human kidney cells with NRF2 activators conferred greater protection than post-treatment. Interestingly, pre-treatment of RPTECs with oleanolic acid increased cell viability at high concentrations of cisplatin (30-100 μM) by ~40%. By contrast, HEK293 cells pretreated with oltipraz or sulforaphane had enhanced cell viability (60% and 43%, respectively) at high concentrations of cisplatin (30-100 μM). RPTECs showed reduced NRF2, GCLC, and increased NQO1 mRNA expression after exposure to cisplatin. Significant up-regulation of NRF2, GCLC, and NQO1 mRNA expression with NRF2 activators was observed in RPTECs treated with cisplatin.

**Conclusions:** Treatment of RPTECs with NRF2 activators with exposure to clinically-relevant cisplatin concentrations enhances human renal cell viability and increases expression of detoxifying genes (NQO1 and GCLC) and NRF2 itself.NRF2 activators are potentially novel treatments to mitigate drug-induced kidney injury.

**Renalase Protects against Ischemic and Toxic Acute Kidney Injury via a Receptor-Mediated Mechanism Independently of Catecholamines Metabolism**

Gary V. Desir,[1] Ling Wang,[1,3] Heino Velazquez,[1] John J. Chang,[1] Ahrom Ham,[2] H. Thomas Lee,[2] Robert L. Safirstein.[1] *[1]Yale, VACHS; [2]Columbia School Med; [3]Renji Hosp.*

**Background:** Acute kidney injury (AKI) is an important clinical syndrome predominantly caused by ischemic and toxic renal insults, and for which effective therapies are currently unavailable. Renalase, a secreted flavoprotein, oxidizes catecholamines, and certain gene polymorphisms are associated with essential hypertension, stroke and diabetes. Gene deletion aggravates acute ischemic kidney (AKI) and cardiac injury. Recombinant renalase prevents ischemic injury in wild type mice. Although renalase's crystal structure has been solved, its mechanism of action remains uncertain.

**Methods:** The effect of renalase and renalase peptides in cell models of cisplatin and hydrogen peroxide toxicity, and in in vivo models of cisplatin and ischemic acute kidney injury were determined. Cell signaling pathways were examined be western blot. Renalase peptides were chosen by examining renalase's crystal structure and by testing the effect of peptide antibodies on renalase function.

**Results:** Renalase increased the survival of human proximal tubular (HK-2) cells exposed to either cisplatin or hydrogen peroxide. We identified a 20 amino acid renalase peptide (RP-220) conserved in all known isoforms, and with no detectable oxidase activity, that was as effective as renalase at protecting HK-2 cells against toxic injury, and wild type mice against ischemic AKI. RP-220 and recombinant renalase rapidly activated AKT, ERK, and p38, and down-regulated. Inhibition of ERK and AKT activation abrogated RP-220's protective effect against ischemic AKI.

**Conclusions:** These data indicate that renalase protects against ischemic AKI independently of its enzymatic properties, and interacts with a yet to be identified receptor to activate intracellular signaling in a manner that promotes cell survival. Renalase and related peptides show potential as therapeutic agents for the prevention and treatment of AKI. We predict that the eventual identification of the renalase receptor will catalyze the development of additional novel therapeutic agents.

## SA-PO082

**Paricalcitol Attenuates Renal Ischemia-Reperfusion Injury via Prostaglandin E2 Receptor EP4**

Hyeon Seok Hwang,[1] Cheol Whee Park,[2] Yoon-Kyung Chang,[1] Chul Woo Yang,[2] Suk young Kim,[1] Sangju Lee.[1] *[1]Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, Daejeon, Republic of Korea; [2]Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

**Background:** Paricalcitol has protective effects in several kidney injury models but the mechanism by which this occurs remains unclear. We investigated whether paricalcitol regulates the prostaglandin E2 (PGE2) receptor EP4, and whether paricalcitol prevents renal ischemia-reperfusion injury (IRI) through the EP4 in models.

**Methods:** Human proximal tubular cell line (HK-2) was exposed to lipopolysaccharide (LPS) and ischemia by mineral oil monolayer. Male C57BL/6 mice were subjected to 23 min of bilateral kidney ischemia and 24 h reperfusion. The effects paricalcitol pretreatment with or without AH-23848 (EP4 antagonist) was investigated in both *in vitro* and *in vivo models*.

**Results:** Paricalcitol pretreatment significantly increased the cyclooxygenase (COX)-2 expression, PGE2 production and EP4 expression in HK-2 cells. Paricalcitol increased the viability of HK-2 cell exposed to ischemia or LPS. The cotreatment of AH-23848 with paricalcitol offset these protective effects of paricalcitol. LPS-induced p65 NF-κB phosphorylation was abolished in paricalcitol-treated HK-2 cells, and AH-23848 cotreatment blocked its inhibition of p65 NF-κB phosphorylation. In vivo, paricalcitol pretreatment improved serum creatinine levels, tubular necrosis and apoptotic cell death in IRI-mice kidneys. The infiltration of inflammatory cells (T cells and macrophages), and the production of proinflammatory cytokines (RANTES, tumor necrosis factor-α, interleukin-1β and interferon-γ, MIP-1α) were reduced in paricalcitol-treated kidney with IRI. These protective effects of paricalcitol on functional, tubular necrosis, apoptosis and inflammatory infiltration were inhibited by AH-23848 cotreatment.

**Conclusions:** In conclusion, our study demonstrated that paricalcitol attenuates proximal tubular cell death and inflammatory infiltration after renal IRI through the PGE2 receptor EP4.

## SA-PO083

**Vitamin D Deficiency Is a Risk Factor for Iodinated and Gadolinium Contrast Media Nephrotoxicity**

Weverton M. Luchi, Maria H.M. Shimizu, Daniele Canale, Pedro H.F. Gois, Antonio C. Seguro. *Nephrology, Univ of São Paulo - School of Medicine, Brazil.*

**Background:** Vitamin D deficiency(VDD) is widespread in general population. Iodinated(IC) and Gadolinium(Gd) contrasts may decrease renal function in high-risk patients.The aim of this study was to evaluate the effect of VDD on IC and Gd nephrotoxicity.

**Methods:** Male Wistar rats of 3-week-old were fed standard or vitamin D-free diet for 30 days. IC(Diatrizoate,6mL/kgBW) or Gd(Gadoterate 1.5mmol/kgBW) were given i.v. Six groups(n=12/group) were studied: Sham,IC,Gd,$VDD_{30}$,$VDD_{30}$+IC,$VDD_{30}$+Gd. Urinary thiobarbituric acid reactive substances were assayed(TBARS, oxidative stress marker). Inulin clearance(GFR),blood pressure(BP), renal vascular resistance(RVR) were measured 48h after contrast infusion. Renal tissue was immunoblotted for angiotensin II(AII) and endothelial nitric oxide synthase(eNOS).Data are mean±SEM.

**Results:** Serum 25(OH)D(ng/mL) was 15.4±1.0 in Sham and 4.1±0.8 in $VDD_{30}$ GFR was normal in IC and Gd. $VDD_{30}$ increased BP, RVR, TBARS, AII and eNOS. $VDD_{30}$+IC and $VDD_{30}$+Gd showed higher TBARS and AII and reduced eNOS, decreasing GFR.

| | GFR(mL/min/100gBW) | BP(mmHg) | RVR(mmHg/mL/min) | TBARS(nmol/24h) | AII(%) | eNOS(%) |
|---|---|---|---|---|---|---|
| Sham | 0.94±0.04 | 114±2 | 20.5±0.3 | 110±11 | 97±3 | 99±3 |
| IC | 0.91±0.03 | 121±2 | 21.5±0.4 | 152±8 | 120±6 | 156±15[b] |
| Gd | 0.92±0.03 | 116±2 | 21.1±0.3 | 168±24 | 149±16 | 125±9[a] |
| $VDD_{30}$ | 0.84±0.01[a] | 132±2[b] | 23.8±0.3[b] | 184±26[a] | 124±9[a] | 141±5[b] |
| $VDD_{30}$+IC | 0.64±0.03[eh] | 131±2[d] | 23.8±0.3[c] | 303±52[di] | 186±20[dh] | 92±5[eh] |
| $VDD_{30}$+Gd | 0.60±0.03[eh] | 132±2[e] | 24.1±0.4[e] | 310±42[fi] | 178±21[i] | 95±11[gh] |

[a]p<0.05,[b]p<0.001 vs.Sham;[c]p<0.001,[d]p<0.01 vs.IC;[e]p<0.001,[f]p<0.01,[g]p<0.05 vs.Gd;[h]p<0.001,[i]p<0.05 vs.$VDD_{30}$ BW was similar among 6 groups.

In 2 additional groups(n=5) on VDD for 60 days, a greater fall of GFR occurred:$VDD_{60}$+IC=0.48±0.04;$VDD_{60}$+Gd=0.46±0.04.

**Conclusions:** Our findings suggest that VDD is a risk factor for contrast nephropathy by oxidative stress and endothelial dysfunction.(CNPq, CAPES).

## SA-PO084

**Critical Role of Vitamin D Receptor Downregulation on Triggering the Inflammatory Process and Subsequent Fibrosis Formation in Vitamin D-Depleted Rats Submitted to Renal Ischemia/Reperfusion**

Janaina Garcia Gonçalves, Ana C. de Bragança, Daniele Canale, Maria H.M. Shimizu, Antonio C. Seguro, Lucia Andrade, Rosa M.A. Moyses, Rildo A. Volpini. *Nephrology, Faculty of Medicine - Univ of Sao Paulo, Sao Paulo, Brazil.*

**Background:** Renal diseases are generally followed by Vitamin D deficiency (VDD) which increases with the progression of CKD. Studies suggest that Vitamin D Receptor (VDR) could be a potential mechanism connecting inflammation and fibrosis development. We investigated the VDR expression and its relationship with TGF-ß, macrophages infiltration and fibronectin/collagen expression in VDD rats submitted to renal ischemia/reperfusion (IR).

**Methods:** For 90 days, male Wistar rats were fed a standard diet (control [C] and IR groups) or a 25(OH)D-free diet (VDD and VDD+IR groups). On day 28, IR and VDD+IR rats were submitted to 45-min clamping of both arteries. On day 90, we measured serum levels of 25(OH)D and PTH, immunoblotted for VDR/TGF-ß and performed IHC for collagen IV, fibronectin and ED1. We estimated fibrosis by fractional interstitial area (FIA) and collagen IV/fibronectin expression by escore (ranging from 0 to 4). Data are expressed as mean±SEM.

**Results:**

| Variable | C | VDD | IR | VDD+IR |
|---|---|---|---|---|
| 25(OH)D (ng/mL) | 15.4±1.0 | <1.5* | 15.0±0.6 | <1.5* |
| PTH (pg/mL) | 318.8±59.28 | 1470±628.3 | 453.2±95.92 | 2187±336.3[a,c] |
| VDR (%) | 100.0±10.11 | 14.12±1.98[a,c] | 103.6±11.80[b] | 7.31±1.35[a,b,c] |
| TGF-ß (%) | 100.0±4.49 | 146.8±33.16[a] | 152.4±49.23[a] | 252.2±64.52[a,b,c] |
| Collagen IV (score) | 1.01±0.10 | 1.34±0.04[a] | 1.83±0.15[a,b] | 2.04±0.09[a,b] |
| Fibronectin (score) | 0.31±0.03 | 0.67±0.03[a] | 0.68±0.05[a] | 0.89±0.04[a,b,c] |
| ED1 +cells (+cells per field) | 1.14±0.19 | 2.18±0.14 | 10.92±1.89[a,b] | 16.93±2.49[a,b,c] |
| FIA (%) | 7.3±0.5 | 17.2±0.8[a] | 24.4±2.9[a,b] | 34.9±0.55[a,b,c] |

*undetectable; [a]p<0.05 vs. C; [b]p<0.05 vs. VDD; [c]p<0.05 vs. VDD+IR.

**Conclusions:** Taken together, these data indicate that VDD combined with VDR downregulation may contribute to progressive chronic kidney disease.

*Funding:* Government Support - Non-U.S.

## SA-PO085

**Klotho Deficiency Aggravates Sepsis-Related Multiple Organ Dysfunction**

Lectícia Jorge,[1] Fernanda O. Coelho,[1] Talita R. Sanches,[1] Maria Irigoyen,[1] Maria H.M. Shimizu,[1] Antonio C. Seguro,[1] Niels O.S. Camara,[1] Makoto Kuroo,[2] Lucia Andrade.[1] *[1]Univ of Sao Paulo, Brazil; [2]UT Southwestern Medical Center at Dallas.*

**Background:** Sepsis-induced organ failure is characterized by a massive inflammatory response and oxidative stress. Klotho (Kl) has been shown to protect against renal ischemia-reperfusion injury and to be an antioxidant. We used a cecal ligation and puncture (CLP) model to analyze the role of Kl in sepsis-related organ dysfunction.

**Methods:** 8-12 week old male $Kl^{+/-}$ and $Kl^{+/+}$ mice (n=32) underwent CLP or sham operation. At 24 h post-CLP, we evaluated mean arterial pressure(MAP), baroreflex sensitivity, serum biochemistry, oxidative stress, and cytokines, as well as immunoblotting for Kl in kidney tissue. We also evaluated 14-day survival.

**Results:** Data are mean±SEM.

| Variable | CLP $Kl^{+/-}$ | CLP $Kl^{+/+}$ | Sham $Kl^{+/-}$ | Sham $Kl^{+/+}$ |
|---|---|---|---|---|
| Urinary Volume(ml/day) | 0.4±0.3[a,b] | 1.1±0.6[c] | 2.6±0.3 | 2.7±0.5 |
| MAP (mmHg) | 114±28[b] | 111±27 | 141±10 | 135±18 |
| Urea(mg/dl) | 77±14[a,b] | 57±4[c] | 39±8 | 40±8 |
| Lactate(mg/dl) | 60±23[a,b] | 31±12[c] | 19±12 | 20±15 |
| ALT(IU/L) | 92±39[a] | 39±12 | 40±19 | 37±11 |
| TBARS(nmol/ml) | 49.8±12.3[a,b] | 24.6±6.8[c] | 5.6±0.9 | 3.6±1.7 |
| Glutathione (µmol/ml) | 1.34±0.1[a,b] | 1.72±0.3 | 2.4±0.3 | 1.9±0.6 |
| IL6(pg/ml) | 18241±18486[a,b] | 138.7±104[c] | 20.3±8.4 | 28±5.9 |
| IL10(pg/ml) | 2495±2411[a,b] | 170±276[c] | 2.5±4 | 1.4±2.6 |
| TNFα(pg/ml) | 83±13.5[a,b] | 11.4±8.4[c] | 3.6±1.8 | 3±0.5 |
| KI(%) | 37±10[a,b] | 65±13[c] | 68±9 | 100±6 |

[a]p<0.05 vs.CLP $Kl^{+/+}$;[b]p<0.05 vs.sham $Kl^{+/-}$;[c]p<0.05 vs.sham $Kl^{+/+}$

Post-CLP baroreflex sensitivity and survival were significantly lower in $Kl^{+/-}$ than $Kl^{+/+}$.

**Conclusions:** Our results suggest that sepsis is a state of acute Kl deficiency. Sepsis induces inflammatory responses and multiple organ dysfunction in a Kl-dependent pathway. A modest decrease in Kl expression in chronic kidney disease can be a risk for systemic inflammation.

*Funding:* Government Support - Non-U.S.

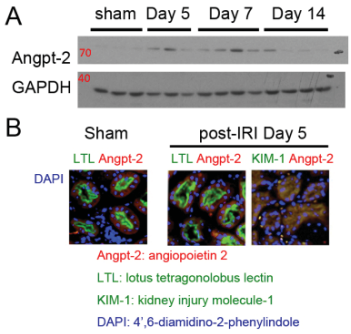
## SA-PO086

**Increased Expression of Angiopoietin-2 in Renal Tubular Epithelial Cells after Ischemia-Reperfusion Acute Kidney Injury** Chun-Fu Lai, Shuei-Liong Lin, Wen-Chih Chiang. *Dept of Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan.*

**Background:** Angiopoietin-2 (Angpt-2) has been identified as a regulator of vascular homeostasis, as well as a link between angiogenesis and inflammation. Clinical studies observed that circulating Angpt-2 levels were elevated in patients experiencing acute kidney injury (AKI). The present study aimed to examine the expression of Angpt-2 in the kidney after ischemic injury.

**Methods:** Using mouse unilateral ischemia-reperfusion-injury (IRI) and contralateral nephrectomy model, we analyzed gene and protein expression of Angpt-2. In addition, we used proximal tubular epithelial (NRK-52E) cells to investigate Angpt-2 expression under hypoxia.

**Results:** In response to the IRI, *Angpt-2* transcripts, measured by Q-PCR, increased in the kidneys significantly since day 5 after surgery and remained high thereafter. Western blot of kidney lysates showed that the expression levels of Angpt-2 protein were enhanced at day 5 and 7, and then decreased toward baseline at day 14. [Fig. A] Immunofluorescence staining indicated that Angpt-2 was expressed mainly in injured and non-injured proximal tubular epithelial cells after IRI. [Fig. B] This was further supported by *in vitro* experiments showing that low-oxygen condition (under 1% $O_2$) stimulated Angpt-2 expression in cultured NRK-52E cells.



**Conclusions:** Renal Angpt-2 expression by tubular epithelial cells is upregulated after IRI. Its role in kidney recovery after injury merits further study.

*Funding:* Government Support - Non-U.S.

## SA-PO087

**Mechanism of Protection by Renalase against Cisplatin-Mediated Cytotoxicity** Gary V. Desir,[1] Ling Wang,[1,2] Heino Velazquez,[1] Robert L. Safirstein.[1] *[1]Yale Univ School Med, VACHS; [2]Renji Hospital, Shanghai.*

**Background:** Acute kidney injury (AKI) is an important clinical syndrome most commonly caused by ischemic and toxic renal insults. Renalase is a secretory flavoprotein that oxidizes catecholamines, and protects against toxic and ischemic injury by its interaction with an as yet unidentified receptor leading to activation of intracellular signaling in a manner that promotes cell survival. A twenty amino acid renalase peptide (RP-220), which is conserved in all known isoforms but is devoid of any detectable oxidase activity is equally effective as intact renalase protein at protecting HK-2 cells and wild type (WT) mice against ischemic injury in a manner that is dependent on extracellular regulated kinase (ERK) and protein kinase B (AKT) activation.

**Methods:** To examine the mechanism of protection against cisplatin cytotoxicity, the effect of the renalase peptide RP-220 on HK-2 cells exposed to cisplatin was determined. Cell signaling pathways were examined by western blot, and chemical inhibition was used to determine the key pathways underlying renalase's protective effect.

**Results:** RP-220 increased the survival of cisplatin treated HK-2 cells by 45% at 24 hrs (n= 4, p<0.002). It rapidly increased the phosphorylation of AKT, p38 mitogen activated protein kinase (p38) and ERK. Chemical inhibition was used to determine the critical mediator of RP-220's protective effect. In control studies in the absence of cisplatin and RP-220, ERK and p38 inhibition had no effect on HK-2 cell survival rates, while AKT decreased cell survival by 37% (n=4, p<0.001) . In the presence of cisplatin alone, inhibition of ERK and p38, were protective and increased cell survival by 38 and 35 % respectively (n=4, p<0.01), while that of AKT was not. With the addition of cisplatin and RP-220, ERK inhibition was still protective, but p38 inhibition completed abrogated RP-220's protective effect.

**Conclusions:** These data indicate that p38 activation is the critical mediator of RP-220's protective action against cisplatin cytotoxicity, and suggest that renalase and related peptides show potential as therapeutic agents for the prevention and treatment of AKI.

*Funding:* NIDDK Support, Veterans Affairs Support

## SA-PO088

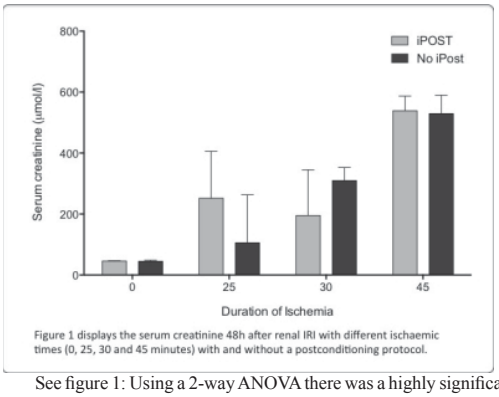
**Post-Conditioning the Kidney – A Cautionary Tale…** Kieran McCafferty, Conor J. Byrne, Magdi Yaqoob. *Dept of Translational Medicine, William Harvey Research Institute, Queen Mary Univ London, London, United Kingdom.*

**Background:** We have previously shown (Byrne/McCafferty, Circulation, 2012) that ischemic postconditioning (iPOST) is a potent cytoprotective strategy in the uremic heart. Others have shown that iPOST can confer cytoprotection in other organs including the kidney. Because iPOST can be applied at the point of reperfusion, it has led to increasing interest in the field of transplantation to reduce reperfusion injury and improve graft function. However, iPOST may be detrimental if the index injury is low, or may be ineffective at reducing reperfusion injury if the injury too great.

The role of the duration of ischemia on the effectiveness of iPOST in the setting of renal IRI is currently unclear.

**Methods:** 56 Male Wistar rats underwent a unilateral nephrectomy with contralateral renal ischemia (for 0, 25, 30 or 45 minutes) followed by either an iPOST procedure (5x10 sec ischemia/reperfusion) or a sham procedure. All animals were left to recover for 48h at which point they were sacrificed and assessed for renal injury.

**Results:**



See figure 1: Using a 2-way ANOVA there was a highly significant association between the duration of ischemia and the serum creatinine concentration (p<0.0001), however surprisingly, at all time points studied the addition of iPOST did not alter serum creatinine concentrations (p=0.63). In addition, other markers of renal injury showed similar trends, with a longer ischemic phase leading to higher urea, phosphate and potassium concentrations and oliguria, with no impact seen with iPOST.

**Conclusions:** Reassuringly iPOST does not appear to be deleterious even at low levels of injury. However in contrast to other studies, our experiments do not confirm cytoprotection over a spectrum of renal injury with iPOST. Further work is required before translational studies of iPOST in the context of renal transplantation are performed.

## SA-PO089

**Increased Transforming Growth Factor-β (TGFβ) Receptor Type2 (TGFBR2) Expression in Regenerating Proximal Tubule (PT) Cells Occurs by Phosphatidylinositol 3-Kinase (PI3K) Activity Mediated Transcription and Decreased Protein Degradation** Hui Geng,[1] Rongpei Lan,[1] Prajjal Kanti Singha,[1] Pothana Saikumar,[1] Joel M. Weinberg,[2] Manjeri A. Venkatachalam.[1] *[1]U. Texas; [2]U. Michigan.*

**Background:** TGFβ signaling increases after renal ischemia reperfusion injury (IRI), accompanied by enhanced expression of TGFβ and its receptors in regenerating PT. Failure of TGFβ signaling to regress during recovery induces tubule atrophy and fibrosis. PT regeneration in a tissue culture model is accompanied by increased TGFβ signaling and TGFBR2 expression, and to a lesser extent, of TGFBR1.

**Methods:** We studied TGFBR2 regulation in confluent differentiated PT cell cultures induced to regenerate by wounding or subconfluent passage, and localized signaling molecules related to TGFβ after IRI of rat kidneys.

**Results:** Wounding to remove ~90% cell mass or subconfluent passage of confluent PT cell cultures resulted in dedifferentiation and proliferation; and rapidly increased TGFBR2 mRNA, protein and reporter activity from a TGFBR2 promoter-luciferase construct. When concurrently increased PI3K signaling was decreased by adenoviral expression of dominant negative (DN) PI3K subunit p85, pan PI3K inhibitor LY294002 or specific PI3Kα or PI3Kβ inhibitors, TGFBR2 expression and reporter activity were suppressed. PDK1 inhibitor

OSU-03012, Akt inhibitor IV, or adenoviral expression of DN Akt similarly suppressed TGFBR2 expression. Conversely, Cre-Lox PTEN knockout increased Akt activity and TGFBR2 expression. On the other hand, normally high TGFBR2 protein degradation in confluent PT cells was diminished by wounding or subconfluent passage. Lysosomal inhibitors (chloroquine, NH4Cl, E64d/pepstatin A) but not proteasomal inhibitors (MG132, lactacystin) markedly increased TGFBR2 protein in confluent PT cells or PI3K inhibited subconfluent PT cells. *In vivo*, after IRI, PI3K activity assessed by phospho-Akt and phospho-S6 ribosomal protein increased rapidly and persistently in protein extracts and localized to regenerating PT, together with elevated TGFBR2 protein.

**Conclusions:** The data suggest that TGFBR2 becomes increased in regenerating PT due to enhanced PI3K activity dependent transcription as well as diminished protein degradation.

## SA-PO090

**Absence of CLIC4 Potentiates Acute Kidney Injury but Has Little Effect on Recovery** John C. Edwards, Jonathan M. Bruno, Phillip N. Key. *Internal Medicine, St. Louis Univ, St. Louis, MO.*

**Background:** CLIC4 is a member of the Chloride Intracellular Channel family expressed in kidney that has been implicated in angiogenesis and in TGFß signal transduction, both of which are important in the response to acute kidney injury (AKI). Specifically, CLIC4 in keratinocytes has been shown to redistribute to the nucleus and potentiate TGFß signalling. We investigated whether absence of CLIC4 alters the course of AKI.

**Methods:** CLIC4 null (KO) and matched wild type (WT) mice were subjected to folic acid-induced AKI. Functional injury was assessed by serum BUN levels at day 2, 7, and 21. Scarring/fibrosis was assessed by 21 day kidney weight. Activation of TGFß signalling was assessed by western blotting for phosphorlyated Smads 2/3 on day 2 following injury.

**Results:** Absence of CLIC4 increased susceptibility to acute kidney injury (median day 2 BUN 65 and 143 for WT and KO respectively, p=0.021), but did not alter functional recovery from AKI. There was no significant difference in day 21 BUN between WT and KO. Scarring was indirectly assessed by day 21 kidney weight. There was no difference in the relationship between severity of initial injury and final kidney size between the WT and KO mice. Phosphorylation of Smads 2/3 increased following injury and there was no difference in extent of phosphorylation between WT and KO. CLIC4 did not redistribute to the nucleus in tubular cells following acute injury. Kidneys were assessed for anatomical and functional differences that could predispose to AKI. CLIC4 KO mice were found to have increased proteinuria, smaller kidneys per body weight, have fewer glomeruli, and less dense peritubular capillary network than WT controls.

**Conclusions:** Mice lacking CLIC4 show increased susceptibility to folic acid-induced acute kidney injury, perhaps related to the underlying developmental angiogenic defect in these mice including less dense peritubular capillary density and fewer glomeruli. However, we did not find evidence that absence of CLIC4 alters the long term recovery or scarring following injury, indicating that CLIC4 is not a critical non-redundant regulator of the intensity or duration of TGFß signalling in kidney cells following folic acid injury.

**Combined Treatment of Glucocorticoid with Pioglitazone Enhances Protection against PAN-Induced Nephrosis** Shipra Agrawal,[1] Melinda A. Chanley,[1] Adam J. Guess,[1] Rainer Benndorf,[1,2] William E. Smoyer.[1,2] *[1]Clinical & Translational Research, The Research Institute at Nationwide Childrens Hospital; [2]Dept of Pediatrics, College of Medicine, The Ohio State Univ.*

**Background:** Oral glucocorticoids (GCs) are the primary therapy for nephrotic syndrome (NS), although GCs have serious side effects and are clinically ineffective in ~20% of patients. Notably, the FDA-approved diabetes II drugs, PPARγ agonists have been shown to slow progression of diabetic nephropathy and to partially protect against both puromycin aminonucleoside (PAN)-induced NS in rats and direct podocyte injury. We hypothesized that combination therapy of GCs with PPARγ agonists would improve clinical efficacy by reducing proteinuria in NS.

**Methods:** Proteinuria was induced in male Wistar rats by single PAN injection (50 mg/kg). Treatment groups received low-dose methylprednisolone (MP at 5 mg/kg), high-dose MP (15 mg/kg), pioglitazone (Pio at 10 mg/kg) and combinations of Pio with low- and high-dose MP. Urinary protein/creatinine ratios and serum BUN values were measured. PAN-injured (5 µg/ml) cultured podocytes were also treated with 0.1 and 1 µM Pio, dexamethasone (Dex) or a combination of Pio and Dex and cell viability measured after 3 and 5 days.

**Results:** PAN-induced NS resulted in peak proteinuria on day 11, which was ameliorated by the high-dose MP but not low-dose. Pio alone did not significantly reduce proteinuria. However, low-dose MP in combination with Pio ameliorated proteinuria significantly, similar to the high-dose MP alone. BUN values were also reduced with combination treatment, similar to the high-dose MP at day 9. Moreover, after PAN injury, combination of Pio with Dex tended to restore the viability of cultured podocytes better than either Pio or Dex alone.

**Conclusions:** Combination treatment of Pio with low-dose MP enhances the amelioration of PAN-induced proteinuria and provides similar protection to the high-dose MP. These data suggest that repurposing of Pio as a combination therapy with GCs could increase the clinical efficacy of GCs and/or enable reduced dosing and toxicity of GCs in patients with NS and potentially other glomerular diseases.

## SA-PO092

**A Model of Townes-Brock Syndrome Is Protected from Acute Renal Ischemia Reperfusion Injury** Sara Hirsch,[1] Tarek M. El-Achkar,[2] Michael I. Rauchman.[1,3,4] *[1]Biochemistry, Saint Louis Univ, St. Louis, MO; [2]Medicine, Indiana Univ, Indianapolis, IN; [3]Internal Medicine, Saint Louis Univ, St. Louis, MO; [4]Medicine, Saint Louis Veterans Affairs Medical Center, St. Louis, MO.*

**Background:** Acute kidney injury (AKI) affects 2-10% of hospital patients. Ischemia reperfusion injury (IRI) often contributes to the development of AKI. The cellular and molecular processes that govern injury and recovery from renal IRI are not well understood. Genes that are required for kidney development are upregulated following injury, but their function in IRI is unknown. *Sall1* is a transcription factor required for kidney development. Truncating mutations of *Sall1* cause Townes-Brock Syndrome (TBS). Renal manifestations of TBS include congenital hypoplasia and renal insufficiency.

**Methods:** We tested the response of 8 week old, male *Sall1* mutant mice to IRI. The renal pedicle was occluded for 22 or 30 min. Mice used for this study were: $Sall1^{TBS/+}$ - a model of human TBS expressing truncated Sall1 protein, $Sall1^{GFP/+}$ - a model of haploinsufficiency, $Sall1^{cKO}$ - postnatal homozygous deletion of *Sall1*, and $Sall1^{\Delta SRM/+}$ - where one *Sall1* allele is unable to bind the Nucleosome Remodeling and Deacetylase (NuRD) complex.

**Results:** The serum creatinine (sCr) of $Sall1^{TBS/+}$ mice was significantly lower than wild type (WT) mice 24 hrs after 22 or 30 min of ischemia. In contrast, sCr of other Sall1 mutant mice was not significantly different than WT. $Sall1^{TBS/+}$ mice had lower injury scores, decreased expression of biomarkers Kim-1 and NGAL, and 30% fewer proliferating cells as measured by BrdU incorporation.

**Conclusions:** $Sall1^{TBS/+}$ mice are protected from renal injury within 24 hours of IRI. Neither haploinsufficiency ($Sall1^{GFP/+}$) nor conditional knockout of *Sall1* replicate the protection observed in $Sall1^{TBS/+}$ mice, indicating that *Sall1* loss-of-function is not protective. $Sall1^{\Delta SRM/+}$ mice are also susceptible to IRI, suggesting that the protection observed in $Sall1^{TBS/+}$ mice is not due to mutant Sall1$^{TBS}$ protein interfering with WT Sall1-4 or NuRD function. We propose that $Sall1^{TBS/+}$ mice are protected from renal IRI through a novel, gain-of-function mechanism.

## SA-PO093

**Early Intervention Prevents Sepsis-Induced Tubule-Interstitial Fibrosis, Endothelial Dysfunction and Tubular Apoptosis: Role of Coupled Plasma Filtration Adsorption** Giuseppe Castellano,[1] Alessandra Stasi,[1] Anna Maria Di Palma,[1] Margherita Gigante,[1] Angelica Intini,[1] C. Divella,[1] Giuseppe Stefano Netti,[2] Claudia Curci,[3] Clelia Prattichizzo,[2] Enrico Fiaccadori,[4] G. Grandaliano,[2] G. Pertosa,[1] Loreto Gesualdo.[1] *[1]DETO, Univ Bari, Italy; [2]Med and Surg Sciences Dept, Univ Foggia, Italy; [3]Consorzio Carso, Univ Bari, Italy; [4]Clin and Exp Med Dept, Univ Parma, Italy.*

**Background:** Sepsis-induced acute kidney injury(AKI) is characterized by tubular apoptosis and development of tissue fibrosis. Aim of our study was to investigate the effects of an early treatment by Coupled Plasma Filtration Adsorption(CPFA) in a swine model of sepsis-induced AKI.

**Methods:** After LPS infusion, 8 pigs developed AKI and underwent to renal biopsies at different time points. In the treatment group, 8 animals received CPFA for 6 h, after 3 h from LPS infusion. Endothelial cells (ECs) were cultured in presence of different swine sera for 12h and were analyzed by FACS.

**Results:** We found an acute induction of tubule-interstitial fibrosis in Sepsis-induced AKI, as indicated by extensive collagen deposition (Masson Trichrome staining); in addition, tubular apoptosis was an early event as indicated by intense caspase-3 staining. Finally, tubular damage was associated with dysfunction of ECs that expressed myofibroblast marker (α-SMA). Early treatment by CPFA was able to reduce collagen deposits (25.29 ± 8.9 vs. septic 51.54±8.28 p=.04), tubular apoptosis (Caspase-3$^+$ 20.96 ± 2.68 vs. septic 40.44±3.96 p=.004) and α-SMA$^+$ ECs (CD31$^+$/α-SMA$^+$ 4.05±2.19 vs. septic:16.5±3.53 fold change, p=.04). In vitro, EC cultured with septic sera showed reduced expression of specific EC markers (CD31 49±9.5 MFI) and VE-cadherin (11.1±2.3 MFI), with increased expression of markers of EC dysfunction such as N-cadherin and Vimentin. Surprisingly, sera of treated pigs preserved EC phenotype (CD31: 94.97±3.4 p=.04; VE-cadherin: 24.07±4.9 p=.03) without up-regulation of N-cadherin and Vimentin.

**Conclusions:** Our data indicated that an early treatment by CPFA might be pivotal to counteract the acute effects of LPS on renal tissue, by removing the cytokine responsible of EC dysfunction and tubule-interstitial damage.

## SA-PO094

**Protection against $H_2O_2$-Induced Cell Death by Angelica Sinensis and Astragalus Membranaceus in HK2 Human Kidney Cells** Muhammad Shahzad,[1,2] David M. Small,[1] Christudas Morais,[1] Glenda C. Gobe.[1] *[1]Centre Kidney Disease Res Sch Medicine, Univ Queensland, Brisbane, Australia; [2]Dept Pharmacol, Univ Health Sch, Lahore, Pakistan.*

**Background:** Oxidative stress is an important mechanism for renal epithelial cell destruction in several kidney diseases, including nephrotic syndrome. *Angelica* and *Astragalus spp* have a long history of medicinal use in traditional Chinese medicine, including for treating patients with nephrotic syndrome. The aim was to investigate the protection of *Astragalus membranaceus* and >*Angelica sinensis* against $H_2O_2$-induced cell death in HK2 proximal tubular cells.

**Methods:** Ethanol, methanol and aqueous extracts of roots of *Astragalus membranaceus* and *Angelica sinensis* were prepared by a three-solvent sequential process. HK2 cells were treated with 0.6mM of $H_2O_2$ alone and in combination with different concentrations of extracts for 24h. Cell viability was determined by MTT assay. Cell death was monitored microscopically. Expression of apoptosis-related proteins Bax, Bcl-xL, NF-κB (p65, p50), multi-functional TGFβ1 and pro-inflammatory TNFα were studied by Western blots.

**Results:** Ethanol, methanol and aqueous extracts were all protective. $H_2O_2$ reduced cell viability (approximately 50% control values), whereas significant protection against $H_2O_2$-induced cell death (in the forms of apoptosis and necrosis) was obtained with *Angelica sinensis* and *Astragalus membranaceus* extracts (viability restored to nearly 75% of control). $H_2O_2$ caused significant upregulation of pro-apoptotic Bax, NF-κB (p65, p50) and TNFα; and downregulation of anti-apoptotic Bcl-xL and TGFβ1. The extracts significantly decreased Bax, increased Bcl-xL, but had no significant effect on NF-κB isoforms and TNFα. TGFβ1 expression was upregulated. This may be anti-apoptotic, but a pro-fibrotic role for TGFβ1 should be investigated further.

**Conclusions:** The traditional use of these plant extracts in nephrotic syndrome was validated: oxidative stress-induced cell death in HK2 cells was prevented, and modulation of pro-apoptotic Bax and upregulation of anti-apoptotic Bcl-xL and pro-survival TGFβ1 may be the mechanisms of protection.

## SA-PO095

**Effects of Leucine-Rich Repeat Kinase 2 (LRRK2) Deletion in Normal and Injured Rat Kidneys** Ravindra Boddu,[1] Joao Paulo Lima Daher,[4] Kyoko Kojima,[2] Lisa M. Curtis,[1,3] Anupam Agarwal,[1,3] Andrew B. West.[4] *[1]Medicine; [2]Surgery; [3]Veteran's Administration Medical Center, Birmingham, AL; [4]Neurology, UAB, Birmingham, AL.*

**Background:** Leucine-rich repeat kinase 2 (LRRK2) mutations account for 5-6% of familial Parkinson's diseases (PD) and 1-3% in sporadic PD. LRRK2 knockout (KO) mice do not develop neuropathological changes in the brain.Previous reports suggest that a loss of LRRK2 causes age-dependent accumulation of α-synuclein (60-fold) and ubiquitinated proteins in the kidney, in which LRRK2 is normally expressed at high levels (~6-fold compared to the brain).The role and biology of LRRK2 in the kidney is not well understood. Aged LRRK2 KO mice (~20 months) display impaired activation of autophagy with increased apoptotic cell death, inflammatory responses and oxidative damage. **Objective:**To understand the LRRK2 biology in kidney,we sought to characterize a rat model of LRRK2 deletion and evaluate the phenotype after acute kidney injury (AKI).

**Methods:** We utilized mass spectrometry (MS) and western blots to compare wild-type (WT) and knockout (KO) rat kidneys; and assessed renal function and structure following cisplatin-induced AKI in LRRK2 WT and KO rats. Localization of LRRK2 using immunofluorescence (IF) was also performed.

**Results:** LRRK2 KO kidneys are dark red in color and significantly heavier than WT kidneys, sinking in 10% sucrose solution. IF studies showed localization of LRRK2 in renal tubules. Protein expression for heme oxygenase-1, H and L ferritin and transferrin receptor are significantly decreased in 6 month KO rat kidneys. MS showed increased deposits of hemoglobin and fucosylated glycans (lipofuscin) in 12 month KO kidneys compared to WT kidneys. Following cisplatin-induced AKI, no differences in renal function were noted in young (~2.5 month) LRRK2 KO rats. However,macrophage infiltration was significantly increased in cisplatin-treated LRRK2 KO rats compared to WT rats.

**Conclusions:** The phenotype of the LRRK2 KO animal implicate LRRK2 to have biological significance in the kidney and further studies to dissect the possible role of LRRK2 in older animals will potentially identify a novel pathways for intervention in kidney injury settings.

*Funding:* NIDDK Support

## SA-PO096

**Involvement of Indoxyl Sulfate (IS) in Downregulation of Pulmonary Aquaporin (AQP)-5 in Rats Caused by Bilateral Nephrectomy (BNx)-Induced Acute Kidney Injury (AKI)** Masataka Sagata,[1] Chika Saigo,[1] Go Yoneda,[1] Yuko Yamamoto,[1] Yui Nomura,[1] Kazuhiko Nishi,[3] Hirofumi Jono,[2] Hideyuki Saito.[2] *[1]Dept of Clinical and Pharmaceutical Sciences, Kumamoto Univ, Kumamoto, Japan; [2]Dept of Pharmacy, Kumamoto Univ Hospital, Kumamoto, Japan; [3]Dept of Hemodialysis and Apheresis, Kumamoto Univ Hospital, Kumamoto, Japan.*

**Background:** Despite advances in understanding the pathophysiology, improvements in dialysis and supportive care, the mortality of AKI remains considerably high. The high mortality of AKI is associated with acute lung injury or acute respiratory distress syndrome, which are typical complications of AKI. It is suggested that dysregulation of lung salt and water channels following the AKI plays a pivotal role in ALI, however, the mechanism of dysregulation has not been elucidated. In this study, we examined involvement of a typical oxidative stress-inducing uremic toxin, IS, in dysregulation of pulmonary predominant water channel, AQP-5, in BNx-induced AKI model rats.

**Methods:** AST-120, clinically used oral spherical adsorptive carbon, was orally administered to rats (2.5 g/kg) at -24, -1 h before and 24 h after BNx surgery. Serum was collected at 4 and 48 h following surgery, and IS level was determined by HPLC. AQP-5 protein expression was examined by immunoblot analysis.

**Results:** At 48 h, BNx evoked AKI with the increases in serum creatinine (Scr) (29-fold vs sham-operated rats), BUN (12-fold) and serum IS levels (32-fold) in association with a marked downregulation of pulmonary AQP-5 expression (0.51-fold). Administration of AST-120 resulted in a significant decrease in serum IS level (0.64-fold), which was accompanied with the decreases in IS accumulation in liver and lung. AST-120 treatment had no effects on Scr, BUN and lung Na,K-ATPase expression, whereas the downregulation of AQP-5 was significantly restored (2.2-fold vs BNx rats). At 4 h after BNx surgery, serum interleukin-6 level was not affected by oral AST-120.

**Conclusions:** These results suggested that BNx-induced AKI causes downregulation and/or dysregulation of pulmonary AQP-5 expression, in which IS could play a toxico-physiological role as a mediator involved in renopulmonary crosstalk.

## SA-PO097

**Pretreatment with Saline Loading Ameliorates Ischemic Acute Kidney Injury (AKI), and Reduces Intrarenal Upregulation of (Pro)renin Receptor in Rats** Masafumi Ono,[1] Yukitoshi Sakao,[2] Takayuki Tsuji,[1] Naro Ohashi,[1] Hideo Yasuda,[1] Yoshihide Fujigaki,[1,3] Akihiko Kato.[2] *[1]Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Blood Purification Unit, Hamamatsu Univ Hospital, Hamamatsu, Shizuoka, Japan; [3]Dept of Internal Medicine, Teikyo Univ School of Medicine, Tokyo, Japan.*

**Background:** (Pro)renin receptor (PRR), a trans-membrane receptor for renin and prorenin, is involved in the local activation of renin-angiotensin system (RAS) in the kidney. PRR also directly stimulates intracellular signaling pathway such as MAPK. However, it remains to be determined whether intrarenal PRR play a role in the development of AKI.

**Methods:** Male SD rats were subjected to left renal arterial clamping for 45 min just after right nephrectomy. We assessed the renal expression of PRR, renin/prorenin, angiotensinogen (AGT), and phospho-ERK1/2 protein by western blot and immunohistochemistry at 6, 24, 48 hr and 7 days after the injury. We measured intrarenal angiotensin II (Ang II) level by RIA. We also examined whether pretreatment with oral loading of saline solution (1.0% NaCl) for 48 hr just before AKI induction modifies intrarenal RAS components and MAPK system in the ischemic kidney.

**Results:** Serum creatinine (Scr) increased maximally at 48 hr after the reperfusion. Pretreatment with saline loading significantly decreased the peak of Scr (5.36±1.26 vs. 3.38±1.74 mg/dL, $P<0.05$). Renal ischemia increased the abundance of PRR protein at 48 hr, and then gradually decreased at day 7. PRR staining was mainly increased in the distal and cortical collecting ducts. There was a significant increase in renal AGT at 24 hr, while renal renin/prorenin remained at same levels. Phospho-ERK1/2 was upregulated at 6-24 hr after ischemia. Prior saline drinking suppressed the increment of PRR, AGT and phospho-ERK1/2 protein.

**Conclusions:** Renal ischemia increased the abundance of PRR concomitantly with AGT and phospho-ERK1/2. Saline loading mitigated ischemic injury, and prevented the increment of renal PRR abundance. These findings suggest that saline loading ameliorated ischemic AKI, mediating possibly through the suppression of RAS and MAPK systems via PRR downregulation.

## SA-PO098

**A Mouse Model of Type 1 Hepatorenal Syndrome (HRS)** Daniel E. Carl,[1] Siddhartha S. Ghosh,[1] Todd W. Gehr.[1] *[1]Internal Medicine/Nephrology, Virginia Commonwealth Univ, Richmond, VA; [2]Internal Medicine, Hepatology, Virginia Commonwealth Univ, Richmond, VA.*

**Background:** Type 1 HRS is a life threatening complication of cirrhosis with limited therapeutic options. The lack of a mouse model of HRS is a major gap in the field as it hinders molecular analysis of HRS and identification of therapeutic targets. The aim of this study was to develop a mouse model of type 1 HRS.

**Methods:** C57bl mice were administered CCl4 (1 ml/Kg) for 6-12 weeks to produce cirrhosis. Varying doses of lipopolysaccharide (LPS) were then administered intraperitoneally to identify a sublethal dose of LPS to induce AKI and a dose to cause 50% mortality. The rationale for LPS was the frequent development of HRS following an infection. These mice were compared to: (1) normal mice, (2) normal mice+LPS, and (3) mice treated with CCl4 alone. Animals were maintained in metabolic cages and urine obtained for analysis. Echocardiography was used to determine cardiac output.

**Results:** Mice developed bridging fibrosis with cirrhotic nodule formation after 6 weeks of CCl4. Hyperdynamic circulatory dysfunction (statistically significant increase in cardiac output and drop in systemic venous resistance) developed after 12 weeks of CCl4. Within 16 hours of a sublethal dose of LPS (2mg/Kg), 12 week CCl4-treated mice experienced a drop in urine volume and rise in creatinine. The urine Na decreased and there were no casts or proteinuria. Control mice treated with 2 mg/Kg LPS did not experience AKI.

| | Vehicle | LPS alone | CCl4 alone | **CCl4+LPS** |
|---|---|---|---|---|
| Urine volume(ml) | 1.33±0.6 | 1.28±0.4 | 1.7±0.7 | **0.84±0.4** |
| SCr(mg/dL) | 0.18±0.03 | 0.2±0.04 | 0.4±.1 | **0.8±0.2** |
| UNa(mmol/hr) | 140±57 | 115±34 | 137±37 | **46±12** |

Renal histology lacked glomerular or tubular pathology. A 6mg/Kg LPS dose led to 50% mortality rate in 12 week CCl4-treated mice; with no fatalities in controls+6mg/Kg LPS.

**Conclusions:** We describe a viable mouse model of type 1 HRS. Mice treated with 12 weeks of CCl4 develop histology and hemodynamics consistent with cirrhosis. Furthermore, cirrhotic mice develop AKI following LPS consistent with HRS.

**SA-PO099**

**Osmotic Nephrosis and Contrast-Induced Acute Kidney Injury Are Prevented by the RIPK1-Inhibitor Necrostatin-1 in Mice**
Andreas Linkermann,[1] Jan O. Heller,[1] Agnes Prokai,[2] Joel M. Weinberg,[3] Nina Himmerkus,[4] Attila Szabo,[2] Jan Hinrich Braesen,[5] Ulrich Kunzendorf,[1] Stefan Krautwald.[1] *[1]Clinic for Nephrology and Hypertension, Christian-Albrechts-Univ, Kiel, Schleswig-Holstein, Germany; [2]First Dept of Paediatrics, Semmelweis Univ, Budapest, Hungary; [3]Univ of Michigan, Div Univ of Michigan Medical Center, Ann Arbor, MI; [4]Institute for Physiology, Christian-Albrechts-Univ, Kiel, Schleswig-Holstein, Germany; [5]Institute for Diagnostic Histopathology and Cytopathology, Pathology Hamburg West, Hamburg, Germany.*

**Background:** The pathophysiology of contrast-induced acute kidney injury (CIAKI) is incompletely understood due to the lack of an appropriate *in vivo model that includes reduced kidney function before administration of radiocontrast media (RCM).*

**Methods:** We introduce a murine ischemia/reperfusion-injury (IRI)-based approach that allows induction of CIAKI by a single application of standard RCM. Whereas murine tubular cells and freshly isolated tubules rapidly absorbed RCM, plasma membrane integrity and cell viability remained preserved *in vitro* and *ex vivo* indicating that RCM do not induce apoptosis or regulated necrosis of tubular cells.

**Results:** In vivo, the IRI-based CIAKI model exhibited typical criteria of clinical CIAKI, like RCM-induced osmotic nephrosis and an increase in serum levels of urea and creatinine. Direct evaluation of renal morphology by intravital microscopy (IVM) following RCM-application revealed a brief increase in trans-tubular diameters in renal tubules and an initial dilation of peritubular capillaries within the first 20 minutes which was observed to a lesser extent also upon IRI-pre-treatment.

**Conclusions:** Mechanistically, necrostatin-1 (Nec-1), a highly specific inhibitor of the kinase domain of the receptor-interacting protein kinase 1 (RIP1) prevented osmotic nephrosis and CIAKI in vivo whereas an inactive Nec-1-derivate (Nec-1i) or the pan-caspase-inhibitor zVAD did not. Additionally, Nec-1 completely prevented the effects of RCM on peritubular capillaries, suggesting a previously unrecognized role of the RIP1-kinase domain in the pathophysiology of CIAKI and regulation of microvascular hemodynamics.

**Crosstalk between Interstitial Capillary and Tubular Injuries May Mediate Impaired Renal Microcirculation in Hepatic Acute Kidney Injury in Rats**
Akira Shimizu, Kayori Tsuruoka, Seiichiro Higo, Go Kanzaki, Yusuke Kajimoto, Megumi Fukui, Emiko Fujita, Shinya Nagasaka, Akiko Mii. *Analytic Human Pathology, Nippon Medical School, Tokyo, Japan.*

**Background:** Hepatic acute kidney injury (hepatic AKI) is a common complication in the acute liver dysfunction. In AKI, impaired renal microcirculation is frequently evident with renal peritubular capillary (PTC) injuries. In the present study, we examined the crosstalk between PTC endothelial and tubular injuries in renal microcirculatory disturbance in hepatic AKI.

**Methods:** Acute hepatic failure was induced in rat by liver transplantation from DA (RT1a) to Lewis (RT1l) rats without immunosuppression. Acute rejection progressed, and rats were dead around day 11 with severe acute liver dysfunction. We examined the clinical and laboratory data and pathological characteristics of kidneys by day 11, focusing on the PTC and tubular injuries.

**Results:** During the development of liver graft rejection, acute liver dysfunction (T-Bil 8.9 ± 1.9; AST 844 ± 141 U/l, $p<0.01$) and acute kidney injury (BUN 130 ± 29.3 mg/dl; Cr 1.2 ± 0.2 mg/dl, $p<0.01$) were developed by day 11. During the progression of AKI, renal interstitial PTC injuries developed with decreased expression of eNOS on endothelial cells and reduction of PTC blood flow in vivo (320±122 μm/sec at day 11 vs 860±145 μm/sec in control, $p<0.001$). Renal interstitial microvasculature is controlled by the angiogenic factors secreted from tubular epithelial cells, such as vascular endothelial growth factor (VEGF), angiopoietin-1 (ang-1), and ang-2, and the expression of VEGF, ang-1, and ang-2 was gradually decreased in the kidney by day 11. Renal tubular degeneration with bile pigment accumulation, mitochondrial degeneration was also noted by day 11 with interstitial inflammation.

**Conclusions:** AKI developed in rats in acute liver dysfunction. The crosstalk between interstitial PTC endothelial and tubular injuries may mediate augmentation of impaired renal microcirculation in hepatic AKI.

**SA-PO101**

**Radiocontrast Nephropathy: Role of Endothelial Injury, and Chronic Consequences**
Gunnar Schley,[1] Nada Cordasic,[1] Bernd Klanke,[1] Samuel N. Heyman,[2] Seymour Rosen,[3] Kai-Uwe Eckardt,[1] Carsten Willam.[1] *[1]Nephrology and Hypertension, Univ Hospital Erlangen, Erlangen, Germany; [2]Medicine, Hadassah Hebrew Univ Hospital, Jerusalem, Israel; [3]Pathology, Beth Israel Deaconess Medical Center, Boston, MA.*

**Background:** Contrast nephropathy (CIN) is one of the leading causes of in-hospital acute kidney injury. The classic rat model requires both inhibition of prostaglandin and nitric oxide synthesis followed by contrast medium (CM) administration. In this study, the pathophysiology of CIN is examined in a mice model, whose conditioning depends only on dehydration with subsequent CM administration.

**Methods:** CIN was induced in male mice by sodium iothalamate injection (3 g iodine/kg body weight) after 3 days of water deprivation producing an average weight loss of 20% without any obvious behavioral problems. Renal function and histology were determined 1 (N=28) and 14 days after CM (N=16).

**Results:** After 24 hours, 70% of mice went into renal failure and plasma creatinine rose from 0.09±0.02 to 0.95±0.22 mg/dl ($p<0.001$). The injury pattern at 24 hours was mainly located in the inner stripe of the outer medulla and consisted of capillary congestion, erythrocyte extravasation and necrosis, all of which correlated with the degree of renal failure ($R^2 = 0.85$, $p<0.001$). There was a clear gradient of injury, with the most severe damage in the inter-bundle zone. With progressive degrees of damage, there was increasing loss of endothelial immunohistochemical markers (MECA-32, CD34). Apoptosis of endothelial and tubular epithelial cells could be demonstrated using TUNEL stainings, and apoptotic changes were seen in the vasa recta. 14 days after the acute event, 25% of surviving mice still had renal failure. The injury in the inner stripe of the outer medulla now was chronic and the cortex then showed extensive chronic changes as well, reflecting injury of medullary thick ascending limbs with the loss of their associated convoluted tubules.

**Conclusions:** This novel mouse model underscores a role for medullary endothelial cell injury in the pathogenesis of CIN and shows that the long-term consequences of acute medullary injury are reflected by chronic changes in both the cortex and medulla.

**SA-PO102**

**Iodinated Contrast Media Induce Tubular Necrosis and Dysfunction in Isolated Thick Ascending Limb of Rat**
Zhi Zhao Liu,[1] Kristin Schmerbach,[1] Yan Lu,[2] Erdmann Seeliger,[1] Kathleen Cantow,[1] Andreas Patzak,[1] Ruisheng Liu,[2] Mauricio Michalak Sendeski.[1] *[1]Institut für Vegetative Physiologie, Charite-Universitaetsmedizin Berlin, Berlin, Germany; [2]Dept of Physiology and Biophysics, Univ of Mississippi Medical Center, Jackson, MS.*

**Background:** The prevalence of contrast induced acute kidney injury (CI-AKI) is still increasing. In this study we test the hypothesis that contrast media induce tubular cell death accompanied with oxidative stress and reducing nitric oxide bioavailability.

**Methods:** Isolated thick ascending limbs (TALs) from male Sprague-Dawley rats were perfused with either vehicle solution or iodixanol. Propidium iodide was used to estimate the cell death rate. Superoxide concentration and nitric oxide (NO) bioavailability were quantified by the fluorescent methods. Further, the expression of oxidative stress related genes and the activity of superoxide dismutase (SOD) in tubuli were investigated.

**Results:** Propidium iodide intensity was significantly enhanced by iodixanol (n=8) compared to the control group (n=6) within 20min. Moreover, during total 4-hour perfusion, iodixanol increased fluorescence intensity to 17.7±3.1%, compared to control group (7.0±1.0%) in TALs. Iodixanol increased dehydroethidium fluorescence ratio, a measure for superoxide concentration (9.6±1.4%, n=7), compared to control group (1.7±1.0%, n=8) Tempol, a superoxide dismutase mimic, inhibited the increase. DAF-FM fluorescence, a measure for NO, decreased during iodixanol treatment (-0.6±0.6%, n=7) and by NO synthase inhibitor L-NAME (control: 1.6±0.3%, n=7) within 12min. Only two of 84 investigated genes related to oxidative stress were differentially expressed in the TALs. The SOD activity did not differ between treated and untreated animals.

**Conclusions:** The study suggests that tubular cell damage and accompanying oxidative stress in our model are consequences of contrast media cytotoxicity. Further, oxidative stress and cell damage may impair NO bioavailability.

**SA-PO103**

**Angiotensin III/Angiotensin Type 2 Receptor Axis Inhibits Hyperglycemia-Induced Fibronectin Synthesis through Inhibition of NADPH Oxidase Nox4 in the Kidney**
Robert T. Day, Rita de Cassia Cavaglieri, Khaled Khazim, Yves C. Gorin, Denis Feliers. *Medicine, Univ of Texas Health Science Center at San Antonio, San Antonio, TX.*

**Background:** Angiotensin II, a critical mediator of diabetic nephropathy, exerts its deleterious effects through AT1R. AT2R generally opposes the effects of AT1R, and has antifibrotic properties. Recent studies suggest that Ang III, and not Ang II, could be the physiologic ligand for AT2R.

**Methods:** Cultured rat mesangial cells (MCs) were exposed to high glucose (HG, 25 mM) ± Ang III and expression of fibronectin was measured. For in vivo studies, extracellular matrix and fibronectin deposition were compared in AT2R knockout mice (AT2R-KO) with type 1 diabetes and their wildtype counterparts .

**Results:** In MCs, HG increased fibronectin protein expression at 1 h and 24 h. This was prevented by co-incubation with a selective AT2R agonist or Ang III but potentiated by coincubation with Ang II. Inhibitory effect of Ang III was mediated by AT2R, but potentiating effect of Ang II was mediated by AT1R. Nox4-derived reactive oxygen species is required for HG-mediated oxidative stress and MC fibrotic injury. Ang III prevented rapid increase in Nox4 expression and NADPH-dependent superoxide generation induced by HG. Modelization of Nox4 mRNA 5' untranslated region suggested that Nox4 mRNA is readily translated. Polysome analysis showed that Ang III inhibited HG-induced translation of Nox4 mRNA. Ang III activated AMPK through AT2R in MCs and inhibition of AMPK prevented the inhibitory effect of Ang III on Nox4 expression and fibronectin synthesis.

In diabetic AT2R-wt mice as well as normoglycemic AT2R-KO mice, extracellular matrix expansion (including fibronectin) correlated with increased Nox4 expression and ROS generation, as well as with decreased Ang III and aminopeptidase-A expression.

**Conclusions:** Ang III activates AT2R to limit fibronectin accumulation in response to HG via AMPK-dependent inhibition of Nox4 mRNA translation. AT2R activators such as Ang III may become viable therapeutic interventions to complement traditional therapy to treat diabetic nephropathy.

**Angiotensin 1-7 Prevents Systemic Hypertension and Ameliorates Kidney Injury via Inhibition of Oxidative Stress in Diabetic Akita Mouse Kidneys**

Yixuan Shi,[1] Chao-Sheng Lo,[1] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] Shao-Ling Zhang,[1] John S.D. Chan.[1] *[1]Res. Ctr., CHUM-Hotel Dieu Hosp., Montreal, Canada; [2]Res. Ctr., Maisonneuve-Rosemont Hosp., Montreal, Canada; [3]Pediatr Nephrol Unit, Mass. Gen. Hosp. for Children, Boston, MA.*

**Background:** We investigated whether Ang 1-7 administration could affect systemic hypertension and ameliorate kidney injury via inhibition of oxidative stress in Akita mice with type 1 diabetes.

**Methods:** Ang 1-7 was administered daily (500 μg/kg body weight (BW)/day, subcutaneously) to male Akita mice starting at 14 weeks of age with or without co-administration of A779 (an antagonist of the Mas receptor) (10 mg/kg BW/day). The animals were euthanized at 18 weeks of age. Wild type (WT) mice of the same age served as controls. Blood glucose (BG), systolic blood pressure (SBP) and albumin/creatinine ratio (ACR) were monitored weekly.Kidneys were processed for histology including dihydroethidium (DHE) staining and immunostaining of heme oxygenase 1 (HO-1), WT-1 (podocytes marker), nephrin, transforming growth factor-beta 1 (TGF-β1), collagen IV and Ace2. Proximal tubule expression of TGF-β1, Collagen IV and Ace2 mRNA were evaluated by real-time qPCR; and expression of their proteins was evaluated by Western blotting. Glomerular tuft volume and tubular luminal area were assessed morphometrically.

**Results:** Ang 1-7 administration prevented the increase of SBP and normalized urinary ACR without affecting BG levels in Akita mice. Akita kidneys exhibited significant increase in DHE staining and immunostaining for HO-1, TGF-β1 and collagen IV, whereas WT-1, nephrin and Ace2 immunostaining were decreased. These changes were normalized with Ang 1-7 administration, and the effects of Ang 1-7 were reversed by A-779. Finally, Ang 1-7 administration decreased glomerular tuft volume and tubular luminal area in Akita mice, and these changes were also reversed by A779.

**Conclusions:** Our data suggest that intrarenal Ang 1-7 plays a protective role by attenuating SBP and RPTC injury in diabetes, predominantly through decreasing renal oxidative stress-mediated signaling.

*Funding:* Government Support - Non-U.S.

## SA-PO105

**Indoxyl Sulfate Induces Angiotensinogen Expression in Proximal Tubular Cells through Upregulation of CREB, NF-kB and NOX4**

Toshimitsu Niwa,[1] Hidehisa Shimizu,[1] Shinichi Saito,[1] Fuyuhiko Nishijima.[2] *[1]Nagoya Univ Graduate School of Medicine; [2]Biomedical Research Laboratories, Kureha Co.*

**Background:** In chronic kidney disease (CKD), indoxyl sulfate, a uremic toxin, accumulates in serum, and the expression of angiotensinogen (AGT) is upregulated in renal proximal tubular cells. The present study aimed to determine the relationship between indoxyl sulfate and the upregulation of AGT expression in proximal tubular cells.

**Methods:** For in vitro experiment, HK-2 cells derived from human proximal tubular cells were incubated with indoxyl sulfate (250 mM) . For in vivo experiment, the rat groups consisted of: (1) Dahl salt-resistant normotensive rats (DN, n=8), (2) Dahl salt-resistant normotensive indoxyl sulfate-administered rats (DN+IS, n=8). Indoxyl sulfate (200 mg/kg/day in drinking water) was administered to the rats for 32 weeks.

**Results:** Indoxyl sulfate induced expression of AGT in rat renal cortex and in cultured human proximal tubular cells (HK-2). In proximal tubular cells, indoxyl sulfate induced phosphorylation of cAMP response element-binding protein (CREB) on Ser-133, and small interfering RNA (siRNA) specific to CREB inhibited indoxyl sulfate-induced AGT expression. Our previous study demonstrated that indoxyl sulfate activated nuclear factor-kB (NF-kB) through reactive oxygen species (ROS) production. NF-kB inhibitors (pyrrolidine dithiocarbamate and isohelenin), NF-kB p65 siRNA, an antioxidant (N-acetylcysteine; NAC), and a nicotinamide adenine dinucleotide phosphate (NADPH) oxidase inhibitor (diphenyleneiodonum; DPI) suppressed indoxyl sulfate-induced AGT expression. Both NAC and DPI suppressed indoxyl sulfate-induced expression of NF-kB p65 and CREB. CREB siRNA suppressed indoxyl sulfate-induced NF-kB p65 expression, whereas both NF-kB inhibitors and NF-kB p65 siRNA prevented indoxyl sulfate-induced CREB expression. Indoxyl sulfate induced the expression of NADPH oxidase 4 (NOX4) in proximal tubular cells, which was suppressed by NAC, DPI, NF-kB inhibitors, NF-kB p65 siRNA, and CREB siRNA.

**Conclusions:** Indoxyl sulfate induces angiotensinogen expression in proximal tubular cells through upregulation of CREB, NF-kB and NOX4.

## SA-PO106

**Reactive Oxygen Species Contribute to Angiotensin II Activation of TRPC6 Channels in Rat Primary Podocytes in Isolated Glomeruli**

Stuart E. Dryer,[1,2] Marc Thomas Anderson.[1] *[1]Biology and Biochemistry, Univ of Houston, Houston, TX; [2]Div of Nephrology, Baylor College of Medicine, Houston, TX.*

**Background:** Angiotensin II (Ang II) evokes $Ca^{2+}$ influx into podocytes, but many aspects of its transduction pathway are unknown in this cell type. Some recent analyses have been carried out on immortalized podocytes heterologously over-expressing Ang II receptors, which runs the risk of promiscuous activation of non-physiological transduction cascades.

**Methods:** Whole-cell recordings from primary rat podocytes on the surface of glomeruli isolated by a sieving procedure. The podocytes were still attached to the glomerular capillary.

**Results:** Application of Ang II evoked inward currents with current-voltage characteristics of TRPC6. Robust responses were seen at [Ang II] = 1 nM, half-maximal activation occurred at [Ang II] =10 nM, and responses desensitized rapidly at [Ang II] = 1 μM. Ang II activation of cationic currents was blocked by losartan. Ang II-evoked currents were also inhibited completely by SKF-96365, by 50 μM $La^{3+}$, and by TRPC6 knockdown with siRNA, suggesting all of the Ang II-modulated cationic currents contain TRPC6 subunits. Responses to Ang II were completely blocked by including GDP-βS in recording pipette, and by the PLC inhibitor D-609, but not by the PKC inhibitor chelerythrine. Responses to hypoosmotic stretch persisted under those conditions. Effects of Ang II on TRPC6 were reduced by the NOX2 inhibitors apocynin and diphenylene iodonium and also by the reactive oxygen species (ROS) quencher MnTBAP.

**Conclusions:** Ang II acts through G-protein coupled AT1Rs through PLC to activate TRPC6. Generation of ROS through NADPH oxidase NOX2 contributes to TRPC6 activation by Ang II.

## SA-PO107

**Endogenous NOX2 Interacts with Podocyte TRPC6 Channels and Contributes to Their Activation by Diacylglycerol but Not by Mechanical Stimuli:Essential Role of Podocin in Maintaining the NOX2-TRPC6 Complex**

Stuart E. Dryer,[1,2] Marc Thomas Anderson,[1] Eunyoung Kim.[1] *[1]Biology and Biochemistry, Univ of Houston, Houston, TX; [2]Nephrology, Baylor College of Medicine, Houston, TX.*

**Background:** The endogenously expressed TRPC6 channels of podocytes become active in response to reactive oxygen species (ROS) generated in several different signal transduction cascades. TRPC6 channels are also activated by diacylglycerol (DAG) normally produced during PLC-dependent cascades, for example in response to angiotensin II.

**Methods:** Whole-cell recording, immunoprecipitation, fluorometric analysis of ROS generation in immortalized mouse podocytes.

**Results:** Endogenous TRPC6 channels in mouse podocyte cell lines reciprocally co-immunoprecipitate with the NADPH oxidase NOX2 (gp91phox). However, this interaction is not detected in podocin knockdown cells[1]. In whole-cell recordings, we observed that TRPC6 activation by a DAG analog (OAG, 10 μM) was reduced in podocytes pretreated with the NOX2 inhibitor apocynin, by the pan-NOX inhibitor diphenylene iodonium and by the ROS quencher tempol. Tempol had no effect on TRPC6 activation by hypoosmotic stretch. Application of 10 μM OAG also increased generation of ROS, but not in podocin knockdown cells. OAG also increased surface expression of the NOX2 regulatory subunit p47(phox). Podocin is a cholesterol-binding membrane protein that may function to tether TRPC6 and other slit diaphragm proteins to cholesterol-rich membrane domains. We observed that cholesterol depletion using 10 mM methyl-beta-cyclodextrin reduced but did not eliminate activation of podocyte TRPC6 channels by OAG, and eliminated the NOX2-TRPC6 interaction as assessed by immunoprecipitation.

**Conclusions:** NOX2 assembles with TRPC6 at podocin-organized raft domains, and becomes catalytically active in response to DAG. The localized production of ROS contributes to TRPC6 activation by DAG. Importantly, podocin is required for formation of this signaling complex. 1. Anderson et al. (2013) Am J Physiol-Cell Physiol in press.

## SA-PO108

**Overexpression of Heterogeneous Nuclear Ribonucleoprotein F Attenuates Systemic Hypertension and Normalizes Angiotensin-Converting Enzyme 2 Expression via Down-Regulation of Transforming Growth Factor-Beta 1/TGF-Beta Receptor II Signaling in Diabetic Akita Transgenic Mice**

Chao-Sheng Lo,[1] Shiao-Ying Chang,[1] Yixuan Shi,[1] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] Shao-Ling Zhang,[1] John S.D. Chan.[1] *[1]Res. Ctr., CHUM-Hotel Dieu Hosp, Montreal, Canada; [2]Res. Ctr., Maisonneuve-Rosemont Hosp., Montreal, Canada; [3]Pediatr Nephrol Unit, Mass. Gen. Hosp. for Children, Boston, MA.*

**Background:** We investigated whether heterogeneous nuclear ribonucleoprotein F (hnRNP F) stimulates angiotensin-converting enzyme 2 (Ace2) expression in renal proximal tubular cells (RPTCs) via decreasing transforming growth factor-beta 1/TGF-β receptor II (TGF-β1/TGF-β RII) signaling in Akita mice.

**Methods:** Adult (20 weeks of age) male wild type (WT), Akita and Akita hnRNP F-transgenic (Tg) mice were studied. Kidneys were processed for histology. TGF-β1, TGF-β RII and Ace2 mRNA and their protein expression in renal proximal tubules (RPTs)

were evaluated by real time-qPCR and Western blotting, respectively. Freshly isolated mouse RPTs were studied ex vivo. Rat Ace2 gene promoter activity in pGL4.20 vector was studied in rat RPTCs in vitro.

**Results:** Akita mice exhibited increased systolic blood pressure and glomerular filtration rate as compared to WT mice. TGF-β1, TGF-β RII mRNA and their protein expression in RPTs were significantly increased whereas Ace2 mRNA and its protein were decreased in Akita mice compared to WT. These changes were normalized in Akita hnRNP F-Tg mice. Ex vivo, TGF-β1 inhibited Ace2 mRNA and protein expression in mouse RPTs and reversed by SB431542 (an inhibitor of TGF-β receptor I). In vitro, overexpression of hnRNP F inhibited TGF-β1 and TGF-β RII expression, whereas it increased Ace2 expression in rat RPTCs. TGF-β1 also attenuated Ace2 gene promoter activity and its effect was inhibited by SB431542 and small interference RNA of TGF-β RII. Finally, we identified a putative TGF-β1 responsive element in nucleotides N-1084 to N-499 upstream of transcriptional starting site of rat Ace2 gene promoter.

**Conclusions:** Our data suggest that intrarenal hnRNP F attenuates SBP and enhances Ace2 expression in RPTCs, predominantly through decreasing TGF-β1/TGF-β RII signaling.

*Funding:* Government Support - Non-U.S.

## SA-PO109

**Nuclear Factor Erythroid 2-Related Factor 2 Mediates High Glucose Stimulation of Renal Angiotensinogen Gene Expression and Induction of Hypertension in Diabetic Akita Mice**

Shaaban Abdo,[1] Yixuan Shi,[1] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] Shao-Ling Zhang,[1] John S.D. Chan.[1] *[1]Res Ctr, CHUM-Hotel Dieu Hosp, Montreal, Canada; [2]Res Ctr, Maisonneuve-Rosemont Hosp, Montreal, Canada; [3]Pediatr Nephrol Unit, Mass Gen Hosp for Children, Boston, MA.*

**Background:** We investigated whether nuclear factor erythroid 2-related factor 2 (Nrf2) can mediate the effects of high glucose (HG) on stimulation of angiotensinogen (Agt) gene expression in renal proximal tubular cells (RPTCs), and induction of systemic hypertension (sHTN) and renal injury in type 1 diabetic Akita mice.

**Methods:** Adult male Akita mice specifically overexpressing catalase (Cat) in their RPTCs and Akita mice treated from 12 weeks ± insulin implants for 4 weeks were studied at 16 weeks. Non-Akita mice served as controls. Plasma glucose, systolic blood pressure (SBP) and urinary albumin/creatinine ratio (ACR) were monitored weekly. Kidneys were processed for histology. Renal proximal tubular (RPT) *Agt, Nrf2 and Keap1 mRNA* and their protein expression were evaluated by real time-qPCR and Western blotting, respectively. Freshly isolated mouse RPTs and rat RPTCs stably transfected with a plasmid, pGL4 containing rat *Agt* gene promoter ± Nrf2 activator (Oltipraz) or Nrf2 inhibitor (alkaloid trigonelline[C7H7NO2]) were also studied.

**Results:** Akita mice developed sHTN and exhibited renal hypertrophy.Overexpression of Cat or treatment with insulin normalized sHTN, attenuated renal hypertrophy and decreased urinary ACR in Akita Cat-Tg and Akita mice, respectively. RPT Agt and Nrf2, but not Keap1 expression, were significantly increased; these changes were normalized by Cat overexpression and insulin treatment. *Ex vivo,* Oltipraz stimulated Nrf2 and Agt expression in mouse RPTs and rat RPTCs and trigonelline abolished its effect. *In vitro,* HG and Oltipraz stimulated *Agt* gene promoter activity and their effect was prevented by inhibitors of oxidative stress and trigonelline as well as by transfecting RPTCs with small interfering RNA of *Nrf2*.

**Conclusions:** Our data indicate that HG induce RPTC injury and sHTN in diabetic mice through, at least in part, Nrf2-mediated stimulation of intrarenal *Agt* gene expression.

## SA-PO110

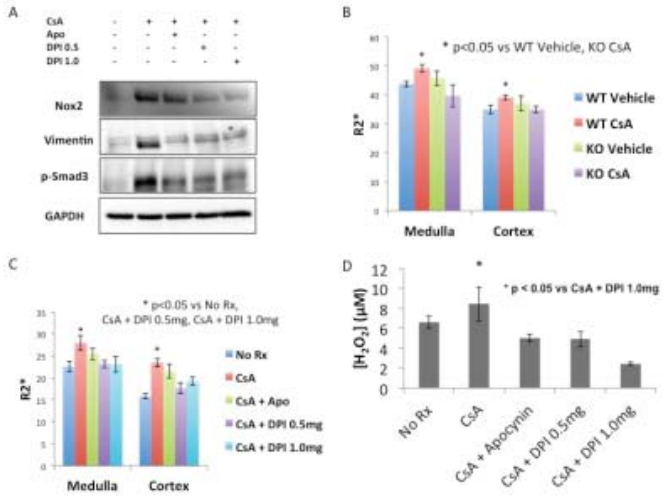
**Nox2 Mediates Cyclosporine A-Induced Hypoxia**

Omeed Hafez,[1] Shannon Reese,[1] Nancy A. Wilson Schlei,[1] Zaheer Akhtar,[2] Elizabeth Sadowski,[2] Arjang Djamali.[1] *[1]Medicine, Univ of Wisconsin; [2]Radiology, Univ of Wisconsin.*

**Background:** The use of Cyclosporine A (CsA), a calcineurin inhibitor, as maintenance immunosuppression in the management of solid organ transplantation is compromised by its chronic nephrotoxicity. This includes increased oxidative stress by an unknown mechanism. We hypothesized that the classical phagocytic Nox2 enzyme plays an important role in renal hypoxia mediated by CsA. We tested this hypothesis using the CsA-induced model of chronic nephrotoxicity in rats and mice.

**Methods:** Fisher344 rats received CsA 15mg/kg/24h, no treatment, or CsA with a non-specific inhibitor of Nox activity for 4 weeks (n=6-8/group). Inhibition was achieved using Diphenyleneiodonium (DPI; 0.5mg or 1.0mg/kg/24h) or Apocynin (Apo; 16mg/kg/24h). Wild-type (WT) and Nox2 knockout (KO) mice received CsA 30mg/kg/24h or vehicle for 8 weeks (n=4-5/group). To characterize the effects of CsA on oxygenation, animals underwent blood oxygen level dependent MRI (BOLD-MRI), a non-invasive imaging method that uses hemoglobin as an endogenous contrast agent. Oxidative stress was further evaluated by measuring $H_2O_2$ levels in rat serum. CsA-induced fibrosis was evaluated with Western blots.

**Results:**



Immunoblot analyses of kidney tissue lysates demonstrated that CsA therapy increased Nox2 and fibrogenesis (vimentin and p-smad3). Nox inhibition decreased fibrogenesis suggesting that Nox2 is a mediator of CsA-induced renal fibrosis (Panel A). BOLD-MRI demonstrated that CsA decreased renal oxygenation (increased R2* levels) while the lack of Nox2 prevented these changes in rats (B) and mice ©. These findings were supported by decreased $H_2O_2$ in serum from rats treated with Nox inhibitors (D).

**Conclusions:** These studies indicate that Nox2 modulates intrarenal oxygenation and is involved in the pathogenesis of CsA-induced hypoxia. Specific Nox2 inhibition may play a role in preventing CsA nephrotoxicity.

*Funding:* NIDDK Support

## SA-PO111

**Nox5 Exacerbates Filtration Barrier Damage and Increases Blood Pressure in a Mouse Model of Diabetes**

Chet E. Holterman,[3] Jean-Francois Thibodeau,[3] Mark E. Cooper,[1] Rhian Touyz,[2] Chris R. Kennedy.[3] *[1]Baker IDI Heart and Diabetes Institute, Melbourne, Australia; [2]Univ of Glasgow, Glasgow, United Kingdom; [3]Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, Canada.*

**Background:** We have previously demonstrated that Nox5 is upregulated in human diabetic kidney and contributes to ROS–induced podocyte damage and filtration barrier dysfunction. While several studies implicate Noxes 1, 2 and 4 in diabetic nephropathy, nothing is known regarding the role of Nox5. Here we show that podocyte-specific Nox5 expression results in earlier and more severe albuminuria, increased systolic blood pressure, and interstitial fibrosis in streptozotocin (STZ) type 1 diabetes.

**Methods:** Transgenic mice expressing Nox5 specifically in podocytes ($Nox5^{Pod+}$) were subjected to low dose STZ (50mg/kg) injection daily for five days. Urinary albumin excretion rates from 24 hour urine collections were assessed by ELISA. Systolic blood pressure was measured weekly by tail-cuff plethysmography. Kidney pathology was further assessed by PAS and Mason-Trichrome staining and electron microscopy to determine morphological changes, glomerular sclerosis, and foot process effacement.

**Results:** Urinary albumin levels in $Nox5^{pod+}$ trended higher at 4 and 8 weeks post-STZ injection and were significantly higher 16 weeks post injection as compared to non-transgenic littermates. Systolic blood pressure was not increased in $Nox5^{pod}$ mice at 4 weeks post-STZ but showed increases over non-transgenic littermates at 8 and 16 weeks. PAS and Mason-Trichrome staining revealed increased glomerular sclerosis and interstitial fibrosis 16 weeks post-STZ in $Nox5^{pod+}$ animals.

| | **4wk post-STZ** | | **8wk post-STZ** | | **16wk post STZ** | |
|---|---|---|---|---|---|---|
| | non-tg | $Nox5^{pod+}$ | non-tg | $Nox5^{pod+}$ | non-tg | $Nox5^{pod+}$ |
| **Albumin**(μg/24hrs) | 1627±242 | 1980±200 | 1960±189 | 2396±396.4 | 1489±290 | 2527±494* |
| **Systolic BP**(mmHg) | 107±8 | 112±2 | 112±6 | 121±5 | 115±4 | 127±7* |
| Data are mean ±SEM, *P<0.05 vs non-tg 16wk post STZ | | | | | | |

**Conclusions:** These novel data identify Nox5 as an important NADPH oxidase isoform in the development of diabetic nephropathy. Nox5 may emerge as a novel therapeutic target for reducing the progression of this disease.

## SA-PO112

**TORC2 Signalling Regulates Stress Response and Longevity in C. elegans**

Elke Neumann-Haefelin,[1] Vanessa Ruf,[1] Gerd Walz.[1] *[1]Renal Div, Univ Hospital, Freiburg, Germany; [2]Dept of Genetics, Harvard Medical School, Boston.*

**Background:** The evolutionarily conserved *target-of-rapamycin* (TOR) kinase controls fundamental metabolic processes to support cell and tissue growth. TOR functions within the context of two distinct complexes, TORC1 and TORC2. The TORC2 with its specific component Rictor has been recently implicated in aging and regulation of growth and metabolism.

**Methods:** We established a C. elegans model system to study functional aspects of TOR signalling in vivo.

**Results:** Here, we identify *rict-1/Rictor* as a regulator of embryonic development and stress response in *C. elegans*. The transcription factor *skn-1* and its mammalian ortholog *Nrf* have conserved functions in stress detoxification and contribute to longevity. *skn-1* is also a critical regulator of embryonic development. Inhibition of TORC2 during adulthood confers stress resistance and longevity in a SKN-1-dependent manner. Moreover, genetic inactivation of *rict-1* partially suppressed the embryonic lethality associated with *skn-1* mutation.

**Conclusions:** These data indicate that TORC2 modulates the transcription factor SKN-1 during embryonic development and adult stress response in *C. elegans*.

*Funding:* Government Support - Non-U.S.

## SA-PO113

**The Regulation of the Nitric Oxide System Can Modulate the Klotho Expression in Kidney via TWIST-2 and E-cadherin** Jae Won Yang,[1] Jae Seok Kim,[1] Minseob Eom,[2] Seung-Ok Choi,[1] Byoung Geun Han.[1] *[1]Internal Medicine, Yonsei Univ Wonju College of Medicine, Wonju, Gangwon, Korea; [2]Pathology, Yonsei Univ Wonju College of Medicine, Wonju, Gangwon, Korea.*

**Background:** The klotho was originally identified as an anti-aging protein but was subsequently discovered to have a multitude of biologic actions. Animal experiments clearly showed a transient renal klotho deficiency in acute kidney injury from a variety of causes, including ischemia–reperfusion injury. We investigated whether relationship existed between the NO pathway and the klotho expression in kidney, and studied the possible pathway as basic helix-loop-helix transcription factors (TWIST)-1, 2, E-cadherin.

**Methods:** The 10th weeks Sprague-Dawley rats (N= 24, 200g, male) were divided four groups. We supplied low salt diet to the control group (N=6), L-NAME 1 mg/mL in drinking water to the L-NAME group (N=6), and udenafil 5 mgSQ to the Udenafil group (N=6), L-NAME and udenafil to the L-NAME and Udenafil group (N=6) for 4 weeks. After the collection of blood and urine on day 28, the both kidneys were ressected surgically.The serum creatinine,urine nitrate/nitrite,cGMP by ELISA, and tissues were investigated by immunohistochemical stain, and RT-PCR for klotho, TWIST 1, 2, E-cadherin.

**Results:** The serum creatinine and urine nitrate/nitrite level did not show the statistical difference between groups. The urine cGMP level showed 2.59±0.88, 1.79±0.99, 1.20±0.52, 0.69±0.59 pmol/well (p=0.0087). The klotho mRNA expression showed 0.98±0.01, 0.30±0.11, 0.68±0.15, 0.54±0.26 (p=0.0017). The TWIST-2 mRNA expression showed 1.90±1.65, 139.27±114.87, 10.33±8.42, 20.19±12.25 (p=0.0163). The E-cadherin mRNA expression showed 0.64±0.32, 1.57±0.97, 1.24±1.27, 13.82±3.04 (p=0.0029). The blocking of NO system decreased the klotho expression via the TWIST-2 increase. The induction of NO system increased the klotho expression via E-cadherin increase.

**Conclusions:** The regulation of the nitric oxide system can modulate the klotho expression in kidney via TWIST-2 and E-cadherin.

## SA-PO114

**Semicarbazide-Sensitive Amine Oxidase (SSAO) Inhibitor Inhibits Extracellular Matrix Deposition in Kidney Fibrosis** May Yw Wong, Jie Zhang, Sonia Saad, Carol A. Pollock, Muh Geot Wong. *Kolling Inst, Univ of Sydney, St. Leonards, NSW, Australia.*

**Background:** Novel anti-inflammatory agents targeting early phases of cellular response to injury are increasingly recognised to have a role in tubulointerstitial fibrosis. SSAO is a protein enzyme known for its role in inflammation by mediating the migration of leukocytes and producing reactive oxygen species. However, the role of SSAO inhibitors in kidney fibrosis is unclear. We sought to determine the role of a semicarbazide-sensitive amine oxidase (SSAO) inhibitor (PXS4728A) as an antifibrotic agent using *an in vivo* model of kidney fibrosis.

**Methods:** A 7 day unilateral ureteric obstruction (UUO) model of acute kidney fibrosis was examined in 6-8 week old male C57BL/6 mice (20–25g, n=5) with groups: (i) Sham operated; (ii) UUO-control; (iii) PSX4728A (2mg/kg;orally gavaged); (iv) Telmisartan, an angiotensin receptor blocker (3mg/kg; administered in drinking water), (v) PSX4728 and Telmisartan. Semiquantitative morphometric analyses of glomerulosclerosis and tubuloinsteritial fibrosis were performed. Kidney tissue was analysed for fibrotic and inflammatory mRNA and protein expression.

**Results:** The mRNA expression of Collagen-IV (C-IV) and Fibronectin (FN) in kidney tissue was lower in PXS4728A groups (2.25±1.59; $p<0.05$ and 3.20±2.73; $p<0.05$) as compared to UUO control (9.62±5.32 and 12.00±8.47). The mRNA expression of Transforming Growth Factor Beta-1 (TGFβ-1) and monocyte chemoattractant protein-1 (MCP-1) were effectively suppressed by PSX4278 (2.58±1.86; $p<0.05$ and 2.69±2.00; $p<0.05$) and Telmisartan (1.68±2.03; $p<0.05$ and 2.31±1.92; $p<0.05$) alone and also when combined (2.141±1.952; $p<0.05$ and 2.557±1.296; $p<0.05$) as compared to the UUO control. In addition, mice treated with PXS4782A had reduced tubular dilatation and glomerulosclerosis with lower FN and C-IV expression by immunohistochemistry.

**Conclusions:** Our data strongly suggest that PSX4728A is an effective antifibrotic agent in kidney fibrosis and comparable to Telmisartan.

## SA-PO115

**Advanced Glycation End-Products Induced Podocyte Migration via Downregulation α-Actinin-4 and Cytoskeleton Reorganization** Cailian Cheng, Zhenda Zheng, Chenggang Shi, Xun Liu, Zengchun Ye, Tan-qi Lou. *Dept of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China.*

**Background:** α-actinin-4 play an important role in podocyte function, and mutation of α-actinin-4 cause focal segmental glomerulosclerosis. In this study, we investigate the effects of advanced glycation end-products(AGEs) on the expression of α-actinin-4 and the changes of cytoskeleton, also we observed podocyte migration and the protection of losartan.

**Methods:** Podocytes were incubated with various concentrations of AGEs (0, 20, 40, 80 μg/mL)for 24 hours, α-actinin-4 protein levels were measured by western blot, cytoskeleton reorganization were observed by laser scanning confocal microscopy. Podocyte migration were assayed by wound healing test. Then podocytes were treated with losartan ($10^{-5}$M) and AGEs (80 μg/mL) for 24 hours, the changes of α-actinin-4, cytoskeleton, and podocyte migration were observed.

**Results:** Our results showed that incubation with AGEs resulted in a significant decrease in the expression of α-actinin-4 [(62±13)% vs. 100%, $P<0.05$] , AGEs also induced F-actin reorganization and increased podocyte migration[(250±32) vs. (75±20), $P<0.05$]. However, pretreatment with losartan ($10^{-5}$M) alleviated the downregulation of α-actinin-4 induced by AGEs [(80±14)% vs.(62±13)%, $P<0.05$]. Also, podocyte migration decreased significantly [(100±28) vs .(250±32), $P<0.05$].

**Conclusions:** AGEs increase podocyte migration via downregulation α-actinin-4 and cytoskeleton reorganization.

*Funding:* Government Support - Non-U.S.

## SA-PO116

**Advanced Glycation End Products Upregulated the Expression of Angiopoietin-Like Protein 4 via Activation the Renin-Angiotensin System in Endothelials** Cailian Cheng, Zhenda Zheng, Chenggang Shi, Xun Liu, Zengchun Ye, Tan-qi Lou. *Dept of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China.*

**Background:** To investigate the effects of advanced glycation end products (AGEs) on the expression of angiopoietin-like protein 4 and its mechanisms in endothelials.

**Methods:** Endothelial cells were incubated with various concentrations of AGEs for 24 hours, the expression of angiopoietin-like protein 4 were detected by real-time PCR and western blot analysis, the concentration of angiotensin IIin conditioned media and cell lysates were measured byenzyme-linked immunosorbent assay, FITC-labeled dextran filtration assay and transendothelial electrical resistance were performed to evaluate endothelial permeability. Then endothelials were pretreated with losartan for 60 minutes before AGEs added, and the changes of angiopoietin-like protein 4 expression and endothelial permeability were assayed.

**Results:** AGEs increased the expression of angiopoietin-like protein 4 mRNA and protein levels (2.60±0.18 vs.1.0, 250±32% vs.100%, respectively, $P<0.05$) parallel with an increase in the levels of angiotensin II[(2.8±0.21) vs. (1.3±0.19) pg/μl in media, (0.35±0.04) vs. (0.19±0.04) pg/μg protein in cell lysates ,$P<0.05$]. Incubation with AGEs also resulted in a significant increase in endothelial permeability [(0.46±0.09) vs.( 0.15±0.09) ]OD, [(43.39±2.82) vs. (73.28±2.64) ]$\Omega \cdot cm^2$ $P<0.05$). However, pretreatment with angiotensin Iireceptor blocker losartan($10^{-5}$M) blunted these effects induced by AGEs ($P<0.05$).

**Conclusions:** AGEs upregulated the expression of angiopoietin-like protein 4 via activation local renin-angiotensin system in endothelial cells, which may be a new mechanism for AGEs increasing endothelial permeability.

*Funding:* Government Support - Non-U.S.

## SA-PO117

**Effects of Advanced Glycation End-Products on Synaptopodin Expression and Cytoskeleton Reorganization in Podocytes** Cailian Cheng, Zhenda Zheng, Chenggang Shi, Xun Liu, Zengchun Ye, Tan-qi Lou. *Dept of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China.*

**Background:** To investigate the effects of advanced glycation end-products(AGEs) on the expression of synaptopodinandpodocyte migration, and to explore their mechanisms.

**Methods:** Podocytes were incubated with different concentrations of AGEs (0, 20, 40, 80 μg/mL)for 24 hours, the expression levels of synaptopodin were measured by western blot, cytoskeleton reorganization was observed by laser scanning confocal microscopy. Podocyte migration were assayed by transwell assay. Then podocytes were pretreated with losartan for 60 min, the changes of synaptopodin, cytoskeleton, and podocyte migration were observed.

**Results:** Our results showed that incubation with AGEs resulted in a significant decrease in the expression of synaptopodin[(50±11)% vs 100%, $P<0.05$], AGEs also induced F-actin reorganization and increased podocyte migration [(47±6) vs (13±3), $P<0.05$]. However, pretreatment with losartan ($10^{-5}$M) alleviated the effects induced by AGEs in podocytes.

**Conclusions:** AGEs downregulate the expression of synaptopodin, induce cytoskeleton reorganization, and increase podocyte migration via activation the local renin-angiotensin system in podocytes.

## SA-PO118

**Mpv17 Protects Podocytes against Oxidative Stress and Apoptosis in Experimental Glomerulonephritis** Gabriella Casalena,[1] Stefanie Krick,[3] Ilse S. Daehn,[1] Liping Yu,[1] Shaolin Shi,[1] Vivette D. D'Agati,[2] Detlef O. Schlondorff,[4] Erwin P. Bottinger.[1] *[1]Dept of Medicine and The Charles Bronfman Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Dept of Pathology, College of Physicians and Surgeons, Columbia Univ, New York, NY; [3]Dept of Medicine, Univ of Miami Miller School of Medicine, Miami, FL; [4]Dept of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.*

**Background:** Mitochondrial dysfunction is increasingly recognized as contributing to renal glomerular diseases, including those secondary to mitochondrial DNA (mtDNA) mutations/deletions. Mitochondria maintain cellular redox and energy homeostasis and are a major source of intracellular reactive oxygen species (ROS).ROS accumulation may contribute to mitochondrial dysfunction/mutations and thereby to glomerulosclerosis. In mice, deletion of the Mpv17 gene predisposes to experimental glomerulosclerosis, but the underlying mechanism remains poorly defined.

**Methods:** Mpv17$^{+/+}$ and Mpv17$^{-/-}$ C57BL/6J mice were injected with nephrotoxic serum to induce a mild or a severe form of nephritis (NTSN). Mpv17$^{+/+}$ or Mpv17$^{-/-}$ podocytes were generated by crossing Mpv17$^{+/+}$ or Mpv17$^{-/-}$ with Immorto®transgenic mice (Charles River,MA).

**Results:** Mpv17 localizes to mitochondria of podocytes and its expression is reduced in several glomerular injury models and in human glomerular diseases. Using a mild or severe form of NTSN we found that deletion of Mpv17 resulted in increased proteinuria (mild NTSN), and increase in serum creatinine (severe NTSN). Renal defects were associated with mtDNA oxidation and depletion, and loss of protective mitochondrial enzymes (MnSOD, PGC1alpha). In vitro,Mpv17 protects mitochondria and hence podocytes from loss of mitochondrial membrane potential and mtDNA content, with Mpv17$^{-/-}$ podocytes showing increased apoptosis in response to oxidative stress-induced injury.

**Conclusions:** Mpv17 is a protective factor in podocyte mitochondria,with essential function for the maintenance of mitochondrial homeostasis and podocyte survival in response to oxidative stress-induced injury associated with experimental glomerulonephritis.

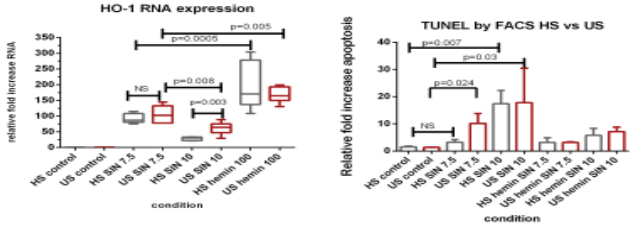
## SA-PO119

**Oxidative Stress Response and Heme Oxygenase 1 Expression in Human Umbilical Artery Endothelial Cells: Uremic versus Healthy Serum Conditions** Kristien El Daenen,[1] Marc Hoylaerts,[2] Bert Bammens.[1] *[1]Laboratory of Nephrology, KU Leuven, Belgium; [2]Molecular and Vascular Biology, KU Leuven, Belgium.*

**Background:** Heme oxygenase 1 (HO-1), an inducible heme-degrading enzyme, protects against atherosclerosis. Increased oxidative stress (OX) contributes to the accelerated atherosclerosis of CKD. We investigated the effect of oxidative stress on human umbilical artery endothelial cells (HUAECs) in uremic (US) compared to healthy serum (HS) conditions and studied HO-1 and its effects in control as well as short and persistent OX conditions.

**Methods:** HUAECs were conditioned in 30% human serum (pooled from 40 hemodialysis patients or 10 healthy volunteers) for 72h, followed by exposure to increasing concentrations of $ONOO^-$ (0.10-1.00 mM) for 5min or SIN-1 7.5 and 10mM for 8h (resp L.OX and H.OX). Additionally, HUAECs were pre-incubated with 100µM Hemin for 6h. HO-1 expression was evaluated by RT-PCR and western blot. Cell viability 30 minutes after $ONOO^-$ exposure was evaluated by MTT assay. Cell apoptosis after SIN-1 incubation ± Hemin pre-incubation (50 µM) was evaluated by western blot for caspase-3 and TUNEL staining by Flow Cytometry.

**Results:** HO-1 RNA expression and apoptosis: see figure.



Western Blot for HO-1 showed equal HO-1 expression in US and HS. $ONOO^-$ reduced US cell viability by MTT assay to a larger extent as compared to HS cells (43% vs 23%, P<0.05 between 0.1-0.5 mM).

**Conclusions:** Cell viability and apoptosis assays show higher OX-induced vulnerability in US, starting from lower concentrations and to a larger extent as compared to HS. In contrast to previously published animal data on kidney tubular cells, endothelial cell HO-1 inducibility is preserved in US. Whereas mild HO-1 induction is seen in response to oxidative stress, Hemin induces HO-1 significantly stronger. Pretreatment by Hemin reverses apoptosis, suggesting a beneficial role of hemin in Uremia.

## SA-PO120

**Activation of Nucleotide Binding Oligomerization Domain-Like Receptor Family, Pyrin Domain Containing-3 Inflammasome due to Production of Reactive Oxygen Species Induced by Calcium Oxalate Crystals in the Kidneys** Sunil Joshi,[1] Wei Wang,[1] Ammon B. Peck,[1] Saeed R. Khan.[1,2] *[1]Pathology, Univ of Florida, College of Medicine, Gainesville, FL; [2]Urology, Univ of Florida, College of Medicine, Gainesville, FL.*

**Background:** We have already shown that production of reactive oxygen species (ROS) is a crucial factor for renal injury and inflammation following exposure to oxalate (Ox) and calcium oxalate (CaOx) crystals. In this study we looked at the role of ROS in activation of Nucleotide binding oligomerization domain-like receptor family, pyrin domain containing -3 (NLRP3) inflammasome and associated genes involved in inflammation.

**Methods:** Eight week old male rats (n=6/group) were given hydroxy-l-proline (HLP) to induce hyperoxaluria and CaOx crystal deposition in the kidneys. Another set of rats getting HLP diet were also given Apocynin-supplemented water. Rats were euthanized on day 28 and kidneys were extracted. Microarray analysis was conducted using Illumina bead array reader™. Gene ontology (GO) analysis and the pathway analysis of the genes was done using DAVID (Database for Annotation, Visualization of Integrated Discovery) enrichment analysis tool.

**Results:** We analyzed a total of 22,226 genes and found that 20 and 24 pathways were highly significant in the cortex and medulla respectively. In the cortex, ECM-receptor interaction, complement and coagulation cascades, focal adhesion and hypertrophic cardiomyopathy were most significant pathways, whereas in medulla, complement and coagulation cascades, ECM-receptor interaction and dilated cardiomyopathy were the major pathways. Genes encoding for PYCARD (ASC: apoptosis –associated spec-like protein containing a CARD), other isoforms of CARD (Caspase activation and recruitment domains), TXNIP (Thioredoxin-interacting protein), caspase-1, IL-1β and IL-18 were significantly up regulated in HLP-fed rats, but the group receiving apocynin had these genes down regulated in the cortex and medulla respectively.

**Conclusions:** Our results show the role of ROS in the activation of NLRP3 inflammasome via TXNIP leading to a robust inflammatory response in the kidneys of rats with hyperoxaluria and CaOx nephrolithiasis.

## SA-PO121

**Chitosan/siRNA Nanoparticle-Mediated COX-2 Knockdown Regulates Inflammatory and Oxidative Stress Response Induced by Unilateral Ureteral Obstruction in Mice** Line Nilsson,[1] Chuanxu Yang,[2] Jorgen Frokiaer,[1] Jorgen Kjems,[2] Rikke Norregaard.[1] *[1]Dept of Clinical Medicine, Aarhus Univ, Denmark; [2]Interdisciplinary Nanoscience Center, Dept of Molecular Biology and Genetics, Aarhus Univ, Denmark.*

**Background:** Cyclooxygenase type 2 (COX-2) is induced in response to unilateral ureteral obstruction (UUO). In this study the role of COX-2 in the progression of inflammation and oxidative stress in response to UUO was examined using a chitosan nanoparticle system containing anti-COX-2 siRNA that targets macrophages as a therapeutic strategy.

**Methods:** Mice were subjected to 3 days UUO and COX-2 knockdown were mediated by intraperitoneal injection of chitosan nanoparticles containing anti-COX-2 siRNA. Sham-operations were performed in parallel. Localization of Cy5-labeled chitosan was determined by in vivo optical imaging for nanoparticle tracking. COX-2 expression was evaluated by QPCR, immunoblot analysis and immunohistochemistry. Inflammation was examined by the expression of tumor necrosis factor-alpha (TNF-α) mRNA. Using immunoblot analysis, the regulation of the oxidative stress marker, heme oxygenase-1 (HO-1) and antioxidant enzymes, superoxide dismutase 1 and 2 (SOD1 and -2) were examined. HE staining was performed to investigate tubular morphology.

**Results:** Cy5-labeled chitosan nanoparticles predominantly accumulated in the macrophages in the obstructed kidney. COX-2 mRNA and protein increased in response to UUO and this was partly attenuated by treatment with COX-2 siRNA. TNF-α and HO-1 increased during UUO, which was prevented in response to COX-2 siRNA treatment. SOD1 and SOD2 protein levels were downregulated in response to UUO. Treatment with COX-2 siRNA attenuated the downregulation of SOD2. HE staining showed lesser tubular damage in COX-2 siRNA treated UUO mice. Plasma creatinine and urea were unchanged after COX-2 siRNA treatment in response to UUO.

**Conclusions:** This study demonstrates that nanoparticle-mediated COX-2 knockdown in mice may contribute to attenuate the development of inflammation and oxidative stress in response to 3 days UUO.

## SA-PO122

**RGD-Peptide Blocks Osteopontin Expression and Oxidative Stress and Prevents Early Diabetic Nephropathy in Type 1 Diabetic Mice** Taehoon Cho, Susanne B. Nicholas. *David Geffen School of Medicine, UCLA, Los Angeles, CA.*

**Background:** Osteopontin (OPN) may have both pro- and anti-inflammatory properties, and may also regulate the cellular response to oxidative stress. We have shown that OPN is highly up-regulated in renal injury and that global deletion of OPN can prevent diabetic nephropathy (DN), but the mechanisms have not been fully explored. OPN contains an

Arginine-Glycine-Aspartate (RGD) motif that binds to the integrin family of receptors, which activates critical intracellular signaling. This study examines the effect of RGD-blocking peptide on OPN expression and signaling in type 1 DN.

**Methods:** Diabetic $Ins2^{Akita/+}$ and non-diabetic $Ins2^{+/+}$ mice (n=4), aged 8 weeks were untreated or treated by intraperitoneal injection with an RGD-peptide against $\alpha_5\beta_1$-integrin and an RGE-control peptide (2,400μg/kg) for 12 weeks. Tail-cuff blood pressures, plasma glucose and 24hr urinary albumin-to-creatinine ratio (ACR) were measured monthly. At the end of the study, kidney cortex was harvested for protein isolation. Western blots quantified the expression of TGF-β1, OPN, and NADPH oxidase.

**Results:** Plasma glucose and urine volumes were 3–fold higher in diabetic compared to non-diabetic mice ($p<0.05$), but there were no changes in blood pressures. Treatment with RGD-peptide significantly attenuated ACR (3-fold, $p<0.001$) compared to either untreated or RGE-peptide treated $Ins2^{Akita/+}$ mice. Further, RGD treatment significantly down-regulated expression of TGF-β1 (2-fold, $p<0.01$), OPN (2.3-fold, $p<0.01$), and NADPH oxidase (p47; 2.5-fold, $p<0.01$).

**Conclusions:** RGD-peptide blockade of $\alpha_5\beta_1$-integrin function in type 1 diabetic mice significantly prevented early Type 1 DN possibly via attenuation of OPN and oxidative stress. The results suggest that RGD-peptide may have some therapeutic potential in human type 1 DN.

## SA-PO123

**Lipid Peroxidation in Metabolic Syndrome Affects Podocyte Physiology and Insulin Signaling** Krisztian Stadler, Christine Howard, Ellen Cleland. *Oxidative Stress and Disease, Pennington Biomedical Research Center, Baton Rouge, LA.*

**Background:** Podocytes are essential cells in the structure of the glomerular filtration barrier. Early podocyte loss is characteristic to chronic kidney disease in obesity, metabolic syndrome and diabetes. The role of redox imbalance has been implicated in chronic kidney diseases but it is not known how metabolic syndrome related accumulation of toxic end products affects podocyte physiology and insulin sensitivity. Lipid radicals are produced in a lipid peroxidation process where the accumulation of end products such as 4 – hydroxynonenal and isoprostanes is well known in human obesity.

**Methods:** To assess this relationship, we investigated the specific effects of lipid peroxyl radicals on podocyte physiology and function in vitro and in vivo. We used conditionally immortalized podocytes and two animal models of metabolic syndrome with renal impairments, our state of the art immuno-spin trapping approach and specific lipid radical scavenging.

**Results:** In vitro, in podocytes lipid peroxyl radicals reduced motility of the cells in a dose dependent fashion. Furthermore, these radicals compromised basal Akt phosphorylation affecting insulin sensitivity and cell survival of podocytes. In vivo, uninephrectomized DBA/2J mice on high fat diet and obese SHHF rats showed impaired Akt or p42/44 MAPK phosphorylation in their podocytes upon insulin stimuli. Increased secondary protein radical formation was detected by a novel immuno-spin trapping approach in the glomeruli. When animals were treated with a specific radical scavenger POBN for 14 days, podocyte insulin sensitivity has significantly improved.

**Conclusions:** These results suggest that redox imbalance and excess lipid peroxyl radical production, accompanying obesity and metabolic syndrome may affect podocyte physiology and insulin sensitivity and therefore may contribute to the loss of podocytes seen in the early phases of chronic kidney disease.

## SA-PO124

**Albumin-Bound Fatty Acids Induce a Peroxide Mediated Redox Sensitive Apoptosis of Proximal Tubular Cells – The Role of Peroxiredoxin 2** Krisztian Stadler, Christine Howard, Ellen Cleland. *Oxidative Stress and Disease, Pennington Biomedical Research Center, Baton Rouge, LA.*

**Background:** Metabolic syndrome is an independent risk factor for albuminuria and chronic kidney disease (CKD). It is associated with an oversupply of the nutrient pool and the accumulation of related toxic end products from lipid peroxidation and irregular fatty acid metabolism. While podocytes are insulin sensitive, proximal tubular cells are almost completely lacking glycolysis and preferably oxidize fatty acids. We have hypothesized that a fatty acid overexposure therefore can induce tubular mitochondrial and cellular redox imbalance, ultimately contributing to the activation of redox sensitive apoptotic pathways.

**Methods:** To test this, we have exposed Nrk-52 proximal tubular epithelial cells to pure albumin(BSA), fatty acid contaminated albumin (BSA(FA)) and palmitate (Palm) in various doses and time points.

**Results:** Both BSA(FA) and Palm but not BSA compromised mitochondrial viability, potential and decreased basal respiration, ATP turnover and spare respiratory capacity. Apoptosis was evident in cells with longer exposure or higher doses, through the activation of a redox sensitive pJNK/caspase-3 pathway. This was associated with a decrease in peroxiredoxin 2 expression and an increase of the overoxidized dimer form $Prx\text{-}SO_3$ and catalase. This suggests a peroxide mediated redox sensitive signaling where FA exposure targets peroxiredoxin 2, ultimately leading to the apoptosis of tubular cells. Transfection with Prdx2 rescued cells from caspase 3 cleavage and death.

**Conclusions:** These results suggest that albumin overloaded with fatty acids but not pure albumin itself changes the redox environment in the tubuli, inducing a peroxide mediated redox sensitive tubular cell apoptosis. Thus mitigating FA levels may be an important factor in maintaining redox balance and for the prevention of tubular cell damage in proteinuric diseases.

*Funding:* NIDDK Support, Private Foundation Support

## SA-PO125

**Sphingomyelinase Activation Triggers in HIV-Induced Podocyte Injury through Altered Cellular Redox and NFkB Pathways** Kamesh R. Ayasolla, Partab Rai, Ashwani Malhotra, Pravin C. Singhal. *Medicine, North Shore LIJ Medical School, New York, NY.*

**Background:** Sphingomyelinase- Ceramide (SM-Cer) cascade has been demonstrated to play an important role in several disease processes leading to inflammation, cell death, tissue and organ damage. However, the role of SM-Cer in the development and progression of HIV-associated nephropathy has not been investigated to date. In the present study, we investigated the effects of HIV-induced SM-Cer activation in altering cellular redox and NFkB pathway in a mouse model of HIVAN (Tg26) as we;as in human podocytes.

**Methods:** Renal tissue sphingomyelinase activity was measured in control and Tg26 (4 week old, n=4) mice. *In vitro* studies, human podocytes (HP) were transduced with either empty vector or HIV (NL4-3). Effect of Tempol (SOD mimetic agent,10 mM) and GW4869 (2 mM, a neutral sphigomyelinase [NSMase] inhibitor) was studied on HIV-induced podocyte reactive oxygen species (ROS) generation and NF-kB activation. In addition, the effect of GW4869 on podocyte activation of MAPK, PKCZ and IKKa, b, and p-p65 was studied in control and HIV milieus. To evaluate alterations in podocyte phenotype, protein blots of EV/HP and HIV/HP were probed for podocyte structural proteins.

**Results:** Renal tissues of Tg26 mice displayed 70-80 percent increases in neutral NSMase activity; similar increase in NSMase activity was observed in HIV/HPs. Both Tempol and GW4869 not only inhibited HIV induced podocyte ROS generation but also attenuated podocyte NF-kB activation. GW48 also inhibited HIV-induced MAPK signaling, PKCz activation, enhanced IKKa, b, p-p65 (Ser311) expressions in HPs. HIV also altered podocyte expression of fibronectin, nephrin, podocin and ZO-1, however, GW4869 and Tempol inhibited these effects of HIV.

**Conclusions:** HIV-induced sphingomyelinase activity contributes to an altered podocyte phenotype in HIVAN.

*Funding:* NIDDK Support

## SA-PO126

**The Uremic Solute Indole-3 Acetic Acid Induces Oxidative Stress via Endothelial Cyclooxygenase-2 Up-Regulation** Marion Sallée,[1,2] Laetitia Dou,[1] Claire Cerini,[1] Stéphane Poitevin,[1] Bertrand Gondouin,[1,2] Noemie Jourde-chiche,[1,2] Francoise Dignat-george,[1] Stephane Burtey.[1,2] *[1]UMR-S 1076, Aix Marseille Univ, Inserm, Marseille, France; [2]Centre de Néphrologie Dialyse Transplantation Rénale, APHM, CHU Conception, Marseille, France.*

**Background:** In chronic kidney disease, uremic solutes induce endothelial dysfunction, inflammation, and oxidative stress, leading to increased cardiovascular risk. Indole-3 acetic acid (IAA) is an indolic uremic solute of tryptophan metabolism. IAA is an agonist of the transcription factor aryl hydrocarbon receptor (AhR). The activation of cyclooxygenase-2 (COX-2) expression by AhR ligands contributes to inflammation and oxidative stress. We therefore hypothesized that IAA participates in inflammation and oxidative stress in chronic kidney disease patients by inducing COX-2 expression via AhR activation.

**Methods:** In cultured human umbilical vein endothelial cells, we studied the effect of IAA on COX-2 induction and activity and on COX-2-dependent reactive oxygen species (ROS) production. We then analyzed the signaling pathways related to AhR, involved in COX-2 up-regulation. We finally measured IAA, malondialdehyde, and C-reactive protein serum levels in 68 chronic kidney disease patients.

**Results:** In endothelial cells, IAA increased COX-2 mRNA and protein expression via an AhR/p38MAPK/NF-kB pathway. Furthermore, IAA increased COX-2 activity, reflected by prostaglandin E2 and ROS production. The participation of IAA in oxidative stress and inflammation was corroborated in chronic kidney disease patients by the association between IAA and the markers of oxidative stress and inflammation, respectively malondialdehyde and C-reactive protein.

**Conclusions:** In conclusion, the uremic solute IAA increases endothelial COX-2 expression via an AhR/p38MAPK/NF-kB pathway and enhances prostaglandinE2 and ROS production. IAA, via AhR activation and COX-2 up-regulation, could contribute to inflammation and oxidative stress in chronic kidney disease.

## SA-PO127

**Post-Transcriptional Regulation of UCP2 by Stanniocalcin-1 in Macrophages, Relevance to Inflammation** Roohi Khan, Luping Huang, Huiming Ju, Tatiana Belousova, Liping Zhang, David Sheikh-Hamad. *Nephrology/Medicine, Baylor College of Medicine, Houston, TX.*

**Background:** Uncoupling proteins (UCPs) reduce mitochondrial superoxide generation and are important for macrophage function. $UCP2^{-/-}$ macrophages generate more ROS compared to WT macrophages and display 5-fold greater toxoplasmacidal activity in vitro; the enhanced activity is abolished by ROS quencher. Mitochondrial ROS in $UCP2^{-/-}$ macrophages potentiate NF-kB, and amplify the inflammatory response. STC1 induces UCP2 in macrophages, reduces ROS – and is critical for macrophage activation; thus, understanding the regulation of UCP2 by STC1 is important. UCP2 mRNA levels are high, contrasting with low protein levels, and because STC1 induces UCP2 in macrophages within 1/2h (3-fold induction within 2-3h), we hypothesized that STC1 regulates UCP2 post-transcriptionally.

**Methods:** We determined: 1) UCP2 mRNA levels (RT-PCR) in STC1-treated macrophages in the presence or absence of actinomycin D, an inhibitor of transcription; 2) UCP2 protein levels (Western blot) in STC1-treated macrophages in the presence or

absence of cycloheximide, an inhibitor of protein synthesis; 3) $C^{14}$-PHE incorporation into UCP2, in macrophages treated with STC1 or vehicle; and 4) residual UCP2 $C^{14}$-PHE in STC1- or vehicle-treated macrophages in the presence of cycloheximide.

**Results:** Induction of UCP2 mRNA by STC1 occurs late (3-fold at 6h and 4-fold at 24h). Treatment with actinomycin D-abolishes UCP2 mRNA levels within 6h (3h half-life), and STC1 does not affect UCP2 mRNA stability. STC1 fails to induce UCP2 protein in the presence of cycloheximide, suggesting that UCP2 induction by STC1 is dependent on protein synthesis. Indeed, STC1 induces $C^{14}$-PHE incorporation into UCP2 10-fold within 3h; but, does not affect its degradation.

**Conclusions:** Early induction of UCP2 protein by STC1 occurs without significant change in mRNA level, consistent with translational control. STC1 induces UCP2 protein synthesis 10-fold; however, since protein degradation is high, STC1-mediated increase in UCP2 protein abundance is only 2-3-fold. This regulatory scheme allows immediate adjustment of UCP2/superoxide and the responses of macrophages to antigenic stimuli or cytokines.

*Funding:* NIDDK Support

## SA-PO128

**Gene Expression Profiling of Young and Aged Wild-Type Mice Reveals Pathways Involved in Kidney Aging** Christine E. Kurschat,[1] Valerie Bartels,[1] Fabian Braun,[1] Peter Frommolt,[2] Bianca H. Habermann,[3] Joachim Schultze,[4] Jan H.J. Hoeijmakers,[6] Peter Nuernberg,[2] Martijn E. Dollé,[5] Thomas Benzing,[1] Roman-Ulrich Mueller,[1] Bernhard Schermer.[1] *[1]Dept II of Internal Medicine, Cologne Univ, Germany; [2]Cologne Center for Genomics, Germany; [3]Max Planck Institute for Biology of Ageing, Cologne, Germany; [4]Life and Medical Sciences Institute, Bonn, Germany; [5]National Institute of Public Health and the Environment, Bilthoven, Netherlands; [6]Erasmus Univ Medical Center, Rotterdam, Netherlands.*

**Background:** Due to the worldwide demographic increase in the elderly population prevention and therapy of aging-related chronic kidney disease have become a major health concern. Currently, models to study renal aging are lacking. To elucidate molecular mechanisms involved in kidney aging we analyzed gene expression profiles of young and aged wild-type mouse kidney tissue to identify novel pathways involved in aging-related kidney disease.

**Methods:** Whole kidney RNA of wild-type mice was extracted at 4, 14, and 96 weeks of age. cDNA was hybridized to Affymetrix microarrays. Statistical analysis was conducted with R/ Bioconductor. GO enrichment and network analyses were performed using the DAVID server and NetBox software.

**Results:** GO term enrichment analysis revealed differentially expressed genes to be involved in lipid metabolism, immune and defense response, and blood vessel morphogenesis. These genes were part of growth receptor and chemokine receptor signaling, inflammation signaling, and complement response. Several genes were already known to be implicated in renal damage, such as Kim1, LFABP1 or N-gal. Histologically, aged mice showed a significant increase in glomerular tuft area and glomerular external diameter.

**Conclusions:** Aged mouse kidney tissue exhibited glomerular hypertrophy and aging-associated histologic alterations. Genes differentially expressed in aged kidney samples were preferentially involved in lipid metabolism, immune response, inflammation signaling and chemokine receptor signaling. Our results will contribute to identifying novel pathways and genes involved in regulating the process of kidney aging.

*Funding:* Government Support - Non-U.S.

## SA-PO129

**Hyperglycemia Enhances Kidney Cell Injury in HIV-Associated Nephropathy (HIVAN)** Partab Rai, Andrei Plagov, Rivka Lederman, Nirupama Chandel, Ashwani Malhotra, Pravin C. Singhal. *Medicine, North Shore LIJ Medical School, Great Neck, NY.*

**Background:** Occurrence of insulin resistance and the development of diabetes has been reported to be increased with the use of protease inhibitors (PI) in HIV patients. In the present study, we evaluated the effect of short term hyperglycemia on renal lesions in a mouse model (Tg26) of HIVAN.

**Methods:** Control (FVBN) and Tg26 mice in groups (n=6) were administered either saline or streptozotocin. Blood sugar and urea nitrogen (BUN) levels were measured. After two weeks, Renal lesions were scored. Renal tissue lysates were probed for vitamin D receptor (VDR) renin, actin and assayed for Ang II. Renal cortical sections were assayed for ROS generation and DNA damage by immunolabeling (dihydroethidum and 8-OHdG).In *in vitro* studies, human podocytes (HPs) were transduced with either empty vector (EV) and NL4-3(HIV). To determine the role of Ang II blockade, oxidative stress, and VDR deficit status, EV/HP and HIV/HP were incubated in media containing either normal glucose (NG, 5mM) or high glucose (HG, 30mM)± losartan ($10^{-7}$M)/tempol (1μM)/EB1089(10pM, VDR agonist) for 24h followed by colabeling for γH2AX (DNA damage) and KU80(DNA repair).

**Results:** FVBN/STZ and Tg26/STZ mice displayed elevated BUN ($P<0.05$) and enhanced proteinuria ($P<0.01$) vs. respective FVBN and Tg26.Tg26/STZ displayed enhanced ($P<0.001$) number of sclerotic glomeruli and microcysts vs. Tg26. Renal tissues of Tg26 displayed down regulation of VDR and enhanced Ang II production vs. control. Hyperglycemia exacerbated down regulation of VDR and production of Ang II in FVBN and Tg26 mice. Hyperglycemia increased kidney cell ROS production and oxidative DNA damage in both FVBN and Tg26 mice. In i*n vitro* studies, HIV down regulated podocyte VDR expression and enhanced renin angiotensin (RAS) activation. Both glucose and HIV stimulated kidney cell ROS generation and DNA damage and compromised DNA repair; however, tempol, losartan (Ang II blocker) and EB1089 provided protection against DNA damaging effects of glucose and HIV.

**Conclusions:** Hyperglycemia activated the RAS and inflicted oxidative stress-mediated DNA damage via down regulation of kidney cell VDR expression in HIV milieu.

## SA-PO130

**The Role of Glycogen Synthase Kinase-3 in Podocyte Apoptosis under Diabetic Conditions** Ji Sun Paeng,[1] Hye-Young Kang,[1] Hyung Jung Oh,[2] Sung Jin Moon,[3] Seung Hyeok Han,[2] Tae-Hyun Yoo,[1,2] Shin-Wook Kang.[1,2] *[1]Severance Biomedical Science Institute, Brain Korea 21; [2]Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul; [3]College of Medicine, Kwandong Univ, Gyoeonggi-do, Korea.*

**Background:** Glycogen synthase kinase-3β (GSK-3β) is involved in the pathogenesis of various kidney diseases. In this study, we examined the changes in GSK-3β activity in podocytes under diabetic conditions and elucidated the functional role of GSK-3β in podocyte apoptosis, a characteristic finding in diabetic nephropathy.

**Methods:** In vivo, 32 rats were injected with either diluent (n=16, C) or with streptozotocin intraperitoneally (n=16, DM), and 8 rats from each group were treated with 6-bromoindirubin-3'-oxime (BIO) for 3 months. In vitro, immortalized mouse podocytes were exposed to 5.6 mM glucose (NG) or 30 mM glucose (HG) with or without BIO. Western blot using sieved glomeruli and cultured podocytes, and TUNEL or Hoechst 33342 staining were performed to identify apoptosis.

**Results:** Urinary albumin excretion was significantly higher in DM rats ($P<0.01$), and this increase was significantly abrogated in DM rats by BIO treatment ($P<0.05$). The protein expression of Tyr216-phospho-GSK-3β was significantly higher in DM glomeruli and in cultured podocytes exposed to HG, indicating that GSK-3β activity was significantly increased in podocytes under diabetic conditions. Western blot analysis revealed that the protein expression of Bax and active fragments of caspase-3 were significantly increased, whereas phospho-Akt, b-catenin, and Bcl-2 protein expression were significantly decreased in DM glomeruli and HG-stimulated podocytes. Apoptosis determined by TUNEL assay and Hoechst 33342 staining were also significantly increased in podocytes under diabetic conditions. The changes in the expression of apoptosis-related molecules and the increase in the number of apoptotic cells in DM glomeruli as well as in HG-stimulated podocytes were significantly ameliorated by BIO.

**Conclusions:** These findings suggest that enhanced GSK-3β activity within podocytes under diabetic conditions is associated with podocyte loss in diabetic nephropathy.

## SA-PO131

**Rosuvastatin Activates Transcription Factor Nrf2 through $p21^{cip1}$ Expression and Prevents Albuminuria through Preservation of Glomerular Endothelial Integrity in AKITA Diabetic Mice** Chieko Ihoriya, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Depto of Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Japan.*

**Background:** Transcription factor Nrf2 plays a crucial role in cellular defense against oxidative stress. Statins have been shown to reduce urinary albumin excretion and maintain the glomerular filtration rate in diabetic kidney disease; however, the mechanism is not fully elucidated. The renoprotective effects of statins may involve their pleiotropic effects, especially anti-oxidant activity. We hypothesized that statin decreases oxidative stress through the modulation of Nrf2 signaling pathway and inhibits urinary albuminuria excretion in diabetic nephropathy. The aims of this study were to assess the role of Nrf2 in rosuvastatin-mediated antioxidant effects in endothelial cells and to further elucidatethe molecular mechanisms of renoprotective effect of rosuvastatin (RSV) treatment.

**Methods:** Wild type (WT) and Akita diabetic mice (AKITA) were treated with RSV for 4 weeks. Urinary albumin excretion and renal histology were examined. Nrf2-antioxidant response element (ARE) activity was measured in human umbilical vein endothelial cell (HUVEC) with luciferase assay after transfection of reporter plasmids containing AREs. The expression of Nrf2-regulated genes was also examined.

**Results:** Increased urinary albumin excretion in AKITA mice was significantly reduced by RSV treatment. The amount of lectin-stained glomerular endothelial surface layer, important for permselectivity in the vascular wall, was significantly reduced in AKITA mice and preserved with RSV treatment. RSV significantly increased the transcriptional activity of the AREs and subsequent expression of Nrf2-regulated genes in HUVEC. Additional experiments with cycloheximide and actinomycin D indicated that RSV extended the half-life of Nrf2 protein. Furthermore, RSV increased $p21^{cip1}$ expression and thereby inhibited degradation of Nrf2 through direct binding of Nrf2 with $p21^{cip1}$.

**Conclusions:** These data indicate that rosuvastatin has anti-oxidative effects through activation of Nrf2, thereby restoring glomerular endothelial function and preventing development of albuminuria in diabetes.

## SA-PO132

**Beneficial Effects of Insulin in Subtotal Nephrectomy May Involve Atypical AMPK Activation** Joseph Satriano, Aihua Deng, Roland C. Blantz. *Nephrology, UCSD & VASDHS, San Diego, CA.*

**Background:** Chronic kidney disease (CKD) is a progressive disorder impacting kidney function and metabolic efficiency, eventually leading to renal lesions and fibrosis. We have previously shown that 5' AMP-activated protein kinase (AMPK) levels are low

in the subtotal nephrectomy (STN) model of CKD and that reestablishing AMPK activity in STN animals via agonist administration normalized kidney function (GFR), metabolic efficiency (oxygen consumption/sodium transport, QO2/TNa) and abrogated kidney lesions and fibrosis apparent at 30 days STN. Insulin administration has beneficial effects in CKD, yet would be expected to further decrease activity of the energy sensor AMPK. To investigate this conundrum we evaluated AMPK activity in STN animals administered insulin.

**Methods:** We examined the effects of acute insulin treatment (Aspart, 500mU/kg bolus, followed by iv 8mU/kg/min) in rats subject to STN for 7 days. Protein expressions were evaluated by Northern blotting. All values are relative densitometry units±SEM normalized against alpha-Tubulin.

**Results:** AMPK activity (p-AMPK T172/total AMPK) decreases from Con (1.26±0.21) to STN (0.094±0.02), yet surprisingly increases markedly with STN+Insulin (1.08±0.25). Evaluating mTOR components reveals mTORC1 activity (via p70S6K), which inhibits insulin sensitivity, expectedly increases from Con (38±1.8) to STN (6034±3017), but decreases to control levels with STN+Insulin (43±6.8). However, although p-Akt S473 does not increase from Con (3048±430) to STN (3430±116), it does increase with STN+Insulin (4692±177), suggesting a total mTOR increase via mTORC2 in STN+Insulin, which would promote insulin sensitivity. Further, PPAR-g is markedly increased in STN+Insulin (7978±881) animals beyond that of Con (1253±316) or STN (1347±274) animals.

**Conclusions:** Thus the unconventional induction of a AMPK activity by insulin rather than the prototypical mTORC1/insulin resistance response holds the potential of increasing the renoprotective AMPK axis as well as mTORC2/insulin sensitivity axis in the STN model of CKD. Following this line of preliminary data requires further investigation of the components involved.

## SA-PO133

### Regulation of Macrophage Phenotype by M-CSF: GM-CSF Ratio and Its Implication in Diabetic Nephropathy

Satyesh K. Sinha,[1] Susanne B. Nicholas.[1,2] *[1]Charles R Drew Univ of Medicine and Science, Los Angeles, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA.*

**Background:** Diabetic nephropathy (DN) involves infiltration of pro-inflammatory macrophages (MΦ) into kidney tissues. In human, macrophage colony-stimulating factor (M-CSF) and granulocyte-macrophage colony-stimulating factor (GM-CSF) are known to independently promote anti- (M2) and pro- (M1) inflammatory MΦ, however, the effect of the ratio of these growth factors in regulating MΦ phenotype in DN is not known.

**Methods:** Using human peripheral blood monocyte, we characterized the phenotype of M-CSF- (M2) and GM-CSF-induced (M1) MΦ under varying concentrations (5, 15 and 25mM) of glucose and investigated the regulation of MΦ phenotype by IL-10 (M2 marker) or IL-6 (M1 marker) production in the presence of varying ratios of M-CSF:GM-CSF concentrations (2, 5 and 10ng/ml) by ELISA, RT-QPCR and microarray of isolated MΦ RNA.

**Results:** Under high glucose condition (25mM), M-CSF:GM-CSF 10:0 ratio stimulated MΦ secretion of IL-10, which was significantly inhibited when the ratio was changed to 10:2(12.94 vs 7.88pg/ml, $p<0.05$). On the other hand, 0:10 ratio of M-CSF:GM-CSF stimulated MΦ secretion of IL-6, which was counteracted by change in the ratio to 2:10(30.96 vs. 17.68pg/ml), $p<0.05$. Similarly, under high glucose, mRNA expression of IL-6 was up-regulated (9-fold) with M-CSF:GM-CSF 10:2 ratio compared to the 10:0 ratio, $p<0.05$. The expression of IL-6 was down-regulated with M-CSF:GM-CSF 2:10 ratio compared to the 0:10 ratio, $p<0.05$. Microarray analysis of MΦ RNA also identified significant (4-10 fold) up-regulation of several pro-inflammatory genes with M-CSF:GM-CSF 10:2 ratio compared to ratio 10:0 under high glucose, $p<0.001$.

**Conclusions:** The balance between M-CSF and GM-CSF is critical to define MΦ phenotype. Therefore, targeting the ratio of M-CSF:GM-CSF may be beneficial in DN.

### Targeting a Novel Enhancer of TGF-β in Diabetic Nephropathy

Zhonglin Chai, Mark E. Cooper. *Diabetic Complications, Baker IDI Heart and Diabetes Institute, Melbourne, VIC, Australia.*

**Background:** We have reported that Cell Division Autoantigen 1 (CDA1) synergistically enhances TGF-b signalling in diabetic nephropathy (DN) (Tu, et al, Kid Int 2011; 79:199). Using our recently generated CDA1 knockout (KO) and CDA1/ApoE double KO (dKO) mice, we have shown that genetic deletion of CDA1 retards diabetes associated renal injury (Chai, et al, J Am Soc Nephrol 2013, in press). These data suggest that CDA1 plays an important role in DN, which can be potentially retarded by pharmacologically inhibiting the activity of CDA1.

**Methods:** Yeast 2-hybrid system was used to indentify CDA1 binding protein 1 (CDA1BP1) which directly interacted with CDA1 and regulated the activity of CDA1. A 12mer short peptide of CDA1BP1 containing the binding site was used to interrupt the CDA1/CDA1BP1 interaction. CHA-061, a "retro-inverso peptide" of D amino acids was synthesized which contains a previously known "cell penetrating peptide" to allow it to enter cells with increased stability. ApoE KO mice were rendered diabetic by streptozotocin injections. At 5 weeks after diabetes diabetic mice were treated with CHA-061 or vehicle by ip injections twice a week for 5 weeks. Renal parameters as well as biochemical changes in kidney were analysed at 10 weeks after diabetes.

**Results:** CHA-061 reduced mRNA levels of target genes of CDA1 and TGF-b such as collagen I and III by >50% in HK-2 cells. Adenoviral-delivered CDA1 increased collagen I mRNA level by >2-fold, which was blocked by CHA-061 at 0.5 and 5 mM in HK-2 cells. A single ip injection of CHA-061 in ApoE KO mice at 1 and 5 mg/Kg bodyweight reduced renal mRNA levels of TGF-b target genes for >5 days. In the 10-week diabetes study in ApoE KO mice, renal gene expression of TGF-b1, TGF-b2, CTGF, MMP2, VCAM1, collagen III and fibronectin were increased by >2-6-fold in the diabetic group treated with vehicle and this effect of diabetes was blocked by CHA-061. CHA-061 also reduced gene expression of TGF-b type I receptor, TNF-α as well as attenuated diabetes associated increases in gene expression of collagens I, IV, MCP1 and ICAM1.

**Conclusions:** These results demonstrate that pharmacological targeting of CDA1 reduces TGF-b signalling and is potentially effective to retard DN.

## SA-PO135

### tRNA Conformational Change Is the Early Marker of Ischemic Tissue Injury

Eikan Mishima, Daisuke Saigusa, Yoichi Takeuchi, Yasutoshi Akiyama, Takehiro Suzuki, Sadayoshi Ito, Yoshihisa Tomioka, Takaaki Abe. *Tohoku Univ, Sendai, Japan.*

**Background:** Tissue damage by ischemic and oxidative stress is a major factor in the progression of renal failure. Recently, it has been reported that transfer RNA (tRNA) metabolism is important response to protect cells. However, how tRNA senses such stress under these conditions is still unclear.

**Methods:** We examined the tRNA behavior using a newly generated antibody against tRNA-specific modified nucleoside, 1-methyladenosine (m1A). We also established measuring system for m1A by LC-MS/MS and for tRNA derivatives by ELISA.

**Results:** Oxidative stress directly generated the conformational change of tRNA structure detected by in vitro immunoprecipitation assay. The conformation change of tRNA was also confirmed in ischemia-reperfusion damaged tissues by IHC. Such conformation change was occurred at earlier phase than DNA damage detected by TUNEL or 8OHdG staining. By ELISA and LC-MS/MS, we next measured the tRNA derivatives in blood under tissue damage conditions. The circulating tRNA derivatives were increased in various animal tissue damage models (renal ischemia-reperfusion, cisplatin nephropathy, and radiation tissue injury). In addition, in human aortic arch replacement surgery which renal ischemia is inevitable, the circulating tRNA derivatives were increased after reperfusion procedure. The onset of the increase was earlier than that of urinary KIM-1. Furthermore, we examined serum m1A level in general population (n=1033) and their relationship with prognosis for 6.7year. As a result, the serum level of tRNA metabolites was correlated with mortality suggesting the continuous stress damage in the high level group. In CKD patients (n=29), high level of serum m1A was decreased by statin treatment.

**Conclusions:** These data suggested that i) under ischemia and other tissue damages, the conformation change of tRNA was induced, ii) following tRNA derivatives release to the blood occurred, iii) resultant circulating levels are correlate with cell damage and mortality. Thus, detection of intracellular tRNA condition and the measurement of circulating tRNA derivatives is important to detect early renal and tissue damages and for intervention.

## SA-PO136

### TGF-β1 and TGF-β2 Synergistically Mediate the Glomerular Endothelial to Mesenchymal Transition Induced by High Glucose through ROCK Activation

Hui Peng, Yuanqing Li, Canming Li, Zengchun Ye, Meirong Zhong, Tan-qi Lou. *Nephrology, Dept of Medicine, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

**Background:** Our previous study found that EndMT occurs in glomeruli of DKD patients. However, the relevance of this change and the mechanism leading to this change remain unclear. In this study, we assessed the co-relationship between permeability of glomerular endothelial cells and EndMT. Additional, we explored the signaling pathway involved in high glucose induced glomerular EndMT in vitro.

**Methods:** Rat Glomerular Endothelial Cells (GEnCs), which pre-treated with or without TGF-β type 1 receptor inhibitor LY364947 or ROCK inhibitor Y27632, were incubated in medium containing normal glucose (5.5 mmol/L) or high glucose (30 mmol/L) for 48 h. In separated experiments, antibody against TGF-β1 or TGF-β2 was added into the medium in advance, respectively. GenC permeability was assessed by TEER. Real-time PCR was conducted to evaluate the expression of TGF-β1 and TGF-β2, while α-SMA, CD31 and phosphorylation of MYPT1 were determined by western blotting.

**Results:** High glucose caused EndMT which was associated with increased permeability in cultured GEnCs, which was evidenced by the down-regulation of CD31 and up-regulation of α-SMA. Simultaneously, high glucose stimulated the expression of both TGF-β1 and TGF-β2 that were associated with a significant increase in phosphorylation of MYPT1, reflecting an activation of ROCK. Pre-treatments of LY364947 or Y27632 improved GEnCs permeability and prevented the changes of CD31 and α-SMA stimulated by high glucose; moreover, LY364947 pretreatment blocked the phosphorylation of MYPT1 caused by high glucose. Notably, pre-incubating with antibodies against to TGF-β1 or TGF-β2 attenuated the influence of high glucose on α-SMA and CD31, as well as the phosphorylation of MYPT1.

**Conclusions:** Our study demonstrates that high glucose promotes glomerular EndMT which contribute to increased GEnCs permeability. TGF-β1 and TGF-β2 mediated this response synergistically via ROCK activation.

## SA-PO137

**Tempol Attenuates Renal Fibrosis in Mice with Unilateral Ureteral Obstruction: The Role of PI3K–Akt–FoxO3a Signaling** Hye Eun Yoon, Sung Jun Kim, Su Jin Choi, Sungjin Chung, Seok Joon Shin. *Internal Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

**Background:** Oxidative stress contributes to the pathogenesis of chronic kidney disease. Phosphatidylinositol 3-kinase (PI3K), Akt, and Forkhead box O (FoxO) transcription factors control oxidative stress. This study investigated whether tempol, an anti-oxidant, protects against renal injury by modulating PI3K–Akt–FoxO signaling.

**Methods:** Mice received unilateral ureteral obstruction (UUO) surgery with or without administration of tempol. We evaluated renal damage and expression of PI3K, Akt, FoxO3a and their target molecules, manganese superoxide dismutase (MnSOD), catalase, Bax, and Bcl-2 in the obstructed kidneys on days 3 and 7.

**Results:** Collagen deposition and F4/80 macrophage infiltration were significantly lower in tempol-treated mice compared with controls on day 7. The expression of PI3K, phosphorylated Akt, and phosphorylated FoxO3a decreased markedly in tempol-treated mice on days 3 and 7. Tempol increased the expressions of MnSODand catalase on days 3 and 7, and decreased the production of hydrogen peroxideand lipid peroxidation. Significantly less apoptosis, a lower ratio of Bax to Bcl-2 expression and fewer apoptotic cells in TUNEL staining, was observed in tempol-treated mice compared with controls.

**Conclusions:** In conclusion, tempol attenuates oxidative stress, inflammation, and fibrosis in the kidneys of mice with UUO, andthe modulation of PI3K–Akt–FoxO3a signaling may be involved.

## SA-PO138

**Ethanol Causes Oxidative Stress in Podocytes by Inducing Cytochrome P450 2E1 (CYP2E1)** Ellen T. McCarthy,[1] Jianping Zhou,[2] Tarak Srivastava,[3] Ram Sharma,[2] Virginia J. Savin,[1,2] Mukut Sharma.[1,2] *[1]Kidney Institue, KUMC, Kansas City, KS; [2]Research Service, KC VA Medical Center, Kansas City, MO; [3]Nephrology, CMH, UMKC, Kansas City, MO.*

**Background:** Excessive ethanol (EtOH) consumption leads to hypertension while low amounts have beneficial cardiovascular effects. We have shown that low concentrations of EtOH (2µl/mL) increase podocyte expression of CYP isoforms, such as CYP4a12a, that synthesize 20-hydroxyeicosatetraenoic acid (20-HETE) and that 20-HETE protects the filtration barrier. High concentrations (10-20 µL/mL) derange the podocyte actin cytoskeleton. EtOH is metabolized by cell-specific cytosolic alcohol dehydrogenase (ADH) and microsomal CYP2E1. Metabolism of EtOH by CYP2E1 produces superoxide. The metabolic consequences of EtOH in podocytes are unknown.

**Methods:** We examined the effect of EtOH (2-20 µl/mL) on the expression of ADH and CYP2E1 in immortalized murine podocytes. These concentrations correspond to blood alcohol levels seen in humans. We measured expression of ADH and CYP2E1 using qRT-PCR and Western blotting and examined superoxide generation using the fluorescent probe hydroethidine (HE). We tested the protective effect of 20-HETE (100 nM) in some experiments.

**Results:** ADH gene and protein expression were detected in all conditions. ADH gene was upregulated by 2 ($P<0.001$) but not by 10 or 20 µl/mL EtOH. CYP2E1 expression was undetectable in untreated podocytes. EtOH (10 or 20 µl/mL) induced robust expression of CYP2E1 ($P<0.001$) and increased superoxide generation as indicated by HE fluorescence ($P<0.001$). Addition of 20-HETE prevented the increase in superoxide ($P<0.001$).

**Conclusions:** Low concentrations of EtOH upregulate both CYP4a12a and ADH expression. In contrast, higher concentrations cause oxidative stress through induction of CYP2E1 and also downregulate expression of CYP4a12a. This complex pattern of enzyme expression in podocytes is consistent with protection by low-level EtOH consumption via enhanced 20-HETE production. Protection from oxidative injury may be lost during excessive EtOH intake. Further studies are needed to determine the contribution of alcohol consumption to renal disease and progression in humans.

## SA-PO139

**Integrin Linked Kinase (ILK) Regulates AQP2 Independently of cAMP Axis. A New Nephrogenic Diabetes Insipidus Animal Model** Jose Luis Cano-peñalver,[1] Mercedes Griera,[1] Paloma Martín-sánchez,[1] Ines Mora,[1] DIEGO Rodriguez-Puyol,[2] Sergio De Frutos Garcia,[1] Manuel Rodriguez-Puyol.[1] *[1]Biología de Sistemas, Unidad Fisiología, Universidad de Alcala, Alcala de Henares, Madrid, Spain; [2]Fundacion de Investigacion Biomedica, Hospital Universitario Principe de Asturias, Alcala de Henares, Madrid, Spain.*

**Background:** AQP2 modifies the tubular water reabsorption through transcriptional and postraslational content as well as its quick cytoplasm-to-apical membrane trafficking. Phosphorilations by kinases are needed in both short and long-term regulations, including the canonical cAMP-dependent axis pathway: Vasopressin (AVP) binds to its tubular receptor V2R that activates Adenilate Cyclase (AC), which in turn produce cAMP that activates PKA. We are interested in the extracellular matrix messenger ILK (integrin linked kinase) implication that may lead renal functional changes.

**Methods:** We previously shown (ASN kidney week 2012) basal poliuria in transgenic conditional ILK-deleted adult mice (cKO-ILK) compared with controls (WT). Decreased urine osmolality was due to both AQP2 reduced expression and traffic.

**Results:** The present work focused in the in vivo ILK-dependent AQP2 regulation origin. Nephrogenic origin of the diabetes insipidus (NDI) observed in cKO-ILK was confirmed since plasma AVP levels and basal V2R renal expression were not different between groups. 24h treatment with the pharmacological V2R activator desmopressin did increase in both WT and cKO-ILK traffic and expression AQP2, as well as urine osmolality. However statistic differences remained between groups.

The canonical cAMP-dependent pathway was studied in ex-vivo kidney tissue that was short-time treated with desmopressin, AC activator FK or PKA activator 8-Br-cAMP. The pharmacological activation of all these enzymes increased the traffic, but did not completely restore the differences when ILK was depleted.

**Conclusions:** ILK regulates tubular water reabsorption, with unaltered changes in central production of AVP levels, V2R expression and activity. The ILK-dependent AQP2 expression and traffic regulation is independent of the canonical cAMP axis pathway.

## SA-PO140

**Evaluation of Two Rat Chronic Kidney Disease (CKD) Models to Study Efficacy of Alternative Anemia Treatment** Anja Verhulst,[1] Felix W. Funk,[2] Patrick C. D'Haese.[1] *[1]Lab of Pathophysiology, UAntwerpen, Belgium; [2]Vifor(Int) Ltd, St. Gallen, Switzerland.*

**Background:** Next to erythropoietin (EPO), hepcidin (Hep), by limiting iron (Fe) efflux from enterocytes/macrophages, plays a central role in the development of CKD induced anemia. A lack of Hep clearance and the inflammatory status of CKD patients result in increased plasma Hep levels potentiating anemia upon the reduced renal EPO synthesis in these patients. The present study evaluates the potential use of rat CKD models to study efficacy of alternative anemia treatment.

**Methods:** Remnant kidney CKD (RK) was induced in 12 rats by 5/6 nephrectomy. Adenine induced CKD (AD) was generated in 12 rats by feeding 0.75% adenine for 4 weeks. RK and AD rats were followed-up for 11 and 8 weeks respectively. For each model a control (Ctr) group (n=5) was included. Blood/serum (S) parameters were followed-up: hematocrit (Hct), creatinine (creat), Hep and EPO. Liver/spleen Fe content was measured. $p<0.05$ was considered significant (sign).

**Results:** CKD was less severe in RK (Screat 1.02±0.15 vs Ctr 0.40±0.07mg/dl at 3 weeks) compared to AD rats (Screat 2.92mg/dl at 4 weeks). Hct was already sign lower in RK rats (40±3 vs Ctr 45±1%) after 1 week and remained constant thereafter. In AD rats Hct steadily decreased to much lower values: 32±2% at week 4 s and 25±3% at week 8. SHep levels were maximal in RK rats at week 3 (53.6±17.6 vs Ctr 32.3±12.4nM, $p<0.05$) and returned to normal at week 11 (20.5±6.2nM). In AD rats, SHep level was maximal at week 4 (66.3±17.4 vs Ctr 14.8±3.7nM, $p<0.05$) and returned to normal at week 8 (16.32±6.6nM). SEPO levels of AD rats were sign decreased (8.4±2.1 vs Ctr 14.5±6.9pg/ml) at week 8 while remained unchanged in RK rats. Liver Fe was sign increased in AD (86.7±17.5 vs Ctr 54.2±12.3 µg/g ww) and RK rats (107.9±30.1 vs Ctr 64.2±8.3 µg/g ww). In AD rats spleen Fe levels were sign increased also (1024.6±367.3 vs Ctr 334.71±135.6 µg/g ww).

**Conclusions:** In conclusion, AD is a suitable model to study efficacy of anemia treatment since the steep decrease in Hct values goes along with reduced SEPO levels, a substantial rise in SHep, and accumulation of Fe in liver and spleen, the latter pointing to deficient Fe incorporation in hemoglobin.

## SA-PO141

**Urinary Procollagen Type III Aminoterminal Propeptide Associates with Anemia Independent of eGFR in Male Pre-Dialysis CKD Patients** Akira Suzuki,[1] Kodo Tomida,[1] Tatsuya Shoji,[1] Noriyuki Okada,[1] Yoshiharu Tsubakihara,[2] Terumasa Hayashi.[1] *[1]Kidney Disease and Hypertention, Osaka General Medical Center, Osaka, Japan; [2]Conprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Japan.*

**Background:** Tublointerstitial fibrosis is the common final pathway to the end stage kidney disease. The severity of fibrosis assessed by renal biopsy is correlated with eGFR. Erythropoietin (EPO) is produced by the renal interstitial fibroblasts. In chronic kidney injury, sustained inflammation causes the proliferation and transformation of the fibroblasts to myofibroblasts, which leads to the renal fibrosis. Transformed fibroblasts were reported to be no longer able to produce EPO. Recent studies had demonstrated that the urinary procollagen type III aminoterminal propeptide (PIIINP) was correlated significantly with the fibrosis. In this study, the hypothesis was tested that the urinary PIIINP may be associated with the severity of renal anemia in pre-dialysis ESA naive CKD patients.

**Methods:** Forty one patients (CKD stage 3-5) were recruited at Osaka General Medical Center, who were not treated with ESAs. The following parameters were measured in each patient, such as urine and serum PIIINP, ferritin, Hb, serum and urine creatinine, serum albumin, urinary protein, and CRP. Correlation between Hb and each one of the parameters were cross-sectionally analysed. Patients with iron deficiency, all liver diseases and lung fibrosis were excluded.

**Results:** The population included 33 male and 8 female. Since female strongly correlated with low Hb level in this population, the analysis was stratified by sex. In female, any analysis couldn't be done because of the limited number of patients. In male, univariate analysis revealed that Hb level was correlated with urinary PIIINP/Cr ($R=-0.52956$, $P=0.0015$), but not with any other parameters. In multiple regression analysis including eGFR, urinary PIIINP/Cr was significantly and independently associated with Hb level.

**Conclusions:** These results suggested that renal fibrosis might be more important for anemia than eGFR in male pre-dialysis CKD patients.

## SA-PO142

**Diagnostic Accuracy of Placental Growth Factor in Women with Chronic Kidney Disease/Chronic Hypertension and Superimposed Preeclampsia**
Kate Bramham,[1] Paul Seed,[1] Liz Lightstone,[2] Hayley Tarft,[1] Josephine Gill,[1] Lucilla Poston,[1] Lucy C. Chappell.[1] *[1]Div of Women's Health, King's College London, London, United Kingdom; [2]Imperial College Healthcare NHS Trust Renal and Transplant Centre, Imperial College London, London, United Kingdom.*

**Background:** Women with chronic kidney disease (CKD) and chronic hypertension (CHT) are at increased risk of superimposed pre-eclampsia (SPE). Diagnosis of SPE using blood pressure and proteinuria is challenging because both pre-exist or develop in women with CKD or CHT without SPE. Inaccurate diagnosis may result in unnecessary maternal admission and iatrogenic preterm delivery. Placental growth factor (PlGF) is a secondary marker of associated placental dysfunction in pre-eclampsia (PE), with known low plasma concentrations, but its role in diagnosing SPE in women with CKD or CHT has never been explored.

**Methods:** Women with CKD or CHT, SPE, PE and low risk controls, were recruited from two tertiary antenatal clinics after 20 weeks gestation. Diagnoses of PE or SPE were made according to International Society of the Study of Hypertension in Pregnancy guidelines. Plasma concentrations of PlGF were measured with Alere Triage® assay. Proportions of women with low PlGF (<100pg/ml) were compared.

**Results:** Samples from 129 women with CKD or CHT (90 CKD/39 CHT, including 18 with SPE), 24 women with PE and 71 healthy controls were analysed. Proportions of women with low PlGF are shown in Table 1.

| | PlGF ≥100pg/ml, N (%) | PlGF ≤100 pg/ml, N (%) |
|---|---|---|
| Low Risk | | |
| **PE: Yes** | 1 (4%) | 23 (96%) |
| **PE: No** | 40 (56%) | 31 (64%) |
| CKD or CHT | | |
| **SPE: Yes** | 3 (17%) | 15 (83%) |
| **SPE: No** | 78 (70%) | 33 (30%) |

Low PlGF for diagnosing PE in low risk women had high sensitivity(95.8%) and NPV(97.6%), but lower sensitivity (56.3%) and PPV(42.6%), and for diagnosing SPE had high sensitivity(83.3%), and NPV(96.3%), but lower specificity(70.3%) and PPV(42.6%).

**Conclusions:** Low PlGF is the first test to have such high sensitivity and negative predictive values for SPE in women with CKD or CHT. This finding has substantial implications for the future antenatal management of these women and their offspring.

*Funding:* Pharmaceutical Company Support - ALERE

## SA-PO143

**Adiponectin Receptor 1 Expression in End Stage Renal Disease**
Maria P. Martinez Cantarin, Bonita E. Falkner. *Medicine, Thomas Jefferson Univ Hospital, Philadelphia, PA.*

**Background:** Adiponectin is an anti-atherogenic, anti-inflammatory and anti-diabetic cytokine mainly produced in adipose tissue whose production is increased in End Stage Renal Disease (ESRD). Despite this increased level, ESRD is associated with increased insulin reistance, accelerated atherosclerosis and increased inflammation. The goal of the study was to examine Adiponectin Receptor 1 (AdipoR1) expression in skeletal muscle in ESRD.

**Methods:** A sample from the rectus abdominis muscle was obtained while ESRD participants were undergoing kidney transplantation. Another muscle sample was obtained from healthy kidney donors while they were undergoing donation surgery. AdipoR1 protein expression was quantified by Western Blot and AdipoR1 mRNA expression was determined by real time PCR. C2C12 myoblasts were grown and differentiated to myotubes under standard procedures. After differentiation, the myotubes were exposed to 20% uremic and normal serum for 8h and cells were lysed for protein blotting.

**Results:** AdipoR1 protein and mRNA expression was higher in muscle from ESRD participants than normal kidney function controls ($p<0.05$). C2C12 myoblasts exposed to uremic serum had higher AdipoR1 protein expression than myoblasts exposed to normal kidney function serum.

**Conclusions:** Our study suggests that higher adiponectin levels in ESRD patients are accompanied by higher expression of AdipoR1 in skeletal muscle. Our study also indicates that uremia is a direct stimulus for adipoR1 expression by skeletal muscle. Adiponectin resistance in chronic kidney disease is most likely downstream of the adiponectin 1 receptor.

## SA-PO144

**Bone Histology in 25 ESRD Patients with High Turnover Renal Bone Disease in China**
Ying Qian,[1] Xiaonong Chen,[2] Nan Chen.[3] *[1]Nephrology, Ruijin Hospital, Shanghai, China; [2]Nephrology, Ruijin Hospital, Shanghai, China; [3]Nephrology, Ruijin Hospital, Shanghai, China.*

**Background:** To investigate the bone histology in CKD stage 5 patients on maintenance hemodialysis by bone biopsy, to observe the characteristic of all types of renal bone disease expecially the high turnover bone disease and the relationship between various traditional biomarkers (Scr ,Ca, P, ALP,25(OH)D,Alb, Hb,Hct,iPTH,PINP,OC,β-CTX) and bone tissure markers (BV/TV, % ,Tb.Wi, um ,O.Wi , μm ,OS/BS , % ,ObS/BS, % ,OcS/BS , % ,ES/BS, % ).

**Methods:** Bone biopsy were performed in 40 chronic kidney disease (CKD) stage 5 patients and 3 normal persons. Bone tissues were studied by histomorphometric measurement using an automatic image analysis system. Serum level of biomarkers and bone histomorphometric parameters were studied by correlation analysis.

**Results:** 25 uremic patients (62.5%) were found to have high turnover bone disease according to the bone histology . A significantly characteristic of high turnover bone disease was over activity of osteoclasts with or without bone mineral deposit impairment. There was a good correlation of serum calcium and osteocalcin concentrations with histomorphometric parameters (Ca vs Obs/BS r=0.041, P=0.047. Ca vs Ocs/BS r=0.474, P=0.017. Ca vs ES/BS r=0.485, p=0.014. OC vs Obs/BS r=0.678, P=0.031) . The rate of osteoporosis by BMD in highturnover renal bone disease was 40% and the abdominal aortic calcification rate was 60% by lateral abdominal X-rays. Compare with the BMD and bone X-ray, bone biopsy had the more positive findings and high value for diagnosing of high turnover renal bone disease.

**Conclusions:** High turnover bone disease is still the majority type of bone disease in CKD stage 5 patients in China. Serum level of calcium and osteocalcin may have predictive role in high turnover bone disease in clinical practice. Bone biopsy is still the golden standard for diagnose.

**The Relationship between Insulin Resistance and Cardiovascular Disease in Non-Diabetic CKD Patients**
Hui Peng, Qianqian Wang, Jun Zhang, Cheng Wang, Xun Liu, Yuanqing Li, Meirong Zhong, Tan-qi Lou. *Div of Nephrology, Dept of Medicine, the Third Affiliated Hospital of Sun Yat-sen Univ.*

**Background:** Many studies have shown that insulin resistance is closely related to cardiovascular disease (CVD) in general population. However, the correlation has not been well established in non-diabetic chronic kidney disease (CKD). The present study wants to investigate the relationship of insulin resistance (IR) and CVD in non-diabetic CKD patients.

**Methods:** 25 non-diabetes non-dialysis CKD patients (stage 2-5) were enrolled in this cross-sectional observational study. IR index was assessed by the homeostasis model assessment. They were divided into two groups according to IR index: insulin-resistant group(HOME-IR≥2, N=7) and insulin-sensitive group(HOME-IR<2, N=18). SBP and DBP, left atrium diameter (LAD),interventricular septal thickness(IVST), left ventricular diameter(LVD), left ventricular posterior wall thickness (LVPWT),cardiac output(CO), ejection fraction(EF),E/A, cardiac index(CI), carotid artery intima-media thickness (CAIMT),HCO3-, serum creatinine, eGFR(calculated by CKD-EPI formula),blood-lipids and urine protein were collected. All data was analyzed by software SPSS 13.0.

**Results:** Serum creatinine, eGFR, blood-lipids and urine protein were not found significantly different between both groups. Correlation analysis showed that IR was not significantly related to SBP or DBP, LAD, IVST, LVD, LVPWT, CO, EF, E/A, CI, CAIMT or HCO3-. Nevertheless, SBP and DBP, LAD,IVST, LVD, LVPWT, CO, EF, E/A and CI were not significant different between both groups. However, insulin-resistant group had significantly thicker left carotid artery intima-media than insulin-sensitive group (1.050+0.129 vs 0.7455+0.242, P=0.035) as well as significantly less serum $HCO_3^-$ (18.329+2.888 vs 21.750+3.453, P=0.03).

**Conclusions:** This small-sample pilot study indicated IR may have no apparent correlation with cardiac function or cardiac morphological changes in non-diabetic CKD patients. However, those CKD patients with IR had thicker left carotid artery intima-media than insulin-sensitive patients, which suggested atherosclerosis was more severe in those non-diabetic CKD patients with IR.

## SA-PO146

**Important Factors Considered in Excluding Patients from Referral for Kidney Transplant – A Survey of Nephrologists' Views**
Ankita Tandon, Jeffrey P. Yourshaw, Kevin C. Roe, Nasrollah Ghahramani. *Dept of Medicine (Nephrology), Penn State College of Medicine - Hershey Medical Center, Hershey, PA.*

**Background:** Provider perceptions about appropriateness of certain patients for kidney transplant (KT) are potentially important contributors to disparities in KT. We examined nephrologists' perceptions about factors which they consider important in excluding patients from KT referral and analyzed the association between these perceptions and nephrologists' demographic and practice characteristics.

**Methods:** Invitations were sent to 3180 nephrologists in the eastern US. 822 expressed interest, and 250 were randomly invited to complete a questionnaire about demographics, practice characteristics, and their perceptions of the importance of various reasons a nephrologist might not refer patients for KT. A total of 216 surveys with complete responses were analyzed. Chi-square and stepwise logistic regression were performed.

**Results:** The three most common reasons regarded by nephrologists as important for excluding patients were "patient's inadequate social support" (70% of respondents), "limited understanding of the transplant process due to patient's inadequate education" (56%), and "patient's age above 65" (53%). In multivariate analysis, physicians with 2 or fewer transplant centers within a 50 mile radius were more likely to report inadequate social support (OR: 3.15; 95% CI:1.59-6.24; p=0.001) and age greater than 65 years (1.88; 95% CI: 1.01 to 3.49; p=0.04) as reasons to exclude patients from KT referral. Considering limited understanding due to patient's education, as an important reason to exclude patients for KT evaluation was more likely among nephrologists whose practice includes patients, majority of whom, have not completed high school (OR: 3.31; 95% CI: 1.60-6.86; p=0.001).

**Conclusions:** Patient's social support, understanding and age are the most common reasons regarded by nephrologists as important for excluding patients from KT referral. Practice location and overall characteristics of the patient population are important determinants of provider perceptions about the importance of these reasons.

**Depression Is Associated with Missed Hemodialysis Treatment**

Veeda O. Landeras,[1] Michael S. Simonson,[1] Sharon D. Aaron,[3] Marcia R. Silver.[2] *[1]Medicine, Div of Nephrology and Hypertesnion, Univ Hospitals Case Medical Center, Cleveland, OH; [2]Medicine, Div of Nephrology and Hypertension, MetroHealth Medical Center, CLeveland, OH; [3]Social Services, Fresenius Medical Center, Cleveland, OH.*

**Background:** Depression is the most common psychological problem encountered in patients with end-stage renal disease (ESRD). Recent studies demonstrated that psychosocial factors are important predictors of patient outcome. Co-occurrence of depression has been shown to be one of the risk factors of poor prognosis in dialysis patients, partly because it is believed that depressed patients are less likely to adhere to their medication regimen and modify their lifestyle appropriately. Because clinical depression is prevalent among patients with ESRD on hemodialysis, we examined the relationship between clinical depression and missed hemodialysis treatments in an outpatient hemodialysis center.

**Methods:** We conducted a cross-sectional analysis of 71 outpatient adult hemodialysis patients. Inclusion criteria: age > 18 years and able to take written Beck Depression Inventory (BDI) in English. Exclusion criteria: clinical dementia. Patients scored positive for missed dialysis treatments if they had more than two unexcused absences over 12 months.

**Results:** Participantswere 38 % female and 45% African American, and average age was 55. The numerical BDI score correlated positively with missed dialysis treatments ($r$ = 0.248, $P$=0.037). The correlation between BDI score and missed dialysis remained significant after adjusting for age, race and sex in a logistic regression model.

**Conclusions:** Higher BDI score, suggesting the presence of depression, was associated with missed hemodialysis treatments in this pilot study. Future studies should include larger number of hemodilaysis patients and examine other covariates that might contribute to missed hemodilaysis treatments. Also, looking into whether effective intervention, Pharmacological and non-pharmacological, would be at value in this hemodialysis population subset to improve hemodialysis attendence.

## SA-PO149

**Perceptions Regarding Genetic Testing in Populations at Risk for Nephropathy**

Barry I. Freedman,[1] Alison J. Fletcher,[1] Vivek R. Sanghani,[1] Angellina Graham,[1] Jessica N. Cooke Bailey,[1] Ana Iltis,[2] Nancy M.P. King.[2] *[1]Wake Forest Sch Med; [2]Wake Forest.*

**Background:** Genetic testing will become increasingly available over the next decade. It remains important to determine attitudes toward applying test results.

**Methods:** Relative to European Americans (EA), African Americans (AA) are at increased risk for ESKD and biologically mediated factors contribute. Concepts regarding acceptability of genetic testing for disease variants associated with common illnesses were explored in a standardized questionnaire administered to 130 individuals (64 AA; 66 EA) at risk for ESKD based on a 1st-degree relative with ESKD. In AA and EA, mean+SD age of surveyed relatives was 45.5+12.8 and 50.5+14.4 yrs, resp. (p=0.04); with similar relationships to ESKD relatives (child, sib, parent) (p=0.22).

**Results:** AA and EA, resp., wished to know their genetic test results if risk could be: (1) reduced by diet or exercise (100% and 98.5%, p=0.99); (2) reduced by physician treatment (100% and 98.5%, p=0.99); (3) no treatments were available (90.5% and 81.8%, p=0.21). If informed they did not have a disease susceptibility variant, 86.9% of AA and 87.9% of EA would be extremely- or pretty-likely to inform relatives of test results (p=0.84). If informed they had a disease risk variant, 91.8% of AA and 89.4% of EA would be extremely- or pretty-likely to inform relatives of test results (p=0.43). This exploratory assessment of attitudes toward accruing and applying genetic test data in family members at risk for ESKD revealed similar attitudes among AA and EA. Both populations generally appear equally receptive to gathering and applying their genetic test results for common disease. A substantial majority of people with a close relative having ESKD would want genetic susceptibility information regardless of the availability of prevention or treatment and would share this information with relatives.

**Conclusions:** These results suggest the importance of careful study design and disclosure regarding return of research results. They provide important information about how particular populations think about access to genetic information and highlight the desirability of extensive information about genetic susceptibility tests.

## SA-PO150

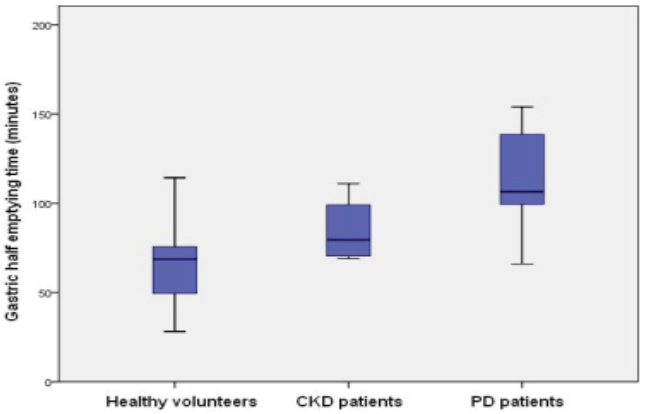
**Dynamic MRI Assessment of Gastrointestinal Motility in Chronic Kidney Disease Patients**

Laura E.A. Harrison,[1] Caroline Louise Hoad,[2] Luca Marciani,[2,3] Penny Anne Gowland,[2] Chris W. McIntyre.[1,4] *[1]Dept of Renal Medicine, Royal Derby Hospital, United Kingdom; [2]School of Physics and Astronomy, Univ of Nottingham, United Kingdom; [3]Nottingham Digestive Diseases Centre, Univ of Nottingham, United Kingdom; [4]Div of Medical Sciences and Graduate Entry Medicine, Univ of Nottingham, Derby, United Kingdom.*

**Background:** Gastrointestinal dysfunction is common in chronic kidney disease (CKD) and associated with malnutrition and inflammation. We assessed gastric emptying in Peritoneal Dialysis (PD) and CKD patients as well as Healthy volunteers (HV) utilising Magnetic Resonance Imaging (MRI) based techniques.

**Methods:** Participants underwent serial MRI fasted and after a mixed liquid/solid meal with measurement of gastric volumes, gastric emptying and motility. Gastric half emptying time (GE $T_{50\%}$) was calculated. 32 participants (8 PD, 8 CKD, 16 HV) were recruited. Data collection included demographics, bloods and GI symptom questionnaires.

**Results:** Gastric volumes immediately post meal ($T_0$) were around 340mls in each group but fell more slowly in PD patients compared to HV. Gastric half emptying time was progressively longer with worsening renal function and slowest in patients on PD. Median GE $T_{50\%}$ in HV was 69 mins [50-76], CKD 72 mins [70-80], PD 107mins [66-140], p=0.005. Three hours post meal, 25% of PD patients had over 30% of $T_0$ volume remaining, compared to 0% in CKD and HV groups. PD patients had significantly higher scores than HV on the Gastrointestinal Symptoms Rating Scale (p=0.01).



**Conclusions:** Gastric emptying is delayed with worsening renal failure and more prolonged in patients receiving peritoneal dialysis, suggesting that dialysis has an additional effect to uraemia related gastric dysmotility. Greater understanding of the factors influencing GI dysfunction is required to address the symptom burden and nutritional challenges these patients are subject to.

## SA-PO151

**Structural, Physical and Functional Characterization of Soluble Ferric Pyrophosphate (SFP), a Novel Iron Compound for Pharmaceutical Applications**

Rameshwar Shukla,[1] Bhoopesh Mishra,[2] Raymond D. Pratt,[1] Ajay Gupta.[1] *[1]Rockwell Medical; [2]Illinois Institute of Technology.*

**Background:** Soluble ferric pyrophosphate (SFP) is the first complex iron salt that does not have a carbohydrate shell for parenteral use. Food grade SFP (FCC-SFP) is a poorly-defined preparation of uncertain composition and is not suitable for pharmaceutical applications. RM-SFP is produced under Good Manufacturing Practice (GMP). RM-SFP has an approximate molecular mass of about 1500 Da and is highly soluble in aqueous solutions. These properties allow its infusion via dialysate (Gupta, Kidney Int. 1999). SFP recently completed Phase III trials in CKD-HD patients.

**Methods:** We synthesized and characterized a RM-SFP, a water-soluble mixed chelate of iron with pyrophosphate (PPi) and citrate (RM-SFP), comprising 7-11% iron, 14-30% citrate and 10-20% PPi (Rockwell Medical Inc., Michigan, US Patent: US 7816404 B2). Because of the amorphous nature of the compound, structural characterization was carried out using Fe K edge X-ray Absorption Near Edge Structure (XANES) and Extended X-Ray Absorption Fine Structure (EXAFS) Spectroscopy to ascertain differences in the coordination environment of Fe in FCC-SFP vs RM-SFP.

**Results:** Linear combination fitting of Fe XANES data showed that iron is in the ferric ($Fe^{3+}$) state and does not complex with sulfate in FCC-SFP or RM-SFP. EXAFS analysis demonstrated that Fe complexation with O in the first coordination sphere (2.02 Å) is similar in both of these molecules. However, significant differences are observed in the coordination environment of Fe with P (3.22 Å) and Fe with and C (2.98 Å) binding in the second coordination sphere of Fe in FCC-SFP compared to RM-SFP. With RM-SFP, significantly faster iron transfer to apotransferrin was observed in-vitro as compared to FCC-SFP.

**Conclusions:** RM-SFP is significantly more soluble than FCC-SFP. In contrast to IV iron-carbohydrate iron complexes, SFP's fast binding kinetics allows $Fe^{3+}$ to bind to apotransferrin (in the blood) for direct transport to the erythron, thereby avoiding reticulo-

endothelial processing and storage. RM-SFP is a unique iron compound and a promising new means of providing iron to CKD-HD patients.

## SA-PO152

**Aortic and Mitral Annular Calcification in Patients with CKD and Diabetes**

Yoshitsugu Obi,[1] Takayuki Hamano,[2] Chikako Nakano,[1] Yasuo Kusunoki,[1] Akihiro Shimomura,[1] Kazunori Inoue,[1] Isao Matsui,[1] Hiromi Rakugi,[1] Yoshiharu Tsubakihara,[2] Yoshitaka Isaka.[1] *[1]Dept of Geriatric Medicine & Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Dept of Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

**Background:** Both CKD and diabetes are well-known risk factors for vascular calcification. We have reported that patients with CKD and diabetes have severe coronary artery calcification (CACS) and high serum calcium-phosphate product. Annular calcification may bring about valvular diseases with stenosis or regurgitation, potentially leading to heart failure. However, the prevalence and etiology of aortic (AAC) and mitral (MAC) annular calcification in CKD with diabetes still remain unclear.

**Methods:** In this cross-sectional study, we quantified AAC, MAC, coronary artery calcification (CAC), and descending aortic calcification (DAC) in patients with stage 3-4 CKD and diabetes using multi-slice computed tomography and the Agatston method. We also assessed the relationships among calcification scores using Spearman's correlation test. Then, the association of calcification scores with patient characteristics was evaluated using multivariate ordinal logistic regression.

**Results:** Among 44 participants, 19 (43%) and 6 (14%) patients had AAC and MAC, respectively. AAC showed a moderate correlation with DAC ($r_s = 0.37$), while only a weak correlation with CAC ($r_s = 0.13$). Older age and lower eGFR were significantly associated with higher AAC and DAC. Other identified risk factors were higher LDL cholesterol for AAC (OR, 3.1 [95%CI, 1.3 to 7.5] per SD, $P = 0.013$) and higher calcium-phosphate product for DAC (OR, 2.2 [95%CI, 1.2 to 4.1] per SD, $P = 0.017$).

**Conclusions:** In patients with stage 3-4 CKD and diabetes, AAC was more common than MAC, and was correlated with DAC, but not with CAC. LDL cholesterol, not calcium-phosphate product, was independently associated with AAC in this population. The different risk factors among AAC, MAC, CAC, and DAC suggest that the different mechanisms are involved in developing calcification.

## SA-PO153

**Reduced Kidney Function, Metabolic Disorders and Male Gender Are Correlates of Serum Uric Acid in Patients Hospitalized due to a Possible Acute Coronary Syndrome**

Zofia I. Niemir,[1] Malgorzata Stasiak-paczkowska.[2] *[1]Dept of Nephrology, Univ of Medical Sciences, Poznan, Poland; [2]Dept of Internal Diseases, HCP Medical Centre, Poznan, Poland.*

**Background:** Raised serum uric acid (Sua) is a known risk factor for the development and progression of both coronary artery and chronic kidney disease. Since acute coronary syndrome (ACS) is a leading cause of morbidity and mortality worldwide, we looked for Sua and its potential relates in patients with this complication.

**Methods:** The study involved 135 consecutive patients with an initial assumption of ACS made in the emergency unit during the period of 3 months and thus hospitalized. The group consisted of 62 females (F) and 73 males (M) with median ages 74 and 63, respectively ($p<0.001$). In addition to the routine cardiologic checkup, and before angiography, serum creatinine (Scr), Sua, lipid profile, albumin, glucose (G), and C-reactive protein (CRP) were measured. Congestive heart failure (CHF) was graded using the New York Heart Association classification. Body mass index (BMI) and estimated glomerular filtration rate (eGFR) were calculated.

**Results:** The median Sua was 5.3 mg/dl in F (2.3 to 15.2 mg/dl) and 6.2mg/dl in M (3.4 to 11.5mg/dl). Diabetes mellitus (DM) was diagnosed in 43.5% of F and 42.5% of M, while CHF in 69.3% of F and 64.4% of M. GFR below 60 ml/min/1.73m$^2$ was found in 54.8% of F and 41.1% of M. After all patient arrangement into Sua quartiles, 37.1% of F allocated to the first quartile vs. 19.5% of M ($p=0.03$). DM was stated in 29.7% of patients from the first compared to 60.6% in the fourth quartile ($p=0.0155$), while CHF in 48.6% and 87.8% ($p<0.001$), respectively. Significant differences between the first and fourth quartile values of Scr ($P<0.001$), eGFR ($p<0.001$), BMI ($p<0.01$), G ($p<0.01$), age ($p<0.05$), and triglycerides (TGL; $p<0.05$) were found. The results of multiple regression analysis showed that eGFR (b=-0.4504; $p<0.0001$), TGL (b=0.3219; $p=0.0002$), BMI (b=0.2598; $p=0.0029$), and male gender (b=0.1830; $p=0.0379$) were independent correlates of Sua in patients with ACS.

**Conclusions:** Our results point to Sua as a biomarker of metabolic and kidney disorders that are involved in the development of ACS.

*Funding:* Government Support - Non-U.S.

## SA-PO154

**Subclinical Cardiovascular Disease Is Associated with High Glomerular Filtration Rate in the Non-Diabetic General Population**

Bjorn Odvar Eriksen,[1,2] Kjell Arne Arntzen,[1,2] Marit Herder,[2] Ulla Dorte Mathisen,[2] Toralf Melsom,[2] Marit D. Solbu,[2] Maja-lisa Løchen.[1,2] *[1]Univ of Tromsø, Norway; [2]Univ Hospital of North Norway, Norway.*

**Background:** Reduced GFR in chronic kidney disease is a risk factor for cardiovascular disease. However, evidence indicates that high normal GFR in apparently healthy persons may also be a cardiovascular risk factor. At present, this issue remains unresolved due to a lack of longitudinal studies of manifest cardiovascular disease with precise GFR measurements. Previous longitudinal studies all used estimates of GFR based on creatinine or cystatin C, which are inaccurate at high levels. Therefore, we performed a cross-sectional study to assess the relationship between high GFR measured as iohexol-clearance and subclinical signs of cardiovascular disease.

**Methods:** GFR was measured in the Renal Iohexol Clearance Survey in Tromsø 6 (RENIS-T6), which consists of a representative sample of middle-aged persons from the general population without prevalent cardiovascular disease. A total of 1521 persons without chronic kidney disease, diabetes, or micro- or macroalbuminuria were investigated with carotid ultrasonography and electrocardiography.

**Results:** GFR in the highest quartile (> 101 mL/min/1.73 m$^2$) was associated with an increased odds ratio of having total carotid plaque area greater than the median of non-zero values (odds ratio 1.56, 95% confidence interval 1.02-2.39) or electrocardiographic signs of left ventricular hypertrophy (odds ratio 1.62, 95% confidence interval 1.10-2.38) compared to the lowest quartile. The analyses were adjusted for cardiovascular risk factors, urinary albumin excretion and fasting serum glucose.

**Conclusions:** High GFR is associated with carotid atherosclerosis and left ventricular hypertrophy in the general middle-aged population and should be investigated as a possible risk factor for manifest cardiovascular disease in longitudinal studies.

*Funding:* Government Support - Non-U.S.

## SA-PO155

**Effects of Low Sodium Intake on the Anti-Proteinuric Efficacy of Olmesartan in Hypertensive Patients with Albuminuria**

Chun Soo Lim,[1] Jin Ho Hwang,[1] Ho Jun Chin,[2] Sejoong Kim,[2] Bum Soon Choi.[3] *[1]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Seoul National Univ Bundang Hospital, Seongnam, Kyunggi-Do, Republic of Korea; [3]Dept of Internal Medicine, Seoul St. Mary's Hospital, Seoul, Republic of Korea.*

**Background:** Blockade of the renin angiotensin aldosterone system (RAAS) reduces albumin excretion rate. The antiproteinuric effect of RAAS blockade can be magnified by dietary salt restriction. We tried to determine the effect of low salt diet in non-diabetic hypertensive patients with albuminuria on blood pressure and urine protein excretion.

**Methods:** This study is open label randomized controlled trial. During a run-in period of eight weeks, patients received Olmesartan. And then, patients were divided into two groups. One group was treated for another eight weeks with Olmesartan plus conventional low salt diet (LSD) education and the other group was treated for eight weeks with Olmesartan plus weekly intensive education on LSD. A total of 270 adult recipients were enrolled, and we performed interim analysis with 195 patients.

**Results:** During a run-in period, daily urinary albumin excretion was significantly decreased after taking Olmesartan for eight weeks (from 928.9 ± 980.8, to 508.6 ± 678.5 mg/day, $P<0.001$). Recipients with intensive LSD education showed more decreased urinary albumin excretion compared to control group (for Δproteinuria, 146.8 vs. -8.3 mg/day, $P=0.028$). The rate of more than 25% reduction in proteinuria was higher in the recipients with LSD education (61.9% vs. 36.7%, $P=0.003$). Urinary sodium excretion for 24-hr was decreased 26.0 mEq/day in the intensive education group. With more reduction in 24-hr urinary sodium excretion, there were tendency of more decrease in systolic BP and urinary albumin excretion (for ΔsBP, 10.1 vs. 8.5 mmHg, $P>0.05$; for Δproteinuria, 221.6 vs. -20.1 mg/day, $P=0.001$).

**Conclusions:** The reduction in salt intake reduced urine protein excretion and systolic BP in RAAS blockade treated hypertensives. Weekly intensive education on LSD would be a suitable method for clinical practice.

*Funding:* Pharmaceutical Company Support - Daiichi Sankyo Company

## SA-PO156

**Urinary Sodium and Kidney Failure in Chronic Kidney Disease**

Li Fan,[1] Hocine Tighiouart,[1] Andrew S. Levey,[1] Gerald J. Beck,[2] Mark J. Sarnak.[1] *[1]Tufts Medical Center; [2]Cleveland Clinic.*

**Background:** Current guidelines recommend less than 2 grams per day sodium intake in individuals with chronic kidney disease (CKD), but there are few data relating sodium intake to long-term outcomes in this population.

**Methods:** 840 patients with CKD enrolled in the Modification of Diet in Renal Disease (MDRD) Study were used to evaluate the association of mean baseline 24-h urinary sodium excretion (as a proxy for sodium intake) with kidney failure (defined as need for dialysis or transplantation) using multivariable Cox proportional hazards models.

**Results:** Mean age was 52 ± 12 years, 60% were men and 85% white. Median proteinuria was 0.32 (IQR, 0.07-1.51) g/day and mean 24-h urinary sodium excretion 3.46 ± 1.13 g/day. 617 participants developed kidney failure during a median follow-up of 6 (range, 0.25 -18.61) years. A two slope model with a cut-off urine sodium of 3 g/day best

fit the data. In those with urine sodium ≥ 3 g/day there was no association between urine sodium and kidney failure in multivariable models. In those with urine sodium < 3 g/day higher urine sodium was associated with increased risk of kidney failure in those with proteinuria <1 g/day [HR 1.72 (95% CI, 1.31-2.24) per 1 g/day urine sodium higher], and lower risk of kidney failure in those with proteinuria ≥1 g/day [HR 0.61 (95% CI, 0.42-0.89) per 1 g/day urine sodium higher]($p$ < 0.001 for interaction). Results were similar using time-dependant values for urine sodium.

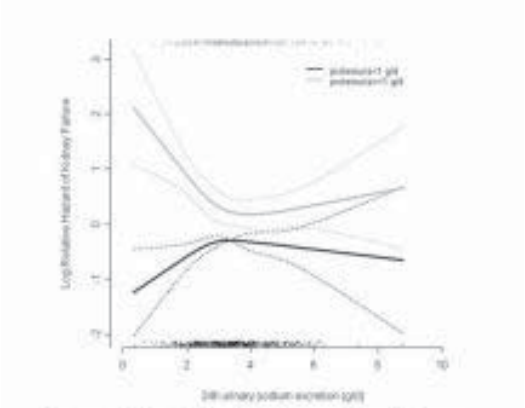

**Figure** Multivariable adjusted association between urine sodium and kidney failure stratified by baseline proteinuria. Splines were adjusted for age, sex, race, cause of kidney disease, measure GFR, log urine protein, BMI, SBP, LDL cholesterol, HDL cholesterol, smoking, diabetes, history of CVD, ACE inhibitor use, diuretic use, randomization to study A or B, and BP and dietary protein target.

**Conclusions:** The association of sodium intake with kidney failure depends on the absolute level consumed, as well as the level of proteinuria. These results need to be verified in additional studies and the mechanism explaining them explored.

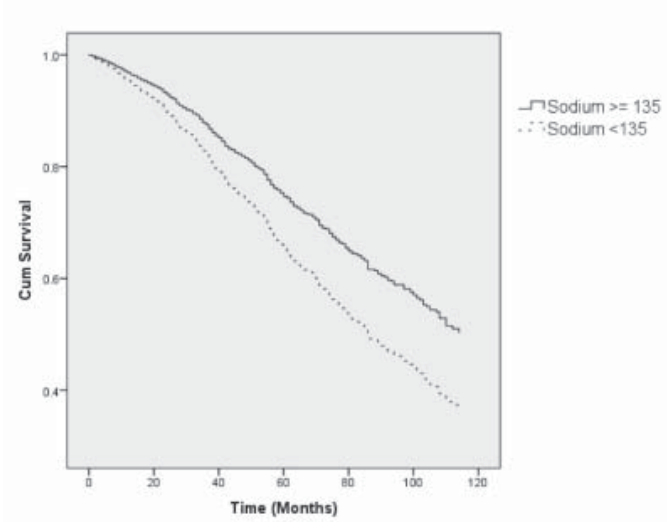
## SA-PO157

**Hyponatremia Is Associated with All-Cause Mortality in Chronic Kidney Disease** Diana Chiu, Darren Green, James Ritchie, Smeeta Sinha, Philip A. Kalra. *Salford Vascular Research Group, Univ of Manchester, MAHSC, Manchester, United Kingdom.*

**Background:** Hyponatremia is one of the commonest electrolyte abnormalities encountered in hospitalized patients. Few studies have investigated the association between hyponatremia and all-cause mortality in Chronic Kidney Disease (CKD).

**Methods:** A cross-sectional analysis of data from the Chronic Renal Insufficiency Standards Implementation Study (CRISIS), a prospective observational study of outcome in patients with all-cause CKD stages 3-5, managed in secondary care, was carried out. Hyponatremia was defined as baseline serum sodium<135mmol/l. Predictors of all-cause mortality were selected from forward stepwise cox regression (including potential confounders: age, gender, smoking status, systolic and diastolic blood pressure, history of heart failure, previous myocardial infarction, diuretic use, renin angiotensin blocker use, eGFR, albumin, hemoglobin).

**Results:** From 2093 patients (mean eGFR 33±16 ml/min/1.73m$^2$), there were 1311 (63%) men, 660 (32%) diabetics, 346 (17%) had a history of heart failure, and 1002 (47.9%) patients were taking diuretics. Mean serum sodium was 140±3mmol/l and 96 (4.6%) patients had hyponatremia (mean 132±2mmol/l, range 125-134mmol/l). After a mean follow-up of 48±33 months, there were 684 (32.7%) deaths. In the final cox regression model, hyponatremia remained a significant independent predictor of all cause mortality (Hazard ratio 1.44, p=0.03, 95% CI 1.03-2.02).



**Conclusions:** There is an association between hyponatremia with all-cause mortality in CKD. It is uncertain whether this is a reflection of the adverse effects of hyponatremia or it is a surrogate marker of existing comorbidities. Further studies are needed to elucidate the cause.

## SA-PO158

**The Effects of Cigarette Smoking in Patients with Chronic Kidney Disease (CKD): Results from the Study of Heart and Renal Protection (SHARP)** Natalie Staplin. *On Behalf of the SHARP Collaborative Group, Clinical Trial Service Unit & Epidemiological Studies Unit, Univ of Oxford, United Kingdom.*

**Background:** Smoking tobacco is a major cause of vascular and non-vascular morbidity and mortality in the general population, but its absolute and relative importance in people with CKD, particularly its relevance to renal progression, is uncertain.

**Methods:** The SHARP study was a randomized trial of LDL cholesterol lowering with ezetimibe/simvastatin in 9270 patients with CKD followed for a median of 4.9 years. The relative risks of particular outcomes associated with baseline smoking status were estimated by Cox regression. Analyses were adjusted for age, sex, ethnicity, country, education and prior disease (vascular disease or diabetes mellitus).

**Results:** At screening, 1243 patients (13%) were current cigarette smokers (median consumption 10 per day), 3272 (35%) were former smokers and 4755 (51%) were never smokers. Compared with never smokers, vascular event risk was 36% higher among current smokers (adjusted hazard ratio 1.36, 95% CI 1.19-1.54) reflecting a 49% increase in atherosclerotic (1.49, 1.26-1.75) and a 25% increase in non-atherosclerotic (1.25, 1.05-1.49) events. All-cause mortality was 48% higher among current smokers than never smokers (HR 1.48, 95% CI 1.29-1.69), with significant increases seen for both vascular (1.35, 1.07-1.69) and non-vascular (1.59, 1.33-1.90) causes of death. Among 6247 patients not on dialysis at randomization, rates of end-stage renal disease (initiation of dialysis or renal transplantation) were similar among current and never smokers (HR 1.02, 95% CI 0.89-1.16) as were (the statistically more sensitive) estimates of annual rates of change in eGFR (mL/min/1.73m$^2$/year: current smokers -2.10 [SE 0.18], former smokers -2.04 [0.11], never smokers -1.97 [0.09]).

**Conclusions:** While smoking does not seem to accelerate renal progression in patients with CKD, it increases vascular morbidity and both vascular and non-vascular mortality to a similar proportional extent as is seen in other populations. The absolute excess risks attributable to smoking in this high risk population are therefore large, and the potential benefits of cessation substantial.

## SA-PO159

**Association of Food Insecurity and End Stage Renal Disease (ESRD) among a National Cohort of Low-Income Adults with Chronic Kidney Disease (CKD)** Tanushree Banerjee,[1] Deidra C. Crews,[2] Donald E. Wesson,[3] Sai Hurrish Dharmarajan,[4] Rajiv Saran,[4] Sharon Saydah,[5] Nilka Rios Burrows,[5] Neil R. Powe.[1] *[1]UCSF; [2]JHU; [3]Texas A&M College of Medicine; [4]UM; [5]CDC.*

**Background:** Poor access to food among low income adults has been recognized as a risk factor for CKD, but there is little data on the impact of food insecurity on development of ESRD. We hypothesized that food insecurity would be independently associated with developing ESRD, that food insecurity would be associated with dietary acid intake and dietary acid intake would modify associations between food insecurity and development of ESRD.

**Methods:** We conducted a national,longitudinal cohort study of 1,451 adult (>20 years) with CKD enrolled in NHANES 2001-2004 with a household income ≤400% of the federal poverty level (FPL). Food insecurity was defined as ≥3 affirmative responses

on the 18-item questionnaire. Net Acid Excretion (NAE) was determined by the dietary recall questionnaire (24 hrs) using a model by Remer and Manz. Development of ESRD was ascertained over an average of 5.4 years of follow-up via linkage to Medicare ESRD Registry. We used a Fine-Gray competing risk model to estimate hazard ratio [HR] for ESRD associated with food insecurity after adjusting for demographics, socio-economic position, diabetes, hypertension, eGFR, urinary albumin:creatinine ratio,daily caloric intake, and NAE.

**Results:** 125 (8.6%) adults with CKD were food insecure. Median NAE in the food secure vs food insecure group was 48.4 mEq/day vs 52.8 mEq/day,(p=0.04). Food insecure individuals were more likely to be males (41.6%), blacks (30.4%), have diabetes (41.6%), or have albuminuria (74.4%) compared to their counterparts (p<0.05). Food insecure adults were far more likely to develop ESRD (HR [95% CI]: 5.5 [5.3-5.6]) compared to food secure adults after adjustment for potential confounders. NAE did not appear to be a mediator of the association between food insecurity and ESRD.

**Conclusions:** Among persons with CKD with a household income ≤400% of the FPL, food insecurity is strongly and independently associated with development of ESRD. Innovative approaches to address food insecurity among CKD patients may be warranted.

## SA-PO160

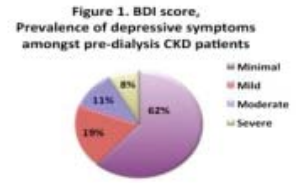
**The FRIENDS Study: Familiarization of Research Regarding Satisfaction with Life and Ways of Coping amongst Chronic Kidney Disease Patients at a Canadian Center** Sassan Ghazan-Shahi, Karen E. Yeates. *Medicine, Queen's Univ, Kingston, Canada.*

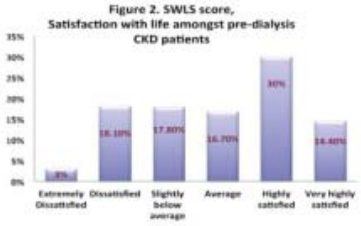
**Background:** The patients with moderate to advanced chronic kidney disease (CKD) are perceived to struggle with high co-morbidity burden related to living with chronic disease. It is the perception that patients may suffer from higher depressive symptoms and poor satisfaction with life and may lack coping mechanisms.The main objectives of this study were to determine the severity of reported depressive symptoms by the subjects and identify the self-perception of satisfaction with life and investigate the existence and frequency of coping strategies.

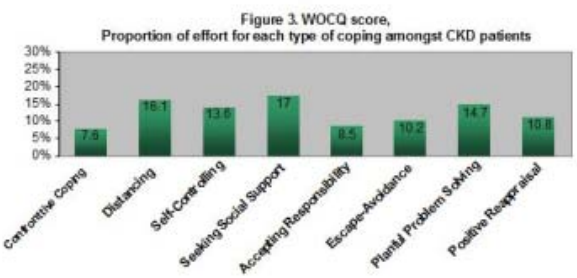
**Methods:** A cross-sectional observational study of Stage III-V CKD patients, enrolled in the multidisciplinary CKD clinic at Kingston General Hospital, Queen's University. The measures used in this study evaluate emotional health and coping through the use of following scales. **Emotional health** § Well-being:Satisfaction with Life Scale (SWLS); § Depression:Beck Depression Index (BDI); **Coping** § Strategy identification:Ways of Coping Questionnaire (WOCQ). Data collection was via self-administered questionnaires and interview.

**Results:** Total of 192 patients fully completed our questionnaires including demographic data and the study measures. 107 patients (55.7%) were male. Mean age ± Standard deviation (Min, Max):70.8±12.5(28.4, 94.9)

62% of patients described minimal depressive symptoms, and 8% described severe symptoms.30% were satisfied with their lives while 18% were dissatisfied. In the Ways of Coping,16% of subjects coped with stressors by distancing themselves and 17% sought social support.







**Conclusions:** Despite having chronic kidney disease, a large proportion of subjects described relatively good satisfaction with life and lower than expected depressive symptoms. Further adjustment with subject co-morbidity and degree of renal insufficiency may yield more specific correlation with these results.

## SA-PO161

**Neighborhood Poverty: A Surprisingly Poor Predictor of Lack of Pre-End-Stage Renal Disease Care at U.S. Dialysis Facilities** Laura Plantinga, Min Kim, Margarethe Goetz, Rachel E. Patzer. *Emory Univ, Atlanta, GA.*

**Background:** Receipt of nephrology care prior to end-stage renal disease (ESRD) is a strong predictor of improved ESRD outcomes, but 34% of U.S. ESRD patients begin dialysis having never seen a nephrologist. Because pre-ESRD care varies geographically, we examined whether neighborhood poverty was associated with lack of pre-ESRD care at facilities.

**Methods:** Geospatially linked data from the 2007-2010 Dialysis Facility Report and 2006-2010 American Community Survey were used in hierarchical mixed-effects models to assess the association of neighborhood poverty (≥20% of households in census tract living below poverty) with facility-level lack of pre-ESRD care (% of patients at a facility with no nephrology care prior to dialysis start), adjusting for facility and neighborhood confounders and allowing for neighborhood and network random effects.

**Results:** Among 5244 facilities, 1799 (34.3%) were located in a poverty area. With adjustment, facility location within a poverty area was not associated with lack of pre-ESRD care: the absolute increase in percentage of patients at a facility with no pre-ESRD care associated with facility location in a poverty area vs. other neighborhood was only 0.1% (95% CI: -13.2%, 14.7%; *P*=0.9). When poverty was examined continuously, potential effect modification by Gini index of income inequality was detected, such that the effect of poverty at a lower, but not higher, level of income inequality was modest but statistically significant.

| Tertile of Gini index | Tertile of % poverty | Absolute % increase in facility-level lack of pre-ESRD care (vs. 0% poverty) | *P* |
|---|---|---|---|
| High (45) | High (20%) | 0.66 | 0.258 |
| High (45) | Low (10%) | 0.32 | 0.258 |
| Low (35) | High (20%) | 1.59 | 0.005 |
| Low (35) | Low (10%) | 0.77 | 0.005 |

**Conclusions:** Despite previously reported detrimental effects of neighborhood poverty on health, it appears to have no substantial effect on facility-level lack of pre-ESRD care in this multi-level, ecological study. However, the observed statistical interaction with Gini index suggests that homogeneity of neighborhood poverty as a predictor of lack of pre-ESRD care may warrant further investigation.

## SA-PO162

**Perceived Racism and Discrimination in Health Care and Medical Mistrust Predict Poorer Health Related Quality of Life in End-Stage Kidney Disease Patients** Michael A. Freeman,[1] John R. Pleis,[2,3] Ron Shapiro,[1] Larissa Myaskovsky.[1,3] *[1]School of Medicine, Univ of Pittsburgh; [2]School of Public Health, Univ of Pittsburgh; [3]VA Pittsburgh Healthcare System.*

**Background:** Health-related quality of life (QOL) is a multi-dimensional concept which measures a patient's subjective experience of their physical, mental, emotional and social functioning. Although many non-medical factors (i.e. financial stress, crime) that influence QOL are beyond the scope of the medical community to address, factors such as experiences of discrimination, racism, and mistrust in health care occur within the medical setting and may be influenced during the course of medical care. Within medicine there has been a renewed focus on a holistic, patient-centered approach to patient care, rather than solely focusing on physiologic markers of health and disease. Given the potential for non-medical factors to affect a patient's QOL, it is important that practitioners be aware of these effects in order to optimize patient care.

**Methods:** Our group is prospectively following a large cohort of end-stage kidney disease (ESKD) patients as they proceed through the kidney transplant (KT) evaluation. In this subsample, 590 patients completed 2 structured interviews: 1 at the time of initial transplant evaluation (T1), and another when transplant evaluation is completed (T2). Perceived racism, experiences of race-based discrimination, medical mistrust and trust in physician were assessed as predictors at T1. QOL was assessed as an outcome at T2 using the KDQOL-SF.

**Results:** Preliminary results indicate that more experiences of discrimination in healthcare, greater medical mistrust and lower trust in one's physician significantly predict poorer QOL across all 9 subscales of the KDQOL-SF (p<0.05). Greater perceived racism in health care predicted poorer QOL on the symptom, effects on daily life, work status and cognitive function subscales of the KDQOL (p<0.05).

**Conclusions:** These data indicate the injurious effect that discrimination and mistrust in health care may have on our patients, and indicate areas for patient-, provider-, and system-level focused interventions.

## SA-PO163

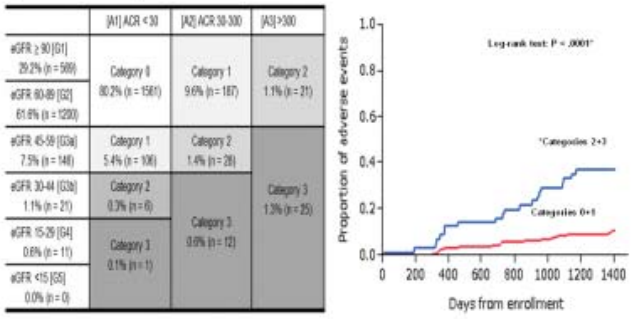
**Clinical Usefulness of KDIGO 2012 CKD Classification in an HIV Population: A Multicenter Study in Japan** Naoki Yanagisawa,[1,2] Minoru Ando,[1,2] Ken Tsuchiya,[1] Kosaku Nitta.[1] *[1]Dept IV of Internal Medicine, Tokyo Women's Medical Univ, Tokyo, Japan; [2]Div of Infectious Diseases, Dept of Medicine, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan.*

**Background:** Chronic kidney disease (CKD) is epidemic among HIV-infected populations, and a determinant of their prognosis. The 2012 KDIGO CKD classification elaborated on how to identify patients at high risk for adverse outcomes.

**Methods:** Distribution of CKD in 1947 HIV-infected subjects (1829 men, 118 women, mean age: 44.9 ± 11.5 years) who regularly visited one of the 5 tertiary hospitals was studied, based on the 2012 KDIGO CKD classification. In addition, prevalence of HIV infection was studied in 176,839 chronic HD patients, according to the questionnaire survey in 1,951 dialysis facilities. Among 1947 pre-dialyzed HIV subjects, 661were prospectively followed up for 3.5 years to determine incidence of composite outcomes, including all-cause mortality, cardiovascular disease and a decline over 25% from baseline in eGFR. Four risk categories were constructed using the combination of 5 stages of eGFR and 3 grades of albuminuria. The cumulative incidence of the outcomes was analyzed with Kaplan-Meier method, and hazard risk (HR) for the outcome incidence was calculated using multivariable proportional hazards regression, adjusted for some known risk factors.

**Results:** The frequency of each category was shown in Table. The prevalence of HIV infection was 0.024% in the chronic HD patients. The Kaplan-Meier estimates were significantly increased over time in the risk categories 2 and 3, compared with the risk categories 0 and 1. The HR of risk categories 2 and 3 was 2-fold greater (HR = 2.00; its 95% confidence interval, 1.08 – 3.57; P = 0.0277), as compared to the other.

Figure. Distribution of CKD among HIV-infected individuals



**Conclusions:** The new KDIGO classification may facilitate targeting of high-risk CKD in the HIV-infected population as well as in the general population.

*Funding:* Government Support - Non-U.S.

## SA-PO164

**Early Start: Co-Morbidities Account for the Lack of Benefit Independently of the Vascular Access Type** Gustavo Laham, Gervasio Soler Pujol, Antonio R. Vilches, Carlos H. Diaz. *Nephrology Section, CEMIC, Ciudad de Buenos Aires, Argentina.*

**Background:** When and how to initiate Hemodialysis (HD) is still controversial. An early start (ES) on HD seems to show a lack of benefit. "Lead time bias" and comorbidities have been associated with different outcomes in ES groups. However, it is well accepted the impact that vascular access (VA) type has on patient survival (PS). Our aim was correlate PS with ES vs. late start (LS) on HD, taking into account the VA used.

**Methods:** Between 1995 and 2012, 322 incidental patients (Pts) initiated HD at CEMIC. eGFR was estimated by the MDRD-EPI equation. Co-morbid conditions were assessed using the Khan index (KI) and Pts were stratified accordingly as having low, median or high risk. Pts were divided in four groups: G1: ES (eGFR > 7 ml/min) with catheter (Cat) access (n=74), G2: ES with native or graft vascular (N/GV) access (n=87), G3: LS (eGFR< 7 /min) with Cat access (n=75), and G4: LS with N/GV access (n=86). The cut-off value to define ES or LS was based on median eGFR for these 322 patients.

**Results:** Mean age was 60.2 years, 60.6% were males, 23.3% were diabetics, median eGFR was 7ml/min/1.73m2 IQR (5-8.9), median follow up time was 30 months, by KI 39,8 %, 28,9 % and 31,4 % belonged to the low, median and high risk groups respectively. 53.4% had a N/GV access. Among the four groups the ES were significantly older (p<0.001), there were more diabetics (p<0.0001) and KI was higher (p<0.0001), while phosphatemia (p<0.0001), albumin (p<0.001), and Hemoglobin (p<0.005), were significantly higher in the LS groups. Survival analysis showed a higher mortality for ES P with a Cat access while LS P with N/GV access had the best survival: log rank p<0.0001. Multivariate analysis revealed that ES with either Cat access (p<0.005) OR 2.285, RIQ (1.29-4.04), N/GV access (p<0.031) OR 1.807, RIQ (1.05-3.08), median KI risk index (p<0.0001) OR 4.8 RIC (2.5-9.3) and high KI risk index (p< 0.0001) OR 12.7 IC (6.7-24.1) were predictors of mortality.

**Conclusions:** In this retrospective study, ES on HD was associated with a higher mortality rate than LS, this was independent of the VA used, but correlated directly with a high prevalence of co-morbidities.

## SA-PO165

**Carbamylated Albumin Is Better Correlated with Time Averaged Urea Levels in Chronic Kidney Disease Than in End-Stage Renal Disease** Tammy Hod, David J. Friedman, S. Ananth Karumanchi, Anders H. Berg. *BIDMC.*

**Background:** Urea carbamylates proteins and amino acids, and carbamylated proteins contribute to atherosclerosis. Deficiencies of free amino acid scavengers promote protein carbamylation. Amino acids stores are depleted in HD patients due to amino acid loss into the dialysate, in contrast to CKD patients in whom protein stores are preserved even when protein intake is decreased. We previously showed that increased urea and decreased amino acid concentrations were independently correlated with protein carbamylation in ESRD patients. Furthermore, the correlation between urea and carbamylated albumin (C-Alb) was significantly stronger in CKD patients as opposed to two ESRD cohorts. We hypothesized that serum levels of C-Alb better represent time-averaged urea concentrations in CKD patients compared to ESRD patients, and that carbamylation in CKD patients is less dependent upon serum amino acid levels.

**Methods:** Serum from 124 subjects with stage 3 or 4 chronic kidney disease were analyzed for carbamylated albumin (C-Alb) and free amino acids using LC-MS/MS. Blood urea nitrogen concentrations were measured using a clinical assay method. Associations between C-Alb, amino acids, and blood urea nitrogen were analyzed using Spearman correlations and partial correlations adjusted for amino acid levels.

**Results:** There was a strong correlation between carbamylated albumin and blood urea nitrogen concentrations amongst our CKD cohort which was not significantly altered when adjusted for differences in amino acid concentrations ($r_s$-0.75, P<0.001). Furthermore, the correlations between carbamylated albumin and serum amino acids were much weaker in these CKD subjects compared to our previously published analysis of ESRD patients.

**Conclusions:** Serum %C-Alb represents a clearer index of average urea concentrations in CKD patients compared to ESRD patients and may serve as an indicator of time-averaged urea levels similar to HbA1C in diabetes.

## SA-PO166

**Has the Prevalence of Hypertension, Diabetes, Obesity Changed among Adults with Chronic Kidney Disease in the U.S. from 1999 to 2010?** Sharon Saydah,[1] Edward Gregg,[1] Meda E. Pavkov,[1] Nilka Rios Burrows,[1] Neil R. Powe,[2] Rajiv Saran,[3] Yi Li,[3] Desmond Williams.[1] *[1]CDC; [2]UCSF; [3]UMich.*

**Background:** Diabetes, hypertension and obesity are risk factors for progression of chronic kidney disease. Whether the prevalence of hypertension, diabetes and obesity has changed in the past decade among adults with CKD in the U.S. is unknown.

**Methods:** Data from the 1999-2010 National Health and Nutrition Examination Surveys in 4 year periods were analyzed to examine trends among adults with CKD (n = 5708). CKD was defined as eGFR < 60 ml/min/1.73 m$^2$ or ACR ≥30 mg/g. Total diabetes (DM) was defined as self report or undiagnosed (undx) DM (A1c ≥ 6.5%). Hypertension (HYTN) was defined self reported HYTN treatment or undx HYTN (blood pressure ≥ 140/90 mmHg). Overweight was body mass index (BMI) 25 to < 30 kg/m$^2$) and obese was a BMI ≥30 kg/m$^2$. Estimates age, sex and race/ethnicity adjusted.

**Results:** Trends and 95% CI in the adjusted prevalence of DM, HYTN and obesity among persons with CKD are shown table.

| CKD population | 1999-2002 | 2003-2006 | 2007-2010 | Absolute % change (95% CI) |
|---|---|---|---|---|
| | % (95% CI) | % (95% CI) | % (95% CI) | |
| Total diabetes | 26.1 (22.8, 29.7) | 26.6 (23.2, 30.4) | 29.6 (27.0, 32.4) | 3.5 (-0.8, 7.9) |
| Undiagnosed diabetes | 4.9 (3.4, 6.8) | 4.0 (2.8, 5.5) | 4.6 (3.7, 5.7) | -0.4 (-2.3, 1.6) |
| Hypertension | 58.6 (55.3, 61.9) | 59.9 (56.9, 62.7) | 61.9 (59.3, 64.5) | 3.3 (-0.8, 7.4) |
| Undiagnosed hypertension | 19.4 (16.7, 22.3) | 14.4 (12.6, 16.4) | 11.5 (10.1, 13.1) | -7.8 (-10.9, -4.74) |
| Obese | 38.7 (33.8, 43.8) | 40.1 (36.8, 43.5) | 42.6 (39.7, 45.6) | 3.9 (-1.8, 9.6) |
| Overweight | 31.0 (27.6, 34.6) | 32.3 (29.6, 35.2) | 29.6 (27.2, 32.4) | -1.2 (-5.5, 3.1) |

The prevalence of undx HYTN decreased by 7.8 percentage points in the past decade.

**Conclusions:** The prevalence of risk factors for CKD progression is high among adults with CKD. While there has been no significant change in the prevalence of DM, HYTN or obesity among adults with CKD in the past decade, the prevalence of undx HYTN decreased.

## SA-PO167

**Natural Experiment with Bosnian Immigrants Who Settled Croatian Endemic Area – Final Epidemiological Evidence** Ivana Vukovic-Lela,[1] Sandra Karanovic,[1] Zivka Dika,[1] Jelena Kos,[1] Ante Cvitkovic,[3] Marica Miletic-medved,[3] Karen Edwards,[4] Arthur P. Grollman,[2] Bojan Jelakovic.[1] *[1]Dept of Nephrology, Arterial Hypertension, Dialysis and Transplantation, Univ Hospital Zagreb, Zagreb, Croatia, Croatia; [2]Dept of Pharmacological Science, State Univ of New York at Stony Brook, New York, NY; [3]Institute for Public Health Slavonski Brod, Slavonski Brod, Croatia; [4]Univ of Washington, Seattle, WA, Croatia.*

**Background:** Endemic nephropathy(EN) represents a form of aristolochic acid nephropathy(AAN) where AA was ingested *via* contaminated bread. Improvement in agriculture that occurred in EN area 25 years ago significantly decreased contamination of flour with AA. A group of immigrants from Bosnian non-EN area settled Croatian EN area 30 years ago(BoEN). This is considered as period long enough for intake of cumulative toxic AA dose. However, due to mentioned improvement it can be supposed that they were no longer exposed to AA. To test this hypothesis we analyzed proximal tubule damage(PTD),an early hallmark of EN, and renal function in BoEN.

**Methods:** 2347 farming villagers were enrolled and divided into 3 groups: autochthonous inhabitants of EN (CroEN;N=1687) and of nonEN villages (Cro-nonEN;N=372), and BoEN(N=102). Subjects were classified according to consensus criteria. Definitions: PTD=α1microglobuline/creatinine(α1CR)>31.5 mg/g;CKD=eGFR<60ml/min/1.73m$^2$.

**Results:** There was no difference in age,gender,BMI,BP,DM among groups(all p>0.05). α1CR values were significantly lower in BoEN than in CroEN diseased and suspect to have EN (7.04 vs.102 vs.48;p<0.001) but did not differ from Cro-nonEN(7.39;p>0.05). Prevalence of PTD and CKD was lowest in BoEN compared to CroEN and nonEN (1.3% vs.3.0 vs.8.3%; 5.9% vs.8.9% vs.15.8%,respectively;p<0.001). No EN cases were detected in BoEN. Twenty years ago BoEN observed significantly less *A.clematitis* in farming fields, less *Aristolochia* seeds among wheat seeds, and less frequently baked own bread ($\chi^2$=21.6;62.6;31.7, respectively; p<0.001).

**Conclusions:** This natural experiment confirmed our hypothesis that nowadays attenuated exposure to AA will lead to decrease in prevalence and probably to disappearance of EN.

*Funding:* Government Support - Non-U.S.

## SA-PO168

**Significance of Symptoms in Chronic Kidney Disease** Ajin John,[1] Anca Tilea,[1] Brenda W. Gillespie,[1] Michael Heung,[1] Fredric O. Finkelstein,[2] Margaret A. Kiser,[3] Peter Kotanko,[5] Rajiv Saran.[1] *[1]Univ of MI; [2]Metabolism Associates; [3]Univ of NC; [4]Med. Col. of Albany; [5]Renal Research Inst.*

**Background:** Little is known about the prevalence of symptoms in CKD. This study examined prevalence of symptoms in CKD and associations with patient outcomes.

**Methods:** We analyzed data from a prospective cohort (N=2,182; CKD stage 3-5). The Kidney Disease Quality of Life (KDQoL) was administered at enrollment and follow-up visits. A composite symptom score was calculated from KDQoL and symptoms were also abstracted by chart review. Seven KDQoL symptoms were matched with symptoms from chart review: *chest pain, itchy skin, shortness of breath, lack of appetite, washed out or drained, numbness in hands or feet, and nausea or upset stomach*. KDQoL-derived symptoms were dichotomized (no symptoms vs. any degree of symptoms) to allow for comparison with the chart review symptoms using McNemar test. Cox regression was used to test association of overall symptom score and individual KDQoL symptoms with mortality and ESRD, adjusted for age, gender, race, diabetes, BP and eGFR.

**Results:** 64% of patients completed at least one KDQoL. Mean age was 64yr; 54% were men and 70% white. Table below summarizes our findings. The most prevalent KDQoL symptom was 'washed out or drained' (n=949) of which only 31% (n=296) were identified as 'fatigue' by chart-review. The table also shows the results from the Cox survival analysis.

| Symptom (≤ 75) (Higher symptom score = better QoL) | $N_{KDQOL}$ (%) | $N_{Chart-Review}/N_{KDQOL}$ (%) | HR (95% CI) Death -- per 5 unit increase-- | HR (95% CI) ESRD -- per 5 unit increase-- |
|---|---|---|---|---|
| Overal Symptom Score | 533 (38%) | -- | 0.91 (0.86, 0.97) | 0.94 (0.92, 0.96) |
| Nausea or upset stomach* | 506 (36%) | 62/506 (12%) | -- | -- |
| Chest pain* | 317 (26%) | 34/371 (9%) | -- | -- |
| Shortness of breath* | 776 (55%) | 213/776 (27%) | 0.96 (0.92, 0.98) | -- |
| Lack of appetite* | 484 (34%) | 84/484 (17%) | 0.95 (0.91, 0.98) | -- |
| Faintness or dizzyness | 495 (35%) | -- | 0.98 (0.93, 0.99) | -- |
| Washed out or drained* | 949 (67%) | 296/949 (31%) | 0.95 (0.92, 0.99) | 0.97 (0.96, 0.99) |
| Numbness in hands or feet* | 729 (52%) | 117/729 (16%) | 0.96 (0.93, 0.99) | 0.96 (0.95, 0.98) |
| Dry skin | 717 (51%) | -- | 0.96 (0.93, 0.99) | 0.97 (0.96, 0.99) |
| Itchy skin* | 780 (55%) | 92/780 (12%) | -- | 0.97 (0.96, 0.99) |
| Cramps | 942 (67%) | -- | -- | 0.98 (0.96, 0.99) |

*Significantly different by McNemar's test

**Conclusions:** Symptom burden was high in this US cohort with CKD stage 3-5. Certain symptoms were associated with mortality; others with time to ESRD. The significantly lower frequency of symptom documentation in clinic charts points to a potential practice improvement opportunity to identify high risk CKD patients.

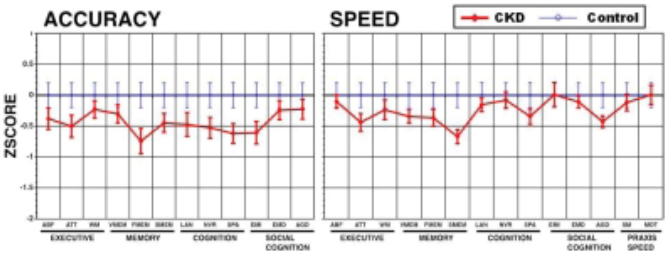
## SA-PO169

**Cognitive Performance on a Computerized Neurocognitive Battery in Children and Young Adults with CKD** Divya Ganeshmurthy Moodalbail,[2] Nina Laney,[2] Ruben C. Gur,[1] Allison M. Mott,[1] Stephen R. Hooper,[3] Jerilynn Radcliffe,[2] Abbas F. Jawad,[2] Kosha Ruparel,[1] Susan L. Furth.[2] *[1]Univ of Pennsylvania, Philadelphia, PA; [2]Children's Hospital of Philadelphia, Philadelphia, PA; [3]Univ of North Carolina School of Medicine, Chapel Hill, NC.*

**Background:** Deficits in IQ, memory, attention and executive function have been reported in children with CKD, which may contribute to poor adherence to complex medical regimens and high rates of morbidity and mortality.

**Methods:** Cross sectional observational study of 42 children and young adults with CKD (eGFR ≤90 ml/min/1.73m2) and 25 healthy controls, ages 8-25 years. Cognitive performance was measured using a cognitive neuroscience-based computerized battery comprised of 14 tests scored on Accuracy and Speed: executive-control (abstraction/ mental flexibility, attention, working memory), episodic memory (verbal, facial, spatial), complex cognition (language and nonverbal reasoning, spatial processing), social cognition (emotion identification, emotion intensity differentiation, age differentiation), and sensorimotor and motor speed. Scores for CKD subjects were transformed to Z-scores using the mean and SDs of the control group as comparison.

**Results:**



Mean(SD) age and eGFR were 15(3) yrs and 42(23)ml/min/1.73m2 for CKD group and 15(3) yrs and 96(15)ml/min/1.73m2 for controls. CKD group was 64% male, 67% Caucasian, control group was 62% female, 58% African-American. Means+/-SEM of the NICK group compared to controls are shown in Figure 1. CKD subjects showed significant deficits in accuracy for face memory and spatial processing, and in speed for spatial memory and age differentiation.

**Conclusions:** Compared to controls, CKD subjects showed relative weaknesses in several areas, particularly for facial memory accuracy and spatial memory speed, with an effect size ≥ 0.5 SD.

*Funding:* Other U.S. Government Support

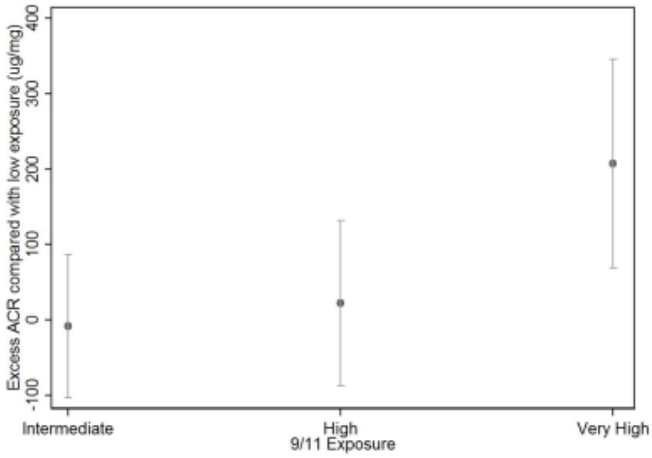
## SA-PO170

**New Evidence That Particulate Matter Exposure at Ground Zero Is Associated with Kidney Damage** Mary Ann McLaughlin,[1] Sarah F. Sanghavi,[1] Cynara Maceda,[1] Mark Woodward,[2] Laura E. Crowley,[1] Christina M. Wyatt.[1] *[1]Mount Sinai School of Medicine, New York, NY; [2]Univ of Sydney, Australia.*

**Background:** First Responders working at Ground Zero following the 9/11 tragedy were exposed to particulate matter including cement dust, smoke, glass fibers, and heavy metals. Particulate matter can deposit in microvascular walls, and inflammatory markers have been shown to be elevated post-exposure. We have previously demonstrated abnormalities in pulmonary and cardiac function in this population, but effects on the kidneys have not been explored. The purpose of this study is to assess renal endothelial damage in first responders exposed to particulate matter at Ground Zero using albuminuria as a marker.

**Methods:** We evaluated 183 consecutively enrolled first responders from the WTC –CHEST Program, a subset of the World Trade Center Clinical Center of Excellence. Participants provided information about particulate matter exposure on entry to the program, and exposure score was calculated based on proximity to Ground Zero, time of arrival, and duration of exposure. We measured urine albumin to creatinine ratio and performed a multivariable regression analysis adjusting for age, gender, race, smoking status, BMI, HbA1c, and hypertension.

**Results:** We demonstrated a significant linear trend (p=0.009) between level of exposure to particulate matter and albumin to creatinine ratio. Participants with the highest exposure to particulate matter had an albumin to creatinine ratio of 207ug/mg greater than the low exposure group (95% CI 69 to 345, p= 0.003) in the adjusted model.



**Conclusions:** We observed a statistically significant independent relationship of high exposure to particulate matter with albuminuria in this cohort after controlling for pertinent risk factors. This novel finding paves the way for future studies of environmental exposures and inflammation in the pathogenesis of albuminuria.

## SA-PO171

**Skin Autofluorescence: A Non-Invasive Test to Improve Mortality Risk Prediction in Chronic Kidney Disease Stage 3** Maarten W. Taal,[1] Simon D.S. Fraser,[2] Paul J. Roderick,[2] Scott Harris,[2] Natasha J. McIntyre,[1] Richard J. Fluck,[1] Chris W. McIntyre.[1] *[1]Royal Derby Hospital; [2]Univ of Southampton.*

**Background:** Novel markers are needed to improve risk prediction in CKD. One potential candidate is tissue advanced glycation end product (AGE) accumulation, a marker of cumulative metabolic stress that can be assessed non-invasively by measurement of skin autofluorescence (SAF). SAF correlates with higher risk of cardiovascular (CV) events in people with diabetes and people requring renal replacement therapy. We aimed to investigate SAF as a predictor of all-cause mortality in a large cohort of people with CKD stage 3.

**Methods:** People with eGFR 59-30ml/min/1.73m$^2$ on 2 occasions prior to inclusion were recruited from Primary Care. Medical history was obtained and participants underwent clinical assessment as well as urine and serum biochemistry tests. SAF was measured using an AGE Reader® (DiagnOptics, Groningen, The Netherlands). The UK Health and Social Care Information Service provided date and cause of all deaths.

**Results:** Mean age was 72.9±9 years and baseline eGFR 52.2±10.4ml/min/1.73m$^2$. After a median of 3.6 years 179 of 1707 (10.5%) had died. The most common cause of death was CV disease (41%). Kaplan-Meier plots showed a progressive increase in all-cause mortality with higher SAF in tertiles. Cox proportional hazards models identified SAF as an independent predictor of all-cause mortality (Table).

| | | HR | 95% CI | p-value |
|---|---|---|---|---|
| SAF (units) | | 1.41 | 1.10-1.80 | 0.007 |
| Age (years) | | 1.07 | 1.05-1.10 | <0.001 |
| Previous CVD | | 2.13 | 1.54-2.94 | <0.001 |
| eGFR (ml/min/1.73m$^2$) | ≥60 | 0.39 | 0.21-0.75 | <0.001 |
| | 30-44 | 1.19 | 0.84-1.68 | |
| | <30 | 2.79 | 1.40-5.56 | |
| Albuminuria | | 1.79 | 1.25-2.56 | 0.001 |

**Conclusions:** We have identified SAF measurement as a simple, non-invasive test that predicts of all-cause mortality independent of several other well-established risk factors in a cohort of predominantly older people with CKD stage 3. Further research should focus on how best to incorporate SAF into risk prediction models and on interventions that may reduce AGE accumulation and the associated risk.

## SA-PO172

**Prevalence and Determinants of Hyperoxaluria in Chronic Pancreatitis** Nathalie Demoulin,[1] Zaina Issa,[1] Ralph Crott,[2] Michel Y. Jadoul,[1] Pierre H. Deprez.[3] *[1]Nephrology, Cliniques Universitaires Saint-Luc, Belgium; [2]Public Health, Cliniques Universitaires Saint-Luc, Belgium; [3]Gastroenterology, Cliniques Universitaires Saint-Luc, Univ Catholique de Louvain, Belgium.*

**Background:** Chronic pancreatitis (CP) has been linked to enteric hyperoxaluria and acute oxalate nephropathy. Our aim was to evaluate the prevalence and determinants of hyperoxaluria in patients with CP.

**Methods:** Adults with CP (diagnosis based on CT or MRI imaging) seen at the gastroenterology day clinic in our hospital from 01/03 to 31/10/2012 were asked to participate. Pancreatic exocrine function was evaluated in all by fecal elastase (a pancreatic enzyme) and fecal acid steatocrit (a reliable measure of steatorrhea on a spot stool specimen). Oxaluria was measured twice.

**Results:** Forty eight patients accepted to participate. The cohort was 96% Caucasian, 50% male and 40% diabetic (63% on insulin). Etiology of CP was alcoholic in 29%, autoimmune, obstructive or hereditary in 19% and idiopathic in 52% of patients. CP was diagnosed a median of 4.5 years before inclusion. Estimated GFR was >60 ml/min/1.73m$^2$ in all patients, 2 had ACR between 30 and 300 mg/g. Clinical steatorrhea was present in 17% of patients and 48% were taking pancreatic enzyme supplementation. The 2 oxaluria measures were well correlated (ρ=0.68). Eleven patients (23%) had hyperoxaluria (>32mg/g of creatininuria, median 49 (35-75)). Oxaluria was moderately correlated with clinical steatorrhea (ρ=0.46), pancreatic enzyme treatment (ρ= 0.32) and fecal steatocrit (ρ=0.44) and inversely correlated with fecal elastase (ρ= -0.42). Age, diabetes, smoking and alcohol habits, BMI, HbA1c, vitamin A, D and E levels, INR and calciuria were not correlated with oxaluria.

**Conclusions:** To our knowledge, our study is the first to define the substantial (23%) prevalence of hyperoxaluria in a cohort of patients with CP. These patients are possibly at risk of developing acute oxalate nephropathy and nephrolithiasis, especially in case of intercurrent hypovolemia. Clinical and fecal indices of steatorrhea were moderately correlated with oxaluria. Intensifying pancreatic enzyme supplements and calcium supplementation could be proposed in patients with hyperoxaluria.

## SA-PO173

**Kidney Magnetic Resonance Imaging Reveals Structural Abnormalities That Are Associated with Kidney Function and Risk Factors for Adverse Outcomes in an Older Community-Based Cohort** Todd Woodard,[1] Sigurdur Sigurdsson,[2] John D. Gotal,[1] Alyssa A. Torjesen,[1] Lesley Inker,[3] Thor Aspelund,[2] Gudny Eiriksdottir,[2] Vilmundur Gudnason,[2] Tamara Harris,[4] Lenore J. Launer,[4] Andrew S. Levey,[3] Gary F. Mitchell.[1] *[1]Cardiovascular Engineering Inc; [2]Icelandic Heart Association; [3]Tufts Medical Center; [4]National Institute on Aging.*

**Background:** Because of the ability of the kidney to autoregulate perfusion and filtration, estimated glomerular filtration rate (eGFR) may underestimate early structural damage such as fibrosis, which contributes to disease progression and may be detectable by kidney imaging.

**Methods:** We performed dynamic contrast enhanced magnetic resonance imaging (DCE-MRI) renography by using rapid 3D imaging of the kidneys for 5 minutes following injection of 1 mmol of Gd in 514 participants (79±4 years old, 57% women) in the AGES-Reykjavik Study. After tracing the kidney contour (excluding large cysts), custom software automatically segmented kidney tissue into 6 types: cortex, medulla, pelvis, fat, fibrosis or none of the above based on template matching of intensity-time data for each voxel. Fibrosis was defined empirically as voxels with persistently low signal intensity during DCE-MRI. A stepwise multiple regression model that entered age, sex, body surface area (BSA) and eGFR was used to examine relations between fibrosis and potential correlates of adverse outcomes.

**Results:** Mean total kidney volume was 335±82 ml, eGFR was 67±15 ml/min/1.73m$^2$ and fibrosis was 8.2±5.0% of kidney volume. Higher fibrosis % (model $R^2$=0.49, P<.001) was related to male sex (P=.002), higher BSA (P<.001), lower eGFR (P=.001), higher cardiac output (P<.001), higher heart rate (P=.006), lower hematocrit (P=.001), lower augmentation index (P=.023) and treated hypertension (P=.034).

**Conclusions:** In a community-based cohort of older people, modest kidney fibrosis detected by DCE-MRI was associated with reduced eGFR and other potential risk factors for adverse outcomes. The association of fibrosis with higher cardiac output and heart rate suggests that sympathetic nervous system activation may be a mechanism by which fibrosis detected by DCE-MRI contributes to chronic kidney disease.

## SA-PO174

**The Prognostic Value of a Combined Renal Artery Patency Score in Atherosclerotic Renal Artery Stenosis** James Ritchie, Darren Green, Philip A. Kalra. *Salford Royal Hospital.*

**Background:** Atherosclerotic renovascular disease (ARVD) is often diagnosed by noninvasive biplane angiography. Most studies define significant disease by the minimum percentage stenosis (MPS) to the most affected kidney and consider bilateral disease in sub-group analyses. We hypothesized that considering both renal arteries (*Suresh et al, NDT 2000*) may better reflect the systemic impact of ARVD.

**Methods:** We compared MPS with a combined renal artery patency score (CPS). CPS is defined as *[200 – combined luminal loss to both kidneys]* such that a score of 200 represents bilateral 0% stenosis and a score of 0 represents bilateral 100% stenosis. 615 patients with ARVD diagnosed using CT or MRI angiography were assessed. Separate Cox models (adjusted for age, eGFR, blood pressure and proteinuria) were constructed to consider prognostic associations of MPS and CPS in relation to death, cardiovascular event (CVE) and progression to dialysis.

**Results:** Baseline age was 70±9 years; eGFR 32 [21-45] ml/min/1.73m$^2$; follow-up of 3.8 [1.8-6.0] years. As a continuous variable CPS significantly associated with risk for death and CVE, MPS did not. When considering bilateral disease, CPS associated more significantly with risk for death than MPS but MPS associated significantly with risk for CVE. Neither measure associated with risk for dialysis.

| | CPS | | | MPS | |
|---|---|---|---|---|---|
| | **Death** | **CVE** | | **Death** | **CVE** |
| Continuous variable | 1.03 [1.01-1.06]** | 1.03 [1.0-1.06]** | Continuous variable | 1.04 [0.9-1.1] | 1.03 [0.9-1.1] |
| <100 vs. >100 | 1.4 [1.1-1.8]*** | 1.3 [1.0-1.7]* | Bilateral >50% vs. not | 1.1 [0.8-1.4] | 1.4 [1.1-1.9]** |
| <80 vs. >80 | 1.3 [1.0-1.6]** | 1.3 [0.9-1.8]* | Bilateral >60% vs. not | 1.2 [0.9-1.6] | 1.5 [1.1-2.0]** |
| <60 vs. >60 | 1.3 [0.9-1.6]* | 1.2 [0.8-1.8] | Bilateral >70% vs. not | 1.5 [1.0-2.1]** | 1.6 [1.0-2.6] |

*Results presented as HR [95% CI]. Continuous variable assessed in 10-unit intervals. * p<0.1; ** p<0.05; ***p<0.01*

**Conclusions:** Defining patients by CPS and MPS appears to have differing prognostic associations in ARVD. Both methods are limited by their inability to consider cross sectional flow.

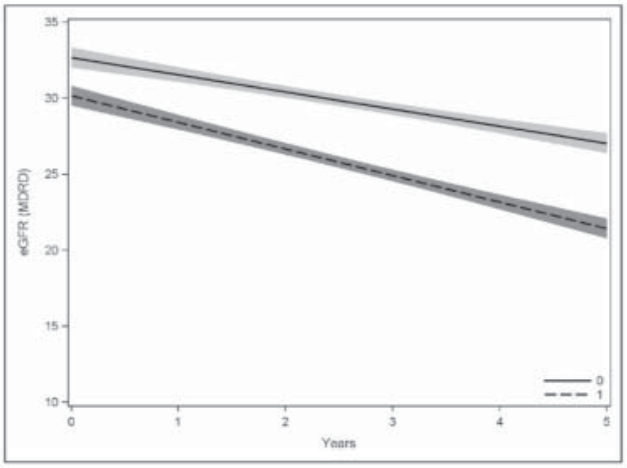
## SA-PO175

**Functional Status Associates with All-Cause Mortality in CKD** James Ritchie, Helen Alderson, Darren Green, Diana Chiu, Smeeta Sinha, Philip A. Kalra. *Salford Royal Hospital.*

**Background:** Global health assessments allow effects of multiple co-morbidities to be compared between patients. Measurements of functional status act as independent predictors for risk of death in the general and dialysis populations, but have not been assessed in a CKD cohort. One commonly used measure is the Karnofsky performance score (KPS).

**Methods:** Patients were selected from the Chronic Renal Insufficiency Standards Implementation Study (CRISIS), a prospective observational study of outcome in patients with CKD 3-5 managed in secondary care. Associations between baseline KPS and risk for all-cause mortality were considered in a multivariate Cox model. Differences in rate of change in eGFR between groups of KPS were assessed in a mixed effects model.

**Results:** 1515 patients with a median follow-up 3.2 [1.5-5.0] years were included in this analysis (584 [39%] KPS 100; 648 [42%] KPS 90; 283 [19%] KPS ≤80). Patients with a higher KPS were younger, had higher eGFR and hemoglobin values and fewer previous macrovascular events. In multivariate analysis (adjusted for age, gender, eGFR, hemoglobin, albumin, diabetes, macrovascular events and diabetes), an association was observed between reductions in KPS at time of recruitment and risk for death; KPS 90 HR 1.2 [0.9-1.5] p=0.1; KPS 80 HR 1.8 [1.4-2.4] p<0.001. In a mixed effects model incorporating proteinuria, diabetes, hemoglobin and blood pressure, annual reduction in eGFR in patients with KPS >80 was 3%, and 5% in patients with KPS ≤80 p=0.008.



*eGFR trajectories predicted from mixed effects model. Solid line – KPS >80; dashed line KPS ≤80. Shaded areas 95% confidence intervals.*

**Conclusions:** This analysis suggests in a secondary care CKD cohort, reduced KPS predicts risk for death independently of renal function and vascular co-morbidities. This increased risk is associated with faster rates of eGFR loss in patients with lower KPS scores.

## SA-PO176

### The Marshfield Epidemiologic Study Area (MESA) Study on Urological Procedures in Urolithiasis and Their Impact on Chronic Kidney Disease

Radmila Mikan Savcic-kos,[1] Jingbo Huang,[1] Matthew R. D'costa,[1] Hong Liang,[1] Andrew D. Rule,[2] Narayana S. Murali.[1] *[1]Dept of Nephrology & Hypertension, Marshfield Clinic, Marshfield, WI; [2]Dept of Nephrology, Mayo Clinic, Marshfield, WI.*

**Background:** Epidemiological evidence exists that stone formers are at increased risk for ESRD. It is unclear if urological intervention impacts prevention or progression of CKD.

The MESA database, established in 1991, performs an automated daily review of all computerized databases of the Marshfield Clinic, finds and follows all residents, 90% of whom receive all care at the Marshfield Clinic or its affiliated centers and hospitals in a 24 zip code area that includes 89,291 patients.

**Methods:** We conducted a retrospective observational cohort study of the patients in MESA between Jan. 1991 and May 2007, where 1340 stone formers were matched by age, gender, and index date with 2712 control subjects. Cox proportional Hazards models adjusted for age, gender, and comorbidities using comorbidity propensity score were performed to evaluate the risk for incident Chronic Kidney Disease (CKD), elevated Serum Creatinine and any-cause mortality. Of the 1340 stone formers, 446 had urological procedures. Stone formers with procedures were compared to those without procedures.

**Results:** Stone formers with a mean of 9.1 yr. of follow-up were at increased risk for elevated SCr (HR (95% CI) = 1.30 (1.16-1.52)) and for CKD (HR (95% CI) = 1.30 (1.03-1.63)). Stone formers had lower rate of any cause mortality (16.2% vs. 25.6% in control group) (HR (95% CI) = 0.49 (0.40-0.59)).

Baseline comorbidities in stone formers with and without procedures were not significantly different except for obesity (p <0.0001). The results did not reveal any significant difference, in prevalence of CKD during the course of follow up after the index date.

**Conclusions:** Stone formers are at increased risk for elevated Creatinine and for CKD but urological procedures per se (e.g., lithotripsy) do not appear to impact prevalence of CKD.

*Funding:* Private Foundation Support

## SA-PO177

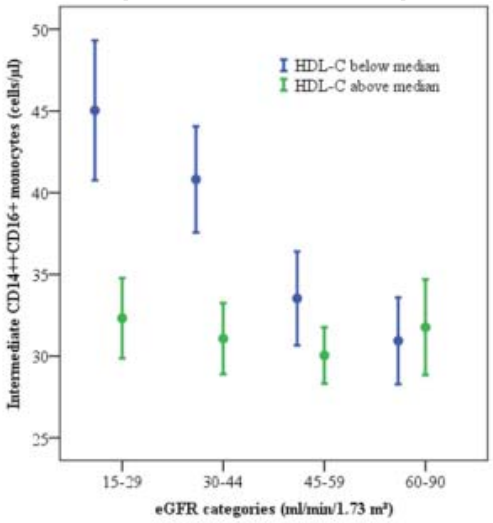
### Interrelationship between Low HDL Cholesterol and Monocyte Subset Distribution in Chronic Kidney Disease

Kyrill S. Rogacev, Adam M. Zawada, Sarah Seiler, Danilo Fliser, Gunnar H. Heine. *Internal Medicine VI, Saarland Uniersity Medical Centre, Homburg, Germany.*

**Background:** In patients with chronic kidney disease (CKD) low HDL and a skewed monocyte subset distribution towards intermediate $CD14^{++}CD16^{+}$ monocytes may contribute to the significantly higher risk of developing cardiovascular (CV) disease. Recent evidence suggests that HDL regulates monocytopoiesis in mice, but it is unknown whether HDL and monocyte subset distribution are linked in CKD patients.

**Methods:** Lipid profiles and monocyte subsets were measured in 438 CKD patients, who were followed-up for the occurrence of a composite CV endpoint.

**Results:** At baseline HDL was inversely correlated with intermediate $CD14^{++}CD16^{+}$ and nonclassical $CD14^{+}CD16^{++}$ monocytes (r = - 0.152; p = 0.001; r = -0.126, p = 0.008, respectively) but showed no significant association with total and classical $CD14^{++}CD16^{-}$ monocyte counts. A significant increase in intermediate monocyte counts with more advanced CKD was seen only in patients with HDL-C below the median [p (for trend) = 0.002], but not in patients with HDL-C above median [p (for trend) = 0.779].



In linear regression analyses, low HDL was an independent determinant of higher intermediate $CD14^{++}CD16^{+}$ monocyte counts (β = -0.138; p = 0.005), but not of total, classical $CD14^{++}CD16^{-}$ and nonclassical $CD14^{++}CD16^{+}$ monocyte counts (p = 0.244; p = 0.504; p = 0.059, respectively). In contrast to HDL, higher intermediate $CD14^{++}CD16^{+}$ monocyte counts predicted adverse cardiovascular outcome in univariate (p = 0.007) and multivariate models (Cox regression analysis: HR per increase of one cell / µl: 1.010, [1.001 – 1.019]; p = 0.034).

**Conclusions:** In CKD, low HDL is linked to higher intermediate $CD14^{++}CD16^{+}$ monocyte counts, which independently predicted adverse outcome. The relationship between HDL cholesterol and monocyte subset distribution in CKD deserves further evaluation.

*Funding:* Private Foundation Support

## SA-PO178

### Evaluation of Stakeholder Opinions on the Use of Surrogate Endpoints in Marketing Authorization of "Renal" Drugs

Bauke Schievink, Hiddo Jan Lambers Heerspink, Dick de Zeeuw, Jarno Hoekman. *Univ Medical Center Groningen.*

**Background:** There is a need for new drugs to delay or halt the progression to end-stage renal disease (ESRD). Drug development can be shortened by using surrogate instead of clinical endpoints. Yet, there is discussion regarding their validity. We designed an online survey to assess stakeholders' opinions on the use of surrogates in nephrology.

**Methods:** The population consisted of a pre-selected panel of experts with a professional background as regulator, industry official or academic researcher (N=145). Respondents were asked to rank 4 stakeholders (patients, industry, academia, regulators) based on the benefits they receive from the use of surrogates, and to value the validity of specific surrogates on a Likert scale from 1 (strongly disagree) to 5 (strongly agree). Analyses were conducted by computing mean scores and by comparing them between professional backgrounds and between nephrologists vs. non-nephrologists using Wilcoxon signed rank tests.

**Results:** Overall, 63 (41%) persons participated. Industry respondents considered use of surrogate endpoints the most beneficial for patients, while other stakeholders considered their use the most beneficial for industry (P<0.01). Respondents disagreed that drugs can only be marketed after hard outcome studies have been done (mean: 2.2, 95% CI: 1.9-2.5). Out of four proposed surrogates (blood pressure (BP), HbA1c, albuminuria, CRP) for two indications (ESRD, CV disease), only use of BP for CV disease was deemed accurate (3.8, 3.6-4.0). Other surrogates had mean scores smaller than 3 (P<0.01 compared to BP for CV disease). For ESRD, use of albuminuria was considered neutral (2.9, 2.6-3.2) and equally accurate as BP (2.8, 2.5-3.1, P=0.53), but more accurate than HbA1c (2.5, 2.2-2.8, P<0.05)

and CRP (1.9, 1.6-2.1, P<0.01). Opinions on the accuracy of these surrogates did not differ between nephrologists and non-nephrologists.

**Conclusions:** Stakeholders in drug development do not oppose to using surrogate endpoints in marketing authorization. However, most surrogates, including albuminuria and BP for ESRD, are not considered accurate.

## SA-PO179

**Serum Cystatin C, Markers of Chronic Kidney Disease and Retinopathy in Indians without Diabetes** Charumathi Sabanayagam,[1,2,3] Boon Wee Teo,[3] Jiemin Liao,[3] Jie Jin Wang,[4] E. Shyong Tai,[3] Sunil Sethi,[3] Tien Yin Wong.[1,3] *[1]Singapore Eye Research Institute; [2]Duke-NUS Graduate Medical School, Singapore; [3]Yong Loo Lin School of Medicine, National Univ of Singapore; [4]Centre for Vision Research, Univ of Sydney, Australia.*

**Background:** Serum cystatin C, a novel marker for chronic kidney disease (CKD) has been shown to be superior to serum creatinine in predicting the onset of diabetes and its complications including nephropathy. Small clinical studies have shown correlations between cystatin C levels and diabetic retinopathy. However, it not clear if cystatin C is associated with retinopathy in subjects without diabetes.

**Methods:** We examined 1,757 Indian adults, aged 40-80 years who participated in the Singapore Indian Eye Study (2007-09) and were free of diabetes mellitus. CKD was defined as an estimated glomerular filtration rate (eGFR) <60 ml/min/1.73m$^2$ determined from serum cystatin C (eGFR$_{cys}$), and serum creatinine (eGFR$_{cr}$). Retinopathy was assessed from digital fundus photographs of both eyes. The associations of CKD-eGFR$_{cys}$ (n=200), CKD-eGFR$_{cr}$ (n=81) and confirmed CKD (eGFR$_{cys}$ <60 and eGFR$_{cr}$ <60, n= 58) with retinopathy were examined using logistic regression models adjusted for potential confounding factors including preexisting cardiovascular disease and albuminuria.

**Results:** The prevalence of retinopathy among those with CKD-eGFR$_{cys}$ and CKD-eGFR$_{cr}$ were 8.5% and 9.9%. In separate models, CKD-eGFR$_{cys}$ showed a significant association with odds ratio (OR, 95% Confidence interval [CI]) of 1.98 (1.06-3.72) while CKD-eGFR$_{cr}$ did not show a significant association with retinopathy 2.22 (0.96-5.13). In models including both markers, compared to optimal kidney function (eGFR$_{cys}$ ≥60,eGFR$_{cr}$ ≥60), confirmed-CKD was associated with a three-fold odds of having retinopathy (OR [95% CI] = 3.10 [1.20-8.00]).

**Conclusions:** In a population-based sample of Indian adults without diabetes, cystatin C in combination with creatinine was strongly associated retinopathy. If confirmed by future prospective studies, our findings may have clinical utility for predicting risk of retinopathy using an equation combining both cystatin C and creatinine.

*Funding:* Government Support - Non-U.S.

## SA-PO180

**The Relationship between the Reduced Number of Nephrons of the Congenital and Surgically Acquired Solitary Kidney with Arterial Hypertension Assessed by Means of the Glomerular Filtration Rate** Gheorghe Gluhovschi, Florica Gadalean, Silvia Velciov, Ligia Petrica, Cristina A. Gluhovschi. *Univ of Medicine and Pharmacy, Timisoara, Romania.*

**Background:** The concept between the number of nephrons and arterial hypertension (AHT) raises the question whether a reduced number of nephrons contributes to AHT. The solitary kidney (SK) represents a study model of this concept because of the presence of a reduced number of nephrons. The aim of our study was to assess the relationship between the reduced number of nephrons of the SK with AHT.

**Methods:** We conducted a study on 295 patients (pts) with a SK hospitalized in our department. Fifty-six pts (24M and 32F), mean age: 40.73±14.32 years had a congenital SK and 239 pts (69M and 170F), mean age: 56.81±13.42 years had a surgically acquired SK. All patients were assessed for the presence of AHT. GFR was measured by the CKD-Epi formula.

**Results:** Out of the 56 pts with a congenital SK 31 pts (55.35%) had AHT, the mean age at onset of AHT being 35.46±10.38 years. Out of the 239 pts with a surgically acquired SK 96 pts (40.41%) developed AHT after nephrectomy after a mean duration of 12.22±11.45 years. The distribution of pts according to stage of CKD and AHT is presented in Table 1.

| CKD STAGE | NUMBER OF PATIENTS | CONGEN-ITAL SK WITH AHT | CONGENITAL SK WITHOUT AHT | NUMBER OF PATIENTS | SURGICALLY-ACQUIRED SK WITH AHT DEVELOPED AFTER NEPHRECTOMY | SURGICALLY-ACQUIRED SK WITH AHT BEFORE NEPHRECTOMY | SURGICALLY-ACQUIRED SK WITHOUT AHT |
|---|---|---|---|---|---|---|---|
| 1 | 12 (21.42%) | 1 (8.33%) | 11 (91.66%) | 11 (4.6%) | 2 (18.18%) | 1 (9.09%) | 8 (72.72%) |
| 2 | 23 (41.07%) | 14 (60.86%) | 9 (39.13%) | 77 (32.21%) | 23 (29.87%) | 14 (18.18%) | 40 (51.94%) |
| 3 | 18 (32.14%) | 13 (72.22%) | 5 (27.77%) | 109 (45.6%) | 50 (45.87%) | 35 (32.11%) | 24 (22.01%) |
| 4 | 2 (3.57%) | 2 (100%) | 0 (0%) | 25 (10.46%) | 11 (44%) | 12 (48%) | 2 (8%) |
| 5 | 1 (1.78%) | 1 (100%) | 0 (0%) | 17 (7.11%) | 10 (58.82%) | 6 (35.29%) | 1 (5.88%) |

**Conclusions:** The prevalence of AHT increases with GFR decline, sustaining the concept of a relationship between a reduced nephron number and AHT. The prevalence of AHT is higher in patients with a congenital SK.

*Funding:* Clinical Revenue Support

## SA-PO181

**Targeted LC/MS Based Metabolomic Platform for Quantification of Nucleosides in Biofluids: Potential Biomarkers for Chronic Kidney Disease** Anna V. Mathew, Jaeman Byun, Subramaniam Pennathur. *Dept of Internal Medicine Nephrology, Univ of Michigan, Ann Arbor, MI.*

**Background:** Nucleoside metabolism plays an important role in several proliferative and catabolic conditions. Chronic kidney disease (CKD) is characterized by proliferation and increased catabolism, in addition to diminished clearance of the nucleosides. We hypothesized nucleosides such as uracil, pseudouridine, dimethyl guanosine, and allantoin would predict the rate of decline in renal function in CKD.

**Methods:** We developed a stable isotope-dilution liquid chromatography –mass spectrometry (ESI/LC/MS/MS) based quantitation technique to measure nucleosides in biological samples. Biological samples were purified with cation- exchange cartridges and the nucleosides were separated on a Luna $C_{18}$ column. The mobile phase was 0.1% formic acid and acetonitrile with 0.1% formic acid. MRM transitions monitored in positive mode were m/z 113 to 70 for uracil; m/z 116 to 71 for $^{13}C_1{}^{15}N_2$ uracil; m/z 245 to 209 for pseudouridine; m/z 312 to 180 for $N^2$,$N^2$-dimethyl guanosine, m/z 159 to 116 for allantoin and m/z 161 to 118 for $^{13}C$ allantoin respectively. Calibration curves were created with the concentration of the nucleosides spiked in the biological matrix.

**Results:** Initial validation of this method was done with pooled plasma samples from BKS db/db mice, a well-validated model of diabetic nephropathy. In order to determine if the nucleoside metabolism was able to discriminate rates of progression in CKD subjects, we utilized 15 baseline samples from subjects with Stage 3 and 4 CKD from the CPROBE, an ongoing biological and clinical data repository for CKD patients in the Michigan O'Brien Kidney Center. In this discovery cohort, we found three fold elevations in plasma levels of pseudouridine (3.56 vs. 1.04μM) and dimethyl guanosine (0.07 vs. 0.02 μM) in the progressors (defined as 20% decrease in eGFR or 1.5 fold increase in proteinuria in one year of follow-up) compared with non-progressors.

**Conclusions:** Further studies are warranted to validate the mechanistic and prognostic significance of these nucleoside markers by simultaneous assessment in plasma and urine from a larger cohort of CKD patients.

## SA-PO182

**Initial Characterization of Novel Loci of Kidney Function: The CKDGen Consortium** Adrienne Tin. *Johns Hopkins Bloomberg School of Public Health, On Behalf of the CKDGen Consortium.*

**Background:** Genome-wide association (GWA) studies of markers of kidney function and damage have yielded many loci, each with small effects, with much unexplained heritability. We conducted a meta-analysis of 50 population-based studies of individuals of European ancestry to identify additional loci and performed follow-up bioinformatics and functional experiments.

**Methods:** GFR estimated using the 4-variable MDRD study equation (eGFRcrea), CKD (eGFRcrea < 60 ml/min/1.73m^2), urinary albumin-to-creatinine ratio (UACR), and microalbuminuria (MA) were analyzed. The total sample sizes were 133,728 for eGFRcrea/CKD and 52,716 for UACR/MA. Study-specific results were pooled through inverse-variance weighted, fixed-effects meta-analyses. SNPs in significant loci were interrogated for their mapping to specific chromatin states in kidney tissues obtained from ChIP-Seq experiments. Based on pathway analyses and prior biological knowledge, eight genes were studied for their effects on kidney development using morpholino knock-down in zebra fish.

**Results:** The new analyses confirmed all previously identified loci for eGFRcrea and UACR. In addition, we identified 18 new independent loci for eGFRcrea (P-values from 6.0E-13 to 4.7E-8), and 16 of these showed direction-consistent association with cystatin C-based GFR, pointing towards a role in affecting kidney function. Chromatin state mapping analyses showed significant SNPs in these kidney function-associated loci mapped more often to regulatory regions in kidney tissues compared to those from other tissues studied in the ENCODE project. In zebra fish experiment, knock down of one of the eight genes analyzed led to visible tubular deformity in embryos.

**Conclusions:** We have identified additional novel loci that are associated with kidney function. Moreover, bioinformatics and functional experiments provide further evidence for their role in kidney development and function for many of these loci. Upon confirmation through independent replication, these new findings may advance our understanding of the biologic mechanisms underlying kidney disease.

## SA-PO183

**Association of Arsenic with Estimated GFR in U.S. Adolescents** Darcy K. Weidemann,[1] Ana Navas-acien,[2] Chin-chi Kuo,[2] Virginia Weaver,[2] Jeffrey J. Fadrowski.[1,2] *[1]Johns Hopkins Children's Center; [2]Johns Hopkins Bloomberg School of Public Health.*

**Background:** Emerging evidence suggests adverse health effects of long-term low-level exposure to arsenic. Few epidemiological studies have investigated the association of arsenic and kidney function, especially in children. Our objective is to examine the association of urinary arsenic and estimated glomerular filtration rate (eGFR) in a representative population of adolescents.

**Methods:** Cross-sectional study of 1,379 participants ages 12-17 years in the 2003-2010 National Health and Nutrition Examination Survey. Using linear regression adjusted for kidney disease risk factors, urinary dilution, and markers of seafood intake, we examined the association of eGFR and urinary total arsenic and DMA quartiles.

**Results:** The mean age was 14.5 years, 50% female, 63% white, 15% black, 13% Mexican-American, 78% active or involuntary tobacco smoke exposure, 35% overweight/obese, 2.4% hypertensive, and 0.4% diabetic. The median total urinary arsenic concentration and DMA (IQR, interquartile range) was 6.7 µg/L (IQR 3.8 – 12.1) and 3.6 µg/L (IQR 2.1 – 5.5), respectively. Higher quartiles of total arsenic and DMA were associated with higher eGFRs compared to the lowest quartile (Table).

| Difference in estimated GFR[a] associated with urinary total arsenic and DMA[b] | | | |
|---|---|---|---|
| **Total arsenic quartiles (µg/L)** | **eGFR (mL/min/1.73m²)** | **95% CI** | **p-value for trend** |
| 1 (<4.3) | - | | 0.05 |
| 2 (4.3 - 7.1) | 2.2 | (-1.4, 5.8) | |
| 3 (7.2 - 13) | 3.9 | (-1, 8.7) | |
| 4 (> 13) | 4.7 | (0.2, 9.3) | |
| **DMA quartile (µg/L)** | | | |
| 1 (<2.4) | - | | 0.03 |
| 2 (2.4 - 3.9) | 5.1 | (1.5, 8.6) | |
| 3 (4.0 - 6.0) | 3.3 | (-0.1, 7.2) | |
| 4 (> 6) | 7.4 | (1.6, 13.1) | |

[a] eGFR: bedside Schwartz equation
[b] Adjusted for urinary creatinine, arsenobetaine, and clinical/demographic characteristics in Results

**Conclusions:** Higher total urinary arsenic and DMA levels were associated with higher eGFR. This relationship could be explained by glomerular hyperfiltration induced by arsenic. Alternatively, among this population of adolescents with eGFR in the normal range, relatively higher eGFRs may be associated with greater urinary arsenic excretion, with implications for exposure assessment using urinary biomarkers.

## SA-PO184

**Genetic Polymorphism of Transporters and Protein in Renal Tubules and Urinary Excretion of Uric Acid in the Japanese General Population: The Takahata Study** Kazuko Suzuki, Keita Kamei, Hiroko Sato, Kosuke Kudo, Kazunobu Ichikawa, Tsuneo Konta, Isao Kubota. *Dept of Cardiology, Pulmonology, and Nephrology, Yamagata Univ School of Medicine, Yamagata, Japan.*

**Background:** A cluster of transporters and proteins expressed in renal tubules play a role in the metabolism of uric acid and the function of these molecules are genetically modified. To examine how the polymorphism of genes related with the metabolism of uric acid affect renal excretion of uric acid, we conducted a cross-sectional study in participants of community-based health checkup.

**Methods:** We genotyped the SNPs of 7 uric-acid-related genes, including 5 transporters (URAT1, GLUT9, ABCG2, SLC17A3 and SLC22A4) and 2 proteins (UMOD and ALDH2) in 1001 Japanese subjects. Urinary fractional excretion of uric acid (FEUA) was determined from morning spot sample and the association between FEUA and genotypes of these genes were examined.

**Results:** In total subjects, the analysis of variance (ANOVA) showed that FEUA was significantly different between the genotypes of rs505802 in URAT1, rs4293393 in UMOD and rs671 in ALDH2. Multiple regression analysis with adjustment for potential confounders showed that the genotypes of URAT1 and UMOD were independently associated with FEUA, in addition to male gender, systolic blood pressure, body mass index (BMI), salt intake and estimated GFR. The genotypes of ALDH2 was an independent factor of FEUA, not in total subjects, but in the subjects with renal insufficiency and BMI <25 kg/m$^2$.

**Conclusions:** This study revealed that the genotypes of URAT1, UMOD and ALDH2 were independently associated with FEUA. This indicates that genetic background of renal transporters and protein might affect renal excretion of uric acid in the Japanese general population.

## SA-PO185

**Factors Associated with Vasopressin Concentration in a General Population Cohort** Marieke Van Gastel,[1] Esther Meijer,[1] Lieneke E. Scheven,[1] Joachim Struck,[2] Stephan J.L. Bakker,[1] Ron T. Gansevoort.[1] *[1]Dept Nephrology, UMC, Groningen, Netherlands; [2]Sphingotec, Germany.*

**Background:** Vasopressin (AVP) plays an important role in maintaining volume homeostasis. Recent studies, however, suggest that AVP also plays a detrimental role in progression of chronic kidney disease. It is therefore of interest to identify factors that influence AVP concentration, particularly modifiable ones, because intervention on these factors may have beneficial renal effects.

**Methods:** This study was performed in a large, general population based cohort study (PREVEND Study, Groningen, the Netherlands). Copeptin (pro-AVP) was measured in 6,821 available plasma samples as surrogate for AVP. Associations of patient related factors with copeptin concentration were assessed in uni- and multivariable linear regression analyses.

**Results:** Median copeptin concentration was 4.70 pmol/L (IQR 2.94-7.62). We found a reverse association between copeptin concentration and eGFR (p<0.001) and a positive association with albuminuria (p<0.001) when analyzed univariable and when adjusted for age and gender. The final stepwise backward model (adjusted for age and gender) revealed associations with higher copeptin concentration for, in order of the strength of their association, lower fluid intake (p<0.001), higher sodium intake (p<0.001), higher blood pressure (SBP, p<0.001), current smoking (p<0.001), higher alcohol use (p<0.001), higher serum glucose (p<0.001), higher BMI (p<0.001), use of diuretics (p<0.01) and use of antidiabetics (p<0.05). No associations with copeptin concentration were found for characteristics as protein intake, C-reactive protein and use of non-diuretic antihypertensives.

**Conclusions:** A higher copeptin concentration is associated with a decreased kidney function and higher albuminuria, compatible with the alleged deleterious renal effects of AVP. Important modifiable subject related factors associated with copeptin concentration are current smoking, use of alcohol, and particularly intake of fluid and sodium. These data form a rationale to investigate whether intervening on these factors results in lower AVP concentration with concomitant beneficial renal effects.

*Funding:* Government Support - Non-U.S.

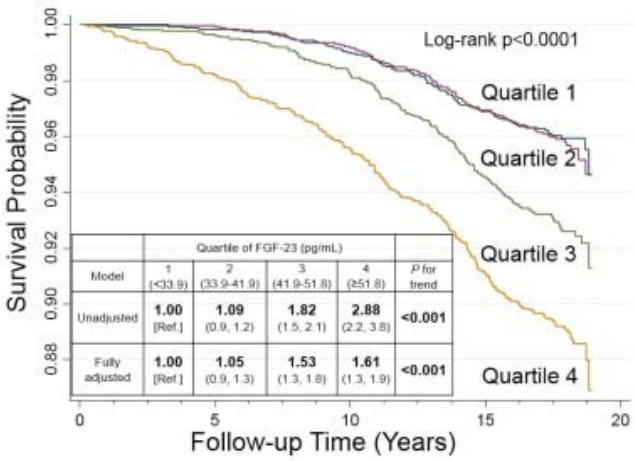
## SA-PO186

**Association of Serum Fibroblast Growth Factor-23 (FGF-23) Levels with Risk of Kidney Failure: 21-Year ARIC Follow-Up for the CKD Biomarkers Consortium** Casey M. Rebholz,[1] M. Grams,[1] Josef Coresh,[1] Elizabeth Selvin,[1] Lesley Inker,[2] Andrew S. Levey,[2] Paul L. Kimmel,[2] Vasan S. Ramachandran,[2] Harold I. Feldman,[2] Chi-yuan Hsu,[2] John H. Eckfeldt,[2] Pamela L. Lutsey.[2] *[1]Johns Hopkins Univ; [2]CKD Biomarkers Consortium.*

**Background:** FGF-23 is a bone-derived hormone with several endocrine functions in the kidney, including promoting urinary phosphorus excretion and inhibiting vitamin D activation. Elevated FGF-23 predicts kidney failure (KF) in moderate kidney disease patients, but has not been assessed in a community-based cohort.

**Methods:** FGF-23 levels were measured by Kainos ELISA (CV 14.5%) on 13,500 ARIC study participants in serum stored in 1990-92. KF was defined by ICD-9 and ICD-10 codes for hospitalizations and deaths from 1990 to 2010. Cox proportional hazards regression was used to relate baseline FGF-23 to KF during follow-up adjusted for baseline eGFR, covariates and clustering by study center.

**Results:** Mean age was 56.9 years, 56.0% were women, 5.8% had coronary heart disease, and mean baseline eGFR was 89.5 mL/min/1.73 m$^2$. During a median follow-up of 17.9 years, 599 (4.4%) participants developed KF. Time to KF was significantly different by quartile of baseline FGF-23 level (**Figure**; p<0.0001). There was an increased risk of KF among those with baseline FGF-23 levels in the higher quartiles after adjusting for eGFR, age, sex, race, diabetes, systolic blood pressure, antihypertensive medication, education, high-density lipoprotein, body mass index, C-reactive protein, $\beta_2$-microglobulin, hemoglobin A1c, and phosphate [**Table**; HR: 1.61; 95% CI: 1.34, 1.94; p<0.001]. Sensitivity analysis using USRDS-identified cases (n=256) showed similar results (HR: 1.94; p<0.001).



| | Quartile of FGF-23 (pg/mL) | | | | |
|---|---|---|---|---|---|
| Model | 1 (<33.9) | 2 (33.9-41.9) | 3 (41.9-51.8) | 4 (≥51.8) | P for trend |
| Unadjusted | 1.00 [Ref.] | 1.09 (0.9, 1.2) | 1.82 (1.5, 2.1) | 2.88 (2.2, 3.8) | <0.001 |
| Fully adjusted | 1.00 [Ref.] | 1.05 (0.9, 1.3) | 1.53 (1.3, 1.8) | 1.61 (1.3, 1.9) | <0.001 |

**Conclusions:** In a large, biracial, population-based study, higher baseline levels of FGF-23 were associated with an increased risk of KF independent of kidney function and other risk factors.

*Funding:* NIDDK Support, Other NIH Support - The Atherosclerosis Risk in Communities Study is carried out as a collaborative study supported by National Heart, Lung and Blood Institute contracts (HHSN268201100005C, HHSN268201100006C, HHSN268201100007C, HHSN268201100008C, HHSN268201100009C, HHSN268201100010C, HHSN268201100011C, and HHSN268201100012C). ## SA-PO187

**Temoporal Trends in Area-Level Poverty and End-Stage Renal Disease (ESRD) Incidence** Bridget Garrity,[2] Holly J. Kramer,[1] Kavitha Vellanki,[1] David J. Leehey,[1] David A. Shoham.[2] *[1]Medicine, Loyola Medical Center; [2]Public Health Sciences, Loyola Medical Center.*

**Background:** Poverty is associated with end-stage renal disease (ESRD). The economic downturn in the U.S population which started during years 2007-2008 may have impacted ESRD incidence.

**Methods:** We examined ESRD incidence using data from the United States Renal Data System (USRDS). Analysis incuded adults aged ≥18 years who initiated dialysis during years 1995-2010 (n=1,253,541). Data were then linked with the 2000 and 2010 U.S. Census data. Negative-binomial regression was used to analyze temporal trends in the association between ESRD incidence and living in a poverty area defined by ZIP code with ≥20% of the population in that zip code living below the US federal poverty line. The numerator for each rate was the number of incident ESRD cases in a given race-ethnicity/sex/age group for a given period for each ZIP code. Analyses were stratified by time period (pre and post recession). Time period 1 was defined as January 1, 1995 - December 31, 2004 (pre-recession). Period 2 was defined as January 1, 2005 - December 31, 2010 (recession and post recession). Rates were calculated per million population per year.

**Results:** Between January 1, 1995 and December 31, 2010, there were 1,253,541 incident cases of ESRD in the USRDS network. Of these, 697,279 observations were in Period 1 and 556,262 observations were in Period 2. During period 1 (1995-2004), individuals living in a poverty area (17.4% of incident cases) had 24% higher ESRD incidence compared to those not living in a poverty area (95% CI 1.22, 1.25). During period 2 (2005-2010), a greater proportion of incident cases came from a poverty area (23.8%), and the association between poverty area and ESRD incidence was significantly stronger (p<0.001), with an incidence rate ratio of 1.28 (95% CI: 1.27, 1.30).

**Conclusions:** The influence of area-level poverty on ESRD incidence is increasing over time. Future surveillance and interventions for CKD prevention should target high poverty areas.

*Funding:* Clinical Revenue Support

## SA-PO188

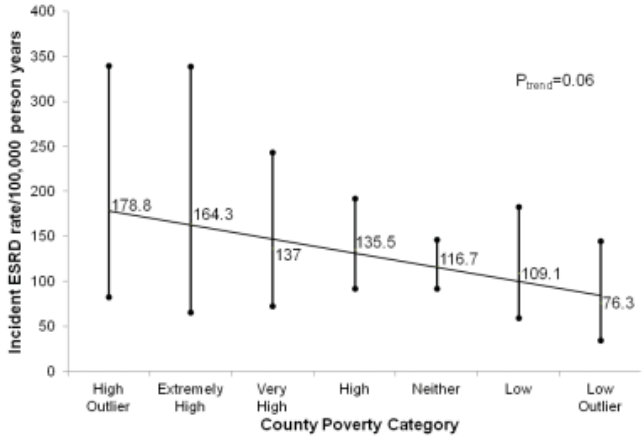
**Low Income, Community Poverty and Risk of End Stage Renal Disease**
Deidra C. Crews,[1] Orlando M. Gutierrez,[2] Suzanne E. Judd,[2] David G. Warnock,[2] William M. McClellan.[3] *[1]Johns Hopkins Univ; [2]Univ of Alabama, Birmingham; [3]Emory Univ.*

**Background:** The risk of ESRD is increased among poor individuals and in low income communities. We examined the associations of individual and community measures of socioeconomic status with incident ESRD.

**Methods:** In the population-based Reasons for Geographic and Racial Differences in Stroke (REGARDS) study of 23,314 U.S. adults aged 45 years and older, we used ANOVA and chi-square tests to assess participant differences across geospatially-linked categories of county poverty [outlier poverty, extremely high poverty, very high poverty, high poverty, neither (reference), high affluence and outlier affluence defined using data obtained from the 2000 US Census]. We used multivariable Cox proportional hazards models to examine the independent association of annual family income and county poverty measures with incident ESRD. Confounders included age, sex, race and region of residence (stroke belt, stroke buckle, other regions), and education.

**Results:** Participants residing in impoverished counties were more likely to be female and/or black, and were less likely to have completed high school than those in affluent counties (P<0.05 for all). There were 158 cases of ESRD per 100,000 person-years ($10^5$ py) of follow up. Incident ESRD rates declined as the affluence of counties increased.

**Figure. Incident ESRD rate/100,000 Person Years by County Poverty Category**



In adjusted models, only income was independently associated with risk of ESRD [hazard ratio (HR) 4.0, 95% confidence interval (CI) 1.7-9.2 comparing the <$20K group to the >=$75K group]; there were no statistically significant associations of geospatially-linked county measures of poverty and ESRD.

**Conclusions:** In contrast to annual family income, geospatially-linked measures of community poverty have little relation with risk of ESRD. Efforts to mitigate socioeconomic disparities in CKD may be best appropriated at the individual level.

## SA-PO189

**Testing the Validity of a New Quantitative Image Analysis Technique to Measure Severity of Abdominal Aortic Calcification on Lateral Lumbar Radiographs**
Mark D. Grant,[1] Rachel M. Holden,[1,2] Michael A. Adams.[1] *[1]Queen's Univ, Canada; [2]Kingston General Hospital, Canada.*

**Background:** Vascular calcification represents a serious complication of chronic kidney disease. Lateral lumbar radiograph images are inexpensive and prominently display abdominal aortic calcification (AAC); however, to date, there remains no fully quantitative method to report severity of calcification. The present study focuses on testing the reliability of a new quantitative image analysis technique compared to the previously validated semi-quantitative technique (AAC-24) when measuring severity of AAC on a lateral lumbar radiograph.

**Methods:** The quantitative image analysis technique was developed using Image Pro 6.0 and Microsoft Excel software. One hundred and ninety three subjects were selected from the Kingston cohort of the Canadian Multicenter Osteoporosis Study (CaMOS) based on availability of radiographic data. Subjects were sorted according to bone mineral density values and compared within standard deviation groups. Inter-observer reliability was assessed by having two readers analyze the same fifty images for severity of AAC using both the semi-quantitative technique, and the quantitative technique in proposal. Additionally, one reader analyzed the same set of fifty images twice, using both techniques previously mentioned, to assess their respective intra-observer reliabilities. Two scores were generated for each technique: L2-L4 and L3-L4 Sum.

**Results:** For the L2-L4 Sum, the intra- and inter-class correlation coefficients for the quantitative and semi-quantitative techniques were 0.975, 0.962 and 0.917, 0.892, respectively (n=35). For the L3-L4 Sum, the intra- and inter-class correlation coefficients for the quantitative and semi-quantitative techniques were 0.982, 0.964 and 0.899, 0.762, respectively (n=50).

**Conclusions:** The quantitative technique in proposal is a more reliable method to assess severity of AAC than the semi-quantitative technique. In addition to improved reliability, it is also a more informative assessment of AAC in the regions adjacent L2, L3, and L4 vertebrae. This quantitative method demonstrates promise for future application in clinical and epidemiological studies.

## SA-PO190

**The Characteristics of Advanced Aged IgA Nephropathy**
Yasuko Oshima, Takahito Moriyama, Chihiro Iwasaki, Kayu Tanaka, Kosaku Nitta. *Medicine, Tokyo Women's Medical Univ, Tokyo, Japan.*

**Background:** The susceptible age for IgA nephropathy (IgAN) is younger. However IgAN is sometimes developed in the advanced age, and its characteristics remains unknown.

**Methods:** We selected 600 IgAN patients, observed at least half a year and aged over 20 years old. We divided them into three groups as advanced aged group (AAG, n=31, aged over 50 years old), middle aged group (MAG, n=163, aged between 30 and 49 years old), and young aged group (YAG, n=407, aged between 20 and 39 years old). We analyzed clinical and histological background, renal outcome, and risk for progression.

**Results:** In AAG, mean arterial pressure (MAP) was significantly higher than YAG (97.0 vs. 85.7 mmHg, P=0.0004). In the clinical findings, total protein, serum albumin, and estimated glomerular filtration rate (eGFR) were significantly lower, and blood urea nitrogen, the amount of proteinuria (U-Prot) and N-acetyl-β-D-glucosaminidase (NAG) were significantly higher in AAG than in MAG and YAG [eGFR; 42.3 vs. 59.4 and 79.3 ml/min (P<0.0001, P<0.0001), U-Prot; 2.04 vs. 0.80 and 0.66 g/day (P=0.021, P=0.003), NAG; 10.6 vs. 5.8 and 4.5 U/l (P=0.003, P=0.004), in AAG vs. MAG and YAG, respectively]. In the histological findings analyzed by Oxford classification, interstitial fibrosis/tubular atrophy was severe in AAG than YAG (T0/T1/T2; 40.7/52.9/7.4 % in AAG vs. 76.9/29.0/4.1 % in YAG, P=0.001). Also arteriolar sclerosis was severe in AAG than MAG and YAG [grade as none/mild/middle/severe: 9.5/19.0/35.7/11.9 % in AAG vs. 20.6/47.5/24.5/7.5 % in MAG and 61.7/40.0/6.1/1.2 % in YAG (P=0.014, P<0.0001)]. Renal survival rate analyzed by Kaplan Meyer Method was significantly lower in AAG (27.2 % / 17.5 year in AAG vs. 69.2 and 84.9 % / 20 year in MAG and YAG, P<0.0001). The patients advanced to end stage renal disease (ESRD) in AAG were higher MAP and severe U-Prot than non-advanced patients [MAP: 103.5 vs. 92.5 mmHg (P=0.019), U-Prot: 3.02 vs. 1.57 g/day (P=0.036)].

**Conclusions:** The characteristics of IgAN in advanced age were higher blood pressure, lower renal function, severe proteinuria, severe interstitial change, and arteriolar sclerosis. The prognosis was very severe and over 70% was developed to ESRD within 20 years.

## SA-PO191

**Effect of Hematuria on the Outcome of IgA Nephropathy with Moderate Proteinuria**
Chihiro Iwasaki, Takahito Moriyama, Kayu Tanaka, Yasuko Oshima, Kosaku Nitta. *Medicine, Tokyo Women's Medical Univ, Tokyo, Japan.*

**Background:** Recently, hematuria has been recognized to be excreted from the active inflammatory lesion of glomerular capillaries in IgA nephropathy (IgAN). However, the relationship between hematuria and histological lesion, and the effect of hematuria on the reaction against steroid therapy and the outcome for IgAN have still unknown.

**Methods:** We examined 80 IgAN patients with proteinuria greater than 1g/day and were treated with predonisolone (0.8mg/kgBW). We divided them into two groups: low urinary red blood cells (U-RBC) group [(L group, n=30,U-RBC < 40 counts/high-power field(HPF)] and high U-RBC group (H group, n=50, U-RBC ≥ 40 counts/HPF). We analyzed the clinical and histological background, the relationship between hematuria and histological lesion, renal outcome, and the risk factors for progression.

**Results:** Median U-RBC in H group was significantly higherthan L group (L:16 vs.H:80counts/HPF, p<0.0001), and the other clinical findings were similar between both groups [Mean Arterial pressure (L group: 95.2 vs. H group: 93.4 mmHg), estimated glomerular filtration rate (eGFR) (67.9 vs. 74.1 ml/min) and proteinurea (2.58 vs. 2.16 g/day)]. Histological backgrounds were also similar between both groups. There was no correlation between U-RBC and active histological lesion. After starting steroid therapy, median proteinuria was soon decreased and remained less than 1g/g•creatinine until 5 years in both groups. Also, median U-RBC was soon decreased and remained less than 10 U-RBC/HPF in both groups. The 20-year renal survival rate was analyzed by Kaplan-Meier method was higher in H group (L:41.2 vs. H:49.5%), but it was not significant. By multivariate Cox regression analysis, lower eGFR(HR 3.22, 95%CI 1.74-6.23, p=0.0002) and severe histological lesion (HR 2.60, 1.11-6.59, p=0.0233) were independent risk factors for progression, but U-RBC was a factor for good prognosis (HR 0.55, 95%CI: 0.34-0.81, p=0.0016).

**Conclusions:** Our results indicate that the degree of hematuria at the biopsy in IgAN is not associated with severe clinical findings, active pathological findings, resistance to steroid treatmentand poor outcome.

## SA-PO192

**Obesity as a Risk Factor for Chronic Kidney Disease: Health Survey for England 2010** Helen L. MacLaughlin,[1,2] Wendy L. Hall,[2] Iain C. Macdougall.[1] *[1]King's College Hospital, London, United Kingdom; [2]King's College London, United Kingdom.*

**Background:** Observational studies in North America, Europe, & Asia indicate that obesity is a risk factor for CKD, yet there is no similar study of a nationally representative sample in the United Kingdom (UK). The aim of this study was to determine if overweight and obesity are independently associated with the prevalence of CKD in the Health Survey for England (HSE) 2010 cross-sectional cohort.

**Methods:** CKD was defined as estimated glomerular filtration rate (eGFR) <60ml/min/1.73m$^2$ using the CKD-EPI formula. Multivariable logistic regression models were developed to estimate CKD risk by BMI in 5 categories (reference category 18.5–24.9 kg/m$^2$), and were repeated with eGFR calculated using the 4-variable MDRD study equation for comparison with previous studies.

**Results:** The analytic cohort consisted of 3, 463 men & women (mean age 51y; SD 17y). The prevalence of CKD in the HSE was 5.9%. The prevalence of obesity was 43% in the CKD group vs 26% in the non-CKD group (p <0.001). Those with CKD were older, had more diabetes & hypertension, & a higher mean BMI than those without CKD. The risk of CKD was over 2.5 times higher in obese participants, but not under- or over-weight participants, compared to normal weight participants, after adjustment for age, gender, ethnicity, smoking, diabetes & hypertension: BMI <18.5 kg/m$^2$ adjusted OR 2.08 (95% CI 0.27 to 15.74 NS), BMI 25.0-29.9 kg/m$^2$ adjusted OR 1.47 (95% CI 0.94 to 2.31 NS), BMI 30.0-39.9 kg/m$^2$ adjusted OR 2.78 (95% CI 1.75 to 4.43, p<0.001), & BMI ≥40.0 kg/m$^2$ adjusted OR 2.68 (95% CI 1.05 to 6.85, p<0.05). Results were similar, although attenuated, using the MDRD equation to define CKD status: BMI <18.5 kg/m$^2$ adjusted OR 1.73 (95% CI 0.32 to 9.47 NS), BMI 25.0-29.9 kg/m$^2$ adjusted OR 1.37 (95% CI 0.95 to 1.99 NS), BMI 30.0-39.9 kg/m$^2$ adjusted OR 2.02 (95% CI 1.37 to 2.97, p<0.001) & BMI ≥ 40.0 kg/m$^2$ adjusted OR 2.01 (95% CI 0.89 to 4.54, NS).

**Conclusions:** The risk for CKD increases with obesity in the UK population, supporting findings from previous epidemiological studies. Future service delivery planning should account for increasing CKD risk in the years following an epidemic rise in population obesity rates.

*Funding:* Government Support - Non-U.S.

## SA-PO193

**The Impact of Initial and Subsequent Blood Pressure Control on Renal Outcme in Moderate to Severe Chronic Kidney Disease** Ping-min Chen, Ping Yu Chen, Tai-shuan Lai, Wen-Chih Chiang, Shuei-Liong Lin. *Dept of Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan.*

**Background:** Blood pressure (BP) is an important risk factor of end stage renal disease. The protective effect of BP control is well known in early stage chronic kidney disease (CKD). Limited data is available in late stage CKD. This study is to examine the impact of baseline and subsequent BP control on renal outcome in late stage CKD patients.

**Methods:** This is a retrospective single-center study, enrolling total 1210 stage 3B-5 CKD patients (age 18~80). The baseline BP when enrolling and in the first year were collected. The primary outcome was initiation of long-term renal replacement therapy (RRT). The outcome was first compared between different baseline BP groups. Good BP was defined as BP <130/80 mmHg, otherwise high BP. Patients were then stratified into four groups according to the baseline BP and subsequent BP control in the first year, if they were followed-up for more than one year. Survival analysis of the four groups was performed. Multivariate cox regression model was used to evaluate the effect of risk factors, baseline BP and subsequent BP on renal outcome. Subgroup analysis according to the baseline urine protein/creatinine ratio (UPCR) was performed.

**Results:** High baseline BP was a risk factor of RRT (HR 1.487, p = 0.001). Those with baseline and subsequent good BP (Group 1) showed the best renal survival, followed by those with baseline high BP and subsequent good BP control (Group 2). Group 3 (good baseline BP but high subsequent BP) and group 4 (high baseline and subsequent BP) patients had the worst outcome. Comparing group 2 and group 4, subsequent good BP control was associated with less risk of RRT (HR 0.515, p = 0.009). This renal protective effect of subsequent BP control was more prominent for patients with higher proteinuria ( UPCR ≥ 1 g/g, HR 0.485, p = 0.012).

**Conclusions:** Baseline high BP is a risk factor for CKD progression. Patients with subsequent good BP control had lower risk of RRT even baseline BP is high. This study indicats the beneficial role of good BP control in slowing CKD progression in late stage CKD patients.

## SA-PO194

**Gastrointestinal Bleeding in End-Stage Renal Disease** Juliana F. Yang, Aniko Szabo, Hariprasad S. Trivedi. *Medical College of Wisconsin.*

**Background:** We investigated the epidemiology of serious gastrointestinal bleeding (GIB) in end-stage renal disease (ESRD) subjects receiving dialysis.

**Methods:** Serious GIB was defined as GIB requiring hospitalization or during hospitalization for inter-current illness. The United States Renal Data System database was used to identify patients with non-HMO Medicare as payer and first service date between January 1, 1996 and December 31, 2005. The patients were followed 90 days after the first service date to the first occurrence of death, transplant, loss of Medicare, or December 31, 2006. Analysis of predictors of GIB incidence was performed using overdispersed Poisson regression. A Cox regression model with time-dependent predictors was used to evaluate the effect of GIB on survival. The process of recurrent GIB was modeled using a partially conditional Cox regression model.

**Results:** A total of 395,717 patients were followed for 841,192 person-years during which 66,679 GIB events (79/1000 person-years) were identified. The incidence of GIB was relatively stable from 1996 to about 2000, with an increasing trend thereafter. In 2006 the relative risk [RR] was 1.37 as compared to 1996 (95% CI 1.23-1.53). Females (vs. males), blacks (vs. whites), those with hypertension as cause of ESRD (vs. diabetes), and persons > 49 years of age (progressively in each age decile) had a higher RR of GIB. The first episode of GIB increased the hazard of death by about 2-fold (hazard ratio [HR] 1.91, 95% CI 1.88-1.95); each additional episode of GIB further increased the hazard by about 3% [HR 1.029, 95% CI 1.02-1.04). Having had a previous episode of GIB increased the hazard of recurrence substantially (HR 3.21; 95% CI 3.07-3.37), and each further episode kept increasing the hazard (HR 1.22; 95% CI 1.19-1.26).

**Conclusions:** In patients new to long-term dialysis the risk of serious gastrointestinal bleeding has increased by about 37% over a 10-year period and is associated with a higher risk of death. **Notice:** The data reported here have been supplied by the United States Renal Data System (USRDS). The interpretation and reporting of these data are the responsibility of the authors and in no way should be seen as an official policy or interpretation of the U.S. government.

## SA-PO195

**Genetic Influence on the Variation in Serum Uric Acid Levels in Western Alaska Natives** V. Saroja Voruganti,[1] Shelley A. Cole,[1] Karin Haack,[1] Sandra L. Laston,[1] Sven O.E. Ebbesson,[2] Jean W. Maccluer,[1] Anthony Comuzzie,[1] Jason G. Umans.[3] *[1]Genetics, Texas Biomedical Research Institute, San Antonio, TX; [2]Norton Sound Health Corporation, Nome, AK; [3]Medstar Health Research Institute, Hyattsville, MD.*

**Background:** Serum uric acid (SUA) levels are heritable and are correlated not only with renal urate transporters but with adiposity and inflammation.

**Methods:** We assessed genetic contributions to the variation in SUA in both phases of the Genetics of Coronary Artery Disease in Alaska Natives (GOCADAN) study, having reported previously that SUA was independently associated with prevalent CKD and hypertension in this population. Additionally, we investigated the relationship between SUA and cardiometabolic disease risk biomarkers in this population.

**Results:** Mean SUA levels were 5.27 ± 1.3 mg/dl (phase1 , 2000-04) and 5.26 ± 1.4 mg/dl (phase 2, 2006-10). SUA was significantly heritable in both phases; 0.50 (SE= 0.09, p = 3 x $10^{-9}$, phase1) and 0.37 (SE= 0.18, p 0.011), phase 2). Genome wide linkage analysis identified a novel locus on chromosome 15 (83cM) near marker D15S131 (15q21-q23) which may be regulating SUA. The LOD scores were 2.5 and 3.2 for the first and second phases, respectively. By contrast, we failed to detect evidence for linkage at sites on chromosomes 3 and 11, identified in our previous studies of Mexican Americans and American Indians, respectively. Our bivariate analyses showed significant genetic correlations between SUA and triglycerides (rhog = 0.41), percent body fat (rhog = 0.41), waist circumference (rhog = 0.51) at p < 0.005 and c-reactive protein (rhog = 0.48), diastolic BP (rhog = 0.31), and insulin (rhog = 0.42) at p < 0.05.

**Conclusions:** In summary, we detected a novel locus influencing SUA and significant pleiotropy between SUA and cardiometabolic disease risk factors in a unique Alaska Native population.

## SA-PO196

**Association between Osteoprotegerin, Baseline and Change in Arterial Stiffness in CKD** Helen Alderson, James Ritchie, Philip A. Kalra. *Salford Royal Hospital.*

**Background:** Osteoprotegerin (OPG) is elevated in CKD and has been associated with vascular calcification and aortic stiffness. We sought to investigate the relationship between OPG and rate of change in arterial stiffness in a CKD population.

**Methods:** Patients were selected from the Chronic Renal Insufficiency Standards Implementation Study (CRISIS), a prospective observational study of outcome in patients with CKD 3-5. OPG was measured in stored baseline sera from 140 patients who had a contemporaneous and follow-up measurement of arterial stiffness. Arterial stiffness was assessed using augmentation index corrected for heart rate (AIx) measured with a Sphygmocor device. Patients were grouped by quartiles of OPG.

**Results:** At baseline, mean age was 63±13 years, eGFR 31±12ml/min/1.73m$^2$, OPG 6.9 (5.5-9.2) pmol/L. 75% of follow up measure of AIx were performed at 12-months and 25% at 24-months. Baseline AIx was not significantly correlated with OPG level (r 0.09 p=0.3); no significant difference in AIx existed between quartiles of OPG. No significant correlation between OPG level and rate of change in Aix existed (r 0.12 p=0.2). When quartiles of OPG were compared, only patients in the highest quartile had a mean increase in vascular stiffness, with a significant difference observed between the highest and lowest quartiles (-1.5±4 vs. 0.7±5.7 p=0.03). Similarly when change in Aix /year was considered as a binary variable (increased / decreased), a greater proportion of patients in the highest OPG quartile had an increase in Aix.

| | Quartile 1 ≤5.5 | Quartile 2 5.5-6.9 | Quartile 3 6.9-9.2 | Quartile 4 >9.2 | p overall | p q1 vs q4 |
|---|---|---|---|---|---|---|
| N | 36 | 44 | 27 | 33 | | |
| Change in AIx /yr (Mean ±SD) | -1.5±4.3 | -0.4±3.1 | -0.9±3.9 | 0.7±5.7 | 0.17 | 0.03 |
| Increased AIx N (%) | 11 (31%) | 22 (50%) | 13 (48%) | 19 (58%) | 0.14 | 0.02 |

**Conclusions:** Any relationship between OPG level and rate of change in vascular stiffness appears to be non-linear, with patients who have the highest OPG levels at the greatest risk. Further work should include a larger sample size and consider possible confounding effects of renal function and other bone-mineral parameters.

## SA-PO197

**Association of Cystatin C and Urine Albumin to Creatinine Ratio with Change in Ankle Brachial Index: The Multi-Ethnic Study of Atherosclerosis** Pranav S. Garimella,[1] Joachim H. Ix,[2] Ronit Katz,[3] David Siscovick,[3] Holly J. Kramer,[4] Michael Shlipak,[5] Mark J. Sarnak.[1] *[1]Tufts Medical Center; [2]UC San Diego; [3]Univ of Washington; [4]Loyola Univ; [5]UC San Francisco.*

**Background:** Low ankle brachial index (ABI), a reflection of atherosclerotic disease, and high ABI, a reflection of calcified vessels, are both measures of subclinical cardiovascular disease (CVD). The association of serum cystatin C and albumin-creatinine ratio (ACR) with development of either high or low ABI is unknown.

**Methods:** We investigated the longitudinal associations of cystatin C and ACR with development of low (ABI 0.9-1.4 to ABI < 0.9), and high ABI (0.9-1.4 to > 1.4) over 10 years in 5,591 MESA (Multi-Ethnic Study of Atherosclerosis) participants with follow-up ABI values using multinomial regression.

**Results:** Mean (SD) age was 61 (10) years, 57% were women and 27% were blacks. Mean (SD) cystatin C was 0.88 (0.2) mg/L and median (IQR) ACR was 5.1 (3.2-10.0) mg/gm. Higher cystatin C was associated with progression to both low and high ABI in univariate, but not multivariable analyses (p>0.05). Elevated levels of ACR were significantly associated with progression to both low and high ABI in univariate and multivariable analyses.

**Conclusions:** Elevated levels of ACR are significantly associated with risk of progression to both low and high ABI.

**Prognostic Value of Red Cell Distribution Width in Advanced Chronic Kidney Disease** Pablo Marcos Braillard Poccard, Cesar Garcia-canton, Noemí Esparza, Celia Lopez, Ana Ramirez Puga, Elvira Bosch, Rita Guerra, Eduardo Baamonde, Dolores Checa. *Nephrology, Hospital Universitario Insular, Las Palmas, Gran Canaria, Spain.*

**Background:** Increased red cell distribution width (RDW) is related to oxidative stress and pro-inflammatory states and is associated with higher mortality risk in the general population and in patients with cardiovascular diseases.

Our objective was to evaluate the association between RDW and mortality risk in a population with advanced Chronic Kidney Disease (CKD) and to describe the possible relationship with other prognostic factors.

**Methods:** Prospective observational cohort study of incident advanced CKD patients, who attended our clinic between January 2008 and December 2012 and were followed-up until March 30th 2013. The relationship between RDW and the rest of prognostic variables was studied. A survival analysis based on RDW terrtiles was conducted by using the Kaplan Meier method and the Cox proportional hazards model.

**Results:** The study included 533 patients aged 67.5 years, 55.9% male, 67.4% diabetic. Subjects were classified into RDW tertiles. Median follow-up times were: 16.7 months tertile 1 (T1), 17.6 months tertile 2 (T2), 17.9 months tertile 3 (T3). Mortality was 8.2%, 14.2% and 30.2% for T1, T2 and T3 respectively p<0.001. Tertile groups were diferents in age, %diabetes,%cardiovascular disease, hemoglobin, albumin, cholesterol T and CRP. and no differences were shown in gender, uric acid, phosphorus, GF MDRD, proteinuria or triglycerides. In a binary logistic regression model for mortality, RDW tertiles remained significant with OR of T3 against T1 2.929 (CI95% 1.498 -5.727) independently of the rest of variables. Kaplan-Meier survival curves for RDW tertiles showed survival means of 50.6m T1, 47.7m T2 and 37.8m T3; p<0.001. The Cox proportional hazards model showed a relative mortality risk of 2.325 for T3 against T1 (CI95% 1.266-4.271) adjusted for the rest of variables.

**Conclusions:** In this study, RDW appeared to be a marker for mortality risk independent of other known markers in CKD. The physiopathological meaning and prognostic value of this finding for advanved CKD patients should be verified in further studies.

## SA-PO199

**Prevalence and Control of High Blood Pressure in a German Cohort with Chronic Kidney Disease: Cross-Sectional Data from the German Chronic Kidney Disease (GCKD) Study** Karl F. Hilgers, Matthias Schmid, Silvia Huebner, Martin Busch, Hermann G. Haller, Anna Kottgen, Florian Kronenberg, Elke Schaeffner, Thomas Sitter, Georg Schlieper, Claudia Sommerer, Christoph Wanner, Stephanie Titze, Kai-Uwe Eckardt. *On Behalf of the GCKD Investigators, Germany.*

**Background:** We assessed blood pressure control in a large german cohort of chronic kidney disease (CKD) patients in nephrology specialist care.

**Methods:** The German Chronic Kidney Disease (GCKD) study is a prospective observational cohort study which enroled 5217 german patients with CKD of various aetiologies, who are under nephrology specialist care. Inclusion criteria were an estimated glomerular filtration rate (eGFR) of 30-60 mL/min×1.73 m2 or overt proteinuria in the presence of an eGFR>60 mL/min×1.73 m2. Office blood pressure measured according to WHO criteria by trained study nurses was available from 5181 participants. Hypertension was defined as systolic > 140 mm Hg or diastolic > 90 mm Hg or intake of antihypertensive medications. Blood pressure was considered as controlled if systolic <= 140 and diastolic <= 90 mm Hg.

**Results:** Office blood pressure (mean±SD) of 5181 participants was 139.5 ± 20.4 / 79.3 ± 11.7 mm Hg; no less than 4958 (95 %) of the patients were hypertensive. The prevalence of hypertension was only slightly lower in patients included because of proteinuria (94 %) than in patients included because of the eGFR criterion (95 %). Of all hypertensive patients, only 2410 (49 %) exhibited a sufficient control of blood pressure; the remaining 51 % exhibited a blood pressure of 156.3 ± 15.3 / 85.3 ± 11.7 mm Hg. Among patients with diabetes (35 % of the cohort), office blood pressure was 142.1 ± 21.4 / 76.3 ± 11.9 mm, 98 % were hypertensive, and 52 % of the latter were controlled. Blood pressure in uncontrolled diabetic patients was 158.2 ± 15.3 / 81.6 ± 11.6 mm Hg.

**Conclusions:** Blood pressure control of CKD patients in Germany is less than optimal, even in nephrology specialist care. Identifying potential reasons will require further analyses of e.g. medication patterns. Improving blood pressure control provides an opportunity to ameliorate progression of CKD and prevent some of its complications.

**Self-Reported Cardiovascular Disease and Long Term Renal Outcomes in Chronic Kidney Disease (CKD) – A Report from the Chronic Renal Insufficiency Cohort (CRIC) Study** Mahboob Rahman,[1] Dawei Xie,[2] Harold I. Feldman,[2] Alan S. Go,[3] Jiang He,[4] John W. Kusek,[5] James P. Lash,[6] Akinlolu O. Ojo,[8] Stephen L. Seliger,[9] Susan P. Steigerwalt,[10] Valerie L. Teal,[2] Raymond R. Townsend.[2] *[1]Case Western Reserve Univ; [2]Univ of Pennsylvania; [3]Kaiser Permanente; [4]Tulane Univ; [5]NIDDK; [6]Univ of Illinois; [7]Univ of Michigan; [8]Univ of Maryland; [9]St. Johns Health System.*

**Background:** Although CKD and cardiovascular disease (CVD) are commonly observed together, it is unclear whether CVD increases risk of progression of CKD. We evaluated whether CVD is an independent risk factor for progression of kidney disease among a cohort individuals with CKD.

**Methods:** A prospective study of 3939 participants with CKD enrolled in the CRIC Study between June 2003 and June 2008. Self-reported cardiovascular disease (myocardial infarction/revascularization, chronic heart failure (CHF), stroke or peripheral arterial disease) was ascertained by questionnaire at study entry. Our primary endpoint was a composite of end-stage renal disease or a decline in glomerular filtration rate (GFR) to one-half from baseline.

**Results:** Mean GFR at baseline was 42.8 ml/min/1.73m$^2$. One third (33.4%) of the study participants reported a history of cardiovascular disease, and 10.7 % reported a history of chronic heart failure. Over a median follow up of 3.3 years, 779 (19.8%) participants experienced a renal endpoint. In multivariable models, a composite of any prevalent CVD at baseline was not an independent predictor a renal endpoint (HR 1.08; 95% CI: 0.92 - 1.28). However, self-reported history of CHF was independently associated with a 32% higher relative rate of the endpoint (HR 1.32; 95% CI: 1.05 - 1.66). This relationship was consistent across subgroups defined by age, race, gender and diabetes status.

**Conclusions:** Although overall prevalent CVD was not an independent predictor of decline in kidney function, self-reported history of CHF was a strong predictor of CKD progression. Future work is needed to investigate mechanisms for this association.

*Funding:* NIDDK Support

**SA-PO201**

**Renal Function and Outcome in Thrombolysed Stroke Patients** Hardi Hassan,[1] Asim Majeed,[2] David Sandler,[2] Don Sims,[1] Shahid A. Kausar,[3] Indranil Dasgupta.[2] *[1]Geriatric Dept - Stroke Unit, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; [2]Stroke Unit and Nephrology Dept, Birmingham Heartlands Hospital, Birmingham, United Kingdom; [3]Geriatric Dept - Stroke Unit, Sandwell and City Hospitals Birmingham, Birmingham, United Kingdom.*

**Background:** Stroke and renal impairment are common with ageing. Thrombolysis in stroke is offered to acute stroke patients aiming at significant reduction in disability after stroke. Little is known about the effects of eGFR on disability after stroke thrombolysis. This study tries to find any possible association between the baseline impaired renal function and disability in thrombolysed stroke patients.

**Methods:** A retrospective study analyzing the data from a group of thrombolysed stroke patients in three teaching hospitals in the West Midlands UK, between October 2008 and December 2012. Patients were categorized into two groups; group-1 with eGFR less than 60, and group-2 with eGFR more than 60. The outcomes studied were the admission National Institutes of Health Stroke Scale (NIHSS) as an indicator of severity of the stroke, discharge Modified Rankin Scale (mRS) as a general disability measure, and length of stay in hospital. We also looked at the discharge destinations for the two groups.

**Results:** Data from 263 patients were analysed. Among these, 68 patients belonged to group-1, and 195 to group-2. The mean age was significantly different (group-1 76 vs group-2 64, p =0.0001). The mean for admission NIHSS was 15.4 for group-1 vs 13 for group-2 (p = 0.0014). Group-1 were more disabled on discharge with mean mRS of 2.7 vs 1.9 for group-2 (p = 0.0001). The mean length of stay was 23 and 13 for group-1 and 2 respectively (p = 0.0061).

Mortality among group-1 patients was 16% compared to 6% in group-2, and more patients among group 2 went home compared to group-1 ( 75% vs 53% respectively) and less ended in institutional care ( 4% compared to 10% respectively).

**Conclusions:** This study shows that patients with impaired renal function are older, have more severe stroke and have poorer outcome following thrombolysis. These patients have longer length of stay in hospital, higher mortality,more disability, and increased risk of institutionalization.

**SA-PO202**

**Association of Vitamin D Status and Inflammation with Mortality in Hemodialysis Patients form the U.S. and Europe** Darius Mason,[1] Len A. Usvyat,[2,3] Daniele Marcelli,[4] Aileen Grassmann,[4] Inga Bayh,[4] Laura Scatizzi,[4] Peter Kotanko,[2] Mondo Consortium.[2,3] *[1]Albany College of Pharmacy/Health Sciences, Albany; [2]Renal Research Institute, New York, NY; [3]Fresenius Medical Care North America, Waltham, MA; [4]Fresenius Medical Care, Bad Homburg, Germany.*

**Background:** Neutrophil/lymphocyte ratio (NLR) and Vitamin D (vitD) deficiency are associated with inflammation and mortality in hemodialysis (HD) patients. Whereas NLR is an indicator of inflammatory status, vitD deficiency may promote a pro-inflammatory environment. The aim of this present study was to evaluate the relationship of NLR and vitD deficiency and mortality in HD patients.

**Methods:** The MONDO initiative encompasses global HD patients (Usvyat, Blood Purif, 2013). We enrolled incident HD patients from the US (n=6208) and Europe (EUR) (n=905) between 2000 and 2012. We included first vitD level, concurrent neutrophil and lymphocyte counts, and routine clinical and laboratory measurements. The NLR was calculated as the ratio of neutrophil and lymphocyte counts. We built Cox models to determine the association of NLR (≤4, >4) and vitD levels (≥20, <20 ng/mL) with all-cause death with adjustment for age, gender, diabetes, race, BMI, and albumin levels. Descriptive data are median (interquartile range).

**Results:** US and EUR, respectively, age at HD initiation was 62.0 (51.1-73.0) and 71.8 (58.6-80.8) yrs, 57% and 62% were male. In the US, 46% of patients were black. There were 830 (9.8 deaths per 100 pt yrs) and 164 (17.9 deaths per 100 pt yrs) deaths in the US and EUR, respectively. VitD and NLR were 19.5 (13.1-29.0) ng/mL and 3.5 (2.4-5.3) for the US, and 24.0 (13.0-36.5) ng/mL and 3.0 (2.1-4.4) for EUR, respectively. Concurrent vitD status modified the associations between NLR and death. While in EUR a NLR>4 was associated with mortality irrespective of vitD status (vitD ≥20: HR 1.57 (P=.06); vitD <20: HR 1.80 (P=.01)), this association was less strong in the US (vitD ≥20: HR 1.29 (P=.01); vitD <20: HR 1.17 (P=.14)).

**Conclusions:** NLR is useful for predicting mortality in US and EUR HD patients. Despite adequate VitD status, NLR maintains predictive ability for mortality in US patients with comparable trends in EUR patients.

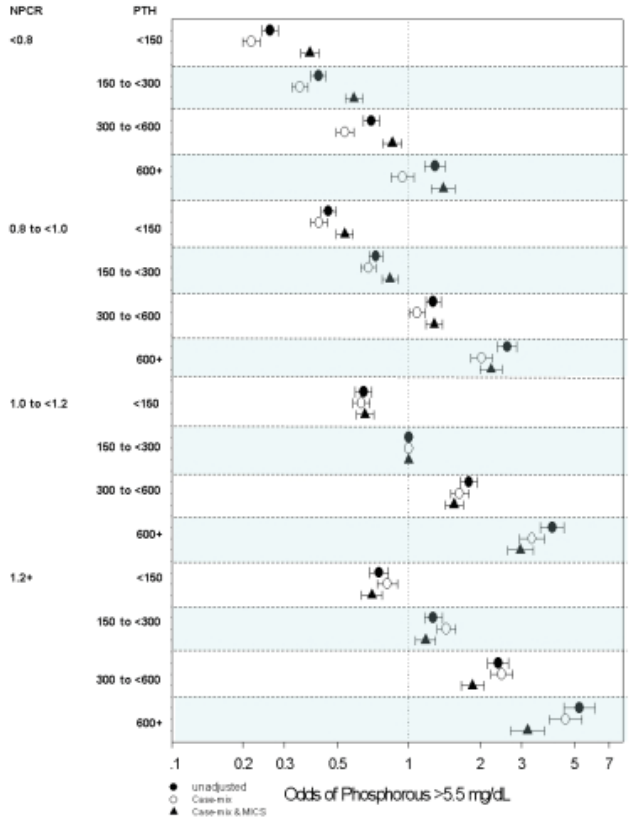
**SA-PO203**

**Concurrence of Higher Serum PTH and Higher Dietary Protein Intake Predict Hyperphosphatemia in Hemodialysis Patients** Elani Streja,[1] Wei Ling Lau,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, UCI, Orange, CA; [2]Memphis VA Medical Center, Memphis, TN.*

**Background:** High phosphorus (P) level is associated with higher risk of death in maintenance hemodialysis (MHD) patients. Previous studies have suggested that both higher serum intact parathyroid hormone (iPTH) level and higher dietary protein intake may contribute to higher levels of P. However, it is not well known how these two factors contribute to the risk of hyperphosphatemia when taken into account simultaneously. We hypothesized that the likelihood of hyperphosphatemia increases across higher serum iPTH and higher normalized protein catabolic rate (nPCR) levels, a surrogate of protein intake.

**Methods:** Over an 8-year period (7/2001-6/2009), we identified 69,355 MHD patients with iPTH, nPCR and P data. Logistic regression models were examined to assess the association between likelihood of hyperphosphatemia (P>5.5 mg/dL) and serum iPTH and nPCR increments.

**Results:** Patients were 61±15 years old and included 46% women, 33% blacks, and 57% diabetics. Both higher serum iPTH level and higher protein intake were associated with higher risk of hyperphosphatemia in dialysis patients (see Figure). Compared to patients with iPTH level 150-<300 pg/ml and nPCR level 1.0-<1.2 g/kg/day, patients with iPTH> 600 pg/ml and nPCR> 1.2 g/kg/day had a 3-fold increased risk of hyperphosphatemia (OR: 3.17, 95%CI: 2.69-3.75). Furthermore, increasing serum iPTH levels was associated with a linear incremental increase risk of hyperphosphatemia across levels of nPCR, and within each increasing level of nPCR the risk-trend was further incrementally magnified.



**Conclusions:** High serum P level is associated with both dietary protein intake and serum PTH level in MHD patients. Management of hyperphosphatemia not only requires attention to dietary interventions but also correction of hyperparathyroidism.

## SA-PO204

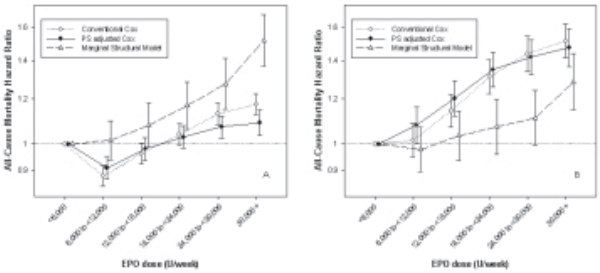
**Erythropoiesis-Stimulating Agent and Mortality in Hemodialysis: Multi-Level Model Comparison**

Elani Streja,[1] Jongha Park,[2] Ting-yan Chan,[1] Janet Lee,[1] Csaba P. Kovesdy,[3] Connie Rhee,[1] Daniel L. Gillen,[4] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, UCI, Orange, CA; [2]Univ of Ulsan College of Medicine, Ulsan, Korea; [3]Memphis VA Medical Center, Memphis, TN; [4]Dept of Statistics, Univ of California, Irvine, Irvine, CA.*

**Background:** It is unclear as to whether high erythropoiesis-stimulating agents (ESA) doses are harmful in hemodialysis (HD) patients. Dynamic ESA dosing can create time-dependent confounding because ESA dose is titrated in response to hemoglobin (Hb), a marker that is influenced by prior ESA dose and is also an independent prognostic factor for mortality.

**Methods:** Among a 2001-2006 cohort of incident and prevalent HD patients, ESA dose was averaged at successive *quarterly* intervals. ESA dose (U/week) was categorized into 6 levels. We compared the association between high-dose ESA and all-cause mortality across 3 models: a Cox model using baseline covariates, a propensity score adjusted Cox model stratifying on baseline propensity for ESA dosing, and a marginal structural model (MSM) weighting subjects by the inverse probability of ESA dosing in a time-dependent fashion. We adjusted for case-mix, inflammation, and nutrition covariates in all models.

**Results:** Compared to ESA<6000U/wk, mortality linearly increased with increasing ESA dose >1,200 U/week in overall (prevalent and incident; fig A) and incident HD patients (fig B) using MSM. These trends were comparable to those from the 2 comparison Cox regression models. ESA>24000U/week was associated with increased mortality in overall and incident patients in all models.



**Conclusions:** Higher ESA doses are associated with worse outcomes in MSM. Given randomized trials in which targeting higher Hb with ESA resulted in worse outcomes, our study suggests high ESA dose itself may be harmful. Focusing on ESA dose instead of Hb level should be considered in anemia management.

## SA-PO205

**Change in Serum Phosphorus Level over Time and Mortality in Hemodialysis Patients**

Jongha Park,[1] Elani Streja,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[2] *[1]Ulsan Univ Hospital, Ulsan, Korea; [2]Harold Simmons Center, UCI, Orange, CA; [3]Memphis VA Medical Center, Memphis, TN.*

**Background:** Previous studies have found an association of hyperphosphatemia with mortality in maintenance hemodialysis (MHD) patients. However, an association between change in serum P over time and mortality has been insufficiently explored.

**Methods:** A total of 66,084 MHD patients treated from (6/2001 to 6/2006) in the US were analyzed. Patients were stratified by baseline serum P values (<3.5, 3.5 to <5.5 and ≥5.5 mg/dL), then were divided into 3 groups in within each stratum based on mean level during the 3rd calendar quarter. Cox proportional hazard models were used with adjustments for casemix and malnutrtion inflammation complex markers.

**Results:** Compared with patients whose serum P level was sustained greater than 5.5 mg/dL, survival benefit was revealed in patients with decrease in serum P level from ≥5.5 mg/dL to 3.5–<5.5 mg/dL. In the same vein, increase in serum P level from 3.5–<5.5 mg/dL to ≥5.5 mg/dL tended to be associated with higher mortality compared with no change in serum P level within 3.5–<5.5 mg/dL . In contrast, decrease to low level (<3.5 mg/dL) was paradoxically associated with increased mortality in comparison with no change in each baseline serum P stratum.

| Baseline P (mg/dL) | 3rd quarter P (mg/dL) | N | HR (95% CI) |
|---|---|---|---|
| ≥5.5 | <3.5 | 396 | 1.40 (1.24–1.58) |
| | 3.5–<5.5 | 9,525 | 0.93 (0.90–0.96) |
| | ≥5.5 | 22,720 | Ref |
| 3.5–<5.5 | <3.5 | 1,789 | 1.28 (1.21–1.36) |
| | 3.5–<5.5 | 19,723 | Ref |
| | ≥5.5 | 9,225 | 1.03 (0.99–1.06) |
| <3.5 | <3.5 | 669 | Ref |
| | 3.5–<5.5 | 1,689 | 0.78 (0.69–0.87) |
| | ≥5.5 | 348 | 0.86 (0.73–1.02) |

**Conclusions:** Decrease in serum P level may be associated with better survival. However, decrease in serum P level below normal range seems to be associated with increased mortality, in which low serum P may be a proxy of poor nutritional state.

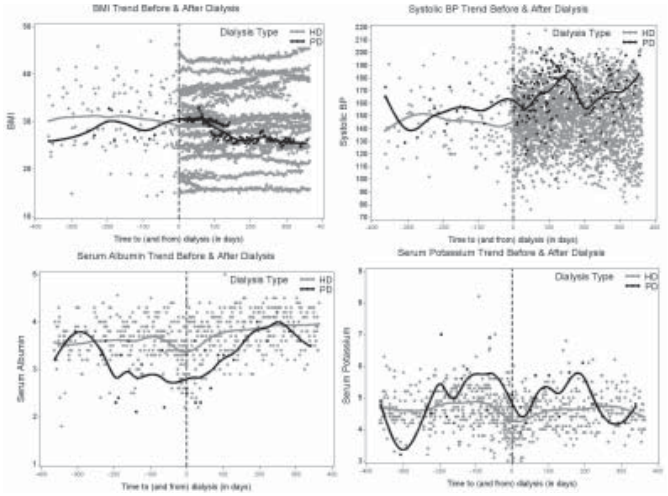
**Trends in Key Clinical Parameters before and after Initiation of Dialysis: The Renal Research Institute (RRI)-CKD Extension Study**

Aleksandar Milovanovic,[1] Anca Tilea,[1] Brenda W. Gillespie,[1] Michael Heung,[1] Peter Kotanko,[2] Rajiv Saran.[1] *[1]Univ of MI; [2]Renal Research Inst.*

**Background:** There is a paucity of studies examining the critical transition and continuum through advanced stages of CKD through initiation of dialysis and beyond.

**Methods:** We conducted a follow-up study of CKD patients at University of Michigan (UM), one of the sites in the RRI-CKD study (a 4-center prospective cohort), using electronic chart review among patients where follow-up had previously ended at or prior to ESRD. Electronic records were abstracted to track clinical events and outcomes 1year pre- and post-dialysis (hemodialysis-HD or peritoneal dialysis-PD).Spline regression examined trends in clinically relevant parameters in the period before and after initiation of dialysis, stratified by HD/PD.

**Results:** 74 of 280 UM patients were identified in the dialysis database.Mean age at dialysis initiation was 57 yrs.,83% were white,56% male;95% had hypertension and 40% were diabetic.52% were on HD and 39% on PD; 21 subjects had died. Comparative trajectories of key clinical parameters are shown in the Figure by dialysis type.Among HD patients,BMI,BP,and serum albumin were relatively stable pre- and post-dialysis. For PD patients, BMI steadily decreased and serum albumin showed a significant dip at 6 months pre- and post-dialysis,while systolic BP increased by an average of 20mmHg after initiation of dialysis.Serum potassium levels showed a dip for both dialysis types 3-months around the time of initiation of dialysis.However, PD patients on average had higher serum potassium levels than those on HD.



**Conclusions:** This pilot study points to significant differences between PD and HD patients in key clinical parameters during the transition from CKD to ESRD.Association between these trajectories and outcomes may provide guidance regarding patient management during this critical transition period.

## SA-PO207

**Healthcare Use before and after Initiation of Dialysis: Renal Research Institute (RRI) CKD Extension Study** Aleksandar Milovanovic,[1] Anca Tilea,[1] Brenda W. Gillespie,[1] Michael Heung,[1] Scott L. Hummel,[1] Peter Kotanko,[2] Rajiv Saran.[1] *[1]Univ of MI; [2]Renal Research Inst.*

**Background:** There is a paucity of studies examining the critical transition and continuum from late stage CKD through initiation of dialysis and beyond. We examined healthcare use 1 year pre- and post-dialysis in a CKD cohort.

**Methods:** We conducted a follow-up study of CKD patients at University of Michigan (UM), one of the sites in the RRI-CKD study (a 4-center prospective cohort), using electronic chart review to extend follow-up previously ending at or prior to ESRD. Clinical events and outcomes 1 year pre- and post-dialysis initiation (hemodialysis-HD or peritoneal dialysis-PD) were abstracted. Rates of hospitalization, emergency (ED), specialist and nephrologist visits were calculated and expressed per 100 person-days. Poisson regression was used to predict number of hospital-days within the year pre- and post-dialysis. Association between type of first vascular access and post-dialysis hospital days was examined adjusted for age, sex, race, diabetes and hypertension.

**Results:** 74 of 280 patients at UM were identified in the dialysis database. Mean age at dialysis initiation was 57yrs, 83% were white, 56% male; 95% had hypertension and 40% were diabetic. Initial modality was HD in 52% and PD in 39%; 21 subjects died (10 on HD, 11 on PD). PD patients had higher nephrology and specialist visit rates than HD patients (0.22 vs. 0.10 and 0.15 vs. 0.10, respectively), with the ED and hospitalization rates being similar between the two groups. Use of catheter as first vascular access type was associated with 2.3 more hospital days and AV Graft with 1.6 more days in hospital vs. arteriovenus (AV) Fistula. The 3 months pre-dialysis and 0-4 months post-dialysis were associated with greater hospital days compared with 5-12 months post dialysis. However, 4-12 months pre-dialysis was associated with the lowest number of hospital days when compared to 5-12 months post-dialysis.

**Conclusions:** Healthcare use was high among CKD patients both during the late CKD and early ESRD. AVF use as first vascular access was associated with lower number of days in hospital compared with AVG or catheter.

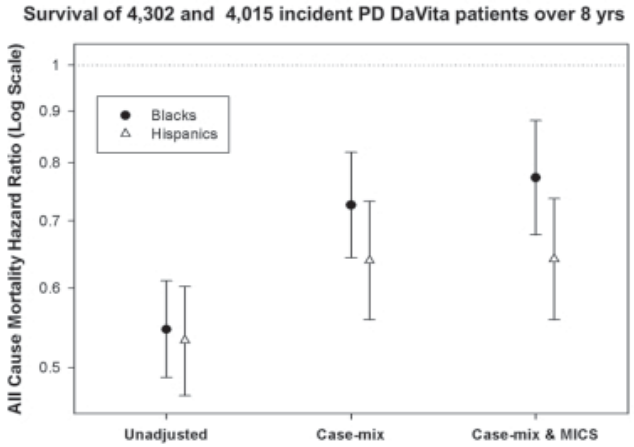
## SA-PO208

**Association of Race-Ethnicity with Mortality in Incident Peritoneal Dialysis Patients** Chunyang Li,[1] Elani Streja,[1] Connie Rhee,[1] Wei Ling Lau,[1] Miklos Zsolt Molnar,[1] Csaba P. Kovesdy,[3] Rajnish Mehrotra,[2] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, UCI, Orange, CA; [2]Harborview Medical Center, Univ of Washington, Seattle, WA; [3]Memphis Veterans Affairs Medical Center, Memphis, TN.*

**Background:** It has been previously reported that African-American and Hispanic dialysis patients have greater survival than whites ("African-American Paradox"). Survival advantage has also been reported in Hispanics despitelower socioeconomic status and faster chronic kidney disease progression to dialysis dependency ("CKD Hispanic Paradox within Paradox"). However the association between race and mortality peritoneal dialysis (PD) patients is still unclear.

**Methods:** We examined 8-year (7/2001-6/2009) all-cause mortality for a cohort of 5,067 DaVita incident (< 90 days dialysis vintage days at the time of entry into cohort) PD patients including 1,052 African-Americans, 765 Hispanic, and 3,250 Whites using Cox proportional hazard models adjusted for case-mix and malnutrition-inflammation complex syndrome (MICS) covariates.

**Results:** Among African-Americans, Hispanics, and shites the mean age (mean + SD) was 52+14, 53+16, and 59+15 yrs old and included 55%, 48% and 42% women; and 46%, 57% and 48% diabetics, respectively. Compared to Whites, African-Americans and Hispanics have a lower risk of mortality; even after adjusting for case mix and MICS markers: HRs (95%CI) 0.77 (0.68-0.88) and 0.64 (0.56- 0.74), respectively. Compared to African-Americans, Hispanics had slightly lower risk of mortality.



**Conclusions:** Incident African-American and Hispanic PD patients have greater survival in comparison to white PD patients. Further studies are needed to examine these racial-ethnic differences.

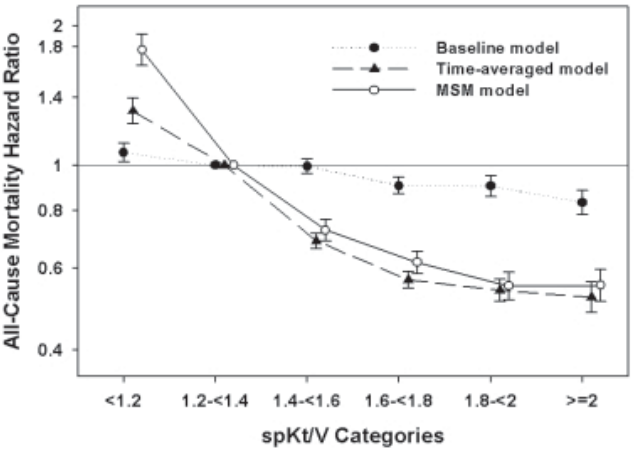
## SA-PO209

**Hemodialysis Dose and Survival: A Marginal Structural Model Analysis** Paungpaga Lertdumrongluk,[1] Elani Streja,[1] Onyebuchi A. Arah,[2] Jongha Park,[5] Csaba P. Kovesdy,[6] Connie Rhee,[1] Steven M. Brunelli,[3] Daniel L. Gillen,[4] Kamyar Kalantar-Zadeh,[1] Mark L. Unruh.[7] *[1]Harold Simmons Center, UCI, Orange, CA; [2]Dept of Epidemiology, Fielding School of Public Health, UCLA, Los Angeles, CA; [3]DaVita, Needham, MA; [4]Dept of Statistics, Univ of California, Irvine, Irvine, CA; [5]Univ of Ulsan College of Medicine, Ulsan, Korea; [6]Memphis Veterans Affairs Medical Center, Memphis, VA; [7]Univ New Mexico, Albuquerque, NM.*

**Background:** Observational studies have consistently demonstrated the survival benefits of greater dialysis dose, whereas randomized controlled trials show conflicting results. The causal analysis of the impact of dialysis dose on mortality requires investigation with novel statistical methods such as marginal structural models (MSM) that account for time-varying confounding.

**Methods:** We quantified the effect of delivered dose of hemodialysis (spKt/V) on mortality in a 2001-2005 cohort of 68,060 patients undergoing thrice-weekly hemodialysis (HD). We compared conventional Cox regression and MSM analyses, accounting for time-varying confounding by applying longitudinally modeled inverse-probability-of-dialysis-dose weights.

**Results:** In Cox models, baseline spKt/V showed a weak negative association with mortality, while higher time-averaged spKt/V was strongly associated with lower mortality risk. In MSM analyses, a spKt/V <1.2 was associated with increased mortality (HR [95% CI] 1.77 [1.64-1.92], whereas lower mortality risk was observed with spKt/V values >1.4 (ref: spKT/V 1.2->1.4): HRs (95%CI) 0.72(0.69-0.76), 0.62(0.58-0.65), 0.55(0.51-0.59), and 0.55(0.51-0.60) for spKt/V ranges of 1.4-<1.6, 1.6-<1.8, 1.8-<2.0, and ≥2.0, respectively.



**Conclusions:** The data suggest higher dosing of hemodialysis is robustly associated with greater survival in MSM analyses that more completely account for time-varying confounding.

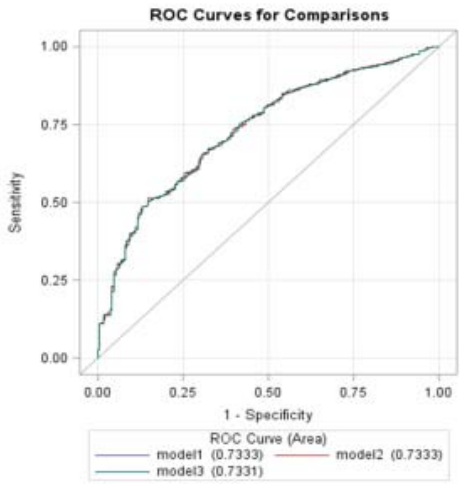
## SA-PO210

**Comparative Effectiveness of Laboratory Measures for One-Year Survival Prediction in Maintenance Hemodialysis Patients** Lu Bai,[1] Elani Streja,[2] Miklos Zsolt Molnar,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh,[2] Daniel L. Gillen.[1] *[1]Dept of Statistics, Univ of California, Irvine, Irvine, CA; [2]Harold Simmons Center, UCI, Orange, CA; [3]Memphis VA Medical Center, Memphis, TN.*

**Background:** It is not clear which potentially modifiable lab measures are associated with greatest survival in maintenance hemodialysis (MHD) patients. We aim to find the best subset of commonly measured markers for prediction of one year survival in patients initiating MHD.

**Methods:** In a 2001-2006 cohort of 63,758 incident MHD patients, we evaluated body mass index (BMI) and 16 lab measures with for ability to predict survival at one year. Logistic regression was used to model probability of survival at one year and the area under the receiver operating characteristic curve (ROC-AUC) was used to assess predictive performance of potential models.

**Results:** The final selected model (Model 1) included 14 variables (albumin, lymphocyte, serum creatinine, BMI, alkaline phosphatase, hemoglobin, phosphorus, ferritin, PTH, WBC, calcium, Kt/v, Kru and nPCR). The second highest rank model (Model 2) included the above covariates in addition to ISAT, while the third most predictive model (Model 3) included only 13 biomarkers, eliminating Kru from the top ranked model. Averaged ROC-AUCs resulting were for the three models 0.7352, 0.7350 and 0.7349, respectively. All three candidate models performed nearly equally (as seen by the heavy overlap in all estimated curves). Models 1 and 2 obtained the same estimated AUC when applied to the test data, however given the greater parsimony of Model 1 it is preferred.



**Conclusions:** We used rigorous prediction model building methods to identify 14 potentially modifiable biomarkers that influence survival at one year among new hemodialysis patients. Identification of these factors provides targets for treatment among new hemodialysis patients.

## SA-PO212

**Patients with Primary Glomerulonephritis on Renal Replacement Therapy May Be Cured: Data from the Veneto Dialysis and Transplantation Registry** Maurizio Nordio, Nicola Tessitore, Cataldo Abaterusso, Barbara Rossi, Giovambattista Virga, Francesco Antonucci. *Veneto Dialysis and Transplantation Registry, Padua, Italy.*

**Background:** Survival on RRT is affected by the primary renal disease (PRD). By using relative survival analysis (patients' mortality is compared with the general population) we observed that patients on RRT with primary glomerulonephritis (PGN) had the best survival. After ten years of RRT, patients with PGN experience the same mortality rate as the general population, suggesting the likelihood of cure. The study aims at estimating the fraction of cured patients with PGN and cure determinants.

**Methods:** We considered the cohort of incident patients with PGN on RRT in the period 01/01/1998 – 31/12/2010 in Veneto (Italy). Demographic features, RRT modality and the main comorbidities were considered. Cure models are a type of survival analysis assuming a proportion of subjects who will never experience the event. These models allow incorporation of the expected background mortality and thus estimate relative survival when cure is a possibility.

**Results:** In the study period, 813 of the 6962 RRT patients had a diagnosis of PGN. Median age was 56, 70% were male. The estimated cured fraction was 48%. Heart disease and cancer were associated with an increased risk of death (HR=2.7 [2.04 – 3.58] and 2.65 [1.85 – 3.80] , respectively), while anti-hypertensive therapy reduced the risk (HR=0.7 [0.49 – 0.84]). By postestimation forecasting, in presence of heart disease and cancer, the cured fraction fell down to 15% and 16%. If both were present, the cured fraction was virtually nil. Being on anti-hypertensive therapy increased the cured fraction up to 64%. Most patients alive after ten years were transplanted (77%).

**Conclusions:** Our study highlights the influence of PRD and comorbidities over the prognosis of RRT patients. Patients with PGN may be cured, since 48% of them reach the same mortality as the general population, indicating the effectiveness of RRT modalities in controlling uremia. Moreover, it underlines the relevance of comorbidities, because of their independent effect on survival rates. Our findings suggest that the tendency of considering RRT as a unique condition may be misleading.

## SA-PO213

**Comparative Effectiveness of Iron Formulation and Dosing Practices on Health-Related Quality of Life in Patients on Hemodialysis** Janet K. Freburger,[1] Abhijit V. Kshirsagar,[3] Lily Wang,[1] Alan R. Ellis,[1] Wolfgang C. Winkelmayer,[4] M. Alan Brookhart.[1,2] *[1]Sheps Center for Health Services Research, Univ of North Carolina, Chapel Hill, NC; [2]Dept of Epidemiology, Univ of North Carolina, Chapel Hill, NC; [3]UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC; [4]Div of Nephrology, Stanford Univ, Stanford, CA.*

**Background:** While studies have examined the effects of intravenous (IV) iron on anemia parameters in the hemodialysis population, we are unaware of any that have examined how IV iron affects health-related quality of life (HRQOL). We examined the associations of different iron formulations and dosing strategies with HRQOL.

**Methods:** We conducted a retrospective cohort study using clinical data from a small dialysis provider (2006-2008) merged with data from the United States Renal Data System. We examined data on 1,253 patients who received center-based hemodialysis. Iron formulation use (ferric gluconate vs iron sucrose) and dosing (bolus: large doses over a short period vs maintenance: smaller, less frequent doses) were assessed during repeated 1-month exposure periods (n=1,782). Generalized linear mixed models, adjusting for dialysis facility, epoetin alfa (EPO) dose, and clinical/laboratory variables were used to estimate the effects of iron on HRQOL (measured by the SF-36) during a 3-month follow-up period. Effects were also estimated within clinically-relevant subgroups.

**Results:** Compared to maintenance dosing, patients receiving bolus dosing had higher HRQOL scores (mental health summary score 4.2 points higher, 95% CI: 0.9, 7.4; physical health summary score 2.4 points higher 95% CI: -1.3, 6.0). These differences were below the minimum clinically important difference of 5 points. The positive effects of bolus dosing were greater among individuals who were EPO hypo-responsive or who had lower baseline hemoglobin or iron indices. Overall, we did not observe clinically meaningful differences in HRQOL between patients receiving ferric gluconate versus iron sucrose.

**Conclusions:** Bolus iron dosing was associated with improvements in HRQOL, particularly for individuals who were EPO hypo-responsive or who had lower hemoglobin or iron indices at baseline.

## SA-PO214

**Proteinuria with High Serum Level of Hepcidin-25 Indicates a Bad Prognosis in Non-Hodgkin's Lymphoma Patients** Masaki Hara,[1] Minoru Ando,[1] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Renal Div, Dept of Medicine, Tokyo Metropolitan Komagome Hospital, Bunkyo-ku, Tokyo, Japan; [2]Dept IV of Internal Medicine, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan.*

**Background:** Serum hepcidin-25 level increases in the state of chronic inflammation including kidney disease and cancers; however, its clinical impact on disease prognosis has not fully understood.

**Methods:** One-year prospective study was conducted to ascertain an impact of serum hepcidin-25 on mortality in non-Hodgkin's lymphoma (NHL) patients with CKD. The cohort comprised 50 NHL patients receiving chemotherapy (mean age, 66 years). Serum hepcidin-25 level was measured by liquid chromatography-mass spectrometry. Proteinuria, a simple sign of kidney disease, was defined as a dipstick test ≥1+, persistent in three consecutive examinations. Cumulative survival curves were drawn with Kaplan Meier method, which were stratified into 4 groups by both presence or absence of proteinuria and presence or absence of elevation in serum hepcidin-25 more than the mean value. Multivariable proportional hazards regression analysis was used to calculate hazard ratio (HR) with its 95% confidence interval (CI) for mortality.

**Results:** Prevalence of proteinuria was 14%. Mean serum hepcidin-25 level was 65.4 ± 60.9 ng/ml (the healthy reference: 22.2 ± 12.3 ng/ml). Distribution of the 4 groups was as follows: non-proteinuria with lower hepcidin-25 (58%), non-proteinuria with higher hepcidin-25 (28%), proteinuria with lower hepcidin-25 (0%), and proteinuria with higher hepcidin-25 (14%). The Kaplan-Meier estimate at 1 year was the highest (85.7%) in the group of proteinuria with higher hepcidin-25 among all. The HR (95% CI) of this group was 7.98 (2.20–29.5), as compared with the group of non-proteinuria with lower hepcidin-25 levels.

**Figure. Kaplan-Meier curves stratified by both proteinuria (presence or absence ) and elevation in serum hepcidin-25 (presence or absence )**

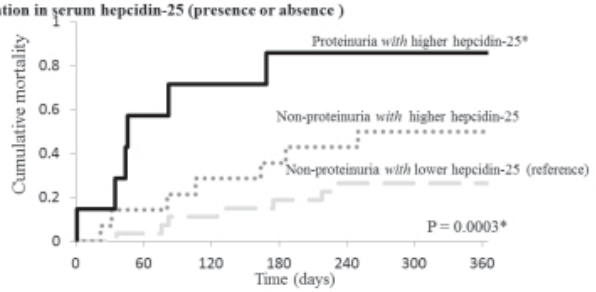

**Table. The joint risk of proteinuria and hepcidin-25 for one year mortality**

| | Multivariable analysis | |
|---|---|---|
| Variable | HR (95% CI) | P value |
| Age | 1.02 (0.99 - 1.06) | 0.2434 |
| Gender, men | 1.07 (0.32 – 3.10) | 0.9031 |
| Stages of NHL | 1.03 (0.57 – 2.15) | 0.9194 |
| Proteinuria *with* higher hepcidin-25 | 7.98 (2.20 – 29.5) | 0.0021 |

**Conclusions:** Proteinuria accompanied by serum hepcidin-25 elevation may predict poor outcome in NHL patients.

## SA-PO215

**Outcomes of Pediatric-Onset CKD Patients Who Underwent Health Care Transition Preparation** Maria E. Ferris, Nicole M. Fenton, Gerald A. Hladik, Abhijit V. Kshirsagar. *UNC Kidney Center, Univ of North Carolina at Chapel Hill.*

**Background:** The impact of health care transition preparation (HCTP) in pediatric-onset CKD patients transitioning from pediatric to adult-focused providers needs to be characterized.

**Methods:** We conducted an IRB approved cross-sectional study of adult nephrology patients who received at least one HCTP session at the UNC pediatric nephrology clinic between July '07 to May '13 (intervention). Disease self-management/readiness to transition was assessed by the provider-administered UNC TRxANSITION Scale and the self-administered STARx Survey. Adherence was ascertained based on health provider notes. Health outcomes were classified as no change or worse medical status, including transplant loss or death, based on chart review. Data was double entered and analyzed in SPSS.

**Results:** We enrolled 90 participants (66 intervention, 24 controls) with the following characteristics: 36 (40%) male; mean age of diagnosis 10.7 ± 5.67 years; 46% African American, 35% White, 8% Hispanic and 11% other race; 48% had private insurance and 50% came from a two-parent household. Currently, 25% of patients receive anti-depressants, 2% ADHD treatment and only 30% reported school attendance/employment. There was one death. Glomerular disease was reported in 59% of patients, transplant 34%, with a mean eGFR 66 ± 33 ml/min/1.73m$^2$(range 5-110); 50% were diagnosed at ≤ 12 years of age (30% prenatally or in the first year of life). Adherence was documented in 63% of patients and 17% were non-adherent. 49% of patients were overweight (BMI ≥ 25 kg/m$^2$), and 31% were obese (≥ 30 kg/m$^2$ ). The BMI of patients with glomerular disease was higher (28.71±7.45) than that of non-glomerular patients (26.93±5.85) (p=0.01). Intervention patients had superior outcomes than controls both in terms of clinical status (F= 5.64, p=0.02) and adherence($X^2$=3.76, p=.05).

**Conclusions:** In this single center cohort, survivors of pediatric-onset CKD have a lower employment rate and higher levels of depression compared to the general population. Health care transition preparation appears to play a significant role in improving health outcomes and adherence.

*Funding:* Private Foundation Support

## SA-PO216

**Renoprotective Effectiveness of Third Generation Calcium Channels Blockers** Ricardo M. Heguilen, Amelia Rita Bernasconi. *Nephrology, Hospital Juan A Fernandez, Buenos Aires, Argentina.*

**Background:** Angiotensin converting enzyme inhibitors (ACEIs) and angiotensin 2 receptor blockers (ARBs) have widely recognized renoprotective properties. Third generation dihydropyridine calcium channel blockers (3dhpCCBs), acting on L as well as T-type calcium activated channels, would reduce intraglomerular pressure (P-GC) and urine protein excretion (UprotV) in several nephropathies. The main aim of this study was to assess whether the addition of the 3dhpCCB lecarnidipine (LER) has similar renal effects to the addition of an ARB in patients (Ps) with chronic kidney disease (CKD) receiving renoprotection with enalapril (ENL).

**Methods:** Normotensive, stage 2-3 CKD Ps with UprotV < 2 g/d, and receiving ENL for > 12 months were included. Renal function as well as UprotV were assessed at baseline; then Ps were assigned to fixed dose of losartan (LOS) or LER. Blood pressure, creatinine clearance and UprotV was assessed every 4 ± 0.5 months. All data are expressed as mean ± SD; repeated measures ANOVA was used and p values < 0.05 were considered statistically significant.

**Results:** Sixty four (44 men) 48 – 79 years old Ps, receiving ENL (10-25 mg/d) were included. LOS (50 mg/d) was added in 31 while LER (10 mg/d) was added in 33. The addition of LOS or LER produced no changes in BP. Serum creatinine –SCr- (LOS 1,48 ± 0,28 and LER 1,44 ± 0,29 mg/dL) and CrC (LOS 46.2 ± 5.8 and LER 45.1 ± 8.7 mL/min/1.73 m2) remained stable (p: NS) at 2 ½ years.

UprotV (g/day) decreased (p< 0,05) similarly in both groups (p: NS) from 1.36 ± 0,4 to 0,71 ± 0,3 –LOS- and from 1,32 ± 0,44 to 0,67 ± 0,31 –LER-).

**Conclusions:** 1. The addition of LER to the standard therapy with ENL has similar renoprotective effect to ENL plus LOS.

2. 3dhpCCBs could be an alternative for those Ps not responding to the dual blockade of the RAS or in whom such measure produced adverse consequences.

3. Additional adequately designed studies in a larger number of individuals are necessary to confirm the benefit of this group of agents.

## SA-PO217

**Effect of Steroid Pulse Therapy in Patients with IgA Nephropathy According to the Oxford Classification** Kyeong Woo Nho, Wonseok Yang, Su-Kil Park. *Div of Nephrology, Dept of Internal MedicineCollege of Medicine, Univ of Ulsan, Asan Medical Center.*

**Background:** Steroids have been shown to reduce proteinuria and preserve renal function. We investigated the effect of steroid pulse therapy in patients with IgA nephropathy according to the Oxford classification.

**Methods:** We assessed 33 IgA nephropathy patients. Pathologist reviewed biopsy slide was not over 6 years according to the Oxford classification. All patients had been maintained ARB or ACEi. 17 Patients were treated with 500 mg intravenous MP every 2 weeks for 6 months to improve renal function. The efficacy of MP pulse was analyzed by comparing the slopes of eGFR(ml/min/1.73m2) and log transformed urine albumin/creatinine ratios before,during,and after therapy using linear regression coefficients. We compare outcome between 17 steroid pulse groups(Group1) and 16 untreated groups(Group2).

**Results:** Median duration between biopsy and pulse therapy is 1month(range 0~73). Mean follow-up is 33.6months(12~46) after pulse.

| | ΔeGFR/month | P |
|---|---|---|
| Group 1(before&after steroid) | -0.68(0.52) vs -0.34(0.35) | 0.08 |
| Group1(before)&Group2 | -0.68(0.52) vs -0.29(0.55) | 0.05 |
| Group1(after)&Group2 | -0.34(0.35) vs -0.29(0.55) | 0.81 |

According to the Oxford classification 1/17 patient was M1, 2/17 were E1, 14/17 were S1, 6/17 were T0, 10/17 were T1, 1 patient was T2 in group1. Using $\chi 2$ test, we found no significant differences in Oxford classification of histological grade between group 1 and 2. Mean eGFR for group1 was 41.3±15.7. Linear regression analysis showed improvement of decline of eGFR after steroid pulse in 9 of 14 group1 patients with initial GFR>30. After steroid pulse, the rate of monthly decline of eGFR decreased in group1(-0.68±0.52 vs -0.34±0.35, p=0.08). There was no improvement of urine albumin/creatinine ratio in group1. As the grade of T increased, the rate of decline of eGFR increased in both group(p=0.02). Other parameters in Oxford classification were not a significant variable.

**Conclusions:** Steroid pulse therapy could improve the decline of eGFR in IgA nephropathy. Among the Oxford classification, only T grade affects the change of eGFR irrespective of steroid pulse therapy.

## SA-PO218

**Sedentary Activity Is Associated with Increased Mortality and Light Intensity Activity Is Associated with Decreased Mortality in CKD** R. Filipowicz,[1] G. Wei,[1] R. Marcus,[1] Michel Chonchol,[2] Tom Greene,[1] Srinivasan Beddhu.[1] *[1]U of Utah; [2]U of Colorado.*

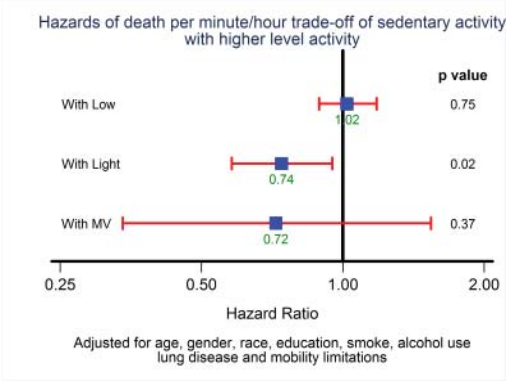
**Background:** Sedentary activity(SA) is emerging as a major risk factor for mortality in the general population. However, the associations of SA and physical activity (PA) intensity levels with mortality has not been studied in CKD. Therefore, we examined the associations of objectively measured SA and PA intensity levels with mortality in CKD using 2003-2004 National Health & Nutrition Examination Survey (NHANES) data.

**Methods:** PA levels were measured with Actigraph 7164 accelerometer in NHANES. Mortality data until Dec 31, 2006 were obtained by NHANES. For the current analyses, we included 405 NHANES participants aged >20 yrs with eGFR <60 ml/min/1.73m$^2$ & valid accelerometer data (wore the device ≥10 hr/day & ≥4 days). Cox regression models adjusted for age, gender, race, education, smoking, alcohol use, lung disease and mobility limitations were used to examine the associations of PA levels with mortality.

**Results:** The mean ± SD age was 69.3± 11.8 yrs. 39% were men and 6% were black. There were 154 deaths over 1190 years of follow-up. Table 1 summarizes the definitions and duration of PA.

| Definitions and duration of PA levels | | |
|---|---|---|
| | Accelerometer Counts (counts/min) | Average Duration Spent in PA Level (min/hr) |
| SA | <100 | 40± 6 |
| Low | 100 to 499 | 13 ± 4 |
| Light | 500 to 2019 | 6 ± 4 |
| MV | ≥ 2020 | 1 ± 1 |

Each min/hr ↑ in SA was associated with ↑ hazard of mortality (HR 1.10, 95% CI 1.04, 1.17, p=0.004). Figure 1 shows the association of trade-off of 1 min/ hr of SA with each of low, light or MV activity holding the other two activities constant.



These data suggest that trade off of SA with light PA is significantly associated with ↓ mortality while MV might also confer a lower mortality.

**Conclusions:** SA is associated with increased mortality in CKD and replacing SA with light or MV activities are likely to reduce mortality.

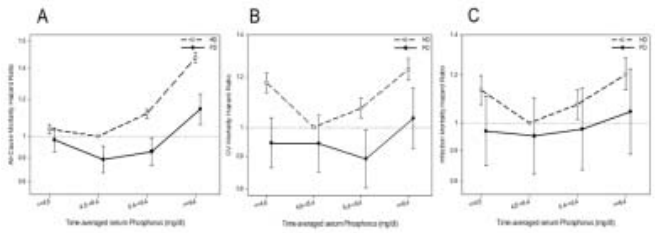
## SA-PO219

**Comparative Survival Predictability of Phosphorus and Albumin-Adjusted Calcium in HD and PD Patients** Vanessa A. Ravel,[1] Elani Streja,[1] Jongha Park,[3] Wei Ling Lau,[1] Connie Rhee,[1] Csaba P. Kovesdy,[4] Rajnish Mehrotra,[2] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, UCI, Orange, CA; [2]Harborview Medical Center, Univ of Washington, Seattle, WA; [3]Univ of Ulsan College of Medicine, Ulsan, Korea; [4]Memphis VA Medical Center, Memphis, VA.*

**Background:** While the association of calcium (Ca) and phosphorous (P) levels with death risk is well established in patients undergoing hemodialysis (HD), there is a paucity of data for peritoneal dialysis (PD) patients. Furthermore, there are no data to determine whether the thresholdCa and P levels above which risk for death is increased is the same for those on PD vs HD.

**Methods:** Among a 2001-2006 cohort of 129,604 dialysis (10,066 on PD and 118,998 on HD at study entry) patients with Ca and P data. Time-averaged Cox models were examined to assess the comparative survival predictability of P and albumin-corrected Ca in HD vs PD patients.

**Results:** Risk for death was higher for HD patients with albumin-corrected Ca≤9.1mg/dl or >9.5mg/dl, but was lower in all sub-groups of PD patients with Ca<9.9 mg/dl (ref: HD patients with Ca 9.4-<9.5mg/dl). Risk for death was higher for individuals undergoing HD with P<4.5 mg/dl or >5.4 mg/dl (ref: HD patients with P 4.5-<5.4mg/dl), and PD patients with P>6.4 mg/dl. The risk for death for HD was higher than for PD patients at all levels of P and across all causes of death.



(A) All-cause mortality. (B) Cardiovascular mortality. (C) Infection related mortality. Reference group: hemodialysis patients with serum phosphorus levels from 4.5-5.4 mg/dl.

**Conclusions:** The associations between Ca and P with mortality are disparate between HD and PD patients. Low P level is associated with poor outcomes in HD, whereas high P levels predict mortality for patients with either modality, with the threshold above which risk is increased being higher in PD patients. Further studies exploring differences in the association of death risk of mineral metabolism parameters in HD vs. PD patients are warranted.

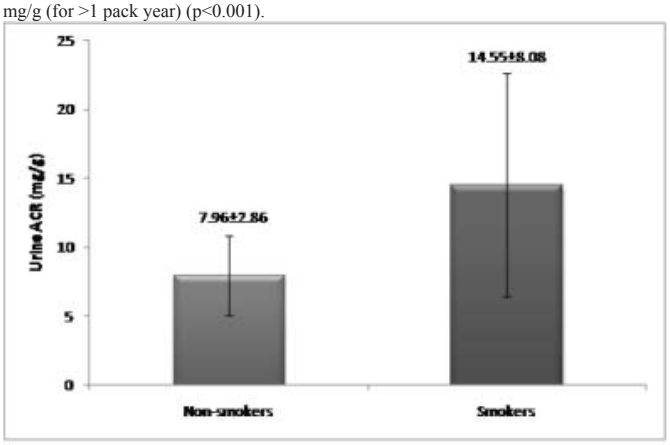
## SA-PO220

**Effect of Cigarette Smoking on Renal Function in Healthy Subjects** Om Parkash Kalra, Abhishek V. Patil, Sunil Agarwal, Amitesh Aggarwal, Ashok K. Tripathi, Anil Kumar Yadav. *Univ College of Medical Sciences and Guru Teg Bahadur Hospital, Delhi, India.*

**Background:** The prevalence of chronic kidney disease (CKD) is increasing, hence there is need to identify various risk factors associated with etiopathogenesis of renal disease. Smoking as a risk factor for pathogenesis of renal dysfunction has been less well studied. In our study, we attempted to study the effect of smoking on renal function in healthy adults.

**Methods:** This cross-sectional study was conducted on healthy male subjects in the age group of 31-40 years. The study consisted of 40 subjects in each of the two groups: non-smokers and smokers (cigarettes only). The claimed smoking status of study subjects was verified using smokerlyzer. Various laboratory investigations included assessment of renal function (eGFR) using CKD-EPI and MDRD equations, and urine albumin creatinine ratio (ACR).

**Results:** Using EPI equation, mean eGFR was 110.7±9.6 mL/min/1.73m$^2$ (non-smokers) and 110.7±9.4 mL/min/1.73m$^2$ (smokers) (p=0.999). Using MDRD formula, mean eGFR was 109.0±16.3 mL/min/1.73m$^2$ (non-smokers) and 110.1±15.7 mL/min/1.73m$^2$ (smokers) (p=0.750). Mean urine ACR was significantly (p<0.001) higher in smokers (14.55±8.08 mg/g) as compared to non-smokers (7.96±2.86 mg/g) as shown in Figure 1. Further within smokers, pack years of cigarette smoking showed a significant positive correlation with urine ACR levels (p<0.001) (r=0.858). In smokers urine ACR based on number of pack years of smoking was: 7.97±2.74 mg/g (for ≤1 pack year) 17.73±7.90 mg/g (for >1 pack year) (p<0.001).



**Conclusions:** In healthy young males, cigarette smoking was associated with significantly higher urine ACR even within normal limits of albumin excretion rates. Higher degrees of cigarette smoking was associated with increasing urine ACR levels; however, there was no significant effect of smoking on eGFR in our cross sectional study.

## SA-PO221

**Risk of CKD Progression and Hypertension: U.S. Adults, NHANES 2007-2010** Lori D. Bash, Sheng-wei Wang, Panagiotis Mavros. *Global Health Outcomes, Merck & Co., Inc., Whitehouse Station, NJ.*

**Background:** We assessed 1839 US adults with chronic kidney disease (CKD), including 1336 with comorbid hypertension (HTN).

**Methods:** Among non-pregnant 2007-10 NHANES participants with blood pressure (BP), serum, and urinary measures, CKD patients were identified by KDIGO 2012 albuminuria and eGFR based definitions; HTN status was based on self-report and/or measured BP. Estimated risk of CKD progression was based on KDIGO 2012 guidelines for eGFR and albuminuria levels. All proportions are representative of the US population.

**Results:** Adults with CKD (13.5% of US), were on average 61 yrs old, 58% female, 72% white, 11% black, 7.5% Mexican American, 67% had HTN, 25% diabetes, 8.7% a history of CHD, and 54% dyslipidemia. Those with both HTN and CKD were older (66 vs 51 yrs), with more comorbidities compared to those without HTN. Among subjects with both, 76% were treated for HTN, 50% reaching target BP. Only those with CKD can be at risk of CKD progression. Those with both CKD and HTN were more often at higher risk than those without HTN; among them, those with controlled BP were less often at higher risk. Independent of patient characteristics, among adults with CKD, those with controlled HTN were 1.70 (95% CI 1.08-2.67) times more likely to be at high or very high risk compared to those without HTN. Those with HTN and uncontrolled BP were more likely to be at high or very high risk (OR: 1.88, 1.19-2.97).

| | US (n=10270) | All CKD (n=1839) | CKD, No HTN (n=503) | CKD and HTN (n=1336) | CKD&HTN, BP Controlled (n=653) | CKD&HTN, BP Not Controlled(n=683) |
|---|---|---|---|---|---|---|
| Low Risk (%) | 86.51 | 0 | 0 | 0 | 0 | 0 |
| Moderately Increased Risk (%) | 9.64 | 71.51 | 82.85 | 65.85 | 66.32 | 65.39 |
| High Risk (%) | 2.47 | 18.39 | 13.7 | 20.75 | 21.54 | 19.96 |
| Very High Risk (%) | 1.36 | 10.1 | 3.44 | 13.39 | 12.14 | 14.65 |

**Conclusions:** HTN, a risk factor for and of CKD, affects $^2/_3$ of those with CKD. HTN, especially uncontrolled, is independently associated with a higher risk of CKD progression. Observations suggest secondary prevention measures such as controlling BP may be critical in decreasing CKD progression among US adults. Findings should be further studied to inform treatment guidelines, therapeutic developments, and patient care.

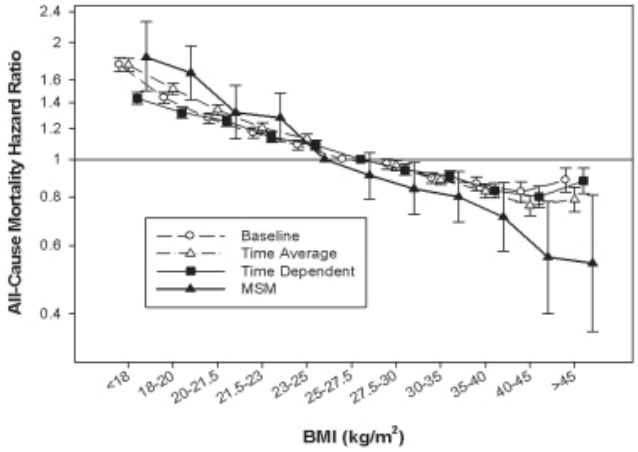
## SA-PO222

**Examining the Obesity Paradox in Hemodialysis: A Marginal Structural Model Analysis** Megha Mahendra Doshi,[1] Elani Streja,[1] Connie Rhee,[1] Wei Ling Lau,[1] Allen R. Nissenson,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, UCI, Orange, CA; [2]Davita Inc., El Segundo, CA; [3]Memphis Veterans Affairs Medical Center, Memphis, VA.*

**Background:** Prior studies have found an inverse association between body mass index (BMI) and mortality for hemodialysis (HD) patients (obesity paradox). It has been suggested that these observations are a result of biases such as selection bias and that studies are needed to investigate the association between BMI and mortality accounting for time-dependent confounders using marginal structural modeling (MSM) and inverse probability of censoring weights. We hypothesize that even after applying these novel methods, the inverse association between BMI and mortality in HD patients is robust.

**Methods:** We examined the associations between BMI with all-cause mortality among a 2001-2006 cohort of 127,324 adult HD patients using 11 categories of BMI. We examined baseline, time-averaged, and time-varying BMI using multivariable adjusted Cox models, as well as an MSM considering time-varying BMI and time-dependent confounders.

**Results:** In all four models, BMI showed a linear incremental inverse association with all cause-mortality. In MSM analyses, compared to a BMI of 25-27.5, BMI<18 was associated with a 83% higher risk of mortality (HR 1.83, 95% CI 1.48-2.26), whereas the mortality risks were significantly lower with higher BMI: HRs (95%CI) 0.84(0.72-0.98), 0.80(0.69-0.93), 0.71(0.58-0.87), 0.56(0.40-0.78), and 0.55(0.36-0.81) for BMI ranges of 27.5-<30, 30-<35, 35-<40, 40-<45,and ≥45, respectively. The greatest survival advantage of higher BMI was observed with a BMI range of 40-<45 in MSM.



**Conclusions:** The linear inverse relationship between BMI and all-cause mortality is robust across models including MSM analyses that more completely account for time-dependent confounding and potential selection biases.

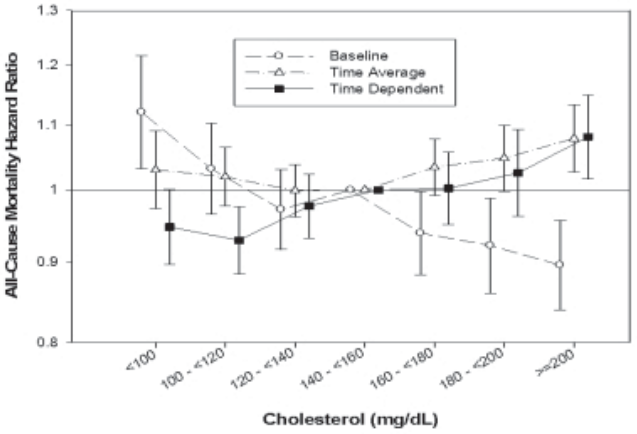
## SA-PO223

**Association of Cholesterol and Mortality in Hemodialysis Patients: A Joint Model Analysis** Megha Mahendra Doshi,[1] Elani Streja,[1] Hamid Moradi,[1] Connie Rhee,[1] Allen R. Nissenson,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, UCI, Orange, CA; [2]Davita Inc., El Segundo, CA; [3]Memphis VA Medical Center, Memphis, TN.*

**Background:** Earlier data has shown a paradoxical linear inverse association with cholesterol levels and mortality in hemodialysis (HD). However, these data did not account for cholesterol changes over time. We hypothesize that this inverse linear association is robust when using methods such as joint modeling that account for variations over time.

**Methods:** We examined associations between cholesterol with all-cause mortality in a 2001-2006 cohort of 22, 435 adult HD patients. We conducted Cox models for baseline, time-averaged, and time-dependent cholesterol, as well as a joint-model using longitudinal portion to model exposure over time combined with a Weibull proportional hazard survival submodel and accounts for the random effects variance covariance matrix. All models were adjusted for case-mix and malnutrition and inflammation (MICS) covariates.

**Results:** Baseline cholesterol showed a linear inverse association with mortality. When examining a time-dependent or time-averaged model, the pattern of association reverses direction. In joint model analyses, we observed a decreasing linear trajectory 0.98 for cholesterol over time, and an 18% mortality increase.



| Joint Models: Level of Adjustment | Estimate | 95% CI |
|---|---|---|
| Chol_50 longitudinal slope | 0.98 | 0.98-0.98 |
| Unadjusted HR | 0.89 | 0.86-0.93 |
| Casemix HR | 0.93 | 0.89-0.97 |
| Casemix + MICS HR | 1.18 | 1.13-1.22 |

**Conclusions:** The linear relationship between cholesterol and mortality is no longer inverse after accounting for cholesterol time variations. Further studies are needed to examine the relationship between change in cholesterol and mortality over time.

## SA-PO224

**Age and Gender Variations in the Management of Renal Disease in South India: An Epidemiological Experience from State Sponsored Insurance Programme** Devaraju Sree Bhushan Raju. *Nephrology, Nizams Institute of Medical Sciences, Hyderabad, Andhra Pradesh, India.*

**Background:** There is no major epidemiological study done in India based on insurance data especially among those with various kidney diseases.The government of Andhra Pradesh has sponsoredfree, cash less health Insurance programme called Aarogyasri (AS) to cover all the people below the poverty line in the state.

We aim to study the Nephrology services provided under this programme especially the age and gender variations in them.

**Methods:** We analysed all the patients admitted under AS for Renal disease like Acute Kidney Injury ( AKI; n=9083), Chronic Kidney Disease stage V (CKD; n=14146), Nephrotic syndrome (NS; n=2951), Rapidly progressive Renal failure (RPRF;n=1785), maintenance hemodialysis (MHD; n=111158) and renal transplantation (Tx; n=737)was between April 2007 to July 2012.

**Results:** Younger patients (<40yrs) constitute nearly 40%. Patients of AKI, CKD and MHD were majorly between 40-60 yrs. RPRF was common between 20—40 yrs of age. NS was seen predominantly before 20 yrs (45%).Tx was not a preferable choice for many and majority continued on MHD. Nearly 70 % of the patients of Tx group were less than 40 yrs. Less than 10 % of patients on MHD were > 60 yrs. Only one third of patients in AKI, CKD and MHD groups were females. Tx was opted for males only and 80% of the Tx patients were males.

| Age groups | AKI | CKD | RPRF | NS | Tx | MHD |
|---|---|---|---|---|---|---|
| Total no of patients | 9083 | 14146 | 1785 | 2951 | 737 | 1111158 |
| <20 | 684 | 852 | 334 | **1322** | 102 | 4383 |
| 21-40 | 2862 | 4761 | **789** | 1149 | **501** | 42927 |
| 41-60 | **4136** | **6792** | 549 | 440 | 132 | **53515** |
| >61 | 1401 | 1738 | 110 | 37 | 1 | **10330** |
| Females | **3033** | 4129 | 638 | 1315 | 129 | 28964 |
| Males | 6050 | 10017 | 1145 | 1634 | **608** | **82194** |

**Conclusions:** 40% of patients with kidney disease were young (< 40 yrs) and is male preponderant. MHD was the preferred modality and Tx was not opted by many. Further analysis of this largest epidemiological study on renal diseases would help in planning preventive and treatment strategies at national level.

*Funding:* Government Support - Non-U.S.

## SA-PO225

**Clinical Outcomes in Australian Chronic Kidney Disease (CKD) Patients** Helen G. Healy,[1,2,3] Andrew John Mallett,[1,2,3] Anne Salisbury,[1,2,3] Zaimin Wang,[1,3] Wendy E. Hoy.[1,3] *[1]CKD.QLD; [2]Dept of Renal Medicine, Royal Brisbane and Women's Hospital (RBWH), Brisbane, Queensland, Australia; [3]Centre for Chronic Disease, School of Medicine, Univ of Queensland, Brisbane, Queensland, Australia.*

**Background:** CKD is the most common chronic disease in Australia, and renal replacement therapy (RRT) the most common cause of hospitalisation.

**Methods:** To describe longitudinal outcomes of patients with CKD managed in a metropolitan Australian Renal Unit through a registry of all consenting patients in public renal practices in Queensland (~10,800, CKD.QLD). Clinical outcomes and non-dialysis admissions were documented for all CKD patients followed in renal clinic at the RBWH over the first year after their recruitment to the CKD.QLD registry. At this analysis 46.7% of prevalent CKD patients at RBWH had consented and 612 had been enrolled for at least 12 months.

**Results:** After ≥12 months, of these 612 patients, 33 had started RRT (5.4%), 14 had died (3.2%), all prior to start of RRT (if planned), and 12 had been discharged or transferred. Cause of death was ESRD (4), cardiovascular (5), malignancy (3), other/unknown (2).

286 of these 612 patients (47%) had at least one RBWH hospitalisation, with a range of 1 to 25 episodes, and a median of 2. They had a total of 919 hospital episodes, with length of stay (LOS) ranging 1 to 95 days, mean LOS of 10.9 days and total LOS of 3110 days. Admitting units were renal (26.7%), general medical (22%), surgical (18.1%), specialist medical (12.1%), urology (7.9%), vascular (3.3%) and "others" (9.9%).

29% of hospitalised CKD patients, (13.6% of the total eligible cohort) generated 65% of admissions, LOS and costs. This group of 83 frequent and heavy users accounted for 602 admissions, 2035 bed days and AUD$1,523,130.51 of costs over the 1year period. Their mean age was 65.9 years, 50% were female and they most commonly CKD Stage 4 (33.7%). A higher proportion had CKD Stage 5 (18% vs 8.5%) and diabetic nephropathy (29% vs 18%).

**Conclusions:** This is the first report of longitudinal outcomes in CKD.QLD. The hospitalisations and costs are considerable with most generated by a subset of frequent heavy users. Further definition of this subset is required.

*Funding:* Government Support - Non-U.S.

## SA-PO226

### Heart Valvular Calcification: Epidemiology in Different Stages of Chronic Kidney Disease and Association with Cardiovascular Morbidity

Zhilian Li, Xinling Liang, Shuangxin Liu, Wenjian Wang, Ruizhao Li, Lixia Xu. *Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

**Background:** Heart valvular calcification (VC) in dialysis patients is associated strongly with incident all-cause and cardiovascular mortality. However, its epidemiologic data in earlier stages of chronic kidney disease (CKD) are scarce, and its association with cardiovascular (CV) morbidity remains unknown.

**Methods:** We retrospectively analyzed 2,452 Chinese CKD in-patients with complete clinical records and echocardiography data in 2008-2012. Patients were divided into 6 groups: CKD stage 1-4, Stage 5 for those still not on or initiated hemodialysis for <3 months, Stage 5D for patients undergoing hemodialysis for ≥3 months. Prevalence of PH and CV morbidity was investigated. Risk factors for CV morbidity were evaluated by logistic regression model. Cardiovascular morbidity were defined as myocardial infarction, angina, sudden death, heart failure, stroke, TIA, for hospitalization and peripheral vascular disease.

**Results:** VC was detected in 265(10.8%) patients. Prevalence of VC in CKD Stage 1-5D was 0.7%, 0.5%, 7.1%, 6.9%, 8.9% and 30.8%, respectively, whereas CV morbidity were found in 648(26.4%) patients, and in stage of CKD1-5D, 2.0%, 17.2%, 19.1%, 23.2%, 29.2%, 48.8%, respectively. CV morbidity was more prevalent in VC group than non-VC group. Patients with VC had higher risk for CV disease (OR: 1.56, 95%CI: 1.07-2.28) by logistic regression.

**Conclusions:** Our study provided the epidemiologic data of heart VC in different stages of CKD patients. Even in earlier stages of CKD, VC may be a risk factor for CV morbidity. However, evidence of VC in predicting CV morbidity from prospective studies in this population is needed.

*Funding:* Government Support - Non-U.S.

## SA-PO227

### Gender, Nephrosclerosis and Descent in Serum Uric Acid Are Prognostic Factorts for Hyperuricemic CKD Patients Treated with Febuxostat

Hidetoshi Kanai, Yasuhisa Tamura, Yasuhiro Kawai, Yoshi Koi Kaizu, Akihiko Nagase, Yasuyuki Somyo, Daisuke Oishi. *Nephrology, Kokura Memorial Hospital, Kitakyushu City, Fukuoka, Japan.*

**Background:** Hyperuricemia has been known as one of major risk factors for progress in CKD. Xanthine oxidase inhibitor (XOI) such as allopurinol was established as treatment, however, allopurinol might be limited to use for advanced CKD patients. Febuxostat, recently introduced as a novel XOI, potentiates to reduce serum uric acid (sUA) markedly and safely. We investigated the reno-protective effect of febuxostat on hyperuricemic CKD patients and the impact of prognostic factors.

**Methods:** 139 CKD patients (70yo, M/F=107/32, diabetes:30%, nephrosclerosis:33%) were administered 12.2 (10–40) mg/day of febuxostat for 10 (3-19) months. 63 patients had not been treatment with any OXI. 76 patients, administered 103 (50–200) mg/day of allopurinol previously, were converted to febuxostat (13.9mg/day). EGFR and sUA at 0, +/-1,3,6,12 months after starting febuxostat were applied. Multiple regression analysis was performed to select the independent variables, including gender,age, original kidney disease and sUA value, which have an influence on eGFR using stepwise variable selection method with p< 0.15.

**Results:** After administration of febuxostat, sUA was significantly reduced (p<0.01), and eGFR declining before febuxostat remained stable, independent with pretreatment by any doses of other XOI. There was no difference in eGFR with the dose of febuxostat (10 vs 20mg/day), age (over 65yo), presence of diabetes. Multiple regression analysis selected the change from baseline of sUA as the independent variable, which showed the estimated increase in eGFR per 1% decrease in sUA was 0.219 (p<0.05). Both female (p<0.01) and nephrosclerosis (p=0.03) also remained as beneficial factors for preserving eGFR. Alloprinol used was not selected as an independent variable in the model.

**Conclusions:** Treatment of hyperuricemia with XOI partially improved prognosis in CKD patients. Even in the patients already treated with allopurinol, converse from allopurinol to febuxostat may be benefit to maintain kidney function through enhanced lowering sUA, especially in nephrosclerotic female CKD subjects.

## SA-PO228

### N-Terminal Pro-Brain Natriuretic Peptide Is a Novel Valuable Biomarker for Progression of CKD Patients: A Longitudinal Follow-Up Study

Yoshiko Shimamura,[1] Kazu Hamada,[1] Koji Ogata,[1] Kosuke Inoue,[1] Yoshinori Taniguchi,[1] Masayuki Ishihara,[1] Taro Horino,[1] Kenji Yuasa,[2] Shigeo Yamanaka,[3] Tetsuro Sugiura,[3] Yoshio Terada.[1] *[1]Endcrinology, Matabolism and Nephrology, Kochi Medical School; [2]Kochi-Takasu-Hospital; [3]Laboratory Medicine, Kochi Medical School.*

**Background:** N-terminal pro-brain natriuretic peptide (NTpro-BNP) is known as diagnostic and prognostic biomarker of cardiac events. Recent report showed that cardio-renal interaction is an important problem in chronic kidney disease (CKD) patients. However , only few longitudinal follow-up studies have been reported to evaluate NTpro-BNP as a biomarker for renal prognosis. Accordingly, we elucidated the relation between NTpro-BNP and renal function in CKD patients.

**Methods:** Alongitudinal follow-up study for 24 months was performed in 318 consecutive CKD patients in Kochi prefecture. NTpro-BNP, serum creatinine, hemoglobin, albumin, calcium, phosphate and urine protein amount were measured. This study was approved by the Kochi Medical School review board. All patients provided written informed consent.

**Results:** The serum level of NTpro-BNP was positively correlated to creatinine (P<0.0001: r=0.437), age (P<0.05: r=0.136), urine protein amount (P<0.05: r =0.170) and phosphote (P<0.0001:r=0.379) and negatively to estimated glomerular filtration rate (eGFR) (P<0.0001: r=-0.300), hemoglobin (P<0.01: r=-0.308) and albumin (P<0.0001: r=-0.280). NTpro-BNP level in patients with heart failure was higher than in those without (P<0.0001). Furthermore, NTpro-BNP level elevated according to the progression of CKD stage. During the study period of 24 months observation, eGFR declined in all the patients and NTpro-BNPvalues had a positive correlation with the decline rate of eGFR (P<0.05: r =0.263). The eGFR decline rate had a correlation with urine protein amount (P<0.005: r =0.433), iPTH (P<0.005: r=0.407) and calcium (P<0.05: r =-0.235).

**Conclusions:** In CKD patients, serum level of NT-proBNP had a positive correlation with the decline rate of eGFR. Thus, NT-proBNP might be an novel valuable biomarker to predict the prognosis of CKD patients.

## SA-PO229

### Hyperuricemia Is a Risk Factor for the Progression to ESRD in Biopsy-Proven Benign Nephrosclerosis

Hiroyuki Suzuki,[1] Tomomi Endo,[1] Tatsuo Tsukamoto,[2] Eri Muso.[1] *[1]Dept of Nephrology and Dialysis, Tazuke Kofukai Medical Research Institute Kitano Hospital, Osaka, Japan; [2]Graduate School of Medicine, Kyoto Univ.*

**Background:** End stage renal disease due to benign nephrosclerosis is increasing in Japan. Diagnosis of benign nephrosclerosis is usually made based on existence of hypertension related organ damages (hypertensive retinopathy, cardiac hypertrophy etc) without renal biopsy. However, little is known about clinical characteristics and prognostic factors in biopsy-proven benign nephrosclerosis.

**Methods:** We selected 42 cases which were diagnosed by renal biopsy as having benign nephrosclerosis. Clinical and histological parameters and prognostic factors were investigated retrospectively.

**Results:** Clinical characteristics at renal biopsy were male to female ratio: 76.1%, age: 59.8±10.6 years, BMI: 24.9±5.0kg/m$^2$, hypertensives: 80.9%, hypercholesterolemia: 50%, diabetes: 14.2%, hyperuricemia: 73.8%, and smoker: 52.5%. Laboratory data were urinary protein excretion: 0.57±1.2g/day, occult blood: 26.1%, serum creatinine: 1.25±0.5mg/dl, and uric acid: 6.93± 1.6 mg/dl. Among these patients, 22 cases (male 68.1%) that could be followed more than 2 years (mean observation period, 3.2 years) were analyzed. Mean decline of eGFR in these patients was -2.95±4.4 ml/min/year. Four patients showed more than -5ml/min/year (rapid decline) and 1 patient reached end stage renal disease in 5 years. Existence of occult blood and hyperuricemia were related to rapid decline (RR 2.7, 95%CI:1.060, 6.880 and RR 2.0, 95%CI:1.260, 3.174, respectively). Blood pressure and urinary protein excretion tended to be higher in rapid decline but not significant (149.5±15/78.5±12 vs 121.5±34/71.7±22 mmHg p=0.069 and 2.5±3.5 vs 0.4±0.5 g/day p=0.323, respectively). Histological examination indicated that adhesion of glomerular tuft to Bowman's capsule was related to rapid decline (p=0.042), but rate of global sclerosis was not significant (p=0.095).

**Conclusions:** Hyperuricemia, occult blood, and adhesion were related to rapid decline of eGFR in biopsy-proven benign nephrosclerosis patients. There might be a possibility that hyperuricemia was related to formation of adhesion.

## SA-PO230

**Inter Study and Inter-Operator Variabilities of CMR-Derived LV Mass Measurements in CKD Patients** Ketan Kanji Vekaria,[1] Nihil Chitalia,[2] Debasish Banerjee,[3] David Goldsmith.[2] *[1]School of Medicine, King's College London, London, United Kingdom; [2]Nephrology, Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom; [3]Nephrology, St. George's Healthcare NHS Trust, London, United Kingdom.*

**Background:** Patients with CKD have increased risk of mortality from Cardiovascular Disease (CVD). We are conducting the 5CVitaminD RCT with LVM cardiac remodelling as an endpoint. To validate the use of a small study population - ideal for a complex intervention such as this - we needed to use a cardiac imaging technique that was precise and accurate.

**Methods:** Subjects were imaged on a 1.5T Philips Intera MRI Scanner with 32 channel cardiac coil to obtain short axis stack (30 cardiac phases). Analysis was carried out on a Viewforum workstation (Philips Healthcare) by delineating the diastolic LV endocardial and epicardial borders. (a)5 patients were scanned twice using the same CMR protocol. Patients were scanned and then re-scanned again 10 mins later. Analysis was performed by the same observer twice. (b)16 patients on the 5CVitaminD study were analysed for LV mass using the same CMR analysis protocol by 2 independent observers.

**Results:**

| (a) Inter study | | | |
|---|---|---|---|
| Mean±SD LVM 1 | Mean±SD LVM 2 | Difference of mean (g) | Standard Deviation of mean difference |
| 108.52±30.52 | 108.43±31.74 | 0.09 | 1.53 |
| (b) Inter operator | | | |
| Mean±SD LVM 1 | Mean±SD LVM 2 | Difference of mean (g) | Standard Deviation of mean difference |
| 103.84±29.26 | 96.41±33.39 | 7.43 | 5.25 |

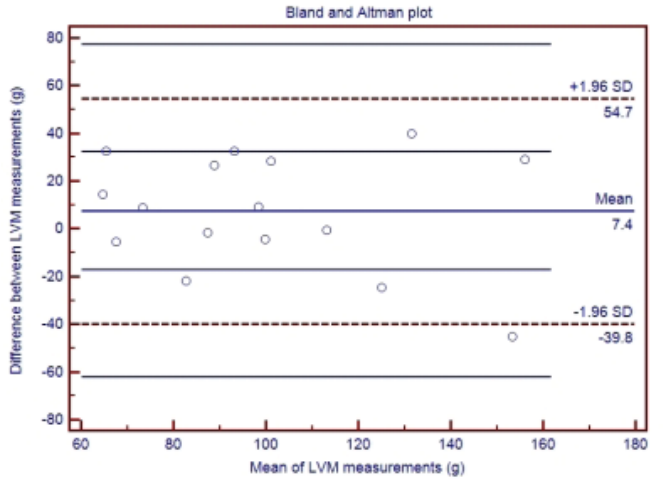

Fig. 1 Bland-Altman Plot of data from 16 paired samples analysed independently by two different observers.

**Conclusions:** The average discrepancy between the two LVM measurements was 7.43g, which is both small, and below the threshold of clinical significance for this study. These data validate our choice of CMR over echocardiography as the imaging technique for our study.

## SA-PO231

**Screening for Kidney Disease among Pre-Term and Low Birth Weight Children in Jalisco, Mexico** Jose Raul Reyna Raygoza,[1] Ricardo Martinez,[3] Laura Lopez,[3] Katia Valenzuela,[1] Alfonso Gutierrez Padilla,[2] Eusebio Angulo,[2] Susan M. Samuel,[2] Guillermo G. Garcia.[1] *[1]Div of Nephrology, Hospital Civil de Guadalajara, Mexico; [2]Univ of Calgary, Canada; [3]Dept of Pediatrics, Hospital Civil de Guadalajara, Mexico.*

**Background:** Pre-term infants (<37 weeks gestation) or low birth weight infants (<2500 grams) are at risk of developing hypertension and chronic kidney disease later in life. We sought to examine the prevalence of hypertension, albuminuria and either reduced estimated glomerular filtration rate (eGFR) or hyperfiltration among low birth weight or pre-term infants born in Jalisco, Mexico.

**Methods:** We evaluated records of all patients born at the Guadalajara Civil Hospital and those hospitalized in the Neonatal Intensive Care Unit during 1996-2011. Individuals born pre-term (<37 weeks gestation) and/or with low birth weight (<2500 gm) and/or intrauterine growth restriction were included. Pre-hypertension and hypertension were defined as BP between 90th to 95th percentile and BP ≥95$^{th}$ percentile respectively. Microalbuminuria was defined as urine microalbumin to creatinine ratio >30 mg/g. eGFR was determined from serum creatinine using Schwartz equation. In those with low eGFR or albumin to creatinine ratio >30 mg/g at baseline, the findings were confirmed 3 months later.

**Results:** Among 55 patients screened, mean gestational age was 34.2 (SD 2.5) weeks and mean chronological age at time of screening was 4 (SD 3.8) years. 56.4% were males. All patients were pre-term and 94.5% of patients had low birthweight. One patient had blood pressure >90$^{th}$ percentile. 32.7% (18/55) of patients had microalbuminuria and 33.3% (6/18) continued to have microalbuminuria upon re-test. One patient had hematuria. In total, 31(56.4%) patients had hyperfiltration. Of these, 22(40%) had eGFR 125-175 ml/min/1.73m$^2$, 8(14.5%) had GFR 176-225 ml/min/1.73m$^2$, 1(1.8%) had eGFR >225 ml/min/1.73m$^2$. Eight (14.5%) of patients had eGFR <90 mL/min/1.73m$^2$.

**Conclusions:** Glomerular hyperfiltration, reduced eGFR and microalbuminuria were common among children with a history of prematurity or low birth weight in Mexico. Continued surveillance for progression of chronic kidney disease is needed in this group of children.

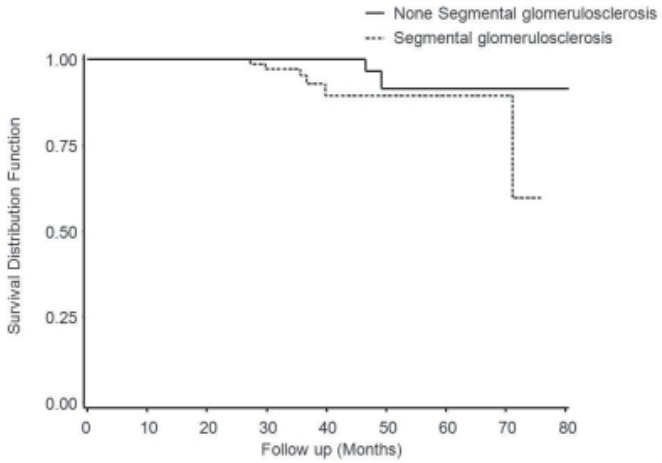
## SA-PO232

**Segmental Glomerulosclerosis in Oxford IgAN Classification Is Associated with the Poor Outcome of IgAN Patients: A Cohort Study of 240 Cases** Bin Zhu, Yongjun Wang, Yi Lin, Hongyu Chen. *Dept of Nephrology, Hangzhou Hospital of Traditional Chinese Medicine (Guangxing Hospital), Zhejiang Chinese Medical Univ, Hangzhou, Zhejiang, China.*

**Background:** To investigate the parameters in Oxford IgAN classification associated with the outcome in a cohort of 240 Chinese patients.

**Methods:** A total of 240 patients with biopsy proven IgAN and CKD stage 1-4 were enrolled. Renal clinical and histopathologic parameters according to Oxford IgAN classification were assessed. A Kaplan-Meier survival analysis was performed to compare the survival rate. A Cox proportional hazard model was adopted to test the independent prognostic value of clincal paramters and pathological parameters. The primary outcome of chronic renal injury was defined as the serum creatinine increased to 1.5 times of baseline.

**Results:** Enrolled patients were followed up for a median of 38.35 (32.98, 44.76) monthes. A logrank test indicated that segmental glomeruloscerlosis is associated with the poor outcome of these patients(P=0.01).



A COX regression model indicated that segmental glomeruloscerlosis increased the risk of chronic renal injury by 6.39 times(95% CI, 1.28,31.95). The other parameters did not correlate to clincal outcomes.

**Conclusions:** This cohort study suggested that segmental glomerulosclerosis in Oxford IgAN classification is associated with the poor outcome of IgAN patients.

## SA-PO233

**Outcome of Renal Biopsy Proven Membranous Nephropathy Receiving Immunosuppressive Therapy** Muhammad A. Imtiaz,[1] Rosa M. Montero,[1] Katie Ht Wong,[2] Mona Wahba.[1] *[1]Dept of Renal Medicine, St. Helier Hospital, Surrey, United Kingdom; [2]Dept of Medicine, St. Peter Hospital, Surrey, United Kingdom.*

**Background:** Membranous Nephropathy(MN) is the commonest cause of nephrotic syndrome in adults. Previous studies looked at progression of MN in patients having immunosuppressive therapy versus no immunosuppressive therapy.

**Methods:** Single centre retrospective study from 1995-2010 with biopsy proven MN. Data points of urine protein creatinine ratio(UPCR in mg/mmol), baseline eGFR at 2, 5 10 years, with onset renal replacement therapy(RRT) and patient survival. Immunosuppression regimens were; Prednisolone alone(P) and P+Cyclophosphamide(P+CYP). Those on Modified ponticelli were included in the P+CYP group. Those on maintenance therapy were on a combination of P+ Azathioprine(AZA) or P+ Mycophenolate mofetil(MMF).

**Results:** 48/125 were immunosuppressed. 18/48 were given P, 22/48 P+CYP, 4 P+MMF, 3 P+AZA, 1 MMF. All patients received angiotensin converting enzyme inhibitors(ACEi) or Angiotensin 2 receptor blockers(ARB) and a statin. 27 male, 22 female with median age of 60 years in P and 54.5 years in P+CYP group. UPCR was significantly lower at 5 years from baseline with P therapy($p<0.01$), contrary to those in the P+CYP who established significant reduction in UPCR at 2 and 5 years($p<0.05$, $p<0.01$, respectively). There is no difference in Cr or eGFR over time in either group. A trend in declining eGFR was seen over 10 years with P. The improvement in albumin from baseline continued over 2, 5 and 10 years($p<0.05$) with P. No difference between the two groups following the initial significant decline in cholesterol from baseline. Those treated with P show a significant improvement in Albumin at 2 and 5 years($p<0.01$) with a greater level of significance in

P+CYP($p<0.01$, $p<0.001$, respectively) compared with baseline levels. Those on P had 3 on RRT compared with P+CYP that had 5. In P treated group there were 3 deaths compared with 4 deaths in P+CYP.

**Conclusions:** Survival and dialysis dependency was similar amongst those on P or P+CYP treatment. Both groups had similar effects on creatinine and cholesterol levels. P+CYP treatment produced a significantly sustained reduction in UPCR and improving albumin over 10 years.

## SA-PO234

**Quo Vadis? Plasma Exchange and Intravenous or Oral Cyclophosphamide in Dialysis-Dependent ANCA-Associated Vasculitis** Wladimir M. Szpirt,[1] Elizabeth Krarup,[2] Martin Egfjord.[1] *[1]Nephrology, Rigshospitalet, Denmark; [2]Nephrology, Herlev Hospital, Univ of Copenhagen, Copenhagen, Denmark.*

**Background:** Salama et al. published in cJASN (2013,Nov.15) results on 41 ANCA Associated Vasculitis (AAV) patients (pts) requiring **dialysis** on admission, who were treated with Plasma Exchange (PLEX), standard prednisolone 1 mg/kg/day (STOCS), I.V. CYC (IVCYC) (6-10 pulses given over 13 weeks; 7.5 - 12.5 mg/kg depending on age). Their mortality and dialysis dependency at 3 and 12 months were superior to and compared with MEPEX oral CYC (ORCYC) arm (2.5 mg/kg daily). The total doses of IVCYC given were 2.96-7.38 g, whereas MEPEX pts. received up to 15-16 g in cumulative CYC dose.

**Methods:** We analysed this report in connection to a subgroup of 39 HD pts -out of-132 AAV pts referred to our centre between 2000-2010 and treated in 105 pts by 7 PLEX sessions, ***low*** ORCYC regimen (1.5 mg/kg/day < 65 years, 0.75 mg/kg/day > 65 years) and STOCS. Totally our pts received a estimated cumulative CYC dose of 4.75 g for older and 9.5 g for younger pts. Azathioprine or mycophenolate mofetil was given for maintenance of remission after 4 months.

**Results:** At 3 months 3 of IVCYC treated and 3 pts in our low ORCYC cohort died, 12 pts were dialysis dependent compared to our 8 low ORCYC pts.

At 1 year 13 IVCYC pts remained dialysis dependent, whereas 13 in of 39 our pts were on dialysis at 12 months. *Patient survival* in ORCYC cohort at 3 years was 72% (97% in no HD group) and 5 years 56% (87% in no HD group). *Kidney survival* in ORCYC cohort was 53% at 3 years (95% in no HD) and 40% (80% in no HD group) at 5 years. 11 of ICCYC pts had leukopenic episodes, 17 experienced infectious complications during 3 months of IVCYC therapy. This compared to 10 of our pts being leukopenic and 16 having infections during follow up. 5 relapses in IV CYC pts were observed compared to 12 relapses occurred during the 12 years of follow up in our pts. Furthermore no difference in observed malignacy can be reported (4 cases in ORCYC pts).

**Conclusions:** In our opinion low oral CYC induction regimen is not inferior to IV CYC in HD dependent AAV pts, when combined with PLEX and STOCS.

## SA-PO235

**Epidemiology of Cardiovascular Mortality in Patients with Chronic Kidney Disease and End-Stage Renal Disease** Navneet Kumar,[1] Peter A. McCullough.[2] *[1]Internal Medicine, Providence Hospital & Medical Centers, Southfield, MI; [2]Cardiology, St. John Providence Health System, Novi, MI.*

**Background:** Chronic kidney disease (CKD) patients, particularly end-stage renal disease (ESRD) have higher mortality than those without renal dysfunction. Estimated glomerular filtration rate (eGFR) and mortality have inverse relationship. ESRD patients die most commonly from cardiovascular events (acute myocardial infarction/heart failure/strokes/ventricular arrhythmias). But studies to individually subcategorize cardiac causes of death in CKD patients are lacking.

**Objective:** Prevalence of specific causes of in-hospital cardiac death in CKD and to find demographic and clinical factors associated with each cause.

**Methods:** Retrospective, non-randomized, multi-center, medical record review of patients with CKD (eGFR<60 ml/kg) who died at Providence Hospital and St. John Hospital and Medical Center during 1/1/2008-12/31/2011. Patients with circulatory system disease (ICD-9 codes:390-459) as cause of death were selected. 300 patients were randomly included. We collected demographic, clinical and co-morbid conditions data. History of coronary artery bypass graft, percutaneous angiography, pacemaker or implantable defibrillator and medications use related to circulatory system (statins, anti-platelet agents, anti-coagulant agents, beta-blockers, renin system inhibitors and diuretics) was obtained. Mortality was assigned into sub-classification as per Chronic Renal Insufficiency Cohort Study (CRIC). If patient cannot be assigned to these categories, then that patient was excluded.

**Results:** One-third CKD patients who died in-hospital were "Full Code". Most common terminal rhythm was sinus tachycardia. Most common cause of known death was congestive heart failure and primary witnessed arrhythmia.

**Conclusions:** It is the first attempt to find specific causes of in-hospital cardiac death in CKD patients. Study shows that the most common cause of known death was congestive heart failure and primary witnessed arrhythmia. This shows need for aggressive fluid management, telemetry, aggressive electrolytes management and to be more vigilant in these CKD patients who are not on dialysis.

## SA-PO236

**Serum Cystatin c (CyC) Has a Significant and Negative Correlation with Lymphocyte Count in Predialysis Chronic Kidney Disease (CKD) Patients** Hirotsugu Iwatani, Yusuke Sakaguchi, Hiroaki Kawabata, Ryohei Yamamoto, Hiromi Rakugi, Yoshitaka Isaka. *Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

**Background:** Serum creatinine (Cr) is a marker of renal function, but is affected by muscle volume or renal tubular excretion. Unlike Cr, CyC has been reported to be an early excellent marker of renal glomerular filtration rate (GFR). Although serum CyC has been regarded as a mere marker of GFR, CyC has a physiological activity of cysteine protease inhibitor and, therefore, potentially affects antigen presentation in antigen presenting cells such as dendritic cells. It is also well known that immune function is impaired in patients with decreased GFR. We assessed an association between CyC and lymphocyte count in patients with CKD in the predialysis stage.

**Methods:** The present cross-sectional study included 71 hospitalized CKD patients in the department of nephrology in Osaka University Hospital between April 2012 and May 2013. Because of its skewed distribution, lymphocyte count was normalized by logarithmic transformation. Associations of lymphocyte count ($\log_{10}[/\mu l]$) with Cr, CyC, or eGFR (based on Cr and CyC) were assessed in multivariate linear regression models adjusting for clinically relevant factors, including age, sex and total cholesterol.

**Results:** In univariate models lymphocyte count were significantly associated with Cr (per 1.0 mg/dL, $\beta$ -0.0222 ± SE 0.00575, $P<0.001$), CyC (per 1.0 mg/L, -0.0593 ± 0.0124, $P<0.001$) and eGFR (per 10 mL/min/1.73m$^2$, 0.0270 ± 0.00586, $P<0.001$). Even after the adjustment for clinically relevant factors, CyC had the significant association with lymphocyte count (-0.0409 ± 0.0178, $P=0.0257$), whereas not Cr (-0.0134 ± 0.00735, $P=0.0726$) and eGFR (0.0211 ± 0.0109, $P=0.0583$).

**Conclusions:** Cystatin c is significantly and negatively associated with lymphocyte count in CKD patients in the predialysis stage. Elevated serum cystatin c might be able to explain the decrease of lymphocyte count in renal failure.

*Funding:* Government Support - Non-U.S.

## SA-PO237

**The Use of a Previously Validated Renal Risk Score in an Irish Cohort of Stroke Patients** Caitriona M. McEvoy,[1] Sean Murphy.[2] *[1]Nephrology Dept, Mater Misericordiae Univ Hospital, Dublin, Ireland; [2]Stroke Dept, Mater Misericordiae Univ Hospital, Dublin, Ireland.*

**Background:** Patients presenting with a suspected cerebrovascular accident undergo emergency CT scanning to identify those suitable for thrombolysis. Imaging often involves administration of iodinated contrast, incurring the risk of contrast induced nephropathy (CIN) in those with underlying renal dysfunction. Scans are performed emergently, frequently without knowledge of the patient's renal function. A 5-point Renal Risk Score (RRS), aiming to identify patients with acute stroke at highest risk of CIN, in the absence of an available estimated glomerular filtration rate (eGFR) was recently described (Vergouwen et al). We examined the potential of the RRS to identify significant renal impairment in consecutive stroke patients at our institution.

**Methods:** We obtained data on 106 consecutive stroke cases from the hospital in-patient stroke portal. Demographic information, RRS components, presenting creatinine & eGFR were collected. RRS calculated as follows: Age (years) + (5 if female) + (5 if diabetic) + (15 if using insulin) + (10 if history of hypertension).The diagnostic value of RRS for predicting the presence of CKD was measured using sensitivity, specificity, and receiver operator characteristic (ROC) curves. Statistical analysis performed with SPSS Version20.

**Results:** Data from N=101 (45 male) patients were analysed. Average age: 70.02 years. 92/101(91%) patients had acute ischaemic events, 8/101 (7.9%) were haemorrhagic. Average RRS : 81.28 (30-113). The prevalence of moderate (CKD stage ≥3) and severe (CKD 4&5) renal impairment were 31.68% and 3.96% respectively. Using a ROC curve the diagnostic value of an RRS as a tool to predict CKD3 or greater was analysed: AUC 0.738 ($p<0.0001$). A cut-off value of 82.5 maximised sensitivity(80%) and specificity(63%). In a subgroup analysis of CKD4&5 patients, a RRS score >82.5 was associated with a sensitivity and specificity of 75% and 45.8% respectively.

**Conclusions:** Moderate to severe renal impairment is common in this population. The RRS is a useful tool in assessing for this at initial presentation. A cut-off score of >82.5 was most useful in our study population.

## SA-PO238

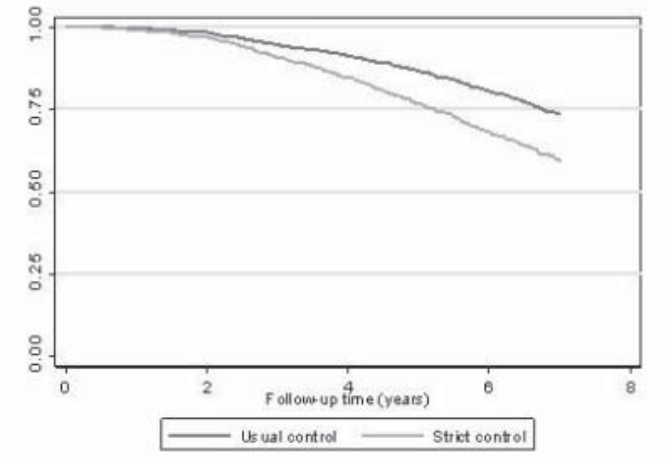
**The Use of a U.S. Veterans' Chronic Kidney Disease Database to Model the SPRINT (Systolic Blood Pressure Intervention) Trial** Anthony J. Bleyer,[1] Jun Ling Lu,[2] Miklos Zsolt Molnar,[3] Jennie Z. Ma,[4] Robert B. Canada,[2] Kamyar Kalantar-Zadeh,[5] Csaba P. Kovesdy.[6] *[1]Wake Forest Medical School; [2]Univ of Tennessee; [3]Univ of Toronto; [4]Univ of Virginia; [5]Univ of California, Irvine; [6]Memphis VA Medical Center, Univ of Tennessee Health Science Center.*

**Background:** Some retrospective studies accurately predict outcomes of prospective trials. In this study, we used a CKD database of U.S. Veterans to model mortality in the SPRINT (Systolic Blood Pressure Intervention) Trial, a prospective study comparing the effect of different SBP targets in CKD patients on cardiovascular (CV) outcomes.

**Methods:** Patients were selected if they met SPRINT criteria for BP, age (>50 years), and no diabetes. 2 groups were created modeling the SPRINT target SBP goups of <120 (strict control, SC) vs. 120 to <140 mm Hg (usual control, UC). As older patients with lower baseline SBP, CV disease, and higher Charlson index were more likely to have an SBP

<120 vs 120-<140 mm Hg, propensity scores were calculated from these characteristics plus gender, race, and baseline eGFR. 2500 patients were selected for each group based on the propensity scores using the 1:1 nearest neighbor matching method.

**Results:** The mean SBP in follow up was 119.4±5.5 mm Hg in the SC group and 132.8±5.7 mm Hg in the UC group. The death rate over a median of six years was 63.1/1000 patient-years (95%CI: 59.0-67.4) in the SC group and 37.8 (34.8-41.1) in the UC group (Hazard ratio, 95%CI: 1.74, 1.57-1.94, p < 0.001). Figure 1 shows the survival curves.



**Conclusions:** In our model of the SPRINT cohort to lower BP in patients with CKD stages 1 to 5, there was increased mortality in the strict control group vs. the usual control group. Significant limitations of this study included the small number of women and African-Americans in the study and its retrospective nature.

*Funding:* NIDDK Support, Veterans Affairs Support

## SA-PO239

**GFR Decline as an Alternative Endpoint for Clinical Trials in CKD – A Meta-Analysis of Individual Associations from Randomized Trials: Report of an NKF-FDA Workshop**

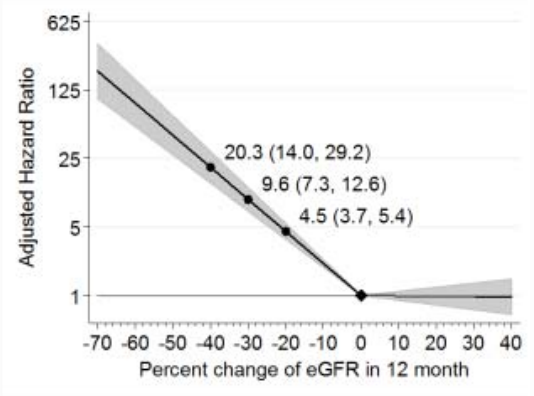
Hiddo Jan Lambers Heerspink,[1] Hocine Tighiouart,[2] Yingying Sang,[3] Shoshana Ballew,[3] Kunihiro Matsushita,[3] Josef Coresh,[3] Andrew S. Levey,[2] Lesley Inker.[2] *[1]UMC Groningen, Netherlands; [2]Tufts Medical Center, Boston; [3]Johns Hopkins, Baltimore.*

**Background:** ESRD and doubling of serum creatinine (2X Scr) are established clinical endpoints for studies of CKD progression. However, a Scr doubling (57% decline in eGFR) is generally a late event in CKD. Alternative endpoints defined by lesser eGFR declines may reduce trial duration and increase feasibility of trial conduct. As part of an evaluation of lesser declines in GFR as alternative endpoints, we describe the associations of a GFR decline with subsequent development of clinical endpoints.

**Methods:** Using a pooled dataset of 12821 patients from 43 clinical trials, we assessed the association between a 20%, 30%, and 40% decline in eGFR from baseline to month 12 with subsequent development of an established endpoint (EE) of dialysis, GFR <15 or 2X SCr. Cox analyses were performed within study, followed by random effects meta-analyses, and were adjusted for age, sex, race, baseline eGFR, proteinuria, and blood pressure, and diabetes. Meta-regression was used to explore baseline eGFR, proteinuria, disease aetiology, and intervention treatment as potential source of heterogeneity.

**Results:** Over a median follow-up of 2.0 [IQR 1.2–3.1] years, 2661 EE were observed after the 1-year baseline period. A strong linear association was observed between eGFR decline and subsequent EE (Figure 1). Hazard ratios of EE for 20%, 30%, or 40% decrease in eGFR were 4.5, 9.6, and 20.3, resp. The associations were consistent regardless of baseline eGFR, proteinuria, disease aetiologies, and treatments.

**Conclusions:** These analyses provide some support that changes in eGFR lesser than 57% can be used as alternative endpoints for trials of CKD progression.



## SA-PO240

**Association of Urinary Biomarkers of Kidney Injury with All-Cause Mortality and Cardiovascular Events: The Health Aging and Body Composition (Health ABC) Study**

Mark J. Sarnak,[1] Ronit Katz,[2] Anne B. Newman,[3] Tamara Harris,[4] Carmen A. Peralta,[5] Prasad Devarajan,[6] Michael R. Bennett,[6] Linda F. Fried,[3] Joachim H. Ix,[7] Suzanne Satterfield,[8] Eleanor Marie Simonsick,[4] Chirag R. Parikh,[9] Michael Shlipak.[5] *[1]Tufts Medical Center; [2]Univ of Washington; [3]Univ of Pittsburgh; [4]NIA; [5]UCSF; [6]Univ of Cincinnati; [7]UCSD; [8]Univ of Tennessee; [9]Yale Univ.*

**Background:** Kidney damage is a common sequel of several chronic pathologic conditions. Whether biomarkers of different forms of kidney damage are prognostic for cardiovascular disease (CVD) and all-cause mortality is unknown.

**Methods:** We measured three urinary biomarkers, kidney injury molecule (KIM) 1, urinary interleukin (IL) 18 and urinary albumin, in 3010 individuals enrolled in the Health ABC. KIM-1, IL-18 and albuminuria were all standardized to urine creatinine. Cox proportional hazards were used to investigate the associations of quartiles of urinary KIM-1/cr, IL-18/cr and albumin/cr (ACR) with all cause mortality and CVD. Multivariable models adjusted for demographics, traditional CVD risk factors, and estimated glomerular filtration rate.

**Results:** Mean age was 74 years, 49% were men, and 41% black. There were 1450 deaths and 797 CVD outcomes during a median follow up of 12.4 years. KIM-1/cr had a modest association with mortality, while the association of ACR with mortality was stronger and more linear. In similar analyses only ACR showed an association with CVD.

**Conclusions:** Urinary KIM-1 had a modest, independent association with all-cause mortality but not CVD, while urinary IL-18 showed no association. In contrast, albuminuria was strongly and independently associated with all cause mortality and CVD. Future studies should evaluate reasons for differences in the prognostic importance among kidney injury markers.

**Association of KIM-1, IL-18 and UACR with Mortality**

## SA-PO241

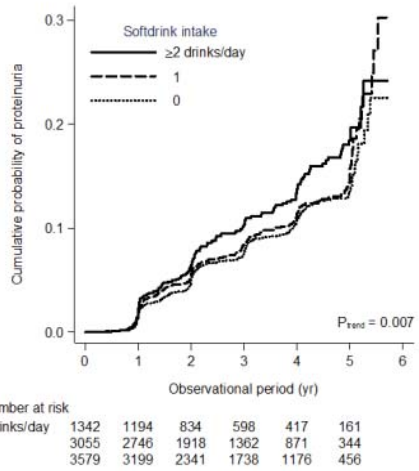
**Soft Drink Intake and Prediction of Proteinuria: A Retrospective Cohort Study**

Ryohei Yamamoto,[1] Maki Shinzawa,[1] Junya Teranishi,[1] Toshihiro Ishigami,[1] Noritaka Kawada,[2] Makoto Nishida,[2] Keiko Yamauchi-Takihara,[2] Hiromi Rakugi,[1] Yoshitaka Isaka,[1] Toshiki Moriyama.[2] *[1]Dept of Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Osaka Univ Health Care Center, Toyonaka, Osaka, Japan.*

**Background:** Association of soft drink intake and incidence of chronic kidney disease is controversial.

**Methods:** Study design: A retrospective cohort study in a single center. Participants: Among 12026 university employees who underwent their annual health checkup in Osaka University Health Care Center between Apr 2006 and Feb 2011, 7976 employees (66.3%) with ≥60mL/min/1.73m² of eGFR and negative or trace of urinary protein by dipstick test. Exposure: A questionnaire of daily soft drink intake (0, 1, or ≥2 drinks/day) at the first health checkup during the study period. Outcome: Incidence of proteinuria defined by ≥1+ of dipstick test. Statistics: Log-rank test for trend and multivariate Poisson regression model.

**Results:** Baseline characteristics of 7976 employees were as follows; age, median 33 yr (interquartile range 28 - 41), male 50.1%, BMI 21.4±3.2 kg/m² and blood pressure 113±14/71±12 mmHg. Among 3579, 3055 and 1342 employees with 0, 1 and ≥2 drinks/day of the baseline soft drink intake, 301 (8.4%), 272 (8.9%) and 144 (10.7%) employees developed proteinuria during median 2.9 years (interquartile range 1.5-4.2) of the observational period, respectively (P = 0.007 for trend).



Number at risk

| | | | | | | |
|---|---|---|---|---|---|---|
| ≥2 drinks/day | 1342 | 1194 | 834 | 598 | 417 | 161 |
| 1 | 3055 | 2746 | 1918 | 1362 | 871 | 344 |
| 0 | 3579 | 3199 | 2341 | 1738 | 1176 | 456 |

Even after adjusting for clinically relevant factors, ≥2 drinks/day of soft drink was identified as a significant predictor of proteinuria (incident rate ratio [95%CI] of 0, 1 and ≥2 drinks/day: 1.00 [reference], 1.03 [0.88, 1.22] (P=0.698) and 1.28 [1.05, 1.56] (P=0.015), respectively).

**Conclusions:** At least 2 drinks/day of soft drink is associated with incidence of proteinuria.

## SA-PO242

**State Variation in Awareness of Chronic Kidney Disease in the United States** Sai Hurrish Dharmarajan,[1] Hal Morgenstern,[1] Neil R. Powe,[2] Delphine S. Tuot,[2] Rajiv Saran.[1] *[1]Univ of Michigan, Ann Arbor, MI; [2]Univ of California San Francisco, San Francisco, CA.*

**Background:** Although low awareness of chronic kidney disease (CKD) in the US has been reported, the extent of geospatial variation in CKD awareness is unknown. We estimated state-level awareness and examined variation across the continental US.

**Methods:** Using 2011 Behavioral Risk Factor Surveillance System (BRFSS) data, we identified adults who reported being told they have "kidney disease". Although the BRFSS provides state-level data on self-reported CKD, there is no clinical/lab information to serve as the "gold standard" for identifying who actually has CKD. To deal with that limitation, we estimated CKD awareness in each state indirectly by comparing--as a ratio--the observed prevalence of self-reported CKD in the BRFSS sample to the prevalence predicted from clinical data in the 2005-06 National Health and Nutrition Examination Survey (NHANES), using a logistic model adjusting for age, sex, race/ethnicity, hypertension status, and diabetes status. CKD in NHANES was defined as MDRD eGFR <60 ml/min/1.73m$^2$ or urinary albumin:creatinine ratio >30mg/g. We also compared estimated CKD awareness by category of age, race/ethnicity, sex, hypertension, and diabetes status.

**Results:** The state-specific prevalence of self-reported CKD ranged from 2% in Iowa to 4% in Arizona. The predicted prevalence of CKD ranged from 4% in Arkansas to 9% in Florida. Estimated CKD awareness in the US was 34%, and it ranged from 17% in Iowa to 61% in Arkansas. Overall CKD awareness in the US was higher in adults with self-reported diabetes (40%), non-Hispanic blacks (64%) and adults less than 65 years of age (96%).

**Conclusions:** The prevalence of self-reported CKD is low throughout the US, reflecting a low level of awareness that appears to vary appreciably across states and by category of major CKD risk factors. A method for indirectly estimating CKD awareness, perhaps improved by incorporating state variation, could be applicable in CKD surveillance programs to study CKD awareness.

## SA-PO243

**Quality of Care of Chronic Kidney Disease in a Community Practice** Pradeep Arora,[1,2] Brian M. Murray,[2] Chester H. Fox,[2] Robert N. Anderson,[3] Rocco C. Venuto.[2] *[1]Medicine, VAMC, Buffalo, NY; [2]Medicine, Univ of Buffalo, Buffalo, NY; [3]Computer Task Group, Buffalo, NY.*

**Background:** Chronic kidney disease (CKD) is a major public health problem in the United States. There is a rising incidence and prevalence of kidney failure, with poor outcomes and high cost. Kidney disease is the ninth leading cause of death in United States. Data from United States Renal Data System (USRDS) indicates that there has been a 104% increase in the prevalence of chronic renal failure (CRF) between the years 1990-2002. There is an even higher prevalence of earlier stages of CKD. We aimed to study the prevalence and resource utilization of CKD in Western NY.

**Methods:** We analyzed data collected from 4.8 million claim records which included claims on >30,000 CKD patients from local payers and providers between 2006 and 2010. Patient demographics (age, gender), lab data and outcomes (hospitalization, ESRD, cardiovascular events and death) were captured from this data base. CKD was defined as per NKF-KDOQI guidelines.

**Results:** Mean age of the patients was 69.2+/-15.3 SD, 50.4% were male, 54% were above age of 70 years. 94% of patients with CKD had hypertension, and 55% had diabetes. Urine albumin/ creatinine ratio was available in only 25% of the patients with CKD. As per diagnsotic code for CKD,7028 had stage 3, 1592 stage 4, 244 stage 5 and 1428 were ESRD. The remainder were coded as CKD without stage.17% of patients with advanced CKD (stage 4 and 5) were not seen by a nephrologist. Only 5.7% of patients had AV fistula prior to initiation of dialysis and 22% required extensive hospital initiated dialysis.

**Conclusions:** More than 3/4 of patients with stage 4/5 CKD were seen by nephrologist. However AV fistula rate prior to start of dialysis was dismal. These data allows specific focus on regional deficiencies in CKD care that could be addressed and improve outcomes. The success of quality improvement programs can be evaluated by analysis of future claim based data.

## SA-PO244

**Enhancing ESRD Risk Prediction Using Age Based Risk Calculation in Stage 4 CKD** Shayan Shirazian, Candace D. Grant, Joseph Mattana. *Medicine, Winthrop Univ Hospital, Mineola, NY.*

**Background:** Accurate ESRD risk prediction is essential in identifying patients who will require preparation for renal replacement therapy as well as low risk patients who are unlikely to reach ESRD in whom such preparation should be avoided. Stage based risk classification may overestimate risk especially in some older patients. In this study we applied a validated risk calculator, which incorporates age, to determine the frequency with which ESRD risk may be overestimated in a CKD-4 population.

**Methods:** In this cross-sectional study, the electronic health records of patients with CKD-4 seen in our nephrology practice were reviewed. Variables necessary for ESRD risk prediction were extracted, including age, sex, glomerular filtration rate (GFR), spot urine albumin to creatinine ratio, calcium, phosphorus, albumin, and bicarbonate. All CKD-4 patients are designated as very high risk according to KDIGO guidelines. Two year estimated risk of progression to ESRD was calculated using a risk calculator developed and validated by Tangri et al. (JAMA 2011;305(15):1553-9). Patients were considered to be low risk for progression to ESRD if their 2 year calculated risk was <10%.

**Results:** Two hundred and four records were reviewed and 85 patients met study criteria. The average age was 69.8 years, 61% were male, 74% were white and the average GFR was 22 mL/min/1.73m$^2$. The average 2 year calculated ESRD risk was 19%. Despite their all being deemed very high risk based on stage, 41% of patients were found to be low risk using the risk calculator. Further analysis of the low risk subgroup revealed a mean age of 76.5±13,which was significantly older compared to the remainder of the population (65.1±15.4, p< 0.01). Other variables including age, gender and race were not significantly different between the groups.

**Conclusions:** Using an age-based calculator, a substantial proportion of patients with CKD-4 were found to be at low risk for progression to ESRD over 2 years. These patients were significantly older than those at high risk of progression. Age-based calculators may better estimate risk of progression to ESRD in the elderly, potentially saving these patients from the risks of unnecessary dialysis preparation.

## SA-PO245

**Traditional Risk Factors Predict Renal Outcomes in Cancer Patients with Chronic Kidney Disease** Elerson Costalonga, Veronica T. Costa e Silva, James Hung, Luis Yu, Emmanuel A. Burdmann. *Nephrology, Cancer Institute of São Paulo.*

**Background:** Cancer patients have a high prevalence of chronic kidney disease (CKD). The aim of this study was to assess prognostic factors for kidney failure and CKD progression.

**Methods:** Among 350 outpatients with cancer referred to nephrology evaluation (2009-12) 173 had CKD according KDIGO definitions and at least 3 months of follow up. Clinical and biochemical data were retrieved from patient medical records. The primary endpoint was defined as kidney failure (eGFR < 15 ml/min/1.73m$^2$, CKD-EPI formula). Rapid CKD progression (sustained decline in eGFR of more than 5ml/min/1.73 m$^2$/yr) was defined as the secondary endpoint.

**Results:** Patients baseline characteristics and outcomes data are shown in Table 1. Results are expressed as mean±SD and percentage.

| | |
|---|---|
| Age (yr) | 66±12 |
| Male (%) | 69 |
| BMI (kg/m$^2$) | 26±5 |
| Solid tumors (%) | 87 |
| Metastasis (%) | 28 |
| Active cancer (%) | 68 |
| Hypertension (%) | 44 |
| Diabetes (%) | 25 |
| Cardiovascular disease (%) | 11 |
| ECA inhibitor use (%) | 31 |
| Baseline eGFR (ml/min/1.73 m$^2$) | 39±19 |
| **CKD etiology** (%) | |
| Diabetic nephropathy | 25 |
| Obstructive uropathy | 21 |
| **eGFR categories** (%) | |
| G1 | 1 |
| G2 | 9 |
| G3a | 18 |
| G3b | 40 |
| G4 | 26 |
| G5 | 6 |
| **Albuminuria categories** (%) | |
| <30 mg/g | 40 |
| 30-300 mg/g | 34 |
| >300 mg/g | 26 |
| **Risk categories** (%, KDIGO 2012) | |
| Low | 6 |
| Moderately | 16 |
| High | 25 |
| Very high | 53 |
| **Outcomes** (%) | |
| Rapid CKD progression | 26 |
| Kidney Failure | 14.5 |
| Death or Palliative care | 27 |
| Follow up (m) | 17±8 |

Multivariate logistic regression identified baseline eGFR (OR =8.9; 95% CI 2.4-33; p<0.01) and albuminuria categories (OR =7.9; 95% CI 2-31; p<0.01) as independent factors associated to the primary endpoint. Obstructive uropathy (OR =5.4; 95% CI 1.5-19.7; p=0.011) and ACR > 300mg/g (OR =3.8; 95% CI 1.4-10; p<0.01) were associated to rapid CKD progression.

**Conclusions:** Traditional risk factors as baseline eGFR and albuminuria can predicted renal outcomes in cancer patients with CKD.

## SA-PO246

### Prognostic Factors for Death or Palliative Care in Patients with Cancer and Chronic Kidney Disease

Elerson Costalonga, Veronica T. Costa e Silva, James Hung, Luis Yu, Emmanuel A. Burdmann. *Nephrology, Cancer Institute of Sao Paulo, Brazil.*

**Background:** Cancer patients have a high prevalence of chronic kidney disease (CKD). The aim of this study was to assess prognostic factors for death or palliative care in cancer patients with CKD.

**Methods:** Among 350 outpatients with cancer referred to nephrology evaluation (2009-12) 173 had CKD according KDIGO definitions and at least 3 months of follow up. Clinical and biochemical data were retrieved from patient medical records. The primary endpoints were defined as death or palliative care.

**Results:** After a follow-up of 17±8 m, 27% of the patients reached the endpoints. Their baseline features are shown in Table 1.

| | Surviving(n=126) | Death/Palliative Care(n=47) |
|---|---|---|
| Age (yr) | 66±11 | 66±14 |
| Male (%) | 71.4 | 61.7 |
| BMI (kg/m$^2$) | 26±5 | 24±4 |
| Diabetes (%) | 33 | 25 |
| Cardiovascular disease (%) | 10 | 6 |
| Solid tumors (%) | 85 | 91 |
| Metastasis (%) | 20 | 51* |
| Active cancer (%) | 59 | 94* |
| Karnofsky<80 (%) | 5 | 36* |
| Obstructive nephropathy (%) | 16 | 36* |
| eGFR (ml/min/1.73 m$^2$) | 40±20 | 35±18 |
| Serum albumin (g/dL) | 4.3±0.4 | 3.6±0.7* |
| Hemoglobin (g/dL) | 11.8±1.8 | 10.3±1.7* |
| PTH (pg/ml) | 108±94 | 157±135* |
| Vitamin D (ng/ml) | 19±8 | 18±8 |
| Protein C Reactive (mg/L) | 8±25 | 41±70* |

*p<0.01 vs Surviving

Multivariate logistic regression identified active cancer(OR = 25.8; 95% CI 3.2-206.9; p<0.01), serum albumin<3.5 g/dL(OR = 29.7; 95% CI 5.0-176.9.9; p<0.01), baseline eGFR<30 ml/min/1.73m$^2$(OR =4.3; 95% CI 1.4-12.8; p<0.01), and hemoglobin<10 g/dL(OR = 4.2; 95% CI 1.4-12.6; p<0.05) as independent factors associated to the endpoints.

**Conclusions:** Patients with cancer and CKD have a poor prognosis. Active cancer, lower baseline eGFR, albumin and hemoglobin were independent factors associated to poor prognosis.

## SA-PO247

### RAS Blockade in Diabetic Patients with Renal Dysfunction in China

Chuanming Hao,[1] Qionghong Xie,[1] Dayi Hu,[2] Danyi Zhang.[3] *[1]Div of Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China; [2]Peking Univ People's Hospital; [3]Vitalstrategic, Research Institute.*

**Background:** It is well documented that RAS blockade is associated with improved outcome in patients with diabetic kidney disease. This study examined the usage of angiotensin-converting enzyme inhibitors (ACEI) and angiotensin receptor blockers (ARB) in type 2 diabetes patients (2-DM) with or without chronic kidney disease (CKD) in China.

**Methods:** Data from the China Cardiometabolic Registries on blood pressure, blood lipid and blood glucose in 2-DM patients (CCMR-3B Study) were used to analyze ACEI/ARB use in this population. Outpatients who had been diagnosed of 2-DM for > 6 months were recruited to this non-interventional, observational, cross-sectional study. CKD was defined as having urine albumin creatinine ratio (ACR) > 30mg/g or eGFR < 60 ml/min. Serum creatinine-based eGFR was calculated using MDRD equation.

**Results:** A total of 25,454 outpatients from 6 regions in China (north, south, east, west, northeast and central China) were enrolled. The mean age was 63.0±11.9 yrs, 47.0% were male, 55.1% with HbA1C >7%, 63.8% with cholesterol >4.5mmol/L and 59.8% with hypertension (SBP > 130 mmHg, DBP> 80mmHg). Serum creatinine data was available in 22,628 patients, and 2258 (10.0%) had an eGFR<60ml/min. ACR was measured in 6,383 patients, and 3,231 (50.6%) of them had ACR > 30mg/g. Among hypertensive patients, 73.0% were on antihypertensive medications, and 39.7% were on ACEI/ARBs. A total of 2157 patients with hypertension had positive albuminuria, 1040 (48.3%) of them used ACEI/ARB, 22.9% used CCBs without ACEI/ARB, 7.7% used other antihypertensives and 21.1% not treated. In the non-hypertensive patients with or without albuminuria, ACEI/ARB utilizations were < 1%.

**Conclusions:** In diabetic patients with hypertension and albuminuria in CCMR-3B population, more than half of the patients were not treated with ACEI/ARB. This real world evidence suggest that the current treatment for diabetes with hypertension and albuminuria is sub-optimal.

## SA-PO248

### Classification Tree Method Analysis Related Factors of Early Renal Damage by Type 2 Diabetes Mellitus

Wenbo Zhao,[1] Lin Wei,[2] Hui Peng,[1] Xun Liu,[1] Jia-ling Rao,[1] Tan-qi Lou.[1] *[1]Nephropathy, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Neurology, The Guangdong Province Traditional Chinese Medical Hospital, Guangzhou, Guangdong, China.*

**Background:** To explore the factors influencing classification $T_2$DM early nephropathy by the tree model, in order to provide evidence for prevention and treatment.

**Methods:** The 1040 hospitial patients from January 2011 to January 2013, according to eGFR and the urine albumin, divided into $T_2$DM group (755 cases) and early diabeticrenal impairment group (285 cases ), to analyze the main factors to developed to microalbuminuria by Exhaustive CHAID classification tree.

**Results:** Classification tree model screened Fib, retinopathy, SBP, DPVD, gender from 34 candidate variables, related to the early renalimpairment. Elevated Fib was the main factor. The incidence of Fib>4.34 was 52.9%, higher than the Fib ≤ 3.30 (14.9%) . Fib between 3.30 and 3.85 group (26.0%) and between 3.85 and 4.34 group (41.5%), Fib≥4.34 group was high-risk group. Influencing factors screened with different fibrinogen were not same, SBP, DR, Gender and DR dividedly. Fib>4.34 group with DR were higher risk, 75.0%, comparing no DR, 43.9%. Fib>3.85 and≤4.34group, correlated with gender, the female was higher risk than male. Fib>3.30 and≤3.85 group with DR, had a higher risk; A history of DPVD without DR mean a higher risk. Female without DPVD was lower risk. Fib≤3.30 group screened influence factors was SBP; Respectively the three groups were 6.5%, 18.1% and 42.5% with SBP increasing. SBP 127 to 161mmHg group, the main influencing factor was retinopathy. Compared with no retinopathy team, the incidence was higher.

**Conclusions:** Classification tree model analysis of early renal impairment was feasible, multi-factors increased the risk of early renal impairment, that could improve the prevention and treatment as reference.

## SA-PO249

**Renal Function as a Predictor of Mortality in Patients with Left Ventricular Assist Device Support** Jeffrey P. Yourshaw, Kevin C. Roe, David M. Anwar, Umar Farooq. *Internal Medicine, Penn State College of Medicine, Hershey, PA.*

**Background:** Impaired renal function is an independent predictor of mortality in patients with cardiac disease. We studied whether serum creatinine predicted mortality in patients receiving left ventricular assist device (LVAD) support.

**Methods:** We retrospectively collected data on all patients who underwent LVAD placement at Penn State Hershey Medical Center between June 2006 and February 2012. Indications of bridge-to-transplant and destination therapy were included. Creatinine before LVAD placement, 1, 3 and 6 months post-device placement were assessed as predictors of 1-year mortality using bivariate t-test analysis.

**Results:** 80 patients were included in the study. The mean age was 56.5 years (SD 11.67). 67 (84%) were males and 13(16%) females. Mean serum creatinine prior to device placement was 1.28 (SD 0.57) and mean creatinine at 1 year was 1.34 (SD 0.50). One year mortality was 26.25% (n=21). Baseline serum creatinine did not differ between living or deceased patients at one year (1.12 vs. 1.34, p =0.11). Similarly, serum creatinine at 1 month, 3 months, and 6 months also was not associated with mortality at 1-year (p=0.50, p=0.96, and p=0.52 respectively).

**Conclusions:** In patients at our institution, creatinine at baseline, 1 month, 3 months and 6 months did not predict mortality at 1-year post-LVAD placement.

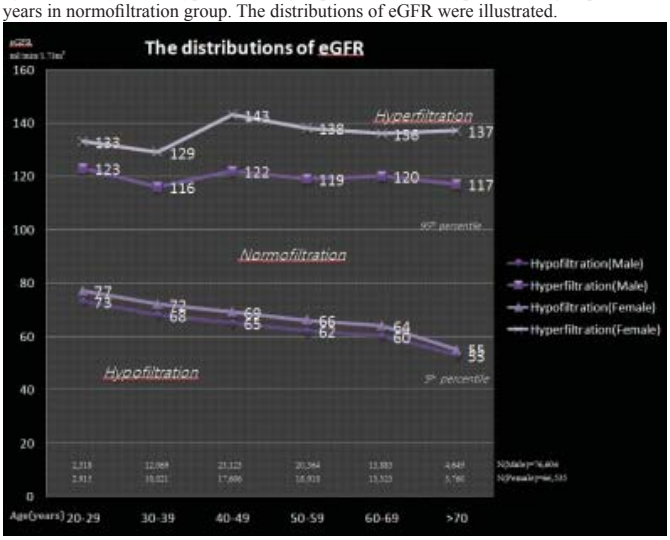
## SA-PO250

**Relationship between Glomerular Hyperfiltration and All-Cause Mortality in General Population** Kyung Don Yoo, Dong Ki Kim, Ho Jun Chin, Yon Su Kim, Hajeong Lee. *Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Jongno-gu, Korea.*

**Background:** Glomerular hyperfiltration has been known to be a marker of early damage of kidney disease. However, the association of glomerular hyperfiltration and individual's long term prognosis remains unknown.

**Methods:** Clinical and biochemical data had been collected in 143,271 routine health checkups from 1995 to 2009. We extracted the mortality data from Statistics Korea to our data using personal unique identifier. Hyperfiltration was defined as an estimated glomerular filtration rate (eGFR) over 95th percentile by age and sex-matched. Hypofiltration was defined as an eGFR below the 5th percentile by age and sex matched.

**Results:** A total of 143,271 individuals was included, and 53.5% of them were men. Among of them, 7.4% of participants had diabetes, and 24.8% had hypertension. The mean age was 50.5 years in hyperfiltration group, 50.2 years in hypofiltration group,and 52.6 years in normofiltration group. The distributions of eGFR were illustrated.



During the 58.9 months of follow up, 1,840 (1.3%) participants were dead. Interestingly,the mortality rate of hyperfiltration group was higher than normofiltration group in both men (3.8% vs 1.6%, P<0.001) and women (1.3% vs 0.7%, P<0.001). In the survival analysis, hyperfiltration compared with normofiltration was proved to be an independent risk factor for all-cause mortality after adjustment for by age,diabetes,hypertension,body mass index,lipid profile,C-reactive protein,and serum albumin in men (hazard ratio 1.119, 95% CI 1.002–1.437, P=0.047). In contrast, hyperfiltration failed to predict mortality in women.

**Conclusions:** In this study, we disclose that glomerular hyperfiltration might be an independent risk factor for all-cause mortality, especially in men. The mechanism and clinical implication of glomerular hyperfiltration should be more clarified.

## SA-PO251

**Clinical Significance of Subclinical Carotid Atherosclerosis and Its Relationship with Echocardiographic Parameters in Non-Diabetic Chronic Kidney Disease Patients** Jwa-kyung Kim, Sun Ryoung Choi, Jong-woo Yoon, Jung-woo Noh, Sung Gyun Kim. *Internal Medicine, Hallym Univ Sacred Heart Hospital, Kidney Research Institute, Korea.*

**Background:** Risk stratification of chronic kidney disease (CKD) patients is of particular interest and the presence of subclinical carotid atherosclerosis may be a good indicator of high-risk group. We investigated long-term outcomes of subclinical carotid atherosclerosis in non-diabetic CKD patients and tried to find echocardiographic parameters suggesting the presence of subclinical carotid atherosclerosis.

**Methods:** As a prospective design, a total of 182 patients underwent carotid ultrasonography and Doppler echocardiography at the time of CKD diagnosis. Carotid atherosclerosis was defined as carotid intima-media thickness >1.0 mm and/or the presence of plaque.

**Results:** Subclinical carotid atherosclerosis was found in 99 (54.4%) patients and they were significantly older and had a higher prevalence of hypertension, increased pulse pressure and serum high-sensitivity C-reactive protein (hs-CRP) levels than those without carotid atherosclerosis. Regarding echocardiographic results, left ventricular hypertrophy and markers of elevated LV filling pressure were closely related with the presence of carotid atherosclerosis. According to multivariate analysis, age, hs-CRP levels, and the ratio of early peak transmitral inflow velocity (E) to early diastolic mitral annular velocity (E') (E/E') were significant determinants of carotid atherosclerosis. During the study period of 28.8 ± 16.1 months, 23 cases of adverse CV events were occurred. Patients with carotid atherosclerosis showed significantly higher rates of annual cardiac event rates than those without (8.6% vs. 1.5%, p <0.001). Smoking (OR 3.13, 95% CI 1.10-9.09), increased E/E' ratio (OR 1.10, 95% CI 1.01-1.21), and the presence of carotid plaque (OR 7.80, 95% CI 1.45-45.97) were independent predictors for adverse CV events.

**Conclusions:** Subclinical carotid atherosclerosis was closely associated with poor prognosis in non-diabetic CKD patients. Increased age, hs-CRP, and E/E' ratio may be useful indicators suggesting the presence of subclinical carotid atherosclerosis.

## SA-PO252

**Characteristics of Uninephric Chronic Kidney Disease (CKD) Patients**
Andrew John Mallett,[1,2,3] Anne Salisbury,[1,2,3] Zaimin Wang,[1,2] Helen G. Healy,[1,2,3] George T. John,[1,3] Wendy E. Hoy.[1,2] *[1]CKD.QLD; [2]Centre for Chronic Disease, School of Medicine, Univ of Queensland, Brisbane, Queensland, Australia; [3]Dept of Renal Medicine, Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia.*

**Background:** CKD due to uninephria is infrequently reported. 0.9% of Australian and New Zealand patients starting renal replacement therapy (RRT) in 2011 had either "Loss of Single Kidney" (n=6) or "Congenital Renal Hypoplasia and Dysplasia" (n=20). Its frequency in the general CKD population is undefined.

**Methods:** To define characteristics of uninephric patients with CKD. CKD.QLD is a registry and research platform involving all consenting patients in public renal practices in Queensland (~10,800). Uninephric patients among the first 2359 enrolled were sought through Primary Renal Disease coding for nephrectomy, hypo/dysplastic, atrophic, and congenital kidneys. They were compared to all patients in the CKD.QLD registry.

**Results:** 136 uninephric patients were identified, or 5.8% of the total. Of these 76 (56%) had a surgical nephrectomy, 17 (12.5%) had a congenital malformation, 16 (11.7%) had an atrophic/dysplastic kidney, 13 (9.5%) had congenital single kidney, 10 (7.3%) had a functional nephrectomy, and 4 (3%) had a partial nephrectomy.

Uninephric patients in total and by subgroups were most commonly CKD Stage 3b(30%) and 4(26%). Their mean age was 64.2 years, compared to 65.5 years for CKD.QLD. 47% of uninephric patients were female vs 45% of the CKD.QLD registry.

Among the 76 surgically nephrectomised patients, 6 were living kidney donors while 70 were for "other/non-living kidney donor" reasons. All living donors were female compared to 37% of the "other" group. CKD Stage 3a was most common in living donors (50%) and CKD Stage 3b most common in the "other" group (34%). Living donor mean age was 63yrs vs 67.5yrs in the "other" group.

**Conclusions:** There are small numbers of uninephric patients in this CKD group, though a greater proportion than represented in RRT data. They are younger that the broader CKD.QLD population and have greater prevalence in CKD stages 2 to 5. The identification of 6 living kidney donors is of concern.

*Funding:* Government Support - Non-U.S.

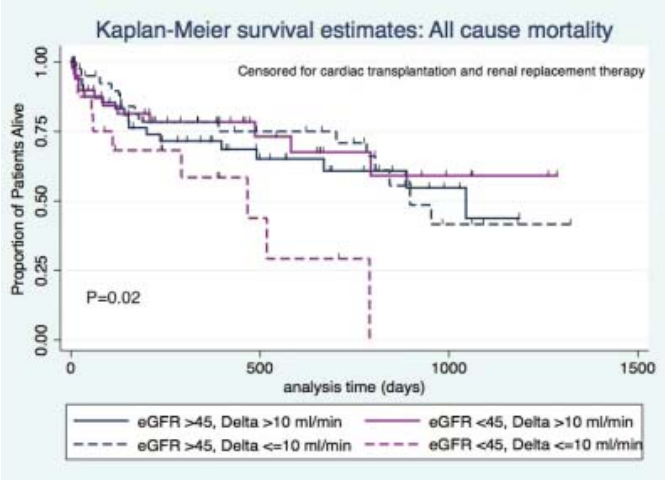
## SA-PO253

**Improvement in Renal Function Is Associated with Improved Outcomes after Ventricular Assist Device Implantation**
Jay L. Koyner, Abhijit S. Naik. *Sect. of Nephrology, Univ of Chicago.*

**Background:** Renal dysfunction is common in those with end stage heart failure including those requiring a ventricular assist device (VAD). Renal function improves following VADs in some patients although data on its impact on long-term mortality is limited.

**Methods:** We identified all patients who received a VAD from Jan. 2008 through Jan. 2012 at the University of Chicago and excluded subjects with ESRD and those who received pre-op renal replacement therapy (RRT). We defined Improved Renal Function (IRF) as a change in eGFR (MDRD) from baseline to day 7 of >10 ml/minute. The primary outcome was all cause mortality. The survival data was censored for cardiac transplantation and first RRT treatment. Kaplan Meier curves were then constructed and a Cox proportional hazards model was used to estimate the risk of mortality.

**Results:** 152 subjects were included in the cohort, 62 (41%) had baseline eGFR ≤45 ml/minute and 90(59%) had an eGFR > 45 ml/min There was no difference in the number of patients who had postop AKI (RIFLE- Risk) between the eGFR ≤ 45 and > 45 ml/min groups (p=0.57). Patients with eGFR≤45 and no IRF (n=18) had an increased risk of all-cause mortality [HR =2.87 (1.15,7.15) P=0.02] compared to those with an eGFR ≤45 ml/min and IRF (n=41). There was no mortality difference in patients with eGFR >45 ml/minute irrespective of their IRF status. Patients with eGFR ≤45 ml/min and IRF experienced outcomes similar to patients with eGFR > 45 ml/minute regardless of their IRF (p=0.85).



**Conclusions:** Patients with an eGFR ≤45 ml/min with IRF experienced outcomes on par with those who had a eGFR > 45 ml/min; these outcomes were significantly superior when compared to those with a eGFR ≤45 ml/min without IRF. The factors that impact IRF require further investigation which in turn may lead to improved VAD patient outcomes and may better identify patients who may benefit from a combined heart kidney transplant.

*Funding:* NIDDK Support

## SA-PO254

**Nephropathy in Illicit Drug Abusers – A Post-Mortem Analysis**
Oliver Jung,[1] Stefan Büttner,[1] Helmut Geiger,[1] Kerstin U. Amann,[2] Maike Julia Buettner.[2] *[1]Nephrology, Goethe Univ Hospital, Frankfurt/Main, Germany; [2]Pathology, Insitute of Nephropathology, Friedrich-Alexander-Univ, Erlangen, Germany.*

**Background:** Illicit drug abuse is an independent risk factor for chronic renal disease, but the pathogenic role of chronic exposure to illicit drugs and their contaminants under unsterile conditions remains unclear.

**Methods:** Retrospective investigation of all deceased that underwent forensic autopsy because of a suspected conjunction with illicit drug abuse between 01.01.2009 and 30.04.2011 in the Frankfurt/Main metropolitan area, Germany (3.8 million inhabitants).

**Results:** A total of 129 deceased were studied. Individuals were mostly Caucasian (99.2%), male (82.2%) and intravenous drug users (IVDU) (81.4%). Median age at time of death was 39 years and documented duration of drug abuse was 17 years, with the majority (87.2%) taking various drugs in parallel as assessed by toxicological analysis. Despite young age deceased had a high burden of co-morbidities, especially cardiovascular disease, liver cirrhosis and infections. Evaluation of kidneys demonstrated a broad spectrum of pathological alterations predominated by arteriosclerotic and ischemic damage, mostly mild interstitial inflammation, calcification of renal parenchyma and interstitial fibrosis/tubular atrophy, with hypertensive-ischemic nephropathy as the most common cause of nephropathy. Interstitial inflammation (OR: 16.59, 95%CI: 3.91-70.39) and renal calcification (OR: 2.43, 95%CI: 1.03-5.75) were associated with prolonged as well as severe IVDU, whereas hypertensive and ischemic damage were associated with toxicological confirmed cocaine abuse (OR: 6.00, 95%CI: 1.27-28.44) in multivariate analysis. Neither specific glomerular damage indicative for heroin- and hepatitis C related disease, e.g. FSGS or MPGN, nor signs of analgesic nephropathy were found.

**Conclusions:** In the majority of illicit drug abusers chronic progressive renal failure is attributable to repeated insults to the kidney caused by multiple antigenic and pharmacological challenges. In addition, our data demonstrate the deleterious role of cocaine abuse in this setting by inducing hypertensive and ischemic damage, promoting progression of renal disease.

## SA-PO255

**How to Estimate Glomerular Filtration Rate in HIV Patients?**
Corinne Isnard-Bagnis,[1] Laurence Pieroni,[2] Philippe Maksud,[3] Rachida Inaoui,[4] Stephanie Lallauret,[5] Nathalie I. Mbarga-Iobe,[5] Jerome Tourret,[1] Anne Bissery,[5] Alain Mallet,[5] Gilbert Deray,[1] Christine Katlama,[6] Sophie Tezenas du Montcel.[5] *[1]Nephrology, Groupe Hospitalier Pitie Salpetriere et Univ Pierre et Marie Curie, Paris, France; [2]Biology, Centre Hospitalier D'Avignon, Avignon, France; [3]Nuclear Medicine, Groupe Hospitalier Pitie Salpetriere et Univ Pierre et Marie Curie, Paris, France; [4]Rhumatology, Groupe Hospitalier Pitie Salpetriere et Univ Pierre et Marie Curie, Paris, France; [5]Clinical Research Unit, Groupe Hospitalier Pitie Salpetriere et Univ Pierre et Marie Curie, Paris, France; [6]Infectious Diseases, Groupe Hospitalier Pitie Salpetriere et Univ Pierre et Marie Curie, Paris, France.*

**Background:** Chronic kidney disease is a frequent complication in the HIV population. The optimal way to estimate glomerular filtration rate (GFR) in HIV patients is not known.

**Methods:** 44 $HIV_1$ patients were included in a transversal monocentric comparative study evaluating the accuracy of the different diagnostic tests available compared to the gold standard measurement of GFR. Adult, male, caucasian patients exhibiting an estimated (either Cockcroft or MDRD) GFR between 60 and 30 ml/min/1,73 $m_2$ were included. Plasma creatinine dosages (Jaffé and enzymatic), urea, albumin, proteinuria, Cystatin C were obtained. GFR was estimated using Cockcroft, MDRD, sMDRD, CKD Epi, CKD $Epi_{cyst}$, $CKDEpi_{cyst/creat}$ and measured using isotopic $Chrome^{51}$ EDTA clearance.

**Results:** Mean age was 62±10 with 82%>50 years, mean time from HIV diagnosis was 19±7 years. Mean BMI 23±4, with 9%>30. Prevalence of diabetes was 26%, HTA 47%. Viral load was <40 for 91% of patients and mean CD4 count was 438±195 cells/$mm^3$. Mean measured GFR was 63.39±13.47 ml/min/1,73$m^2$. All formulae under estimated GFR. Best precision was afforded by sMDRD and best accuracy by MDRD formulae. CKDEpi, $CKDEpi_{cyst}$ and $CKDEpi_{cyst/creat}$ performed worse than the MDRD formula.

**Conclusions:** In HIV patients in stable immunovirologic conditions with CKD stage 3 and high prevalence of metabolic associated conditions, MDRD formula performs best although all formulae under estimate GFR. Cystatin C formulae do not perform any better.

## SA-PO256

**Hyperuricemia Predicts Progression of Chronic Kidney Disease in Patients with Reduced Kidney Mass** Isabel Galán Carrillo, Marian Goicoechea, Soledad Garcia de Vinuesa, Ursula Verdalles, Alba Santos, Santiago Andrés Cedeño Mora, Nicolas Macias, Abraham Rincon, Jose Luno. *Hospital General Universitario Gregorio Marañón, Madrid, Spain.*

**Background:** Hyperuricemia has been associated with an increase in the incidence of chronic kidney disease (CKD) in general population and with kidney disease progression in CKD patients. The aim of this study was to evaluate the role of hyperuricemia in kidney disease progression in patients with reduced kidney mass.

**Methods:** Three hundred thirty seven patients (182M, 155F), median age 59.8±17.1 years, being followed on an outpatient basis, were included in the study. The etiology of the reduced kidney mass was: nephrectomy in 188, kidney agenesis in 27 and kidney atrophy in 122. The median follow-up was 60.0 (36.0-97.5) months. The primary composite end-point was: doubling baseline serum creatinine, end stage renal disease or death.

**Results:** The mean reduction of GFR was 2.32 ml/min/1.73 m². Sixty-five (5.2%) progressor patients had a reduction of GFR higher than 2.32 ml/min/year/1,73m2. The composite end point was reached by 24 patients (14 deaths, 5 patients entering dialysis, 15 patients doubling serum creatinine) and 48 patients suffered from a cardiovascular event. The independent factors associated with the composite event adjusted to blood pressure were: age (HR 1,112 (1,055-1,173), p=0,001),hyperuricemia, defined as uric acid ≥7 mg/dl (HR 3,31 (1,24-8,85), p=0,017) and albuminuria (HR 3,56 (1,40-9,05), p=0,007). These factors also predicted CKD progression : age (HR 1,055 (1,027-1,083), p=0,001), hyperuricemia (HR 2,95 (1,64-5,28), p=0,001), and albuminuria (HR 2,44 (1,32-4,51), p=0,004). Age (HR 1,031 (1,006-1,056), p=0,014) and previous vascular disease (HR 5,14 (2,66-9,94), p=0,001),were independent predictors of cardiovascular events. Diabetes, dyslipidemia and renin angiotensin system blockers were not associated with CKD progression.

**Conclusions:** In patients with reduced renal mass due to lost of one kidney, progression of CKD is not frequent. Hyperuricemia is a risk factor for progression of renal disease and may be established as a new therapeutic target together with blood pressure and albuminuria.

## SA-PO257

**Plasmatic Renin Activity in Patients with Chronic Kidney Disease** Lidia Anguiano,[1] Marta Riera,[1] Julio Pascual,[1] Clara Barrios,[1] Angels Betriu,[2] Jose M. Valdivielso,[2] Elvira Fernandez,[2] Maria Jose Soler.[1] *[1]Nephrology, IMIM-Hospital del Mar, Barcelona, Spain; [2]Nephrology, Hospital Arnau de Vilanova, Lleida, Spain.*

**Background:** The renin-angiotensin system is activated in Chronic Kidney Disease (CKD), with an increase of Plasmatic Renin Activity (PRA). Our aim is to study PRA in patients in different stages of CKD patients without a history of cardiovascular (CV) disease.

**Methods:** A total population of 148 patients from the NEFRONA study in different stages of CKD and without a history of CV disease was analyzed. Patients were distributed into three groups: CKD stages 1-2 (CKD1-2, n=51), non-dialysis CKD stages 3-5 (CKD3-5, n=50) and dialysis (CKD5D, n=48). Variables analyzed were: gender, diabetes, dyslipidemia, hypertension, age, antihypertensive treatments (ACEi and ARA2) and treatment with vitamin D analogues (calcitriol, paricalcitol, colecalciferol and hidroferol). PRA was analyzed using a fluorimetric assay.

**Results:** Distribution of the population: mean age of 56.97±12.24, 60.1% men, 49.3% diabetics, 62.8% dyslipidemias, 69.6% hypertensive, 21.6% with ACEi treatment and 35.8% with ARA2 treatment.

There were significant differences in PRA levels between groups, with an increased PRA in CKD3-5 (199.1±12.1 RFU/µl/h) as compared to CKD5D (151.4±10.4) and CKD1-2 (116.5±6.1) ($p<0.05$).

In CKD3-5 patients, diabetic patients showed higher levels of PRA as compared to non-diabetic (229.9±20.9 vs 168.2±8.8; $p<0.05$). In this group, treatment with paricalcitol showed a decrease in PRA compared to those patients without treatment (137.2±11.9 vs 205.9±12.9; $p<0.05$). In CKD1-2, patients treated with ARA2 had higher levels of PRA compared to those not treated (153.8±12.5 vs 102.4±5.4 $p<0.05$).

**Conclusions:** In CKD patients without a history of CV disease, CKD3-5 showed an increase in PRA. Patients on dialysis have lower levels of PRA as compared to CKD predialysis. In the CKD3-5 group, diabetic patients have an increased PRA, while the treatment with vitamin D (paricalcitol) analogues is associated with lower levels of PRA.

## SA-PO258

**Impact of the Great East Japan Earthquake on Chronic Kidney Disease without Renal Replacement Therapy Patients in Severely Destroyed Coastal Area of Japan** Gen Yamada,[1] Mariko Miyazaki,[1] Tasuku Nagasawa,[2] Yasumichi Kinoshita,[2] Tae Yamamoto,[1] Kazuto Sato,[2] Masaaki Nakayama,[3] Hiroshi Sato,[1] Sadayoshi Ito,[1] Yaeko Murata.[1] *[1]Nephrology, Endocrinology, and Vascular Medicine, Tohoku Univ Hospital, Sendai, Japan; [2]Internal Medicine, Ishinomaki Redcross Hospital, Ishinomaki, Japan; [3]Nephrology, Hypertension, Diabetology, Endocrinology and Metabolism, Fukushima Medical Univ, Fukushima, Japan.*

**Background:** While there is serious impact by the great disaster for the dialysis patients, the disaster impact on chronic kidney disease(CKD) patients of pre-renal replacement therapy(RRT) has not been reported. The tsunami caused by Great East Japan Earthquake in March 2011 destroyed the coastal area of Miyagi prefecture. We conduct the prospective cohort study for CKD patients from 2006 in this area. We followed 156 patients treated in the severely devastated coastal zone, Ishinomaki. The applicable population is 220,000. The died or missed victims were 5,800 people, as well as 30,000 buildings totally collapsed in Ishinomaki medical zone.

**Methods:** Using data from Miyagi Gonryo study, we identified 156 patients who registered July and August/2008 in Ishinomaki Redcross Hopital.They were followed GFR, urinary findings, blood biochemistry findings, treatment and outcome annually. The Great East Japan Earthquake occurred after 3 years from registration. We described the outcome of 1 year after disaster compared with previous 3 years.

**Results:** One hundred and seventeen patients were valid in 2010. Annual check confirmed that 5 started dialysis and 3 died by disease. Four lossed after January 2011, 4 died by the tsunami. After 1 year from disaster, 1 lossed from June 2011, 7 moved, and 2 died by infectious disease in April 2011 and by heart failure in December 2011. Death and cardiovascular events didn't increase compared with 2010. While 29.9% of patients showed eGFR decline over 5%/year between 2008 and 2010 of 77 patients observed through study period to 2012, 58.4% of them decreased eGFR over 5%/year between 2011 and 2012.

**Conclusions:** We concluded that the great tsunami disaster was possible to affect pre-RRT CKD patients. We should treat them carefully for more long term about the cardiovascular event and renal outcome.

## SA-PO259

**Total Kidney Volume Is a Prognostic Biomarker for Worsening of Kidney Function in Patients with Autosomal Dominant Polycystic Kidney Disease** J.F. Marier,[1] Nathalie H. Gosselin,[1] Jason T. Chittenden,[1] Frank S. Czerwiec,[2] Daniel I. Levy,[3] Arlene B. Chapman,[4] Berenice Y. Gitomer,[5] Vicente E. Torres,[6] Eslie H. Dennis,[7] Klaus Romero,[7] D. Miskulin,[8] Ronald D. Perrone.[8] *[1]Pharsight, St. Louis, MO; [2]Otsuka, Rockville, MD; [3]Pfizer, Collegeville, PA; [4]Emory Univ, Atlanta, GA; [5]Univ of Colorado, Colorado, CO; [6]Mayo Clinic, Rochester, MN; [7]Critical Path Institute, Tucson, AZ; [8]Tufts Medical Center, Boston, MA.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common hereditary kidney disease. The growth of cysts increases total kidney volume (TKV) and result in interstitial fibrosis and renal failure. The goal of this project was to qualify TKV as prognostic biomarker for 30 and 57% decline of estimated glomerular filtration rate (eGFR) in ADPKD patients.

**Methods:** TKV data collected by the Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease (CRISP) and longitudinal research registries were used (University of Colorado, Emory University, and Mayo Clinic). TKV was measured by ultrasonography, computer assisted tomography scan or magnetic resonance imaging. Longitudinal TKV and the probability of 30 or 57% eGFR decline was assessed using a joint model.

**Results:** Patients with 30 or 57% eGFR decline had higher baseline TKV (1.5 and 1.9 L, respectively) than patients without (1.0 L). Baseline age and predicted TKV at the time of 30 or 57% eGFR decline were statistically significant. Probabilities of not meeting the 30 or 57% eGFR decline are shown below.

| Endpoints | Baseline Age (Years) | Baseline TKV | | |
|---|---|---|---|---|
| | | 1 L | 2 L | 3 L |
| Probability of No 30%eGFR in 3 years | 20 | 88.5% | 81.8% | 76.0% |
| | 40 | 92.6% | 88.0% | 83.9% |
| Probability of No 57%eGFR in 10 years | 20 | 86.6% | 73.5% | 62.0% |
| | 40 | 80.5% | 63.4% | 51.2% |

**Conclusions:** Baseline TKV can be applied as a prognostic biomarker along with baseline age to predict eGFR decline. Patients with larger TKV have a greater risk of 30 or 57% eGFR decline. This information can be used to improve drug development programs and for trial enrichment.

*Funding:* Private Foundation Support

## SA-PO260

**Total Kidney Volume Is a Prognostic Biomarker for the Progression to End-Stage Renal Disease in Patients with Autosomal Dominant Polycystic Kidney Disease over 10 Years** J.F. Marier,[1] Mohamad-samer Mouksassi,[1] Fredrik Jonsson,[1] Frank S. Czerwiec,[2] Daniel I. Levy,[3] Arlene B. Chapman,[4] Berenice Y. Gitomer,[5] Vicente E. Torres,[6] Eslie H. Dennis,[7] Klaus Romero,[7] D. Miskulin,[8] Ronald D. Perrone.[8] *[1]Pharsight, St. Louis, MO; [2]Otsuka, Rockville, MD; [3]Pfizer, Collegeville, PA; [4]Emory Univ, Atlanta, GA; [5]Univ of Colorado, Colorado, CO; [6]Mayo Clinic, Rochester, MN; [7]Critical Path Institute, Tucson, AZ; [8]Tufts Medical Center, Boston, MA.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common hereditary kidney disease. The growth of cysts increases total kidney volume (TKV) and lead to renal failure. Radiological imaging can be used to measure TKV and monitor disease progression. The goal of this project was to qualify TKV as a prognostic biomarker for progression to end-stage renal disease (ESRD) in ADPKD patients.

**Methods:** TKV data collected by the Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease (CRISP) and longitudinal research registries were used (University of Colorado, Emory University, and Mayo Clinic). Ultrasonography (US), computer assisted tomography (CT) scan and magnetic resonance imaging (MRI) were included. A joint model linking longitudinal TKV and the probability of ESRD was used.

**Results:** Mean baseline age of patients with and without ESRD were 42.8 and 33.1 years, respectively. Mean baseline TKV of patients with and without ESRD were approximately 2.2 and 1.0 L, respectively. Baseline age and the predicted TKV at the time of ESRD were statistically significant. Probabilities of not reaching ESRD are presented below.

| Baseline Age | Typical Baseline TKV (probability of no ESRD in 10 years) | | |
|---|---|---|---|
| | 1 L | 2 L | 3 L |
| 20 | 93.9% | 83.7% | 74.4% |
| 40 | 88.6% | 71.5% | 58.1% |

The above results were consistent with those derived with the US or CT-MRI datasets.

**Conclusions:** Baseline TKV can be applied as a prognostic biomarker along with baseline age to predict the risk of ESRD over 10 years. Younger subjects with large TKV are at greater risk of progression than older subjects with smaller TKV. This information can be applied to improve drug development programs and for trial enrichment.

## SA-PO261

### Relationship between Renal Complications and Total Kidney Volume in Autosomal Dominant Polycystic Kidney Disease from the Consortium for Radiologic Imaging of Polycystic Kidney Disease Cohort

Frederic F. Rahbari-Oskoui,[1] Doug Landsittel,[2] Vicente E. Torres,[3] Kyongtae Ty Bae,[2] Michal Mrug,[4] Marie C. Hogan,[3] Lisa M. Guay-Woodford,[7] Jared J. Grantham,[6] Michael F. Flessner,[5] Arlene B. Chapman,[1] William M. Bennett.[8] *[1]Emory Univ; [2]U of Pittsburgh; [3]Mayo Clinic, MN; [4]U of Alabama-Birmingham; [5]NIDDK-NIH; [6]Kansas Univ; [7]Children's Nat Med Ctr, DC; [8]Legacy Good Samaritan Med Ctr, Portland, OR.*

**Background:** Inclusion of renal complications of autosomal dominant polycystic kidney disease (ADPKD) as new endpoints for interventional clinical trials has been suggested by the FDA. The relationship between these factors and height adjusted Total Kidney Volume (htTKV), is unknown.

**Methods:** We used the CRISP cohort to establish the frequency of kidney pain (P), hypertension (HT), urinary tract infection (UTI), gross hematuria (H) and nephrolithiasis (N) and their relationship to the last observed htTKV. Differences in htTKV by those with a baseline complication vs the No Complication group were calculated using the t-test; odds ratios (ORs) were calculated using logistic regression adjusting for age, BMI, gender, race, and baseline corrected iothalamate clearance.

**Results:** 11 year follow up data from 202 participants were analyzed. Baseline (& cumulative) percentage frequencies of P, HT, UTI, H and N were 60.8(84.7), 61 (71.4), 45.2 (52.7), 32.8 (48.1), and 13.3 (21.2) respectively. Mean (±SD) baseline htTKV, were significantly higher ($p < 0.05$) in: 1- HT patients vs non-HT (736.0 ± 394.5 vs 401.6 ± 224.9 cc), 2-Patients with H vs without H (728.6 ± 409.3 vs 537.3 ± 297.2 cc), 3- patients with P vs without P (690.1 ± 405.3 vs 478.5 ± 274.3 cc). The differences in htTKV based on UTI and N were not significant. The adjusted ORs (CI) for development of KP, HT, H, UTI, N based on (a 100 cc difference in) baseline htTKV were 1.17 (1.01, 1.36), 1.41 (1.19, 1.66), 1.17 (1.07, 1.28), 0.98 (0.89, 1.07) and 1.07 (0.98, 1.17).

**Conclusions:** In addition to established correlation with renal function, HtTKV is associated with specific renal complications of ADPKD. These findings reiterate the importance of htTKV as a marker of disease severity and support its use in the design of future studies.

## SA-PO262

### Kidney Length Measured by Ultrasound (US) Predicts Development of Chronic Kidney Disease (CKD) Stage 3 in Autosomal Dominant Polycystic Kidney Disease (ADPKD): Findings from the Consortium for the Radiographic Imaging Studies of Polycystic Kidney Disease (CRISP) Cohort

Arlene B. Chapman,[1] Vikram Smith,[1] Frederic F. Rahbari-Oskoui,[1] Jared J. Grantham,[2] Vicente E. Torres,[3] Kyongtae Ty Bae,[4] Doug Landsittel,[4] W. Charles O'Neill.[1] *[1]Emory Univ; [2]Kansas Univ; [3]Mayo Clinic; [4]Univ of Pittsburgh.*

**Background:** ADPKD causes kidney cysts, enlargement and ultimately renal failure. Total kidney volume (TKV) measured by magnetic resonance imaging (MR) is a measure of kidney cyst burden that strongly predicts future CKD Stage 3 within 8 years in ADPKD. Using simultaneous baseline US and MR imaging in the (CRISP), we established the predictive power of US length for future CKD Stage 3 in ADPKD.

**Methods:** Correlations between baseline US length and MR TKV and length and the future development of CKD Stage 3 by iothalamate clearance determinations were examined in 241 ADPKD subjects, 15-45 years, and baseline estimated creatinine clearance ≥ 70 ml/min. Correlations were assessed using Pearson's correlations. Area under the curve using receive operator characteristics were performed based on US measured renal length at baseline in CRISP.

**Results:** Correlations between Baseline US length and MR TKV and length were strong (r=0.98, r=0.97 respectively). Bland Altman plots demonstrated consistent agreement between US length and MR length and TKV until US length reached 17 cm. MR based lengths predicted future CKD Stage 3 (r=0.85, P<0.01) at an optimal length of 16 cm. Area under the curve ROC analyses demonstrated that US length predicted future CKD Stage 3 strongly (0.84. P<0.01) similar to MR baseline TKV.

**Conclusions:** Results support the strong predictive value of baseline US length for future kidney function decline (ie CKD Stage 3), consistent with MR based TKV measures in the CRISP II cohort. US length had a reduced agreement with MR based TKV and length when > 17 cm. US length can be used to predict future CKD Stage 3 in ADPKD.

*Funding:* NIDDK Support

## SA-PO263

### Correlation of Total Kidney Volume and eGFR in Patients with ADPKD: Results from the TEMPO 3:4 Trial

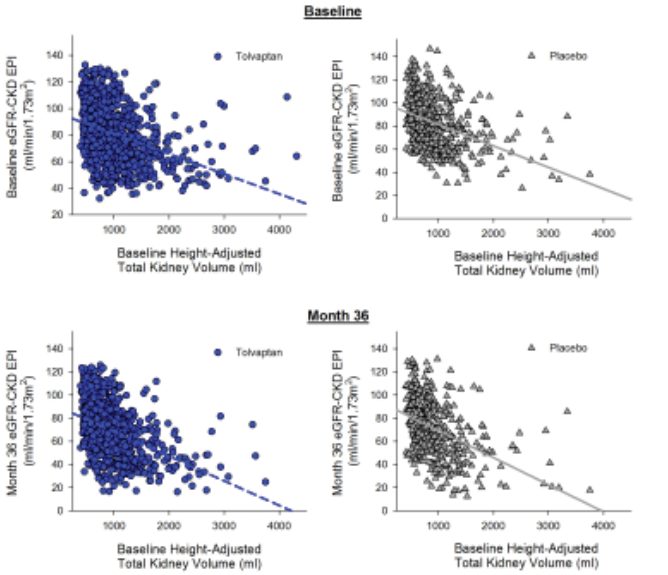
Ronald D. Perrone,[1] Arlene B. Chapman,[2] Frank S. Czerwiec,[3] Olivier Devuyst,[4] Ron T. Gansevoort,[5] Jared J. Grantham,[6] Eiji Higashihara,[7] Holly Krasa,[3] John Ouyang,[3] Vicente E. Torres.[8] *[1]Boston, USA; [2]Atlanta, USA; [3]Otsuka USA; [4]Zurich, Switzerland; [5]Groningen, Netherlands; [6]Kansas City, USA, Japan; [7]Mitaka, Japan; [8]Rochester, USA.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) causes kidney cysts often associated with pain, hypertension, and kidney failure. Total kidney volume (TKV) is a measure of kidney cyst development and enlargement that has been correlated with renal function decline in smaller studies.

**Methods:** Correlations between baseline TKV and height-adjusted TKV slope and changes in $eGFR_{CKD\text{-}EPI}$ were examined as post-hoc exploratory analyses. Correlations were assessed using Pearson's correlations at different time points and by treatment group.

**Results:** Correlations between htTKV at baseline and eGFR improved from Baseline to Year 3 with no difference between placebo and tolvaptan (Table). The correlation between baseline htTKV and eGFR slope on treatment was blunted in the tolvaptan compared to the placebo group.

| **Table** Pearson Correlation Coefficients with baseline height-adjusted TKV | | | |
|---|---|---|---|
| | **All Patients (N=1445)** | **Tolvaptan (N=961)** | **Placebo (N=483)** |
| Baseline eGFR | -0.378 | -0.370 | -0.395 |
| Month 36 eGFR | -0.435 | -0.434 | -0.439 |
| eGFR slope on treatment | -0.185 | -0.162 | -0.247 |
| *p<0.001 for all comparisons | | | |



**Conclusions:** Results support the strong predictive value of baseline htTKV for predicting GFR decline, consistent with data reported from the CRISP II cohort. Since there is approximately 30% less eGFR decline in the tolvaptan group regardless of CKD stage, greater variability likely reflects a differential response among the treated population which is not entirely accounted for by baseline htTKV or baseline eGFR.

## SA-PO264

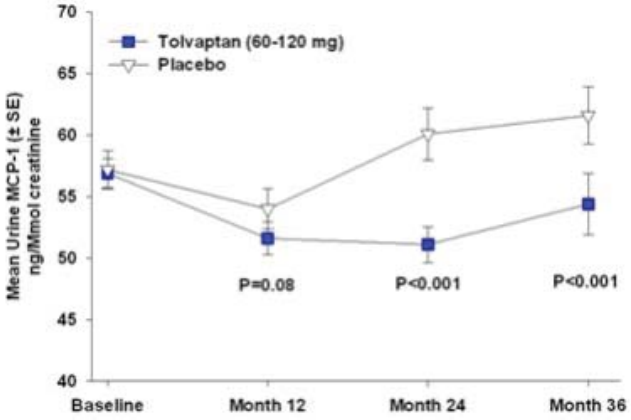
### Tolvaptan Administration to Patients with ADPKD Suppresses Urine MCP-1 Excretion: Results from the TEMPO 3:4 Trial

Jared J. Grantham,[1] Arlene B. Chapman,[2] Frank S. Czerwiec,[3] Olivier Devuyst,[4] Ron T. Gansevoort,[5] Eiji Higashihara,[6] Holly Krasa,[3] John Ouyang,[3] Ronald D. Perrone,[7] Vicente E. Torres.[8] *[1]Medicine, Kansas Univ, Kansas City, KS; [2]Medicine, Emory Univ, Atlanta, GA; [3]Development, Otsuka, Rockville, MD; [4]Medicine, Univ Zurich, Zurich, Switzerland; [5]Medicine, Univ Gronengin, Gronengin, Netherlands; [6]Urology, Kyorin Univ, Kyorin, Japan; [7]Medicine, Tufts Med Ctr, Boston, MA; [8]Medicine, Mayo, Rochester, MI.*

**Background:** Monocyte chemotactic protein-1 is produced by cysts and excreted in the urine in ADPKD. MCP-1 accumulates in cysts and interstitium and attracts macrophages. Urine MCP-1 derives from cysts that remain connected to downstream segments or from the cells of patent tubules. The effect of treatment that slows cyst development and enlargement on urine MCP-1 levels is unknown.

**Methods:** MCP-1 was prospectively measured (pre-treatment baseline, Month 12, 24, and 36) in 1445 patients treated with either tolvaptan or placebo for 36 months. Urine MCP-1 (ng/Mmol creatinine) was determined in 784 Tolvaptan and 429 Placebo subjects. Treatment group comparisons at each time point were determined using an observed case, intent to treat, MMRM analysis on log-transformed ratios.

**Results:** At baseline, the mean MCP-1 to creatinine ratio was balanced between treatment groups and associated positively with total kidney volume (R= 0.221, P<0.0001) and negatively with eGFR (R= -0.124, P<0.0001) and Uosm (R= -0.148, P<0.0001). Urine MCP-1 creatinine ratio was less with tolvaptan than placebo beginning at Month 12, with significant reductions at Months 24 and 36 (mean difference -12%).



**Conclusions:** Tolvaptan administered over a period of 3 years reduced the excretion of the biomarker MCP-1 into the urine relative to placebo, consistent with potential amelioration of renal interstitial inflammation.

## SA-PO265

**The Effect of Tolvaptan on Albuminuria in ADPKD. Results of the TEMPO 3:4 Trial** Ron T. Gansevoort,[1] Arlene B. Chapman,[2] Frank S. Czerwiec,[3] Olivier Devuyst,[4] Jared J. Grantham,[5] Eiji Higashihara,[6] Holly Krasa,[3] John Ouyang,[3] Ronald D. Perrone,[7] Vicente E. Torres.[8] *[1]For the TEMPO 3:4 Investigators, Groningen, Netherlands; [2]Atlanta, USA; [3]Otsuka Pharma, USA; [4]Zurich, Switzerland; [5]Kansas City, USA; [6]Mitaka, Japan; [7]Boston, USA; [8]Rochester, USA.*

**Background:** The TEMPO 3:4 Trial, including 1445 ADPKD patients, suggested that use of tolvaptan (T) had no effect compared to placebo (P) on albuminuria. However, the use of categorical "albuminuria events" to express albuminuria may have resulted in a loss of sensitivity to detect changes. In the present study we therefore specifically investigated the effects of T on albuminuria.

**Methods:** Post-hoc analysis of prospective, blinded RCT. Microalbuminuria or higher (MA) was a priori defined as spot albumin:creatinine ratio (ACR) ≥2.8 in males and ≥2.0 mg/mmol in females.

**Results:** Baseline median ACR was 3.1 (T) and 3.4 (P) mg/mmol. 58.6% of ADPKD patients had MA. Subjects with MA had higher TKV and lower eGFR, but were as likely to be male, hypertensive and to use RAASi than subjects without MA. During follow-up P treated patients with MA had a similar rate of growth in TKV when compared to patients without MA (5.51 versus 5.47 %/yr), but more rapid eGFR loss (median -4.13 vs. -2.63 mL/min/1.73m$^2$/yr). ACR rose in P treated patients (+0.23 mg/mmol), whereas it decreased in T treated patients (-0.40 mg/mmol). The difference in ACR in T versus P treated patients increased over time, reaching a maximum of 23% at month 36 (p<0.001), whereas no difference in blood pressure was observed. After T withdrawal the difference in ACR between the two treatment groups remained significant (16%, p=0.003). A beneficial effect of T on TKV growth and eGFR loss was observed in both MA subgroups, but stronger in patients with MA than without MA (effect on TKV growth: -53.7% vs -43.7%; on eGFR slope: -29.5% vs -20.2%%, resp.).

**Conclusions:** In ADPKD patients MA is associated with eGFR loss. Tolvaptan decreased albuminuria compared to placebo, independent of blood pressure, and this effect remained after withdrawal of study drug. Treatment efficacy of tolvaptan was more readily detected in patients with MA.

*Funding:* Pharmaceutical Company Support - Otsuka Pharma, USA

## SA-PO266

**Effects of Tolvaptan in ADPKD: Subanalysis of Japanese Patients from the TEMPO 3:4 Trial** Shigeo Horie,[1] Eiji Higashihara,[2] Satoru Muto,[3] Kikuo Nutahara,[4] Yasuhiko Iino,[5] Ichiei Narita,[6] John Ouyang,[7] Vicente E. Torres.[8] *[1]Urology, Juntendo Univ, Tokyo, Japan; [2]Polycystic Kidney Research, Kyorin Univ, Mitaka, Tokyo, Japan; [3]Urology, Teikyo Univ, Tokyo, Japan; [4]Urology, Kyorin Univ, Mitaka, Tokyo, Japan; [5]Nephrology, Nippon Medical School, Tokyo, Japan; [6]Clinical Nephrology and Rheumatology, Niigata Univ, Niigata, Japan; [7]Biostatistics, Otsuka PDC, Rockville, MD; [8]Internal Medicine, Mayo Clinic, Rochester, MN.*

**Background:** Tolvaptan, a vasopressin V2 receptor antagonist, slowed the increase of total kidney volume (TKV) and the decline of kidney function in ADPKD patients during a 3-years treatment period in the global TEMPO 3:4 study. This study included 177 Japanese patients in total 1445 patients. The purpose of this study is to evaluate the efficacy and safety of tolvaptan in Japanese patients.

**Methods:** 276 Japanese patients were screened and 177 patients were enrolled: assigned 118 patients to tolvaptan treatment and 59 patients to placebo treatment. We evaluated the same primary and secondary endpoint and safety profile in Japanese population as originally planned in the TEMPO 3:4 study (NEJM 368(13):1258-9.).

**Results:** 92 of 118 patients (78.0%) in the tolvaptan group and 55 of 59 patients (93.2%) in the placebo group completed the 3-year treatment. Baseline eGFR was lower and higher rates of proteinuria were noted in Japanese patients compared to global subjects. The increase of TKV was 1.3% per year in tolvaptan group, versus 5.0% per year in placebo (P<0.001). The relative treatment effect of 74.9% in Japanese patients was greater than global subjects (49.2%). Analysis of the key secondary endpoint showed fewer ADPKD-related events per 100 person-years of follow-up with tolvaptan than with placebo (41 vs. 52 events). Tolvaptam significantly inhibited the decline of renal function assessed by reciprocal of serum creatinine compared to placebo (-4.84 vs -6.28 (mg per milliliter)-1/year, P<0.05). Tolvaptan showed the similar safety profile in Japanese patients including hepatotoxicity.

**Conclusions:** Tolvaptan showed the similar efficacy and safety profile in Japanese ADPKD patients compared to the global subjects.

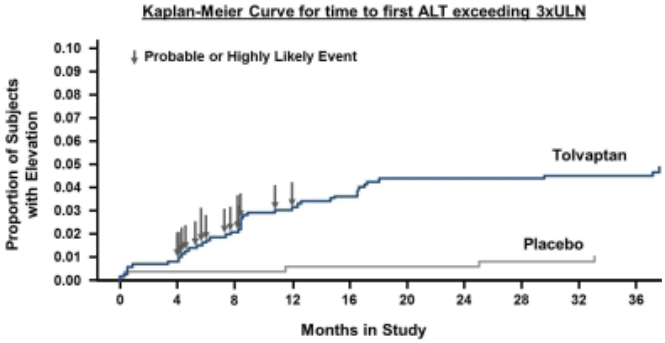
## SA-PO267

**Profile of Transaminase Elevations in Autosomal Dominant Polycystic Kidney Disease–Results from the TEMPO 3:4 Trial** Christopher Zimmer,[1] Arlene B. Chapman,[2] Frank S. Czerwiec,[1] Olivier Devuyst,[3] Ron T. Gansevoort,[4] Eiji Higashihara,[5] Holly Krasa,[1] John Ouyang,[1] Ronald D. Perrone,[6] Vicente E. Torres.[7] *[1]Otsuka, USA; [2]Atlanta, USA; [3]Zurich, Switzerland; [4]Groningen, Netherlands; [5]Mitaka, Japan; [6]Boston, USA; [7]Rochester, USA.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) subjects treated with tolvaptan(T) in the TEMPO 3:4 trial were more likely to have significant liver TA elevations than those treated with placebo(P). This imbalance was not previously observed with T, requiring further elucidation.

**Methods:** The potential of T to cause hepatocellular injury was explored with adverse event and laboratory data. Subjects with events meeting criteria indicative of liver injury were adjudicated. An expert panel assessed drug-causality considering co-morbid conditions, concomitant medication use, onset, offset, and dose-relationship.

**Results:** Forty-six of 1445 subjects (35 T and 11 P) met criteria for adjudication. 16 T and 1 P subject met drug-related causality criteria with onset of qualifying events after 3 months of treatment.



The incidence of new onset ALT elevations >3xULN in T subjects was low after 14 months. The TA elevations associated with T returned to 3xULN typically within 1 to 4 months and were not associated with fulminant liver failure, or permanent liver injury or dysfunction. No association with dose or exposure was found.

**Conclusions:** Hepatocellular injury was identified as a new risk of tolvaptan treatment in subjects with ADPKD enrolled in the TEMPO 3:4 trial. No subjects experienced hepatic failure, permanent liver damage or death from hepatocellular injury. Results from these analyses suggest that regular TA monitoring should be done during use of T. The mechanism of T-induced liver injury in ADPKD patients requires further study.

## SA-PO268

**Achievement and Maintenance of Blood Pressure Targets in HALT:PKD**
Vicente E. Torres,[1] Robert W. Schrier,[2] Arlene B. Chapman,[3] Ronald D. Perrone,[4] D. Miskulin,[4] Theodore I. Steinman,[5] Franz Winklhofer,[6] William E. Braun,[7] Marie C. Hogan,[1] Frederic F. Rahbari-Oskoui,[3] Kaleab Z. Abebe,[8] Michael F. Flessner.[9] *[1]Mayo Clinic; [2]U CO; [3]Emory U; [4]Tufts U; [5]Beth Israel; [6]KUMC; [7]Cleveland Clinic; [8]U Pittsburgh; [9]NIH/NIDDK HALT Study Group.*

**Background:** HALT-PKD seeks to determine whether ACEI/ARB is superior to ACEI alone and low BP(<110/75) is superior to standard BP(120-130/70-80) in delaying cystic progression (eGFR>60mL/min/1.73m$^2$, Study A) and whether ACEI/ARB is superior to ACEI alone (BP target 110-130/70-80mmHg) in slowing eGFR decline (eGFR 25-60mL/min/1.73m$^2$, Study B).

**Methods:** Stepwise dosing of lisinopril(L) and telmisartan/placebo(T/P)(steps 1-4) followed by stepwise dosing of other agents (steps 5-10) is used to achieve BP targets. During 1/2006-4/2012, 519, 501, 490, 474, 433, 273, 154 A and 458, 447, 437, 411, 362, 191, and 80 B patients completed 4, 12, 24, 36, 48, 60, and 72-mth followup. BP control is assessed by home BP measurements.

**Results:**

| | Mths | Study A Std | Study A Low*[a] | Study B |
|---|---|---|---|---|
| MAP† | 4 | 91.5 (5.8) | 85.0 (6.5) | 91.0 (6.9) |

| | 60 | 2.5; 15.6, 52.7 | 4.0; 25.8, 66.2 | 2.9; 15.9, 52.9 |
| | 72 | 2.7; 15.6, 54.4 | 4.2; 26.0, 67.4 | 2.7; 16.0, 51.8 |

†mean SD *Underlined: P<0.001 compared to Study A standard

[a] Step and dosage comparisons made using Wilcoxon test

Based on random regressions, negative MAP slopes in Study A low and significantly positive BP slopes in Study A standard result in increasing BP separation over time.

**Conclusions:** ACEI alone or ACEI/ARB achieves BP control and MAPs are within target in most subjects at 4-72 months of followup. Excellent separation in BP and doses of LIS and T/P between study A arms is achieved, without detectable differences in heart rate.

*Funding:* NIDDK Support

## SA-PO269

**Cardiac Magnetic Resonance Assessment of Left Ventricular Ejection Fraction in the ADPKD HALT A Cohort**
Kyongtae Ty Bae,[1] Diana Kaya,[1] Kaleab Z. Abebe,[1] Robert W. Schrier,[2] Arlene B. Chapman,[3] Vicente E. Torres,[4] Theodore I. Steinman,[5] William E. Braun,[6] Franz Winklhofer,[7] Cheng Tao,[1] JinHong Wang,[1] Marie C. Hogan,[4] D. Miskulin,[8] Frederic F. Rahbari-Oskoui,[3] Michael F. Flessner,[9] Charity G. Moore,[1] Ronald D. Perrone.[8] *[1]U Pittsburgh; [2]U Colorado; [3]U Emory; [4]Mayo; [5]Beth Israel; [6]Cleveland Clinic; [7]U Kansas; [8]Tufts U; [9]NIH/NIDDK.*

**Background:** To measure left ventricular ejection fraction (LVEF) from magnetic resonance images (MRI) in HALT-PKD Study A subjects aged 15-49 with eGFR>60mL/min/1.73m$^2$ and to associate LVEF with clinical and imaging parameters including total kidney volume (TKV) and left ventricular mass index (LVMI).

**Methods:** ECG-gated cine cardiac MRI covering left ventricle (LV) were acquired in 458 subjects at baseline, prior to study intervention. From the end-diastolic (ED) and end-systolic (ES) MRI, ED and ES volumes of LV chamber were measured using a semi-automated program. LVEF was calculated as %(ED-ES)/ED LV volumes. LVMI was measured from end-diastolic MRI. TKV was measured from T1-weighted MRI of kidney. Univariate and multivariate analysis of the association of baseline parameters with LVEF was performed.

**Results:** Mean LVEF was 64.4±7.5% (range 40-87%) and did not differ between M and F. The baseline parameters that showed significant univariate associations with LVEF were LVMI, height-corrected TKV (htTKV), body mass index (BMI), age, and urine aldosterone. Only htTKV, BMI, and urine aldosterone remained significant in the multivariate regression. eGFR, RBF, BP, and urine albumin/sodium/potassium were not significant in the univariate analysis.

| | Coef | Standardized Coef | P |
|---|---|---|---|
| htTKV | -0.003 | -0.140 | 0.009 |
| BMI | 0.15 | 0.098 | 0.067 |
| Urine aldosterone | -0.096 | -0.116 | 0.030 |

**Conclusions:** In relatively young ADPKD subjects with preserved GFR, reduction in LVEF was associated with increased urine aldosterone and htTKV and decreased BMI. Subclinical renal hypoperfusion due to reduced LVEF or enlarged kidneys may result in increased urinary aldosterone excretion, contributing to the pathogenesis of HTN in ADPKD.

## SA-PO270

**Analysis of Octreotide LAR Therapy after Four Years in Polycystic Liver and Kidney Disease**
Marie C. Hogan, Eric J. Bergstralh, Maria V. Irazabal, James Glockner, Xujian Li, Vicente E. Torres. *Mayo Clinic, MN.*

**Background:** We completed follow up of 25 patients with ADPKD or ADPLD who received up to 4 yrs of the somatostatin analog OctLAR; 27/ 42 patients who participated in a prospective two-year clinical trial of OctLAR (40mg/mo) in PLD consisting of a 1 year RCT and a 2nd year of open label OctLAR re-enrolled into an open label extension study (OLE).

**Methods:** Liver/kidney MRIs at baseline, yr 1 & 2 were compared to re-enrollment scan for OLE (OLEi) and at OLE completion (OLEo). Primary end point was ΔTLV, annualized rate), 2º end points included ΔTKV & eGFR. TLV & TKV at OLEo were compared to baseline, yr 2 & OLEi.

**Results:** Twenty-five of 42 patients (60%) on OctLAR (16 of the original 28 (O→O) group)) or placebo (9 of original 14; (P→O) group) completed OLE. While off OctLAR, TLV increased at 3.4% per annum. After resuming OctLAR, TLV decreased again by 4.7% per annum. Despite regrowth off OctLAR, there was a progressive reduction in (mean ± SD) TLV (-11%; p=0.006; paired t test) on long-term OctLAR. Baseline TKV (777 ± 468ml) increased to 819 ± 508ml by yr2 & to 861 ± 525ml at OLEi & was again suppressed to (879 ± 593 ml; 0.7±13.6%) at OLEo. ΔGFR were similar in both groups.

| TLV (n=21)* | n | Baseline - Yr1(%) | Year 1 - 2(%) | Yr2 - OLEi(%) | OLEo(%) |
|---|---|---|---|---|---|
| OctLAR (n=13) | 13 | -6.5 (4.9) | -3.9 (5.9) | 4.0 (10.2)‡ | -5.7 (6.7) |
| Placebo (n=8) | 8 | 1.7(8.9)‡ | -8.3 (12.3) | 2.4 (4.7)‡ | -3.2 (5.1) |
| Total | 21 | n/a | -5.6 (9.0) | 3.4 (8.2)‡ | -4.7 (6.1) |
| p value (mean rate=0) | | n/a | 0.0113 | NS | 0.0020 |
| p value (On vs OFF drug) | | n/a | 0.0001 | -- | 0.0013 |
| **TKV (n=15)** | 15 | n/a | 4.0 (6.8) | 5.5 (7.7)† | 0.7 (13.6) |
| p value (mean rate=0) | | n/a | 0.0477 | 0.0249 | NS |
| p value (On vs OFF drug) | | n/a | NS | -- | NS |
| **eGFR%** | | | | | |
| OctLAR (n=16;11 w/o ADPLD, KTx) | | | | | -12 (21.8) |
| Placebo (n=9; 6 w/o ADPLD, KTx) | | | | | -0.3 (8.8) |
| Total (n=25; 17 w/o ADPLD, KTx) | | | | | -7.9(18.8) |
| p value (mean rate=0) | | | | | NS |

* Censored for liver cyst aspirations. ‡ Stat significant. † Off drug

**Conclusions:** Prolonged therapy with OctLAR over 4 yrs in a subgroup of symptomatic PLD patients shows the beneficial effects in arresting PLD progression. Discontinuation of therapy leads to further organ regrowth.

## SA-PO271

**Autosomal Dominant Polycystic Kidney Disease Cyst-Cell Implants Develop Cysts and Vasculature That Is Inhibited by Antiangiogenic Treatment**
Elsa Bello-Reuss. *Internal Medicine, Texas Tech Univ Health Siences Center, Lubbock, TX.*

**Background:** Previously we described angiogenesis in Autosomal Dominant Polycystic Kidney Disease (ADPKD) kidneys, as well as increases in Vascular Endothelial Growth Factor (VEGF) and its receptors in ADPKD kidney sections and cyst cells in culture. It has been reported that angiogenic growth factors expression correlate with disease severity in young patients with ADPKD and that interleukin-8 (IL-8) gene expression is also increased in ADPKD cells.

**Methods:** We studied the expression of IL-8 (at mRNA and protein level) and its receptors in ADPKD cyst cells and used ADPKD cyst cells -mixed with Matrigel™ - implanted in the immunoincompetent nude mouse and removed after 14 days, to study the development of cysts and angiogenesis in the implants and the inhibition of cyst growth by antiangiogenic drugs.

**Results:** We report that, in cyst cells in culture, there is constitutive expression of IL-8 (at the mRNA and protein levels) and that IL-8 secretion is inhibited by an anti-IL-8 neutralizing antibody (anti-IL-8) but no by dexamethasone (DEXA), a nonspecific IL-8 inhibitor. Cyst cells seeded in Matrigel and implanted in nude mice form cysts and the host provides the vasculature. Cysts grew to different sizes and the cells exhibit cuboidal or flat shapes. In this model of angiogenesis, cyst cells express IL-8, VEGF and their receptors. Cyst volume and vascularization is significantly decreased in the implants removed from mice treated with anti-IL-8, compared with untreated controls.

**Conclusions:** These studies underscore the importance of IL-8 secretion by ADPKD cyst cells in the recruitment of vasculature, creating a positive feedback for the continued growth of ADPKD cysts. The cysts in the nude-mouse implants reproduce the heterogeneous cyst size and morphology of the ADPKD kidney and could be used to study potential treatments for ADPKD using multi-target inhibitors.

## SA-PO272

**Analysis of Coronary Endothelial and Smooth Muscle Function Using $^{15}$O-Labeled Water PET in Early Stage Autosomal Dominant Polycystic Kidney Disease** Naoko Matsuoka,[1] Yasunobu Ishikawa,[1] Sekiya Shibazaki,[1] Osamu Manabe,[2] Keiichiro Yoshinaga,[2] Saori Nishio,[1] Tatsuya Atsumi.[1] *[1]Dept of Medicine II, Hokkaido Univ Graduate School of Medicine, Sapporo, Hokkaido, Japan; [2]Dept of Molecular Imaging, Hokkaido Univ Graduate School of Medicine, Sapporo, Hokkaido, Japan.*

**Background:** Cardiovascular problems are a major cause of morbidity and mortality in autosomal dominant polycystic kidney disease (ADPKD). Endothelial dysfunction (ED) has been used to predict future coronary artery disease before atherosclerotic changes. It has been reported that significant ED occurs in both normotensive and hypertensive patients with ADPKD. Polycystins are expressed is in endothelial and vascular smooth muscle cells. However, the association between ED and smooth muscle dysfunction has not been fully studied. Positron emission tomography (PET) can non-invasively myocardial blood flow (MBF). Using a cold pressor test (CPT) and adenosine triphosphate (ATP) infusion, PET can evaluate coronary endothelial function and coronary flow reserve (CFR). This study aimed to examine the coronary endothelium function in normotensive patients with ADPKD using $^{15}$O- labeled water PET.

**Methods:** Nine normotensive patients with ADPKD and 9 healthy controls were included in the study. Coronary endothelial function using was measured during CPT and vasodilator capacity, CFR was measured during ATP stress using $^{15}$O-labeled PET.

**Results:** There was no significant difference between groups regarding age, body mass index, blood pressure, and lipid levels. The resting MBF was significantly higher in patients than in control (0.93±0.07 vs 0.73±0.13; P<0.001). MBF during CPT was no significantly difference between the two groups. MBF during ATP infusion to that at rest, as an index of CFR, was significantly reduced in patients than in control (3.27±0.91 vs 5.06±1.28; P<0.01).

**Conclusions:** Normotensive patients with ADPKD with well-preserved renal function have reduced CFR indicating early atherosclerosis even in early stage of the disease. In contrast, there was no significant change in coronary endothelial function. Atherosclerotic changes might precede predominantly in vascular smooth muscle rather than endothelial dysfunction in ADPKD.

## SA-PO273

**Pravastatin and Angiogenesis in ADPKD** Wei Wang, Melissa A. Cadnapaphornchai, Michel Chonchol, Robert W. Schrier, Berenice Y. Gitomer. *Univ of Colorado Anschutz Medical Campus.*

**Background:** We have shown that serum levels of vascular endothelial growth factor (VEGF) correlate with total renal volume and renal function in young ADPKD patients suggesting that VEGF plays a key role in early cystogenesis. VEGF activity is regulated by its receptors including VEGF receptor -1 (Flt-1). A splice variant, soluble Flt-1 (sFlt-1) antagonizes VEGF signaling. Statins have diverse effects on angiogenesis and in human studies pravastatin has been shown to lower circulating VEGF levels. More recently pravastatin has been shown to slow the progression of renal structural disease in young patients with ADPKD. We hypothesized that statin may slow renal growth by mediating angiogenesis through reduction of VEGF levels in young ADPKD patients.

**Methods:** Subjects aged 8-22 years with ADPKD and normal renal function were randomized to either pravastatin (20mg or 40mg/day by age) or placebo. All subjects also received lisinopril. Serum and 24 hour urine were collected at each visit. VEGF and sFlt-1 levels were assayed by ELISA (R&D systems).

**Results:** After 18 months (m) of follow-up serum VEGF increased significantly compared to baseline in placebo (P) group (137.1±85.1pg/ml vs 109.2±71.0pg/ml, n=26, p<0.05) and was unchanged in the statin (S) group (157.1±115.9pg/ml vs 148.1±122.6pg/ml, n=25). Serum VEGF/sFlt-1, an index of VEGF bioavailability, increased significantly in group P at 18 m (1.5±1.2 vs 1.1±0.8, n=26, p<0.05) and 36m (1.2±0.6 vs 0.9±0.6, n=23, p<0.05) and was unchanged in group S at 18m (1.8±1.5 vs 1.7±1.4, n=24) and 36m (1.7±1.3 vs 1.4±1.2, n=23) relative to baseline. Urine VEGF levels increased significantly in group S at 36 m (7.0±4.0ng/mmol Cr vs 3.4±3.2ng/mmol Cr, n=15, p<0.05) and were unchanged in group P (7.6±4.7 vs 6.2±4.8ng/mmol Cr).

**Conclusions:** Based on the outcome of the pravastatin clinical trial in young ADPKD patients, statin therapy significantly slows renal growth. Our present results suggest that this is related to stabilization of serum VEGF and serum VEGF/sFlt-1 ratio as well as increased urine VEGF. The current study indicates a potential anti-angiogenic effect of pravastatin by regulation of VEGF level.

*Funding:* NIDDK Support

## SA-PO274

**Thombospondin and Autosomal Dominant Polycystic Kidney Disease** Wei Wang, Michel Chonchol, Godela M. Brosnahan, Robert W. Schrier, Berenice Y. Gitomer. *Dept of Medicine, Univ of Colorado Anschutz Medical Campus.*

**Background:** Thrombospondins(TSP) including TSP-1, TSP-2 are glycoproteins that inhibit endothelial cell migration, proliferation and survival as well as vascular endothelial growth factor (VEGF) activity. In contrast, VEGF and angiopoietins(Ang) 1,2 are established angiogenic factors that correlate with renal structure and function in autosomal dominant polycystic kidney disease (ADPKD). We hypothesized that dysregulated TSP expression results in an imbalance between pro- and anti-angiogenic factors in ADPKD that may favor angiogenesis early in disease.

**Methods:** Healthy adults were included and ADPKD patients stratified according to eGFR either ≥ 60 (I) or< 60 ml/min/1.73m$^2$(II). Serum levels of VEGF, Ang-1, Ang-2, TSP-1 and TSP-2 were assayed by ELISA.

**Results:** The key differences in pro and anti-angiogenic growth factor levels are summarized in table 1. Serum TSP-1 levels positively correlated with Ang-1 and Ang-2 levels in group I. Serum TSP-2 and Ang-2 levels were positively correlated in group II.

| | I | II | CON | p value |
|---|---|---|---|---|
| n | 26 | 25 | 10 | |
| Age(y) | 35±9 | 50±8*# | 36±14 | <0.001 |
| eGFR(ml/min/1.73m$^2$) | 100.2±13.2 | 36.6±5.4# | ND | <0.001 |
| TSP-1(µg/ml) | 10.5±5.5* | 10.7±5.9* | 0.45±0.2 | <0.001 |
| TSP-2(ng/ml) | 28.5±11.3 | 31.7±14.5 | 29.1±8.7 | NS |
| VEGF(pg/ml) | 229±165* | 204±190* | 15.3±15.5 | <0.001 |
| Ang-1(ng/ml) | 86.6±51.2 | 53.6±37.8# | ND | <0.05 |
| Ang-2(pg/ml) | 2100±1140 | 2878±2153* | 1539±690 | <0.001 |
| Ang-1/TSP-2 | 8.3±2.1 | 1.8±1.1# | ND | <0.001 |

*P vs Con; # P vs I; ND: not determined.

**Conclusions:** Serum levels of VEGF, Ang-2 and TSP-1 are elevated in ADPKD patients as compared to the normal controls. The relationships between pro and anti-angiogenic factors differ in ADPKD patients based on renal function. The increased Ang-1/TSP-2 ratio in patients with earlier stages of ADPKD favors a pro-angiogenic environment in earlier disease. TSP's are potent inhibitors of angiogenesis and tumor growth and as such may have potential therapeutic benefits in slowing cyst growth in ADPKD.

## SA-PO275

**Secreted Frizzeld-Related Protein 4 Is a Marker of Autosomal Dominant Polycystic Kidney Disease Progression** Stefan Zschiedrich,[1] Klemens Budde,[2] Christoph Wanner,[3] Claudia Sommerer,[4] Ulrich Kunzendorf,[5] Bernhard Banas,[6] Walter H. Hoerl,[7] Nicholas Obermueller,[8] Wolfgang Arns,[9] Hermann Pavenstaedt,[10] Jens Gaedeke,[2] Lothar Faerber,[11] Peter Wimmer,[11] Kai-Uwe Eckardt,[12] Gerd Walz.[1] *[1]Renal Div, Univ Hospital Freiburg, Freiburg, Germany; [2]Dept of Nephrology, Charité Universitätsmedizin Berlin - Campus Mitte; [3]Univ Hospital Würzburg; [4]Center for Nephrology, Heidelberg; [5]Univ Hospital Kiel; [6]Univ Hospital Regensburg; [7]Medical Univ of Vienna; [8]Univ Hospital Frankfurt; [9]Merheim Medical Center, Cologne; [10]Univ Hospital Münster; [11]Novartis Germany, Nuremberg; [12]Univ of Erlangen and Community Hospital of Nuremberg.*

**Background:** Secreted frizzeld-related protein 4 (sFRP4) is expressed at elevated levels in the tissue of autosomal dominant polycystic kidney disease (ADPKD) kidneys, and detectable in blood, urine and cyst fluid of APDKD patients. It is a molecule known to antagonize Wnt signaling, an intracellular pathway that controls cell migration, proliferation and cellular polarity. To monitor future therapeutic interventions, there is a need for reliable and inexpensive biomarkers of ADPKD disease progression.

**Methods:** We investigated sFRP4 levels from patient samples of the 'Everolimus in patients with Autosomal Dominant Polycystic Kidney Disease' trial to determine its capability as a progression marker. 3126 probes were analyzed and correlated to kidney function and total kidney volume of ADPKD patients followed over 24 months.

**Results:** sFRP4 levels were significantly increased after the two years follow-up of the study, correlating with an increase of serum creatine and deterioration of renal function. The increase was independent of the intervention and observed in everolimus- and placebo-treated patients. Total kidney volume (measured by MRI) did not correlate with sFRP4 levels.

**Conclusions:** Our results demonstrate that sFRP4 plasma levels increase in patients with ADPKD. Everolimus had no effect on sFRP4 levels. Thus, measurement of sFRP4 may be a reliable (and cheap) parameter of disease progression in ADPKD.

## SA-PO276

**Association of Plasma and Urinary GDF-15 Levels with Disease Severity in ADPKD Patients** Ivan Formentini,[1] Carolina Haefliger,[6] Paolo Piraino,[5] Maria Chiara Magnone,[1] Anders Fernstrom,[3] Peter F. Barany,[4] Guillemette Duchateau-Nguyen,[1] Matthias Meier,[1] Maria Bobadilla.[1] *[1]Cardiovascular & Metabolism DTA, F. Hoffmann - La Roche Ltd, Basel, Switzerland; [2]Dept of Medical Sciences, Univ Hospital, Uppsala, Uppsala, Sweden; [3]Dept of Medical and Health Sciences, Faculty of Health Sciences, Linköping Univ, Linköping, Sweden; [4]Div of Renal Medicine, CLINTEC, Karolinska Institutet, Stockholm, Sweden; [5]PP Statistical Consulting, Rende, Italy; [6]Novartis Pharma AG, Basel, Switzerland.*

**Background:** Growth differentiation factor 15 (GDF-15) is a distant TGF-β family member suggested to reflect inflammation and apoptosis processes under stressful conditions. Clinically, several investigations have demonstrated that circulating GDF-15 levels are increased and independently prognostic across a wide spectrum of cardiovascular diseases. The relationship between GDF-15 levels and renal functional loss /severity has been described but not yet fully established, making of this marker a potential integrative predictor of kidney damage and CV risk in all CKD patients.

**Methods:** In the current study, we aim to investigate if urine and plasma GDF15 levels are associated to renal functional parameters in a cross-sectional ADPKD patient (n=56) and controls (n=20) (TH-PO645, ASN 2012) cohort.

**Results:** Urine GDF-15 levels were not associated to disease stage ($R^2$=0.057, p=1.5e$^{-2}$), baseline $eGFR_{MDRD}$ ($R^2$=0.082, p=4.3e$^{-3}$) or UACR ($R^2$=0.056, p=7.2e$^{-3}$) in cross-sectional cohort of ADPKD patients. Matching serum samples instead demonstrated

a strong relationship to CKD staging ($R^2$=0.52, p<1.0e$^4$), $eGFR_{MDRD}$ at screening ($R^2$=0.58, p<1.0e$^4$) while lacking correlation to log urine albumin levels ($R^2$=0.0027, p=3.2e$^{-1}$). In a Bayesian additive regression trees classification model plasma GDF-15 contributed to the prediction of ADPKD vs controls ($ROC_{AUC}$=0.867) much better then urinary levels ($ROC_{AUC}$=0.687). Plasma levels were also capable of discriminating control subjects vs. renal impaired patients ($ROC_{AUC}$= 0.852).

**Conclusions:** In conclusion, the present results show that higher levels of plasma GDF-15 are associated to renal impairment state and CKD severity in ADPKD.

## SA-PO277

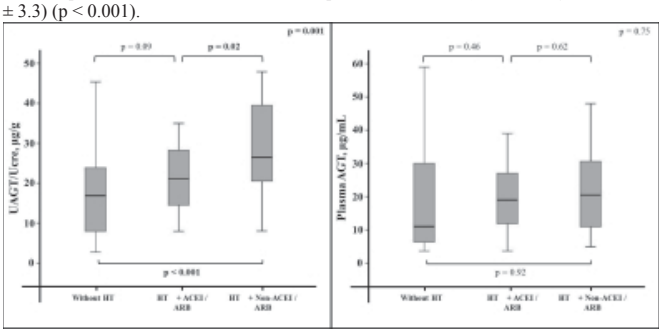
### Is the Intrarenal Renin Angiotensin System the Culprit for Hypertension in Patients with Autosomal Dominant Polycystic Kidney Disease?

Ismail Kocyigit,[1] Mahmut Ilker Yilmaz,[2] Aydin Unal,[1] Fahir Ozturk,[3] Eray Eroglu,[3] Cevat Yazici,[4] Ozcan Orscelik,[5] Murat H. Sipahioglu,[1] Bulent Tokgoz,[1] Oktay Oymak.[1] *[1]Dept of Nephrology, Erciyes Univ Medical School, Kayseri, Turkey; [2]Dept of Nephrology, Gülhane School of Medicine, Ankara, Turkey; [3]Dept of Internal Medicine, Erciyes Univ Medical School, Kayseri, Turkey; [4]Dept of Biochemistry, Erciyes Univ Medical School, Kayseri, Turkey; [5]Dept of Cardiology, Erciyes Univ Medical School, Kayseri.*

**Background:** Early onset of hypertension and its consequences account for the great majority of death in patients with autosomal dominant polycystic kidney disease (ADPKD). Renin angiotensinogen system(RAS) components have been shown in ADPKD kidneys. Thus we examined the urinary angiotensinogen (UAGT) levels as a biomarker of intrarenal RAS status in ADPKD patients with/without hypertension and healthy subjects.

**Methods:** Eighty-four ADPKD patients (43 with hypertension and 41 without hypertension) and 40 healthy controls were studied cross-sectionally. Hypertension diagnosed with ambulatory blood pressure monitoring. Urinary and plasma concentration of angiotensinogen, spot urine microprotein and creatinine levels recorded for each participants.

**Results:** UAGT/UCre levels were higher in hypertensive ADPKD patients (23.7 ± 8.4) compared with normotensive ADPKD patients (16.6 ± 5.2) and healthy controls (6.9 ± 3.3) (p < 0.001).



In univariate analysis, UAGT correlated with systolic blood pressure, diastolic blood pressure and proteinuria. The independence of these correlations were analyzed in a regression model, and shown UAGT to be significantly predicted by proteinuria and DBP.

**Conclusions:** Intrarenal RAS activation which is monitoring by UAGT levels clinically may be a harbinger for the development of hypertension and kidney disease in ADPKD patients.

## SA-PO278

### Prevalence of and Survival on Renal Replacement Therapy for ADPKD in Europe

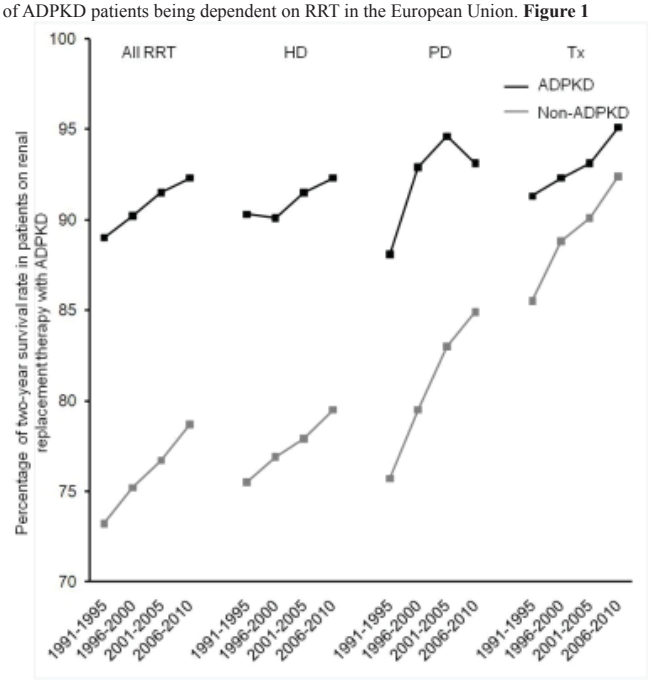
Edwin M. Spithoven,[1] Anneke Kramer,[2,3] Christoph Wanner,[3] Kitty J. Jager,[2,3] Ron T. Gansevoort.[1,4,5] *[1]Dept Nephrology, UMC Groningen, The Netherlands; [2]ERA-EDTA Registry, AMC Amsterdam, Netherlands; [3]For the ERA-EDTA Registry; [4]For the EuroCYST Consortium; [5]For the WGIKD.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the fourth most common diagnosis for starting renal replacement therapy (RRT). Still, there are few epidemiological data on the prevalence of and survival on RRT for ADPKD.

**Methods:** This study used data of the ERA-EDTA Registry on RRT prevalence and survival on RRT of 18 European countries with 385 million inhabitants. We studied four 5-year periods (1991-2010). Survival analysis was performed by the Kaplan-Meier method and by Cox proportional hazards regression.

**Results:** In 20 years time, the prevalence of RRT for ADPKD increased from 56.8 to 91.3 per million of the population (country range 71.1-104.0 pmp), whereas the percentage of ADPKD patients of the total number of patients on RRT remained stable at 9.8%. Two-year survival of ADPKD patients on RRT (adjusted for age, sex and country) has increased significantly from 89.0 to 92.3%, and was higher than for non-ADPKD subjects (Figure 1). Improved survival was noted for all RRT modalities (Figure 1): hemodialysis (adjusted Hazard Ratio for mortality last versus first time period 0.79; 95% CI 0.65-0.98), peritoneal dialysis (0.54; 0.37-0.80) and transplantation (0.53; 0.36-0.78). Especially cardiovascular mortality as cause of total mortality on RRT decreased in ADPKD patients i.e. from 53% to 29%, whereas it decreased from 44% to 35% in non-ADPKD patients. Of note, the incidence rate of RRT for ADPKD remained relatively stable at 7.6 vs. 8.1 pmp.

**Conclusions:** In ADPKD patients on RRT survival has improved markedly, especially due to lower cardiovascular mortality. This has led to a considerable increase in the number of ADPKD patients being dependent on RRT in the European Union. **Figure 1**



## SA-PO279

### Incidence of Renal Replacement Therapy for ADPKD in Europe

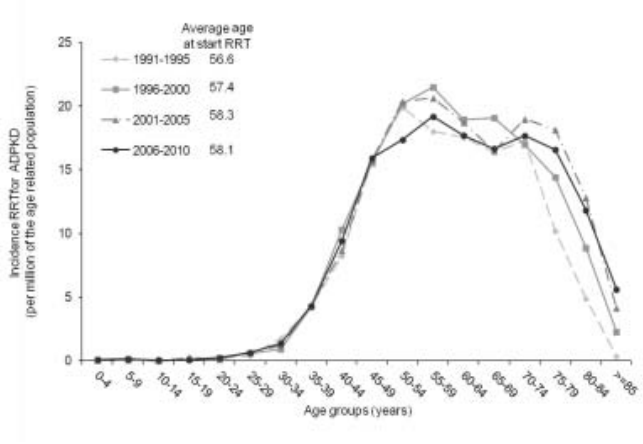
Edwin M. Spithoven,[1] Anneke Kramer,[23] Christoph Wanner,[3] Kitty J. Jager,[23] Ron T. Gansevoort.[145] *[1]Dept Nephrology, UMC Groningen, The Netherlands; [2]ERA-EDTA Registry, AMC Amsterdam, Netherlands; [3]For the ERA-EDTA Registry; [4]For the EuroCYST Consortium; [5]For the WGIKD.*

**Background:** Several treatment options, known to postpone the need for renal replacement therapy (RRT), have also been tested in RCTs including specifically ADPKD patients, with disappointing results. However, in general these RCTs were underpowered and selected patients with relatively stable eGFR, thus not allowing firm conclusions on renoprotective efficacy. We investigated whether epidemiological data on RRT incidence provide evidence for effective renoprotection in ADPKD.

**Methods:** This study used data of the ERA-EDTA Registry on RRT incidence rates in 18 European countries with 385 million inhabitants. We studied four 5-year periods (1991-2010).

**Results:** Over the four periods the average incidence rate of RRT for ADPKD, adjusted for general population age and gender, increased slightly from 7.6 to 8.1 per million of the population (pmp). Differences in the incidence of RRT for ADPKD were noted among countries (range 5.3-9.9 pmp). The mean age at start of RRT increased from 56.6 to 58.1 years (Figure 1) No change over time was observed in the incidence of RRT for ADPKD up to the age of 50 years (Figure 1) However, in recent time periods the incidence of RRT for ADPKD above the age of 70 years increased. Among countries there was a clear positive association between take-on rate of RRT for non-ADPKD renal disease and for ADPKD (r=0.64, p<0.001).

**Conclusions:** During the last two decades the incidence of RRT for ADPKD, as well as the age at which RRT was started, has increased slightly. Our data suggest that this is likely due to an increased access of elderly APDKD patients to RRT rather than providing evidence that effective renoprotective treatments have become available.



## SA-PO280

**Maternal and Fetal Outcomes in Women with Autosomal Dominant Polycystic Kidney Disease** Min Wu,[1] Diping Wang,[2] Peter C. Harris,[2] Ladan Zand,[2] Vesna D. Garovic,[2] Cindy A. Kermott.[3] *[1]Dept of Cardiovascular Diseases, Guang'anmen Hospital, China Academy of Chinese Medical Sciences, Beijing, China; [2]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [3]Div of Preventive Medicine, Mayo Clinic, Rochester, MN.*

**Background:** Autosomal Dominant Polycystic Kidney Disease (ADPKD), a common genetic cause of chronic renal failure in children and adults, is characterized by the accumulation of fluid-filled cysts in the kidney and other organs. As the diagnostic techniques advance, more and more female patients are diagnosed with ADPKD before or during their birth age. However, it is still not clear how ADPKD affects the maternal and fetal outcomes in these patients. The aim of this study is to determine whether ADPKD is associated with adverse fetal and infant outcomes, maternal complications and long-term post-pregnancy prognosis.

**Methods:** We identified a cohort of 146 patients seen for pregnancy and cystic kidney disease at the Mayo Clinic from 1975 to 2010. From this cohort, 54 patients met the ultrasound diagnostic criteria for ADPKD (ADPKD group) while the other 92 patients had been diagnosed as 'Simple Cyst' (the control group). We compared the fetal and maternal outcomes of pregnancy between these two groups as well as report on long-term maternal prognosis.

**Results:** Overall, the fetal complication rates were similar between the ADPKD group and the control group. The spontaneous abortion rate (15.1% vs.14%, P=0.77) and premature rate (11.1% vs. 6.8%, P=0.44) were comparable in these two groups while the rates of fetal distress (3.4% vs. 0.7%, P<0.01) and birth defects (6% vs. 0%, P<0.001) were increased in ADPKD patients. Compared to the control group, pregnant ADPKD patients had higher risks for hypertension, proteinuria, edema, UTI, renal dysfunction and preeclampsia. Finally, follow-up studies after the last pregnancy clearly showed that rates of chronic hypertension and renal insufficiency were significantly increased in ADPKD patients.

**Conclusions:** ADPKD is associated with increased maternal complications during pregnancy but only has a slight potential of increased rates of fetal complications.

## SA-PO281

**Autosomal Dominant Polycystic Kidney Disease (ADPKD): A Risk Factor for New Onset Diabetes after Transplantation** Ankush Mittal, Ashtar Chami, Arlene B. Chapman. *Emory Univ Hospital, Atlanta, GA.*

**Background:** ADPKD is the fourth leading cause of ESRD and accounts for 8.3% of deceased donor and 11.7% of living donor yearly kidney transplants in the US. Our goal is to use an established cohort of PKD individuals evaluated for transplant to characterize their outcomes.

**Methods:** This is a retrospective cohort analysis of all ADPKD patients who presented for transplant evaluation at the Emory Transplant Center between 1/1/2002 and 1/1/2012, utilizing electronic medical records, prescription lists, and the organ transplant tracking record (OTTR). Individuals were evaluated with regard to their pre- and post-transplant course and conditions and complications that were related to ADPKD.

**Results:** 55 (32.5%) of transplanted patients developed new onset diabetes after transplantation (NODAT). 30.1% of Caucasians and 40.0% of African Americans developed NODAT (p>0.05). There was not a statistically significant difference in the BMI of patients who developed NODAT when compared to the rest of the population (28.7±0.9 vs. 27.3±0.4, p>0.05). Caucasians and African Americans with NODAT had BMIs prior to diagnosis of 28.9±1.0 and 28.3±1.9 (p>0.05), respectively, while those without NODAT had BMIs of 27.2± 0.5 and 27.2±1.3 (p>0.05), respectively. 32.1% of men and 32.9% of women developed NODAT (p>0.05). Patients with and without NODAT had BMIs of 28.0±1.3 and 28.2±0.05 (men, p>0.05) and 29.3±1.2 and 26.4±0.7 (women, p>0.05), respectively. 13.6% of transplanted patients were on belatacept. 21.7% of patients on belatacept and 34.7% of patients on tacrolimus developed NODAT (p>0.05).

**Conclusions:** Our cohort confirms previous reports of an increased incidence of NODAT in ADPKD patients despite similar BMIs, race, and gender profile and the use of belatacept in a proportion of the population.

## SA-PO282

**Nephrectomy and Renal Transplantation in Autosomal Dominant Polycystic Kidney Disease (ADPKD)** Ankush Mittal, Ashtar Chami, Arlene B. Chapman. *Emory Univ Hospital, Atlanta, GA.*

**Background:** ADPKD is the fourth leading cause of ESRD and accounts for 8.3% of deceased donor and 11.7% of living donor yearly kidney transplants in the US. Our goal is to use an established cohort of PKD individuals evaluated for transplant to characterize their outcomes.

**Methods:** This is a retrospective cohort analysis of all ADPKD patients who presented for transplant evaluation at the Emory Transplant Center between 1/1/2002 and 1/1/2012, utilizing electronic medical records and the organ transplant tracking record (OTTR). Individuals were evaluated with regard to their graft and patient survival rates in those that did and did not have a nephrectomy.

**Results:** Of 286 ADPKD who presented for transplant evaluation, 169 (59.1%) were transplanted, 80 (28.0%) were evaluated but not yet transplanted, and 37 (12.9%) were ineligible for transplant. 5-year patient survival was 92.3% and 93.8% with and without a nephrectomy (p<0.001), respectively. 5-year patient survival for living and deceased donors was 98.0% and 92.9% (without a nephrectomy, p<0.001) and 100.0% and 89.7% (with a nephrectomy, p<0.001), respectively. 5-year graft survival was 82.9% and 89.8% with and without a nephrectomy (p<0.001), respectively. 5-year graft survival was 94.0% and 86.8% (without a nephrectomy, p<0.001) and 79.5% and 84.4% (with a nephrectomy, p<0.001) for living and deceased donor transplants, respectively. 5-year graft survival was 95.7% and 89.7% for African Americans and Caucasians, respectively, without a nephrectomy (p<0.001). 5-year graft survival was 75.0% and 84.1% for African Americans and Caucasians, respectively, with a nephrectomy (p<0.001). 5-year graft survival was 100.0% and 69.8% in men and women with a nephrectomy (p<0.001), respectively. 5-year graft survival was 77.7% and 88.9% for pre- and post-transplant nephrectomies (p<0.001).

**Conclusions:** Nephrectomy is a significant risk fact for graft survival in this ADPKD cohort. Men are shown to have significantly higher graft survival than women with a nephrectomy, and patients with a nephrectomy after transplant are shown to have significantly higher graft survival than those with a nephrectomy before transplant.

## SA-PO283

**Patient-Reported Pain in Autosomal Dominant Polycystic Kidney Disease: Initial Concepts Based on Patient Focus Group Discussions** Dorothee Oberdhan,[1] Arlene B. Chapman,[2] Sara N. Davison,[3] Frank S. Czerwiec,[1] Holly Krasa,[1] Jason C. Cole.[4] *[1]Otsuka Pharmaceutical Development & Commercialization, Inc., Rockville, MD; [2]Emory Univ, Atlanta, GA; [3]Univ of Alberta, Edmonton, Canada; [4]Covance Inc., San Diego, CA.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) involves significant kidney enlargement due to cyst development and expansion leading to kidney infections, bleeding, stones, chronic kidney disease and pain that is common, intermittent and debilitating, severely impacting a patient's health-related quality of life. Surgical intervention and medications may be needed. Previous research demonstrated consistency in disease burden across regions and suggested ADPKD patients report pain varyingly.

**Methods:** In 18 focus groups, conducted in 5 cities in Europe (n=72) and 4 cities in the US (n=53), patients were asked about their pain symptoms and impact on daily life. New conceptual domains discussed were summarized based on themes mentioned by ≥2 participants within a group.

**Results:** Patients report chronic and episodic dull kidney pain, chronic fullness/discomfort and acute severe kidney pain plus general pain. Severe kidney pain is usually associated with cyst rupture or infection. Kidney pain is easily distinguished from other pain, especially with progressing disease. Pain severity is distinct for each of the types of pain reported.

| General Pain | Chronic Dull Kidney Pain | Fullness/Discomfort | Severe Kidney Pain |
|---|---|---|---|
| Need warmth | Severity >7*<br>Comes and goes<br>On side/back<br>Easy to distinguish from other pain<br>Sleep disturbances<br>Impacts relationships<br>Irritable/on edge/impatient | Fullness/discomfort<br>Severity averages 2 or 3*<br>Impact on mild physical activity<br>Bending/stretching<br>Impact on moderate physical activity<br>Impacts relationships<br>Unable to eat/loss of appetite<br>Irritable/impatient | Pain<br>infrequent<br>memorable |

* Based on a scale of 1 to 10

**Conclusions:** Patients reported 3 distinct types of pain (chronic dull pain, fullness/discomfort and acute severe pain) beyond general pain. This categorization should allow easier pain identification using patient terms to help facilitate treatment.

*Funding:* Pharmaceutical Company Support - Otsuka Pharmaceutical Development & Commercialization, Inc.

## SA-PO284

**Which Cyst to Drainage? — Mass Reduction Therapy for Autosomal Dominant Polycystic Kidney Disease Patients with Huge Liver Cysts**
Takashi Iijima, Tatsuya Suwabe, Koki Mise, Rikako Hiramatsu, Yoshifumi Ubara. *Nephrology Center, Toranomon Branch Hospital.*

**Background:** Percutaneous needle aspiration of cysts with subsequent sclerosis by injection of minocycline (drainage therapy) has been reported to be effective for patients with autosomal dominant polycystic kidney disease (ADPKD) who have one or a few very large and easily accessible cysts. However, a detailed investigation of the factors that influence the success of cyst drainage has not yet been performed. Accordingly, we evaluated the factors with an influence on this therapy.

**Methods:** At our institution, cyst drainage therapy was performed in 16 ADPKD patients with a hepatic cyst volume of over 500 ml between January 2010 and April 2012. The hepatic cyst area was calculated with area assessment software after precisely outlining the cyst(s) on CT scans, and the cyst volume was calculated by summing up each areas of 1-cm thickness CT slices. The mean CT value of each cyst was also calculated, as was the ratio of the cyst volume at one year after treatment to that before treatment. Drained cyst fluid was submitted for analysis of its specific gravity. Then CT values and specific gravity were compared between group A cysts showing over 80% volume reduction (mean of 92.4%) at one year after drainage and group B cysts with less than 80% volume reduction (mean of 31.1%). Statistical analysis was done by using the Mann-Whitney U test.

**Results:** Group A cysts had significantly lower CT values than group B cysts, with the values being 6 HU (4 to 10) and 19 HU(6 to 23) (p=0.004), respectively. Specific gravity was also significantly lower in group A than in group B, being 1.013 g/ml (1.007 to 1.017) versus 1.021g/ml (1.009 to 1.031) (p=0.017). When the cut-off value to predict responsiveness of drainage therapy is set at 13 HU of CT value, the sensitivity was 70% and specificity was 100%.

**Conclusions:** Drainage therapy was effective for hepatic cysts with lower CT values and lower specific gravity, while the response was poor when hepatic cysts had higher CT values and higher specific gravity, which probably indicate "complicated" cyst with prior infection and/or hemorrhage.

## SA-PO285

**Transcatheter Arterial Embolization with Embosphere: Evaluation of Technical Safety and Outcome**
Saori Nishio,[1] Yuske Sakuhara,[2] Naoko Matsuoka,[1] Junya Yamamoto,[1] Tasuku Nakagaki,[1] Daigo Nakazawa,[1] Daisuke Abo,[2] Sekiya Shibazaki,[1] Tatsuya Atsumi.[1] *[1]Dept of Medicine II, Hokkaido Univ School of Medicine, Sapporo, Hokkaido, Japan; [2]Dept of Radiology, Hokkaido Univ School of Medicine, Sapporo, Hokkaido, Japan.*

**Background:** Polycystic liver disease (PLD) is the most common extrarenal manifestation associated with autosomal dominant polycystic kidney disease (ADPKD). Patients with PLD often suffer from abdominal discomfort, dyspepsia, or dyspnea. Transcatheter arterial embolization (TAE) for hepatic artery branches using metallic coils has been reported as an effective and less invasive treatment for PLD. The disadvantages of coils are the need to use many of them before achieving complete obstruction and high cost. Furthermore, it is difficult to re-treat a patient in whom a previous TAE procedure with metallic coils had failed as a result of recanalization.

This study aimed to evaluate the technical safety and effectiveness of TAE using Embosphere for enlarged polycystic liver.

**Methods:** Five PLD patients with severe symptom (1 male, 4 females) underwent TAE for hepatic artery branches using Embosphere100-300μm and 300–500μm. One patient had undergone TAE with metallic coils had failed as a result of recanalization. We evaluated change of hepatic volume and intra-hepatic cyst volume by MRI, symptoms by visual analog scale and FACT-Hep health-related QOL scores before TAE and at 3, 6, and 12 months after treatment.

**Results:** TAE was considered technically successful when the target hepatic arteries were fully embolized, as demonstrated by hepatic arterial angiography performed at completion of the procedure. Technical success was achieved in all cases. No major complication related to TAE was found. Common adverse events were fever, epigastric pain, nausea, and vomiting. Two patients improved symptoms significantly one month after TAE. We found hepatic cyst volume reduction. No patient complained of worsening of the symptoms after the procedure.

**Conclusions:** We suggest that TAE using Embosiphere is effective and safe in treating symptomatic polycystic liver in ADPKD patients, even who had treated by TAE using metallic coils.

## SA-PO286

**Characterization and Management of Patients with Renal or Hepatic Cyst Infection**
Marten A. Lantinga,[1] Tom JG Gevers,[1] Wim J.G. Oyen,[2] Rudolphe De Sevaux,[3] Joost P.H. Drenth.[1] *[1]Hepatology, Radboud Univ Nijmegen Medical Centre, Netherlands; [2]Nuclear Medicine, Radboud Univ Nijmegen Medical Centre, Netherlands; [3]Nephrology, Radboud Univ Nijmegen Medical Centre, Netherlands.*

**Background:** Cyst infection is the most critical complication in autosomal dominant polycystic kidney disease (ADPKD) and autosomal dominant polycystic liver disease (PCLD). Guidelines for diagnosis and treatment are absent. The aim was to assess the clinical characteristics and therapeutic approach of patients with cyst infection.

**Methods:** Patients with cyst infection were ascertained and identified from clinical and radiological registries in a tertiary referral center from 2001-2013. Patients were included when there was a positive cyst aspirate, positive $^{18}$FDG-PET/CT and/or clinical findings suggestive for cyst infection. Clinical, radiological, biochemical and/or microbiological data were derived from medical records.

**Results:** We included 49 patients (86% ADPKD, 45% renal transplant, mean age 56 years, male 41%) with renal (57%, RCI) or hepatic cyst infection (43%, HCI). Some 20% had diabetes mellitus and 47% used immunosuppressive drugs. Urine cultures were positive in 13/24 (RCI) and 2/15 (HCI) of patients, whereas blood cultures were positive in 6/19 (RCI) and 11/16 (HCI) of patients. *E. coli* was the most frequent pathogen and was cultured from urine (53%) and blood (59%). The antibiotic therapy of choice for RCI and HCI were fluoroquinolones in 52% and 52%, followed by cephalosporin in 26% and 14% and penicillin in 14% and 24% of patients. Some 21% of RCI were treated by nephrectomy and 10% of HCI by percutaneous cyst drainage or liver transplantation.

**Conclusions:** Diabetes mellitus and immunosuppressive drugs are associated with renal and hepatic cyst infection. *E. coli* is the most frequent isolated pathogen and fluoroquinolones the most often initiated antibiotic therapy. Persistent or recurrent cyst infection frequently demands invasive treatment.

## SA-PO287

**Cyst Infection in Autosomal Dominant Polycystic Kidney Disease: New Diagnostic Criteria and Prognostic Factors**
Tatsuya Suwabe, Yoshifumi Ubara, Takashi Iijima, Koki Mise, Satoshi Hamanoue, Keiichi Sumida, Junichi Hoshino, Rikako Hiramatsu, Kenmei Takaichi. *Dept of Nephrology, Toranomon Hospital, Tokyo, Japan.*

**Background:** Cyst infection is a common and serious problem in patients with autosomal dominant polycystic kidney disease and sometimes becomes refractory. However, diagnosis of cyst infection and the prognostic factors remain unclear. We have established new diagnostic criteria for cyst infection in ADPKD patients (Clin Exp Nephrol 2012; 16). This study was performed to clarify the characteristics and prognostic factors of patients with cyst infection and to evaluate the usefulness of our new diagnostic criteria.

**Methods:** All patients admitted to Toranomon Hospital with a diagnosis of cyst infection from 2004 to 2012 were reviewed. The symptoms, the laboratory and imaging findings at the onset, and the outcome of all patients were investigated. We classified the patients according to our diagnostic criteria and analyzed their prognostic factors.

**Results:** A total of 214 patients with 492 episodes were enrolled, among which 62.2% of episodes satisfied our diagnostic criteria for cyst infection and 27.8% satisfied the criteria for probable cyst infection. The sensitivity was increased in the episodes with positive cyst culture test (definite cyst infection). A total of 148 patients (306 episodes) had hepatic cyst infection and 85 patients (143 episodes) had renal cyst infection. Sixty-six patients died and 26 of them died from cyst infection. The age, ascites, serum cholinesterase (ChE) and hepatomegaly (>8,000 cm$^3$) were significant risk factors for all-cause mortality (HR [95%CI]: age, 1.048 [1.007-1.092]; ascites, 2.175 [1.093-4.325]; ChE, 0.991 [0.983-0.999]; hepatomegaly 3.550 [1.292-9.751]). Serum ChE and hepatomegaly (>8,000 cm$^3$) were significant risk factors for death from cyst infection (ChE, 0.830 [0.722-0.955]; hepatomegaly, 6.238 [1.522-25.561]). The prognosis of hepatic cyst infection was worse than that of renal cyst infection.

**Conclusions:** Our criteria were useful for diagnosis of cyst infection and for evaluating its severity. Hepatomegaly, liver dysfunction, ascites, and hepatic cyst infection were significant determinants of a poor prognosis.

## SA-PO288

**Causative Bacteria of Cyst Infection in Patients with Autosomal Dominant Polycystic Kidney Disease**
Tatsuya Suwabe, Yoshifumi Ubara, Takashi Iijima, Koki Mise, Satoshi Hamanoue, Keiichi Sumida, Junichi Hoshino, Rikako Hiramatsu, Kenmei Takaichi. *Dept of Nephrology, Toranomon Hospital.*

**Background:** Cyst infection is a common and serious problem in patients with autosomal dominant polycystic kidney disease (ADPKD) and these infections sometimes become refractory. Lipophilic antibiotics such as fluoroquinolones, which show good penetration into cysts, are recommended for the treatment of cyst infection. However, we sometimes encounter cyst infections that are resistant to lipophilic antibiotics.

**Methods:** All ADPKD patients with a positive blood culture or cyst fluid culture who were admitted to Toranomon Hospital with a diagnosis of cyst infection from 2004 to 2013 were enrolled. We investigated the causative bacteria detected by cyst fluid culture or blood culture and their sensitivity to lipophilic antibiotics.

**Results:** A total of 95 patients with 127 episodes of infection were enrolled from among 229 patients (453 episodes) who were hospitalized with a diagnosis of cyst infection. 80 patients were on dialysis. There were 91 episodes of hepatic cyst infection and 36 episodes of renal cyst infection. For hepatic cyst infection, 63 bacteria in blood culture and 98 bacteria in cyst fluid culture were detected. For renal cyst infection, 30 bacteria in blood culture and 24 bacteria in cyst fluid culture were detected. Escherichia coli (E. coli) was the most frequent bacterial isolate, while Enterococcus (which is not usually treated with fluoroquinolones) was the 2$^{nd}$ mostfrequent organism. Enterococcus infection showed a higher frequency in cyst fluid culture. Fluoroquinolone resistance was seen with 72.7 % of E. coli and 31.9% of other gram-negative organisms. Bacteria with extended spectrum beta lactamase, which require carbapenem treatment, were detected in 6 cyst fluid culture (4.9%) and in 2 blood culture (2.2%).

**Conclusions:** 20-50% of all causative bacteria were micro-organisms that are not usually treated with lipophilic antibiotics, and frequency of fluoroquinolone resistance was high in E. coli. This study suggested that lipophilic antibiotics are not always appropriate for treating cyst infection in ADPKD patients, although these are first-line agents.

**SA-PO289**

**The Compiling Data at the Time of Enrollment in J-PKD Registry**
Satoru Muto,[1] Toshio Mochizuki,[2] Ken Tsuchiya,[2] Saori Nishio,[3] Kazushige Hanaoka,[4] Kouichi Kamura,[5] Kazuhiko Tsuruya,[6] Eiji Ishimura,[7] Ichiei Narita,[8] Kouichi Kamura,[9] Yoshifumi Ubara,[10] Masahiko Ando,[11] Kikuo Nutahara,[12] Shigeo Horie.[13] *[1]Urology, Teikyo Univ, Tokyo, Japan; [2]Nephrology, Tokyo Woman's Medical Univ, Tokyo, Japan; [3]The 2nd Dept of Internal Medicine, Hokkaido Univ, Sapporo, Japan; [4]Nephrology, Jikei Univ, Tokyo, Japan; [5]Urology, Chiba East Hospital, Chiba, Japan; [6]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [7]Nephrology, Osaka City Univ, Osaka, Japan; [8]The 2nd Dept of Internal Medicine, Niigata Univ, Niigata, Japan; [9]Urology, Chiba East Hospital, Chiba, Japan; [10]Nephrology, Toranomon Hospital, Tokyo, Japan; [11]Center for Advanced Medicine and Clinical Research, Nagoya Univ, Nagoya, Japan; [12]Urology, Kyorin Univ, Mitaka, Japan; [13]Urology, Juntendo Univ, Tokyo, Japan.*

**Background:** The PKD Sectional Committee of a Grant-in-Aid for Progressive Renal Diseases Research, from the Ministry of Health, Labour and Welfare of Japan established the first nationwide, web-based, and prospective registry system, the Japan PKD Registry (J-PKD), to record clinical, and laboratory data in Japan. Although the follow-up periods of this study were 5 years, we will report the compiling data at the time of enrollment in J-PKD registry.

**Methods:** Patient data including age, gender, family history, complication, medical history, and laboratory data were electronically recorded at each institution and registered via the Internet Data and Information Center for Medical Research system, which is part of the University Hospital Medical Information Network.

**Results:** We included 271 ADPKD patients in this study (176 female and 95 male). Median age was 52 years. The mean estimated GFR was 49.3ml/min/1.73m$^2$. Several parameters including waist circumference ($r^2$=0.06, p=0.001), systolic blood pressure ($r^2$=0.05, p<0.001), total kidney volume ($r^2$=0.25, p<0.001) were significantly inversely correlated with eGFR. There were significant correlations between eGFR and Hemoglobin level ($r^2$=0.26, p<0.001), serum alubumin ($r^2$=0.08,p<0.001).

**Conclusions:** In this cohort study, we will clear the actual treatment course of PKD in Japan.

**SA-PO290**

**A Comprehensive Mutation Search within the *PKD1/2* for Japanese Subjects with Autosomal Dominant Polycystic Kidney Disease**
Mahiro Kurashige,[1,2] Kazushige Hanaoka,[1] Minako Imamura,[2] Yoshindo Kawaguchi,[1,3] Toshio Hasegawa,[1,3] Tatsuo Hosoya,[1] Shiro Maeda,[2] Takashi Yokoo.[1] *[1]Div of Kidney and Hypertension, Dept of Internal Medicine, The Jikei Univ, School of Medicine, Minato, Tokyo, Japan; [2]Laboratory for Endocrinology, Metabolism and Kidney Diseases, RIKEN Center for Integrated Medical Science, Yokohama, Kanagawa, Japan; [3]Dept of Medicine, Kanagawa Prefectural Shiomidai Hospital, Yokohama, Kanagawa, Japan.*

**Background:** Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a common hereditary kidney disease, and most of its heritability could be explained by mutations in two genes, *PKD1* and *PKD2* in populations of European origin. However little is known about Japanese ADPKD. To elucidate genotypic and phenotypic characteristics of the Japanese ADPKD, we performed a comprehensive mutation search within *PKD1/2* by using 180 Japanese ADPKD patients from 161 unrelated families.

**Methods:** We screened the entire coding regions and their flanking regions of the *PKD1/2* by direct sequencing. We also examined large genomic rearrangements within *PKD2* by using quantitative PCR. We further investigated phenotype-genotype correlation using linear regression analyses.

**Results:** We identified 102 mutations within 128 families, through direct sequencing, including 81 *PKD1* mutations (43 truncated, 10 splicing, 23 missense, 5 in-frame) and 21 *PKD2*mutations (15 truncated, 3 splicing, 3 missense). We also found a novel 3.1-kb deletion within *PKD2* (intron13 to exon15). Decline of eGFR was significantly faster in patients with *PKD1* mutation than in patients with *PKD2* mutation (-3.11 and -2.01 ml·min$^{-1}$·year$^{-1}$ for *PKD1* and *PKD2*, respectively, p<0.01). Mutation type or nucleotide position was not associated with eGFR decline. Lower urinary osmolality was found to correlate with eGFR decline in a multiple linear regression analysis.

**Conclusions:** Mutations within *PKD1/2* contribute to the pathogenesis of most Japanese ADPKD. Our present finding suggests that *PKD1* mutations and lower urinary osmolality are risk factors for declining renal function in Japanese patients with ADPKD.

**SA-PO291**

**In Vitro and Family Analysis to Assess the Significance of Indeterminate PKD1 Variants**
Binu M. Paul, Jamie L. Sundsbak, Christina M. Heyer, Katharina Hopp, Maria V. Irazabal, Marie C. Hogan, Vickie J. Kubly, Vicente E. Torres, Peter C. Harris. *Medicine, Mayo Clinic, Rochester, MN.*

**Background:** ADPKD molecular diagnostics is complex because of the high level of allelic heterogeneity at *PKD1 and PKD2*, and hence determining the pathogenic significance of some missense changes *in silico* is problematic. Quantitative *in vitro* assays of these alleles could help to determine their significance.

**Methods:** Segregation and detailed clinical analysis in conjunction with *in vitro* analysis of PC1 cleavage at the GPS domain was performed to test the significance of a group of unresolved variants.

**Results:** The proband in pedigree M599 presented with a few kidney cysts and multiple liver cysts at 45 years. Mutation screening revealed a novel variant, *PKD1*: p.S2612W, that was scored *in silico* as likely pathogenic. The *in vitro* assay indicated that p.S2612W significantly blocked cleavage proving a pathogenic role. The proband in M517 developed ESRD at 25 years and had the novel *PKD1* variant p.G2452C *in trans* with *PKD1*: c.9246_9252del7. A cousin with just p.G2452C had a few cysts in both kidneys. Although G2452C does not show strong evolutionary conservation, *in vitro* analysis showed a moderate impairment of GPS cleavage and so a likely modifying role. The proband in M190 presented with Potter's phenotype, PKD and perinatal death. The proband had the *PKD1*: p.W3298X mutation inherited from the mother and maternal grandmother with typical ADPKD and the novel *PKD1* variant, *PKD1*:p.R2213W (at a highly conserved site) from his unaffected father. *In vitro* analysis showed that this is a hypomorphic cleavage variant and *in trans* with p.W3298X results in just ~20% functional PC1. Collection and categorization of variants in the ADPKD Mutation Database can help with future diagnostics. However, in some cases limited clinical data is available to determine their significance. *PKD1*: p.R2516H is an example of such a variant that is at a highly conserved site but is a very conservative change. *In vitro* analysis showed that p.R2516H affects GPS cleavage and so is likely a pathogenic mutation.

**Conclusions:** Overall, our results indicate the value of family studies and *in vitro* assays to functionally test indeterminate variants.

**Numbers and Activation State of Parenchymal Kidney Cells Change with Age and Disease State in db/db Mice**
Lisbeth N. Fink, Helena Cucak, Christopher Mayer, Carsten F. Gotfredsen, Maiken H. Pedersen, Bidda Rolin, Alexander Rosendahl. *Diabetes Research Unit, Novo Nordisk A/S, Maaloev, Denmark.*

**Background:** The db/db mouse model of diabetic nephropathy shows histological lesions reminiscent of early human diabetic nephropathy. We hypothesized that alterations in parenchymal cell numbers and activation state could serve as biomarkers for pre-late stage disease. Herein, we present a novel method for enumeration of kidney parenchymal cells and for cell-specific protein expression analysis during disease development in db/db mice.

**Methods:** db/db and db/+ mice were sacrificed at 8-28 weeks of age. Kidneys were enzymatically digested and the resulting cell suspensions were subjected to multiple parameter flow cytometric analysis. Staining of specific cell types was confirmed by immunohistochemistry. Kidney function was assessed by measuring plasma urea nitrogen.

**Results:** Proximal (PTEC) and distal (DTEC) tubular epithelial cells expanded dramatically with age (300% and 50% respectively from 8 to 28 weeks) in db/db mice, but not in db/+ mice. db/db DTECs progressively expressed higher levels of TLR4 and lower levels of PDGFR1 compared to db/+. In addition, PTECs acquired high TGFb1 expression at 28 weeks in db/db only. Arteriolar smooth muscle cells and endothelial cells also increased with age and db/db endothelial cells had elevated ICAM-1 compared to db/+. Although the frequency of podocytes was reduced, absolute podocyte numbers were not changed with advancing disease. Isolated db/db glomeruli became progressively more susceptible to in vitro cytokine-induced apoptosis. Histological analysis showed that db/db kidneys developed moderate mesangial expansion, but not glomerulosclerosis or interstitial fibrosis.

**Conclusions:** In db/db mice, progression of disease with increased age caused an increased expression of inflammatory markers and expansion of tubular epithelial cells, endothelial cells and arteriolar smooth muscle cells, and decreased podocyte frequency, but not numbers. The increase of TGFb in PTECs suggests a potential pre-stage 3 phenotype development in db/db mice even though neither sclerosis nor fibrosis was evident. These changes coincided with a decrease in plasma urea nitrogen.

**SA-PO293**

**Effect of Enalapril on Albuminuria and Cellular Kidney Parameters in db/db Mice**
Lisbeth N. Fink, Helena Cucak, Maiken H. Pedersen, Carsten F. Gotfredsen, Alexander Rosendahl. *Diabetes Research Unit, Novo Nordisk A/S, Maaloev, Denmark.*

**Background:** Blockade of the renin-angiotensin system is the first-line therapy for microalbuminuric diabetes patients, whereas ACE inhibition has shown variable results in db/db mice. Herein, we characterized the kidney cellular dynamics in order to elucidate the albuminuria-reducing mechanism of action of Enalapril in db/db mice.

**Methods:** db/db mice were fed Enalapril for 12 weeks (5mg/kg/day) mixed with the chow. Albuminuria was measured before commencement of treatment and after 6 and 12 weeks of treatment. Kidneys were enzymatically digested and the kidney cell suspensions were analysed by flow cytometry for parenchymal and leukocyte cell parameters.

**Results:** Albuminuria increased in vehicle treated db/db mice during the first 6 weeks and was reduced to starting values after 12 weeks. Enalapril significantly reduced albuminuria after 6 weeks of treatment (P<0.001), whereas no significant reduction remained after 12 weeks of treatment compared to vehicle treated animals. Enalapril had no effect on mesangial expansion. After 12 weeks of treatment, Enalapril caused an expansion of podocytes, endothelial cells, arteriolar smooth muscle cells and distal tubular epithelial cells and consequently almost doubled cell numbers compared to vehicle control. Furthermore, Enalapril increased ICAM-1 protein expression on endothelial cells and restored epithelial

PDGFR1 expression, which was lost in db/db mice. Numbers of leukocytes (T cells and macrophages, including CD11c$^{+}$ macrophages) in Enalapril treated db/db mice were restored to comparable levels as in db/+ mice.

**Conclusions:** Enalapril treatment showed a temporary beneficial effect on albuminuria during the progression of diabetic nephropathy in db/db mice. However, despite lack of effect on albuminuria at 12 weeks of treatment, Enalapril increased numbers of distal tubular epithelial cells and other parenchymal cells and seemed to promote vascular inflammation, but also restored PDGFR1 and macrophage numbers to non-diabetic levels. The trophic effect and restoration of M1 macrophage numbers suggests beneficial effects even in absence of reduction of albuminuria.

## SA-PO294

**Urinary Aminopeptidase A but Not ACE2 Is Upregulated by RAS Blockade in *db/db* Mice** Jan A. Wysocki, Philipp K. Haber, Christoph Maier, Minghao Ye, Daniel Batlle. *Div of Nephrology & Hypertension, Northwestern Univ, Chicago, IL.*

**Background:** Aminopeptidase A (APA) and ACE2 are Ang II-degrading enzymes abundantly expressed in the kidney. Abundance of these peptidases in the urine could indicate the capacity of the diabetic kidney to counteract the Ang II-overactivity characteristic of diabetic nephropathy.

**Methods:** Urinary APA and ACE2 activities were measured fluorometrically in the urines from db/db mice under physiological conditions and during pharmacological interventions with RAS blockers. Measurements from 4 consecutive urine collections 1-3 weeks apart were averaged for each experimental condition and expressed as enzyme activity/creatinine ratio.

**Results:** In the urines from db/db mice under baseline condition, APA (188±18 vs. 107±8, RFU/ug creat/hr, $p<0.001$) and ACE2 activity (46±12 vs. 10±2 RFU/ug creat/hr, $p<0.05$) were both increased as compared to db/m controls. When administered for several weeks, an ACE inhibitor, captopril (60 mg/kg/d) and a specific AT1 receptor blocker, telmisartan (2mg/kg/d), increased significantly the levels of urinary APA activity in db/db mice as compared to baseline (650±114 and 378±72 vs. 188±18, $p<0.001$ and $p<0.05$, respectively) whereas they had no effect on urinary ACE2 activity (39±6 and 51±7 vs. 46±12, respectively). Both RAS blockers reduced albumin creatinine ratio significantly ($p<0.05$).

**Conclusions:** Urinary APA and ACE2 activities are increased in db/db mice. Whereas RAS blockade increases urinary APA activity, ACE2 activity in the urine is unaffected by either captopril or telmisartan. Altogether these findings suggest that urinary ACE2 and APA appear to be differentially regulated by RAS blockers and, moreover, raise the possibility that the therapeutic renal action of RAS blockers involves up-regulation of kidney aminopeptidase A and thus enhanced Ang II degradation.

## SA-PO295

**In Vivo Quantification of Nephrin Endocytosis Mediated by MAPK p38 in Diabetic Animals** Magdalena Woznowski, Sebastian Alexander Potthoff, Eva Koenigshausen, Johannes Stegbauer, Lars C. Rump, Lorenz Sellin, Ivo Quack. *Dept for Nephrology, Heinrich Heine Univ, Duesseldorf, Germany.*

**Background:** Microalbuminuria is an early sign of diabetic podocyte damage. We could recently demonstrate that even new-onset hyperglycemia causes nephrin endocytosis and albuminuria. So far it has been difficult to quantify the loss of surface nephrin in diseased animals. Therefore we developed a biotinylation assay which allows monitoring the amount of nephrin present at the slit diaphragm. Here we use this tool to dissect the role of p38 as mediator of hyperglycemia-induced nephrin endocytosis.

**Methods:** C57BL/6 mice were administered streptozotocin i.p. to induce hyperglycemia. For inhibition of p38, the mice were subsequently treated with SB202190 i.p. Albuminuria was quantified as albumin/creatinin ratio. To quantify the surface expression of nephrin the kidneys were perfused with biotin. Afterwards glomeruli were instantly harvested and analyzed with streptavidin via Western blot.

**Results:** Diabetic mice developed a significant albuminuria already four days after streptozotocin application. Inhibition of p38 nearly completely prevented albuminuria. For the first time we could show that new-onset hyperglycemia leads to a loss of surface expression of nephrin in glomeruli simultaneously to the occurrence of albuminuria. This cascade could be prevented by treatment with SB202190. Further we found evidence that endocytosis of nephrin is mediated by its phosphorylation by p38, facilitating binding of PKC$\alpha$ to nephrin.

**Conclusions:** Acute hyperglycemia rapidly induces albuminuria, but the underlying mechanisms have not been fully understood. Here we show for the first time in vivo that the occurrence of albuminuria in hyperglycemic animals is paralleled by nephrin endocytosis. Inhibition of p38 decreases nephrin phosphorylation and endocytosis, supporting the hypothesis that stabilization of the slit diaphragm prevents albuminuria. These findings suggest p38 as pivotal mediator of early diabetic damage and thus as a promising therapeutic target.

## SA-PO296

**Vitamin D Improves Podocyte Hyperpermeability Induced by High Glucose and Advanced Glycosylation Endproducts** Tae-Sun Ha,[1] JAE IL SHIN,[2] Se Jin Park.[3] *[1]Dept of Pediatrics, Chungbuk National Univ College of Medicine; [2]Dept of Pediatrics, Yonsei Univ College of Medicine; [3]Dept of Pediatrics, Ajou Univ School of Medicine.*

**Background:** The aim of this study was to investigate the effect of vitamin D on the pathologic changes of podocyte beta-catenin and P-cadherin and podocyte permeability induced by diabetic conditions.

**Methods:** We cultured mouse podocytes under: 1) normal glucose (5 mM, = control); 2) high glucose (HG, 30 mM); 3) AGE-added; or 4) HG plus AGE-added conditions and treated with vitamin D. The distribution of podocyte beta-catenin and P-cadherin was shown by confocal microscopy, and protein levels of them by western blotting. Podocytes were incubated with vitamin D at the concentrations of 10 and 50 nM for 6, 24 and 48 hours.

**Results:** HG and AGE increased the dextran filtration of monolayered podocytes at 18 hrs in permeability assay, which was improved by vitamin D. In confocal imaging, the distribution of beta-catenin and P-cadherin were internally concentrated by diabetic conditions, which was improved by vitamin D. In Western blotting, HG and AGE decreased beta-catenin protein levels at 6, 24 and 48 hours ($P<0.01$). Vitamin D improved the decreased beta-catenin protein levels at 6, 24 and 48 hours.

**Conclusions:** These findings imply that HG and AGE have an influence on the redistribution of beta-catenin and P-cadherin and amount of beta-catenin protein of podocytes thereby causing hyperpermeability, which can be reversed by vitamin D.

## SA-PO297

**Therapeutic Potential of Suramin in Diabetic Nephropathy** Leah J. Siskind,[1,3] Midhun C. Korrapati,[1] Ryan Whitaker,[1] Judit Megyesi,[2] Rick G. Schnellmann.[1,3] *[1]Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC; [2]Dept of Internal Medicine, Univ of Arkansas for Medical Sciences, Little Rock, AR; [3]Ralph H. Johnson, Veterans Administration Medical Center, Charleston, SC.*

**Background:** Delayed administration of a single dose of suramin, a FDA-approved drug, decreased renal inflammation and fibrosis in an early model of type 1 diabetes-induced renal injury. These studies tested the hypothesis that delayed administration of a single dose of suramin decreases early and late stage diabetic nephropathy in a leptin receptor deficient C57BLKS/J *db/db* type 2 diabetic nephropathy (T2DN) mouse model.

**Methods:** Non-diabetic *db/m* and diabetic *db/db* mice of 8 and 17 weeks of age were treated with 10 mg suramin/kg, i.v. or saline and euthanized one week later. Measurements in 9 and 18 week mice before and following treatment included: body weight; blood glucose; urinary protein excretion; pathological lesions in glomeruli and proximal tubules; changes in protein of the pro-inflammatory transcription factor nuclear factor κB (NF-κB), endothelial intracellular adhesion molecule-1 (ICAM-1), profibrotic transforming growth factor-β1 (TGF-β1), phospho-SMAD-3 and alpha-smooth muscle actin (α-SMA); and IHC analysis of leukocyte infiltration and collagen 1A2 (COL1A2) deposition.

**Results:** Immunoblot analysis revealed increased NF-κB, ICAM-1, TGF-β1, phospho-SMAD-3, and α-SMA proteins in 9 and 18 week *db/db* mice as compared to *db/m* mice. IHC analysis revealed moderate leukocyte infiltration and COL1A2 deposition in 9 week *db/db* mice that increased in 18 week *db/db* mice. Importantly, suramin significantly decreased expression of all markers in 9 week *db/db* mice and partially decreased them in 18 week *db/db* mice. There was no difference in creatinine clearance between 9 week *db/m* and *db/db* mice ± suramin. Importantly, in the 18 week *db/db* mice suramin reversed impaired creatinine clearance and overt histological damage.

**Conclusions:** Delayed administration of a single dose of suramin in a model of T2DN attenuated inflammation and fibrosis as well as improved renal function, supporting the use of suramin to treat T2DN.

## SA-PO298

**The Role of Glycosphingolipids in Diabetic Nephropathy** Leah J. Siskind,[1,2,3] Subathra Marimuthu,[1] Midhun C. Korrapati,[1] Lauren P. Wills,[1] Jennifer L. Blakely,[1] Rick G. Schnellmann.[1,2] *[1]Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC; [2]Ralph H. Johnson, Veterans Administration Medical Center, Charleston, SC.*

**Background:** Glycosphingolipids, a subtype of sphingolipids, are found in abundance in kidney diseases and an inhibitor of their synthesis prevented the progression of polycystic kidney disease in a rodent model. A role for glycosphingolipid species in diabetic nephropathy (DN) has not been determined. This study tested the hypothesis that glycosphingolipids accumulate in the kidney in response to hyperglycemia in type II diabetes and mediate DN.

**Methods:** Non-diabetic *db/m* and diabetic *db/db* mice were obtained from Jackson Laboratories. Glycosphingolipids were measured by HPLC-MS/MS in homogenates of kidney cortices and mesangial cells and proximal tubules cells purified from kidney cortices. Primary cultures of mesangial and proximal tubule cells (RPTC) were cultured under normal and hyperglycemic conditions (17 mM) and glycosphingolipids quantified. In addition, primary mesangial and proximal tubule cells were treated with exogenous glycosphingolipids and inflammatory cytokine expression and mitochondrial function, respectively, were determined.

**Results:** The glycosphingolipids glucosylceramide (GlcCer) and lactosylceramide (LacCer) were elevated in the urine of type II DN patients and the *db/db* mice model of type II DN. GlcCers and LacCers were also increased in kidney cortices of db/db mice, specifically within mesangial and RPTC. Hyperglycemia elevated GlcCer and LacCer in primary cultures of mesangial and RPTC and induced inflammatory cytokine production in mesangial cells and mitochondrial dysfunction and cell death in RPTC. Exogenous GlcCer and LacCer addition was sufficient to induce inflammatory cytokines in mesangial cells and mitochondrial dysfunction and cell death in RPTC.

**Conclusions:** Data support the hypothesis that hyperglycemia in type II diabetes leads to renal dysfunction at least in part by inducing GlcCer and LacCer accumulation in mesangial and RPTC, resulting in activation of inflammatory signaling pathways and mitochondrial dysfunction/cell death, respectively, and DN.

*Funding:* NIDDK Support, Veterans Affairs Support

## SA-PO299

**Cathepsin S Promotes Endothelial Dysfunction, Proteinuria, Podocyte Loss, and Glomerulosclerosis in Type 2 Diabetes** Murthy Narayana Darisipudi,[1] Onkar Kulkarni,[1] Shrikant R. Mulay,[1] Hartmann Guido,[2] Hans J. Anders.[1] *[1]Nephrologisches Zentrum, Klinische Biochemie, Medizinische Klinik und Poliklinik IV der LMU, Munich, Germany; [2]CV & Metabolism DTA, Hoffmann La Roche, Basel, Switzerland.*

**Background:** Cathepsin S is an elastolytic cysteine protease, known to drive atherogenesis and vascular wall degeneration in aging as well as in the accelerated atherogenesis of chronic kidney disease. To date a pathogenic role of cathepsin S in microvascular complications of type 2 diabetes is entirely speculative.

**Methods:** Male db/db uninephrectomized mice were fed either with food-drug mix contained cathepsin S inhibitor, RO5461111 and standard food from 16 weeks of age till 24 weeks. Kidneys were harvested for histopathological evaluation and spleens were used to estimate the Lip10 level. Blood and urine samples were obtained at monthly intervals.

**Results:** We found increased plasma cathepsin S activity and increased cathepsin S protein expression in kidney especially upon accelerating the onset of disease by early uninephrectomy. Immunostaining localized cathepsin S protein to tubular epithelial cells, endothelial cells and infiltrating leukocytes in advanced human diabetic nephropathy, while in db/db mice with less advanced disease the tubular signal was most obvious. However, tubular cathepsin S mRNA expression was excluded by in situ hybridization. Treatment with RO5461111 significantly reduced albuminuria, podocyte loss, and glomerulosclerosis in association with lower macrophage infiltrates as well as pro-inflammatory cytokines, adhesion molecules mRNA expression and restored eNOS expression. In vitro studies with glomerular endothelial cells documented a toxic effect of cathepsin S in terms of viability, detachment, and permeability. In vivo microscopy studies revealed that cathepsin S inhibition improved oxidative stress-induced microvascular permeability.

**Conclusions:** Cathepsin S is a circulating mediator of endothelial dysfunction driving albuminuria and progressive kidney disease in type 2 diabetes, a process that can be prevented by cathepsin S inhibition, e.g. with RO5461111.

## SA-PO300

**Complement C3a, C5a Regulate Endothelial-Myofibroblast Transition via Wnt/β-Catenin Signaling Pathway in Diabetic Nephropathy** Lijia Chen,[1] Ling Li,[1] Jing Zang,[1] Jie Zhang,[2] Qinghua Yin,[1] Lu Cheng,[1] Yanrong Lu,[2] Jingqiu Cheng,[2] Ping Fu,[1] Fang Liu.[1] *[1]Div of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China; [2]Key Laboratory of Transplant Engineering and Immunology, Ministry of Health, Regenerative Medicine Research Center, Chengdu, Sichuan, China.*

**Background:** Endothelial-myofibroblast transition (EndMT) is considered to be involved in the development and progression of renal fibrosis in diabetic nephropathy (DN). We aimed to investigate whether the C3a and C5a as the novel profibrotic factors could induce EndMT via Wnt/β-catenin signaling pathway in DN.

**Methods:** Male SD rats were randomized into four groups: normal control, DN, DN+C3aRA (C3a receptor antagonist) and DN+C5aRA (C5a receptor antagonist), which were sacrificed after eight weeks. In vitro Cultured human renal glomerular endothelial cells (HRGECs) were divided into ten groups: normal glucose, mannitol, TGFβ1, high glucose, HG+C3a, HG+C3a+C3aRA, HG+C3a+DKK1, HG+C5a, HG+C5a+C5aRA and HG+C5a+DKK1. DKK1 was used as Wnt/β-catenin pathway inhibitor. Double-labeled fluorescent staining was performed to detect the co-expression of CD31 with α-SMA or β-catenin. The expression of α-SMA, CD31, C3a, C5a, C3aR, C5aR, β-catenin, TGFβ and col-1 were detected by real time-PCR, western blot and immunohistochemistry.

**Results:** C3a, C5a, C3aR and C5aR were found up-regulated in glomeruli in DN group. Strong staining of α-SMA and β-catenin with decreasing staining of CD31 were observed in glomerular endothelial cells in DN group, which were retrieved by C3aRA or C5aRA treatment. And up-regulation of α-SMA, β-catenin, TGFβ1, col-1 and down-regulation of CD31 were also detected by real time -PCR, western blot and double-labeled fluorescent stainingin HRGECs stimulated by high glucose, C3a and C5a, which were retrieved by C3aRA or C5aRA and DKK1.

**Conclusions:** Complement C3a and C5a-induced EndMT is a novel mechanism in DN. Blockage of Wnt/β-catenin signaling pathway may alleviate EndMT and fibrosis in DN.

## SA-PO301

**Renoprotective Effects of Luseogliflozin (TS-071), a Novel SGLT2 Inhibitor, in Diabetic *db/db* Mice** Yumi Takiyama, Manami Kobayashi, Jun Honjo, Yukihiro Fujita, Tsuyoshi Yanagimachi, Hiroya Kitsunai, Yuichi Makino, Masakazu Haneda. *Div of Metabolism and Biosystemic Science, Dept of Medicine, Asahikawa Medical Univ, Asahikawa, Hokkaido, Japan.*

**Background:** Sodium glucose cotransporter 2 (SGLT2) represents a novel target for normalizing glycemia. To address *in vivo* the issue of the efficacy and tolerance of a novel SGLT2 inhibitor Luseogliflozin(LUSEO), we investigated whether LUSEO can prevent renal insufficiency and glomerulosclerosis in diabetic mice, and determined potential mechanisms of renoprotecitve effects.

**Methods:** *db/db* mice were treated with 15 mg/kg LUSEO for 8 weeks. The regulation of SGLT2 expression was evaluated using human renal proximal tubular epithelial cells (HRPTEC) by RT-qPCR.

**Results:** LUSEO significantly improved plasma glucose levels in *db/db* mice. Then, consistent with lowerd filtrated glucose load, urinary glucose excretion in *db/db* treated with LUSEO was decreased. Moreover, LUSEO showed renoprotective effects, which significantly attenuated urinary albumin excretion rates, glomerular mesangial matrix expansion, glomerular and interstitial fibronectin accumulation, and Armanni-Ebstein lesions in *db/db* mice. Of interest, LUSEO augmented pimonidazole staining of the S3 segment of the proximal tubules cells which expressed SGLT1, in the outer stripe of the kidney of *db/db* mice, suggesting hypoxia caused by the overload of glucose and sodium via blocking SGLT2 in the S1 segment. HRPTEC constitutively expresses SGLT2 mRNA. High glucose did not affect the expression of SGLT2 mRNA. Whereas, TGF-β1 markedly decreased SGLT2 mRNA expression. Intriguingly, Hepatocyte Nuclear Factor (HNF)-1α, a modulator of SGLT2 expression, was drastically decreased by TGF-β1 treatment, thereby providing a mechanism by which TGF-β1 represses SGLT2 mRNA expression through decreased HNF-1α. In addition, LUSEO alone failed to affect the expressions of SGLT2 and the inflammatory molecules, however, significantly inhibited TGF-β1-induced fibronectin expression.

**Conclusions:** These data demonstrate that LUSEO can protect against the progression of diabetic nephropathy, which is probably sufficient to overcome the adverse effects of TGF-β1 or compensatory hypoxia.

## SA-PO302

**Defective Autophagy Sensitizes Podocytes to Secondary Attack by Amplifying Inflammasome Activation in Diabetic Nephropathy** Li Fang, Weichun He, Chunsun Dai, Junwei Yang. *2nd Affiliated Hospital, Nanjing Medical Univ.*

**Background:** The mechanisms for the development of diabetic nephropathy (DN), the leading cause of end-stage renal disease (ESRD) in many industrialized countries, are not fully understood. Our previous data demonstrated that defective podocyte autophagy was associated with the progression of DN, here the underlying mechanism for defective podocyte autophagy leading to the progression of DN was investigated.

**Methods:** Both diabetic patients and animal experiment were included in this study. For the animal experiment, the CD-1 mice were divided into four groups: normal control, hyperuricemia group (250mg/kg/d uric acid intraperitoneal injection for 14 days), diabetic group (3 months after onset) and diabetic plus hyperuricemia group.

**Results:** In the diabetic patients, immunohistochemical staining for the kidney sections showed that thedefective autophagy in podocytes was always associated with the inflammasome activation in the glomeruli. In the animal experiment, more albuminuria, podocyte injury as well as inflammasome activation were detected in the diabetic plus hyperuricemia group compared to those in the other groups. In conditionally immortalized mouse podocyte cell line (MPC), 3-methylamphetamine (3-MA), an inhibitor of autophagy, could aggravate uric acid induced inflammasome activation in a dose- and time-dependent manner. Conversely, rapamycin, an inducer of autophagy, could alleviate uric acid induced inflammasome activation in a dose- and time-dependent manner.

**Conclusions:** These findings suggest that the defective autophagy sensitizes the podocytes to the secondary attack by amplifying inflammasome activation in DN. Thus, enhancement of autophagy will provide a novel avenue for preventing inflammasome activation and ameliorating podocyte injury in DN.

*Funding:* Government Support - Non-U.S.

## SA-PO303

**Hypovolemia, Not Hyperoxaluria, Causes Nephropathy following Gastric Bypass in Obese Rats** Benjamin Canales,[1] Marguerite Hatch,[2] Saeed R. Khan.[2] *[1]Urology, Univ of Florida, Gainesville, FL; [2]Pathology, Immunology and Laboratory Medicine, Univ of Florida, Gainesville, FL.*

**Background:** In the morbidly obese, Roux-en-Y gastric bypass (RYGB) can decrease renal hyperfiltration, improve glycemic control, and lower blood pressure. Its overall effect on renal function remains debatable, as RYGB can be also associated with recurrent oxalate lithiasis and post-procedural hypovolemia. We hypothesized that a diet-induced obese (DIO) model of RYGB with appropriate controls could address this question, providing end of study renal histology while controlling dietary oxalate content.

**Methods:** Male DIO Sprague-Dawley rats, aged 23 weeks, were randomly assigned to RYGB (n=74) or sham control (n=40). Once recovered, animals were placed ad lib normal calcium, high fat (40%) diet with 1.5% potassium oxalate (Ox) or without (No Ox). Weekly weights, food and water intake, complications, and clinical interventions were recorded.

Urine and serum were collected at baseline and every 5 weeks until euthanasia. At study endpoint, renal histology was assessed using a quantitative glomerular and tubular scoring system (0-4 scale) by two experienced veterinary pathologists, and animals were grouped into normal (NH) or abnormal (AH) histology. Animals that died prior to reaching endpoint were excluded from final analysis.

**Results:** Survival to endpoint was 63% (47/74) in RYGB and 90% (36/40) in controls. Over 36% (17/47) of RYGB animals had AH compared to 6% (2/36) of controls. Factors associated with developing RYGB AH included: age 20 weeks, 4 or more fluid boluses for hydration after surgical recovery, serum creatinine >0.6 mg/dL, clinical anemia, total body weight loss >28%, urine volume >30 ml/24 hours, and serum bicarbonate <25 mmol/L. There were significant increases in urinary oxalate in both RYGB No Ox and Ox groups as well as crystal deposits. However, neither dietary oxalate nor renal crystal deposition correlated to AH.

**Conclusions:** Results indicate that chronic hypovolemia in this RYGB model leads to AH, irrespective of dietary oxalate. The cause of volume loss appears to be of renal and not gastrointestinal origin. Studies to better define this polyuria mechanism are underway.

## SA-PO304

**Effect of Angiotensin Receptor Blockade on Sodium-Glucose Co-Transporters and Renal Gluconeogenesis in Diabetic Rats** Akihiro Tojo, Satoshi Kinugasa. *Div of Nephrology & Endocrinology, The Univ of Tokyo, Tokyo, Japan.*

**Background:** The kidney has a crucial role in glucose reabsorption via sodium-glucose co-transporters (SGLTs), which amounts to approximately 144 g/day. Although the main organ of gluconeogenesis is the liver, about 10% of gluconeogenesis is undertaken by the kidney under normal conditions, and 40% in the fasting condition. It has been reported that angiotensin receptor blockade inhibits the onset of diabetes, although its mechanism is not clarified yet. We investigated the effect of angiotensin receptor blockers (ARBs) on the SGLT and renal gluconeogenesis in diabetic rats.

**Methods:** We prepared 3 groups of rats (each n=5); sham-injected controls, untreated STZ-induced diabetic rats at 4 weeks, and STZ-induced diabetic rats that were administered the ARB, telmisartan for 2 weeks. One kidney was used for immunohistochemistry and pre-embedding immune electron microscopy, and the other kidney was homogenized for western blot analysis.

**Results:** SGLT2 was expressed exclusively in the brush border membrane of proximal convoluted tubules in normal rats, and its expression was increased and also appeared in apical vesicles in the diabetic rat. Western blotting revealed that both SGLT2 and SGLT1 were increased in the membrane fraction of kidney homogenates in diabetic rats, and they were suppressed in rats treated with telmisartan. The restriction enzymes of gluconeogenesis, glucose-6-phosphatase (G6Pase) and phosphoenolpyruvate carboxykinase (PEPCK), were increased in the cytoplasm of proximal and distal convoluted tubules in diabetic rats. Both G6Pase and PEPCK were suppressed in kidneys of rats treated with telmisartan. Cytoplasmic glucose levels were significantly increased in the diabetic rats compared with controls (80.4±4.9 vs. 16.6±0.7 mg/mg protein, $p<0.005$), which were significantly reduced in rats treated with telmisartan (35. 7±5.5 mg/mg protein, $p<0.0005$).

**Conclusions:** The diabetic kidney showed increased cytoplasmic glucose levels mediated by enhanced SGLT expression in the proximal tubules and increased gluconeogenesis enzymes, which were suppressed by ARB treatment.

**TNFα Causes Podocyte Cholesterol Accumulation and Apoptosis in Diabetic Kidney Disease** Christopher E. Pedigo,[1] Armando Mendez,[4] Matthias Kretzler,[2] Robert G. Nelson,[3] George William Burke,[4,5] Alessia Fornoni,[1,4] Sandra M. Merscher-Gomez.[1] *[1]Div of Nephrology and Hypertension, Univ of Miami, Miller School of Medicine, Miami, FL; [2]Univ of Michigan - Ann Arbor, MI; [3]NIDDK, Phoenix, AZ; [4]Diabetes Research Institute, Univ of Miami, Miller School of Medicine, Miami, FL; [5]Dept of Surgery, Univ of Miami, Miller School of Medicine, Miami, FL.*

**Background:** Diabetic Kidney Disease (DKD) is the most common cause of end-stage renal disease in the United States, and serum concentrations of Tumor Necrosis Factor alpha (TNFα) and TNFa Receptor 1 and 2 correlate with the development and progression of DKD. In DKD, decreased podocyte number and glomerular cholesterol accumulation are both associated with albuminuria. We tested the hypothesis that TNFα or TNFR1/R2 induce podocytes apoptosis via increased cholesterol accumulation.

**Methods:** Caspase 3 activity was used to quantify apoptosis in human podocytes treated with TNFα or TNFR1/R2. Lipid droplets were determined by Opera high Content Screening analysis of Bodipy 493/503 stained cells. $^3$H-cholesterol was used for efflux experiments and cyclodextrin to deplete cholesterol. Gene expression profiling was performed using Affymetrix GeneChip arrays.

**Results:** TNFα but not TNFR1/R2 induce apoptosis in podocytes ($p<0.05$). TNFα induced apoptosis was associated with a significant increase in the number of lipid droplets ($p<0.01$). ApoA1 mediated cholesterol efflux was decreased in TNFα-treated podocytes($p<0.05$) and was accompanied by decreased ATP-binding cassette transporter A1 (ABCA1) protein ($p<0.01$) and mRNA expression ($p<0.001$). Down-regulation of ABCA1 expression also occurred in glomeruli of patients with type 2 diabetes and DKD (N=70) when compared with healthy living donors (N=32). Cholesterol depletion with cyclodextrin partially prevented TNFα-induced podocyte apoptosis ($p<0.05$).

**Conclusions:** TNFα attenuates reverse cholesterol transport in podocytes leading to cholesterol accumulation and apoptosis. Our data suggest that strategies targeting the TNFα- cholesterol axis in podocytes may protect from the development of DKD.

**Transcriptional Regulation of WNT Pathway Genes in Diabetic Nephropathy** Gareth J. McKay, David Kavanagh, Alexander P. Maxwell. *Renal Research Group, Queen's Univ Belfast, Belfast, N. Ireland, United Kingdom.*

**Background:** Diabetic nephropathy (DN) is a microvascular complication of diabetes. Members of the WNT/ β-catenin pathways have been implicated in interstitial fibrosis and glomerular sclerosis, characteristic hallmarks of DN. These processes are controlled, in part, by transcription factors (TFs), proteins which bind to gene promoter regions attenuating their regulation. We sought to identify known *cis*-acting transcription factor binding sites (TFBS) over-represented within the promoter regions of WNT pathway members compared to genes across the genome.

**Methods:** We used TFBS data from the JASPAR databases on 65 WNT pathway genes to identify known binding motifs. *P*-values were estimated on the hypergeometric distribution for each TF. Gene expression profiles of enriched motifs were examined from DN-related datasets to assess clinical significance.

**Results:** TFBS motifs Transcription factor AP-2 alpha (*TFAP2A*), Myeloid zinc finger 1 (*MZF1*), and Specificity protein 1 (*SP1*) were significantly enriched within WNT pathway genes (*P*-values$<6.83\times10^{-29}$, $1.34\times10^{-11}$ and $3.01\times10^{-6}$ respectively). *MZF1* gene expression was significantly increased in DN in a whole kidney dataset (fold change = 1.16; 16% increase; $P = 0.03$). *TFAP2A* gene expression was decreased in an independent dataset (fold change = -1.02; $P = 0.03$). *SP1* was not differentially expressed in any datasets examined.

**Conclusions:** We identified three TFBSs significantly enriched within the WNT pathway genes examined highlighting the use of *in silico* analyses for identifying key regulators of this pathway. Modification of TF binding to gene promoter regions affecting DN pathology may limit progression, making refinement of targeted therapeutic strategies possible through clearer delineation of their role.

## SA-PO307

**Involvement of Renal Cytochrome P450 and Arachidonic Acid Metabolites in Diabetic Nephropathy** Stephanie Atef Eid, Assaad Antoine Eid. *Anatomy, Cell Biology and Physiology, American Univ of Beirut.*

**Background:** Diabetic nephropathy (DN), a serious complication of diabetes leads to loss of renal function. Proximal tubular cells (PTs) contribute to the hypertrophic response of the kidney. Early stages of DN are also associated with alterations in renal sodium handling as well as hypertension; processes linked by involvement of the arachidonic acid (AA) metabolites 20-hydroxyeicosatetraenoic acid (20-HETE) and epoxyeicosatrienoic acids (EETs). This study aims to determine the specific AA-metabolizing CYP450 isoforms present in proximal tubules that are altered by high glucose (HG) or hyperglycemia and to investigate the effects of their alterations on DN.

**Methods:** Kidney injury assesment, ROS generation, 20-HETE and EETs formations, CYP4A and CYP2C11expression.

**Results:** We show that exposure of rats proximal tubular epithelial cells to high glucose (HG) resulted in increased extracellular matrix accumulation and hypertrophy. HG treatment increased ROS production and was associated with alteration in CYPs 4A and 2C11 expression and alteration in 20-HETE and EETs formation. HG-induced tubular injury were blocked by 20HETE inhibition. In contrast, inhibition of EETs promoted the effects of HG on cultured proximal tubular cells. We also show that alteration in CYPs 4A/2C expression and 20-HETE/EETs formation regulates the activation of the mTOR/p70S6Kinase pathway, having a major role in the development of DN. In parallel experiments we show that inhibition of the Cyp4A-mediated 20-HETE production or induction of EETs formation in animal model of diabetes prevent tubular cells injury and proteinuria. Our in vivo observations were correlated by increased urine levels of 20-HETE in diabetic rats and these levels were reduced by modulation of 20-HETE with its inhibitor HET0016.

**Conclusions:** Our results indicate that hyperglycemia in diabetes has a significant effect on the expression of AA-metabolizing CYPs, manifested by increased AA metabolism, and might thus alter kidney function through alteration of type and amount of AA metabolites. These observations provide a strong rationale to study cytochrome P4504A as a promising target for therapeutic drug development in DN.

## SA-PO308

**Role of Bone Morphogenetic Protein-7 (BMP7) in Diabetic Tubulopathy** Ruixi Li, Wai Han Yiu, Hao-Jia Wu, Miao Lin, Dickson WL Wong, Loretta Y.Y. Chan, Joseph C.K. Leung, Kar Neng Lai, Sydney C.W. Tang. *Medicine, Queen Mary Hospital, Hong Kong, China.*

**Background:** The potential renoprotective role of BMP7 in diabetic nephropathy remains unknown.

**Methods:** Nine-week-old *db/db* mice and their *db/m* littermates underwent uninephrectomy (Unx) or sham operation, and received rh-BMP7 (300ug/kg body weight) or vehicle intraperitoneally every other day for 8 weeks before sacrifice. Primary human proximal tubular epithelial cells (PTECs) were growth-arrested and exposed to glycated human serum albumin (AGE-HSA) with or without rh-BMP7.

**Results:** Compared with vehicle control, Unx *db/db* mice treated with rh-BMP7 for 8 weeks had significantly lower urinary albumin-to-creatinine ratio (4,566±2,767 ug/mg *vs.* 7,338±5,748 ug/mg, $p<0.05$), serum BUN (33.3±3.46 mg/dL *vs.* 37.5±2.95 mg/dL, $p<0.05$), and renal cortical gene expression of IL-6, ICAM-1, CCL-2 and CCL-5. PAS staining of kidney tissue showed significantly less severe tubular damage and interstitial inflammatory cell infiltration in the BMP7-treated group. In cultured human PTECs, exposure to AGE-HSA induced overexpression of sICAM-1, CCL-2, IL-8 and IL-6, involving activation of p44/42 and p38 MAPK signaling. BMP7 dose-dependently attenuated AGE-induced upregulation of sICAM-1, CCL-2, IL-8 and IL-6 at both mRNA and protein levels. Moreover, BMP7 suppressed AGE-induced p38 and p44/42 MAPK phosphorylation and reactive oxygen species production in PTECs.

**Conclusions:** Our results demonstrated for the first time that BMP7 attenuates tubular pro-inflammatory responses in diabetic kidney disease by suppressing oxidative stress and multiple signaling pathways including p38 and p44/42 MAPK. Its potential application as a therapeutic molecule in diabetic nephropathy warrants further investigation.

This study is supported by a General Research Fund of the Research Grants Council (Grant number: HKU 7770/09M) of Hong Kong.

## SA-PO309

**Activated Local Renin-Angiotensin System within Glomerular Endothelial Cells Is Associated with Morphological and Functional Changes under Diabetic Conditions** Shin-Wook Kang,[1,2] Ji Sun Paeng,[1] Hye-Young Kang,[1] Hyung Jung Oh,[2] Seung Hyeok Han.[2] *[1]Brain Korea 21, Yonsei Univ, Seoul, Korea; [2]Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea.*

**Background:** The role of renin-angiotensin system (RAS) within glomerular endothelial cells (GECs) in the pathogenesis of diabetic nephropathy (DN) has not been fully explored. We aimed to investigate the existence and changes of RAS components in high glucose (HG)-stimulated GECs and the role of local RAS in morphological and functional changes of GECs under diabetic conditions.

**Methods:** In vitro, GECs were exposed to 5.6 mM glucose (NG) or 30 mM glucose (HG) with or without $10^{-7}$ M losartan for 24 hours. In vivo, 32 Sprague-Dawley rats were injected with diluents (n=16, C) or streptozotocin intraperitoneally (n=16, DM), and 8 from each group were treated with 10 mg/kg losartan for 6 weeks. The activation of local RAS was examined by Real-time PCR, Western blot analysis, and ELISA. Morphological changes were evaluated by scanning electron microscopy (SEM). FITC-tagged albumin permeability was determined by a transwell assay.

**Results:** Angiotensinogen mRNA and protein expression were significantly increased in HG-stimulated GECs compared to NG cells ($p<0.01$). AI and AII concentrations were also significantly higher in HG-conditioned media ($p<0.01$). However, there were no differences in the mRNA and protein expression of ACE and AII type 1 and type 2 receptors. On SEM examination, the number and diameter of fenestrae were significantly increased in HG-stimulated GECs and these changes were significantly abrogated by losartan ($p<0.05$). A transwell assay revealed that FITC uptakes in filtered media through HG-stimulated GECs were 4.3-fold higher compared to NG cells, and the increased uptakes were significantly ameliorated by losartan ($p<0.05$). In addition, diameter of GEC fenestrae and urinary albumin excretion were significantly greater in DM rats than those in C rats ($p<0.05$), which were significantly attenuated by losartan ($p<0.05$).

**Conclusions:** Local RAS within GECs was activated under HG conditions, and it seemed to be associated with alterations in GEC fenestration, resulting in the development of albuminuria in DN.

## SA-PO310

**Oral Treatment with PBI-4050, a Novel First-in-Class Anti-Fibrotic Compound, Improves Kidney Function and Reduces Hepatic Steatosis in the Diabetic db/db Mouse Model** Lyne Gagnon, Lilianne Geerts, François Sarra-Bournet, Mikaël Tremblay, Kathy Hince, Shaun Abbott, Jean-Simon Duceppe, Boulos Zacharie, Christopher Penney, Pierre Laurin, Brigitte Grouix. *ProMetic BioSciences Inc., Laval, Canada.*

**Background:** Diabetic nephropathy is now the leading cause of end-stage renal disease. The aim of this study was to investigate the effect of PBI-4050, a novel first-in-class compound with anti-inflammatory, anti-oxidant and anti-fibrotic properties, on biological markers and kidney function in uninephrectomized (NX) diabetic (db/db) mice.

**Methods:** Total nephrectomy of the right kidney was performed on day 0 and animals were treated with vehicle or PBI-4050 (100 mg/kg, oral once a day) from day 1 through 130. Kidney function, kidney mesangial lesions, and hepatic steatosis were examined. Inflammatory/fibrotic and remodeling markers were assessed by qPCR in kidney and liver tissue.

**Results:** Urinary creatinine was significantly reduced in NX-db/db mice compared to sham and NX-C57BL/6 (negative control) mice, but returned to the normal level in PBI-4050-treated NX-db/db mice. Albuminuria was increased by 1.5 to 2 fold in NX-C57BL/6 and NX-db/db compared to sham C57BL/6 mice. Treatment of NX-db/db mice with PBI-4050 reduced albuminuria and proteinuria to the sham C57BL/6 mice level. NX-db/db mice demonstrated a significant increase in GFR (hyperfiltration), which was significantly reduced by treatment with PBI-4050. Db/db mice had larger glomeruli with increased mesangial matrix. Mesangial lesion scores were reduced in NX-db/db mice treated with PBI-4050. Lipid peroxidation (TBARS) in kidney was increased in NX-db/db mice and reverted to the control level following treatment with PBI-4050. Hepatic steatosis, observed in NX-db/db mice, was significantly reduced (50%) with PBI-4050-treatment. Furthermore, qPCR analysis of NX-db/db mice indicated that PBI-4050 treatment resulted in a significant reduction of the expression of IL-6, collagen I, TIMP-1 and MMP-2 in kidney tissue, and of TGF-β1, collagen I, TIMP-1 and MMP-2 in liver tissue.

**Conclusions:** Our results suggest that PBI-4050 offers the potential as a novel therapy for the reduction of diabetic nephropathy.

## SA-PO311

**Myo-Inositol Oxygenase (MIOX) Modulates Mitochondrial Dynamics and Autophagy in Diabetic Tubulopathy** Ming Zhan, Tatsuya Tominaga, Lin Sun, Yashpal S. Kanwar. *Pathology Dept, Northwestern Univ, Chicago, IL.*

**Background:** Diabetic nephropathy (DN) is often associated with mitochondrial injury and oxidative stress. MIOX, a tubular enzyme, modulates redox imbalance and apoptosis in tubular cells in diabetes, but the mechanisms remain unclear.

**Methods:** We investigated the role of MIOX in perturbation of mitochondrial dynamics and autophagy under high glucose (HG) ambience contributing to mitochondrial-mediated ROS generation and apoptosis in vitro and in vivo.

**Results:** Following HG treatment of HK-2/LLC-PK1 cells, an increased expression of MIOX and mitochondrial fission proteins, Drp1 & Fis1, and mitochondrial fragmentation was observed. Expression of fusion protein, Mfn2, and autophagy related proteins (LC3B, Atg5 and Beclin1) was decreased. MIOX-transfected tubular cells had an increased Drp1 expression and mitochondrial fission under LG & HG ambience, whereas LC3B, Atg5 and Beclin1 expression was decreased. At times, mitophagy was also suppressed. These changes were accompanied with Bax activation, mitochondrial cytochrome C release, ROS overproduction and apoptosis. MIOX siRNA & D-glucarate, an inhibitor of MIOX partially reversed these perturbations. An increased MIOX expression and mitochondrial fragmentation was also seen in proximal tubules during early stages of STZ-induced DN in mice, together with upregulation of Drp1, Bax and cytochrome C expression, but reduced expression of Mfn2 and autophagy related proteins. Dietary supplementation of D-glucarate to diabetic mice decreased MIOX expression and improved renal functions, as reflected by the reduction of serum creatinine, urinary albumin-to-creatinine ratio and tubular damage score. D-glucarate treated mice had partial attenuation of mitochondrial fragmentation and restoration of autophagy, accompanied with decreased oxidative stress and apoptosis in tubules. Conceivably, MIOX regulates mitochondrial dynamics, autophagy and apoptosis under HG ambience via modulation of Drp1 & Mfn2 activation.

**Conclusions:** Data suggest that MIOX modulates mitochondrial dynamics and autophagy in tubular cells in diabetic milieu, which may be a novel mechanism for ensuing redox imbalance and tubular cell injury and death.

*Funding:* NIDDK Support

## SA-PO312

**High Glucose Increases Formation and Pro-Oxidative Activity of Endothelial Microparticles** Dylan Burger, Kevin D. Burns. *Kidney Research Centre, Ottawa Hospital Research Institute, Univ of Ottawa, Ottawa, Canada.*

**Background:** Microparticles (MPs) are submicron membrane fragments released from the cell surface under conditions of stress or damage. In diabetic subjects, plasma endothelial MP levels are increased and predict risk of future cardiovascular events. Moreover, emerging evidence suggests that MPs may themselves exert deleterious biological effects. However, the stimuli responsible for increased MPs in diabetes, and the impact of diabetic conditions on the biological activity of endothelial MPs are not clear.

**Methods:** Human dermal microvascular endothelial cells (ECs) were cultured in media containing 5.6 mM glucose, 25 mM D-glucose, or 25 mM L-glucose (osmotic control). MP levels were assessed by Annexin V labeling and flow cytometry as well as nanoparticle tracking analysis (NTA). Finally, the effects of endothelial MPs, formed under normal and high glucose conditions, on formation of reactive oxygen species (ROS) was assessed by dichlorofluorescin fluorescence.

**Results:** Exposure of ECs to high glucose conditions was associated with a significant increase in MP formation over 24 hrs as assessed by flow cytometry (~2.5-fold vs. osmotic control, $P<0.05$, n=4) and NTA (~2.5 fold vs. osmotic control, $P<0.01$, n=6). Similarly, high glucose increased MP formation from human vascular smooth muscle or proximal tubule epithelial cells, although it had no effect on human mesangial cell MP formation. Interestingly, exposure to 25 mM glucose increased the mean size of endothelial MPs (5.6 mM: 203±7 nm vs. 25 mM: 260±14 nm, $P<0.05$ n=6). Moreover, MPs generated under high glucose conditions were more potent inducers of endothelial cell ROS production than MPs generated under normal glucose (25 mM MPs: ~6-fold vs untreated control, 5.56 mM MPs: ~2.5 fold vs. control, $P<0.05$, n=4).

**Conclusions:** Our results suggest that elevated glucose is a potent inducer of endothelial MP formation while also increasing the pro-oxidative effects of endothelial MPs. Such effects may contribute to progressive endothelial injury in diabetes.

*Funding:* Government Support - Non-U.S.

## SA-PO313

**The Paradoxical Effect of Lycopene on Diabetic Nephropathy in Type 2 Diabetic Mice** Young Sun Kang,[1] Mi Jin Lee,[1] Jin Joo Cha,[1] Young Youl Hyun,[2] Ji Eun Lee,[3] Hyunwook Kim,[3] Jung Eun Kim,[1] Mihwa Lee,[1] Hye Kyoung Song,[1] Jee-young Han,[4] Dae R. Cha.[1] *[1]Nephrology, Korea Univ Ansan Hospital, Ansan, Kyungggido, Republic of Korea; [2]Nephrology, Sungkyunkwan Univ Kangbuk Samsung Hospital, Seoul, Republic of Korea; [3]Nephrology, Wongwang Univ Sanbon Hospital, Gunpo, Republic of Korea; [4]Pathology, Inha Univ Hospital, Incheon, Republic of Korea.*

**Background:** Lycopene, a dietary carotenoid found in fruits, has been under investigation for its anti-oxidant benefits in cancer, CVD, and the metabolic syndrome. There is rare data of lycopene in kidney disease. The aim of this study is to investigate the effect of lycopene on diabetic nephropathy in type 2 diabetic animal models.

**Methods:** 8-week-old male diabetic *db/db* mice were treated with vehicle or lycopene of 1mg/kg/day intraperitoneally for 4 weeks. The biochemical parameters were measured and RT-PCR, western blot analysis, and IHC were performed.

**Results:** After lycopene treatment, there was a noticeable decrease in body weight, food and water intake, urine amount, and blood sugar level. But, lycopene had no significant effect on plasma Cr level, HbA1c level, BP, and HR. Interestingly, Lycopene improved ITT(insulin tolerance test), plasma lipid profile such as total cholesterol, triglyceride and LDL cholesterol in diabetic mice group. However, lycopene aggravated renal injury in diabetic animal model. This result was the opposite of the known anti-inflammatory effect. Lycopene increased proteinuria, the expression of renal inflammatory markers of PAI-1, TGFb1, and TNF-a, and 8-isoprostane as the oxidative stress marker. It increased the gene expression of lipid-regulating enzyme of FAS, and activated the insulin signaling pathway of insulin receptor, p85, and IRS. More interestingly, lycopene suppressed the nephrin expression and it increased the expressions of Akt, MAPK, IR, P85, and IRS.

**Conclusions:** Lycopene presented the paradoxical effect of the aggravation of proteinuria via the insulin signaling and nephrin pathway, although it is believed to activate AMPK in liver leading to improve the metabolic syndrome. Our results suggest the anti-diabetic or anti-lipid agents are able to have a harmful effect on the kidney.

## SA-PO314

**Collagen-Secreting Angiogenic Macrophages in Diabetic Nephropathy** Chhanda X. Bose,[1] Sudhir V. Shah,[1] Sundararaman Swaminathan.[3] *[1]Dept of Internal Medicine, Div of Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR; [2]Dept of Internal Medicine, Div of Nephrology, Univ of Virginia Health System, Charlottesville, VA.*

**Background:** Inflammatory mechanisms, including recruitment of macrophages into the glomerulus and tubulointerstitial region, play an important role in diabetic nephropathy. In diabetic kidneys, macrophage development and accumulation is angiotensin II-dependent.

**Methods:** We examined the effect of high glucose and/or angiotensin II on cellular responses of peripheral blood mononuclear cells (PBMC) in vitro, specifically on the development of collagen-secreting angiogenic macrophages. Total PBMC were incubated with 5mM (normal) and 25 mM (high) glucose for 2-8 days. Angiotensin II (0.1 or 1.0 μM) was added to the cultures for 24h to 4 days using immunofluorescence and Western blot analysis to check the expression of CD163, the fibrotic marker procollagen-1, and the angiogenic markers lectin and acetylated LDL by human PBMC in hyperglycemic conditions.

**Results:** Treatment of cells with 25 mM glucose induced CD163 and procollagen-1 expression. When 1 μM angiotensin was added to the glucose-treated cells, procollagen and CD163 expression were further enhanced. Further, we demonstrate that collagen-expressing macrophages are angiogenic in nature, as lectin and acetylated LDL (the angiogenic markers) were markedly up-regulated by high glucose and angiotensin II. Western blot analysis of glucose and angiotensin-treated cells confirmed our observations from immunofluorescence studies. We also demonstrate the infiltration of CD163+ macrophages and procollagen-1+ cells in the interstitium of human kidneys with diabetic nephropathy.

**Conclusions:** Overall, we present a novel observation that collagen-secreting fibrotic and angiogenic macrophages are induced in PBMC, which are further augmented with low doses of angiotensin II in hyperglycemic conditions. The presence of these cells in vivo may be an important pathophysiological mechanism for progression in diabetic nephropathy.

## SA-PO315

**Association of Uromodulin Genetic Variant and Serum Levels with Renal Function in Diabetic Kidney Disease** Celine Klessens,[1] Verena Peters,[2] Claus P. Schmitt,[2] Ana Zutinic,[1] Emile De Heer,[1] Hans J. Baelde.[1] *[1]Pathology, Leiden Univ Medical Center, Leiden, Netherlands; [2]Pediatrics, Univ of Heidelberg, Heidelberg, Germany.*

**Background:** *CNDP1* codes for the enzyme carnosinase-1(CNDP1), in which the number of leucine repeats and resulting activity is associated with the susceptibility for diabetic nephropathy(DN) in woman with DM2. Considering the protective properties of carnosines, we hypothesize that local production and degradation in the kidney play a role in developing nephropathy in a subset DM2 patients.

**Methods:** Rabbit serum against CNDP1 and monoclonal antibody against carnosine synthase(CARNS) were used to investigate nephron segment-specific distribution of CARNS and CNDP1. Double label immune-stainings with megalin and Tamm Horsfall for the proximal and distal tubules respectively were performed. mRNA levels were measured in isolated glomeruli and whole kidney tissue from control and DN kidneys. Q-PCR was also performed on cultured podocytes, endothelial, mesangial and tubular cells.

**Results:** CNDP1 was predominantly detectable in the distal tubules and CARNS was found in proximal tubules(brush border pattern). In the glomerulus CNDP1 and CARNS were detectable to a lesser extent. mRNA measurements show expression of both CNDP1 and CARNS in the whole kidney, as well as in isolated glomeruli. We found high mRNA expression of *CARNS* and *CNDP1* in cultured podocytes, intermediate expression in mesangial and tubular cells, and very low expression in endothelial cells. No significant difference was found between normal and DN kidneys, but the mRNA expression levels of *CARNS* and *CNDP1* were significantly correlated(r=0.77).

**Conclusions:** We found evidence for local carnosin metabolism in the glomerulus (podocytes) as well as in the tubuli. mRNA level shows simultaneous regulation of both genes, which indicated common response elements in their promoters. The fact that their expression level is independent from diabetes provides the therapeutic opportunity to intervene in carnosine metabolism, since this can be manipulated without affecting diabetic disease. Future research will be focused on quantification and modulation of carnosine levels in DN kidneys.

## SA-PO316

**Oxidative Stress and Mitochondrial Disfunction in Genetic Model of Obese Rats** André Soares Trindade,[1] Thiago S. Rosa,[1] Priscila Afonso de Faria,[3] Anderson Sola de Haro,[1] Marcelo Macedo Rogero,[2] Tiago Rodrigues,[3] Elisa MS Higa.[1] *[1]Medicine, Universidade Federal de São Paulo, São Paulo, Brazil; [2]Shool of Public Health, Universidade de São Paulo, São Paulo, Brazil; [3]Natural and Human Science Center, Universidade Federal do ABC, Santo André, Sao Paulo, Brazil.*

**Background:** Obesity is characterized as chronic inflammatory disease associated with insulin resistance, increased activity of the renin-angiotensin-aldosterone system, and increased oxidative stress. In this study, the oxidative status and the mitochondrial integrity were screened in the cardiac, renal, and hepatic tissue by using the genetic model of obese rats (Zucker).

**Methods:** Isolation of rat mitochondria from liver, heart and kidney were isolated by standard differential centrifugation. Mitochondrial swelling was estimated from the decrease in the absorbance. The reduced glutathione (GSH) levels were estimated in a spectrofluorimeter by using OPT (o-phthaldialdehyde). The ROS generation was estimated by the changes in the DCF fluorescence, in a spectrofluorimeter. Statistical analysis were performed using the Microcal Origin 6.0 software.

**Results:** The homogenate and isolated mitochondria from liver of Zucker rats exhibited decreased GSH levels compared to Lean rats (33.3% and 46.5%, respectively). Similar result was found in the kidney homogenate but not in the isolated mitochondria. The production of ROS was significantly higher in the liver mitochondria from Zucker compared to Lean (50%), while no difference was observed in the heart. Mitochondria isolated from heart, liver and kidney were challenged with increasing Ca2+ concentrations and the swelling was higher in Zuckervs Lean, only in the liver.

**Conclusions:** Mitochondria from Zucker liver was more susceptible to permeabilization than that Lean. However, kidney and heart mitochondria showed no significant differences in the swelling. Our results show that obesity promotes oxidative stress with mitochondrial dysfunction primarily in the liver. Kidney and heart seems to be less affected. The increased susceptibility of liver mitochondria to permeabilization in obese rats may be associated to cell death and consequently to organ failure.

## SA-PO317

**Association of Uromodulin Genetic Variant and Serum Levels with Renal Function in Diabetic Kidney Disease** Krishan L. Gupta,[1] Vinod Sharma,[2] Ashok Kumar Yadav,[2] Vinay Sakhuja,[1] Vivekanand Jha.[1] *[1]Nephrology, PGIMER, Chandigarh, India; [2]Translational and Regenerative Medicine, PGIMER, Chandigarh, India.*

**Background:** Uromodulin a UMOD gene encoded 95kDa, glycoprotein exclusively synthesized in kidney cells and released into urine. Mutation in UMOD lead to Uromodulin misfolding and retention in kidney cells, where it interact and stimulate cells of immune system to cause inflammation and progression of chronic kidney disease (CKD). Diabetic nephropathy is one of the most severe complications of type 2 diabetes leading to end-stage renal disease (ESRD). Recent genome wide association studies have identified the Uromodulin locus associated with hypertension and diabetic nephropathy. This study was designed to investigate variations in UMOD genes with type diabetes mellitus (T2DM) and susceptibility to nephropathy.

**Methods:** A total of 649 subjects (196 T2DM subjects without nephropathy (DM), 167 with diabetic nephropathy stage II-IV (DN); 186 healthy control (HC ) and 40 DN stage V C KD) were genotyped for UMOD variant rs4293393T>C by restriction fragment length polymorphism (RFLP). Serum uromodulin levels were quantified by using human uromodulin enzyme linked immunosorbent assay (ELISA).

**Results:** A significant difference was found in genotype and allelic frequency of UMOD gene (rs4293393 T>C ) among DM, DN II-IV, DN-V, C KD and HC . UMOD TC /C C genotype and C allele were found to be significantly more frequent in DN II-IV, DN-V compared to DM and HC ($p<0.01$). Significant higher serum uromodulin levels 12/ 10/ 12 WCN 2013 : Abst r act # 452065 Pr eview www. cal4abst r act s. com/ wcn/ f inalpr eview. php?absnum=452065 2/ 2 were found in DN-II-IV and DN-V compared to DM

(<0.003). Serum uromodulin levels showed a positive correlation with serum creatinine (R=0.42; p<0.0001), stages of disease (R=0.47; p<0.0001) and negative correlation with eGFR (R=-0.42; p<0.0001).

**Conclusions:** This study shows that variations in UMOD rs4293393 T>C , might have a bearing on susceptibility to nephropathy in type 2 diabetes. Serum uromodulin levels are increased in subjects with decreased eGFR.

## SA-PO318

**Angiotensin II Inhibition Corrects Increased Oxygen Consumption in Diabetic Rat Kidneys** Aihua Deng, Roland C. Blantz, Scott C. Thomson. *Nephrology/Hypertension, UCSD&VASDHS, San Diego, CA.*

**Background:** Studies have demonstrated that angiotensin (ANG) II blockade has beneficial effects on chronic kidney disease, especially for diabetic nephropathy, but the mechanism is unknown. The present study tests our hypothesis that ANG II blockade corrects increased oxygen consumption ($QO_2$) in diabetic kidneys, which may be part of the mechanism underlying the therapeutic effects of ANG II blockade.

**Methods:** Rats were made diabetic by a single intraperitoneal injection of streptozotocin (65mg/kg,). 4 groups of rats were used: 1) Normal; 2) Diabetic rats (DM) untreated; 3) DM + dual ANG II inhibition; and 4) DM + apocynin. Captopril (C, 20mg/kg/day), losartan (L, 20 mg/kg/day) and apocynin (40 mg/kg/day) were administrated in the drinking water for 4 weeks. Glomerular filtration rate (GFR) and renal blood flow (RBF), $QO_2$ and renal metabolic efficiency ($QO_2/T_{Na}$, where $T_{Na}$ = total sodium reabsorbed) were measured at week 4 after induction of DM.

**Results:** Compared with the normal, in 4wk untreated diabetic kidney GFR and RBF tended to increase but did not reach statistical significance. $QO_2$ was double increased and renal metabolic efficiency was decreased indicated by an elevation of $QO_2/T_{Na}$. The altered $QO_2$ and $QO_2/T_{Na}$ were corrected by ANG II inhibition but not by apocynin, a NADPH oxidase inhibitor.

| | Normal | 4wk DM | 4wk DM+ C/L | 4wk DM + apocynin |
|---|---|---|---|---|
| GFR (ml/min) | 1.63±0.05 | 2.34±0.35 | 1.85±0.19 | 2.04±0.2 |
| RBF (ml/min) | 9.72±0.54 | 13.5±1.87 | 12.57±1.16 | 13.8±0.88 |
| $QO_2$ (ml/min) | 0.22±0.01 | 0.59±0.08* | 0.29±0.02** | 0.52±0.05* |
| $QO_2/T_{Na}$ (ml/mmole) | 1.03±0.07 | 1.90±0.07* | 1.27±0.11** | 1.94±0.09* |
| BP (mmHg) | 113±2 | 112±8 | 79±3* | 117±3 |

**Conclusions:** The normal kidney is on the border of hypoxia. A huge increase in $QO_2$ occurs in diabetic kidney, which may intensify renal tissue hypoxia. The substantial elevation of $QO_2/T_{Na}$ suggests that diabetic kidney has a much higher demand for $O_2$ to support Na transportation and nontransport events. Chronic ANG II inhibition reduces the demand for $O_2$ without altering GFR.

## SA-PO319

**High Fat Feeding Accelerates Decline of Renal Function in db/db Mice** Li-Jun Ma,[1] Margaret S. Wu,[1] Yonghua Zhu,[2] Qing Shao,[2] Emamuel Zycband,[2] Effie Tozzo.[1] *[1]Diabetes & Endocrinology, Merck Sharp & Dohme Corp.; [2]PPDM Molecular Biomarkers, Merck Sharp & Dohme Corp., Kenilworth, NJ.*

**Background:** Most animal models represent early stage of human diabetic nephropathy (DN). Few mouse models showed decline in renal function. Accelerating the development of DN in mice would be desirable for experimental validation of potential targets that mediate the progression to late stage DN.

**Methods:** 12 week old male db/db mice were fed high fat diet (HFD, 60% fat) for 6-8 weeks (n=8 per time point) and the development of nephropathy was compared to age-matched db/db mice on regular chow (n=8 per time point). Urinary albumin was determined using a mouse Albuwell ELISA kit (Exocell). Serum and urine Creatinine levels were measured by GC/MS. Mesangial expansion was scored semiquantatively (score 0-5). mRNA expression of MCP-1 and nephrin in renal cortex was assessed by qPCR. Urine MCP-1 levels were analyzed by a quantikine ELISA Kit (R&D).

**Results:** db/db mice challenged with HFD for 8 weeks showed increased body weight (54.1±1.5 vs 44.4±1.3 g, p<0.01), increased ratio of kidney weight/body weight (1.1±0.1 vs 0.9±0.1 %, p<0.05), decreased urine volume (3.1±0.3 vs 10.3±2.2 ml/24hr, p<0.01), increased ACR (15-fold, p<0.01), increased total urine protein (5.7±1.0 vs 1.6±0.4 mg/24hr, P<0.01), decline of renal function as evidenced by increased serum creatinine (1.2±0.4 vs 0.7±0.1 mg/dl) and decreased creatinine clearance rate (99±20 vs 475±122 ul/min/mouse, p=0.07), and increased mesangial expansion (2.8±0.1 vs 0.4±0.1, p<0.05). We assessed following biomarkers after HFD feeding in db/db for 6 weeks, and our data showed an upregulation of renal cortex MCP-1 mRNA expression (1.5 fold increase), an elevation of urine MCP-1 levels (894.3±192.9 vs 6.6±2.2 pg/ml, p<0.01) and downregulated nephrin mRNA expression (p<0.05) when compared to db/db on regular chow. It is of interest to note that all these above changes occurred in the absence of an increase in glucose levels.

**Conclusions:** HFD feeding accelerates decline of renal function in db/db mice and increases kidney and urine MCP-1 levels. We are in the process of testing diets with more intermediate HF content closer to human diet such as 20-30 % fat.

## SA-PO320

**Activation of $P2X_7$ Receptors and the Oxidative Stress in the Diabetic Nephropathy** Adelson M. Rodrigues,[1] Cassia T. Bergamaschi,[3] Maria José S. Fernandes,[5] Marcello Franco,[4] Giovana R. Punaro,[1] Fabiane R. Maciel,[2] Thamires Fernandes,[1] Guilherme B. Nogueira,[1] Elisa MS Higa.[1,2] *[1]Nephrology and Emergency Div, UNIFESP; [2]Translational Medicine, UNIFESP; [3]Cardiovascular Div, UNIFESP; [4]Investigative Pathology, UNIFESP; [5]Neurology, UNIFESP, Brazil.*

**Background:** Previous studies in our Laboratory showed the role of oxidative stress and the favorable effects of exercise training, on the progression of diabetic nephropathy in rats. $P2X_7$ receptors ($P2X_7$-R), in pathological conditions, are significantly up-regulated, increasing the levels of oxidative stress. The aim of this study was to evaluate the $P2X_7$-R and the oxidative stress in the kidneys of diabetic rats submitted to aerobic training.

**Methods:** Diabetes mellitus (DM) was induced in adult Wistar rats, with streptozotocin (60mg/kg, i.v.); control animals (CTL) received its vehicle. The animals were submitted to aerobic training on treadmill at a work rate of 16m/min for 60 min/day, 5 days a week/8weeks (DM+EX and CTL+EX); DM+SE and CTL+SE were kept resting on the treadmill at the same schedule (n=12 for each group). Half of the animals all groups were treated with N-acetylcysteine (NAC); the other, water as vehicle. One way ANOVA; significance at p<0.05.

**Results:** DM+SE vs CTL+SE increased the urinary excretion and renal tissue thiobarbituric acid reactive substances; there was also a reduced urinary excretion and renal tissue nitric oxide (NO). NAC and exercises reduced TBARS and increased NO in urine and the kidney. Confocal microscopy analysis of $P2X_7$-R in the kidneys showed with 100μM BZATP (preferential agonist to receptor) there was an increase in DM+SE vs CTL+SE (1.0 ±0.23 vs 0.14 ±0.06), which was reduced in groups received NAC (0.27 ±0.06), aerobic training (0.31 ±0.08) or both (0.17 ±0.04) , all p<0.05.

**Conclusions:** Our data show that the NAC administration, routine of exercise or both expressively decrease the activation of $P2X_7$-R in the kidneys of diabetic rats. The attenuation of oxidative stress through this mechanism, which also resulted in the increase of NO bioavailability, suggests that the control of these receptors' up-regulation could be useful to delay the progression of diabetic nephropathy.

## SA-PO321

**Diabetic Kidney Macrophages Display a Pro-Fibrotic Phenotype** Helena Cucak, Lisbeth N. Fink, Alexander Rosendahl. *Diabetes Research Unit, Novo Nordisk A/S, Maaloev, Denmark.*

**Background:** Diabetic nephropathy is one of the major complications of diabetes mellitus and is the leading cause of end-stage renal disease worldwide. Recently, it has been recognized that patients have low grade systemic inflammation, but how this is manifested on a cellular level in the diabetic kidney remains unclear. Experimental models suggest a central role for infiltrating macrophages in the pathogenesis, but their phenotype and the mechanism by which they contribute to tissue damage and fibrosis is unknown. Therefore, we evaluated the macrophage subsets present in the diabetic db/db and the healthy db/+ kidney during disease progression.

**Methods:** Kidneys from db/db and db/+ mice were enzymatically digested and kidney cell suspensions were analyzed by flow cytometry using an array of macrophage markers.

**Results:** 60% of the leukocytes in the kidney were macrophages in both healthy db/+ and diabetic db/db mice. The tissue derived macrophages could be divided into two major subsets based on expression of two cell surface markers; $CD68^+F4/80^+$ and $CD68^+F4/80^-$ macrophages. There were no differences in total macrophage numbers between diabetic and healthy kidneys. A similar fraction (40%) of both $CD68^+F4/80^+$ and the $CD68^+F4/80^-$ macrophages expressed CD206, a marker of alternatively activated 'M2' macrophages. In contrast, $CD68^+F4/80^-$ macrophages expressed 2.1-fold higher high levels of the 'M1' classical activation marker CD11c and displayed a 2.5-fold increase of the pro-fibrotic molecule galectin-3 compared to $CD68^+F4/80^+$ macrophages. Importantly, in diabetic kidney there was a clear shift towards a more pronounced pro-fibrotic macrophage phenotype. This was evident by 1.7-fold increased numbers of $CD68^+F4/80^-$ galectin-3-expressing cells, a 1.7-fold increase of TGFb-expressing $CD68^+F4/80^+$ cells, as well as a reduced CD11c expression.

**Conclusions:** We found that the db/db mouse kidneys are characterized by a qualitative phenotypic switch of resident macrophages towards more fibrotic phenotypes in late stage disease rather than a quantitative increase of macrophages. The emerging diabetic kidney macrophage subsets may possess a pathogenic function in the renal fibrosis central to the progression of diabetic nephropathy.

*Funding:* Pharmaceutical Company Support - Novo Nordisk A/S

## SA-PO322

**Megalin-Mediated Mechanism of High Fat Diet-Induced Kidney Disease** Michihiro Hosojima,[1] Shoji Kuwahara,[2] Hideyuki Kabasawa,[1] Hiroyuki Aoki,[2] Reika Kaneko,[2] Ichiei Narita,[1] Akihiko Saito.[2] *[1]Clinical Nephrology, Niigata Univ, Niigata, Japan; [2]Applied Molecular Medicine, Niigata Univ, Niigata, Japan.*

**Background:** Megalin, an endocytic receptor in proximal tubule cells (PTECs), is involved in uptake and metabolism of glomerular-filtered substances. This study aimed to investigate the role of megalin in high fat diet (HFD)-induced kidney disease.

**Methods:** Kidney-specific mosaic megalin KO mice (apoE cre+/-, megalin loxP+/+, ~60% megalin knocked out) and control mice (apoE cre-/-, megalin loxP+/+) were

uninephrectomized at age 10 weeks and fed a HFD (60% fat energy ratio) or normal fat diet (NFD) (10% fat energy ratio) for 12 weeks. Mice overexpressing LC3-GFP, an autophagosome marker, were also studied under the same protocol.

**Results:** Mice fed a HFD showed increases in body weights and blood glucose levels, compared with NFD-fed mice, with no differences in these parameters between HFD-fed megalin KO and control mice. In HFD-fed control mice, cytosolic vacuolar formation was observed in PTECs with increased nuclear expression of p27, a marker of cellular hypertrophy. The vacuoles were found to contain osmium-stained, onion-skin-like structures by electron microscopy. The vacuolar membranes were immunostained with LAMP1, LC3 and p62, indicating that the vacuoles were derived from dysfunctional autophagolysosomes. Autophagy in PTECs was actually impaired after 24-hr fasting in HFD-fed LC3-GFP transgenic mice. However, the vacuolar formation in PTECs was significantly suppressed in HFD-fed mosaic megalin KO mice with decreased nuclear expression of p27. Peritubular capillary rarefaction, demonstrated by decreased CD31 immunostaining, was induced in HFD-fed control mice, which was ameliorated in HFD-fed megalin KO mice. Glomerular hypertrophy with mesangial expansion, evident in HFD-fed control mice, was also ameliorated in HFD-fed megalin KO mice. Advanced glycation endproduct-modified BSA, an endocytic ligand of megalin, induced giant autophagolysosme formation in cultured PTECs.

**Conclusions:** In conclusion, megalin-mediated autophagolysosomal dysfunction in PTECs is primarily associated with the development of tubulo-glomerular alteration in HFD-induced kidney disease.

## SA-PO323

**Linagliptin Ameliorates Free Fatty Acid-Bound Albumin-Induced Tubulointerstitial Injury**

Yuki Tanaka,[1] Shinji Kume,[1] Shin-ichi Araki,[1] Daisuke Koya,[2] Masakazu Haneda,[3] Takashi Uzu,[1] Hiroshi Maegawa.[1] *[1]Dept of Medicine, Shiga Univ of Medical Science, Otsu, Shiga, Japan; [2]Dept of Diabetology and Endocrinology, Kanazawa Medical Univ, Kahoku, Ishikawa, Japan; [3]Div of Metabolism and Biosystemic Science, Asahikawa Medical Univ, Asahikawa, Hokkaido, Japan.*

**Background:** Severe proteinuria-induced tubulointerstitial injury indicates poor renal prognosis in patients with diabetic nephropathy. Establishment of new therapeutic strategy against proteinuria-induced tubulointerstitial injury in diabetic nephropathy is required. Dipeptidyl peptidase (DPP) 4 inhibitors, a new class of oral antidiabetic agents for type 2 diabetes, have recently been suggested exerting pleiotropic effects beyond glucose lowering.

**Methods:** We thus examined renoprotective effect of linagliptin, a DPP4 inhibitor, on free fatty acids (FFA)-bound albumin-induced tubulointerstitial injury in mice. Mice were fed either standard diet (SD) or SD with linagliptin, and intraperitoneally injected with FFA-bound albumin or PBS for 11 days. In addition, renoprotective effect of linagliptin was examined in cultured mouse proximal tubular (mProx) cells stimulated with FFA-bound albumin.

**Results:** We first confirmed that neither FFA-bound albumin injection nor linagliptin treatment altered systemic characteristics including body weight, fasting blood glucose and food intake. In SD group, FFA-bound albumin caused tubular cell apoptosis, interstitial inflammation characterized by macrophage infiltration and increased mRNA expression of inflammatory cytokines, such as MCP-1, IL-6 and TNF-α, and interstitial fibrosis with increased expression of fibronectin and PAI-1. These alterations were all prevented by the treatment with linagliptin. Furthermore, in cultured mProx cells, linagliptin inhibited FFA-bound albumin-induced increases in mRNA expression level of inflammatory cytokines and fibrotic markers.

**Conclusions:** These results indicate that DPP4 inhibitors exert anti-inflammatory and anti-fibrotic effect as an additional pleiotropic effect, and may serve as a therapeutic strategy to protect proximal tubular cells against proteinuria in patients with diabetic nephropathy.

## SA-PO324

**Linagliptin-Mediated DPP-4 Inhibition Ameliorates Kidney Fibrosis in Streptozotocin-Induced Diabetic Mice by Inhibiting Endothelial-to-Mesenchymal Transition**

Keizo Kanasaki, Shi Sen, Megumi Kanasaki, Swayam Prakash Srivastava, Daisuke Koya. *Diabetology and Endocrinology, Kanazawa Medical Univ, Kahoku, Ishikawa, Japan.*

**Background:** Kidney fibrosis is the final common pathway of all progressive chronic kidney diseases, of which diabetic nephropathy is the leading cause. Endothelial-to-mesenchymal transition (EndMT) has emerged as one of the most important origins of matrix-producing fibroblasts. Dipeptidyl peptidase-4 (DPP-4) inhibitors have been introduced into the market as anti-diabetic drugs.

**Methods:** Diabetes was introduced in CD1 mice by streptozotocin injection and some of the diabetic mice were treated with linagliptin (5mg/kgBW/day) 20 weeks after diabetes initiation. At 24 weeks after initiation of diabetes, all mice were sacrificed. In in vitro experiment, we used human dermal microvascular endothelial cells and analysed anti-EndMT effects of linagliptin.

**Results:** Streptozotocin-induced diabetic CD1 mice exhibited severe kidney fibrosis and strong immunoreactivity for DPP-4 24 weeks after the onset of diabetes. Linagliptin-treated diabetic mice exhibited an amelioration of kidney fibrosis and restored normal kidney structure. These anti-fibrotic effects of linagliptin were associated with the inhibition of EndMT. The therapeutic effects of linagliptin on diabetic kidneys were associated with the suppression of profibrotic programs, as assessed by mRNA microarray analysis. We found that the induction of DPP-4 observed in diabetic kidneys may be associated with suppressed levels of microRNA29s in diabetic mice. Using cultured endothelial cells, we found that linagliptin inhibited TGFβ2-induced EndMT and the motility of fibroblast-like EndMT cells.

**Conclusions:** These results indicate the possible novel pleiotropic action of linagliptin to restore normal kidney function in diabetic patients with renal impairment.

*Funding:* Private Foundation Support, Government Support - Non-U.S.

## SA-PO325

**Autophagy Maturation Interruption in CKD and Diabetic Nephropathy**

Ying Wang,[1] Cynthia C. Nast,[2] Janine A. La Page,[1] Sharon G. Adler.[1] *[1]Nephrology, LABiomed Research Institute, Torrance, CA; [2]Pathology, Cedars-Sinai Medical Center, LA, CA.*

**Background:** Autophagy (Atg),induced by cell stress, aids in repair in modest injury, but facilitates death in major injury.DBA2J mice lack HGFIN (aka gpnmb) and are Atg insufficient. HGFIN recruits the Atg protein LC3B-II to autophagosomes (AP)(Li et al: FASEB J, 2010). Renal HGFIN mRNA is increased in rat SZ-DN & Type 1 DN. After 5/6Nx, HGFIN co-localized with LC3B in injured tubules (KI 79:1138-48). We tested if high glucose (HG) stimulates HGFIN and Atg in vitro, and if the DBA2J genome contributes to initiation/progression in CKD or DN in DBA2Js, Akitas (Ak, $Ins2^{+/-}$), & backcrossed Akitas (Ak/DBA2J).

**Methods:** 1. HGFIN was localized by immunohistochemistry (IH) in DN patients. 2. MDCT cells +/- HGFIN overexpression were cultured in normal (5.5 mM) or HG (10-25 mM) medium. LC3B activation (LC3B-II/I) was immunoblotted. 3. In mice, we measured urine ACR, plasma glucose (Glu), BUN, performed kidney lysate immunoblotting for LC3B-II/I and the autophagolysosome protein LAMP2, and assessed kidney light and electron microscopies (LM, EM) at 6 mos.

**Results:** 1. In DN patients, HGFIN was increased in glomerular & cortical tubular epithelial cells. 2. In vitro in the absence of Atg blockade, HG and HGFIN overexpression increased the LC3B-II/I ratio additively ($p<0.05$). 3. Glu was similarly elevated in Ak and Ak/DBA2Js (NS); normal in DBA2J. 4. ACR was highest in Ak/DBA2J; higher in non-diabetic DBA2Js than Ak at 3 mos ($p<10^{-4}$), then increased over the next 3 mos ($p<0.05$), and was similar to Ak as DN advanced in mos 4-6. 5. Mean BUNs were similar in DBA2J and Ak and higher in Ak/DBA2J (34, 35, 66 mg/dl; NS) 6. Renal lysate LC3BII/I was highest in mice with DBA2J and LAMP2 lowest in mice with DBA2J, consistent with arrested AP maturation contributed by DBA2J. 7. LM cytoplasmic tubule vacuoles (AP by EM) in DBA2J and Ak/DBA2J further substantiate AP maturation block.

**Conclusions:** In vitro, without Atg blockade, HG stimulated HGFIN and Atg. In vivo, high LC3BII/I and low LAMP2 implicate DBA2J contributing to initiation/exacerbation of CKD/DN, at least in part by interrupting Atg at the AP step. Modulating Atg and/or HGFIN may be renoprotective in CKD/DN.

## SA-PO326

**Tadalafil Integrates Nitric Oxide-Hydrogen Sulfide-AMPK Pathway to Inhibit High Glucose-Induced Matrix Protein Synthesis in Podocytes**

Hak Joo Lee, Denis Feliers, Meenalakshmi M. Mariappan, Kavithalakshmi Sataranatarajan, Yves C. Gorin, Goutam Ghosh-Choudhury, Balakuntalam S. Kasinath. *Univ of Texas Health Science Center, San Antonio, TX.*

**Background:** Hydrogen sulfide ($H_2S$) inhibits high glucose (HG)-induced matrix increment in renal cells. We hypothesized that tadalafil (Tada) inhibits HG stimulation of matrix proteins by generating $H_2S$ in podocytes.

**Methods:** Mouse podocyte culture, Immunoblotting, Polysome analysis.

**Results:** Tada abrogated 30 mM (HG)-induced increase in global protein synthesis, cellular hypertrophy, and, laminin$\gamma$1 and fibronectin expression. Tada abrogated critical events in mRNA translation induced by HG by inhibiting mTORC1. As AMPK inhibits HG-induced protein synthesis, its role was examined. Tada dose- and time-dependently stimulated AMPK phosphorylation. Compound C (AMPK inhibitor) abolished Tada effect on HG stimulation of mTORC1, mRNA translation and laminin$\gamma$1 synthesis. Tada rapidly increased the expression of cystathionine-γ-lyase (CSE), a $H_2S$ generating enzyme, by promoting translation of its mRNA (Polysome analysis) and not by transcription. DL-propargylglycine (PAG), a CSE inhibitor, inhibited Tada-induced AMPK phosphorylation and abrogated Tada effect on HG stimulation of laminin$\gamma$1. As Tada promotes cGMP accumulation by PDE5 inhibition, we examined the role of nitric oxide (NO) pathway. Tada rapidly augmented inducible nitric oxide synthase (iNOS) expression by increasing transcription. L-NAME and ODQ, inhibitors of NOS and guanylyl cyclase, abolished Tada induction of $H_2S$ and AMPK phosphorylation. DETA-NONOate and sodium nitroprusside, 2 structurally distinct NO donors, mimicked Tada effect on CSE expression and AMPK phosphorylation. Tada given intraperitoneally to normal mice augmented kidney expression of CBS and stimulated AMPK activity.

**Conclusions:** Tada ameliorates HG stimulation of synthesis of proteins including matrix proteins in mouse podocytes. This requires sequential stimulation of NO-$H_2S$-AMPK axis leading to inhibition of HG-induced mTORC1 activity and mRNA translation. Thus, Tada integrates NO-cGMP pathway with $H_2S$-AMPK axis to inhibit HG effect on podocytes, bringing together two gaseous signaling molecules.

## SA-PO327

**Resveratrol Ameliorated High-Glucose Induced Oxidative Stress through Nrf2 Activation** Min Zhang, Chuanming Hao. *Nephrology Div, Huashan Hospital, Shanghai, China.*

**Background:** Hyperglycemia-mediated oxidative stress plays a crucial role in the progression of DN. Nrf2 controls the ARE-dependent gene regulation in response to oxidative stress. Resveratrol is a polyphenolic phytoalexin that exhibits benefits including antioxidant and anti-inflammatory. Resveratrol is also shown to confer renoprotection in animal models of type 2 diabetes. However, the mechanisms by which resveratrol exerts its antioxidative protective effects are not completely understood.The current study is aimed at examining the mechanism of resveratrol on defense against high glucose-induced oxidative damage in glomerular endothelial cells.

**Methods:** Endothelial cells were serum starved for 24h, and then exposed to media containing low glucose plus mannitol (2.5mM+22.5mM, LG+M), normal glucose plus mannitol(5mM+20mM, NG+M) or high glucose (25mM, HG) with resveratrol(1,5,10,25μM) for 24 hours. Then the cells were treated with Nrf2 activator sulforaphane (Sigma, USA) or transfected with Nrf2-siRNA. Cells were harvested for either protein or RNA assay. The expression levels of Nrf2, HO-1 and SIRT1 were measured by Western blot and qPCR. For ROS measurement, cells were incubated for 30 min with H2DCFDA (Sigma,USA), and the fluorescence intensity was measured by flow cytometry.

**Results:** High glucose increased ROS production in glomerular endothelial cells. The expression levels of SIRT1 and Nrf2 were down-regulated at high glucose concentration ($P<0.05$). Sulforaphane, an agonist of Nrf2, significantly increased the expression of HO-1 and decreased the production of ROS. Resveratrol, in a dose-dependent manner, significantly increased expression level of Nrf2. Accordingly, resveratrol significantly upregulated the expression of the Nrf2 target gene: HO-1. Resveratrol treatment also significantly attenuated high glucose-induced oxidative stress.The aforementioned effects were significantly attenuated by the small interfering RNA downregulation of Nrf2. The results of co-immunoprecipitation showed a relationship between Nrf2 and SIRT1.

**Conclusions:** Our results indicated that resveratrol ameliorated high-glucose induced oxidative stress through Nrf2 activation.

## SA-PO328

**Effect of an Oral Adsorbent AST-120 on Proteinuria, Albuminuria and Oxidative Stress in Metabolic Syndrome/Diabetes Rats** Rieko Aoki, Fujio Sekine, Yusuke Yamashita, Kaori Kikuchi, Kenji Bannai, Ryoko Tateoka, Yoshiharu Itoh. *Kureha Corporation, Tokyo, Japan.*

**Background:** Metabolic syndrome is known to be an important risk factor involved in the development of diabetic nephropathy. An oral adsorbent AST-120 has been used clinically as a drug for treatment of chronic kidney disease (CKD) patients to slow the progression of CKD. However, there is little evidence when AST-120 should be prescribed for subjects with early stage overt diabetic nephropathy. In this study, we aimed to assess the effect of AST-120 in the early stage of nephropathy using SHR/NDmc-cp, a rat model of metabolic syndrome/ type 2 diabetes.

**Methods:** Male SHR/NDmc-cp (SHR/ND) rats, aged 7 weeks, were administered 0% or 8% AST-120 for 12 weeks in their diets. WKY rats were used as a normal. At every 4 weeks, serum and 24-hour urine samples were collected for biomedical studies. We analyzed serum metabolites in normal and SHR/ND rats with or without AST-120 for 8 weeks by capillary electrophoresis mass spectrometry with time-of-flight (CE-TOFMS) and applied CE-TOFMS data to principal component analysis (PCA). We also examined the gene expression of oxidative stress markers by real-time PCR and the glomerular podocyte damage by immunohistochemistry in renal tissues treated with or without AST-120.

**Results:** AST-120-administered SHR/ND rats showed significantly lower level of urinary albumin excretion, urinary protein excretion and urinary 8-OHdG excretion as compared with SHR/ND rats. PCA score plot showed clear separation among three groups (Normal, SHR/ND and AST-120-administered SHR/ND). We could detect 40 metabolites, such as o-hydroxybenzoic acid, hippuric acid and indole-3-acetic acid, which accumulated in the serum of SHR/ND rats, and of which serum levels were reduced by administration of AST-120. The gene expression of oxidative stress markers in renal tissues was lower in AST-120-administered SHR/ND rats than in SHR/ND rats. And also the ratio of podocyte injured maker, desmin, positive glomeruli was lower in AST-120-administered SHR/ND rats than in SHR/ND rats.

**Conclusions:** It indicated that the administration of AST-120 at an early stage has a protective effect on the progression of diabetic nephropathy.

## SA-PO329

**Inflammation Stress Induces Lipid Redistribution in db/db Mice via the Disruption of LDL Receptor Pathway** Kun Ling Ma,[1] Yang Zhang,[1] Jing Liu,[1] Wu Yu,[1] Bi-Cheng Liu.[1] *[1]Institute of Nephrology, Southeast Univ School of Medicine, Nanjing, China; [2]Institute of Nephrology, Southeast Univ School of Medicine, Nanjing, China; [3]Institute of Nephrology, Southeast Univ School of Medicine, Nanjing, China.*

**Background:** Dyslipidemia and inflammation play crucial roles in the progression of diabetic nephrology (DN). Our previous studies *in vivo* and *in vitro* demonstrated that inflammation induced lipid accumulation in liver, aorta, and kidney in apolipoprotein E knockout mice through the disruption of low-density lipoprotein receptor (LDLr) feedback regulation. This study aimed to investigate the effects of inflammation on lipid redistribution in DN.

**Methods:** Twenty db/db mice were injected with casein to induce an inflamed DN model.Serum levels of inflammatory cytokines and lipid profile were respectively measured by enzyme-linked immunosorbent assay and clinical biochemistry assay. The effects of inflammatory stress on lipid accumulation in liver, aorta, and kidney were evaluated by hematoxylin-eosin staining, Oil Red O staining, filipin staining, and intracellular cholesterol quantitative assay. The protein expression of low density lipoprotein receptor (LDLr), sterol regulatory element binding protein-2 (SREBP-2) and SREBP-cleavage-activating protein (SCAP) in tissues was checked by immunohistochemical staining, immunofluorescent staining, or Western blotting.

**Results:** Significantly elevated serum levels of tumour necrotic factor-α and serum amyloid A in casein injected mice confirmed successful induction of inflamed diabetic model. Serum levels of lipid profile (total cholesterol and triglyceride, LDL and high density lipoprotein) in flamed mice were no obvious difference compared to the controls. Inflammatory stress increased lipid accumulation in liver, aorta, and kidney. Further analysis showed that inflammatory stress increased the protein expression of LDLr, SREBP-2, and SCAP in liver, aorta, and kidney of inflamed mice.

**Conclusions:** Inflammatory stress may induce lipid redistribution of db/db mice from circulation to target organs. The potential mechanism is through the disruption of LDLr feedback regulation.

## SA-PO330

**Role of HDAC in the Development of Type 2 Diabetes Related Nephropathy** Hang Yuan, Nian Liu, Ye Jia, Yingchun Cui, Ping Luo, Lining Miao. *Div of Nephrology, Second Hospital of Jilin Univ, Chang Chun, Ji Lin, China.*

**Background:** Histone deacetylase (HDAC) emerged as a new molecular target in the control of obesity and type 2 diabetes. Inhibition of HDACs has been demonstrated as players in ameliorated renal fibrosis, and the internal mechanism is associated with profibrotic genes regulation such as collagen and PAI-1. But the role of HDACs in the process of diabetic complications development is still unclear. In this study, we evaluated potential role of HDAC in type 2 diabetes related nephropathy.

**Methods:** Blood karyocyte and serum were separately collected from 20 health adults, new diagnosed type 2 diabetes (18 cases) as well as type 2 diabetic renal dysfunction patients (23 cases). We detected HDAC genes expression by QRT-PCR. In vivo relevance was tested using renal cortex come from high fat diet with streptozotocin injection induced type 2 diabetic rat, as well as diabetic rat fed with valproic acid, which was known as HDAC inhibitor.

**Results:** In compare with health adults, HDAC 1, 2, 3, 4, 10, 11 mRNA expression were increased in new diagnosed diabetes patients; while HDAC 2, 5, 9, 11 and SIRT 1 mRNA expression were significantly enhanced but HDAC 10, SIRT 4 expression decreased in diabetic renal dysfunction patients compared with new diagnosed diabetes patients. Interestingly, in vivo results showed that diabetic rats have more HDAC 1, 2, 3, 5, 11 mRNA expression in the renal cortex in compare with none diabetic control group; valproic acid administration inhibited HDAC 1, 2, 3, 11 expression; at same time increased proteinuria as well as profibrotic genes such as collagen 1a1, CTGF and α-smooth muscle actin (α-SMA) in diabetic kidney were attenuated by valproic acid.

**Conclusions:** These results demonstrate that overexpressed HDACs such as HDAC 1, 2, 3, 5, 9, 11 may involve in the pathogenesis of type 2 diabetes and related nephropathy; select inhibition of HDACs by valproic acid attenuated renal fibrotic genes expression and diabetes related proteinuria, therefore suggest HDACs might be a new target in the control of diabetic nephropathy.

## SA-PO331

**Non-Esterified Fatty Acid Levels Modulate Adiponectin and Insulin Sensitivity in a Rat Model of Type 2 Diabetes Mellitus through a Nitric Oxide Dependent Mechanism** Sharma S. Prabhakar. *Internal Medicine, Texas Tech Univ Health Sciences Center.*

**Background:** Mechanisms leading to insulin resistance in type 2 diabetes mellitus (T2DM) remain incompletely understood. Adiponectin levels and signaling mechanisms are down regulated in obesity induced T2DM. Recent work from our laboratory showed that angiotensin blockade enhanced insulin sensitivity besides the renoprotection in diabetic rats (J Invest Med 2013). We hypothesized that adiponectin activity and insulin signaling is regulated by non-esterified fatty acid (NEFA) levels in obesity induced DM.

**Methods:** To test our hypothesis we used obese ZSF rat, a murine model of T2DM previously characterized in our laboratory (JASN 2007). Lean ZSF rats were used as controls as they do not develop DM. Obese rats were fed high calorie diet while control rats were given standard rat chow. Another group of obese ZSF rats received losartan (1mg/ml). All rats were obtained at 7th week and euthanized at 26 weeks and adipose tissue harvested. Plasma samples were collected at the start and end of the study to measure adiponectin (by ELISA), NEFA levels(by colorimetric assay) and Nitric Oxide metabolites or Nox (by chemiluminescence). Adipose tissue was homogenized and the protein was examined for the expression of adiponectin receptor 1, insulin receptor substrate 1 and glucose transporter GLUT 4 using immunoblotting.

| Group | Lean | Obese | Obese+Losartan |
|---|---|---|---|
| Adiponectin (μg/ml) | 4.15±0.56 | 2.93±0.44* | 3.89± 0.39 |
| NEFA (mM/L) | 0.194± 0.021 | 0.562± 0.042# | 0.275± 0.033 |
| NOx (μM) | 28±3.1 | 7.8±1.6# | 13.5± 2.4* |

N=6 in all groups, *p,0.01 #p<0.001 compared to lean rats.

**Results:** Our results showed that the plasma levels of adiponectin and NOx were decreased and NEFA levels increased in obese ZSF rats compared to lean ZSF rats. Furthermore the expression of AdipoR1 and IRS1 and GLUT4 were decreased in fat cells of obese rats compared to lean counterparts. Losartan treatment increased NOx and adiponectin levels and insulin sensitivity.

**Conclusions:** We conclude that NEFA may be involved in modulation of adiponectin activity and insulin signaling through mechanisms that involve NO generation in murine T2DM.

**Glycemic Memory in Diabetes Nephropathy, Potential Role of SHP-1**
Farah Lizotte,[1] Nicolas Drapeau,[1] Andréanne Guay,[1] Chris R. Kennedy,[2] Marie-Odile Guimond,[1] Pedro Miguel Geraldes.[1] *[1]Medecine, Div of Endocrinology, Univ of Sherbrooke, Quebec, Canada; [2]Kidney Research Center, Canada.*

**Background:** Renal podocytes apoptosis induced by hyperglycemia and insulin resistance is an early event leading to diabetic nephropathy (DN).Intensive blood glucose control reduced the development of DN. However, if not started early in the disease, it is not sufficient to prevent DN progression, introducing the concept of **"**glycemic memory**"**. Recent studies demonstrated that SHP-1, a protein tyrosine phosphatase, is elevated in renal cortex of type 1 diabetic mice (Akita)causing insulin unresponsiveness and DN. We hypothesize that SHP-1 expression remains elevated in spite systemic blood glucose normalization after 4 months of diabetes that triggers insulin inhibition, podocytes apoptosis and glycemic memory in DN.

**Methods:** The in vivo contribution of SHP-1 in glycemic memory was evaluated using Akita mice treated with insulin implants after 4 months of diabetes. Also, mouse and human podocytes were cultured in normal (5.6mM; NG), high glucose concentrations (25mM; HG) or HG prior returning glucose levels to NG for an addition 24-48h (HG+NG).

**Results:** Renal function was assessed by measuring urinary albuminuria secretion and glomerular filtration rate. Both parameters were significantly increased in diabetic mice and remained elevated after normalization of blood glucose levels, compared to non-diabetic mice. Renal dysfunction was associated with a 98% increase of SHP-1 expression in renal cortex and insulin action inhibition that were not normalized following insulin implants to decrease glucose levels. In vitro, we observed that Akt and ERK phosphorylation induced by insulin (10 nM) was reduced in HG and maintained lower following glucose normalization (HG+NG). The increase of SHP-1 protein and mRNA expression in HG conditions remained elevated in spite returning glucose concentration from HG to NG.

**Conclusions:** In conclusion, hyperglycemia causes persistent and irreversible high expression of SHP-1 leading to podocyte unresponsiveness to insulin leading to glycemic memory in DN.

## SA-PO333

**TGF-β1-Mediated Signalling Is Increased by TZDs through Increased IHG-1 Expression**
Fionnuala B. Hickey,[1] James B. Corcoran,[2] Finian Martin,[2] Madeline Murphy,[2] Catherine Godson.[2] *[1]Trinity Health Kidney Centre, Trinity College Dublin, Dublin 2, Ireland; [2]UCD Diabetes Complications Research Centre, Univ College Dublin, Dublin 4, Ireland.*

**Background:** *Induced in high glucose-1* (IHG-1) is a highly conserved transcript upregulated in experimental models of renal fibrosis and in human diabetic nephropathy (DN). We have reported that IHG-1 enhances responses to TGF-β1 [Murphy *et. al.* JASN 2008]. IHG-1 is a mitochondrial protein and increases mitochondrial mass through stabilisation of PPARγ coactivator 1-alpha (PGC-1α) [Hickey *et. al.* JASN 2011]. Thiazolidinediones (TZDs) are PPARγ agonists that act as insulin sensitising agents and are effective therapeutic agents in diabetes. Here we have explored the effect of TZDs on TGF-β1-mediated signalling and fibrosis.

**Methods:** mRNA was measured by qRT-PCR. Mitochondrial biogenesis was assessed by comparison of mitochondrial to nuclear DNA and by analysis of a TFAM promoter reporter. Oxygen consumption was measured using a Seahorse XF analyser. TGF-β1-mediated signalling was analysed via western blotting. Expression of endogenous IHG-1 was inhibited using tetracyclin-inducible shRNAi.

**Results:** We demonstrate that increased IHG-1 expression in a human kidney epithelial cell line (HK2) results in enhanced mitochondrial biogenesis and oxygen consumption. We have confirmed that TZDs increase mitochondrial biogenesis. Critically we report that treatment of renal epithelial cells with TZDs results in increased IHG-1 expression. Renal tubular hypoxia has been proposed as a mechanism of disease in DN. In this context it is likely that increased oxygen consumption due to upregulated IHG-1 would exacerbate tubulointerstitial hypoxia. In addition, we demonstrate IHG-1-dependent enhancement of TGF-β1-mediated signalling downstream of TZDs.

**Conclusions:** Increased mitochondrial biogenesis has been postulated as a therapeutic benefit of TZDs. However, sustained increases in mitochondrial biogenesis would lead to elevated levels of IHG-1, which we have linked to increased oxygen consumption and enhanced TGF-β1-mediated signalling. Taken together, this leads us to hypothesise that TZD-mediated increases in IHG-1 may drive the hypoxia-fibrosis axis in DN.

## SA-PO334

**Astragaloside IV Attenuates Glycated Albumin-Induced Proximal Tubular Epithelial-to-Mesenchymal Transition via Inhibiting ERK1/2 and JNK Phosphorylation**
Yong Gu,[1,2] Jianying Niu,[1] Weiwei Qi.[1] *[1]Div of Nephrology, The Fifth People's Hospital of Shanghai, Fudan Univ, Shanghai, China; [2]Div of Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China.*

**Background:** Diabetic kidney disease (DKD) is the leading cause of end-stage renal disease (ESRD) in developed countries. Tubulointerstitial accumulation of extracellular matrixc leads to tubulointerstitial fibrosis which closely correlates with the development of ESRD. The epithelial-to-mesenchymal transition (EMT) is the main source of ECM in kidney. Our previous study showed that glycated albumin (GA) could cause EMT in tubular cells and Astragaloside IV (AS- IV), the main active ingredients of *Astragalus membranaceus,* alleviated such damage by inhibiting oxidative stress. In order to further study the mechanism of AS-IV on tubular cells in DKD, we observed the changes of redox balance and MAPK pathway by adding AS-IV under GA stimulation.

**Methods:** The NRK-52E cells's intercellular reactive oxygen species (ROS) level was detected by $H_2$ DCFDA. NADPH oxidase activity was assayed by adding exogenous NADPH oxidase. The activities of superoxide dismutase (SOD), glutathione peroxides (GSH-Px) and catalase (CAT) were tested by assay kit. Western blot was used to examine the protein expression of α-SMA, E-cadherin, phosphorylation of ERK1/2, JNK and p38 MAPKs.

**Results:** AS-IV significantly attenuated GA-induced generation of ROS, lowered the increased level of NADPH oxidase activity. GA reduced the contents of SOD, GSH-Px and CAT in NRK-52E cells but there was no obvious change by adding AS-IV. Moreover, GA-induced NRK-52E cells showed increased expression of α-SMA and decreased expression of E-cadherin which could be attenuated by AS-IV. GA stimulated the phosphorylation of ERK1/2, p38 and JNK and AS-IV reversed the changes in ERK1/2 and JNK but not p38 phosphorylation.

**Conclusions:** Our data demonstrate that GA could induce tubular cells EMT through oxidative stress. Supplementation of AS-IV attenuates GA-induced EMT. AS-IV weakens the oxidative stress by inhibited NADPH oxidase activity but not increasing the contents of antioxidants. ERK1/2 and JNK intracellular signaling pathways, not p38 pathway, mediate the effect of AS-IV on EMT.

## SA-PO335

**PKC-Alpha Mediates Albuminuria by Heparanase-Dependent Loss of Endothelial Cell Glycocalyx in Diabetic Mice**
Joon-Keun Park, Torsten Kirsch, Nelli Shushakova, Anna Bertram, Putri Andina Agustian, Jan Menne, Hermann G. Haller. *Clinic of Hypertension and Nephrology, Hannover Medical School, Hannover, Germany.*

**Background:** We have recently demonstrated that hyperglycemia induces albuminuria in hyperglycemic mice via the activation of PKC isoform alpha. Since the polysaccharide-rich endothelial glycocalyx and surface layer (ESL) acts as a filtration barrier, and heparanase is the predominant enzyme that degrades heparan sulfate (HS), the main polysaccharide of the ESL we tested the hypothesis that PKC-alpha in hyperglycemia leads to loss of ESL on glomerular endothelium via the activation of heparanase.

**Methods:** PKC-α-/- and wild-type (WT) mice received STZ or buffer. After 2 or 8 weeks of hyperglycemia, the animals were analyzed. Albumin in urine was measured by ELISA. Immunohistochemistry was performed on cryostat /paraffin sections. EM analysis of ESL was carried out after perfusion with Alcian blue. Gene and protein expression was analyzed by real-time qPCR and western blot analysis.

**Results:** PKC-α was predominantly expressed in the glomeruli. Under diabetic conditions, an increased expression of PKC-α in glomeruli was observed. The increase in albumin excretion was prevented in hyperglycemic PKC-α-/- mice. Only a weak expression of heparanase was observed in nondiabetic control animals of both groups. Under hyperglycemic conditions, a significant increase of heparanase was observed in the WT but not in PKC-α-/- mice. Loss of HS in the glomeruli was significantly reduced in PKC-α-/- mice. We also observed that ESL-associated molecules such as thrombomodulin were regulated by PKC-α.

**Conclusions:** Hyperglycemia-mediated loss of endothelial glycocalyx is mediated by the PKC isoform alpha. PKC-alpha regulates heparanase expression under diabetic conditions. Inhibition of PKC-alpha in diabetic nephropathy may restore damaged glycocalyx and thereby influence inflammation and proteinuria.

## SA-PO336

**Low Dose of Vitamin D Analog, Paricalcitol, May Promote Carbonyl Stress and Kidney Disease in Diabetic Mice**
Xiaoyi Zheng, Wuxing Dong, Vivek Bhalla. *Medicine / Nephrology, Stanford Univ School of Medicine, Stanford, CA.*

**Background:** Diabetic nephropathy (DN) represents the primary cause of morbidity and mortality for patients with diabetes mellitus. Because Vitamin D analog therapy has been shown to attenuate diabetic nephropathy in combination with losartan, and genetic deletion of the Vitamin D receptor worsens diabetic nephropathy, we investigated the role of carbonyl stress in diabetic mice treated with paricalcitol, 19-nor-1,25-dihydroxyvitamin D2, an activated vitamin D analog.

**Methods:** Diabetic DBA/2J mice were induced by STZ injection (40mg/kg body weight) for 5 consecutive days, then administered paricalcitol (0.4 ug/kg body weight) or vehicle intraperitoneally thrice weekly for 24 weeks. Diabetes was validated by glucose tolerance tests at the end of the study. Urine albumin to creatinine ratio, glomerular volume

and podocyte number, and quantification of the carbonyl stress marker, 4-hydroxynonenal (4-HNE) were tested. Additionally, MES-13 mesangial cells were treated with 4-HNE and paricalcitol vs. vehicle prior to qPCR.

**Results:** Fewer diabetic mice survived until the study end-point with a trend toward decreased survival in the paricalcitol-treated vs. vehicle-treated diabetic mice. Surprisingly, paricalcitol-treated mice had significantly higher albuminuria (207.7 +/- 35.3 vs. 31.0 +/- 14.7 ug albumin / mg creatinine, $p<0.05$). Glomerular volume was not significantly different between these two groups, but there were significantly fewer podocytes per glomerulus in the paricalcitol-treated mice. Glomerular 4-HNE was lower in paricalcitol-treated mice (0.47 +/- 0.01 vs. 0.31 +/- 0.05 positive cells/mm2, $p<0.05$). Low-dose paricalcitol (0.5 nM) significantly increased 4-HNE-induced fibronectin1 expression while higher doses (5 nM or 50 nM) were not significantly different or lower vs. vehicle alone. Paricalcitol did not modulate 4-HNE-induced TGF-B1 expression vs. vehicle.

**Conclusions:** Taken together, in contrast to shorter duration of therapy, low dose, longer-term paricalcitol treatment may worsen diabetic nephropathy and survival, possibly by modulating the response to 4-HNE through increased fibronectin production, podocytopenia, and consequently increased albuminuria.

### Effects of Cannabinoid Receptor Type 2 (CB2) Agonist in a Mouse Model of Type 2 DN

Carlamaria Zoja,[1] Daniela Rottoli,[1] Daniela Corna,[1] Monica Locatelli,[1] Mauro Abbate,[1] Agnes Benardeau,[3] Karin Conde-knape,[3] Giuseppe Remuzzi,[1,2] Ariela Benigni.[1] *[1]IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Bergamo, Italy; [2]Unit of Nephrology and Dialysis, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy; [3]F. Hoffmann-La Roche AG, Basel, Switzerland.*

**Background:** Experimental evidence suggested that CB2 activation had a protective role in early STZ-induced diabetes in mice. Here we investigated the effects of the CB2 agonist RO6806207 given at a phase of overt disease in BTBR *ob/ob* mice, a recently characterized model of type 2 DN.

**Methods:** BTBR *ob/ob* mice received from 10 to 21 wks of age vehicle, CB2 agonist (10mg/kg i.p.) or lisinopril (30mg/kg in drinking water) as standard therapy for comparison (n=7-9 mice/group). BTBR wild-type mice (n=6) served as controls.

**Results:**

| Groups | Albuminuria (ug/24h) | Albuminuria (ug/24h) | Mesangial matrix (score) | Mesangial sclerosis % | Interstitial F4/80+cells/HPF |
|---|---|---|---|---|---|
| | 16wks | 21wks | | | |
| D+vehicle | 211±41 | 245±41 | 1.3±0.10 | 9.3±2.0 | 53±9 |
| D+CB2 | 86±16* | 158±30 | 0.9±0.05* | 3.5±0.9* | 34±12 |
| D+ACEi | 63±14** | 111±24* | 0.9±0.11** | 3.1±0.7* | 21±7* |
| Control | 30±4 | 36±8 | 0 | 0 | 18±6 |

Data are mean±SE; *p<0.05, **p<0.01 vs Diabetic mice (D)+vehicle. HPF: high power field

Both CB2 agonist and lisinopril reduced albuminuria. The antiproteinuric effect was associated with amelioration of defective nephrin expression of diabetic mice. CB2 agonist limited renal lesions to a similar extent as ACEi. Interstitial inflammation was lowered by 36% and 60% after CB2 agonist and lisinopril, respectively. Both compounds reduced osteopontin and TGFβ1 urinary excretion. Treatments did not affect hyperglycemia and dyslipidemia of diabetic mice.

**Conclusions:** CB2 agonist halted progressive renal damage when given to BTBR *ob/ob* mice during overt nephropathy. These findings may have therapeutic implications for type 2 DN.

*Funding:* Pharmaceutical Company Support - F. Hoffmann-La Roche AG, Basel, Switzerland

## SA-PO338

### L-carnitine Protects against Cyclosporine-Induced Pancreatic and Renal Injury in Rats

Can Li,[1] Chul Woo Yang.[2] *[1]Nephrology, YanBian Univ Hospital, YanJi, JiLin, China; [2]Nephrology, The Catholic Univ of Korea, Seoul, Korea.*

**Background:** L-carnitine has a protective effect against various types of injury. This study was designed to evaluate the beneficial effects of L-carnitine on pancreatic and renal injuries caused by cyclosporine A (CsA).

**Methods:** Rats maintained on a low sodium diet were given vehicle (olive oil, 1 mL/kg/day), CsA (15 mg/kg/day), L-carnitine (50 or 200 mg/kg/day), and a combination of CsA and L-carnitine for 4 weeks. The impact of L-carnitine on pancreatic injury was assessed by blood glucose level, plasma insulin concentration, and HbA1c. In addition, the protective effect of L-carnitine against CsA-induced renal injury was evaluated in terms of renal function, histopathology (inflammatory cell influx and tubulointerstitial fibrosis), oxidative stress (8-hydroxy 2'-deoxyguanosine, 8-OHdG), the transforming growth factor-beta1 (TGF-β1), apoptosis (caspase-3), and autophagy (LC3-II).

**Results:** CsA treatment caused diabetes, renal dysfunction, tubulointerstitial inflammation (ED-1-positive cells), and fibrosis, which were accompanied by an increase in 8-OHdG production and upregulation of TGF-β1, caspase-3, and LC3-II. Concomitant administration of L-carnitine increased plasma insulin concentration and decreased the levels of plasma glucose and HbA1c. In the kidney, L-carnitine induced a dose-dependent improvement of renal function, inflammation, and fibrosis in parallel with suppression of the expression of TGF-β1 and 8-OHdG. Furthermore, the administration of L-carnitine at a high dose inhibited the expression of caspase-3 and LC3-II.

**Conclusions:** These findings suggest that L-carnitine has a protective effect against CsA-induced pancreatic and renal injuries.

## SA-PO339

### Effects of Plant Steroid α-Spinasterol on Regulating Cell Proliferation and TGF-β Signaling Pathways through Thrombospondin-1 in Mesangial Cells

Jung Sub Song, Ju-Hung Song, Seon-Ho Ahn. *Internal Medicine, Wonkwang Univ College of Medicine & Hospital, Iksan, Jeonbuk, Republic of Korea.*

**Background:** TGF-β is the central cytokine responsible for the development of diabetic nephropathy, and usually secreted as a latent procytokine complex that has to be activated before it can bind to its receptors. It is reported that thrombospondin-1 (TSP-1) is the major activator of latent TGF-β in diabetic nephropathy in vivo. So this study is to examine the effect of α-spinasterol on TSP-1 production and downstream of TGF-β through TSP-1 induced by high glucose in mesangial cells.

**Methods:** α-spinasterol was isolated from roots of *Phytolacca americana*. Mouse mesangial cells were incubated for 24 hour with normal (5.6 mM) or high (30 mM) glucose-containing medium in the presence or absence of α-spinasterol (1 ng/mL). Mesangial proliferation was determined by cell number. Real time qRT-PCR was performed to observe the TSP-1, TβRI, TβRII, and fibronectin mRNA expression. Protein expressions of TSP-1, Smad2/3, p38, and fibronectin were determined by western blot.

**Results:** α-spinasterol inhibited the high glucose-stimulated proliferation of mouse mesangial cells, but did not affected to the growth of mouse mesangial cells cultured under normal glucose. TSP-1 mRNA expression and protein expression was increased in cultured mouse mesangial cells under the high glucose concentration. α-spinasterol attenuated TSP-1 mRNA expression and protein expression in cultured mouse mesangial cells under the high glucose, but not under the normal glucose concentration. TGFR1 mRNA expressions was increased in high glucose-stimulated mesangial cell, but decreased by α-spinasterol. Smad2/3 and p38 activities were increased in high glucose-stimulated mesangial cell, but decreased by α-spinasterol. Fibronectin mRNA and protein expression were decreased by α-spinasterol.

**Conclusions:** we demonstrated that α-spinasterol attenuated TSP-1 protein expression in mesangial cells under the high glucose, and resulted in regulating cell proliferation and TGF-β signaling pathways, Smad2/3 and p38 signaling. These results suggest that α-spinasterol may be considered as a promising future treatment option for diabetic nephropathy.

## SA-PO340

### Anti-Oxidative Effect of β-Blocker Carvedilol on Diabetic Nephropathy

Yuriko Yonekura,[1] Hideki Fujii,[1] Shunsuke Goto,[1] Kentaro Nakai,[1] Keiji Kono,[1] Riko Kitazawa,[2] Masami Shinohara,[3] Shinichi Nishi.[1] *[1]Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan; [2]Div of Molecular Pathology, Dept of Biomedical Informatics, Kobe Univ Graduate School of Medicine, Kobe, Japan; [3]CLEA Japan, Inc., Tokyo, Japan.*

**Background:** Oxidative stress has a major role in the pathogenesis of diabetic nephropathy. β-blocker carvedilol has been shown to have a protective effect from oxidative stress. In this study, we investigated the effect of carvedilol on the progression of diabetic nephropathy using non-obese type 2 diabetes mellitus model rats.

**Methods:** In the present study, we used Spontaneously Diabetic Torii (SDT) rats, which is a model of non-obese type 2 diabetes. Sprague-Dawley (SD) rats were used as control (SD, n = 5). At 20 week, SDT rats were divided into three groups: vehicle-treated SDT rats (DM, N=6), Insulin-treated SDT rats (INS, N=6), and carvedilol-treated SDT rats (CAR, N=6). At 30 week, blood and urine analysis, histomorphometrogical analysis, analysis of mRNA expression of NADPH oxidase and blood pressure measurement were performed among these four groups.

**Results:** At baseline, characteristics of these rats were comparable. At 30 week, despite comparable blood pressure, urinary excretion of albumin and 8-hydroxydeoxyguanosine (8-OHdG) were lower in the CAR group than in the DM group. In addition, relative kidney weight was lower in the CAR group compared to the DM group. The mRNA expressions of NADPH in the whole kidney were significantly decreased in the CAR group compared to the DM group. Further iummunohistological analysis revealed that the number of 8-OHdG positive cell in glomeruli and tubules was reduced by administration of carvedilol.

**Conclusions:** Our findings suggested that carvedilol prevent the progression of glomerular and tubular injury possibly through the reduction of oxidative stress in non-obese type 2 DM.

## SA-PO341

### COX-2, but Not mPGES-1 Mediates Renal PGE2 Synthesis and Nephropathy in STZ-Induced Type-1 Diabetes

Ying Sun,[1,2] Zhanjun Jia,[1,2] Kevin Yang,[1] Mi Liu,[1] Tianxin Yang.[1,2] *[1]Internal Medicine, Univ of Utah, Salt Lake City, UT; [2]VA Medical Center, Salt Lake City, UT.*

**Background:** It has been shown that local PGE2 in kidney is elevated in streptozotocin (STZ) induced diabetic mice and blockade of PGE2 action attenuates the diabetic nephropathy (DN). Present study is to elucidate whether mPGES-1, the best characterized PGE2 synthase, is involved in the development of diabetic nephropathy.

**Methods:** mPGES-1 WT and KO mice were employed to induce type I diabetes by STZ (120mg/kg IP).

**Results:** After STZ treatment for 6 weeks, mPGES-1 KO and WT mice presented the similar elevations of blood glucose (WTSTZ: 430±10.25 vs. KO STZ 436±47.8mg/dl, $p>0.01$). Meanwhile, both genotypes exhibited the paralleled increases of urinary and renal PGE2 productions (Urine: WTCont: 892.98±134.2 vs. WTSTZ: 4165.0±801.7 pg/24h, $p<0.01$; KOCont: 360.5±33.4 vs. KOSTZ 3145.1±465.4 pg/24h, $p<0.01$; kidney: WTCont: 810.9±48.4 vs. WTSTZ: 1153.3±147.8 pg/mg protein, $p<0.05$; KOCont: 634.7±76.6 vs.

KOSTZ: 1057.9±120.0 pg/mg protein, p<0.05). In parallel with these findings, kidney injury indexes including urinary ulbumin excretion (WTCont: 20.3±4.7 vs. WTSTZ 79.61±15.1 ug/24h, p<0.01, KOCont: 24.15±6.9 vs. KOSTZ: 84.12±15.1 ug/24h, p<0.01), kidney weight (WTSTZ: 0.825±0.032 vs. KOSTZ: 0.79±0.029%, p>0.05), and kidney histological changes (PAS staining) didn't show any difference between WT and KO mice. By western-blotting and quantitative real-time PCR, mPGES-1, mPGES-2, cPGES and 15-Hydroxyprostaglandin dehydrogenase (15-PGDH) remain unaltered after six weeks of diabetes. However, administration of selective COX-2 inhibitor celecoxib (50mg/kg/day) significantly reduced urinary albumin excretion in KO mice (KOSTZ: 141.5±38.4 vs. KOSTZ+Celebrex: 48.7±20.8 ug/24h, p<0.05), as well as renal PGE2 content(KOSTZ: 588.7±89.2 vs. KOSTZ+Celebrex: 340.8±58.7 ug/24h, p<0.05), without affecting blood glucose(KOSTZ: 421.4±44.4 vs. KOSTZ+Celebrex: 375.8±28.8 mg/dl, p>0.05).

**Conclusions:** COX-2, but not mPGES-1, is responsible for renal PGE2 synthesis and the development of DN in STZ-induced diabetes. These results also suggest the existence of an unknown PGE2 synthase contributing to renal PGE2 production under diabetic status.

## SA-PO342

**Angiotensin-Receptor Blockade Does Not Protect against Early Renal Tubular Injury in Streptozotocin-Induced Diabetes** Emily W. Nance, John Jason White. *Medicine, Georgia Regents Univ, Augusta, GA.*

**Background:** Diabetes is the leading cause of renal failure in the United States. Blocking the renin-angiotensin system (RAS) protects against glomerular injury but does not prevent the ultimate decline in renal function. Disease progression is strongly linked to the degree of tubulointerstitial injury, therefore, we examined the effects of RAS blockade on renal tubular injury in a rat model of diabetes.

**Methods:** Rats were made diabetic using streptozotocin (STZ) (I.V. 65mg/kg) and were supplemented with insulin allowing for modest hyperglycemia (n=10). One group (n = 5) received an angiotensin receptor blocker (ARB), candesartan (3 mg/kg/day) for 4 weeks. Blood glucose levels were monitored twice weekly and blood pressures were obtained weekly using the tail cuff method. After 4 weeks, rats were placed in metabolic cages to measure dietary intake and to collect 24 hour urine for protein and creatinine, and were then sacrificed. Tubular injury was assessed by measuring the urinary biomarkers, kidney injury molecule-1 (KIM-1), neutrophil gelatinase-associated lipocalin (NGAL), and N-acetyl-β-D-glucosaminidase (NAG) using ELISA.

**Results:** As expected, all rats exhibited polydipsia, polyphagia, and hyperglycemia. ARB treatment resulted in lower blood pressure ($P < 0.05$) and a trend towards lower urinary protein excretion ($P = 0.08$). Our previous studies demonstrated after 4 weeks of diabetes, there was an increase in urinary KIM-1, NGAL, and NAG in diabetic rats compared to controls without a concomitant rise in proteinuria. In this study, ARB treatment had no effect on urinary KIM-1, NGAL, or NAG.

**Conclusions:** In conclusion, short-term treatment with ARB does not prevent early tubular damage in STZ diabetes. These findings justify additional studies of longer duration and also highlight the need for alternate therapies targeting the tubulointerstitium in diabetic kidney disease.

## SA-PO343

**Inhibition of Nephrin Signaling by SHP-1 in Diabetic Nephropathy** Benoit Denhez,[1] Chris R. Kennedy,[2] Marie-odile Guimond,[1] Pedro Miguel Geraldes.[1] *[1]Univ of Sherbrooke, Canada; [2]Kidney Research Centre, Ottawa, Canada.*

**Background:** Diabetic nephropathy is the leading cause of end-stage renal disease and is characterized by dedifferentiation and apoptosis of podocytes, which are highly specialized epithelial cells involved in the glomerular filtration process. Nephrin, a transmembrane protein found in the slit diaphragm, has been found to play a role in the integrity of the podocytes. Clinical observations indicated that nephrin expression was reduced in kidney biopsy of diabetes patients. However, recent studies have shown that phosphorylation of tyrosine residues of nephrin participate in intracellular pathways regulating actin dynamics and play a role in podocyte survival. Our laboratory has recently published that the expression of SHP-1, a protein tyrosine phosphatase which contains two SH2 domains, is elevated in cultured podocytes exposed to high glucose concentrations. Since nephrin can interact with proteins that contain SH2 domains, we hypothesize that SHP-1 binds with nephrin and deregulates nephrin-mediated pathways in diabetes.

**Methods:** Six-months of age male Akita mice, a type 1 diabetes model, were used for in vivo experimentations. Akita mice develop early renal dysfunction characteristic of diabetic nephropathy such as elevated albuminuria, glomerular filtration rate and glomerular hypertrophy.

**Results:** Immunoblots of proteins extracted from the kidney cortex show that nephrin expression and phosphorylation was reduced by 35% and 40% respectively, while SHP-1 expression was elevated by 100%. In vitro, coimmunoprecipitation assays in HEK cells expressing both nephrin and SHP-1 showed an interaction between the two proteins. Immunoblot analysis indicated that this interaction decreased tyrosine phosphorylation of nephrin by 50% (p=0.0071). Moreover, SHP-1 overexpression reduced phosphorylation of nephrin tyrosine 1176/1193 and 1217 by 65% (p=0.0004) and 55% (p=0.0077), respectively.

**Conclusions:** In conclusion, our results suggest that diabetes triggered SHP-1 expression in podocytes which reduced nephrin tyrosine residue phosphorylation that participate in actin remodeling and survival and contributed to the development of diabetic nephropathy.

## SA-PO344

**The Effects of COMP-Angiopoietin-1 on Lipolysis, Vascular Endothelial Cells and Macrophages in Streptozotocin-Induced Diabetic Mice** Won Kim, Aesin Lee, Dal Kim, Kyung Pyo Kang, Yujin Jung. *Internal Medicine, Chonbuk National Univ Medical School, Jeonju, Republic of Korea.*

**Background:** Streptozotocin(STZ)-induced diabetes mellitus increased inflammatory immunity and STZ-induced hyperglycemia leads to diabetic microvascular complications like diabetic nephropathy. Angiopoietin-1 (Ang1) is a potent angiogenic factor. We previously demonstrated that a variant of Ang1, COMP-Ang1 preserves diabetic nephropathy. However, there is controversy in mechanism of COMP-Ang1 in kidney protection. Especially metabolic effects of COMP-Ang1 in STZ-induced diabetic complications remain to be clarified. Therefore, in this study, we examined effects of COMP-Ang1 on fat droplet size, vascular endothelial cell (EC), and macrophage infiltrations in epididymal adipose tissue and metabolic parameters in STZ-induced diabetic mice.

**Methods:** To investigate the effects of COMP-Ang1, we administered COMP-Ang1 or LacZ adenovirus intravenously 2 weeks after STZ injection and harvested epididymal adipose tissue and blood 4 weeks after STZ injection.

**Results:** COMP-Ang1 ameliorated STZ-induced decrease of fat droplet size (lipolysis) and preserved PECAM-1-positive vascular EC in EAT. We also found that COMP-Ang1 decreased F4/80–positive macrophage infiltration. COMP-Ang1 diminished CD86 (M1 macrophage) and FIZZ1 expression (M2 macrophage) in EAT. COMP-Ang1 reduced STZ-induced hyperglycemia (fasting glucose). Serum levels of triglyceride and free fatty acid after COMP-Ang1 treatment were decreased than that after STZ injection. Phosphorylation of Akt in adipose tissue was significantly increased after administration of COMP-Ang1. We also injected COMP-Ang1 at same time with STZ to evaluate the preventive effect. Co-treatment COMP-Ang1 preserved PECAM-1-positive EC and reduced macrophage infiltrations in EAT. In addition, COMP-Ang1 decreased random blood glucose level in STZ-induced diabetic mice.

**Conclusions:** All of these results demonstrate that COMP-Ang1 treatment can decrease STZ-induced inflammatory molecule and hyperglycemia, and conserve vascular EC and lipid droplet size. Our data suggest that COMP-Ang1 may ameliorate STZ-induced diabetic nephropathy through metabolic regulation.

## SA-PO345

**Interactions of PPAR Alpha and the Canonic Wnt Pathway in Renal Fibrosis** Rui Cheng, Lexi Ding, Jian-xing Ma. *Dept of Physiology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.*

**Background:** Peroxisome proliferator-activated receptor alpha (PPARα) has displayed reno-protective effects in animal models. However, its mechanism of action is unclear. The canonic Wnt pathway is known to regulate pathophysiological processes including inflammation and fibrosis. This study was to test the hypothesis that PPARα regulates renal fibrosis through interactions with the canonic Wnt pathway.

**Methods:** PPARα$^{-/-}$ mice were crossed with the BAT-gal Wnt-reporter mice to generate PPARα$^{-/-}$ or PPARα$^{+/-}$ mice carried the BAT-gal transgene. Streptozotocin (STZ)-induced diabetes and db/db mice were used as diabetic models. Diabetes and UUO were induced in age-matched wild-type (Wt) mice and PPARα$^{-/-}$ mice. Primary renal tubular cells were cultured from Wt mice or PPARα$^{-/-}$ mice.

**Results:** In STZ-induced diabetic rats and db/db mice, renal PPARα expression was down-regulated, compared to non-diabetic animals. PPARα agonist, fenofibrate, reduced urine albumin and renal fibrosis in STZ-induced diabetic rats. PPARα$^{-/-}$ mice with 3 months of diabetes showed more severe protein urea and significantly enhanced renal expression of fibronectin and CTGF, compared to diabetic Wt mice. Diabetic PPARα$^{-/-}$ mice showed more prominent increases of non-phosphorylated β-catenin levels in the kidney, compared to diabetic Wt mice. Wnt3a condition medium induced more prominent increases of phosphorylated LRP6 levels and transcriptional activity of β-catenin in PPARα$^{-/-}$ cells compared to Wt cells. TGFβ induced more fibronectin expression in PPARα$^{-/-}$ cells than in Wt cells, which can be rescued by over-expression of PPARα. The relationship of PPARα with the canonic Wnt pathway was further confirmed in PPARα$^{-/-}$/BAT-gal mice. X-gal staining at 7 days after UUO operation showed significantly higher β-catenin transcriptional activities in PPARα$^{-/-}$/BAT-gal mice vs their PPARα$^{+/-}$/BAT-gal littermates.

**Conclusions:** The beneficial effects of PPARα on renal fibrosis are at least in part through interactions with the canonical Wnt pathway. The interaction between PPARα and the canonic Wnt pathway renders a new therapeutic target for renal fibrosis.

## SA-PO346

**Effect of Ace2 Deletion and the Role of Gonadectomy in Male Mice with Diabetic Nephropathy** Sergi Clotet-Freixas, Maria Jose Soler, Julio Pascual, Marta Riera. *Nephrology, Hospital del Mar - IMIM, Barcelona, Spain.*

**Background:** Whereas ace2 deletion accentuates renal disease, its amplification ameliorates diabetic nephropathy.Gonadectomy(GDX) in ace2KO diabetic(DB) male mice has not been previously studied.

**Methods:** We study ace2 deletion in STZ–induced male mice. Groups: Wild-type(WT) cont, WTdb, KOcont, KOdb, GDX-KOdb. Variables: blood pressure(BP), urinary albumin excretion(UAE), kidney/body weight(KW/BW), glomerular size(GS), serum(s) and kidney(k) ACE activity and renal ACE and collagenIV gene expression.

**Results:** KW/BW and sACE were significantly higher in KOcont as compared to WTcont. Blood glucose(BG), KW/BW, GS, UAE and sACE were significantly increased in DB mice. GDX significantly decreased these parameteres. kACE activity and gene

expression significantly decreased in DB mice, and correlated(r=0.6, p<0.01). ACE gene expression decreased in KO groups. CollagenIV was higher in DB and KO groups.

## SA-PO347

**Endoplasmic Reticulum Was Stressed in Rat Kidney on Hyperinsulinemia Induced by High Palmitate Feeding** Jianling Tao, Yingjiu Liu, Yubing Wen, Hang Li, Xuewang Li. *Div of Nephrology, Peking Union Medical College Hospital, Peking Union Medical College & Chinese Academy of Medical Sciences, Beijing, China.*

**Background:** Insulin resistance is the basic pathophysiological feature of metabolic syndrome, carrying higher risk to the renal diseases onset and progression. Endoplasmic reticulum stress(ERS) is believed to play a triggering role in many diseases development. We tried to explore if ERS occur in kidney challenged by hyperinsulinemia induced by high palmitate feeding.

**Methods:** Four-week-old Wistar male rats (n=36) were either fed by a regular diet (Control n=18) or a high palmitate diet(n=18). At three, six and nine weeks later, six mice in either group were sacrificed. Body weight, serum insulin, creatinine, BUN, lipid profile, and glucose were assayed. Renal histology were reviewed by PASM. WT-1 stain was applied to trace podocyte loss. Kidney synaptopodin, and ERS marker Glucose-regulated protein 78 (GRP78) was assayed by Western Blot.

**Results:** Serum insulin level was significantly increased after six weeks' feeding by palmitate. Even without statistical significance, serum glucose and body weight tended to rise at the same time point. Lipid profile, and renal functions remain similar between two groups at any observation time point. Renal histology including WT-1 positive podocyte number and kidney synaptopodin amount did not change much during nine weeks' palmitate feeding. While GRP 78 protein expression started to significantly increase at six weeks after palmitate feeding and continue to be higher at the nine weeks' point.

**Conclusions:** ERS is initiated by hyperinsulinemia in kidney before measurable biochemical or histological abnormalities occur.

## SA-PO348

**New Vertebrate Model for Human Obesity-Related Glomerulopathy** Tomoko Obara. *Cell Biology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.*

**Background:** Obesity, an ongoing significant public health problem, is a part of a complex disease characterized as metabolic syndrome. Despite the growing public health imperative, substantial hurdles exist in developing new animal models to study the mechanisms of obesity-related kidney diseases and identify newer modes of therapy to slow progressive chronic kidney disease (CKD) and halt end-stage renal disease (ESRD). We have recently generated a versatile vertebrate model that allows rapid *in vivo* dissection of the mechanisms of obesity-related-glomerulopathy (ORG). This model is the genetically tractable medaka that in response to a high fat diet (HFD) develops ORG, which mimics the human counterpart.

**Methods:** In the present study, to explore the possibility that the adult medaka fed with HFD (HFD-medaka) can be used as an animal model for human ORG, we analyzed, serum glucose, glomerular histopathology and alterations in protein expression in the kidney of HFD-medaka.

**Results:** In 4 weeks, the HFD-medaka exhibited hyperglycemia, developed enlarged glomerulular (glomerulomegaly) and mesangial proliferation. In addition, by proteomic analysis with mass spectroscopy, 18 human CKD-related proteins were found up-regulated while two proteins [Neprilysin (Nep) and Mitochondrial enoyl CoA hydratase]were down-regulated in kidneys from HFD-medaka compared to medaka fed a control diet. Recent studies involving humans and mice also suggest that NEP has a role in obesity. *NEP* knockout mice as well as mice treated with a NEP inhibitor (candoxatril) developed obesity due to dysregulation of hyperglycemia and lipid metabolism. The role of NEP in ORG has not been studied. Therefore, we knocked down the *nep* gene in medaka on a control diet and found that they developed glomerulomegaly, suggesting that mutations in *nep* or Nep protein deficiency could result in ORG.

**Conclusions:** This is the first study to systematically investigate using HFD-medaka as a metabolic syndrome model that will help us to explore the mechanism underling human ORG, to identify protein markers and candidate genes for ORG. Successful completion of this study will lead us for new therapeutic strategies for patients in combating ORG and halting progression of CKD into ESRD.

## SA-PO349

**The Hypoglycemic Events in the Patients with Diabetic Nephropathy on Insulin Therapy and Its Clinical Impacts on Cardiovascular Systems** Hitoshi Minakuchi, Shu Wakino, Kozi Hosoya, Koichi Hayashi, Hiroshi Itoh. *Internal Medicine, Keio Univ, Tokyo, Japan.*

**Background:** Since the patients with CKD (chronic kidney disease) have insulin resistance, impaired glyconeogenesis in the kidney and/or reduced degradation of insulin, the circadian profile of blood glucose is supposed to be disturbed in CKD. However, this derangement has not been analyzed fully in the patients with diabetic nephropathy (DN) especially those on insulin therapy.

**Methods:** We recruited 20 DN patients on insulin therapy from March 2011 to April 2013 at the Ichikawa Hospital of Tokyo Dental College. They were all in the G3-G5 levels of CKD. The circadian blood glucose and blood pressure levels were monitored with CGMS (Continuous glucose measurement system) and ABPM (ambulatory blood pressure monitoring), respectively. To assess their vascular or neurological complication, head CT (Computed Tomography), IMT (intima-Media thickness) in carotid artery ultrasound, ABI (Ankle Brachial Index), PWV (Pulse Wave Velocity), and CVR-R (Coefficient of Variation of R-R intervals) were measured.

**Results:** Among all 20 participants, events of hypoglycemia (BS<70mg/dl) were detected in 9 participants (45.0%) by CGM analysis. Patients with hypoglycemic event (Hypo(+)) showed significantly lower eGFR, lower HbA1c, higher serum glucagon, and higher urinary excretion of free cortisol and metanephrine as compared with those in patients without hypoglycemic events (Hypo(-)). PWV levels were higher in patients in Hypo(+) as compared with those in Hypo(-), although CVR-R values were not different between the two groups. Non-dipper type alteration of sleeping blood pressure measured in ABPM were detected 8 out of 9 in Hypo(+) (88.9%) and 4 out of 11 in Hypo(-) (36.4%) with significant difference. Multiple logistic regression analysis revealed that the event of hypoglycemia was the independent risk factor for non-dipper type blood pressure change.

**Conclusions:** Among DN patients on insulin therapy, the events of hypoglycemia were not infrequently detected. This event was associated with the cardiovascular organ damages through non-dipper type blood pressure change or activation of sympathomimetic nerve system.

## SA-PO350

**Can Urine Glucose Be Used to Adjust Diabetes Therapy** Anil K. Mandal,[1] Linda M. Hiebert,[2] Harry J. Khamis.[3] *[1]Dept of Medicine, Univ of Florida, Gainesville, FL; [2]Dept of Veterinary Biomedical Sciences, Univ of Saskatchewan, Saskatoon, Canada; [3]Statistical Consulting Center, Wright State Univ, Dayton, OH.*

**Background:** Assay of urine glucose is simple and cheaper than finger-stick glucose testing. Validity of urine glucose assay to adjust diabetes therapy has not been widely studied. In the kidney, glucose is filtered and reabsorbed by the proximal tubules until blood glucose exceeds 180 mg/dL then appears in urine, 180 mg/dL is tubular maximum. This number may be less with reduced kidney function. Our aim was to gauge if urine glucose levels relate to blood glucose in fasting or postprandial periods, determining if urine glucose testing could replace blood glucose testing to adjust therapy. Average monthly cost in the USA of urine glucose testing, $17.00, is much less than finger-stick glucose testing, $78.00.

**Methods:** 66 diabetic patients were treated with insulin Glargine twice daily, and regular insulin with meals. Urine samples were tested for glucose (UG) in the fasting state (FUG) and at 2-hour postprandial (2hPPUG), along with blood samples [fasting blood glucose (FBG), 2hPP blood glucose (2hPPG) and fasting hemoglobin (Hgb) g/dL]. Serum creatinine (Scr, mg/dL) and estimated glomerular filtration (eGFR, ml/min) were obtained at both time periods (FScr, 2hPPScr and FeGFR, 2hPPeGFR, respectively). UG was verified by Roche chemstrip IOUA as normal (negative), trace (50 mg/dL), 1+ (100 mg/dL), 2+ (250 mg/dL), 3+ (500 mg/dL), 4+ (≥1000 mg/dL). Correlation between parameters was determined using Spearman's nonparametric correlation. P<0.05 was deemed significant.

**Results:** Correlation was high between FUG and FBG (P<0.0001, r=0.4867) but not between FUG and FScr or FeGFR (P=0.8810 and 0.2005; r=-0.0193 and 0.1635 respectively). Likewise correlation was high between 2hPPUG and 2hPPG (P<0.0001, r=0.5228) but not between 2hPPUG and 2hPP Scr or 2hPPeGFR (P=0.5002 and 0.5084; r=--0.0911 and 0.0886, respectively). No correlation was seen between Hgb and FUG (p=3078, r=0.1388).

**Conclusions:** These data suggest that urine glucose predicts changes in FBG and 2hPPG but these changes are independent of renal function.

**SA-PO351**

**A Gene Variant in the CERS2 Gene Is Associated with Worsening Albuminuria in Diabetic Patients of ON TARGET and TRANSCEND**
Dov Shiffman,[1] Guillaume Pare,[2] Judy Z. Louie,[1] Charles M. Rowland,[1] James J. Devlin,[1] Matthew McQueen.[2] *[1]Celera, Alameda, CA; [2]Population Health Research Institute, Hamilton Health Sciences and McMaster Univ, Hamilton, Canada.*

**Background:** Microalbuminuria is a risk factor for chronic kidney disease (CKD) among diabetics. However, the rate of albuminuria worsening varies among patients. Genome-wide association studies identified genetic variants associated with estimated glomerular filtration rate (eGFR). We asked whether these genetic variants were also associated worsening albuminuria among diabetic patients of the ON TARGET and TRANSCEND studies—two randomized controlled trials of ramipril, telmisartan, both, or placebo in patients with vascular disease or high-risk diabetes.

**Methods:** We investigated 16 genetic variants that were reported to be associated with eGFR at a genome-wide level ($P<5\cdot10^{-8}$). We evaluated the association of these variants with annual rate of change in urine albumin: creatinine ratio (uACR).

**Results:** We found that only one of the 16 variants (rs267734) was associated with differential rate of uACR progression (P=0.0013, P<0.05 after Bonferonni correction for testing 16 variants). The annual rate of increase in uACR was 11.3% (95%CI 7.5% to 15.3%) for carriers of two risk alleles, 5.0% (95%CI 3.2% to 6.7%) for heterozygotes, and 1.6% (95%CI -1.8% to 5.2%) for non-risk homozygotes, after adjustment for age, sex, hypertension, treatment group, self-reported ethnicity, and the principal components of genetic variability. Consistent with previous reports, this variant was also associated with baseline eGFR in those with European ancestry (P=0.002), although not in other ethnic groups. This variant (rs267734) is in almost perfect linkage disequilibrium ($r^2$=0.96) with rs267738, a single nucleotide polymorphism encoding an alanine to glutamic acid change at position 115 of the ceramide synthase 2 protein encoded by the CERS2 gene. This enzyme catalyzes the synthesis of dihydro-ceramide from sphinganine and is expressed in the kidney. However, it is not known how CERS2 function might influence albuminuria.

**Conclusions:** We found that rs267734 in CERS2 is associated with uACR progression rate among diabetics in ON TARGET and TRANSCEND.

**SA-PO352**

**The Association of Glucose Variability with Diabetic Complication in Korean Diabetic Patients**
Mi Jin Lee,[1] Jin Joo Cha,[1] Young Youl Hyun,[2] Dae R. Cha,[1] Jung Eun Kim,[1] Mihwa Lee,[1] Hye Kyoung Song,[1] Young Sun Kang.[1] *[1]Nephrology, Korea Univ Ansan Hospital, Ansan, Kyunggido, Republic of Korea; [2]Nephrology, Sungkyunkwan Univ Kangbuk Samsung Hospital, Seoul, Republic of Korea.*

**Background:** Tight glycemic control lowers the risk of diabetic complications, but it is uncertain that glycemic variability influences diabetic complications.

**Methods:** We examined the associations of plasma glucose variability with diabetic complications in a prospective cohort of 161 Korean diabetic patients from 2002 to 2013. Intra-personal mean and standard deviation(SD) of fasting plasma glucose calculated. Also we calculated percent coefficient of variation ( %CV= 100X SD/mean).

**Results:** Over the duration of 11 years follow up, diabetic retinopathy and neuropathy, nephropathy developed 14%, 9%, 9.9% of patients compared to start of study. Patients who had retinopathy until the end of study, had higher percentage of coefficient of variation(23.25±10.31 vs 18.46±9.40, p[thinsp]=0.005) than patients without retinopathy. Patients who had neuropathy, nephropathy until the end of study, had higher percentage of coefficient of variation(25.56±10.73 vs 18.15±8.74, p <0.001, 24.08±10.77 vs 18.12±8.66, p<0.001) than patients without neuropathy, nephroapthy. Also patients who progressed to cerebrovascular disease had higher percentage of coefficient of variation(27.94±12.09 vs 20.34±9.34, p =0.014) than non-progressor.

**Conclusions:** Taken together, long-term glycemic variability was association with diabetic complication.

**SA-PO353**

**Differential Contribution of 25-Hydroxyvitamin D Status to Insulin Resistance According to Body Mass Index in Normoglycemic Korean Population**
Seong Woo Lee, Sejoong Kim, Kwon Wook Joo, Chun Soo Lim, Yon Su Kim, Dong Ki Kim. *Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea.*

**Background:** There has been a paucity of literature on the interaction between 25-hydroxyvitamin D (25OHD) status and insulin resistance (IR) according to the severity of obesity in Asian population.

**Methods:** Data from the Korea National Health and Nutrition Examination Survey in 2008-2010 were analyzed. The study subjects comprised 12,895 normo-glycemic participants aged ≥ 20 years. IR was estimated by Homeostatic model assessment (HOMA). Obesity and its severity were assessed by body mass index (BMI) and its quartile. The association between HOMA-IR and 25OHD was assessed by multiple linear regression analysis. In addition, the breakpoint between HOMA-IR and 25OHD was assessed by segmented linear regression.

**Results:** In scatter plot of HOMA-IR against 25OHD with segmented linear regression line, we found the break point within the range of 10-20 ng/ml of 25OHD. In multiple linear regression analysis, the beta value of 25OHD on HOMA-IR was -0.016 (p<0.001). In subgroup analysis according to the severity of obesity, the beta values of 25OHD on IR were -0.003 (p=0.68), -0.007 (p=0.39), -0.028 (p=0.002) and -0.033 (p=0.001) in Q1-4 of BMI, respectively.

**Conclusions:** The relationship between 25OHD and IR was inverse, but there might be threshold value in the range of 10-20 ng/ml of 25OHD in decreasing IR. Since the effect of 25OHD on IR increased as BMI increased, the benefit from 25OHD supplementation in reducing IR might be maximized by stratified approach according to the severity of obesity. Future studies need to be followed.

**SA-PO354**

**Independent Predictors of Development of Albuminuria and GFR Decline in Japanese Type 2 Diabetic Patients**
Michino Takagi, Tetsuya Babazono, Izumi Nyumura, Yasuko Uchigata. *Diabetes Center, Tokyo Women's Medical Univ School of Medicine, Tokyo, Japan.*

**Background:** Diabetic kidney disease has been diagnosed by albuminuria and decreased eGFR; however, whether these renal manifestations share common risk factors in type 2 diabetic patients remain to be elucidated. The aim of this study was to determine independent predictors of albuminuria and eGFR decline in Japanese type 2 diabetic patients.

**Methods:** This was a single-center observational cohort study involving 1,803 Japanese type 2 diabetic patients with normoalbuminuria and an eGFR ≥ 60 mL/min/1.73 $m^2$. There were 740 women and 1,062 men, and the mean age was 58 ± 12 years. Two independent endpoints were specified: development of albuminuria (≥ 30 mg/g creatinine, albuminuria cohort, N=1,777) and eGFR decline (< 60 mL/min/1.73 $m^2$, GFR cohort, N=1,655). Cox proportional hazard model was used to identify significant predictors of each endpoint.

**Results:** During the median follow up period of 6.9 (IQR: 3.5-8.1) years for albuminuria cohort and 8.0 (IQR: 3.8-8.5) years for GFR cohort, 181 and 316 patients reached each endpoint, respectively: the 5-year cumulative incidence of reaching the endpoint was 8.3% for albuminuria cohort and 10.4% for eGFR cohort. In the multivariate Cox model, increased albuminuria, higher HbA1c levels, and the presence of diabetic retinopathy at baseline were commonly associated with both endpoints. Additional independent risk factors for albuminuria were male gender and elevated uric acid levels; those for eGFR decline were higher age, lower eGFR, and lower HDL cholesterol levels.

**Conclusions:** Identification of some distinct predictive factors for albuminuria and GFR decline suggests that different mechanisms are implicated in the development of these two renal manifestations in diabetic patients.

**SA-PO355**

**Urinary Sodium Excretion in Regard to All-Cause Mortality and GFR Decline in Diabetic Nephropathy**
Gudbjörg Andrésdóttir,[1] Tine Hansen,[1] Peter Rossing.[1,2,3] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Århus Univ, Århus, Denmark; [3]Copenhagen Univ, Copenhagen, Denmark.*

**Background:** The association of urinary sodium excretion with all-cause mortality and decline in GFR in patients with type 1 diabetes and nephropathy, but without heart failure needs clarification.

**Methods:** In a retrospective observational setting we included all 281 patients with three or more 24h urinary samples during 2000-2010. Mean urinary sodium excretion was calculated from all (median 24) samples. Vital status was determined with a mean follow-up of 8.8 years. GFR($^{51}$Cr-EDTA) was measured annually. The excretion was analyzed as a continuous variable in regression analysis and as quintiles in mortality analysis due to nonlinearity (cutoff-points: 7.0, 8.6, 10.1 and 12.1 g/24h).

**Results:** At baseline 62% were men, mean age 47(11) years, GFR 79(28) ml/min/1.73$m^2$, $HbA_{1c}$ 9.2(1.4) %, >95% were treated with RAS blockade, and 10% had previous CVD. 42 (15%) died. Regardless of adjustments, patients in the 2.nd quintile consistently had the lowest mortality risk and the 1.st quintile the highest risk.

| Model | Variables | Hazard Ratio (95% CI) of mortality [1.st quintile with 2.nd as reference] | p |
|---|---|---|---|
| A | Sodium excretion | 4.49 (1.50- 13.42) | <0.01 |
| B | A + age, gender and previous CVD | 4.60 (1.53-13.78) | <0.01 |
| C | B + smoking and total cholesterol | 5.11 (1.67–15.58) | <0.01 |
| D | B + GFR, systolic blood pressure, $HbA_{1c}$ and albuminuria at baseline | 3.85 (1.04-14.32) | 0.04 |

The analyses were repeated after exclusion of 50 patients not prescribed diuretics - with same trend, albeit with higher hazard ratios. Mean (SE) GFR decline was 3.9(0.4), 3.0(0.4), 3.1(0.4), 2.5(0.3) and 3.2(0.5) ml/min/1.73$m^2$/year in ascending quintiles of sodium excretion. The rate declined 0.13(0.02-0.25) ml/min/1.73$m^2$ with each g/day rise in NaCl (p=0.02) in fully adjusted models.

**Conclusions:** In unselected patients with type 1 diabetes and nephropathy, but without known heart failure, the association of urinary sodium excretion and mortality appears j-shaped, and values below <7g/24h NaCl are associated with the highest mortality and the steepest rate of GFR decline independent of other risk factors.

## SA-PO356

**Diabetes Mellitus Is Not Associated with Increased 5-Year Mortality in Adult Patients with Vascular Access for End Stage Renal Disease** Paola De Rango, Basso Parente, Luca Farchioni, Beatrice Fiorucci, Lydia Romano, Giuseppe Giordano. *Vascular and Endovascular Surgery; Hospital S.M. Misericordia; Univ of Perugia, Perugia, Italy.*

**Background:** Patients with end stage renal disease (ESRD) are exposed to limited life expectancy. As to whether diabetes mellitus may further decrease survival in these patients is not universally demonstrated. This study aimed to investigate the impact of diabetes on survival of patients with vascular access performed at a single vascular surgery center.

**Methods:** Data from consecutive patients with ESRD admitted for vascular access surgery from 2006 to 2013 were reviewed. Data were collected prospectively. Five-year outcomes of diabetic and non-diabetic patients patients were compared. Primary end-point was 5-year survival assessed by Kaplan Meier analysis with log rank test.

**Results:** A consecutive series of 458 patients (293 males; mean age 69.9+14.3) received 686 vascular access procedures during the study period. One hundred nineteen were affected by Type II diabetes mellitus at the time of admission. Diabetic patients showed higher comorbidity profile due to the increased prevalence of hypertension (90.7% vs 77.6%;P=.002), coronary disease (58.3% vs. 42.8%;P=.06), hyperlipidemia (27.2% vs. 17.6%; P=.04) and were more common on statins therapy (51.0% vs 29.5%; P<.001) when compared to non-diabetic patients. Kaplan Meier survival rates at 3 and 5 years were 71.8%% and 61.3% for patients with diabetes mellitus and 70.9% and 58.5% for non-diabetics (P=.86). Cox regression analysis failed to show any significant association between diabetes mellitus and mortality. Primary patency rates of vascular accesses at 3 years were 44.8% in diabetic and 41.5% in non-diabetics (P=0.895).

**Conclusions:** Diabetes mellitus is not associated with worse major outcomes in patients with ESRD requiring vascular access.

## SA-PO357

**The Circulating microRNA Expression Profile of Diabetic Nephropathy Patients** Qiuling Fan. *Dept of Nephrology, The First Hospital, China Medical Univ, Shenyang, China.*

**Background:** To explore the pathogenesis and the biomarkers for early detection of diabetic nephropathy (DN), the circulating microRNA expression profile of DN patients was analyzed by AB Taqman human miRNA array.

**Methods:** We obtained serum samples from 5 diabetic nephropathy patients proven by renal biopsy as nodular diabetic glomerulosclerosis, 5 diabetic patients without microalbuminuria (DM) and 5 healthy controls (N). Serum miRNAs were analyzed with the TaqMan Low Density Array and then validated with a quantitative reverse-transcription PCR assay with 30 individual samples.

**Results:** The urinary microalbumin/creatinine ratio and serum creatinine in diabetic nephropathy patients were higher than that of diabetic patients and healthy control($p<0.05$). 20 miRNAs were upregulated and 22 miRNAs were downregulated in serum of diabetic patients compared with that of healthy controls. 42 miRNAs were upregulated and 19 miRNAs were downregulated in serum of diabetic nephropathy patients compared with that of diabetic patients. Among them, along with the progression of diabetes and diabetic nephropathy, miR-1179 was gradually increased (2.03 times in DM/N and 2.14 times in DN/DM) , miR-148b, miR-150 were gradually reduced (2.04 times in DM/N, 2.02 times in DN/DM and 2.03 times in DM/N, 2.02 times in DN/DM respectively).

**Conclusions:** The differentially expression of serum miR-1179, miR-148b and miR-150 may be responsible for the pathogenesis of diabetic nephropathy and are potential biomarkers for DN.

## SA-PO358

**The Usefulness of the New Classification for CKD by the KDIGO for Analyzing Progression of Diabetic Kidney Disease and Vascular Complications in Type 2 Diabetic Patients** Ming Li,[1] Huiqing Chen,[2] Xun Liu,[1] Wenbo Zhao,[1] Tan-qi Lou.[1] *[1]Dept of Nephrology, The Third Affiliated Hospital of SUN Yat-sen Univ, Guangzhou, Guangdong, China; [2]Dept of Paediatrics, The First Affiliated Hospital of SUN Yat-sen Univ, Guangzhou, Guangdong, China.*

**Background:** To investigate the clinical features of patients with type2 diabetic kidney disease and analyze the risk factors for the progression of Diabetic Kidney Disease, also to evaluate the risk for diabetic vascular complication.

**Methods:** 1645 Chinese adult patients with type 2 diabetic from June 2008 to September 2012 were included in this study. They were grouped according to Composite ranking for relative risks by GFR and albuminuria(KDIGO 2009).The clinical features and risk factors of DKD were compared and analyzed.

**Results:** 1) Rate of T2DM patients with CKD was 37.2%; According to Composite ranking for relative risks by GFR and albuminuria(KDIGO 2009), the low-risk group was 62.8%, and moderate risk group was 17.8%, the high-risk group was 7.9%, the very high risk group was 11.5%. (2) Multivariates regression analysis indicated that diabetic retinopathy (DR) (OR:1.770,95% CI 1.060-2.956), systolic pressure(OR:1.012, 95%CI 1.001-1.023), CysC (OR: 5.369, 95%CI 2.306 -12.499) were the independent risk factors for the progression of low risk group to moderate risk group. The risk factor for the progression of moderate risk group to high-risk group were DR(OR:3.318, 95%CI 1.399-7.039), systolic pressure(OR:1.033, 95%CI 1.013-1.053), CysC(OR:9.723, 95%CI 3.110 -30.394). Serum creatine(OR:1.105, 95%CI 1.069-1.142) was the risk factor for high-risk group to very high risk group. (3) Among the GFR(G1+G2,G3a,G3b and G4+G5), CVD% were 13.4%, 34.0%, 50.9%, 53.7% ($p<0.05$). Cerebrovascular disease% were 8.3%, 27.7%, 43.9%, 58.5% ($p<0.05$). DR% were 23.6%, 41.1%,67.9%, 54.3%($p<0.05$). The brachial-ankle index was significantly greater in the G3b group compared to the G3a group.

**Conclusions:** DR and CysC can predict the progression of DKD well. And good control of blood pressure can delay the progression of DKD.The subdivision of the G3 stage in the new classification proposed by the KDIGO is useful to evaluate vascular complications with T2DM.

## SA-PO359

**The Correlation between Renal Tissue Disorder and Mast Cell Chymase on Patients with Diabetic Nephropathy** Sayuri Shirai,[1] Daisuke Ichikawa,[1] Kayori Tsuruoka,[1] Yugo Shibagaki,[1] Takashi Yasuda,[1] Kenjiro Kimura.[1] *[1]Nephrology and Hypertension, St. Marianna Univ School of Medecine, Kawasaki, Kanagawa, Japan; [2]Cardiovasucular Disease, Fukuoka Univ Chikushi Hospital, Chikushino, Fukuoka, Japan.*

**Background:** Human chymase is known to produce angiotensin II (AII) from angiotensin I (AI) but the pathophysiological role of chymase is not fully understood. We investigated relationships between chymase and renal pathological abnormality on patients with diabetic nephropathy.

**Methods:** We enrolled 34 type 2 diabetic patients with diabetic nephropathy who underwent renal biopsy from 2002 to 2012. Immunohistochemical staining for chymase (C) and tryptase (T) was performed on renal sections from patients. The number of C positive (C+) and T positive (T+) mast cell per unit area were counted. Correlation between those positive cells and patients' clinical and pathological indices was analyzed.

**Results:** Both C+ mast cells and T+ mast cells were found in the interstitium, but not in the glomeruli, of renal cortex. Both cell numbers had positive correlation with tubulointerstitial injury, progression of diabetic nephropathy, and advanced CKD stage, respectively. The ratio of C+ to T+ cell number had same correlation with above clinical parameters. The positive correlation between global sclerosis and interstitial injury were found on low intensity C+ group (<2 /mm$^2$), but was not found on high intensity C+ group (>2 /mm$^2$).

**Conclusions:** This study suggests that mast cells, especially C+ mast cells, are involved in development of diabetic nephropathy. Through release of bioactive substances like tryptase and chymase into the tubulointerstitial area, mast cells could promote renal inflammation and fibrosis, and thus contribute to diabetic nephropathy.

## SA-PO360

**Hyperglycemia Is Associated with Tubular Injury in Subjects with Type 2 Diabetes Mellitus** Ernesto Sabath,[1] Ma. Ludivina Robles-osorio.[2] *[1]Renal Dept, SESEQ; [2]Metabolism and Endocrinology, Universidad Autónoma de Querétaro.*

**Background:** Microalbuminuria indicates the presence of early glomerular disease in patients with diabetes and it has yet to be determined whether testing for markers of tubular injury can also identify persons who are at risk of progressive renal disease. The association of hyperglycemia with markers of tubular injury is currently unknown and the aim of the current study was to determine if hyperglycemia is associated with tubular injury.

**Methods:** Subjects aged >20 years old were included, and those with uncontrolled hypertension, current urinary tract infection and pregnant women were excluded. Blood samples were taken after a fasting ≥ 8hrs; measurements of the biochemical variables were done by standard technique. GFR was estimated using the CKD-EPI equation. Spot urine samples for albumin and α1-microglobulin (a1M) analysis were collected and the α1M determinations were done by ELISA. Descriptive statistics were calculated and comparisons between groups were done by t-student analysis and chi-square. For variables correlated with a1M excretion a multiple linear regression analysis was used.

**Results:** A total of 190 subjects with T2DM were included; the mean age was 52.6 ± 12.5 yrs, median time from diagnosis was 7.6 ± 7.2 years and mean BMI was 29.9 ± 5.4.

In 168 subjects we have determination for a1M, 76 (45.2%) had aIM higher than 10 µg/gCr; these subjects were older (56 ± 11 vs 48 ± 11, p= 0.002), and glucose serum concentration was significantly higher (227 ± 78 vs 166 ± 60 mg/dl, p= 0.00), but not differences in AUE was found; in multiple regression analysis the most important factor associated with a1M was serum glucose (p=0.001) and there was a significant correlation between fasting glucose levels with A1M excretion (r= 0.27, p=0.01). Subjects >50 yrs and abnormal a1M had a decrease in GFR (66.2 ± 16 vs 77.3 ± 18 ml/min, p=0.04) compared with those with normal values of a1M.

**Conclusions:** Hyperglycemia is associated with higher urinary excretion of a1M, reflecting a clinical significant effect of glucose concentration on tubule-interstitial injury; a1M excretion is associated with decrease in renal function in a subgroup of patients with T2DM.

*Funding:* Government Support - Non-U.S.

## SA-PO361

**The Clinical Evaluation of the Mechanisms of Natriuresis by DPP-4 Inhibitors** Koichi Kanozawa, Nobuyuki Onizawa, Hajime Hasegawa, Takatsugu Iwashita, Taisuke Shimizu, Juko Asakura, Tomonari Ogawa, Tetsuya Mitarai. *Div of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical Univ, Kawagoe, Japan.*

**Background:** Glucagon-like peptide(GLP)-1 receptor has been expressed at renal proximal tubule, and acts on natriuresis through Na(+)/H (+) exchanger isoform 3 (NHE3). On the other hand, not only GLP-1 but also brain natriuretic peptide (BNP) is contained in the substrate of dipeptidyl peptidase-4 (DPP). The aim of study is to clarify the mechanisms of natriuresis of DPP-4 inhibitors, clinically.

**Methods:** We gave DPP-4 inhibitor (either of sitagliptin 50-100 mg, vildagliptin 50-100 mg, alogliptin 12.5-25 mg) for Japanese patients with Type 2 diabetes less than 2.0 mg/dl of serum creatinine level. The inpatients were collected first morning urine within one week around DPP-4 inhibitors administration, and the outpatients were collected first or second urine before and ten weeks and 20 weeks after DPP-4 inhibitors administration. The average value of twice urinary Na and K excretion was evaluated. Furthermore, the changes of BNP were also examined.

**Results:** The 46 inpatients and 60 outpatients ware enrolled, and the diuretics was used together at 43%, and 65% each, respectively. By administration of DPP-4 inhibitors, urinary Na excretion significantly increased from 112±16 to 179±19 mEq/gCr ($p< 0.01$) in the inpatients with diuretics combination, and also increased from 140±17 to 180±28 mEq/gCr ($p< 0.05$) in the diuretics combined use outpatients. In both the inpatient and outpatient who are without combination of diuretics, the increase of the urinary Na excretion was not statistically significant. The urinary K excretion also significantly increased from 44±5 to 53±6 mEq/gCr ($p< 0.05$) in the inpatients with diuretics combination, and increased from 34±3 to 39±4 mEq/gCr ($p< 0.05$) in the outpatients who combined diuretics other than K+sparing diuretics. On the other hand, BNP observed the upward tendency in 94±25 to 112±28 pg/ml in the outpatients by dosage of DPP-4 inhibitors.

**Conclusions:** It was considered that DPP-4 inhibitors regulate Na re-absorption in upper renal tubule since urinary Na and K excretion in diuretics combined use, and BNP might participate in natriuresis.

## SA-PO362

**25(OH)D3 Is an Effective Indicator of Mineral Metabolism for Patients with Diabetic Nephropathy** Li Wang. *Renal Dept, Sichuan Provincial People's Hospital.*

**Background:** Serum P, Ca and PTH concentration are traditional indicators to reveal the mineral metabolism. However they are usually affected by other factors, and hence not sensitive. VitD is also associated with mineral metabolism. We assess the impact of 25(OH) D3 on early screening of mineral metabolism for patients with type 2 diabetic nephropathy.

**Methods:** Cross-sectional study of 162 type 2 diabetic patients with diabetic nephropathy, where no statistical significance exists for age, gender, duration and season. They are sorted by different concentration of 25(OH)D3 according to KDOQI Clinical Practice Guidelines for Bone Metabolism. The distributions of three concentration groups are compared, for serum P, Ca and PTH respectively.

**Results:** This statistical analysis shows that, along with 25(OH)D3 concentration decreases, for insufficient and deficient groups, the proportions of high-P, low-Ca and high-PTH patients increases significantly, which are (3.6%-10.7%-85.7%, $p<0.05$), (9%-37.3%-53.7%, $p<0.05$) and (0%-12%-88%, $p=0.256$) respectively. The clinical data for PTH groups is limited (only 60 patients), which would be the reason for its non statistical significant difference. Meanwhile, a large proportion patients belonging to normal serum P, Ca and PTH groups have the phenomenon of 25(OH)D3 anomaly (deficiency or insufficient), which count to 82.9%, 83%, 100% respectively.

**Conclusions:** 25(OH)D3 is an effective indicator of mineral metabolism for patients suffering type 2 diabetes with diabetic nephropathy, and it is more sensitive comparing to serum P, Ca and PTH concentration. We suggest to detect 25(OH)D3 in mineral metabolism for early screening of the type 2 diabetic nephropathy.

## SA-PO363

**Role of Magnesium, Fibroblast Growth Factor-23 and Phosphorus in Cardiovascular Outcomes in Type 2 Diabetic Patients with Diabetic Nephropathy** Ana Paula Silva, André Fragoso, Pedro Neves. *Nephrology, Hospital de Faro E.P.E, Faro, Portugal.*

**Background:** To evaluate the role of magnesium (Mg), fibroblast growth factor-23 (FGF-23) and Phosphorus (Pi) levels in co-morbidity (hospitalization) and cardiovascular mortality. To evaluate the association between Mg and cardiovascular risk factors in type 2 diabetic patients with mild to moderate CKD.

**Methods:** An observational, prospective study involving 191 patients divided into groups according to baseline magnesium levels: 1< 1.2 mg/dL,2=1.2-2.3mg/dL and 3≥ 2.3 mg/dL. Baseline characteristics were analyzed and compared. Multivariate Cox regression was used to find out predictors of cardiovascular mortality and multivariate logistic regression was used to find out predictors of hospitalization. Simple linear regression and Pearson correlation were used to investigate correlations between magnesium and renal function, inflammation, oxidative stress, mineral metabolism parameters and left ventricular mass index.

**Results:** Patients' survival at 55 months on group 1, 2 and 3 was 21%, 30.1% and 91.2%, respectively ($P=0.004$). Mg (HR: 0.450, $p=0.007$), FGF-23 (HR: 1.005, $p=0.023$), Pi (HR: 1.105, $p=0.004$) and age (HR=1.954, $p=0.045$) were independent predictors of mortality. Mg (OR=0.889, $p=0.003$), FGF-23 (OR=1.027, $p=0.045$), Pi (OR=1.056, $p=0.032$) and creatinine (OR=1.016, $p=0.023$) were independent predictors of hospitalization. Mg levels were negatively correlated with left ventricular mass index ($R = -0.788$, $p = 0.0001$), creatinine ($R= -0.346$, $p = 0.0001$), PTH ($R= -0.7101$, $p = 0.0001$), FGF-23 ($R= -0.798$, $p = 0.0001$) and was positively correlated with vitamin D ($R= 0.840$, $p = 0.0001$).

**Conclusions:** Magnesium, FGF-23 and phosphorus levels might have a significant clinical use as markers/predictors of cardiovascular mortality and hospitalization in type 2 diabetic patients with mild to moderate CKD.

*Funding:* NIDDK Support

## SA-PO364

**What Is the Role of Apelin Regarding Cardiovascular Risk and Progression of Renal Disease in Type 2 Diabetic Patients with Diabetic Nephropathy?** Ana Paula Silva, André Fragoso, Nelson Almeida Tavares, Pedro Neves. *Nephrology, Hospital Faro E.P.E, Faro, Portugal.*

**Background:** To evaluate the association of different apelin levels with cardiovascular mortality, hospitalizations, renal function and cardiovascular risk factors in type 2 diabetic patients with mild to moderate CKD.

**Methods:** An observational, prospective study involving 150 patients divided into groups according to baseline apelin levels: 1≤ 98 pg/mL,2=98-328 pg/mL and 3≥ 329 pg/mL. Baseline characteristics were analyzed and compared. Multivariate Cox regression was used to find out predictors of cardiovascular mortality and multivariate logistic regression was used to find out predictors of hospitalization and disease progression. Simple linear regression and Pearson correlation were used to investigate correlations between apelin and renal disease, and between apelin and cardiovascular risk factors.

**Results:** Patients' survival at 83 months on group 1, 2 and 3 was 39%, 40% and 71.2%, respectively ($P=0.046$). Apelin, age and eGFR were independent predictors of mortality, and apelin, creatinine, eGFR, resistin and visfatin were independent predictors of hospitalization. Apelin levels were negatively correlated with cardiovascular risk factors IMVE ($R = -0.588$, $p = 0.0001$), creatinine ($R= -0.316$, $p = 0.0001$), IL-6 ($R= -0.708$, $p = 0.0001$), IMT ($R= -0.621$, $p = 0.0001$), systolic BP ($R= -0.441$, $p = 0.0001$), PP ($R= -0.588$, $p = 0.0001$) and OxLDL ($R= -0.669$, $p = 0.0001$), while it was positively correlated with eGFR ($R= 0.357$, $p = 0.0001$). Patients with lower apelin levels were more likely to start a depurative technique ($P=0.001$).

**Conclusions:** Apelin levels might have a significant clinical use as a marker/predictor of cardiovascular mortality and hospitalization or even as a therapeutic agent for CKD patients with cardiovascular disease.

*Funding:* NIDDK Support

## SA-PO365

**Endothelial Function in Type 2 Diabetic Patients with Renal Dysfunction** Lee Ying Yeoh, Tavintharan Subramaniam, Su-chi Lim. *Medicine, Khoo Teck Puat Hospital, Singapore.*

**Background:** Study the relationship of endothelial function, arterial stiffness in T2DM with reduced GFR.

**Methods:** Cross sectional study was done from August 2011 to May 2013 to explore novel risk factors for endothelial dysfunction and diabetic micro-angiopathies. Pulse wave velocity(PWV) was measured using applanation tonometry(SphymCorÒ).Iontophoresis followed by laser doppler flowmetry(Moor Instruments Ltd, England) were used to assess forearm cutaneous micro-vascular endothelial reactivity in response to acetylcholine chloride(Ach) and sodium nitroprusside(NT). Estimated glomerular filtration rate(eGFR) was calculated using CKD EPI equation and stratified into>90,60-90 or 30-59ml/min. ANOVA and multinomial logistic regression were used.

**Results:** There were 1515patients(48.5%Male and 51.2%Chinese). Mean duration of DM was 10.9±8.6years. GFR decline was associated with increasing age and albuminuria as opposed to HDL-cholesterol ($p<0.01$). Vascular function was affected when GFR<60ml/min as evidenced by impaired endothelium dependent vasodilatation(Ach) and increase PWV($p<0.01$).

| eGFR(ml/min) | 30-59 | 60-90 | >90 | Multivariate (compare to GFR>90) | |
|---|---|---|---|---|---|
| N | 211 | 448 | 856 | 30-59 | 60-90 |
| Age(years) | 64.2±9.2 | 61.7±9.1 | 53.5±10.0 | 1.15(1.13-1.18) | 1.11(1.09-1.13) |
| HDL-C(mmol/l) | 1.19±0.31 | 1.29±0.35 | 1.30±0.36 | 0.18(0.10-0.34) | 0.56(0.38-0.82) |
| ACR(ug/mg) | 412.8±815.5 | 165.8±557.3 | 91.1±257.4 | 1.001(1.001-1.002) | 1.001(1.000-1.001) |
| PWV(m/s) | 11.1±3.1 | 10.0±2.8 | 8.9±2.5 | 1.12(1.05-1.19) | 1.03(0.98-1.09) |
| Ach(%increment) | 86.5±67.3 | 118.7±99.1 | 129.0±96.1 | 0.997(0.994-0.999) | 1.000(0.999-1.002) |
| NT(%increment) | 58.8±46.9 | 72.1±54.3 | 81.4±57.1 | 0.997(0.993-1.001) | 0.998(0.996-1.001) |

**Conclusions:** Endothelial dysfunction and arterial stiffness are seen in T2DM patients when GFR<60ml/min. Changes in the micro-circulatory function and arterial stiffness might have taken place in early renal dysfunction.

## SA-PO366

**High Fibroblast Growth Factor-23 Levels Are Associated with Early Diastolic Dysfunction in Type 1 Diabetic Patients with No or Early Diabetic Nephropathy** Burcu Dogan,[1] Izzet Hakki Arikan,[2] Derya Guler,[2] Nursen Keles,[1] Banu Isbilen,[1] Ferruh Isman,[1] Aytekin Oguz.[1] *[1]Istanbul Medeniyet Univ Goztepe Hospital, Istanbul, Turkey; [2]Marmara Univ Pendik Hospital, Istanbul, Turkey.*

**Background:** Recent studies showed that higher fibroblast growth factor-23 (FGF-23) and lower soluble klotho levels are associated with cardiovascular disease. The aim of the study is to investigate the possible links between klotho and FGF-23 levels and cardiovascular risk factors in type I DM patients.

**Methods:** We included 87 type 1 diabetic patients with eGFR > 60 ml/min (DM) (50 female, mean age 34,2 ± 9,1 years) and 78 healthy controls (43 female, 34.5 ± 9.8 years) in the study. Demographic characteristics, albuminuria, lipid profiles, Ca, P, PTH and vitamin D levels were recorded. Echocardiographic examination was performed and eGFR was calculated. The presence of diabetic retinopathy and neuropathy were also noted. Serum klotho and FGF-23 levels were determined by ELISA method.

**Results:** FGF-23 levels were not different in diabetics (76.2±16.4 pg/ml) compared with controls (77.3±15.7 pg/ml). FGF-23 levels were only correlated with IVRT (isovolumetric relaxation time) (r=0,321, p=0,023) and E'med (early diastolic velocity at medial/septal annulus) (-0,293 p=0,041) in DM. There were no relationships between FGF-23 and albuminuria, eGFR, diabetic retinopathy, vitamin D levels and other parameters. Soluble klotho levels in DM (532,58±228,68 pg/ml) were also similar with controls (552,19±425,22 pg/ml). Soluble klotho levels were found not to be related with demographic, laboratory and echocardiographic parameters.

**Conclusions:** Elevated FGF-23 levels are associated with higher IVRT and E'med which indicate early diastolic cardiac dysfuction in type 1 DM patients with eGFR>60 ml/min. Soluble klotho levels are not changed in type 1 DM with early or no diabetic nephropaty in contrast with type 2 DM. High rate of hypertension, advanced age and other cardiovascular risk factors in type 2 DM might be responsible for this discrepancy between type 1 and 2 DM.

## SA-PO367

**Impacts of Dyslipidemia on Diabetic Nephropathy, Cardiovascular Mortality, and All-Cause Mortality in Patients with Diabetes: A Systematic Review and Meta-Analysis** Tadashi Toyama,[1] Miho Shimizu,[1] Kengo Furuichi,[1] Takashi Wada.[1] *[1]Div of Nephrology, Kanazawa Univ, Kanazawa, Ishikawa, Japan; [2]Dept of Disease Control and Homeostasis, Institute of Medical, 11 Pharmaceutical and Health Sciences, Kanazawa Univ, Kanazawa, Ishikawa, Japan.*

**Background:** Some meta-analysis reported the effects of statins for renal and cardiovascular outcome, and all-cause mortality. However, treatment of statins has two main effects. One is improvement of dyslipidemia and another one is other pleiotropic effects. When we treat patients with diabetes, we should understand precise impacts of dyslipidemia, because lifestyle changes are first-line treatment. In this study, we explored impacts of dyslipidemia on cardiovascular mortality, all-cause mortality, and renal failure in diabetes mellitus and examined inconsistency between studies.

**Methods:** Relevant studies were searched from MEDLINE and CINAHL by using key words of medical subject headings that included words related to "dyslipidemia", "diabetes mellitus," "renal failure," "cardiovascular diseases," and "mortality". Studies examining the risk of three endpoints (cardiovascular mortality, all-cause mortality, renal failure) associated with high LDL cholesterol (LDL-C) were included. The extracted estimates were combined using a random-effects model. To investigate the cause of heterogeneity, we performed a meta-regression analysis.

**Results:** The literature search yielded 8624 articles, of which 390 papers were reviewed in full. Seventeen studies, which fulfilled criteria, were included in the analysis. The presence of dyslipidemia (LDL-C +1 mmol/l) was 1.08-fold increase in risk of presence of albuminuria. The presence of dyslipidemia was also a risk factor for cardiovascular mortality (relative risk 1.37), and all-cause mortality (relative risk 1.21). In the meta-regression analysis, long-term follow-up period was associated with higher relative risks in the outcome of cardiovascular mortality and all-cause mortality.

**Conclusions:** High LDL-C is risk factor for cardiovascular mortality, all-cause mortality, and renal failure in diabetic patients. Long-term follow-up may have stronger impact of high levels of LDL-C on outcomes of diabetic patients.

## SA-PO368

**Impaired Physical Fitness in Obese Diabetic Patients with Chronic Kidney Disease** Vamsi K. Kanneganti, Eileen Collins, Jolene Butler, Susan O'Connell, Christine Jelinek, Conor McBurney, Anne Garabedian, Holly J. Kramer, David J. Leehey. *Medicine and Research, Hines VA Hospital, Hines, IL.*

**Background:** Patients with diabetes, obesity, and chronic kidney disease (CKD) are generally physically inactive which may be an important contributor to their high mortality rate.

**Methods:** We examined baseline data from a VA funded randomized controlled trial (NCT01036490) to assess physical fitness in this population. Inclusion criteria are type 2 diabetes, obesity (body mass index > 30 kg/m$^2$), chronic kidney disease (stage 2-4) and persistent proteinuria (> 200 mg/day for at least 3 months). Data from the baseline symptom-limited treadmill test were analyzed. We calculated a perceived exertion-workload index (PEWI) for each subject, defined as the ratio of peak perceived exertion (Borg scale) to the energy cost of peak physical activity (METS).

**Results:** Baseline data (mean ± SD) on 30 subjects were evaluated. Mean values (± SD) were as follows: age 66 ± 8.1 yrs, body mass index 36.5 ± 4.9 kg/m$^2$, percent body fat 41.3 ± 6.6%, hemoglobin 12.5 ± 1.7 g/dL, glycated hemoglobin 8.1 ± 1.8 %, serum creatinine 2.3 ± 1.0 mg/dL, creatinine clearance 46.5 ± 35.7 mL/min, urinary albumin excretion rate 1013 ± 1073 mg/24h. Average treadmill time was 6.8 ± 3.8 minutes and peak oxygen consumption ($VO_2$ peak) was 13.1 ± 3.6 mL/kg/min (peak METS 3.7 ± 1.0; range 2.0-5.8). Peak METS was positively correlated with baseline average weekly pedometer step count ($r = 0.62$, $p < 0.01$). The peak perceived exertion-workload index (PEWI) was 1.4 ± 0.86, with higher values indicating greater perceived exertion relative to workload. There was a negative correlation between peak PEWI and both treadmill time ($r = - 0.60$, $p < 0.001$) and average weekly pedometer step count ($r = - 0.63$, $p < 0.01$). There was no correlation between peak PEWI and hemoglobin, glycated hemoglobin, serum creatinine, creatinine clearance, body mass index, or percent body fat.

**Conclusions:** These data indicate that obese diabetic subjects with CKD have markedly impaired baseline physical fitness, which may in part be due to increased perceived exertion at a given workload with resultant decreased ability to exercise.

## SA-PO369

**Phase 2 Clinical Trial of Orally Administered CCR2 Antagonist CCX140-B in Diabetic Nephropathy** Pirow Bekker, Antonia Potarca, Timothy Sullivan, Shichang Miao, Daniel Dairaghi, Lisa Lohr, Lisa C. Seitz, Zhenhua Miao, Bin N. Zhao, Jay P. Powers, Juan C. Jaen, Thomas J. Schall. *ChemoCentryx, Inc.*

**Background:** Monocyte chemoattractant protein-1 (MCP-1) and its C-C chemokine receptor CCR2 are implicated in diabetic nephropathy. The CCR2 antagonist CCX140-B has been tested in clinical trials in >550 patients. CCX140-B was effective in reducing glycemia, biochemical and histological markers of kidney disease in multiple mouse models. CCX140-B also reduced glycemia in a Ph2 clinical trial in type 2 diabetes and is currently in Ph2 testing in diabetic nephropathy (DN).

**Methods:** This is a randomized, double-blind, placebo-controlled Phase 2 clinical trial in 270 patients with DN. The primary efficacy measure is change from baseline in first morning urinary albumin:creatinine ratio (ACR). Eligible patients have been on stable ACE inhibitor or ARB, and anti-diabetic treatment for at least 8 wks, with ACR 100-3000 mg/g creatinine, HbA1c 6-10%, and eGFR ≥25 mL/min/1.73 m$^2$. Patients are stratified based on ACR and eGFR, and then randomized to receive placebo, 5 mg or 10 mg CCX140-B QD for 1 year.

**Results:** A total of 270 pts have been enrolled. Baseline characteristics, mean (SD): 64 (7) years old, 79% males, BMI 33 (5) kg/m$^2$, duration of diabetes 15 (8) years, duration of diabetic nephropathy 5 (4) years, geometric mean urinary ACR 475 (range 101-2708) mg/g creatinine, eGFR 60 (23) ml/min/1.73 m$^2$. 67% of patients had urinary ACR ≥300 mg/g and 33% between 100 and 299 mg/g inclusive. 52% had eGFR 25-59 ml/min/1.73 m$^2$ and 48% ≥60 ml/min/1.73 m$^2$. An external independent data monitoring committee has concluded after all reviews to date that there has been no evidence based on safety data to alter the protocol or study conduct. CCX140-B has been well tolerated in completed clinical trials, with no significant safety concerns. 12-week interim results from this trial are expected in Q3 2013.

**Conclusions:** Clinical development of the orally administered CCR2 antagonist CCX140-B is progressing well. CCX140-B has been well tolerated and safe in clinical trials, and has shown efficacy in a Phase 2 trial in type 2 diabetes. The first results from a clinical trial in DN are anticipated soon.

## SA-PO370

**Alogliptin Improves Steroid Diabetes by Decrease of Plasma Glucagon Levels in Chronic Kidney Disease Caused by Immunological Abnormalities** Naro Ohashi,[1] Takayuki Tsuji,[1] Hideo Yasuda,[1] Akihiko Kato,[2] Yoshihide Fujigaki.[3] *[1]First Dept of Medicine, Hamamatsu Univ School of Medicine, Hamamatsu, Japan; [2]Blood Purification Unit, Hamamatsu Univ School of Medicine, Hamamatsu, Japan; [3]Dept of Internal Medicine, Teikyo Univ School of Medicine, Tokyo, Japan.*

**Background:** Chronic kidney disease (CKD) is a risk factor for end-stage renal failure and cardiovascular disease, and a strategy to counteract CKD must be established. CKD caused by immunological abnormalities is treated by steroids, frequently resulting in steroid diabetes. Although insulin resistance is one of the mechanisms of steroid diabetes, and insulin is the most effective drug, it is not easy for patients to accept insulin therapy. Dipeptidyl peptidase-4 (DPP-4) inhibitors were developed for diabetes mellitus with a new mechanism of action. However, their efficacies and mechanisms of action for steroid diabetes are unclear.

**Methods:** We studied 11 CKD patients treated with steroids who were admitted to our hospital (3 men and 8 women; age, 66.0 ± 15.9 years). DPP-4 inhibitor alogliptin was administered for steroid diabetes. Levels of markers related to glucose metabolism were measured before alogliptin treatment and after alogliptin treatment, before the prednisolone dose was reduced.

**Results:** Alogliptin treatment significantly increased plasma glucagon-like peptide-1 (GLP-1) levels from 1.16 ± 1.71 pmol/L to 4.48 ± 1.53 pmol/L ($p = 0.0014$) and significantly reduced plasma glucose levels recorded 2 h after lunch and hemoglobin A1c (HbA1c). No significant differences were seen in either insulin secretory ability of homeostasis model assessment (HOMA) (HOMA-β) and insulin resistance index of HOMA (HOMA-R) before

and after alogliptin treatment. In contrast, alogliptin treatment significantly decreased plasma glucagon levels from 116.1 ± 38.7 pg/mL to 89.6 ± 17.3 pg/mL (p = 0.017). Moreover, there were significant correlations among HbA1c, GLP-1, and glucagon levels.

**Conclusions:** Alogliptin improves steroid diabetes by decrease of glucagon levels through an increase in plasma GLP-1 levels. Thus, alogliptin may be effective for the treatment of steroid diabetes in CKD caused by immunological abnormalities.

### SA-PO371

**Insulin-Sitagliptin Combination Therapy Stabilizes Blood Glucose Level in Japanese Patients with Diabetic Nephropathy** Masao Toyoda, Masafumi Fukagawa. *Internal Medicine, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.*

**Background:** The use of oral hypoglycemic agents in patients with diabetic nephropathy is often limited; therefore, intensive insulin therapy (IIT) is often prescribed. Similar to Western countries, the concomitant use of dipeptidyl peptidase-4 inhibitors and insulin has also been recently approved in Japan, and it is expected that the combination treatment could lead to stable euglycemia. In Western countries, adjusted doses of sitagliptin can be administered to patients with severe renal dysfunction or end-stage renal disease (ESRD); but this is contraindicated in Japan. Therefore, a retrospective study was conducted to evaluate the safety and efficacy of the combination of sitagliptin and IIT in Japanese type 2 diabetic patients with low estimated glomerular filtration rates (eGFR).

**Methods:** We selected 116 patients who were already receiving IIT combined with sitagliptin. From these patients, we selected 40 patients with eGFR of <60 mL/min/1.73 m$^2$. We analyzed hemoglobin A1c (HbA1c) levels, blood glucose (BG) levels, body weight, and changes in insulin dose. As an indicator of the stability of BG control, the M values were calculated through 4-times-daily self-monitoring of BG levels. Fluctuations in these levels were also analyzed using a continuous glucose monitor (CGM) in patients who could be monitored. The effect of treatment on BG level was assessed statistically.

**Results:** The mean eGFR in 40 patients was 47.8±9.1mL/min/1.73 m$^2$. The mean sitagliptin dose was 45.0±11.6mg, lower than the doses commonly used in Europe and North America. The mean HbA1c decreased significantly from 8.1±1.0 to 7.7±1.2%. The M value also improved significantly from 10.1±8.1 to 3.5±3.1. No significant changes were noted in body weight and insulin dose.

**Conclusions:** Our results showed that the combination of IIT and sitagliptin reduced fluctuations in BG level and reduced HbA1c level safely without weight gain even in patients with renal dysfunction. The lower dose of sitagliptin used in Japanese patients relative to their Western counterparts calls for further studies to examine inter-racial differences in the effects of incretin-related drugs.

### SA-PO372

**Effect of Angiotensin Converting Enzyme Inhibitors and Angiotensin II Receptor Blockers on Cardiovascular Events in Patients with Diabetes Mellitus: A Meta-Analysis** Jianghua Chen. *Kidney Disease Center, First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

**Background:** Angiotensin converting enzyme inhibitors (ACEIs) and angiotensin II receptor blockers (ARBs) maybe have different effects on cardiovascular (CV) events in diabetic patients. We conducted a meta-analysis to separately evaluate the effects of ACEIs and ARBs on major CV events in diabetic patients.

**Methods:** MEDLINE, Embase, Cochrane Library, and article reference lists were searched for RCTs that compared ACEIs and ARBs with controls in diabetic patients.

**Results:** Twenty-one RCTs compared ACEIs with controls (32,141 patients) and twelve compared ARBs with controls(23,617 patients). When compared with controls, ACEIs significantly reduced the risk of major CV events by 14%(0.86, 0.77-0.95), including myocardial infarction(MI) by 21% ( 0.79, 0.65-0.95) and heart failure by 19%(0.81, 0.71-0.93). ARBs treatment did not significantly affect major CV events(0.94, 0.87-1.01) except for heart failure(0.70,0.59-0.82). Both ACEIs and ARB agents did not significantly affect the risk for stroke.

**Conclusions:** In view of the high prevalence of CV disease in diabetic patients, ACEIs as the first choice of treatment may result in considerable benefit and reduction in MI and heart failure risk. More data are needed to clarify the role of ARB in survival benefits for diabetic patients.

### SA-PO373

**No Overall Increase in Volume Depletion Events with Empagliflozin (EMPA) in a Pooled Analysis of More Than 11,000 Patients with Type 2 Diabetes (T2DM)** Robert D. Toto,[1] Christoph Wanner,[2] John Gerich,[3] Afshin Salsali,[4] Thomas Hach,[4] Gabriel Kim,[4] Stefan Hantel,[5] Hans-Juergen Woerle,[4] Uli Christian Broedl.[4] *[1]Univ of Texas Southwestern Medical Center, Dallas; [2]Univ of Würzburg, Germany; [3]Univ of Rochester School of Medicine, Rochester, NY; [4]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; [5]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany.*

**Background:** The SGLT2 inhibitor EMPA is in development for the treatment of T2DM. SGLT2 inhibitors lead to osmotic diuresis, which could lead to volume depletion.

**Methods:** Using pooled data from Phase I, II and III trials, adverse events (AEs) consistent with volume depletion were evaluated through a search of investigator-reported AEs (8 prospectively defined preferred terms: BP decreased, BP ambulatory decreased, BP systolic decreased, dehydration, hypotension, orthostatic hypotension, hypovolemia, syncope) in patients with T2DM treated with placebo (PBO; n=3522), EMPA 10 mg (n=3630) or EMPA 25 mg (n=4602) in subgroups of age (<50, ≥50–<65, ≥65–<75, ≥75 yrs), eGFR (≥90, ≥60–<90, ≥30–<60, <30 mL/min/1.73m²) and diuretic use. Mean (SD) baseline age was 59.6 (10.0) yrs and eGFR 80.1 (22.1) mL/min/1.73m².

**Results:** The percentage of patients with volume depletion events was similar with PBO (49/3522 [1.4%]), EMPA 10 mg (52/3630 [1.4%]) and EMPA 25 mg (67/4602 [1.5%]). The percentage of patients with events increased from 0.9%, 0.4% and 0.7% with PBO, EMPA 10 mg and EMPA 25 mg, respectively, in the youngest group to 2.1%, 2.3% and 4.4%, respectively, in the oldest group. The percentage of patients with events increased from 0.8%, 0.9% and 0.6% with PBO, EMPA 10 mg and EMPA 25 mg, respectively, in the highest eGFR group to 9.6%, 14.3% and 7.1%, respectively, in the lowest eGFR group. Percentages were similar with PBO and EMPA in age and eGFR groups except as shown in the oldest group. More patients on diuretics (2.2–2.7%) than not (0.9–1.0%) reported these events; percentages were similar with PBO and EMPA.

**Conclusions:** EMPA was not associated with an increased frequency of volume depletion events versus PBO, except with EMPA 25 mg in patients ≥75 yrs of age.

*Funding:* Pharmaceutical Company Support - Boehringer Ingelheim

### SA-PO374

**Improvement in Insulin Resistance, Adipokines and Kidney Function following Bariatric Surgery** Sankar D. Navaneethan,[1] Steven K. Malin,[2] John P. Kirwan,[2] Philip R. Schauer.[3] *[1]Nephrology; [2]Pathobiology; [3]Bariatric Surgery, Cleveland Clinic.*

**Background:** Bariatric surgery improves metabolic function and is the most effective weight loss treatment for obesity. However, the efficacy of bariatric surgery on improving kidney function is unclear. Therefore, we determined the effects of bariatric surgery on kidney function, body composition, insulin resistance, and inflammation/adipokines in obese subjects with CKD.

**Methods:** Eleven subjects (8M/3F, age: 55 years, BMI 46 kg/m$^2$, iothalamate glomerular filtration rate [iGFR] 50 ml/min/1.73m$^2$) underwent either Roux-en-Y gastric bypass or gastric banding. Body composition (DEXA), inflammation (hs-CRP), insulin resistance (fasting insulin), adipokines (HMW-adiponectin and leptin) and kidney function (iGFR) were measured before and after 12 months of surgery. Pre-post data were compared with t-tests and Pearson's correlation was also performed.

**Results:** At 12 month follow-up, there was a significant decrease in BMI and fat mass. Bariatric surgery increased kidney function (Table). Fasting insulin, hs-CRP and leptin levels decreased, while HMW-adiponectin increased following surgery (Table).

| Variable | Median (Inter-quartile range) | p-value |
|---|---|---|
| Change in BMI (kg/m$^2$) | -9.3 (-15.2, -5.5) | 0.002 |
| Change in Fat mass (kg) | -25.4 (-32.6, -18.0) | 0.002 |
| Change in Log CRP | -0.54 (-0.69, -0.16) | 0.002 |
| Change in 1/insulin | -42.7 (-89.8, -0.21) | 0.03 |
| HMW Adiponectin change | 4666.9 (953.5, 6548.9) | 0.002 |
| Change in Leptin | -14.9 (-30.1, -5.9) | 0.004 |
| Change in Iothalamate GFR (ml/min/1.73 m$^2$) | 8 (5, 22) | 0.03 |

The improvement in kidney function correlated with the reduction in leptin (rho=-0.89, p<0.001) and insulin resistance (rho=-0.67, p=0.03). Decreased leptin was significantly correlated with lower fat mass (rho=0.63, p=-0.04) and insulin resistance (rho=0.73, p=0.01).

**Conclusions:** In CKD, bariatric surgery improves kidney function, inflammation, insulin resistance, and adipokines at one-year follow-up. Reductions in fat mass were linked to lower circulating leptin and insulin, suggesting that weight loss might contribute to the improvement in kidney function. Studies with longer follow-up data related to kidney function and the mechanisms that may contribute to the improvement in kidney function are warranted.

*Funding:* Other NIH Support - NCRR

### SA-PO375

**Glycemic Indices and Dialysis Modality in Diabetic (DM) and Non-Diabetic (NDM) Patients** Neal Mittman,[1] Lin Ma,[2] Mark E. Williams,[3] Julia I. Brennan,[4] Chinu M. Jani,[4] Curtis D. Johnson,[4] Franklin W. Maddux,[2] Eduardo K. Lacson.[2] *[1]Long Island College Hospital, Brooklyn, NY; [2]Fresenius Medical Care, North America, Waltham, MA; [3]Joslin Diabetes Center, Boston, MA; [4]Spectra Laboratories, Rockleigh, NJ.*

**Background:** Small studies have documented varying correlations between 2-3 glycemic indices. However, correlations among multiple types of novel glycemic indices have not been reported.

**Methods:** We explored simultaneous measurement of serum glucose (BG), glycosylated hemoglobin (A1c), serum fructosamine (SF), and glycated albumin (GA) in a national sample of 1659 DM and 1130 NDM hemodialysis (HD) and 318 DM and 324 NDM peritoneal dialysis (PD) patients from 26 FMCNA facilities distributed across the US. We

report mean values in these pts for the period January-March 2013, stratified by dialysis modality. In addition, SF was albumin-corrected (AlbF) and GA was expressed as a percentage glycation (%GA).

**Results:** We found that these glycemic markers correlated with each other and with blood glucose in both DM and NDM dialysis pts (all p≤0.001). However, there is a variability in the correlation coefficients (R-value) particularly in NDM relative to DM. Correlations were stronger in DM pts and less modality-related than in NDM pts. Interestingly, in the NDM pts, correlations were consistently stronger in PD vs. HD with BG and A1c. However, between the protein-based assays, the reverse was observed.

| r values HD/PD | A1c | SF | AlbF | GA | %GA |
|---|---|---|---|---|---|
| BG DM | 0.68/0.73 | 0.54/0.48 | 0.57/0.51 | 0.60/0.61 | 0.63/0.67 |
| BG NDM | 0.40/0.61 | 0.11/0.32 | 0.20/0.29 | 0.33/0.44 | 0.41/0.49 |
| A1c DM | | 0.69/0.64 | 0.66/0.63 | 0.77/0.78 | 0.78/0.83 |
| A1cNDM | | 0.19/0.34 | 0.13/0.25 | 0.35/0.50 | 0.36/0.54 |
| SF DM | | | 0.87/0.80 | 0.91/0.80 | 0.87/0.75 |
| SF NDM | | | 0.67/0.70 | 0.69/0.62 | 0.58/0.56 |
| AlbF DM | | | | 0.78/0.58 | 0.88/0.74 |
| AlbF NDM | | | | 0.38/0.18 | 0.58/0.35 |
| GA DM | | | | | 0.96/0.94 |
| GA NDM | | | | | 0.90/0.93 |

**Conclusions:** Differences between glycemic indices may reflect distinct exposure times to glycemia, i.e. A1c reflecting 2-3 months of exposure while SF and GA reflects only 2-3 weeks. Since GA is the predominant SF, stronger correlation between them is expected. In addition, modality comparisons may be influenced by differential protein losses and dialysate glucose exposure times.

## SA-PO376

**Effectiveness of the Diabetic StepAhead Program in Improving Patient Care among Diabetic ESRD Patients** Stephen D. McMurray,[1] Christine Ordway,[1] Carey Colson,[2] Pooja C. Oberai,[2] Anne N. Bubb.[1] *[1]DaVita VillageHealth, Vernon Hills, IL; [2]DaVita Clinical Research, Minneapolis, MN.*

**Background:** Diabetes mellitus (DM) is a leading cause of mortality and morbidity in end-stage renal disease (ESRD). StepAhead is an integrated DM care management program aimed at enhancing patient outcomes via physician-driven DM-management, regular eye exams and foot checks, and patient education on DM self-management. While the program is undergoing a year-long study to assess the reduction in lower limb amputations and mortality rates among this population, this interim analysis assessed its effectiveness after 6 months of implementation.

**Methods:** StepAhead was initiated in January 2012 and included 447 identified diabetic ESRD patients from 11 participating clinics. Information on clinical management of DM as well as DM-education was obtained from the electronic medical record at baseline and at 6 months.

**Results:** At 6-month follow-up, enrolled patients were 64 years old, 54.5% male, and 48.9% black. Cumulative outcome metrics (N = 356) show that 336 (94.4%) were provided physician management; 319 (89.6%) had an eye exam within the past year; 333 (93.5%) had received blood glucose education; and 330 (92.7%) had a glucometer by the end of six months. Of the 211 patients who were not physician managed for DM at baseline, 151 (72%) completed 6 months in the program, 136 (86.8%) became physician managed, and 36 (23.9%) were referred to a physician for DM-management at 6 months. Among the 218 patients who did not have an eye-exam within a year of enrollment at baseline, 120 (76.4%) received an eye-exam and 33 (21.0%) were referred for one at 6 months. Of the total 163 (73.0%) patients without a glucometer at baseline, 136 (84.0%) received one. Finally, 322 (89.2%) of the patients underwent at least one foot-check within 6 months of enrollment.

**Conclusions:** The data suggest that the StepAhead Program successfully enhances physician-driven DM-management and self monitoring. The preventive measures included in the program potentially allow for early detection of complications and delay progression, which will be evaluated in subsequent data cuts.

## SA-PO377

**Effect on the Improvement of Prognosis in Simultaneous Pancreas-Kidney Transplantation and Kidney Transplantation Alone for Type 1 Diabetic Patients with End-Stage Renal Disease** Izumi Nyumura, Tetsuya Babazono, Michino Takagi, Yasuko Uchigata. *Diabetes Center, Tokyo Women's Medical Univ, Tokyo, Japan.*

**Background:** Kidney transplantation has been demonstrated to prolong survival in diabetic patients with ESRD; however, it is unclear whether simultaneous pancreas-kidney transplantation (SPK) yields additive benefit in type 1 diabetes (T1DM) patients with ESRD compared with kidney transplantation alone (KTA). We therefore conducted this study to compare prognosis in patients with T1DM undergoing chronic dialysis, KTA, and SPK. The results of transplantations were also compared between the two transplant groups.

**Methods:** 128 T1DM patients with EASD (84 women and 44 men) were studied, comprising of 54, 45 and 27 patients undergoing dialysis, KTA and SPK respectively. We compared survival among the three renal replacement therapy (RRT) groups after the start of dialysis. Patient and graft survival rates were also compared between the two transplant groups.

**Results:** Age of dialysis initiation, diabetes onset and duration of diabetes were significantly higher in SPK and KTA than chronic dialysis group. There were no significant differences among the three RRT groups in terms sex and dialysis treatment. Recipient's age was not different between SPK and KTA. In KTA 96% were from living donors. Ten-year patient survival rates after the start of dialysis was 63 % for the dialysis group, 94 % for the KTA group, and 92% for the SPK group, respectively (P<0.001). In multivariate analysis, SPK and KTA were associated with a lower mortality risk than dialysis patients, respectively (hazard ratio 0.10 and 0.28, p=0.003 and 0.029). Patient survival at 10 years was 90 % for the KTA group, 91 %for the SPK group, respectively (P=0.25). Graft survival at 10 years was 74 % for the KTA group, 59 % for the SPK group (P=0.52).

**Conclusions:** Prognosis for patients receiving SPK or KTA may be superior to that for patients undergoing dialysis. Patient and kidney graft survival were similar for SPK and KTA, because favorable results would be achieved with KTA.

## SA-PO378

**The Role of Circulating Fibroblast Growth Factor-21 in the Chronic Peritoneal Dialysis Patients** Jin Joo Cha,[1] Mi Jin Lee,[1] Young Youl Hyun,[2] Dae R. Cha,[1] Jung Eun Kim,[1] Mihwa Lee,[1] Hye Kyoung Song,[1] Young Sun Kang.[1] *[1]Nephrology, Korea Univ Ansan Hospital, Ansan, Kyunggido, Republic of Korea; [2]Nephrology, Sungkyunkwan Univ Kangbuk Samsung Hospital, Seoul, Republic of Korea.*

**Background:** In experimental studies, fibroblast growth factor-21(FGF-21) has shown to exert positive metabolic effects, inducing overweight reduction, lowering elevated glucose and triglyceride levels and increasing insulin sensitivity. A number of human studies also have reported elevated levels of FGF21 in patients with obesity, increased insulin resistance and fatty liver. However, the physiologic role in the humans is still controversial. We therefore investigated whether circulating FGF21 may act as a metabolic regulator in the setting of chronic renal failure.

**Methods:** Baseline plasma FGF21 levels were measured using an enzyme-liked immunosorbent assay in total 68 patients on peritoneal dialysis. Baseline metabolic parameters were assessed and prospective association of FGF21 with clinical morbidity was analyzed in a 2 year prospective study.

**Results:** All 68 patients (mean age= 49.1±10.6, PD vintage 44.5±29.9months) had residual GFR less than 2ml/min/1.73m2. Baseline FGF 21 showed wide variation ranging from 256.00 to 35896.00pg/ml (mean 4400.18±6100.35). Serum FGF21 level did not significantly differ in the presence of diabetes, hypertension. There were no associations between BMI, HOMA IR, HOMA beta levels, inflammatory markers(CRP, MCP-1, IL-6, TNF-α) and FGF21. Lipid profile and the fat component of the body (ATI) were also not correlated with FGF21. The use of CAPD decreased FGF21 level comparedto APD (p=0.01) and those with increased vascular calcifications (measured by calcification score) showed increased level of FGF21 (p=0.035). During median follow up of 30months, 9 (13.6%) patients had cardiovascular events and 35(53%) patients experienced infection which needed hospitalization. Serum FGF21 level did not increase the risk of cardiovascular complications nor infection.

**Conclusions:** These findings suggest that FGF21 might not have any metabolic role in the setting of chronic dialysis patients.

## SA-PO379

**Novel Coding Variants in NPHS1 Are Associated with Diabetic and All-Cause End-Stage Kidney Disease (ESKD) in African Americans** Jason A. Bonomo,[1] Maggie Ng,[1] Nicholette D. Palmer,[1] Barry I. Freedman,[2] Donald W. Bowden.[1] *[1]Ctr for Genomics & Personalized Med Res, Wake Forest School of Medicine, Winston Salem, NC; [2]Int Med/Nephrology, WFSOM.*

**Background:** Familial clustering and presumed genetic risk for diabetic- and non-diabetic ESKD appears strong in African ancestry populations. The genetic architecture of diabetes (DM)-associated ESKD has not been fully elucidated.

**Methods:** We reviewed exome sequencing data from 500 African American cases with DM-ESKD and 500 population-based controls in the T2D-GENES study focusing on previously implicated nephropathy genes (ie, NPHS1). Variants were genotyped in an independent replication cohort composed of 1,250 African American DM-ESKD cases and 850 population-based controls. Next, a trait discrimination study was performed in a cohort of 1,450 African American non-DM ESKD cases and 600 African American T2D non-ESKD cases. 1000 Genomes and the Exome Variant Server were used to identify additional rare- and low-frequency NPHS1 variants in African Americans. 25 additional NPHS1 missense variants were genotyped in DM-ESKD and non-DM ESKD cases and population-based controls. Finally Sequence Kernal Association Testing (SKAT) was performed.

**Results:** Initial analysis identified a low-frequency missense mutation (rs35238405, T233A) in the nephrin gene (NPSH1) associated with DM-ESKD (p=0.043, OR=3.01). Following adjustment for age, gender, admixture, and the apolipoprotein 1 (APOL1) G1/G2 alleles, association was confirmed in the replication cohort (p=0.038, OR=2.28). Rs35238405 was associated with non-DM ESKD (p=0.011, OR=2.5) but not T2D *per se* (p=0.14) after adjustment for covariates. In a combined, all-cause ESKD analysis, rs35238405 had an OR of 2.54 (p=0.0041) after covariate adjustment. Of the 25 genotyped NPHS1 variants, 9 were monomorphic and two were associated with all-cause ESKD in single-SNP association testing (rs146400394 p=0.0089, OR=0.04; rs143649022 $p=7.9\times10^{-6}$, OR=0.18) following covariate adjustment. P values of $4.2\times10^{-7}$ and $2.4\times10^{-4}$ were obtained in an unadjusted and adjusted SKAT analysis.

**Conclusions:** Coding variants in NPSH1 appear to alter the risk for common forms of diabetic and non-diabetic ESKD in African Americans.

## SA-PO380

**Does Iron Status Affect Platelet Counts in Hemodialysis Patients?** Kiyomi Koike,[1] Kei Fukami,[1] Kazumasa Shimamatsu,[2] Atsushi Kawaguchi,[3] Seiya Okuda.[1] *[1]Div of Nephrology, Dept of Medicine, Kurume Univ School of Medicine, Kurume, Fukuoka, Japan; [2]Shimamatsu Naika Iin, Chikushino, Fukuoka, Japan; [3]Biostatistics Center, Kurume Univ, Kurume, Fukuoka, Japan.*

**Background:** Normalizing hemoglobin(Hb) levels by ESAs has been reported to be associated with risk of cardiovascular death/events via thrombocytosis due probably to ESA-induced iron deficiency 'platelet link hypothesis' in CKD patients. However, whether or not disturbed iron status really affects platelet counts.

**Methods:** In our cohort, 117 HD outpatients followed for 4 years in a single center. Target Hb level was 11.0 g/dl. The outcome variable is increase in platelet counts. Potential predictors are iron indices such as transferring saturation (TSAT), serum iron and ferritin. We investigated the association between iron indices and increase in platelet counts by mixed effect model adjusted for time, age, gender, Hb, CRP, alb, a weekly ESAs dose and a monthly i.v. iron dose with non-linear analysis. Next, in the analysis for the first difference of a time series which is the series of changes from one period to the 3 months later (Δ), the correlation between Δiron indices and Δplatelet counts was examined. Further, we analyzed whether or not ESAs dose was associated with iron status.

**Results:** Mean age; 61.9 yrs and mean Hb; 10.8 g/dl. In multivariate regression analyses, lower TSAT levels (increase in platelet counts $0.3\times10^4/\mu L$ per 10% decrease in TSAT, 95%CI, -4.8 to -1.7; p<.0001) and higher ESAs dose (95%CI, 0.03 to 0.22; p=.0077) were significantly correlated with larger increase in platelet counts independently of Hb, Alb, CRP and i.v. iron dose. ΔTSAT was negatively and Δferritin was positively correlated with Δplatelet counts (95%CI, -4.9 to -1.7; p<.0001 and 95%CI, 0.0007 to 0.004; p=.003, respectively). Higher ESAs dose to keep target Hb levels was significantly associated with lower TSAT and ferritin (<330ng/ml) levels (p<.0001, respectively).

**Conclusions:** These observations suggest that iron status, especially decreased TSAT, may directly affect increased platelet counts and subsequently cause cardiovascular events in HD patients on ESAs treatment.

## SA-PO381

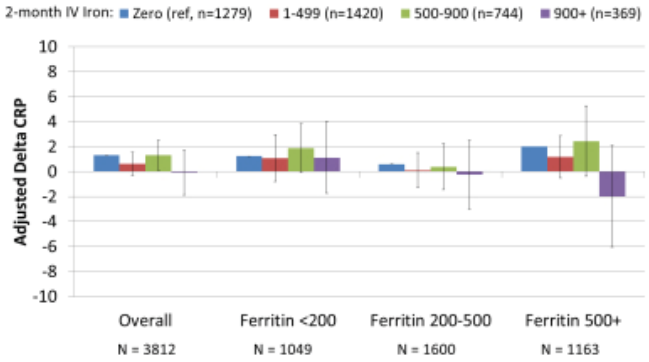
**IV Iron Is Not Associated with Change in CRP across Dose and Ferritin Levels: A DOPPS Study** Laura H. Mariani,[1] Keith McCullough,[2] Mark R. Marshall,[3] Patricia De Sequera,[4] Ananda Sen,[1] Masaaki Inaba,[5] Ronald L. Pisoni,[2] Bruce M. Robinson.[2] *[1]U. of Michigan; [2]Arbor Research Collaborative for Health; [3]Middlemore Hospital; [4]Hospital Infanta Leonor; [5]Osaka City U. Graduate School of Medicine.*

**Background:** Inflammation and CRP levels are positively associated with mortality in hemodialysis patients. The sustained effects of IV iron on CRP levels are unclear, and may depend on patient iron and inflammatory status. This study examined the association between iron dose and change in CRP.

**Methods:** Observational DOPPS phase 4 (2009-11) data from facilities that measured CRP at least quarterly on 75+% of patients, in seven European countries and Australia/New Zealand were used to determine IV iron dose over two consecutive months (iron dose measurement period, or IDMP). Baseline CRP was the most recent value prior to the IDMP. Final CRP was collected during the 2nd month of the IDMP or up to 1 month later. Linear models were used to determine the association between delta (final – baseline) CRP levels and total IV iron dose during the IDMP, controlling for patient demographics (age, race, sex, BMI); comorbidities (15 factors); and IV iron dose, TSAT, ferritin, Hgb, and ESA use in the month preceding the IDMP.

**Results:** Change in CRP did not differ meaningfully across iron dose categories, overall or by ferritin levels.

**Figure 1: Adjusted Change in CRP by Ferritin and IV Iron**



Additionally, no pattern for change in CRP was seen when excluding baseline ESA use, IV iron dose or lab values from the model, or in separate models based on the following at baseline: CRP < 10 v. 10+; TSAT < 20% v. TSAT 20%+; IV iron dose 0 v. >0 mg/month.

**Conclusions:** We found no association between two-month IV iron dose (including doses suggestive of replacement IV iron dosing) and change in CRP across a range of markers indicative of iron and inflammatory status. Associations with longer-term IV iron dosing also merit study.

## SA-PO382

**Achieved Iron Stores and Clinical Outcomes in a Trial of Ferric Citrate as a Phosphate Binder** Kausik Umanath,[2] Mohammed Sika,[1] Mark Koury,[1] Jamie P. Dwyer,[1] Julia Lewis,[1] The Collaborative Study Group.[3] *[1]Vanderbilt Univ; [2]Henry Ford Hosp; [3]CMM.*

**Background:** The safety of achieved iron stores in dialysis patients is controversial. Utilizing data from a multicenter, randomized trial in 441 dialysis subjects treated with ferric citrate (FC) or active control (AC) (calcium acetate, sevelamer carbonate, or a combination), we grouped subjects based on their achieved iron stores and examined their safety profiles.

**Methods:** Subjects were randomized 2:1 to FC or AC, and followed during a 52-week safety assessment period (SAP). IV iron use was at the discretion of the site as long as the serum ferritin was ≤ 1000ng/mL and the transferrin saturation (TSAT) was ≤ 30%. All oral iron and vitamin C supplements were prohibited. Adverse events, ferritin, and transferrin saturation (TSAT) were collected and analyzed.

**Results:** In the SAP, baseline mean serum ferritin was 594 + 297ng/mL. At week 52, mean ferritin was 776 + 444 ng/mL. Mean TSAT at baseline was 31 + 11%. At week 52, mean TSAT was 34 + 14%. Treatment emergent adverse events (TEAE), death, and serious adverse events (SAE) by tertiles of mean ferritin and TSAT averaged over 52 weeks are shown in Tables 1 and 2.

Table 1

| Ferritin, ng/mL | <500 | 500-1000 | >1000 |
|---|---|---|---|
| Subjects (*N*) | 117 | 232 | 92 |
| Subjects with Death (%) | 7.7 | 3.4 | 4.3 |
| Subjects with Any SAE (%) | 49.5 | 41 | 37 |
| Subjects with Any TEAE (%) | 95 | 99 | 97 |

Table 2

| TSAT, % | < 30 | 30-50 | >50 |
|---|---|---|---|
| Subjects (N) | 160 | 243 | 38 |
| Subjects with Death (%) | 6.9 | 3.7 | 2.6 |
| Subjects with Any SAE (%) | 52 | 37 | 39 |
| Subjects with Any TEAE (%) | 97 | 97 | 100 |

**Conclusions:** There was no evidence of an increase in adverse events associated with higher ferritin and TSAT levels.

## SA-PO383

**Anemia Management: To HOLD or Not to HOLD** Adam E. Gaweda,[1] Michael A. Jacobs,[1] Yossi Chait,[2] Joseph Horowitz,[2] Michael J. Germain,[3] Christopher V. Hollot,[2] Michael E. Brier.[1] *[1]Univ of Louisville; [2]UMass Amherst; [3]Western New England Renal and Transplant Associates.*

**Background:** Safety issues related to the use of Erythropoiesis Stimulating Agents (ESA) in treating anemia of End-Stage Renal Disease (ESRD) affect practice patterns of anemia management. The FDA recommends ESA dose reduction or hold when hemoglobin (Hgb) exceeds 11 g/dL. We compared these two dose adjustment strategies through simulation of anemia management.

**Methods:** We performed a simulation of two clinical scenarios: 1) Hgb exceeding 11 g/dL following increase in ESA dose 2) Stable Hgb of 10.5 g/dL exceeding 11 g/dL due to random variability. The two dose adjustment strategies tested were (1) HOLD: hold ESA when Hgb reaches 11 g/dL and restart at 50% previous dose when Hgb falls below 10 g/dl, and (2) REDUCE: reduce ESA by 50% when Hgb reaches 11 g/dL. We calculated the following outcomes: a) percent time Hgb is less than 10 g/dL, b) percent time Hgb is in range 10-11 g/dL, c) mean weekly ESA dose. All outcomes were calculated over the period of 4 months after dose adjustment. We used an erythropoiesis model with two parameters: a) erythropoietic sensitivity and b) red cell lifespan, to generate a virtual population of 42 subjects. Statistical analysis was performed using mixed effect regression to account for multiple measurements within subjects.

**Results:** Scenario 1): HOLD resulted in the Hgb below 10 g/dL 50% of the time VS 0% of the time with REDUCE ($p < 0.001$). Mean weekly ESA dose was 21% lower with HOLD compared to REDUCE ($p < 0.001$)

Scenario 2): HOLD results in the Hgb below 10 g/dL 60% of the time VS 53% with REDUCE ($p = 0.017$). Mean weekly ESA dose was 10% lower with HOLD compared to REDUCE ($p = 0.138$).

**Conclusions:** When Hgb persistently rises above 11 g/dL, the choice of dose adjustment strategy should be based on the risk assessment for an individual patient (risk of transfusion due to low Hgb vs. risk of cardiovascular side effects due to ESA). When Hgb incidentally exceeds 11 g/dL, both strategies result in an unnecessary Hgb fall and should be avoided. To differentiate between the two scenarios in clinical practice, attention must be paid to proper monitoring and trending of Hgb.

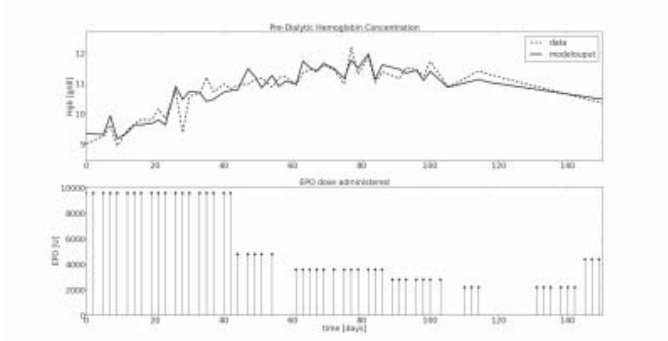
## SA-PO384

**A Mathematical Erythropoiesis Model Adjusted to Individual Hemodialysis Patients** Doris Helene Fuertinger,[1] Franz Kappel,[2] Stephan Thijssen,[1] Peter Kotanko.[1] *[1]Renal Research Institute, New York; [2]Univ of Graz, Austria.*

**Background:** Interindividual variability in red blood cell (RBC) lifespan, bone marrow response to erythropoietin (EPO), endogenous EPO production and half-life is high in hemodialysis (HD) patients. Routine measurement of these quantities is elusive, thus making it almost impossible to predict the individual response to EPO administration schemes. Here we describe the adaptation of a complex mathematical model of erythropoiesis to individual HD patients.

**Methods:** A mathematical model (Fuertinger et al, JMathBiol 2013) is adjusted to individual HD patients treated with EPO. The patient's blood volume and number of stem cells are estimated based on height and weight. Crit-Line™ devices were used for intradialytic hemoglobin (Hgb) measurements. Hgb data is used to identify the RBC lifespan, bone marrow response to EPO, endogenous EPO production, and EPO half-life in individual HD patients.

**Results:** We studied 1,866 HD sessions in 36 patients (mean (range) age 59.8 (25-85) years; 66.7% Blacks; 52.8% females; 61.1% diabetes; body mass index (BMI) 26.3 (17.9-50.4) kg/m$^2$). Independent of gender and BMI the mean (range) of the identified erythropoiesis parameters were biologically plausible: RBC lifespan 72.7 (50.5-103.4) days, and EPO half-life 6.98 (4.1-12.3) hours. The model accurately represented the Hgb dynamics in all patients. For an example for an adaption of the model to an individual HD patient, see Figure.



**Conclusions:** Our results indicate that this model can be adjusted to HD patients based on gender, height, weight, 3x weekly Hgb measurements, and EPO doses. The model quantitatively describes the specific dynamics of erythropoiesis and Hgb levels in EPO treated HD patients. The model can be used to investigate, compare, and improve EPO administration schemes based on metrics of accuracy, precision, and cost-effectiveness.

## SA-PO385

**Statin Therapy in Dialysis Patients and Its Effects on Erythropoietin Resistance Index** Jerome Pineault, Jean-Philippe Lafrance, Martine Leblanc, Georges Ouellet, Robert Zoël Bell, Michel Vallee, Vincent Pichette. *Medicine, Div of Nephrology, Maisonneuve-Rosemont Hospital, Montreal, Canada.*

**Background:** Erythropoietin (EPO) resistance and anemia is a burden among dialysis patients and efficient therapies are lacking. We studied the effect of statin therapy on EPO responsiveness in our dialysis population.

**Methods:** We reviewed the records of 662 patients receiving chronic dialysis from September 2008 to March 2011. We measured EPO resistance index (ERI) from the weekly dose of EPO/kg divided by Hb (g/dL) each month. Association between statin use and ERI was estimated using a multivariate linear mixed-effects, adjusting for sex, age, diabetes, dialysis modality and ACEi/ARB use.

**Results:** A total of 503 patients underwent analysis after exclusion. The multivariate regression analysis showed that ERI was not improved with statin therapy ($e^{\beta} = 0.97$, with $P > 0.05$). Patients getting started on statins during the study (N=42) had increased ERI after statin exposure and those getting off statins (N=47) had their ERI decreased after statin was stopped, the exact opposite of what was expected, even though results were non statistically significant. Male sex and peritoneal dialysis were associated with a lower EPO resistance. Also, ACEi/ARB and diabetes were associated (but not significantly) with higher EPO resistance.

**Conclusions:** Statin use was not associated with improved EPO responsiveness. Also, male sex and peritoneal dialysis appeared to be potential protectors from EPO resistance. However, a confirmation of these results is needed by larger randomized-controlled trials.

## SA-PO386

**Hyporesponsiveness to Erythropoiesis-Stimulating Agent as a Prognostic Factor in Japanese Hemodialysis Patients: The Q-Cohort Study** Rieko Eriguchi,[1] Masatomo Taniguchi,[2] Kazuhiko Tsuruya,[2] Hideki N. Hirakata,[3] Satoru Fujimi,[1] Takanari Kitazono.[2] *[1]Fukuoka Renal Clinic, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Div of Nephrology and Dialysis Center, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan.*

**Background:** Several longitudinal studies have shown that responsiveness to erythropoiesis-stimulating agent (ESA) is related to the prognosis in hemodialysis (HD) patients. We investigated the effects of hyporesponsiveness to ESA on mortality in Japanese HD patients, taking factors modifying its effects into account.

**Methods:** A total of 2,905 Japanese HD patients aged ≥18 years, who received ESAs, were prospectively followed up for 4 years. The responsiveness to ESA was estimated using a erythropoietin resistance index (ERI), defined as erythropoietin dosage for a week divided by the post-HD weight and hemoglobin value. Patients were divided into three groups with tertiles of ERI values; low ERI: ≤5.10, intermediate ERI: 5.11-9.43, and high ERI: ≥9.44. The risk estimates were calculated by using a Cox proportional hazards model.

**Results:** During the follow-up period, 482 patients died from any causes. The mortality rate for 4 years increased linearly with higher ERI levels, being 12.5%, 17.1%, 28.0% for low, intermediate, and high ERI levels (p for trend < 0.001). Compared with those with lower ERI levels, the multivariate-adjusted hazard ratio (mHR) was significantly higher in patients with high ERI level (mHR, 1.59 [95%, confidence interval, 1.24-2.04]. Among high ERI group, patients with Kt/V≥1.57 had a significantly lower risk of death from any causes, than those with Kt/V<1.57 (mHR, 0.74 [0.55-1.00]).

**Conclusions:** Our findings suggest that ESA responsiveness can be considered a significant prognostic factor in Japanese HD patients, and higher dose of dialysis seems to be effective for improving prognosis of HD patients with hyporesponsiveness to ESA.

## SA-PO387

**Virdaglin, an Inhibitor of Dipeptidyl Peptidases 4 (DPPI-4), May Enhance the Effects of Continuous Erythropoietin Receptor Activator (CERA) in Treating Renal Anemia in Hemodialysis (HD) Patients** Jyunichiro Hashiguchi,[1] Satoshi Funakoshi,[1] Kenji Sawase,[1] Yoshiaki Lee,[1] Masatoshi Hayashida,[1] Takashi Harada,[1] Kenichi Miyazaki,[1] Tomoya Nishino,[2] Yoko Obata,[2] Shigeru Kohno,[2] Kazunori Utsunomiya.[3] *[1]Div of Blood Purification, Nagasaki Renal Center, Nagasaki, Japan; [2]Dept of Internal Medicine, Nagasaki Univ Graduate School of Medicine, Nagasaki, Japan; [3]Dept of Diabetology, Jikei Univ, Tokyo, Japan.*

**Background:** DPP-4 (=CD26) is expressed on activated lymphocytes and posess hematopoietic effects via pathways for regulating cytokines (Jones B, et al. Blood 2003). Continuous eythropoietin receptor activator (CERA) is a long-acting erythropoiesis-stimulating agent, and the effects may possibly be enhanced by hematopoietic effect of DPP-4 inhibitor.

We evaluated the erythropoietic effects of DPP-4 inhibitor in HD patients treated with CERA when converted from sulfonyl urea (SU) or phenylalanine analogues (PA).

**Methods:** From September to December 2010, 15 HD outpatients were enrolled in this study after appropriate IC, and were monitored by various parameters including fasting plasma glucose (FPG), HbA1c, Hb, albumin or body weight. CERA doses had stayed the same.

**Results:** All the subjects were administered CERA at 134 ± 27.5 mg. FPG and HbA1c level had been stabilized after dose adjustment of virdaglin. As shown in Table 1, there was significant increase in Hb level (10.8 ± 1.49 to 11.6 ± 1.08, p=0.018) though CERA doses had been unchanged.

| | SU / PA | Virdaglin | p value |
|---|---|---|---|
| HbA1c (%) | 6.87±2.21 | 6.55±2.89 | 0.25 |
| n-PCR (g/Kg/day) | 0.86±0.09 | 0.88±0.11 | 0.39 |
| T-cho (mg/dL) | 166.3±29.3 | 148.5±30.6 | 0.40 |
| i-PTH (μg/dl) | 117.6±86.9 | 85.87±0.4 | 0.15 |
| WBC (/mm$^3$) | 6510±3880 | 6920±4040 | 0.39 |
| **Hb (g/dL)** | **10.8±1.49** | **11.6±1.08** | **0.018** |
| Plt (/mm$^3$) | 20.5±8.5 | 19.4±9.9 | 0.27 |

Other nutritional parameters stayed the same.

**Conclusions:** Virdaglin can potentially enhance the hematopoietic effects of CERA in the treatment of anemia for diabetic HD patients.

*Funding:* Private Foundation Support

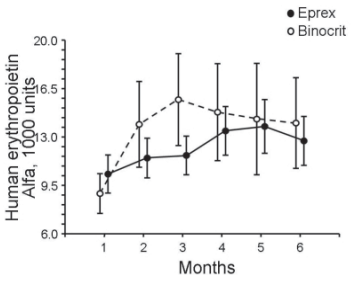
**SA-PO388**

**Human Erythropoietin Alfa Originator and Biosimiliar: Safety, and Therapeutic Equivalence in a Cohort of Emodialysis Patients. A Pilot Study** Paolo Lentini,[1] Luca Zanoli,[2] Massimo de Cal,[1] Stefania Rastelli,[2] Anna Basso,[1] Graziella Berlingò,[1] Valentina Pellanda,[1] Andrea Contestabile,[1] Roberto Dell'Aquila.[1] *[1]Nephrology, San Bassiano Hospital, Bassano del Grappa, Italy; [2]Internal Medicine, Catania.*

**Background:** Compared with erythropoietin originator, the use of erythropoietin biosimilar is suggested only for economic reasons.Therefore, we aimed to compare the therapeutic equivalence of human erythropoietin Alfa Originator (Eprex) and Biosimiliar (Binocrit) to maintain haemoglobin and haematocrit levels in the therapeutic range and the monthly cost of each therapy.

**Methods:** 63 chronic haemodialized patients(64±17yrs)on treatment with Eprex were assigned to Eprex or Binocrit harm and followed up for 6 months.42 subjects treated with Eprex and 11 subjects treated with Binocrit were included in this analysis.A general linear model for repeated measures,adjusted for haemoglobin and haematocrit levels was used.In this analysis a cost of £55.31 for 10,000 UI of Eprex and £50.91 for 10,000 UI of Binocrit was used.

**Results:** Monthly erythropoietin Alfa dose was 12,078±1,440 and 12,981±2,677 UI in Eprex and Binocrit group; mean haemoglobin and haematocrit levels were comparable between groups.In multivariate analysis,adjusted for monthly haemoglobin and haematocrit levels, erythropoietin Alfa dose was higher in Binocrit than Eprex group.



Even if Binocrit was 8% cheaper than Eprex, the monthly cost of erythropoietin Alfa to maintain haemoglobin and haematocrit levels in the therapeutic range was only 1% lower with Binocrit than with Eprex.

**Conclusions:** Our preliminary data showed that the switch from human erythropoietin Alfa originator to biosimiliar is associated with an increase of erythropoietin dose during a follow-up of 6 months and with a comparable monthly cost of Binocrit and Eprex therapy.

**SA-PO389**

**Elevated Cobalt Levels in Chronic Hemodialysis Patients Are Not Associated with Increased Morbidity or Mortality, but Are Associated with Higher Hemoglobin Levels and Decreased Erythropoiesis Stimulating Agent Requirements** Rebecca Backenroth,[1] Dvora Rubinger,[1] Shade Artoul.[2] *[1]Nephrology, Hadassah Univ Medical Center, Jerusalem, Israel; [2]Pediatrics, Kaplan Medical Center, Rehovot, Israel.*

**Background:** We have previously shown that chronic hemodialysis patients(CHD) have higher mean Cobalt levels (Co) than healthy controls. The higher Co were associated with higher hemoglobins(Hb), and lower erythropoiesis stimulating agent(ESA) doses. Furthermore, ESA free patients with good Hb had strikingly higher Co.

Since Co can be toxic, we evaluated possible detrimental effects of the spontaneously elevated Co.

**Methods:** Morbidity and mortality were evaluated retrospectively in all CHD who had Co determinations, with clinical and lab variables from charts and computerized lab and hospitalization records. Statistical analysis included T test, Mann Whitney, Chi Sq, Fisher's Exact, Pearson correlation, Regression analysis, Kaplan Meier survival and the Log Rank tests. Numbers are mean + SD.

**Results:** 150 CHD, 66% male, age 65±15, on dialysis for 6±4 yrs were studied.

There was no difference in underlying or new onset of illnesses, hospitalizations nor mortality between patients with Co lower or equal to the mean and those with higher levels, except the incidence of skin malignancy, which was less in CHD with lower initial Co. This relation disappeared when all Co levels were averaged. There were no melanomas or aggressive skin tumors. Kaplan Meier analysis was similar for low and high Co groups.

Mean Co was similar in groups with prevalent and incident diseases, with and without hospitalizations or survival.

Background illness and causes of mortality were similar to literature reports.

Targets of Co toxicity such as cardiac, thyroid and pulmonary disease were similar in low and high Co groups.

**Conclusions:** Spontaneously elevated Co in CHD are not associated with elevated morbidity or mortality. Minor skin malignancies may increase with higher Co. Since Co is associated with higher Hb and less ESA use, it may have therapeutic potential as an ESA. Randomized clinical trials are required to determine the possible role of low dose Cobalt in the treatment of anemia in dialysis patients.

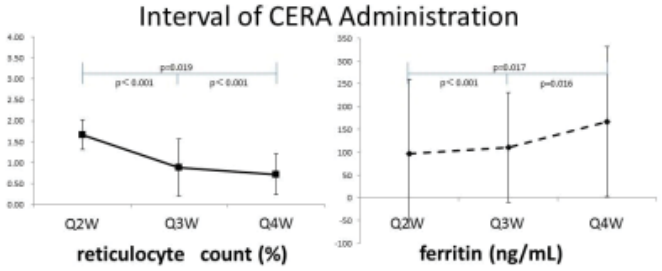
**SA-PO390**

**Biweekly Administration of a Continuous Erythropoietin Receptor Activator (CERA) Is Recommended in the Treatment of Anemia in Hemodialysis (HD) Patients: A Longitudinal, Single Institutional Study** Satoshi Funakoshi,[1] Jyunichiro Hashiguchi,[1] Yoshiaki Lee,[1] Kenichi Miyazaki,[1] Kenji Sawase,[1] Takashi Harada,[1] Tomoya Nishino,[2] Yoko Obata,[2] Shigeru Kohno,[2] Kazunori Utsunomiya.[3] *[1]Div of Blood Purification, Nagasaki Renal Center, Nagasaki, Japan; [2]Dept of Internal Medicine, Nagasaki Univ Graduate School of Medicine, Nagasaki, Japan; [3]Dept of Diabetology, Jikei Univ, Tokyo, Japan.*

**Background:** CERA is a long-acting erythropoiesis-stimulating agent that is approved for the treatment of renal anemia, but data on routine use of either once-monthly or biweekly in HD patients are scarce. In several phase 3 trials CERA once every two weeks were compared to results with other ESAs, and other phase 3 trials evaluated the effects of once-monthly CERA.

**Methods:** This study to evaluate the efficacious intervals of CERA administration was a prospective, single-center trial with duration of up to 18 months. Seventy-eight HD patients receiving CERA in our facility were included, and CERA administration was converted from once-monthly to twice-monthly (with half CERA dose). Since there were 5-week months, the parameters were compared in once biweekly (Q2W), every 3 weeks (Q3W) and every 4 weeks (Q4W). The CERA doses were adjusted in each patients to maintain Hb levels in the range 10-12 g/dL.

**Results:** At the end of the 18-month study, CERA doses per month were reduced in 24 out of 78 subjects. Mean Hb level was 10.5 ± 1.4 g/dL at baseline and 10.7 ± 1.7 g/dL at the end of the study. As shown in Figure 1, in biweekly administration of CERA, but not Q3W or Q4W, significantly higher reticulocytes counts and lowest ferritin levels were observed, indicating biweekly CERA was potentially the most efficacious in terms of red blood cell iron utilization or erythropoiesis.



**Conclusions:** Biweekly administration of CERA is recommended, and may potentially be cost-effective.

*Funding:* Private Foundation Support

**SA-PO391**

**The Relationship between Serum Angiopoietin-Like Protein 2 Levels and Atherosclerosis Factors in Hemodialysis (HD) Patients** Terumasa Nakagawa, Rika Yamazoe, Jun Morinaga, Yoshikazu Miyasato, Miki Ueda, Tomoaki Onoue, Teruhiko Mizumoto, Kohei Uchimura, Manabu Hayata, Yutaka Kakizoe, Kenichiro Kitamura. *Nephrology, Kumamoto Univ Graduate School of Medical Science, Kumamoto, Japan.*

**Background:** Angiopoietin-like protein 2 (Angptl2), a proinflammatory protein, was recently revealed to contribute to the pathogenesis of atherosclerosis in mice. However, its role in humans still remains poorly understood. The purpose of this study is to identify the factors associated with serum angptl2 levels and to elucidate the relationship between serum angplt2 levels and atherosclerosis in hemodialysis patients (HD).

**Methods:** Three hundred and eighty eight HD patients (men: 63%, mean age: 65±12 year, mean HD duration: 9.0±8.6 year) were enrolled. Serum Angptl2 levels and Hs-CRP levels were determined by the ELISA kit. Routine laboratory data, clinical history were collected. Cardio-ankle vascular index (CAVI) and carotid artery intima-media thickness were also measured.

**Results:** Mean serum Angptl2 level in all patients was 3.40μg/mL, which was higher than in healthy subjects in Japan. In diabetic HD patients (N=136, mean age: 65±10 year, mean HD duration: 5.1±3.9 year, mean serum Angptl2 levels: 3.53±1.09μg/mL), CAVI, the frequency of percutaneous transluminal AV shunt angioplasty, and serum triglyceride levels were significantly associated with serum Angptl2 levels (R=0.54, P<0.001) in multiple regression analysis. In non-diabetic patients (N=116, mean age: 61.7±11.5 year, mean HD duration: 13.7±9.95 year, mean serum Angptl2 levels: 3.09±1.17μg/mL), HD duration, BMI, and Hs-CRP levels were significantly associated with serum Angptl2 levels (R=0.73, P<0.001). Cerebral infarction in non-diabetic patients was related to serum Angptl2 levels (β=0.62, P=0.01) in multiple regression analysis (R=0.54, P<0.01). Furthermore, in a multiple logistic regression, serum Angptl2 levels ≥ 4μg/mL was a significant risk factor for cerebral infarction in male diabetic HD patients (P=0.04, odds ratio: 2.90, 95%confidence interval: 1.05 - 8.02).

**Conclusions:** Serum Angptl2 levels are associated with several atherosclerosis factors, and it could be a biomarker for cerebral infarction in HD Patients.

## SA-PO392

**Peripheral Monocytes May Be Predisposed to Uptake of Pro-Atherogenic Low-Density Lipoprotein through Genetically-Enhanced Expression of Scavenger Receptors in Hemodialysis Patients** Miki Nishida,[1] Minoru Ando,[2] Yusuke Iwamoto,[3] Ken Tsuchiya,[1] Kosaku Nitta.[1] *[1]Dept of Medicine, Kidney Center, Tokyo Women's Medical Univ, Sinjyuku-ku, Tokyo, Japan; [2]Dept of Nephrology, Tokyo Metropolitan Komagome Hospital, Bukyo-ku, Tokyo, Japan; [3]Dept of Nephrology, Saito Memorial Hospital, Warabi-shi, Saitama, Japan.*

**Background:** Atherosclerosis is accelerated in hemodialysis (HD) patients. Monocyte-macrophage scavenger receptor (SR) plays a pivotal role in promoting foam cell formation by binding and internalizing pro-atherogenic low-density lipoprotein (LDL).

**Methods:** Transcriptional levels of SR class A (SR-A) and class B (CD36) were simultaneously measured in peripheral monocytes by quantitative real-time RT-PCR, using the comparative threshold (Ct) method. Peripheral monocytes were magnetically labeled and isolated using a MACS Separator (Miltenyi Biotec Inc). Subjects included 39 chronic HD patients (mean age, 72 years) and 14 healthy controls. Multivariate logistic analysis was used to determine an association of SR expressions with prevalence of cardiovascular disease (CVD), including myocardial and cerebral infarctions and peripheral artery disease.

**Results:** The relative expressions of SR-A and CD36 mRNA ($2^{-\Delta\Delta Ct}$) were significantly greater in monocytes from HD patients than in those from controls (mean [95% CI of the mean]: 3.14 [2.58-3.69] versus 1.09 [0.79-1.39], P <.0001; and 4.45 [3.62-5.28] versus 1.15 [0.78-1.51], P=0.0004, respectively). Each SR receptor expression was significantly higher in HD patients who had CVD than in those who did not: SR-A, 3.56 [2.89-4.22] versus 2.19 [1.29-3.10], P=0.0137; and CD36, 2.43 [1.92-2.93] versus 1.65 [1.22-2.08], P=0.0479, respectively. Moreover, each SR expression was significantly associated with prevalence of CVD, after adjustment by age, gender, presence of diabetes, HD vintage and serum LDL-cholesterol level: odds ratio (95% CI), 1.95 (1.06-4.63) for SR-A and 4.18 (1.44-22.6) for CD36.

**Conclusions:** Transcriptional expressions of two SR types were enhanced in the HD patients, particularly in those with CVD. Prospective studies are warranted to ascertain the association between SR expressions and incidence of CVD.

## SA-PO393

**Plasma Calprotectin Levels in Chronic Kidney Disease** Denise Mafra,[1] Natalia Alvarenga Borges,[1] Amanda Barros,[1] Julie Lobo,[1] Denis Fouque.[2] *[1]Federal Univ Fluminense, Niteroi, Rio de Janeiro, Brazil; [2]Dept of Nephrology and Nutrition, CENS, Centre Hospitalier Lyon Sud, France.*

**Background:** Calprotectin (MRP8/14) is the main neutrophil cytosolic protein, which exerts potent proinflammatory effects through activation of Toll-like receptor-4 (TLR-4). Elevated plasma MRP-8/14 predicts the risk of future cardiovascular events. The aim of this study was to evaluate calprotectin plasma levels in CKD patients without acute infection under different treatments by comparison to healthy individuals.

**Methods:** Sixteen conservative treatment (CT) pts (44% men; 62.5±8.3 yrs; BMI 26.3±3.8 kg/m$^2$, CKD stage III - IV), nineteen hemodialysis (HD) pts (50.0% men; 55.1±13.1yrs; BMI 24.4±4.7; dialysis vintage, 49.5 [10-234]months), 8 peritoneal dialysis (PD) pts (12.5% men; 59.4±15.8yrs; BMI 23.1±2.4; dialysis vintage, 27.0 [20-52] months) and 16healthy subjects (43.7% men; 53.6±5.0yrs; BMI 24.6±2.7) were studied. Blood samples were obtained after a 12h fast and calprotectin was measured by enzyme immunometric assay (Bühlmann, France).

**Results:** Calprotectin levels were higher in all CKD groups (CT: 13.6±5.0, HD: 11.4± 3, PD: 12.0±3.9 ng/mL) compared with healthy individuals (9.5±0.8 ng/mL), but a significant difference was observed only between CT pts and healthy individuals (p<0.05). No correlation was found between plasma calprotectin levels and dialysis vintage.

**Conclusions:** We found increased levels of plasma calprotectin in CKD pts, particularly during conservative treatment. This may contribute to the chronic inflammation status and may allow a better identification of the cardiovascular risk in these patients.

## SA-PO394

**Lipoxin A4 and Resolvin E1 Reduce Inflammatory Monocytes in Haemodialysis Patients** Eileen Nolan,[1,2] Debra F. Higgins,[1] Yvonne M. O'Meara,[2,3] Catherine Godson.[1,2] *[1]UCD Diabetes Complications Research Centre, UCD Conway Institute, Univ College Dublin, Dubin, Ireland; [2]UCD School of Medicine and Medical Science, Univ College Dublin, Dublin, Ireland; [3]Dept of Nephrology, Mater Misericordiae Univ Hospital, Dublin, Ireland.*

**Background:** An increase in CD16+ circulating monocytes occurs in haemodialysis (HD) and is associated with cardiovascular risk. CD16+ monocytes are pro-inflammatory and contribute to micro-inflammation. Lipoxin A4 (LXA4) and resolvin E1 (RvE1) are lipid mediators which promote the resolution phase of inflammation. Our hypothesis is that LXA4 and RvE1 may have a role in reducing inflammatory monocytes in HD.

**Methods:** Peripheral blood samples taken from 6 HD patients and 3 healthy controls were treated with LXA4 (0.01 nM) or RvE1 (0.01 pM), stained with mAb to CD14, CD16 and HLA-DR, and analysed by flow cytometry. ELISA was used to measure the cytokine content of plasma and of monocyte supernatant. THP-1 monocytes were stimulated with LPS (0.1 ng/ml) and treated with LXA4 or RvE1; protein was isolated and p-IkB-alpha levels assessed by western blotting.

**Results:** HD patients have higher levels of CD16+ monocytes (p<0.01) and higher plasma levels of TNF-a (p<0.001) and IL-6 (p<0.05) than healthy controls. Treatment of HD blood samples with LXA4 or RvE1 reduces CD16+ monocytes (p<0.05), while treatment of isolated monocytes with either agent reduces the production of TNF-a (p<0.01) and IL-6 (p<0.05). THP-1 monocytes cultured in uraemic plasma adopt an inflammatory phenotype with increased production of TNF-a compared to cells cultured in control plasma (p<0.001); this is attenuated by treatment with LXA4 and RvE1 (p<0.05). Treatment of stimulated THP-1 monocytes with LXA4 (p<0.001) or RvE1 (p<0.01) also leads to a reduction in p-IkB-alpha.

**Conclusions:** HD patients have evidence of inflammation and monocyte activation. Both LXA4 and RvE1 reduce inflammatory monocytes and cytokines in blood from HD patients. These agents may act through inhibition of the NF-kB signalling pathway. These results suggest that LXA4 and RvE1 have therapeutic potential in the management of inflammation in the haemodialysis population.

## SA-PO395

**Upper Stream Reactions of Oxidative Stress in Hemodialysis Patients** Aki Hirayama,[1] Atsushi Ueda,[2] Sohji Nagase,[3] Hirofumi Matsui,[4] Kazumasa Aoyagi,[1] Shigeru Owada.[5] *[1]Center for Integrative Medicine, Tsukuba Univ of Technology, Tsukuba, Japan; [2]Tsukuba Univ Hospital Hitachi Medical Education and Research Center, Hitachi, Japan; [3]Nagase Naika Clinic, Moriya, Japan; [4]Faculty of Medicine, Univ of Tsukuba, Tsukuba, Japan; [5]Asao Clinic, Kawasaki, Japan.*

**Background:** Upper stream reactions against oxidative stress that evoke following cellular responses still remain unclear. This study aimed to reveal the dynamics of multiple reactive oxygen and nitrogen species (ROS/RNS) which act as stimulators of oxidative responses in hemodialysis (HD) patients.

**Methods:** Dynamics of multiple ROS, namely hydroxyl radical, superoxide radical, alkoxyl radical, alkylperoxyl radical, alkyl radical, and singlet oxygen, were investigated measuring the scavenging activities against these ROS by a newly developed electron paramagnetic resonance (EPR) method, MULTIple free-radical Scavenging (MULTIS). Nitric oxide (NO) metabolites and inflammatory cytokines were also measured. These methods were applied to a cohort of HD patients (n=23) and healthy control subjects (n=16).

**Results:** ROS scavenging activities of HD patients were significantly augmented against superoxide, alkoxyl radical and singlet oxygen, and attenuated against alkyl and alkylperoxyl radical, compared to the healthy group. Hydroxyl radical scavenging activity showed no difference between the two groups. In the healthy group, superoxide scavenging activity showed strong positive correlation with serum NOx concentration. This relation was not observed in HD patients, suggesting disintegration of superoxide-NO balance. Superoxide scavenging activity correlated with that of hydroxyl and alkoxyl radical in the healthy group, while this was related with alkylperoxyl radical in HD patients. ROS scavenging activities were not related with TNF-a, IL-6, and adiponectin in both groups.

**Conclusions:** These results indicate that alterations of cellular oxidative response stimulators in HD patients. Radical chain reaction pathway involving alkyl and alkylperoxyl radical are notably attenuated. Also, ROS-NO balance, which is a controlling factor of in vivo oxidation-antioxidation, is disintegrated in HD patients.

*Funding:* Government Support - Non-U.S.

## SA-PO396

**Decreased Insulin-Like Growth Factor-1 Levels Potentiate Association of Inflammation with All-Cause and Cardiovascular Mortality in Prevalent Hemodialysis Patients** Ilia Beberashvili,[1] Inna Sinuani,[2] Ada Azar,[3] Hadas Kadoshi,[3] Gregory Shapiro,[1] Leonid Feldman,[1] Zhan Averbukh.[1] *[1]Nephrology, Assaf Harofeh Medical Center, Zerifin, Israel; [2]Pathology, Assaf Harofeh Medical Center, Zerifin, Israel; [3]Nutrition, Assaf Harofeh Medical Center, Zerifin, Israel.*

**Background:** Insulin-like growth factor-1 (IGF-1) and inflammation have both been linked to high cardiovascular risk and mortality in the general population, as well as in hemodialysis (HD) patients. We hypothesized that the association of low IGF-1 with chronic inflammation may increase the mortality risk in HD patients.

**Methods:** We investigated the interactions between inflammatory biomarkers (IL-6 and TNF-α) and IGF-1 as predictors of death over a 4 years of follow-up (median - 47 months, interquartile range - 17.5-75 months) in 96 prevalent HD patients (35% women, mean age of 64.9±11.6 years).

**Results:** A significant interaction effect of low IGF-1 (defined as a level less than median) and high IL-6 (defined as a level higher than median) on all-cause and cardiovascular mortality was found: crude Cox hazard ratios (HR) for the product termed IGF-1 X IL-6 were 3.06, with a 95% confidence interval (CI): 1.59 to 5.88 (P=0.001) and 5.07, with a 95% CI: 1.72-14.94 (P=0.003), respectively. Across the four IGF-1-IL-6 categories, the group with low IGF-1 and high IL-6 exhibited the worse outcome in both all-cause and cardiovascular mortality (multivariable adjusted hazard ratios were 5.88, 95% CI 2.12 to 16.32, and 16.96, 95% CI 1.71 to 168.4, respectively). The main clinical characteristics of patients in the low-IGF-1-high IL-6 group didn't differ from other IGF-1-IL-6 categorized groups besides gender that consequently was inserted in all multivariable models together with the other potential confounders.

**Conclusions:** An increase in mortality risk was observed in HD patients with low IGF-1 and high IL-6 levels, especially cardiovascular causes.

## SA-PO397

**Fluid Retention in Hemodialysis (HD) Patients Is Associated with Endothelial Dysfunction through an Increased Pentraxin 3 (PTX3) and ROS Production by Neutrophils** Simona Simone,[1] Maria Pia dell'Oglio,[1] Marco Ciccone,[2] Roberto Corciulo,[1] Giuseppe Castellano,[1] Cosima Balestra,[1] G. Grandaliano,[3] Loreto Gesualdo,[1] G. Pertosa.[1] *[1]DETO, Nephrology, Dialysis and Transplantation Unit; [2]DETO, Cardiology Unit, Bari; [3]Dept of Medical and Surgical Sciences, Nephrology, Dialysis and Transplantation Unit, Foggia, Italy.*

**Background:** Fluid retention in HD patients is associated with increased cardiovascular morbidity and mortality. Long PTX3, a marker of inflammatory responses, may be involved in endothelial dysfunction and is a predictor of mortality in HD patients. The aim of the study was to evaluate in vivo the association between fluid retention, pulmonary artery systolic pressure (PASP), endothelial dysfunction (flow-mediated dilation, FMD), PTX3 and ROS production in HD patients.

**Methods:** Sixty uremic patients (mean age 62.5 yrs; mean dialytic age 44.3 months) on stable HD treatment with synthetic membranes and 20 healthy subjects were enrolled. Neutrophils activation ($CD62L^+$) and PTX3 protein expression were evaluated by flow cytometry and ELISA. Intracellular ROS generation in neutrophils was measured by 2',7'Diclorodiidrofluorescein. PASP and FMD of brachial artery were assessed non-invasively, using echocardiography and high-resolution ultrasound. The arterial stiffness was evaluated using cardio-ankle vascular index (CAVI).

**Results:** HD increased FMD from 4.23±1,8% (nv:7.5±2.1%; p<0.01) to 7.03±0.734%, ( p<0.001). These changes returned to baseline by 24h (5.59±0.4%). FMD, observed pre and post-HD, were significantly (p=0.002) and inversely correlated with PASP values(pre-HD:27,7±2,4mmHg; post-HD 18,1±1,6mmHg). The change in FMD and PASP were associated with a significant increase (p=0.0001) in neutrophil activation, intracellular and circulating PTX3 expression and ROS generation. Pre/post-HD (D) FMD was inversely correlated with CAVI (p<0.002) and P and PTH serum levels (p<0.02). PTX3, P serum levels and PASP were independent predictors of altered FMD.

**Conclusions:** In conclusion, fluid retention in HD patients may contribute to endothelial dysfunction and arterial stiffness by increasing PTX3 and ROS production.

## SA-PO398

**Increased Prevalence of Eosinophilia in a Hemodialysis Population: Longitudinal and Case Control Studies** Sarah Hildebrand, Neill D. Duncan, Damien Ashby. *West London Renal and Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom.*

**Background:** Eosinophilia associated with dialysis reaction was frequently reported in the 1980s which decreased with the use of more biocompatible membranes. Recent observations at a local level suggest a possible recurrence of eosinophilia amongst hemodialysis patients without apparent relationship to dialysis sessions.

**Methods:** In this single-centre case-control study, hemodialysis patients with eosinophil count greater than 1 $x10^9$/litre during a 3 month period were identified and paired with controls matched for age, gender and dialysis satellite facility. Comorbidity, dialysis and medication data were collected. A sample of patients on hemodialysis 5 years ago was analysed to provide historical prevalence. Statistical analysis was performed using the Fisher exact test for categorical variables and t-test for continuous data.

**Results:** 24 patients (aged 31– 81, 46% male) from a population of 510 were identified as having eosinophilia with a mean level of 2.2 $x10^9$/l (range 1.1-7.5 $x10^9$/l). Between cases and controls there were no differences in comorbidities, dialysis vintage or most medications. There was a significantly higher frequency of angiotensin converting enzyme inhibitors (ACEi) use in patients with eosinophilia (10/24 vs 3/24, p=0.049). There were no patients with an allergic syndrome related to dialysis sessions, and generally, intradialytic symptoms were no more common in cases either. One patient did develop a dialysis-related febrile reaction 3 months after the onset of eosinophilia resolving with a change of dialysis membrane. A historical sample of 200 dialysis patients identified eosinophilia in only 3, demonstrating a significant increase in prevalence over time (1.5 vs 4.7%, p=0.049).

**Conclusions:** The prevalence of eosinophilia appears to have increased within this dialysis population over the last 5 years. No clear cause was identified in this study. More frequent use of ACEi may support a medication hypothesis for some patients. The development of intradialytic symptoms in one patient suggests components of the dialysis circuit as a possible cause so an empirical change of membrane is planned.

## SA-PO399

**Parathyroid Hormone (PTH) in Hemodialysis Patients Is Significantly, Positively Affected by Body Size: Both by Fat Mass and Lean Mass, Independently** Eiji Ishimura,[1] Senji Okuno,[1] Akihiro Tsuda,[1] Akinobu Ochi,[1] Shinya Nakatani,[1] Masaaki Inaba.[1] *[1]Osaka City Univ Graduate School of Medicine; [2]Shirasagi Hospital.*

**Background:** A significant positive relationship between PTH and body size has been reported in the general population (Eur J Endocrinol 2004) and in patients with primary hyperparathyroidism (J Clin Endcrinol Metab 2005). We hypothesize if PTH is affected by body size in hemodialysis patients, in whom PTH is abnormally regulated. We further examined whether fat mass or lean mass are associated with serum PTH.

**Methods:** 590 hemodialysis patients (age: 60.2±12.2 yr; median hemodialysis duration: 59.6 mo.; 343 males and 247 females; diabetics: 27.7%). were examined. Fat mass and lean mass were measured by dual X-ray absorptiometry.

**Results:** Intact PTH correlated significantly, positively with body weight and body mass index (p<0.001). Intact PTH correlated significantly and positively with fat mass and lean mass in males (p<0.01), and tended to correlate positively with fat mass and lean mass in females (p<0.1). In multiple regression analyses after adjustment for age, gender, hemodialysis duration, calcium, phosphate, vitamin D use and phosphate binder use, intact PTH was associated significantly with body weight, body mass index, fat mass and lean mass. Further, intact PTH was associated significantly and independently with both fat mass and lean mass after adjustment ($R^2$=0.206, p<0.0001).

| **Dependent variable: intact PTH** | | |
|---|---|---|
| **Independent variables** | β | p |
| Age (years) | 0.084 | 0.0551 |
| Gender (male vs. female) | - 0.159 | 0.0066 |
| Hemodialysis duration (years) | 0.229 | <0.0001 |
| Diabetes (yes vs. no) | - 0.153 | <0.0001 |
| Calcium (mg/dL) | - 0.233 | <0.0001 |
| Phosphate (mg/dL) | 0.188 | <0.0001 |
| Vitamin D use (yes vs. no) | 0.153 | <0.0001 |
| Phosphate binder use (yes vs. no) | 0.005 | 0.8934 |
| Fat mass (kg) | 0.134 | 0.0006 |
| Lean mass (kg) | 0.176 | 0.0047 |

**Conclusions:** We demonstrated, for the first time, that serum intact PTH correlated significantly, positively with body size in hemodialysis patients. Further, PTH was significantly, independently associated with fat mass and lean mass.

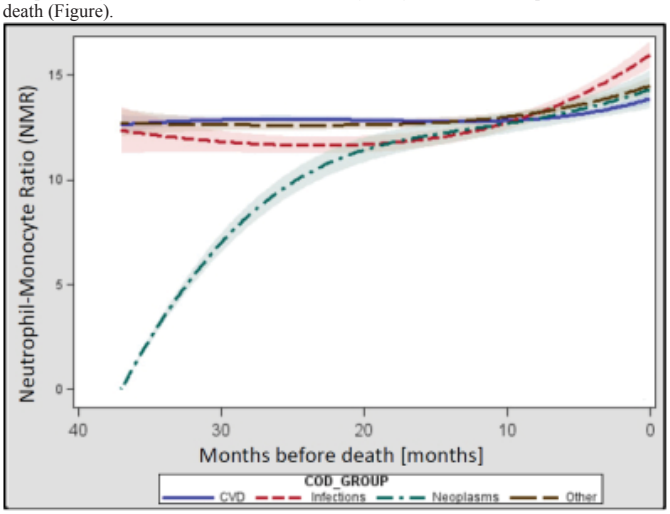
## SA-PO400

**Changes in Neutrophil-Monocyte Ratio Allow Prediction of Death from Infectious Causes in Incident Hemodialysis Patients: Results from a Retrospective Database Analysis** Laura Rosales,[1] Jochen G. Raimann,[1] Len A. Usvyat,[1] Stephan Thijssen,[1] Peter Kotanko,[1] Nathan W. Levin.[1] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care North America, Waltham, MA.*

**Background:** Chronic systemic inflammation determines survival and disease progression in hemodialysis (HD) patients. Neutrophil to lymphocyte ratio (NLR) was previously proposed as predictor of all-cause mortality comparing well to established inflammatory markers. Immune dysfunction may be associated with decreased functional toll-like receptors (TLR) with adverse outcomes. We investigated the predictive value of monocyte-lymphocyte ratio (MLR), neutrophil-monocyte ratio (NMR) and NLR for all-cause mortality and if death due to infectious causes is preceded by changes in MLR, NMR, and NLR.

**Methods:** Relevant laboratory markers and white blood cell count were collected monthly. Cox regression models (adjusted for age, gender, height, body mass index, diabetes, HD vintage, HIV and hepatitis C status) were developed to study the relationship between NLR, MLR and NMR to all-cause mortality and death from cardiovascular, infectious, neoplastic and other causes. Spline analysis of NLR, MLR and NMR prior to death was employed to depict their changes.

**Results:** 2269 incident HD patients (67.4±13.8years; 45% female; 55% White, 58% DM) were followed up to 3 years. Higher values of MLR, NLR and NMR were independently associated with all-cause mortality. Only NMR increased prior to infectious death (Figure).



NLR and MLR showed similar patterns and did not allow differentiation of infectious death from others causes.

**Conclusions:** Increase MLR, NLR and NMR predict all-cause death in incident HD patients. NMR shows a distinctive increase prior to infectious death and may be a potential tool to identify patients at risk of infectious death. The reasons are unclear but decreased in TLR expression is possibly involved.

## SA-PO401

**Importance of Food Labeling: Bromatological Study for Determination of Phosphorus and Potassium in Food Consumed by Hemodialysis Patients**
Camila Machado de Barros,[1] Isabela Santos Areias,[2] Bárbara Margareth Menardi Biavo,[1] Edeli Simioni Abreu,[2] Jacqueline Santos,[1] Elzo Ribeiro Júnior,[1] Carmen B. Tzanno-martins.[1] *[1]Grupo CHR; [2]Universidade Presbiteriana Mackenzie.*

**Background:** Adding nutritional information on food labels about these minerals becomes increasingly urgent, considering the growing population of patients on HD.

Conduct chemical analyzes of some processed foods in order to determine their amount of phosphorus and potassium, since this information does not appear on their label. Objective: Conduct chemical analyzes of some processed foods in order to determine their amount of phosphorus and potassium, since this information does not appear on their label.

**Methods:** The study was based on secondary data on food consumption by HD patients, from three hemodialysis clinics in São Paulo, Brazil. Laboratory tests were performed in the Bromatology Laboratory at the Mackenzie University. Each food was analyzed separately and twice. For the potassium measurement, it was used atomic absorption spectrophotometer; and for phosphorus, it was used phosphate by titration.

**Results:** We analyzed thirteen foods - Brazilian *human ration*; juice powder; milk pudding; hamburger, chicken nuggets; *bis* (a brazilian chocolate bar), instant soup, four cheese industrialized lasagna, industrialized bolognese lasagna; dark *cocada* (a brazilian coconut candy); white *cocada*; broth; *goiabada* (a brazilian guava candy). Regarding phosphorus concentration of per serving, the higher value foods were *ready lasagna* (39.2454 mg and 44.7886 mg), *chicken nuggets* (21.1259 mg) and milk pudding (19.2532 mg). When potassium concentration was analyzed, values shown were very low, even for patients undergoing hemodialysis, with recommended intake value of approximately 3000 mg daily.

**Conclusions:** Nutritional information with phosphorus content proved valuable and decisive in the choice of food for these patients. According to the foods surveyed, it was determined that the potassium content was not very high as was the level of phosphorus. This shows that one should pay greater attention to levels of inorganic phosphorus. However we believe there is need for more studies on the subject.

## SA-PO402

**Nutriton Education as a Tool for Knowledge about Potassium in Hemodialysis Patients**
Camila Machado de Barros,[1] Amanda Mafei,[2] Fabiana Valverde,[2] Luiza Sacanavini,[2] Edeli Simioni Abreu,[2] Rosana Farah,[2] Bárbara Margareth Menardi Biavo,[1] Jacqueline Santos,[1] Elzo Ribeiro Júnior,[1] Carmen B. Tzanno-martins.[1] *[1]Grupo CHR; [2]Universidade Presbiteriana Mackenzie.*

**Background:** Potassium levels are generally high (hyperkalemia) in patients with chronic kidney disease (CKD) on hemodialysis (HD). Therefore it is important to control food with high potassium content.

Objective: To evaluate the effects of a nutrition educational program regarding potassium in food on the knowledge of a patient with hyperkalemia in HD treatment.

**Methods:** This was a longitudinal study with 243 patients with CKD who perform dialysis in three nephrology clinics, located in São Paulo, being 36% of them with hyperkalemia. In a given dialysis session, we have applied the group dynamics, "Potassium Minefield". The game consisted of a board with 60 squares in which there were food illustrations distributed randomly. Some of these foods were "bombs", i.e. they contained high concentration of potassium and should be avoided. Other foods were low in potassium and could be consumed more often. Patients were asked to choose a food. Then we asked them if it was a "bomb" or not. After the answer, the square was turned. On the back of squares of foods with high potassium content, there was an illustration of a bomb. In order to assess the acquired knowledge, we applied a questionnaire with five multiple choice questions before and after the intervention.

**Results:** was observed that the knowledge on foods with high potassium content increased in the three units after completion of nutritional dynamics. The percentage of correct answers increased from 63.3% (± 13.9) before the intervention to 73.5% (± 16.3) after the intervention.

These values showed a good level of knowledge about the consequences of hyperkalemia and its treatment, as well as a better understanding of the nutritional recommendations regarding diet.

**Conclusions:** The nutritional intervention program applied resulted in increased knowledge about the low and high potassium content found in foods, demonstrating the effectiveness of nutrition education for the improvement and adjustment of treatment of patients in hemodialysis.

## SA-PO403

**Efect of Citrate on the Proteome of the Secondary Protein Layer of the Dialysis Membrane**
Jaromir Eiselt, Jan Mares, Jiri Moravec, Lukas Kielberger. *Internal Dept 1, Charles Univ.*

**Background:** A secondary protein layer formed on the dialysis membrane affects the efficacy of the purification procedure. Previous studies have shown higher Kt/V in dialysis using citrate instead of acetate as an organic acid in the acid concentrate. We tested the hypothesis that citrate in the dialysis fluid can change the amount and/or composition of the protein layer.

**Methods:** A total of ten patients were assessed during routine nadroparine high-flux hemodialysis using acetate (3.0 mEq/L) or citrate (2.4 mEq/L) in an acidic component of the dialysis solution. After the session dialyzers were flushed with 500 mL of saline and protein adsorbed to the membrane was eluted by 40% acetic acid. Amounts of protein and hemoglobin in the eluates were determined by spectrophotometric assays. Protein was resolved with 2D electrophoresis and spot patterns were compared between acetate and citrate dialysis. Spots showing difference ($p < 0.01$) were identified by tandem mass spectrometry.

**Results:** Total amounts of protein in the eluates in acetate and citrate dialysis were 5.11 mg (3.49-17.42) and 8.24 mg (3.39-10.26), respectively; $p = 0.72$. Total amounts of hemoglobin in the eluates of acetate and citrate dialysis were 3.57 mg (2.57- 8.21) and 2.75mg (2.,02-3.28), respectively; $p = 0.022$. In eluates, 208 protein fractions (spots) were considered (arbitrarily) characteristic, i.e. present in at least 75% of gels of either group. Of these, 88 protein fractions were differently expressed between both groups. Among these, 27 spots were identified as alpha fibrinogen fragments. Quantitatively, these fragments prevailed in citrate eluates by a factor of 3.04 (2.46-3.42), $p = 0.005$. Reuslts are expressed as median (interquartile range) and Wilcoxon test was used for statistical analysis.

**Conclusions:** After dialysis using citrate, dialyzer eluates contain significantly less hemoglobin and more alpha fibrinogen fragments. This finding could reflect an additional anticoagulation effect provided by citrate and, speculatively, achieved through inhibition of alpha fibrin crosslinking.

*Funding:* Government Support - Non-U.S.

## SA-PO404

**Efficient Removal of Beta2 Microglobulin and Leptin by Online Hemodiafiltration: Comparison of Three State of the Art Dialyzers**
Andreas H. Bock, Beatrice Paul. *Nephrology Div, Kantonsspital Aarau, Aarau, Switzerland.*

**Background:** Hemodiafiltration (HDF) removes high molecular weight solutes better than hemodialysis. This study compared three state-of-the-art highflux dialyzers in oHDF mode with respect to the elimination of leptin (18.6 kD), ß2- microglobulin (ß2M, 11.8 kD) and phosphate. Improved ß2M elimination is expected to delay ß2M amyloidosis, and lowering leptin levels should increase appetite, which may help to improve nutritional status.

**Methods:** During three consecutive weeks, each of 29 stable hemodialysis patients underwent a midweek study dialysis, using in randomized order a FX100 (FX100), Polyflux 210H (PF210) or FXCorDiax100 (CorDiax) dialyzer . The study dialysis was a 4 hour oHDF with 350 ml/' blood flow, 800 ml/' dialysate flow and 80 ml/' (19.2 L/4h) substitution rate. Arterial samples were taken at oHDF start, at 60/240 minutes (t60/t240) as well as 30 minutes after the end (t270). Bloodside clearances were computed using pre- and post-dialyzer blood samples at t60 and t240. Equilibrated removal ratios (eRR) were calculated from t0 and t270 samples. Dialysate obtained using a 1/25 split dialysate collector was assayed for ß2M, phosphate and albumin.

**Results:**

| | | PF210 | FX100 | CorDiax |
|---|---|---|---|---|
| **Leptin** | **eRR (%)** | 26.7 ± 23.0 | 39.2 ± 21.7 [p] | 40.6 ± 27.5 [p] |
| | **Clearance240 (ml/min)** | 89.7 ± 19.2 | 102.8 ± 20.4 [p] | 110.8 ± 13.4 [p] |
| **ß2M** | **eRR (%)** | 62.7 ± 5.3 | 67.9 ± 5.0 [pf] | 72.3 ± 5.3 [pf] |
| | **Clearance240 (ml/min)** | 115.5 ± 9.8 | 136.3 ± 12.8 | 150.4 ± 10.9 [pf] |
| | **Dialysate removal (mg/4h)** | 191.0 ± 67.8 | 204.9 ± 62.4 | 215.1 ± 63.3 [p] |
| **Albumin** | **Dialysate loss (g/4h)** | 1.31 ± 0.12 | 2.10 ± 1.00 [p] | 1.74 ± 1.01 |
| Data are mean ± SD [p] p<0.001 vs. PF210 [f] p<0.001 vs. FX100 | | | | |

The decrease of plasma leptin paralleled the height of baseline leptin ($r^2 = 0.62$). eRR, clearance and dialysate removal for phosphate was high and similar for all three dialyzers.

**Conclusions:** oHDF with modern highflux dialyzers removes significant amounts of ß2M and can substantially lower plasma leptin without relevant albumin losses, all of which should be beneficial at longterm. The CorDiax dialyzer in these real-life conditions performed better than the two other dialyzers.

*Funding:* Pharmaceutical Company Support - Fresenius

## SA-PO405

**A Study of the Immunoregulation of Double Filtration Plasmapheresis in Maintenance Hemodialysis Patients with Chronic Hepatitis C**
Cao Hongdi, Chunsun Dai, Junwei Yang. *2nd Affiliated Hospital, Nanjing Medical Univ, Nanjing, China.*

**Background:** To clarify the immunnoloregulation of double filtration plasmapheresis (DFPP) in maintenance hemodialysis (MHD) patients with chronic hepatitis C (CHC).

**Methods:** DFPP were performed in 20 MHD patients with CHC (HCV-antibody positive and serum HCV-RNA >500 IU/ml more than 6 months). The serum titer of HCV-RNA was monitored and peripheral blood mononuclear cell (PBMC) was analyzed by flow cytometry at the time of hour 0, hour 3, day 3, day 7 and day 28 during the DFPP.

**Results:** Compared to MHD patients without CHC, the frequencies of innate immune cells were similar in MHD patients with CHC, while the ratio of Th1 to Th2 was elevated and the frequencies of Th17 cells and Treg cells were higher in MHD patients with CHC. Serum HCV particles could be removed partially by the DFPP. The titer of serum HCV could remain in a lower level one month after the treatment. There were no significant changes of monocytes, NK cells, Th1, Th2 and Th1/Th2 in PBMC after DFPP in MHD patients with CHC. Single DFPP could reduce the frequency of Th17 cells in PBMC from 7 days after the therapy in MHD patients with CHC. Single DFPP could reduce the frequency of Treg cells in PBMC from 7 days after the therapy in MHD patients with CHC.

**Conclusions:** DFPP could partially remove the serum HCV particles mechanically. The titer of HCV-RNA could remain in a lower level at least for one month probablely due to the redistribution of the immunocytes in circulation.

## SA-PO406

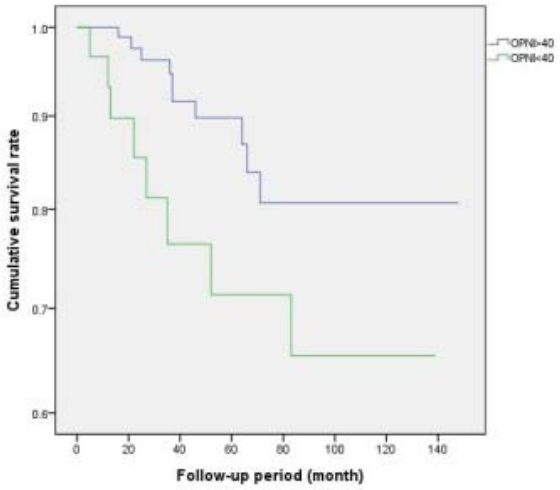
**Onodera's Prognostic Nutritional Index May Be a Significant Predictor of Mortality in Hemodialysis Patients**

Kiryong Park,[1] Sangeon Gwoo,[2] Ye Na Kim,[2] Ho Sik Shin,[2] Yeon Soon Jung,[2] Hark Rim.[2] *[1]Internal Medicine, Changwon Fatima Hospital, Changwon; [2]Internal Medicine, Kosin Univ College of Medicine.*

**Background:** No standard method for assessing the nutritional status in HD patients exists. Onodera's Prognostic Nutritional Index (OPNI) is a method that considers serum albumin level and total lymphocyte count. This simple method may involve common measures and can be applied rapidly in a large number of patients. Validation of OPNI has been performed for patients with end-stage liver disease, active tuberculosis, and gastrointestinal malignancies.

**Methods:** We examined the OPNI scores of 140 maintenance HD patients (59.8 ± 12.9 years; 64 men and 76 women) and followed these patients for 140 months. The OPNI is calculated based on the serum albumin level and total lymphocyte count and uses the following equation: OPNI = 10 × serum albumin (g/dL) + 0.005 × total lymphocyte count (/mL). Predictors of all-cause death were examined using a life table and Cox proportional analyses.

**Results:** The average OPNI value was 43.8 ± 6.5, and the values were negatively correlated with age. A total of 18 patients died during the 120-month follow-up period. OPNI values were normally distributed. Life table analysis revealed that patients with an OPNI < 40 (n = 31) had a significantly lower survival rate than those with an OPNI ≥ 40 (n = 109) (Wilcoxon test, P = 0.044).



Multivariate Cox proportional hazards analyses demonstrated that OPNI was a significant predictor of mortality (hazard ratio [HR], 6.491; 95% confidence interval [CI], 1.985–21.233; P = 0.002] even after the adjustment for age, gender, presence of diabetes, and body weight.

**Conclusions:** These results suggest that OPNI is a significant predictor of mortality in HD patients. The simple OPNI method is a clinically useful marker for the assessment of nutritional status in Korean HD patients.

## SA-PO407

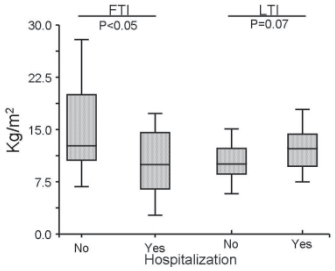
**Poor Nutritional Status Is Associated with Increased Calcifications and Higher Incidence of Hospitalization in Chronic Hemodialysis Patients**

Paolo Lentini,[1] Luca Zanoli,[2] Stefania Rastelli,[2] Massimo de Cal,[1] Graziella Berlingò,[1] Anna Basso,[1] Andrea Contestabile,[1] Valentina Pellanda,[1] Roberto Dell'Aquila.[1] *[1]Nephrology, San Bassiano Hospital, Bassano del Grappa, Italy; [2]Internal Medicine, Univ of Catania, Catania, Italy.*

**Background:** Calcifications are increased in chronic hemodialysis and associated with increased cardiovascular events.The nutritional status may influence, via the metabulism Ca/P, the outcome of the patients.We aimed to study the relations between the nutritional status, calcification score and hospitalization in chronic hemodialysed subjects during a follow-up of 1 year.

**Methods:** Body composition was evaluated with Bioimpedance spectroscopy technique (Fresenius BCM) and hospitalization was collected during follow-up; abdominal aortic calcifictions (Kauppila score) were evaluated by lateral lumbar radiographs at baseline and after 1 year.

**Results:** 36 hemodialysed subjects (age 64±15 yrs; 50% males; hemoglobin 11.3±0.7 mg/dl; Kt/Veq Daugirdas 1.50±0.29) were enroled.20 subjects (56%) were hospitalized during follow-up.Nutritional status (lean tessue index [LTI], positively; fat tissue index[FTI], negatively)was associated with the increase in Kauppila score during follow-up (Δ score: 1.2±1.0 points/year) and with hospitalizations, suggesting that subjects with poorest nutritional status are at risk of calcification and poor outcome.



In multivariate analysis adjusted for age, FTI was associated with Hospitalization (OR: 0.83; 95%CI 0.70-0.99;P<0.05). Adding the variation in Kauppila score during follow-up in a model with age and FTI produce the lost of significance of the association between FTI and hospitalization, suggesting that the effect of nutritional status on hospitalization is at least in part mediated by an increase in calcifications.

**Conclusions:** Nutritional status influences the development of calcifications and hospitalizations.

## SA-PO408

**Tryptophan Metabolism in Hemodialysis Patients**

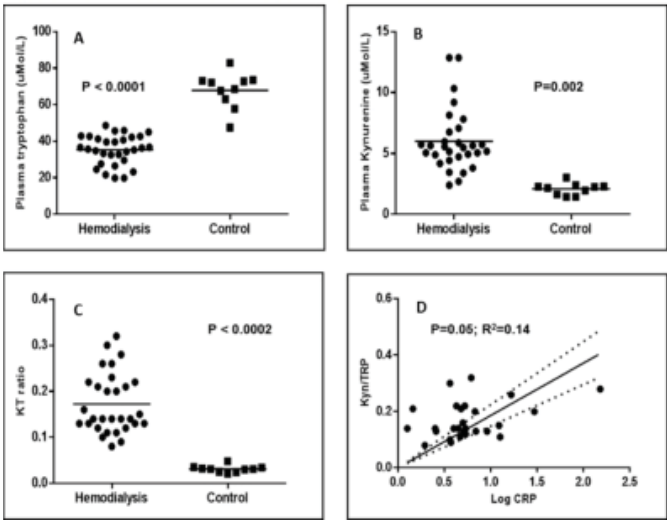
Rakesh Malhotra,[1] Vanja Persic,[2] Weifang Zhang,[3] Garry J. Handelman,[3] Laura Rosales,[4] Mary Carter,[4] Stephan Thijssen,[4] Len A. Usvyat,[4] Fredric O. Finkelstein,[5] Mark L. Unruh,[6] Nathan W. Levin,[4] Peter Kotanko.[4] *[1]UMDNJ-New Jersey Medical School; [2]Univ Medical Center Ljubljana; [3]Univ of Massachusetts Lowell; [4]Renal Research Institute; [5]Yale Univ School of Medicine; [6]Univ of New Mexico School of Medicine.*

**Background:** Tryptophan (TRP) levels and augmented concentrations of its metabolites have been shown to be significantly lower in animal models of renal insufficiency. We sought to compare the levels of TRP and its metabolites between hemodialysis (HD) patients and healthy subjects and to examine the extent to which TRP metabolites are associated with inflammation in HD patients.

**Methods:** Venous blood samples were drawn in healthy subjects and HD patients. TRP, para-cresol sulfate (PCS) and kynurenine (KYN) metabolites were measured by reverse-phase high-performance liquid chromatography (HPLC), with appropriate detection wavelength for each compound. C-reactive protein (CRP) was measured with an immunoturbidometric technique. We used Spearman rank test for correlational analysis.

**Results:** We studied 30 HD patients (70% male; mean age 58.8±13.3 yrs) and 10 healthy control subjects (60% male; mean age 43.9±12.4 yrs). KYN and KYN/TRP (6.0±2.5 uMol/L vs. 2.1±0.5 uMol/L; p=0.002 and 0.17±.06 vs. 0.03±0.01; P<0.0002, respectively) were significantly higher and TRP levels were significantly lower (35.3±8.1 uMol/L vs. 67.9±9.8 uMol/L; p<.0001) in the HD patients than those in the controls. KYN/TRP ratio and CRP levels were positively correlated in HD patients ($r^2$= 0.14; P=0.05).

**Figure 1: (a-c) Serum levels of TRP and its metabolites in HD patients and healthy subjects; (d) Correlation analysis between KYN/TRP and CRP in HD patients**



**Conclusions:** Low TRP and high metabolite levels were observed in HD patients, indicating increased TRP catabolism, possibly related to immune activation/inflammation. Further studies exploring the biological and functional consequences of increased TRP catabolism in HD patients are warranted.

**SA-PO409**

**Effect of Kibow Probiotic Renadyl™ on sCD30 Levels in Hemodialysis Patients** Subodh J. Saggi,[1] Eli A. Friedman,[1] Lorraine L.A. Thomas,[1] Natarajan Ranganathan,[2] Pari Ranganathan,[2] Gary R. Briefel,[1] Mary C. Mallappallil,[1] Usha N. Vyas,[2] Bohdan Pechenyak,[2] Peter Liang,[1] David Hochman,[1] Allen J. Norin.[1] *[1]SUNY Downstate Medical Center, Brooklyn, NY; [2]Kibow Biotech, Newton Square, PA.*

**Background:** Our prior studies in patients with CKD 3-4 (n=31) given Renadyl™, a safe proprietary dietary supplement, which metabolizes various nitrogenous wastes in the bowel, at a dose of 180-270 B CFU, over a 6 month period showed that BUN, creatinine and $K^+$ levels declined. How azotemia impacts QoL is unknown, though increased inflammation is a postulated mechanism. We now report on the effects of Kibow Probiotic Renadyl™ on 26 hemodialysis patients where we detected a reduction in their WBC counts, C-reactive protein (CRP) and total indoxyl glucuronide levels. In order to link the reduction to markers of inflammation, we looked at one biomarker of T cell activation, sCD30. This marker has previously been shown to be elevated in patients with CKD and lower levels of sCD30 have been associated with better prognosis in kidney transplant patients.

**Methods:** We conducted a prospective, double blind crossover trial with placebo and Renadyl™ for 8 weeks, followed by an 8-week washout period. Patient's serum was taken at 3 time points (baseline, after probiotics, and after placebo) and sCD30 levels were measured by ELISA (Bender MedSystems). Patient adherence was assessed by pill count and stool culture to verify probiotic growth during study and absence during placebo period. Data were analyzed with ANOVA for a crossover design with a mixed model methodology in SAS to detect differences in least square means in treatment, period and sequence effect.

**Results:** Mean sCD30 levels were 94.74ng/ml and decreased to 89.84ng/ml with probiotic administration. This difference is not statistically significant (p= 0.49).

**Conclusions:** Our results show that sCD30 levels are not affected with the administration of probiotics, which suggests that patients do not become immunocompromised by this treatment. Larger population studies or longer term studies might be needed to give a better insight into the role of T cell modulation by Probiotics in this population.

**SA-PO410**

**Effect of Kibow Probiotic Renadyl™ on NF-κB Levels in Hemodialysis Patients:** Subodh J. Saggi,[1] Eli A. Friedman,[1] Natarajan Ranganathan,[2] Pari Ranganathan,[2] Usha N. Vyas,[2] Bohdan Pechenyak,[2] Mary C. Mallappallil,[1] Gary R. Briefel,[1] Lorraine L.A. Thomas,[1] Peter Liang,[1] Allen J. Norin,[1] David Hochman.[1] *[1]SUNY Downstate Medical Center, Brooklyn, NY; [2]Kibow Biotech, Inc, Newton Square, PA.*

**Background:** End-stage renal disease (ESRD) is when the kidneys are unable to function effectively to sustain life and requires dialysis. As a consequence of this condition, uremic toxins build up and this has been associated with increased inflammation. NF-κB is an inflammatory marker that has been shown to increase in uremia. Previous studies showed that Renadyl™, a safe proprietary dietary supplement, decreased BUN, creatinine, and $K^+$. This study was done to see if Renadyl™ has an effect on NF-κB in ESRD patients on hemodialysis.

**Methods:** We conducted a prospective, double-blind crossover trial with placebo and Renadyl™ in 26 ESRD patients on hemodialysis. Each patient had 3 time points measured: Baseline, after taking probiotics for 8 weeks, and after taking placebo for 8 weeks. Peripheral blood mononuclear cells (PBMC) were extracted from the patient blood samples using ficoll hypaque and NF-κB levels were assayed using the TransAM p65 ELISA kit (Active Motif). Viability of cells was assessed using trypan blue exclusion. Patient adherence was assessed by pill count and stool culture to verify probiotic growth during study and absence during placebo period. Data were analyzed using ANOVA for a crossover study with a mixxed model methodology in SAS to account for treatment, period and sequence effect.

**Results:** NF-κB levels were 0.407U/uL when treatment with probiotic was first in sequence and 0.409U/uL when placebo was administered first. There were no differences in least square means between placebo and probiotic (p=0.9407).

**Conclusions:** These results indicate that NF-κB pathway is not activated and not modulated under the effect of Probiotic Renadyl™. This further suggest that the administration of probiotics to ESRD patients in itself is not harmful as the neither this pathway is activated nor suppressed as activation of this pathway is required in the settings of active infections.

**SA-PO411**

**Daily Physical Activity and Physical Function in Relatively Healthy Maintenance Hemodialysis (MHD) Patients** Bryan B. Shapiro,[1] Jun Chul Kim,[1,2] Rachelle Bross,[1] Usama Feroze,[1] Rajeev Upreti,[1] Kamyar Kalantar-Zadeh,[1,3] Joel D. Kopple.[1,3,4] *[1]Harbor-UCLA Med Cntr; [2]CHA Gumi Med Cntr, CHA Uni, Korea; [3]UCLA Schl Pub Hlth, LA, CA; [4]UCLA Schl Med, LA, CA.*

**Background:** MHD patients reportedly display reduced daily physical activity (DPA). Such studies included debilitated patients, and it is unclear to what extent kidney failure and MHD per se contribute to decreased DPA. Physical performance capacity may influence DPA, and few data examined relationships between DPA and physical performance in MHD. We hypothesized that DPA is reduced even in healthier MHD patients and is correlated with physical performance.

**Methods:** DPA and 6-minute walk distance (6-MWD), sit-to-stand and stair climbing tests were measured in 72 relatively healthy MHD patients (52 years, 32% diabetics) and 39 normal adults(51 years) of similar age and gender mix. Patients very debilitated from comorbid illnesses were excluded from study. DPA was examined by a physical activity monitor usually worn for 10 days and by the Human Activity Profile(HAP).

**Results:** Evidence that the MHD patients were relatively healthy included serum albumin of 4.1g/dL, BMI 27.8 $kg/m^2$, nPNA 1.10 g/kg/day & Charlson Comorbidity Index 5.7. DPA with the activity monitor, time-averaged over 7 days, and all 3 physical performance tests were impaired in MHD patients, to about 60-70% of normal values ($p<0.0001$ for each measurement). HAP was also impaired ($p<0.0001$). MHD patients spent increased time sleeping or in marked physical inactivity($p<0.0001$) and less time in ≥moderate activity($p<0.0001$). These findings persisted when comparisons to normals were restricted to men or women alone or to non-diabetic or diabetic patients separately. In comparing non-diabetic to diabetic patients, only HAP scores and 6-MWD were more impaired in diabetics. DPA assessed by the activity monitor, after adjustment, correlated with 6-MWD but not the 2 other performance tests. HAP scores correlated more closely with all 3 physical performance tests than did DPA.

**Conclusions:** Even in relatively healthy MHD patients, DPA and physical performance are substantially impaired and correlated. Impairment in these measures was not much greater in diabetic vs nondiabetic patients.

**SA-PO412**

**Relationship between the Frequency of Monitoring Laboratory Parameters and the Outcome in Maintenance Hemodialysis Patients** Li Wang. *Renal Dept, Sichuan Provincial People's Hospital, Chengdu, China.*

**Background:** To compare different impact on clinical status by frequency of monitoring laboratory parameters in the maintenance hemodialysis patients(MHD).

**Methods:** 310 MHD patients in our hemodialysis center were enrolled with HD vintage from 13-216 month(58.78±39.68 months).We retrospective analysed the status of hemoglobin,serum calcium,serum phosphorus,serum albumin,iPTH and the frequency of monitoring the status above from July 2010 to June 2011.Acorrding to the KDOQI guidelines for CKD-anemia and the KDIGO guidelines for CKD-MBD,we calculated the qualified rate of the statuses above of each patient.The relationship between the frequency and the status was analyzed.

**Results:** Patients were divided into 3 groups according to the frequency of monitoring(A group,frequency≤3/year,B group,4-5/yesr,C group,frequency≥6/year). There was no significant difference among the 3 groups in age,gender,the course of CKD and HD.The Hgb was significantly lower in A group than in B and C group(A group vs B group,104.89±19.40g/L *vs* 111.06±15.37g/L,$p<0.05$.A group *vs* C group,104.89±19.40g/L *vs* 112.16±12.27g/L,$p<0.05$),and was not significantly different between B and C group(111.06±15.37g/L *vs* 112.16±12.27g/L,p=0.793).The same results were also observed in the qualified rate of Hgb(A group vs B group,18.06%±30.00% *vs* 24.39%±22.00%,$p<0.01$.A group vs C group,18.06%±30.00% vs 27.39%±22.23%, $p<0.01$),serum calcium (A group vs B group,40.20%±41.42% *vs* 43.86%±31.46%, $p<0.05$.A group *vs* C group,40.20%±41.42% *vs* 50.58%±32.37%,$p<0.01$)and serum phosphorus (A group vs B group,48.63%±45.48% vs 50.81%±38.64%, $p<0.05$.A group vs C group,48.63%±45.48% *vs* 52.15%±36.33%.$p<0.05$).

**Conclusions:** The frequency of monitoring laboratory parameters the KDOQI and KDIGO guidelines recommended was beneficial to MHD patients.Despite of the difficulties,the MHD patients should take clinical Lab test at least 4 times per year for better prognosis.

**SA-PO413**

**Single Purse-String Suture versus Double Purse-String Sutures: Complications in Shorter Break-In Periods CAPD Patients** Li Wang. *Renal Dept, Sichuan Provincial People's Hospital.*

**Background:** It recommends break-in periods at least 2 weeks to reduce catheter associated complications in CAPD patients. Double purse-string sutures were made on the posterior rectal sheath to fix the peritoneum when catheter implantation was done in Chinese CAPD patients. However, it prolongs hospitalization and complicates operative procedure. We investigated the complications and feasibility of different Tenckhoff catheter implantation methods in early initiate patients.

**Methods:** We reviewed surgical catheter placement in our unit from January 2012 to March 2013. 100 patients without history of abdominal operation were enrolled and f0llowed up at least two months. We defined break-in periods less than 14 days as shorter break-in periods patients. The single purse string suture group comprised 27 patients is using one purse string suture to fix peritoneum around the PD catheter, 44 patients with two string sutures were enrolled in double string sutures group, and 29 patients with two string sutures and break-in periods >2 weeks as control group.

**Results:** Time to initiation CAPD was shorter in single purse string suture group(9.77±2.37 days)and double string sutures group(8.60±3.06 days) than control group(25.00±9.86 days)($P<0.001$).The hospitalization after implantation was extended in control group than single purse string suture group and double string sutures group(28.00±10.43, 21.26±7.11, 18.00±6.99)($P<0.01$).2 single purse string suture group(7.41%), 3 double string sutures group(6.82%) and 3 control group(10.34%) observed catheter related complications including migration, peritonitis and tunnel infection. Catheter related complications were similar among groups($P=0.856$).

**Conclusions:** Shorter break-in periods of CAPD with single purse string suture technique in Tenckhoff catheter placement did not increase catheter related complications in our patients. The hospitalization was significantly shorten when PD was initiated <14 days. We suggest that single purse string suture and early initiation PD are applicable.

Future studies with long time follow-up and larger patient numbers are needed to validate the role of shorter break-in period and single string suture in PD practice.

## SA-PO414

**Non-Surgical Treatment to Reduce Periodontitis Associated Inflammation in ESRD** Wilner Samson,[1] George Fares,[3] Effie Ioannidou.[2] *[1]Medicine, Univ of Connecticut School of Medicine, Farmington, CT; [2]Medicine, Bay State Medical Center, Springfield, MA; [3]Univ of Connecticut School of Dental Medicine, Farmington, CT.*

**Background:** Periodontitis (PDT) is a polymicrobial infectious disease affecting the hard and soft tissues that leads to tooth loss. PDT is prevalent in ESRD, and may contribute to systemic inflammation associated mortality. In a randomized clinical trial, we assessed clinical and systemic response to non-surgical periodontal treatment in ESRD subjects with PDT.

**Methods:** 12 ESRD subjects were recruited using the following criteria: presence of chronic PDT, > 15 teeth, no periodontal treatment within the past 6 months, and no use of systemic antibiotics within 30 days. All subjects received a full-mouth periodontal exam including clinical attachment levels (CAL), pocket depths (PD), bleeding on probing (BOP) and plaque scores (PS). Chronic PDT was defined by the presence of minimum of one site with 5mm or greater PD and minimum of 2 sites with 6mm or greater CAL. ESRD patients with PDT were randomized to two groups by a computer generated randomization list. The test group received oral hygiene instructions and scaling and root planning, whereas the control group received oral hygiene instructions and full mouth supragingival debridement. Subjects were recalled at 2 months for clinical periodontal measures and systemic inflammatory assessment (serum CRP**).**

**Results:** Baseline periodontal parameters and systemic inflammatory markers were compared between the two groups, no difference was found. The serum CRP levels decreased for the test group after treatment, however increased for the control group showing a trend to significance (p=0.1). When comparing the difference between pre- and post-therapy measures, CAL in the test group decreased but increased for the control group (Δ=-0.1mm) confirming significance (p<0.05). PD was reduced in the test group, but in the control group PD showed increased trend (p=0.07). Reduction in serum CRP levels was significantly correlated with the improvement in PD, CAL, BOP and PS.

**Conclusions:** Non-surgical treatment for PDT in ESRD patients may improve gum disease as well as systemic inflammation, a marker of mortality.

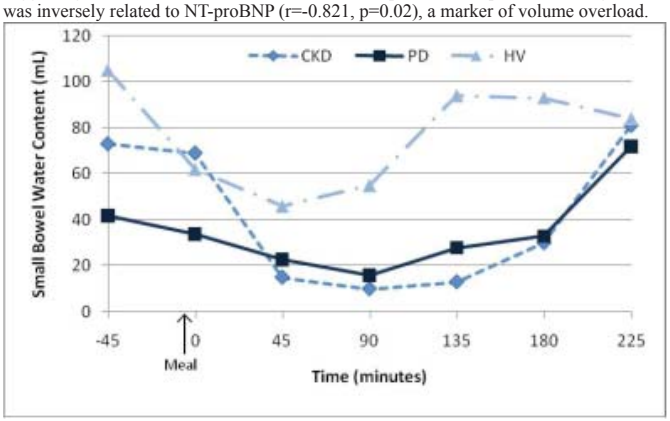
## SA-PO415

**Abnormal Gastrointestinal Function in Chronic Kidney Disease: Role of Uraemia, Peritoneal Dialysis and Volume Status** Laura E.A. Harrison,[1] Caroline Louise Hoad,[2] Luca Marciani,[2] Penny Anne Gowland,[2] Chris W. McIntyre.[1,3] *[1]Renal Medicine, Royal Derby Hospital, United Kingdom; [2]School of Physics and Astronomy, Univ of Nottingham, United Kingdom; [3]Div of Medical Sciences & Graduate Entry Medicine, Univ of Nottingham, Derby, United Kingdom.*

**Background:** Gastrointestinal (GI) dysfunction is common in chronic kidney disease (CKD), potentially driven by uraemia, volume status and dialysis modality. We assessed postprandial changes in the upper GI tract in a cross-sectional CKD study utilising Magnetic Resonance Imaging (MRI) techniques.

**Methods:** Participants underwent serial T2-weighted MRI fasted and after a 331kcal meal to assess small bowel water content (SBWC), a measure of free intraluminal water reflecting net intestinal secretion/absorption. 24 participants (9 Peritoneal Dialysis (PD), 6 CKD4, 9 non-CKD) were recruited.

**Results:** Fasting SBWC was lowest in PD patients, less than half that of non-CKD, (PD 34mL [IQR 10-63]; CKD 58 mL [IQR 22-138]; non-CKD 96 mL [IQR 50–157], p=0.04). Postprandially, SBWC fell to a nadir by $T_{90}$ in all groups (PD 12mL, CKD 7 mL, non-CKD 35 mL, p=0.01). PD and CKD patients had a delayed increase in SBWC, in contrast to non-CKD which returned to fasting levels by $T_{135}$. PD patients reported more postprandial abdominal pain and distension. AUC for total SBWC $T_0$-$T_{225}$ was significantly different between PD and non-CKD (PD 6772 mL/min vs non-CKD 16,430mL/min, p=0.001), suggesting reduced GI secretion or increased absorption. In PD patients, fasting SBWC was inversely related to NT-proBNP (r=-0.821, p=0.02), a marker of volume overload.



**Conclusions:** The altered GI physiological response to food in CKD patients is more marked in individuals receiving PD, and appears to be influenced by dialysis modality, in addition to uraemia. Volume overload and bowel congestion may be crucial factors in this process and potential future therapeutic targets.

## SA-PO416

**Development and Validation of Novel Equations for Estimating Lean Body Mass and Evaluation of Their Prognostic Values for Mortality in Peritoneal Dialysis Patients** Jie Dong,[1] Rong Xu.[1] *[1]Renal Div, Institute of Nephrology, Peking Univ First Hospital, Beijing, China; [2]Peking Univ First Hospital, China; [3]Peking Univ First Hospital, China.*

**Background:** Malnutrition is a strong predictor of mortality for dialysis patients. Early dignosis and intervention for malnutrition is based on a simple surrogate marker in clinical practice. Lean body mass is a good marker for somatic protein store but is not easily determined by the golden standare. Our study is to develop and validate estimating equations for lean body mass (LBM) in patients on peritoneal dialysis (PD), and then evaluate their prognostic value in a large prospective cohort.

**Methods:** Two equations for estimating LBM based on midarm muscle circumference (MAMC) and hand grip strength (HGS) respectively were developed in 106 and validated in 107 PD patients with dual-energy x-ray absorptiometry (DEXA) as referenced gold method, as compared to LBM estimated from creatinine kinetic (CK) and anthropometry (A) method. The prognostic values of LBM estimated from above four equations were further explored for all-cause mortality in 889 incident PD patients.

**Results:** Two new equations based on MAMC or HGS combined with gender, height and dialysis duration were developed. Bias of two new equations with LBM-DEXA were smaller than those of LBM-CK and LBM-A equation, with a median difference of 0.9 kg and -0.3kg between measured and estimated LBM by LBM-MAMC and LBM-HGS equation respectively, as compared to 3.0kg with LBM-CK equation and -5.0kg with LBM-A equation. Better precision and accuracy were achieved with LBM-MAMC and LBM-HGS equation reflected by smaller interquartile range of the difference and percentage of estimates that were 20% of measured LBM respectively. The prognostic value of LBM-MAMC and LBM-HGS was better than LBM-CK and LBM-A with the higher Chi-square by Omnibus tests for models of all-cause mortality.

**Conclusions:** LBM estimated from MAMC and HGS were verified to be more precise methods and reliable predictor of total mortality for PD population.

## SA-PO417

**Clinical Assessment Is Not Sufficient to Evaluate Volume Status in Hemodialysis Patients** Branko Braam,[1,2] Ryan Reid,[1] Sylvia Kalainy,[1] Kailash K. Jindal.[1] *[1]Medicine/Nephrology, Univ of Alberta; [2]Physiology, Univ of Alberta, Edmonton, Canada.*

**Background:** Determining the dry weight of hemodialysis (HD) patients remains a challenge. Yet, hypervolemia is associated with hypertension, heart failure and mortality. Therefore, it remains important to search for clinical parameters that can predict hypervolemia in a HD patient. Using bio-impedance to assess fluid volume, we hypothesized that a combination of clinical parameters could be used to predict volume status in HD patients.

**Methods:** Multifrequency bioimpedance spectroscopy (BCM, Fresenius Canada) was performed before the start of a midweek dialysis session in 32 stable chronic HD patients to assess extracellular fluid volume (ECFV) and overhydration (OH). Physical signs (Blood pressure, BP; edema), plasma Na, K and albumin, urea reduction ratio (URR), and a recent CXR (cor-thorax ratio) were investigated as potential markers for fluid overload.

**Results:** Volume status of 32 HD patients (age 59 (23-83) years, 68% males, 53% diabetic) was divided into 2 groups: nomovolemia (OH<1.1L, n=17) and hypervolemia (OH≥1.1L, n=15). None of the parameters except for the OH and OH/ECFV were significantly different between groups. When the entire group was evaluated, no significant correlations between continuous variables and OH was detected. An attempt to combine variables into a 'fluid overload score' failed.

| | Normovolemic | Hypervolemic |
|---|---|---|
| Gender, M/F | 8/9 | 14/1 |
| Predialysis-BP, mmHg | 130±22/ 75±16 | 140±19/ 80±14 |
| Postdialysis-BP, mmHg | 137±24/ 77±19 | 138±16/ 75±11 |
| OH,L | -1.0±0.9 | 2.9±1.3 (P<0.05) |
| OH/ECV% | -0.8±4.5 | 14±5.4 (P<0.05) |
| HTN, % | 58 | 86 |
| Diabetes, % | 40 | 60 |
| Smoking, % | 11 | 53 |
| CTR | 0.47±0.06 | 0.45±0.05 |
| Edema, % | 11 | 40 |

**Conclusions:** Assessment of volume status using clinical parameters in HD patients failed to identify patients with volume overload. The absence of a relationship between OH and BP could be due to the use of antihypertensive medication. To identify and treat hypervolemia, more objective measures such as bio-impedance should be used rather than clinical parameters.

*Funding:* Pharmaceutical Company Support - The body composition monitor was provided by Fresenius Canada

**Life in the Fishtank: AVF Monitoring for Dummies** David H. King,[1] Asmaa Y.M. Al-Chidadi,[1] Michael Graeme Taylor,[2] Mo Al-qaisi,[1] Sumith C. Abeygunasekara,[1] Anthony Chan,[1] Eric S. Chemla,[3] William D. Paulson,[4] Abdelgalil Abdelrahman Ali.[1] *[1]Broomfield Hospital, Chelmsford, Essex, United Kingdom; [2]Div of Imaging Sciences & Medical Engineering, Kings College London, London, United Kingdom; [3]Div of Medicine & Cardiovascular Sciences, St. George's Hospital, London, United Kingdom; [4]Georgia Regents Univ, Augusta, GA.*

**Background:** Time and resources tend to limit attempts at effective global monitoring for AVF patients. Clinical monitoring appears to be a poor substitute. We have devised a non-invasive version of Static Pressure Ratio ***SPRn*** which features rapid 'point and click' data acquisition by ***BlueDop*** pocket Doppler (www.bluedop.co.uk), paired with a smart database, the 'Fishtank' which allows patients with failing AVF to 'float' to the top of the list for easy identification by the clinical team.

**Methods:** ***SPRn*** data was acquired during normal uninterrupted dialysis sessions using a unique algorithm to measure mean pressure at any desired point on the fistula, typically either distal brachial or radial artery. The ***SPRn*** algorithm is shown in Figure 1. Hospital number,Date,Time,BP and ***SPRn*** were automatically archived in the 'Fishtank' database. An ***SPRn*** value of greater than 0.64 was assumed to be associated with a > 60% (PSVR>6) significant stenosis in the venous outflow segment.

**Results:** 340 measurements were made over a 10 week period on 73 patients. A further 60 patients formed a control group. 23% of the monitored group rose to the top of the 'Fishtank' of which 82% were subsequently shown by Duplex Ultrasound to have a significant venous stenosis of 60% or greater.

**Conclusions:** Retrospective analysis over 30 months of clinically initiated Duplex Ultrasound requests for AVF assessment showed that only 38% were candidates for intervention, 48% had excellent blood flow and 14% had already thrombosed. This compares with 82% suitable for planned procedures shown by the 'Fishtank'. Figure 1. SPRn algorithm; SPRn = 1/(1+Pff/Vff); Pff = (S-D)/MAP derived from an automatic BP reading taken from the non fistula arm; Vff = (max-min)/mean derived automatically from the Doppler blood flow spectrum.

## SA-PO419

**Outpatient Dialysis Hospitalization Rates: A Comparison between Fellow (FL) and Non-Fellow (NF) Managed Units in NY State** George N. Coritsidis,[1] Adedoyin G. Akintide,[1] Carol Lyden,[2] Marie France R. DeLeon,[1] Jasjit Singh.[1] *[1]Internal Medicine/Nephrology, Elmhurst Hospital Center, Elmhurst, NY; [2]IPRO, Lake Success, NY.*

**Background:** Hospitalization rates of dialysis patients are an important measure of proper care in ESRD patients. Renal fellows may provide for greater physician presence or possibly lower the threshold for hospital admissions. We were interested to see how the presence of renal fellows impacts on this measure, and whether it provides for more efficient care.

**Methods:** We reviewed the de-identified records of Network 2 which includes all of NY State for 2010 regarding demographics, emergency department (ED)visits and hospitalization rates. The hospitalization rates were then compared to 2009 data. Fellow managed units (FL) were compared with non-fellow managed units (NF). Data was corrected for the number of patients per unit (pt).

**Results:** We identified a total of 24 fellow managed units (4432 patients) and 196 Non fellow units (29837 patients). Compared to the NF units, patients in the FL units were more likely to be African American (52.7% vs 38.5%, p<0.0001). Age, URR metrics, ethnicity and the incidence of diabetes and hypertension were similar.

| Year | Unit Type | ED Visit/pt | ED hospitalization/pt | Days hospitalized/pt | All hospitalizations/pt | Readmission within 30 days/pt |
|---|---|---|---|---|---|---|
| 2009 | FL | 1.21 | 0.63 | 8.59 | 0.97 | 0.34 |
| | NF | 1.20 | 0.60 | 8.25 | 0.98 | 0.32 |
| 2010 | FL | 1.24 | 0.65 | 6.50 | 0.95 | 0.33 |
| | NF | 1.26 | 0.64 | 7.40 | 1.00 | 0.33 |

**Conclusions:** There was a significantly higher percentage of African Americans in the fellow managed units. ED visits, hospitalization and readmission rates were similar regardless of the presence of a renal fellow.

## SA-PO420

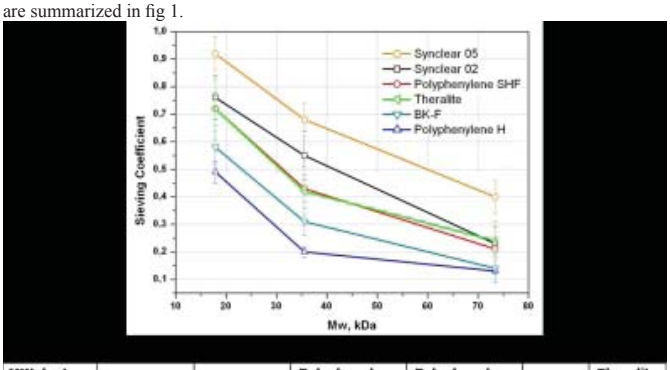
**In Vitro Characterization of High-Flux and High Cut-Off Membranes** Mauro Atti, Luca Corazza, Marialuisa Caiazzo, Luisa Sereni, Giuseppe Palladino. *Scientific Affairs, Bellco S.r.l., Mirandola, Modena, Italy.*

**Background:** The conventional dialysis membranes are classified as low-flux or high-flux membranes, depending on their permeability.Today a new class of High cut-off blood purification membranes are commercially available and this represent a challenge for blood purification in different pathologies treatable with extracorporeal treatments.

Dextran sieving experiments is an achievable and simple method, to classify High flux and High cut off membranes. Here we present preliminary results based on vitro method, obtained from six different membranes.

**Methods:** Dextrans (Sigma-Aldrich; Average MW 17.9, 35.6 and 73.4 kDa) solutions were prepared in distilled water at concentration of 1 g/L for each dextran. The dextran solution was recirculated at 300 ml/min flow rate and 50 ml/min as ultrafiltration flow. Feed (blood side entrance), retentate (blood side exit), and filtrate (dialysate exit) samples were taken at 15 and 60 min. Relative concentration of the samples were analyzed by spectrophotometric analyzer. The sieving coefficient SC was calculated according to Eq 1; SC= (2*Cf)/(Cp+Cr) , where Cf is the concentration of the solute in the filtrate, Cp its concentration in the permeate and Cr its concentration in the retentate.

**Results:** Six different commercially available dialyser were characterized and results are summarized in fig 1.



| MW dextran (kDa) | Syncear 0.5 | Synclear 0.2 | Polyphenylene SHF | Polyphenylene HF | BK-1.6F | Theralite 2100 |
|---|---|---|---|---|---|---|
| 17,9 | 0,92±0,06 | 0,76±0,08 | 0,72±0,06 | 0,49±0,04 | 0,58±0,06 | 0,72±0,11 |
| 35,6 | 0,68±0,06 | 0,55±0,09 | 0,43±0,05 | 0,20±0,02 | 0,31±0,05 | 0,42±0,09 |
| 73,4 | 0,4±0,06 | 0,23±0,06 | 0,21±0,03 | 0,13±0,01 | 0,14±0,05 | 0,24±0,07 |

As Aspected, we found an inverse proportionality between dextrans molecular weight and sieving coefficient .

**Conclusions:** The new membrane Synclear 0.5 showed encouraging behaviours in term of sieving coefficient, indicating a possible superior performance in the clearance of high molecular weight toxins. Innovative field for blood depuration could be explored due to its high depuration properties. Use of Synclear 0.5 membrane must be coupled with a specific sorbent system that allow reinfusion of albumin and retention of toxins substances.

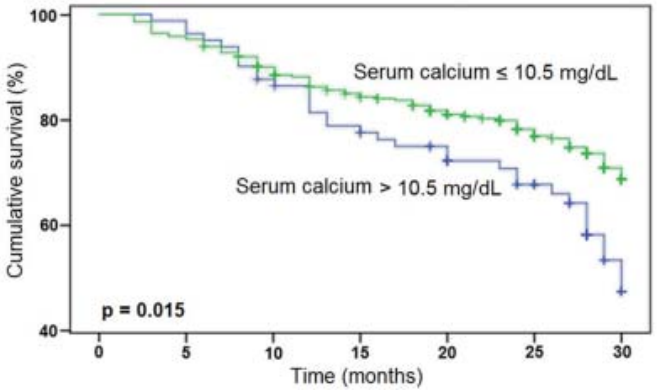
## SA-PO421

**Prevalence of Hypercalcemia and Hyperparathyroidism with Two Dialysate Calcium Concentrations** Patricia Coral Ruiz Palacios, Manolo Ramos Gordillo, Juan Francisco Fernández-pellón, Jose C. Pena. *Nephrology and Mineral Metabolism, Centro de Diagnostico Angeles, Mexico, Distrito Federal, Mexico.*

**Background:** The "calcium and alkaline" syndrome is a frequent complication in hemodialysis(HD) patients. The aims were to identify the presence of hypercalcemia in HD patients and to evaluate the effect of both a high dialysate calcium concentration compared to a low dialysate calcium concentration upon the serum calcium and PTHi concentrations.

**Methods:** From January 2010 to March 2011, 447 patients, age 52.6 ± 16 years old, 269 men(60%), were treated with high flux HD during 3 to 4 hours, 3 times per week, with a high dialysate calcium concentration(3.5 mEq/L). Then, during 14 months in the same cohort, the dialysate calcium concentration was lowered to 2.5 mEq/L. Oral calcium intake was held constant in all patients during both periods(1163 ± 757 mg/day). Hypercalcemia was defined as serum corrected calcium > 10.5 mg/dL. Serum calcium, PTHi and mortality were evaluated in all patients during both study periods. Results are expressed as mean ± SD. Mean values were compared with paired t test, hypercalcemia prevalence was compared with chi-squared test. Survival analysis was performed by Kaplan Meier curves and Log Rank(Mantel-Cox) test.

**Results:** Hypercalcemia prevalence was higher with high dialysate calcium(81 patients, 18.1 %) than with low dialysate calcium(15 patients, 3.3 % p < 0.01). With high calcium dialysate, mean serum corrected calcium was higher(9.61 ± 1.07 vs 9.24 ± 0.84 mg/dL p < 0.01) and mean PTHi was lower(898 ± 71.7 vs 992 ± 75.9 pg/mL p = 0.02) compared to low calcium dialysate. Survival rate was lower with high calcium dialysate compared to low calcium dialysate.



**Conclusions:** High calcium dialysate concentration was associated with hypercalcemia and increased mortality. Low calcium dialysate may stimulate PTH secretion, negative calcium balance and a reduction of the mortality rate.

## SA-PO422

**Comparing Accuracy of Assessment of Clotting of Dialyzer during Heparin Anticoagulation for Hemodialysis** Ki-won Kwon,[1] Young Hye Song,[1] Eun Hye Seo,[2] Jung-Hwan Park,[1,2] Jong-Ho Lee,[1,2] Young-Il Jo.[1,2] *[1]Dialysis Center, Konkuk Univ Medical Center, Seoul, Republic of Korea; [2]Div of Nephrology, Konkuk Univ Medical Center, Seoul, Republic of Korea.*

**Background:** Clinical assessment is useful for identifying coagulation problems during anticoagulation for hemodialysis (HD), the accuracy of visual assessment has yet not to be clarified. This study was designed to evaluate the accuracy of visual assessment of clotting within dialyzer during heparin anticoagulation for HD.

**Methods:** Adult ESRD patients who received maintenance HD were recruited. At the end of each dialysis session, the dialyzer was inspected for visible signs of thrombus formation and scored semiquantitatively (0=no clotting, 1=minimal, 2=moderate, 3=heavy, 4=complete clotting). The clotting volumes in dialyzer were calculated as follows: total blood compartment volumes (TBCV) of dialyzer before HD - TBCV after HD. The area of clotting in cross-section of dialyzer was measured by using squared paper. Each parameter was compared.

**Results:** A total of 244 dialyzer from 82 adult patients (male:female 41:41, age 62.6±11.6, DM 49%) were assessed and assorted into five groups (G-0:G-1:G-2:G-3:G-4=98:71:38:34:3) according to visual assessment of clotting within dialyzer. The grades of clotting within venous chamber estimated by visual inspection (G-0:G-1:G-2:G-3:G-4=239:4:1:0:0) were not correlated with the degrees of clotting within dialyzer. However, there were significant correlation ($p<0.001$) between the clotting within dialyzer and the coagulation volumes in dialyzer and the area of clotting in cross-section of dialyzer.

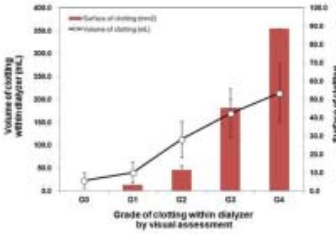


Figure 1. Correlation between the grade of clotting within dialyzer estimated by visual assessment and the clotting volumes within dialyzer and the surface areas of clotting of dialyzer.

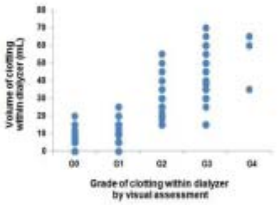

Figure 2. Distribution of volumes of clotting within dialyzer according to the grade estimated by visual assessment of clotting within dialyzer.

**Conclusions:** These results suggested the grade of clotting within dialyzer estimated by visual assessment may be useful indicator in decision of heparin dose for anticoagulation during HD.

## SA-PO423

**Ratios of Plasma Bicarbonate Increase to Dialysate-Plasma Bicarbonate Gradient at Early and Late Hemodialysis on 34 and 40 mEq/L Dialysate Bicarbonate Concentrations** David Tovbin,[1] Roberto Fudin,[1] Nayef Mohamed Habbashe,[1] Yakov Kuperman,[1] Saher Srur,[1] Alla Reitman,[1] Amir Abd Elkadir,[1] Shimon Storch.[2] *[1]Nephrology, Emek Medical Center, Afula; [2]Bnai-Zion Medical Center, Haifa, Israel.*

**Background:** Acidosis correction in hemodialysis (HD) requires bicarbonate (BIC) transfer to expanded extra-plasma compartments through narrow plasma compartment (P-EP transfer). Dialysate-plasma (D-P) transfer depends on D-P BIC concentration gradient (DBIC-PBIC). Intra-dialytic PBIC increase reach alkalotic range & counteracts gradient, D-P transfer & acidosis correction. We hypothesized that in pre-HD PBIC<22 mEq/L on standard BIC (SDBIC-34mEq/L), high DBIC (HDBIC-40 mEq/L) corrects inter-dialytic acidosis with limited intra-dialytic PBIC increase & alkalosis. Thus, we assessed intra-dialytic PBIC increases & their relations/ratios with DBIC-PBIC gradients on SDBIC & HDBIC.

**Methods:** In a prospective bi-center study, 15 patients were assessed for 3 weeks on SDBIC & HDBIC. Blood gases/electrolytes were assessed weekly at start, after 2 hours (mid-HD) & end HD. 3rd week data is presented as mean (SD) & evaluated using non-parametric tests.

**Results:** On SDBIC, pre-HD & mid-HD PBIC were 21.5 (2.7) & 27 (1.9) mEq/L, respectively. Early PBIC increase was 5.5 (1.9) mEq/L & correlated with DBIC- PBIC gradient ($r=0.71$, $p<0.005$). Mid-end PBIC increase was 1.3 (2) mEq/L. On HDBIC, pre-HD & mid-HD PBIC were 24.7 (2.3) & 33.2 (2) mEq/L, respectively. Early PBIC increase was 8.5 (1.7) mEq/L & correlated with DBIC- PBIC gradient ($r=-0.85$,$p<0.05$). Mid-end PBIC increase was 1.75 (2) mEq/L. In the 8 acidotic patients, on SDBIC pre-HD, mid-HD & end-HD PBIC were 19.3 (1.5), 26 (2) & 28 (2.9) mEq/L & on HDBIC 24 (2.6), 33.2 (2.4) & 34.9 (3.2) mEq/L, respectively. PBIC increase/DBIC-PBIC ratios decreased from early to late HD on both SDBIC & HDBIC {0.4357 (0.1124), 0.1634 (0.2834) & 0.5589 (0.1061), 0.2778 (0.3457), respectively, both $p<0.05$}.

**Conclusions:** Acidotic patients develop intra-dialytic alkalosis on SDBIC & more on HDBIC, which corrects inter-dialytic acidosis. Late HD decreased PBIC increase/DBIC-PBIC ratios suggest larger P-EP transfer for gradient. Thus, smaller gradient & DBIC are needed, which may limit alkalosis.

## SA-PO424

**Effects of Peritoneal Dialysis Using Icodextrin Dialysis Solution in Patients with Chronic Renal Failure Complicated by Refractory Congestive Heart Failure** Masahito Tamura, Tetsu Miyamoto, Ryota Serino, Yumi Furuno, Kenichiro Bando, Yoko Fujimoto, Akihiro Kuma, Emi Hasegawa, Yutaka Otsuji. *Dept of Nephrology, Univ of Occupational and Environmental Health, Kitakyushu, Fukuoka, Japan.*

**Background:** Chronic heart failure is likely to cause renal impairment and often becomes resistant to conventional treatments. We evaluated the usefulness of peritoneal dialysis (PD) using icodextrin solution in patients with refractory congestive heart failure (CHF) complicated by chronic renal failure.

**Methods:** In patients at CKD stage 5 who presented with symptoms of NYHA III or above CHF resistant to conservative therapy and had a medical history of hospitalization for CHF, PD using icodextrin solution was initiated to prospectively evaluate its usefulness. One bag of icodextrin dialysis solution was administered overnight as the basal dose, and dextrose dialysis solution was added as renal function declined.

**Results:** Four patients classified as NYHA IV were enrolled to this study. The mean estimated GFR level was 7.12 ml/min/1.73m$^2$ in the PD initiation period. The mean amount of PD fluid removal was 817 ml/day. Urinary output increased from 812 ml/day before to 1,083 ml/day after PD initiation. The NYHA classification showed improvement to class II in all patients. Duration of hospitalization due to CHF decreased from 29 days/year before to 0 days/year after PD initiation. Improvements of the following parameters were observed after as compared to before PD initiation: atrial natriuretic peptide, from 294.1 to 12.7 pg/ml; left ventricular ejection fraction, from 37.5 to 48.3%; end-diastolic left ventricular diameter, from 56.5 to 46.6 mm; and end-systolic left ventricular diameter, from 42.8 to 31.9 mm. Body weight showed no significant change from 55.1 kg before to 57.2 kg after PD initiation. In 1 patient, residual renal function declined after PD initiation, and hemodialysis was used in combination due to poor body fluid control.

**Conclusions:** It was suggested that PD with icodextrin dialysis solution might be useful in patients with chronic renal failure complicated by refractory CHF. Improvement of the NYHA classification might be attributable to improved cardiac function.

## SA-PO425

**NeutroPhase Shows Improvement in the Infections Associated with Peritoneal Dialysis Catheters** Allan G. Kavalich,[1] Dmitri Debabov,[2] Ramin (ron) Najafi,[2] Russell Hoon,[2] Thomas Paulson.[2] *[1]Medical Director, San Bernardino Valley Home Dialysis Center, Inc., San Bernardino, CA; [2]NovaBay Pharmaceuticals, Emeryville, CA.*

**Background:** *S. aureus* accounts for most exit site and tunnel infections associated with peritoneal dialysis catheters. Gram negative bacteria and fungi are less common, but difficult to eradicate and frequently lead to peritonitis if catheter removal is delayed.

**Methods:** NeutroPhase spray (a stabilized 0.01% pure hypochlorous acid in a NS solution) was used to treat five patients with infections associated with peritoneal catheters.

**Results:** A 59 year old male with exduative tunnel infection due to heavy growth of multi-resistant E.coli was treated with Levequin. After 10 days he was re-tested and grew out resistant E.coli and started on NeutroPhase. Patient was brought into unit TID, NeutroPhase was induced into tunnel via 30cc syringe and flexible IV catheter to bathe area with 5cc for 10 minutes repeated X four. NeutroPhase was allowed to dry, catheter was anchored and dressing was applied. Process was repeated X 2 weeks, then at home three times per day for six weeks with complete resolution. 55 year old male developed a Candida Albicans PD exit site infection; was treated with IV Diflucan and Nystatin cream. Culture remained positive. Treated with NeutroPhase 4 sprays to the exit site BID X six weeks with complete resolution. Continues to use spray daily at exit site X six months with no further infections. A 64 year old male with MRSA exit site infection was treated solely with NeutroPhase spray TID for eight weeks with complete resolution. 55 year old female with chronic staph epi exit site infections in the past treated with Vanco and Rifampin. NeutroPhase spray started. Exit site clean after six weeks. Continued spray QD without infection X six months. 29 year old female with recurrent exit site infections treated with NeutroPhase spray QID with complete resolution X four weeks.

**Conclusions:** NeutroPhase was the only treatment showing improvement in these patients. Our data show that there is a clear utility for the use of NeutroPhase for treatment of infections associated with peritoneal dialysis catheters.

## SA-PO426

**Encapsulating Peritoneal Sclerosis in PD Patients or on Renal Transplantation after Peritoneal Dialysis** Valerio Vizzardi, Massimo Sandrini, Luigi Manili, Silvio Sandrini, Gisella Setti, Laura Econimo, Giovanni Cancarini. *UO Nefrologia, Spedali Civili and Univ of Brescia, Brescia, Italy.*

**Background:** Encapsulating Peritoneal Sclerosis (EPS) is one of the most severe complication of peritoneal dialisys (PD). Prevalence of EPS after PD discontinuation has been increasing in the last years, mainly after kidney transplantation (50% of cases).

**Methods:** Retrospective analysis of EPS diagnosed in our Center from Jan 2000 to Dec 2012.

**Results:** 13 cases of EPS(2.5%) occurred in 517 non-TX patients still on PD. In the same period, 81 PD patients received a TX and two of them (2.5%) developed EPS. **TX Pt1**: 53 yrs old man: hemodialysis (HD) from 1982 to 1987. 1st TX from 1987 to 2002 [cyclosporine (Cys) and steroids (ST)]. APD from 2002 to 2005. In 2005 he received a 2nd

TX (Mycophenolate (Myc) and ST). In 2009 renal function failed and the pt started PD. EPS was diagnosed on peritoneal biopsy obtained during the placement of the Tenckhoff catheter. Clinical history: no episodeof bowel obstruction. The patient was shifted to HD and continued Myc and ST (8mg/day). Abdomen CT scan (2011 after an episode of intestinal sub-obstruction) showed "distension ofbowel loops, some focal thickening along the parietal peritoneum (previously absent)." The pt started Tamoxifen 20 mg/day. In the following months the clinical condition deteriorated and in December 2012 parenteral nutrition was started. **TX Pt2**: 57 yrs old man, on APD for 79 months. On April 2007 he received a TX. Therapy: Myc, ST and Tacrolimus (after 36 months shift to Cys). The patient is still on Cys, Myc and ST. 2003, abdomen CT-scan: "calcifications of the parietal peritoneum"; peritoneal biopsy: "chronic peritonitis with fibrosis and sclerosis." 2005, abdomen CT-scan: no peritoneal calcification. In 2007 the pt underwent enterolysis surgery for bowel obstruction. He continue on 5 mg of ST and, at present, six years after enterolysis, is asymptomatic.

**Conclusions:** In literature EPS prevalence increases after PD discontinuation mainly after TX. In our experience the incidence of EPS do not differ between TX and non-TX PD patients. The evolution of the two cases was acceptable after 3 and 6 years since the time of diagnosis.

## SA-PO427

### Effect of Peritoneal Dialysis Modality and Peritoneal Membrane Characteristics on Phosphorus Level and Managment

Rafael Garcia, Sheru Kansal, Martin J. Schreiber. *Hypertension & Nephrology, Cleveland Clinic Foundation, Cleveland, OH.*

**Background:** Hyperphosphatemia is highly prevalent in peritoneal dialysis (PD). Prior studies have suggested that phosphate (P) removal in continuous ambulatory PD (CAPD) and automated PD (APD) was regulated by peritoneal membrane (PM) transport type. The current study examined the impact of PD modality and PM transport type on P values, P binder equivalent doses (PBED), calcium and PTH values.

**Methods:** In this retrospective and single cohort study, we included 40 patients (24 M), mean age 53 y/old all new to PD dialysis. Baseline PM transport type, PD modality, ultrafiltration, residual renal function (RRF), total creatinine clearance (TCrCl), PCrCl and Kt/V were identified. Serial P level and PBED were documented every 3 months for 1 year. Longitudinal data analysis on repeated measures of outcomes by mixed effects models for continuous binary outcomes were conducted.

**Results:** 65% of patients utilized APD and 35% CAPD. PM transport distribution: low-low average :17, high average- high:23. At baseline (mean): RRF 6.57 ml/min, PCrCl 39.39 L/wk, TCrCl 143.58 L/wk, Kt/V 2.55, P 4.7 mg/dl, PBED 1666 mg. At 12 months, P and PBED were higher at 5.1 mg/dl and 2853 mg. PM transport type did not affect P levels or PBED. The slope of P change was not affected by PD modality, however, PCrCl and TCrCl significantly correlated with P level. PD type was significant for PBED; CAPD demonstrated significantly higher PBED than APD. RRF and TCrCl but not PCrCl also significantly affected PBED.

| P levels | Estimate | P-value |
|---|---|---|
| PCrCl | -0.04 | 0.004 |
| TCrCl | -0.01 | 0.03 |
| **PBED** | | |
| CAPD | 942 | 0.03 |
| RRF | -329 | 0.0009 |
| TCrCl | 18 | 0.02 |

**Conclusions:** The change in P level or PBED was not significantly impacted by PM transport type. Patients on CAPD have higher PBED suggesting an advantage to APD for phosphate control. PCrCl significantly affected P levels but not PBED whereas TCrCl significantly affected both suggesting creatinine clearance may be a better measurement of adequacy with regard to phosphate control as compared to Kt/V and should be examine in all patients to optimize P control. Prescription design focused on achieving the highest TCrCl should be a priority in settings of hyperphosphatemia.

## SA-PO428

### Survival Predictors in Anuric Korean Peritoneal Dialysis Patients: Prospective Multicenter Propensity Score Matched Cohort Study

Jang-Hee Cho,[1,2] Hye Min Jang,[1,2] Yon Su Kim,[1,3] Shin-Wook Kang,[1,4] Chul Woo Yang,[1,5] Nam Ho Kim,[1,6] Ji-Young Choi,[1,2] Sun-Hee Park,[1,2] Chan-Duck Kim,[1,2] Yong-Lim Kim.[1,2] *[1]Clinical Research Center for End Stage Renal Disease in Korea; [2]Kyungpook National Univ School of Medicine; [3]Seoul National Univ College of Medicine; [4]Yonsei Univ College of Medicine; [5]Catholic Univ of Korea College of Medicine; [6]Chonnam National Univ Medical School.*

**Background:** This study aims to evaluate predictors of survival in the absence of residual renal function using anuric peritoneal dialysis (PD) patients.

**Methods:** Anuric PD patients (n=505, <100 ml of daily urine) enrolled in Korean nation-wide prospective cohort from September 1, 2008 to June 30, 2011 were analyzed. Survived and non-survived anuric PD patients were compared by propensity score matching analysis by a ratio of two to one. Propensity method was used to adjust patient age, dialysis duration and presence of diabetes.

**Results:** In total anuric PD patients, non-survived patients showed significantly older age, higher proportion of diabetes, coronary artery disease, arrhythmia, lower serum creatinine and albumin. On Kaplan-Meier analysis, patient survival was significantly lower in lower ultrafiltration volume (<1000ml/day), serum creatinine (<10.7mg/dL) and serum albumin (<3.7g/dL). After propensity score matching, only serum albumin and cholesterol were decreased in non-survived patients compared to survived patients (3.44±0.45g/dL vs. 3.63±0.52g/dL, p=0.0388 and 169.9±41.8mg/dL vs. 185.7±50.9mg/dL, p=0.0416, respectively). Multivariate analysis revealed serum albumin was independent predictor of mortality in matched cohort (hazard ratio=0.548, p=0.0085). Analysis using the receiver-operating-characteristic curve showed that mortality could be predicted with a sensitivity of 59.4% and a specificity of 63.2% using a cutoff value of 3.6mg/dL of serum albumin in unmatched total PD patients.

**Conclusions:** Mortality of anuric PD patients was associated with age, comorbidities, and nutritional factors such as creatinine and albumin. After adjustment by propensity score matching, hypoalbuminemia was independent risk factor for mortality in anuric PD patients.

## SA-PO429

### Risk Factors for Peritoneal Dialysis Associated Peritonitis

Loke Meng Ong, N. Punitha, Z. Hadzlinda, B. Sunita, M. Lily, B.L .Goh, Ghazali T.V. Ahmad. *Ministry of Health (MOH), Malaysia.*

**Background:** Peritonitis remains the Achilles heel of peritoneal dialysis (PD) and adversely affect technique and patient survival. Many factors contribute to the risk of peritonitis.

**Methods:** We conducted a prospective observational study for 1 year to determine the patient and centre factors contributing to peritonitis. All episodes of peritonitis were independently verified.

**Results:** 2001 patients from 20 adult and paediatric PD centres in MOH were included. Their mean age was 48 years and 53% were females. 455 episodes of peritonitis occurred in 425 patients. The mean peritonitis rate was 41.8 patient-months per episode (PMEP). 29% of causative organisms were gram +ve, 32% gram -ve, 3% fungal and 32% had no organisms. The main risk factors for peritonitis were nasal Staph aureus carriage and manual PD (Table 1). There was a wide variation of peritonitis among PD centres (range 17.7-86.3 PMEP) but no centre factors could be identified. The number and experience of staff, staff-patient ratio, distance of residence to centre and number of home visits made did not affect the peritonitis risk.

**Table 1. Incidence Rate Ratio (IRR) for Peritonitis**

| | Univariate IRR (95% CI) | Multivariate IRR (95% CI) |
|---|---|---|
| Staph nasal carriage | 2.02(1.37-3.00) | 1.73(1.02-2.94) |
| Manual vs APD | 1.69(1.09-2.36) | 1.76(1.02-3.02) |
| Diabetes | 1.24(1.01-2.36) | 1.33(0.95-1.86) |
| Topical antibiotics | 0.74(0.58-0.94) | 1.08(0.65-1.77) |
| Need for assistance | 1.23(0.99-1.52) | 1.04(0.75-1.45) |
| Poor vision | 0.91(0.51-1.63) | 0.89(0.43-1.84) |
| Obesity | 1.56(0.99-2.47) | 1.23(0.62-2.48) |
| Female | 1.04(0.86-1.27) | 1.15(0.86-1.55) |
| Chinese | 0.69(0.54-0.88) | 0.85(0.49-1.48) |
| Elderly | 1.15(0.78-1.71) | 0.88(0.46-1.65) |
| High income | 0.80(0.56-1.15) | 0.77(0.44-1.36) |
| No education | 0.73(0.46-1.18) | 1.01(0.48-2.12) |

69% of peritonitis resolved with antibiotics and 2% relapsed then resolved. 23% required catheter removed and 6% of patients died.

**Conclusions:** There was a wide variation of peritonitis among PD centres. Staphylococcus aureus nasal carriage was the most important risk factor for peritonitis while automated PD reduced the risk.

## SA-PO430

### Effects of Walking Ability on Risk of Hospitalization for Cardio-Cerebrovascular Events in Hemodialysis Patients

Yoshifumi Abe,[1] Atsuhiko Matsunaga,[1] Ryota Matsuzawa,[1,2] Akira Ishii,[1,2] Kei Yoneki,[1] Manae Harada,[1] Toshiki Kutsuna,[1] Yutaka Takagi,[2] Atsushi Yoshida,[2] Yasuo Takeuchi,[1] Kouju Kamata.[1] *[1]Kitasato Univ, Sagamihara, Japan; [2]Sagami Junkanki Clinic, Sagamihara, Japan.*

**Background:** Hemodialysis (HD) patients are at high risk for cardio- and cerebrovascular events, yet very few studies have examined physical activity and function as a way to reduce the risk of cardio-cerebrovascular events among HD patients. We investigated the prognostic significance of walking ability on cardio-cerebrovascular events requiring hospitalization among HD patients.

**Methods:** A total of 148 Japanese outpatients undergoing maintenance HD three times per week at a HD center from October 2002 to August 2012 were followed up to 5 years. We measured maximum walking speed and characteristics (age, sex, body mass index, HD duration, comorbid conditions, serum albumin, and serum C-reactive protein) at baseline. HD patients were divided into two groups based on maximum walking speed: the fast speed group (women, ≥1.35 m/s; men, ≥1.50 m/s) and the slow speed group. A Cox proportional hazard regression was used to assess how walking speed affected hospitalization from all-cause, cardio-cerebrovascular events and non-cardio-cerebrovascular events.

**Results:** Median (25$^{th}$, 75$^{th}$ percentile) age of this study population was 64 (56, 72) at baseline, and 57.4% of the patients were women. Sixty percent of the patients were included in the fast speed group. There were 35 hospitalizations for cardio-cerebrovascular events and 21 hospitalizations for other causes. After adjusting for the effects of clinical characteristics, the hazard ratios for hospitalization from all-cause, cardio-cerebrovascular events and non-cardio-cerebrovascular events in the fast speed group were 0.48 (95% CI: 0.25-0.93; $P = 0.03$) , 0.33 (95% CI: 0.15-0.74; $P = 0.01$) and 0.89 (95% CI: 0.31-2.56; $P = 0.83$), respectively, compared with those in the slow speed group.

**Conclusions:** Walking speed is closely associated with physical activity of daily living.These results suggest that specific instruction on how to improve and maintain walking ability may be necessary to reduce the risk of cardio-cerebrovascular events among HD patients.

## SA-PO431

**Low Serum Magnesium Is Related with Vascular Stiffness in Patients on Maintenance Hemodialysis (MHD) but Not in Non-Dialysis Chronic Kidney Disease Patients (ND-CKD)** Takahiro Kuragano, Takeshi Nakanishi. *Internal Medicine, Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

**Background:** Recent clinical studies have shown that lower serum magnesium (Mg) levels are associated with vascular calcification and cardiovascular mortality in MHD. In this study, we evaluated the factors affecting Mg in MHD or ND-CKD. Furthermore we evaluated the relationship between Mg and the markers of arteriosclerosis in these patients.

**Methods:** We measured blood levels of Mg, hemoglobin (Hb), total cholesterol, creatinine (Cr), urea nitrogen (UN), β2microblobuin (MG), albumin (alb), Calcium (Ca), phosphate (P), intact parathyroid hormone (int-PTH), and tumor necrosis factor (TNF)-α in 69 patients with various stages of ND-CKD and 129 MHD. Furthermore, we measured brachial-ankle pulse wave velocity (ba-PWV) and ankle-brachial index (ABI).

**Results:** There was no significant difference in Mg between ND-CKD (2.19±0.26 mg/dL) and MHD (2.34±0.35 mg/dL). In MHD, Mg was significantly correlated with age (P=0.004, R=-0.25), Ca (P=0.02, R=0.21), TNF-α (P=0.005, R=-0.25), alb (P=0.001, R=0.32) and ba-PWV (P=0.001, R=-0.29). In multiple regression analysis, alb (P=0.0001, β=0.31) and Ca (P=0.029, β=0.18) were selected as the significant predictors of Mg in MHD. In the analysis for determining the factors affecting vascular stiffness of MHD, Mg (P=0.012, β=-0.22) was selected as the significant predictor of ba-PWV as well as systolic blood pressure (P=0.0001, β=0.32) and age (P=0.005, β=0.25). In ND-CKD, Mg did not related to Cr, UN, β2MG, alb, Ca, P, and int-PTH, ba-PWV and ABI.

**Conclusions:** Mg were associated with the index of vascular stiffness (ba-PWV) in MHD, and related with serum levels of Ca and alb. In ND-CKD, we could not show any parameters associated with Mg level.

## SA-PO432

**Neutrophil/Lymphocyte Ratio as a Predictor of Cardiovascular Events in Japanese Patients Starting Renal Replacement Therapy** Sawako Kato,[1] Bengt Lindholm,[2] Yukio Yuzawa,[3] Seiichi Matsuo,[1] Shoichi Maruyama.[1] *[1]Nephrology, Nagoya Univ Graduate School of Medicine, Aichi, Japan; [2]Baxter Novum & Renal Medicine, Karolinska Institute, Stockholm, Sweden; [3]Nephrology, Fujita Health Univ School of Medicine, Toyoake, Aichi, Japan.*

**Background:** Previous studies have suggested that a high neutrophil/lymphocyte ratio (NLR) is related to worse outcome in patients with cardiovascular diseases (CVD). Patients with chronic kidney disease (CKD) have an increasing risk for premature mortality, primarily as a result of CVD; however, the association between NLR and CVD risk is not known.

**Methods:** Eighty seven incident Japanese dialysis patients (58 males, age 58 ±11 years) without acute infections and severe liver dysfunction were enrolled and followed for a median of 38.7 months (range 1-68.9 months). Laboratory biomarkers including white blood cell count (WBC) and its differential count, were checked.

**Results:** NLR was 3.72 (1.19-24.4). NLR positively correlated to WBC ($R^2$=0.16, P<.0001), neutrophil count ($R^2$=0.55, P<.0001) and CRP levels ($R^2$=0.07, P=0.013), and negatively to lymphocyte count ($R^2$=0.51, P<0.0001). The duration from start of dialysis therapy to the first CVD events was significantly shorter in patients with higher NLR (Log rank 6.95, P=0.0084). The patients with high NLR had a significantly increased relative risk (Cox hazard model; 3.07 95% CI; 1.32-8.00) of CVD compared with those with lower NLR, even after adjustments for age, gender and presence of diabetes, while the relations between WBC, neutrophil and lymphocyte count and CVD events respectively were much weaker. The number of CVD events per year during the observation period was higher in patients with higher NLR (28.5 events per 100 person-years) than in patients with lower NLR (6.43 events per 100 person-years).

**Conclusions:** A higher NLR associates with increasing risk of cardiovascular events and is a stronger predictor of future CVD events compared with WBC, neutrophil, and lymphocyte counts.

## SA-PO433

**Importance of Brain Natriuretic Peptide in Assessing Overhydration in Patients on Maintenance Hemodialysis: A Validation Study Using Three-Dimensional Echocardiography** Attila Kovács,[1] Mihaly B. Tapolyai,[2] Katalin Solymossy,[1] Maria Faludi,[2] Astrid Apor,[1] Andrea Nagy,[1] Virag Reti,[2] Klara Berta,[2] Bela Merkely.[1] *[1]Heart and Vascular Center, Budapest, Hungary; [2]Dialysis, Fresenius Medical Care, Semmelweis Univ, Budapest, Hungary.*

**Background:** Precise estimation of overhydration in end-stage renal disease (ESRD) patients remains a major clinical issue. We sought to investigate the significance of brain natriuretic peptide (BNP) levels in assessing overhydration and its correspondence with left ventricular geometry and function measured by three-dimensional (3D) echocardiography.

**Methods:** In our cohort study forty-four prevalent ESRD patients on maintenance hemodialysis (HD) were enrolled. Exclusion criteria were medical history of coronary artery disease, diabetes mellitus, any cardiomyopathy or significant valvular disease. Prior to regular HD session, overhydration percentage (OH%) was assessed with bioimpedance (Fresenius Body Composition Monitor) and blood sample was collected for BNP measurement. 3D echocardiography was performed both before and after HD (GE Vivid E9). End-diastolic (EDVi), end-systolic (ESVi) volumes indexed to body surface area, ejection fraction (EF) and sphericity were measured using dedicated software (4D AutoLVQ). Data are presented as median (interquartile range).

**Results:** EDVi and ESVi were reduced, while EF increased after ultrafiltration [pre- vs. post-HD; EDVi: 56.3(17.2) vs. 55.6(13.9), ESVi: 19.6(8.6) vs. 19.3(5.7) ml/m$^2$, EF: 63(9.5) vs. 66(10) %, all p<0.001]. 3D sphericity describing full shape of the left ventricle decreased with fluid removal [0.37(0.12) vs. 0.31(0.15), p<0.001]. Serum BNP levels significantly correlated with pre-dialysis values of EF (Spearman's rho=-0.478), sphericity (ρ=0.491), OH% (ρ=0.484, all p<0.01). In a multivariate linear regression model BNP (β=-0.455) and sphericity (β=-0.456) were found to be independent predictors of EF.

**Conclusions:** Brain natriuretic peptide implies overhydration through the alterations of cardiac geometry and function. 3D echocardiographic assessment of the left ventricle provides valuable and instantaneous information on intravascular fluid load.

## SA-PO434

**Amputation-Free Survival in Dialysis Patients Undergoing Angioplasty of the Lower Limbs: Is Vascular Intervention Futile?** Ashraf Omar Oweis, Rory F. McQuillan, Joanne M. Bargman. *Nephrology, Univ Health Network, Toronto, Canada.*

**Background:** Previous studies have shown that dialysis patients are at increased risk for peripheral arterial disease. With improvement in interventional technology, more patients are undergoing angioplasty of the arterial tree to try to avoid amputation, and to maintain mobility and quality of life. However, there are few studies that have examined the outcome of lower limb angioplasty in these patients.

**Methods:** A retrospective analysis of all dialysis patients evaluated and treated by the interventional radiology department of a large referral hospital from 1 January 2005 to August 30 2012 with at least one-year follow up was conducted using electronic patient records. The Kaplan-Meier method was used to assess the main time-to-event outcomes (mortality and amputation) in comparison to non-dialysis patients during the same period of time. Cox proportional hazards models were fitted to examine the independent association among comorbidities, the use of antiplatelet and lipid-lowering agents, ACE/ARB and time-to-event outcomes.

**Results:** We evaluated 153 patients with lower limb angioplasty or stent of whom 51(33.3%) were on dialysis (2 PD and 49 HD) and 102 (66.7%) were not on dialysis. Mean time on dialysis was 76.9 months (SD 49.2). In the dialysis group there were 33(64.7%) deaths and 26(51%) amputations vs. 22 (21.6%) and 31(30.4%) in the non-dialysis group, with a P value of 0.0001 and 0.013 respectively. Almost half the deaths occurred within the first year after angioplasty: 16(31.4%) for the dialysis group vs. 10(9.8%) for the non-dialysis group, P=0.001. All patients in the dialysis group who had an amputation within a year of angioplasty died within that year.

**Conclusions:** This study shows a remarkably higher mortality and amputation rates in dialysis vs. non-dialysis patients who underwent lower limb angioplasty and/or stenting. This suggests that vascular intervention in dialysis patients may not be as effective as in those not on dialysis. A shift may be needed to focus on the benefits of early diagnosis, preventive measures, and the need for involving the palliative service early in the course along with nephrology and vascular teams.

## SA-PO435

**Association of Physical Activity with HDL-C Level in Hemodialysis Patients** Ryota Matsuzawa,[1,2] Atsuhiko Matsunaga,[1] Akira Ishii,[1,2] Yoshifumi Abe,[1] Kei Yoneki,[1] Manae Harada,[1] Yutaka Takagi,[2] Atsushi Yoshida,[2] Yasuo Takeuchi,[1] Kouju Kamata,[1] Naonobu Takahira.[1] *[1]Kitasato Univ, Sagamihara, Japan; [2]Sagami Junkanki Clinic, Sagamihara, Japan.*

**Background:** The Japanese Society for Dialysis Therapy reports that decreased high-density lipoprotein cholesterol (HDL-C) levels are associated with increased mortality in dialysis populations. Although physical activity increases HDL-C levels in the general population, this remains unclear in hemodialysis patients. After confirming the relationship between HDL-C levels and survival, we investigated the effect of physical activity on HDL-C levels in hemodialysis patients.

**Methods:** First, 266 hemodialysis patients (age, 64±13 years; duration of hemodialysis, 9±8 years; HDL-C, 43.5±13.4 mg/dL) were monitored prospectively for 5 years. Serum lipid levels were obtained at baseline. Cox proportional-hazards regression was used to confirm the contribution of HDL-C level to mortality. Second, before investigating the association between physical activity and HDL-C level, we excluded patients who had severe comorbidities or who needed help in walking. As a result, 116 patients (age, 67±9 years; duration of hemodialysis, 9±9 years; HDL-C, 42.8±12.8 mg/dL) were recruited in the cross-sectional study. We evaluated their physical activity and characteristics including age, sex, body mass index, duration of hemodialysis, comorbid conditions, serum albumin and creatinine levels, smoking habit, and use of antilipemics. Physical activity was evaluated with an accelerometer as the number of steps per day for a consecutive 5-day period. We used multiple regression analysis to evaluate the association between physical activity and HDL-C level.

**Results:** During the follow-up period, 77 patients died. We confirmed that HDL-C level was a significant predictor of all-cause mortality (hazard ratio, 0.975; 95% CI, 0.954-0.997; $P = 0.03$). After adjustment for patient characteristics, physical activity was independently associated with HDL-C level (adjusted β coefficient, 0.244; adjusted $R^2$, 0.255; $P = 0.005$).

**Conclusions:** Physical inactivity was strongly associated with decreased HDL-C level in hemodialysis patients.

## SA-PO436

**Decline of Peripheral Resistance over Time in Patients with End Stage Renal Disease. Results from the CONvective TRAnsport STudy (CONTRAST)**
Irina Mostovaya,[1] Michiel Bots,[2] Muriel Grooteman,[3] Marinus A. Van Den Dorpel,[4] Pieter M. Ter Wee,[3] Peter J. Blankestijn.[1] *[1]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]2 Julius Center for Health Sciences and Primary Care, Univ Medical Center Utrecht, Utrecht, Netherlands; [3]Nephrology, VU Medical Center, Amsterdam, Netherlands; [4]Internal Medicine, Maasstad Hospital, Rotterdam, Netherlands.*

**Background:** Peripheral resistance is a well established marker of sympathetic activity in end stage renal disease (ESRD) patients. However, data on changes over time are scarce. The aim of this study was to examine changes over time of peripheral resistance (PR), cardiac output (CO), mean arterial pressure (MAP), systolic blood pressure (SBP) and diastolic blood pressure (DBP).

**Methods:** A subpopulation of 84 patients from the CONvective TRAnsport STudy (CONTRAST), a randomized trial comparing online hemodiafiltration with low-flux hemodialysis, received echocardiography and simultaneous blood pressure measurements on a non-dialysis day at baseline, 6 months, 12 months and annually thereafter. PR was computed as MAP/CO. A total of 190 measurements were thus performed over a follow-up period of 3 years. The rate of change over time of PR, CO, MAP, SBP and DBP was estimated using linear mixed effects models.

**Results:** At baseline, patients had a mean age of 62 ± 14 years and 55% were male. Median PR was 17.7 (IQR 15.3 – 22.5) mmHg•min/L, mean CO was 5.5 ± 1.5 L/min, mean MAP was 97 ± 15 mmHg and mean SBP and DBP were 137 ± 29 and 76 ± 12 mmHg respectively. PR (Δ-1.6 95%CI:-3.0 to -0.2 mmHg•min/L per year), MAP (Δ-4.2 95%CI:-7.5 to -0.8 mmHg per year) and DBP (Δ-3.8 95%CI:-6.7 to -0.9 mmHg per year) decreased over time, while CO (Δ0.3 95%CI:-0.1 to 0.7 L/min per year) and SBP (Δ-4.3 95%CI:-10.3 to 0.9 mmHg per year) remained stable.

**Conclusions:** in ESRD patients MAP decreases over time, mainly due a decrease in DBP. As CO remained stable, this decline can be explained by a decrease of PR over time. Precise mechanisms were not investigated, but a decrease in renin-angiotensin-aldosteron system activation and renal sympathetic nerve activity could be a plausible explanation.

## SA-PO437

**Influence of Methodology on Left Ventricular Mass Measurement by Cardiac Magnetic Resonance in the Frequent Hemodialysis Network (FHN) Nocturnal Trial**
Gerald J. Beck, Glenn M. Chertow, Paul W. Eggers, Tom Greene, Brett Larive, Nathan W. Levin, Sanjay Rajagopalan, Michael V. Rocco, Javier Sanz, Tam Tran, Christopher Kramer, Alan S. Kliger, The FHN Trial Group. *NIH, NIDDK.*

**Background:** The FHN previously reported in the Daily Trial that left ventricular mass (LVM) by cardiac magnetic resonance (CMR) declined more over 12 months (unadjusted mean difference 13.9g) among patients randomized to 6x/week in-center hemodialysis (HD) compared to conventional 3x/week HD controls. In the smaller Nocturnal Trial (n=87 vs. 245), although LVM declined by 8.8g in the 6x/week nocturnal (NHD) vs. conventional HD (CHD) patients, these results were not significant. In the FHN trials, baseline and month 12 CMR studies were centrally read sequentially during the trial by 3 trained readers blinded to treatment group. Readers had rigorous training in standardized assessment of LVM and volumes.

**Methods:** Given the two trials' similar LVM effect sizes, we explored the impact of a single trained reader concurrently evaluating LVM for all Nocturnal Trial patients using matched baseline and 12 month MRIs (n=76) while blinded to treatment and time of visit.

**Results:** The standard deviation of the change in LVM was 28.2g using sequential measurements and 23.8g with concurrent measurements; a reduction of 16.6%. LV volumes showed closer agreement between sequential and concurrent readings. The original reported primary outcome (change in LVM or death) did not differ between the NHD vs. CHD arms: hazard ratio (HR) of 0.69 (95% CI 0.44 to 1.07, p=0.095). Use of concurrent readings yielded similar results: HR = 0.73 (95% CI 0.46 to 1.14, p=0.16).

**Conclusions:** Measurement of LVM using a single reader who read studies concurrently, modestly reduced the variability of LVM but did not change the primary outcome results from that reported previously for the FHN Nocturnal Trial. This was due to the magnitude of the treatment effect being reduced (along with the LVM variability) with the concurrent readings, which may reflect better reproducibility due to a single reader and use of matched (but blinded) pre and post-images.

*Funding:* NIDDK Support

## SA-PO438

**Hemodialysis Induced Cardiac Stunning: Impact on Segmental and Global Longitudinal Myocardial Strain**
Shih-Han S. Huang,[1,2] Lisa E. Crowley,[2] James O. Burton,[2] Aghogho Odudu,[2] Chris W. McIntyre.[3] *[1]Medicine, Nephrology, London Health Sciences Centre, Western Univ, London, Canada; [2]Dept of Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [3]Div of Medical Sciences and Graduate School, Univ of Nottingham, Nottingham, United Kingdom.*

**Background:** Conventional hemodialysis (HD) results in recurrent cardiac injury. This is associated with left ventricular regional wall abnormality. Strain analysis derived from analysis of speckle tracked imaging (STI) echocardiography can be used to examine both global and segmental contractile function. In this study, we examined the relationship of HD induced circulatory stress with overall ventricular function (assessed as global longitudinal strain (GLS), segmental distribution of strain and their impact on patient survival).

**Methods:** Averaged values of segmental and GLS were determined from pre- and peak-dialysis (225 minutes) echocardiography of 104 conventional HD patients. These values were compared to the reference values of healthy individuals. Impact on survival was assessed over a follow up period of up to 7 years.

**Results:** The segmental and global strain values were -8.65 to -16.51 ± 4.91 to 8.13 and -11.48 ± 4.42, respectively. Significant HD induced changes to segmental strain were restricted to the mid- and apical-septal segments (r=-0.29 to -0.33 = p<0.05). Global and most of the segmental (10 of 12) contractile function was reduced in HD patients c.f. normal control values, with segmental and global strain values significantly higher than healthy individuals (2.70-9.83, p<0.001). Of the forty-six patients who died, there were statistically significant negative correlations between survival time and the GLS (r=-0.30, p=0.04) and the apical, inferior and septal segments (r=-0.31 to -0.32, and p<0.04).

**Conclusions:** Global and segmental strain as measured from STI provides additional information relating to the effects of HD induced cardiac injury. The clustering of dialysis induced segmental strain abnormalities to the apical, inferior and septal watershed area of the left ventricle suggests a higher degree of vulnerability to demand ischaemia in this part of the uremic heart to challenged perfusion.

## SA-PO439

**The Prevalence of Oral Lesions in People on HemoDialysis: Oral-D Study**
Giovanni F.M. Strippoli,[1,2,3,4] Suetonia Palmer,[5] Marinella Ruospo,[1,2] Patrizia Natale,[1] Valeria Maria Saglimbene,[1,2] Michela Sciancalepore,[1] Letizia Gargano,[1] Fabio Pellegrini,[2] David W. Johnson,[6] Pauline J. Ford,[6] Jonathan C. Craig,[4] Paul Stroumza,[1] Luc Frantzen,[1] Miguel Rodrigues Leal,[1] Marietta Torok,[1] Anna Bednarek,[1] Jan Dulawa,[1] Eduardo Jorge Celia,[1] Ruben Gelfman,[1] Jorgen B.A. Hegbrant,[1] Charlotta Wollheim,[1] Staffan Schön,[1] Michele De Benedittis,[3] Massimo Petruzzi.[3] *[1]Diaverum; [2]Mario Negri Sud Consortium; [3]Univ of Bari; [4]Univ of Sydney; [5]Univ of Otago; [6]Univ of Queensland.*

**Background:** It has been shown that oral diseases are common in the general population and are associated with socioeconomic status. the prevalence of oral diseases could be increased in people on hemodialysis, but this has not been formally established. We conducted a systematic prospective survey of oral lesions in hemodialysis and are also evaluating their association with death and adverse vascular outcomes.

**Methods: ORAL-D** is a multinational prospective cohort study. We consecutively enrolled adults receiving hemodialysis in 75 outpatient clinics selected randomly from a collaborative dialysis network in Europe and South America. A dental surgeon conducted a standardized oral examination. We analyzed prevalence of oral diseases using descriptive statistics and will analyze prospective association with death and adverse vascular outcomes with Cox regression.

**Results:** 4324 (mean age 61 years (SD 16) adults on hemodialysis in the participating clinics received a complete oral examination. Of these, 868 (20%) were edentulous, 996 (30%) had dental erosion. The mean decay/missing/filled teeth (DMFT) score was 22 (9), salivary pH was 7.3 (1.4). Salivary flow rate before dialysis was 0.5 ml/min (0.8), versus 0.4 ml/min (0.8) post dialysis. 1880 (43%) patients reported mouth dryness and 304 (7%) reported mouth pain. Periodontitis was present in 3036 (91%) of 3340 dentate patients. Analysis of association with death and adverse vascular outcomes is in progress.

**Conclusions:** Oral lesions are prevalent in people receiving hemodialysis and may indicate impaired healthcare practices, although further research on the predictors of oral disease in this population is needed.

## SA-PO440

**Oral Hygiene Habits in People on Hemodialysis and Association with Death and Adverse Vascular Outcomes: Oral-D Study**
Giovanni F.M. Strippoli,[1,2,3,4] Suetonia Palmer,[5] Marinella Ruospo,[1,2] Patrizia Natale,[1] Valeria Maria Saglimbene,[1,2] Michela Sciancalepore,[1] Letizia Gargano,[1] Fabio Pellegrini,[2] David W. Johnson,[6] Pauline J. Ford,[6] Jonathan C. Craig,[4] Paul Stroumza,[1] Luc Frantzen,[1] Miguel Rodrigues Leal,[1] Marietta Torok,[1] Anna Bednarek,[1] Jan Dulawa,[1] Eduardo Jorge Celia,[1] Ruben Gelfman,[1] Jorgen B.A. Hegbrant,[1] Charlotta Wollheim,[1] Staffan Schön,[1] Michele De Benedittis,[3] Massimo Petruzzi.[3] *[1]Diaverum; [2]Mario Negri Sud Consortium; [3]Univ of Bari; [4]Univ of Sydney; [5]Univ of Otago; [6]Univ of Queensland.*

**Background:** Oral hygiene habits in people with end end-stage kidney disease on hemodialysis are poorly described. We prospectively surveyed global oral hygiene habits in a large outpatient hemodialysis population, evaluating association with death and adverse vascular outcomes.

**Methods: ORAL-D** is a multinational prospective cohort study of oral diseases in people on hemodialysis. We enrolled adults on hemodialysis in 75 outpatient clinics selected randomly in Europe and South America. We assessed oral hygiene habits using standard self-administered patient questionnaires. We summarized data using descriptive statistics and association with death and adverse vascular outcomes will be analyzed using Cox regression.

**Results:** 4324 hemodialysis patients in the participating clinics from Italy, Hungary, Poland, Argentina, Portugal, France and Spain responded to the questionnaire. Of these, 2237 (52%) did not remember when they had last dental visit or reported they did not have a regular dental practitioner. 1171 (27%) reported their first dental visit at 30 years or older, 494 (11%) never brushed their teeth, 1570 (36%) used mouthwash and only 295 (7%) used dental floss. Only 1339 (31%) spent more than 2 minutes on daily oral hygiene cares. Analysis of association with death and adverse vascular outcomes is in progress.

**Conclusions:** Using validated instruments to evaluate oral hygiene, nearly half of adults on hemodialysis do not regularly visit a dental practitioner and many have poor oral hygiene habits. Additional studies of whether these variables on oral hygiene have any influence on clinical outcomes may be warranted.

## SA-PO441

**Association of Periodontal Disease and All Cause and Cardiovascular Mortality in Hemodialysis Patients: Oral-D Study**

Giovanni F.M. Strippoli,[1,2,3,4] Suetonia Palmer,[5] Marinella Ruospo,[1,2] Valeria Maria Saglimbene,[1,2] Patrizia Natale,[1] Michela Sciancalepore,[1] Letizia Gargano,[1] Fabio Pellegrini,[2] David W. Johnson,[6] Pauline J. Ford,[6] Jonathan C. Craig,[4] Paul Stroumza,[1] Luc Frantzen,[1] Miguel Rodrigues Leal,[1] Marietta Torok,[1] Anna Bednarek,[1] Jan Dulawa,[1] Eduardo Jorge Celia,[1] Ruben Gelfman,[1] Jorgen B.A. Hegbrant,[1] Charlotta Wollheim,[1] Staffan Schön,[1] Michele De Benedittis,[3] Massimo Petruzzi.[3] *[1]Diaverum; [2]Mario Negri Sud Consortium; [3]Univ of Bari; [4]Univ of Sydney; [5]Univ of Otago; [6]Univ of Queensland.*

**Background:** Periodontal disease is associated with increased cardiovascular mortality according to several studies done in the general population. We evaluated the association between periodontital disease and all-cause and cardiovascular mortality in hemodialysis.

**Methods: ORAL-D** is a multional prospective cohort study of consecutive adults receiving hemodialysis in 75 outpatient clinics selected randomly from a dialysis network in Europe and South America. A dental surgeon evaluated presence of periodontitis during a standardized oral examination. We are assessing survival at 12 months using centralized mortality data. We conducted analysis with Cox regression controlling for age, gender, previous cardiovascular event, income status, clinical performance measures, dialysis prescription and performance indicators.

**Results:** 3324 dentate hemodialysis patients in the participating clinics received a complete evaluation for periodontitis and completed follow up. Median follow up was 8.0 (6.5 to 8.7) months. 3036 patients (91%) had periodontitis and 344 (10%) died during follow up. While unadjusted analysis suggested an association between periodontitis and mortality, adjusted analysis had shown no associations with risks of all-cause (HR 1.11 [95% CI 0.68-1.82]) or cardiovascular (HR 2.20 [95% CI 0.94-5.11]) mortality.

**Conclusions:** Contrary to data in the general population, periodontitis at present follow-up of 8 months has uncertain associations with all-cause or cardiovascular mortality in patients on hemodialysis. ORALD will be completed at the end of 1 year follow up by September 2013.

## SA-PO442

**Left Ventricular Mass Is a Powerful Risk Factor for All-Cause and Cardiovascular Death in End Stage Kidney Disease (ESKD) Patients on Dialysis but Does Not Contribute to Prognosis: An Analysis in Two European Cohorts**

Giovanni Tripepi,[1] Bruno Pannier,[2] Francesca Mallamaci,[1] Gerard M. London,[2] Carmine Zoccali.[1] *[1]Nephrology Unit, CNR-IBIM, Reggio Calabria, Italy; [2]Service d'Hémodialyse, Hôpital F.H. Manhès, Fleury-Mérogis, INSERM, Nancy, France.*

**Background:** Left Ventricular Hypertrophy (LVH) is one of the strongest risk factors for death and CV events in end stage kidney (ESKD) patients. Causality apart, the concept that LVH is useful for risk stratification in ESKD has never been formally tested by state-of-art statistical analyses [risk discrimination(ROC curve area, AUC), calibration and re-classification].

**Methods:** We re-analysed the prognostic power of LVMI for all-cause and CV mortality in 2 independent ESKD cohorts in Italy and in France, the Cardiovascular Risk Extended Evaluation cohort (CREED,n=254) and the Hospital Manhes cohort (HM,n=270].

**Results:** In both cohorts, LVMI predicted all-cause [CREED, hazard ratio(HR):1.05;HM,HR:1.03] and CV death [HR:1.06 and 1.05] (P<0.001). In these cohorts, the AUCs of LVMI for all-cause death were 0.71 (CREED) and 0.67 (HM) and those for CV mortality were 0.64 and 0.69, figures lower than those by age alone both for all-cause (CREED:0.81;HM:0.88) and CV death (CREED:0.66;HM:0.78]. All predictive models were calibrated. In the CREED cohort a predictive model including Framingham factors, anti-hypertensive treatment, CV comorbidities, heart rate, Hb and albumin produced an AUC of 0.89 for all-cause and 0.76 for CV death, figures similar to those in the HM cohort (0.92 and 0.87). The incusion of LVMI did not improve the discrimination power of these models (all-cause death, CREED 0.89 vs.0.89; HM:0. 93 vs.0.92; CV mortality, CREED:0.76 vs.0.76; HM:0.88 vs.0.87). In an aggregate analysis of the 2 cohorts (n=524) the net reclassification index (NRI) by LVMI was not significant both for all-cause (NRI:4.5%,P=0.11) and CV death (NRI:3.4%,P=0.33).

**Conclusions:** LVMI is a strong risk factor in ESKD. However, the prognostic power of LVMI is by far lower than that by age alone or combined with standard risk factors. While LVH remains a fundamental treatment target in ESKD, measurement of LVMI solely for prognosis is unwarranted in these patients.

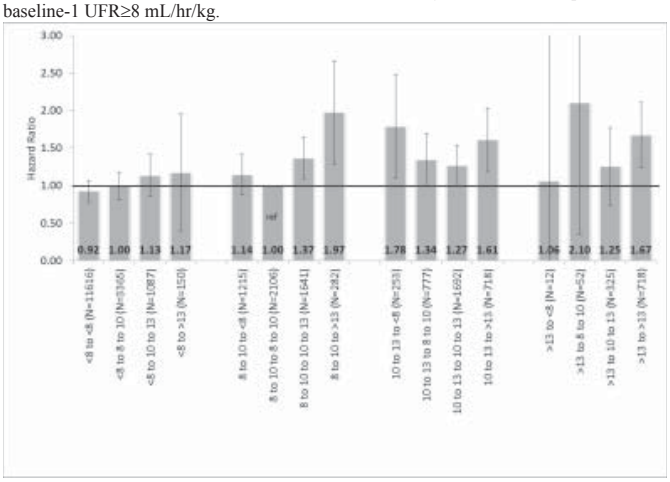
**Longitudinal Change in Ultrafiltration Rate in the First Year and Survival**

Len A. Usvyat,[1] Peter Kotanko,[2] Franklin W. Maddux,[1] Eduardo K. Lacson.[1] *[1]FMCNA, Waltham, MA; [2]RRI, NY, NY.*

**Background:** Higher ultrafiltration rate (UFR) during HD may be associated with poor outcomes. As UFR is measured in mL/hr/kg, interdialytic weight gain, HD time, and body size all contribute towards differences in mortality. We aim to determine association b/n changes of UFR at different levels of baseline UFR and survival.

**Methods:** All incident HD patients in FMCNA who initiated dialysis b/n Jan 1, 2010 and May 1, 2012, survived>365 days, with Kru<0.1 ml/min at the initiation were included. UFR (in mL/hr/kg) was calculated for 1st 6 months of dialysis [baseline-1] and in months 7 to 12 [baseline-2]. Patients were stratified into 4 groups at baseline 1 and 2 by UFR: <8, 8-10, 10-13, and >13 mL/hr/kg. Mortality was tracked until May 1, 2013. The Cox model adjusted for age, gender, DM status, race, ethnicity, and baseline BMI levels were constructed to assess survival after the first year on dialysis in 16 combinations of UFR categories at Baseline 1 and 2.

**Results:** Among 26009 incident patients, 16132 (62%) had stable UFR at both baseline 1 and 2. Mean age was 62.3±14.8; 52% male. The median survival follow-up time was 650 (range 1-851) days. We found significant negative correlation between UFR and BMI in baseline: r=-0.28 (p<0.001). Mortality risk tended to increase not only with an increment of UFR but also with decline of UFR in univariable and adjusted models, for patients with baseline-1 UFR≥8 mL/hr/kg.



**Conclusions:** This analysis demonstrates that patients with both increasing and decreasing UFR have a trend toward poorer survival than stable UFR (particularly >8 mL/hr/kg). Since larger patients have better outcomes, inverse correlation b/n UFR and BMI signals residual confounding. Further analyses are needed to determine contributions of the patients' body size, HD time, interdialytic weight gains, and/or changes in those parameters to the survival differences.

## SA-PO444

**Non-Traditional Blood Pressure Medications (BPM) Instructions for Hemodialysis (HD) Patients**

Sana Waheed,[1] Stephen M. Sozio,[1] Wendy L. St. Peter,[2] Patti Ephraim,[1] Jason Luly,[1] L. Ebony Boulware,[1] Tariq Shafi.[1] *[1]Dept of Medicine, Johns Hopkins Univ, Baltimore, MD; [2]Dept of Pharmacy, Univ of Minnesota, Minneapolis, MN.*

**Background:** Most studies of BPM use in HD patients assume that they take BPM similar to non-HD patients. However, with blood pressure (BP) fluctuations in HD patients, BPM are sometimes held before HD (HOLD) or administered as needed (PRN). Our study describes the frequency of the non-traditional instructions (HOLD and PRN) in HD patients.

**Methods:** We performed a retrospective cohort study of patients starting HD at Dialysis Clinic, Inc. facilities from 2003-2008 who were on a BPM at 6 months. Three independent abstractors reviewed medication instructions from free text comments entered in electronic medical records. We assessed distribution of HOLD and PRN instructions across patient demographics, dialysis related factors and BPM regimens.

**Results:** Of 11,291 incident HD patients who were on a BPM at 6 months, mean age was 62 years; 55% were men and 53% White. At 6 months, there were 30,212 BPM prescriptions of which 1,683 (5.6%) prescriptions had non-traditional instructions [HOLD: 1,191 (3.9%); PRN: 496 (1.6%)]. HOLD orders were commonest with β-blockers (5% of all β-blocker prescriptions) whereas PRN orders were commonest with clonidine (12.7% of all clonidine prescriptions). Patients with HOLD orders were likely to be older, white, had greater comorbidities and lower pre- and post- dialysis systolic BP whereas those with PRN orders where younger, less likely to be white and had higher pre and post dialysis systolic BP and greater BP variability (all p<0.05).

| | Overall (N=11,291) | Hold | | p-value | PRN | | p-value |

## SA-PO445

**Association of Age and Blood Pressure Variability with Long-Term Mortality in Hemodialysis Patients** Ha Yeon Kim, Yong Un Kang, Chang Seong Kim, Joon Seok Choi, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea.*

**Background:** Blood pressure (BP) variability is known as a poor prognostic factor for cardiovascular disease and mortality. This study assessed the prognostic significance of BP variability in association with increasing age in hemodialysis patients.

**Methods:** We retrospectively analyzed 2,174 patients on hemodialysis at chonnam national university hospital between January 2000 and December 2012. BP data were collected three times in each hemodialysis session at start and finish times. Highest and lowest points of BP over the first month of dialysis initiation were collected as well. Intradialytic systolic BP variations over 20 mm Hg and diastolic BP variation over 10 mm Hg were defined as BP variability, respectively. Interdialytic systolic BP variations over 10 mm Hg and diastolic BP variation over 5 mm Hg were defined as BP variability, respectively.

**Results:** In patients aged <55 years, Kaplan-Meier survival curves for 5-year cumulative mortality showed significant higher mortality in patients with higher intradialytic systolic and diastolic BP variability as well as interdialytic systolic and diastolic BP variability (log-rank p=0.006, 0.001, 0.018 and 0.001). Cox proportional analysis revealed that 5-year mortality was associated with intradialytic diastolic BP variability (HR, 2.034 CI, 1.246-3.321). On the other hand, in older patient groups, 5-year mortality has no significant association between intradialytic systolic and diastolic BP variability as well as interdialytic systolic and diastolic BP variability by Cox proportional analysis (p=0.383, 0.828, 0.708 and 0.642 in 55 ≤ age < 75 group, n=1099, p=0.335, 0.246 0.272 and 0.059 in 75 ≤ age group, n=290).

**Conclusions:** For patients aged <55 years, the mortality was significantly higher in patients with BP variability. The association of BP variability with long-term mortality was weaker with increasing age, indicating that the prognostic significance of BP variability in hemodialysis patients is age dependent.

## SA-PO446

**Outcomes of Dialysis Patients after Coronary Revascularization: A Nationwide Cohort Study in Taiwan** Te-Chao Fang,[1,2,3] Chulin Chou,[2] Tsung-cheng Hsieh.[2] *[1]Dept of Internal Medicine, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]Institute of Medical Sciences, Tzu Chi Univ, Hualien, Taiwan; [3]School of Medicine, Tzu Chi Univ, Hualien, Taiwan.*

**Background:** The outcomes of Chinese patients undergoing dialysis after coronary revascularization are unknown. We examined the outcomes of Taiwanese dialysis patients after coronary artery bypass grafting (CABG), percutaneous transluminal coronary angioplasty (PTCA), or coronary stenting.

**Methods:** Using data from the National Health Institutes Research Database, we determined the outcomes of 1,287 dialysis patients who underwent initial coronary revascularization between 1997 and 2008.

**Results:** The 7-year all-cause survival rates were 69% ± 4%, 68% ± 3%, and 57% ± 2% for the CABG, stent, and PTCA patients ($P$ = 0.001), respectively. After demographic and comorbidity adjustment, the hazard ratios (HRs) for all-cause death in the CABG (*versus* PTCA) and stent (*versus* PTCA) patients were 0.695 ($P$ = 0.015) and 0.721 ($P$ = 0.009). Additionally, no significant difference in all-cause death was found between the CABG and stent patients ($P$ = 0.906). Moreover, the ≥65-year-old CABG group patients and the <65-year-old coronary stent group patients showed better survival than the PTCA group patients. Compared with the PTCA and CABG groups, the coronary stent group was significantly associated with a higher risk for a recurrent AMI.Based on age stratification, the ≥65-year-old stent group had a higher risk for a recurrent AMI than PTCA group (HR, 1.486; $P$ = 0.031).

**Conclusions:** Chinese patients undergoing dialysis who underwent CABG or coronary stenting had better survival than those who underwent PTCA. Moreover, being ≥65 years old, CABG has better survival compared with PTCA; being <65 years old, coronary stenting has better survival compared with PTCA.

## SA-PO447

**Hybrid Myocardial Imaging for Risk Stratification prior to Kidney Transplantation: Added Value of Coronary Calcium and Epicardial Adipose Tissue** Antonio Bellasi,[1] Cristina Karohl,[2] Luis D'Marco,[3] Paolo Raggi.[4] *[1]Dept of Nephrology, Ospedale Sant' Anna, Como, Italy; [2]Hospital de Clinicas de Porto Alegre, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; [3]Nephrology, Hospital Universitario Ruíz y Páez, Universidad de Oriente, Ciudad Bolívar, Venezuela; [4]Mazankowski Alberta Heart Institute, Univ of Alberta, Edmonton, Canada.*

**Background:** Patient selection and what clinical or imaging markers may help improve risk stratification prior to kidney transplantation remain uncertain. We looked for imaging markers that help predict an abnormal result in screening nuclear stress testing prior to surgery.

**Methods:** Cross-sectional study of 411 consecutive chronic kidney disease (CKD) stage 4-5D patients awaiting kidney transplantation referred for risk stratification. PET-computed tomography (PET-CT) or SPECT-CT were used to assess myocardial perfusion and quantify coronary artery calcium (CAC) and epicardial adipose tissue (EAT). Abnormal myocardial perfusion was defined as a perfusion defect involving >5% of the left ventricular myocardium.

**Results:** Fixed (necrotic myocardium) or reversible myocardial perfusion defects (ischemia) were present in 41 patients (10%). Male sex, smoking, and history of cardiovascular disease were more prevalent and age, CAC and EAT were greater in patients with myocardial perfusion defects than in those with normal myocardial perfusion (all p-values<0.05**).** On multivariate logistic regression, EAT and CAC were independent predictors abnormal myocardial perfusion while diabetes mellitus was of borderline significance ($P$=0.08). EAT added incremental diagnostic value to a model including age, CAC and diabetes mellitus [AUC 0.73 (95% CI: 0.64-0.81) to 0.76 (95%CI: 0.68 – 0.84); P=0.02] for the prediction of abnormal perfusion. Furthermore, the model containing EAT showed improved diagnostic discrimination (integrated discrimination improvement; IDI).

**Conclusions:** Abnormal myocardial perfusion on screening stress testing appears to be rare in patients awaiting kidney transplantation suggesting an excess of testing. EAT and CAC may help predict what patients are at higher risk of having an abnormal myocardial perfusion.

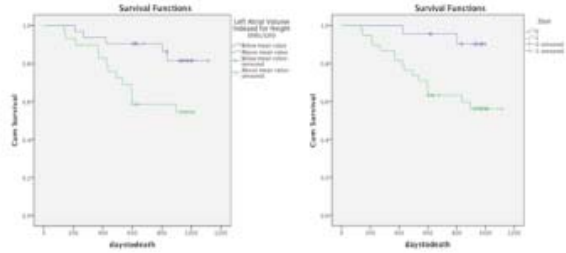
## SA-PO448

**Left Atrial Volume and Dialysis Induced Cardiac Injury** Lisa E. Crowley,[1] Adam Kirk,[1] Richard J. Fluck,[1] Maarten W. Taal,[1] Chris W. McIntyre.[2] *[1]Dept of Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]Div of Medical Sciences and Graduate Entry Medicine, School of Medicine, Univ of Nottingham, Nottingham.*

**Background:** Left atrial volume (LAV) has been demonstrated to be a powerful determinant of cardiovascular mortality in HD patients. Haemodialysis (HD)-induced myocardial stunning driven by ischaemia is a recognised complication of HD and a pivotal part of the pathophysiology of the observed excess in CV mortality. We aimed to assess the hierarchy of importance of ventricular hypertrophy, increased LAV and presence/severity of dialysis induced cardiac injury.

**Methods:** 60 established HD patients underwent echocardiography at rest assessing cardiac structure and function. Dialysis induced cardiac stunning was detected and quantified from the measurement of left ventricular regional wall motion abnormalities (RWMA) under dialytic stress.

**Results:** 38/60 patients experienced dialysis induced cardiac stunning. Higher LAVI was significantly correlated with severity of stunning (as measured by number of RWMAs (r=0.37, p=0.004) and humoral evidence of volume overload (NT-proBNP r=0.56, p<0.001). Both increased LAVI and dialysis induced stunning were associated with reduced survival. There was a clear hierarchy of effect demonstrated in multi-variable Cox Proportional Hazard modelling. Stunning was most strongly associated with mortality (HR 4.92 [1.0-23.1] p=0.04), followed by LAVI (HR 1.065 [1.001-1.1000] p= 0.038) and LVMI (HR 0.99 [0.97-1.00] p=0.36).



**Conclusions:** This study demonstrates the hierarchical relationship (stunning>LAVI>LVMI) between the principal recognised morphological and functional echocardiographic determinants of increased CV mortality in HD patients and suggests that dynamic echocardiographic parameters may be more predictive of outcome than structural measures.

**SA-PO449**

**Association between Cardiac Valvular Calcification and Myocardial Ischemia in Asymptomatic High Risk Patients with End Stage Renal Disease**
Soo Jin Kim, Young Rim Song, Jwa-kyung Kim, Sung Gyun Kim, Jieun Oh, Jong-woo Yoon, Jung-woo Noh, Ja-Ryong Koo. *Internal Medicine, Hallym Univ, Hallym Kidney Research Institute, Seoul, Republic of Korea.*

**Background:** Valvular calcification is associated with significant morbidity and mortality in patients with end stage renal disease (ESRD). This study examined the hypothesis that valvular calcification is a marker of myocardial ischemia in asymptomatic high-risk patients with ESRD.

**Methods:** Echocardiography and myocardial perfusion single-photon emission computed tomography were performed in 285 asymptomatic high-risk patients with ESRD at initiation of dialysis. We evaluated the extent and severity of myocardial ischemia by the summed difference score (SDS) and defined the presence of myocardial ischemia as SDS ≥ 3 and moderate to severe ischemia as SDS ≥ 8. The presence of cardiac valvular calcification was assessed by echocardiography and defined as aortic valve calcification or mitral valve calcification.

**Results:** Eighty-five (29.9%) patients had echocardiographic evidence of cardiac valvular calcification. The presence of myocardial ischemia was significantly associated with aortic valve calcification (odds ratio [OR] = 3.19; 95% confidence interval [CI] = 1.76–5.78; p < 0.001), mitral valve calcification (OR = 3.31; 95% CI = 1.74–6.28; p < 0.001), and cardiac valvular calcification (OR = 3.18; 95% CI = 1.79–5.65; p < 0.001). The presence of moderate to severe myocardial ischemia (SDS ≥ 8) was independently associated with cardiac valvular calcification (OR = 2.86; 95% CI = 1.12–7.27; p = 0.028).

**Conclusions:** Valvular calcification was significantly associated with the presence of inducible myocardial ischemia in asymptomatic patients with ESRD, and may be a potential marker of patients at high-risk for the presence of silent myocardial ischemia.

**SA-PO450**

**Experience of Antegrade Trasseptal Percutaneous Transcatheter Aortic Valvuloplasty in Hemodialysis Patients**
Manabu Asano,[1] Kenichi Oguchi,[1] Masahiro Shimoyama,[1] Tokuya Nakahara,[1] Machiko Okamoto,[1] Hitoshi Iwabuchi,[1] Yoshihito Sakata.[2] *[1]Renal Unit, Ikegami Genaral Hospital, Tokyo, Japan; [2]Heart Center, Ikegami General Hospital, Tokyo, Japan.*

**Background:** Aortic stenosis (AS) due to accelerated sclerotic-calcific degeneration of valve is one of prevalent cardiovascular comorbidities in chronic dialysis patients. Percutaneous trans-catheter valvuloplasty (PTAV) is expected to function as an alternative AS treatment, providing immediate hemodynamic improvement with minimal invasion. The modification of procedure by a combination of trans-venous antegrade approach and utilization of Inoue balloon (Ante-PTAV) has been reappraised in terms of its improved therapeutic effect, procedural safety and possibly long-term symptomatic palliation. In this study, we evaluated the clinical efficacy of Ante-PTAV particularly on hemodialysis (HD) patients in order to define its therapeutic role.

**Methods:** Total 16 HD patients with severe AS (age 76.3±8.8 years old; 56.3 % males and 12.5 % diabetics) underwent Ante-PTAV with Inoue balloon (mean balloon size 20.5mm).Trans-Aortic valve gradients (ΔP) and valve area (AVA) were measured both by catheterization and echocardiography. Hemodynamic data were obtained in all treated patients, and symptomatic improvement over Ante-PTAV was evaluated and early clinical outcomes were followed up.

**Results:** From 1/2009 to 12/2012, 16 HD patients successfully underwent Ante-PTAV in our unit. The mean dialysis vintage of those patients was 119.9±110.4 months (range 11- 390 months; median 90 months). Critical aortic valve calcification was present in 94% of patients. The mean AVA increased from 0.65±0.17 $cm^2$ to 1.28±0.39 $cm^2$ ($p<0.05$) and mean ΔP decreased from 57.9±16.5 mmHg to 19.7±10.4 mmHg ($p<0.05$) over Ante-PTAV. In the short-term follow-up (within 3 month after Ante-PTAV), hemodynamic stability and tolerance during HD was remarkably increased in over 80% of treated patients. The median hospital stay was 4 days. No significant complications were noted.

**Conclusions:** Ante-PTAV is a useful and safe procedure to treat symptomatic critical AS in HD patients who are high risk for surgical valve replacement or ineligible for trans-catheter valve implantation.

**SA-PO451**

**The Impact of Non-High-Density Lipoprotein Cholesterol Levels on the Clinical Outcome in Incident Hemodialysis Patients**
Chan Ho Kim,[1] Mi Jung Lee,[1] Hye-Young Kang,[2] Hyung Jung Oh,[1] Tae-Hyun Yoo,[1,2] Shin-Wook Kang.[1,2,3] *[1]Dept of Internal Medicine, College of Medicine; [2]Brain Korea 21, Yonsei Univ, Seoul, Korea; [3]On Behalf of the Clinical Research Center for End-Stage Renal Disease Investigators.*

**Background:** Even though hyperlipidemia is a well-established risk factor for cardiovascular(CV) disease in the general population, the association between abnormal lipid levels and CV disease in ESRD patients remains unclear. Recently, non-high-density lipoprotein cholesterol(NHDL-C) has been demonstrated as a risk factor for CV events in patients with combined dyslipidemia. In this study, we investigated the impact of NHDL-C on the clinical outcome in incident hemodialysis(HD) patients.

**Methods:** A prospective cohort of 867 incident HD patients from 36 centers of the CRC for ESRD in Korea was selected for this study. The subjects were divided into 'high' and 'low' groups based on the baseline NHDL-C concentrations(≥ and <100mg/dL). Primary outcome was defined as a composite of all-cause mortality or CV events. Cox proportional hazard analysis was performed to determine the independent prognostic value of NHDL-C for the clinical outcome.

**Results:** The mean age was 57.6 years and 59.5% were male. During a median follow-up duration of 23 months, 53 patients(6.1%) died and CV events occurred in 78 patients(9.0%). The composite outcome was observed in 81 patients(15.1%) in the 'high' NHDL-C group compared to 35(10.6%) in the 'low' NHDL-C group, but this difference did not reach statistical significance(P=0.06). However, after adjustment for demographic and clinical characteristics, and parameters related to inflammation and malnutrition, the risk for reaching the composite outcome was significantly higher in the 'high' NHDL-C group compared to the 'low' NHDL-C group(HR,1.58;95%CI,1.03-2.44;P=0.038). In subgroup analyses, a significant association of NHDL-C with adverse clinical outcome was observed in patients with diabetes, patients without CV disease, and patients with increased high sensitivity C-reactive protein levels.

**Conclusions:** Serum NHDL-C at the time of HD commencement was a significant independent risk factor for adverse clinical outcomes in incident HD patients.

**Relationship between Pre HD Serum Sodium Concentration and Blood Pressure: Results from a Global Hemodialysis Cohort**
Jochen G. Raimann,[1] Michael Etter,[2] Jeroen Kooman,[3] Nathan W. Levin,[1] Daniele Marcelli,[4] Cristina Marelli,[5] Frank van der Sande,[3] Stephan Thijssen,[1] Len A. Usvyat,[1,6] Peter Kotanko,[1] Mondo Consortium.[7] *[1]Renal Research Institute; [2]FMC Asia/Pacific; [3]Maastricht Univ Medical Centre; [4]Fresenius Medical Care; [5]Fresenius Medical Care Argentina; [6]Fresenius Medical Care North America; [7]MONDO.*

**Background:** Recent evidence from a small study from the UKindicates a relationship between pre-hemodialysis (HD) serum sodium (SNa) and systolic (SBP) and diastolic (DBP) blood pressure (He 2013) in chronic HD patients. Here we extend this analysis to a global cohort of incident HD patients.

**Methods:** The Monitoring Dialysis Outcomes (MONDO) initiative encompasses HD patients from 26 countries who started HD between 2000 and 2010 (Usvyat 2013). Monthly pre-HD SNa levels were used as predictors of pre-HD SBP in a linear mixed model (LMM). LMMs were adjusted for age, gender, race (reference: white race), interdialytic weight gain (IDWG; in % of post-HD body weight), diabetes and serum albumin and calcium. A similar model was constructed with DBP as outcome. Analyses were carried out in the whole data set and after stratification by continent (North America; Latin America; Asia). LMMs were also constructed for the entire observation period, the first year, and the second year.

**Results:** We included 7675 incident patients. Including all patients, SNa was a significant predictor of pre-HD SBP and DBP (**Table 1**). The results were materially identical by by continent Separate analysis for first and second year gave comparable results. **Table 1:** Estimate of of Sna as a fixed effect in a Linear Mixed Model.

| Dependent Variable | Estimates SNa (per 1 mEq/L] (95% CI) | | | |
|---|---|---|---|---|
| | All patients | North America | South America | Asia |
| a) SBP | 0.23 (0.19 to 0.27) | 0.21 (0.16 to 0.26) | 0.24 (0.01 to 0.48) | 0.20 (0.12 to 0.28) |
| b) DBP | 0.12 (0.09 to 0.14) | 0.10 (0.07 to 0.12) | 0.18 (0.05 to 0.32) | 0.14 (0.10 to 0.18) |

**Conclusions:** Our analysis corroborates the findings of He et al. on a global level, indicating that the positive relationship between SNa and BP is a profound biological phenomenon in chronic HD patients.

**SA-PO453**

**Evaluating Time in Therapeutic Range for Hemodialysis Patients on Warfarin**
Laura Quinn,[1,2] Marisa Battistella,[1,2] Karen Cameron.[1,2] *[1]Pharmacy, Univ Health Network, Toronto, Canada; [2]Pharmacy, Univ of Toronto, Toronto, Canada.*

**Background:** Warfarin is frequently used in the hemodialysis (HD) population for patients with atrial fibrillation (AF) and venous thromboembolism (VTE); however, there is a lack of literature to support this practice. Given that HD patients have a 3-10 times higher risk for both stroke and bleeding than the general population, anticoagulation in these patients is controversial. Time in therapeutic range (TTR) has been accepted as a surrogate outcome of clinical effectiveness and safety of warfarin and is used extensively as an endpoint in clinical trials with a benchmark goal of 66%.

**Methods:** In order to evaluate TTR in an HD population, a six-year retrospective chart review was performed in 46 HD patients with AF or VTE on warfarin. One year of individual patient data was collected, which included weekly INR values, demographics, medication histories and clinical outcomes. TTR was calculated using the Rosendaal, *fraction of INRs in range* (FIR) and *cross-section-of-the-files* methods.

**Results:** The mean TTR using Rosendaal and FIR was, respectively, 49.2%±14.6 and 44.2%±13.5. The *cross-section-of-the-files* method captured INR data for 35 patients and TTR was 33.3%, 36.4%, 31.4% and 43.3% at four points during 2011. The percentage of time spent below and above target INR was 39.3%±16.2 and 10.0% (6-15.5) respectively for the Rosendaal method, suggesting that more often patients were at risk of inadequate efficacy rather than toxicity. There were 9 serious bleeding and 9 thrombotic events; these all occurred in patients with a TTR <60%. A survey of nephrologists in the unit revealed that they often target an INR range lower than 2-3 due to insufficient evidence and higher bleeding risk.

**Conclusions:** In conclusion, our data suggests this HD unit is not meeting the TTR goal previously established and that clinicians are conservative with INR management. Further studies to investigate ways to improve TTR are warranted. Ultimately, a prospective study evaluating the safety and efficacy of warfarin in HD patients is needed.

## SA-PO454

**Association of Sleep Apnea and Sleep Quality with Left Ventricular Mass in Hypertensive Hemodialysis Patients in Blood Pressure in Dialysis (BID) – SLEEP Study** Manisha Jhamb,[1] D. Miskulin,[2] Jennifer J. Gassman,[3] David W. Ploth,[4] Brigitte Schiller,[5] Raymond Y. Kwong,[9] Cynthia A. Kendrick,[3] Jose L. Vega,[6] John W. Kusek,[7] P. Zager,[6,8] Mark L. Unruh.[8] *[1]Pitt; [2]Tufts; [3]Cleveland Clin; [4]MUSC; [5]Satellite Hlth; [6]DCI; [7]NIH; [8]UNM; [9]Brigham Womens.*

**Background:** Sleep apnea (SA) and short and fragmented sleep may contribute to cardiovascular morbidity and mortality in hemodialysis patients. The association between SA severity and LV mass in these patients is not well described.

**Methods:** Maintenance HD patients joined this ancillary SLEEP study after enrolling in the Blood Pressure in Dialysis (BID) Pilot, a randomized trial of two levels of BP control. SA was monitored for 1 night with a portable home monitor (ApneaLink with oximetry). Sleep-wake behavior was assessed by actigraphy over a 5-day period. Subjective sleep quality was assessed with Pittsburgh Sleep Quality Index (PSQI) and Epworth Sleepiness Scale. LV mass was measured centrally by MRI.

**Results:** Currently 27 patients (52.6±13.3 yrs, 63% male, 41% AA) have completed baseline sleep study. 23 had SA (85%) and of those 9 had mod-severe SA (AHI >15). Actigraphy showed 13 (57%) of patients slept <6 hrs/night. Most had poor sleep efficiency (87%) and poor sleep quality (86% with PSQI score>5). Body mass index, systolic BP, diastolic BP, heart rate, number of antihypertensive medications, inter-dialytic weight gain, hemoglobin level, history of myocardial ischemia, and MRI characteristics did not differ between those with no-mild SA (AHI≤15) as compared to those with mod-severe SA (AHI>15).

| | No-mild SA (n=18) | Mod-Severe SA (n=9) |
|---|---|---|
| | Mean±SD | Mean±SD |
| LV Mass(g) | 141 ± 38.4 | 140 ± 41.3 |
| LV Mass Index(g/m$^2$) | 74.3 ± 20.9 | 72.9 ± 21.7 |
| LV End Diastolic Volume(ml) | 189 ± 56.5 | 176 ± 78.5 |
| LV End Systolic Volume(ml) | 87.8 ± 34.7 | 85.3 ± 56.9 |
| RV End Diastolic Volume(ml) | 143 ± 41.9 | 159 ± 68.1 |
| RV End Systolic Volume(ml) | 69.7 ± 20.2 | 82.1 ± 47.3 |
| LV EF(%) | 54.1 ± 7.84 | 54.1 ± 10.0 |

**Conclusions:** Sleep apnea and poor sleep quality were common among hypertensive HD patients we studied. Based on preliminary data we did not observe a relationship between severity of sleep apnea and LV mass.

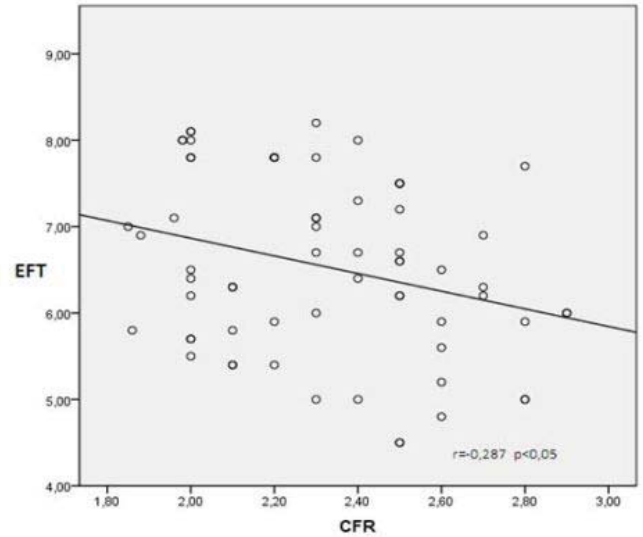
## SA-PO455

**Accelerated Atherosclerosis in Hemodialysis Patients; Correlation of Epicardial Fat Tissue Thickness with Coronary Artery Flow Reserve** Elif Ari Bakir,[1] Beyza Macunluoglu.[2] *[1]Nephrology, Kartal Research and Training Hospital, Istanbul, Turkey; [2]Nephrology, Uskudar State Hospital, Istanbul, Turkey.*

**Background:** The aim of this study was to evaluate the relation between epicardial fat tissue (EFT) thickness and coronary artery flow reserve (CFR) in HD patients as an indicator of accelerated atherosclerosis.

**Methods:** Seventy-one chronic HD patients and 65 age and sex-matched healthy controls were included in the study. EFT thickness and CFR were assessed by transthoracic Doppler echocardiography.

**Results:** EFT thickness was higher (6,53±1,01 mm vs 5,79 ±1,06 mm, p<0.001); CFR was lower (1,73[lrm]±0,11 vs 2,32[lrm]±0,28, p<0.001) in HD patients compared to controls. There was a significant negative correlation between EFT thickness and CFR (r = -0.287, p<0.05).



Multiple linear regression analysis showed that CFR, age, body mass index and total cholesterol levels were independently correlated with EFT thickness.

**Conclusions:** Our data have demonstrated that HD patients exhibit increased EFT thickness and decreased CFR. To our knowledge this is the first study to demonstrate the inverse relationship between EFT thickness and CFR in HD patients**.**

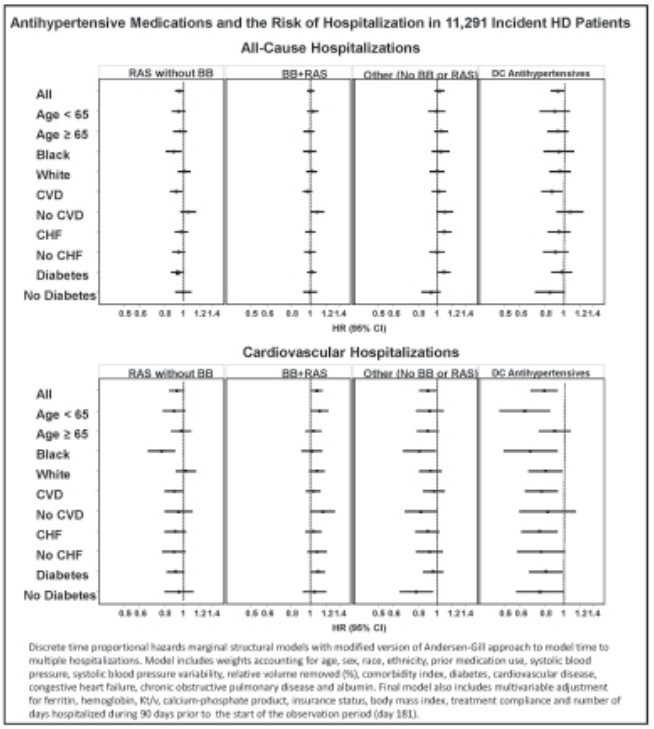
## SA-PO456

**Antihypertensive Medication Regimens and Hospitalization Risk in Incident Hemodialysis (HD) Patients** Tariq Shafi,[1] Stephen M. Sozio,[1] Wendy L. St. Peter,[2] Karen J. Bandeen-roche,[1] Patti Ephraim,[1] Jason Luly,[1] L. Ebony Boulware.[1] *[1]Johns Hopkins Univ; [2]Univ of Minnesota.*

**Background:** Optimal strategies to reduce hospitalizations, a frequent occurrence in HD patients, are not known. We compared the effectiveness of different blood pressure medication (BPM) regimens on reducing hospitalizations in HD patients.

**Methods:** We performed a retrospective cohort study of all adult patients initiating HD at Dialysis Clinic, Inc. facilities from 2003-2008 and prescribed a BPM at 6 months. We linked their dialysis electronic medical records to USRDS data, and the National Death Index. We categorized BPM use as 4 mutually exclusive regimens: β-blockers (BB), renin-angiotensin system agents (RAS), BB+RAS or OTHER regimens not including BB or RAS. Patients with BPM discontinued during follow-up constituted the DC group. We used discrete time proportional hazards marginal structural models accounting for repeated events, confounding and mediation by numerous clincial and demographic factors including blood pressure and HD session volume removal to quantify the association between BPM regimen and hospitalizations [all cause and cardiovascular (CV)] censoring for death.

**Results:** Of the 11,291 patients, mean age was 62 years, 55% were male and 53% were White. 22,384 hospitalizations (7,070 from CV causes) occurred during follow-up (median, 22 months). Compared to BB, patients treated with a RAS had lower risk of hospitalizations, particularly among those with CV disease at baseline [HR (95%CI) for all-cause: 0.92 (0.85-0.99); CV: 0.90 (0.80-1.01)]. DC group had lower risk of hospitalization but higher risk of death [1.5 (1.1-2.06)] compared with BB group.



**Conclusions:** HD patients treated with a RAS regimen (without BB) had a lower risk of hospitalization compared to BB containing regimens. RAS agents may be preferred antihypertensive medications for patients starting HD.

*Funding:* NIDDK Support, Other U.S. Government Support

## SA-PO457

**Prognosis of Dialysis Patients with Normal Stress Myocardial Perfusion Imaging at the Initiation of Dialysis: Long-Term Outcome and Predictors** Jwa-kyung Kim, Soo Jin Kim, Sun Ryoung Choi, Jong-woo Yoon, Jung-woo Noh, Sung Gyun Kim. *Dept of Internal Medicine, Hallym Univ Sacred Heart Hospital, Kidney Research Institute, Gyunggi-do, Korea.*

**Background:** Normal myocardial perfusion is closely associated with very low rates of cardiac events and better long-term outcomes in general population. However, little is known about its prognostic value in patients with end-stage renal disease (ESRD).

**Methods:** A total of asymptomatic 286 incident patients underwent baseline cardiac evaluation with echocardiography and stress/rest single-photon emission computed tomography. One hundred seventy seven (61.9%) patients displayed "normal" perfusion scan with a summed stress score (SSS) < 4.

**Results:** During the 4-year follow-up period, 79 cardiac events occurred. Patients with SSS<4 had significantly lower annual rates of cardiac events than those with SSS ≥ 4 (6.4% vs. 13.2%, hazard ratio, 0.54, 95% confidence interval, 0.31–0.94). Among 177 patients with SSS < 4, there were 40 cardiac events over 3.0 ± 1.9 years of follow up. In multivariable analysis, age, diabetes, a previous CAD history and C-reactive protein levels were significant clinical predictors of cardiac events in patients with normal myocardial perfusion imaging. In addition, baseline echocardiographic characteristics such as the presence of left ventricular (LV) systolic dysfunction, LV hypertrophy, and increased LV filling pressure strongly influenced to the occurrence of cardiac events.

**Conclusions:** Normal myocardial perfusion imaging does not always indicate a good clinical outcome in patients with ESRD. Echocardiographic parameters, diabetes, C-reactive protein level and a previous CAD history may improve the predictive value of normal myocardial perfusion imaging in patients with ESRD.

## SA-PO458

### National Study of Acute Stroke in Patients on Renal Replacement Therapies

Albert J. Power,[1] Retha D. Steenkamp,[2] James Fotheringham,[3] Damian G. Fogarty.[2] *[1]Imperial College London, United Kingdom; [2]UK Renal Registry, Bristol, United Kingdom; [3]Sheffield Kidney Institute, United Kingdom.*

**Background:** Stroke in patients on renal replacement therapy [RRT] remains poorly studied especially in peritoneal dialysis [PD] & transplant cohorts and particularly in Europe. We therefore conducted a national study to characterize the distribution and impact of stroke in all RRT patients.

**Methods:** We studied all patients incident to RRT in England [Jan 2002–Dec 2006] with follow up to Dec 2009 [n=21175, 62% male, 47% diabetic, 74% hemodialysis, 23% PD]. Demography & comorbidity at the start of RRT and hospitalization for first acute stroke were derived from ICD-10 codes in national Hospital Episode Statistic [HES] datasets linked to UK Renal Registry data.

**Results:** Overall 12% of the study cohort [n=2484] experienced first acute stroke [40% events prior to RRT start] compared to 2.3% in the general population. During RRT, 77% strokes occurred in hemodialysis [HD], 16% on PD & 4% in renal transplant patients.

Acute stroke patients were older [mean 65.9 vs 60.3yrs, p<0.001] with 62% strokes clustering in those ≥65yrs old. Stroke associated with cardiac & peripheral arterial disease [p<0.001], diabetes [p<0.001], and especially prior cerebrovascular disease [51% vs 7%, p<0.001]. There was no association between stroke and ethnicity [p=0.5], health network area [p=0.6] or social deprivation [Townsend index, p=0.1] with a trend to more events in females [p=0.08] in keeping with UK population data.

**Conclusions:** Stroke affects a significant proportion of patients on all RRT modalities and remains over-represented in dialysis cohorts particularly HD. Current ongoing analyses of national patient- & treatment-level stroke risk factors will allow for interventions to reduce stroke burden in all RRT populations.

## SA-PO459

### Ventricular Diastolic Function before, during and after Hemodiafiltration

Israel Campos González, Sujail Estrada, Patricia Zarate Rojas, Magdalena Madero, Armando Vazquez-Rangel, Hector Perez Grovas. *Div of Nephrology/ Echocardiography, National Heart Institute, Mexico City, Mexico.*

**Background:** Kidney disease is associated with cardiovascular(CV) mortality. There is limited data regarding the effect of hemodiafiltration(HDF) on cardiac function. The objective of the study was to evaluate the diastolic function(DF) at different HDF times.

**Methods:** Prospective study conducted between May-August 2011 in HDF patients. Tissue Doppler & 3D Echocardiography were captured pre, during & post-HDF. Dyssynchrony index and DF parameters were measured and the change in measurements was evaluated at different time points.

**Results:** 11 patients were included, the median age was 34±12y and 72% were female. The mean HDF duration was 232±18min. Blood flow(QB) was 442±37 mL/min, substitution volume was 17.4±1.2 L, weight gain was 2.63±0.58 Kg. Left ventricular ejection fraction was 52±0.3%, 51±0.2%, 51±0.5% for pre, during and post HDF(p=0.45). There were significant changes in diastolic function parameters at different time points.

| DIASTOLIC FUNCTION PARAMETERS | PRE-HDF | DURING-HDF | POST-HDF | p Value |
|---|---|---|---|---|
| E/A rate | 1.4±0.4 | 1.19±0.38 | 1.09±0.29 | 0.02 |
| Deceleration time of early mitral flow (DAT)/ms | 206±35 | 244±74 | 224±49 | 0.12 |
| Isovolumetric relaxation time in (IVRT)/ ms | 93±14 | 97±13 | 95.6±12 | 0.50 |
| Lateral mitral annular velocity in cm/s (Lateral E´) | 11.9±2.3 | 10.3±2.4 | 10.3±0.35 | 0.01 |
| E/E´rate | 8.3±2 | 6.6±2.1 | 6.7±2.1 | 0.01 |

Diastolic dysfunction occurred in 44% of the patients in the PreHDF phase and increased to 82% during and post HDF(p<0.05). Diastolic & systolic diameter, telesystolic, telediastolic and stroke volume(SV) had significant changes(p<0.001).There was significant correlation between SV & QB (r=0.63, p=0.03) and SV & transmembrane pressure (r=0.84, p=0.001).

**Conclusions:** Diastolic dysfunction is prevalent in HDF patients but increases dramatically during & after HDF. In contrast, systolic function remains intact throughout. These findings may contribute to understand CV disease in HDF. Larger studies are needed to confirm our findings.

## SA-PO460

### Mean Platelet Volume as a Predictor for Coronary Artery Disease in Chronic Hemodialysis Patients

Jong-woo Yoon, Myung Jin Choi, Youngki Lee, Won Jae Shin, Soo Jin Kim, Ja-Ryong Koo, Jung-woo Noh. *Hallym Univ, Kidney Research Institute, Chuncheon, Republic of Korea.*

**Background:** Mean platelet volume (MPV), as a marker of platelet activation, has been shown to be related to coronary artery disease and mortality after myocardial infarction. However, the effects of MPV on cardiovascular complication and vascular access failure in hemodialysis (HD) patients is not known.

**Methods:** 180 chronic HD patients (age 59.1 ± 12.1 years, male 47.8 %, diabetes 53.9 %, mean dialysis duration 48.3 ± 51.0 months) were enrolled. After baseline evaluation, all patients were monitored continuously for the development of coronary artery disease, cerebrovascular disease, vascular access failure and death.

**Results:** MPV was 9.14 ± 0.78 fl (range 7.7 to 12.0). Patients were grouped according to half-tile values of MPV (>9.0 fl, group 1 (n=98); ≤ 9.0 fl, group 2 (n=89)). Patients with higher MPV had a higher level of platelet count (p=<0.001) and a lower level of triglyceride (p=0.006), 25(OH) Vitamin D total (p=0.013) and parathyroid hormone (p=0.03). During a follow-up period of median 127 weeks, 133 composite events (31 deaths, 33 coronary artery disease, 9 cerebral artery disease, and 60 vascular access thrombosis or stenosis) occurred. The Kaplan-Meier curve showed significant difference in the cumulative events of coronary artery disease between two groups (23.5 % vs 12.3 %; log-rank test, p <0.05). In multivariate Cox analysis, MPV was an independent risk factor for coronary artert disease (hazard ratio, 0.459; 95% confidence interval, 0.211 to 0.998; p.049 CI 1.21-2.30 for 10mmHg increase; p<0.002).There were no significant differences between the two groups in death (14.3 % vs 20.7 %; log-rank test, p=0.301), cerebral artery disease (CVA) (6.1 % vs 6.7 %; log-rank test, p=0.452) and vascular access failure (33.7 % vs 32.9 %; log-rank test, p=0.932).

**Conclusions:** High MPV was significantly associated with increased risk of coronary artery disease in chronic HD patients, but not with CVA, access failure and death. Considering critical role of platelet in atherosclerosis, MPV may be a potential marker for prediction of coronary artery disease in HD patients.

## SA-PO461

### Prevalence of Abnormal Hemoglobin A1c in Non-Diabetic (NDM) Dialysis Patients

Neal Mittman,[1] Lin Ma,[2] Mark E. Williams,[3] Julia I. Brennan,[4] Chinu M. Jani,[4] Curtis D. Johnson,[4] Franklin W. Maddux,[2] Eduardo K. Lacson.[2] *[1]Long Island College Hospital, Brooklyn, NY; [2]Fresenius Medical Care, North America, Waltham, MA; [3]Joslin Diabetes Center, Boston, MA; [4]Spectra Laboratories, Rockleigh, NJ.*

**Background:** While a significant minority of ESRD pts begin dialysis without prior nephrologic care and CKD is known to be associated with insulin resistance, A1c measurement is not routinely performed in ESRD pts without a history of DM. In a single center experience, we (Desiraju et al, ASN 2005) identified NDM ESRD pts maintained on HD with abnormal A1c >5.6%.

**Methods:** We explored the distribution of A1c in a national sample of 1454 NDM pts from 26 FMCNA facilities distributed across the US. Residual blood from routine monthly draws was analyzed. We report on mean casual blood glucose and A1c in these pts for the period January-March 2013. Pts were classified as undiagnosed (UndxDM) if A1c≥6.5% and pre-diabetic (PreDM) if A1c was >5.6 but <6.5%.

**Results:** The A1c values were consistent with non-DM diagnosis in >98% of pts. However, ~16% met pre-diabetic A1c range and are potentially at risk for increased future morbidity (Table). Pre-diabetic status was associated with age, male gender, shorter dialysis vintage, and peritoneal dialysis (PD) modality (all p<0.05 vs. A1c≤5.6%), while race and ethnicity were similar. Undiagnosed DM was similarly associated with even shorter dialysis vintage and with use of PD.

| Table | N (%) | Mean A1c% (range) | Median | Mean glucose mg% (range) | Median |
|---|---|---|---|---|---|
| UndxDM | 25 (1.7) | 7.7% (6.5-11.5) | 7.4% | 187 (88-383) | 162 |
| PreDM | 230 (15.8) | 5.8% (5.6-6.5) | 5.8% | 116 (69-250) | 109 |
| NDM | 1199 (82.5) | 5.2% (3.8-5.6) | 5.2% | 102 (50-221) | 100 |

**Conclusions:** While the absence of a diagnosis of DM was consistent with A1c values for most patients, physicians should be vigilant in detecting rare cases of undiagnosed DM. One in every 6-7 dialysis patients may be pre-diabetic and it is not clear if this finding is associated with worse outcomes. We will prospectively follow these patients to determine the prognostic significance of the prediabetic range of A1c.

## SA-PO462

### Impact of Nephrological Care on Dialysis Initiation and Survival

Laura Sola,[1] Maria Carlota Gonzalez-Bedat,[2] Alejandro Ferreiro.[2] *[1]Renal Healthcare Program, Montevideo, Uruguay; [2]Uruguayan Registry of Dialysis, Montevideo, Uruguay.*

**Background:** Despite significant improvement in dialysis technology, mortality rate (MR) in chronic dialysis (CD) patients (Pts) still remains extremely high. Late referral to nephrologist has been linked to higher morbidity and short term mortality. The objective of the study is to analyze the impact of predialysis nephrological care (PNC) on selected clinical indicators and first year survival on CD.

**Methods:** Data from the Uruguayan Registry of Dialysis of Pts beginning CD between 11/1/2008-12/31/2011 were analyzed. PNC was assessed by stage 4 Pts included in the CKD Registry with follow-up ≥ 3 months. Quality of care indicators at CD initiation

included: hemoglobin (Hb) ≥10 g/dL, fistula ≥ 60 days (FAV60) and hepatitis B (HB) immunization. Initial CD modality was assessed. Hospitalization time at CD initiation and first year survival were compared regarding PNC, including PNC time and number of visits. Logistic regression analysis age, gender and diabetes adjusted was performed for hospitalization <5 days and Cox regression analysis for MR risk factors. Significant differences were considered as $p<0.05$.

**Results:** Of 1666 Pts that began CD, 194(11.6%) had PNC. Pts with PNC had older age (mean 67.1 vs 60.5 years) and were more commonly woman (49.5% vs 40.12%) than those without PNC. PNC was significantly associated to higher Hb (61.0 vs 41.5%), HB immunization (54.6 vs 23.1%), and FAV60 (34.6 vs 17.3 %), but not to PD choice (14.9 vs 9.8%).Hospitalization time was significantly lower in PNC Pts (8.5 ± 14.5 vs 15.6 ± 20.2 days) and didn't differ with PNC duration or number of visits. Less hospitalization was associated to PNC and Hb ≥ 10g/dL. First year survival was higher in Pts with PNC (Kaplan Meier). Adjusted to age, gender and diabetes, PNC reduced 34.8% mortality risk. Adjusted to FAV60, PNC didn't significantly improved survival.

**Conclusions:** Pts with PNC had better quality of care indicators, lower initial hospitalization time CD and of most importance greater first year survival allowing timely fistula confection. Our study emphasizes the importance predialysis care in order to reduce costs and improve outcomes.

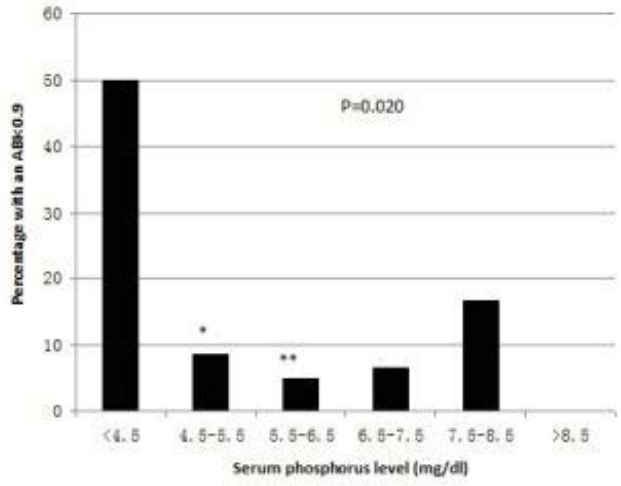
## SA-PO463

**Serum Phosphorus Is Associated with Ankle-Brachial Index in Maintenance Hemodialysis Patients: A Different Reference Range?** Ziyong Tang, Yue Wang, Ning Zhang, Huijing Ge, Xinhong Lu. *Renal Div, Peking Univ Third Hospital, Beijing, China.*

**Background:** Abnormally low ankle-brachial index (ABI) values (ABI<0.9) and high ABI (ABI>1.3) are associated with high cardiovascular morbidity and mortality in maintenance hemodialysis (MHD) patients. This study is aimed to assess the relationship of serum phosphorus level with ABI in MHD patients.

**Methods:** A total of 89 MHD patients were included in this retrospective study. ABIs were measured using an ABI-form device. The patients' serum phosphorus in the past 6 months were recorded. Other clinical and laboratory data were also collected.

**Results:** The mean of past six months' serum phosphorus levels in this group ranging from 2.45mg/dl to 12.34mg/dl, with the median 6.36 mg/dl. As normal homeostasis maintains serum phosphorus concentrations between 2.5–4.5mg/dl, serum phosphorus levels in our group were divided into following levels: level 1: <4.5, level 2: 4.5-5.5, level 3: 5.5-6.5, level 4: 6.5-7.5, level 5: 7.5-8.5, level 6: >8.5, respectively. The number of patients with low (<0.90) or high (>1.30) ABI were compared among the levels. Low ABI were present in 50%(3/6) of patients in level 1, 8.70%(2/23) in level 2, 5%(1/20) in level 3, 6.67%(1/15) in level 4, 16.67%(2/12) in level 5, and 0% in level 6. High ABI were present in 0% of patients in level 1, 4.35%(1/23) in level2, 15%(3/20) in level 3, 0% in level 4, 16.67%(2/12) in level 5, and 15.38%(2/13) in level 6. Chi-square tests show that there is a significant difference of low ABI among the levels (p=0.020), but the difference doesn't reach significant of high ABI among the levels (p=0.406).



**Conclusions:** In MHD patients, low ABI is prevalent in the phosphorus level lower than 4.5mg/dl, and high ABI is prevalent in the phosphorus level higher than 6.5mg/dl. The reference range of serum phosphorus level in MHD patients may be different from that of general population.

## SA-PO464

**Reduced Number of Endothelial Progenitor Cells Predicts Future Cardiovascular Events in End Stage Renal Disease Patients on Maintenance Hemodialysis** Hong Joo Lee,[1] Dongyoung Lee,[2] Ju Young Moon,[3] Sang Ho Lee,[3] Chun-Gyoo Ihm,[3] Tae-won Lee,[3] Kyung Hwan Jeong.[3] *[1]Nephrology, Gachon Univ Dongincheon Gil Hospital; [2]Internal Medicine, Seoul Veterans Hospital; [3]Nephrology, School of Medicine, Kyung Hee Univ.*

**Background:** Endothelial progenitor cells (EPCs) have emerged as the key regulator of maintenance of endothelial integrity by repair of injured endothelium. The low number of circulating EPCs has been identified as an independent predictor of cardiovascular(CV) events, progression of atherosclerosis and CV death in general population. We ascertained whether the number of circulating EPCs may be the independent variables associated with incident CV events in ESRD patients on hemodialysis.

**Methods:** This study is the prospective observational descriptive study complemented by a retrospective chart review. We quantified EPCs in blood samples from 70 outpatients who underwent maintenance hemodialysis therapy, Circulating EPCs were quantified by flow cytometry as the number of $CD45^{low}CD34^{+}VEGFR2^{+}$ cells. The occurrence of CV events defined as coronary, cerebrovascular and peripheral vascular disease was observed.

**Results:** Mean age was 57.77 ± 12.68 years and 58.6% of all patients were male. The patients were divided into two groups according to a cutoff value for circulating EPCs determined by a ROC curve analysis. High ECP group had long CV event free period. In univariate analyses with Cox proportional hazard models, the incidence of CV events was significantly associated with a level of circulating EPCs lower than $9.5/2x10^4$ events, a history of CVD, the level of 25-(OH) vitamin D, serum creatinine, or hemoglobin $A1_C$. In multivariate analysis, a level of circulating EPCs lower than $9.5/2x10^4$ events was identified as independent predictors of CV events among ESRD patients on hemodialysis.

**Conclusions:** Reduced levels of circulating EPCs independently predict future cardiovascular events in ESRD patients on maintenance hemodialysis, thus supporting that endothelial injury in the absence of sufficient circulating EPC may unfavorably affect on occurrence of CV events.

## SA-PO465

**Impact of Genetic Polymorphisms of the Renin-Angiotensin-Aldosterone System on Coronary Artery Disease, Cardiovascular Complications and Mortality in Dialysis Patients** Katrin Ivens, Christos Bantis, Philip Reis, Nicoletta-Maria Kouri, Nicola Kuhr, Christina Schwandt, Peter J. Heering. *Dept of Nephrology, Heinrich-Heine Univ, Düsseldorf, Germany.*

**Background:** Renin angiotensin system plays an important role in the regulation of arterial pressure and the progression of atherosclerosis. We studied impact of the four major genetic polymorphisms of the renin angiotensin system [angiotensin converting enzyme gene I/D, angiotensinogen gene M235T, aldosterone synthasegene C-344T and A1166C polymorphism of angiotensin II-type 1 receptor ($AT_1R$)-gene ] on coronary artery disease (CAD) in chronic dialysis patients.

**Methods:** We studied n=462 patients on chronic dialysis with angiographically confirmed (n=217) or excluded (n=245) CAD followed up for 5.4±4.0 years. The genetic polymorphisms were determined by PCR amplification. Cardiovascular complications and the need for intervention (coronary angioplasty or coronary artery bypass grafting) were monitored.

**Results:** Patients with CAD were comparable to those without CAD regarding age at coronary angiography, time on dialysis, LDL cholesterol levels and prevalence of arterial hypertension (ns). Among patients with CAD there were significantly more men (73.9 vs. 61.2%, $p<0.01$), more diabetics (29.8 vs. 17.6%, $p<0.01$) and smokers (42.8 vs. 34.3%, $p<0.05$). Patients with CAD had also significantly higher CRP (1.15 ± 1.17 vs. 0.94 ± 1.15mg/dl, $p<0.05$) and fibrinogen levels (453 ± 134 vs. 417 ± 109 mg/dl, $p<0.05$). There was no difference in the genotype distribution of the four investigated polymorphisms in patients with or without CAD (ns). Furthermore, no impact of the investigated polymorphisms was detected in the Kaplan-Meier of intervention-free or myocardial- infarction-free survival as well in the general patient survival (ns).

**Conclusions:** Our results suggest that ACE gene I/D, angiotensinogen gene M235T, aldosterone synthase gene C-344T and $AT_1R$ geneA1166Cpolymorphisms are not risk factors for the development of coronary artery disease in chronic dialysis patients. Furthermore, they do not influence the incidence of myocardial infarction, need for intervention and mortality in this patient group.

## SA-PO466

**High Fibroblast Growth Factor (FGF) 23, CRP and IL-6 Levels Are Associated with Left Ventricular Hypertrophy (LVH) in Pediatric (ped) Patients (pts) Receiving Chronic Dialysis** Poyyapakkam Srivaths,[1] Rajesh Krishnamurthy,[2] Michael R. Bennett,[3] Qing Ma,[3] Rene' G. VanDeVoorde,[3] Stuart Goldstein.[3] *[1]Pediatric Nephrology, Baylor College of Medicine, Houston, TX; [2]Pediatric Radiology, Texas Childrens Hospital, Houston, TX; [3]Pediatric Nephrology and Hypertension, Cincinnati Children's Hospital, Cincinnati, OH.*

**Background:** LVH is a risk factor for mortality in adults recieving chronic dialysis (CD). LVH is widely prevalent in ped CD pts. Only 1 study has studied association of LVH and FGF23 in ped CD pts. No ped study has examined association of inflammation (inflam) and FGF23 and LVH in CD. Aim: Assess associations of inflam and mineral imbalance with LVH.

**Methods:** 2 centers Houston and Cincinnati (38 pts, 19 M, mean age 15.5 ± 4 yr) receiving CD (21 HD, 17 PD). Echo done within 3 months of enrollment. LVH defined left ventricular mass index (LVMI) >38.6 g/m^2.7 in pts <18 yr of age (yoa), >44 g/m^2.7 in F >18 yoa, and >48 g/m^2.7 in M >18 yoa. Cardiac calcifications (CC) assessed by ultrafast CT . Pts received thrice weekly HD for 3-3/12 hrs or daily CCPD. FGF 23, IL-6, IL-8 and CRP levels obtained on enrollment. Time averaged (6 months prior to enrollment) serum Ca, P, Alb and iPTH obtained. Patients on aspirin, with infection, underlying collagen vascular disease excluded.

**Results:** Mean LVMI 43.2 ± 13.1. LVH present in 63% (24/38) pts. FGF 23, CRP and IL6 levels significantly higher in patients with LVH (table).

| | FGF23 pg/ml[a] | P (mg/dl) | iPTH (pg/ml) | CRP(mg/dl)[b] | IL6(pg/ml)[c] | IL8(pg/ml) |
|---|---|---|---|---|---|---|
| No LVH | 1745(1367) | 6.4(1.6) | 396(251) | 0.33(0.47) | 3.44(2.04) | 39.3(65) |
| LVH | 2926(1482) | 6.8(1.6) | 425(335) | 1.8(2.02) | 5.29(2.8) | 28.1(16.8) |

values expressed mean(sd); a=0.02, b=0.018, c=0.04

No difference with age, gender, modality, vintage, serum P, Ca, albumin, PTH or IL8 levels and LVH. 11 pts had CC. Pt with CC had higher LVMI (54 ± 15.9 with CC vs. 41 ± 9.8 with noCC).

**Conclusions:** LVH is highly prevalent in ped pts receiving CD. Pts with CC have higher prevalence of LVH. High FGF 23 and CRP and IL6 levels are associated with LVH. We conclude that inflam and high FGF 23 contribute to cardiovascular morbidity in ped pts receiving CD.

## SA-PO467

### Improvement in Left Ventricular Hypertrophy and Diastolic Dysfunction in Patients on Nocturnal Home Hemodialysis as Assessed by Echocardiography and Cardiac Magnetic Resonance Imaging

Frederick Eng, Davinder S. Jassal, Tyler Friesen, Mike Zhu, Manish M. Sood, Navdeep Tangri, Claudio Rigatto, Paul Komenda. *Medicine, Univ of Manitoba, Winnipeg, Canada.*

**Background:** Cardiovascular disease (CVD) is the leading cause of morbidity and mortality in patients with end-stage renal disease (ESRD). Left ventricular hypertrophy (LVH) is present in more than 70% of ESRD patients and is an independent risk factor for cardiac death in this patient population. Nocturnal home hemodialysis (NHD) is a form of renal replacement therapy whereby hemodialysis is performed for six hours overnight at least four days per week. NHD has several benefits over conventional hemodialysis (CHD) including improved blood pressure control, mineral metabolism, and degree of anemia. Limited studies are conflicting however, about the effects of NHD on cardiovascular remodeling as assessed by transthoracic echocardiography (TTE) and cardiac magnetic resonance imaging (CMR).

**Methods:** Patients enrolled in the NHD training program at a single tertiary care centre were invited to participate in the study between 2009-2011 inclusive. Eligible patients had a life expectancy greater than 12 months and had no reliable expectation of receiving a kidney transplant within 12 months. Participants underwent TTE and CMR at baseline and after one year of NHD. Data regarding blood pressure, mineral metabolism and degree of anemia were also collected and analyzed.

**Results:** A total of 11 patients were included in the study (6 male, mean age 48±16 years). Left ventricular mass index (LVMI) decreased significantly at one year by both TTE (152±7 to 129±8 g/m$^2$, p<0.05) and CMR (162±4 to 124±4 g/m$^2$, p<0.05). There were also significant reductions in left and right atrial volume as well as right ventricular mass index. Diastolic dysfunction, graded from 0 to 4, improved from a baseline of 3.4 to 1.2 at one year follow-up. There was no significant effect of NHD on blood pressure, mineral metabolism, or degree of anemia.

**Conclusions:** Long-term nocturnal hemodialysis leads to favorable cardiovascular remodeling with a reduction in cavity dimensions, regression of LVH, and improved diastolic function as assessed by both TTE and CMR.

## SA-PO468

### Relationship between Serum Cancer Antigen 125 (Ca125) and Left Ventricular (LV) Function in Patients on Maintance Hemodialysis

Hakki Yilmaz, Ozgul Malcok Gurel, Huseyin tugrul Celik, Ayse Mukadder Bilgic, Nuket Bavbek, Ali Akcay. *Turgut Ozal Univ, School of Medicine, Ankara, Turkey.*

**Background:** The aim of the study was to analyze associations between serum Ca125 levels and LV function in patients on maintance hemodialysis.

**Methods:** The study group included 110 patients {(54 women, 56 men) aged 62.83 ±13.66 years, treated with HD for 38.4±36.3 months} and 47 healthy age and sex matched volunteer controls were enrolled in the study. Ca125 and biochemical parameters were measured and echocardiography was performed. Hemodialysis patients were divided into different groups based on heart function.

**Results:** Mean Ca125 levels in patients were significantly higher compared with controls (38.78±35.48 vs 9.20 ±4.55 U/ml; P =0.003). Serum levels of Ca125 in the patient group1 were significantly higher than in the group2 and group3 (74.47±27.74; 13.14±4.84 ; 9.20±4.55 U/ml; p <0.001, respectively).

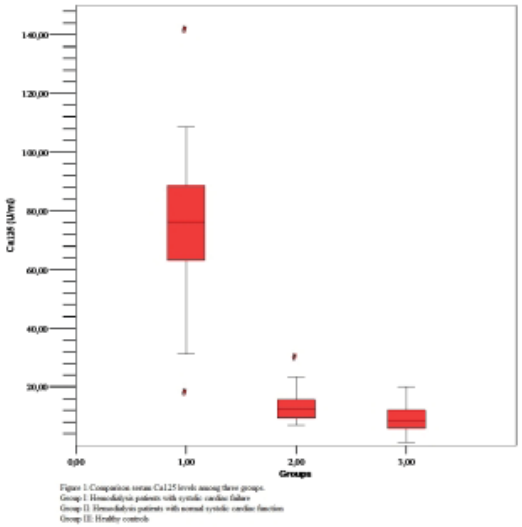

Figure 1 Comparison mean Ca125 levels among three groups.
Group I: Hemodialysis patients with systolic cardiac failure
Group II: Hemodialysis patients with normal systolic cardiac function
Group III: Healthy controls

Patients with elevated Ca125 (n=40) had significantly lower albumin, RWT, LVEF, FS while B-type natriuretic peptide levels, LVEDd, LVESd were significantly higher. Correlation analysis showed that CA 125 was positively related proBNP(r=0.596, P < 0.05), Crp ( r=0.439, P < 0.05), LVEDd (r=0.599, P < 0.001), LVESd( r=0.750, P < 0.001), LVMI( r=0.378, P < 0.05). But serum Ca 125 levels were negatively correlated with albumin (r=-0.513, P < 0.05), hemoglobin( r=-0.475, P < 0.05), HDL( r=-0.336, P < 0.05), EF( r=-0.878, P < 0.0001). Presence of depressed ejection fraction (ß=-1.121, p<0.0001) and increased CRP levels (ß= 0.247, p=0.035) were independent predictor of high Ca125 levels in whole group in multivariate-model.

**Conclusions:** Our study demonstrated an association between Ca125 and LV systolic dysfunction in patients with ESRD treated with HD. We conclude that Ca125 appears to be useful in establishing the presence of systolic heart dysfunction in HD patients.

## SA-PO469

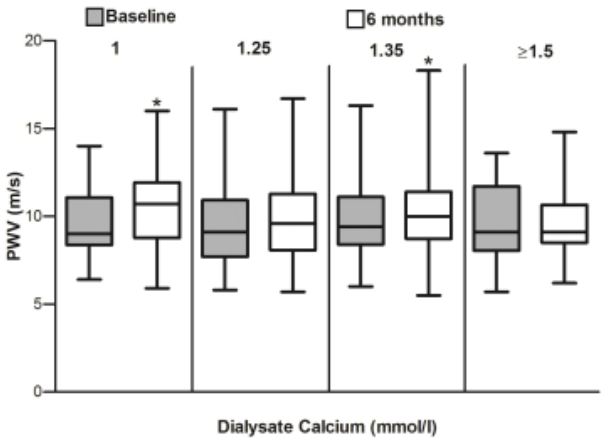
### The Effect of Dialysate Calcium Concentration on Vascular Stiffness in Haemodialysis Patients Measured by Aortic Pulse Wave Velocity

Evangelia E.M. Charitaki, Andrew Davenport. *UCL Centre for Nephrology, Royal Free Hospital, London, United Kingdom.*

**Background:** Higher dialysate calcium concentrations have been reported to acutely increase arterial stiffnessin haemodialysis patients. The aim of this study was to determine whether higher dialysate calcium concentrations are associated with chronic changes in arterial stiffness,raising the risk of sudden cardiac arrhythmic death, heart failure, and stroke in these patients.

**Methods:** This study included 289 maintenance dialysis patients [62.2% male, mean age 65.5±15.7 years,47.9% diabetic], dialysing with calcium concentrations of 1.0, 1.25, 1.35 and ≥1.5 mmol/l. The groups were matched for demographics and serum biochemistries. Patients dialysing with the lowest calcium dialysate concentration showed an increased incidence of hypertension and higher serum phosphate and parathyroid levels compared to those dialysing against the highest dialysate calcium concentrations. Pulse wave velocity(PWV) and aortic augmentation index(AoAXi) were measured before dialysisusing a brachial oscillometric device [Arteriograph]. Measurements were repeated after six months.

**Results:** Mean PWV increased over the six-months period (9.66±2.0 vs 10.13±2.16 m/s ,p<0.001), but no change was seen in AoAXi (38.7±16.3 vs 39.8±15.6%), or central aortic pressure (149.6±33.3 vs 150.4±31.9 mmHg).PWV did not differ between the four groups, either at the start or the end of the study, but increased significantly in the groups dialysing with a calcium concentration of 1.0 mmol/l (9.64±1.94 vs 10.45±1.98 m/s, p=0.0028) and 1.35 mmol/l (9.75±1.96 vs 10.21±2.18 m/s, p=0.02).



**Conclusions:** The increase in pulse wave velocity observed over time with the lowest calcium dialysate group suggests that factors other than the dialysis calcium balance determined by the dialysate calcium concentration, may be more important in promoting vascular stiffness in haemodialysis patients.

## SA-PO470

**Relation between Diastolic Dysfunction, Physical Function and Body Composition in Hemodialysis Patients** Jin Hee Jeong,[1] Pei-tzu Wu,[1] Peter J. Fitschen,[1] Brandon Kistler,[1] Hae Ryong Chung,[1] Annabel Biruete,[1] Ken Wilund,[1] Mohamed Ali,[2] Bo Fernhall,[2] Shane Phillips.[2] *[1]Kinesiology, Univ of illinois at Urbana-Champaign, Urbana, IL; [2]Univ of Illinois at Chicago, Chicago, IL.*

**Background:** Cardiovascular (CV) complications are the main cause of death in hemodialysis (HD) patients. Although metrics related to left ventricular systolic dysfunction (LVSD) such as ejection fraction (EF) are commonly used to predict adverse CV outcomes, LV diastolic dysfunction (LVDD) measures may provide better prognostic values in HD patients because they are less sensitive to blood volume changes. Additionally, muscle wasting and declines in physical function are common in HD patients. This can result from abnormalities in cardiac function, which can be further worsened by physical deconditioning. Little is known about the relationship between cardiac function and physical function in HD patients. **Aim:** To evaluate the prevalence of LVDD and to assess its relationship to physical function and body composition in HD patients.

**Methods:** Walking performance, leg strength, and whole body lean mass (WBLM) by DXA were measured in 83 HD patients (age=52.9± 11y). Echo was used to assess LVSD (EF) and LVDD (peak mitral inflow velocities (E and A), peak early diastolic mitral annular velocity(E') and deceleration time of E (DT)). LVDD classification: 1)mild DD (E/A< 0.8, E'<8cm/s, E/E'<8, and DT<200ms) and 2) advanced DD (E/A>0.8, E'<8, E/E'>9, and DT<200).

**Results:** The prevalence of LVDD was 48.2% (mild DD:14.5% and advanced DD: 33.7%) and of LVSD (EF < 40%) was 12.2%. 50% of patients with LVSD also had LVDD. BMI was significantly higher in patients with LVDD(p=0.017). After adjusting for age, gait speed, right leg peak strength, and WBLM% were significantly higher in the group without LVDD than with LVDD(p=0.006, 0.001 and 0.007;respectively). However, there was no significant difference in any measure of physical function or body composition between patients with and without LVSD.

**Conclusions:** This data indicates that LVDD is more closely related to physical function and body composition than LVSD in HD patients, and suggests that LVDD may be an important therapeutic target.

## SA-PO471

**Bradycardia as a Cause of Hypotensive Episodes during Routine Hemodialysis** D. Miskulin,[1] Klemens B. Meyer,[1] John E. Moran.[2,3] *[1]Nephrology, Tufts Medical Center, Boston, MA; [2]Intelomed, Inc, Pittsburgh, PA; [3]Nephrology, Stanford Univ School of Medicine, Stanford, CA.*

**Background:** Patients on maintenance hemodialysis (HD) have a high cardiovascular (CV) mortality and often suffer CV events such as hypotension during HD. One manifestation of CV stress is the appearance of arrhythmias which may be associated with hypotension.

**Methods:** 25 patients with a history of frequent hypotensive episodes during routine HD were monitored during 4 HD treatments using the CVInsight device (Intelomed, Inc), which captures and processes the signal from a standard pulse oximeter (Nonin Medical, Inc) to provide real-time display of CV status based on rate of change of pulse rate and of pulse amplitude. Bradycardia was defined as a 15% decrease in pulse rate during treatment.

**Results:** 8 patients experienced 18 episodes of bradycardia during the study; 3 patients had episodes in all 4 HD treatments studied, 1 patient experienced 2 episodes, and 4 patients 1 episode. 15/18 episodes (83%) were associated with a defined CV event requiring intervention; in 2 of the other 3 episodes the systolic BP fell by more than 60 mm Hg. Four of the 8 patients were receiving beta blocker therapy. In 7 patients the fall in pulse rate was gradual over the course of treatment; in 1 patient there was an abrupt fall in all 4 treatments which was preceded by a fall in BP.

**Conclusions:** Some HD patients have an inappropriate fall in pulse rate during HD treatment, not necessarily related to beta blockade. Real-time monitoring will allow recognition of such events and facilitate intervention.

*Funding:* Pharmaceutical Company Support - Intelomed, Inc

## SA-PO472

**Mortality Rates among Prevalent Hemodialysis Patients in Turkey: A Comparison with USRDS Data** Gulay Asci,[1] Daniele Marcelli,[2] Aygul Celtik,[1] Aileen Grassmann,[2] Mustafa Yaprak,[1] Abdulkerim Furkan Tamer,[1] Mehmet Nuri Turan,[1] Mehmet S. Sever,[3] Ercan Ok.[1] *[1]Nephrology, Ege Univ, Turkey; [2]Fresenius Medical Care, Germany; [3]Nephrology, Istanbul Univ, Turkey.*

**Background:** There are significant differences between countries in mortality rates of hemodialysis patients(HD). We compared mortality rates in Turkey and the US and analyzed potentially related differences in patient-treatment characteristics.

**Methods:** All patients undergoing HD or hemodiafiltration in March 2009 for >3 months(n=4041) in the Turkish clinics of the NephroCare network were enrolled. Data were prospectively collected for 2 years through the database EuCliD. Mean age was 58.7±14.7 years, 45.9% female, 22.9% diabetic. Comparison with US data was performed by applying indirect standardization technique, using as reference specific mortality rates for patients on HD by age, gender, race and primary diagnosis as provided by the 2012 USRDS Annual Data Report.

**Results:** Crude mortality rate was 9.5 per 100 pt-yrs. Comparison of specific unadjusted mortality rates(per 1000 pt-yrs) of Turkish Patients with US whites is reported in table.

| | All | Female | Male | Diabetes | 20-44 | 45-64 | 65+ |
|---|---|---|---|---|---|---|---|
| Turkey | 95.1 | 90.4 | 99.0 | 154.8 | 21.6 | 72.4 | 164.2 |
| US white | 236.3 | 234.2 | 237.9 | 245.6 | 75.2 | 162.9 | 330.3 |
| Relative risk reduction | 0.59 | 0.61 | 0.58 | 0.37 | 0.71 | 0.55 | 0.50 |

The mortality advantage for Turkish patients was present in all subgroups. Standardized mortality rate of Turkish cohort was 0.50 (95%CI 0.46-0.54, p<0.001) compared to US. The differences in treatment characteristics between two populations are given in figure.

| | Turkish cohort | US cohort* |
|---|---|---|
| AV fistula (%) | 86.1 | 55.5 |
| Treatment time (min) | 240±13 | 214±17 |
| Systolic blood pressure >140 mmHg (%) | 24.1 | 89.0 |
| Hemodiafiltration (%) | 9.7 | NA |

**DOPPS-US data were used except AV fistula (USRDS)*

**Conclusions:** Annual mortality rate is significantly lower in Turkish cohort than US HD patients. Higher use of AV fistula, longer treatment time, better volume control and hemodiafiltration treatment are possible contributing factors.

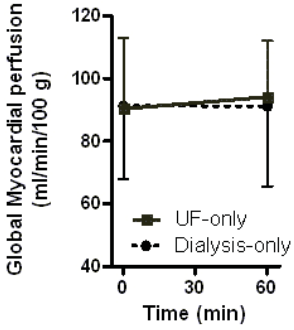
## SA-PO473

**Acute Effects of Isolated Ultrafitration and Isolated Dialysis on Myocardial Perfusion and Function Assessed by Intra-Treatment Positron Emission Tomography (PET)** Solmaz Assa,[1] Johanna J. Kuipers,[2] Esmee M. Ettema,[1] Judith J. Dasselaar,[1] Yoran M. Hummel,[3] Adriaan A. Voors,[3] Paul E. de Jong,[1] Ralf Westerhuis,[2] Rene A. Tio,[3] Riemer Hja Slart,[4] Casper F.M. Franssen.[1] *[1]Nephrology; [2]DCG; [3]Cardiology; [4]Nuclear Medicine, UMCG, Netherlands.*

**Background:** Previous studies showed that hemodialysis with combined dialysis and ultrafiltration is associated with significant reductions in myocardial perfusion and development of regional left ventricular (LV) systolic dysfunction. We studied the effect of isolated ultrafiltration (UF-only) and dialysis (dialysis-only) on myocardial perfusion and function.

**Methods:** 8 patients (7 male, 55±18 years) underwent 1h UF-only (UF-rate 1 l/h) and dialysis-only (zero fluid balance). Myocardial perfusion and LV ejection fraction (EF) were assessed by $^{13}$N-$NH_3$ PET before and during the last 15 min of treatment. Regional LV systolic function was assessed by echocardiography.

**Results:** Blood pressure, heart rate and body temperature were comparable during treatments. Global myocardial perfusion did not change during UF-only and dialysis-only, however, during dialysis-only a non-significantly greater number of LV segments showed reductions in perfusion compared with UF-only (7.9±5.3 vs 5.0±5.1). LVEF rose during UF-only (p=0.06) and did not change during dialysis-only. Two patients developed regional LV hypokinesia only during isolated dialysis (3 segments in both); 1 other patient developed regional LV hypokinesia during both UF-only and dialysis-only (in 4 and 2 segments, respectively).



**Conclusions:** Global myocardial perfusion was not compromised by isolated UF or isolated dialysis. However, regional decreases in myocardial perfusion and regional LV dysfunction were more pronounced during isolated dialysis indicating that, besides hypovolemia, acute dialysis-associated factors are involved in the pathogenesis of hemodialysis-induced LV dysfunction.

*Funding:* Pharmaceutical Company Support - Amgen

## SA-PO474

**Effect of Personalized Dialysate Sodium on Clinical Outcomes and Sodium Setpoint Stability, in Patients on Nocturnal and Frequent Hemodialysis Modalities** Benjamin Ka Thomson,[1] Christopher T. Chan,[2] Shih-Han S. Huang,[1] Robert M. Lindsay.[1] *[1]Western Univ; [2]Western Univ; [3]Univ Health Network, Univ of Toronto; [4]Western Univ.*

**Background:** Personalized dialysate sodium alters blood pressure, interdialytic weight gain, and perhaps mortality. We have previously shown that the Post- to Pre-dialysis sodium gradient (PPNa+) predicts clinical outcomes in home hemodialysis population. Moreover, modifiable factors affecting interdialytic weight gain in this population include dialysis duration and frequency, and dialysate sodium concentration, while patient age, sex and pre-dialysis serum albumin also have a role. Our objectives were to validate prospectively our equation for predicting interdialytic weight gain, and to confirm our retrosptive data that pre-dialysis sodium setpoint is modifiable.

**Methods:** All patients in the Southwestern Ontario regional home hemodialysis program were included in a randomized crossover design. Patients differed in dialysis frequency and duration. Each patient was treated with two consecutive three month periods with dialysate sodium concentration that was 3 mmol/L above then below (or vice versa) the most recently recorded pre-dialysis sodium setpoint. Clinical outcomes were compared between each three month interval. Clinical outcomes considered included pre-dialysis systolic and diastolic blood pressure (mm Hg), interdialytic weight gain (Liters). We also evaluated the stability of the pre-dialysis sodium setpoint by comparing the pre-dialysis sodium slope and difference across each 3 month interval.

**Results:** Data for this trial will be collected and analyzed completely by October 17, 2013. Results will be considered in two categories: 1. Clinical outcomes, which will be compared between each three month period and 2. Sodium setpoint, to determine if personalization of dialysate sodium alters the stability of the sodium setpoint.

**Conclusions:** The results of this trial will determine if and how dialysate sodium should be chosen in hemodialysis patients with increased dialysis frequency or duration. In addition, whether sodium setpoint can be altered prospectively will be determined.

*Funding:* Government Support - Non-U.S.

## SA-PO475

**Arterial Stiffness and Cardiovascular Outcomes in Minorities with End Stage Renal Disease** Kalyani Perumal,[1] Peter D. Hart,[1] James P. Lash.[2] *[1]Nephrology, John H Stroger Hospital, Chicago, IL; [2]Nephrology, Univ of Illinois at Chicago, Chicago, IL.*

**Background:** Cardiovascular disease is the leading cause of mortality in patients with end stage renal disease (ESRD). Although arterial stiffness is now recognized as an independent predictor of cardiovascular mortality in ESRD, there are no data on arterial stiffness in minorities with ESRD and its impact on cardiovascular outcomes.

**Methods:** We therefore conducted a prospective study to investigate the measures of arterial stiffness (pulse wave velocity, PWV) and reflected wave (augmentation index, Aix) in a predominately minority cohort of 77 patients on hemodialysis and its effect on composite outcome- cardiovascular event or all-cause mortality. PWV and AIx were determined from arterial waveforms recorded by SphygmoCor® device. 80% of measurements were taken prior to dialysis sessions. Cardiovascular events were defined as new onset myocardial infarction, congestive heart failure, arrhythmia, acute cerebrovascular event, peripheral arterial disease requiring medical or surgical intervention.

**Results:** In this group, 72% were African Americans , 24% Hispanics, and 4% were non-Hispanic whites. Mean age was 55 yrs; 61 % were male. Major causes of ESRD were diabetes (58 %) and hypertension was present in 91 %. Mean duration of dialysis was 41 mos. Mean PWV was 11 m/s and mean AIx was 24% in this cohort. All patients were followed for a mean of 36 mos. A total of 4 fatal and 24 non-fatal cardiovascular events occurred in 19 patients. In multivariate regression analysis, age and diabetes were identified as significant predictors of PWV ($p < 0.05$). In multivariate Cox analysis, after adjustment of confounding factors, the risk ratio for each 10% increase in PWV was 1.12 (CI 1.00- 1.23, $p< 0.05$) for composite outcomes. Survival analysis showed that the group in lowest tertile of PWV (PWV< 8m/s) had greater event free survival when compared to the group in upper tertile (PWV>12 m/s) ($p < 0.01$).

**Conclusions:** Thus, our study provides the first direct evidence that PWV is a significant predictor of cardiovascular morbidity and mortality in the minority population on hemodialysis.

## SA-PO476

**Pulmonary Hypertension in Hemodialysis Patients Is Associated with High Pulse Pressures** Brittany Jamille Thomas,[1] Muhammad Sarmini,[2] Rachel E. Patzer,[1] Janice P. Lea.[1] *[1]Emory Univ; [2]Univ of Missouri.*

**Background:** Pulmonary hypertension (PHT) is an independent predictor of mortality in ESRD patients. Etiology has been attributed to presence of arteriovenous fistulas, vascular calcifications, volume overload, and anemia. Aim of this study was to determine prevalence of PHT in our dialysis population and its relationship to blood pressure.

**Methods:** PHT defined as PAP > 35 mm Hg per echocardiogram( echo). Retrospective data analyses were conducted on a total number of 410 ESRD patients who had echos performed as usual standard of care with dialysis BP measurements averaged over a 6 month period prior to date of echo.

**Results:** We found that 61% had PHT and diabetics were more likely to have PHT , p=.021, OR- 1.7 (1.1-2.6). Mean values for pre and post systolic blood pressures (SBP), diastolic blood pressures (DBP), and pulse pressures are listed in table below. Patients with PHT had lower pre and post diastolic BP (p=.023 and .022), and higher pre and post pulse pressures, p=.003, and p=.015. Pre and post systolic BP was not statistically different between those with and without PHT. In addition, calcium-phosphorus product nor hemoglobin level were not statistically different between those with or without PHT.

| PAP | mean pre-SBP/post-SBP | mean pre-DBP/post-DBP | mean pre-pulse pressure | mean post-pulse pressure |
|---|---|---|---|---|
| > 35 | 154.3+ 2.2.8/140 + 19 | 83.5+14.4/76.1+11.7 | 70.7+15 | 63.9+13.3 |
| < 35 | 152.91+8.6/139.5+18 | 87.3+ 79.4+12.2 | 65.6+12.9 | 60.1+12.7 |

**Conclusions:** In summary, we show that ESRD patients with PHT have elevated pulse pressures attributed to lower DBP and not due to elevated SBP. Since pulse pressure is also an independent predictor of mortality, studies investigating mortality related to PHT need to be adjusted for pulse pressure. Furthermore, other potential mechanisms to explain these findings need to be explored.

## SA-PO477

**Progression of Pulmonary Hypertension in Dialysis Population Is Associated with Increased Mortality** Farhanah Yousaf, Nimra Sarfaraz, Haroon Rashid, Chaim Charytan, Bruce S. Spinowitz. *New York Hospital Queens, Flushing, NY.*

**Background:** There is increased prevalence of pulmonary hypertension in the dialysis population. Little is known about the progression and predictors of progression of pulmonary hypertension in patients undergoing dialysis. Therefore, a retrospective review was undertaken to explore the progression of pulmonary hypertension in dialysis patients, risk of all-cause mortality, and to investigate the routinely drawn biochemical parameters as predictors of progression of pulmonary hypertension.

**Methods:** IRB approval was obtained. Medical records of prevalent dialysis patients who had at least two right ventricular systolic pressures (RVSP) derived from echocardiography were reviewed. Patients were divided into normal (< 35 mmHg), mild (35 – 50 mmHg), moderate (51 – 70 mmHg), and severe (> 70 mmHg) pulmonary hypertension groups. Biochemical parameters from the interval between the two RVSPs were collected. Linear multi-logistic regression analysis was performed using SPSS.

**Results:** 38 patients, 18 males and 20 females, aged 72 ± 12 years, met inclusion criteria. The mean initial RVSP was 32 ± 16 mmHg and the follow up mean RVSP was 37 ±27 mmHg and the difference was statistically significant ($p<0.001$). Based on initial echocardiogram, 16 (42%) patients had pulmonary hypertension defined as a RVSP greater than 35 mmHg. On follow up, 20 (52%) patients remained stable, 12 (32%) worsened, and 6 (16%) improved. Among patients with worsening pulmonary hypertension, 6 (50%) of the 12 patients died during a mean follow up of 4.1 years compared to zero mortality among stable or improved RVSP group. Of the analyzed biochemical parameters, only ferritin was found to be an independent predictor of worsening pulmonary hypertension in our analysis ($r^2 = 0.354$, $p= 0.003$).

**Conclusions:** Our study confirms a high prevalence of pulmonary hypertension in end stage renal disease. There is a trend of worsening pulmonary hypertension in patients undergoing dialysis and it is associated with increased mortality. Additional studies in the dialysis population are warranted to explore the progression of pulmonary hypertension and its predictors.

**SA-PO478**

**Stroke and the "Stroke Belt" in Dialysis: Contribution of Patient Characteristics to Ischemic Stroke Rate and Its Geographic Variation**
James B. Wetmore,[2] Edward F. Ellerbeck,[3] Jonathan D. Mahnken,[2] Milind A. Phadnis,[2] Sally K. Rigler,[3] John Spertus,[4] Purna Mukhopadhyay,[2] Theresa I. Shireman.[3] *[1]Medicine, Div of Nephrology, Hennepin County Medical Center, Minneapolis, MN; [2]Biostatistics, Univ of Kansas Medical Center, Kansas City, KS; [3]Preventive Medicine and Public Health, Univ of Kansas Medical Center, Kansas City, KS; [4]Medicine, Div of Cardiology, Mid America Heart Institute of St. Luke's Hospital, Univ of Missouri - Kansas City, Kansas City, MO.*

**Background:** Geographic variation in stroke rates is well-established in the general population, with higher rates in the south than in other areas of the U.S. End-stage renal disease (ESRD) is a potent risk factor for stroke, but whether regional variations in stroke risk exist among dialysis patients is unknown.

**Methods:** Medicare claims from 2000-05 were used to ascertain ischemic stroke events in a large cohort of incident dialysis patients. A Poisson generalized linear mixed model was generated to determine factors associated with stroke and to ascertain state-by-state geographic variability in stroke rates by generating observed-to-expected (O/E) adjusted rate ratios for stroke.

**Results:** A total of 265,685 Medicare-eligible incident dialysis patients were studied. Older age, female sex, African-American race and Hispanic ethnicity, unemployed status, diabetes, hypertension, history of a previous stroke, and permanent atrial fibrillation were all significantly associated with ischemic stroke, while body mass index > 30kg/m$^2$ had an inverse association with stroke (P < 0.0001 for each). After full multivariable adjustment, the 3 states with O/E rate ratios > 1.0 were all in the south: North Carolina, Mississippi, and Oklahoma.

**Conclusions:** Regional efforts to increase primary prevention in the 'stroke belt,' or to better educate dialysis patients on the signs of stroke so that they may promptly seek care, may improve stroke care and outcomes in dialysis patients.

**SA-PO479**

**Race and Ethnicity Largely Account for State-by-State Geographic Variation in Hemorrhagic Stroke in Dialysis Patients**
James B. Wetmore,[1] Milind A. Phadnis,[2] Jonathan D. Mahnken,[2] Edward F. Ellerbeck,[3] Sally K. Rigler,[3] Theresa I. Shireman.[3] *[1]Medicine, Div of Nephrology, Hennepin County Medical Center, Minneapolis, MN; [2]Biostatistics, Univ of Kansas Medical Center, Kansas City, KS; [3]Preventive Medicine and Public Health, Univ of Kansas Medical Center, Kansas City, KS.*

**Background:** Geographic variation in stroke rates is well-established in the general population, with higher rates in the south than in other areas of the U.S. A similar pattern of geographic variation in ischemic strokes has also recently been reported in chronic dialysis patients, but whether this is also the case for hemorrhagic stroke is unknown.

**Methods:** Medicare claims from 2000-05 were used to ascertain hemorrhagic stroke events in a large cohort of incident dialysis patients. A Poisson generalized linear mixed model was generated to determine factors associated with stroke and to ascertain state-by-state geographic variability in stroke rates by generating observed-to-expected (O/E) adjusted rate ratios for stroke.

**Results:** A total of 265,685 Medicare-eligible incident dialysis patients were studied. Over a mean follow-up of approximately 2 years, 2397 (0.9%) of patients suffered a hemorrhagic stroke. African-Americans (adjusted rate ratio [ARR] 1.43, 95% confidence intervals [CI's] 1.30 – 1.57), Hispanics (ARR 1.78, 95% CI's 1.57 – 2.03) and individuals of other races (ARR 1.51, 1.26 – 1.80) had significantly higher risk for hemorrhagic stroke compared to Caucasians. In models adjusted for age & sex, four states had observed:expected ARR's for hemorrhagic stroke significantly > 1.0 (CA, 1.15; MD, 1.25; NC, 1.25; TX, 1.19), while only 1 had an ARR < 1.0 (WI, 0.79). However, after adjustment for race and ethnicity, no states had ARRs that varied significantly from 1.0.

**Conclusions:** Race and ethnicity, or some proxy for these, largely account for geographic variabilty in hemorrhagic stroke rates in the U.S.

**Stroke as a Watershed Event: Impact of Stroke on Mortality in Dialysis Patients**
James B. Wetmore,[1] Milind A. Phadnis,[2] Jonathan D. Mahnken,[2] Theresa I. Shireman,[3] Sally K. Rigler,[3] Edward F. Ellerbeck.[3] *[1]Medicine, Div of Nephrology, Hennepin County Medical Center, Minneapolis, MN; [2]Biostatistics, Univ of Kansas Medical Center, Kansas City, KS; [3]Preventive Medicine and Public Health, Univ of Kansas Medical Center, Kansas City, KS.*

**Background:** Hemorrhagic stroke is a devastating clinical event, but the hazard ratio for mortality following a hemorrhagic stroke in chronic dialysis patients is unknown.

**Methods:** A large cohort of dually-eligible (Medicare-Medicaid) patients initiating chronic dialysis from 2000-05 was constructed. Medicare claims from this period were used to ascertain new hemorrhagic stroke events. A Cox regression model was generated to estimate the effects of time-dependent hemorrhagic stroke on mortality and to calculate survival time following hemorrhagic stroke.

**Results:** The cohort consisted of 69,371 incident dialysis patients with > 111,000 person-years of follow-up. There were 5.6 hemorrhagic strokes per 1000 patient-years. Of those with a hemorrhagic stroke, 81.8% died, compared to 52.0% of those without (P < 0.0001). One-quarter died by 0.35 months following a hemorrhagic stroke, 50% by 0.8 months, and 75% by 10.8 months. This survival pattern was similar whether the stroke occurred within the first, second, third, or fourth year following dialysis initiation. The hazard ratio (HR) for death was approximately 45 at 2 weeks, 24 at one month, and 7.0 at 2 months. The HR then fell rapidly thereafter to 2.8 at 4 months, 2.5 at 6 months, 1.7 at 12 months, and 1.1 at 18 months.

**Conclusions:** Hemorrhagic stroke confers substantial mortality, with a striking initial mortality and a dramatic decrease in remaining years of life. However, the HR for death after hemorrhagic stroke falls rapidly, and after only a year begins to approach 1.0. This pattern for mortality is generally similar whether the stroke occurs soon after dialysis initiation or after several years of dialysis.

**SA-PO481**

**Fibroblast Growth Factor 23 and the Risk of All-Cause Mortality and Cardiac Hospitalizations and Death in Hemodialysis Patients: Results from the HEMO Study**
Kristen L. Jablonski,[1] Jessica B. Kendrick,[1] Alfred K. Cheung,[2,3] Tom Greene,[3] Michel Chonchol.[1] *[1]Univ of Colorado Denver, Aurora, CO; [2]VASLCHCS, Salt Lake City, UT; [3]Univ of Utah, Salt Lake City, UT.*

**Background:** Elevated serum levels of fibroblast growth factor 23 (FGF23), have been associated with adverse outcomes in patients requiring long-term dialysis therapy. Although the values of FGF23 often evolve over time, no study has examined the accumulated effects on important clinical end points.

**Methods:** The HEMO Study was a randomized multicenter study evaluating the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. Serum intact FGF23 levels were measured in stored serum samples obtained at baseline and annually in 1,340 patients in this cohort. Quartiles of FGF23 concentrations were chosen as the primary predictor variable, with the lowest quartile serving as the reference category. Time-dependent Cox proportional-hazards models were used to examine the association between FGF23 levels with all-cause mortality (ACM) and a composite of first cardiac hospitalization or death.

**Results:** Participants had a mean age of 57±14 years, 55% were females and 46% were white. During a median follow-up of 3.0 years, 582 (43%) died from any cause, and 514 (41%) had a cardiac event. Median (IQR) serum FGF23 level was 3118 [726, 12928] pg/mL. Overall, median levels of FGF23 rose during follow-up (p=0.01). After adjustment for potential confounders available in the database, including inflammatory markers and usage of calcitriol, the highest quartile of FGF23 was associated with an increase risk of ACM (HR;1.51, 95% CI 1.05-2.15; p=0.02) and cardiac events (HR; 1.51, 95% CI 1.07-2.13; p=0.02) when compared to the lowest quartile. Similarly, when FGF23 was evaluated as a continuous variable, higher levels of FGF23 were associated with an increased risk of ACM and cardiac outcomes (HR; 1.10, 95% CI 1.01-1.13 per doubling of FGF23; p=0.01).

**Conclusions:** In the HEMO study, higher serum FGF23 levels were independently associated with all-cause morality and cardiac hospitalizations and death in time-dependent Cox regression models.

**SA-PO482**

**Interdialytic Weight Gain Is an Independent Risk Factor for All-Cause Mortality and Cardiovascular Events in Incident Hemodialysis Patients**
Hye-Young Kang,[1] Shin-Wook Kang,[1,2,3] Mi Jung Lee,[2] Chan Ho Kim,[2] Hyung Jung Oh,[2] Seung Hyeok Han,[2] Tae-Hyun Yoo.[1,2] *[1]Brain Korea 21; [2]Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea; [3]On Behalf of Clinical Research Center for End-Stage Renal Disease Investigators.*

**Background:** Excessive interdialytic weight gain (IDWG) represents fluid overload and non-compliance in end-stage renal disease (ESRD) patients on hemodialysis (HD), and thus it is associated with unfavorable clinical outcome. Meanwhile, the amount of food intake also contributes to IDWG, which can reflect nutritional status. Such a paradoxical meaning of IDWG requires further investigation, particularly in terms of its prognostic value for adverse clinical outcomes.

**Methods:** A prospective cohort of 1,013 incident HD patients from 36 dialysis centers of the Clinical Research Center for ESRD in Korea was selected for this study. The percentage of IDWG (IDWG%) was expressed as a ratio of absolute IDWG to dry weight, and patients were divided into 5 groups according to IDWG%; <1.0, ≥4.0, and every 1.0 increment in between. Cox proportional hazard analysis was performed to determine the prognostic value of IDWG% for primary outcome, a composite of all-cause mortality or cardiovascular events.

**Results:** The mean IDWG% was 2.7±1.8%. During a mean follow-up duration of 18.7 months, 84 patients died and 99 cardiovascular events occurred. Compared to patients with IDWG% of 1.0-1.9, the adjusted hazard ratios (HRs) of IDWG% <1.0, 2.0-2.9, 3.0-3.9, and ≥4.0 groups were 1.30 [95% confidence interval (CI), 0.73-2.31; P=0.37], 1.37 (95% CI, 0.78-2.42; P=0.27), 1.91 (95% CI, 1.10-3.33; P=0.02), and 1.81 (95% CI, 1.04-3.16; P=0.03), respectively. In addition, sensitivity analysis revealed that a significant impact of high IDWG% (≥3.0) on the clinical outcome was consistent in male patients (HR, 1.57; 95% CI, 1.01-2.44; P=0.04), patients with older age (≥65 years) (HR, 1.69; 95% CI, 1.04-2.75; P=0.03), diabetes (HR, 1.75; 95% CI, 1.15-2.67; P=0.01), and BMI ≥22 kg/m2 (HR, 1.79; 95% CI, 1.08-2.99; P=0.02).

**Conclusions:** High IDWG% (≥3.0) was a significant independent predictor of all-cause mortality and cardiovascular events in incident HD patients.

**Atrial Natriuretic Peptide Prophylaxis Does Not Improve Short-Term Survival or Contrast-Induced Nephropathy: A Meta-Analysis**
Sayyad F. Kyazimzade,[1] Daniel M. Pearlman,[1] Vinay Rao,[1] Alex L. Yerukhimov,[2] Jeremiah R. Brown.[1] *[1]The Dartmouth Institute for Health Policy and Clinical Practice at the Geisel School of Medicine, Lebanon, NH; [2]Dartmouth College, Hanover, NH.*

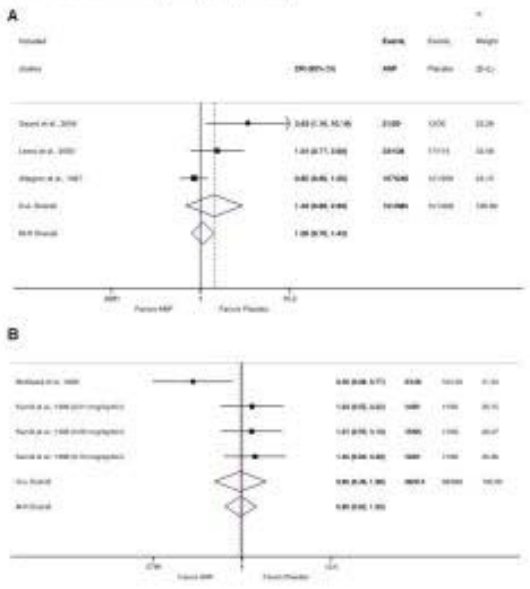
**Background:** Atrial natriuretic peptide (ANP) has been shown to improve renal function in individual randomized controlled trials (RCTs). Yet, other studies have not replicated this finding. To determine the true effect of ANP, we performed a systematic review of existing studies that assessed renal function and/or its relationship to patient survival. We hypothesized that prophylactic administration of ANP would improve the risk of contrast-induced nephropathy (CIN) and 21-day dialysis-free survival.

**Methods:** We conducted a meta-analysis of published RCTs involving prophylactic administration or treatment with ANP in participants who had renal failure. Eligible studies reported the number of participants experiencing 21-day dialysis-free survival or CIN among the total number of study participants. Our search identified 71 records, of which 5 RCTs, including 1288 patients, met our pre-specified eligibility criteria. We calculated random-effects summary estimate odds ratios (OR) and 95% confidence intervals (CI) for the 3 trials that provided data on 21-day dialysis-free survival and for the 2 trials that reported CIN occurrence.

**Results:** Pooled analyses revealed a nonsignificant difference in the odds of CIN occurrence among participants receiving ANP relative to those receiving placebo (15.3% *vs.* 13.8%; OR: 0.77; 95% CI, 0.44–1.35; $P$=.57; $I^2$=59.3%). Odds of 21-day dialysis-free survival in pooled ANP versus placebo study arms were also nonsignificant (39.2% *vs.* 37.8%; OR, 1.06; 95% CI, 0.79–1.43; $P$=.33; $I^2$=72.2%).

**Conclusions:** Existing trials show a nonsignificant improvement in the odds of both CIN and 21-day dialysis-free survival following prophylactic administration and treatment with ANP.

**Figure 1.** Atrial natriuretic peptide vs. placebo for 21-day dialysis-free survival (Panel A) and contrast-induced nephropathy (Panel B).



## SA-PO484

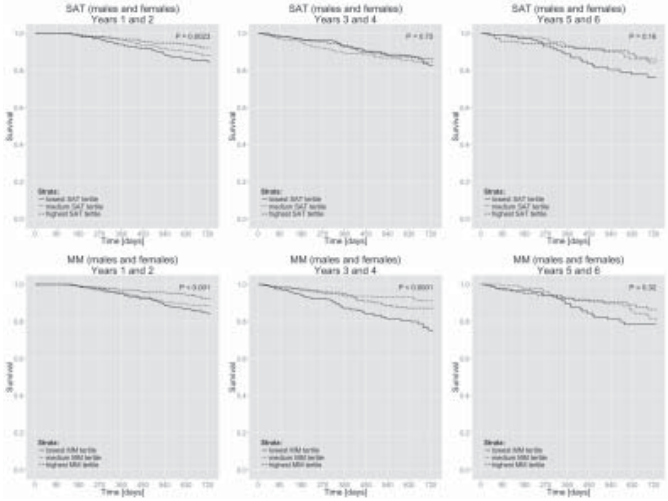
**Muscle and Fat Mass and Their Relationship to Survival in Hemodialysis Patients**
Stephan Thijssen, Nathan W. Levin, Peter Kotanko. *Renal Research Institute, New York, NY.*

**Background:** Mortality among dialysis patients is strongly associated with anthropometric measures, such as body mass index (BMI) and lean body mass, estimated as the volume of distribution of urea. In contrast to the general population, in dialysis patients a high body mass index is associated with improved survival. We have previously developed a set of regression equations for estimation of subcutaneous adipose tissue (SAT) mass and muscle mass (MM) in African-American hemodialysis (HD) patients (Thijssen, WCN 2007; $R^2$ ranging from 0.85 to 0.98). In this study, we applied these equations to elucidate the relationship between body composition and survival.

**Methods:** SAT and MM were estimated at baseline in 1,598 incident African-American HD patients who started HD between 1/1/2000 and 12/31/2010. For the purpose of run-in stability, only patients who survived for at least 120 days were analyzed. Crude time to death was compared between tertiles of fat and muscle mass by Kaplan-Meier analysis and log-rank test for consecutive 2-year segments up to 6 years after start of HD.

**Results:** There was a significant relationship between tertiles of SAT and mortality, with better survival in patients with greater SAT. The association was lost after the first 2 years on HD (Figure, top 3 plots). Similarly, greater MM was associated with significantly better survival, but this relationship was retained for the first 4 years on HD and only then disappeared (Figure, bottom 3 plots).

**Conclusions:** SAT and MM are significantly related to survival in HD patients, and it appears that the improved survival related to greater MM can be traced substantially longer than that related to SAT. Future studies dealing with the relationship between body composition and outcomes in HD patients should focus on individual components of body composition (like fat and muscle mass) rather than vague surrogates such as BMI.



*Funding:* Pharmaceutical Company Support - Renal Research Institute

## SA-PO485

**Opioid Analgesic Use among Dialysis Patients**
Eric D. Weinhandl,[1] Akeem Yusuf,[1] Yi Peng,[1] Wendy L. St. Peter.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Univ of Minnesota, Minneapolis, MN.*

**Background:** Pain is a common and potentially debilitating symptom among dialysis patients. Although opioid analgesics are frequently prescribed in the United States, there are relatively few data regarding use among dialysis patients. We used Medicare Part D data to describe utilization of opioid analgesics (OAs) among adult dialysis patients between 2007 and 2011.

**Methods:** For year *Y*, included patients initiated dialysis no later than March 31 of year *Y*-1; received dialysis and carried Medicare Parts A and B as primary payer from June 1 to December 31 of year *Y*-1; and carried Part D coverage from January 1 of year *Y* to the earliest of kidney transplant, death, or December 31 of year *Y*. Patients were categorized as having received the low-income subsidy (LIS) or not having received the subsidy (non-LIS).

**Results:** Between 2007 and 2011, the percentage of patients with ≥1 OA fill ranged from 60.8% to 62.2%, while the percentage of patients with ≥6 fills increased from 21.7% to 24.3%. Among users, cumulative OA supply increased from 108 days per patient-year in 2007 to 130 days in 2011. In 2011, most widely prescribed OAs were hydrocodone/acetaminophen (APAP) (42.1%), oxycodone/APAP (17.9%), tramadol (13.5%), codeine/APAP (7.1%), and oxycodone (6.1%); other agents with use in >1% of patients were fentanyl, hydromorphone, morphine, and tramadol/APAP. Use of propoxyphene was negligible, following withdrawal of branded formulations in November 2010. The prevalence of patients with ≥6 OA fills was relatively high with age <65 years, Native American race, and polycystic kidney disease as primary cause of end stage renal disease; and relatively low with Asian race and peritoneal dialysis. Furthermore, 27.1% of LIS versus 15.0% of non-LIS patients had ≥6 OA fills.

**Conclusions:** Opioid analgesic use is widespread among dialysis patients, exceeding estimates of 5% to 36% in a recent systematic review (*CJASN*, 6:326-333). Among users, the duration of use is increasing. Hydrocodone and oxycodone, each in combination with acetaminophen, are most commonly prescribed. Studies investigating the potential for opioid analgesic overuse and the relative safety of opioid analgesics in dialysis patients are needed.

*Funding:* NIDDK Support

## SA-PO486

**Widespread Opioid Use in the U.S. End-Stage Renal Disease Population**
Anne Mobley Butler,[1] Abhijit V. Kshirsagar,[2] M. Alan Brookhart.[1] *[1]Dept of Epidemiology, Univ of North Carolina at Chapel Hill; [2]UNC Kidney Center, Univ of North Carolina at Chapel Hill.*

**Background:** Almost half of patients with end-stage renal disease (ESRD) report chronic pain, and over three-quarters rate it moderate to severe. The etiology of the pain is multifactorial, often related to comorbidities, renal osteodystrophy, and complications of the dialysis procedure. Because non-steroidal anti-inflammatory drugs have adverse effects on renal function, opioids may be perceived as the preferred analgesic agents in this population. We sought to quantify the magnitude of opioid use among U.S. ESRD patients.

**Methods:** Using data from the United States Renal Data System (USRDS), a national registry of patients in the Medicare ESRD program, we identified patients ≥ 18 years receiving dialysis on January 1, 2008 with Medicare as a primary payer and parts A, B, and D coverage. Information on opioid use was ascertained from Medicare part D claims. We calculated the proportion of patients receiving opioid prescriptions. Patients were censored at: end of continuous enrollment in Medicare Parts A, B, and D; loss-to-follow-up; kidney transplantation; death; or end of study on June 30, 2008.

**Results:** During the 6-month study period, there were 335,888 opioid prescriptions. Of 156,476 eligible dialysis patients, 77,697 (50%) patients used an opioid. Hydrocodone, oxycodone, and propoxyphene were prescribed to 30%, 14%, and 10% of the study population, respectively. The study population was middle-aged (mean, 60 years), 52% male, 50% white, 43% black, and 8% low income subsidy status. Opioid use was higher among patients of younger age, female gender, black or white race, and without low income subsidy status. Opioid use varied by primary cause of ESRD, years on dialysis, and dialysis modality. In a separate analysis with similar eligibility criteria, quarterly opioid use increased slightly from quarter 3 of 2006 (38%) to quarter 4 of 2008 (39%).

**Conclusions:** We document widespread and increasing use of opioids in the U.S. ESRD population. Given increasing concerns about opioid safety in the elderly, research is needed to better understand the safety and effectiveness of opioids in ESRD patients.

## SA-PO487

**Depressive Affect in Incident Hemodialysis Patients Is Associated with Increased Hospital Days and Hospital Admissions** Kathryn A. McDougall, John W. Larkin, Len A. Usvyat, Rebecca L. Wingard, Eduardo K. Lacson, Franklin W. Maddux. *Fresenius Medical Care North America (FMCNA), Waltham, MA.*

**Background:** Depression is a key disorder that affects chronic dialysis patients. However, it is not consistently recognized and outcomes related to the disease have not been well-defined, particularly for the first 120 days in incident hemodialysis (iHD) patients. This study investigated the associations between depressive affect (DA) in iHD patients and hospital days/hospital admissions.

**Methods:** Among a random selection of 108 dialysis centers, 429 iHD patients in the first month of chronic outpatient dialysis at FMCNA clinics from Jan-Mar 2013 were identified and telephone contact was attempted for up to three times to administer the Patient Health Questionnaire 2 (PHQ2). The PHQ2 has two questions screening for DA in the previous two weeks. Scores range from 0-6 with a positive DA score defined as ≥3. Hospital admissions and clinical parameters were captured for 120 days after the patients initiated dialysis (up to 30 Apr 2013). Multivariate Poisson regression models were constructed to determine whether hospital days and hospital admissions differ for depressed patients.

**Results:** Among 172 screened iHD patients, DA was detected in 23.3%. Increased hospital days of 15.8 versus (vs) 7.4 days per patient year (ppy) occurred in DA positive vs non-DA patients. Hospital admissions were also greater with 2.9 vs 1.5 events ppy, respectively. Poisson regression identified DA as an independent predictor of hospital days ($p<0.001$) and a trending predictor of hospital admissions ($p=0.096$) even after adjustment for covariates typically associated with depression (figure 1).

## SA-PO488

**Increased Depression and Anxiety Are Associated with Decreased Adherence in ESRD Patients** Daniel Cukor,[1] Nisha Ver Halen,[1] Yvette Fruchter,[1] Subodh J. Saggi.[2] *[1]Psychiatry and Behavioral Science, SUNY Downstate Medical Center, Brooklyn, NY; [2]Medicine, SUNY Downstate Medical Center, Brooklyn, NY.*

**Background:** A significant relationship between depression and medical outcome has been demonstrated in ESRD patients on hemodialysis (HD). There may be a direct, neurobiological relationship between depression and medical outcome or the association may be mediated by adherence behaviors. The current study investigates depression, anxiety, and adherence at a Brooklyn dialysis center that serves a predominantly African American population.

**Methods:** Fifty-seven hemodialysis patients completed questionnaires during dialysis sessions. Depressive and anxious symptoms were assessed with the Beck Depression Inventory (BDI) and the State-Trait Anxiety Inventory (STAI), respectively. Higher scores on the BDI and STAI state and trait subscales represent increased severity. Adherence behaviors were measured by the End-Stage Renal Disease Questionnaire (ESRD-AQ) behavior subscale, a self-report questionnaire, concerning adherence with dialysis sessions, medications, fluid limitations, and dietary restrictions. Higher scores on the ESRD-AQ behavior scale represents better adherence.

**Results:** Depressive symptoms ($r= -.36$, $p = .01$), state anxiety ($r = -.38$, $p = .01$), and trait anxiety ($r= -.43$, $p=.003$) negatively correlated with adherence. Utilizing a regression, with a model correcting for age and gender, the Beck Depression Inventory explained 24.9% of the variance in adherence ($t=-2.84$, $p = .01$). Separate regressions were run with state and trait anxiety to examine their predictive abilities for adherence behaviors when correcting for age and gender. State anxiety explained 19.1% of the variance in adherence ($t= -2.07$, $p = .045$) and trait anxiety explained 25.7% of the variance in adherence ($t= -2.73$, $p = .01$).

**Conclusions:** Depression and anxiety play an important role in treatment adherence, a known predictor of medical outcome.

## SA-PO489

**NOTICE Initiative Post- versus Pre-Infection Control Evaluation (ICE) Results** Erik Roys, Natalie Scholz, Casey Parrotte, John Kalbfleisch, Rajiv Saran, Carol Chenoweth, Joseph M. Messana. *Univ of Michigan, Ann Arbor, MI.*

**Background:** The National Opportunity to Improve Infection Control in ESRD (NOTICE) project was designed to assess infection control practices at US dialysis facilities, to identify areas for quality improvement, and to reduce infections. Infection rates were measured before and after use of procedural and audit checklists, along with an on-site ICE.

**Methods:** Monthly NHSN vascular access-related infection (VAI), NHSN positive blood culture (PBC), and Medicare claims vascular access-related infection (ICD-9) data were collected from 34 facilities over 12 months with ICE visits occurring at 4-6 months. Generalized linear mixed models were used to assess changes in infection rates. Poisson models were used with log link and offset=log of the number of patients in the facility each month. Random effects for provider were included. The ICD-9 rates for NOTICE facilities were compared to controls matched on size, ownership, infection rates, and SES.

**Results:**

| Outcome | Pt mo. (Pre/Post) | Pre-ICE Visit Rate | Post-ICE Visit Rate | % Change | P-value |
|---|---|---|---|---|---|
| VAI | 134/185 | 1.42 | 0.98 | Post v Pre -28% | 0.01 |
| PBC | 134/185 | 0.88 | 0.69 | Post v Pre -17% | 0.23 |
| ICD-9 (NOTICE) | 162/240 | 2.53 | 2.12 | Post v Pre -18% | 0.03 |
| ICD-9 (NOTICE (N) & matched controls (C)) | 324/428 | N-2.53<br>C-2.31 | N-2.12<br>C-1.90 | Post vs. Pre -16%<br>N v C +9%<br>Interaction +1% | 0.04<br>0.65<br>0.92 |

The avg rates for all measures decreased from pre to post periods. VAI and ICD-9 rates were reduced by 28% and 18%, respectively. Differences were statistically significant ($p<0.03$). The reduction in PBC was not significant. When the change in ICD-9 rates were compared between NOTICE and control facilities, no difference was identified (RR=1.01, p=0.92).

**Conclusions:** Improvement in VAI and ICD-9 rates was statistically significant, and based on the pre post rates alone would suggest a marked improvement during the project. However, the ICD-9 rates showed similar declines in matched controls. The national decline in reported ICD-9 suggests that factors other than those included in NOTICE likely contributed to the pre-post changes reported here.

## SA-PO490

**Urgent-Start Peritoneal Dialysis: A Multicenter Clinical Trial** Arshia Ghaffari,[1,2] Tracey L. Milligan,[2] Mark H. Shapiro,[2,3] Michelle Cassin,[2] John E. Moran.[2,4] *[1]Nephrology, Univ of Southern California, Los Angeles, CA; [2]DaVita HealthCare Partners, Inc, Denver, CO; [3]Univ of California, San Diego, La Jolla, CA; [4]Nephrology, Stanford Univ School of Medicine, Stanford, CA.*

**Background:** Patients who present with advanced chronic kidney disease (CKD) in need of urgent dialysis are usually started on hemodialysis (HD), most commonly via a central venous catheter (CVC). Very few patients are given the option of peritoneal dialysis (PD) in this situation due to a number or issues, including nephrologists' unease and inexperience in urgently starting PD in unplanned, late-presenting patients. We initiated this study to demonstrate urgent-start PD can be safely applied in a protocol-driven, outpatient model.

**Methods:** Protocols were developed to standardize patient selection and management in the urgent-start period. Patients were provided with small-volume, in-center, supine PD thrice weekly less than two weeks after PD catheter placement. Catheters were placed by locally available methods.

**Results:** 181 patients (55% male, mean age 54 ± 16 years, 49.4% diabetic) started PD urgently at 36 facilities. 62.5% had received prior nephrology care. On average, PD was started in the outpatient facility 5.0 ± 3.2 days after PD catheter placement. 51 patients had a CVC placed and 50 had one or more HD treatments. 10 patients did not start PD within 14 days and were excluded from the analysis. With a mean follow-up of 6.8 months, 154 patients (90%) remain alive and on PD, 8 transferred to in-center HD (5 patient choice, 1 non-compliance, 1 bleeding during PD catheter insertion, 1 could not be trained for PD), 5 patients died (3 sudden cardiac deaths, 1 sepsis, and 1 liver cancer). 3 patients transferred to outside facilities while on PD, and 1 patient withdrew from dialysis.

**Conclusions:** This multi-center study demonstrates urgent-start PD can be broadly and successfully used in patients with advanced CKD in urgent need of dialysis in a structured, protocol-driven program. This management strategy allows patients the opportunity to choose PD as a modality. A major benefit is the avoidance of CVC use in many patients.

**SA-PO491**

**Peritoneal Dialysis First Policy of Thailand Brought about Much Higher Penetration Rate and Good Outcomes** Dhavee Sirivongs,[1] Piyatida Chuengsaman,[2] Siribha Changsirikulchai,[3] Adisorn Lumpaopong.[4] *[1]Renal Service Center, Srinagarind Hospital, Khon Kaen Univ, Khon Kaen, Thailand; [2]CAPD Service and Training Center, Banphaeo Hospital (Public Organization), Bangkok, Thailand; [3]Dept of Medicine, Srinakharinwirot Univ, Nakhon-Nayok, Thailand; [4]Phramongkutklao Hospital, Bangkok, Thailand.*

**Background:** Since October 2007, Thai government has provided PD first policy for non-health security population covering about 48 million people. This policy provides free of charge continuous ambulatory peritoneal dialysis(CAPD) for ESRD patients, so it has brought about rapidly increasing number of CAPD patients.

**Methods:** To analyze outcomes of CAPD treatment under the policy, we reviewed a first 60-month data from the 137 hospitals, 114 of them were new to CAPD, that recruited the patients during October 2007-September 2012.

**Results:** Total number of the registered patients was 19,464 cases, but only 15,211 cases actually received the treatment. Female to male ratio was 1:1.04, average age was 55.36 ± 14.3 years. Diabetes mellitus (DM) was found in 51.31%.Mean eGFR at the registered step was 8.01 + 5.0 ml/min. Drop-out rate was 3.47%: death in 30.10%, shift to HD 7.45 % and kidney transplantation 0.91%. Regarding causes of death, cardiovascular disease was the most common cause, only 10.96% of total death died from PD related peritonitis. The 1-year, 2-year, 3-year and 5-year patient survival rates were 82.1%, 66.3% 53.1% and 38.6% respectively. PD penetration was increased from 4% to 25% by 5 years of the policy. DM had significant negative impact to the survival ($p<0.05$).

**Conclusions:** PD first policy has markedly influence on patterns of treatment in Thailand, and saves a number of ESRD patients. Even most participating hospitals were new to CAPD, the outcomes of treatment are quite acceptable. The success of Thai PD-First policy is due to combination of strong policy, systematic manipulation, and good attitude of medical personnel to the treatment.

**Decreasing ESRD Patients' Hospital Length of Stay and Readmissions through Patient Centered Care Redesign Using Quality and Design Methods** Amy W. Williams, Kathryn Zavaleta, John J. Dillon, Mary Tibor, Susan Dornack, Mary Ann Ryan, Mark Nagele, Jerilyn Sue Wilson, Bradley D. Wick, Aaron Eckblad, Stephen F. Gudgell, Robert C. Albright. *Mayo Clinic, Rochester, MN.*

**Background:** In 2011 we began a quality and design methods approach to improve ESRD patient outcomes by creating high value patient-centered care across all settings. One aim was to decrease chronic dialysis patients' hospitalizations.

**Methods:** The multi-disciplinary team completed process mapping of current & future ideal states followed by small scale pilots and spread for in-center & home (PD & HD) dialysis patients (pts). Interventions included standardization of hospital care & hospital care team communication, roles and EMR tools, handoffs and transitions between care settings enhanced by consistent integrated flow of information, expansion of multidisciplinary care teams to include pharmacists and palliative care specialists, improved pt preference-focused education materials/decision aids for advanced CKD & ESRD, EMR alerts to all providers if GFR <25ml/min to consider CKD clinic referral and an evidence based practice CKD care algorithm electronically available for all providers. Hospitalization data was collected from the patients' medical records.

**Results:** The mean number of chronic dialysis pts per month cared for in the system from 2011 through YTD 2013 was 420.67 ± 15.50 pts/month. The number of in-hospital dialysis runs represented by quarter 1 data decreased each year: 2996 in 2011, 2032 in 2012, 1734 in 2013 (differences: 2011 vs. 2013, -1262 (-72.78%), 2012 vs. 2013, -298 (-14.67%)). Although end of year 2011 vs. 2012 data showed increased admission episodes in 2012 (508 vs. 543, +35 admissions (+6.89%)), length of stay decreased from 5.99 to 5.21 days (-0.78 days, -13.02%, $p=0.041$) and total pt hospital days decreased from 3043 to 2831 (-212 days, -6.97%). Total number of 30-day readmissions decreased 39.45% from 2011 to 2012 (difference in proportion of pts 23.6%, $p=0.000$).

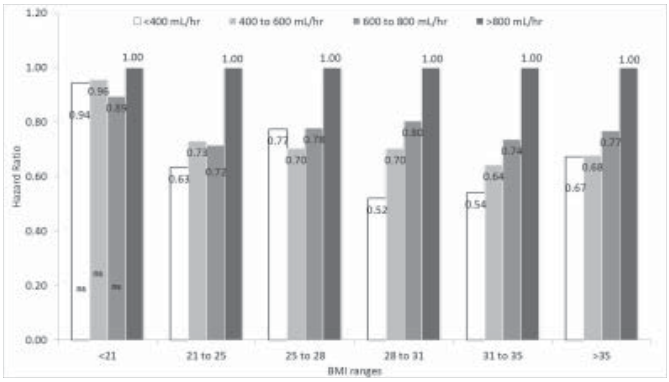
**Conclusions:** The use of quality and design methodology to redesign ESRD pt care to improve transitions of care and enhance pt focused care led to decreased total hospital days, length of stay and 30 day readmissions.

**SA-PO493**

**Higher Ultrafiltration Rates Are Associated with Greater Mortality at Higher BMI Levels** Len A. Usvyat,[1] Peter Kotanko,[2] Franklin W. Maddux,[1] Eduardo K. Lacson.[1] *[1]FMCNA, Waltham, MA; [2]RRI, NY, NY.*

**Background:** Higher ultrafiltration rate (UFR) during HD may be associated with poor survival. With the strong negative correlation b/n UFR and BMI observed by our group, we evaluated whether differences in survival persist if UFR is calculated in mL/hr within strata of BMI.

**Methods:** We studied incident HD patients in FMCNA who initiated dialysis b/n Jan 1, 2010 and Jan 31, 2013, tracking mortality until May 1, 2013. Only patients who survived first 90 days and with Kru<0.1 ml/min at initiation were included. The average UFR (in mL/hr) was computed in first 90 days. Patients were stratified into 4 groups of baseline UFR: <400, 400 to 600, 600 to 800, and >800 mL/hr and into 6 groups of BMI: <21, 21 to 25, 25 to 28, 28 to 31, 31 to 35, and >35 kg/m$^2$. Stratified Cox models adjusted for age, gender, DM status, race, ethnicity, and albumin levels were constructed to assess survival after the first 90 days in these 4 groups of UFR; in each analysis, UFR>800 was ref group.



**Results:** The study cohort consisted of 49,617 patients with mean age of 62.8±15.0, 54% male, 64% white, 63% DM and median survival follow-up of 304 (range 1-1126) days. All subgroups had >1000 patients except the group with BMI<21 and UFR of 800ml/hr (N=386). Except in patients with BMI<21, patients with UFR>800 mL/hr had consistently poorer outcomes than lower UFR ranges. Within each range of BMI>28, there was a gradient increase in the risk of death with increasing UFR (figure 1).

**Conclusions:** Higher UFR (in mL/hr) is associated with poorer outcomes at BMI>21 and there appears to be effect modification associated with BMI. Therefore, indexing UFR to body size requires further exploration, particularly with regards to gender/race. Although higher UFR is associated with worse mortality, the ultimate form and optimal threshold remains to be determined in future clinical trials.

**SA-PO494**

**Serum Phosphorus, Hemodialysis Social Networks, and Mortality Prediction** Avrum Gillespie,[1] Vladimir Ouzienko,[2] Heather Hammer,[3] Zoran Obradovic.[2] *[1]Nephrology, Hypertension, and Kidney Transplantation, Temple Univ School of Medicine, Philadelphia, PA; [2]Center for Data Analytics and Biomedical Informatics, Temple Univ, Philadelphia, PA; [3]SRBI, Silver Springs, MD.*

**Background:** Although the social diffusion and effects of healthy and unhealthy behaviors have been observed in studies of other chronic medical conditions, the characteristics of end stage renal disease patient social networks have yet to be well defined. Our study uses dietary and medication adherence measured by serum phosphorus correlations to demonstrate the existence of social links among hemodialysis patients and improve the accuracy of a mortality prediction model based on survey and medical record data.

**Methods:** A sample of 116 predominately African American patients receiving hemodialysis at two outpatient clinics in Philadelphia was divided into eight distinct groups based on the time and day of treatment. Patient interactions within groups were analyzed with social network methods, and a novel mortality prediction model was developed based on the discovered social links. Experiments validated the discovered social links and confirmed the contribution of the social network information to the accuracy of mortality prediction.

**Results:** Six of the eight social networks based on serum phosphorus were statistically significant with the highest network density (0.24) found in the Monday, Wednesday, Friday afternoon shift (t-value 5.97, Confidence 99.9%). Comparing the accuracy of our model to five alternative models showed that incorporating the social network data yielded the greatest predictive accuracy with an Area Under the Curve of 0.67 ± 0.02.

**Conclusions:** To the best of our knowledge ours is the only study to have modeled patient social networks within a hemodialysis clinic. We use phosphorus correlations to demonstrate the existence of social networks. Furthermore, we show that social link information improves mortality prediction.

**SA-PO495**

**Health-Related Quality of Life by Hemoglobin Status in Chronic Kidney Disease Patients Receiving Hemodialysis from 2010 to 2012** Carly J. Paoli,[1] Emmanuel A. Anum,[2] Akhtar Ashfaq,[1] Chris Evans,[3] Thomas Alfieri,[2] Matthew Gitlin.[1] *[1]Amgen, Thousand Oaks, CA; [2]DaVita Clinical Research, Minneapolis, MN; [3]Endpoint Outcomes, Boston, MA.*

**Background:** In 2011, reimbursement and regulatory changes in dialysis care altered treatment patterns and patient outcomes, possibly affecting health-related quality of life (HRQOL). This study examines HRQOL from 2010-2012.

**Methods:** This retrospective cohort study analyzed adult CKD patients on hemodialysis in a large US dialysis organization who completed the Kidney Disease Quality of Life (KDQOL)-36 survey in Quarter 1 of 2010, 2011, & 2012. Item scores were converted to a discrete scale from Likert-style responses and averaged over the cohort. Mean scores were stratified by Hemoglobin (Hb) status (Table) and assessed over the entire cohort (data not shown) and in patients whose Hb declined by ≥1g/dL (defined a priori) from 2010-2012.

**Results:** The cohort had 1017 patients; mean 2010 age was 60 yrs, vintage 3.70 yrs and 47% female. Mean(SD) Hb levels (g/dL) declined over time: 11.9(1.2) in 2010; 11.5(1.1) in 2011, 10.8(1.1) in 2012. Overall, patients had no changes in HRQOL, but for the 453 patients (45%) with Hb decline ≥1g/dL, mean scores by Hb category declined for many anemia-related items, items with most change shown in Table 1.

| Mean KDQOL-36 Item Scores: Patients With Hb Decline ≥1g/dL (n=453) | | | | | | | |
|---|---|---|---|---|---|---|---|

| **<8(n=0)** | | | | | | | |
| **≥8<9(n=0)** | | | | | | | |
| **≥9<10(n=1)** | 100 | 100 | 100 | 75 | 100 | 100 | 25 |
| **≥10<11(n=26)** | 42.3 | 42.3 | 53.8 | 76.9 | 76 | 69.2 | 58.7 |
| **≥11<12(n=144)** | 53.1 | 41.7 | 72.9 | 71.7 | 83.2 | 71.2 | 62.5 |
| **>12(n=282)** | 52.8 | 44.7 | 71.6 | 74.5 | 82.8 | 70.6 | 59.3 |
| **2012** | | | | | | | |
| **Mean** | **47.9** | **40.3** | **66.2** | **77.3** | **78.8** | **74.5** | **64.2** |
| **<8(n=2)** | 25 | 25 | 50 | 87.5 | 62.5 | 75 | 62.5 |
| **≥8<9(n=34)** | 44.1 | 33.8 | 64.7 | 86.8 | 73.5 | 78.7 | 75 |
| **≥9<10(n=135)** | 44.1 | 37 | 67.4 | 78.3 | 74.1 | 75 | 67.2 |
| **≥10<11(n=190)** | 49.7 | 41.8 | 63.7 | 74.2 | 82.1 | 72.5 | 62.2 |
| **≥11<12(n=87)** | 51.1 | 43.7 | 69 | 77.9 | 80.7 | 77 | 59.8 |
| **>12(n=5)** | 60 | 60 | 100 | 90 | 85 | 65 | 65 |
| Higher KDQOL-36 scores indicate better HRQOL. | | | | | | | |

**Conclusions:** Overall, HRQOL did not change from 2010-2012 in this cohort, but in the sub-sample of patients (45%) who had Hb declines ≥1 g/dL, HRQOL decrements were observed in several anemia-related items.

*Funding:* Pharmaceutical Company Support - Amgen, Inc.

## SA-PO496

**Associations of Race, Obesity and Diabetes on Risk of Attrition from the Kidney Transplant Waiting List** John C. Sieverdes,[1] David J. Taber,[2] Titte Srinivas,[2] John McGillicuddy,[2] Frank Treiber,[1,2] Kenneth Chavin,[2] Prabhakar Baliga.[2] *[1]College of Nursing, Medical Univ of South Carolina, Charleston, SC; [2]College of Medicine, Medical Univ of South Carolina, Charleston, SC.*

**Background:** This study examined the associated variables related to why patients become inactive on the kidney transplantation waiting list.

**Methods:** Between January 2006 and December 2010, 4,494 referrals to the center for evaluation for transplantation wait-list suitability were cross-sectionally examined.

**Results:** Thirty-four percent (n=1,531) who met eligibility requirements were placed on the waiting list. Follow-up analyses revealed that 489 (32%) patients subsequently had their status changed from active to inactive. Multiple medical comorbidities was the predominant factor for removal from the wait list (26%), followed by socioeconomic status (18%), and cardiovascular events (16%)(Figure 1). Binary logistic regression demonstrated that age at referral (p=0.05), diabetes status (p=0.04), marital status (p=0.02), and education (p=0.05) were independently associated with wait list inactivity. African American race (odds ratio [OR]: 1.34 [CI: 1.08-1.66]) and obesity (BMI ≥ 30 kg/m$^2$) (OR 1.60 [CI: 1.27-2.03]) were risk factors for having diabetes. Patients with diabetes had a 41% increased risk of becoming inactive (OR: 1.41 [95% CI: 1.31-1.77]), twice as likely to be inactive due to cardiovascular events (OR: 2.08 [CI: 1.27-3.41]), and 73% more likely to die while waiting for a kidney (OR: 1.73 [CI: 1.13-2.66]).

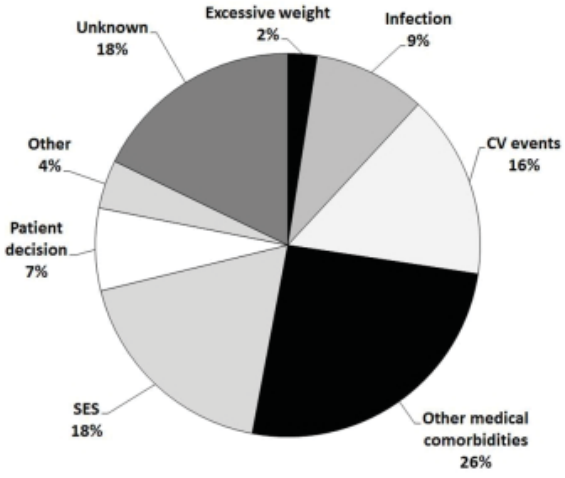

**Figure 1. Proportions for becoming inactive on the transplant list (n=489)**

**Conclusions:** These results demonstrate that obesity and race, which are well known risk factors for the development of diabetes, may indirectly increase the risk of being listed inactive or dying before receiving a kidney transplant. Future research should be focused on developing interventions to modify obesity rates in multiple socioeconomic and age-related areas.

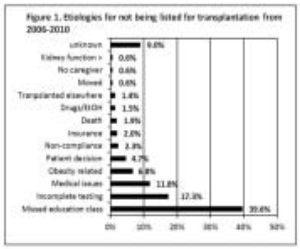
## SA-PO497

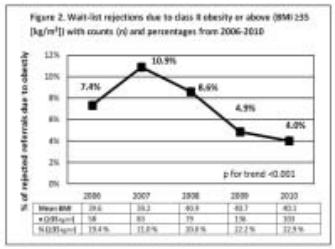
**Obesogenic Associations among End-Stage Renal Disease Patients Not Listed for Kidney Transplantation** John C. Sieverdes,[1] David J. Taber,[2] Kenneth Chavin,[2] John McGillicuddy,[2] Titte Srinivas,[2] Frank Treiber,[1,2] Prabhakar Baliga.[2] *[1]College of Nursing, Medical Univ of South Carolina, Charleston, SC; [2]College of Medicine, Medical Univ of South Carolina, Charleston, SC.*

**Background:** Rising obesity rates may be causing kidney transplant centers to shift their allowable BMI thresholds, which is a potential concern for successful outcomes. The purpose of this study is to examine the reported reasons end-stage renal disease (ESRD) referrals are not being listed for transplantation and to describe the rates of obesity at a large academic transplant program in the southeastern United States.

**Methods:** Between January 2006 and December 2010, there were 4,494 referrals who underwent evaluation for potential transplantation; 34% of which met eligibility and were placed on the waiting list, leaving 2,961 included in this cross-sectional analysis.

**Results:** The four predominant etiologies cited for not being initially listed over the 5-year period included missed education classes (39.5%), incomplete testing (17.3%), medical issues (11.8%), and obesity (6.8%) (Figure 1). Overall, the analysis demonstrated that even though a higher percentage of patients were presenting with class II obesity or above (body mass index (BMI) ≥ 35) in 2010 compared to 2006 ($X^2$,p=0.03), fewer patients were being rejected due to their BMI (p for trend <0.001) (Figure 2).





**Conclusions:** These results imply that the transplant community is extended the boundaries of weight-suitability in response to the obesity epidemic. Future studies are warranted to determine how this is impacting perioperative outcomes, quality of life, and graft and patient survival rates after transplant. Interventions promoting active lifestyle changes and weight management for ESRD patients should be used to manage these modifiable risk factors.

## SA-PO498

**Active Vitamin D and Nutrition Are Predictors of Infectious Diseases in Secondary Hyperparathyroidism of Uremia (SHPT) on Maintenance Hemodialysis Patients: Results from the MBD-5D Study** Yasuo Imanishi,[1] Ikue Kobayashi,[1] Masaaki Inaba,[1] Masafumi Fukagawa,[2] Tadao Akizawa,[4] Shunichi Fukuhara.[3] *[1]Osaka City Univ, Japan; [2]Tokai Univ, Japan; [3]Kyoto Univ, Japan; [4]Showa Univ, Japan.*

**Background:** Although nutrition is a significant predictor of mortality in dialysis patients, little is known about the role of nutrition in infectious diseases. This study examined the combination effects of nutritional status and intravenous (iv) vitamin D receptor activator (VDRA) administration on infectious diseases.

**Methods:** The Mineral and Bone Disorder Outcomes Study for Japanese CKD Stage 5D Patients (MBD-5D) is a multicenter, prospective observational study of hemodialysis patients with SHPT in Japan. This study is a subcohort of MBD-5D, and 2,022 prevalent patients, who were receiving hemodialysis for more than 3 months and met at least one of the following conditions: having intact PTH levels >180 pg/ml, or receiving iv vitamin D receptor activators (VDRAs) or oral VDRA analog, were employed. Nutritional status was assessed by Geriatric Nutritional Risk Index (GNRI) which was calculated using serum albumin, dry weight and ideal body weight. Patients were categorized into quartiles by GNRI and assessed the association between GNRI and infection related mortality or hospitalization.

**Results:** At follow-up time of 36 months, highest risks for both infection-related mortality and hospitalization were observed in the 1st GNRI quartile (poorest nutritional status). Time dependent Cox regression model revealed hazard ratio (HR) for the 1st GNRI quartile was 6.22 in mortality (95% confidence interval, 1.58- 24.45), and 1.85 in hospitalization (1.13- 3.02) in the iv VDRAs non-receiving group compared to the 4th GNRI quartile. In the iv VDRAs receiving group, these associations were not observed in mortality (HR 1.67, 0.83- 3.36) or in hospitalization (HR 1.07, 0.68- 1.67).

**Conclusions:** These results demonstrated that GNRI is a significant predictor for mortality in CKD-5D patients with SHPT. Administration of iv VDRA may have a preventive effect on the incidence of both infection related mortality and hospitalization in the patients with poor nutritional status.

*Funding:* Pharmaceutical Company Support - The MBD-5D study is supported by research grants from Kyowa Hakko Kirin co.,Ltd. without restrictions on publications.

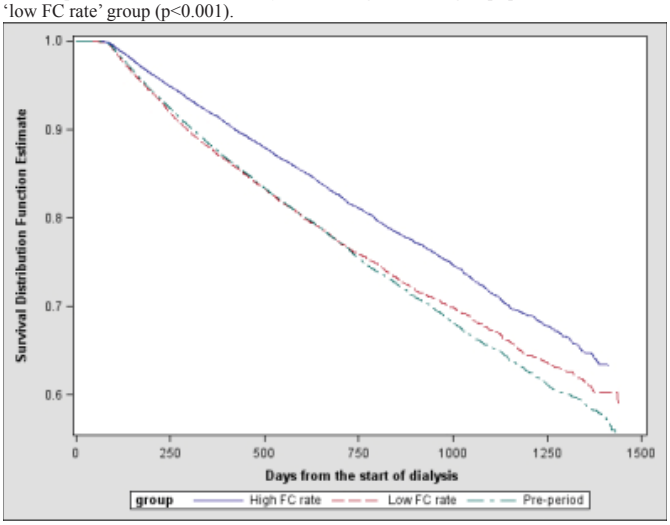
## SA-PO499

**Improvements in Survival and Major Amputations Observed with the Implementation of a Foot Check Program in Diabetic Hemodialysis Patients**
Andreja Marn-pernat,[1] Vanja Persic,[1] Len A. Usvyat,[2,3] John Rogus,[3] Franklin W. Maddux,[3] Eduardo K. Lacson,[3] Peter Kotanko.[2] *[1]Univ Medical Center, Ljubljana, Slovenia; [2]RRI, NY, NY; [3]FMCNA, Waltham, MA.*

**Background:** Diabetic HD patients (pts) are at high risk of lower limb amputations. In order to improve foot care in diabetic HD pts, monthly intra-dialytic foot checks [FC] were implemented as part of a standard clinic operating procedure in FMCNA clinics in January 2008 ['foot check program implementation date']. We aim to understand whether regular FCs are associated with reductions in major lower limb amputations and survival.

**Methods:** We compared incident diabetic HD pts before [pre-period;between 1/2004 and 12/2007] and after [post-period; between 1/2008 and 12/2011] FC program implementation. In post-period, we divided patients into those who are in clinics performing FC on >1/15 [high FC rate] or ≤1/15 [low FC rate] HD tx in diabetic pts. We employed Kaplan-Meier analysis to evaluate time to death. Poisson regression was constructed with # of major amputations.

**Results:** We studied 37624 pts in pre-period and 40651 pts in post-period. In latter cohort, 29335 were in 'high FC rate' group and 11316 were in 'low FC rate' group. Compared to pre-period, all-cause mortality decreased by 25% in 'high FC rate' group and 3% in 'low FC rate' group (overall log-rank test p<0.001, figure). The major lower limb amputation rate was reduced by 18% in 'high FC rate' group (p<0.001) and 16% in 'low FC rate' group (p<0.001).



**Conclusions:** Frequent FCs are associated with reduction of all-cause mortality and major amputations in diabetic HD pts (less frequent FC are associated with notably smaller reduction in mortality). Implementation of intra-dialytic FCs has a potential of saving lives and preventing major lower limb amputations. Further analyses should also check for overall reductions in mortality and amputation rates.

## SA-PO500

**Candidate Gene Analysis of Mortality in Dialysis Patients**
Gurbey Ocak,[1] Jeffrey J.W. Verschuren,[2] Carolien Rothuizen,[3,4] Friedo W. Dekker,[1] Ton J. Rabelink,[3,4] J.wouter Jukema,[2] Joris I. Rotmans.[3,4] *[1]Clinical Epidemiology, Leiden Univ Medical Center, Netherlands; [2]Cardiology, Leiden Univ Medical Center, Netherlands; [3]Nephrology, Leiden Univ Medical Center, Netherlands; [4]Einthoven Laboratory for Experimental Vascular Medicine, Leiden Univ Medical Center, Netherlands.*

**Background:** Dialysis patients have high mortality risks with cardiovascular mortality as an important cause of death. The aim of this study was to investigate the association between SNPs involved in vascular processes and mortality in a large population of incident dialysis patients.

**Methods:** We followed 1330 incident dialysis patients in which 42 SNPs in 25 genes involved in vascular processes (endothelial function and vascular remodeling, growth factors, inflammation, coagulation, and calcium/phosphate metabolism) were genotyped. Cox regression analysis was used to investigate the effect of these SNPs on five-years mortality.

**Results:** The mortality rate was 114 per 1000 person-years for the 1330 dialysis patients. We showed that vascular endothelial growth factor rs699947 (hazard ratio (HR) 1.48, 95% CI 1.14-1.92), vitamin D receptor rs2238135 (HR 0.58, 95% CI 0.35-0.94), interleukin 6 rs1800795 (HR 1.32, 95% CI 1.00-1.74), lymphotoxin alpha rs1799964 (HR 0.60, 95% CI 0.37-0.98) and CD180 rs5744478 (HR 2.27, 95% CI 1.07-4.79) were associated with an increased mortality risk.

**Conclusions:** In this large cohort of dialysis patient, we found that three SNPs related to inflammatory processes, one SNP involved in endothelial function, and one SNP related to vitamin D metabolism were associated with an increased mortality risk. This study provides further evidence for an important role of these processes in the comorbid conditions of dialysis patients. Future studies are warranted to unravel the underlying mechanisms responsible for the increased mortality in these patients.

## SA-PO501

**A Comorbidity Index for Outcome Analysis in Chinese Patients with End-Stage Renal Disease**
Jinn-Yang Chen. *Div of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan.*

**Background:** Chinese end-stage renal disease (ERSD) patients have different comorbidity patterns than Caucasian ESRD patients. We focused this study on the differential effects of these comorbidities on mortality in different populations and different dialysis modalities.

**Methods:** Records for patients who aged 20 years and older, started dialysis therapy between January 2006 and December 2009, and had received dialysis treatment for more than 90 days were reviewed for our study. Model was developed separately in peritoneal dialysis (PD) and hemodialysis (HD) patients. Integer weight of comorbid condition was derived from coefficient estimates of Cox regression for all-cause mortality, and the index was internally validated by data-splitting in 1000 simulations. The performance in discrimination, calibration and reclassification were assessed.

**Results:** 34371 patients were recruited for this study. Predictors for mortality and the weight for individual comorbid condition differed between PD and HD patients. Our index demonstrated the best model fit statistics and overall predictive ability in PD and HD patients. Although USRDS index did slightly better in discrimination (*c*-statistic = 0.644 and 0.766 in PD and HD), our index had the best calibration ability in PD patients (H-L test, $X^2 = 11.54$, $P = 0.17$) among 3 indices.

| | | AIC | $R^2$ | *c*-statistics | H-L Test |
|---|---|---|---|---|---|
| PD | Taiwan Index | 9093.74 | 0.457 | 0.630 | $X^2$=11.54, $P$=0.17 |
| | USRDS Index | 9148.4 | 0.431 | 0.644 | $X^2$= 59.07, $P$<0.0001 |
| | Charlson Index | 9108.83 | 0.451 | 0.636 | $X^2$= 33.61, $P$<0.0001 |
| HD | Taiwan Index | 163054.31 | 0.303 | 0.759 | $X^2$= 77.28, $P$<0.0001 |
| | USRDS Index | 163310.43 | 0.292 | 0.766 | $X^2$= 101.43, $P$<0.0001 |
| | Charlson Index | 163296.15 | 0.295 | 0.770 | $X^2$= 86.23, $P$<0.0001 |

Compared to USRDS index, our index significantly reclassified more patients to the right risk categories, with net reclassification improvements of 26.33 % ($P < 0.0001$) in PD and 14.57 % ($P < 0.0001$) in HD patients.

**Conclusions:** Our index improved the risk prediction for mortality in Chinese ESRD patients than other indices, especially in PD patients. External validation of this index is required.

## SA-PO502

**A Propensity Score-Based Comparison of Mortality in Patients on Hemodialysis and Peritoneal Dialysis in Korea: A National Population-Based Study**
Dong-Ryeol Ryu,[1] Hyunwook Kim,[2] Jung-hwa Ryu,[1] Seung-Jung Kim,[1] Duk-Hee Kang,[1] Kyu Bok Choi.[1] *[1]Dept of Internal Medicine, School of Medicine, Ewha Womans Univ, Seoul, Korea; [2]Dept of Internal Medicine, Wonkwang Univ College of Medicine Sanbon Hospital, Gunpo, Korea.*

**Background:** Given a lack of prospective randomized controlled comparison, there have been many debates whether the choice of dialysis modality affects mortality rate of end-stage renal disease (ESRD) patients. In this study, we aimed to compare survival of incident dialysis patients between hemodialysis (HD) and peritoneal dialysis (PD) using the Health Insurance Review & Assessment Service (HIRA) database, with the intention for a complete survey.

**Methods:** We included 32,280 adults who initiated dialysis from January 1, 2005 to December 31, 2008 and followed up (median 26.5 months, range of 3-59 months). An intention-to-treat analysis was performed both in a propensity score-matched cohort and in propensity score-adjusted multivariate model.

**Results:** We matched 7,049 patient pairs with similar propensity scores from each modality and compared survival rate, and found that there was a significantly higher mortality rate in PD patients compared to HD patients (log-rank test, $P < 0.001$). In addition, propensity score-adjusted multivariate Cox regression analysis including the entire participants was performed and showed a similar pattern (PD vs. HD, hazard ratio, 1.23; 95% confidence interval, 1.17-1.29; $P < 0.001$). Subsequent subgroup analyses according to various comorbidities revealed that in older patients (≥ 55 years), except only for the subgroup of patients having no comorbidities, PD was consistently associated with a higher mortality rate, whereas, in younger patients (< 55 years), regardless of comorbidities, the survival rate of PD patients was comparable to that of HD patients.

**Conclusions:** While overall mortality rate was higher in PD patients, mortality rate of PD patients aged over 55 years with no comorbidities or those aged less than 55 years was comparable to that of HD patients.

## SA-PO503

**Asymmetric Dimethyl-Arginine (ADMA), Race, and Mortality in Hemodialysis Patients** David A. Drew,[1] Hocine Tighiouart,[1] Tammy Scott,[1] Kristina Lou,[1] Li Fan,[1] Saeed Kamran Shaffi,[1] Mario Plebani,[2] Daniel E. Weiner,[1] Mark J. Sarnak.[1] *[1]Tufts Medical Center; [2]Univ Hospital, Padova-Italy.*

**Background:** Asymmetric dimethylarginine (ADMA) levels are elevated in kidney disease and associated with mortality in studies evaluating predominantly Caucasian and European hemodialysis (HD) populations. No studies have explored whether this association extends to African American (AA) hemodialysis patients.

**Methods:** ADMA levels were measured at baseline in 258 maintenance HD patients. Multivariable Cox proportional hazards models were used to evaluate the association of ADMA to all-cause mortality. An interaction between race and ADMA level was evaluated and subgroup analyses were performed.

**Results:** The mean (SD) age was 63 (17) years, 54% were women and 22% were African American, with the remaining participants predominantly Caucasian. Mean (SD) ADMA level in non-AA patients was 0.79 µmol/L (0.16) vs 0.70 µmol/L (0.11) in A-As (p <0.001). 132 deaths occurred over median follow up of 2.3 years, with death rates of 23.4 and 7.0 per 100 person years among non-AA and AA, respectively. Higher ADMA levels were associated with an increased risk of all-cause mortality (adjusted HR [95%CI] =1.24 per SD increase [1.03, 1.49]). An interaction was found between AA race and ADMA level (p value = 0.01), such that, when analyzed by race, higher ADMA levels were associated with increased mortality in non-AAs (adjusted HR =1.34 [1.10, 1.63]) but trended towards protective in AAs (adjusted HR =0.51 [0.25, 1.04]).

Association between 1 SD increase (0.16 µmol/L) in ADMA level and risk for all-cause mortality

| | Unadjusted HR (95% CI) | Model 1* HR (95% CI) | Model 2** HR (95% CI) |
|---|---|---|---|
| Total Cohort | 1.25 (1.06, 1.48) | 1.28 (1.07, 1.53) | 1.24 (1.03, 1.49) |
| African American | 0.65 (0.30, 1.44) | 0.66 (0.31, 1.40) | 0.51 (0.25, 1.04) |
| non-African American | 1.20 (1.01,1.42) | 1.33 (1.11, 1.60) | 1.34 (1.10, 1.63) |

*Model 1: Adjusted for age and sex
**Model 2: Adjusted for age, sex, dialysis vintage, cause of ESRD, vascular access type, history of cardiovascular disease, Kt/V, and albumin

**Conclusions:** African Americans have lower ADMA levels in comparison with non African Americans. High ADMA was a risk factor for mortality only in non African Americans. Given historically better survival among AA dialysis patients, these results need to be explored in larger, racially diverse studies, which will be able to investigate potential etiologies for this relationship.

*Funding:* NIDDK Support, Private Foundation Support

## SA-PO504

**Health Related Quality of Life in the Saudi Arabia Dialysis Outcomes and Practice Patterns Study (DOPPS)** Mohammed A. Al-Ghonaim,[1] Lindsay Zepel,[2] Jamal S. Alwakeel,[1] Ayman Karkar,[4] Fayez F. Alhejaili,[5] Haroun Zakaria Ahmed,[3] Saeed Mohammed G Al-ghamdi,[6] Faissal A. Shaheen,[3] Ronald L. Pisoni,[2] E.L. Cope,[2] Brian Bieber,[2] Bruce M. Robinson.[2,7] *[1]King Saud U.; [2]Arbor Research; [3]SCOT; [4]Kanoo Kidney Center; [5]King Fahad Nat. Guard Hosp.; [6]King Faisal Specialist Hosp.; [7]UofM.*

**Background:** This study provides the first comparison of quality of life and depression in hemodialysis (HD) patients (pts) in Saudi Arabia (SA) with that in 12 other countries in DOPPS 4 (2009-2011).

**Methods:** SA dialysis facilities (N=20) were randomly chosen to represent different SA regions, facilities, and types of SA pts. Physical component summary (PCS), mental component (MCS) summary and kidney disease burden (KDB) scores were based on patient responses to the Kidney Disease Quality of Life survey. The Center for Epidemiologic Studies Depression (CES-D) survey assessed patient-reported symptoms of depression.

**Results:** Among SA pts (N=318), mean age was 54 years, 58% were male. Age-adjusted mean MCS (44.1) and PCS (36.7) scores were similar to pts in other DOPPS countries. In SA: (1) PCS scores were higher among pts of younger age and male gender; diabetes, coronary heart disease, and catheter use related to lower PCS (2) MCS did not differ by gender but was higher for married pts, and was lower for pts >65 yrs old. Age-adjusted KDB scores in SA were among the highest in all 12 DOPPS countries, indicating a lower perceived burden of kidney disease upon a pt's life. In SA, being married was strongly related to higher KDB scores. Physician diagnosed depression (18%) and patient-reported symptoms of depression (42%) were similar in SA to most other DOPPS countries.

**Table 1a:** Saudi Arabia DOPPS: patient characteristics by age group

| Characteristic (mean ± SD) or % | Age (years) 18-45 | 46-55 | 56-65 | > 65 | All |
|---|---|---|---|---|---|
| Patients, N (%) | 93 (29) | 75 (24) | 72 (23) | 78 (25) | 318 |
| QoL measure | | | | | |
| PCS | 42.4 ± 11.2 | 39.5 ± 10.3 | 35.6 ± 9.7 | 33.4 ± 11.3 | 37.9 ± 11.2 |
| MCS | 44.0 ± 11.5 | 46.0 ± 12.3 | 44.7 ± 13.6 | 41.7 ± 12.2 | 44.1 ± 12.4 |
| KDB score | 43.6 ± 26.9 | 49.5 ± 26.4 | 44.8 ± 25.6 | 40.2 ± 23.3 | 44.4 ± 25.7 |
| Depression categories (%) | | | | | |
| Patient-Reported (CES-D ≥ 10) | 38 | 43 | 42 | 46 | 42 |
| Physician-Diagnosed | 16 | 19 | 18 | 22 | 18 |
| *Patient-Reported Pruritus (%) | 42 | 41 | 46 | 44 | 43 |

*Moderately to extremely bothered by itchy skin

**Table 1b:** Association between patient characteristics and patient-reported outcomes

| Characteristic | MCS score[A] | PCS score[A] | KDB score[A] | OR CESD ≥ 10 (vs. CESD <10)[B] |
|---|---|---|---|---|
| Male (vs. female) | +2.4 | **+4.9**** | +4.2 | 0.53 |
| Married (vs. not married) | **+3.5*** | +2.0 | **6.0*** | 0.71 |
| Vintage, years on dialysis (vs. 1-3) | | | | |
| < 1 | -4.5 | -0.6 | -7.3 | **2.05*** |
| 3-6 | -3.0 | **-4.8**** | -3.0 | 1.30 |
| > 6 | **-4.8*** | -0.5 | **-7.3*** | 0.93 |
| Diabetes (yes vs. no) | -0.7 | **-4.8**** | -0.7 | 1.13 |
| Coronary heart disease (yes vs. no) | -1.6 | **-3.2*** | -6.1 | 0.86 |
| Congestive heart failure (yes vs. no) | -3.9 | -2.6 | -0.7 | 0.84 |
| Serum creatinine > 9.4 mg/dl (vs. ≤ 9.4 mg/dl) | +1.6 | **+2.8*** | +4.9 | 1.17 |
| Hemoglobin > 11 g/dl (vs. ≤ 11 g/dl) | +0.5 | +1.0 | +1.8 | 0.86 |
| Catheter (vs. AVF or graft) | +1.4 | **-3.7*** | -2.4 | 1.29 |
| Treatment time > 208 minutes (vs. ≤ 208 minutes) | -0.4 | -0.03 | -3.2 | 0.57 |

All models adjusted for age and account for facility clustering; mean vintage in SA was 5.3 yrs.
[A]Estimates were obtained from separate linear mixed models with each QoL measure as the outcome; estimate indicates difference in score from referent group
[B]Odds ratios were obtained from separate logistic models; odds ratios indicate likelihood of depression (score ≥10) compared with the referent group
*0.01 ≤ p < 0.05; **p <0.01

**Conclusions:** Health related quality of life was similar in SA pts versus pts in 12 other DOPPS countries, despite notable differences in pt characteristics and HD practices across countries.

*Funding:* Pharmaceutical Company Support - The DOPPS is supported by research grants from Amgen (founding sponsor, since 1996), Kyowa Hakko Kirin (since 1999, in Japan), AbbVie (since 2009), Sanofi Renal (since 2009), Baxter Healthcare (since 2011), and Vifor Fresenius Medical Care Renal Pharma (since 2012), with additional country-specific support provided in Canada by Amgen-Canada, Janssen, BHC Medical, Takeda and Kidney Foundation of Canada, and in Germany by Hexal and WiNe Institute. Support from the DOPPS sponsors is provided without restrictions on publications.

## SA-PO505

**Survival among Elderly versus Younger Maintenance HD Patients – Results from the International MONDO Consortium Database** Matan J. Cohen,[1] Daniele Marcelli,[2] Len A. Usvyat,[3] Cristina Marelli,[4] Michael Etter,[5] Peter Kotanko,[3] Yosef S. Haviv,[1] Mondo Consortium.[3] *[1]Hadassah-Hebrew Univ Medical Center, Jerusalem, Israel; [2]Fresenius Medical Care-Germany; [3]Renal Research Institute, NY; [4]Fresenius Medical Care-Argentina; [5]Fresenius Medical Care-Asia Pacific.*

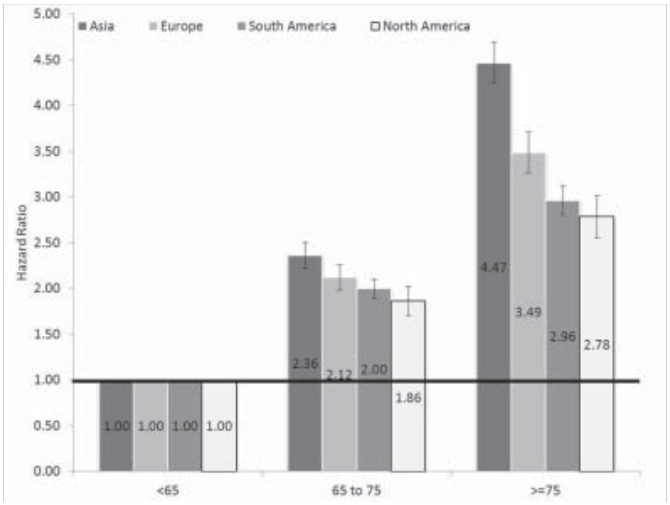
**Background:** The largest growing segment of hemodialysis (HD) patients is the elderly population. Previously the DOPPS III study described survival of elderly vs. younger HD patients (N=8,161) in 12 countries using age stratification of >45, 45-75 and >75-yr-old. In this study we evaluate the hazard ratio of elderly HD patients (≥75) vs. 65-75 vs. <65 in the MONDO international database (N=86,169).

**Methods:** The MONDO research initiative consists of HD databases from the US, Europe, Asia & Latin America [Usvyat, Blood Purif 2013]. We extracted data for all incident patients from RRI, FMC Europe, Latin America, and Asia Pacific between 2000 and 2012. Patients were stratified by age <65, 65-75, ≥75. Cox proportional hazards models were constructed for each database to assess the hazard ratio of death adjusted for gender, initial access type, race (for RRI only), and comorbidities (diabetes, cancer, cardiovascular and hepatitis).

**Results:** We studied 86,169 HD patients from 4 continents (Table):

| Continent | No. of Patients |
|---|---|
| South America | 20,880 |
| Asia | 12,521 |
| Europe | 41,698 |
| North America | 11,070 |
| Total | 86,169 |

In general, risk of death increased with age. In Asia, older patients had the highest hazard ratio of death vs. younger patients, compared to their counterparts in other continents. In the US, older patients had the lowest hazard ratio vs. younger patients (Figure):



**Conclusions:** The mortality hazard ratio of elderly vs. younger HD patients, within the same geographical region, varies across continents; It is highest in Asia and lowest in the US.

## SA-PO506

**Higher Mortality for Women Beginning Dialysis Treatment in the United States** Austin G. Stack,[1,2] Hoang Thanh Nguyen,[2] Ahad Abdalla,[1,2] Liam F. Casserly.[1,2] *[1]Nephrology and Internal Medicine, Univ Hospital Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick, Ireland.*

**Background:** Studies to date have yielded conflicting results on the survival of men and women who begin dialysis therapyin the US and may reflect differences in baseline comorbidity, differences in access to pre-dialysis care or differences in treatments following dialysis initiation. The overall goal of this study was to explore mortality differences between men and women who initiated dialysis from 1995-2008.

**Methods:** We identified 662, 985 men and 557, 015 women who commenced dialysis from 1995-2008 in the US Renal Data System. Baseline clinical health of patients was assessed at dialysis initiation and patients were followed from date of first dialysis to death and survival times were compared at the end of 2 years. Patients were censored at death, kidney transplantation, lost to follow-up or at the end of the study period. Mortality comparisons between men and women were stratified by race: White, Black, Asian and Native American. Adjustments were made for baseline clinical and laboratory health indicators, measures of pre-dialysis care and the timing of dialysis initiation. Ethical approval was received from the University Hospital Ethics Committee.

**Results:** Adjusted hazard ratios were significantly higher for White and Black women compared to White men and Black men respectively at follow-up. In contrast the hazard ratios of Asian and Native American women were similar to their male counterparts. White women experienced the highest overall risks.

| Race and Sex Group | Hazard Ratios for Death (HR) at 2 years | |
|---|---|---|
| | Unadjusted | Adjusted[2] |
| | **Unadjusted** | **Adjusted[2]** |
| White women (vs men) | 1.03 (1.02-1.03) | 1.07 (1.06-1.08) |
| Black women (vs men) | 1.15 (1.13-1.16) | 1.10 (1.08-1.12) |
| Asian Women (vs men) | 1.02 (0.98-1.05) | 1.02 (0.97-1.08) |
| Native Am. Women (vs men) | 1.05 (0.99-1.11) | 1.00 (0.92-1.10) |

| Race and Sex Group | Hazard Ratios for Death (HR) at 2 years | |
|---|---|---|
| | Unadjusted | Adjusted |
| White women (referent group) | 1.00 | 1.00 |
| Black women (vs white) | 0.69 (0.68-0.70) | 0.83 (0.82-0.84) |
| Asian Women (vs white) | 0.55 (0.54-0.57) | 0.65 (0.62-0.67) |
| Native Am. Women (vs white) | 0.62 (0.59-0.64) | 0.71 (0.67-0.76) |

**Conclusions:** Women experience higher mortality risks than men starting dialysis treatment in the US, with the greatest risks for white women. Differences in the severity of underlying disease or access to therapeutic interventions prior to or following dialysis onset may account for some of these differences and require further exploration.

## SA-PO507

**Factors Predicting Survival during the First 90 Days of Hemodialysis (HD): A Global Perspective** Adrian Marcos Guinsburg,[1] Cristina Marelli,[1] Daniele Marcelli,[2] Len A. Usvyat,[3,4] Michael Etter,[5] Peter Kotanko,[3] Mondo Consortium.[3] *[1]Fresenius Medical Care, Buenos Aires, Argentina; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]Renal Research Institute, New York, NY; [4]Fresenius Medical Care North America, Waltham, MA; [5]Fresenius Medical Care, Hong Kong, Hong Kong.*

**Background:** Mortality during first 3 months on HD may indicate predialysis care (preDC) and patient status at HD initiation. We aimed to analyze factors predicting survival in the first 3 months on HD in a large international sample of incident HD patients.

**Methods:** The MONitoring Dialysis Outcomes (MONDO) consortium was described previously [Usvyat, Blood Purif, 2013]. Incident HD patients between 01/2000 and 12/2010 were followed until day 90 or death. Cox reg models were constructed to identify factors associated with survival in the first 90 days.

**Results:** We studied 14,829 patients (Asia 4,277; Europe 3,083; LA 2,500; USA 4,969). HR (p value) of factors are summarized in table 1.

| | Asia | Europe | Latinamerica | USA |
|---|---|---|---|---|
| Age (yrs) | *1.03 (0.03) | *1.05 (<.0001) | *1.03 (<.0001) | *1.03 (<.0001) |
| Male (yes) | 0.97 | 0.88 | *0.73 (0.04) | 1.01 |
| Diabetic (DBT, yes) | *3.07 (<.0001) | 1.32 | 1.03 | 1.01 |
| Albumin (g/dL) | *0.48 (0.01) | *0.4 (<.0001) | *0.4 (<.0001) | *0.33 (<.0001) |
| Calcium (Ca, mg/dL) | 1.16 | 0.97 | 1.12 | *1.28 (0.006) |
| Hgb (g/L) | *0.83 (0.03) | *1.17 (0.02) | 1.02 | 1.05 |
| PO4 (mg/dL) | 1.01 | 1.09 | 1.07 | 0.96 |
| Pre-SBP (mmHg) | 1.001 | *0.98 (<.0001) | *0.99 (0.0004) | *0.98 (<.0001) |

*p<0.05

Age predicts mortality in all regions while gender (male) only in LA and DBT only in Asia.

Albumin was positively associated to survival in all regions and pre-SBP in all regions except Asia. Ca and PO4 showed no effect (exception of Ca in USA). The association of Hgb with mortality was heterogeneous: no association in LA and USA, positive association in Asia and negative in Europe.

**Conclusions:** Age, albumin and preSBP showed a similar pattern across regions suggesting an underlying biology independent of practice patterns and health policies. Ca, PO4 and Hgb showed variable effects possibly indicating differences in preDC and policies.

## SA-PO508

**Uninsured Unemployed and Insured Employed ESRD Patients Have Similar Mortality Outcomes** Paul L. Kimmel,[1] Chyng-Wen Fwu,[2] Jonathan Ratner,[3] Kevin C. Abbott,[4] Paul W. Eggers.[1] *[1]Div of Kidney, Urologic and Hematologic Diseases, NIDDK, NIH, Bethesda, MD; [2]Social & Scientific Systems, Inc., Silver Spring, MD; [3]Westat, Inc., Rockville, MD; [4]Walter Reed National Military Medical Center, Bethesda, MD.*

**Background:** Uninsured US adults in the general population have less health-care access and utilization, but analogous evidence on mortality is sparse and contradictory. Nearly all US ESRD patients have Medicare available. Whether health insurance status before Medicare entitlement due to ESRD varies with probability of death is unknown.

**Methods:** We included ESRD adult patients less than 65 years old from 2000-2008 US Renal Data System. To account for competing risks (transplantation and transfer to peritoneal dialysis [PD]), we used Fine-Gray sub-distribution proportional-hazards regression models, estimating cumulative incidence of death, controlling for known risk factors including residential income and income inequality parameters. Separate models by employment status were analyzed, because of a significant interaction between insurance and employment status.

**Results:** 274,921 patients were included. 23% were employed and 86% were insured (including private insurance, Medicare, and Medicaid) at ESRD onset. After follow-up (median 26.8 months), 110,373 (40.2%) patients died, 37,741 (13.7%) patients received renal transplant, and 14,079 (5.1%) started PD. Uninsured patients were younger, poorer, and healthier than the insured. Among the employed, the uninsured had higher mortality than the insured (sub-hazard ratio: 1.12, 95% confidence interval: 1.06-1.19). Among unemployed patients, the uninsured survived longer than the insured (0.84, 0.82-0.86).

**Conclusions:** As expected, in ESRD patients, mortality increases with unemployment. In the employed at ESRD onset, mortality increases with lack of insurance. Counterintuitively, in unemployed ESRD HD patients, lack of insurance is associated with improved survival. Selection bias - people with better perceived health opting to not buy insurance - may explain these surprising findings. In addition, entry into the ESRD program may differentially benefit the previously uninsured.

## SA-PO509

**Age, Race and Ethnicity, and Risk of Hospitalization among Patients Undergoing Hemodialysis** Guofen Yan,[1] Keith C. Norris,[2] Tom Greene,[3] Wei Yu,[1] Jennie Z. Ma,[1] Alfred K. Cheung.[3] *[1]Univ of Virginia; [2]Charles R. Drew Univ; [3]Univ of Utah.*

**Background:** Recent literature suggests overall hemodialysis (HD) mortality is lowest in Hispanics, intermediate in non-Hispanic blacks (blacks), and highest in non-Hispanic whites (whites), except for those under 30 years. Whether a similar pattern exists for hospitalization is unclear. We compared overall and age-stratified (18-30, 31-40, 41-50, 51-60, 61-70, 71-80, >80 yrs) hospitalization rates among the racial/ethnic groups.

**Methods:** We identified 563,281 (55% white, 33% black and 12% Hispanic) patients in the USRDS aged ≥18 yrs who initiated maintenance HD between 1995 and 2009, and survived the first 90 days, received in-center HD at day 91 for >60 days, with Medicare as primary payer. Hospital admissions and hospital days for all causes (AC), cardiovascular (CV), any infection, and dialysis-related infection (DRI) over one year were examined with Poisson regression.

**Results:** For both AC hospital days and admissions, unadjusted rates were highest in whites, intermediate in blacks, and lowest in Hispanics. After adjusting for various covariates, this pattern was evident only in the middle 2 age groups (51-60, 61-70 yrs), whereas among patients under 40 or above 70 years old, blacks had much higher rates than whites. Thus, the adjusted rate ratios (RRs) of blacks vs. whites exhibited a U-shaped relationship with age: RRs of 1.29 ($p<0.001$), 1.20 ($p<0.001$), 1.02 ($p=0.3$), 0.91 ($p<0.001$), 0.97 ($p=0.008$), 1.08 ($p<0.001$) and 1.22 ($p<0.001$) for the hospital days from younger to older groups. Hispanics consistently exhibited the lowest adjusted AC rates for all ages under 70 years (RRs ranging from 0.84 to 0.94 for the hospital days). However, hospitalization rates for DRI were consistently much higher in blacks than whites across all age groups, and higher in Hispanics than whites in age groups >60 yrs.

**Conclusions:** Our findings suggest that age modified the association of racial/ethnic factors with the overall and cause-specific hospitalizations. The delineation of the factors responsible for excess hospitalization rates among select subgroups may lead to reduced costs and improved quality of care for all dialysis patients.

*Funding:* NIDDK Support

## SA-PO510

**Association of Number of Comorbidities with Number of Readmissions** Eduardo K. Lacson, Weiling Wang, Franklin W. Maddux. *Fresenius Medical Care, North America, Waltham, MA.*

**Background:** Comorbidity influences hospital readmission rates in the general population. We evaluated the association between comorbid diagnoses and 30-day readmission rates in hemodialysis (HD) patients.

**Methods:** All adult HD patients, treated 3x/week on 1/1/11 in Fresenius Medical Care, North America facilities with ≥1 hospital discharge in 2011 were included and readmissions tracked until 12/31/11. Case-mix (age, gender, race, diabetes, vintage, access type) and lab variables as well as 23 comorbidity categories from the Medicare Dialysis Facility Reports were recorded as of 1/1/11. The frequency of comorbidities was counted per patient among 16 categories identified by univariate logistic models to associate with readmission rate and assigned into groups: 0, 1, 2, 3, >3 (Table). Poisson regression was used to assess the association between number of comorbidities & readmissions.

| Number of Comorbid Diagnoses | Patient N | Patient % | % Readmission Rate |
|---|---|---|---|
| 0 | 12194 | 19.0 | 32.4 |
| 1 | 18095 | 28.2 | 34.1 |
| 2 | 14565 | 22.7 | 37.7 |
| 3 | 10016 | 15.6 | 39.1 |
| >3 | 9258 | 14.4 | 43.8 |

**Results:** In 2011, 64,128 HD patients were hospitalized: mean age of 62.8±14.5 years, 52.5% male, 55.6% white, 39.3% black,and 28.8% HD catheters. Dialysis vintage was 3.8±3.7 years and the mean number of comorbidities was 1.9±1.5 (IQR: 1-3, median: 2). 50,380 readmissions occurred with mean of 0.79 ±8.1 (median: 0) per patient. Readmission rate increased by 8% for each additional comorbid diagnosis ($p<0.0001$). Compared to no comorbidity, the rate of readmission with 2 comorbidities increased by 23% and by 45% for >3 (all $p<0.0001$). Results were similar after case-mix & lab adjustment.

**Conclusions:** Comorbidity is a significant risk factor for 30-day readmission. Further study is needed to determine potentially actionable attributes of specific comorbid diagnoses that contribute to both specific and all causes of readmissions. Patients with multiple comorbidities will need to be considered in performance measure development to avoid unintended consequences such as selection bias that may limit subsequent access to care.

## SA-PO511

**Impact of Target Parathyroid Hormone (PTH) Range and Risk of Fractures in End-Stage Renal Disease (ESRD)** Chi-yuan Hsu,[1] David V. Glidden,[1] Jeffrey R. Curtis,[2] Barbara A. Grimes,[1] Linda McCann,[3] Brigitte Schiller,[3] Kirsten L. Johansen.[1] *[1]Univ of California, San Francisco; [2]Univ of Alabama, Birmingham; [3]Satellite Healthcare.*

**Background:** The optimal target range for PTH levels in hemodialysis (HD) patients is unclear. In the absence of randomized controlled trial data, "natural experiments" such as changes in protocol PTH target range implemented across a dialysis organization (in response to expert guidelines) regardless of individual patient characteristics may provide estimates of treatment effect that are relatively un-confounded.

**Methods:** We studied fracture risk among in-center maintenance HD patients treated at Satellite Healthcare, a non-for-profit dialysis organization, which has a uniform mineral metabolism protocol across all its dialysis facilities. The target PTH range was 150-300 pg/ml from April 2003-Jan 2005 and 150-400 after Feb 2005. We followed patients who had Medicare as their primary insurance starting Jan 2003. Using US Renal Data System data and time varying Cox regression analysis, we assessed the impact of changes in PTH target on rates of fracture. Fractures were identified using ICD-9 codes 820.x and 733.14 for hip, 813.x, 733.12, 812.x, and 733.11 for radius/ulna, 805.x, 806.x and 733.13 for spine and 814.x for wrist/carpal after 6-month lag. Outcomes were ascertained through Dec 2009 or 3 months after transfer out of a Satellite dialysis unit (for transplant or other reasons).

**Results:** We observed 36 factures over 1786 person-years of follow-up (2.0 per 100 person-yrs) when the target PTH was 150-300 pg/ml and 150 fractures over 6563 person-years of follow-up (2.3 per 100 person-yrs) when the target PTH was 150-400 pg/ml. The hazard ratio (HR) for 150-400 (vs. 150-300 pg/ml) was 1.04 (95% CI 0.71-1.53; $p=0.83$). Similar results were seen after controlling for demographics and comorbid conditions known to be fracture risk factors (adjusted HR 1.17; 95% 0.78-1.74; $p=0.45$).

**Conclusions:** Raising the upper limit of target PTH range from 300 to 400 pg/ml did not appear to be associated with significantly higher risk of fractures in maintenance HD patients, although confidence intervals were relatively wide.

## SA-PO512

**Relative Impact of Selected Indicators on Mortality: Results from the Dialysis Outcomes and Practice Patterns Study (DOPPS)** Francesca Tentori,[1] Lindsay Zepel,[1] Angelo Karaboyas,[1] David C. Mendelssohn,[2] T. Alp Ikizler,[3] Brenda W. Gillespie,[4] Werner Kleophas,[5] Brian Bieber,[1] Ronald L. Pisoni,[1] Bruce M. Robinson.[1] *[1]Arbor Research; [2]Humber River Regional Hosp.; [3]Vanderbilt U.; [4]U. of Michigan; [5]Dialysezentrum Karlstrasse.*

**Background:** The proportion of facility patients meeting a clinical target is often used as an indicator of quality of care ("quality indicator"). Achievement of targets varies for different markers. The impact of quality indicators on outcomes is likely greater for indicators that are highly prevalent and have a strong association with mortality. We aim here to assess the proportion of deaths that could have been prevented by achievement of selected quality indicators.

**Methods:** We analyzed 15,118 hemodialysis patients from 539 facilities in DOPPS 3 (2005-08) and 4 (2009-11) in North America, Europe, Australia and New Zealand. Quality indicators were based on guidelines during the study period. In prior work, the 4 quality indicators included had the strongest association with mortality. The proposed goal was chosen based on observed distribution and clinical judgment about feasibility. Using an adjusted Cox model, we calculated the attributable fraction (AF) as the predicted reduction in number of deaths if facilities below the goal were set counterfactually to the target goal.

**Results:** Achievement of the quality indicators varied widely, with higher % of facilities not meeting the albumin and fistula guidelines. The AF ranged from 3.2% (for albumin) to 9.5% (for fistula use), with a cumulative AF of 23.4% (Table 1).

**Table 1**: Distribution of facility quality indicators and attributable fractions

| Quality indicator | Observed facility % of patients achieving indicator: (median [IQR]) | Proposed goal* | % of facilities below goal | AF** |
|---|---|---|---|---|
| Kt/V ≥ 1.2 | 90% (83%-95%) | 100% | 85% | 8.3% |
| Hemoglobin ≥ 10 g/dl | 92% (87%-96%) | 95% | 68% | 4.7% |
| Albumin ≥ 4 g/dl | 34% (17%-47%) | 40% | 60% | 3.2% |
| Fistula use | 67% (52%-79%) | 85% | 87% | 9.5% |
| **Cumulative AF** | | | | 23.4% |

*Goal = proposed % of facility patients to achieve the quality indicator
**The AF for mortality was adjusted for patients, demographics, comorbidities, all quality indicators shown, and the 4 additional quality indicators: IDWG < 5.7%, phosphorus 3.5-5.5 mg/dl, calcium 8.4-9.5 mg/dl, RAS inhibitor use; AF was averaged across 5 imputed datasets.

**Conclusions:** Though these results cannot establish causality, they indicate that ~23% of deaths could be prevented if all facilities below the Kt/V, hemoglobin, albumin, and fistula targets improved to the proposed goals. Increasing the facility % of patients with Kt/V ≥ 1.2 or fistula may yield the greatest improvement in mortality.

*Funding:* NIDDK Support, Pharmaceutical Company Support - The DOPPS is supported by research grants from Amgen (founding sponsor, since 1996), Kyowa Hakko Kirin (since 1999, in Japan), AbbVie (since 2009), Sanofi Renal (since 2009), Baxter Healthcare (since 2011), and Vifor Fresenius Medical Care Renal Pharma (since 2012), with additional country-specific support provided in Canada by Amgen-Canada, Janssen, BHC Medical, Takeda and Kidney Foundation of Canada, and in Germany by Hexal and WiNe Institute. ## SA-PO513

**End Stage Renal Disease due to HIVAN in the United States 2000-2010** Donal J. Sexton,[1,2] Scott Reule,[1,2] Craig Solid,[1] Shu-cheng Chen,[1] Allan J. Collins,[1,2] Robert N. Foley.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, Univ of Minnesota, Minneapolis, MN.*

**Background:** The management of HIV has changed considerably in the last decade, and the effect of contemporary treatment on the standardized incidence of end stage renal disease (ESRD) due to HIV has not been characterized.

**Methods:** We combined US census data with data from the USRDS patients to determine whether incidence rates and outcomes of ESRD due to HIV associated nephropathy (HIVAN) have improved simultaneously with improvements in the management of HIV.

**Results:** 8839 of 1,141,026 (0.8%) patients initiated dialysis due to HIVAN between 2000 and 2010. Using incidence rates for 2000 to calculate expected rates for subsequent years (based on age, sex and race/ethnicity), standardized incidence ratios remained unchanged between 2000 and 2003 and then declined to 0.66 in 2010. Characteristics of HIVAN patients included residence in the South (59.5% vs. 41.5% in non-HIVAN), age < 45 yrs (55.7% vs. 13.1%), male sex (66.9% vs. 55.3%), African American race (87.6% vs. 28.3%), catheters for hemodialysis (90.9% vs. 82.5%), nephrology care < 1 year (90.9% vs. 76.4%), and body mass index < 18.5 kg/m$^2$ (12.2% vs. 4.4%). HIVAN was associated with a greater likelihood of failure to be listed for transplant (adjusted hazard ratio [AHR] 4.55), failure to receive a transplant (AHR 6.67) and death (AHR 2.53). Among patients with HIVAN, while mortality (AHR for 2005-2010 0.94 vs. 2000-2004) and non-listing declined (AHR 0.76), non-transplantation increased (AHR 1.50). Regional variation in outcomes was apparent, with HIVAN patients in the South having higher risks of non-listing (AHR 1.52 vs. the Northeast), non-transplantation (AHR 1.96) and death (AHR 1.17).

**Conclusions:** While ESRD due to HIV has declined in the United States in the last decade, associated outcomes remain poor and exhibit substantial regional heterogeneity.

*Funding:* NIDDK Support

## SA-PO514

**End Stage Renal Disease due to Lupus Nephritis in the United States 2000-2010** Donal J. Sexton,[1,2] Scott Reule,[1,2] Craig Solid,[1] Shu-cheng Chen,[1] Allan J. Collins,[1,2] Robert N. Foley.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, Univ of Minnesota, Minneapolis, MN.*

**Background:** Despite advances in the treatment of lupus nephritis (LN), the impact of these developments on the standardized incidence of ESRD due to LN in recent years has not been defined.

**Methods:** We combined US census data with data from the USRDS patients to determine whether incidence rates and survival of ESRD due to LN have improved in parallel with developments in treatment.

**Results:** 11,612 of 1,127,050 (1.0%) patients initiated dialysis due to LN between 2000 and 2010. Using incidence rates for 2000 to calculate expected rates for subsequent years (based on age, sex and race/ethnicity), standardized incidence ratios peaked in 2007 at 1.01, declining subsequently to 0.85 by 2010. Characteristics of ESRD due to LN included age < 40 yrs (53.7% vs. 8.4% in non-LN), female sex (81.5% vs. 44.3%), African American race (50.2% vs. 28.6%), catheters for hemodialysis (89.4% vs. 82.5%), and nephrology care > 1 year (30.5% vs. 23.4%). LN was associated with a lower likelihood of death (adjusted hazard ratio [AHR] 0.99) and a higher likelihood of listing for (AHR 1.58) and receiving a renal transplant (AHR 1.32). Among patients with LN, mortality did not change over time (AHR for 2005-2010 0.99 vs. 2000-2004), and although the likelihood of listing increased (AHR 1.36), transplantation actually decreased (AHR 0.9). Regional variation in outcomes was substantial, with LN patients in the South having lower survival (AHR 0.82 vs. the Northeast) coupled with a higher likelihood of non-listing (AHR 1.39) and non-transplantation (AHR 1.32).

**Conclusions:** ESRD due to LN in the United States has declined in the last decade, however significant regional variation exists in terms of LN patient outcomes.

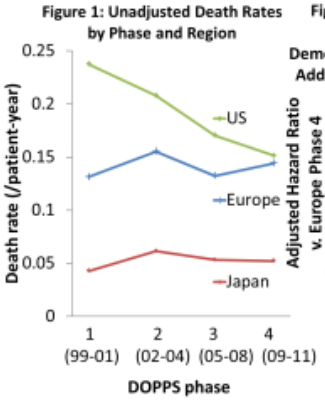
## SA-PO515

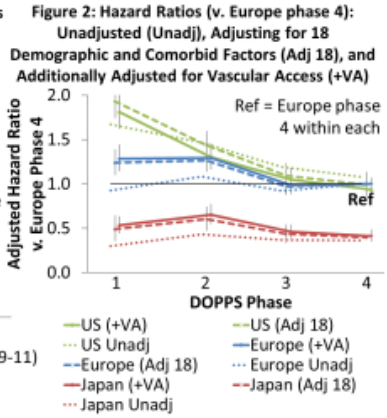
**International Mortality Trends among Hemodialysis Patients in the DOPPS** Keith McCullough,[1] Hugh C. Rayner,[2] David A. Goodkin,[1] Hal Morgenstern,[3] Friedrich K. Port,[1] Michel Y. Jadoul,[5] Akira Saito,[4] Ronald L. Pisoni,[1] Bruce M. Robinson.[1] *[1]Arbor Research Collaborative for Health; [2]Heart of England; [3]U. of Michigan; [4]Yokohama Dai-ichi Hospital; [5]U. of Louvain Medical School.*

**Background:** Case-mix-adjusted mortality rate in DOPPS has been higher in the US than in Europe or Japan. Patient population and clinical practices have changed over time. We are evaluating the effects of case mix and practice patterns on trends in mortality rates across three regions.

**Methods:** 1999-2011 DOPPS data from hemodialysis facilities in France, Germany, Italy, Japan, Spain, the UK, and the US were used to assess trends in mortality rates. Cox models with covariates for age, sex, vintage, 15 comorbid factors, and vascular access type among 29,660 patients selected from prevalent cross-sections within each phase were fitted to estimate adjusted hazard ratios (HR).

**Results:** The unadjusted death rate in the sample over phases 1-4 has fallen in the US (HR/phase=0.86; 95% CI 0.83-0.88), and has been stable in Europe (1.00; 0.97-1.04) and Japan (1.01; 0.95-1.08). [Figure 1] After phase 1, the HR/phase (unadjusted, case-mix adjusted (adj 18), and adjusted for vascular access (+VA)) were: in the US=(0.85*,0.82*, 0.83*), in Europe=(0.96^,0.88*, 0.86*) and in Japan=(0.93^,0.77*, 0.76*) (^p>0.1,*p<0.001). Mortality rates in Japan were lowest in all phases (p<0.0001). Adjustment for vascular access (+VA) explained some of the difference in the mortality rate between the US and Europe [Figure 2].





**Conclusions:** After phase 1, US and European trends in adjusted mortality have been similar. Differences in vascular access practices partly explain lower mortality rates in Europe v. US, but further investigation is needed to determine other reasons for patient-mix-adjusted differences in mortality rates over time and between regions.

*Funding:* Pharmaceutical Company Support - The DOPPS is supported by research grants from Amgen, Kyowa Hakko Kirin, AbbVie, Sanofi Renal, Baxter Healthcare, and Vifor Fresenius Medical Care Renal Pharma, with additional country-specific support provided in Canada by Amgen-Canada, Janssen, BHC Medical, Takeda and Kidney Foundation of Canada, and in Germany by Hexal and WiNe Institute. Support from the DOPPS sponsors is provided without restrictions on publications.

## SA-PO516

**Estimated GFR at Dialysis Initiation: Associations with Clinical and Non-Clinical Factors** Yun Li,[1,2] Alissa Kapke,[2] Yan Jin,[2] Jeffrey Pearson,[2] Friedrich K. Port,[2] Bruce M. Robinson.[2] *[1]Univ of Michigan; [2]Arbor Research Collaborative for Health.*

**Background:** The average estimated glomerular filtration rate (eGFR) at dialysis start has continued to increase in the US. Our objectives are to examine the predictors of eGFR at dialysis start and its change over time.

**Methods:** The US Renal Data System ESRD database was used to identify 242,957 patients who initiated dialysis between 2006 and 2009, treated by 8,470 physicians and had complete information on variables of interest. Separate random effect models are used to model eGFR and its change over time (2006-2009).

**Results:** The eGFR at dialysis initiation averaged 10.9 (SD=4.6), rising by 0.5 from 2006 to 2009. On average, patients who were younger, female, uninsured, had fewer comorbidities, initiated dialysis in larger or free standing facilities, and/or in counties with higher poverty rates or lower education levels (Table 1) started dialysis at lower eGFR. The increase in eGFR at dialysis start was significantly steeper among patients who were non-Hispanic whites, received no prior nephrology care, and treated in hospital-based facilities or counties with less poverty (Table1). The mean eGFR and its change over time also varied significantly by geography (ESRD Network). Between-physician variation accounted for 10% of the total variation in eGFR at initiation. The total variation was reduced by 14% after adjusting for measured patient characteristics and by an additional 4% after further adjustment of facility/county contextual factors.

**Conclusions:** Analysis of national US data indicates that the majority of variation in eGFR at dialysis initiation occurrs at the patient level, though most is unexplained by measured variables in this dataset. Later initiation is correlated with some variables indicative of barriers in access to dialysis.

Table 1. Characteristics Associated with eGFR at Dialysis Start (2006-2009) and eGFR change over time

| | | | eGFR[a] Estimate | eGFR Change over Time[a] Slope |
|---|---|---|---|---|
| Patient-level | Age, per 10 years | | **0.17** | 0.037 |
| | Race/Ethnicity (vs. NH White) | Black | **0.14** | **-0.11** |
| | | Other | **-0.49** | **-0.27** |
| | Employment Status (vs. Unemployed) | Employed | **-0.76** | 0.014 |
| | | Other/Unknown | **-0.12** | 0.024 |
| | Any insurance (vs. No) | | **0.73** | 0.17 |
| | Prior nephrology care (vs. No) | | **-0.28** | **-0.14** |
| Facility-level | Free Standing Facility (vs. Hospital-based) | | **-0.12** | **-0.28** |
| | Facility-size | | **-0.034** | **0.004** |
| County-level | % Below Poverty, per 5% | | **-0.038** | **-0.088** |

a: Adjusted for listed variables and **year, sex, comorbid conditions**, cause of ESRD, **albumin, hemoglobin, modality, ESRD Network**, nurse to patient ratio, **facility size** and type (profit vs. non-profit and **urban vs. rural**), %high school graduates, and physician clustering. Bolded variables indicate p<0.05 in the adjusted model for eGFR. b: Estimate indicates average change in 4-year slope of eGFR for each listed variable after adjustments in a.

## SA-PO517

**Time Trends in the Association of Influenza Vaccination (IV) with Mortality and Hospitalization in U.S. Medicare Dialysis Patients (2006-2011)**

E.L.Cope,[1] K.A. Wisniewski,[2] M. Curran,[1] Bruce M. Robinson,[1] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]KECC, Univ of Michigan, Ann Arbor, MI.*

**Background:** To assess the stability of the association between IV and improved health outcomes, we examined the association between facility-level IV and all-cause mortality and hospitalization over 5 seasons.

**Methods:** We examined 5 seasons (2006-2007 thru 2010-2011). Each season included Medicare ESRD patients on dialysis Oct 1-Dec 31. Vaccinations were counted using Medicare claims from any setting between Aug 1-Dec 31. Poisson regression was used to assess the relationship of facility IV rate with outcomes in the following year via each facility's standardized mortality (SMR) and hospitalization (SHR) ratios. Models were adjusted for facility and patient characteristics.

**Results:** Median facility IV rates fluctuated from 67.6%-71.1%. Facility IV rate was inversely associated with relative risk of mortality and hospitalization for all 5 seasons (Table 1). For mortality, the association was strongest during the 2006-2007 season (2.3% lower SMR per 10% higher facility IV rate, p<0.01), and weakest during the 2010-2011 season (0.8% lower SMR per 10% higher facility IV rate, p<0.01). The association between facility IV rate and hospitalization was relatively stable over time (1.6-2.2% lower SHR per 10% higher facility IV rate, all p<0.01).

Table 1. Mean facility SMR and SHR by percent of facility patients vaccinated against influenza.

| % Facility Patients Vaccinated (Quintiles) | 2006-2007 | 2007-2008 | 2008-2009 | 2009-2010 | 2010-2011 |
|---|---|---|---|---|---|
| Mean SMR | | | | | |
| 0-47.0 | 1.07* | 1.07* | 1.05* | 1.06* | 1.06* |
| 47.1-61.5 | 1.05* | 1.01 | 1.02 | 1.05* | 1.02 |
| 61.6-70.5 (Ref) | 1.00 | 1.00 | 1.00 | 1.00 | 1.00 |
| 70.6-78.0 | 0.96* | 0.97* | 0.99 | 1.00 | 1.01 |
| 78.1-100 | 0.93* | 0.92* | 0.97* | 0.97* | 0.99 |
| Mean SHR | | | | | |
| 0-47.0 | 1.08* | 1.05* | 1.07* | 1.05* | 1.06* |
| 47.1-61.5 | 1.04* | 1.04* | 1.07* | 1.06* | 1.05* |
| 61.6-70.5 (Ref) | 1.00 | 1.00 | 1.00 | 1.00 | 1.00 |
| 70.6-78.0 | 0.96* | 0.95* | 0.95* | 0.97* | 0.97* |
| 78.1-100 | 0.92* | 0.92* | 0.91* | 0.92* | 0.94* |

*p < 0.05

**Conclusions:** An IV performance gap remains with 29% of patients appearing not to be vaccinated in 2010. However, this may be an overestimate due to underreporting of IV in the claims. Associations between facility IV rate and lower hospitalization appeared robust across seasons, whereas those with mortality were less stable and suggest a more modest effect than previously published. Variation in vaccine efficacy and seasonal severity may contribute to fluctuations in the associations over time.

*Funding:* Other U.S. Government Support

## SA-PO518

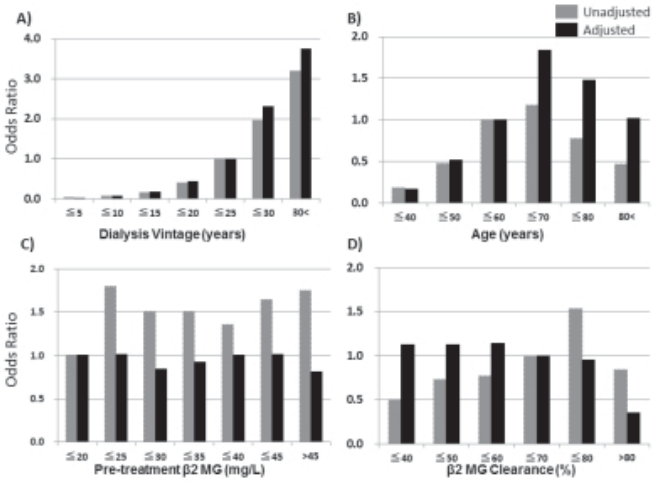
**Recent Risk Factors Associating with Development of Dialysis-Related Amyloidosis: A Nationwide Analysis from Japanese Dialysis Patient Registry**

Junichi Hoshino,[1] Kunihiro Yamagata,[2] Ikuto Masakane,[3] Shinichi Nishi,[4] Kunitoshi Iseki,[5] Yoshiharu Tsubakihara.[6] *[1]Nephrology Center, Toranomon Hospital, Tokyo, Japan; [2]Univ of Tsukuba, Ibaraki, Japan; [3]Yabuki Hospital, Yamagata, Japan; [4]Kobe Univ Graduate School of Medicine, Hyogo, Japan; [5]Univ Hospital of Ryukyus, Okinawa, Japan; [6]Osaka General Medical Center, Osaka, Japan.*

**Background:** The aim of this study was to clarify recent risk factors associated with development of dialysis-related amyloidosis, with risk of carpel tunnel syndrome operation (CTS) as a proxy.

**Methods:** The cohort consisted of 166,237 patients on dialysis (mean age, 66.1±12.4 years) who could be followed for a year between 2010 and 2011. Of these,2,275 (1.37%) needed a new CTS. Logistic regression was used to calculate adjusted odds ratios (OR) and 95 % confidence intervals (95% CI) for new CTS, after adjusting patient's backgrounds and dialysis factors.

**Results:** Adjusted OR (aOR) for dialysis vintage (vintage) 10-15, 15-20, 20-25, 25-30, and over 30 years were, respectively, 0.18 (0.12-0.26), 0.44 (0.31-0.62), 1.00 (referent), 2.32 (1.60-3.34), and 3.76 (2.43-5.82). The aOR for ages 40-50, 50-60, 60-70, 70-80, and over 80 were 0.52 (0.29-0.92), 1.00, 1.84 (1.38-2.46), 1.48 (1.05-2.08), and 1.01 (0.59-1.75), respectively. In addition, female , low serum albumin, and diabetic nephropathy were factors associated with new CTS. On the other hand, the pre-treatment β2-microglobulin (β2MG) and β2MG clearance less than 80 % were not significant, although β2MG clearance more than 80% was negatively associated with new CTS (OR 0.35 [0.13-0.92]).



**Conclusions:** The OR of new CTS almost doubled every 5 years vintage increased. The OR of CTS was highest for patients aged 60-70. The other factors associated with new CTS were gender, serum albumin, and diabetic nephropathy. β2MG clearance over 80% may decrease new CTS.

## SA-PO519

**End-Stage Renal Disease from Autosomal Dominant Polycystic Kidney Disease in the United States, 2000-2010**

Scott Reule,[1,2] Donal J. Sexton,[1,2] Shu-cheng Chen,[1] Craig Solid,[1] Allan J. Collins,[1,2] Robert N. Foley.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, Univ of MN, Minneapolis, MN.*

**Background:** As early detection and treatment are usually feasible and kidney disease is typically not a consequence of other organ dysfunction, autosomal dominant polycystic kidney disease (ADPKD) can provide a useful perspective on the overall quality of nephrology care. Hence, we determined whether incidence rates and survival of dialysis-requiring ESRD from autosomal dominant kidney disease (ADPKD, N=22,262, 2% of all ESRD in the US) changed between 2000 and 2010.

**Methods:** Using incidence rates for 2000 to calculate expected rates for subsequent years (based on age, sex and race/ethnicity), standardized incidence ratios, stable with until 2008, declined to 0.89 in 2010.

**Results:** Characteristics of ADPKD at dialysis initiation included age 40-65 (65.5% vs. 40.8%), white race (80.9% vs. 65.0%), fistulas (35.8% vs. 13.4%), and > 1 year nephrology care (45.3% Vs. 23.1%). On dialysis, ADPKD was associated with a lower likelihood of death (demography-adjusted hazards ratio [AHR] 0.41) and a higher likelihood of listing for (AHR 2.22) and receipt (AHR 2.83) of a renal transplant. Amongst patients with ADPKD, white race was associated with higher AHR for listing (AHR 1.34 Vs. African American) and transplantation (AHR 2.31).

**Conclusions:** While ESRD due to ADPKD may have declined and outcomes on dialysis are better than in many other conditions, disparities are present and seamless transition into renal replacement therapy appears to be the exception and not the rule.

*Funding:* NIDDK Support

## SA-PO520

**A Retrospective Study on Outcome of MPO-ANCA Associated Vasculitis in Renal Replacement Therapy**

Midori Hasegawa, Kyoko Hattori, Kazuo Takahashi, Hiroki Hayashi, Shigehisa Koide, Yukio Yuzawa. *Nephrology, Fujita Health Univ School of Medicine, Toyoake, Aichi.*

**Background:** There are few reports on the clinical course of myeloperoxidase - antineutrophil cytoplasm autoantibody (MPO-ANCA) associated vasculitis in renal replacement therapy (RRT). The aim of this study was to conduct a retrospective review of patients with MPO-ANCA associated vasculitis in RRT.

**Methods:** Birmingham Vasculitis Activity Score (BVAS), patient survival, relapse, and relationships with treatment were examined in our institution, 2 related hospitals, and 5 outpatient clinics in the past 21 years.

**Results:** Of 90 patients (67±13 years, M/F 51/39) recruited, 69 had microscopic polyangiitis, 20 had renal limited vasculitis, and 1 had granulomatosis with polyangiitis. BVAS at the start of RRT was 12.7±3.9. RRT was needed in 43.3% at the first medical examination. The initial dose of prednisolone (PSL) was 0.7±0.3mg/kg/day. The total prescribed duration of GC was 46.8 months. Cyclophosphamide (CY) was prescribed to 20%. During the period of 54±50 months after the onset of RRT, relapse occurred in 11.1%. Lung hemorrhage was noted in 8 patients, while 2 patients had generalized symptoms. The duration from the onset of RRT to relapse was 63±59 months. At the relapse, 5 patients were not receiving immunosuppressive therapy and PSL (4 ± 8 mg/day) was prescribed for the remaining 5 patients. Survival rates for 1, 3 and 5 years after RRT were 83.2%, 76.4% and 66.8%, respectively. The causes of death were infection (59.5%), cardiovascular event (24.3%), gastrointestinal bleeding (8.1%), malignancy (5.4%) and interstitial pneumonia

(2.7%). By Cox's multivariate analysis, patient year (HR1.09, P<0.0001) and pulmonary involvement (HR 3.39, P=0.043) were significant positive risks and the use of CY (HR 0.12, P=0.001) was a significant negative risk for mortality.

**Conclusions:** In patients with MPO-ANCA associated vasculitis, relapse could occur even after a long period from the onset of RRT . Infection was the most frequent cause of death and pulmonary involvement was related with mortality. It is important to clarify the optimal duration of maintenance therapy after RRT.

## SA-PO521

**Outcomes in Infants Initiating Chronic Dialysis Less Than 24 Months of Age** Kera E. Luckritz, Rachel Galimberti, Kathryn S. Plomaritas. *Pediatric Dailysis, Univ of Michigan, Ann Arbor, MI.*

**Background:** Infants < 2years of age make up less than 15% of the pediatric dialysis population. Survival is also the lowest of all the pediatric dialysis age groups. While peritoneal dialysis (PD) remains the preferred modality in this age group, hemodialysis (HD) is often necessary. Whether outcomes differ for either modality remains unclear.

**Methods:** Electronic health records were extracted for all patients who started chronic dialysis at <24months of age at our center between 1997 and 2012. Gender, cause of end stage renal disease (ESRD), age at dialysis start, dialysis modality, any modality changes, dialysis prescription, transplant status, age at transplant, and 6 month, 12 month, 18 month and 24 month survival were queried. Data was entered into a RedCap© database and analyzed with SAS© 9.2 (Cary, NC).

**Results:** Thirty three patients were identified with a mean age at dialysis initiation of 5.6 months (0.2-22). Most common diagnosis was dysplasia (48.4%). Seventy five percent of the patients started on PD. Twelve (36%) patients never required a change in modality. Six patients are still receiving chronic dialysis (2 HD, 4PD). Six patients (18%) died before reaching transplant. Only two of the patients who died were on HD at the time of death. Average age at time of death was 504 days. Causes of death included heart failure (1), liver failure (2), sepsis (2) and pneumonia/complications from ESRD (1). Average time from dialysis start to successful transplant was 446 days for those reaching transplant. One patient stopped dialysis and was successfully medically managed until transplant. Neither gender nor dialysis modality influenced mortality. There was no statistical significant in survival or transplant status by modality.

| | PD Alone N=11 | HD Alone N=2 | PD &HD N=20 | Total N=33 |
|---|---|---|---|---|
| Survival N(%) | 10(90%) | 2(100%) | 15 (75%) | 27 (82%) |
| Iransplant N(%) | 7(64%) | 1 (50%) | 13 (65%) | 22 (66%) |

**Conclusions:** The North American Pediatric Renal Transplant Collaborative Studies 2011 report cites a 75% survival in pediatric patients starting dialysis at less than one year of age. Our center demonstrates an overall survival rate >80% with no statistical difference between gender or dialysis modality.

## SA-PO522

**Changes in Incidence and Prevalence of Diabetic Kidney Disease (DKD) Patients on Renal Replacement Therapy (RRT) in Austria** Friedrich C. Prischl,[1] Martin Auinger,[2] Marcus Saemann,[3] Gert J. Mayer,[4] Alexander R. Rosenkranz,[5] Manfred Wallner,[1] Reinhard Kramar.[6] *[1]4th Dept Medicine, Klinikum Wels-Grieskirchen, Wels, Austria; [2]3rd Dept Medicine, Hospital Hietzing, Vienna, Austria; [3]Dept Nephrology, Medical Univ Clinic 3, Vienna, Austria; [4]Dept Medicine 4, Medical Univ, Innsbruck, Austria; [5]Clin. Div Nephrol., Medical Univ, Graz, Austria; [6]Austrian Dialysis and Transplant Registry, Rohr/Kremstal, Austria.*

**Background:** DKD is the leading cause of end stage renal disease (ESRD) in Austria.

**Methods:** We analyzed the Austrian Dialysis- and Transplant Registry for DKD-related ESRD for changes from 1965-2010.

**Results:** Over 45 years, 7557 and 20468 patients with DKD- and non-DKD-ESRD, respectively, started RRT. While DKD was not present until 1974, in 1975 7 type 1- (T1-DKD) and 1 type 2- (T2-DKD) diabetics started RRT (1.0 per million population - PMP). Around 1985, DKD increasingly led to RRT (1986: 14.7 PMP, 1996: 31.4 PMP) until 2006 (peak incidence n=436; 52.7 PMP). Then numbers decreased annually (2010: n=350 , 41.7 PMP) despite a growing diabetic population estimated to be 5.9% of population in 2006. Point prevalence of RRT-patients increased from 65.3 PMP in 1976 to 992.0 PMP in 2010 and also in DKD (1976: 0.9 PMP, 1986: 27.5 PMP, 1996: 96.4 PMP, 2006: 191.1 PMP ; 2010: 210.2 PMP). Mean age increased over time in all patients. In T2-DKD-patients (T1-DKD) mean age was 53.3 (33.0), 64.2 (47.3), 68.4 (46.3), 66.7 (45.1) and 69.0 (48.2) years in 1976, 1986, 1996, 2006 and 2010, respectively. T2-DKD females always were 3.4±3.3 years older than males. Numbers of females increased less than of males and reached peak incidence 2 years earlier. Finally, 5-year-survival probability in two DKD-cohorts (1997/98 versus 2007/08) was calculated. It was 28% in 1997/98 and 37.5% in 2007/08. Relative risk reduction unadjusted was 22% (HR 0.78, CI 95% 0.67-0.89; p=0.001).

**Conclusions:** Despite an increasing prevalence of diabetes, incidence of DKD-RRT-patients decreases since 2007. 5-year survival probability has improved significantly in recent years. It is speculated that RAAS-blockers and/or the recommended multifactorial therapeutic interventions may have resulted in this improvement.

## SA-PO523

**Dialyzing Ladies or Gentlemen: Does It Matter?** Mehmet S. Sever,[1] Serra Artan,[1] Fatih Kircelli,[2] Murvet Yilmaz,[3] Gulay Asci,[4] Cengiz Dogan,[5] Kutay Gunestepe,[2] Ali Basci,[4] Ercan Ok.[2,4] *[1]Istanbul Medical Fac., Turkey; [2]Fresenius Medical Care, Turkey; [3]Bakirkoy EAH, Turkey; [4]Ege Medical Fac., Izmir, Turkey; [5]CEND Consulting, Turkey.*

**Background:** Application and consequences of hemodialysis treatment may differ between genders. This observational study analyzes hemodialysis practice in a large cohort of male and female patients.

**Methods:** Data on 1,599,694 hemodialysis sessions performed in 7668 prevalent patients, who were treated in 55 centers between May 2009 - May 2012 were retrieved from the European Clinical Database (EuCliD)-Turkey, and submitted for analysis.

**Results:** Results on various demographic, clinical, laboratory and outcome features of the patients are provided in table-1.

*Table-1.* Various parameters of the male and female prevalent patients.

| | Female (n=3329) | Male (n=4339) | Overall (n=7668) | P |
|---|---|---|---|---|
| Age (yrs.) | 58,3±15,2 | 56,5±14,9 | 57,2±15,1 | <0,001 |
| Diabetic (%) | 28,5 | 27,2 | 27,7 | NS |
| A-v fistula usage (%) | 77,2±37,9 | 85,4±31,1 | 81,9±34,5 | <0,001 |
| Kt/V | 1,6±0,3 | 1,4±0,2 | 1,5±0,3 | <0,001 |
| Body mass index | 25,8±5,6 | 24,6±4,4 | 25,1±5,0 | <0,001 |
| IDWG/Dry weight (%) | 3,3±1,4 | 3,4±1,3 | 3,4±1,3 | <0,001 |
| Serum P (mg/dl) | 4,7±1,1 | 4,9±1,2 | 4,8±1,2 | <0,001 |
| Serum PTH (pg/ml) | 401,5±370,3 | 429,6±388,9 | 417,2±381,0 | 0,016 |
| Hb (g/dl) | 11,2±1,1 | 11,7±1,3 | 11,5±1,2 | <0,001 |
| ESA usage (%) | 75,2 | 65,0 | 69,4 | <0,001 |
| Hospitalization (%) | 31,4 | 27,7 | 29,3 | 0,001 |

*Abbreviations:* IDWG: interdialytic weight gain.

Survival at 3 years were similar both in female and male patients.

**Conclusions:** Many parameters, which may affect prognosis differ significantly between female and male dialysis patients. Measures to idealize unfavorable parameters in each group may improve ultimate outcome.

*Funding:* Pharmaceutical Company Support - Fresenius Medical Care - Turkey

## SA-PO524

**Associations of the Conicity Index, an Indication of Abdominal Fat Deposition, with Health-Related Quality of Life in Maintenance Hemodialysis Patients** Gildete Barreto Lopes,[1] Lucas Resende,[1] Elen S. Oliveira,[2] Barbara De Alencar Costa,[1] Pamella R. Conceição,[2] Gentil Luz Junior,[1] Luciana Ferreira Silva,[2] Antonio Alberto Lopes.[1] *[1]Universidade Federal da Bahia; [2]Universidade do Estado da Bahia, Brazil.*

**Background:** A high percentage of abdominal fat relative to peripheral fat represented by high **conicity index (CI)** is associated with higher death risk in maintenance hemodialysis (MHD) patients (Nephrol Dial Transplant 2010; 25: 562–68) but there is a lack of studies to investigate associations of **CI** with health-related quality of life (HRQOL). We investigated associations of the **CI** with HRQOL in MHD patients.

**Methods:** Cross-sectional analysis of data of 627 patients in the Prospective Study of the Prognosis of Chronic Hemodialysis Patients (PROHEMO) developed in 4 clinics in Brazil. SF-36 was used to generate HRQOL scores of 8 primary scales and two composite summaries, i.e., the physical (PCS) and mental components. **CI** was calculated by the following equation(J Clin Epidemiol 1991; 44:955-56): waist circumference (WC) in meters/ [0.109 x square root of (weight in kilograms/height in meters)]. **CI** represents how many times the WC is greater than the circumference of a cylinder formed by the person's height and weight. **CI** was categorized by quartiles: ≤1.23, 1.24 to 1.30, 1.31 to 1.36 and ≥1.37. Wilcoxon-type test was used to test the trend in HRQOL across **CI** quartiles.

**Results:** For all HRQOL scales there was a trend to reduction in scores toward higher **CI**. Steady reductions (P<0.005) in scores across **CI** quartiles were observed for PCS (scores of 44.4, 42.7, 41.5, 38.0), physical functioning (scores of 75.4, 70.4, 67.1, 54.7), role physical (scores of 49.4, 42.0, 41.5, 36.4) and pain (scores 74.1, 72.9, 68.8, 61.9). In linear models adjusted for numerous covariates each 0.2-point more in **CI** was associated (P<0.05) with decrease in HRQOL scores by 2.6 points for PCS, 9.1 points for physical functioning and 6.2 points for pain.

**Conclusions:** The results suggest that MHD patients with high abdominal fat relative to peripheral fat have, in general, poorer HRQOL, mainly for physical dimensions. **Conicity index** is a simple indicator of abdominal fat deposition that may help identify MHD patient with poorer HRQOL.

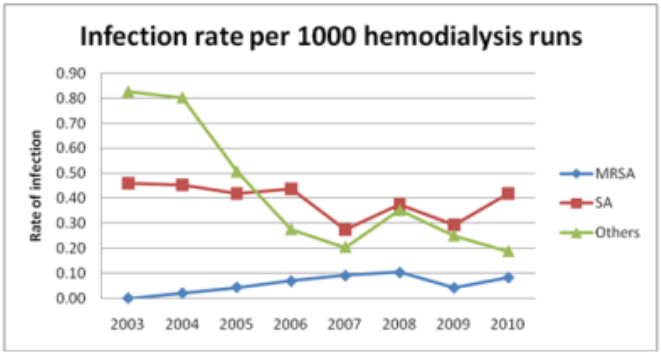
## SA-PO525

**Changes in Rate of *Staphylococcus aureus* Bacteremia in Hemodialysis Population** Emily A. Christie, Neesh I. Pannu. *Nephrology, Univ of Alberta, Edmonton, Canada.*

**Background:** Despite advances in antimicrobial therapies and preventative measures to decrease the rates of catheter-related bloodstream infection (CRBSI) in hemodialysis patients, these infections remain an overwhelming cause of morbidity and mortality.Serious complications from CRBSI occur in approximately 30% to 40% of hemodialysis patients. A landmark study published in 2003 demonstrated a significant mortality benefit of topical antibacterial ointment to central line sites. We evaluated the effects of Northern Alberta Renal Program (NARP) topical antibiotic protocol changes and to study any associated impact on the spectrum of pathogens.

**Methods:** The population studied were adult patients on hemodialysis within NARP, using temporary or tunneled catheters. All patients with documented bacteremia between January 1,2003-December 31,2009 within the Infection Control Database were included. Our analysis focused on the changes in the spectrum of pathogens over time.

**Results:** Our results revealed a decrease in the overall infection rate from 1.29 to an average of 0.69 bacteremias per 1000 HD runs, a 46.4% decrease. The analyis of the bacterial spectrum causing CRBSI showed a decrease in the proportion of infection caused by common pathogens and a corresponding rise in the rate of Staphylococcus aureus (SA). MRSA rates have shown a gradual increase over time.



**Conclusions:** The rate of hemodialysis catheter related infections in the NARP population has decreased over the past ten years. The spectrum of pathogens responsible for line-related bacteremias has shifted toward a greater proportion of SA infections. The rate of SA bacteremia in the NARP population is high compared to current published data. Further work is currently underway to investigate if there has been a corresponding impact on patient outcomes, as well as investigating the antibiotic regimens employed in this patient population.

## SA-PO526

**Overview of Regular Hemodialysis Treatment in China (as of 31 December 2012): Data from Chinese National Renal Data System** Xiang-Mei Chen, Dong Zhang, Qiang Qiu, Xuefeng Sun. *Dept of Nephrology, State Key Laboratory of Kidney Disease, General Hospital of Chinese People's Liberation Army, Beijing, China.*

**Background:** This report provides a summary of the 2012 Chinese Renal Replacement Therapy Registry Annual Report.

**Methods:** The data was recorded on the nationwide, web-based, and prospective registry system, the Chinese National Renal Data System (CNRDS). The patient data including age, gender, laboratory data and clinical and pathology diagnoses was recorded on the web page of the CNRDS. We analyzed the characteristics and trends of chronic hemodialysis in 2012.

**Results:** There were 3,540 hemodialysis centers in China having been registered in CNRDS. The total number of patients undergoing hemodialysis at the end of 2012 was 221,628. The mean age of all patients was 52.4±14.4 years and the proportion of male was58.7%. The mean duration of hemodialysis was 2.9±2.8 years. Primary diseases of all patients were respectively primary glomerular diseases (58.1%), diabetic nephropathy (16.5%), hypertensive nephropathy (10.1%), polycystic kidney disease (3.3%), renal calculus (2.0%) and others (10.0%). The standard-achieving rate of blood pressure in predialysis (≤140/90 mmHg) was 36.8%. The average dose of erythropoietin was 7498.33IU/week and the standard-achieving rate of hemoglobin in predialysis (≥110g/L) was 30.2%. The level of serum total calcium was 2.1-2.37mmol/L in 37.0% of patients. There were 32.8% of patients whose serum phosphorus was 1.13-1.78mmol/L. There were 24.9 percent of patients whose serum iPTH was 150 to 300pg/ml. 12,866 hemodialysis patients died in 2012. The causes of death were respectively cardiovascular events (45.6%), cerebrovascular events 20.8%), infection (11.1%) and others.

**Conclusions:** Compare to 2011, there was an increase of 7.2% with the number of hemodialysis centers in 2012. There was no obviously difference in primary diseases between 2011 and 2012. But the level of Hb and Alb were improved in 2012. There were no significant changes in standard-achieving rates of Ca, P and PTH. We should pay more attention to the management of disorders of calcium and phosphorus metabolism in Chinese dialysis patients.

*Funding:* Government Support - Non-U.S.

## SA-PO527

**Calciphylaxis in ESRD Patients from the USRDS** Lu Y. Huber,[1] Shalini Saith,[1] Mufaddal F. Kheda,[1] Stephanie L. Baer,[2] N. Stanley Nahman,[2] Rhonda E. Colombo,[1] Kristina W. Kintziger.[1] *[1]Nephrology, Georgia Regents Univ, Augusta, GA; [2]Nephrology, Charlie Norwood VAMC, Augusta, GA.*

**Background:** Calciphylaxis (CPX) is a complication of ESRD with a high mortality. It is a small vessel vasculopathy of unexplained etiology, but thought to be associated with calcium-phosphorus dysregulation. Because of its low prevalence, conducting large scale studies to assess the disease has proven difficult. We therefor queried the USRDS to investigate the natural history and relevant co-morbidities associated with CPX.

**Methods:** All prevalent ESRD patients in the USRDS were queried. CPX was defined using the ICD-9 diagnosis code 275.49 (other disorders of calcium metabolism) plus at least one of 7 additional relevant diagnosis codes identifying skin lesions common to the disease (i.e. nodules, ulcers, skin necrosis, etc) during the same inpatient visit. Basic descriptive statistics were used to assess frequencies and percentages for categorical variables, and mean ± standard deviation for continuous variables.

**Results:** A total of 2,133,440 individuals with ESRD diagnosed between 1963 and 2009 were identified, and 13,560,760 hospital records from 1977 through 2008 were available for analysis. There were 459 (0.02%) patients who met the criteria for CPX. For this group: age was 50.4±15.7 years with 20.3% > 65 years, 71.0% female, 59.0% white, and 37.3% African American. Treatment modality at the time of CPX diagnosis: center-based hemodialysis (HD) (361; 78.7%), peritoneal dialysis (PD) (68; 14.8%) and transplant (11; 2.4%). The median survival time for individuals with CPX was 1.1 years and 50% of the deaths were within 87 days of their CPX diagnosis. Co-morbidities associated with CPX included: obesity (79.1%), diabetes mellitus (65.8%), coronary artery disease (47.7%), bacteremia (43.1%), and history of parathyroidectomy (28.1%).

**Conclusions:** Although rare, CPX is associated with a very high mortality. It is more commonly seen in diabetics, obese individuals, females, and patients on in-center HD. Cardiovascular disease and severe mineral bone disorders may also be present. Bacteremia is a common complication and may contribute to the rapid demise associated with the diagnosis.

## SA-PO528

**Risks for Mortality in Hemodialysis Patients with Bacteremia** Stephanie L. Baer,[1,2] Rhonda E. Colombo,[2] Jay Desai,[1,2] Lu Y. Huber,[2] Puja Chebrolu,[2] Mufaddal F. Kheda,[2] N. Stanley Nahman,[1,2] Kristina W. Kintziger.[1,2] *[1]Augusta VAMC, Augusta, GA; [2]Georgia Regents Univ, Augusta, GA.*

**Background:** Bacteremia (BAC) occurs in over 20% of incident hemodialysis (HD) patients (Chebrolu, IDSA 2012). BAC is clinically associated with significant morbidity and mortality. We queried the USRDS to assess risk factors associated with 30-day mortality after a diagnosis of BAC.

**Methods:** All incident adult HD cases from the USRDS for 2005-2008 were queried for a diagnosis of BAC, mortality, and comorbidities, using ICD-9 codes and data from form 2728. Bivariable and multivariable analyses were performed.

**Results:** There were 359,882 adult incident HD patients available for analysis, of which 78,425 (21.8%) had BAC during the study period. Of these, 15,576 (19.9%) died within 30 days of BAC. Those with a significantly greater risk of 30-day mortality were 65+ years [relative risk (RR) 2.19, 95% confidence interval (CI) 2.12-2.27], and had: *Candida* colonization [RR 1.15, 95% CI 1.08-1.22], cirrhosis [RR 1.73, 95% CI 1.64-1.83], peripheral vascular disease [RR 1.20, 95% CI 1.16-1.24], meningitis [RR 1.62, 95% CI 1.28-2.0], pneumonia [RR 1.23, 95% CI 1.18-1.27], endocarditis [RR 1.30, 95% CI 1.21-1.40], pancytopenia [RR 1.17, 95% CI 1.02-1.35], decubitus ulcer [RR 1.53, 95% CI 1.48-1.59 ], *C. difficile* colitis [RR 1.18, 95% CI 1.12-1.24], TPN [RR 1.73, 95% CI 1.62-1.85], or critical care [RR 1.42, 95% CI 1.38-1.46]. The following factors significantly reduced the risk of 30-day mortality: being black [RR 0.79, 95% CI 0.77-0.82], Hispanic [RR 0.76, 95% CI 0.72-0.80], diabetes [RR 0.87, 95% CI 0.84-0.89], kidney transplant [RR 0.56, 95% CI 0.45-0.70], lupus [RR 0.79, 95% CI 0.68-0.93], glomerulonephritis [RR 0.81, 95% CI 0.72-0.92], osteomyelitis [RR 0.80, 95% CI 0.74-0.87], and MRSA infection [RR 0.72, 95% CI 0.67-0.77].

**Conclusions:** Of HD patients, over 20% will acquire BAC and 20% of those will die in 30 days. Risk factors for mortality include age, *Candida* colonization, cirrhosis, peripheral vascular disease, meningitis, pneumonia, endocarditis, pancytopenia, decubiti, *C. difficile*, TPN, or critical care.

## SA-PO529

**Restless Legs Syndrome and Drug Therapy among Dialysis Patients: USRDS Part D and Special Study Data** Nancy G. Kutner,[1] Rebecca H. Zhang,[1] Donald L. Bliwise.[1,2] *[1]USRDS Rehabilitation/QoI Special Studies Ctr, Emory Univ, Atlanta, GA; [2]Neurology, Emory Univ, Atlanta, GA.*

**Background:** Restless legs syndrome (RLS) is reported by 15%-30% of dialysis patients, but RLS contributors are not well specified. Use of medications with central nervous system (CNS) effects, shown to be associated with symptoms of RLS in the general population, merits study.

**Methods:** In USRDS Part D data for incident patients 10/1/06-12/31/10 we identified 4,879 RLS cases by ICD-9 RLS code (333.94) and 4 age-sex-race matched non-RLS controls (n=19,516), excluding patients with Parkinson Disease Dx. The odds of RLS Dx yes/no for antidepressants, anti-histamines, anti-psychotics, and metoclopramide were investigated in stratified logistic regression analyses, adjusting for vintage, drug supply days, and demographic variables, for drug use prior and following RLS Dx date.Use of drugs commonly prescribed for RLS was also examined. In addition, among 377 prevalent patients undergoing hemodialysis 2009-11 in the Atlanta USRDS ACTIVE-ADIPOSE study cohort, patient-reported RLS was identified by the International Restless Legs Syndrome Study Group criteria, with symptom frequency of 5 times/month or more and severity rated at least moderate or more severe over the last month, and patients' current home medication lists were reviewed.

**Results:** RLS Dx was clearly associated with use of Requip, Mirapex, and Sinemet, drugs commonly prescribed to treat RLS. However, the odds of patients with RLS Dx having CNS drugs prescribed were significantly greater for every comparison except anti-psychotics prior to RLS Dx.

| Drug Classes | RLS (n=4,879) Prior to Dx | After Dx | No RLS Dx (n=19,516) |
|---|---|---|---|
| Antidepressants, % | 25.7 | 37.8 | 20.5 |
| Anti-histamines, % | 2.8 | 5.3 | 2.3 |
| Anti-psychotics, % | 4.4 | 7.9 | 4.3 |
| Metoclopramide, % | 12.2 | 19.9 | 10.8 |

In the Atlanta prevalent cohort (median vintage = 3 years), RLS was reported by 17.8%, and 40% of these participants had one or more antidepressant, anti-histamine, anti-psychotic, and/or metoclopramide therapy prescribed.

**Conclusions:** These data suggest the value of carefully reviewing prescription of CNS drugs known to increase the risk for RLS symptoms.

*Funding:* NIDDK Support

## SA-PO530

**Maternal and Long Term Offspring´s Outcomes Derived from Pregnancies in Women Suffering from End Stage Renal Disease under Renal Replacement Therapy** Amelia Rita Bernasconi,[1] Ricardo M. Heguilen.[1] *[1]Medicine, Hospital J.A. Fernandez, Caba, Bs As, Argentina; [2]Medicine, Hospital J.A. Fernandez.*

**Background:** Despite fertility is compromised in women with end stage renal disease (ESRD), pregnancy occurs even in those receiving renal replacement therapy (RRT). In this retrospective study we report a 13-year experience of a nephro-obstetric group. The main aim was to analyze the outcome of a large cohort of pregnant women under RRT. Long-term maternal follow up with emphasis in perinatal and childhood outcomes are described.

**Methods:** Transversal study which including non-DBT RRT-requiring ESRD women and their offspring's.

**Results:** 40 consecutive P (3 twin, and 1 triple) in 38 non-DBT ESRD pts (30.6 ± 1.2 y/o), assisted from January 1, 2000 until June 1, 2013 were analyzed. 27/38 pts were already undergoing RRT (26 on HD and 1 on PD) at the time of gestation while 11 started HD because of P at 10.2 + 6.4 weeks of gestation. 3/4 of them were hypertensive and received amlodipine, alone or in combination with α methyldopa or labetalol. Hypertension worsened in 8 so dose had to be increased or an additional drug had to be added. Polyhydramnios developed in 17 P and preterm delivery was the rule (100%). Gestational age was 30.6 ± 0.9 wks and 28 P ended in caesarean sections. Leading causes of prematurity were polyhydramnios,premature membranes rupture, uncontrolled hypertension. Fetal weight at delivery was 1725 + 140 g while 23 weighed <1500 g. 14 of these 23 survived. Fetal demise was high, especially for the multiple pregnancies. Respiratory distress, congenital abnormalities and necrotizing enterocholitis were causes of fetal death. Low weight at birth neonates were followed up. Four developed retinopathy and underwent laser therapy, 2 developed hearing disorders, 4 developmental delay disorders with dyslexia, 1 had arrhythmia, 1 underwent ortopedic surgery because of congenital deformities. Children whose mothers receivded intensified HD had improved weight and no one reported adverse long term outcome.

**Conclusions:** Pts. In RRT seems to get benefits of intense dialysis, EPO and advances in dialysis, obstetrics and neonatal care improved the outcomes. It remains difficult to advise this women to conceive during HD.

## SA-PO531

**Procalcitonin (PCT) as Bacterial Infection Marker in Patiens with Renal Disease** Alba Santos, Nayara Panizo, David Arroyo, Javier Reque, Borja Quiroga, Isabel Galán Carrillo, Marian Goicoechea, Jose Luno. *Nephrology, Hospital General Universitario Gregorio Marañón, Madrid, Spain.*

**Background:** PCT is a helpful marker to identify bacterial infections in general population. However, the usefulness of this biological marker has not been proved in patients with renal disease. The aim of this study was to evaluate the accuracy of PCT as bacterial infection marker in patients with renal dysfunction.

**Methods:** 62 patients (mean age: 60.1 ±15.1 years, 33 M ,29 W) with renal disease (34 on dyalisis, 34 transplant recipients and 4 with AKI) who were admitted to the emergency department with fever ( > 38ºC) were included in the study. Baseline characteristics, analytical and microbiological data were collected.

**Results:** Positive microbiological cultures was found in 33 patients. PCT levels were higher in patients with positive cultures than in negative-cultured patients (17.7±33.4 vs 2.1±4.9 µg/l, p=0.012). No differences in CRP, leucocytes and fibrinogen levels were found between patients with positive or negative cultures. Positive cultures included 27 bacterial (17 gram–positive and 10 gram-negative ) , 2 fungi and 4 viral infections. PCT levels were higher in bacterial vs viral infection (20.06±35.02 µg/L vs 0.47±0.33 µg/L, p=0.018). PCT levels were correlated to CRP (r=0.689, p=0.001), fibrinogen (r=0.413,p=0.003) and neutrophil count (r=0.243,p=0.05). PCT concentration was negatively correlated with systolic (r=-0.412 p=0.01) and dyastolic blood pressure (r=-0.287,p=0.029). Positive microbiological cultures and CRP levels determined PCT concentration in mutivariate lineal regression analysis (β=0,258 y 0,484 , p=0,045 y p=0,001, respectively). The ROC curve for PCT was 0.640 with pooled specificity 97% and sensitivity 31%; LR positive: 10.33 and LR negative: 0.71.

**Conclusions:** PCT is a useful infection marker in patients with renal disease, as it helps to identify bacterial infection, with high specificity although low sensitivity. Other clinical and biological markers do not permit to identify bacterial infection in renal disease patients.

## SA-PO532

**Glycemic Control Is a Predictor of Infection in Hemodialysis Patients: Miyazaki Dialysis Cohort Study (MID Study)** Tatsunori Toida,[1] Yuji Sato,[1] Hiroyuki Komatsu,[1] Masao Kikuchi,[1] Shouichi Fujimoto.[2] *[1]Dept of 1st Internal Medicine, Faculty of Medicine, Univ of Miyazaki; [2]Dept of Hemovascular Medicine and Artificial Organs, Faculty of Medicine, Univ of Miyazaki, Japan.*

**Background:** There are limited data on the association between infection and glycemic control in diabetic patients on hemodialysis (HD). We investigated the impact of glycemic control on infection risk among diabetic patients on HD.

**Methods:** Patients with maintenance HD (n=1551) were enrolled in the MID Study in December 2009 and followed up for 3 years. The diagnosisof diabetes at baseline and information on clinical events of infection (1) hospitalization with infection, 2) hospitalization with pneumonia, 3) onset of pneumonia) during follow-up were extracted from the medical records.Cox regression analysis was used to examine the association between glycemic control and the events.

**Results:** At baseline, there were 493 patients with diabetes and 1058 patients without it. Compared with those in the bottom criterion of HbA1c level (HbA1c3.8-5.0%), the multivariable-adjusted hazard ratio for hospitalization with infection was not increased in the second and third criteria of HbA1c (HbA1c 5.1–6.0% to 6.1–7.0%), but was significantly increased to 8.43 (95% CI 2.62-27.11) in the group with poorest glycemic control (HbA1c≥7.1%). Similarly for hospitalization with pneumonia and onset of pneumonia, the multivariable-adjusted hazard ratios in the group with poorest control were 6.30 (95% CI 1.15-34.55) and 3.88 (95% CI 1.061-14.17), respectively.

**Conclusions:** Poor glycemic control (HbA1c≥7.1%) was associated with high infection risk among HD patients. The relationship between glycemic control and infection risk is not linear, so there might be a possibility of increasing the risk of infection depending on the glycemic control threshold.

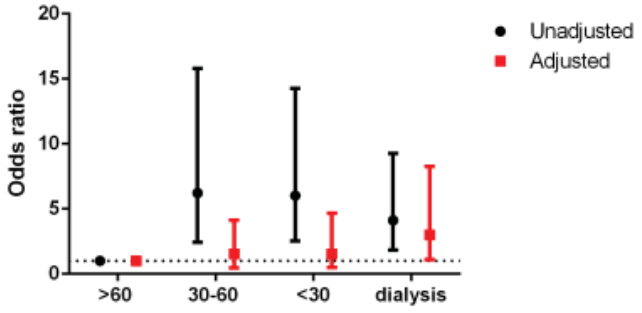
## SA-PO533

**p-Cresyl Sulfate Directly Associates with FGF23 and Aortic Calcification in Chronic Kidney Disease Patients, Independent of Kidney Function** Liesbeth Viaene,[1] Sam Heye,[2] Kathleen Claes,[1] Bjorn Meijers,[1] Pieter Evenepoel.[1] *[1]Nephrology, Univ Hospitals, Belgium; [2]Radiology, Univ Hospitals, Belgium.*

**Background:** Vascular calcification is common in patients with chronic kidney disease (CKD) and associates with increased cardiovascular morbidity and mortality. As opposed to coronary artery calcification, data on the prevalence and risk factors of aortic calcification (AC) in CKD are scarce. Recent studies suggested that uremia-related risk factors may be of great importance, as they may act synergistically with traditional risk factors. The present cross-sectional observational study aimed to clarify the role of *p*-cresyl sulfate (PCS), indoxyl sulfate (IndS) and mineral metabolism disturbances in the pathogenesis of AC in CKD.

**Methods:** Parameters of mineral metabolism, including FGF23, calcidiol, calcitriol and PTH, and PCS and IndS (HPLC) were assessed in 264 CKD patients (61% males; 58 ±14 years, CKD stage 1-5D). AC was assessed by lateral lumbar X-ray.

**Results:** AC was present in 60% of patients. Age and diabetes were identified as major determinants of AC. The adjustment for traditional risk factors attenuated but did not erase the association between CKD and AC.



PCS and FGF23 levels showed an inverse relationship with renal function and a direct relationship with AC. PCS was identified as determinant of FGF23, independent of classical determinants. In multivariate regression analysis, age, diabetes mellitus and PCS were identified as independent determinants of AC. When FGF23 was included, it replaced PCS in the final model.

**Conclusions:** High PCS and FGF23 levels are associated with an increased risk of aortic calcifications, independent of traditional risk factors and renal function. The link between PCS, FGF23 and AC requires further research. Experimental data suggest that Klotho deficiency might be the common pathway.

## SA-PO534

**Correlation of Fibroblast Growth Factor-23 with Carotid Atherosclerosis in Patients with Chronic Kidney Disease** Anil Kumar Yadav, Alok Goel, Sunil Agarwal, Shuchi Bhatt, Basu Dev Banerjee, Om Parkash Kalra. *Univ College of Medical Sciences and Guru Teg Bahadur Hospital, Delhi, India.*

**Background:** FGF-23 is increased early in CKD and is recognized as an important predictor of cardiovascular morbidity and mortality in these patients. Carotid Intima Media Thickness (CIMT) has been used as a surrogate marker of atherosclerosis and can be used to predict cardiovascular risk in these patients. Study was designed to estimate the levels of FGF-23 and intact parathyroid hormone(iPTH) and measure CIMT and then assess the correlation between these parameters in patients with various stages of CKD.

**Methods:** This cross-sectional study consisted of 75 subjects in the age group of 21 to 60 years, divided into 3 groups (25 in each). Group I: Healthy controls, Group II: CKD stage 2, 3 and 4 patients and Group III: CKD stage 5 patients on hemodialysis for ≥ 3 months. C-FGF-23 and iPTH estimation was done by ELISA method. CIMT was measured using Doppler ultrasound.

**Results:** All the 3 groups were age and sex matched. Mean C-FGF-23 was found to be significantly higher in Group III patients (622.17±42.45 rU/mL) when compared with group I (53.95±8.11 rU/mL), or Group II patients (213.59±107.21 rU/mL) ($p<0.001$ for all). Further, C-FGF-23 levels in stage 2 CKD patients were found to be significantly higher than healthy controls ($p<0.001$). Similarly mean iPTH was significantly higher in group III patients (543.90±59.24 pg/mL) as compared to group I (42.99±8.84pg/mL), and group II patients (150.39±126.48pg/mL) ($p<0.001$ for all). Further, no significant difference in iPTH was found between healthy controls and stage 2 CKD patients ($p=0.708$). Mean CIMT was significantly higher in Group III (0.71±0.1 mm) when compared with Group I (0.45±0.1 mm) or Group II patients (0.50±0.1 mm) ($p<0.001$ for all). A significant positive correlation was found between C-FGF-23 and CIMT in all groups ($r=0.716$).

**Conclusions:** FGF-23 is the earliest marker of mineral bone disorder and is increased in CKD even in stage 2 patients and shows a positive correlation with carotid atherosclerosis.

*Funding:* Government Support - Non-U.S.

## SA-PO535

**Urinary Soluble Klotho Significantly Predicts Renal Outcomes in Patients with Chronic Kidney Disease** Masashi Kitagawa, Hitoshi Sugiyama, Hiroshi Morinaga, Ayu Ogawa, Toshio Yamanari, Akifumi Onishi, Yoko Kikumoto, Shinji Kitamura, Yohei Maeshima, Hirofumi Makino. *Dept of Medicine and Clinical Science, Okayama Univ Graduate School of Medicine Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

**Background:** Low serum Klotho levels have been reported to be associated with adverse kidney disease outcomes, while the urinary Klotho levels have been suggested to be a more sensitive biomarker than the serum Klotho levels in patients with chronic kidney disease (CKD). The purpose of this study was to identify the relationship between the urinary Klotho levels and the renal function in patients with CKD and investigate whether the urinary Klotho levels can predict kidney disease outcomes in patients with CKD.

**Methods:** We analyzed the urinary soluble Klotho levels in a cohort of 161 patients with stage 1-5 CKD and assessed the relationships between the urinary Klotho-to-creatinine ratio (Klotho/Cr), proteinuria and the kidney function. The patients were prospectively followed for two years to monitor for doubling of the baseline serum creatinine concentration and the initiation of renal replacement therapy.

**Results:** The urinary Klotho/Cr level was positively correlated with eGFR and proteinuria and negatively correlated with changes in proteinuria during the follow-up period. The patients were categorized into two groups according to the baseline median urinary Klotho value. Renal survival was significantly lower in the patients with a urinary Klotho/Cr ratio of ≤ 0.321 μg/gCr than in those with a urinary Klotho/Cr ratio of > 0.321 μg/gCr ($p=0.0398$). A Cox regression analysis adjusted for age, gender, hypertension, diabetes, dyslipidemia, eGFR, proteinuria, hemoglobin, phosphate and fibroblast growth factor 23 showed that a urinary Klotho/Cr ratio of > 0.321 was significantly associated with a reduced risk for the renal end point. The adjusted odds ratio for a urinary Klotho/Cr ratio of > 0.321 was 0.62 (95% confidential interval: 0.37-0.99; $p = 0.0471$).

**Conclusions:** In this study, lower levels of urinary Klotho were significantly associated with renal outcomes, suggesting that a lower urinary Klotho level can serve as a novel biomarker for CKD progression.

## SA-PO536

**Klotho Deficiency Contributes to Uremic Cardiac Hypertrophy and Fibrosis in Mice** Jian Xie, Joonho Yoon, Makoto Kuroo, Chou-Long Huang. *UT Southwestern Medical Center, Dallas, TX.*

**Background:** Klotho (KL) is a membrane protein produced mostly in the kidney; its ectodomain is released as a soluble protein. We have reported that soluble Klotho (sKL) protects the heart against stress-induced cardiac hypertrophy and fibrosis, by inhibiting TRPC6 channel in the heart & independently of FGF23. We examined whether reduced serum sKL contributes to cardiomyopathy in CKD.

**Methods:** Wild type (WT) and heterozygous (Het) KL-deficient (*kl*) mice (129/SvJ) were rendered CKD by 5/6 nephrectomy (Nx) or sham surgery for 4 wk.

**Results:** Serum sKL levels (assayed by IP + western blot) were lower in Het vs WT mice, and both were further reduced by 5/6 Nx. CrCl was reduced ~60% by 5/6 Nx, but not different between WT and Het. Heart weight/body weight ratio (HW/BW, mg/g) of WT mice was increased by 5/6 Nx (sham & CKD: 4.1±0.1 & 5.4±0.2, $p<0.01$); CKD-induced increase was enhanced in Het (sham & CKD: 4.0±0.1 & 6.2±0.2, $p<0.01$; also $p<0.01$, WT/CKD vs Het/CKD). Supporting the HW/BW results, *BNP* expression was increased in hearts of WT CKD vs sham mice, and CKD-induced increase was enhanced in Het *kl* mice. BP was not different between WT and Het sham mice, but equally elevated in both CKD mice. Feeding CKD mice with antihypertensives and diuretics in drinking water normalized their BP to the level of sham mice. Under which, HW/BW ratio remained significantly increased in CKD vs sham mice. Hct levels were decreased in CKD vs sham mice, but not different between WT & Het mice. Serum Pi was not different between WT CKD & Het CKD. Ejection fraction (EF) measured by MRI showed no difference between WT sham and CKD mice (63±3 vs 61±3 %). LV end-diastole volume (LVEDV) was slightly lower & HW/LVEDV ratio increased in WT CKD vs sham, indicating concentric hypertrophy and diastolic dysfunction of WT CKD hearts. In contrast, relative to sham, EF was decreased in Het CKD (47±4 vs 62±4 %, $p<0.05$), LVEDV was markedly increased, and HW/LVEDV unchanged, indicating progression of Het CKD hearts to dilatation and systolic dysfunction.

**Conclusions:** Soluble Klotho is cardioprotective. Reduced serum sKlotho in CKD is an important cause of uremic cardiomyopathy, independent of serum Pi and FGF23.

## SA-PO537

**Role of Parathyroidectomy in Achieving Therapeutic Targets in Dialysis Patients with Mineral Bone Disorder in the Cinacalcet Era** Gurmukteshwar Singh, Abdul Qadir, Jane Garb, Dhivya Sundaramurthy, Barbara A. Greco. *Baystate Medical Center, Springfield, MA.*

**Background:** Parathyroidectomy (PTX) is recommended to manage mineral bone disorder (MBD) in dialysis patients who fail medical therapy. Over the past decade, surgical approach has shifted away from total PTX and cinacalcet was introduced. We evaluated MBD parameters, medication use, and mortality in a cohort of dialysis patients who underwent PTX during this time frame.

**Methods:** Adult patients from 8 Fresenius dialysis units who underwent their first PTX between 2000 and 2010 were included. Uniform, evidence-based protocols were used for management of MBD. Patients were referred for PTX if their MBD was uncontrolled on maximum tolerated treatment including phosphorus binders, vitamin D analogs, and cinacalcet. Medical records were reviewed to extract patient characteristics, laboratory data, and medication use pre- and post-PTX.

**Results:**

| **Clinical Characteristics of 101 patients included in the study** | |
|---|---|
| **Type of PTX** | |
| Total | 42.6% |
| Total with auto-implant | 43.6% |
| Sub-total | 13.8% |
| **Age at PTX (Mean)** | 50.1 |
| **Race** | |
| Caucasian | 37.2% |
| African American | 34.9% |
| Hispanic | 27.9% |
| **Years on dialysis** | 4.5 |
| **Cause of ESRD** | |
| HT | 37.2% |
| GN | 27.9% |
| DM | 18.6% |
| Oth | 16.3% |
| **Study end-point** | |
| Transplanted | 53.5% |
| Died | 27.9% |
| Alive | 4.7% |
| Moved | 14% |
| **Median follow-up (yrs)** | 7.3 |

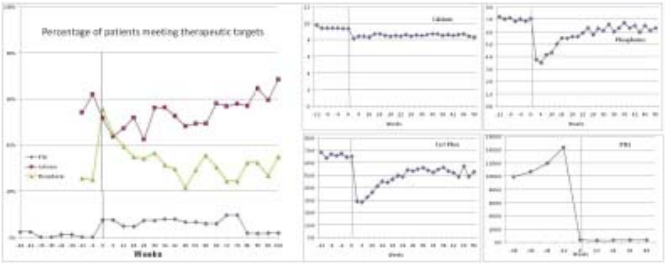


**Figure 1:** Percentage of Patients Meeting MBD Targets and Median Lab Values at Various Time Points

The percentage of patients meeting phosphorus goal increased following PTX but the benefit was transient. Most patients had sustained hypoparathyroidism after surgery despite attempts to preserve remnant tissue. Vitamin D and calcium requirements are being analyzed currently.

**Conclusions:** PTX does not uniformly lead to achievement of MBD therapeutic targets. PTX resulted in sustained hypoparathyroidism in a large percentage of patients. Further study is needed to determine risks and benefits of PTX in the cinacalcet era.

**SA-PO538**

**Comparison of Cinacalcet plus Paricalcitol to Cinacalcet plus Calcitriol Therapy in Hemodialysis Patients with Severe Hyperparathyroidism**
Siren Sezer,[1] Zeynep Bal,[1] Emre Tutal,[1] Öznur Kal,[1] Demet Yavuz,[2] Ibrahim Yildirim,[3] Burak Say?n,[1] Ruya Ozelsancak,[1] Sultan Ozturk,[4] Nurhan Özdemir Acar.[1] *[1]Dept of Nephrology, Baskent Univ Faculty of Medicine, Turkey; [2]Dept of Nephrology, Sakarya Univ Education and Research Hospital, Turkey; [3]Dept of Nephrology, Bulent Ecevit Univ Faculty of Medicine, Turkey; [4]Dept of Nephrology, Hitit Univ Education and Research Hospital, Turkey.*

**Background:** Clinical guidelines and literature reviews support the combination therapy with cinacalcet and VDRA treatment in patients with SHPT however, there is no consensus on the most effective type and dose of combination. The aim of this study is to evaluate and compare the effectiveness of cinacalcet and paricalcitol or calcitriol treatment of MHD patients with severe SHPT.

**Methods:** 146 patients with severe SHPT on chronic hemodialysis three times a week for at least 3 months were enrolled into the study. Patients with serum calcium concentration < 10.5mg/dL, serum Ca × P<75 and PTH level ≥ 1000 pg/ml were divided into two groups either who received cinacalcet plus intravenous paricalcitol (Group CP) or cinacalcet plus intravenous calcitriol (Group CC) for the treatment at least one year.

**Results:** 78 patients in group CP and 68 subjects in group CC were evaluated. In group CP, mean PTH values in 1st and 12th month were 1257.6 ± 668.4 pg/ml and 929.8 ± 497.3 pg/ml whereas in CC group, mean PTH values were 1226.9 ± 595.6 pg/ml and 1210.9 ± 574.8 pg/ml (p<0.003). At baseline both groups' alkaline phosphatase levels were similar however at the end of the study in group CP, ALP levels were significantly lower than the group CC (p<0.002). Despite the mean dose of vitamin D administration was significantly higher in paricalcitol group than the calcitriol group we observed less hyperphosphatemia and elevated CaxP in group CP (p<0.01, p<0.05 respectively).

**Conclusions:** This observational study showed that combination therapy with paricalcitol and cinacalcet is superior in terms of PTH response to treatment, less hyperphosphotemia and decrease in alkaline phosphatase levels to combination calcitriol and cinacalcet in dialysis patients with severe SHPT.

**SA-PO539**

**Vitamin D Analogs and Calcimimetics Use in CKD Can Influence Levels of Vitamin K Dependent Proteins (VIKI Study)**
Maria Fusaro,[1] Davide Miozzo,[2] Marianna Noale,[1] Giovanni Tripepi,[3] Antonio Piccoli,[2] Agostino Naso,[4] Rosalba Cristofaro,[2] Maurizio Gallieni.[5] *[1]CNR, Padua, Italy; [2]Univ of Padua; [3]CNR, Reggio Calabria; [4]Hospital of Padua; [5]Ospedale San Carlo Borromeo, Milano.*

**Background:** Vitamin K is involved in the production of Bone and Matrix Gla Proteins (BGP and MGP), regulating bone and vascular health. We carried out an observational study to evaluate associations between bone disease therapy and levels of BGP and MGP in patients on hemodialysis (HD).

**Methods:** Cross-sectional study of 387 HD patients. We determined BGP, MGP and routine biochemistry. We evaluated both vertebral fractures (VF) and aortic (AoVC) calcifications in the same spine radiograph. Three-year patients' survival was analyzed.

**Results:** VF and AoVC were associated with reduced BGP levels (for VF 213 *vs* 151 ng/ml, p<0.01; AoVC 262 vs 164 ng/ml). A total of 77 patients died during follow-up (19.9%). Mean follow-up was 2.7±0.5 years. Median MGP was significantly lower (15.0 versus 19.7 nmol/L, p=0.02) in nonsurvivors.

In a first multivariate stepwise regression BGP levels were 37.7% higher (p=0.0002) in patients treated with calcimimetics (19.4% of total). Patients treated with Vitamin D analogs (19.9% of total) also showed an increase of 20.1 % ( p=0.0228 ). Patients treated with calcium acetate (5.4%) showed increased MGP levels (+30.4%, p<=0.05), while in patients treated with calcimimetics MGP levels were increased by 21% (p=0.0142). A second multivariate stepwise regression considered alone or combined each of the previously identified predictors for BGP and MGP levels: calcimimetic alone increased BGP and MGP levels of 42% and 19%, respectively; combined treatment of calcimimetics, Vitamin D analogs and calcium acetate binding was associated with increased BGP levels (+59.8%) and MGP levels (+77%). Vitamin D analogs alone increased BGP levels (+24%).

**Conclusions:** We found lower BGP levels in patients with high prevalence of VF and AoVC. Lower MGP levels in non survivors. Both calcimimetics and vitamin D analogs are associated with increased BGP levels while increased MGP levels are found only in patients treated with calcimimetics. These drugs could have a relevant role in the protection of bone and vascular health.

**SA-PO540**

**Ferric Citrate as a Phosphate Binder Has a Safety Profile Similar to Sevelamer Carbonate and Calcium Acetate**
Mohammed Sika,[2] Kausik Umanath,[1] Simin Goral,[4] Shahabul S. Arfeen,[5] Isai G. Bowline,[7] Gil Chernin,[8] Mark Koury,[2] Jamie P. Dwyer,[2] The Collaborative Study Group.[3] *[1]Henry Ford Hosp; [2]Vanderbilt Univ; [3]CMM; [4]Univ of Penn; [5]Neph Specialist; [6]Barzilai Med Center, Israel; [7]Wake Forrest Univ; [8]Ichilov Med Center, Israel.*

**Background:** Ferric citrate (FC), a phosphate binder, binds phosphorus safely and effectively in phase 2 trials. We report the safety profile of FC in a multicenter, randomized, open-label phase 3 trial in 441 dialysis subjects treated with FC or Active control(AC) [calcium acetate(CA), sevelamer carbonate(SC) or combo(CB)].

**Methods:** Entry criteria required subjects to be tolerant to AC. After a washout period in which all binders were stopped, subjects were randomized 2:1 to FC or AC, and followed during a 52-week safety assessment period (SAP). Adverse events were collected throughout the trial.

**Results:** 292 subjects were on FC. The 149 AC subjects included 78 on SC, 41 on CA and 30 (CB). During the SAP, 49% of subjects in the AC group experienced a serious adverse event (SAE) while only 39.4% of subjects did so in the FC group. There were 5.2% deaths in AC and 4.5% in FC. The percentages of AC subjects with SAE's in the infection, gastrointestinal (GI), cardiac and vascular categories were greater than those in the FC group.The number of treatment emergent adverse events (including serious and non-serious adverse events) per subject was 5.6 in FC and 6.5 in AC.14.2% of FC subjects and 9.4% of AC subjects discontinued from the trial or stopped study drug and continued in the trial. Despite a greater percentage of GI SAEs in the AC group, the single most common reason for discontinuation of study drug or withdrawal from the trial in the FC group was a GI adverse event. The difference in GI adverse events was expected because of the entry criterion requiring tolerance to AC drugs, while all subjects were naïve to FC.

**Conclusions:** FC, an efficacious phosphate binder, had an excellent safety profile when compared to currently available phosphate binders.

**SA-PO541**

**A Prospective Study to Evaluate the Efficacy of Total PaRathyroidectOmy in Retarding Vascular/Valvular Calcification and Improving Bone MinEral Density in End-Stage Renal Disease Patients – PROCEED Study**
Angela Yee Moon Wang,[1] Brian Lang,[2] Yat Y. Yau,[3] Wai Kei Lo.[4] *[1]Medicine, Queen Mary Hospital, Univ of Hong Kong, Hong Kong, Hong Kong; [2]Surgery, Queen Mary Hospital, Univ of Hong Kong, Hong Kong, Hong Kong; [3]Radiology, Biomedical Imaging Center, Hong Kong, Hong Kong; [4]Medicine, Tung Wah Hospital, Hong Kong, Hong Kong.*

**Background:** Severe secondary hyperparathyroidism (SHPT) has been associated with increased risk of mortality & cardiovascular deaths in chronic kidney disease (CKD)-5D patients. We hypothesized that total parathyroidectomy (PTx) may retard vascular/valvular calcification & improve bone mineral density (BMD).

**Methods:** We conducted a prospective longitudinal study in 62 CKD-5D patients (mean age:55±11y;28% with previous fracture) with severe SHPT resistant to conventional medical therapy who underwent total PTx with forearm autograft. Primary endpoints were changes in vascular & valvular calcification assessed by plain coronary multislice computed tomography 1 year after PTx. Secondary endpoint was changes in BMD, Z-score & t-score by dual X-ray absorptiometry scan.

**Results:** Pre-operative median (interquartile range) total coronary artery calcium score (CACS) was 560 (190 - 1338) & increased significantly to 609 (228 - 1558)(P=0.014) at 1 year while mitral & aortic valve calcium score did not change significantly after 1 year. BMD at forearm [P=0.05], femur [P<0.001] & lumber spine [P<0.001] showed significant increase 1 year after PTx & was associated with sig. improvement in t-score & z-score at corresponding sites. CACS was stabilized or reduced in 30 patients while progression in CACS (as defined by ≥15% increase from pre-op CACS) was observed in 20 patients (40%). iPTH [P<0.001], serum calcium [P<0.001], phosphorus [P<0.001] & alkaline phosphatase [P<0.001] showed sustained significant reduction 1 year after total PTx.

**Conclusions:** Total PTx significantly improves biochemical parameters of CKD-mineral bone disease & BMD but did not necessarily retard vascular/valvular calcification in CKD-5D patients with severe SHPT, contrary to previous reports. The exact mechanisms whereby PTx improves clinical outcomes of 5D patients warrant further investigation.

**SA-PO542**

**Ferric Citrate Binds Phosphorus, Delivers Iron, and Reduces IV Iron and Erythropoietic Stimulating Agent Use in End-Stage Renal Disease**
Julia Lewis,[1] Jamie P. Dwyer,[1] Mark Koury,[1] Mohammed Sika,[1] Gerald Schulman,[1] Mark T. Smith,[2] Frederick C. Whittier,[3] Douglas R. Linfert,[4] Claude Mabry Galphin,[5] Peale Chuang,[6] The Collaborative Study Group.[7] *[1]Vanderbilt Univ; [2]Kidney Care Assoc; [3]Clin Res; [4]Neph Assoc; [5]Renal Res Inst; [6]Metrolina Neph Assoc; [7]CMM.*

**Background:** We conducted a multi-center, randomized, open-label trial of an oral phosphate binder, ferric citrate (FC) in 441 dialysis subjects.

**Methods:** A 52-week Safety Assessment Period (SAP) in which subjects were randomized 2:1 to FC or active control (AC) (calcium acetate and/or sevelamer carbonate) was followed by a 4-week Efficacy Assessment Period (EAP) in which 192 subjects completing the SAP on FC were randomized 1:1 to continue FC or receive placebo.

**Results:** The EAP baseline mean serum phosphorus was 5.1 ± 1.2 mg/dL in FC subjects and 5.4 ± 1.5 mg/dL in placebo subjects. At the end of the EAP, serum phosphorus was lower in FC subjects (4.9 ± 1.3 mg/dL) vs placebo subjects (7.2 ± 1.8 mg/dL, p < 0.0001). During the 52-week SAP, serum phosphorus was similar in FC and AC groups (mean difference at week 52 = 0.04 mg/dL, p = 0.8). SAP baseline mean serum ferritins were 593 ± 293 ng/mL in FC subjects and 609 ± 308 ng/mL in AC subjects. At the end of the SAP, mean serum ferritin was 898 ± 489 ng/mL in FC subjects and 624 ± 361 ng/mL and AC subjects, p<0.0001. Transferrin iron saturation (TSAT) at baseline was 31% in both groups; at the end of the SAP, TSAT was higher, 39% FC group vs 29% AC group, p< 0.0001. IV iron use was prohibited, if serum ferritin was > 1000 ng/mL or TSAT was > 30%. FC subjects received less IV elemental iron (1.86mg/day) than AC subjects (3.84mg/day; p<0.001). FC subjects received less epoetin units (U) per day than AC subjects (756 U/day vs 993 U/

day, p<0.05). At week 52, hemoglobin was 11.4 and 11.1g/dL in the FC vs AC(treatment difference p=0.01).Serious adverse events and adverse events were similar in the EAP and the SAP in the FC, AC and placebo groups.

**Conclusions:** Ferric citrate is an efficacious and well-tolerated phosphate binder that also increases iron stores, and decreases IV iron and ESA use.

*Funding:* Pharmaceutical Company Support - Keryx Biopharmaceuticals

## SA-PO543

**Impact of Ferric Citrate, an Oral Phosphate Binder, on Mineral and Bone Metabolism Markers in Dialysis Patients** Daniel E. Weiner,[7] Mohammed Sika,[2] Jamie P. Dwyer,[2] Kausik Umanath,[3] Stephen Z. Fadem,[4] Marvin V. Sinsakul,[5] Peter N. Van Buren,[6] Jo Abraham,[1] The Collaborative Study Group.[2] *[1]Univ of Utah; [2]Vanderbilt; [3]Henry Ford; [4]Kidney Assoc; [5]Rush Univ; [6]UT Southwestern; [7]Tufts.*

**Background:** We conducted a multicenter, international, randomized, open-label clinical trial of a novel phosphate binder.

**Methods:** 441 dialysis subjects were enrolled in a trial consisting of a two week washout period during which all binders were stopped and a 52 week Safety Assessment Period (SAP) in which participants were randomized 2:1 to ferric citrate (FC, 1 gram caplets) or active control (AC), followed by a one month efficacy assessment period. There were 292 participants randomized to FC and 149 to AC. The AC group consisted of 78 participants treated with sevelamer carbonate, 41 with calcium acetate, and 30 with a combination of these agents.

**Results:** Results for mean serum phosphorus, calcium, iPTH and aluminum post-washout and at the completion of the SAP are in the table. Throughout the study, between 51% and 61% of participants had phosphorus in the 3.5 to 5.5 mg/dL range, without significant between group differences (p=0.41 to 0.98 at various time points). Four participants in the AC group had serum calcium greater than 10.5mg/dL, necessitating discontinuation of AC therapy versus none in the FC group; specifically, calcium was lower in FC subjects compared to calcium acetate only (9.1±0.9 vs 9.5±1.0, p=0.008).

**Conclusions:** Traditional markers of bone and mineral metabolism were similar in the AC and FC groups over a 52 week safety assessment period, with overall low aluminum levels in both groups despite the citrate component of FC and as expected given the use of calcium-containing binders, several episodes of hypercalcemia in the AC group. We conclude that FC can achieve control of MBD parameters comparable to current usual care.

| | Ferric Citrate | Active Control | p-value |
|---|---|---|---|
| Serum Phosphorus (mg/dL) | | | |
| Post-Washout | 7.4 ± 1.6 | 7.6 ± 1.7 | |
| Post-SAP | 5.3 ± 1.4 | 5.4 ± 1.6 | 0.96 |
| Serum Calcium (mg/dL) | | | |

**The Effect of JTT-751 (Ferric Citrate Hydrate) on Phosphorus and FGF-23 in Chronic Kidney Disease** Keitaro Yokoyama,[1] Hideki N. Hirakata,[2] Takashi Akiba,[3] Masafumi Fukagawa,[4] Masaaki Nakayama,[5] Kenichi Sawada,[6] Yuji Kumagai,[7] Geoffrey A. Block.[8] *[1]The Jikei Univ School of Medicine, Tokyo, Japan; [2]Japanese Red Cross, Fukuoka Hospital, Fukuoka, Japan; [3]Tokyo Women's Medical Univ, Japan; [4]Tokai Univ School of Medicine, Isehara, Japan; [5]Fukushima Medical Univ School of Medicine, Fukushima, Japan; [6]Akita Univ, Akita, Japan; [7]Kitasato Univ East Hospital, Sagamihara, Japan; [8]Denver Nephrology, Denver, CO.*

**Background:** JTT-751 is a novel iron-based phosphate (P) binder being developed for hyperphosphatemia in patients with chronic kidney disease (CKD).

**Methods:** A Phase 3, multicenter, randomized, double-blind, placebo-controlled study investigated the efficacy and safety of JTT-751 in non-dialysis dependent patients with CKD. A total of 90 patients with a serum P level of 5.0 mg/dl or higher were randomized 2:1 to JTT-751 (1.5–6.0 g/day, n=60) or placebo (n=30) for 12 weeks. The primary endpoint was change in serum P level from baseline to the end of treatment (EOT). Secondary endpoints included the percentage of patients achieving target serum P levels (2.5-4.5 mg/dl), and change from baseline in fibroblast growth factor-23 (intact-FGF-23) at EOT.

**Results:** The mean change in serum P level at EOT was –1.29 mg/dl in the JTT-751 group and 0.06 mg/dl in the placebo group (P<0.001). The percentage of patients achieving target serum P levels at EOT was 64.9% in the JTT-751 group and 6.9% in the placebo group (P<0.001). Treatment with JTT-751 significantly reduced intact-FGF-23 levels (P<0.001).

| | JTT-751:Baseline | JTT-751:EOT | Placebo:Baseline | Placebo:EOT |
|---|---|---|---|---|
| **P (mg/dl):Mean** | 5.66 | 4.37 | 5.57 | 5.62 |
| **FGF-23 (pg/ml):Median** | 453.0 | 209.0 | 358.0 | 478.0 |

JTT-751 significantly increased iron parameters (P<0.001) and hemoglobin (P=0.04). Adverse drug reactions were similar in patients receiving JTT-751 or placebo with gastrointestinal disorders occurring in 30.0% of JTT-751 patients and 26.7% of those receiving placebo.

**Conclusions:** In patients with non-dialysis dependent CKD, 12 week treatment with JTT-751 resulted in significant reductions in serum P and FGF-23.

## SA-PO545

**Calcium Supplementation Affects Calcium Balance but Not Bone Mineral Density in Older Women with Moderate Chronic Kidney Disease** Anna Jeanette Jovanovich, Michel Chonchol, Gerard John Smits, Jessica B. Kendrick. *Div of Renal Diseases and Hypertension, Univ of Colorado Denver, Aurora, CO.*

**Background:** To examine whether calcium supplementation is associated with an improvement in bone mineral density (BMD) in women with moderate chronic kidney disease (CKD).

**Methods:** We performed a post-hoc analysis of the DECALYOS II, a 2-year randomized, double-blind, placebo-controlled study of 610 women randomized to calcium-vitamin $D_3$ fixed combination, calcium plus vitamin $D_3$ separate combination, or placebo. Both active treatment groups received the same daily amount of calcium (1,200 mg) and vitamin $D_3$ (800 IU). Dietary intake of calcium, 24-hour urine calcium excretion, and BMD of the distal radius measured by single X-ray absorptiometry were recorded at baseline (m 0), 12 (m 12) and 24 (m 24) months. Only participants (N=89) receiving calcium and vitamin D with CKD (eGFR < 60 ml/min/1.73m$^2$) after the baseline visit were included in this analysis. Linear regression models were used to assess the relationship between change in calcium balance and change in BMD.

**Results:** Mean age, eGFR, dietary calcium, urinary calcium excretion, and BMD were 78±5 years, 49±7 ml/min/1.73m$^2$, 527±191 mg/day, 103±63 mg/24h, and 0.32±0.1 g/cm$^2$. Serum calcium and intact parathyroid hormone (iPTH) were 9.3 ± 0.4 mg/dL and 66 ± 34 pg/mL, respectively. Fecal calcium excretion was assumed to be 1,000 mg/day. Participants were in negative calcium balance at baseline. During the course of the study the change in calcium balance was positive and significantly higher than baseline (m 0 to m 12: 1170.8 ± 67 mg/day; p<0.0001 and m 0 to m 24 1168.3±57 mg/day; p<0.0001). In linear regression models adjusted for age, height, weight, serum calcium, iPTH, 25-hydroxyviatmin D, eGFR, and intervention, a positive calcium balance was not associated with increased radial BMD at 12 (p=0.70) or 24 months (p=0.08). Serum calcium remained unchanged during the course of the study.

**Conclusions:** Calcium supplementation of 1,200 mg/day produced a positive calcium balance in older women with CKD, which was not related to improvements in radial BMD.

## SA-PO546

**Cinacalcet Improves Survival in Dialysis Patients – A European Cohort Study** Claudia Friedl,[1] Gilbert Reibnegger,[2] Reinhard Kramar,[3] Alexander R. Rosenkranz.[1] *[1]Dept of Internal Medicine, Clinical Div of Nephrology, Graz, Austria; [2]Institute of Physiological Chemistry, Graz, Austria; [3]Austrian Dialysis and Transplant Registry, Austria.*

**Background:** Dialysis patients are at excess risk of mortality. Observational studies have shown that high PTH, serum phosphorus and calcium are independent risk factors for cardiovascular and all-cause mortality in dialysis patients. Cinacalcet has proven to be efficient to improve these parameters. Aim of the present study was to test whether Cinacalcet treatment is associated with better survival in a cohort of Austrian dialysis patients.

**Methods:** Data from all prevalent dialysis patients from 01.01.2004 to 31.12.2009 (n=8225) were retrospectively evaluated. Data were obtained from the Austrian Dialysis and Transplant Registry. Patients without information about prescription of cinacalcet (n=164), age <18 years as well as a survival time of <90 days were excluded. Survival analysis was performed using the Kaplan Meier model and the Royston-Parmar model.

**Results:** The final study cohort included 7983 dialysis patients (n= 7251 hemodialysis; n=752 peritoneal dialysis), whereby 1572 (19.7%) had a prescription of cinacalcet. Compared to those without cinacalcet prescription patients receiving cinacalcet were younger (median [25th; 75th percentile] 57.9 [46.1; 67.7] vs. 66.0 [55.7; 74.8]), they were less likely to suffer from diabetes or cardiovascular diseases. During a median follow-up time of 2.6 years, 3574 (44.8%) patients died including 1342 (16.8%) deaths due to cardiovascular causes. Risk of all-cause and cardiovascular mortality was significantly decreased in the cinacalcet group. Odds ratio (OR) (with 95% CI) remained significant even after multivariable adjustment for age, sex, BMI, diabetes, cardiovascular comorbidity, registration status on kidney transplant waiting list, medication with phosphate binder and vitamin D compounds, hemoglobin, CRP, calcium, phosphorus and iPTH: all-cause mortality OR 0.50 (0.43-0.59), cardiovascular mortality OR 0.60 (0.48-0.75); p<0.0001.

**Conclusions:** In this observational retrospective study of a large homogenous European cohort, treatment with Cinacalcet significantly improves survival in dialysis patients.

**SA-PO547**

**Meal-Induced Change in Bone Mineral Variables in End-Stage Renal Disease** Hariprasad S. Trivedi, Aniko Szabo. *Medical College of WI.*

**Background:** Management of mineral and bone disorder is one of the important facets of care of end-stage renal disease (ESRD) subjects. As part of the same, bone mineral variables are regularly tested. However, these are randomly tested generally depending on when the patient presents for dialysis. Whether meals consumed by the patient affects these variables is not known.

**Methods:** As part of a study of circadian variation of bone mineral variables in ESRD we pre-planned evaluation of the effect of a mid-day meal on bone mineral variables in these subjects. Consenting subjects with ESRD and controls consumed a study diet containing 1200 mg calcium and 1000 mg of phosphorus per day for 5 days. In ESRD subjects phosphate binders, active vitamin products, and cinacalcet were discontinued prior to beginning the study diet. On the 6th day while the same diet was continued blood was drawn around 12 noon, followed by lunch and a second blood draw at 2:00 pm. In each sample phosphate, ionized calcium, intact parathyroid hormone (PTH), and 25-hydroxy vitamin D (25OHD) were tested. Within each group, mean difference of log-transformed values of each analyte, post-lunch versus pre-lunch, were analyzed using a paired t-test. Data are presented as ratios (post-lunch/pre-lunch). Two sample t-test was used to compare the effect of the meal between groups.

**Results:** 17 ESRD subjects (15 men, 2 women, mean age 45±12 years, 7 whites, 10 African-Americans) and 8 controls (6 men, 2 women, mean age 55±14 years, 4 whites, 4 African-Americans) participated in the study. In ESRD subjects post-lunch phosphate was significantly higher by about 12% (ratio 1.12, p= 0.0039) while ionized calcium was lower (ratio 0.98, p = 0.0002). PTH tended to be higher post-lunch but did not reach statistical significance (ratio 1.12, p=0.06). In control subjects only 25OHD was significantly different after the meal (ratio 0.94. p =0.0365). The between-group comparison showed that post-lunch the change in phosphate tended to be greater in ESRD subjects versus controls (p=0.05).

**Conclusions:** In ESRD phosphate is higher while calcium is lower after a meal. These variations should be considered during clinical testing.

**SA-PO548**

**Circadian Variation of Bone Mineral Variables in End-Stage Renal Disease** Hariprasad S. Trivedi, Hershel Raff, Aniko Szabo. *Medical College of WI.*

**Background:** We investigated the circadian rhythm of bone mineral variables in end-stage renal disease (ESRD).

**Methods:** Subjects with ESRD on hemodialysis (n=17) and controls (n=8) were enrolled after written, informed consent. Diabetes mellitus was an exclusion criterion. After discontinuing all confounding medications (phosphate binders, active vitamin D, calcimimetics) for a period corresponding to 5 half lives, subjects ate a research diet controlled for the amount of daily calcium (1200 mg) and phosphorus (1000 mg), After overnight stay in the adult translational research unit, blood was drawn every 2 hours (8 am through following 6 am) for phosphate, ionized calcium, intact parathyroid hormone (PTH), and 25-hydroxy vitamin D (25OHD). A harmonic regression model with group-specific 24- and 12-hour periodic components was fitted to log-transformed values. Comparisons were made using autocorrelation adjusted repeated measures analysis of variance via generalized estimating equations.

**Results:** Characteristics of the subject population were as follows: ESRD subjects 15 men, 2 women, mean age 45±12 years, 7 whites, 10 African-Americans; Controls 6 men, 2 women, mean age 55±14 years, 4 whites, 4 African-Americans. The conditions of testing were optimal, based on typical circadian pattern of concurrent cortisol measurements in controls. Each molecule exhibited significant circadian variation in the ESRD subjects: phosphate (p<0.0001), ionized calcium (p=0.004), PTH (p=0.0004), and 25OHD (p=0.009). Peak and nadirs respectively were around the following times (hours): phosphate 3:30, 11:00; ionized calcium 12:15, 20:00; PTH 17:45, 10:15; 25OHD 9:45, 16:00. In controls only phosphate (p<0.0001; peak at 2:45, nadir 10:15) and PTH (P<0.0001; peak at 2:45, nadir 10:15) exhibited significant circadian variation. No statistical difference could be found between the circadian pattern of ESRD subjects and controls for any of the analytes.

**Conclusions:** Phosphate, calcium, PTH and 25-hydroxyvitamin D show a significant circadian rhythm in patients with ESRD. Knowledge of these phenomena is pertinent for clinical testing and may be valuable for understanding the pathophysiology of mineral bone disorder in ESRD.

**Biochemical and Clinical Results (Phase I) of the Multicentric Study on the Prevalence of Vascular Calcifications and Vertebral Fractures in Parathyroidectomised (PTX) Dialysis Patients (Cave PTX Study)** Sandro Mazzaferro. *Sapienza Univ, Rome, Italy.*

**Background:** The CAVE PTX study aims to evaluate, in PTX dialysis pts, the control of divalent ions and medical therapies (phase I), and the prevalence of aortic calcifications and vertebral fractures (phase II).

**Methods:** Biochemistries (Ca, P, PTH) and therapies of PTX patients were collected from 149 Italian dialysis Units. A control group (C), comparable for age, sex and dialysis duration, was selected from the whole cohort. We report the data of biochemistries and therapies.

**Results:** Out of 12515 patients (HD = 87.7%; PD = 12.3%), 528 (4.22%) received PTX. PTX prevalence was higher in HD (4.5% vs 1,9% in PD). Cases and C (n=437) data are in tab 1.

| TAB 1 | Age, y | M/F, % | Dialysis, y | Ca, mg/dl | P, mg/dl | PTH, pg/ml |
|---|---|---|---|---|---|---|
| **PTX** | 58 ± 13 | 56/44 | 15 ± 8 | 8.8 ± 0.8 | 4.9 ± 1.3 | 182 ± 292 |
| **C** | 58 ± 17 | 54/46 | 12 ± 13 # | 9.0 ± 0.7 # | 5.1 ± 1.3 * | 334 ± 294 # |
| (*) p<.05, (#) p<.001 vs PTX | | | | | | |

| TAB 2 | PTH<150 | | PTH 150-300 | | PTH>300 | |
|---|---|---|---|---|---|---|
| | *PTX* | *C* | *PTX* | *C* | *PTX* | *C* |
| **Ca, mg/dl** | 8,6 ± 0.8 | 9.0 ± 0.9 # | 8.9 ± 0.7 | 9.0 ± 0.7 | 9.2 ± 0.8 | 9.0 ± 0.7 # |
| **P, mg/dl** | 4.8 ± 1.3 | 4.9 ± 1.5 | 4.9 ± 1.3 | 4.8 ± 1.2 | 5.1 ± 1.3 | 5.5 ± 1.3 # |
| **PTH, pg/ml** | 40 ± 30 | 93 ± 42 # | 216± 40 | 223 ± 41 | 630 ± 417 | 577± 331 * |
| (*)p<.05; (#)p<.001, PTX vs C | | | | | | |

Respectively in PTX and C, PTH was low (<150) in 64 vs 23%; optimal (150-300) in 17 vs 39%; and high (>300) in 19 vs 38%. Ca, P and PTH values in three groups are in tab 2. Prescribed drugs, respectively in PTX and C, were: Vitamin D (61 vs 64%); Pi binders (88 vs 75%) and Calcimimetic (13 and 35%). The most frequently prescribed drugs were Calcitriol and Ca based binders in PTX, and Paricalcitol and Sevelamer in C.

**Conclusions:** PTX has a low prevalence in Italy, and mainly involves relatively young, females and long-term haemodialysis patients. In PTX pts PTH values are mostly low and therapeutic choices are accordingly different. Different hard outcomes can be hypothesized.

**SA-PO550**

**Success of Educational Interventions in the Management of CKD-MBD** Nimish Mehta, Anne Le. *Medscape, LLC, New York, NY.*

**Background:** Mineral and bone disorders in patients with chronic kidney disease (CKD-MBD) are frequently underrecognized and inadequately treated. A study was conducted to determine if on-line educational interventions could improve competence and performance of nephrologists and cardiologists with respect to CKD-MBD management.

**Methods:** A cohort of US-practicing nephrologists and cardiologists who participated in 1 of 3 educational interventions designed to address gaps in care of patients with CKD-MBD was assessed. The outcomes survey method, previously validated to measure performance, included knowledge- and case-based, multiple-choice questions focused on current evidence-based recommendations for the assessment and management of patients with CKD-MBD. Responses from the clinical cases and questions aligned with individual interventions were collected from the participant cohort and compared with a matched control group of nonparticipants.

**Results:** For each educational intervention, 200 nephrologists and cardiologists were assessed, divided equally between participants in the education and a matched control group of nonparticipants. Significant improvements were found as a result of participation in the educational interventions. For example, participants were more likely than nonparticipants to determine:

A greater calcium intake than output in a patient, resulting in a positive calcium balance (nephrologists 80% vs 60%, P =.001; cardiologists 74% vs 40%, P =.03)

· The role of the vitamin D-independent pathway for calcium absorption (nephrologists 56% vs 32%, P =.02; cardiologists 36% vs 18%, P =.04)

· Influence of diurnal fluctuation in serum phosphorus levels and dietary protein intake on a patient's serum phosphorus measurements

· Increased risk of cardiovascular calcification with calcium-containing phosphorus binders (cardiologists 52% vs 33%, P =.05).

**Conclusions:** This study demonstrated the success of targeted educational interventions on improving the practice patterns of nephrologists and cardiologists in the assessment and management of patients with CKD-MBD.

**SA-PO551**

**Examination of Tissue Phosphorus Deposition in Patients Undergoing Hemodialysis Using Current Standard Techniques** Toru Hyodo,[1,3] Noriko Mikami,[1] Yasuhisa Kurata,[1] Miho Hida,[1] Daisuke Ishii,[3] Kazunari Yoshida,[3] Masatsugu Iwamura,[3] Junko Kawakami.[2] *[1]Dialysis Center, Eijin Clinic and Kurata Hospital, Sagamihara, Kanagawa, Japan; [2]Clinical Nurtition, Sagami Women's Univ, Sagamihara, Kanagawa, Japan; [3]Urology, Kitasato Univ, School of Medicine, Sagamihara, Kanagawa, Japan.*

**Background:** With advances in dialytic techniques and the development of phosphorus (P) adsorbents, the tissue deposition of P may differ from that previously reported. In this study, we examined P loading in patients undergoing hemodialysis.

**Methods:** The subjects were 73 hemodialysis patients. They consisted of 53 males and 20 females. Thirty patients had diabetes, whereas it was absent in 43. The mean age was 65.4±14.6 years, dialysis period 8.1±13.3 years, dialysis time 4.23±0.47 hours, blood flow volume 209.7±25.7 mL/min, dialyzer membrane area 2.1±0.2 mm, and dialytic fluid flow volume 400 ml/min. The frequency of dialysis was 3 times a week. The tissue deposition of P was calculated using the following formula: Protein catabolic rate (PCR) x 15 x 0.65 – (Removal on dialysis) – (Removal with P adsorbent) – (Urinary excretion). P intake (calculated by multiplying the protein intake by a coefficient of 15) was adopted from the guidelines established by the Japanese Society of Nephrology in 2007. P removal on dialysis was measured by reserving dialytic fluid drainage. The urinary excretion of P was calculated using 24-hour urine. Lanthanum carbonate and sevelamer hydrochloride alone were administered to patients, and regarded as adsorbing 90 and 33.75 mg/g of P, respectively, for calculation.

**Results:** The dialytic fluid excretion of P was 298.6±164.9 mg/day. The urinary excretion of P was 79.1±53.3 mg/day (n=21). The volume of adsorption achieved by P adsorbents was 221.0±108.3 mg/day. The mean tissue deposition of P was -32.1±125.4 mg/day. The following correlation formula was obtained: [Dialytic fluid P removal per dialysis session] (mg) = 157.6 x [P](mg/dL) + 37, $r^2$=0.691.

**Conclusions:** Current dialytic therapy and advances in phosphorus adsorbents have reduced the tissue deposition of phosphorus. It may be important to prepare dialytic prescriptions and perform diet/drug therapies, considering P changes.

## SA-PO552

**PINP in Renal Impaired Patients: The Assay Matters** Etienne Cavalier, Pierre Delanaye. *Clinical Chemistry and Nephrology, Univ of Liege, CHU Sart-Tilman, Liege, Belgium.*

**Background:** The amino-terminal propeptide of type I procollagen (PINP) is produced by osteoblast in equimolar amounts with the collagen deposited in the tissue; it is considered as the reference bone formation marker by the IOF/IFCC. It circulates in different forms, a larger intact trimeric form and several fragment monomers. In healthy individual, circulating PINP is predominantly the trimeric intact with almost non-detectable monomers. In CKD patients, the monomeric form is elevated. Intact PINP (iPINP) assay measures the trimeric, Total PINP (TPINP) assay measures both trimeric and monomeric. We evaluated these two assays in CKD and hemodialyzed (HD) patients.

**Methods:** 157 stage 3-5 CKD patients were analyzed with the IDS-iSYS iPINP and Roche Elecsys TPINP assays; results were evaluated according to our laboratory established reference intervals and eGFR. 125 HD patient samples were also measured; results were compared with b-ALP values. The samples from 22 patients of before and after a single HD session were compared.

**Results:** In CKD subjects, observed ranges for T and iPNP were 8–822 and 8–146ng/mL. 96% (151/157) were within iPINP reference intervals (11–111ng/mL); 63%(99/157) were within TPINP range (15-90ng/mL). Relation between TPINP and eGFR tended to be exponential in <30mL/min whereas it remained linear with iPINP. In HD patients, values for TPINP and iPNP were 18-2192 and 16-641ng/mL. Using b-ALP cut-off of 20 µg/L to discriminate the high bone turnover patients, 56%(70/125) of HD samples were found to be below this threshold. Among these patients, 93%(65/70) presented normal iPINP values vs. 31% (22/70) in TPINP. A single hemodialysis session did not remove the monomers from the circulation.

**Conclusions:** PINP is a promising marker to evaluate bone formation in CKD patients. It might replace the b-ALP in patients where interferences with the liver form of the enzyme can be expected. We have compared two methods for PINP determination, one of which recognizes monomeric fragments that accumulate in CKD patients, TPINP. We have indirect data indicated that this method should not be used in those patients and the "Intact" method is more suitable.

## SA-PO553

**Analytical Performance of a New Bone Specific ALP Automated Immunoassay** Etienne Cavalier,[1] Pierre Delanaye.[2] *[1]Clincial Chemistry, Univ of Liege, CHU Sart-Tilman, Belgium; [2]Nephrology, Dialysis and Transplantation, Univ of Liege, CHU Sart-Tilman, Belgium.*

**Background:** Serum bone–specific alkaline phosphatase (bone ALP), a marker of bone turnover, has been proposed as an alternative biochemical target for clinical management of CKD-MBD patients. We assessed the analytical performance of the IDS-iSYS Ostase BAP (IDS, UK) automated assay and compared this method to the manual Ostase BAP Immunoenzymetric assay [EIA] (IDS, UK). The observed ranges for apparently healthy children and reference intervals for pre-menopausal, post-menopausal women and men were established.

**Methods:** The accuracy profile was determined with serum pool levels. The method linearity was verified with two sets of high/low serum samples. A total of 116 samples [6.1-75.7µg/L] was assayed by each method for method comparison. Serum specimens from overnight fasting, apparently healthy Caucasians subjects, normal Calcium, Phosphates, Intact PTH, and eGFR > 60, were selected to establish the reference intervals for males, pre-menopausal and post-menopausal. The observed ranges were established with apparent healthy young <20years males and females.

**Results:** The precision profile of the IDS-iSYS BAP assay demonstrates precision CV between 1.7% and 7.2%. The dilutions had good linear regression to the expected concentrations: Observed BAP = 1.047 x (Expected BAP) – 1.89; $R^2$ = 0.997. The method Passing Bablok regression was: IDS-iSYS = 1.05 x (EIA) + 0.25 with significant correlation r=0.994 (P<0.0001). We observed a peak between 7 and 8 years for girls, whereas boys showed the peak to be later, between 11 and 12 years.

**Conclusions:** The IDS-iSYS Ostase BAP assay performed well and showed suitable characteristics to achieve acceptable precision and accuracy. The patient comparison between the IDS-iSYS and the Immunoenzymetric showed an excellent relationship. The IDS-iSYS Ostase BAP is a suitable tool in clinical laboratories for the follow-up of osteoporosis therapy or for the differential diagnoses of other metabolic bone diseases such Paget's disease and renal osteodystrophy.

## SA-PO554

**Performance of a Novel Fully Automated Method for the Detection of Dephospho-Uncarboxylated Matrix Gla Protein (dp-ucMGP)** Etienne Cavalier,[1] Pierre Delanaye.[2] *[1]Clinical Chemistry, Univ of Liege, CHU Sart-Tilman, Belgium; [2]Nephrology Dialysis Hypertension, Univ of Lioege, CHU Sart-Tilman, Belgium.*

**Background:** Matrix Gla-protein (MGP) is one of the strongest inhibitor of vascular calcification, produced by vascular smooth muscle cells and chondrocytes. MGP can undergo gamma-glutamate carboxylation (vitamin K dependent step) and serine phosphorylation. Circulating dp-ucMGP reflects the amount of uncarboxylated MGP produced in the arterial vessel wall and is a direct marker for the vascular vitamin K status. Different studies, using cumbersome elisa methods have shown conflicting results regarding association of dp-ucMGP and abdominal aortic calcification score. We assessed the analytical performance of the fully automated IDS-iSYS InaKtif MGP assay (IDS, UK) and compared the results vs. an ELISA method in a cohort of haemodialysis patients.

**Methods:** Precision profile was determined with 4 plasma samples (264-2703pM) measured twice a day for 10 days. Linearity was assessed with 2 sets of high/low samples. dp-ucMGP concentrations were determined with iSYS and ELISA from 118 plasma sample of patients without Vitamin K supplementation and under thrice-weekly hemodialysis for at least 3 months, (mean age 68.7±14.4 years; median dialysis vintage: 21months, range: 3-396); 78(65.0%) had history of cardiovascular diseases.

**Results:** On iSYS, intra-assay coefficient of variation (CV) was 2.9-8.9%; Inter-assay CV was 4.1-13.4%. Linearity equation from 18 dilutions was Obtained = 0.95xExpected+209, $R^2$=0.99. The Passing-Bablock regression was iSYS=1.26xELISA+241. Bland Altman plot showed that iSYS gave higher results than ELISA, especially in the higher range.

**Conclusions:** The IDS-iSYS InaKtif MGP is the first fully automated dp-ucMGP kit which will be soon available commercially for the measuring of the dephosphor-uncarboxylated MGP levels. Different observations in the studies that used the ELISA method might be explained by the its poor linearity in the higher range. The dp-ucMGP blood test could be included as part of routine monitoring biomarkers for hemodialysis patients after further proven its clinical validity.

## SA-PO555

**Seasonal Vitamin D Levels in Untreated Incident Dialysis Patients** Gero D. von Gersdorff,[1] Philipp B. Marquardt,[1] Mathias Schaller,[1] Thomas Benzing,[1] Claudia Barth.[2] *[1]Nephrology - QiN Group, Univ Hospital Cologne, Cologne, Germany; [2]Curatorium for Dialysis and Kidney Transplantation, Neu-Isenburg, Germany.*

**Background:** Studies on the association between VitD and mortality are often not adjusted for season of sample collection. We report on seasonal VitD levels in a current large cohort of chronic ambulatory dialysis patients without VitD Supplementation.

**Methods:** The database of a large dialysis organization in Germany was queried for all patients >18 years in the period 2006–2012 who had a first VitD drawn within 1year after starting hemo- (HD) or peritoneal (PD) dialysis, respectively. VitD levels were grouped by month of draw and by patient's state of VitD supplementation. VitD sufficiency was defined as a level >30 ng/ml and severe deficiency as <12.5 ng/ml. Results are expressed as mean (SD) or %, and as odds ratio (OR) of mortality for VitD <12.5ng/ml.

**Results:** 19,474 patients (pt) were available for analysis. In 3568 VitD naïve pt (age 71.9(14) years, 61.6% male, 44.1% diabetic (DM)), VitD levels were 17.2 (10.9) ng/ml in winter and 20.4 (12.7) ng/ml in summer. Levels in PD were substantially lower than in HD (Fig. 1). VitD levels were also low in women and DM (Fig. 1). Of 3315 incident HD patients without supplementation, 17.5% were VitD sufficient and 36.3% were severely deficient. In corresponding PD patients (N=253), only 7.1% were sufficient and 58.5% were severely deficient. Mortality risk was 1.44 forHD and 1.35 for PD patients with a first VitD level <12.5 ng/ml.

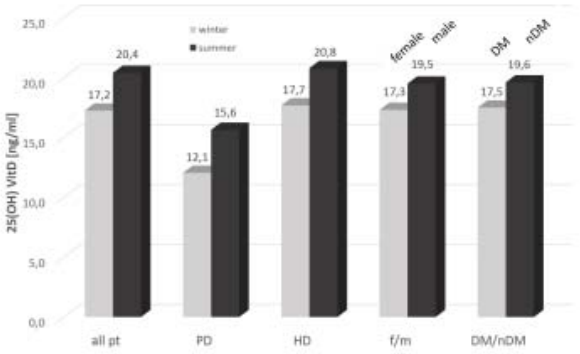

**Figure 1**: Left three columns: Levels of unsupplemented VitD in winter (November - April) and summer (July - October) in all incident, and incident PD and HD patients, respectively. Right two columns: Levels of VitD in women and men, and diabetics and non-diabetics, respectively.

**Conclusions:** In this analysis we could confirm and expand findings from an earlier 1997-2006 cohort (Krause et al, 2012) in ambulatory dialysis patients in routine practice. Severe deficiency was found in a large proportion of dialysis pt. Other factors that were associated with low VitD were female gender and DM as a comorbidity. Seasonal variation (sun exposure) contributed 2-4 ng/dl increase in the summer months.

## SA-PO556

**Seven Years of Experience with the German Calciphylaxis Registry** Vincent Brandenburg,[1] Thilo Krueger,[2] Jürgen Floege,[2] Markus Ketteler.[3] *[1]Cardiology, Univ Hospital RWTH Aachen; [2]Nephrology, Univ Hospital RWTH Aachen; [3]Nephrology, Klinikum Coburg.*

**Background:** Calciphylaxis is a rare disease (ORPHA280062) and devastating condition associated with high morbidity and mortality. Calciphylaxis is characterised by painful, ischemic, partly necrotic skin ulcerations. Pathomorphologically, media calcification of cutaneous arterioles and extracellular matrix remodelling are the hallmarks of the disease.

**Methods:** We established an international internet-based registry in 11/2006 to allow online notification for all cases of established or suspected CUA. A comprehensive data base including various parameters concerning patient characteristics, laboratory data, clinical background and presentation as well as therapeutic strategies was established. The diagnosis of CUA is made on clinical and/or histological grounds by the referring physician.

**Results:** Altogether 184 patients with CUA have been documented in 6.5 years: 61% females; 88% dialysis (HD and PD) patients, median age 67 (21-88) years. Stored serum samples were used for central laboratory analysis in core facility in n = 92 dialysis patients: PTH levels varied broadly between undetectably low and > 1100 pg/ml, mean 191 +/-176 pg/mL; fetuin-A: 0.21+/-0.01 g/L. Fetuin-A levels in control HD pts without CUA were significantly higher (n=65; 0.46+/-0.1 g/L, p < 0.01). Oral anticoagulation with Vit K antagonists was common in ESRD CUA pts (47%). Cutaneous lesions were localized in 79% at the lower extremities or gluteal region. Among the most frequently recorded therapeutic procedures were: surgical necrosectomy, intensifying dialysis modality, i.v. sodium-thiosulfat application. The median survival time was 516 days after online notification.

**Conclusions:** CUA is a rare diease among ESRD pts with increased mortality. PTH levels vary substantially but do not exceed current KDIGO target levels in most cases. Decisions on therapeutic strategies also vary significantly among centers. The present internet based ICCN registry is a valuable tool to collect data upon CUA cases and may become a basis for prospective systematic evaluations of treatment modalities in the near future.

**A 10-Year Retrospective Analysis of Parathyroidectomy (PTX) for Renal Hyperparathyroidism** Alasdair Duguid, Chern Beverly B. Lim, Samina Hussain, Zorica Vujovic, David Monro Smith. *Ninewell's Hospital, Dundee, United Kingdom.*

**Background:** Patients with advanced kidney disease are known to be at risk of developing renal bone disease (CKD-MBD) due to the development of secondary hyperparathyroidism. When this cannot be controlled with medical treatment alone surgical intervention may be indicated. Our aim was to assess the clinical and biochemical outcomes in patients who underwent PTX for renal hyperparathyroidism.

**Methods:** Retrospective review of all renal patients who had PTX from April 2003 to March 2013 at one institution. Relevant patients were identified from electronic medical records and theatre logs.

**Results:** 97 patients underwent PTX for renal hyperparathyroidism. There were 45 women and 49 men with a median age of 55 years (range 25-80 years) plus 3 who were excluded due to incomplete data. At the time of PTX, 20 patients had functioning renal transplants, 66 were on renal replacement therapy, 49 were on haemodialysis, 17 were on peritoneal dialysis and 8 patients were at a pre-dialysis stage. Of these patients, 30 had four parathyroid glands removed, 28 had three and a half removed, 11 had three removed, 9 had two removed and 16 had one removed. Histopathology showed 80 cases had hyperplastic changes, 12 had parathyroid adenomas and 2 were normal. 2 patients experienced recurrent laryngeal nerve injury and 1 patient died secondary to pneumonia. Recurrent hyperparathyroidism led to re-operation in 5 patients and 4 patients were on cinacalcet. Post PTX 66 patients were on alfacalcidol (median 0.5 micrograms, range 0-14 micrograms). When comparing pre and post-operative biochemistry, parathyroid hormone (PTH) levels were found to be significantly different using Wilcoxon matched-pairs test (W=-4183, P<0.001) with a median reduction of 75.2pmol/L (interquartile range 26.3-75.2). Corrected calcium levels were also significantly reduced (W=-3829, P<0.001) with a median reduction of 0.23mmol/L (interquartile range 0.09-0.39).

**Conclusions:** Most patients undergoing PTX were receiving haemodialysis. The majority of patients had a subtotal rather than total PTX with hyperplasia being the prevailing pathology. PTX has been shown in these patients to significantly reduce both PTH and corrected calcium.

## SA-PO558

**Analysis of CKD-MBD Markers in a Phase 3 Study of PA21 and Sevelamer in Patients with Hyperphosphatemia** Stuart M. Sprague,[1] Adrian Covic,[2] Markus Ketteler,[3] Anjay Rastogi,[4] Bruce S. Spinowitz,[5] Jürgen Floege.[6] *[1]NorthShore Univ Health System, Evanston, IL; [2]Gr.T. Popa Univ of Medicine and Pharmacy, Iasi, Romania; [3]Coburg Clinic and KfH-Dialysis Center, Coburg, Germany; [4]Univ of California; [5]New York Hospital Queens; [6]RWTH Univ Hospital Aachen, Aachen, Germany.*

**Background:** Effects of PA21 – a novel polynuclear iron(III)-oxyhydroxide phosphate binder (PB) – and sevelamer carbonate (SEV) on CKD-MBD markers were assessed.

**Methods:** Dialysis patients received PA21 1.0-3.0 g/day (n=710) or SEV 2.4-14.4 g/day (n=349) for 12 weeks' dose titration then a 12-week maintenance period. Eligible patients entered a 28-week extension study. Markers of CKD-MBD were measured.

**Results:** In both treatment groups (Table): serum intact parathyroid hormone (iPTH) decreased initially, then increased to Week 52; fibroblast growth factor 23 (FGF-23) decreased and serum $Ca^{2+}$ levels remained relatively stable over 52 weeks; tartrate-resistant acid phosphatase 5b (TRAP5b) decreased over 52 weeks; carboxyterminal cross-linking telopeptide (CTX) increased initially, then returned to near baseline values at Week 52; bone-specific alkaline phosphatase (BAP) increased initially, then returned to near baseline values with PA21 at Week 52; osteocalcin (OST) increased over 52 weeks. No significant differences between treatment groups were noted.

**Table:** Mean (SD) change from baseline in CKD-MBD markers.

| | Δ at 24 weeks | | Δ at 52 weeks | |
|---|---|---|---|---|
| **Marker** | **PA21 (n=707)** | **SEV (n=348)** | **PA21 (n=707)** | **SEV (n=348)** |
| iPTH (ng/mL) | –66.9 (268.86) | –35.4 (244.65) | 13.5 (355.58) | 34.1 (292.54) |
| FGF-23 (µg/L) | –30.76 (227.48)* | –44.08 (215.38)* | –54.60 (230.66)* | –78.55 (220.92)* |
| $Ca^{2+}$ (mg/dL) | 0.18 (0.84)* | 0.13 (0.82)* | 0.20 (0.79)* | 0.22 (0.91)* |
| TRAP5b (U/L) | –1.12 (2.53)* | –0.93 (2.59)* | –1.41 (2.78)* | –0.80 (2.99)* |
| CTX (ng/mL) | 2.92 (3.99)* | 3.55 (4.12)* | –0.44 (2.64)* | 0.15 (2.76) |
| BAP (ng/mL) | 2.36 (12.24)* | 4.97 (13.82)* | –0.11 (13.77) | 2.56 (13.19)* |
| OST (ng/mL) | 1.74 (19.18) | 2.05 (15.91)* | 8.69 (26.49)* | 12.33 (23.76)* |

*Significant change from baseline.

**Conclusions:** PA21 and SEV produced similar changes in CKD-MBD markers. Further analysis for clinical relevance is warranted, especially considering the FGF-23 lowering effect. As approximately 60% of patients had received prior $Ca^{2+}$-based PBs, treatment with non-$Ca^{2+}$-based PBs in this study may have led to an initial activation of bone metabolism.

## SA-PO559

**Administration of Activated Vitamin D for Patients with Predialysis Chronic Kidney Disease May Reduce Cardiovascular Disease Events after Dialysis Initiation** Daijo Inaguma. *Nephrology, Japan Red Cross Nagoya Daini Hospital, Nagoya, Aichi, Japan.*

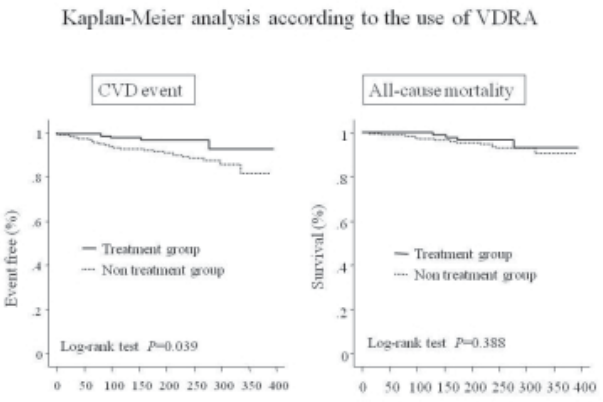
**Background:** Only a few studies have focused on whether or not administration of activated vitamin D (VD) during the predialysis stage can reduce CVD events in patients after dialysis initiation. We therefore examined whether activated VD therapy improves short-term survival after the initiation of dialysis.

**Methods:** We conducted a multicenter prospective cohort study of 487 patients with CKD who began dialysis during the period from October 2011 to January 2012. The last observation was conducted at the end of September 2012. Incidences of CVD events and all-cause mortality were compared between patients in the treatment group (130 patients) before initiation of dialysis to whom activated vitamin D was orally administered for at least 12 weeks, and patients in the non-treatment group (357 patients).

**Results:** The data at the time of dialysis initiation are presented.

| | treatment group | non-treatment group | p value |
|---|---|---|---|
| age | 66.7 ± 12.3 | 68.3 ± 12.7 | 0.216 |
| female gender (%) | 34.4 | 31.5 | 0.586 |
| diabetes (%) | 36.2 | 42.5 | 0.214 |
| eGFR (ml/min/1.73m2) | 5.2 ± 1.4 | 5.5 ± 2.0 | 0.080 |
| adjusted Ca (mg/dl) | 8.69 ± 1.01 | 8.59 ± 1.05 | 0.316 |
| phosphorus (mg/dl) | 6.03 ± 1.69 | 6.29 ± 1.80 | 0.148 |
| calcitriol (pg/ml) | 17.8 ± 7.1 | 11.4 ± 7.0 | <0.001 |

CVD events occurred in 111 patients during the follow-up period. Comparing the two groups revealed a significantly lower CVD-event occurrence in the treatment group.



Based on the results of multivariate analysis using the Cox proportional hazards model, with adjustment for age and gender, administration of activated VD has an inhibitory influence on CVD events.

**Conclusions:** We have shown that for predialysis CKD patients, the use of activated VD may reduce the CVD risk after initiation of dialysis.

## SA-PO560

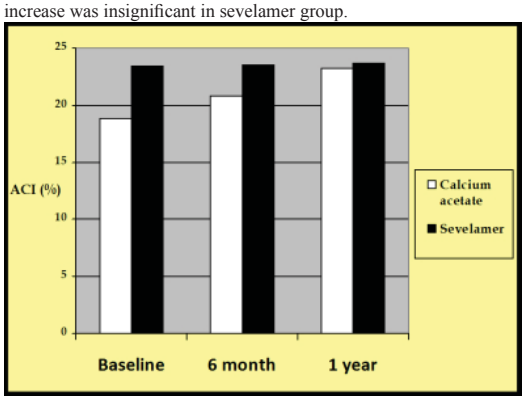
### Comparative Study between the Impact of Calcium Acetate versus Sevelamer Carbonate on Progression of Vascular Calcification in Pre-End Stage Renal Disease (CKD Stage 4 and 5) Patients

Sham Sunder, Himanshu Verma, Venkataramanan K, Satyanand Sathi. *Nephrology, PGIMER & Dr. Ram Manohar Lohia Hospital, Delhi, India.*

**Background:** Disorders of mineral metabolism,mainly hyperphosphatemia,may contribute to increased cardiovascular morbidity in CKD by promoting vascular calcification(VC).There is paucity of data on the extent of VC & the impact of sevelamer carbonate on progression of VC in pre-ESRD patients.

**Methods:** 150 pre-ESRD(CKD stage 4&5)patients were screened for abdominal aortic calcification(AC)using digital X-Ray lumbar spine and multi-slice abdominal CT scan.50 hyperphosphatemic CKD 4&5 patients having AC were selected & randomized to receive calcium acetate or sevelamer carbonate(25 in each group).The patients were serially studied for impact of phosphate binders on the progression of VC by measuring aortic calcification index(ACI)using CT scan at baseline,6 & 12 months.Clinical characteristics and laboratory variables(serum Ca,PO4,ALP,iPTH,Vit $D_3$,lipid profile,hs-CRP,IL-6) were also assessed.

**Results:** Among 150 patients,75% had AC with median ACI of 17.15%.ACI correlated positively with X-Ray AAC score(r=0.8106; *p<0.0001*).Sevelamer and calcium provided equivalent control of s.PO4(4.4+0.51 & 4.4+0.74,respectively,*p<0.01*).At baseline,the mean ACI in sevelamer group was significantly greater than the mean ACI in calcium group(23.45+1.8% vs 18.84+0.9%; *p=0.035*).In calcium treated patients, the mean ACI increased significantly at 6 months(20.8+1.06%) & 1 year(23.2+1.18%) *(p<0.01)*;but the increase was insignificant in sevelamer group.



hs-CRP & IL-6 decreased significantly at 6 month & 1 year with sevelamer, but increased with calcium at 1 year follow up *(p<0.01)*.

**Conclusions:** The prevalence of VC in pre-ESRD patients was 75%.Sevelamer carbonate was more effective in retarding the progression of VC than calcium acetate in pre-ESRD patients,due to it's pleiotropic properties.

## SA-PO561

### Serum Sclerostin as an Independent Predictor of Mortality on Hemodialysis Patients: Results from a 10-Year Follow-Up Cohort

Flávia Letícia Carvalho Gonçalves, Rosilene M. Elias, Luciene dos Reis, Fabiana Graciolli, Claudio Luders, Benedito J. Pereira, Bruno C. Silva, Vanda Jorgetti, Hugo Abensur, Manuel C. Castro, Rosa M.A. Moyses. *Nephrology Div, Univ of Sao Paulo School of Medicine, Brazil.*

**Background:** Chronic kidney disease-mineral and bone disorder (CKD-MBD) is a major syndrome that develops as a complication of CKD and usually predicts outcomes in observational studies. Recently, Wnt pathway disturbances have been identified as a common and early event in these patients, and probably play a role in CKD-MBD pathophysiolgy. In this study, we tested whether serum sclerostin (Sct), a Wnt pathway inhibitor, would be associated with mortality in a hemodialyisis (HD) patients' cohort.

**Methods:** On January 2003, all patients from a single HD center were evaluated (n=91). Clinical and biochemical data were collected and serum samples were stored for further analysis. Ten years later, serum Sct was measured and data was analysed.

**Results:** At baseline, their mean age was 42 ± 19 years, 60% male, 15% diabetic and had been on dialysis for 10 years. Their mean Hemoglobin (Hb), creatinine (Cr), albumin, PTH and Sct were respectively 11.6 ± 1.6 g/dl, 11 ± 3.3 mg/dl, 4.2 ± 0.5 g/dl, 169 (94-325) pg/ml, and 0.88 (0.54-1.6) ng/ml. After 10 years of follow-up, 28 deaths were observed. Variables associated with a higher mortality risk were older age, lower serum Cr, Hb and PTH, as well as higher serum Sct. When patients were divided into two groups according to median serum Sct , we found a higher prevalence of deaths in the higher Sct group (19 vs. 9, $p < 0.05$). Cox regression survival analysis showed that age (1.056), Hb (0.674) and Sct (1.874) were significant and independent predictors of death, even adjusted for diabetes, Cr and PTH.

**Conclusions:** Our data confirmed elevated Sct as an independent risk factor for mortality in HD patients. Prospective, interventional studies are needed to elucidate whether clinical interventions to modulate serum Sct would be able to improve these patients survival.

*Funding:* Government Support - Non-U.S.

## SA-PO562

### Serum Bicarbonate and Bone Mineral Density in United States Adults

Wei Chen, Michal L. Melamed, Matthew K. Abramowitz. *Dept of Internal Medicine/Nephrology Div, Albert Einstein College of Medicine, Bronx, NY.*

**Background:** Chronic acidosis leads to bone mineral loss by inducing calcium efflux from bone. In this study, we examined the association of serum bicarbonate levels with bone densitometry on a population-wide level in participants of the National Health and Nutrition Examination Survey 1999-2004.

**Methods:** Our analysis included 10,610 adults (≥20 years old) with estimated glomerular filtration rate (eGFR) ≥15 mL/min/1.73 $m^2$ who completed dual-energy X-ray absorptiometry (DEXA) testing. We excluded participants who were pregnant, taking bisphosphonates or had a diagnosis of chronic obstructive pulmonary disease. Bone mineral density (BMD) was measured by DEXA. Low total BMD was defined as 1.0 standard deviation below the sex-specific mean. Linear and logistic regression models were created to examine associations of serum bicarbonate levels with lumbar and total BMD.

**Results:** Participants with lower serum bicarbonate were younger, more likely to be female and smokers, had higher BMI, and were less likely to use diuretics. In the fully adjusted model, compared with participants with bicarbonate <24mEq/L, those with ≥27mEq/L had 0.012 g/$cm^2$ higher lumbar BMD (95% CI 0.00002, 0.025). In sex stratified analyses, compared with bicarbonate <24mEq/L, only bicarbonate ≥27mEq/L was associated with higher lumbar BMD among men; but among women, bicarbonate between 24-25, 25.1-26.9 and ≥27mEq/L were all associated with higher lumbar BMD. For total BMD, no statistically significant association was observed with serum bicarbonate among all participants. However, in sex-stratified analyses, bicarbonate level was independently associated with total BMD among women but not men. The odds of having low total BMD were 1.48 times higher in women with bicarbonate level <24 mEq/L compared to ≥27 mEq/L [OR 1.48 (95% CI 1.03, 2.14)].

**Conclusions:** Higher serum bicarbonate levels were significantly associated with higher lumbar BMD with a difference in threshold effect among men and women. For total BMD, an association with serum bicarbonate was observed only among women. This suggests a gender difference in the association of acidosis and bone density.

## SA-PO563

### Measures of Arterial Stiffness Independently Correlate with Bone Mineral Density and Osteoprotegerin in Patients with Long-Standing Type 1 Diabetes

Maria Lajer,[1] Simone Theilade,[1] Lise Tarnow,[1,2] Peter Rossing.[1,2,3] *[1]Steno Diabetes Center, Denmark; [2]Univ of Aarhus, Denmark; [3]Univ of Copenhagen, Denmark.*

**Background:** Abnormal bone metabolism and increased arterial stiffness are common in both diabetes and chronic kidney disease and are related to increased morbidity and mortality.

**Methods:** Prospectively followed cohort of 371 type 1 diabetic patients (55% men; age [mean±SD] 53±9 years, 42±8 years of diabetes, and 35% with long duration of diabetic nephropathy (DN)) Femoral neck bone mass density (BMD) ($g/cm^2$) was measured by dual energy x-ray. Measures of arterial stiffness were heart rate (HR) adjusted augmentation index (AI75), augmentation pressure (AP), and pulse wave velocity (PWV) (SphygmoCor, Atcor Medical). The calcification markers sclerostin, endostatin and osteoprotegerin (OPG) were measured in serum by immunoenzymetric assays (Biomedica Medizinprodukte).

**Results:** In total, 105 (28%), 197 (53%) and 69 (19%) had BMD (T-score) corresponding to normal, osteopenia and osteoporosis (>-1, -2.5 to -1.0 and <-2.5, respectively). Mean±SD AI75 18±10, 18±10, and 22±10; p=0.011 and PWV 10.2±3.3, 11.0±3.1 and 12.1±3.8 m/s; p=0.002 increased while AP tended to increase 10.4±7.7, 9.8±6.7, and 12.1±7.5; p=0.10 with deteriorating BMD group.

Following multivariate adjustment (ANCOVA: Sex, diabetes duration, $HbA_{1c}$, height, HR, mean arterial pressure, eGFR, urinary albumin excretion, cholesterol, smoking, and antihypertensive treatment), AI75 and AP were elevated with decreasing BMD status (p=0.002 and 0.006, respectively).

Similarly, sclerostin and endostatin correlated with PWV (p<0.018) while OPG correlated with AI75, AP and PWV (p<0.001). However, after the adjustment only OPG remained significantly related to all three measures of arterial stiffness (p<0.035).

**Conclusions:** These data suggest that in patients with longstanding type 1 diabetes, augmentation index and arterial pressure as measures of arterial stiffness correlates with bone mass and OPG independent of potential confounders.

## SA-PO564

**Relationship between Coronary Artery Calcification and Cardiac Valve Calcification at Hemodialysis Initiation in Patients with End Stage Renal Disease** Ken Kitamura, Hideki Fujii, Kentaro Nakai, Keiji Kono, Shinichi Nishi. *Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan.*

**Background:** Coronary artery calcification (CAC) and cardiac valvular calcification (VC) are common in patients with end-stage renal disease (ESRD) and may affect significant morbidity and mortality.The purpose of this study was to investigate CAC and VC at hemodialysis initiation in patients with ESRD.

**Methods:** This study included 63 patients with ESRD who were just planned to start hemodialysis therapy. Multi-detector computed tomography for quantification of CAC using the Agatston score and transthoracic echocardiography for assessing VC were performed for all the study patients. We semi-quantitated the severity of VC as VC score by counting the number of calcified valve cusp of aortic valve (AV), mitral valve (MV) and the presence of mitral annular calcification (MAC).

**Results:** Among 63 patients at hemodialysis initiation, 51 (81.0%) had CAC and 35 (55.6%) had VC. Twenty-five (49.0%) of 51 patients with CAC had severe CAC (CAC score ≥ 400). AV calcification, MV calcification and MAC were observed in 30 patients (47.3%), 17 patients (26.3%) and 8 patients (12.2%), respectively. CAC score is closely and significantly associated with VC score (r=0.39, p<0.005). Especially, significant associations of CAC score with AV calcification and MAC were detected. In addition, when the patients were divided into the following three groups on the basis of the degree of CAC and VC (group 1: severe CAC- and VC-; group 2: severe CAC+ or VC+; group 3: severe CAC+ and VC+), the number of patients with left ventricular hypertrophy was the highest in the group 3 and it was higher in the group 2 than in the group 1.

**Conclusions:** At hemodialysis initiation, most of the patients with ESRD had CAC and VC and these were well correlated with each other. These findings suggested that we need to follow hemodialysis patients with CAC and/or VC carefully as high risk patients for cardiovascular disease.

## SA-PO565

**Maxacarcitoriol Prevents the Progression of Cardiac Damage in Diabetes by Suppressing Oxidative Stress** Hideki Fujii,[1] Kentaro Nakai,[1] Keiji Kono,[1] Shunsuke Goto,[1] Riko Kitazawa,[2] Masami Shinohara,[3] Michinori Hirata,[4] Shinichi Nishi,[1] Masafumi Fukagawa.[1,5] *[1]Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan; [2]Div of Diagnostic Molecular Pathology, Kobe Univ Graduate School of Medicine, Kobe, Japan; [3]Planning and Development Section, CLEA Japan, Inc., Tokyo, Japan; [4]Fuji Gotemba Research Labs, Chugai Pharmaceutical Co., Ltd., Gotemba, Japan; [5]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan.*

**Background:** Diabetes mellitus (DM) is an important risk factor for chronic kidney disease (CKD) and cardiovascular disease (CVD). Recent reports have shown the significant association between vitamin D and CVD. Recently, we have reported that maxacarcitoriol (OCT), which is a vitamin D receptor activator, reduces oxidative stress. In this study, we investigated the effect of OCT on oxidative stress and cardiac damage in DM.

**Methods:** In this study, we used SDT rats, which are non-obese type 2 diabetes model rats. Twenty-week-old male SDT rats were divided into three groups: vehicle-treated SDT rats (DM, N=6), insulin-treated SDT rats (INS, N=6), and maxacalcitol-treated SDT rats (OCT, N=6). At 30 weeks of age, urinary and blood biochemical analysis and cardiac histological analysis were performed in these groups.

**Results:** At 30 weeks of age, despite comparable blood pressure and renal function, urinary excretion of 8-hydroxydeoxyguanosine (8-OHdG) and serum NT-proBNP levels were significantly lower in the OCT group than in the DM group. In addition, heart volume was significantly lower in the OCT group compared to the DM group. The mRNA expressions of NADPH p22 and BNP in the heart were significantly decreased in the OCT groups compared to the DM group. Further iummunohistological analysis revealed that the number of 8-OHdG positive cardiomyocyte was reduced and cardiac and perivascular fibrosis was ameliorated by OCT administration.

**Conclusions:** Oxidative stress may play a key role for the development of cardiac hypertrophy and cardiac fibrosis in DM. Furthermore, it is suggested that OCT suppresses oxidative stress and ameliorated the cardiac damage in DM.

## SA-PO566

**Higher Serum Alkaline Phosphatase Is Associated Not Only with Mortality but also the Incidence of Hip Fracture among Patients Receiving Hemodialysis in Japan** Yukio Maruyama,[1] Keitaro Yokoyama,[1] Takashi Shigematsu,[2] Masatomo Taniguchi,[3] Junichiro J. Kazama,[4] Tatsuo Hosoya,[1] Takashi Yokoo.[1] *[1]Div of Kidney and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan; [2]Div of Nephrology and Blood Purification Medicine, Wakayama Medical Univ, Wakayama, Japan; [3]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [4]Div of Blood Purification Therapy, Niigata Univ Medical and Dental Hospital, Niigata, Japan.*

**Background:** The monitoring of serum alkaline phosphatase (ALP) is widely recommended in the management of chronic kidney disease-mineral and bone disorder (CKD-MBD). However, unlike calcium, phosphate, or parathyroid hormone, relationship between serum ALP and outcome of the patients receiving hemodialysis (HD) in Japan is unknown.

**Methods:** We collected the baseline data of 187,792 patients receiving HD thrice weekly (66 ± 12 years, males 61.9%, and median HD vintage of 7.9 years) extracted from a nationwide dialysis registry at the end of 2009 in Japan. Then we evaluated the patient survival and development of complication using the registry at the end of 2010.

**Results:** During one-year follow-up, 14,439 (7.9%) died of all causes including 6485 (3.6%) cardiovascular death. Additionally, 1,614 patients (1.1%) was newly-diagnosed as hip fracture. All-cause mortality, cardiovascular mortality, and the incidence of hip fracture were higher in line with the increase of baseline serum ALP. In a multivariable logistic regression analysis, patients of the highest quartile of ALP had higher all-cause and cardiovascular mortality and incidence of hip fracture compared with those of the lowest quartile (OR, 1.45; 95% CI, 1.34 to 1.57, and OR, 1.26; 95% CI, 1.13 to 1.40, and OR, 1.69; 95% CI, 1.37 to 2.09, respectively).

**Conclusions:** In this large observational cohort study, higher levels of serum ALP were independently associated not only with mortality but also the incidence of hip fracture among Japanese HD patients. Close monitoring of serum ALP is thought to be useful for the management of CKD-MBD.

**Aluminum Intoxication: The Problem Has Not Disappeared** Clarissa Jacob Barros Carvalho,[1] Camila Barbosa L. Oliveira,[1] Carla Queiroz Neves,[1] Alline S.A. Oliveira,[1] Vanda Jorgetti,[2] Jose Edevanilson Gueiros,[1] Ana Paula Gueiros.[1] *[1]Nephrology, UFPE, Recife, Pernambuco, Brazil; [2]Nephrology, USP, Sao Paulo, Brazil.*

**Background:** Aluminum intoxication (AI) is associated with low bone formation rates and incresead risk for fractures. The aim of this study was to evaluate the prevalence of AI in hemodialysis patients who underwent bone biopsy in a Brazilian center.

**Methods:** We performed a retrospective analysis of 158 patients underwent bone biopsy from March 2003 to March 2013. Patients were divided into 2 groups: AI group (patients with AI) and NAI group (patients free of AI). Clinical data were evaluated: age, sex, time on dialysis, occurrence of vascular calcification and fractures. Laboratory tests: total calcium, phosphorus, intact parathyroid hormone (iPTH pg/mL), alkaline phosphatase (ALP U/L). Bone biopsy was performed after double tetracycline labeling and specimens were classified as osteitis fibrosa (OF), mixed disease (MD), adynamic bone disease (ABD), osteoporosis (OS) or osteomalacia (OM). AI or iron intoxication were defined when more than 20% of the trabecular bone surface were covered by metal. We performed a comparative analysis between the groups to assess factors associated with AI. The frequency of IA was evaluated in two periods of 5 years (2003-2007 and 2008-2013).

**Results:** The prevalence of AI was 51.3% and did not decreased with the time. There were no diferences between the groups regarding clinical parameters. ALP (median 155 vs 430; p<0.001) and iPTH (median 814 vs 1732; p<0.001) levels were lower in the AI group. ABD (p=0.021) and iron intoxication (p<0.001) were closely associated with AI. Patients with MD had lower frequency of AI (p=0.003). A cox regression multivariate analysis showed that variables associated with AI were: time on dialysis (p=0.024), ALP (p=0.006) and iPTH (p=0.008).

**Conclusions:** Although the prevalence of aluminum-related bone diseases has declined in the world, AI still persists at a high prevalence in Brazil. Futhermore, IA had a close association with ABD and with iron intoxication.

**Post-Hoc Analysis of Pharmacodynamic Interaction of PA21 with Statins in a Phase 3 Study of PA21 in Dialysis Patients with Hyperphosphatemia**
Victoria Levesque,[1] Edward M.F. Chong,[1] Patrick Moneuse.[2] *[1]Vifor Pharma, Canada; [2]Vifor Pharma, Glattbrugg, Switzerland.*

**Background:** Dialysis patients often require phosphate binders (PBs) for hyperphosphatemia, and concomitant statins for hyperlipidemia. *In vitro* studies showed interactions between PA21 and atorvastatin, especially in an absence of phosphate. Clinical data showed sevelamer (SEV) lowered total cholesterol (Tot-C) and low-density lipoprotein cholesterol (LDL-C), but not triglycerides (TG). Therefore, an analysis of data from a Phase 3 study investigating PA21, a novel polynuclear iron(III)-oxyhydroxide PB, and SEV assessed whether these PBs altered the lipid-lowering effects of statins.

**Methods:** Dialysis patients received PA21 1.0-3.0 g/day (n=707) or SEV carbonate 2.4-14.4 g/day (n=348) for up to 52 weeks. A *post-hoc* analysis investigated lipid parameters to assess potential interactions between PA21 or SEV and atorvastatin, simvastatin, or other statins.

**Results:** The *post-hoc* analysis included 677 and 333 patients treated with PA21 or SEV, respectively. PA21 had minimal effect on lipid parameters in patients taking stable dose of atorvastatin, simvastatin, other statins or no statins (Table). Decreases in LDL-C and Tot-C, but minimal effects on TG, were observed in SEV subjects. Mixed model analyses confirmed that PA21 did not alter the lipid-lowering effects of statins.

**Table:** Mean (SD) change (mmol/L) in lipid parameters: baseline to Week 52 endpoint*.

| Baseline medication | PA21 (n=677) | | | SEV (n=333) | | |
|---|---|---|---|---|---|---|
| | LDL-C | Tot-C | TG | LDL-C | Tot-C | TG |
| Atorvastatin analysis | | | | | | |
| Atorvastatin (n=120) | -0.0 (0.82) | -0.1 (0.95) | -0.1 (2.27) | -0.7 (0.72) | -0.7 (0.84) | 0.2 (1.07) |
| Other statin (n=264) | -0.0 (0.58) | -0.0 (0.77) | -0.0 (1.20) | -0.6 (0.60) | -0.6 (0.73) | -0.0 (1.00) |
| Simvastatin analysis | | | | | | |
| Simvastatin (n=185) | -0.0 (0.58) | -0.0 (0.82) | -0.0 (0.96) | -0.5 (0.56) | -0.5 (0.72) | 0.0 (0.78) |
| Other statin (n=199) | -0.0 (0.74) | -0.0 (0.84) | -0.1 (2.04) | -0.7 (0.70) | -0.8 (0.80) | 0.1 (1.20) |
| Atorvastatin and simvastatin analyses | | | | | | |
| No statin (n=626) | -0.0 (0.72) | -0.1 (0.84) | 0.0 (0.88) | -0.6 (0.67) | -0.7 (0.84) | 0.0 (0.97) |

*Last available observation under stable dose of statin.

**Conclusions:** PA21 did not interfere with the lipid-lowering effects of statins, despite prior *in vitro* data showing an interaction. SEV lowered LDL-C and Tot-C, consistent with its known effects on these parameters.
